The issuance of the certificate may be preceded by compliance tests to observe the requirements resulting from Portuguese tax legislation and a set of defined technical requirements [25]. It should be noted that the certified version of an ISw must comply with the corresponding requirements, which is the responsibility of the ISw producer, even after the compliance tests and throughout the life of the ISw [23].

The compliance tests are conducted by AT, being responsible for analyzing, clarifying and conducting the face-to-face compliance testing meeting an AT Inspector, with functions assigned to certification of ISw.

Since the beginning of the COVID-19 pandemic declaration, faced with the impossibility of free movement and other restrictions, AT has prepared a videoconference solution that would allow to give support to software producers and to safely perform compliance tests. After all the relevant requirements have been verified by videoconference, a meeting would be scheduled to conduct compliance tests, in a face-to-face meeting. Thus, it was possible to keep the certification process active.

AT maintains, on the Finance Portal, an updated list of programs and respective certified versions, as well as the identification of the software producers, proving that during the COVID-19 confinement months, several ISw were certified.

3.5. Ordinance No. 363/2010

The preamble to Ordinance No. 363/2010, of 23 June, states that the increasing use of ISw has undeniable advantages in terms of the speed of information processing. However, it introduces new risks in terms of fiscal control, due to the possibility of subsequent adulteration of recorded data, enhancing situations of tax evasion [25].

In this perspective, the aforementioned ordinance defines rules so that the ISw observe the requirements that guarantee the inviolability of the information initially registered, allowing, consequently, that only the ISw that respect such requirements can be used, after certification by AT. The certification of ISw depends on the cumulative verification of several requirements, among them must be able to export the SAF-T (PT) file, have access control to ISw and respect the technical requirements defined in Order No. 8632/2014.

3.6. Order No. º 8632/2014

Order No. 8632/2014, of July 3, from the Ministry of Finance, was published to comply with the provisions of Ordinance No. 363/2010, which states that one of the requirements for obtaining ISw certification is to observe the technical requirements approved by the AT. Thus, ISw even if already certified, must comply with its approximately 100 technical requirements in different areas, including backup policies, data recovery, access controls or document signing and security [22].

4. Methodology

The research-action methodology in the realistic perspective was the main axis of the investigation protocol. It helped to reduce the complexity of the problem, due to the variety of categories of organizations and their ICT strategies [26], as well as business specificities. It would be a hindrance to integrate the requirements and the hypotheses for solving the problem in a single approach [27]. Thus, a questionnaire was created for ICT managers as a way of capturing relevant information about the invoicing solution implemented in the organization. From the data analysis, it's inferred a BCP proposal that integrates the researcher's knowledge about the problem, the applicable legal and normative requirements, the constraints and the various conceptual technological alternatives of resolution in order to outline a sufficiently comprehensive guide for most of the organizations in Portugal.

5. Results

The guide for the design of a BCP is outlined, starting with a questionnaire with the main questions, structured in specific knowledge areas that the ICT managers must ask in the analysis of the problem, as shown in Figure 3. It culminates in a better understanding of the business processes and procedures involved that will be the target of the BCP, regarding procedures to be designed for disaster recovery and business continuity of the ISw. It enhances the understanding of ISw's data backup policies and

approaches to the implementation of a technological conceptual solution capable of eliminating vulnerabilities and mitigating the effects of a disruptive event in the invoicing business processes.

Structurally, the questionnaire contains a set of multiple-choice questions, each contributing to the perception of the organization invoicing solution and to the compliance with specific requirements defined in the tax legislation, standards and good practices researched.

Figure 3 shows the decision support process with the questions that make up the questionnaire. The word “invoice” refers to all relevant tax documents, including, for example “orders” or, “credit note”. The order in which the questions are answered is not important, since the software that supports the guide adapts to each new question answered. Three questions allow diverting the flow of the program, as its answer invalidates the following interconnected questions:

9. "Is there an Invoicing Software?" - if not, it is not needed to ask about the producer responsible for the ISw and its architecture;

13. "Is the Invoicing Software connected to a central software?" - if not, there is no need to conclude about the location of the central database in the client/server configuration;

15. “Are invoices issued electronically?” - if not, there is no need to question if, or how Electronic Data Interchange (EDI) is used.

All other questions follow a common reasoning flow and are positioned according to the theme of the question, which may be important to request answers to the questionnaire from another employee of the organization. It is important to note that the guide was specially designed for organizations that have an ISw, and it is not an objective to find proposals outside this scope. The questions areas are:

- Organization: Allows the organization to be classified according to the criteria of Small and Medium Enterprises (SME) [28], to know the sector of activity in order to understand the investment capacity [29] and the total turnover to infer, and also about the obligation to have an ISw certified by AT;
- Invoicing volume: Allows to verify the invoicing issuance days; whether the organization has continuous invoicing (for example for scheduling jobs in periods of less activity) or only during normal working hours, as well as the average number of documents issued per day. It aims to reveal the periodicity of backup copies and more appropriate techniques, taking into account the conclusions about investment inferred in the “Organization” area;
- Printing: The objective is to understand whether organizations print the documents issued and keep the accounting archive in paper, in order to suggest scanning and archiving in electronic format, as well as the possibility of recovering documents in case of corruption of the database;
- Invoicing Software: Find out if the organization uses an ISw, even if not required, inferred by the conclusions in "Organization". Know if the ISw was developed in-house or acquired in order to understand the decision-making capability on requirements and technical capability on the ISw. It is important to understand if the ISw is desktop-based, web-based or a terminal application in order to infer the technological infrastructure associated with the physical location of the database;
- Electronic issuance: It aims to infer the processing of the documentation produced and propose the electronic issuance according to the technique used and with the conclusions in “Invoicing volume”;
- Manual issuance: Intends to assess the need to comply with the requirements set out in point 2.4 of Order 8632/2014 [22]. Propose business continuity in case the ISw is inoperable, taking into account the conclusions in “Invoicing volume”.
- Electronic Archive: Intends to assess the need to comply with the requirements set out in Decree Law No. 28/2019. Aims to propose a reduction of archiving costs, the efficiency of archiving procedures, especially those supported on remote work business processes and improve business continuance readiness.

The flow of decisional process and the questions that are part of the questionnaire are presented in Figure 3.

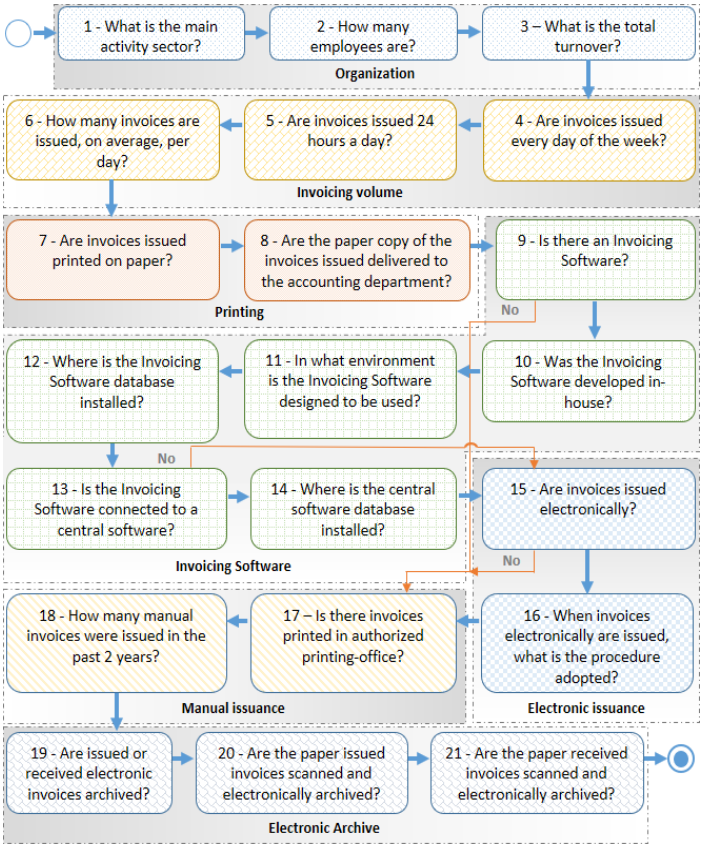

Figure 3: Decision support process for the design of the guide.

The questionnaire presented in Figure 3 has the basic or relevant questions to ask, and the multiple-choice answer will drive the decisional process conclusions. For example, when questioned about the connection to a central software, the answer will have a variety of options to try to determine the architectural solution implemented.

5.1. Discussion

Stablished or entrepreneurial entities, when starting or reformulating their commercial activity and business processes, should take into account the potential of legislative considerations mentioned in this work. The focus on online businesses, amplified by the increased use of telework, resulting from the measures to contain this recent pandemic, allows some management, optimization and control functions to be performed remotely. The effects are reflected in the need to optimize business processes, the time spent on activities, but above all in technological innovation that mitigates the gaps underlying this new vision of the business and digital world. This new vision will depend on the dynamization of ICT in business processes and the quick response to this desire, where there is a need to make quick and effective decisions, but with the necessary efficiency so that the change is adequate.

5.2. Future work

The aim is to design an approach that allows the questionnaire to be published online and to obtain more data for treatment, in order to refine the design of a BCP supported by technological solutions.

Nevertheless, for questionnaire evolution, some other requirements need to be addressed, especially the ones who improve the security of the software system and some other ones that enhance business continuity and disaster recovery.

Another research direction is to design a case study, to evaluate the business processes dynamization or optimization and obtain the return on investment achieved. The study should occur before and after the implementation of electronic invoicing and/or electronic archiving in the organization, in a set of preselected business processes. The target organization is one that intents to transform its business processes for telework, triggered for example, by restrictions due to pandemic situations.

6. Conclusions

The previous identification of the constraints felt by the organizations in the design of a BC solution allowed to conduct the literature review and the identification of the issues, considered relevant, in the context of supporting the design of a guide for the design of BCP. The review of the literature on the theme of BC, including standards and good practices, and the relevant applicable tax legislation was important in this work. The systematization of information in this field adds value to the scientific community, as well as to users who are part of this type of problem.

On the other hand, the change in the paradigm of issuing and communicating invoices and tax relevant documents triggered the need for organizations to prepare for the challenge of innovation or technological adequacy for electronic invoice issuing, as well as for the electronic archive. The current pandemic situation has accelerated this need for digital transformation.

The tax legislation points to the requirements to be met and provides for the possibility of issuing documents by electronic means, the possibility of their electronic transmission to AT, and the possibility of their electronic archive. Understanding what are the correct procedures and what are the requirements involved in the certification of an ISw in Portugal it is considered relevant for organizations that develop the software, as well as for organizations that decide to purchase a solution. This work aimed to help the identification of the main regulatory documents in the thematic, as well as the legal characterization of invoicing in Portugal, in order to support organizations in the design or adaptation of the ISw. The implementation of electronic invoicing and electronic archiving procedures can enhance business continuity and boost the innovation that leads to new software products, digital transformation, marketing approaches, or new ways of making business.

The questionnaire made it possible to systematize the variables involved underlying the tax requirements, the existing technological infrastructures, and the invoicing and archiving procedures implemented. Through a process of analysis of the answers, vulnerabilities can be perceived, as well as the needs for business continuity and disaster recovery. It is considered that the constraints perceived by organizations were reduced by improving the understanding of the variables that they must observe, the areas in the legislation and regulations that they must integrate, as well as the needs of human and technological resources, according to their investment capacity.

This work encourages the adoption of concrete strategies and procedures for business continuity, where invoicing and electronic archiving may be relevant, for organizations with an ISw, certified or not by AT.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Connected and self-driving cars have emerged over the last decade as a leading example of cyber-physical systems, which seek to considerably enhance traffic safety, reduce emissions, decrease costs, and improve efficiency. Google, TESLA, Uber ATG are becoming pioneers in the autonomous vehicles industry. Autonomous vehicles can have a large codebase and with a large volume of messages exchanged. The concepts of connected driving, cooperative driving, and intelligent transportation systems increase the connectivity of vehicles to the internet or other cloud services. High connectivity, misconfiguration, and insecure coding widen the attack surface of autonomous vehicles. A conceptual model of autonomous vehicles is presented in this paper to better understand autonomous vehicles' attack surface. In addition, specific threat modeling techniques are discussed. Experiments were carried out to demonstrate the security risks to autonomous vehicles due to third party Electronic Control Units.

1 Introduction

The term autonomous vehicles is used to designate technology-oriented vehicles with robotic and self-driving features (self-parking, GPS sensing tools, and higher automation capabilities). Both connected and self-driving cars have emerged over the last decade as a leading example of cyber-physical systems, which seek to enhance traffic safety, reduce emissions, decrease costs and improve efficiency. At the same time, the automobile industry has experienced a major transformation from monolithic manufacturing processes to distributed procurement. The paradigm of distributed procurement allows automobile manufacturers to acquire software and sensor/hardware components from numerous third parties.

Distributed systems usually comprise of a complex connectivity layer with different nodes. The features of connectivity in autonomous vehicles provide real-time connections to the web, sensors, radar, GPS with user privacy, and other measurement units [1, 2]. In other words, autonomous vehicles are empowered to acquire all relevant information needed to perform the self-driving functions [3].

As the market penetration of autonomous vehicles has increased, there is a growing demand among organizations, consumers, and regulatory bodies for the underlying technologies to be tested to guarantee their overall safety, as well as evaluate their cloud and cyber security together with data privacy. The augmented diversity of software, sensors, and communication channels has driven this demand [4]. During the process of critical-information exchange between the vehicle and the external infrastructure, a new attack surface can emerge, as several stakeholders (telematics, hardware, and software components, etc.) and rapid modifications (i.e., software processes) are involved.

Sensors can provide an extensive amount of information on the environment surrounding the vehicle together with sensing the internal components. Electronic Control Units (ECUs) and sensors are the focal point of information exchange inside autonomous vehicles, as they provide critical information to the engine control unit of the vehicle. The data obtained from sensors can be shared and utilized for all types of assessments and calculations by other automotive systems.

Sensors and ECUs contain a large codebase that was enhanced to provide features required by autonomous vehicles. This "functional abundance" has widened the attack surface, adding to the existing vulnerabilities that have not been identified in the old code bases. Sensors and ECUs can talk to each other with different networks equipped in modern vehicles. The design of such networks has focused on efficiently wiring these components rather than on security.

There are 6 different levels of autonomous driving defined by

[*]Corresponding Author: Abdulla Al Zaabi, Abu Dhabi 127788, abdulla.alzaabi@ku.ac.ae

the Society of Automotive Engineers as shown in Figure 1. Modern vehicles nowadays can achieve levels between two and three.

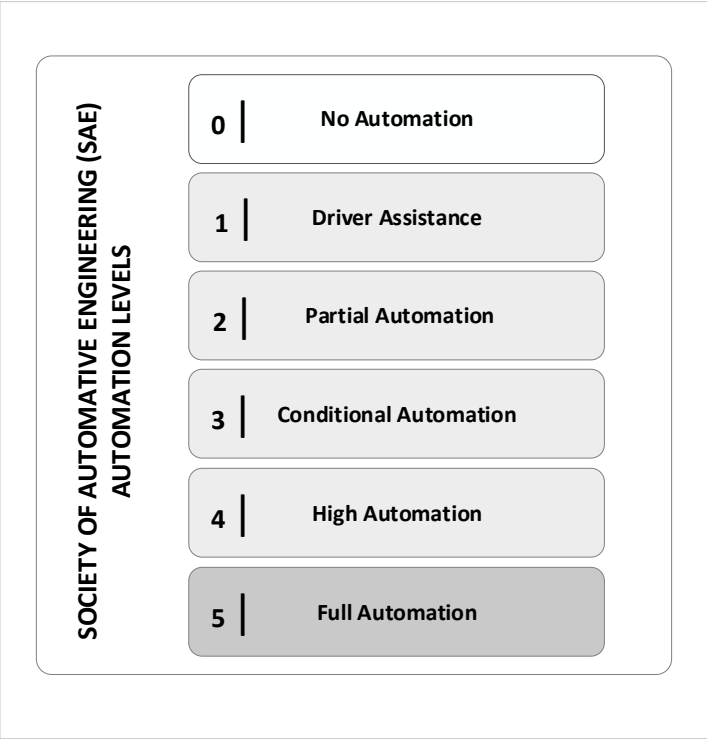

Figure 1: SAE automation levels

The motivation behind this work is to develop a conceptual model for autonomous vehicle to better understand the attack surface of autonomous vehicles and support their security testing. This will allow researchers and manufacturers to better understand the attack surface on autonomous vehicles and bridge the gap in the areas that have not been explored.

This paper develops on our previous work on defining a conceptual model for autonomous vehicles [5], where we modeled the autonomous vehicles' assets, their vulnerabilities and the corresponding threats. Here, we take a closer look to modeling the assets related to the Controller Area Network (CAN) of the vehicles. The rationale behind this choice is that many aftermarket gadgets and smart applications taking advantage of the CAN bus could contain vulnerabilities exploitable by malware. We conduct an experiment on a simulated CAN bus to illustrate different security attack scenarios such as traffic sniffing, replay attack and packet injection. Based on our experiment, we discuss and compare different threat modeling techniques that can be used to identify security threats based on the conceptual model presented.

The contribution of this article is, therefore: (i) enhanced conceptual model of autonomous vehicles to better understand their attack surface, (ii) analysis of Controller Area Network and cyber security attacks on modern vehicles, (iii) analysis of specific threat modeling techniques, (iv) demonstration of the cyber security risks to autonomous vehicles due to third party Electronic Control Units.

The paper is organized as follows. In Section 2 we present an autonomous vehicle conceptual model. Section 3 describes Controller Area Network protocols. Section 4 overviews cyber security attacks on modern vehicles. Section 5 focuses on a remote attack that had an impact on millions of vehicles. Section 6 provides an overview of different threat modeling techniques that could be used for threat modeling of autonomous vehicles. Section 7 illustrates the experimental results of sniffing and injecting traffic on CAN network using a simulated environment. In section 8 we summarize and discuss the future direction of research.

2 Autonomous Vehicle Conceptual Model

This section describes our enhanced conceptual model of autonomous vehicles [5]. The model consists of three main areas; vehicle, communications, and edge-cloud (Figure 2).

2.1 Vehicle

The vehicle component of the conceptual model focuses on the physical boundary of the vehicle. In the conceptual model, we focused on the important items that will support future work in security modeling and analysis of autonomous vehicles. The main categories of the vehicle layer are Electronic Control Units (ECUs), they are the brain of the vehicle, Sensors, and Inter-Vehicle communication. In addition, it is important to highlight the internal connectivity items such as the On-Board Diagnostic port (OBD-II). Different types of networks exist in autonomous vehicles with different speeds. The ECUs in the vehicle are usually connected to at least one or more internal vehicle network. The gateway is used to facilitate communication between different communication buses. The OBD-II connection provides access to the vehicle's internal network and interaction with various low-level sensors.

ECUs are essential components of modern vehicles. Each ECU is responsible for performing actions such as door locks, power steering, fuel injection, and many other critical functions. ECUs can also be categorized into subcategories based on their functionality [6]. The list below provides categories for ECUs found in modern vehicles:

- Powertrain: controls many factors in vehicles and responsible for transmission, emission controls, and onboard control modules.
- Safety: vehicle safety-related operations such as collision detection, active parking, and air-bag system.
- Body: less critical operations of the vehicle such as power windows and mirrors, cooling and heating, etc.

Examples of some of the key ECUs from the categories above are:

- ECM: engine control module
- VVS: vehicle vision system
- IRM: inflatable restrain module
- NCM: navigation control module

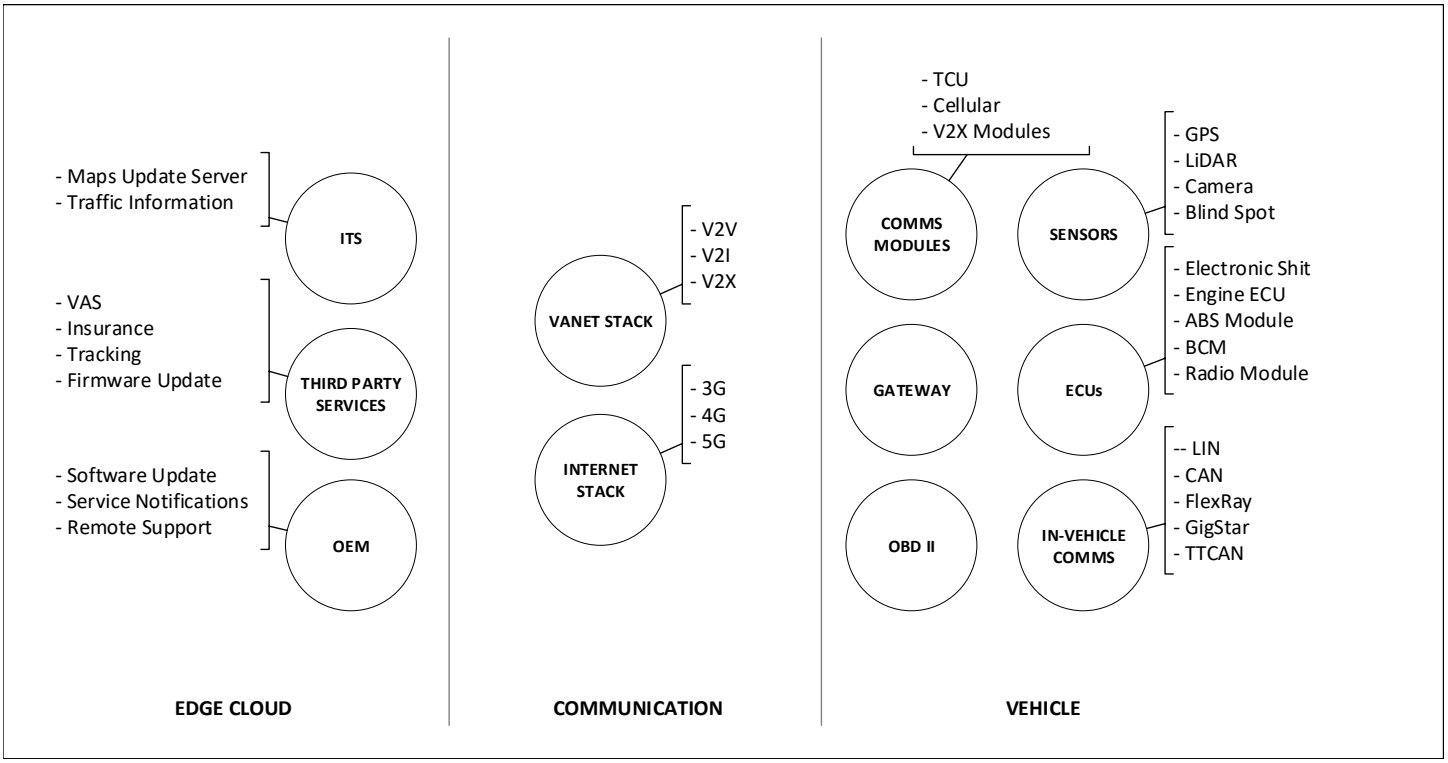

Figure 2: Autonomous Vehicle Conceptual Model

Sensors are used in autonomous vehicles to collect information about the vehicle's surroundings. Vehicles are equipped with various sensors, examples of sensors equipped are GPS, cameras, LiDAR. The vehicle uses the information received from the sensors to perform different actions such as warning messages, navigation capability, distance calculation, and others.

The Inter-vehicle communication component of the conceptual model focuses on the communication networks in the physical boundary of the vehicle. The main purpose of these networks is to allow efficient communication between electronic units in the vehicle. There are different types of networks in vehicles such as CAN, TTCAN, FlexRay, and Local Interconnect Network (LIN) [7, 8]. The CAN is widely used in automotive to support critical applications with a bandwidth of 125 kBits/s. The LIN bus runs at a lower bandwidth (10 kBit/s) to support less critical applications such as power windows and doors lock. FlexRay is a more expensive implementation of CAN, used commonly in BMW. FlexRay has 2 channels at a speed of 5 and 10 Mbit/s [9, 10].

2.2 Communication

The communication layer of the model focuses on the external communication medium for autonomous vehicles. Future transportation system is envisioned to support cooperative driving and information exchanging to enhance the driving experience, increase safety, and reduce collisions. There are two main categories in the communication layer; VANET stack and Internet Stack.

VANET Stack is the vehicular Ad Hoc Networks (VANETs). VANETs can use wireless networking technology to allow vehicles to communicate with each other and share information using Dedicated Short Range Communication (DSRC). There are different types of communication in VANETs. The first one is V2V, which stands for Vehicle to Vehicle communication. V2I: vehicle to station communication. V2R: vehicle to Road Side Unit (RSU) communication. V2X: vehicle to everything.

There are two types of messages in VANETs; beacon messages and special purpose messages [11, 12]. Vehicles broadcast messages that act as heartbeats using beacon messages. Special purpose messages carry information about collisions and warning messages to nearby vehicles [13]. VANETs using DSRC or even cellular network is anticipated as the future of intelligent transportation system [14].

Internet Stack component of the model considers the cellular network as the communication means. Internet stack includes 4G and 5G data link and physical link [15]. Initial research in autonomous driving focused on VANETs as the future of communication for vehicles using DSRC. Modern vehicles are equipped with cellular network connectivity that could enable VANET communication over cellular network.

2.3 Edge Cloud

Edge Cloud layer of the model focuses on the vehicle communication with external entities. Original Equipment Manufacturers (OEM) perform remote updates to vehicles remotely for applying patches, issues fix or enhance features. Many services are currently offered by third party providers such as media services, fleet management, vehicle tracking, and many other applications and services. Below are some examples:

- Maps update service.

- Traffic information.
- OEM firmware update.
- Third-party dongles firmware update.
- Value Added Services.

Some insurance companies nowadays mandate drivers to install OBD-II compatible dongles to monitor driving behavior and adjust insurance tariffs accordingly. Vehicles are expected to be connected to edge cloud services to support smart and green transportation [16]. As part of intelligent transportation system management [17, 18], vehicles are expected to be connected to transportation authorities and share various types of information.

3 Overview of Controller Area Network

The Controller Area Network (CAN) is a standardized network adopted by many car manufacturers for efficiency, safety, and manufacturing purposes. CAN ensures minimum latency, together with other features to handle functional networks of a vehicle. It has been adopted since early 1980s to primarily handle automotive electronics, and more specifically, different types of electronic control units [19]. The CAN protocol has many distinctive features such as being able to discover defects in the communication network and electronic control units (ECUs) [20]. ECUs play a crucial role in operating an autonomous vehicle. By allowing ECUs to exchange information via CAN, the autonomous vehicle can support new intelligent features. In comparison with other networks, however, CAN have some weaknesses such as limited electrical loading, and vulnerability to overflow of undesirable interactions or communications [21].

Known vulnerabilities of CANs have encouraged experts to develop a new security network for ECUs, especially for automated and self-driving vehicles [20]. One of the major motives for developing a new network is that CAN was not designed for communications from outside the vehicle, i.e. vehicle-to-Internet communications, vehicle-to-cloud, vehicle-to-pedestrian, and other types of connectivity. As a result, cyber security challenges, particularly denial-of-service attacks are a major hurdle when using CAN for autonomous vehicles. Moreover, third party dongles have been introduced by different service providers such as insurance or fleet management companies. These devices interface with the vehicle through the On-Board Diagnostics port (OBD-II). Physical OBD-II connection provides access to the vehicle's internal network and interaction with various low-level sensors.

3.1 CAN Protocols

CAN is a simple protocol that was deployed vehicles since 1996. It allows Electronic Control Units (ECUs) to communicate with each other. CAN run on two wires; CAN High (CANH) and CAN Low (CANL). At the physical layer, CANH uses differential signaling, which is used in environments where fault-tolerance to noise is a must. When a signal comes in, CANH raises the voltage on one line and drops the other line of an equal amount.

3.1.1 The OBD-II Connector

Most vehicles are equipped with On-Board Diagnostic Connector named OBD-II. It is usually located under the steering wheel of a vehicle. It is also known as a diagnostic link connector (DLC). CAN Connections can be found in supported vehicles from the OBD port in dual-wire pairs. CANH and CANL can be found on pin 6 and 14 or the OBD-II connector.

- CANH: High-Speed CAN Lines
- CANL: Low Speed or Mid Speed CAN Lines (LS-CAN and MS-CAN).

3.1.2 CAN Packets Layout

There are two types of CAN packets; standard and extended. Extended packets are like the standard ones but with larger space to hold IDs. The Complete frame of standard CAN is shown in Figure 3. Fields of standard packets are described below.

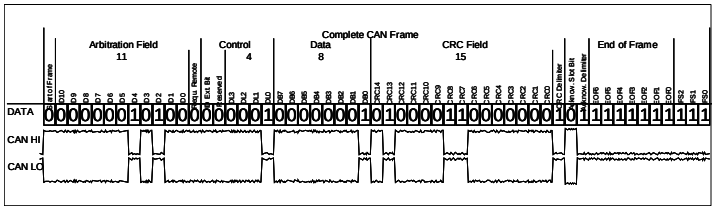

Figure 3: CAN Frame of standard packet [22]

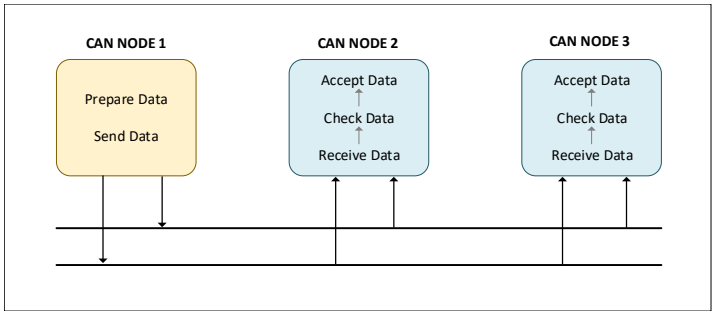

Figure 4: CAN communication based on broadcast messages

- Arbitration ID: a broadcast message that identifies the ID of the target device it tries to communicate with.
- Identifier Extension (IDE): always 0 for standard CAN
- Data length code (DLC): the size of the data, which ranges from 0 to 8 bytes
- Data: data to be transmitted.

Communication on CAN bus is broadcast messages, similar to UDP packets on ethernet networks as shown in Figure 4. All controllers see every packet transmitted on CAN. Extended packets are similar to standard packets, but the can be changed together to create longer IDs. They are designed to fit inside standard CAN packets with backward compatibility.

3.1.3 The ISO-TP Protocol

The ISO 15765-2 is a standard for sending packets over CAN. It extends the limit of sending 8 bytes to 4095 bytes. This protocol is commonly used for diagnostic messages (Unified Diagnostic Services) and KWP messages (alternative protocol to CAN). The first byte is used for extended addressing, leaving only 7 bytes for data per packet. Using ISO-TP can easily flood the CAN bus, thus it should be used carefully [23].

3.1.4 The Local Interconnect Network Protocol

The Local Interconnect Network (LIN) is a master-slave facility that was designed to complement CAN. It can have up to 16 slaves

4 Overview of Cyber Attacks on Modern Vehicles

This section focuses on recent cyber security attacks on modern vehicles. Firstly, the section provides an overview of the interesting vulnerabilities discovered by researchers in different modern vehicles. In the second part of this section discusses in detail one of the most interesting attacks on vehicles, the Jeep Cherokee 2015 attack.

4.1 Vulnerabilities Overview

4.1.1 Jeep Cherokee

Uconnect is an entertainment system that relies on cellular network to deliver entertainment services and applications in Jeep Cherokee entertainment system [24]. The entertainment system had a diagnostic bus port that runs on 6667. Since the port had no authentication requirements, some sensitive information was obtained by connecting to the port, such as GPS information, VIN, and other private information. At the time of the research, around 1.4 million vehicles using the Uconnect system were vulnerable. To identify vulnerable vehicles, a mass scan for the diagnostic bus port could be performed on the IP range of the service provider. The researchers used Sprint Cellular Network IP ranges to identify vulnerable vehicles on 21.0.0.0/8 and 25.0.0.0/8 address ranges. Additional details on the sequence of execution from Uconnect system to cyber-physical actions are explained in next section.

4.1.2 GM Chevy Impala

Another entertainment system related vulnerability was discovered in the GM Chevy Impala by researchers at the University of California at San Diego and the University of Washington [25]. This time, the entertainment system had a buffer overflow vulnerability. The vulnerability was exploited by playing a specially crafted mp3 file in the in-car call system. Successfully exploiting the vulnerability allows an attacker to access the vehicle's system and control most of its critical functions.

4.1.3 BMW

Security researchers identified a vulnerability in BMW ConnectedDrive service to unlock the vehicle remotely. Confidentiality requirement was missing in the communication between the vehicle and the BMW server for ConnectedDrive, the communication was not encrypted. Due to this, the attack performed using a fake cellular network and spoofed the BMW server. The vehicle is equipped with a communication capability using a pre-installed SIM card. An unlock message was sent to the vehicle using the spoofed server and it unlocked the vehicle successfully [26]. At the time, over 2.2 million vehicles were affected by the vulnerability. BMW released a security patch to fix the vulnerability by adding encryption to the communication between the vehicle and the BMW server.

4.1.4 Corvette

Corvette attack was mainly an attack on a third-party device, specifically on an insurance dongle connected to the vehicle via OBD port. The insurance dongle was installed to track driver behavior to determine insurance tariffs. The impact of the vulnerability depends on the commands allowed via OBD port. In the case of the Corvette, the researchers were able to trigger cyber-physical actions on the vehicle via the connected dongle. Through exploiting the vulnerability, the researchers were able to send an SMS to remotely apply breaks on the vehicle. Depending on the commands allowed from the OBD, other vehicles the attack could result in controlling more critical functions [27].

4.1.5 Tesla S Model

Different attackers were performed in Testa S Model, some required physical access to the vehicle and others exploited remotely. For the physical access, researchers were able to connect a laptop to the vehicle's in-car entertainment system and identified multiple vulnerabilities. Researchers were able to successfully implant a trojan in the vehicle's system to control it remotely. All the vulnerabilities identified in the research were patched by Tesla [28].

4.1.6 Nissan LEAF

Nissan application named Companion Application is used to allow users to have access to some information on the vehicle and perform specific actions. Researchers were able to identify vulnerabilities in the Companion Application and gain access to the historical GPS information of the vehicle [29].

5 Analysis of Cyber Security Attack on JEEP Cherokee

In this section, we analyze the attack on Jeep Cherokee that affected over 1.4 million vehicles. The researchers were able to perform the cyber attack remotely, with no physical access to the vehicle. Initial research required reverse engineering some of the components of the vehicle to plan the attack and chain different stages of the attack to reach from remote exploitation to perform physical actions on the vehicle such as applying breaks, vehicle's steering, and others. Although the experiment was conducted on Jeep Cherokee, it was not limited to this model. Vehicles with the same entertainment unit may have suffered similar vulnerabilities and impacts. In research, the attack surface was analyzed and the feasible attack chain was

chosen to perform the full attack chain, from initial access to physical action execution. The first part of this section discusses the CAN connectivity architecture seen in Jeep Cherokee, then discusses the attack phases. This is important to understand how to send messages between two networks in the vehicles (CAN buses).

5.1 CAN Connectivity

In the example of Jeep Cherokee, two CAN buses are used; CAN-HIS and CAN-C connected to different networks. ECUs talk to each other via CAN bus, each CAN bus is connected to a different set of ECUs. The CAN buses of Jeep Cherokee are explained below. The first CAN bus in the vehicle is CAN-IHS, stands for Controller Area Network for Interior High Speed. The CAN-IHS bus is low speed CAN bus that is used for non-critical systems such as climate controls, radios, and others. Examples of the ECUs connected to CAN-IHS bus are as follow:

- AMP Ampilifer Radio Module.
- Body Control Module (BCM).
- AHLM Module – Headlamp Leveling.
- PAM Module – Park Assist.
- DLC Data Link Connector

The second CAN bus is CAN-C bus, which is high-speed bus that is responsible to connect critical ECUs. Examples of the ECUs connected to CAN-C bus is as follow:

- Anti-Lock Brakes Module (ABS)
- Body Control Module (BCM)
- RADIO Module
- Electronic Parking Brake – EPB.
- Electronic Power Steering – EPS.

As we can see in the examples above, some ECUs are connected to both CAN buses, two examples are the radio module and the BCM Module. The direction the researchers took in the research was to target an ECU unit that could talk to both networks to widen the impact of the attack and reach critical ECUs.

5.2 Attack Phases

The attack chain developed by the researchers started from remote device exploitation to execute commands and sending control signals to critical ECUs. In section, the analysis is divided into four phases; target identification, remote code execution, sending CAN messages, and CAN payloads.

5.2.1 Identify Target

Initially, the researchers identified D-Bus service port 6667 by scanning the vehicle internally; connecting to the in vehicle's WiFi network. After examining the networking configurations of Uconnect, the researchers discovered an additional interface with a public IP address, which could result in remote exploitation of Uconnect system. To identify vulnerable Uconnect systems, performing a scan on port 6667 over the provider network. It was initially assumed that the provider blocks connections from other providers. The researchers took an additional step by exploiting a femtocell from the same provider to ensure that traffic is not blocked. It was later discovered that the port is open to all providers which increases the impact of the vulnerability. To avoid false positives, the service error message of services determines if the port belongs to Uconnect system or any other service such as IRC (Internet Relay Chat).

5.2.2 Gain Remote Code Execution

The researchers found more than one way to gain remote execution on the target system via the D-Bus service of Uconnect. Different vulnerabilities identified for remote code execution on the D-Bus service in addition to a feature that was implemented on the D-Bus service to allow code execution for an unauthenticated user. The first vulnerability idenfied was due to unsanitized user input on navTrailService function. The other vulnerabilities are either unauthenticated execution or command injection vulnerabilities.

Since arbitrary command execution achieved using the D-Bus service, researchers developed different payloads to interact with the CAN bus and obtain information using LUA scripts. Examples of the crafted commands sent via the D-Bus service.

- Uconnect system: From the Uconnect system, GPS coordinates can be queried.
- HVAC Module (A/C Heater): controlling heating and A/C of the vehicle.
- Radio Volume: controlling the volume of the radio.
- Knobs: disabling the D-Bus service make knobs unavailable and unresponsive.

5.2.3 Sending CAN Messages

The code execution achieved through the D-Bus service is performed on the OMAP chip. Although the Uconnect system is connected to both CAN buses of the vehicle; CAN-IHS and CAN-C, it cannot send messages to CAN directly. The communication from the OMAP to CAN buses are handled by Renesas V850ES/FJ3 chip. The researchers updated the V850 chip from the OMAP with a modified firmware to be able to send CAN messages. At this point, the execution from OMAP uses V850 chip as a proxy to communicate with CAN buses.

5.2.4 CAN Messages Payloads

The communication between OMAP chip and V850 chip uses a Serial Peripheral Interface (SPI). The V850 chip originally had a

predefined set of command IDs with hardcoded data to communicate with CAN bus. With flushed firmware, the V850 can send arbitrary CAN data from the OMAP chip.

At this point, arbitrary CAN commands can be sent remotely via the D-Bus service. After identifying the messages triggering cyber-physical actions, researchers were able to perform turn signals, locks, RPMS. These messages are considered normal CAN messages, the diagnostic CAN messages could cause greater cyber-physical impact but requires the vehicle to be traveling at a low speed.

6 Analysis of threat modeling frameworks

Threat modeling is in important phase of security engineering process. It involves identifying all security threats to the system regardless of the possibility to exploit them. It requires good understanding of the system. In order to develop meaningful security requirements, it is essential to have threats identified. Proper identification of threats in early stages can greatly reduce the ability of misusing the system [30]. There are different techniques of threat modeling [31]. In general, some of the main threat model techniques are:

- Attacker-centric
- Asset-centric
- Software-centric

These models are general and not specific to autonomous vehicles.

6.1 Attacker-centric approach

This threat modeling technique is built on attacker perspective by profiling an attacker's characteristics, goals and motivation to exploit vulnerabilities. The modeling technique aims to understand potential attackers who are likely to target the system and type of attacks that might be executed. Based on the understanding, mitigation strategies can be developed against studied attackers.

This approach uses tree diagrams for threat modeling. Examples of key elements of this approach include: the goals of the attacker, the techniques used by the attacker, the system components including software and assets and means of detection and mitigation.

A simple example is an attacker trying to obtain data from a database that is hosted in a backend system accessible from a website. Using this approach, the goal of the attacker would be to obtain the information stored in the database. Techniques include SQL injection (using unsensitized input commands) on the website, and use of automated tools by which exploitation could be carried out.

6.1.1 Intel's TARA (Threat Agent Risk Assessment)

This threat modeling technique focuses on prioritizing the most critical areas of the system and most vulnerable to attacks [32]. This ensures that the threat modeling efficiently address the areas that are exposed the most. Moreover, the framework focuses on threat agents that are most dangerous, what techniques and tradecrafts used to achieved their goals. The most exposed areas are then determined by cross-referencing the information obtained with known vulnerabilities. The process is shown in Figure 5. TARA's goal is to build security strategies with focus on areas with highest level of risk. This is achieved by determining the most likely attack vectors and applying efficient security strategy to address them. TARA relies on three main components:

- Threat Agents Library (TAL): unique library containing 22 threat agent and nine threat agent attributes.
- Common Exposure Library (CEL): list of known vulnerabilities and exposures.
- Methods and Objectives Library (MOL): contains threat agent objectives and methods used to achieve goals and objectives.

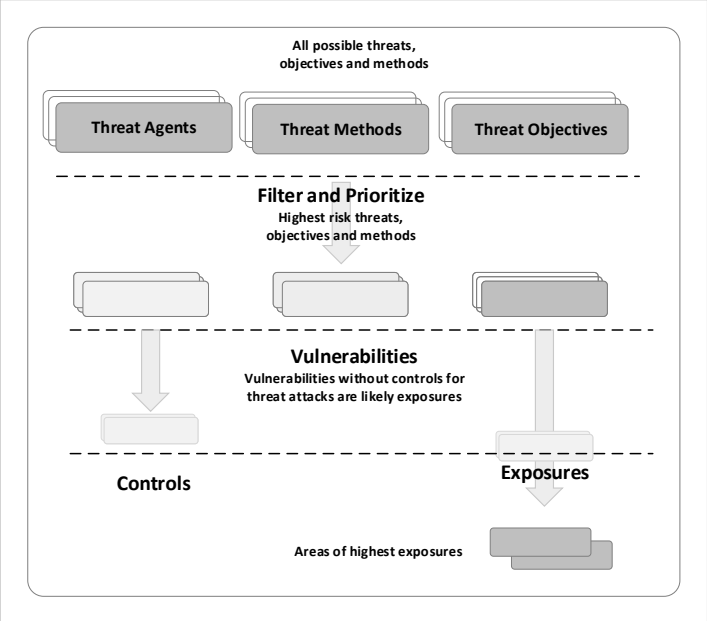

Figure 5: Narrowing down the fields of attacks.

6.1.2 Cyber Kill Chain

The Cyber-Kill threat modeling approach was developed by Lockheed Martin, an American company focusing on global aerospace, defense, security and advanced technologies [33]. The method focuses on the steps taken by an attacker to achieve desired goal. As name implies, the method is chained into multiple phases, each phase has its associated set of goals. Each phase outcomes contribute to the next phase. The cyber kill chain contains the following steps:

- Reconnaissance: research, identification, and selection of targets
- Weaponization: Combining remote access malware with exploit into deliverable payload
- Delivery: Delivering a payload to target (weaponized exploit).
- Exploitation: Exploit vulnerable application or system upon delivery

- Installation: Persistent access via means of installing backdoor in exploited system.
- Command and Control: Outside server communicates with the weapons providing "hands on keyboard access" inside the target's network

6.2 Asset-centric approach

This approach has two main components; assets and threats. The assets taxonomy involves identifying assets, asset groups, asset types, asset details [34]. The threat taxonomy utilizes attack trees, attack graphs and assets' own failure modes in order to prioritize associated risk levels and then mapped to assets. Methodologies based on the asset-centric approach include PASTA, OCTAVE and STRIDE

6.2.1 PASTA

PASTA (Process for Attack Simulation and Threat Analysis) is an asset-centric approach to threat modeling [34]. This methodology was developed by Minded Security and VerSprite. The obvious advantage of this methodology that it providers valuable information about risk reduction and security strategy that could target non-technical staff (example management or stakeholders). The methodology involves seven different stages illustrated below.

- Stage 1: Define Objectives
- Stage 2: Define Technical Scope
- Stage 3: Application Decomposition
- Stage 4: Threat Analysis
- Stage 5: Weaknesses and Vulnerability Analysis
- Stage 6: Attack Modeling and Simulation
- Stage 7: Risk Analysis and Management

The main goals of PASTA methodology are:

- Allows cost and time savings
- Integrates with SDLC
- Better understanding of most likely attack sources
- Better communication between security groups inside the company
- Increases the maturity of the organization in security

6.2.2 OCTAVE

OCTAVE Allegro (Operationally Critical Threat, Asset and Vulnerability Evaluation) a method developed by CERT Survivable Enterprise Management team. This method focuses information assets security in respect to the well-known security requirements, which are Confidentiality, Integrity and Availability (CIA). This method investigates the ways information assets are stored, transferred, used and processed. In addition, it extends to cover threats and vulnerabilities associated with information assets. The OCTAVE Allegro method consists of four different phases, with total of eight steps as shown in Figure 6.

- Phase 1: risk measurement criteria development
- Phase 2: identification and profiling of assets then the identification of containers to the identified assets
- Phase 3: threats to identified containers are identified with respect to assets
- Phase 4: mitigation strategies

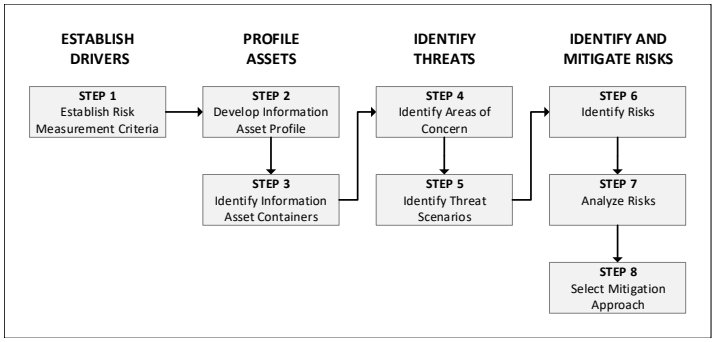

Figure 6: Phases and steps of OCTAVE Allegro.

6.2.3 STRIDE

The acronym STRIDE stands for six categories of security risks: Spoofing, Tampering, Repudiation, Information Disclosure, Denial of Service, and Elevation of Privileges.

- Spoofing refers to the act of posing as someone else (i.e. spoofing a user) or claiming a false identity (i.e. spoofing a process). Spoofing threats affect the authenticity property.
- Tampering refers to malicious modification of data in transit, at rest, or within processes. Tampering threats affect the integrity property.
- Repudiation refers to the ability of denying that an action or an event has occurred. Repudiation threats affect the non-repudiation property.
- Information Disclosure refers to data leaks or data breaches. Disclosure threats affect the confidentiality property.
- Denial of Service (DOS) refers to causing a service or a network resource to be unavailable to its intended users. DOS threats affect the availability property
- Elevation of Privileges (EP) refers to gaining access that one should not have. EP threats affect the availability property

By considering these risks for each asset, STRIDE threat model allows to list the applicable risks (also called failure modes) to each asset, and to map them to threats and known attacks. This way measures can be identified to examine and address gaps in the security posture of applications.

7 Experimental Results

This section of the paper discusses and analyzes a proof of concept of two replay attack and packet injection on a simulated CAN bus. In this experiment, we setup a simulation environment to simulate random CAN traffic generation and identifying control signals to perform specific physical actions.

7.1 Simulation Environment Setup

The simulation environment is setup using a virtual CAN bus than communicated over TCP and other tools that interact with the virtual CAN bus. In this section, we described the tools used to set up the simulation environment.

CAN for vehicle communication have different drivers and software utilities with no unified CAN tools and interfaces. However, there is a set of tools with a common interface available in Linux. The SocketCAN is an interface that was created on the Open Source development site BerliOS in 2006. By extending the Berkeley socket API in Linux, SocketCAN can send and receive traffic from the CAN controller in the model of a network device.

SocketCAN is not limited to physical CAN devices and networks, it supports built-in CAN chips and card drivers, external communication via serial or USB, and virtual CAN devices. More importantly, it supports virtual CAN environments.

- Atmel AT91SAM SoCs
- Bosch CC770
- ESD CAN-PCI/331 cards
- Freescale FlexCAN
- Freescale MPC52xx SoCs (MSCAN)
- Intel AN82527
- Microchip MCP251x
- NXP (Philips) SJA1000

Figure 7 compares the implementation of traditional CAN software with the SocketCAN implementation, which is unified. In traditional CAN software, the application has its protocols stack that talks to a character device, whereas SocketCAN is implemented in the Linux kernel with its own CAN protocol family enabling applications to communicate with a CAN bus interface in a generic network interface fashion.

SocketCAN repository contains various utilities for Linux CAN subsystem. These utilities can work with CAN communications within the vehicle from Linux operating system. Examples of the functions supported by the suite:

- Basic tools to display, record, generate can traffic
- Tools to send, generate, sniff CAN frames.
- Serial line discipline (SLC) configuration
- Log files converters
- CAN access via IP sockets
- CAN bus management

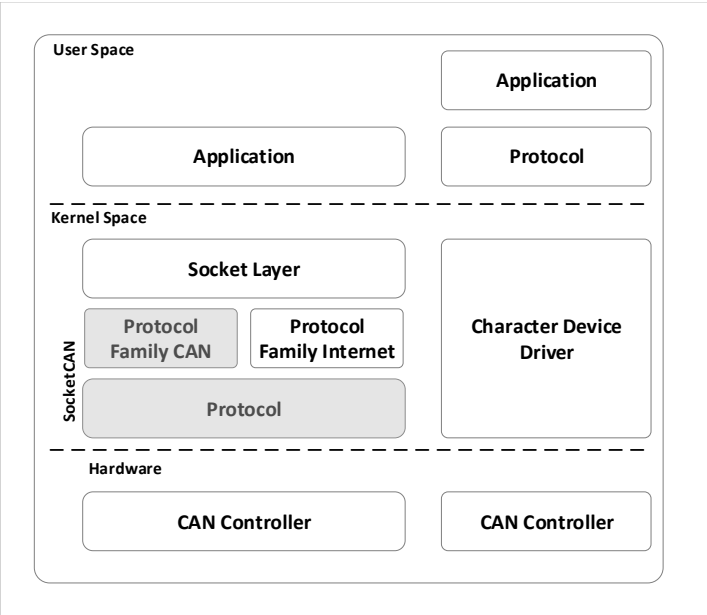

Figure 7: SocketCAN compared to traditional CAN software

Different tools are used in the experiment For CAN bus diagnosis, monitoring, and simulating target vehicle that interacts with the virtual CAN. For CAN diagnostic and monitoring, Kayak application is used. Kayak is a Java-based that can read CAN traffic log files and display information graphically on gadgets.

For target vehicle simulation and CAN traffic fuzzing, the instrument cluster simulator (ICSim) is used, which is an opensource tool developed by Open Garages. The ICSim software is Linux based and relies on virtual CAN devices. ICSim was designed to allow researchers, individuals, developers and others to safely familiarize themselves with CAN reversing. ICSim includes a graphical interface for some of the functions of CAN such as doors, engine RPM, and others.

7.2 Security Attacks on CAN Bus

The following experiment shows how the virtual environment setup can generate, display, and sniff CAN frames. Using the libraries and utilities described earlier in this section, a virtual CAN interface was created in Linux (Debian 4.19-28).

Using the virtual CAN interface is running as “vcan0”, CAN frames can be sent and received using can-utils suite. The current messages are random CAN messages, which are not currently analyzed as per their functions or character device they are trying to communicate with. The first step is generating random CAN messages with default bi trate. The messages generated can be viewed in Figure 8.

Since the messages are communicated over TCP/IP in the virtual environment, messages can be sniffed using different tools such as Wireshark and CANSniffer or Kayak.

7.3 Injecting CAN Frames

This part explains injecting CAN frames into the virtual CAN bus and displays results in the simulator. To identify the CAN message responsible to perform a physical action, the ICSim was used to generate specific actions on the vehicle, and the generated CAN traffic was recorded. Then simply replaying the recorded messages could identify the messages related to the performed actions with other noise that can be discarded for this experiment. The sequence followed in the experiment is explained in Figure 9.

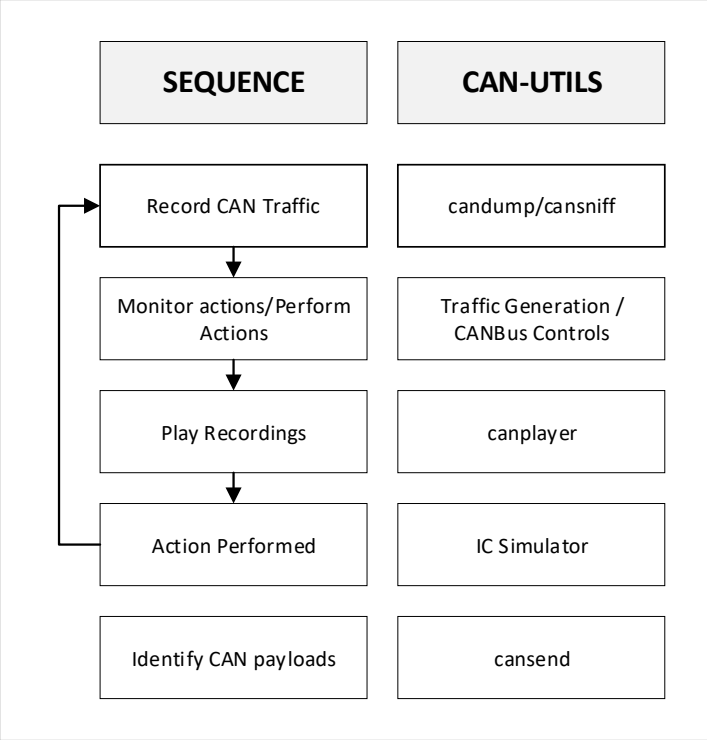

Figure 9: Sequence used to identify CAN messages

Using the generated traffic from the libraries explained earlier, the signals used to perform physical actions were identified. CAN traffic was generated on virtual CAN and recorded in log files. The signals responsible for door locks, RPM and signals identified as shown in Figure 10. At this point, using the CAN ID, we can send specific CAN messages to trigger doors, acceleration or light signals. For example, to accelerate, the CAN ID used is 244 (hex representation).

```

Figure 10: Specific CAN messages for desired functions

After identifying the CAN messages to perform specific physical actions, two security attacks are performed. The first one is a replay attack. This was achieved by recording CAN traffic in a file. Since CAN communication (in the scenario described in the paper) does not use session IDs or encryption to protect against replay attacks, traffic was recorded were played on a different virtual CAN bus successfully. The second security attack performed is traffic injection. In a virtual CAN bus with random traffic being communicated, specific commands were sent to set RPM to a specific value, open doors, and start turn signals. The results of the signals sent are shown in Figure 11.

The tools used in the experiment do not simulate actual ECUs in terms of behavior. Some ECUs are wired directly and do not accept messages from the CAN bus directly. In such situations, additional effort is required to send signals from allowed ECUs. In diagnostic mode, messages might be accepted from the CAN bus. Additional research is required to fully understand what can be controlled directly from the CAN bus. Aftermarket ECUs expose CAN connectivity and expand the attack surface of modern vehicles. In the experiment, we focused on simple scenarios of packet sniffing and packet injection. The CAN bus is designed to allow real-time communication between ECUs but it is not secured by design. These types of attacks are not limited to aftermarket ECUs or gadgets, any successful exploitation or code execution on ECU connect to CAN bus could achieve similar or higher impact.

In the presence of aftermarket devices, new range of vulnerabilities will be introduced. The inter-vehicle communication was not designed to interact outside the perimeter of the vehicle. With the absence of defined threats, it is extremely difficult to provide assurance on security measures taken.

Starting from a conceptual model for autonomous vehicles is essential to capture different components of autonomous driving ecosystem. Threat modeling could be applied to identify potential threats pertaining autonomous vehicles and support the development of security requirements that cover scenarios discussed in this paper. This should support addressing the knowledge gap in the field of autonomous vehicle security.

Our future plans include the research of a test-based security verification framework for autonomous vehicles. Due to the lack of a centralized tests repository for security testing, we will focus on developing a security test-cases repository based on blockchain technology. In addition, the current research was limited to few

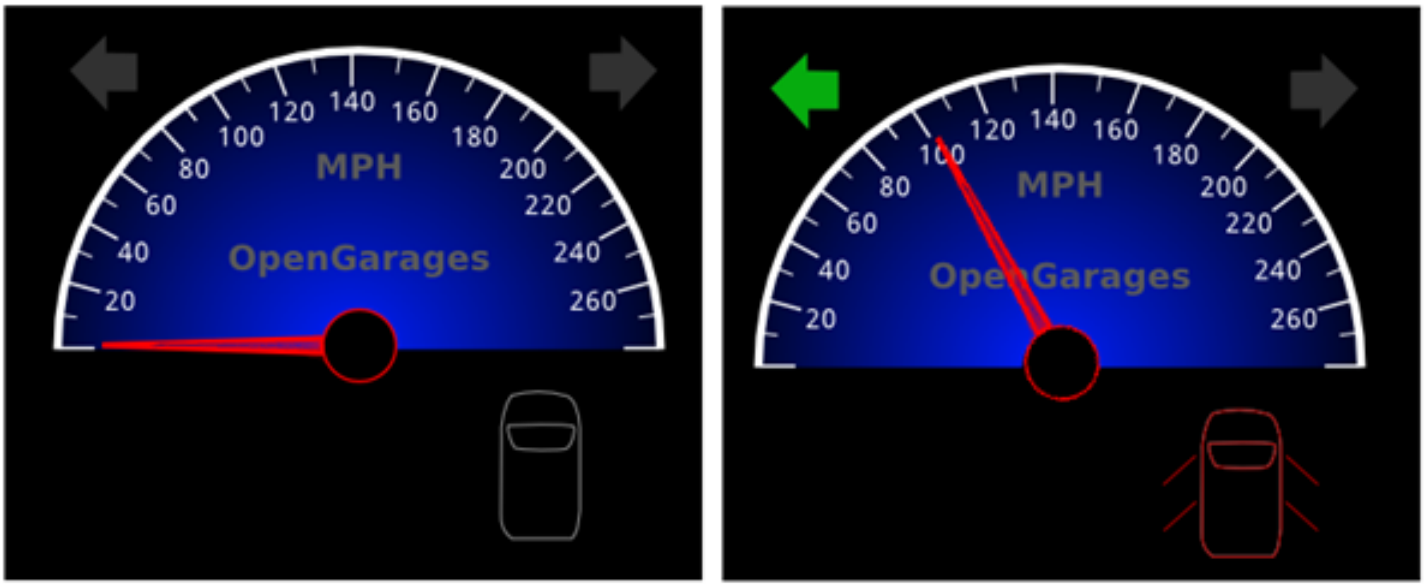

Figure 11: Results of the physical actions displayed on ICS Simulator

scenarios on attacks on CAN bus. We plan to design more attack scenarios against common vulnerabilities in aftermarket ECUs.

8 Conclusion

Several technologies in modern vehicles were designed and built without security in mind. As modern vehicles and future autonomous vehicles are becoming more and more computerized and connected, these technologies present new risks and widen the attack surface.

Threat modeling is an essential step for defining security requirements of autonomous vehicles, or any system in that regard. With the absence of defined threats, it is extremely difficult to provide assurance on security measures taken. The initial work conducted towards the research was focused on establishing a conceptual model for autonomous vehicles. This will support in defining the scope and basing the threat model against it.

The experiment showed briefly how easily CAN traffic can be captured or sniffed. In the presence of aftermarket devices, new range of vulnerabilities will be introduced. The inter-vehicle communication was not designed to interact outside the perimeter of the vehicle. However, these devices open new attack surfaces allowing some components of inter-vehicle communication to be exposed to the outside world.

Conflict of Interest The authors declare no conflict of interest.

ABSTRACT

This paper presents a low voltage, low power, fast settling switched capacitor based Proportional to Absolute Temperature (PTAT) current reference circuit. Unlike in a conventional resistor based PTAT current source, the proposed circuit saves a significant amount of silicon area on chip and hence the circuit becomes less susceptible to process variations. It creates a reference current of 1 nA from a 0.5 V power supply at room temperature (27°C). It has PTAT characteristics in the temperatures from −10°C to 80°C. The circuit draws a very low power of 1.5 nW and exhibits a good supply voltage sensitivity of 3.2 %/V. A startup circuit connected to the PTAT source improves the transient response by reducing the settling time. To test the PTAT current reference circuit, a low power log-domain filter which can be used for biomedical applications is realised and biased with the proposed PTAT current source. Results show that the filter cutoff frequency is constant over temperature variations. The CMOS technology used for designing the circuits is UMC 65 nm and tool used for simulations is Cadence Virtuoso.

1 Introduction

Portable and wearable/implantable devices are gaining worldwide acceptance among consumer/biomedical electronics. Circuit designs in such devices have a bottleneck on power dissipation and chip area. Log-domain circuits are one of the best possibilities in exploring low power, high dynamic range analog designs. Log-domain filters and transconductance-capacitor ($G_m - C$) filters can be used in biological data acquisition system which involves low frequency signals like ECG (electrocardiogram) and EEG (electroencephalogram). Since the transistors in these log-domain filters are working in sub-threshold mode of operation (weak-inversion), a low cutoff frequency can be achieved with low values of bias currents (order of *nA*). This paper is an extension of work originally presented in [1].

The cutoff frequency (f_o) of log-domain and $G_m - C$ filters is given by (1) [2, 3].

$$f_o = \frac{G_m}{2\pi C} = \frac{I_o}{2\pi\eta V_T C} \tag{1}$$

where η, I_o and V_T are sub-threshold slope factor, bias current and thermal voltage respectively. Equation (2) gives the expression for thermal voltage.

$$V_T = \frac{kT}{q} \tag{2}$$

where k, T and q have their usual meanings.

Equation (1) shows the direct relation between cutoff frequency and bias current. I_o is usually generated from a current reference circuit. The current reference should be stable against variations in process and supply voltage. Supply voltage sensitivity is the parameter which shows the stability of the current reference against supply voltage variations. Lower supply voltage sensitivity indicates a better current reference. Depending on the mode of operation of transistors in the circuit or the topology of the filter architecture, the current reference can be a temperature independent or Proportional to Absolute Temperature (PTAT) current reference. From (1) and (2), in log-domain and $G_m - C$ filters, it is evident that f_o has an inverse relationship with temperature. To fix this problem, I_o is generated in such a way that it has also a linear relationship with temperature. Thus a PTAT current reference is used to bias log-domain/$G_m - C$ filters. As a cumulative effect, the filter cutoff frequency remains constant over temperature variations.

Many PTAT current reference designs are explored in the literature. Beta-multiplier based circuits discussed in [4]–[5] have adequate PTAT current characteristics. However, to generate low reference currents under low supply voltage for low frequency filters used in biological data acquisition system, larger values of resistors are needed which occupies large area on chip. Moreover the control over temperature coefficient of resistance also becomes

*Corresponding Author: Muhammed Mansoor C. B., Research scholar, Dept. of Electronics and Communication Engineering, National Institute of Technology Karnataka, Surathkal, India, +91 9497368483, mansoorcb@gmail.com

difficult. A comprehensive research has been carried out on the conventional PTAT designs to tackle such shortcomings [6]–[7]. In [7], self-cascode transistors are used instead of resistor. This improves supply variation rejection, but linearity in current versus temperature characteristic has been compromised. In [8], composite transistors are used in the PTAT circuit to enhance the supply voltage sensitivity, but large resistor values are needed to generate smaller currents. In [2, 9], switched capacitors are used in place of resistor. But PTAT current is generated from PTAT voltage using opamp circuits like voltage to current converter which in turn increases the overall power dissipation of the circuit. [1] shows a good switched capacitor based PTAT reference. But the settling time of the reference current is compromised.

Settling time of current reference becomes a significant aspect especially in high speed applications. When the settling time of the reference current increases, the circuit which uses this reference current to generate its bias current also takes a significant amount of time to settle its bias current to steady state value. In case of a filter used in a wireless communication system, it takes a significant time to fix its cutoff frequency which may lead to attenuation of relevant signal information. For example, the circuit presented in [1] requires 8 ms to stabilise its current which means that it takes around 8 ms for the subsequent filter to fix its cutoff frequency which is biased by this reference current source. This work proposes a feasible solution to this problem.

In this paper, a fast settling PTAT current source is proposed. A startup circuit added to the PTAT source improves the settling time of reference current. The proposed circuit exhibits good PTAT characteristics and better stability against power supply fluctuations. This can be used to bias low frequency filters in biomedical applications. A low power log-domain filter is also designed and biased using the proposed PTAT current source. Results show that the cutoff frequency of the filter remains constant irrespective of temperature variations. This paper is organized as follows. Details of the proposed PTAT circuit along with the results are given in Section 2. Log-domain filter realisation and filter response are detailed in Section 3. Finally conclusions are drawn in Section 4.

2 Proposed Improved PTAT Reference

A conventional beta-multiplier based current source circuit [5] is shown in Figure 1. Depending on the mode of operation of transistors, it can be a constant-G_m biasing circuit [5] or a PTAT current source. It acts as former if all the transistors work in strong-inversion saturation region ($V_{GS} > V_{th}$ and $V_{DS} \geq V_{GS} - V_{th}$) and as latter if all the transistors work in weak-inversion saturation ($V_{GS} < V_{th}$ and $V_{DS} \geq 3V_T$).

When transistor operates in weak-inversion region, its drain current [10] can be expressed as following.

$$I_D = \frac{W}{L} I_{D0} e^{\frac{V_{GS}-V_{th}}{\eta V_T}} (1 - e^{\frac{-V_{DS}}{V_T}}) \tag{3}$$

where $I_{D0} = \mu_n C_{ox} (\eta - 1) {V_T}^2$; μ_n and C_{ox} are electron mobility and gate oxide capacitance per unit area respectively. Other terms have their usual meanings. For $V_{DS} \geq 3V_T$ (weak-inversion saturation region), (3) can be approximated to (4).

$$I_D = \frac{W}{L} I_{D0} e^{\frac{V_{GS}-V_{th}}{\eta V_T}} \tag{4}$$

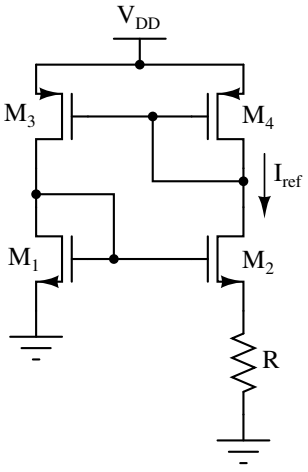

Figure 1: Beta-multiplier circuit

From Figure 1, the reference current I_{ref} which is also the drain current of M_2 (I_{D2}) can be written as (5).

$$I_{ref} = \frac{V_R}{R} \tag{5}$$

Voltage across resistor R (V_R) can be given as (6).

$$V_R = V_{GS1} - V_{GS2} \tag{6}$$

Using (4), gate-source voltages of M_1 and M_2 can be expressed as (7) and (8) respectively.

$$V_{GS1} = \eta V_T ln(\frac{I_{D1}}{I_{D0}(\frac{W}{L})_1}) + V_{th1} \tag{7}$$

$$V_{GS2} = \eta V_T ln(\frac{I_{D2}}{I_{D0}(\frac{W}{L})_2}) + {V_{th2}}' \tag{8}$$

${V_{th2}}'$ can be written as (9) [11] to include the body effect of M_2.

$${V_{th2}}' = V_{th2} + (\eta - 1) V_{SB} = V_{th2} + (\eta - 1)(V_R) \tag{9}$$

By substituting (7) and (8) in (6) and by assuming $V_{th1} = V_{th2}$, V_R can be derived as following.

$$V_R = I_{ref}.R = V_T ln(p) \tag{10}$$

where

$$p = \frac{(W/L)_2}{(W/L)_1}$$

Thus, I_{ref} can be expressed as (11).

$$I_{ref} = \frac{V_T ln(p)}{R} \tag{11}$$

Assuming R is thermally stable, I_{ref} is directly proportional to temperature thereby giving PTAT characteristics. For lower values of currents (order of nAs), large values of resistors are needed. For example, to generate a reference current of 1 nA using circuit shown in Figure 1, a 10 MΩ resistor is required if p is chosen as 1.5. To accommodate such large resistors on chip, huge area is needed

which makes the circuit more process dependent, hence reducing the accuracy of I_{ref}. In a typical SoC (System-on-Chip), where digital circuits and analog circuits co-exist together, a stable and precise clock will be available. In such systems, the resistor R in Figure 1 can be replaced by a switched capacitor driven by this clock which significantly enhances accuracy of I_{ref}.

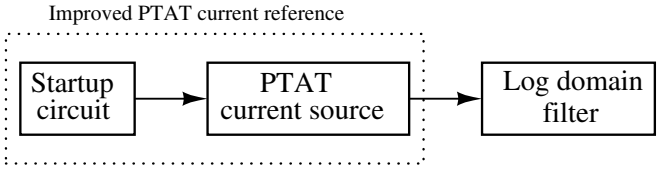

Figure 2: Block diagram

The entire block diagram of the circuit setup explained in this paper is shown in Figure 2. The startup circuit is added to the PTAT current generator to reduce the settling time of I_{ref} thereby improving the transient response.

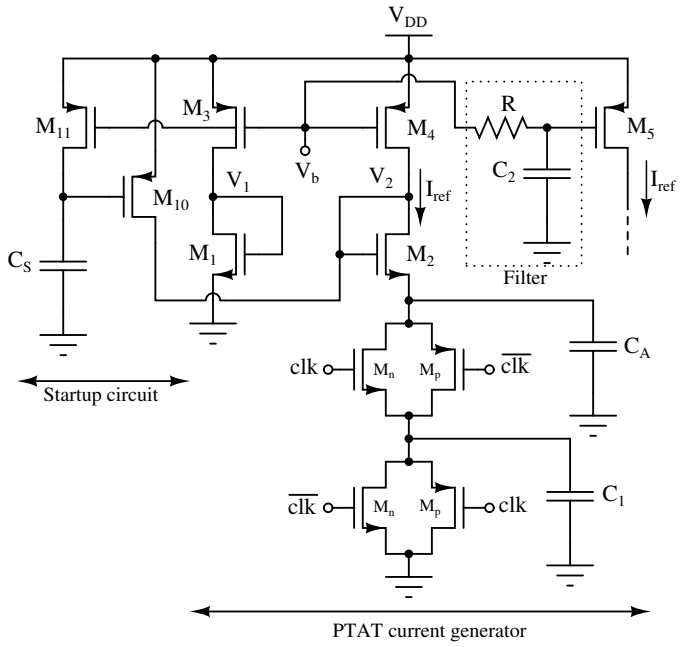

Figure 3: Proposed improved PTAT current reference

The transistor level implementation of PTAT current reference along with startup arrangement is shown in Figure 3. In the proposed circuit, every transistor is working in weak-inversion region. The value of p is chosen as 1.5 which means that the size of M_2 is 1.5 times the size of M_1. A switched capacitor comprising of capacitor C_1 and transmission gate switches (M_n and M_p) is used in place of resistor. M_p is selected 4 times larger than M_n in the transmission gate so that its on resistance does not depend on the voltage across it. Two clocks ('clk' and '$\overline{clk}$') which are complementary to each other and having frequency $\frac{f_{clk}}{}$ are used for the switching operation. When 'clk' becomes high ('$\overline{clk}$' becomes low), capacitor C_1 charges and when 'clk' becomes low ('$\overline{clk}$' becomes high), it discharges. The average resistance (R_{eq}) of the switched capacitor is given as in (12) [5].

$$R_{eq} = \frac{1}{f_{clk} C_1} \tag{12}$$

By substituting R_{eq} (12) in place of R in (11), we get (13).

$$I_{ref} = V_T f_{clk} C_1 ln(p) \tag{13}$$

From (13) it can be seen that, I_{ref} is directly proportional to C_1. If f_{clk} and p are chosen properly, smaller capacitor values can be obtained for the currents in the order of nA.

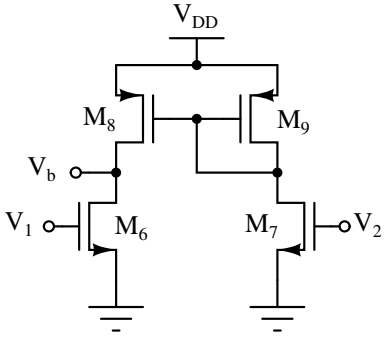

Figure 4: Error amplifier

The purpose of error amplifier which is shown in Figure 4 is to make the drain voltages of M_1 and M_2 equal thereby making currents through them equal. This kind of biasing minimises the dependency of I_{ref} on V_{DD} which improves supply voltage sensitivity.

It takes around *8 ms* for the reference current to settle to the steady state value of *1 nA* in the circuit presented in [1]. To reduce this delay, a startup arrangement comprising of M_{10}, M_{11} and C_S is added to the circuit. A similar kind of startup circuit is discussed in [12]. In Figure 3, when the circuit is switched on and before it reaches the steady state, initially the gates of $M_{1,2}$ and $M_{3,4}$ are at zero volt and V_{DD} respectively. Assuming zero initial voltage across the capacitor C_S, M_{10} turns on and pulls up the gates of $M_{1,2}$ to V_{DD}. $M_{1,2}$ start conducting and I_{ref} rises. Then, potential at the gates of $M_{3,4}$ drops and M_{11} turns on. C_S starts to charge towards V_{DD} and potential at the gate of M_{10} increases and once the circuit reaches steady state, M_{10} turns off. M_{10} and M_{11} do not have a static current path from V_{DD} to ground. Hence startup circuit dissipates zero static power.

Value of capacitor C_S and sizes of M_{10} and M_{11} determine how fast startup circuit can initialise the main circuitry and how fast it can be disconnected once main circuitry reaches the steady state. Transistors M_{10} and M_{11} operate in linear region and the linear on resistance of these transistors are given by (14).

$$R_{on} = \frac{1}{\mu_n C_{ox} \frac{W}{L} (V_{GS} - V_{th})} \tag{14}$$

How fast startup circuit is switched on depends on how fast transistor M_{10} turns on. The on time of M_{10} is limited by the input capacitance of M_{10} which comprises of gate to source and gate to drain capacitances. By properly choosing the size of M_{10}, the on time can be optimised.

When it comes to disconnection of startup circuitry, assuming M_{11} as a linear resistance given by (14), the RC time constant (τ) of the branch consisting of M_{11} and C_S is given by (15).

$$\tau = \frac{C_S}{\mu_n C_{ox} \frac{W}{L} (V_{GS} - V_{th})} \tag{15}$$

When capacitor C_S charges above the voltage $(V_{DD} - V_{th})$, M_{10} turns off. $(V_{DD} - V_{th})$ is approximately 150 mV in this design and time for C_S to charge to this voltage (30 % of final value) from 0.5 V supply through M_{11} is nearly 0.4τ.

A low pass filter which comprises of R and C_2 is added to maintain the ripple content in the output reference current within the accepted level. Capacitor C_2 is chosen as 0.1 pF and resistor R is tuned to obtain the ripple content in I_{ref} less than *1 %*. To remove high frequency noise during switching operation, capacitor C_A is used at the source of M_2. A 100 kHz clock is selected for this work. The capacitors, C_1, C_A, C_S are taken as 0.8 pF, 10 pF, 1 pF respectively. By substituting (13) in (1), f_o can be expressed as (16).

$$f_o = \frac{f_{clk} C_1}{2\pi\eta C} ln(p) \tag{16}$$

From (16), it can be seen that f_o is independent of temperature.

2.1 Simulation results

The proposed circuit is designed using UMC 65 nm CMOS process with a supply voltage of 0.5 V. Periodic Steady State (PSS) analysis is carried out to plot the reference current. Figure 5 shows the output current generated (1 nA) for one clock period (10 μs) at room temperature ($27°C$).

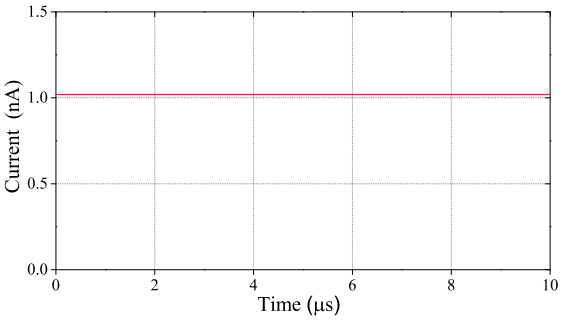

Figure 5: I_{ref} at V_{DD}= 0.5 V

Figure 6 shows I_{ref} variations when temperature is varied from $-10°C$ to $80°C$ for V_{DD} = 0.5 V. It can be observed that I_{ref} changes linearly with temperature and thus has a good PTAT characteristics over the range of temperature.

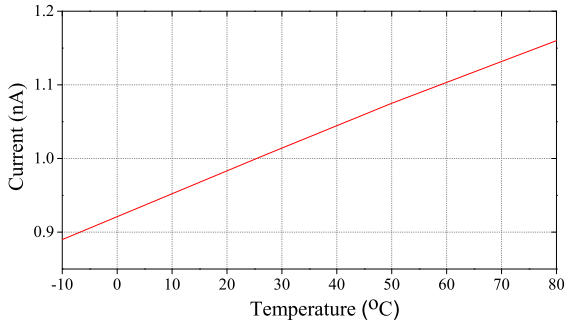

Figure 6: I_{ref} vs. Temperature plot

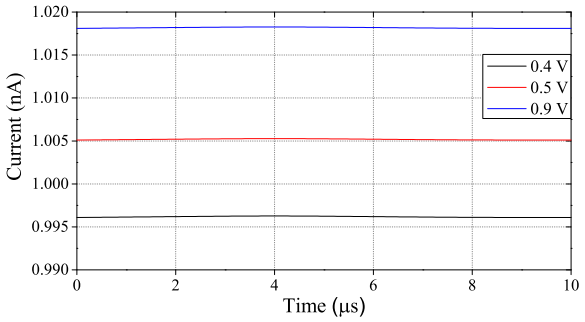

Figure 7: I_{ref} for different supply voltages

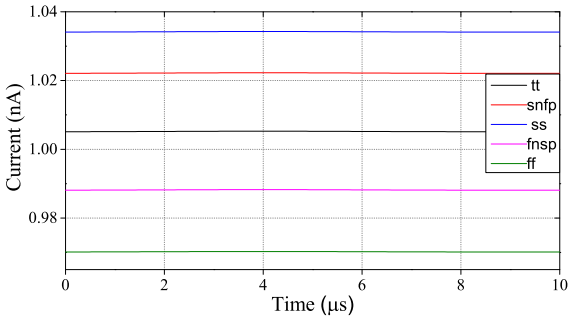

Figure 8: I_{ref} across the process corners

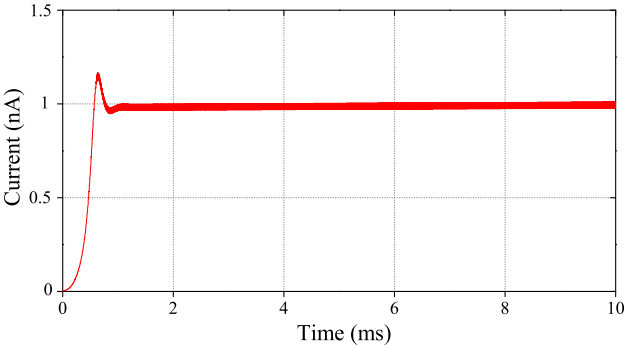

Figure 9: Transient response of the current flowing through M_2

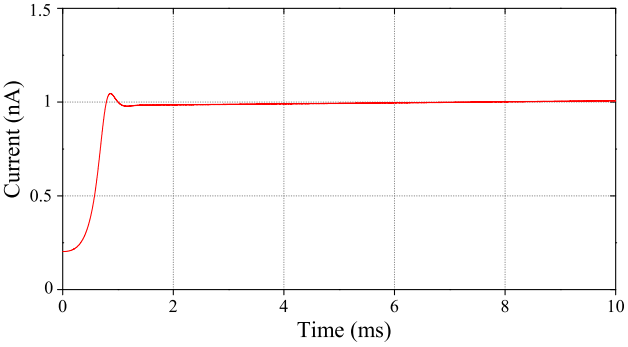

Figure 10: Transient response of the current flowing through M_5

I_{ref} is plotted for different values of V_{DD} at room temperature as shown in Figure 7. I_{ref} is *0.996 nA* and *1.018 nA* for V_{DD} of 0.4 V and 0.9 V respectively. The supply voltage sensitivity of I_{ref} is found to be *3.23 %/V* by considering these extreme values.

Figure 8 plots I_{ref} for various process corners at room temperature and V_{DD} = 0.5 V. I_{ref} deviates maximum in *ss* and *ff* corners (*1.034 nA* and *0.968 nA*). The maximum deviation is less than ±*3.6 %*.

The current flowing through the source of M_2 is shown in Figure 9. It has ripples having peak to peak magnitude of approximately *0.1 nA*. The ripple free current flowing through M_5 is shown in Figure 10. The settling time is found to be approximately *1 ms*.

Table 1: Comparison of the proposed work with other similar works

	[7]	[13]	[14]	[1]	This work
Technology (nm)	1500	180	40	65	65
Supply voltage (V)	1.2	1.2	1	0.5	0.5
Reference current (nA)	0.4	6	100	1	1
Settling time (ms)	-	-	-	8	1
Power (nW)	2	-	350	1.5	1.5
Supply voltage sensitivity (%/V)	6	6.47	2.9	2.7	3.2

The improved PTAT reference consumes a power of *1.5 nW* at room temperature from a supply voltage of 0.5 V. The proposed circuit along with existing PTAT current references in the literature are listed in Table 1 and a fair comparison is done. The proposed PTAT circuit functions under the lowest supply voltage and has a very low supply voltage sensitivity and settles faster than [1] (nearly 87 % improvement in settling time).

3 Log-Domain Filter Realization

The proposed PTAT current source shows excellent PTAT characteristics. To verify this, a low frequency log-domain filter is designed and biased with the proposed switched capacitor based PTAT current reference. This log-domain filter can be used in low power biomedical applications like processing of ECG, EEG signals. The expectation is that the cutoff frequency of the filter remains the same irrespective of the variations in temperature.
The transfer function of a first order low-pass filter is

$$H(s) = \frac{Y(s)}{X(s)} = \frac{\omega_o}{s + \omega_o} \tag{17}$$

where ω_o is the cutoff frequency of the filter. The corresponding time domain differential equation is given by

$$\frac{dy(t)}{dt} + \omega_o y(t) = \omega_o x(t) \tag{18}$$

where x(t) and y(t) represent the input and output currents of the filter respectively. By solving the differential equations and relating the current-voltage in transistor operating in subthreshold operation, we get

$$I_K I_{out} = I_{dc} I_{in} \tag{19}$$

where I_{in} contains both dc current I_{dc} and input current I_{signal}. I_K is the current flowing through M_3 which contains both capacitor current I_C and I_{dc}. I_{out} is the output current. Equation (19) can be realized using a translinear loop having four transistors. These equations can be implemented in the form of a translinear circuit as shown in Figure 11 [15].

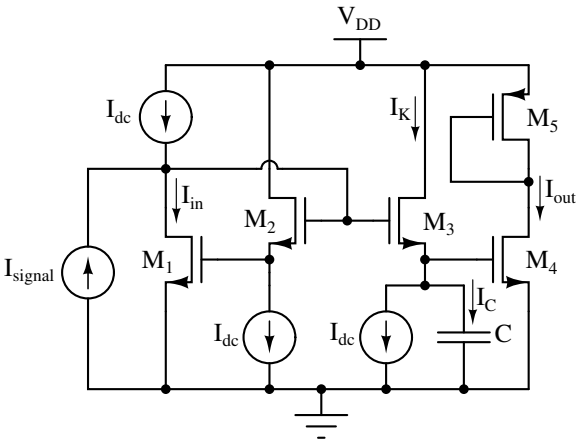

Figure 11: First order log-domain filter

In this circuit, the MOSFETs M_1–M_4 form the translinear loop. These transistors are working in sub threshold saturation region. The cutoff frequency of the filter can be tuned by varying the DC current and is given by following [16].

$$f_o = \frac{I_{dc}}{2\pi\eta V_T C} \tag{20}$$

The ideal DC current sources shown in Figure 11 can be replaced by current sources implemented using MOSFETs. In this work I_{dc} is taken as I_{ref} (1 nA). The cutoff frequency of 100 Hz is obtained by choosing C=37 pF.

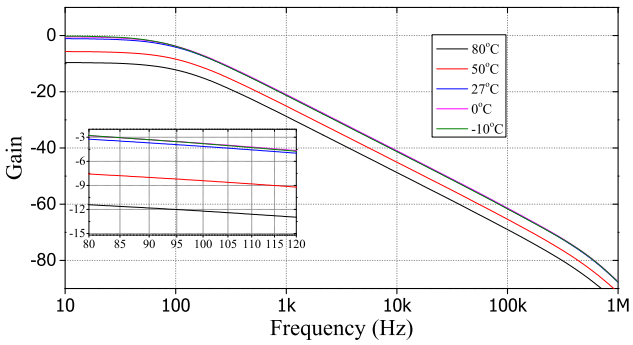

Figure 12: AC response of the filter biased with temperature independent current reference

3.1 Simulation results

The filter is designed using UMC 65 nm CMOS technology with a supply voltage of 0.5 V. For a comparison, I_{dc} is generated from a temperature independent current reference and ac response of the filter is plotted. Figure 12 shows the variation of cutoff frequency

in the temperatures ranging from $-10°C$ to $80°C$. The maximum deviation is found to be *16 %*. To verify the PTAT characteristics, I_{dc} is generated from the proposed PTAT source and ac response is plotted. Figure 13 shows that deviation of cutoff frequency is negligible and maximum deviation is found to be less than *2 %*. The band transitions are enlarged in corresponding inset graphs. Table 2 shows the deviation of filter cutoff frequency for both temperature independent and the proposed PTAT references.

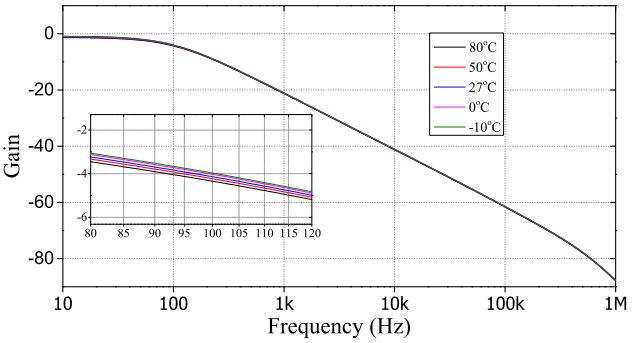

Figure 13: AC response of the filter biased with PTAT current reference

Table 2: Cutoff frequency deviation

Temperature (°C)	Cutoff frequency (Hz)	
	Temp. independent	PTAT
-10	116	101.9
0	107	101.2
27	100	100
50	93	99
80	88	98.4

Table 3 lists the parameters of the filter designed in this work.

Table 3: Parameters of the filter

Technology	65 nm CMOS
Supply voltage	0.5 V
Power	2.5 nW
Cutoff frequency	100 Hz
DC gain (at $27°C$)	0.94
I_{in_pp} at 25 Hz for 1% THD	0.82 nA
Input referred noise from 1 Hz to 100 Hz	3.26 pA_{rms}
Dynamic range	48 dB

4 Conclusion

This paper proposes a low voltage, low power, fast settling switched capacitor PTAT current reference circuit. Settling time is reduced with the aid of a startup circuit. The PTAT circuit exhibits good PTAT characteristics in the temperatures ranging from $-10°C$ to $80°C$ while operating under a very low power. The circuit is less susceptible to power supply fluctuations and can work at supply voltages as low as 0.4 V. To test the PTAT source, a low power log-domain low frequency filter is also designed and biased with PTAT reference. Simulation results imply that the filter cutoff frequency remains unchanged irrespective of temperature variations and this validates the theory explained in the paper.

ABSTRACT

Academic certifications are achievements desired by people, because they have a direct impact, positively, on their social lives. Such an important document, still widely issued in paper format, may be subject to forgery or impossibility of verification due to the unavailability of the issuing entity. This work consists of identifying, analyzing and testing some of the blockchain-based tools that are emerging, to offer more efficiency, reliability and independent degrees. A concept proof is presented, through the implementation of a prototype capable of issuing, verifying and sharing certificates. The results of this experiment are presented, analyzing the use of blockchain technology for this purpose. Finally, the work presents an overview of the current state of development and maturity in which these tools are found, reporting the advances and limitations, and exposing issues that still need to be resolved.

1 Introduction

This work is an extension of the work originally presented in 2019 at the international conference "Cyber-Enabled Distributed Computing and Knowledge Discovery (CyberC)" [1], which aims to present an analysis of the use of blockchain technology in the education area, for issuing and verifying academic degrees in higher education.

Academic certificates attest to the certificate holder's abilities and skills and are accepted internationally [2]. These qualifications have a major impact on income and social position, both in emerging countries and in developed countries.

For example, in Brazil, data from *Pesquisa Nacional por Amostra de Domicilios Continuas* (PNADC) showed that the level of education is decisive for the Brazilian's income [3]. According to the results presented, those who complete higher education achieve almost triple the remuneration compared to those who only have a high school education.

In Europe, according to Eurostat [1], every year higher education graduates in Europe exceed 4.5 million, in which France and the United Kingdom are the leading countries with over 740,000 graduates per year. The fraction of people with university degrees between 30 and 34 years old almost doubled in fourteen years, going from 23 % in 2002, to 39 % in 2016 [4].

As professionals become qualified, knowledge is directly transformed into income, and consequently in a better quality of life. Furthermore, these numbers confirm a continuous increase and constitute a solid basis that justifies the creation of solutions to verify the authenticity of university degrees.

The weakness of the paper model, which is still widely used, was even more evident during the crisis caused by COVID-19, in which the use of digital resources became indispensable.

Although digital initiatives have emerged to address these weaknesses [5], these solutions still depend on the issuing entity, concerning authenticity verification. Fortunately, blockchain promises to offer, besides this innovation, other improvements not yet achieved by digital solutions. Using the resources that the technology offers, it is possible to make the check process disconnected from the issuer and still guarantee authenticity.

The second innovation is related to privacy. Certificates are documents that contain personal information and are sensitive to data leakage. If, on the one hand, student privacy needs to be preserved, on the other hand, its distribution benefits those interested [6].

*Fernando Richter Vidal, Sao Joao da Boa Vista-SP Brazil,37705@ufp.edu.pt
[1] `http://ec.europa.eu/eurostat`

Finally, blockchain solutions offer the third innovation compared to digital certificates, about timestamp. Due to the information being immutable and stored chronologically within the network, they accurately express the dates on which the events occurred.

This paper discusses the use of blockchain technology, aiming to benefit academic certificates with these possible innovations. The document is organized as follows: the next section provides a brief overview of blockchain technology; next, we describe the main differences between the blockchain solution and digital certificates; right after, we present the CertEdu prototype developed by *University Fernando Pessoa* (UFP), as well as a brief discussion of the results obtained and we conclude with some final remarks.

2 Background

2.1 Blockchain

Blockchain is a distributed system, formed by records that are organized in blocks and are linked to each other through cryptographic mechanisms. The technology became well known through the cryptocurrency Bitcoin [7], and soon expanded to several other applications.

There are three types of blockchain: public, private or consortium [8]. Public networks, also called permissionless blockchains, provides a free access environment to any participant who wants to join the network, however, the transaction validation rules are predefined and cannot be changed by any member. Typically, this type of blockchain implements the *Proof of Work* (PoW) consensus mechanism. In private networks, also called permissioned blockchain, the rules are defined according to the business interest. The organization that controls the network can define, for example, which users will decide on consensus or how to manage the network to accept new members. Finally, the consortium network is a category that merges properties from the public and private networks in the same environment. For example, in some scenarios, it would be interesting to keep the access public to the network, but also allow to make some data encrypted to preserve privacy and the anonymity of a participant.

Due to the consensus mechanisms and their *Peer-to-Peer* (P2P) topology, the network has gained strong protection against tampering. The success of an attempt of violation is conditioned to changes in all other previous blocks. Besides, attacks that would be able to take control of the network, such as a 51 % attack, would be extremely costly and could cost USD 500K per hour of processing [9]. In this aspect, the bigger the network, the more secure it becomes, which explains why Bitcoin is more secure when compared to other smaller networks [10]. This blockchain features results in an important property, which is immutability.

A block is always connected to a previous block, except for the genesis block, forming, then, a sequential chronological chain. The maximum size that a block can reach, depends on how each blockchain platform implements it. On Bitcoin, this value cannot exceed 1 Mb [11], while, on Ethereum there is no fixed limit, and the size change according to the number of gas units that can be spent per block (block gas limit).

As shown in figure 1, the block is organized in two areas: header and content. The header stores eighty bytes of control information. We find information like the hash header and the previous block; a software version, the target of the difficulty, a nonce, the root of Merkle [12], and a timestamp. Regarding the content area, they are stored as records. On average, a content area can store over five hundred transactions [5].

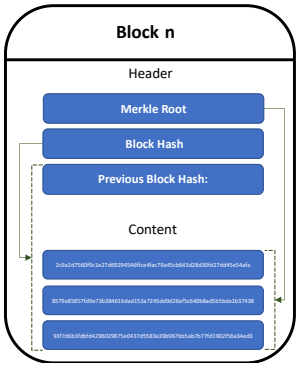

Figure 1: Overview of a Block Structure

Transactions are used to transfer an asset from one account to another account. The owner of an asset can move it inside the blockchain, through an account identified by a public address, which is controlled by its corresponding private key [13].

There is a conceptual difference between the public key and public address. The public key is used to verify the signatures generated by the private key's owner, while the address serves to identify the account. Using the example of Bitcoin, the process of generating the address is as follows: the public key is obtained by applying the function *Elliptic Curve Digital Signature Algorithm* (ECDSA) over the private key; the public key is subjected to two functions, *Secure Hash Algorithm* (SHA)-256, and *Race Integrity Primitives Evaluation Message Digest* (RIPEMD)-160; the resulting string size is reduced by passing the function *Base58Chech*, resulting in an address like *mgAzKQZZi*47*g*4*UMvmGJCsicbJ*4*P*3*B*8*SHRr* [14].

In the next sections, will be discussed how academic certificates can be used as assets in the blockchain. Through the CertEdu application implemented by UFP, questions such as authenticity will be analyzed, as well as universities and students can have their identities verified. Finally, the results obtained by systematic tests are analyzed.

2.2 Certification

Certification involves three processes: issuing, verification, and sharing [15]. This paper evaluates the application of blockchain in each one of the processes, mainly in the verification and sharing. The digital certificates innovate compared to the paper model but do not guarantee verification and sharing because they depend on central points. As Schär notes, academic certificates are useful, only if they can be verified [6].

The disruptive technology of the blockchain allows creating a structure capable of making the verification process independent [16]. The figure 2 presents a typical scenario, in which the university, the student, and the employer are involved. Note that Jane's certificates can be verified directly on the blockchain, without contacting the university.

Table 1: Comparative between digital certificates vs. blockchain solutions

Properties	Digital Certificate	Blockchain Certificate
Reliability	Relies only in the digital signature	Several cryptography mechanisms are used
Privacy	All information are available in the certificate	Only the hash is public
Autonomy	Depend on central regulatory bodies	Technology eliminates the need for third parties
Data Loss	Depend on backup mechanisms	Standard normal distribution
Proof of existence	Dates relies on the suitability of the subscriber	Timestamp represent the date of the facts

Table 2: Comparison between the tools analyzed

Criteria	BTCert	Hyperledger	EduCTX	Blockcerts
Blockchain agnostic	no	no	no	yes
Self-sovereign identity	yes	yes [2]	yes	yes
Community with active user	no	yes	no	yes
Public network	yes	no	no	yes
Privacy concerns	yes	yes	yes	yes

The public information available on the blockchain says nothing about the student. This occurs thanks to the use of the hash, which records the certificate in a unidirectional way on the network, not allowing to retrieve any personal information from Jane. As a result, Jane has the autonomy to share the digital certificate file, only with whomever she wants, and everyone who receives the file will also be able to check it independently on the blockchain.

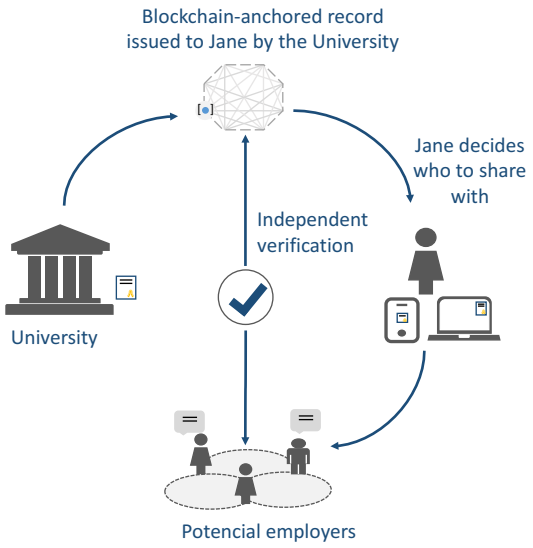

Figure 2: Diploma verification [1]

The table 1 presents a comparison between the properties of the digital certificate solution and the blockchain certificate solution. The blockchain innovation is realized in several aspects. The technology is more secure because unlike the digital certificate, in which all security depends relies only on the digital signature, the use of different cryptographic mechanisms, combined with the adoption of a distributed ledger, offers certificates a higher level of security.

Regarding privacy [17], digital certificates are much more sensitive to data leakage, considering that all personal information is contained in the certificate. This fact can restrict its replication. Analyzing this property in the blockchain solution, the distributed information says nothing about the student, and the certificate can be published without worries.

Digital signatures depend on central regulatory bodies. In some countries, there is not even an authority capable of certifying a signature [15]. In this aspect, blockchain offers complete autonomy, eliminating the need for third parties.

The blockchain, mainly in public architectures and consortium [8], offers a genuine backup mechanism since all information is replicated in pairs. Digital certificates, on the other hand, are easy to destroy electronically and depend on sophisticated backup mechanisms to avoid disappearing [15].

Finally, about the proof of existence, the reliability of the dates generated by digital certificates relies on the reliability of the subscriber. This can be a problem when a university has its private key stolen, and an attacker uses it to sign valid certificates with dates retroactive to the reported date of the theft. In this regard, the blockchain allows identifying the timestamp. As Ronning says, ”every credential issued with a stolen key must fail” [18].

3 CertEdu

3.1 Frameworks analyzed

The CertEdu project begins with the choice of the tool which will be used in the development. In 2018, when the project started, there were not many tools available for this purpose. The use of blockchain in the issue of academic certificate management is re-

[2] Shout combine Hyperledger Fabric + Hyperledger Indy

cent and the first students to receive their diplomas anchored in the blockchain, were from *Massachusetts Institute of Technology* (MIT), in 2017 [19].

We identified four potential platforms. The table 2 shows the comparison between them, and the used evaluated criteria.

Between the evaluated solutions, the Blockcerts tool was chosen to implement the prototype of this paper. The reason was that it better serves the requirements placed, especially about working on any blockchain. In reality, Blockcerts was the only certificate issuing solution that was born with the requirement to work for any blockchain. This requirement greatly increases the complexity of the solution, but it is important because it keeps the application life cycle long. Another point that drew attention is its active community of developers, which makes the project receive constant updates.

Interesting points were also noted on other platforms.

BTCerts, a project inspired by the MIT solution, address to the problem of centralizing the revocation process of Blockcerts. The model proposed by BTCerts solves the issue and can be easily adapted to any type of blockchain, but the costs are concernedly, mainly because it does not explain how the complementary revocation information would be registered, since the OP_RETURN_DATA field has a limited size of 83 bytes [20].

EduCTX, although having a more focused approach to digitizing credits *European Credit Transfer and Accumulation System* (ECTS), the solution brings an approach about how to use the multiple signatures, involving the student and institution to validate the transaction. The solution also raises an interesting question regarding the consensus mechanism used. Depending on the type of application, one consensus mechanism is more suitable than another. Considering education, it makes no sense to mine blocks to record transactions that contain academic certificates or ECTS credits. Universities are reliable nodes and responsible for the data they provide. Operating in a permissive way to create transactions, universities maintain autonomy in the issuing process, but they are unrelated about verification and sharing.

On Hyperledger's evaluation, its flexibility was identified as a strong point, and as a weak point, the lack of models capable of speeding up development. It would be interesting if pre-assembled open-source libraries existed for that purpose. Another issue involving Hyperledger is that to identify the university or the student, it would be necessary to combine the use of two greenhouse technologies (Fabric + Indy), which can make the development of the application even more complex.

Recently, the use of smart contracts has been evaluated for academic record systems[13, 21, 22, 6, 23, 24]. Prototypes are implementing this type of mechanism in the Blockcerts [3], but they are new and still being discussed. This type of approach is interesting but needs to be observed, because not every blockchain implements this type of contracts (example Bitcoin). Besides, the languages implemented by different blockchains can be different, which can make it difficult to create a standard. In the examples shown, the vast majority are based on Ethereum. We believe that because blockchain technology is recent, with many networks likely to disappear and others appearing in the future, the proposed solution should be compatible with any blockchain technology [5] [1]. Also, the blockchain scalability issue [25], may encourage applications to migrate to smaller networks.

3.2 Prototype

UFP has built a prototype and has been testing the application of academic certificates with blockchain technology. The application called CertEdu was built based on the Blockcerts platform and has its architecture designed according to the figure 5. As you can see, CertEdu issues electronic documents on Bitcoin and Ethereum networks. The objective of implementing two networks is precisely to assess the prototype's ability to achieve the desired blockchain compatibility property.

The implementation described in this work shows that even existing different ways to operate the blockchains (permissioned, permissionless, consortium), the implemented solution is easily adapted to operate on any type of network because of these reasons:

- The solution uses its own Merkle Proofs mechanism
- The technique of anchoring the diploma hash on the blockchain, allows verification and overcomes the space limitation
- The solution doesn't need the use of smart contracts

The technical standard of Blockcerts was designed to work with any blockchain, thus preventing the success of the project from being conditioned to the evolution of another product. In 2017 when the project was started, integration was only possible with Bitcoin, but it soon extended to Ethereum. In 2018, Universidad del Rosario, in Colombia, [26] built the integration with Hyperledger.

Blockcerts uses different layers that work together to create the hashes for each batch of certificates, issuing them on the blockchain and subsequently allowing web platforms to print the certificates by using *JavaScript Object Notation* (JSON) objects and verifying them on the blockchain [4].

The figure 3 shows a process of creating a digital certificate on the blockchain by using the components of Blockcerts. As we can see, the asset stored is the hash of the JSON generated file, which in practice means linking the digital file with the blockchain.

The next section describes CertEdu implementation.

3.2.1 Certificate templates

Cert-tools is responsible for creating the certificate templates that will later be signed and anchored on the blockchain. For each model, it is possible to customize information such as the title, logo, description, history. There are also customizable fields, so that peculiar information can be treated. These fields can be created globally (they will appear for all the certificates generated from the model in question) or by the recipient (they will only appear for a specific group of recipients). Next, part of the code of interaction with the component is presented.

--badge_id 370820c5-59ff-4a0b-8c9c-55faa0b9f431
--unsigned_certificates_dir /ufp/unsigned
```

Cert-tools receives as an input the information that will form the certificate and as output, returns a file JSON, ready to be signed by the next component. The file in question is generated by a Blockcerts module called cert-schema [4], which is based on the *Verifiable Credentials* (VC) [5]. The data types mapped by the standard follow the norm *Internationalized Resource Identifiers* (IRIs), the same used by XMLSchema [6]. All this concern in following these standards is to offer entities and interested parties a standardized format for certifications.

The figure 4 shows the implementation of cert-tools in CertEdu. The model stored in the database contains the necessary parameters for the issuance of a certificate. In another system interface, all it takes is to link the model code with a list of students in order to publish the certificates. Note that there is a status indicator, which checks when saving the record if all settings have been applied successfully. For example, there is a parameter that allows you to indicate the public address of the certificate. When it is activated, the application tries to publish on the indicated website with the parameterized access credentials. If it fails, the model remains pending and cannot be used until the error is fixed.

3.2.2 *Publishing area*

Cert-issuer is the component responsible for generating the transaction on the blockchain. The input receives the diploma file generated by cert-tools and returns as output the diploma hash published on the blockchain. Its role, in addition to the signing, is to allow blockchain compatibility, by providing a structure that allows connectors from other networks to be implemented. In the component area called blockchain_handlers, all it takes it to create three functions to connect a new network: connection (connectors.py), transaction (transaction_handlers.py), and subscriber (signer.py). On top of that, it is necessary to change the block below the main function of the component.

```
issue_certificate.py

def main(app_config):
    chain = app_config.chain
    if chain == Chain.ethereum:
        from cert_issuer.blockchain_handlers import ethereum
        certificate_batch_handler, transaction_handler,
        connector = ethereum.instantiate_blockchain_handlers(app_config)
    elif chain == Chain.bitcoin:
        from cert_issuer.blockchain_handlers import bitcoin
        certificate_batch_handler, transaction_handler,
        connector = bitcoin.instantiate_blockchain_handlers(app_config)
    else:
      new blockchain
      ...

    return issue(app_config, certificate_batch_handler,
    transaction_handler)
```

The standard is maintained by the open-source community, to support networks the Bitcoin and Ethererum. The integration to other networks is emerging as initiatives do, such as the University of Rosario, in Colombia [26], which built the connector for Hyperledger, and is testing it experimentally.

Another notable point of the figure 3 is the possibility of signing a group of models at once. Technically, cert-tools generates several certificate files and calculates the group's Merkle root, recording this value on the blockchain.

The figure 6 shows the structure of a certificate file that makes up a batch. All files in the batch have the same value as the merkleRoot field, and additionally store, in addition to the hash itself, the hashes of the nodes needed to verify the root of Merkle (proof 0, 1 and 2 of 6). In practice, when the verifier receives a file, it calculates the hash and checks on the blockchain whether this file belongs to the generated batch. With that, you only need to spend a single time, to be possible to check *n* certificates. Also, this check is very useful for revocation, because canceling a single blockchain registration automatically cancels the entire batch.

Figure 6: Certificate batch structure

Blockcerts implements an independent version of the Merkle root, the 2017 Merkle Proof Signature Suite [7]. This means that the field calculated in the JSON file, always follows the same pattern, contributing at this point for the tool to work on several networks. Each blockchain can implement the field differently, as is in the case Ethereum, which unlike Bitcoin, uses Merkle Patricia [27].

3.2.3 *Embedded authenticity checker*

The verifier has two roles: to inform the authenticity of a certificate and to represent it graphically to the user. The first versions of this component in Blockcerts were called cert-viewer, but later changed to blockcerts-verifier [8].

The technology is based on JavaScript, which makes it easier for applications, such as CertEdu (Figure 8), to embark on a universal certificate verifier within its structure.

[4] https://github.com/blockchain-certificates/cert-schema
[5] https://www.w3.org/TR/vc-data-model/
[6] http://www.w3.org/TR/xmlschema-2/
[7] https://w3c-dvcg.github.io/lds-merkleproof2017/
[8] https://github.com/blockchain-certificates/blockcerts-verifier

How the issuance process is implemented, directly impacts on the complexity of implementing this component. Notably, Blockcerts seeks to use standardized components of the blockchain, such as hashes, transaction recording, Merkle root. With this, the inclusion of new blockchain in the operation of the blockcerts-verifier becomes a simpler process. Considering a different scenario, in which the mechanisms use smart contracts, depending on the way it is implemented, this process of incorporating new networks can become complex.

There is still no defined standard on the display format of the digital certificate (figure 7 and 8). Although this is not a technical security problem, it can cause some distrust for an appraiser who receives the same diploma issued by the same broadcaster but in different formats. Fortunately, the verification function can guarantee the data veracity to the interested party, and can even validate the file in different universal verifiers, such as the one offered by Blockcerts [9]

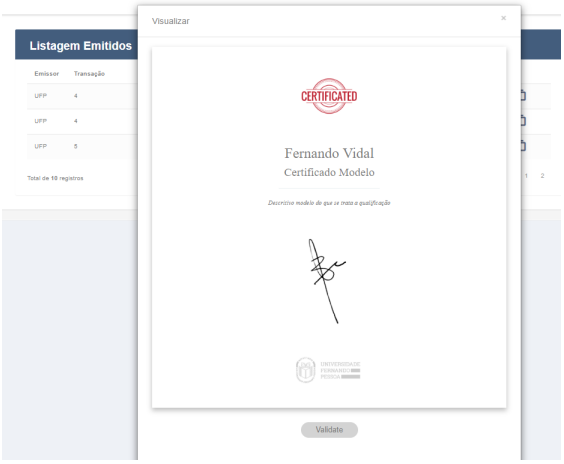

Figure 7: Model 1 for viewing a digital certificate issued by Blockcerts

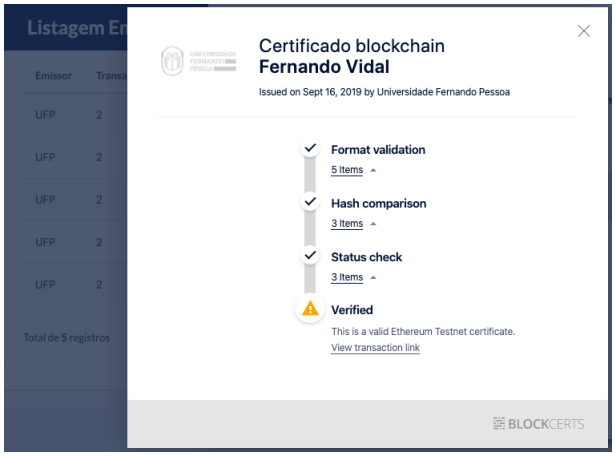

Figure 8: Model 2 for viewing a digital certificate issued by Blockcerts

[9]https://www.Blockcerts.org/

3.2.4 *Mobile application*

Cert-wallet is a Blockcerts application, also available in an open-source format, which aims to offer users autonomy over their records. Once the user downloads the application on their device, their identity is linked to a phrase created automatically by Blockcerts, which becomes a kind of private key.

The student is sovereign to register an issuer in his account and redeem the certificates that were issued by him. Autonomy is also evidenced by the fact that the student has the freedom to send his diploma to whomever he wishes, directly, without the intervention of any third parties. The difference between the digital process and the paper is that the registration received by the third party can be verified directly on a public blockchain network (in the case of this paper, Bitcoin or Ethereum), without any consultation with the issuing university.

The application has three main functions:

1. Automatically generate and send the student's public address to the sending systems
2. Store the digital certificates
3. Share the digital certificates

The figure 9 shows the operation of the first function of the cert-wallet. Note that the user informs an address of a sender profile file, and also a unique and disposable code, in English, called the nonce. This code serves as a kind of student credential to access the available service. Right after this procedure, cert-wallet accesses another address that is embedded in the profile file, and sends it to that address, the public key generated by the application, and also the code entered.

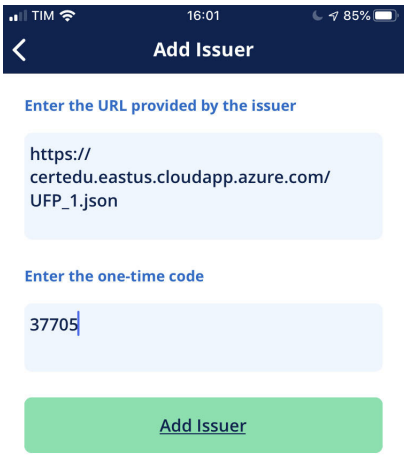

Figure 9: Cert-wallet application interface responsible for generating the student's public address

On the other side of the operation, in the second address mentioned software that is prepared to receive the public key and compare the received code is operating, validating, or not the message. If so, the cert-wallet receives a signal to register the issuer in its

database, and the student's public address is stored in the issuing application so that it can be used in future issues.

The second function of the application refers to the storage of certificates, which, as noted in the figure 10, can be done in two ways: informing an address *Uniform Resource Locator* (URL) in which the certificate is published, for example, `https://certedu.eastus.cloudapp.azure.com/certdata/2137705.json`, or by directly importing a JSON file.

Immediately after importing a credential, the application starts a process of validating and verifying the authenticity of the file, informing at the end of the process whether the certificate is valid or not.

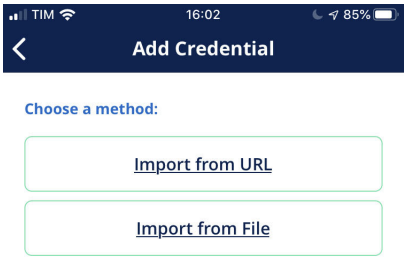

Figure 10: Ways to store a certificate in the cert-wallet

The third and final function of the cert-wallet, refers to the possibility given to the users to share their certificates. When selecting a certificate, it is possible to physically send the file to another user or simply provide the address that references it.

Table 3: Processes and challenges related to the blockchain solution

Process(s)	Challenge	Satisfies
Issuing	A feasible financial solution to large issuing	Yes
Issuing	Identify of universities	Yes
Issuing	Allow revocation	Partial
Verifying	Verifying em local database (decentralizing)	Partial
Verifying	Verifying in universal verifier	Yes
Verifying	High availability	Yes
Sharing	Identify of students	Yes
Sharing	Sovereign to share the certificates	Yes
Sharing	Graphical display of recorded information	Yes
All	Operating compatibility on any type of blockchain	Yes

[13] `https://bitcoinfaucet.uo1.net/send.php`

3.2.5 Goals

The purpose of the application is to simulate an environment close to a real situation, for this reason, it was decided to configure the TestNet (Bitcoin) and Rospten (Ethereum) networks. Faucets [10], [11], [12], [13] were used to transfer credits to the application's accounts, and thus emulate a scenario close to reality, in which there are limited financial resources to generate certificates.

The table 3, presents an analysis by the process, about the main challenges to be addressed. In this way, the work assesses such issues through CertEdu, and highlights which issues are addressed and which still need to be addressed. Concerning the points not yet solved, some possible solutions to these problems are presented.

Below, the topics partially covered are discussed.

3.2.6 Disconnected checking and revocation

One of the innovations proposed by blockchain certificate solutions is disconnected verification. For example, it would be possible to verify the authenticity of the diplomas, using an off-line local copy. All certificates that are already there are perfectly verifiable.

However, the prototype found that this feature was not met, due to the way Blockcerts implements the verification process. There is a dependency on two external files (hosted on the issuer's server), one for university identification, and another for checking certificate revocation.

Regarding the first dependency, Learning Machine and NextID in late 2019, published an article [18] with a proposal to replace the issuer profile. This functionality must be present in versions 3.0 of blockcerts.

Regarding revocation, there is still no definitive solution to the problem. The paper [5], presents different approaches, such as smart contracts [28], control data [29] or even the combined use of *Interplanetary File System* (IPFS) and blockchain [30] , [31], [32].

3.3 Systemic tests

The following tests simulate some of the situations that can occur when issuing a blockchain certificate. Firstly, attempts are made to tamper the certificate, either through data editing or through the usurpation of property. Right after this test, it is evaluated how the validation system behaves in a disconnected way.

3.3.1 Tamper

In this simulation, a diploma issued by CertEdu is changed. Using a simple text editor, the original information of the diploma is modified, including a letter R in the student's name. It is notable that the digital diploma file is not encrypted, and can be easily edited by users who have a minimum of knowledge in text editing tools.

The result of the modified document validation operation can be seen on the figure 11, and the rules processed by the verifier can be observed through the table 4.

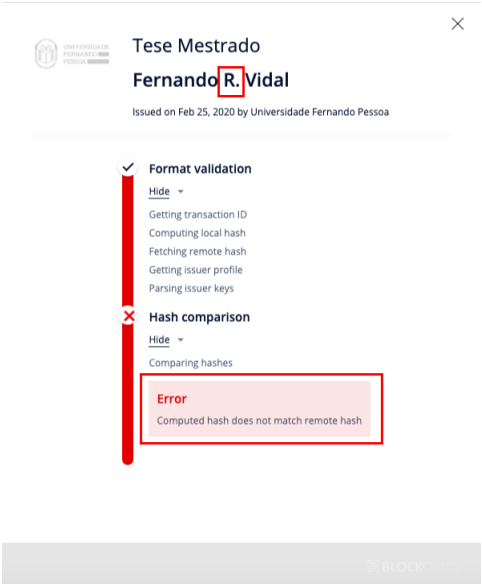

Figure 11: Tampered certificate validation

Table 4: Result of validations performed by the universal verifier

Nº	Rule	Satisfies ?
1	The transaction number contained in the certificate (sourceId) exists in the referenced blockchain ?	Yes
2	The computed hash over the information, match with the targetHash field?	Yes
3	The *targetHash* match with the blockchain stored content ?	No
4	The issuer's public address (server) is available ?	Yes
5	The embedded issuer's public key in the certificate, match with the key hosted in the issuer's server	Yes

We realized in this experience that the verifier can identify any adulterations of the file's content. Analyzing the verifier's rules, even if an attacker tampered a certificate and recalculated the hash data, the tamper would be detected, because the content of the *targetHash* field would not match the value stored in the blockchain.

3.3.2 *Unauthorized appropriation*

This other fraud simulation discusses the possibility for an attacker to change the issuers and /or recipients of a genuine certificate. For example, it would be interesting for criminals to replicate real university certificates with lesser visibility, changing them as if they were from prestigious universities. Likewise, a profitable fraud would be to offer genuine degrees to malicious recipients, who only intend to accumulate "achievements".

Blockcerts embed the student's public key in the certificate data, in the *recipientProfile* section, in the *publicKey* field. Likewise, in the *verification* section, the sender's information is embedded. This means that such fields are part of the hash calculation, which guarantees protection against tampering.

However, an attacker could alter the certificate data, informing other public keys of issuers and recipients, and recalculate the certificate hash. Additionally, to prevent rule 3 (table 4) from identifying the fraud, the attacker could change the *sourceId* field for a transaction that he created, which contains exactly the value of the hash of the defrauded certificate.

In this case, rule 3 will pass as true, because both the local calculation of the hash and the comparison with the information stored in the blockchain will be considered valid. However, Blockcerts can identify this fraud, because in addition to validating the content of the transaction, it checks whether the address of the transaction is owned by the issuing university. This is possible because the system compares the public address of the transaction with the public address hosted on the sender's server.

The figure 12 presents excerpts from the university's profile file, highlighting the public key information. The adulterated certificate, and the forged transaction, point to the *mgAzKQZZi47g4UMvmGJCsicbJ4P3B8SHRr* hash. However, the university's real public key points to the value *JKmg4UDWqBcnhklMEsDgdDHsRrF*.

As shown in figure 13, the validator detects the inconsistency of this information, preventing the fraud from being carried out.

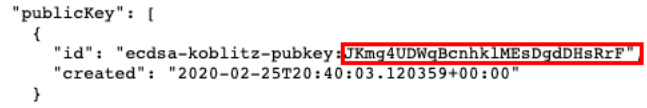

Figure 12: Issuer identification file

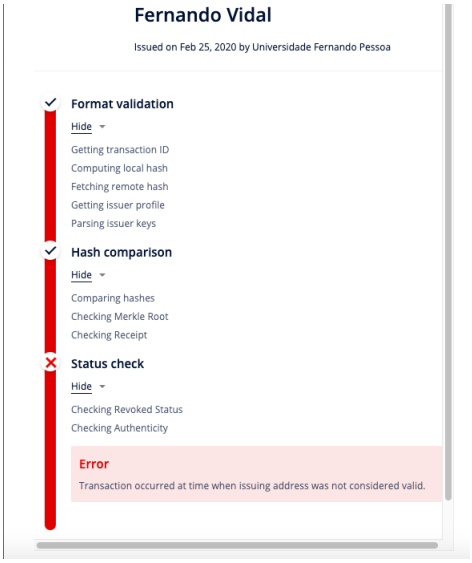

Figure 13: Certificate check with the issuer tampered with

3.3.3 *Stolen key and revocation*

This simulation evaluates Blockcerts' ability to identify frauds that may occur in situations where the university has had its private key stolen.

The digital diplomas issued by non-blockchain solutions, such as those that sign using a *Rivest-Shamir-Adleman* (RSA) key, do not guarantee in their signature proof that the creation date associated with their signature is consistent with reality. In most cases, the

issuer who signs with the keys to their property, must sign with the correct date and time [18].

In situations where the private key is stolen, the attacker may want to issue retroactive diplomas, thus managing to guarantee illegal conquests for any recipient.

When the university realizes that its key was stolen, it revokes the validity from the date on which the theft occurred. However, in non-blockchain solutions, since certificate dates cannot be trusted, it is very difficult to determine which diplomas are still valid.

Therefore, by using a blockchain's reliable timestamp, you can calculate the actual date of issuance of a diploma, and thus, determine the revocation/expiration. With that being said, it becomes more reliable to separate valid and invalid credentials. For example, all credentials that are referenced on a blockchain, before the reported date of the theft, remain securely valid and are not affected by any revocation process.

The figures 14 and 15, demonstrate how the date of the issuance of a certificate can be easily compared with its registration on the blockchain. By consulting the date of the corresponding transaction (indicated in the *sourceId* field), you can easily perform the comparison.

Figure 14: Certificate issue date

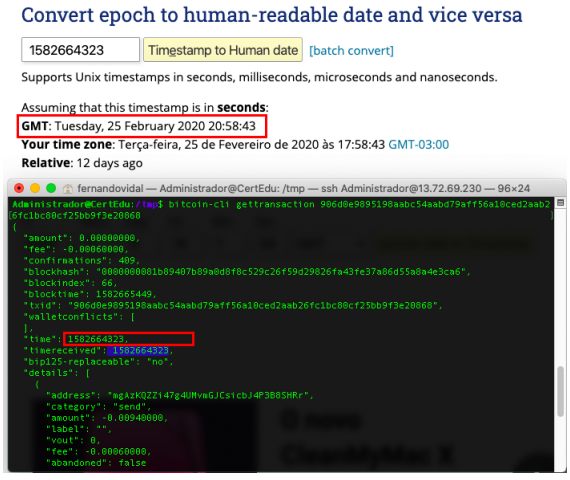

Figure 15: Registration date of certificate issuance on the blockchain

In this matter, it is concluded, that the blockchain solution offers a differential about the solutions without blockchain, since it guarantees students, that their old diplomas will not be affected, even if unexpected situations like a private key theft happens.

3.3.4 Validation without server access

This simulation is divided into two parts. First, the possibility of the issuer's server failing is evaluated and then the functionality of continuing to validate in a non-synchronized way, records on a local blockchain are tested.

In this first test, the sender's server is inaccessible. This simulation intends to evaluate the system's behavior when faced with a failure of the university server. For this, the server on which the profile and revocation files are hosted was turned off and was performed a check for a genuine certificate.

It can be seen through figure 16, that the verifier was unable to tell whether the certificate was valid or not.

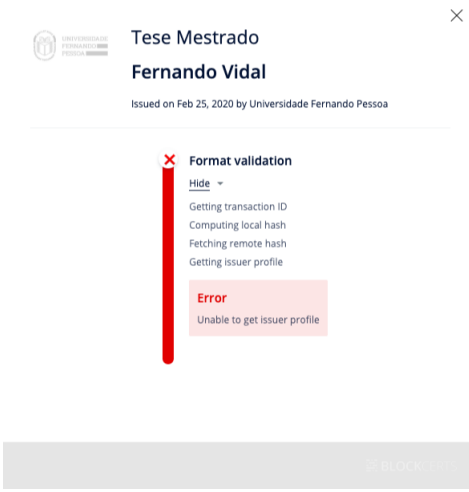

Figure 16: Local check, error when connecting transmitter

The test concludes that the solution is not yet capable of offering independence from the issuer. Besides, if an attacker manages to invade the server, even if it is temporarily, it would be possible to carry out the attacks described in the 3.3.1 section, due to the possibility of changing the information stored in the sender's profile.

In the second test considers a scenario in which the local blockchain is not synchronized. One of the benefits of using the blockchain would be the possibility to continue to validate certificates, on a local blockchain, even if it no longer exists.

Analyzing the libraries of the implemented prototype, it is noticed that the verifier uses interfaces *Application Programming Interface* (API), made available by block query tools, to verify them. This means that for a local validation it would be necessary to modify the verification address for the local base. As this is a relatively easy operation, it can be said that the tool meets this requirement.

Another situation that can be simulated is the verifier validating the issuance of a certificate that has not yet been authorized by the consensus mechanisms. As mentioned in the section, the validation of the blocks is one of the pillars that brings all the security of the technology. Validating a diploma from a registration that has not yet been confirmed could be considered a very serious failure.

Figure 17 shows the result of this operation, and as the result is shown, it can be said that the system also passed this security test.

Figure 17: Block not yet confirmed

4 Conclusion

Diploma fraud is far from being over. The combat mechanisms proved to be extremely inefficient, mainly in the paper models. Digital degrees have evolved with digitalization, but they do not offer privacy to the students, so they can have confidence in freely distributing their certificates.

Blockchain's disruptive technology offers a breakthrough in distribution and ensures protection from tampering. It was also shown that the blockchain offers the best resources to act in case of loss or theft of the university's private key, protecting the entity against undue retroactive emissions. Besides, the level of privacy offered by the technology, by recording only the hash certificate on the blockchain, makes the solution less prone to data leakage than the digital certificate solutions without blockchain.

The materialization of the objective of using the blockchain for the management of diplomas was achieved during the construction of the CertEdu prototype, in which it was possible to operate issuances, revocations, shares, and verifications of academic certificates.

However, tests also pointed out that disconnected operation is still an issue that needs to be worked on. Although some blockchains already offer resources, such as the smart contract, which would allow to easily resolve the centralization points placed, the premise of the solution operating on any type of blockchain has not been met, so those issues that still prevent decentralization are still raised by this work is pending.

There is also concern about the unpredictability of the issuance costs. Thinking of public networks like Bitcoin and Ethereum, you cannot predict the rate of transactions in the long run. This issue can inhibit the adhesion of universities.

Finally, it is concluded that the application of blockchain in the management of academic certificates is perfectly possible and that the technology already offers benefits in terms of privacy, distribution and revocation, compared to digital solutions. However, to be able to take advantage of the full potential of the technology, the centralization points addressed by this work, such as the validation of the issuer's profile and revocation, need to be migrated to features that operate within the blockchain itself.

Ward's method
Web search engines

ABSTRACT

It is well documented that the average length of the queries submitted to Web search engines is rather short, which negatively impacts the engines' performance, as measured by the precision metric. It is also well known that ambiguous keywords in a query make it hard to identify what exactly search engine users are looking for. One way to tackle this challenge is to consider the context in which the query is submitted, making use of query-sensitive similarity measures (QSSM). In this paper, a particular QSSM known as the query-document similarity measure (QDSM) is evaluated, QDSM is designed to determine the similarity between two queries based on their terms and their ranked lists of relevant documents. To this extent, F-measure and the nearest neighbor (NN) have been employed to assess this approach over a collection of AOL query logs. Final results reveal that both the Average Link Algorithm and Ward's method present better results using QDSM than cosine similarity.

1 Introduction

This paper is an extension of work originally presented in the International Conference of the Chilean Computer Science Society (SCCC) [1]. Nowadays, exist a large amount of information available on the Web; additionally, web search engines (WSE) daily index thousands of pages, by which finding relevant and timely information over this growth without constraints becomes quite a challenge. According to [2], this unrestricted growth has not been accompanied by corresponding technical advances in approaches to extract relevant information. Unsuccessful searches are common in WSEs and can be given by several reasons among which we can mention the following. First, the lengths of submitted queries by users are mostly short (e.g., the average size of a web search is 2.4 words [3]). Owing to queries are conformed by a few keywords, it is complicated to determine the specific topic in which the query is inserted, therefore, a result with a few keywords in the query can be formed by unrelated topics. Furthermore, users ignore how to formulate a correct query [4]. The problem is made more complex when the user does not have a specific idea about which should be the result that he/she is looking for (i.e., which turns in relevant information for him/her). In light of the foregoing, it is not easy for WSEs to interpret the meaning of what users are looking for. One way to tackle this issue, is to consider the context in which the queries are submitted at WSEs [5], [6]. To capture the context, WSEs should consider what queries are related among them (i.e., determining if the queries are similar) and how their results have been beneficial for users. A way to determine the relationship between similar queries and relevant documents for these queries is given by the cluster hypothesis, which establishes that all documents considered as relevant for a query are similar to each other (i.e., similar documents can be relevant for the same query)[7]. Accordingly, it can be assumed that relevant documents for a query q, are relevant for a query q', such as q' is similar to q. Thus, having methods that provide the similarity among documents and queries can bring a better characterization about the meaning of a new query, and as a consequence, it entails more effective results.

Whether the WSE is able to establish how similar is a new query regarding queries recently submitted, then the search engine

[*]Corresponding Author: Claudio Gutiérrez-Soto, Casilla 5-C Email: cogutier@ubiobio.cl

should provide documents, which were relevant in previous searches. Hence, the recent past queries along with the relevant documents provide a context, in which is feasible to improve the answers to new searches [8]. Nevertheless, measuring how similar are two queries using their documents is not easy, suitable metrics that allow representing the context are needed.

Aiming to capture the context in which queries are submitted, Tombros and Van Rijsbergen [9] present a pioneering approach introducing the measuring called query-sensitive similarity measure (QSSM). This measure establishes the following; two documents are more similar than others, whether both are more similar regarding a given query. Following this argumentation line, QSSMs can be used as a metric to measure the similarity between two queries considering the context. As such, a WSE using additional information can improve its effectiveness to answer a new query. To achieve this goal, queries alongside their documents should be stored in clusters. Currently, few approaches store the queries along with their documents [10]–[14] (these approaches recommend to the user a list of similar queries, which are related to the submitted query by the user). However, the approaches mentioned previously are not directly related to the approach presented in this paper.

1.1 Contribution

The main contribution of this paper is the effectiveness evaluation of QDSM. Roughly speaking, effectiveness is related to the quality of recovered documents. Better effectiveness occurs when more relevant documents are retrieved (from a total of N documents retrieved, there are more relevant documents than non-relevant documents). By contrast, worse effectiveness occurs when more non-relevant documents are retrieved. With this in mind, grouping similar queries alongside their relevant documents (in clusters) should directly affect the effectiveness. Therefore, improving clusters' effectiveness implies having more relevant documents by clusters, which aligns with the cluster hypothesis.

To evaluate QDSM effectiveness, the F-measure alongside the nearest-neighbor (NN) cluster hypothesis tests were used. Both tests were applied over the following algorithms; Single Link, Complete Link, Average Link, Bisection K-means, and Ward's method. Three relevance models were simulated with the aim to determine which documents are relevant for a specific query. Besides, a wide range of experiments was carried out over five sets of queries. Final results are presented as QDSM improvement percents regarding cosine measure (S_c) (or cosine similarity), which were contrasted with the values obtained applying the Student Paired T-test (two samples).

The remainder of this paper is organized as follows: In Section 2, a detailed review of articles related to the problem of capturing the context using clustering is presented. In Section 3, the methodological description, is exposed. Section 4 presents the experimental environment. Section 5 displays the empirical results, which are then discussed in Section 6. Finally, Section 7 gives some perspectives of future work along with the conclusions.

2 Related Work

There have been many works that deal with the use of clustering in Information Retrieval (IR). Clustering in IR has been employed to improve the effectiveness (i.e., quality of clusters). Overall, clustering-based approaches that intend to capture the context in which the queries are submitted can be classified into two categories, considering the underlying repositories (these are also known as collections or datasets). The first category involves using traditional IR datasets. Some of them use QSSM similarities such as [15]–[17]; meantime, the second category uses log-file data from search engines.

To improve effectiveness in the retrieval process, an approach relies on hierarchic query-specific clustering is presented in [15]. In pursuing this goal, a wide range of experiments was performed. According to the authors, given a specific query, the hierarchy should be adapted to increase the likelihood to situate relevant documents to the query in nearby clusters. Two characteristics stand out in this research. First, an analysis of optimal clusters variation considering the number of top-ranked documents allowing better effectiveness is exposed. Finally, a comparison between their results and inverted file search (IFS) is provided. Five traditional IR collections alongside four hierarchic agglomerative methods were employed in all experiments. Final results indicate that query-specific clustering outweighs static clustering in each of the experiments. On the other side, a framework based on probabilistic co-relevance, which gives a query-sensitive similarity, is presented in [17]. The similarity between two documents corresponds to the ratio between the co-relevance probability and a specific query. Two cases were considered to identify the co-relevance. First, the document's relevance is independent of the rest of the documents. Second, the document's relevance is dependent on the rest. Several experimental scenarios were studied using the nearest neighbor test on TREC collections. The final results reveal that the framework outperforms term-based similarity.

The approaches mentioned above expand the users' judgments grounded on the following assumption. All terms included in a relevant document for a specific query are relevant too. Consequently, it is assumed that all documents that include some of these terms are also relevant. Besides, these approaches do not deal with the similarity among queries, with the exception of [16],[18]. In [18], a method called Scatter/Gather, which explores clusters based on documents, is proposed. The method returns a ranked title's list for the organization and viewing of retrieval results. Scatter/Gather is used as a tool for retrieval of browsing results, which presents summaries to users. Towards that goal, documents are joined in similar topics. A fractional algorithm provides k clusters on TREC/Tipster dataset. As a result of experimentation, the authors assert that their method gives tailored clusters according to the query's characteristics. In such a way, their results corroborate the cluster hypothesis since relevant documents are more similar to each other than non-relevant documents. In [16], the authors introduce the Weighted Borda (WBorda) model, which determines the co-relevance of a document using different similarities' types. To this end, a Support Vector Machine (SVM) was trained to get the estimated co-relevance, fusing the induced rankings using several functions. Each function considers the similarity between documents and the query. Several similarity measures were considered in experiments such as cosine BM25, M1, and M3. The final results in tasks such as nearest-neighbor clustering, cluster-based, and graph-based document retrieval indicate that WBorda provides better results than several proposed

co-relevance models.

On the other hand, approaches such as [10],[19], and [20] belong to the second category. Users' log-based, an approach of query clustering is proposed in [19]. Towards that end, the documents previously read by users are employed to construct cross-references among documents and queries. According to the researchers exist a strong relationship between the selected documents and queries. This approach underlies two fundamental aspects: First, two queries are similar if users clicked on the same documents; Second, if a set of documents was selected for the same queries, then the documents' terms are related to the queries' terms. The empirical results were obtained using the DBSCAN algorithm and the Encarta encyclopedia dataset. The final results show that many similar queries are gathered in the same clusters utilizing this approach. A query-clustering classification, which compares various query similarity measures, is presented in [10]. Three groups: content-based approaches, feedback-based approaches, and results-based approaches are suggested in this classification. In content-based approaches, the common terms of queries are used to describe query clusters. Similarity functions such as Jaccard, Cosine, and Dice were employed to build the clusters. In that regard, the authors claim that this method is not convenient for search engines due to many queries have few terms. On the other side, in feedback-based approaches, the similarity measure is grounded users' selections over search results; therefore, two queries are similar whether they encourage the selection of similar documents. In turn, results-based approaches evaluate the similarity between queries through the overlap of returned documents. In this case, the researchers point out that this approach's principal drawback corresponds to high processing times. Notable results are obtained using the three approaches in parallel. In [20], a WSE provides a user with a list of similar queries regarding the user's submitted query. Semantically similar queries give support to the clustering process. Clusters are formed, taking into account the historical preferences of registered users in the WSE. To build the clusters, term-weight vector representation of queries considering the clicked URLs was employed. The method exhibits two benefits, (1) it discovers the related queries, and (2) sorts the queries rely on a relevance criterion. It is important to mention that the queries are sorted using the following criteria: (a) the similarity between the clusters' queries and the new query and (b) the support, which is related to how much the query answers capture the user interest. The experiments were conducted using the combination of (a) and (b). The results display improvements on average precision.

In summary, the first category is based on traditional IR datasets. A traditional IR dataset is formed by three sets, a set of documents (D), a group of queries (Q), and a set of users' judgments (JU). The user's judgments contain the relevant documents for a query in Q. Note that all works mentioned in this category include new relevant documents (if some document has some relevant term, then it is considered relevant), which are not part of the original JU. On the other hand, it should be noted that there are no JU in the second category (log-files from search engines). Consequently, subject matter experts evaluate the pertinence of a document given a query. Note that all approaches mentioned in this related work modified some documents' relevance, which directly impacts effectiveness. Contrary to these approaches, in this paper, three types of users' judgments are simulated without altering the documents' original-relevance.

The overall procedure and a discussion about the results are presented in the following sections.

3 Methodology

The methodology overview is as follows. Initially, a user submits a query to the WSE. Thereafter, the WSE returns the documents as a result of the query. These documents are ranked from the most similar to the least similar regarding the query. Once this is done, the documents are stored along with the query in clusters inside the WSE. Aiming to form the clusters considering documents and queries, QDSM is used. In this way, when a user submits a new query, it is contrasted with the past queries (these are the queries previously stored) in the query-document clusters. Accordingly, an effectiveness improvement should occur due to the clusters closest to the new query containing relevant documents for the new query.

Document relevances become a crucial factor in enhancing effectiveness. In a traditional IR dataset, document relevances are given by subject matter experts, who determine what documents are relevant given a query. These documents are reflected in the users' judgments. On the other hand, the relevance of documents in a WSE is given by ranking functions. Overall, ranking functions attempt to capture the relevance through users' clicks on documents, which are expressed in the ItemRanks. In this manner, a retrieved document (i.e., URL or web page) with an ItemRank high could be considered as relevant.

It is essential to keep in mind that most approach clustering-based extend or use subject matter experts to give relevance to the documents, due to none of these datasets have been designed to work with similar queries (past queries are part of clusters). According to [21], a good way to tackle this problem is by using simulation. In this paper, document relevances have been simulated. Two notable advantages are obtained with the simulation use. First, it is neither necessary to use subject matter experts nor extend the user's judgments. Second, several models of relevance (a model can be seen as a ranking function) can be used; for instance, given a query, a document can be relevant or non-relevant depending on the model. In this paper, this is given by a relevance function, which determines the relevance of a document considering both its corresponding ItemRank and relevance probability.

Aiming to shed light on how QDSM is evaluated using a relevance function, suppose the following example. Assume that three documents (d_5, d_{10}, and d_{12}) have been recovered for a query q, such as d_5 is the most similar document concerning the query. The respective ItemRank for each document is 20, 25, and 30. Likewise, the probabilities of relevance according to their respective ItemRanks are 90%, 40% 70%. Additionally, suppose a relevance function that only considers the last recovered document (in this case, d_{12}). As d_{12} has an ItemRank of 30, the probability of being relevant is 70%. To simulate the relevance probability of d_{12}, a binary array of 100 elements is used. Initially, this array is instantiated with 0 values; subsequently, 70 random positions with value 1 are assigned in the array using Uniform Distribution. In order to give the relevance to d_{12}, an array position is selected using Uniform Distribution; thus, if this value is 1, then d_{12} is relevant; in another case, d_{12} is

non-relevant (Note that d_5 and d_{10} are non-relevant).

Following the same example, suppose a relevance function that assigns the relevance individually, then the same procedure to give relevance is performed for each document (d_5, d_{10}, and d_{12}). Thus, a possible result could be that d_5 and d_{12} being relevant, meantime d_{10} could be non-relevant. Finally, suppose a relevance function that provides the average relevance, then the average of ItemRanks is obtained, and its relevance probability is used to give relevance to the three documents.

Note that different relevance functions could provide different results on QDSM, due to QDSM considers the relevant documents as part of its metric.

3.1 The Query-Document Similarity Measure

The Query-Document Similarity Measure (QDSM) is a Query-Sensitive Similarity Measure (QSSM), which has as a fundamental purpose to capture the semantic similarity between queries, taking into consideration terms that belong to the queries as well as the position in which appear the relevant documents in both lists. Indirectly, the terms associated with the relevant documents should contribute to providing context. Specifically, each list of documents is presented in descending order according to the similarity of documents regarding the query. From the semantic point of view, two queries are closer if they share more relevant documents in their lists. This can be appreciated by observing the number of relevant documents that form the intersection between the two lists. Therefore, while more relevant documents make up the intersection, the more similar the queries will be. Thus, this paper's primary assumption is that using similar queries alongside their relevant documents should provide clusters with better effectiveness than S_c, since additional information can be captured from documents, including the queries (i.e., information is not complete in each query individually). Specifically, this additional information is given by the union of queries and documents' terms but does not belong to the intersection among them. Using this rationale, QDSM is in line with the cluster hypothesis, which claims that relevant documents for a particular query tend to be close, whereby these relevant documents should tend to be in the same cluster for a specific query.

QDSM takes advantage from the place in which relevant documents appear on the list. As reported by [22], the most similar documents concerning the query tend to appear at the beginning of the list. On this basis, the order in which relevant documents appear in both lists gives information about the context (particularly the terms of relevant documents). QDSM deals with the order of relevant documents through the use of the Longest Common Subsequence (LCS) algorithm. LCS allows acquiring the relative similarity keeping the order in which simultaneously appears a relevant document in both queries. By doing so, the context capturing in which the queries are submitted is possible.

This measure is convenient in two situations:

- When terms of a query are few, as is currently happening in the WSEs.
- In a dynamic environment, where the documents' relevance could change (i.e., the position of a document in the list could change as well as its ItemRank), non-relevant documents could become relevant documents.

Accordingly, the queries are either short length (i.e., few keywords in the query) or ambiguous. Nevertheless, these can be enriched with more information associated with their relevant-documents retrieved.

Aiming to give formality, some definitions are detailed below.

Definition 1

Let D be a set of documents, such as every document in D, is formed by a set of terms (i.e., words contained in d). D is stored in a WSE W. Besides, let q be a single query, such as $q \in Q$, where Q is a set of queries interpretable by W.

Definition 2

The cosine measure between q and d_i, is defined as:

$$S_c(q, d_i) = \frac{\sum_{j=1}^{m} t_{qj} \cdot t_{ij}}{\sqrt{\sum_{j=1}^{m} t_{qj}^2 \cdot \sum_{j=1}^{m} t_{ij}^2}}$$

shuch as $d_i \in D \wedge q \in Q$, t_q are the query'terms and t_i are the document's terms.

Definition 3

Let $|d_i|$ be the number of terms in a document d_i, such as $d_i \in D$. Note that this definition can be applied to obtain the number of terms for a query q.

Lemma 1

$S_c(q, d_i) \neq 0 \iff (q \cap d_i) \neq \emptyset$

Proof by contradiction: Suppose $(q \cap d_i) = \emptyset$. Then, there are no terms in common between q and d_i. Hence, applying the *Definition 2* implies $S_c(q, d_i) = 0$. Likewise, if $S_c(q, d_i) = 0$, then $(q \cap d_i) = \emptyset$. □

Definition 4

Let $\mathcal{L}(q) = \{d_i | S_c(q, d_i) \neq 0 \ \forall d_i \in D\}$ be the set of documents whose similarity with $q \in Q$ is different to 0.

Definition 5

Let $\mathcal{L}_N(q)$ be a list of N retrieved documents from W, such as $\mathcal{L}_N(q)$ is ranked by decreasing order (i.e., they are ordered from highest to lowest according to S_c).

Definition 6

Let $F(ItemRank(d_i), M)$ be a binary function, which provides relevance to a document d_i, such as 1 is relevant and 0 is non-relevant. The function is defined as follows:

$$F(ItemRank(d_i), M) = \begin{cases} 1: & Pr(1) = \mathcal{M}(M, ItemRank(d_i)) \\ 0: & Pr(0) = 1 - Pr(1) \end{cases}$$

where M corresponds to the relevance model (i.e., PartialRel, AvRel or LastRel). *ItemRank* is a function that provides the rank for the document d_i, and $\mathcal{M}$ is the function that gives the probability considering M and *ItemRank*. A binary array formed by 100 elements is used to represent the probability in $\mathcal{M}$. The Uniform Distribution is employed to instantiate the values (the percentage is represented with values 1 in the array) and determine the relevance (if the array's selected position contains a 1, then the document is relevant).

Definition 7

Let $\mathcal{L}_{N,R}(q)$ be a list of retrieved documents along with their relevances, then:

$\mathcal{L}_{N,R}(q) = \{(d_i, F(ItemRank(d_i), M))|d_i \in \mathcal{L}_N(q)\}$.
Definition 8

Given two queries q and q' such as both queries are in Q, and their corresponding lists of documents $\mathcal{L}_{N,R}(q)$ and $\mathcal{L}_{N',R}(q')$. Then QDSM is defined as follow:

$QDSM(q,q') = \frac{S_c(q,q') + LCS(\mathcal{L}_{N,R}(q), \mathcal{L}_{N',R}(q'))}{1 + max(\|\mathcal{L}_{N,R}(q)\|, \|\mathcal{L}_{N',R}(q')\|)}$

where:

- $S_c(q,q')$ corresponds to the cosine measure between the queries q and q'.
- $LCS(\mathcal{L}_{N,R}(q), \mathcal{L}_{N',R}(q'))$ is the LCS algorithm applied over $\mathcal{L}_{N,R}(q)$ and $\mathcal{L}_{N',R}(q')$ [23].
- *max* gives the greatest number of relevant documents between the lists $\mathcal{L}_{N,R}(q)$ and $\mathcal{L}_{N',R}(q')$.

Theorem 1. $QDSM(q,q') = 0 \iff S_c(q,q') = 0 \wedge LCS(\mathcal{L}_{N,R}(q), \mathcal{L}_{N',R}(q')) = 0$.
Proof by contradiction.

- Suppose $S_c(q,q') \neq 0 \vee LCS(\mathcal{L}_{N,R}(q), \mathcal{L}_{N',R}(q')) \neq 0$. If $S_c(q,q') \neq 0$ is enough for $QDSM(q,q') \neq 0$ (by *Definition 8*). Likewise, as $LCS(\mathcal{L}_{N,R}(q), \mathcal{L}_{N',R}(q')) \neq 0$ then $QDSM(q,q') \neq 0$ (by *Definition 8*).
- Finally, as $QDSM(q,q') \neq 0$ then either $S_c(q,q') \neq 0 \vee LCS(\mathcal{L}_{N,R}(q), \mathcal{L}_{N',R}(q')) \neq 0$ (by *Definition 8*). □

Lemma 2
$LCS(\mathcal{L}_{N,R}(q), \mathcal{L}_{N',R}(q')) \neq 0 \iff \exists\, t \in (d \cap q \cap q')$
Proof.

- $LCS(\mathcal{L}_{N,R}(q), \mathcal{L}_{N',R}(q')) \neq 0$, then $\exists\, d \in (\mathcal{L}_{N,R}(q) \cap \mathcal{L}_{N',R}(q'))$ (by the LCS invariant [23]). Thus, $d \in \mathcal{L}_{N,R}(q) \wedge d \in \mathcal{L}_{N',R}(q')$. Since $d \in \mathcal{L}(q) \wedge d \in \mathcal{L}(q')$, then $S_c(d,q) \neq 0 \wedge S_c(d,q') \neq 0$ (by *Definition 4*). Thus, $(d \cap q) \neq \emptyset \wedge (d \cap q') \neq \emptyset$ (by *Lemma 1.*). Hence, $(d \cap q \cap q') \neq \emptyset$. Therefore, $\exists\, t \in (d \cap q \cap q')$.
- Finally, as $\exists\, t \in (d \cap q \cap q')$ then $S_c(q,q') \neq \emptyset \wedge S_c(d,q) \neq \emptyset \wedge S_c(d,q') \neq \emptyset$ (by *Lemma 1.*). Thus $d \in \mathcal{L}_{N,R}(q) \wedge d \in \mathcal{L}_{N',R}(q')$ (by *Definition 7.*). Therefore, $LCS(\mathcal{L}_{N,R}(q), \mathcal{L}_{N',R}(q')) \neq 0$ (by *Theorem 1*). □

Lemma 2 asserts that exists at least a common document in both lists, and therefore at least there is one term in common among queries and the document.

Lemma 3
$|d| \neq |q| \implies \exists t \in (d \triangle q)$
Proof. Suppose $|d| > |q|$, which implies that d has at least one term more than q. On the other hand, can ocurr that $|q| > |d|$, then q has at least one term more than d. Thus, $\exists t \in ((d-q) \cup (q-d)$. Therefore, $\exists t \in (d \triangle q)$. □

Lemma 3 points out that if different numbers of terms form the document and the query, then at least there is one term that does not belong to the intersection between them. Note that d and q are in $\mathcal{L}_{N,R}(q)$.
Theorem 2
$QDSM(q,q') \neq 0 \wedge |d| \neq |q| \neq |q'| \iff \exists\, t \in ((d \triangle q) \triangle q')$; such as d is in both $\mathcal{L}_{N,R}(q) \wedge \mathcal{L}_{N',R}(q')$.
Proof:

- $QDSM(q,q') \neq 0 \wedge |d| \neq |q| \neq |q'|$, then $LCS(\mathcal{L}_{N,R}(q), \mathcal{L}_{N',R}(q')) \neq 0 \wedge S_c(q,q') \neq \emptyset \wedge |d| \neq |q| \neq |q'|$ (by *Definition 8*). As the first part, consider $LCS(\mathcal{L}_{N,R}(q), \mathcal{L}_{N',R}(q')) \neq 0 \wedge |d| \neq |q| \neq |q'|$ then, $\exists\, t' \in (d \cap q \cap q') \wedge |d| \neq |q| \neq |q'|$ (by *Lemma 2*). Thus $\exists\, t' \in (d \cap q \cap q') \wedge ((|d| \neq |q|) \neq |q'|)$. Subsequenlty, $\exists\, t' \in (d \cap q \cap q') \wedge \exists t \in ((d \triangle q) \neq q')$. (by *Lemma 3.*). Hence, $\exists\, t \in ((d \triangle q) \triangle q')$. The another case is $S_c(q,q') \neq \emptyset$, then $\exists\, t \in (q \triangle q')$, considering d in the hypothesis, $(q \triangle q') \subset ((d \triangle q) \triangle q')$. Therefore $\exists\, t \in ((d \triangle q) \triangle q')$.
- Finally and without loss of generality, if $\exists\, t \in ((d \triangle q) \triangle q')$ then $\exists\, t \in ((d-q) \cup (q-d)) \vee ((d-q') \cup (q'-d)) \vee ((q-q') \cup (q'-q)) \wedge ((S_c(q,q') \neq \emptyset \wedge \exists\, t \in (d \cap q \cap q'))$ (by *Lemma 1. and Lemma 2.)* then $QDSM(q,q') \neq 0 \wedge |d| \neq |q| \neq |q'|$. □

Definition 9

Let RQ be a set of queries, along with their retrieved documents and their corresponding relevances, then RQ is defined as follow:

$$RQ = \bigcup_{i=1}^{|Q|} \mathcal{L}_{N,R}(q_i)$$

Definition 10

Let $\widehat{D}$ be a benchmark query set, which is formed by Z subsets of queries, such as:

$$\widehat{D} = \bigcup_{i=1}^{Z} RQ$$

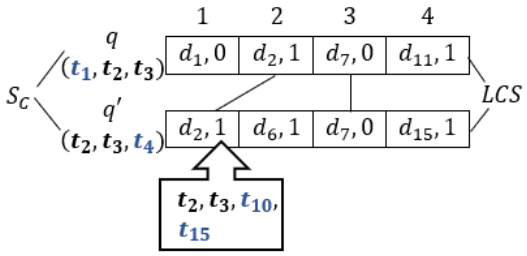

Figure 1: QDSM measure

Theorem 2 ensures that the context in which the queries are submitted in the WSE can be captured by the complementary terms to both queries and their relevant documents (i.e., the symmetric difference of sets d, q and q' ($(d \triangle q) \triangle q'$)). An example of the Theorem 2 essence and how QDSM is computed, is displayed in Figure 1. In Figure 1, the common terms for both queries are presented in bold (i.e., these are t_2 and t_3), note that both terms are common in d_2, which is a relevant document (i.e., all document d_i, 1 are relevant meanwhile d_i, 0 are non-relevant). LCS is applied over both lists of retrieved documents considering only the relevant documents in the lists (i.e., even though d_7 is in both lists, only d_2 is considered). Finally, all terms that give context are in blue color (i.e., t_1, t_4, t_{10} and t_{15}).

It is worth noting that QDSM takes the value 1 (see *Definition 8*) when q and q' are the same queries, and all retrieved documents are relevant. Specifically, this latter can be itemized in two parts. In the first part, $S_c(q,q')$ provides 1 because q and q' are the same. In the second part, both results lists are equal, and all retrieved documents

are relevant; therefore, both lists hold the relevant documents in the same positions.

In summary, QDSM provides a metric that captures the semantic relationship between two queries (context), considering the relevant documents' order in both lists. A wide range of experiments was conducted in order to compare the effectiveness between S_c and QDSM. The experimental setup is displayed in the following section.

4 Experimental Environment

A benchmark query set extracted from the well-known dataset of query log "AOL Query Logs Dataset (AOL) [24]", was used to carry out the experiments. This collection has more than 20 million web query logs stored, submitted by around 650 thousand users in more than 36 thousand lines of data. These queries were stored at an interval of three months in the year 2006. Broadly speaking, queries in AOL are depicted as rows in the database files, which contains five columns with the following fields:
{*AnonID*, *Query*, *QueryTime*, *ItemRank*, *ClickURL*}, where:

- AnonID: an anonymous user ID number.
- Query: the query submitted by the user in the WSE.
- QueryTime: the exact time at which the user submitted the query.
- ItemRank: if the user clicked on a result, it keeps the rank of the selected document; holds empty otherwise.
- ClickURL: The domain portion of the URL is showed as a result if the user clicked on a search result.

4.1 The Benchmark set of Related Queries

Aiming carrying out the clustering experiments, a benchmark set of related queries (*RQ*) (see *Definition 8.*) was processed randomly from AOL. To verify that the queries were partially related, each time a query was chosen, it was checked that at least existed another query, in such a way S_c was neither one nor zero. To achieve this goal, the queries with ClickURLs empty were removed due to these do not have answers associated with the queries. Furthermore, stopwords processing was previously performed before to apply S_c. The core insight is that ClickURLs allow depicting a list of retrieved documents for q (see Definition 5.). It should be noted that register with the same query q (i.e., the same terms), logged by the same user around the same time, corresponds to a single query, which was split into several registers. Providing the maximum amount of information implies to use the longest session, which at least contains one register (i.e., at least one result or document).

On the other side, it is important to highlight that AOL does not possess users' judgments. Note that the users' judgments play a fundamental role in order to know what documents are relevant for a specific query [25]. Furthermore, these relevant documents are necessary to evaluate precision, recall, and, therefore, effectiveness. To tackle this issue, users' judgments were simulated following the approach presented by [26]. Simulations of relevance judgments are presented in the following section.

4.2 Simulation of Relevance Judgments

Simulating document relevance regarding a query is not a trivial task. This task embraces a great variety of aspects, such as users' literacy [27], needed information at any one point of time, and the user's profile [28] among others. To address this problem, the approach proposed by [26], which provides the relevance probabilities for documents depending on their ItemRanks on AOL, is applied in this paper. Towards that end, $F(ItemRank(d_i), M)$ (see *Definition 6.*) is simulated using $\mathcal{M}(M, ItemRank(d_i))$ in *Definition 7.* In simple words, the relevance is assigned using a value 0 (non-relevant) or 1 (relevant), which is obtained considering the values presented in Table I (i.e, M in $F(ItemRank(d_i), M)$). The relevance probabilities were calculated using the ItemRanks, assuming the user clicks provide information about how the user interprets the query [30]. In Table I, two relevance models are presented by "AllRel" and "LastRel" columns. "AllRel" implies all clicked documents are considered as relevant; meantime "LastRel" reports that only the last clicked document is relevant. Regarding "AllRel", two variants were used for it. The first variant is named "PartialRel", which considers the individual ItemRank of each document obtained from Table 1. The second variant ("AvRel") corresponds to the average of ItemRanks of the query's recovered documents. For example, suppose three documents (d_5, d_{10}, and d_{12}) that have been recovered for a query q. The respective ItemRanks are 20, 30, and 40; therefore, the average is 30. Subsequently, the relevance probability is determined by the "ItemRank" (average) row and the "AllRel" column, so for this example, the relevance probability for each document is 0.5106. Although the three documents have the same relevance probability, the relevance for each document is individually obtained.

4.3 Clustering Experiments

Five algorithms were evaluated considering the three relevance models over the same $\widehat{D}$. Five sets of RQ were used; the smallest set of RQ contains 123 queries alongside their documents (i.e., for each document, the relevance has been assigned), meantime the biggest set comprises 2,141 queries. Aiming to compare the clusters' quality between S_C and QDSM, two well-known measures have been used, F-measure and the nearest neighbor (NN) cluster hypothesis test. F-measure was proposed by [29]; the idea behind this measure is to evaluate effectiveness in the post-processing step, in which each cluster is assigned to a class. The F-measure can be seen as a way of combining the precision and recall for a retrieval specific model, and it is defined as the harmonic mean of the model's precision and recall. In simple words, F-measure has as purpose to provide a binary classification as positive or negative according to the belonging of objects to determined classes in the clusters. F-measure allows giving more importance to precision, recall, or both. On the other hand, the nearest neighbor (NN) cluster test (which is also well-known as the (NN) test) was proposed by Voorhees ([30], [31]). In simple terms, the (NN) test reviews each of the retrieved documents for a specific query, identifying how many of its n close neighbors are relevant. The (NN) test is also used as a non-parametric classification and regression technique.

Table 1: Probability of a document being relevant in the AOL dataset if it has rank k, for two different click-based relevance interpretations, as calculated by [26]

ItemRank	AllRel	LastRel
≤ 20	0.4365	0.5702
≤ 120	0.5106	0.6278
≤ 300	0.5395	0.6493
> 300	0.4705	0.3507

Turning towards the cluster hypothesis, QDSM should provide better effectiveness than S_c if it is possible to find more relevant documents per cluster. Each experiment was executed ten times, and results are displayed as percentages of increasing or decreasing of QDSM regarding S_c. Specifically, F-measure was used giving the same weight for precision and recall; meantime, The (NN) test was instantiated with value three in all experiments. In addition, the Student's Paired t-Test (Two Samples test) was used to support the results. Five algorithms Single Link, Complete Link, Average Link, Bisection K-means, and Ward's Method, were used in each experiment.

All experiments were carried out on a server with: Intel Xeon Processor E3-1220 3.00 GHz; 16 GB Ram memory of 2133 MHz; 1 TB 7200 RPM Hard Drive; and Linux Operating System Debian Jessi 8.4.

5 Experimental Results

In this section, the quality of clusters (effectiveness) produced by QDSM and S_c is compared. To achieve this goal, the F-measure and the (NN) test were used considering the Single Link, Complete Link, Average Link, Bisection K-means, and Ward algorithms. Effectiveness was obtained using the relevance models PartialRel, AvRel, and LastRel. Note that the number of documents considered in the (NN) test corresponds to 3, it means that the relevances of the three closest documents with respect to the query were evaluated. To do that, the similarities between documents are checked alongside their relevance regarding the query. Overall, all results presented in each Table corresponds to QDSM, which are expressed in terms of percentages regarding the S_c. In Table 2, the QDSM effectiveness over the three relevance models was evaluated using the Single Link Algorithm. Note that the three relevance models were tested considering five sets of queries (# of q). From this Table, it is possible to appreciate that there is not an improvement of QDSM concerning S_c. Furthermore, Single Link presents better effectiveness for S_c than QDSM; this is consistent with the p-value obtained using The Student Paired T-test (two samples), which was 0.0029 for this Table. Generally speaking, Single Link exhibits the best results considering the "AvRel" relevance model, following by "LastRel" and finally "PartialRel" model. Continuing the same trend, the results for F-measure are exposed in Table 3. Here S_c shows again better results than QDSM, which is in line with the p-value: 0.00036, and notably the best results are presented by "AvRel" relevance model.

Regarding the Complete Link algorithm, similar results to the Single Link algorithm are presented in Tables 4 and 5, where S_c has better results than QDSM. In Table 4, the best results are provided by "LastRel" relevance model using the (NN) test, meantime that the best results using the F - measure are given by "PartialRel" model. The p-value for the (NN) test was 0.720, whilst the p-value for the F - measure was 0.00003.

On the other hand, the Average Link algorithm displays different results to Single Link and Complete Link algorithms, where QDSM is better than S_c. In Table 6, the best results are given by "PartialRel", followed by "LastRel" and "AvRel" respectively. Results showed in Table 6 are in line with the p-value: 0.00041. Following the same trend, in Table 7, QDSM presents better results than S_c for F-measure, which is in accordance with the p-value: 0.000002. It should be noted that there is no substantial difference between "AvRel" and "LastRel".

In turn, the results for the Bisection K-means algorithm are exposed in Tables 8 and 9. Both Tables provide conflicting results since Table 8 two relevance models ("PartialRel and AvRel") give good results for QDSM, meantime these relevance models provide opposing results in Table 9. These latter results are coherent with their respective p-values. The p-value for Table 8 corresponds to 0.124, whilst p-value for Table 9 is 0.904. These values are not significative due to they are not greater than 0.05.

Finally, in Tables 10 and 11, the results for the Ward's method are displayed. Both Tables provide excellent results for QDSM in contrast to S_c (except when the number of queries is 129, using the relevance model "PartialRel"). Furthermore, the p-values associated with both Tables present the more significative value among all algorithms. The p-value associated with Table 10 is 0.00007; meanwhile, the p-value for Table 11 corresponds to 0.00001.

To sum up, considering both measures, the three relevance models, and the p-values obtained, the best results are provided by Average Link algorithm and the Ward's method.

Table 2: The (NN) test over Single Link Algorithm with *PartialRel*, *AvRel*, and *LastRel*.

# of q	*Single Link*		
	PartialRel	*AvRel*	*LastRel*
123	-30.92%	-33.73%	-42.36%

6 Discussion

The main reason traditional IR datasets were not used; it was because autonomous queries build them. As mentioned early, a traditional IR dataset is made up of a set of documents D, a set of queries Q, and a set of users' judgments JU. In a strict sense, evaluating the effectiveness considering similar queries (queries form part of

the clusters) means having a set of similar queries (Q') for Q. Note that Q' must consider a set of users' judgments (JU'). Indeed, the effectiveness of two similar queries should be different. Accordingly, these datasets are not suitable for evaluating approaches based on similar queries because they have neither Q' nor JU'. On the other hand, approaches based on log files employ subject matter experts to extend and evaluate whether a document is relevant or non-relevant given a query. In short, the extension of relevant documents is common in both types of collections. In this manner, aiming to avoid using subject matter experts or extending document relevances using relevant terms, three models of relevance have been simulated in all experiments.

Concerning the effectiveness evaluation for both measures (S_c and QDSM), it is noteworthy that F-measure has been widely used in several approaches, which deal with post-retrieval clustering. Nevertheless, the use of this measure provides two drawbacks. The first one is that the result associated with this measure comprises the number of relevant and non-relevant documents related to recall and precision in its mathematical formula. Thus, the initial effectiveness changes its value once new documents are considered relevant in the post-retrieval process. The second one refers to how the clusters are conformed taking into account the different classes of objects that these contain. Consider that objects can belong to predetermine classes, and the ideal situation is given when the clusters are formed only by objects of the same class. Two terms well-known in the cluster evaluation reflect this situation, homogeneity and completeness. The idea behind homogeneity is that each cluster has few classes; meantime, completeness intends each class to be contained in a few clusters. Thus, two-cluster forming using the same objects and the same classes can have the same F-measure, while their homogeneity and completeness are different. In turn, like F-measure, the NN-test has been extensively used in several approaches to assess effectiveness. Nevertheless, this measure is not sensitive to homogeneity and completeness, since it contemplates the direct search of the n-nearest neighbors. Hence, this test is more appropriate to corroborate the cluster hypothesis, which considers the relevant documents that form the clusters.

Regarding the results presented in section "Empirical Results", it is essential to point out that there is no significant difference between values provided by F-measure and the (NN) test, excepts for the Complete algorithm (Table 4 and 5), in particular for "AvRel" where for the (NN) test, Table 4 presents favorable results for QDSM in contrast to Table 5. Besides, the p-values for both Tables differ. On the other hand, exists a substantial difference with some results presented by [1]. In particular, regarding the relevance models used in that research. There, the relevance "AllRel" is used considering the proposed by [26], meantime in this research "AllRel" has been modified by "PartialRel" and "AvRel", it means that no all documents have been considered relevant such as occurs in [1]. It is important to point out that it is unlikely that all recovered documents are relevant, such as happens in the real world. Nevertheless, the Average Link algorithm presents interesting results in both works. Concerning the results provided by the algorithms in this research, the best results are provided by Average Link and Ward algorithms using both tests (F-measure and the (NN) test). The main Ward characteristic is that it minimizes the variance of the objects belonging to a particular cluster using the "error sum of squares". In this way, each cluster should tend to have objects of a few classes (relevant and non-relevant). Carried to the hypothesis cluster context should have a clear separation between clusters of relevant documents and clusters of non-relevant documents. Therefore, the nearest closest neighbor of a relevant document should be relevant too. On the other hand, the distance (S_c or QDSM) between two clusters for the Average Link Algorithm is determined as the average distance between each object in one cluster to every object in another cluster., by which it is feasible to avoid extreme measures obtaining more homogenous clusters. The latter is in contrast with the way to built clusters in Single and Complete algorithms. Finally, Bisection K-means is a hybrid approach between agglomerative and hierarchic clustering. This algorithm exhibits favorable results in the (NN) test except when the relevance is "LastRel", recall that in this case, only the last recovered document could be relevant.

Although the running times escape from the scope of this paper, it is worth noting that most time complexities are not high. To obtain the time complexities is necessary to consider visiting a distance matrix (i.e., one matrix for S_c and QDSM respectively) with the aim to find the n nearest-neighbor. Furthermore, calculating LCS implies to visit another matrix with M files and N rows. Note that M corresponds to a list of retrieved documents for a query q, whilst N is another list of retrieved documents for a query q'. Therefore, LCS takes $O(MN)$. Recall that LCS is used to evaluate QDSM. According to [32], the optimal implementation of Ward based on the algorithms, nearest neighbor chain, and reciprocal nearest neighbor, takes $O(N^2)$. In turn, the time complexity of Bisection K-means algorithm is $O(N^2 log_2 N)$. As for the implementation of Single Link algorithm takes $O(N^2)$ in time complexity [33]. On the other hand, Complete Link implies $O(N^2 log_2 N)$ [34]. The time complexity for the Average Link algorithm takes $O(N^2 log_2 N)$ [35]. It is important to mention that both matrixes of distances are previously built before using each clustering algorithm.

7 Conclusion and Future Work

This paper is intended to check the quality of clusters (effectiveness) built using Query-Document Similarity Measure (QDSM). To achieve this goal, the F-measure and the nearest neighbor (NN) test were used to evaluate clusters' quality. The clusters of documents were built using the AOL Query Logs Dataset. In order to provide relevance to the documents, three variants related to the ItemRanks over recovered documents were simulated. Extensive experimentation was carried out using the algorithms Single Link, Complete Link, Average Link, Bisection K-means, and Ward. According to results obtained, applying the nearest neighbor (NN) test, QDSM presents significant results using the Average Link, Ward, and Bisection K-means. On the other hand, in accordance with the results obtained by the F-measure; Ward and Average Link algorithms provide better results using QDSM than Cosine Similarity (S_C). The best results are provided by the Average Link algorithm, followed by Ward's method using QDSM, considering the three variants of relevance. Ideas for future research comprises the comparison between QDSM and other state-of-art measures.

Conflict of Interest The authors declare no conflict of interest.

Pre-Seismic Anomaly

ABSTRACT

A new method of analysis and classification of rock acoustic emission signals is proposed. It is based on symbol description of signals and involves the following processing. First, signal segments containing pulses are detected. Second, noise of the detected pulses is reduced by the wavelet filtration method. Fourth-order symlets and adaptive threshold scheme based on empirical Bayes method are used. Application of wavelet filtration allows us to increase the signal-to-noise ratio by 9 dB, on the condition that initial SNR is 8.9 dB. Each pulse is described by a descriptive matrix which represents a square binary matrix reflecting pulse amplitude-phase structure and characterizing the positions of pulse extrema relatively each other. Based on the similarity degree of descriptive matrices, classes are formed. The proposed algorithm classifies correctly 78% of pulses. Each class is considered as a symbol and a set of obtained symbols forms an alphabet. Then, changes of alphabet parameters on subsequent fragments of the signal are studied. The developed method was realized in the form of an application program with the help of which acoustic emission signals were analyzed. The signals were recorded at "Karymshina" site (IKIR FEB RAS), located in a seismically active region, Kamchatka peninsula, in 2016–2019. It was discovered during the analysis that in case of an acoustic emission anomaly, alphabet content redistributed in favor of the symbols described by larger-size descriptive matrices (up to 350 extrema). At the same time, the number of such symbols increased. Analysis of alphabet averaged dynamics discovered a well exhibiting tendency of alphabet cardinality decrease relatively an average 10–18 days before earthquakes and recovery of the value over the period from 2 to 8 days after them. The obtained estimates of the pre-seismic anomaly occurrence periods are consistent with the results of early studies. The proposed method updates the existing methodology of short-term earthquake precursor formation. Thus, applying the developed method for analysis, it is possible to identify pre-seismic anomalies of acoustic emission that is topical in the creation of strong earthquake preparation warning system operating in automatic mode.

1. Introduction

Acoustic emission (AE) in solid bodies is elastic oscillations occurring in the result of dislocation changes in a medium. In such a case, the characteristics of generated pulse emission are directly associated with plastic process features. That determines the interest in the emission investigation with the aim to develop methods for medium acoustic diagnostics.

AE is applied for different problems of diagnosis in seismology, geophysics as well as in non-destructive testing of objects and materials in industry. At the beginning of the XXI century it was shown that acoustic emission anomalies are observed before strong earthquakes and can be consider as their operative precursors [1-3]. In further investigations [4, 5] the nature of generation of pre-seismic acoustic anomalies and the features of their manifestations were considered. In the course of the research carried out at IKIR FEB RAS, it was shown that these anomalies are generated by the change of geomechanics stress field in earthquake preparation zone and appear as the result of the transformation, stress – near-surface rock deformation [6, 7]. The peculiarity of anomaly manifestation is geoacoustic emission intensity increase in the frequency range from hundreds of hertz to

*Corresponding Author: Solodchuk Alexandra, Email: aleksandra@ikir.ru

the first tens of kilohertz. It usually lasts for to several hours and occurs 1–3 days before an earthquake.

Statistics of pre-seismic acoustic anomaly observations in a seismically active region of Kamchatka peninsula, which is a part of the Pacific Ring of Fire, shows high efficiency and prospectivity of AE method to forecast catastrophic earthquakes [6]. Detailed analysis of AE signals shows that they a represented by a sequence of relaxation oscillation pulses with steep edge and smooth drop of different frequency filling [6]. In these circumstances, both separate pulses and their groups with significant overlapping are observed. In case of intensive emission, pulses merge into a continuous signal.

During a background (seismically calm) period, acoustic pulses with the repetition frequency within 0.1–0.5 pulses per a second are usually observed. During the increase of stress and of rock deformation velocity before an earthquake, both pulse amplitude and their number per a time unit grow. Pulse repetition frequency reaches the value of tens and even hundreds per a second [6].

At the present time one of the main and still unsolved problems is automation of search and operative detection of AE pre-seismic anomalies. Application of popular (widely spread in the world) methods for data analysis becomes complicated by several reasons, they are:

- wide dynamic range of recorded data is associated with great volumes of recorded information requiring special methods for storage, transfer, processing and analysis;
- strong irregularity of natural mediums and bad propagation of elastic oscillation causes signal significant distortion and attenuation which limits the capabilities of investigation methods;
- strong noisiness both by natural and industrial noises makes the analysis of inner (morphological) structure of AE pulses more complicated;
- wide variety of signal waveforms complicates the problem of classification and requires analysis methods adapting for a given signal.

The paper proposes a new approach to analyze and classify rock acoustic emission signals in order to identify AE pre-seismic anomalies. The approach is based on the description of acoustic pulses from which a signal alphabet is formed. Then the changes of alphabet parameters of signal subsequent fragments are studied.

2. AE signal model

In a general case, acoustic emission signals can be represented by a classical adaptive model, i.e. as a sum of noise $\varepsilon(t)$ and some function $s(t)$, the analytical expression of which is unknown,

$$x(t) = s(t) + \varepsilon(t), \tag{1}$$

where $\varepsilon(t)$ describes nonstationary background noise containing noises of natural and artificial origin and $s(t)$ is a "useful" AE signal. It is a flux of pulses of different waveform, amplitude and frequency. Moreover, we accept the following constraint $||s(t)|| > ||\varepsilon(t)||$. Figure 1 illustrates an example of AE signal.

Within the framework of the proposed approach, pulses of a "useful" signal $s(t)$ can be described by the means of their singular points. As it is known from the functional analysis theory, when there are no fractures of the first and of the second kind, these points coincide with local extrema and local inflections. It is assumed that signal function intermediate values lying between the singular points are less informative and may be neglected in the course of the analysis.

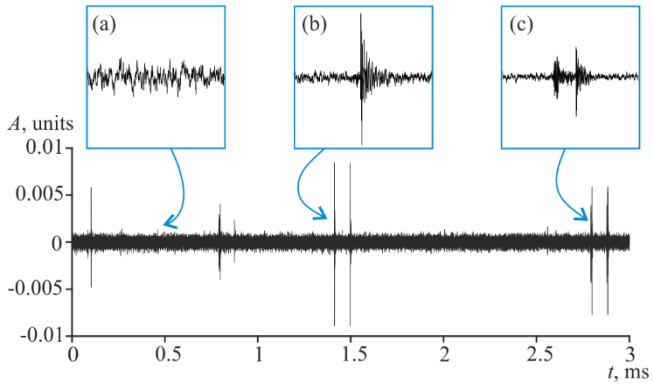

Figure 1: Acoustic emission signal: (a) – noise, (b), (c) – pulses

In order to understand the essence of further transformations, we consider an acoustic emission pulse signal (its graph is illustrated in Figure 2). We fix the values pulse local extreme amplitudes $\{a_i\} = a_0, a_1, \ldots, a_N$ and the time intervals between neighboring extrema $\{\tau_i\} = \tau_0, \tau_1, \ldots, \tau_{N-1}$. On the basis of these values we create a matrix of mutual relation of the fixed values (2). Matrices of **A** and **T** relation reflect pulse amplitude-phase structure. They characterize the positions of local extrema relatively each other and can be considered as a pulse model.

$$\mathbf{A} = \begin{pmatrix} a_0/a_0 & a_0/a_1 & \cdots & a_0/a_N \\ a_1/a_0 & a_1/a_1 & \cdots & a_1/a_N \\ \vdots & \vdots & \ddots & \vdots \\ a_N/a_0 & a_N/a_1 & \cdots & a_N/a_N \end{pmatrix}$$

$$\mathbf{T} = \begin{pmatrix} \tau_0/\tau_0 & \tau_0/\tau_1 & \cdots & \tau_0/\tau_{N-1} \\ \tau_1/\tau_0 & \tau_1/\tau_1 & \cdots & \tau_1/\tau_{N-1} \\ \vdots & \vdots & \ddots & \vdots \\ \tau_{N-1}/\tau_0 & \tau_{N-1}/\tau_1 & \cdots & \tau_{N-1}/\tau_{N-1} \end{pmatrix} \tag{2}$$

We should note that if one knows any one value a_i, any one value τ_i and the relational matrix (2), it is possible to recover the initial waveform of a pulse more or less without loss.

To compose signal symbol description, the obtained pulse diversity is classified by comparing the relational matrices (2), i.e. based on the pulse waveform similarity criterion. However, such selection should take into account two key points: firstly, amplitude attenuation and phase distortions of acoustic pulses occurring during the propagation from a source to a receiver point; secondly, the distortions caused by the interference of additive noise on pulse waveforms at a receiver point. These problems inevitably result in significant increase of the number of pulse classes (redundant classification). The following transformations and computing operations allow us to solve, to a large extent, the problems arising during the classification.

When analyzing a pulse waveform, signal function numerical values at singular points often do not play the major role. In a

greater degree, to detect a pulse waveform, mutual position of these points is important [8]. In the framework of the applied approach, search for the differences in the observed pulse waveforms is of the main interest. Thus, relational matrices can be reduced to matrices of rank relation. In order to do that,it would be enough to transform matrices (2) into binary ones according to the following rule:

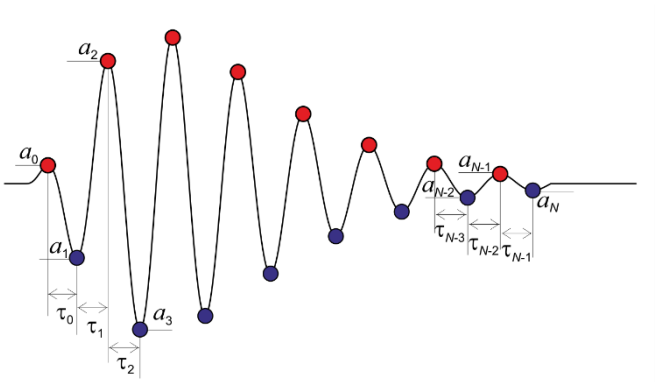

Figure 2: Local extrema of AE pulse

$$r_{i,j} = \begin{cases} 1, & a_i > a_j \\ 0, & a_i \le a_j \end{cases}, \qquad \omega_{i,j} = \begin{cases} 1, & \tau_i > \tau_j \\ 0, & \tau_i \le \tau_j \end{cases}, \tag{3}$$

where $r_{i,j}$ is the result of comparison of the i-th and j-th vales of extreme amplitudes; $\omega_{i,j}$ is the result of comparison of the i-th and j-th values of the intervals between the extrema. We create binary matrices of the comparison (3) results for amplitudes **R** and time intervals **W** separately.

$$\mathbf{R} = \begin{pmatrix} 0 & r_{0,1} & \cdots & r_{0,N} \\ r_{1,0} & 0 & \cdots & r_{0,N} \\ \vdots & \vdots & \ddots & \vdots \\ r_{N,0} & r_{N,1} & \cdots & 0 \end{pmatrix}$$
$$\mathbf{W} = \begin{pmatrix} 0 & \omega_{0,1} & \cdots & \omega_{0,N-1} \\ \omega_{1,0} & 0 & \cdots & \omega_{1,N-1} \\ \vdots & \vdots & \ddots & \vdots \\ \omega_{N-1,0} & \omega_{N-1,1} & \cdots & 0 \end{pmatrix} \tag{4}$$

The obtained binary square matrices **R** and **W** (4) of the sizes N+1 and N, respectively (intervals between local extrema are less by 1) have redundant character since, owing to inequality asymmetry (if $a > b$, then $b \le a$), we have $r_{i,j} = \neg r_{j,i}$ and $\omega_{i,j} = \neg \omega_{j,i}$, and all the elements lying on the main diagonal are equal to 0. In order to represent the pulse waveform more compactly, we join significant elements of both matrices. Transform the matrices **R** and **W** into upper triangular ones zeroing the redundant elements according to (5)

$$r_{i,j} = \begin{cases} r_{i,j}, & i < j \\ 0, & i \ge j \end{cases}, \qquad \omega_{i,j} = \begin{cases} \omega_{i,j}, & i < j \\ 0, & i \ge j \end{cases}. \tag{5}$$

As the result we obtain triangular binary matrices $\mathbf{R}_\Delta$ and $\mathbf{W}_\Delta$ (6).

$$\mathbf{R}_\Delta = \begin{pmatrix} 0 & r_{0,1} & r_{0,2} & \cdots & r_{0,N} \\ 0 & 0 & r_{1,2} & \cdots & r_{1,N} \\ 0 & 0 & 0 & \cdots & r_{2,N} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & r_{N-1,N} \\ 0 & 0 & 0 & \cdots & 0 \end{pmatrix}$$
$$\mathbf{W}_\Delta = \begin{pmatrix} 0 & \omega_{0,1} & \omega_{0,2} & \cdots & \omega_{0,N-1} \\ 0 & 0 & \omega_{1,2} & \cdots & \omega_{1,N-1} \\ 0 & 0 & 0 & \cdots & \omega_{2,N-1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & \omega_{N-2,N-1} \\ 0 & 0 & 0 & \cdots & 0 \end{pmatrix} \tag{6}$$

We reduce the matrix $\mathbf{R}_\Delta$ size to the value N by removing zero elements of the lower line and the left column. We make transposition operation of the matrix $\mathbf{W}_\Delta$ and as the result obtain the matrix $\mathbf{W}_\Delta^{\mathrm{T}}$. After summing up the matrices $\mathbf{R}_\Delta$ and $\mathbf{W}_\Delta^{\mathrm{T}}$, we obtain a square binary matrix **D** of size N (7). It can be used as a model of pulse amplitude-phase structure.

$$\mathbf{D} = \begin{pmatrix} r_{0,1} & r_{0,2} & \cdots & r_{0,N-1} & r_{0,N} \\ \omega_{0,1} & r_{1,2} & \cdots & r_{1,N-1} & r_{1,N} \\ \omega_{0,2} & \omega_{1,2} & \cdots & r_{2,N-1} & r_{2,N} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ \omega_{0,N-2} & \omega_{1,N-2} & \cdots & r_{N-2,N-1} & r_{N-2,N} \\ \omega_{0,N-1} & \omega_{1,N-1} & \cdots & \omega_{N-2,N-1} & r_{N-1,N} \end{pmatrix} \tag{7}$$

We call (7) a pulse descriptive matrix. An example of a pulse and its descriptive matrix are illustrated in Figure 3.

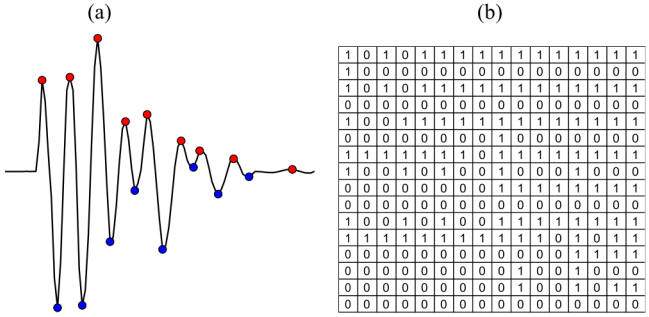

Figure 3: Representation of a pulse by descriptive matrix: (a) – pulse with detected extrema; (b) – pulse descriptive matrix

Descriptive matrices have invariant character under time and amplitude transformations that is proved by the following properties:

- invariance under time compression or expansion (if $k > 0$ and $\tau_i > \tau_j$, then $\tau_i \cdot k > \tau_j \cdot k$);
- invariance under amplitude compression or expansion (if $k > 0$ and $a_i > a_j$, then $a_i \cdot k > a_j \cdot k$).

The invariance is retained, if the coefficient k is substituted by any monotone positive function $f(x) > 0$. Attenuation processes

and nonlinear amplitude-phase distortions, changing AE pulse signal waveforms during its propagation in heterogeneous anisotropic mediums from a source to a receiver, have the character of monotone functions in the majority of practical cases. Thus, descriptive matrix invariance is of great importance when creating algorithms for identification and classification of acoustic emission pulses.

3. Model adequacy

To verify the proposed model adequacy, we generated two artificial AE signals.

It was shown in the paper [9] that AE typical pulses are described by modulated Berlage functions with a reasonable degree of accuracy

$$u(t) = A \cdot t^{n(p_{\max})\cdot\Delta} \cdot \exp\left(-\frac{n(p_{\max})\cdot\Delta}{p_{\max}\cdot t_{end}}\cdot t\right)\cdot\sin(2\pi ft+\varphi_0), \quad (8)$$

where A is the pulse amplitude; t is the time, $0 \le t \le t_{end}$; p_{max} is the pulse envelope maximum position defined relating to t_{end}; $n(p_{max})$ is the minimum value of the parameter affecting pulse envelope slope which is chosen so that $u(p_{max} \cdot t_{end}) \le 0.05 \cdot u(t_{end})$; Δ is the coefficient of pulse envelope slope variation, the more Δ value is, the steeper the envelope is, $\Delta > 1$; f is the pulse modulation frequency; φ_0 is the initial phase. To obtain different pulse waveforms, the parameter values p_{max}, Δ, t_{end}, f, φ_0 vary.

The first artificial signal (Figure 4a) contains five pulsesof similar waveform and the second one contains five pulsesof different waveform (Figure 4b). As long as the model should be invariant under amplitude and time transformations of the signal, the length and the amplitude of each pulse were drawn at random. Instead of the frequency f, the number of periods k on the time interval from 0 to t_{end} was defined. Parameters of the generated pulses are listed in Table 1.

Table 1: Parameters of test pulses

Wave-form	Number of periods, k	Maximum position, p_{max}	Steepness, Δ	Initial phase, φ_0
I	10	0.2	1.5	0
II	5	0.1	1.2	0
III	15	0.25	2	0
IV	11	0.01	1	$\pi/3$
V	20	0.4	1.5	0

Signal graphs and modeling results are illustrated in Figure 4a–b. Pulses having similar descriptive matrices are shown by the same color. Thus, application of the proposed model allowed us to determine correctly the similarity/difference of pulse waveforms. We should note that the pulses of the first signal have different frequency-time structures (Figure 4c), and would be attributed to different classes when applying frequency-time methods. Pulses of the second signal have the same frequency (Figure 4d), but different waveforms and would be attributed to the same class when applying frequency-time methods.

Figure 5 shows the real AE signal containing five pulses. Three pulse waveforms are distinguished visually. The suggested model describes real signals adequately. Pulses of the same waveform have similar descriptive matrices.

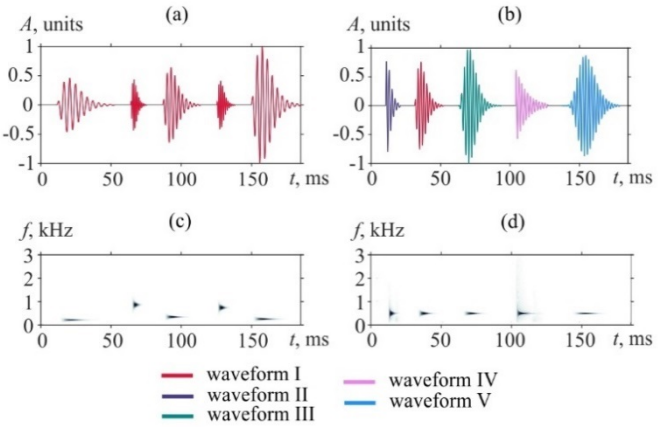

Figure 4: Modeling results for two signals. Pulses described by the same descriptive matrix are of the same color: (a) – signal containing five pulses of the same waveform; (b) – signal containing five pulses of different waveform; (c) – Wigner-Ville transformations of the first signal pulses; (d) – Wigner-Ville transformations of the second signal pulses

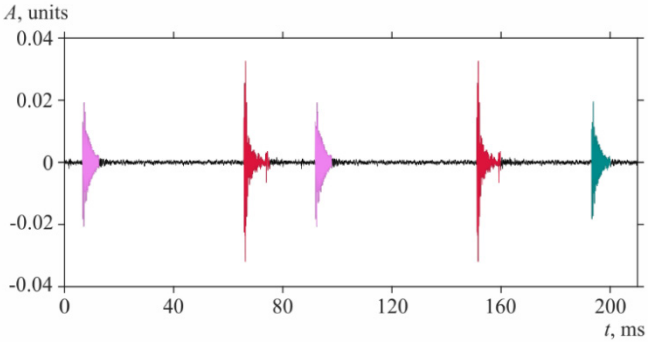

Figure 5: Modeling results for real AE signal. Pulses described by similar descriptive matrices are of the same color

In the considered examples we analyze the signals in which noises are either absent or insignificant. Real AE signals often contain noises of artificial and natural origin, thus perturbing a signal. Distortion may result in a gap, false detection or amplitude change of some extrema. Then the size and some elements of pulse descriptive matrices differ (Figure 6).

4. Classification of pulse diversity

We define initial conditions for classification. We put bounds on the size of descriptive matrices detected during the analysis by the values N_{min} and N_{max} from the bottom and from the top, respectively. Analysis epoch is the length of the time window in which an AE signal is observed. In practice, this index should provide formation of stable classes. N_{min} is determined by the minimum number of oscillations during pulse duration and cannot be set less than 3. N_{max} is defined according to the capabilities of a computing device and the maximum run-time.

Pulses are classified accorded to the results of calculation of descriptive matrix similarity coefficient. First, we restrict ourselves to descriptive matrices of the same size. In order to do that we divide descriptive matrices into groups $\mathbf{D}^{(Z)}$ of matrices of the same size Z, $N_{min} < Z < N_{max}$.

For the two descriptive matrices of the same size $\mathbf{D}_1^{(Z)}$ and $\mathbf{D}_2^{(Z)}$ the similarity coefficient $g(\mathbf{D}_1^{(Z)}, \mathbf{D}_2^{(Z)})$ is determined as a ratio of elements, coinciding in value and taking the same positions, to the

total number of elements in the matrix. In case of exact identity, the similarity coefficient is 1.

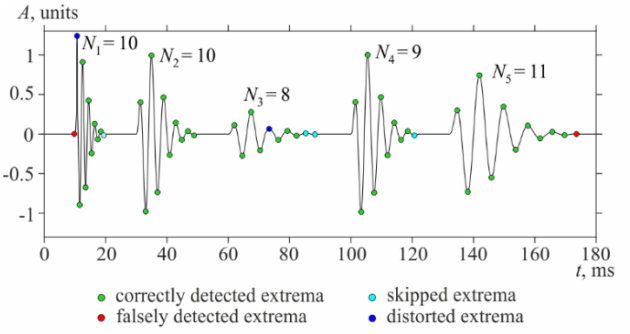

Figure 6: Examples of errors occurring during extreme detection

$$g(\mathbf{D}_1^{(Z)}, \mathbf{D}_2^{(Z)}) = \frac{\#(d_{1ij} = d_{2ij})}{Z^2}, \quad (9)$$

where #(*condition*) is the operator for calculation of the number of elements satisfying the condition, d_{1ij} are the elements of the matrix $\mathbf{D}_1^{(Z)}$, d_{2ij} are the elements of the matrix $\mathbf{D}_2^{(Z)}$.

The calculated similarity coefficient $g(\mathbf{D}_1^{(Z)}, \mathbf{D}_2^{(Z)})$ is compared with the selected threshold value G_0 (it is chosen empirically). If

$$g(\mathbf{D}_1^{(Z)}, \mathbf{D}_2^{(Z)}) > G_0,$$

then the pulses described by $\mathbf{D}_1^{(Z)}$ and $\mathbf{D}_2^{(Z)}$ belong to the same class.

Classification is the comparison of descriptive matrices of the same size and selection of the empirical threshold G_0 ($0 < G_0 \leq 1$) with which the similarity coefficient (9) is compared.

The possibility that two pulses of the same source will have exactly the same number of local extrema is very low. So, the obtained classification is too restrictive. Thus, we developed a procedure to compare descriptive matrices of different sizes. It takes into account false extrema or gaps of some extrema and allows us to reduce the number of detected classes. However, when descriptive matrix sizes are widely scattered, they are compared in erratic manner that may cause random merging of classes described by descriptive matrices of smaller sizes. We put bounds on the possibility for merging of descriptive matrices of smaller sizes by the threshold coefficient S_0:

$$N_L / N_M \geq S_0, \quad 0 < S_0 \leq 1,$$

where N_L and N_M are the sizes of smaller and larger descriptive matrices, respectively, S_0 is the empirically defined threshold.

Assume that there are two descriptive matrices $\mathbf{D}_1$ and $\mathbf{D}_2$ of the sizes N_1 and N_2, respectively ($N_1 \geq N_2$). If $N_2/N_1 \geq S_0$ ($N = S_0 \cdot N_1$), then the matrices are comparable. For the meaningful comparison, the matrices $\mathbf{D}_1$ and $\mathbf{D}_2$ are matched so that the latest N elements of the main diagonal $\mathbf{D}_2$ are overlapped on the first N elements of the main diagonal $\mathbf{D}_1$. Then we calculate the similarity coefficient (9) of matrices of size N in the domain bounded by the intersection. Elements are further compared after $\mathbf{D}_2$ shift along the main diagonal $\mathbf{D}_1$. The similarity coefficient (9) is calculated for each subsequent shift so far as the matrices in the domain bounded by the intersection have the size of not less than N (Figure 7). The comparison result is the maximum value of the similarity coefficient.

If the maximum similarity coefficient (9) exceeds the empirically defined threshold G_0 or is equal to it, the decision on sufficient closeness of descriptive matrices of compared pulses is made. In this case, the pulse with descriptive matrix of the smaller size is included into the class described by larger-size descriptive matrix (larger object absorbs a smaller one).

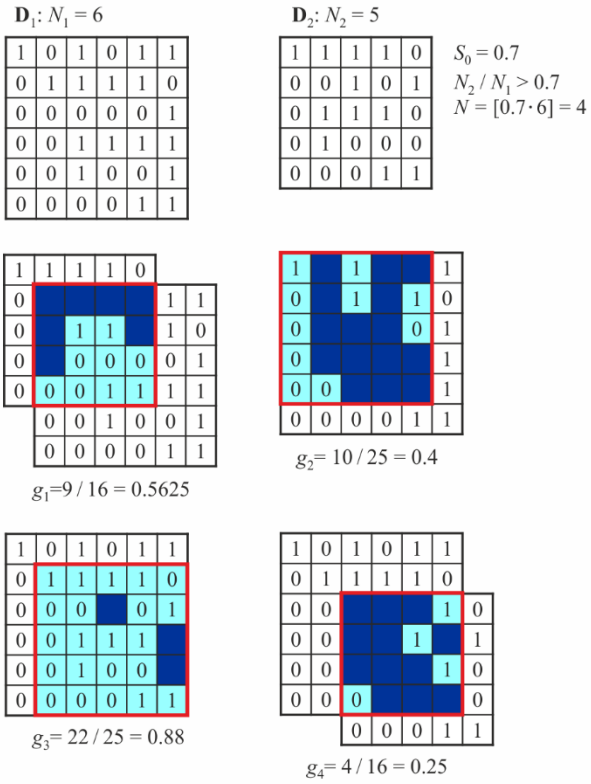

Figure 7: Comparison of descriptive matrices of sizes 6 and 5

In the result of classification many classes are formed. Each of them unites the pulses close in amplitude-phase structure with the accuracy up to the values determined by the coefficients G_0 and S_0. Each class can be considered as some symbol and the whole set of obtained symbols composes a signal alphabet.

In order to estimate the classification algorithm noise immunity for different values of the thresholds G_0 and S_0, we realized a simulation experiment. We processed the data containing 100 pulses of similar waveform (the alphabet cardinality is 1 symbol) with signal/noise ratio (SNR) from ∞ to 2.7 dB.

At the first stage of the experiment we compared the descriptive matrices with sizes differing by less than 30% ($S_0 \geq 0.7$). Similarity coefficient threshold was chosen to be $G_0 = 1$ (case when a matrix of smaller size is the sub-matrix of a larger-size matrix).

Figure 8 shows the dependences of alphabet cardinality on SNR for different values of the coefficient S_0 (0.7–1). Insignificant difference of the graphs proves that descriptive matrix element values significantly depend on local influence of noise on pulse waveform and are weakly sensitive to changes in the threshold S_0 at a high value G_0. When SNR values are less than 30 dB, the

classification does not work since matrices do not match with 100% agreement ($G_0 = 1$).

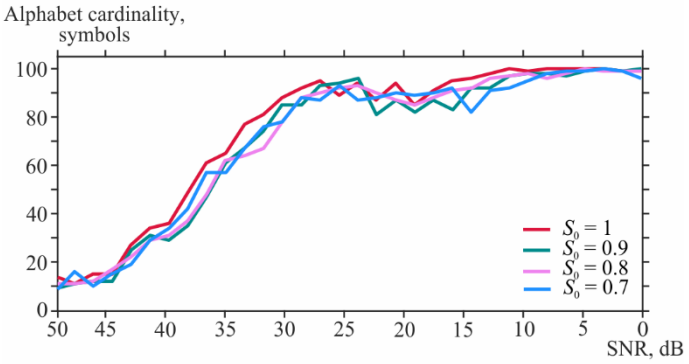

Figure 8: Dependence of alphabet cardinality on SNR for different values of the threshold S_0 (0.7–1) and for a fixed valued of the threshold G_0 =1

At the next stage of the computational experiment, we investigated class formation during threshold G_0 changes (from 0.6 to 0.9). In this case, matrices of the same size ($S_0 = 1$) were compared. The results of the second stage of the computational experiment are illustrated in Figure 9. The graphs show that decrease of the threshold G_0 causes significant reduction of alphabet cardinality. Moreover, the number of detected classes reduces with G_0 decrease.

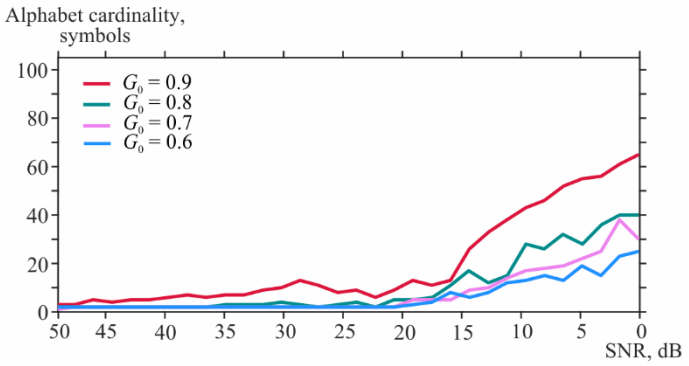

Figure 9: Dependences of alphabet cardinality on SNR for different values of the threshold G_0 (0.6–0.9) and for a fixed value of the threshold $S_0 = 1$

At the third stage of the computational experiment we investigated the dependence of alphabet cardinality on SNR for $S_0 = 0.7$ and different values of G_0. The results are shown in Figure 10.

The experiment shows that the classification method is nonlinearly sensitive to the choice of threshold functions of G_0 and S_0: decrease of S_0 causes pulse redistribution into classes with larger-size descriptive matrices and decrease of G_0 makes it possible to compact classes. Based on the experiment results, the recommended values of the thresholds S_0 (from 0.6 to 0.9) and G_0 (from 0.7 to 0.9) were selected.

As long as the developed method of classification is expectedly sensitive to the performance quality of the algorithms for pulse detection and noise reduction, one of the important tasks in AE signal investigation is the improvement of methods for signal pre-processing.

Classical digital filtration, empirical mode decomposition (EMD), and wavelet filtration were considered as methods of noise reduction and detection of signal useful component. Digital filtration was not used because the AE pulses have short duration (100–400 samples per pulse). Problem of mode functions selection complicated the usage of EMD for signal denoising (for example, in [10]), since rejected modes are different for different pulses. So, the authors chose wavelet filtration technology with adaptive threshold scheme. Wavelets are widely used in various signal processing tasks [11], in particular in noise reduction tasks [12, 13]. Denoising has three stages: direct wavelet transforms, application of a selected threshold scheme to every detailing component, inverse wavelet transforms. In order to choose a wavelet family, a threshold scheme and an algorithm for calculating threshold value, a computational experiment was carried out on model and real AE signals. The best results were obtained applying fourth-order symlets (maximum possible level of decomposition), median threshold scheme and empirical Bayes rule to calculate the threshold value [14, 15]. The selected wavelet filtration method allows us to increase the signal-to-noise ratio by about 9 dB, on the condition that initial SNR is 8.9 dB.

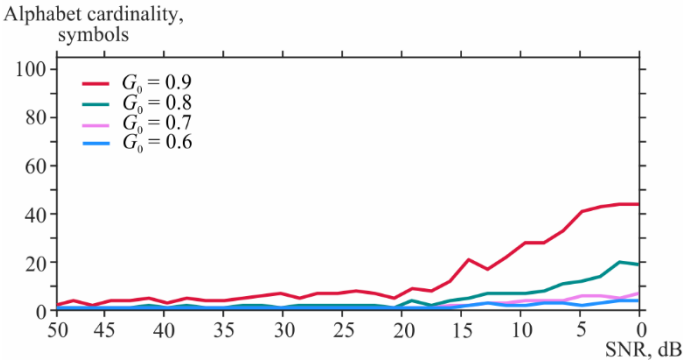

Figure 10: Dependences of alphabet cardinality on SNR for different values of the threshold G_0 (0.6–0.9) and for a fixed value of $S_0 = 0.7$

Figure 11a–b illustrates the process of detection of local extrema in a noised pulse and in a pulse with additive noise. Figure 11c shows how the wavelet filtering algorithm recovers the waveform of a perturbed signal.

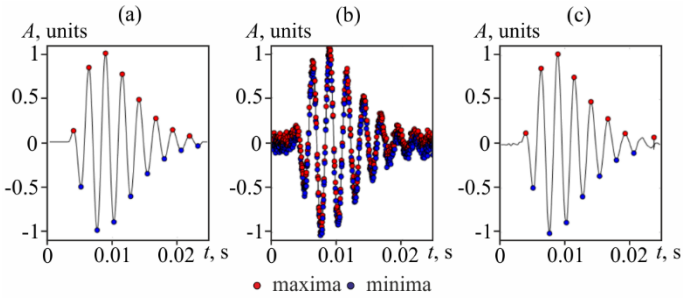

Figure 11: Noise effect on detection of local extrema: (a) – initial pulse; (b) – pulse with overlapped white noise, SNR = 12.4 dB; (c) – pulse denoised by wavelet filtration, SNR = 22.7 dB

Application of wavelet filtering with adaptive threshold schemes allows us to apply the proposed methods of analysis to perturbed and noisy signals.

Figure 12 illustrates the results of classification of model signal pulses with the signal/noise ratio of 8.9 dB. The signal contains 50 Berlage pulses described by three waveforms the parameters of which are listed in Table 3. Before being classified, each detected pulse was denoised by the selected method of wavelet filtering (after wavelet filtration, the SNR of a single pulse is about 20 dB).

When constructing descriptive matrices, we did not take into account the extrema the amplitudes of which were less than 15% from the maximum one. Classification algorithm thresholds were selected as $S_0 = 0.6$ and $G_0 = 0.7$. For a noisy signal (Figure 12a) we succeeded to define correctly the number of classes and to structure the pulses into classes (Figure 12b). In the course of multiple repetition of the experiment it was discovered that the obtained structuring into the classes is stable to the changes of initial conditions of white noise generator.

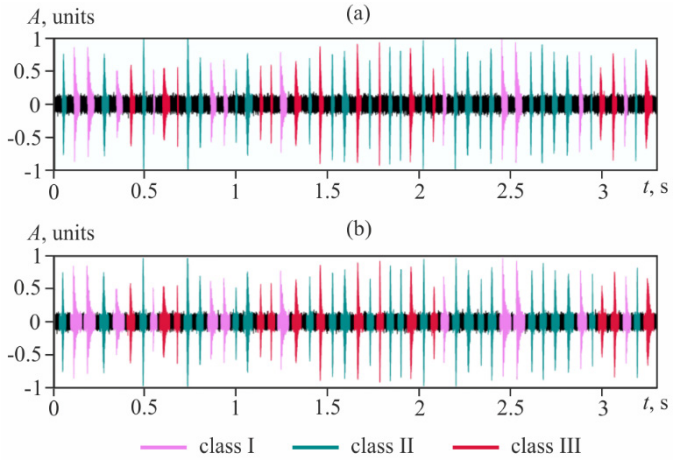

Figure 12: Classification results: (a) – signal with overlapped white noise and initial structuring into classes; (b) – classification of $S_0 = 0.6$, $G_0 = 0.7$; 3 classes were defined

Table 2: Waveform parameters

Class	Number of periods, k	Maximum position, p_{max}	Steepness, Δ	Initial phase, φ_0
I	7	0.05	1.1	0
II	20	0.35	3	$\pi/3$
III	40	0.2	2	$\pi/2$

The proposed algorithm classifies correctly 78% of pulses, on the conditions that thresholds are selected as $S_0 = 0.6$, $G_0 = 0.7$ and SNR is 8.9 dB before wavelet denoising. This estimate is based on the results of 100 experiments.

Efficiency of the proposed classification method can be estimated by a contraction coefficient

$$b = \frac{|A_{input}|}{|A_{output}|}$$

where $|A_{input}|$ is the alphabet cardinality (number of pulses) before classification, $|A_{output}|$ is the cardinality of the alphabet obtained as the result of classification.

Table 3 illustrates the classification results for 12 files containing 15-minute records of AE signals from IKIR FEB RAS archive data for January 1, 2018. The classification was carried out with the coefficients $G_0 = 0.8$, $S_0 = 0.8$.

As the result of further processing of AE data for the period 2016-2019, it was determined that contraction coefficient (10) varies from 50 to 200.

The developed methods of pulse description and classification were realized in the form of software. Preprocessing procedures such as centering, normalization, and noise reduction were performed by MATLAB system.

Table 3: Classification results

File number	Alphabet cardinality, $\|A_{input}\|$	Alphabet cardinality, $\|A_{output}\|$	Contraction coefficient, b
1	2864	37	77.4
2	3233	36	89.8
3	3581	46	77.8

5	4593	45	102.0
6	3132	46	68.0
7	3778	43	87.9
8	4424	38	116.4
9	4836	36	134.3
10	3968	39	107.7
11	4734	36	131.5
12	3475	44	78.9

5. Examples of identification of pre-seismic AE anomalies

The developed method of classification was realized in the form of an application program. It was used to process and to analyze acoustic emission signals recorded in 2016–2019 at "Karymshina" site of IKIR FEB RAS (52.83º N, 158.13º E). AE signals are stored in the database in the form of 15-minute sound files (WAVE format). In the course of processing of each file, signal alphabet was constructed. Then alphabet symbols were ranked according to the size of their descriptive matrices and frequency (number of pulses described by the symbols).

Based on the conception of the relation of AE signal parameters with the state of a system generating a signal, we should analyze quantitative and qualitative parameters of symbol description of a signal for different time periods (from a day to a year) and to compare the defined anomalies with occurred earthquakes according to the data of regional seismic catalogue (Kamchatka Branch of the FRC GS RAS, Earthquake Catalogue for Kamchatka and Kuril Islands (1962 – present time), http://sdis.emsd.ru/info/earthquakes/catalogue.php).

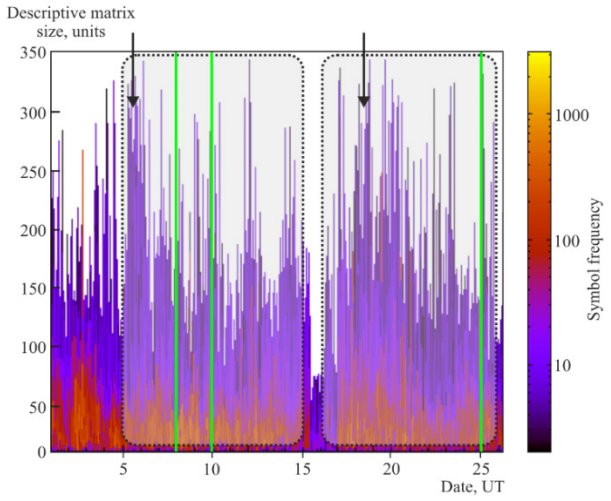

Figure 13: Anomalous dynamics of AE signal alphabet in October 2017

In order make the analysis, alphabets of each 15-minute AE signal were formed. Then three-dimensional images of a special type were drawn. Descriptive matrix size was measured on the vertical axis. Time (with 15-minute step) was measured on the horizontal axis. Color denotes symbol frequency.

Examples of anomalies observed 1–12 days before earthquakes and 1–6 days after earthquakes are illustrated in Figures 13–15.

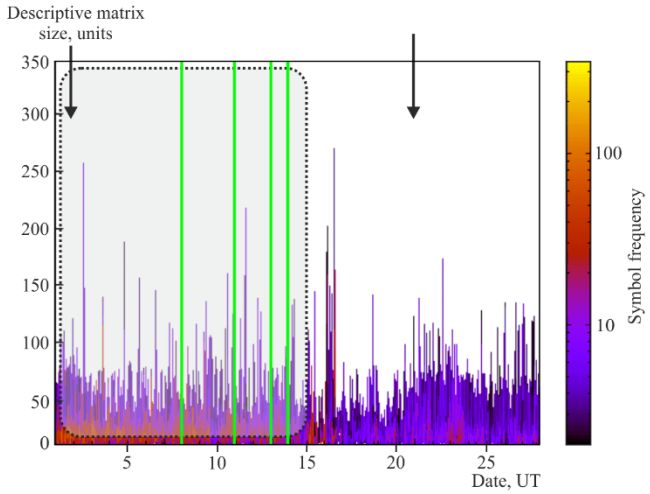

Figure 14: Anomalous dynamics of AE signal alphabet in February 2019

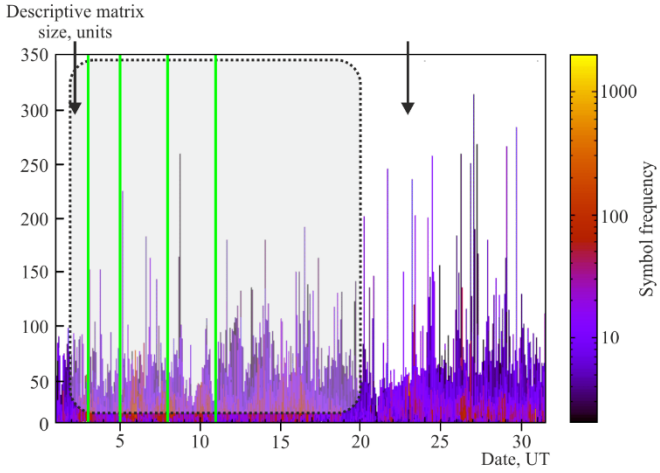

Figure 15: Anomalous dynamics of AE signal alphabet in October 2019

Anomaly peaks in the Figures are marked by black arrows. Green lines indicate earthquake times. These anomalies are alphabet content redistribution in favor of the symbols described by larger-size descriptive matrices (up to 350 extrema). Simultaneously with that the number of such symbols increases. Alphabet cardinality also grows from 20 to 150. Assumed areas of anomalies associated with earthquakes are marked by rounded rectangles. Short-term changes of alphabet content (less than 305 peaks) were not taken into consideration.

We should note that not all the analyzed AE anomalies in the form of redistribution of alphabet symbol frequency are associated with earthquake preparation processes. In the experiment the acoustic emission is recorded in sedimentary rocks and is a sensitive indicator of their stress-deformed state. Both global tectonic processes (for example, earthquake preparation) and local deformations, associated with the impact of different natural factors, may influence that state. Thus, not all the recorded AE anomalies are pre-seismic.

Figures 13–15 illustrate examples of AE anomalies observed during the periods when earthquakes occurred quite rarely, from one to four strong events per a month. Such a choice allows us to demonstrate the relation of detected anomalies with earthquakes. When earthquakes repeat quite frequently, the anomalous behavior is not so clear that may be explained by overlapping of fragments of evoked anomalous effects. Example of such behavior of alphabet content dynamics is shown in Figure 16.

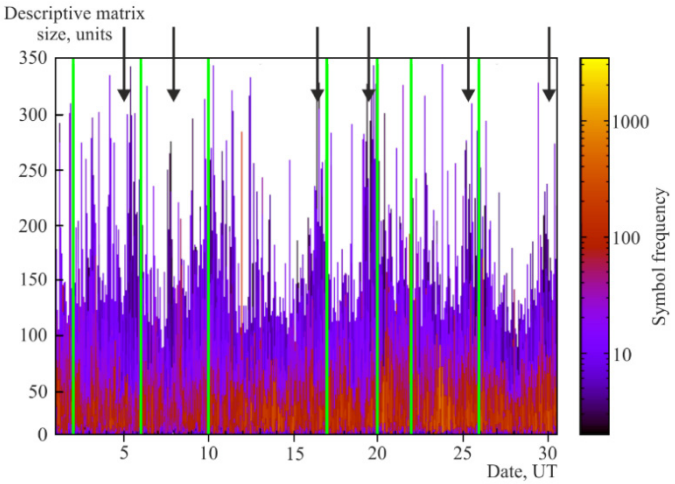

Figure 16: Anomalous dynamics of AE signal alphabet in April 2017

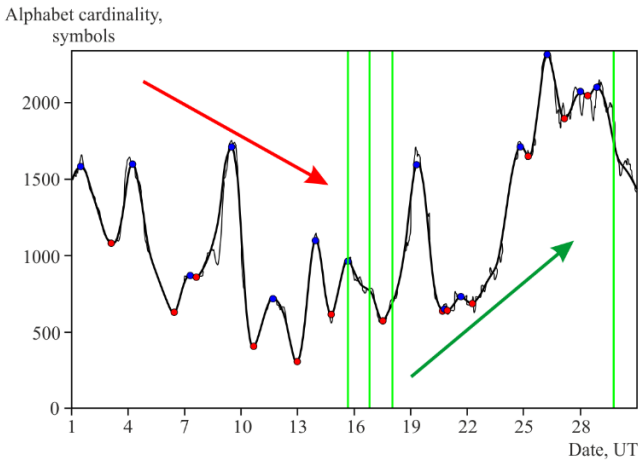

Figure 17: Graphs of AE signal alphabet cardinality dynamics in September 2017

Further analysis of the dynamics of AE signal alphabet parameters allowed us to find some regularities associated with the anomalies of the envelope of day-averaged alphabet cardinality. For the averaging we applied a sliding window of the width of 96 values of alphabet current cardinality. As an example, Figures 17–19 illustrate alphabet cardinality dynamics for one month, September 2017, December 2018 and September 2019. Thin gray line shows the result of alphabet averaging and the thick black line shows the result of approximation of the least square method. The graphs clearly show an oscillating process with small uncertain deviations of phase and amplitude the average period of which is from 2 to 3 days. The nature of this oscillating process was not determined and is under the study now. Blue dots on the graph are local maxima of detected oscillations. Red dots are their

minimums. Vertical green lines show the earthquake times. Red arrows indicate alphabet transformation tendencies before a series of earthquakes. Green arrows indicate transformation tendencies after a series of earthquakes. We can clearly distinguish the tendency of decrease of alphabet cardinality relatively the average 10–18 days before earthquakes and recovery of the value over the period from 2 to 8 days after them. This decrease is evidently determined by the fact that acoustic process before an earthquake becomes significantly more nonstationary. More pulses of similar waveforms appear and, consequently, alphabet set gets narrow.

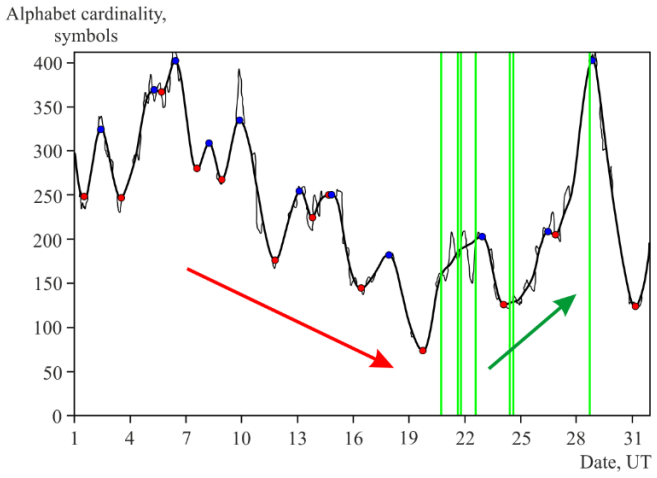

Figure 18: Graphs of AE signal alphabet cardinality dynamics in December 2018

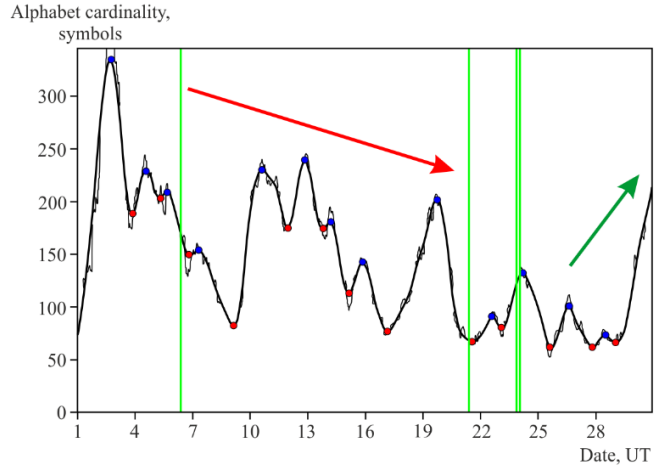

Figure 19: Graphs of AE signal alphabet cardinality dynamics in September 2019

The obtained estimates of the pre-seismic anomaly occurrence periods are consistent with the results of early studies. It was shown in [1, 2] that AE intensity increases at the frequency of 25 kHz 2–3 days before strong earthquakes. According to [16, 17], anomalies in the form of signal level increase appear in the frequency range of more than 6.5 kHz in the AE signals accumulated by 1 s. The results of time-frequency analysis of single AE pulses registered 1–7 days before earthquakes are presented in [18, 19]. According to these results, the number of pulses of a certain frequency increases before strong earthquakes. The above methods analyze signal frequency spectrum and, unlike the one described in the article, do not take into account waveform features. The proposed method of AE signals analysis updates the existing methodology and allows us to form more accurate short-term precursors of strong earthquakes.

Note that at all stages of the investigation, we had to face known nonlinear manifestations of the natural system under the study. These manifestations reflected in the chaotic character of AE signal dynamic characteristics. As it had been expected, the attempt of application of traditional methods for signal statistical processing, such as calculation of probability density function, ensemble averaging, estimation of statistic parameters of different orders, to nonstationary AE signals did not provide stable results. Thus, the attention was focused on the search for invariant transformations which would be applied to AE chaotic character properly. On the whole, we think that we are at the beginning of a perspective survey which, owing to the chosen approach and the developed computer tools for analysis, will allow us to investigate deeper and to extend general and personal knowledge on seismic process behavior and, consequently, to predict catastrophic effects of earthquakes at different stages and with more confidence.

6. Conclusions

A new method for analysis and classification of rock acoustic emission signals has been proposed. It is based on their symbol description. First of all, signal sections containing pulses are determined. Each of the sections is described by a descriptive matrix. Based on the similarity degree of the descriptive matrices, pulses are structured into classes. Each class is considered as a symbol and a set of obtained symbols composes an alphabet. Then we study the changes of alphabet parameters on signal subsequent fragments.

The developed method allows us to:

- distinguish informative features in AE signals based on their qualitative peculiarities;
- solve the problem of processing of a large volume of data by unifying pulse description and systematization;
- identify anomalies in AE signals distinguishing pre-seismic ones.

The method was implemented as an application program by the means of which we analyzed acoustic emission signals which were recorded at “Karymshina” site of IKIR FEB RAS in the seismically active region, Kamchatka peninsula, in 2016-2019. It was discovered during the analysis that in case of acoustic emission anomaly occurrence, alphabet content is redistributed in favor of the symbols described by larger-size descriptive matrices (up to 350 extrema). Simultaneously with that the number of symbols increases. Analysis of alphabet averaged dynamics detected a clear tendency of alphabet cardinality decrease relatively the average 10–18 days before earthquakes and recovery of the value over the period from 2 to 8 days after them.

Thus, a new approach to the analysis of acoustic emission signals has been developed. The approach updates the existing methodology of short-term earthquake precursor formation. On the basis of it, a system for automatic identification of pre-seismic AE anomalies can be created. It is topical for prediction of strong earthquakes which are catastrophic natural phenomena.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

A nonlinear adaptive robust controller is proposed in this paper for trajectory-tracking control problems of robot manipulators. On one hand, to effectively approximate the systematic dynamics, a simple time-delay estimator is first adopted. On the other hand, to minimize the control error, the controller is designed based on a sliding mode structure using the obtained estimation results. A fast learning mechanism is then proposed for automatically tuning control gains. Another proper adaptation law is furthermore developed to support the nominal inertia-matrix selection of the time-delay estimation. Effectiveness of the closed-loop system is intensively discussed using Lyapunov-based constraints and extended simulation results.

1. Introduction

Nowadays, robots play a crucial role in modern industry thanks to excellent performances in conducting complicated, repetitive, and dangerous tasks [1–4]. Day by day, high-precision intelligent robots are required to fulfill the given demands [2], [5]. To design such controllers, two important steps of the controller design are taken into account: nonlinearities and uncertainties in system models as well as unexpected effects of complex working environments have to be tackled to push the closed-loop system in a stationary state; in the second step, a driving robust control signal is generated to force the control objective stabilizing around origin [6–8].

Robot dynamics could be derived using Newton-Euler analyses, Lagrange formulations or virtual decomposition methods [6,9]. Although general systematic models could be obtained, but they contain lots of uncertainties due to particular structures of robots and disturbances [10,11]. To cope with the mathematical problems, soft-computing approaches are reasonable solutions [7,8]. Nonlinear uncertain dynamics could be well estimated by fuzzy-logic approximators and neural networks but heavy-computation burdens along with lots of tuning parameters are new obstacles in real-time applications. The time-delay estimation (TDE) is increasingly adopted as one of the most effective tools to reckon unknown dynamics in modern control, owing to the simplicity in design and easiness in real-time implementation [12,13]. This technique uses measured information of the acceleration and control signals to result in offset terms of the dynamics based on predefined nominal values of inertia matrices [5,14]. Effectiveness of the TDE methods has been gradually confirmed in both theoretical proofs and experimental validations [15,16].

To effectively complete control objectives in industrial applications, a proper control strategy with impressive adaptation and robustness ability is next required [17–19]. The sliding mode control (SMC) technique has a special attraction to designers thanks to the simplicity, widespread applications, and robustness to unknown system dynamics [20–23]. However, excellent control performances of the SMC controllers may be hard to maintain in different working cases. As a solution, gain-adaptive SMC schemes have been recently noted for servo systems [18,24–26]. Driving gains or robust gains were actuated by various learning mechanisms to effectively force the control objective to zero as fast as possible [25,26]. In these learning schemes, only one degree-of-freedom learning law is proposed, and the control error is stabilized to a bound around zero [17,24]. In another direction, intelligent approaches based on Type-2 fuzzy logic theory could be found as possible solutions of the gain adaptation [27,28]. Solving optimal problems of the closed-loop system under robustness constraints in a horizontal time yields the expected gains along with excellent control performances [29]. However, intensive behaviors of the gain variation that could judge the real-time control quality were ignored.

This paper is an extension of work originally presented in

2019 International Conference on System Science and Engineering (ICSSE) [1]. In the previous work, both driving and robust gains of a conventional TDE sliding mode controller were actively self-tuned subjecting to a minimal control error. Its effectiveness was confirmed by intensive simulation results. The controller was operated with a fixed nominal value of the inertia matrix of the system dynamics. Improperly selecting this term could lead to instability of the closed-loop system [15]. An excellent control performance is obviously associated with a perfect value of the matrix [16]. Nevertheless, the best nominal matrix is not same for different running states. As a sequence, a dynamical learning mechanism for such the term is the main motivation of this research for maintaining high control precision in various working conditions.

In this study, an adaptive TDE sliding mode controller is developed for trajectory-tracking control of serial robot manipulators with the following contributions:

- The system behaviors are first approximated by a basic time-delay estimator (TDE). To support selection of a proper inertia matrix in the estimation process, an adaptation rule is designed to search the optimal nominal one.
- The control objective is then realized by a robust sliding mode control method. To provide the flexibility in tuning the control gains in divergent operation cases, a fast gain-learning law is proposed. The adaptation mechanism is worked as a damping low-pass filter that could yield smooth responses of the closed-loop system. Different from the previous work [1], nonlinear leakage functions are employed to speed up the learning process.
- Control performances of the overall system are analyzed by a Lyapunov-based approach and comparative simulation results.

The rest of this paper is structured as follows. Section 2 presents system modeling and problem statement. Section 3 describes design of the proposed controller incorporated with the adaptation laws. Section 4 discusses validation results, and the paper is then concluded in Section 5

2. System Dynamics and Problem Statement

Dynamics of a *n*-joint robotic manipulator are generally expressed as follows [6,9,17,24]:

$$\mathbf{M}(\mathbf{q})\ddot{\mathbf{q}} + \mathbf{C}(\mathbf{q},\dot{\mathbf{q}})\dot{\mathbf{q}} + \mathbf{g}(\mathbf{q}) + \mathbf{f}(\dot{\mathbf{q}}) + \boldsymbol{\tau}_\mathbf{d} = \boldsymbol{\tau} \quad (1)$$

where $\mathbf{q},\dot{\mathbf{q}},\ddot{\mathbf{q}} \in \Re^n$ are the joint angles, velocities, and accelerations, respectively, $\boldsymbol{\tau} \in \Re^n$ is the joint torques or control inputs, $\mathbf{M}(\mathbf{q}) \in \Re^{n\times n}$ is the inertia matrix, $\mathbf{C}(\mathbf{q},\dot{\mathbf{q}})\dot{\mathbf{q}} \in \Re^n$ is the Centripetal/Coriolis vector, $\mathbf{g}(\mathbf{q}) \in \Re^n$ is the gravitational term, $\mathbf{f}(\dot{\mathbf{q}}), \boldsymbol{\tau}_\mathbf{d} \in \Re^n$ is the frictional torque, and $\boldsymbol{\tau}_\mathbf{d} \in \Re^n$ denotes disturbances.

The dynamics (1) could be simply rewritten in a following form:

$$\bar{\mathbf{M}}(\mathbf{q})\ddot{\mathbf{q}} + \mathbf{v}(\mathbf{q}) = \boldsymbol{\tau} \quad (2)$$

where $\bar{\mathbf{M}} \in \Re^{n\times n}$ is an proper nominal diagonal inertia matrix, $\mathbf{v} = (\mathbf{C}\dot{\mathbf{q}} + \mathbf{g} + \mathbf{f} + \boldsymbol{\tau}_\mathbf{d} + (\mathbf{M} - \bar{\mathbf{M}})\ddot{\mathbf{q}}) \in \Re^n$ is a lumped term that is defined as a combination of other dynamic terms such as the Centripetal/Coriolis, gravity, inertia variation, frictions, disturbances, modeling errors and unmodeled terms.

Remark 1: Assume that the system outputs $(\mathbf{q},\dot{\mathbf{q}})$ are measurable and a desired trajectory $(\mathbf{q_d})$ is bounded and differentiable up to the second order. The main objective of this paper is to find out an appropriate control signal to drive a tracking error of the system output $(\mathbf{q})$ and the given profile $(\mathbf{q_d})$ to zero or as small as possible. However, maintaining high control quality of the closed-loop system is a not-easy yet interesting work due to existence of the uncertain nonlinear dynamics and complicated working environments. Additional characteristics of the controller are required to be model-free, adaptive, and robust with high control performances.

3. An Adaptive Time-delay Nonlinear Controller

To accomplish the aforementioned features, the motion controller is built up based on a simple sliding mode framework incorporated with an adaptive time-delay estimator. Fast learning laws are then integrated to search proper control parameters. The proposed controller is sketched in **Figure 1.**

3.1. Simple Sliding Mode Control

The main control error is mathematically defined as

$$\mathbf{e} = \mathbf{q} - \mathbf{q_d} \quad (3)$$

A sliding manifold is employed as an indirect control objective of the closed-loop system:

$$\mathbf{s} = \dot{\mathbf{e}} + \boldsymbol{\Lambda}\mathbf{e} \quad (4)$$

where $\boldsymbol{\Lambda}$ is a selected positive-definite diagonal gain matrix.

For obtaining high-precision control results, the controller is designed with a model-free compensator - that could cope with the systematic uncertain nonlinearities and disturbances - and a robust control signal, as follows:

$$\boldsymbol{\tau} = \boldsymbol{\tau}_\mathbf{MOD} + \boldsymbol{\tau}_\mathbf{SMC} \quad (5)$$

Here, $\boldsymbol{\tau}_\mathbf{MOD}$ is a model-dynamical eliminator that is used to compensate for unexpected effect of the offset vector ($\mathbf{v}$) on the control behaviors and other terms of the surface dynamics (4). The signal is thus selected as follows:

$$\boldsymbol{\tau}_\mathbf{MOD} = \hat{\mathbf{v}} + \hat{\mathbf{M}}(\ddot{\mathbf{q}}_\mathbf{d} - \boldsymbol{\Lambda}\dot{\mathbf{e}}) \quad (6)$$

Note that the estimate $(\hat{\mathbf{v}})$ of the offset dynamics ($\mathbf{v}$) is computed using the basic time-delay estimator [15,22]:

$$\hat{\mathbf{v}} = \boldsymbol{\tau}_{t-T_s} - \hat{\mathbf{M}}\ddot{\mathbf{q}}_{t-T_s} \quad (7)$$

where the subscript $(t-T_s)$ is a time-delay value, T_s is the sampling time, and $\hat{\mathbf{M}} = \text{diag}(\hat{\mathbf{m}}) \in \Re^{n\times n}$ is estimate of the nominal matrix $\bar{\mathbf{M}}$.

The remaining term $\boldsymbol{\tau}_{\mathbf{SMC}}$ is designed to drive the sliding manifold from the stationary state back to around zero and stabilize thereafter by dealing with a model perturbance $\boldsymbol{\delta}$:

$$\boldsymbol{\tau}_{\mathbf{SMC}} = -\mathbf{K}_1\mathbf{s} - \mathbf{K}_2\,\text{sgn}(\mathbf{s}) \tag{8}$$

where $\mathbf{K}_{i|i=1,2} = \text{diag}(\mathbf{k}_i) = \text{diag}([k_{i1};...;k_{in}])$ is positive-definite diagonal gain matrices.

Remark 2: With the robust sliding mode design, excellent control outcome can be resulted in by a proper selection of the control gains $(\mathbf{K}_1, \mathbf{K}_2)$ and nominal inertia matrix $(\hat{\mathbf{M}})$ regardless of the existence of the disturbances. It is however sometimes a challenge to perfectly tune the gains to achieve good transient performance and especially ensure high control accuracies for unpredictable execution conditions in the real-time control.

3.2. Gain-adaptation Laws

To treat difficulty of the gain selection, the strategy for gain tuning is proposed in that the control gains $(\mathbf{K}_i|_{i=1,2})$ are separated into two terms: nominal gains $(\bar{\mathbf{K}}_i|_{i=1,2})$ and variation gains $(\breve{\mathbf{K}}_i|_{i=1,2})$. The nominal ones are chosen for stability of the closed-loop system. The variation ones are automatically tuned for the desired transient performance.

A fast adaptation rule for the automatic control-gain tuning is designed as follows:

$$\begin{cases} \dot{\breve{\mathbf{k}}}_1 = \boldsymbol{\Xi}_k\,\text{diag}(\mathbf{s})\mathbf{s} - \text{diag}(\boldsymbol{\eta}_1)\left(\mathrm{I}+\text{diag}\left(\mathbf{s}^2\right)\right)^{-1}\text{sat}\left(\breve{\mathbf{k}}_1\right) \\ \dot{\breve{\mathbf{k}}}_2 = \boldsymbol{\Xi}_k\,\text{diag}\left(\text{sgn}\left(\mathbf{s}\right)\right)\mathbf{s} - \text{diag}\left(\boldsymbol{\eta}_2\right)\left(\mathrm{I}+\text{diag}\left(\mathbf{s}^2\right)\right)^{-1}\text{sat}\left(\breve{\mathbf{k}}_2\right) \end{cases} \tag{9}$$

where $\boldsymbol{\Xi}, \text{diag}\left(\boldsymbol{\eta}_1\right)$ and $\text{diag}\left(\boldsymbol{\eta}_2\right)$ are positive-definite diagonal constant matrices.

On the other hand, properly choosing the nominal inertia matrix could reduce bound of the system perturbance ($\boldsymbol{\delta}$). To efficiently support this task, a new learning law is proposed as follows:

$$\dot{\hat{\mathbf{m}}} = \boldsymbol{\Xi}_m\,\text{diag}(\mathbf{s})\left(\ddot{\mathbf{q}}_{t-T_s} - \ddot{\mathbf{q}}_{\mathbf{d}} + \boldsymbol{\Lambda}\dot{\mathbf{e}}\right) - \text{diag}\left(\boldsymbol{\eta}_m\right)\text{diag}\left(\mathbf{s}^2\right)\hat{\mathbf{m}} \tag{10}$$

where $\boldsymbol{\Xi}_m$ and $\text{diag}\left(\boldsymbol{\eta}_m\right)$ are positive-definite diagonal constant matrices.

3.3. Stability Analysis

The theoretical effectiveness of the closed-loop system is investigated using the following theorem:

Theorem 1: Employing the model-free sliding mode control signals (3)-(8) to the robot dynamics (2), in which the driving-robust gains and nominal inertia matrix are automatically updated using the laws (9)-(10), asymptotic convergence of the closed-loop system is resulted in if the following condition holds:

$$\begin{cases} \min\left(\text{eig}\left(\bar{\mathbf{K}}_1\right)\right) > \max\left(\text{eig}\left(0.25\boldsymbol{\Xi}_m^{-1}\text{diag}(\boldsymbol{\eta}_m)\bar{\mathbf{M}}\bar{\mathbf{M}}\right)\right) \\ \bar{k}_{2i|i=1..n} \geq \max\left(|\delta_i|\right) \end{cases} \tag{11}$$

Proof:

The time derivative of the sliding manifold (4) along the system (2) is expressed

$$\dot{\mathbf{s}} = \bar{\mathbf{M}}^{-1}\left(\boldsymbol{\tau} - \mathbf{v}\right) - \ddot{\mathbf{q}}_{\mathbf{d}} + \boldsymbol{\Lambda}\dot{\mathbf{e}} \tag{12}$$

By substituting the control signal (5)-(8) into the dynamics (12), we have

$$\dot{\mathbf{s}} = \bar{\mathbf{M}}^{-1}\left(\boldsymbol{\delta} + \tilde{\mathbf{M}}\left(\ddot{\mathbf{q}}_{\mathbf{d}} - \ddot{\mathbf{q}}_{t-T_s} - \boldsymbol{\Lambda}\dot{\mathbf{e}}\right) - \mathbf{K}_1\mathbf{s} - \mathbf{K}_2\,\text{sgn}(\mathbf{s})\right) \tag{13}$$

where $\boldsymbol{\delta} = [\delta_1;\delta_2;...;\delta_n] = \bar{\mathbf{v}} - \mathbf{v} = \left(\boldsymbol{\tau}_{t-T_s} - \bar{\mathbf{M}}(\mathbf{q})\ddot{\mathbf{q}}_{t-T_s} - \mathbf{v}\right) \in \Re^n$ is the system perturbance mentioned above, and $\tilde{\mathbf{M}} = \text{diag}(\tilde{\mathbf{m}}) = \hat{\mathbf{M}} - \bar{\mathbf{M}} \in \Re^{n\times n}$ is the estimation error of the nominal matrix $\bar{\mathbf{M}}$.

Now, we consider a Lyapunov function:

$$V = 0.5\mathbf{s}^T\bar{\mathbf{M}}\boldsymbol{\Xi}_k\mathbf{s} + 0.5\sum_{i=1}^{2}\left(\breve{\mathbf{k}}_i^T\breve{\mathbf{k}}_i\right) + 0.5\tilde{\mathbf{m}}^T\boldsymbol{\Xi}_k\boldsymbol{\Xi}_m^{-1}\tilde{\mathbf{m}} \tag{14}$$

Substituting (9), (10), and (13) into the time derivative of the Lyapunov function leads to

$$\begin{aligned} \dot{V} &= \mathbf{s}^T\boldsymbol{\Xi}_K\left(\boldsymbol{\delta} - \bar{\mathbf{K}}_1\mathbf{s} - \bar{\mathbf{K}}_2\,\text{sgn}(\mathbf{s})\right) \\ &\quad - \sum_{i=1}^{2}\left(\breve{\mathbf{k}}_i^T\,\text{diag}(\boldsymbol{\eta}_i)\left(\mathrm{I}+\text{diag}\left(\mathbf{s}^2\right)\right)^{-1}\breve{\mathbf{k}}_i\right) \\ &\quad - \tilde{\mathbf{m}}^T\boldsymbol{\Xi}_k\boldsymbol{\Xi}_m^{-1}\text{diag}(\boldsymbol{\eta}_m)\text{diag}\left(\mathbf{s}^2\right)\tilde{\mathbf{m}} \\ &\quad + \tilde{\mathbf{m}}^T\boldsymbol{\Xi}_k\boldsymbol{\Xi}_m^{-1}\text{diag}(\boldsymbol{\eta}_m)\text{diag}\left(\mathbf{s}^2\right)\bar{\mathbf{m}} \end{aligned} \tag{15}$$

From the condition (11), there always exist two positive constants α_k and α_m such that

$$\begin{aligned} \dot{V} &= -\alpha_k\mathbf{s}^T\boldsymbol{\Xi}\bar{\mathbf{K}}_1\mathbf{s} - \sum_{i=1}^{2}\left(\breve{\mathbf{k}}_i^T\,\text{diag}(\boldsymbol{\eta}_i)\left(\mathrm{I}+\text{diag}\left(\mathbf{s}^2\right)\right)^{-1}\breve{\mathbf{k}}_i\right) \\ &\quad - \alpha_m\tilde{\mathbf{m}}^T\boldsymbol{\Xi}_k\boldsymbol{\Xi}_m^{-1}\text{diag}(\boldsymbol{\eta}_m)\text{diag}\left(\mathbf{s}^2\right)\tilde{\mathbf{m}} \le 0 \end{aligned} \tag{16}$$

Theorem 1 has been proven:

Remark 3: As seen in Figure 1 as well as stated in Theorem 1**,** the controller is just designed under a simple TDE sliding mode control framework to ensure the stability of the overall system**.** However, control performance of the system is significantly improved by injecting excellent adaptation laws for the control gains and nominal inertia matrix. The proposed controller hence possesses strong robustness, model-free, and self-learnable ability.

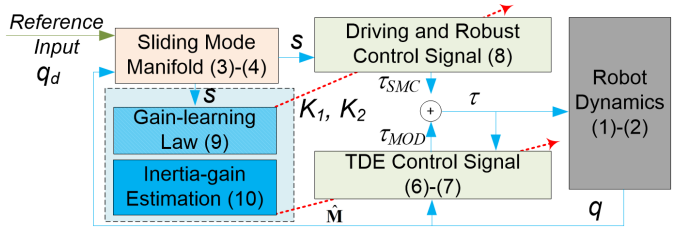

Figure 1: An overview of the designed controller.

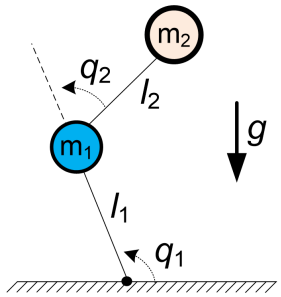

Figure 2: Configuration of a 2DOF manipulator.

Table 1: Selected Parameters for the simulation model

Description	Parameters	Values	Unit
Link length	l_1, l_2	0.2, 0.1	m
Gravitational Accel	g	9.81	m/s2
Friction coefficient	a_1, a_2	1	
Mass of links	m_1, m_2	10, 5	kg

4. Simulation Validation

4.1. Setup

To assess tracking performance of the proposed controller, extended simulations were carried out on a 2DOF robot. Configuration of the robot is depicted in Figure 2. The robot was selected to work in the vertical plane in which the gravity force was critically affected on the system performance. Dynamics of the robot are presented as follows [6,24]:

$$\mathbf{M} = \begin{bmatrix} m_2(l_2^2 + l_1^2) + 2l_1 l_2 m_2 \cos(q_2) + m_1 l_1^2 & m_2 l_2^2 + l_1 l_2 m_2 \cos(q_2) \\ m_2 l_2^2 + l_1 l_2 m_2 \cos(q_2) & m_2 l_2^2 \end{bmatrix}$$

$$\mathbf{C}\dot{\mathbf{q}} = \begin{bmatrix} -m_2 l_1 l_2 \sin(q_2)\dot{q}_2 (\dot{q}_2 + 2\dot{q}_1) \\ m_2 l_1 l_2 \sin(q_2)\dot{q}_1^2 \end{bmatrix}$$

$$\mathbf{g} = \begin{bmatrix} m_2 l_2 g \cos(q_1 + q_2) + l_1 g \cos(q_1)(m_1 + m_2) \\ m_2 l_2 g \cos(q_1 + q_2) \end{bmatrix}$$

$$\mathbf{f} = \begin{bmatrix} a_1 \dot{q}_1 \\ a_2 \dot{q}_2 \end{bmatrix}$$

where $q_{1,2}$ are the robot joint angles. The detailed parameters of the robot model are given in **Table 1**.

Another robust-gain-learning TDE controller (RLTDE) was also applied to the same system as a benchmark for evaluating the effectiveness of the proposed controller.

The design of the RLTDE controller was referred as in the previous work [24], as follows:

$$\begin{cases} \mathbf{s} = \dot{\mathbf{e}} + \mathbf{\Lambda}_c \mathbf{e} \\ \boldsymbol{\tau} = \bar{\mathbf{M}}\left(-\ddot{\mathbf{q}}_{t\text{-}T_s} + \bar{\mathbf{M}}^{-1}\boldsymbol{\tau}_{t\text{-}T_s} + \ddot{\mathbf{q}}_\mathbf{d} - \mathbf{\Lambda}_c \dot{\mathbf{e}} - \mathbf{K}_{c1}\mathbf{s} - \mathbf{K}_{c2}\,\mathrm{sgn}(\mathbf{s})\right) \\ \dot{\hat{k}}_{c2i} = \begin{cases} \varphi_i \left(\alpha_i^{-1}|s_i(t)|\right)^{\theta(t)} \theta(t), \text{if } \hat{k}_{c2i} > 0 \\ \varphi_i \alpha_i^{-1}|s_i(t)| \qquad \text{otherwise} \end{cases} \\ \theta(t) = \mathrm{sgn}\left(\|\mathbf{s}\|_\infty - \varepsilon\right) \end{cases}$$

The basic control gains of the two controllers were inherently selected as [24]:

$$\begin{cases} T_s = 0.001, \mathbf{\Lambda}_c = \mathrm{diag}([10;10]); \\ \boldsymbol{\alpha} = [0.6;1.57], \boldsymbol{\varphi} = [4000;3000]; \varepsilon = 0.015 \end{cases}$$

For a pair comparison, the RLTDE controller was operated with four distinct parameter sets as given in Table 2, denoted as RLTDE1, RLTDE2, RLTDE3 and RLTDE4, respectively.

Table 2: Different Control Parameters Selected for the RLTDE Controller Implementation

Name	Nominal Inertia Matrix ($\bar{\mathbf{M}}$)	Control Gain ($\mathbf{K}_{c1}$)
RLTDE1	diag([0.01;0.01])	diag([1;1])
RLTDE2	diag([0.04;0.04])	diag([1;1])
RLTDE3	diag([0.01;0.01])	diag([60;60])
RLTDE4	diag([0.04;0.04])	diag([60;60])

Besides, the additional parameters of the proposed controller were manually tuned as follows:

$$\begin{cases} T_s = 0.001; \mathbf{\Lambda} = \mathrm{diag}([10;10]), \\ \bar{\mathbf{K}}_2 = \mathrm{diag}([0.5;0.5]), \bar{\mathbf{K}}_1 = \mathrm{diag}([1;1]); \\ \mathbf{\Xi}_k = \mathrm{diag}([300;300]); \boldsymbol{\eta}_1 = \boldsymbol{\eta}_2 = [1;1] \\ \mathbf{\Xi}_m = \mathrm{diag}([0.003;0.003]); \boldsymbol{\eta}_m = [3\times10^{-4};3\times10^{-4}]. \end{cases}$$

4.2. Simulation Results

In the first scenario, reference inputs of the robot joints were selected to be sinusoidal signals plotted in Figure 3. By applying the controllers to the system, the simulation results obtained are presented in Figures 4 and 5.

As seen in Figure 4, the RLTDE1 provided very good control performances, 0.53 (RMS deg) and 0.44 (RMS deg) of the control errors at joints 1 and 2, thanks to employment of the strong robust gain ($\mathbf{K}_2$) generated by a nonlinear learning algorithm [24]. Behaviors of the robust gain adaptation are demonstrated in Figure 5. The key purpose of using such the gain in the RLTDE control method was to attenuate effect of the incomplete TDE estimation. Figure 4 also reveals that the control performances were further improved if the more proper control gains were found out. When increasing only the nominal inertia matrix ($\bar{\mathbf{M}}$), or only the driving gain ($\mathbf{K}_{c1}$), or both of them ($\bar{\mathbf{M}}$ and $\mathbf{K}_{c1}$), higher

control accuracies were exhibited such as: the RLTDE2 controller obtained 0.17 (RMS deg) and 0.12 (RMS deg) of the control errors at joints 1 and 2, respectively; the RLTDE3 controller got 0.2 (RMS deg) and 0.11 (RMS deg) ones; and the RLTDE4 controller provided 0.09 (RMS deg) and 0.06 (RMS deg) ones. It seems larger the control gains would create better the control performance. In fact, structures of the RLTDE and proposed controllers are almost same.

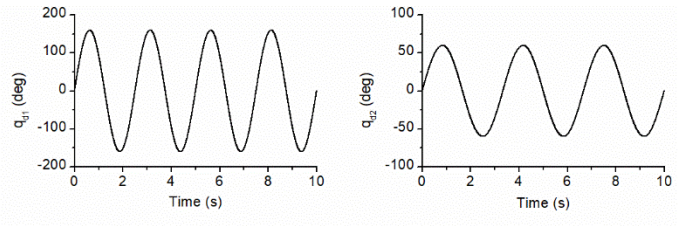

Figure 3: Reference inputs of the robot joints in the first simulation.

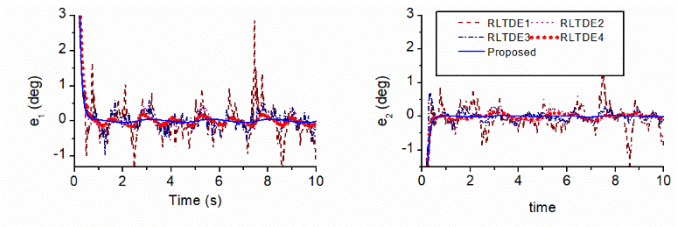

Figure 4: Control errors obtained in the first simulation

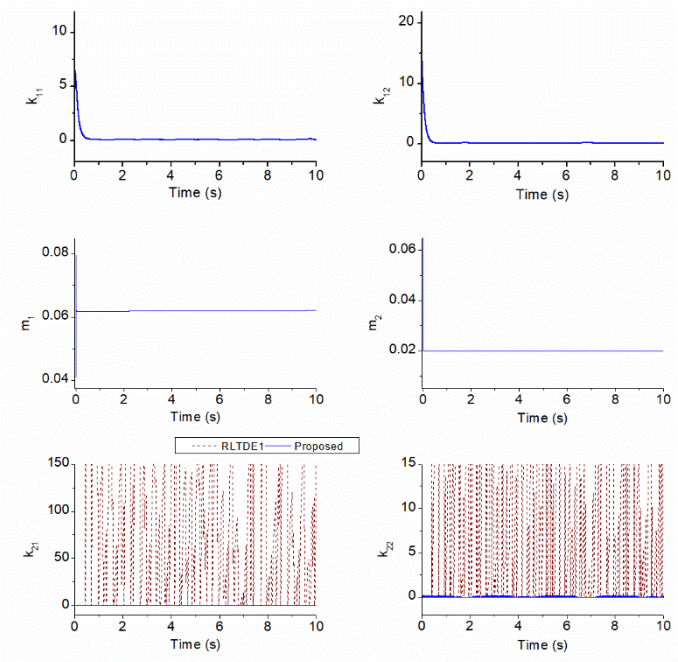

Figure 5: Comparative gains learning in the first simulation.

The core difference is that the proposed controller adopts the adaptation rules for the driving-robust gains and optimal nominal inertia matrix. Properly searching an optimal set of the driving gain and nominal inertia matrix could effectively reduce bound of the gain ($\mathbf{K}_2$) that could be clearly observed in Figure 5. Hence, as shown in Figure 4, the highest control precision, 0.03 (RMS deg) and 0.014 (RMS deg) of the control errors at joints 1 and 2, was resulted in by the proposed controller. Also noted in Figure 5, the optimal values did not need to be so large for the best control performance: the variation of the driving gain converged back to zero and the stationary nominal inertia matrix was found to be *diag(0.062; 0.021)*. This implies the flexibility of the proposed controller over the previous one.

In the second scenario, the robot joints were controlled to track smooth step signals. Applying the same controllers to the system, the simulation results are presented in Figure 6, 7 and 8.

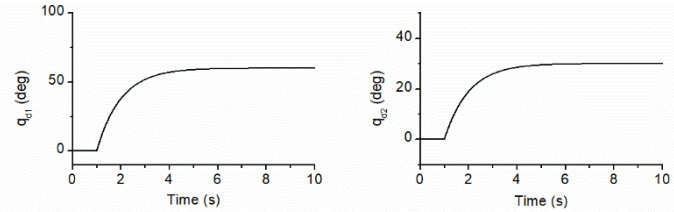

Figure 6: Reference signals of the robot joints in the second simulation.

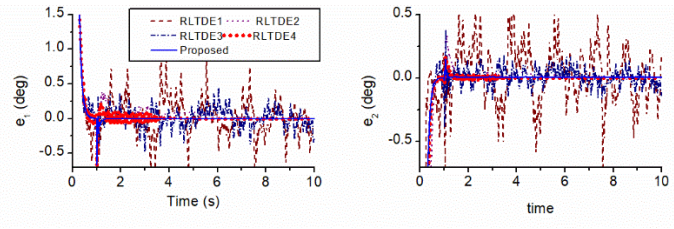

Figure 7: Control errors obtained in the second simulation.

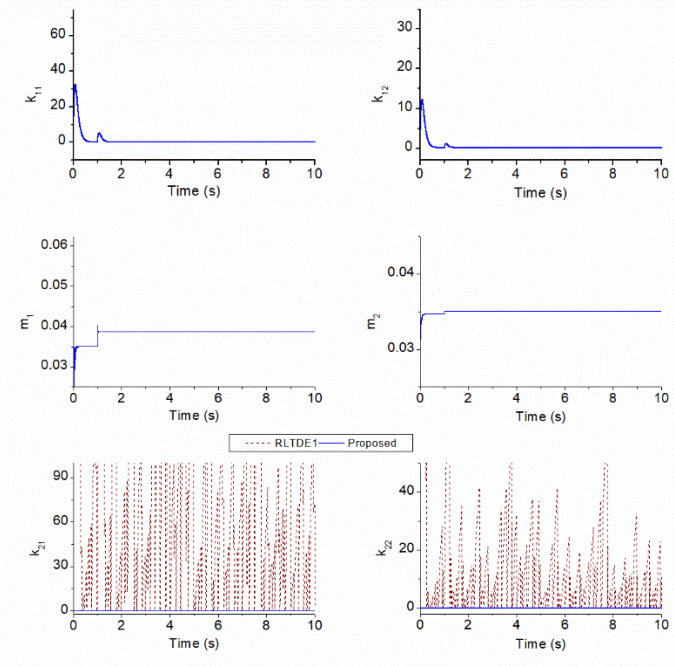

Figure 8: Comparative gains learning in the second simulation.

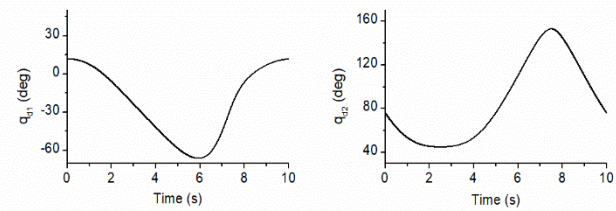

Figure 9: Desired joint angles computed from the eclipse trajectory of the end-effect in the third simulation.

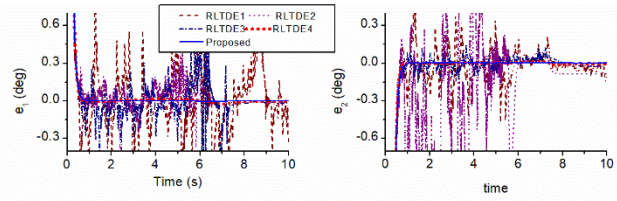

Figure 10: Control errors obtained in the third simulation.

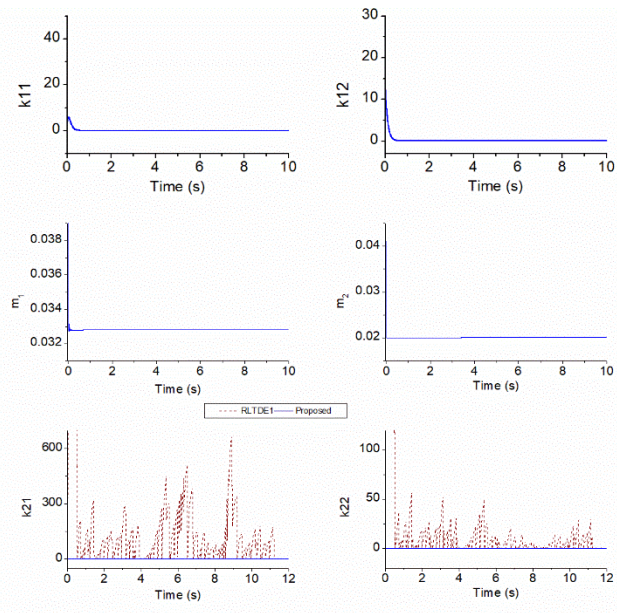

Figure 11: Comparative gains learning in the third simulation.

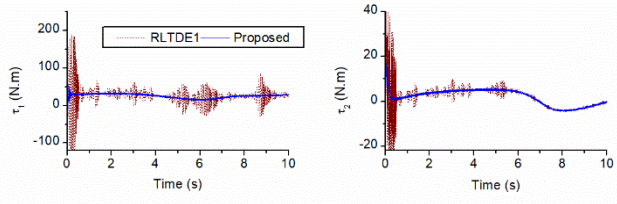

Figure 12: Control signal generated in the third simulation.

As shown in Figure 7, the control performances of the RLTDE1, 1.1 (MA deg) and 0.73 (MA deg) of the control errors at joints 1 and 2, were degraded as comparing to those of the other controllers. An improper selection of the nominal inertia matrix would make the systematic perturbance ($\boldsymbol{\delta}$) become large. Meanwhile, the driving gain ($\mathbf{K}_{c1}$) was fixed with a small value, it means that the control performance was covered only by the robust gain ($\mathbf{K}_{c2}$). Another reason came from the special learning mechanism of the RLTDE: the robust gain ($\mathbf{K}_{c2}$) was respectively increased and decreased as the sliding surfaces were outside and inside of specific regions. It implies that the RLTDE control outcome in this case depended on the regions predefined. New features integrated in the proposed controller could make the system avoid the aforementioned problems: as observed in Figure 8, the adaptation laws of the inertia matrix and control gains worked well to ensure the closed-loop system stabilize at origin or force the control error to be as small as possible. Hence, outperformance of the proposed controller, 0.005 (MA deg) and 0.01 (MA deg) of the control errors at joints 1 and 2, over the RLTDE1, 2, and 3 has been exhibited in this simulation scenario. Interestingly, once the perfect values of the driving gain ($\mathbf{K}_{c1}$) and nominal inertia matrix ($\bar{\mathbf{M}}$) were used, the RLTDE4 obtained an excellent control accuracy: 0.002 (MA deg) and 0.0004 (MA deg) of the control errors at joints 1 and 2.

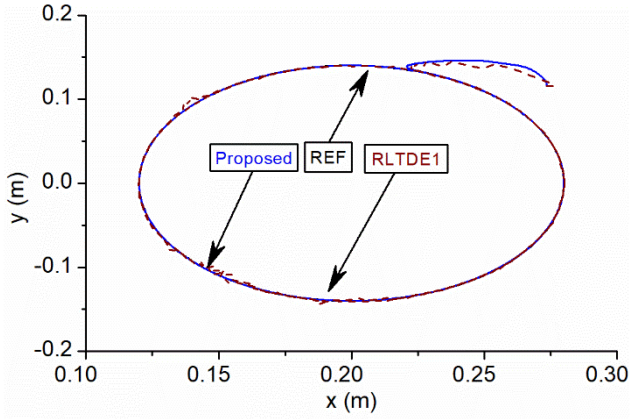

Figure 13: Comparison of control results in Cartesian space

In the third verification case, the end-effector of the robot was controlled to track an eclipse trajectory. By applying inverse kinematic computation for the testing robot, the desired joint angles are displayed in Figure 9. Tracking control errors of the controllers for the new trajectory are plotted in Figure 10. The control results indicate that the RLTDE controllers tried to automatically adjust their gains to minimize the control error. However, using only one degree-of-freedom adaptation of the control gains was not adequate to result in the minimal sliding manifold even though they were supported with various control gains and nominal inertia matrices fine-tuned. The best control quality, 0.024 (MA deg) and 0.015 (MA deg) of the control errors at joints 1 and 2, were accomplished by the RLTDE4 which had just shown the outstanding performance in the second simulation. The control accuracy was significantly improved, 0.004 (MA deg) and 0.005 (MA deg) of the control errors at joints 1 and 2, by using three degree-of-freedom in the gain learning proposed by this paper.

Indeed, control input data generated by the controllers shown in Figure 12 reveal that sharing the robustness burden of the control mission into three learning spreads provided a faster response and a smaller control error. Its effectiveness and feasibility are demonstrated more clearly by plots of the comparative end-effector positions obtained by the proposed controller and a certain RLTDE one, as shown in Figure 13.

4.3. Discussion

The key properties of the proposed adaptation laws could be evidently expressed by data shown in Figure 5, 8 and 11: in transient time, the closed-loop system needed strong power to drive the control objective back to desired position regardless of uncertain nonlinearities and disturbances. To serve this mission, the driving and robust gains were promptly activated under the designed constraint (9), and the optimal nominal gain matrix was also searched according to the strategy (10). After that, the whole system would relax in steady-state time with the small-activated gains. By further considering these figures, much high-frequency oscillation could be observed in the learning gains of the RLTDE1

controller. In real-time operation with smooth control signals, the proposed controller could maintain the lifetime of the actuators.

Table 3: Statistical Evaluation of the Control Performances in the Simulation Scenarios

Control Error		Joint 1		Joint 2	
		MA	RMS	MA	RMS
Test 1	RLTDE1	2.87	0.53	1.98	0.44
	RLTDE2	0.6	0.17	0.26	0.12
	RLTDE3	0.9	0.2	0.38	0.11
	RLTDE4	0.22	0.09	0.11	0.06
	Proposed	0.05	0.03	0.04	0.014
Test 2	RLTDE1	1.1	0.25	0.73	0.2
	RLTDE2	0.09	0.03	0.024	0.01
	RLTDE3	0.48	0.13	0.18	0.06
	RLTDE4	0.002	0.0004	0.0004	0.0001
	Proposed	0.005	0.001	0.01	0.007
Test 3	RLTDE1	2.02	0.4	0.47	0.09
	RLTDE2	0.39	0.08	1.17	0.2
	RLTDE3	2.2	0.27	0.13	0.03
	RLTDE4	0.024	0.01	0.015	0.009
	Proposed	0.004	0.0018	0.005	0.002

Table 3 summarizes static values of the control errors using maximum absolute (MA) and root-mean-square (RMS) computation for a specific time (5s to 12s). As seen in the table and by recalling the second simulation results, if the optimal set of the control gains and nominal inertia matrix were known, an exceptional control performance would be achieved. However, the optimal one was not same in different working conditions. Instead of searching the optimal values with time consuming, the designed controller integrated an automatic gain-tuning algorithm for suboptimal ones. The statistical data in Table 3 show that the proposed controller yielded the excellent MA and RMS results as comparing to the RLTDE ones in most of the simulation cases. Hence, the influence of such the suboptimal gains and inertia matrices on the control performance was acceptable. Here, advantages of the proposed controller are confirmed throughout both the analytical and validation results.

5. Conclusion

In this paper, a new adaptive robust control method is developed for position tracking-control problems of robot manipulators. The controller design is mainly based on the sliding mode control framework. Effect of the systematic uncertain nonlinearities and disturbances are well treated by an adaptive time-delay estimator. The driving-robust control signal is then employed for realizing the control objective. Fast gain-learning laws are properly designed to increase flexibility of the controller in various working conditions. The control gains are automatically tuned to provide both the desired transient performance and the steady-state behavior. Effectiveness of the closed-loop system is intensively investigated by theoretical proofs and comparative simulations.

ABSTRACT

Optical sensors exist in various forms and one of them is Fiber Bragg Gratings (FBG). Performance evaluation was simulated for FBG sensing. The simulation involves different grating profiles tested with complete optical sensing system. The system involves a broadband light source, FBG of various profiles and optical spectrum analyzer for data interpretation. Different profile of gratings imprinted on an FBG outputs wavelength spectra and simulated results satisfy this theory obtained from literatures. Temperature sensing was also simulated for the FBG at various temperature ranges that suit different industrial demands. At low temperatures FBG does give noticeable sensing capabilities. When reaching 400°C and above, the FBG was still capable of providing response, however when in real environments the fiber may suffer from thermal damage. FBG performance when integrated within a system with long distances of fibers were also simulated. Power attenuation was noticed at the reflectivity spectra.

1. Introduction

This paper is an extension of work originally presented in "IEEE International Conference on Sensors and Nanotechnology 2019" [1]. Environmental monitoring have been a main topic in most fields of study. Conventional sensors nowadays such as microelectronic mechanical sensors (MEMS) or probe sensors are vulnerable to electromagnetic (EM) interference and wiring complications. This phenomena prevents its use in long-range sensing applications [2]. Fiber optic sensors is a promising alternative to conventional sensors due to its compact nature, EM proofing and multiplexing capabilities [3]. The simplicity of optical based sensors allows various sensing configurations such as absorption based sensors (interferometers) and grating based sensors. Fiber Bragg Grating (FBG) sensor is an example of an optical sensor that operates by creating a periodic perturbation of light signals within the refractive index of its core. The gratings serves as wavelength filter that permits only light with wavelengths that dissatisfy the Bragg's equation to permeate through while the light waves that satisfy the Bragg equation will be reflected back. Therefore, strains acting on the gratings with a set periodicity can induce a shift in the wavelength spectra. The shift in wavelength defines the condition of the parameter being sensed [4]. Commonly, FBG sensors are used for pressure and thermal sensing. However, FBG sensors can be modified to sense other forms of parameter such as humidity by introducing a sensitive coatings onto the sensitized regions of the sensor.

Operations of FBG sensors require a source of propagated broadband light. In some cases, FBG sensors are positioned in remote areas where power input availability is scarce. Normally, the light source are powered by conventional batteries which could have a short lifespan and can be inconvenient maintenance wise. Hence, a sustainable power source is desired. A promising source of green energy is from ambient vibrations within the earth's crust [5]. The concept of vibration energy harvesting involves converting amplified vibrations at resonance into useful electrical power by means of kinetic energy distribution. Ambient vibration frequencies generally fall below 100.0 Hz. However, in civil structures, the frequency can drop to less than 10.0 Hz [6]. The acceleration level of these vibrations are very low being less than 1.0 g where g = 9.81 ms^{-2}, making it more suitable for low-power electronic application such as powering a light source.

This paper focuses on reporting simulated results of FBG tested with various different grating profiles, temperature sensing and transmission distance. Whilst simulating the FBG in different grating configurations, basis of the system which will be explained further sections will be tailored to a vibrational energy harvester power output. Since the proposed harvester design provides a low but steady power output to act as a light source, the whole FBG system will be run under low power to be simulated within various

*Corresponding Author: Yun Ii Go, Email: y.go@hw.ac.uk

conditions including thermal and attenuation. It is an opportunity to simulate how well the system of FBG can be run with sufficient power with different types of gratings which differs from most other closely similar articles involving FBG simulation [7-9].

1.1. Optical vs Conventional Sensor

Environment sensors that are still in use comes in various types. Electrical based sensor types such as the resistive probes, p-n junction diodes and MEMS sensors have been the staple sensor devices used over the years in monitoring various parameters [10]. Some sensors that have a very low power consumption of <1.0 mW and are made to be self-sustained by equipping the sensor with a solar panel harvester [11]. However, the operation these conventional sensors require electrical flow on the active sensitized regions of the sensor. This will render the sensors to be susceptible to electromagnetic interference and damage due to short circuit. Besides having a high maintenance cost, the complexity of the sensing mechanism in electrical based sensors available in market limits its capability to be embedded within a structure [12]. These drawbacks propel researchers to find alternatives such as optical fiber sensors.

Optical sensors alone can have many different configurations based on how the modification is formed on the surface, cladding, core or tip of the fiber. In addition to FBG sensors, other optical sensors include interferometers and absorption based sensors, which function based on the principal of the energy absorption spectrum and refractive index changes. However, grating based sensors possess an advantage over other optical based sensors in terms that they are more compact and ease of modification. In addition, FBG sensors have low noise, high sensitivity and a high multiplexing imprint capabilities via phase masking, which helps provide a large mapped sensing area within an environment [13].

1.2. FBG Sensing Principle

FBG are made typically from phase masking, where periodic modulations of the refractive index are imprinted within the fiber core by intense UV laser, exposed perpendicularly to a single mode optical fiber. The modulated refractive indexes within the fiber core that has different refractive index values than the core and cladding acts as the wavelength filter for the incident propagated light. Based on Figure 1, light signals at wavelengths other than the Bragg wavelength would pass through whereas light signals with wavelength equal to the Bragg wavelength that would be reflected back. Therefore, the transmitted ray that passes the grating will have the Bragg wavelength absent in the main spectrum [14]. FBGs can be serially imprinted into one fiber at multiple sensitized regions (multiplexing). This allows the FBGs to have multiple functional sensor nodes along a fiber length which is essential for area mapping.

On their own, FBGs are strain, pressure and temperature sensitive. In temperature sensing, different temperatures would impose axial strain upon the FBG fiber based on coefficient of thermal expansion of the FBG material (which would normally be silica). This would cause a change in the pattern spectrum of the reflected light, resulting in a shift in the reflected wavelength. This shift in wavelength can be calibrated to identify temperature change [15]. Detection of non-physical parameters requires the FBG to be modified by coating the sensitized region with a reversibly reactive material nanostructures that can induce mechanical strain or reaction to the FBG when exposed to a measurand [16]. Generally, it is possible for a FBGs to sense chemical parameters such as salinity concentration [8], chemical gas concentration [17] and relative humidity of the environment [18]. Ease of modification of FBG to suit various environmental sensing applications makes FBG a viable sensing device to be studied and optimized.

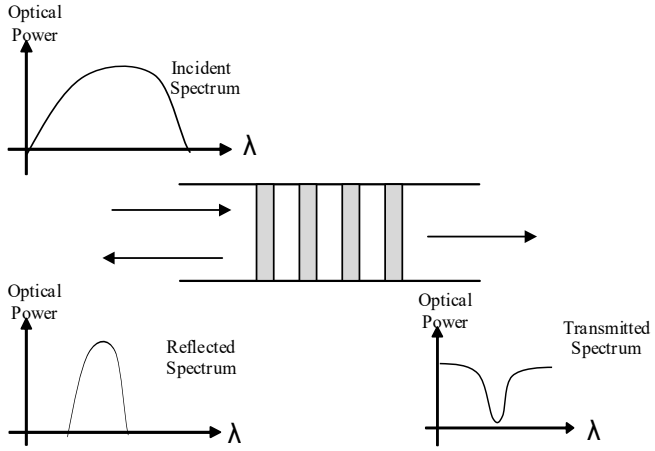

Figure 1: Principle of FBG.

2. Methodology

In this study, the behaviour of FBG fiber is simulated with different grating profiles. Different grating profiles can have an effect to the output transmission and reflectivity of the fibers. The behaviour of the FBG as a temperature sensor are simulated in temperature ranges that relates to certain industries. Connection of fibers in a long range fiber setup are also simulated to show the viability of FBG sensor array assembly in a long-range network.

2.1. Overall System Description

FBG sensors typically involve several components to be available for environmental monitoring. The following subsections explain each of the components in Figure 2 that are mandatory for FBG sensor implementation. Table 1 presents the constant parameters used in this study.

Table 1: System Setting.

Source Spec.	Optical Fibers	FBG Spec.	OSA Spec.
Broadband white light source Frequency: 193.1 THz Power: 130 dBM	Silica SMF Length: 10 cm	Grating profile: Uniform Bragg wavelength: 1550 nm IM: 0.0002	Resolution: 0.001 nm

2.2. Source

Optical based devices require sources in form of propagated photons. Light source of broad spectrum is preferred when using FBG. Broad spectrum light source examples include white light source, amplified spontaneous emission (ASE) source and broadband light source.

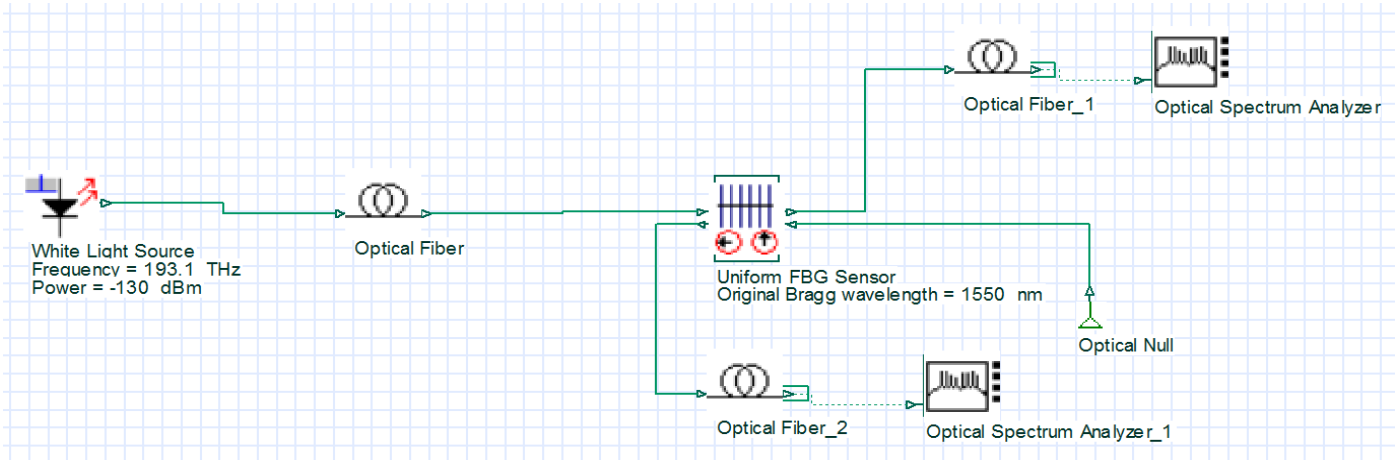

Figure 2: Arrangement of FBG setting.

2.3. FBG

The FBG component is the main component in the simulation that has variables manipulated. The Bragg grating wavelength chosen is 1550 nm since it is among the commonly used wavelength for FBG sensing. The grating length of fiber is set constant at 10 mm throughout the study. Index modulation is set at 0.0002 for the FBG and is also a controlled parameter. The grating profile will be varied in order to observe the effects of different grating profiles on the transmission and reflectivity spectra in the simulation.

2.4. OSA

Optical spectrum analyser or optical receiver is mandatory for any optical based sensors including FBG as it detects the incoming light propagation. The optical receiver then sends the received light signals to be converted into readable data. In lab-based study, OSA typically combine these functions of receiving and signal conversion into transmission and reflectivity spectrum. The OSA settings used in this simulation is with resolution of 0.001 m. The resolution value allows for more data points to be recorded brings more accurate results.

3. Results and Discussion

3.1. Effect of Grating Profiles

There are many different grating profiles of an FBG. These grating profiles may affect the spectrum of both the transmission and reflectivity. The grating profiles are made different with the periods or arrangement of the grating follows different model. Different phase mask can be used for the imprinting of different grating profiles. In this study, Uniform grating along with several other grating profiles is tested.

3.1.1. Uniform Profile

Uniform grating profiles is the most common imprinted FBG profiles that has seen its use in sensing. The uniform periodicity profile affects light modulation and follows the Braggs equation which is:

$$\lambda_B = 2n_{eff} \cdot \Lambda_G \quad (1)$$

where, λB is the Bragg wavelength, n_{eff} is the refractive index of the propagating light and ΛG is the index modulation periodicity [19]. In this study, light modulation across a uniform profile FBG has been simulated. In Figure 3 transmission and reflectivity of light propagated pass the profiles has been recorded. As predicted, the response have showed that the peak power exists on the 1550 nm wavelength. This is the wavelength at which the grating was imprinted on. Figure 2(a) showed the transmission power trough occurring and on Figure 2(b), reflectivity spectra showed peaks at the same Bragg wavelength. This simulation has demonstrated the regular uniform FBG profiles connected with regular power source. There appears to be minor side lobes occurring on Figure 2(b). These side lobes may not be favourable for FBG sensors that are tailored for high precision sensing. However, the side lobes does not hinder the uniform profiles from entering the market as region or array monitoring system.

3.1.2. Chirped Profile

A different profile than the typical uniform profile of FBG is the chirped FBG. The gratings in a chirped FBG varies in terms of periodicity along the grated regions depending on the chirp pattern on the phase mask. This produces spectrums that are different than the original, uniform and non-apodized FBGs. The wavelength spectrums produced via chirped FBGs are much broader than uniform profiled FBGs which can range between several nanometers or even thousands of nanometers depending on the chirp rate, grating length and phase mask used for writing the FBG in a fiber [20].

Based on Figure 4, chirped FBG with uniform apodization and follows similar Bragg wavelength, index modulation and grating length as table 1, has been simulated. It was seen that both Figure 4(a) and Figure 4(b) showed broader spectrum that uniform FBG. No shifts of transmission peaks and reflectivity troughs was seen which is expected. The breadth of the peaks is observed to be approximately 4 nm. Both transmission power and reflectivity shows no deterioration when chirp profile is applied without altering other parameters. Figure 4 has successfully demonstrated a chirp profile via simulation that satisfy with other studies [21, 22]. While having wider Bragg peaks in both reflectivity and transmission, chirped FBGs can have certain suitable purposes.

However, if high accuracy detection is preferred, chirped FBG may not be the best grating profile to be utilised. This is due to small shifts that occur upon detection may not be visible or detected and could lead to misinterpretation at the end signal-to-data conversion.

3.1.3. Gaussian Apodized Profile

Another variant of FBG profile other than chirped and uniform are apodized FBGs. These FBGs differ in terms of the way the gratings are imprinted on to the fiber. They are written in a manner that the grating intensities gradually change along the grated region until it becomes similar to the rest of the fiber. Specifically, in gausian apodized FBG, the grating intensity change along the grating length follows Gaussian modelling variant of the original Bragg wavelength equation. The emergence of this type of grating profile serves to reduce side lobes that may appear on uniform grated FBG [8]. Apodized FBG are also known to result in more narrow peaks of both reflectivity and transmission spectra. Besides gaussian model for index modulation and grating intensity determination, other models include Nuttal model and Pi (π) apodized model [23].

In this study, Gaussian apodized profile was simulated based on table 1 properties of the FBG. Figure 5 shows the simulated transmission and reflectivity spectra of the aforementioned FBG. Side lobe reduction occured and is observable on both of the spectra when compared to a uniform FBG. The peaks reflectivity and transmission trough are slightly narrower if compared with uniform profiles. Reflectivity and transmission power however, does suffer loss of ~10 dbm in comparison with uniform profile FBG. With the presence of side lobe reduction and narrow Bragg peak, utilization of apodized FBG is favourable for accurate sensing. Even though Gaussian apodized FBG may have lower side lobe appearance and narrow peaks, the low transmission power may be a hindrance if the FBG system is to take part in longer distances.

3.2. Effect of Temperature with FBG

FBG type sensors are used in wide variety of temperature ranges depending on the type of industries that utilize it. Simulation of FBG in different range of temperatures is shown on Figure 6. When used in oceanography for monitoring ocean temperatures, a sensor should be at least sensitive at temperature ranges of 10˚C [24]. This posed no problem for FBG sensors array as simulated in Figure 6. At higher than ambient temperatures of around 60˚C, A notable shift of the spectrum from its original wavelength of 1550 nm is detectable. At the said temperature, is observed when an FBG sensor is used in conjunction of a surgical tool to ablate cancer cells [25]. Upon higher temperature use for nuclear reactor temperature monitoring, an FBG may require modifications or special temperature proof casing. As mentioned by Mohamed, et al. [26], temperatures can reach up to 1600˚C. When using normal SMF made of silica, melting point of 400C should be taken into account. This limits the use of FBG if it is grated within a standard SMF down to only ~380˚C. While 390-400˚C is still possible to simulate, in reality, engineering constraints have to be considered for safety.

3.3. Effect of Transmission Power and Distance

Transmission power is at its ideal value when it is simulated or close to its ideal value when tested within lab scale lengths (<1m). When incorporating FBG within an array where the source is further than 1km in distance, power attenuation will occur. The reason for simulating this is to show that at what distance will the transmission and reflected power will deteriorate. The chosen length was based on different uses in the industry. At a distance of 10 km chosen due to most small and medium industries or premises require this distance of FBG array for environment monitoring [27]. For larger area coverage such as land and oceanic surveying applications, 50 km distance may be favourable therefore it is chosen as one of the simulation parameter for fiber distance [28]. For remote sensing in rural areas where the source and signal receiver has to be far from the area of monitoring due to power source availability, may require fiber length of up to 100 km.

Figure 7 (a) and (b) are the spectra of FBG sensor simulated within an optical circuit over various distances. The FBG used for simulation is a uniform profile variant due to it being the most stable in terms of providing low power loss due to attenuation. Furthermore, uniform FBGs are much easier to mass produce due to uniform phase mask availability. Within 10 km distance, there are hardly any power loss for both reflectivity and transmission spectra as shown on Figure 7 (a) and (b). Reflectivity on Figure 7 (b) shown significant attenuation power loss when distance of FBG optical circuit is extended to distances of 50 km and 100 km. Transmission spectra in Figure 6 (a) shown a minimal and slightly noticeable power loss. This is due to that reflected power may experience loss when reflected by the Bragg gratings due to leakage of evanescent waves occurring on FBG grated regions.

3.4. Sustainable Power Source

In environmental sensing, it is essential for light sources of sensors to have stable power input and output. While access to power may be available in established areas and urban environments, some other areas may not connected to main power grid. To remedy this issue, a light source powered by sustainable and renewable energy is favoured. A good candidate for powering light source can be a vibrational sensor which rely on the continuous minute vibration of the earth's crust [1]. In powering light source for optical sensing applications, at least 25 - 50 mW power is required. Vibrational sensors that can resonate with frequencies of <10 Hz at acceleration level (g) by <1.0 can supply enough power to FBG sensors [1]. To achieve this, vibrational sensor proposed within our previous paper [1] was equipped with rectangular clamp-free cantilever beams with attached magnet at the tips. The magnets will vibrate at the low acceleration level causing change in magnetic flux and inducing voltage in the coil. This in turn can produce electrical DC power which can be use with various low power consumption devices. By having a renewable energy source powering the FBG sensors, environmental condition mapping in remote locations is possible.

4. Conclusion and Recommendation

Several forms of FBG grating profiles has been reported via simulation of its transmission and reflectivity spectra. Temperature sensing of FBG has been simulated at various temperatures that are used in different industries ranging from as low as 10˚C to as high as 400˚C. Higher temperatures of >400˚C may require modifications that protects the FBG thermally and mechanically for certain rough applications such as monitoring greater nuclear reactor or volcanic core. When used within a high distance optical circuit, reflectivity was seen to suffer greatly with increasing distance and nearly not usable at distances spanning >100 km. Therefore, it is advisable to rely on remote optical source that is powered by renewable energy source within a FBG sensing system or array that spans greater distances. Multiple FBG of 50 km length should be optimal for use with one remote optical source. For greater coverage, multiple system of FBG and power source each with only 50 km distances between each other may be required for monitoring over a very large area. Furthermore, when an independent and self-powering optical broadband source is used, more remote areas can be monitored such as in vast open seas or subterranean regions. It has been demonstrated that FBG sensor can is capable to operate in power as low as 130 dBm but still maintains proper functions as shown in the obtained results. Although power loss due attenuation was apparent, it does not limit the sensing capability of the FBG to other environmental parameters such as temperature to some extent. This paper provided performance evaluation for FBG of various grating profiles and satisfied the theory of each grating performance.

Conflict of Interest

The authors declare no conflict of interest.

Barriers
Supports
Engineering student retention

ABSTRACT

Previous research has found that first-years in college is challenging due to changes in academic demands and the adaptation process. In addition to this, research on career development has found that barriers and supports may influence career interest, motivation to continue and student retention. This study explores the influence of specific supports and barriers among first-year engineering college students. To reach this goal, a case study was conducted with 425 engineering students at three universities in Lima, Peru. Based on Social Cognitive Career Theory (SCCT), we performed a Structural Equation Model (SEM) to assess effects of contextual factors such as barriers and supports on self-efficacy, coping self-efficacy, and goals. Results showed that certain supports and barriers influence self-efficacy, cope self-efficacy and goals. Effects of these factors in first-year students and possible strategies for retention in STEM careers are discussed.

1. Introduction

Science and technology are critical subjects for the advancement in societies because they create prosperity, wellbeing and more opportunities [1, 2]. Despite its increasing importance in daily life, the necessary number of science, technology, engineering and mathematics (STEM) workers is not being produced [3]. As a result, this gap has become a major problem, especially in developing countries, given the pressure to become competitiveness in the global economy. Therefore, increase and retention of STEM students, graduates, and workers have vital importance for Latin-American organizations, governments and educational institutions.

Accordingly, Peru showed an increase in higher education enrollments, however, this tend to vary significantly in specific careers. A recent report showed that between 2008 and 2019, 771 900 and 1'509 400 students were registered at national level [4]. Although, the same report showed that in 2017, more than a half (52%) were in social sciences and only 27.8% were in engineering and technology. Nonetheless, the rates of registered students in STEM fields indicated that there was a decline between 2018 and 2019 [4]. Besides, previous official reports indicated that economic issues (31%), job responsibilities (28%), and family issues (14%) [5] were the main reasons to suspend higher education in STEM. Based on the above-mentioned reports, it seems that several factors are involved in Peruvian STEM students' choice to stay or leave university. In addition to this, these rates and factors may contribute to the gap in STEM careers in Peru. As a result, this may have economic and social consequences for the country development.

Therefore, exploring how environmental and behavioral process interact in engineering career behavior may help to understand the STEM gap and first-year Peruvian students experiences in STEM careers. What is more, research on these factors is scarce in Peruvian STEM careers. Therefore, by using a survey design, the present study aims to explore how specific barriers and supports may influence self-efficacy, cope self-efficacy and goals.

1.1. Who leaves and who stays?

First-years in higher education are critical for students due to changes in study style and the time that it takes to adapt from high school to college. Previous research suggested that it is critical to focus on factors related to students retention in early years of STEM careers [6–9]. This advice is particularly relevant especially in certain areas of Peru where a lack of knowledge from parents about higher education constitute an additional challenge for students. Moreover, lack of support in first-year students may generate a biased perception of higher education that may result in withdrawal. Therefore, it is crucial to get insights based on theory and evidence to understand first-year engineering career development in the Peruvian context.

*Corresponding Author: Rosmery Ramos-Sandoval, Email: rramos@uch.edu.pe

Consequently, the literature on engineering career behaviors has highlighted several factors involved in career progression. Previous studies identified that lack of enjoyment, interest in engineering courses, demotivation and unpreparedness were the main reasons to leave engineering careers [8, 10]. In addition to this, Snyder and colleagues [7] found that self-perception, beliefs and motivations may influence competence and expectations for achievement in engineering career. Based on this, psychological factors seems to have effects in how students behave and take decisions as well as their drive to continue engineering careers.

1.2. Self-efficacy, coping self-efficacy and goals

One particular theory that has been useful in the explanation of career development is Social Cognitive Career Theory (SCCT) [11]. SCCT model hypothesizes the association between self-efficacy, outcome expectation, interest, goals, barriers and supports [11, 12]. SCCT proposed that when someone feels competent concerning a specific activity (self-efficacy), they will anticipate positive results (outcome expectation) and will develop interest in that particular domain. As a result, subjects will set goals that later will become in actions, however, these will be affected by barriers and supports. However, this study will focus in how specific barriers and supports affect certain variables of the model. For instance, several models have been constructed in order to explore in more detail specific SCCT variables [13, 14].

The term self-efficacy is defined as beliefs that people has regarding their capabilities to achieve successfully a specific task [15, 16] whereas goals is defined as student's intentions to persist in their career. The term cope self-efficacy is defined as beliefs about one's ability to manage environmental obstacles in a particular domain [12]. In this regard, previous reports have found that specific contextual factors may influence student's self-efficacy, career goals and cope self-efficacy [6, 17, 18]. In addition to this, relationships between barriers and supports may be indirectly related through coping self-efficacy [19]. Similarly, recent reports indicated that goals may affect determination to engage in career behaviors and that it is mediated by barriers and supports [11, 17, 20]. Taken together, these studies support the notion that certain individual variables of SCCT are suitable to understand career progress. Therefore, using certain core variables from SCCT seems suitable to understand in more detail how specific barriers and supports (e.g. Economics, Institutional and Family) interact with self-efficacy, cope self-efficacy and goals.

1.3. Barriers

Much of the current literature on contextual factors in career development pays particular attention to barriers and supports. Barriers refer to negative contextual influences that hinder different aspects of career progress [12, 21]. In addition to this, previous research identified that barriers are associated with career-related behaviors, engineering college student's progress and attrition [22–24]. Moreover, recent studies found that barriers associated with family, social networks and lack of social support may influence career choice and decision to stay or leave current careers [25, 26]. These studies suggest that there is an interaction between internal and contextual factors that may affect student's decision to continue engineering degrees and possible consequences such as withdrawal. Besides, specific differences in culture and context may change how these barriers are expressed in the Peruvian context. Therefore, exploring in more detail how these barriers interact could provide useful insights into Peruvian universities and possible interventions to reduce possible dropouts in engineering college students.

1.4. Support

On the other hand, support is defined as an environmental variable that facilitates the formation and pursuit of an individual's career choice [12]. Previous research has established that parents or family support have a critical role on vocational behavior and educational outcomes in undergraduate students [22]. In addition to this, peer social support was also positively associated with higher levels of aspiration and expectation in high school students [27]. Furthermore, Lent et al. [28] proposed that certain supports such as teaching staff or family are relevant in career decision-making and expectancies of career success. Therefore, by identifying specific supports, we could explore to what degree these may affect students career behavior (e.g. self-efficacy, coping self-efficacy and goals). In addition to this, by exploring these factors, Peruvian educational institutions may minimize the pre-existent barriers that exist in state engineering faculties such as the lack of resources, materials, equipment and quality standards. Moreover, it may contribute to develop strategies for education as a whole and increase student's retention.

Therefore, the present study aimed to explore the relationship between self-efficacy, cope self-efficacy and goals and how they interact with specific barriers and supports. Based on previous research [21–23, 29], the following hypotheses are proposed:

- H1. Social acceptance support have a direct effect on self-efficacy, goals, and cope self-efficacy.
- H2. Family support have a direct effect in self-efficacy, goals, and cope self-efficacy
- H3. Economic support have a direct effect on self-efficacy, goals, and cope self-efficacy.
- H4. Teacher support has a direct effect on self-efficacy, goals, and coping self-efficacy.
- H5. Social barriers have negative effects on engineering student's self-efficacy, goals, and their cope self-efficacy.
- H6. Economic barriers have negative effects on self-efficacy, goals, and cope self-efficacy.
- H7. Gender barriers have negative effects on self-efficacy, goals, and cope self-efficacy.
- H8. Teacher barriers have negative effects on self-efficacy, goal, and cope self-efficacy.
- H9. Racial barriers in have negative effects on self-efficacy, goal, and cope self-efficacy.

2. Methodology

2.1. Data collection

This research was carried out by contrasting the reference sample universe (N=40962; Male=77%; Female=23%) in students population enrolled at three university campuses in the North of Lima, Peru. This information was obtained from government public information [30]. To calculate the sample size, we used the finite population analysis formula which is considered to have a 95% confidence level. The final sample was composed of 425 engineering students (77.4% males; 22.6% females) from ten engineering fields. The mean age of participants was 21 years

(SD=4.02; Min=16; Max=38). As mentioned before, female students in this sample were low (< 23%) and this was aligned with national reports for female engineering students (25%) [30]. Before data collection, ethical standards were considered such as the right to withdrawal, inform consent and anonymity protection.

2.2. Survey characteristics

The Spanish version from the Engineering Field Questionnaire [31] was used from the original version of Social Cognitive Career Theory proposed by Lent, Brown & Hackett [11,12]. This study employed the following SCCT core variables to model the multiple relationships in the hypotheses mentioned before.

The first construct was designed to test participant's self-efficacy. This scale had 4-items with a 9-point Likert scale that ranges from 0 (no confidence at all) to 9 (complete confidence). Example items included: "How confident are you about performing well in your training over the next two courses?" To find out participants goals, 4 items were used to measure student's intention to persist. Each item was scored on a 5-point Likert scale (strongly disagree, disagree undecided, agree, strongly agree). An example item included: "I expect to remain enrolled in this course for the next year". To assess coping self-efficacy, a 7-item scale was used with a 9-point Likert scale that ranges from 0 (no confidence at all) to 9. Some of the questions were: "I feel confident to be able to continue my studies, even if I feel that the classroom environment was not welcoming".

To explore specific supports, a 5-item scale was used. These items were related to positive environmental cues that students received from friends, family, teachers as well as economic factors that facilitate their career. The response format was a 4-point Likert that ranges from 1 (No at all likely) to 5 (Extremely likely). Example items included: "During the first year, did you get financial support to continue your studies?" To identify barriers, a 6-item scale was used. This scale described obstacles that students receive during their career such as discrimination, lack of teacher support and issues with peers. The response format was in Likert format that ranges from 1 (No at all likely) to 5 (Extremely likely). Example items included: "During the first year, have you felt discouraged by the lack of social support?". This questionnaire was adapted using specific procedures to adapt psychological tests [32].The engineering field questionnaire has shown good psychometric properties and it has been used in engineering students [21,33].

2.3. Statistical analysis

Since the study aim was to confirm and explore effects from supports and barriers in first-year students, we designed a Structural Equation Model (SEM) [34]. In addition to this, data were analyzed in SPSS© IBM 23 and modelling was executed in AMOS© 21 [35].

3. Results

3.1. Independent Variables

Barriers and supports were tested as independent variables, individual scores were obtained through exploratory factor analysis (Table 1).

Table 1: Independents variables from barriers and support in first-year

Factors	Independent variable	Number of categories	Estimate
First-year Support	Social Acceptance Support	4	0.705
	Family Support		0.716
	Economic Support		0.632
	Teacher Support		0.620
First-year Barriers	Social Barriers	5	0.606
	Economic Barriers		0.420
	Teacher Barriers		0.367
	Gender Barriers		0.870
	Racial Barriers		0.843

Estimate > 0.50.

3.2. Confirmatory Factor Analysis

A confirmatory factor analysis (CFA) was implemented in order to confirm correlation relationships between the three factors proposed (self-Efficacy, goals & cope self-efficacy). A maximum likelihood (ML) estimation method was performed, providing acceptable model fit to the data: X^2= 216.806; df = 83; p<0.001; CFI = 0.963; TLI = 0.954; RMSEA [90% CI] = 0.062 (0.052; 0.072); SRMR = 0.059.

As shown in Table 2, validity measures and the internal consistency were explored through Cronbach's alpha (α), Composite reliability (CR) and the Average Variance Extracted (AVE). These were confirmed in reliability and convergent validity measures.

Table 2: Cross-construct correlation and validity measures

Factors	α	CR	AVE	Goal	Self-Efficacy	Cope Self-Efficacy
Goal	0.800	0.834	0.568	**0.754**		
Self-Efficacy	0.878	0.866	0.624	0.406	**0.790**	
Cope Self-Efficacy	0.896	0.887	0.531	0.365	0.540	**0.728**

Reliability measures: α > 0.7; CR > 0.7; Convergent validity: AVE > 0.5.

3.3. The validity of the causal structure

When CFA was confirmed, the path diagram modelled was tested in this phase. In order to determinate the predictive effects of barriers and supports on cognitive variables (self-efficacy, goals & cope self-efficacy), a SEM analysis was conducted using ML estimation. The SEM estimation including ML produced the following goodness of fit indices: X^2= 405,946; df = 193; p<0.001; CFI = 0.957; TLI = 0.938; RMSEA [90% CI] = 0.051 (0.044; 0.058); SRMR = 0.079.

The results of path relationships confirmed the model proposed (Fig. 1), indicating a significant standardized regression coefficient and a positive relationship between family supports and self-Efficacy (SE), goals (GL) and cope self-efficacy (CSE), thus, confirming H2a (β=0.192; ρ<0.05), H2b (β=0.166; ρ<0.05),

and H2c (β=0.135; ρ<0.05); at the same time, a relationship between teacher support and CSE was identified, confirmed H4c (β=0.186; ρ<0.05).

Accordingly, negative effects were found on individual variables because barriers were perceived during first year; social barriers on SE & CSE was established as a significant negative condition, confirming H5a (β=-0.185; ρ<0.05) and H5c (β=-0.129; ρ<0.05). Also, teacher barriers had negative effects on SE & CSE, confirming H8a (β=-0.161; ρ<0.05) and H8c (β=-0.300; ρ<0.001); while racial barriers had negative effects on Goals, confirming H9b (β=-0.212; ρ<0.05). In relation to economic barriers, although effects on CSE were identified as significant, the effects were not recognized as negative, thus, rejecting H6c (β=0.11; ρ<0.05).

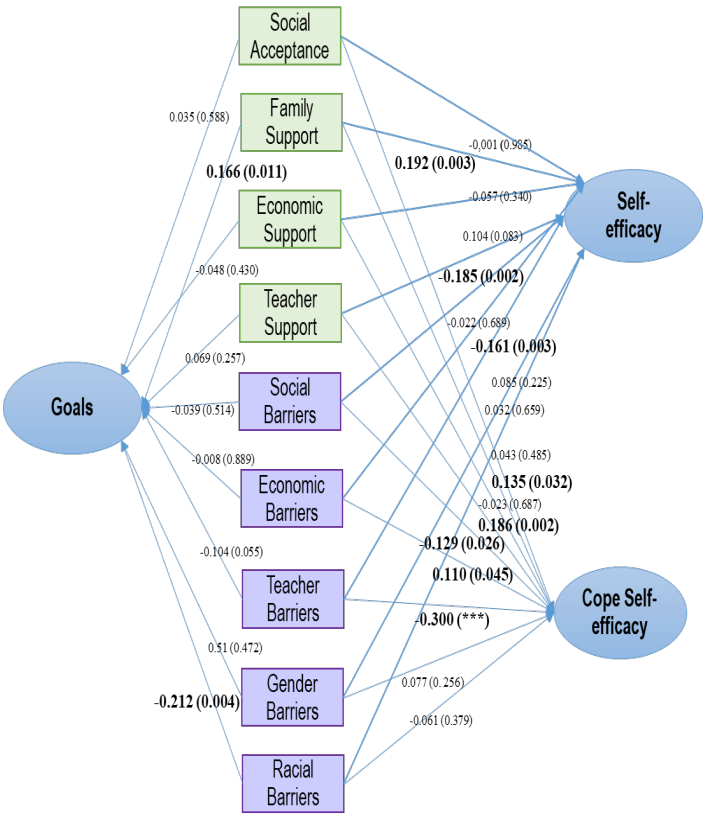

Figure 1: Path relationships confirmed the model proposed. *** p < 0.001; **p < 0.01; *p < 0.05

4. Discussions and Conclusions

The present research aimed to generate insights into contextual factors that may hinder or promote Peruvian engineering student's career progress during their first-year. The present study identified that family support was the major factor that contributes to self-efficacy, goals and cope self-efficacy. A possible explanation for this is that family support may represent acceptance among students because it guarantees economic support for other family members. This study confirms the findings from Peña-Calvo and colleagues [21], who found that family has a strong direct and indirect influence on SCCT factors in undergraduate engineering students. This finding reflects the importance of the effective role that family play in student's college life. For instance, parents may need to understand that students not only face academic challenges but also social and personal challenges (making friends, extracurricular activities, take own responsibility, time management, etc.). Future studies should assess and intervene family dynamics (e.g. authoritarian, permissive parenting style) and misconceptions that parents of first-year students may have about college life.

One interesting finding was the positive and negative effects of teacher's support on cope self-efficacy. This result may be explained by the fact that most of the students in our sample came from families who only had basic education and low income. In addition to this, Peruvian national state universities lack specialized online resources for engineering students, thus, making the role of teacher support critical for students coping and success. These conditions may limit students to find extra academic support and make the role of teachers critical to influence student's capacity to solve issues during their career. These results further support the idea that contextual factors among Peruvian students may influence the decision to continue or dropout higher education [4]. This finding also accords with earlier reports that identified that poor quality in teaching and advice influenced the decision to leave engineering careers [9]. These results have practical implications for Peruvian engineering faculties and teachers because first-year courses are challenging and there are high expectations of academic performance among students [9,10]. Teachers may have the potential to boost self-efficacy on students by providing adequate supports such as positively interpreting their failures, reduce career biases and minimize possible withdrawal.

Another interesting finding was the effect of social barriers (e.g. family, friends) on self-efficacy and coping self-efficacy. It seems possible that negative comments, a sense of not belonging to that particular group and family pressure may diminished students repertoire to cope with adverse situations as well as their judgment on their own capabilities. This result was also reported by Peña-Calvo and colleagues [21] who concluded that peer barriers is a predictor of self-efficacy and goals, which may be determinant for students career development. This finding further support the idea of Wilcox and colleagues [25] who showed the importance of family and friends support in first-year students. This finding highlights implications for student's social relationships and family dynamics. With intention or due to a lack of knowledge, family members and students may negatively influence in the decision to continue engineering degree. As a result, this situation may increase engineering career gaps in Peruvian engineering faculties. Therefore, strategies to enhance positive student's relationships and provide training to families on how to support first-year students may be beneficial.

In this study, racial discrimination had effects on goals. One possible explanation is that racial discrimination may be perceived as a long-term issue and this may affect student's determination to continue engineering career. Another possible explanation is the lack of policies related to race/ethnicity discrimination in student's universities. This finding is consistent with previous studies that found that racial discrimination influence student's decisions to leave engineering career [14, 36, 37]. Further research should be undertaken to investigate other

types of aversive interactions among students such as bullying, sexual orientation and sexual harassment.

The aim of the present research was to examine specific barriers and supports and possible effects on self-efficacy, coping-self efficacy and goals among first-year Peruvian engineering college students. This study may lay the foundation for further exploration in college dropouts, teacher support, racial discrimination and the role of peers in continuing engineering careers. For instance, further studies may explore these issues using qualitative research or longitudinal designs.

A limitation of this study is the low number of women, which may biased results. However, this gender proportion was aligned with national statistics reports [4]. The major limitation of this study is the low number of items to explore specific barriers and supports. Despite its exploratory nature, this study offers some insights into environmental factors that influence engineering career development in the Peruvian context. Further research might explore these weaknesses by using robust psychometric questionnaires and/or conducting multi-group analyses. These findings suggest several courses of action at many levels in Peruvian universities with engineering careers. For instance, policies that systematically assess these specific barriers and supports among students may be helpful to promote engineering persistence in first-year students. In addition to this, economic incentives from government agencies to universities who minimize these barriers (e.g. by creating students unions) may be useful and beneficial to students and society as a whole. In addition to this, training psychologists and tutors with SCCT framework may boost the quality of staff and student's relationships.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Dynamic positioning, a system to maintain vessel position and heading, is a technology that is used in many vessels and being intensively used as research topic in marine engineering. In order to make this system work properly, an accurate parameters value is needed. This research focuses on finding several parameters needed in this control system, which are resistance and added mass. These parameters are identified using CFD simulation. The method has an advantage of being fairly high accuracy and has a lower cost than the experimental method. The results released from this simulation verified by several empirical methods, namely Holtrop and Mennen for resistance and Ellipsoid for added mass. Baruna Jaya III is used as an implementation object for the simulation. The simulation resulted in a small error compared to the verification method. So, this computational fluid dynamics simulation can be an alternative method for obtaining resistance and added mass values on ships.

1. Introduction

This paper is an extension of work originally presented in ICEVT 2019 [1]. Vessel is still considered as one of the most important vehicles for transportation as it is the largest vehicle for transporting objects in the world. Although it maneuvers at a slow speed, shipping transportation is the most effective mode for moving objects in large quantities and masses. In terms of cost, freight transport by sea also known to be efficient. Not only moving objects, several jobs, such as oil refineries, cable planting, system checking, and welding on the seabed, to monitoring marine areas; require underwater vehicles to facilitate. Recent research in this field has led to a vessel that is more efficient, sustainable, and reduces many human errors while working.

Research that is being intensively currently in progress is the autonomous control system, a control system that allows a vehicle to operate automatically without human intervention. One of the control systems that currently being developed is dynamic positioning. Dynamic Positioning (DP) is a computer-controlled system that automatically maintain the position and the direction of vessel using existing thrusters. It takes many components that must be considered to create a DP control system, such as: computers, sensors, drivers, etc. The determination of the hydrodynamic parameters of the vessel is considered to be important in designing the DP control system.

When talking about vessel, certainly it is necessary to also discuss hydrodynamics. Hydrodynamics is the study of fluid motion with media/substances in the form of a liquid, where the substance cannot be pressed (incompressible), which are influenced by external and internal forces. In the DP control system, there are two important parameters that must be extracted from hydrodynamics, which are drag and added mass. These hydrodynamic forces values can be obtained in several ways, including analytical, experimental, and numerical.

Computational fluid dynamics is the commonly used numerical to obtain the hydrodynamic forces that occur in a vessel. This method is used because it has a fairly high accuracy for initial predictions compared to analytics, but it doesn't require much cost than experiments. To be able to use this method, it is necessary to do some modeling from the real problem to the equations that can be understood by the computer system that will calculate the model.

This paper presents the work of CFD simulation that composed into 8 sections. Section 1. Introduction, talking about the review of the CFD simulation research. Section 2. Literature Reviews, mentioning some literatures that support the work. Section 3. Materials and Methodologies, containing some materials like the system, equation, parameters, vessel dimension, and methodology to conduct the simulation. Section 4. Result and Analysis, presenting the simulation result and analyze it. Section 5. Conclusion and Future Works, presenting the conclusion of the work and review what needed to be developed on next research. Section 6. Conflict of Interests, statement from the author for submitting the paper. Section 7. Acknowledgements, gratitude from the authors to whom revise or give any critics to this work. And last Section 8. Reference, presenting the list of reference used in this work.

2. Literature Reviews

There are several literatures that serve as references and paradigms in this research and paper. Basically, this work is referring to [1], which discuss the use of computational fluid dynamics on a barge to find dynamic positioning control system parameters. This publication is the continuation and the expansion of reference [1].

Vessel modeling and control system design is explained further in [2]. This thesis discusses the equation of motion of a ship, where there are several basic parameters that affect the moving ship, namely: mass, Coriolis, and drag/resistance. These parameters will be sought from a ship design to design its dynamic positioning control system [2].

One of the parameters to obtain is added mass. Paper that discuss further about added mass identification is found on [3]. The method to design using computational fluid dynamics to obtain the added mass value is also stated on the reference. The other parameter is drag or resistance. The presence of ship resistance is caused by a combination of several factors. These factors are heavily influenced by a dimension of the ship [3].

Validation is carried out to ensure that the simulation that has been done correctly. The validation uses the empirical calculation of Holtrop and Mennen's Method described in [4]. The calculation for the parameters needed. For added mass calculation, validation uses the ellipsoid and/or strip theory method. These methods explained well in [4], [5].

For the basic theory of computational fluid dynamics and the additional theory are explained well in [6], [7].

Another reference used is the proceedings "Preliminary Computational Fluid Dynamics (CFD) Simulation of EIIB Push Barge in Shallow Water". This paper describes a method for finding the resistance of a ship using computational fluid dynamics. The formation of ship geometry to support the method discussed is described in "Analysis of Hull Resistance of Pushed Barges in Shallow Water". Then, the required mesh is discussed in "Viscous Drag Calculations for Ship Hull Geometry" [8]-[10].

This research main goal is to obtain the hydrodynamic parameters from a vessel through CFD simulation. The detailed parameters can be found from mentioned reference above which are in [1], [2]. The parameters are added mass and vessel drag, where the calculation explained in [3]. This simulation result needs to be verified with the others method. The verification can be done by a method mentioned in [4], [5]. The correct way to do a proper CFD simulation can be found in [8]-[10].

3. Materials and Methodologies

3.1. Dynamic Positioning Control System

DP System consists of the position reference system, propulsion system, and computer control at the deck room. Position reference system acting as a navigation and guidance system for DP. The sensors commonly used for this subsystem are GPS and gyro-compasses. This will inform the vessel position and heading and act as state feedback for control calculation as well.

The control calculation is conducted on the DP computer, which generates a thrust command to each thruster every defined sampling time. The signal from feedback control calculation is converted through a certain allocation algorithm. The full block diagram of the control system shown in Figure 1.

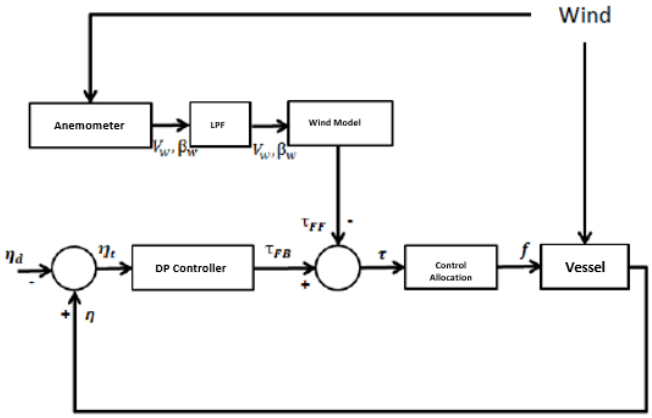

Figure 1: Dynamic Positioning Control System

A wind feedforward control is a common algorithm implemented on DP nowadays. It prevents a bigger deviation of position earlier. The wind signal is filtered with low pass filter to prevent a big oscillation of the control signal. Feedback, feedforward, control allocation, and full control system implementation are explained in [2].

In order to design or implement the controller, a vessel model is required. The model is derived from its dynamic equation of motion which consists of mass, Coriolis, and drag. The equation is can be found in equation 1 with a further detail explanation of the equation can be found in [2].

$$\mathbf{M\dot{v}} + \mathbf{C(v)\dot{v}} + \mathbf{D(v)\dot{v}} = \boldsymbol{\tau} + \boldsymbol{\tau_e} \quad (1)$$

M, C(v), and D(v) stand for mass, Coriolis, and Drag. While τ and τ_e are internal force and external force respectively. DP controls the 3 DoF motion of the vessel, surge, sway, and yaw. Equation 1 is modeled with respect to the motion so the fixed variable, mass, drag, and Coriolis are 3x3 matrix while the rest is a 3x1 matrix.

Mass and Coriolis consist of a rigid body and added mass. While there are linear and nonlinear drags. The variable of the parameters is shown in equation 2 to 10.

$$\mathbf{M} = \mathbf{M_{RB}} + \mathbf{M_{AM}} \tag{2}$$

$$\mathbf{M_{RB}} = \begin{bmatrix} m & 0 & -m\,y_g \\ 0 & m & m\,x_g \\ -m\,y_g & m\,x_g & I_z \end{bmatrix} \tag{3}$$

$$\mathbf{M_{AM}} = \begin{bmatrix} -X_{\dot{u}} & 0 & 0 \\ 0 & -Y_{\dot{v}} & -Y_{\dot{r}} \\ 0 & -N_{\dot{v}} & -N_{\dot{r}} \end{bmatrix} \tag{4}$$

$$\mathbf{C(v)} = \mathbf{C_{RB}} + \mathbf{C_{AM}} \tag{5}$$

$$\mathbf{C_{RB}} = \begin{bmatrix} 0 & 0 & -m(x_G r + v) \\ 0 & 0 & -m(y_g r - u) \\ m(x_G r + v) & m(y_g r - u) & 0 \end{bmatrix} \tag{6}$$

$$\mathbf{C_{AM}} = \begin{bmatrix} 0 & 0 & Y_{\dot{v}} v + \frac{Y_{\dot{r}} + N_{\dot{v}}}{2} r \\ 0 & 0 & -X_{\dot{u}} u \\ -Y_{\dot{v}} v - \frac{Y_{\dot{r}} + N_{\dot{v}}}{2} r & X_{\dot{u}} u & 0 \end{bmatrix} \tag{7}$$

$$\mathbf{D(v)} = \mathbf{D_{linear}} + \mathbf{D_{non-linear}} \tag{8}$$

$$\mathbf{D_{linear}} = \begin{bmatrix} X_u & 0 & 0 \\ 0 & Y_v & 0 \\ 0 & 0 & N_r \end{bmatrix} \tag{9}$$

$$\mathbf{D_{non-linear}} = \begin{bmatrix} X_{u|u|} & 0 & 0 \\ 0 & Y_{v|v|}|v| + Y_{v|r|}|r| & Y_{r|v|}|v| + Y_{r|r|}|r| \\ 0 & N_{v|v|}|v| + N_{v|r|}|r| & N_{r|v|}|v| + N_{r|r|}|r| \end{bmatrix} \tag{10}$$

where

- M_{RB} : mass of constant variable (rigid body)
- M_{AM} : mass of mass dependent variable (added mass)
- C_{RB} : coriolis of constant variable (rigid body)
- C_{AM} : coriolis of mass dependent variable (added mass)
- $X_{\dot{u}}$: surge added mass dependent to surge acceleration
- $Y_{\dot{v}}$: sway added mass dependent to sway acceleration
- $N_{\dot{r}}$: yaw added mass dependent to yaw acceleration
- $Y_{\dot{r}}$: sway added mass dependent to yaw acceleration
- $N_{\dot{v}}$: yaw added mass dependent to sway acceleration
- X_u : surge drag dependent to surge velocity
- Y_v : sway drag dependent to sway velocity
- N_r : yaw drag dependent to yaw velocity
- $X_{u|u|}$: surge drag dependent to surge velocity
- $Y_{v|v|}$: sway drag dependent to sway velocity
- $N_{r|r|}$: yaw drag dependent to yaw velocity

The rigid body of the vessel could be measured. While the added mass and drag parameters should be derived from a computational simulation through Computational Fluid Dynamics (CFD) simulation. Therefore, further hydrodynamic analysis is required to generate an exact model of the vessel.

3.2. Hydrodynamic Forces on a Ship

Hydrodynamic forces on ships can be classified into two forces, which are drag or resistance and added mass. Cited from [3], for an object which moves through a surrounding fluid, the force balance would be denoted by the equation of motion as equation 11. The separated component of hydrodynamics forces can be seen in equations 12 and 13.

$$M\mathbf{a} = \mathbf{F} - \mathbf{F_H} \tag{11}$$

where

m = Mass of the object

a = Acceleration of the object

F = Driving forces of the object

F_H = Hydrodynamic forces acting on the object

$$\mathbf{F_H} = \mathbf{F_D} + \mathbf{F_A} \tag{12}$$

$$\mathbf{F_A} = m_A\mathbf{a} \tag{13}$$

where

F_D = Drag forces acting on the object

F_A = Hydrodynamic reaction forces

m_A = Proportionality constant (added mass)

a = Acceleration of the object

The main idea was to accelerate the fluid that surrounds the body and measures the forces that are acting on the surface of the body. By subtracting the drag F_D from the total forces, we could obtain the hydrodynamic reaction forces F_A that is proportional to the acceleration of the fluid (i.e. the body). [3]

- Resistance of a ship

As the ship moves through the water, the ship would experience opposing forces which are often referred to as drag or resistance. The presence of the drag is caused by a combination of several factors. Some major components of the total drag can be denoted as written in equation 14.

$$R_T = R_V + R_W + R_{AA} \tag{14}$$

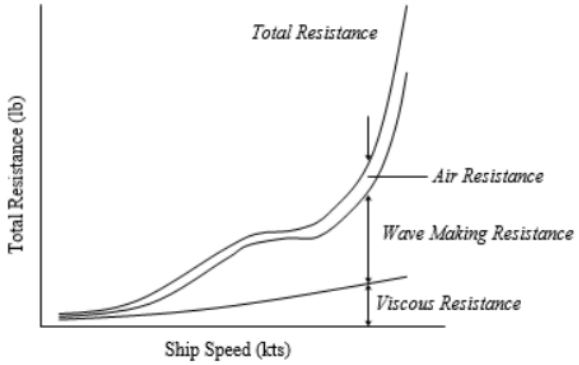
where

R_T = Total hull resistance

R_V = Viscous (friction) resistance

R_W = Wave making resistance

R_{AA} = Air resistance caused by ship moving through calm air



As portrayed in Figure 2, the effect of the wave making resistance tends to dominates as the speed of the vessel increases.

In order to quantify this effect, a dimensionless parameter, "Froude number" (F_n) is used. The Froude Number defined as equation 15.

$$F_n = V/\sqrt{gL} \quad (15)$$

where

V = Velocity

g = Gravity

L = L_{PP}, L_{BP} or L_{WL} of the ship

Sketch of L_{PP}, L_{BP} and L_{WL} of ship can be seen on Figure 3.

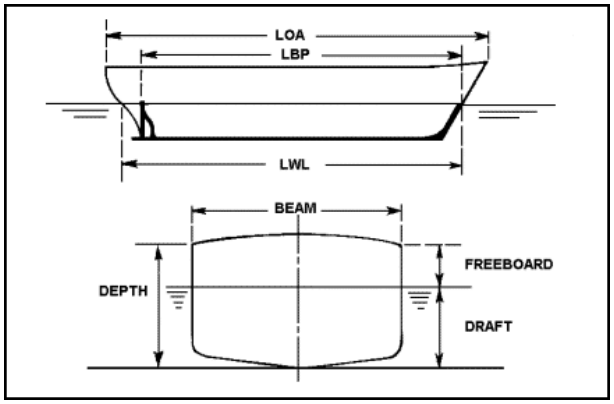


Figure 3: Ship Parameter

L_{PP} or L_{BP} is the length between perpendicular, a longitudinal distance between the forward and aft perpendiculars, and L_{WL} is the length of the hull that is intersecting with the surface of the water. The relation between this Froude number and the effect of the generated wave can be seen in Figure 4. Typically, at service speed, the effect of surface dynamics on the vessel cannot be ignored.

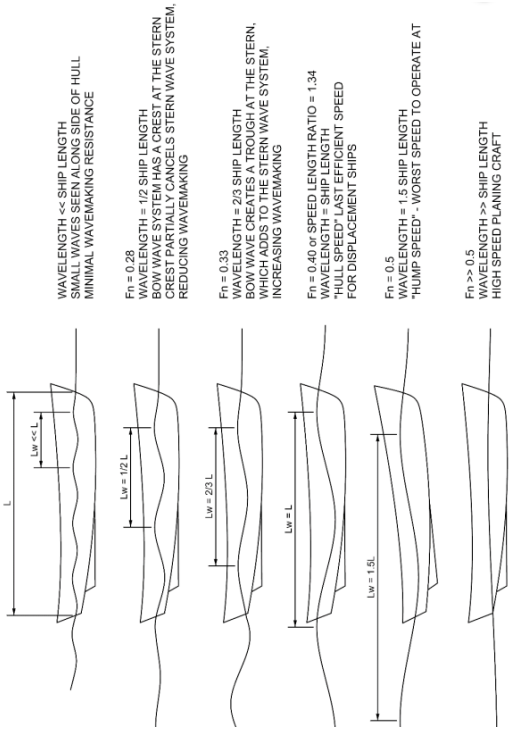

Figure 4: The Effect of Vessel's Speed on Generated Wavelength

The drag or resistance of the ship can be calculated using analytical, computational, and experimental method. Each method has its own advantages and disadvantages. One of the analytical methods that commonly used is Holtrop and Mennen's method. This method used a regression analysis of a vast range of model tests and trial data. However, recommended that, in order to obtain reasonable results from Holtrop's method, the ship should fulfill the following criteria, written in equation 16 to 18. [4]

$$F_n \leq 0.45 \quad (16)$$

$$0.55 \leq C_p \leq 0.85 \quad (17)$$

$$3.9 \leq L/B \leq 9.5 \quad (18)$$

where

F_n = Froude number

C_P = Prismatic coefficient

L/B = Length to breadth ratio

The prismatic coefficient is a dimensionless number from the ratio of the volume of the ship to the volume of the prism, a sketch of the picture can be seen in Figure 5. The equation can be written as in equation 19. [4]

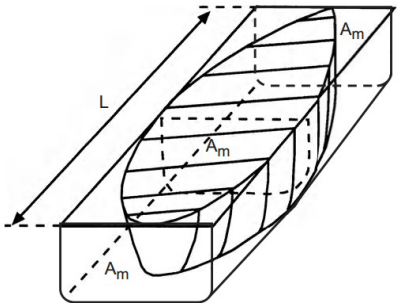

Figure 5: The Prismatic Coefficient

$$C_p = \frac{V}{A_m L} \quad (19)$$

where

V = Submerge volume of the ship

A_m = Maximum cross-sectional submerge area of the ship

L = L_{PP}, L_{BP} or L_{WL} of the ship

Holtrop method computes the total drag by dividing it into several components that can be calculated easily. Equation 20 provides the components contained in the Holtrop calculation. The calculation for each component is shown in equation 21 to 44. [4]

$$R_T = (1 + k)R_F + R_{APP} + R_W + R_B + R_{TR} + R_A + R_{AA} \quad (20)$$

where

R_F = frictional resistance

R_{APP} = appendage resistance

R_A = model–ship correlation resistance

R_W = wave resistance

R_B = resistance due to bulbous bow near the water surface

R_{TR} = pressure resistance due to immersed transom

R_{AA} = air resistance

$$R_F = \frac{1}{2}\rho v^2 S C_F \quad (21)$$

$$C_F = \frac{0.075}{[\log_{10}(Re)-2]^2} \quad (22)$$

$$Re = \frac{\rho v L_{WL}}{\mu} \quad (23)$$

$$k = -0.07 + 0.487118\, c_{14}\, [a_1\, a_2\, a_3\, a_4\, a_5] \quad (24)$$

$$a_1 = \left(\frac{B}{L_{WL}}\right)^{1.06806} \quad (25)$$

$$a_2 = \left(\frac{T}{L_{WL}}\right)^{0.46106} \quad (26)$$

$$a_3 = \left(\frac{L_{WL}}{L_R}\right)^{0.121563} \quad (27)$$

$$a_4 = \left(\frac{{L_{WL}}^3}{V}\right)^{0.36486} \quad (28)$$

$$a_5 = (1 - C_P)^{-0.604247} \quad (29)$$

$$R_{APP} = \frac{1}{2}\rho v^2 (1 + k_2)_{eq} C_F \sum_i S_{APP_i} + \sum R_{TH} \quad (30)$$

$$(1 + k_2)_{eq} = \frac{\sum_i (1+k_{2i}) S_{APP_i}}{\sum_i S_{APP_i}} \quad (31)$$

$$R_{TH} = \rho v^2 \pi d^2 C_{D_{TH}} \quad (32)$$

$$R_W(Fr) = \begin{cases} R_{W_a}(Fr) & \text{if } Fr \le 0.4 \\ R_{W_{a,b}}(Fr) & \text{if } 0.4 < Fr \le 0.55 \\ R_{W_b}(Fr) & \text{if } Fr \ge 0.55 \end{cases} \quad (33)$$

$$R_{W_a} = c_1 c_2 c_5 \rho g V \exp\left[m_1 Fr^d + m_4 \cos(\lambda Fr^{-2})\right] \quad (34)$$

$$R_{W_b} = c_{17} c_2 c_5 \rho g V \exp\left[m_3 Fr^d + m_4 \cos(\lambda Fr^{-2})\right] \quad (35)$$

$$R_{W_{a,b}} = R_{W_a}(0.4) + \frac{20Fr-8}{3}\left[R_{W_b}(0.55) - R_{W_a}(0.4)\right] \quad (36)$$

$$R_B = 0.11\rho g\left(\sqrt{A_{BT}}\right)^3 \frac{{Fr_i}^3}{1+{Fr_i}^2} e^{-3.0{P_B}^{-2}} \quad (37)$$

$$P_B = 0.56\frac{\sqrt{A_{BT}}}{T_F - 1.5h_B + h_F} \quad (38)$$

$$Fr_i = \frac{v}{\sqrt{g(T_F - h_B - 0.25\sqrt{A_{BT}} + h_F + h_W)}} \quad (39)$$

$$R_{TR} = \frac{1}{2}\rho v^2 A_T c_6 \quad (40)$$

$$R_A = \frac{1}{2}\rho v^2 (C_A + \Delta C_A)[S + \sum S_{APP}] \quad (41)$$

$$C_A = 0.00546(L_{WL} + 100)^{-0.16} - 0.002 + 0.003\sqrt{\frac{L_{WL}}{7.5}}\, {C_B}^4 c_2 (0.04 - c_4) \quad (42)$$

$$\Delta C_A = \begin{cases} 0 & \text{if } k_s = 150\ \mu m \\ \dfrac{0.105 k_s^{\frac{1}{3}} - 0.005579}{L_{WL}^{\frac{1}{3}}} & \text{if } k_s > 150\ \mu m \end{cases} \quad (43)$$

$$R_{AA} = \frac{1}{2}\rho v^2 A_V C_{DA} \quad (44)$$

where

ρ = density of the fluid

μ = viscosity of the fluid

v = ship velocity

L_{WL} = length in waterline

B = beam

T = mean draft

T_A = draft at aft perpendicular

T_F = draft at forward perpendicular

V = volumetric displacement

C_P = prismatic coefficient (based on L_{WL})

C_M = midship section coefficient

C_{WP} = waterplane area coefficient

C_{stern} = stern shape parameter

c_i, m_i = specific coefficient, detail explanation in [4]

A_V = area of ship and cargo above waterline

A_T = immersed transom area

A_{BT} = transverse area of bulbous bow

h_B = height of center of A_{BT} above basis

D = propeller diameter

S = wetted area of the hull

S_{APP} = wetted surface of appendages

- Added mass of a ship

As the vessel accelerates through the surrounding fluid, the vessel would experience an opposing force that is proportional to the magnitude of acceleration. Recalling the general equation of motion for the vessel is on equation 1, The matrix **M** could be separated into 2 components; the inertia matrix of the rigid body, and the added mass, can be seen in equation 2 to 4.

The computational fluid dynamics simulation can be a solution for obtaining the value of added mass. Another approach to calculate the added mass is explained in [5]. The paper compared the ellipsoid and Lewis transformation method to the experimental value and gives recommendations on which method to use.

The equivalent ellipsoid method is used to estimate the amount of added mass on the ship by modeling the ship as an ellipsoid form. The modeling sketch can be seen in Figure 6. Thus, the added mass value in the surge direction can be calculated using equation 45 to equation 48. [5]

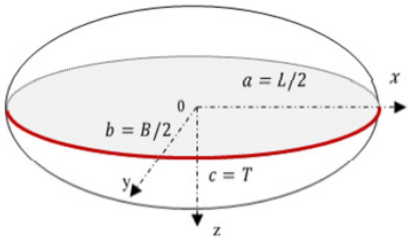

Figure 6: The ship is modeled as an ellipsoid

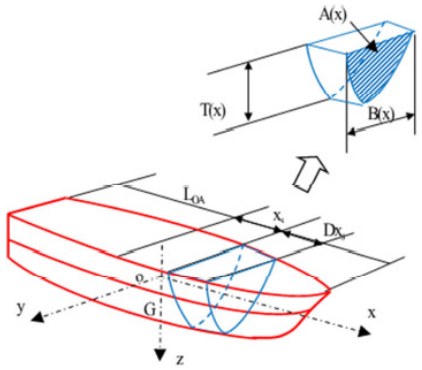
$$m_{11} = mk_{11} \quad (45)$$

$$k_{11} = \frac{A_0}{2-A_0} \quad (46)$$

$$A_0 = \frac{2(1-e^2)}{e^3}\left(\frac{1}{2}\ln\left(\frac{1+e}{1-e}\right) - e\right) \quad (47)$$

$$e = \sqrt{1-\frac{b^2}{a^2}} \quad (48)$$



Meanwhile, the strip theory method divides the ship into several pieces that resemble the hull shape of the ship. The sketch of this method can be seen in Figure 7. Due to the complexity of each hull cut to shape on the ship, the Lewis transform is used to simplify calculations. However, to simulate the added mass of ships in the surge direction, it is recommended to use the ellipsoid method. [5]

3.3. Computational Fluid Dynamics

Computational Fluid Dynamics is a method that uses numerical analysis and data structures to analyze and solve problems involving fluid flow. Computers are used to carry out the calculations needed to simulate fluid flow and fluid interactions with surfaces determined by boundary conditions. Analysis using the CFD method requires some modeling which is the conversion of physical data in the real world to a property understood by the software. Therefore, a technical approach is needed for each variable to be analyzed. Figure 8 shows the process of the computational fluid dynamics method [6].

Turbulence in CFD can be modeled with several governing equations. Each model has advantages and disadvantages. The choice of turbulent models is determined by the flow phenomenon to be simulated or analyzed. For obtaining the resistance and added mass, this research is using k-epsilon for the turbulence model. This model was chosen because it has the advantage of being robust and good for getting initial values based on what ANSYS has written. It also tends to require less computer memory [7].

Because the effect of surface dynamics on the vessel cannot be ignored, in order to obtain the whole value of drag force on the ship, it is necessary to conduct a two-phase simulation. The two-phase simulation consists of water on the bottom and air on the top of the computational domain. To perform a two-phase simulation, a computational domain that can capture the phenomena is needed. A suitable domain for the simulation described in [8], the sketch can be seen in the Figure 9.

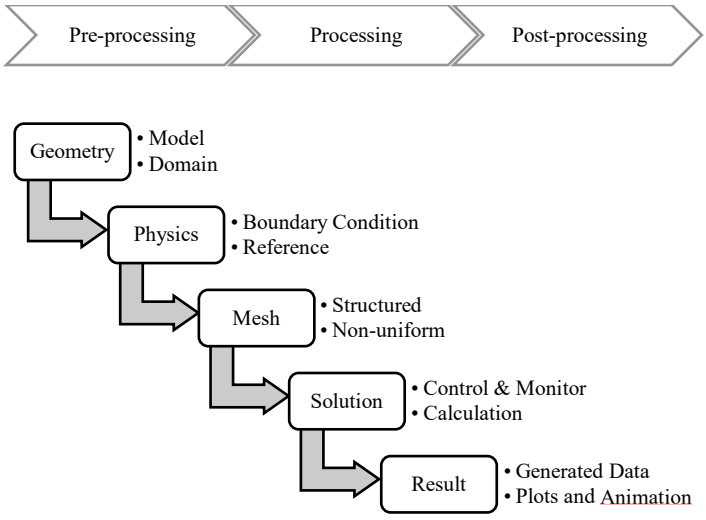


Figure 8: CFD Simulation Flowchart

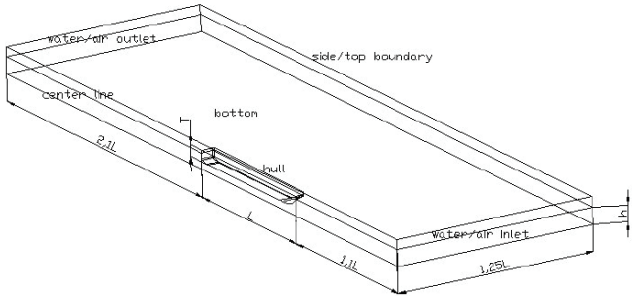
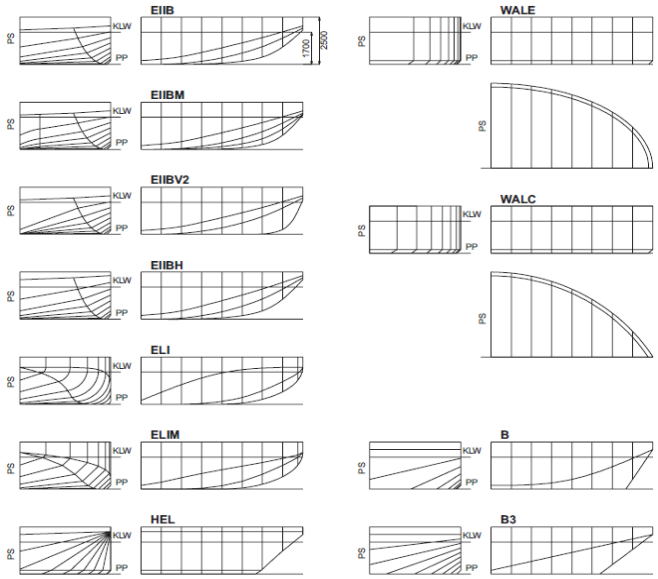


The model of the ship should also be created in a way that would reflect the original ship. Oversimplification of the hull shape may result in a significant difference in the CFD results. For simulations in shallow water, the results might be significantly different from the ones that are conducted in the deep-water computational domain. As a rule of thumb, for barge ship, there exist several types of ship hulls discussed in [9]. These types of hulls can be seen on Figure 10.



For free surface flows, the meshing process needs to be able to discretize the boundary layer and the free surface. Scaling and the usage of structured mesh might be used to save computational time [8]. The computational domain for two-phase simulation could be created based on flat-plate boundary layer theory and setting the parameter $y^+ = 1$. Y^+ can be approached by using equation 49 [10].

$$y^+ = 0.172 \left(\frac{y}{L}\right) Re^{0.9} \quad (49)$$

where

y = Distance from wall surface

L = Body length

Re = Reynold numbers

3.4. Methodology

The methodology is divided into two parts: obtaining the value of resistance and added mass. Although using the same method, computational fluid dynamics, these two components have quite different steps for obtaining them because of the unique characteristics of each component. Flowcharts can be seen in Figure 11 and Figure 12 respectively.

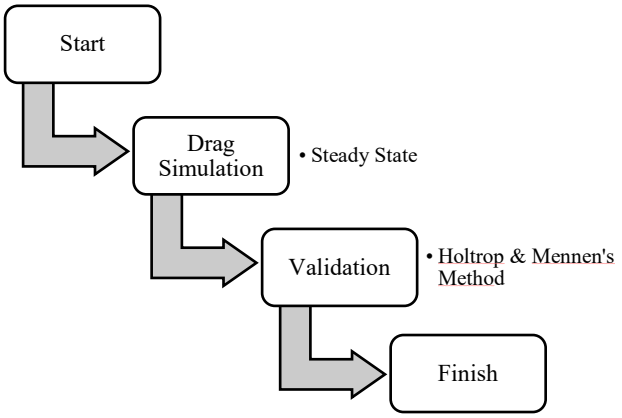


Figure 11: Drag Simulation Flowchart [8]

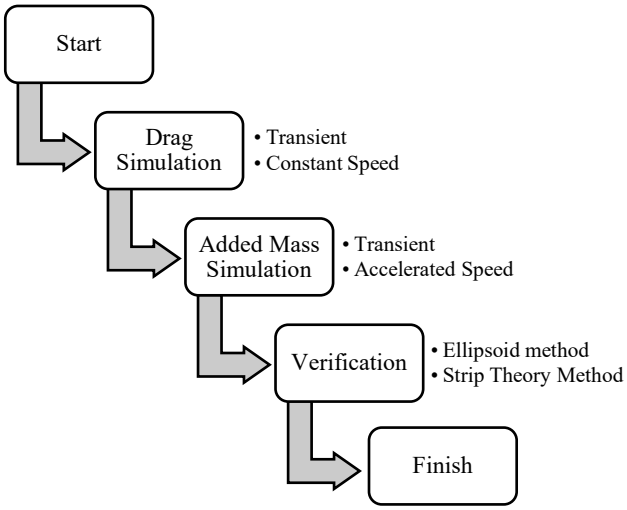

Figure 12: Added Mass Simulation Flowchart [3]

The CFD was conducted by using ANSYS FLUENT software. Both obtaining value of resistance and added mass use the same simulation settings and boundary conditions. Simulation settings and boundary conditions are listed in Table 1 and Table 2 respectively. The boundary condition for resistance is similar to the one that is listed in [8] and for added mass is similar to [3]. For the calculation of added mass, it is necessary to define the speed change of the ship in the simulation.

Table 1: Simulation Settings

Parameters	Settings
Solver	Pressure based, steady/transient
Model	Multiphase, VOF
Vol. Fraction Parameters	Open channel flow - implicit
Interpolation method	Presto! QUICK

Table 2: Boundary Condition

Region	Settings
Ship	Wall
Top/Side/Bottom	Wall
Inlet	Pressure inlet, open channel, vessel speed, free-surface and bottom level defined.
Outlet	Pressure outlet, open channel, free-surface and bottom level defined.
Symmetry	Symmetry

Air (FLUENT database) and sea water (user defined, $\rho = 1025$ kg/m^3, $\mu = 0.00109$ Pas) were used as the fluids in the analysis. The choice of viscous model such as k-epsilon or SST would significantly affect the result as demonstrated in [8]. As the symmetry method were used in the analysis, the results obtained to describe forces must be multiplied by two for the full-scale result. The value of coefficient might result in wrong amount if the references values were not defined. The simulation should be iterated until convergence criteria are achieved. Typically, the criteria for convergence are as follow.

- RMS residual values are below 10^{-4}
- The solution imbalance is less than 1%
- Quantity of interest shows a steady value

To make sure that the result obtained is mesh independent, the simulation above should be repeated several times with multiple number of mesh. The solution is considered to be mesh independent if the increase on number of mesh doesn't affect the result by significant values.

The result should be validated with data in order to make sure that the simulation reflect the actual situation. The easiest method would to compare the results with experimental data obtained from the vessel. However, the experimental data is unavailable, so, this research will use Holtrop and Mennen's method [4] for the validation of the drag and approximation for added mass.

3.5. Implementation

This particular research used ship called Baruna Jaya III as the geometric model and calculation references. Baruna Jaya III is one of the former TNI-AL warships built in 1990. This ship is used for mapping tasks for areas in Indonesia. Figure 13 shows the photo of the Baruna Jaya III ship. Technical drawings of Baruna Jaya III can be seen in Figure 14 to Figure 17.

Figure 13: Baruna Jaya III: Ship Photo

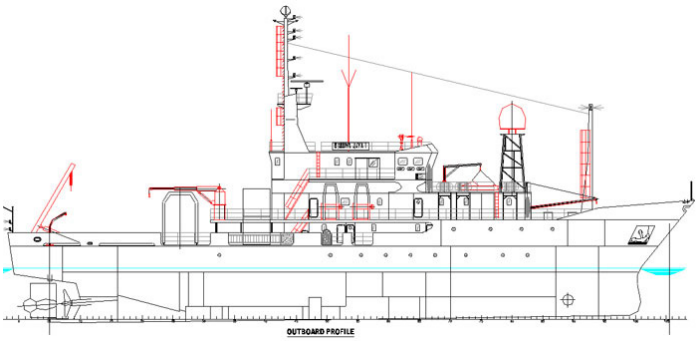

Figure 14: Baruna Jaya III: Outboard Profile

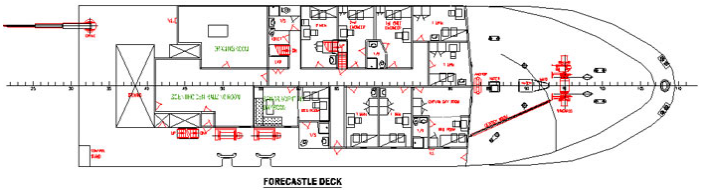

Figure 15: Baruna Jaya III: Wheelhouse deck dan Forecastel deck

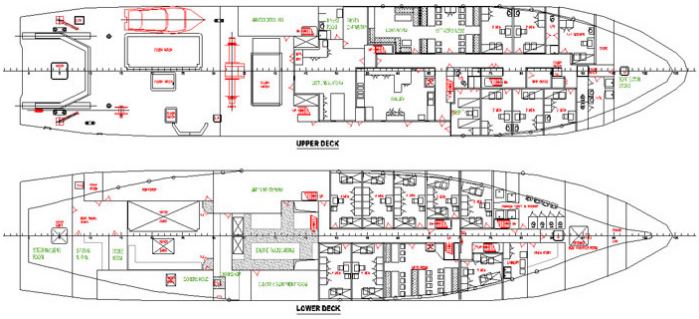

Figure 16: Baruna Jaya III: Upper deck dan lower deck

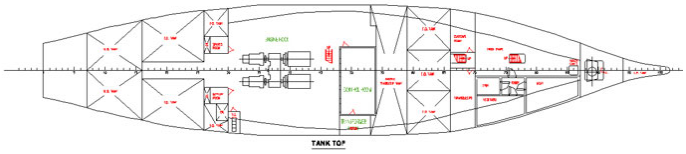

Figure 17: Baruna Jaya III: Tank Top

Table 3: Baruna Jaya III Dimension

Dimension	Value
LOA	60.40 m
LBP	52.39 m
Breadth	11.60 m
Draft Mean	5.70 m
Speed	8 knots

The pictures and dimensions listed in Table 3 will be used as references for modeling the ship to be carried out the simulation and calculating the analytical solution.

Geometry

The geometry of the ship was modelled to be able to represent its original shape while considering the approximation as discussed earlier. The geometry of the ship made must be able to represent its original shape. Therefore, the approximation discussed earlier is needed. Figure 19 shows the CAD of the Baruna Jaya Ship which has been approximated from its original form and ready for further processing. Detailed approximations are required on the bottom of the vessel which is subject to the seawater phase. This section needs to be quite detailed because even a few changes will affect the final result.

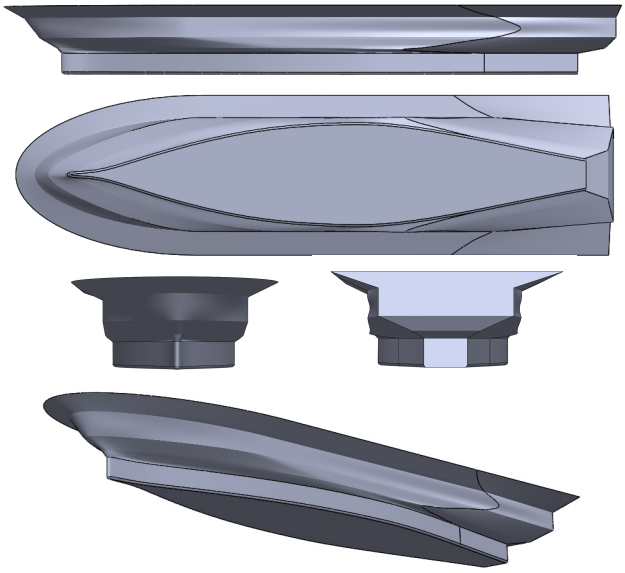

Figure 18: CAD for CFD Simulation of Baruna Jaya III

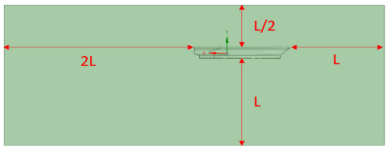
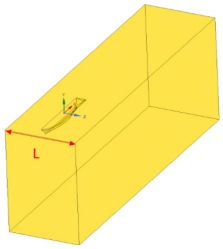
Meshing

After obtaining a suitable geometry to represent the ship, the next process is meshing the ship's far-field. The computational domain must be defined here. Figure 19 gives the computational domain used by this implementation.





Additional geometry in the form of blocks was added in the computational domain to form a body of influence in the computing domain. This is done to form a body of influence in the computing domain. Thus, the mesh will be smoother on that part. The computational domain for body of influence can be seen on Figure 20.

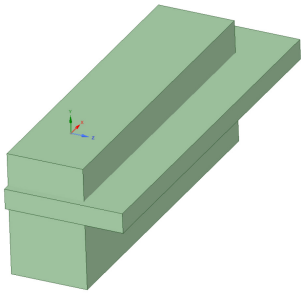


Figure 20: Computational Domain for Baruna Jaya III

The meshing process or discretization of the model is done using face sizing on the surface area of the ship with the dimensions of the mesh is 0.84 m. Meanwhile, for other computing domains, body sizing with a size of 1.2 m is used with the choice of the body of influence activated. The total number of mesh is 1,701,030 elements. The result mesh can be seen on Figure 21 and Figure 22.

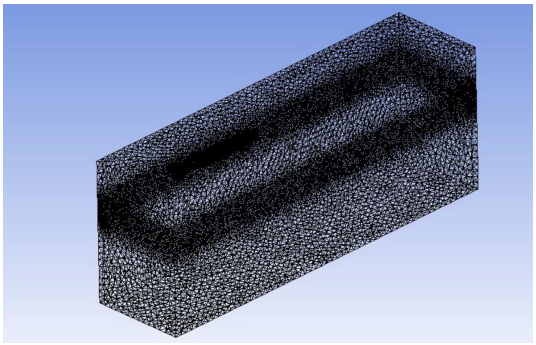

Figure 21: Mesh for Baruna Jaya III

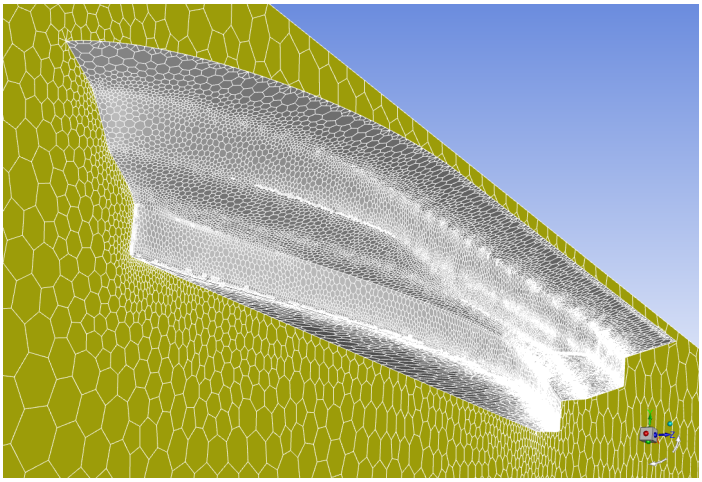

Figure 22: Symmetry and Hull Mesh of Baruna Jaya III

Simulation Setting

As mentioned before, simulation settings will follow [8] for resistance and [3] for added mass. Time setting should be steady for resistance and transient for added mass. Figure 23 shows the simulation settings, the other settings will follow the default one.

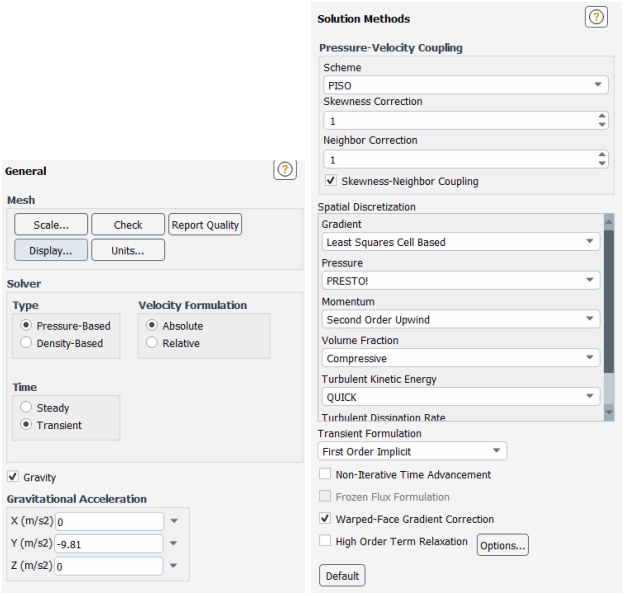

Figure 23: Simulation Settings on Fluent: General and Solution Method

The multiphase model used is the volume of fluid (VOF). The formulation is set to implicit form and the open channel flow option is activated. For the turbulence model, the simulation uses Realizable k-epsilon. These settings can be seen on Figure 24.

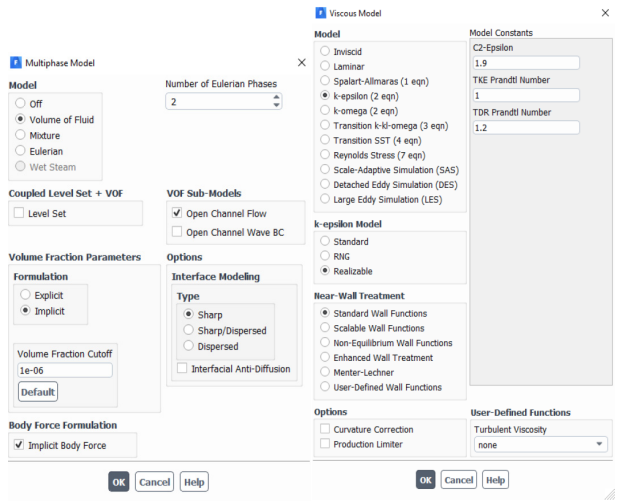

Figure 24: Simulation Settings on Fluent: Multiphase and Turbulence Model

The inlet portion of the computational domain is defined as the pressure inlet. In the inlet, the open channel option is activated and defined based on the entry speed and the location of the bottom and free surface in the compute domain. Based on measurements in the model, -62.5 m refers to the lower part of the computational domain and 2.2 m is equivalent to a draft height of 5.7 m. The input settings are listed in Figure 25.

The simulation is carried out until the convergence criterion is reached. Based on previous experiments, the simulation will converge before 900 iterations. The timestep is set to automatic with a scale factor of 0.2. The convergence criterion is set to obtain loose convergence, or the value of each residue is below 10^{-4}.

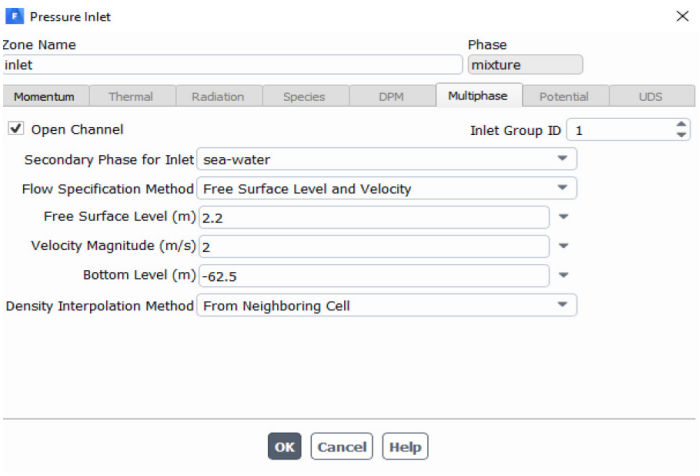

Figure 25: Simulation Settings on Fluent: Inlet Input

For the added mass, there is one simulation setting that has to be defined, which is the function of velocity magnitude to get the effect of added mass. The simulation setting should be defined as Figure 26.

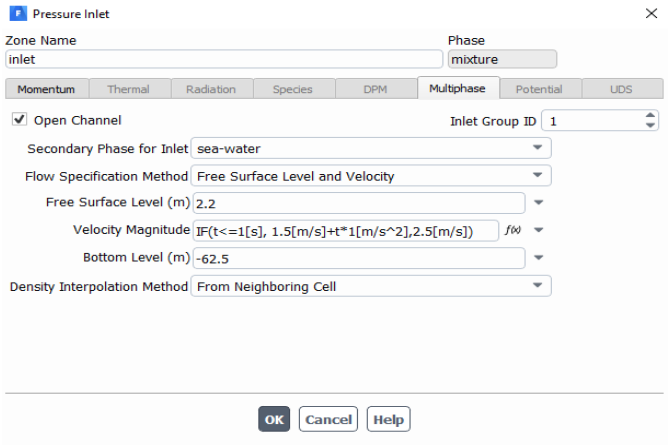

Figure 26: Simulation Setting Addition for Added Mass

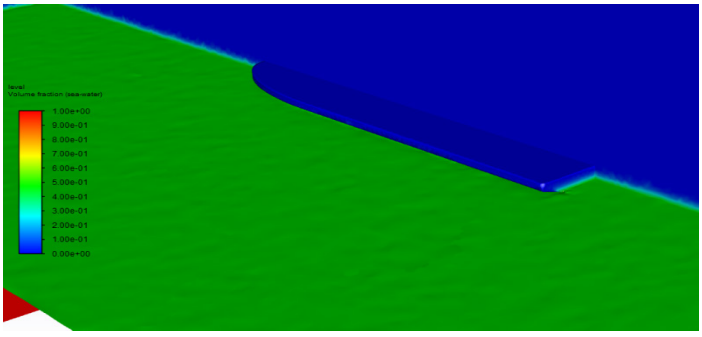

Figure 27: Visualization of CFD Simulation

4. Result and Analysis

The results obtained from the simulations that have been carried out are the value of drag in Newton units and the value of added mass in kilograms which is derived from the force by the acceleration. Visualization of both can be seen in Figure 27.

The validation of the drag simulation results on the ship is done by comparing the values obtained from CFD, with the theoretical values proposed by Holtrop and Mennen. The geometric parameters of the ship are calculated first to check whether this method is valid for use on the ship that is tested. The geometric model parameters of the ship that obtained from the CAD can be seen in Table 4 and the prerequisite geometry table can be seen in Table 5.

Table 4: Geometric Model Parameters

Parameter	Symbol	Value	Unit
Waterline Length	L_{WL}	57.576	m
Length Overall	L_{OA}	60.4	m
Beam/Breadth	B	12.379	m
Depth	d	6.5	m
Draft/Draught	T	5.7	m
Displacement	∇	2580.207	m^3
Wetted Surface Area	S	1170.01	m^2
Cross Section Area	A_M	61.23	m^2
Immersed Transom Area	A_T	38.819	m^2

Table 5: The Geometric Prerequisites for the Holtrop and Mennen Method

Parameter	Symbol	Value
Froude Number	F_n	0.084
Prismatic Coefficient	C_p	0.732
Length to Breadth Ratio	L/B	4.651

Because the values obtained are based on the calculations in Table 5 in correspondence with the criteria, Holtrop and Mennen's method is suitable for use as a verification method. Calculation of Froude number used equation 15 and prismatic coefficient using equation 19. The ship parameters used for this calculation use the specifications previously given.

In this verification, the components that are considered to have a large contribution to the total drag on the ship are drag due to friction, drag due to wave generation, and additional pressure drag due to the submerged transom area of the ship. The other components are considered to have no significant effect on the total drag, so they are assumed to be zero. Based on the calculation method written in [4], equation 21 to 44, it is found that the value of each component is listed in Table 6.

Table 6: Resistance Component of Baruna Jaya III

Resistance Components	Value
Friction	7003.9 N
Wave Generation	0.012 N
Submerge Transom Area	14830.2 N
Total	21834.14 N

For added mass, validation uses the ellipsoid method. The calculation can be done by substituting the ship dimension parameters into equations 19 to 20. From these calculations, the results are shown in Table 7.

Table 7: Surge Added Mass (Ellipsoid Method)

Parameter	Symbol	Value	Unit
Ellipticity	e	0.9850246	
	A_0	0.0907254	
	k_{11}	0.0475182	
Surge Added Mass	m_{11}	123547.40	kg

Recaps for the simulation results of resistance and added mass data can be seen in Table 8 and Table 9, combined with the method values for validation.

Table 8: Result for Drag Simulation

Method for Resistance	Result
CFD Simulation	21030.37 N
Holtrop and Mennen	21834.14 N
Error	-3.681%

Table 9: Result for Added Mass Simulation

Method for Added Mass	Result
CFD Simulation	115719.91 kg
Ellipsoid	123547.40 kg
Error	-6.764%

The simulations carried out can capture the phenomena that occur well and have a value that is quite close to the analytical results. The error has a value below 5% for resistance or drag simulation and has 6% error for added mass simulation. It means this CFD simulation method is accurate in analyzing a ship, especially Baruna Jaya III.

The difference between the simulation and analytical results could occur due to modelling and analytical result value. Error in modelling could happen due to simplification of the original shape that was modelled into 3D Model, the convergence of the mesh, or the simplified equations used. If the modeling of the CFD simulation is the problem, it is necessary to check the step-by-step modeling to be able to trace what went wrong. In terms of analytical result value, further comparison with experimental results must be done do verify the results. Further research should be taken to solve this problem.

5. Conclusion and Future Works

Drag and added mass estimation using computational fluid dynamics has been carried out and gives a drag simulation result of 21030.37 N, verified using the Holtrop and Mennen method, and added mass value of 115719.91 kg, verified by the Ellipsoid method. These estimated values have a very low error compared to the verification value. This means that the CFD simulation can be an alternative method to obtain drag and added mass. The methodology can be used to capture the hydrodynamic forces that occur on the ship, especially Baruna Jaya III, and complete the parameters required for a dynamic positioning control system. With a cost lower than the experimental method, computational fluid dynamics could be considered as the best option for getting the hydrodynamic parameters of the dynamic positioning control system.

In the future, it is necessary to investigate the added mass method in the CFD simulation further so that it can have a value closer to the analytical solution. Validation also needs to be compared with the experimental results so that values are more convincing because they are compared with actual values. The values of drag and added mass that occurs in the sway and yaw direction of the ship also will be further investigated in order to complete all the parameters needed to create a dynamic positioning control system.

Conflict of Interest

The authors: Nu'man Amri Maliky, Nanda Pratama Putra, Mochamad Teguh Subarkah, and Syarif Hidayat; declare that we have no conflict of interest for writing this paper to be submitted to ASTES Journal: Special Issue Paper (Special Issue on Multidisciplinary Innovation in Engg Science & Tech).

Acknowledgement

The authors are very grateful to all reviewers who have checked and criticized the papers that have been written to become a great paper in this journal. Thank you also to all ASTES committees, especially those who take care of the Special Issue Paper (Special Issue on Multidisciplinary Innovation in Engg Science & Tech) section who has invited us to submit our paper to the journal here.

ABSTRACT

According to IEC 61805 and ISO 26262 standards requirement inclusion of LBIST (Logic Built in Self-Test) became mandatory to achieve safety critical application such as automotive field. In such systems, once device is switched ON LBIST (Logic Built in Self-Test) is activated and testing of digital logic is performed. After safety subsystem says that the LBIST passed, the SoC (System on Chip) moves into the functional mode otherwise, the SoC moves into a safe state. In this entire start-up sequence the LBIST interacts extensively with the safety sub-system of the SoC. Startup sequence remains un-verified at RTL (Register-Transfer Level) leading to painful ECOs (Engineering Change Orders) and post Silicon issues in some cases. LBIST verification can only run if scan chains are present in design which is not the case at RTL. The paper describes design of a Design-for-Testability (DFT) technique to enable LBIST based system verification with different test approaches at RTL which eliminates the possibility of ECOs by catching most of the issues at RTL level. Simulation results are demonstrating the feasibility of the approach with emphasizing the benefits obtained on significant computational modules.

1. Introduction

LBIST became alternative approach for ATPG (Automatic Test Pattern Generation) due to increased complexity and test cost requirement for functional blocks [1]-[3]. Electronic component general safety-critical applications [4] are referenced in IEC 61805 [5] and Automotive Safety Integrity Level (ASIL) for automotive domain is referenced in ISO 26262 standard [6].

Latent faults (LFs) detection for automotive systems using power on self-test (POST) based on logic built in self-test (LBIST) is executed during engine start -up to test safety – critical devices before staring any functional operations [7]. POST is having limited test application time in automotive systems [8]. Getting required LF coverage (>90%) within less test application time is primary requirement [9].

the pass/fail comparison of the unit [10], [11]. PRPG (Pseudo Random Pattern Generator) is used for generating input stimulus for the design, and MISR (Multiple Input Signature Register) to capture the compact the response. Test patterns which is supplied to internal scan chains are output of PRPG block and response is the input to the MISR compaction. Signature is the compacted response for that cycle of operation [12], [13]. The LBIST implementation is as shown in Figure 1.

LBIST is based on 'scan' methodology to test digital logic [14], this suffers from limitation – The design cycle will be delayed by the time the netlist is ready with Scan insertion, X-bounding [15] and Test-point insertion done [16] to perform LBIST verification. Performing LBIST patterns gate-level simulations early in the design cycle will take weeks to complete since execution is performed in series and are large number [17].

In this paper, we propose an innovative strategy for the in-field testing of automotive devices. Methodology to perform parallel verification of sub-modules of System on Chip (SoC) is described. Section 2 describes proposed design methodology to per-form Logic BIST verification at RTL level with dummy netlist. Section 3 describes implementation details such as scan chain insertion steps, dumpy netlist creation and direct mode entry. Simulation results with debugging analysis details are discussed in section 4 and in section 5 conclusion of the work is described.

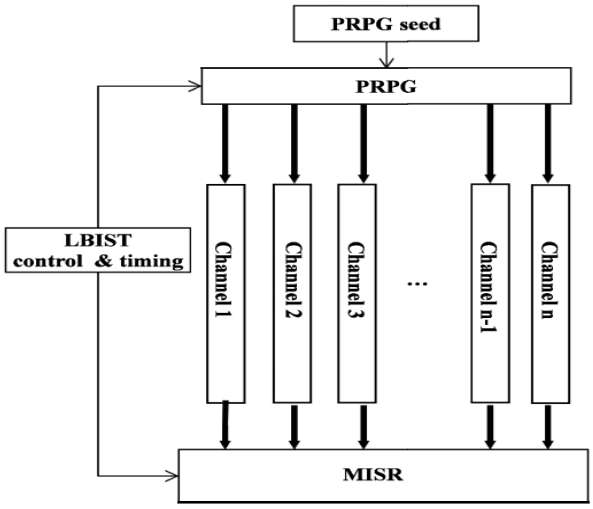

Figure 1: Standard LBIST Implementation

2. Proposed Design Methodology

Logic Built-In Self-Test (LBIST) is implemented by several LBIST controllers which operate independently on different partitions of the device as shown in Figure 2. This is needed to fulfil safety requirements about the independence and diversity of replicated IP, helps in physical flow and helps to avoid exceeding power limits. For applying traditional external scan patterns, LBIST controllers are put into trans-parent mode. Typically scan chains used for LBIST are shorter than scan chains used for compressed ATPG (Automatic Test Pattern Generation). Therefore, in LBIST transparency mode, the short LBIST chains are concatenated during to longer pro-duction scan chains which then are connected to the EDT (Embedded Deterministic Test) scan compression IP.

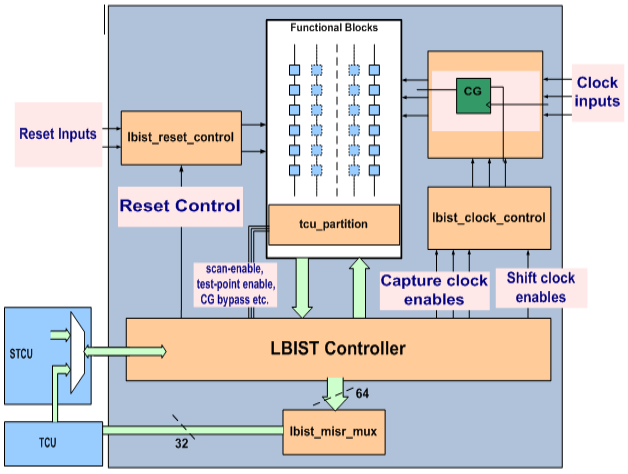

Figure 2: LBIST Architecture

LBIST controller IP itself will become part of the scan chains used for external scan patterns. Certain registers may not change value during LBIST operation but should be part of regular ATPG scan. These registers are put into one or more separate scan chains which are not shifted during LBIST. During LBIST their values are not influenced by shifting. These special scan chains are only used for ATPG. These registers will be identified during implementation. Each of the LBIST controllers is connected independently to the STCU (Self-Test Control Unit). The STCU can either start all LBIST controllers at the same time in parallel or in a sequence defined by the STCU. Only for debug reasons it is possible to access and operate each LBIST controller separately. This is done via JTAG (Joint Test Action Group) and a path through TCU (Test Control Unit) to the selected LBIST controller.

2.1. LBIST Partitioning

According to the safety concept eight LBIST partitions are implemented. They are numbered A0, A1, B0, B1, C0, C1, P0, P1. Each LBIST partition is contained in a separate LBIST island or lake as shown in Table 1. List of blocks where LBIST implementation is exempted:

- JTAG Controller
- TCU
- IO_top level ((Input-Output) / Pad ring
- PMU (Power Management Unit)/ PMU-Controller
- STCU
- PLL (Phase Locked Loop)
- XOSC (Oscillator)

Table 1: Characteristic data of LBIST partitions

	Characteristics				
Partition	**Size**	**LBIST chains**	**PRPG size**	**Clock domains**	**Chain overhead**
A0	77K	1600	46	System, tck	10%
A1	60K	1100	36	System, tck	10%
B0	24K	500	24	System, tck	10%
B1	60K	1100	36	System, tck	10%
C0	45K	1000	34	System, tck	10%
C1	60K	1100	36	System, tck	10%
P0	26K	600	26	System, tck	10%
P1	60K	1100	36	System, tck	10%

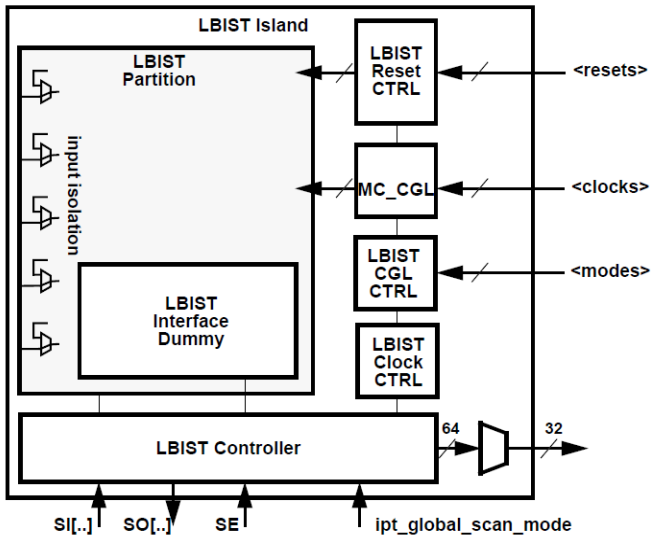
2.2. LBIST Integration

The design is split into several LBIST islands, where each LBIST island contains the actual LBIST partition, i.e. the logic to be covered by LBIST, a dedicated LBIST controller, dedicated clock and reset control blocks as shown in Figure 3. LBIST Controller:

Essential features of the LBIST controller IP used are:

- External clock control.
- Serial and parallel interface (to simplify communication, both functional and test/debug).
- Neg-edge lockup registers after PRPG and before MISR (to simplify LBIST scan chain timing)

With the introduction of lockup registers after PRPG and before MISR all LBIST scan chains must begin and end with a pos-edge flop. With this architecture all LBIST clock domains with less than half a cycle clock skew can be handled safely.



LBIST Controller Hierarchy: The controller needs to be generated with the following parameters:

set rtl hierarchy -Clk_mux Out -external_clk_enables
set lbist Controller -programmable_shift_rate ON
set shift_rate Divisor 8

This generates the LBIST controller IP in a hierarchy. The LBIST clock controller is entirely based on clock enable rather than the clocks generated by the LBIST IP in order not to generate a new clock path. Figure 4 gives an overview of the generated Controller IP and its hierarchy.

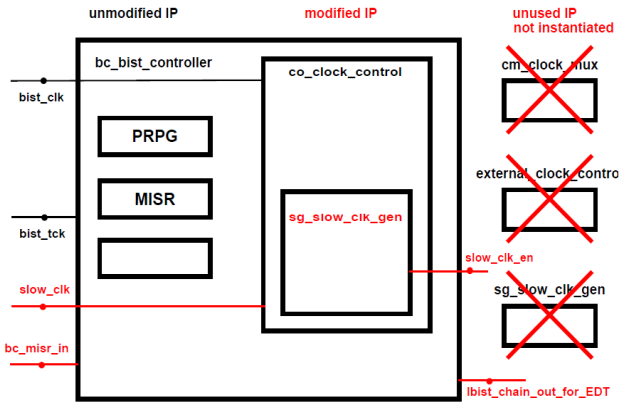


Figure 4: LBIST Controller IP Hierarchy

2.3. LBIST Controller Clocks

The LBIST controller operates on three different clocks, the LBIST engine clocks, bist_clk, and slow_clk, as well as the STCU communication clock bist_tck. The LBIST engine clocks bist_clk and slow_clk must fulfill the following requirements:

- The clock source for 'bist_clk' and 'slow_clk' must be identical.
- The clock source for 'bist_clk' and 'slow_clk' must be the fastest clock used inside the LBIST partition.
- The clock source for 'bist_clk' and 'slow_clk' must be the clock with the highest clock insertion delay used inside the LBIST partition.

2.4. LBIST Interface Dummy

The LBIST interface dummy propagates a standard LBIST interface into the LBIST partition, to ensure, that all relevant signals are present and preserved through synthesis and scan insertion. The LBIST interface dummy combines the following interfaces / features:

- LBIST controller IP interface
- LBIST clock interface
- LBIST clock gating control ('ipt_cg_bypass' and 'ipt_se_gatedclk')
- Test points that can be connected by the physical team to improve coverage if required
- Production Scan: Launch-Off-Shift (LOS) per clock domain and blocking of LBIST control signals for at-speed scan.

The LBIST interface dummy is protected during synthesis because connections to the module are created during scan chain stitching and automatic clock gate insertion only.

2.5. LBIST Interface Dummy

For direct execution of LBIST, the optional parallel interface of Mentor's LBIST controller is used. It provides the following interface signals:

- bist_run_input- triggers LBIST run
- bist_done - flags a finished LBIST run
- misr_value - vector output providing parallel read access to MISR value

Debug and diagnosis require access to LBIST control registers. It is done through LBIST's serial interface. Writing and reading control registers happens in a JTAG-like serial mode. The LBIST serial debug interface is used by the STCU to con-figure LBIST run parameter, such as pattern count. Full debug and diagnosis are performed through the TCU only. The interface is based on a JTAG-like protocol with shift- and update-DR states. Both TCU and STCU share the interface to the LBIST controller IP, where the muxing between TCU and STCU is performed inside the STCU controlled by 'tcu_lbist_direct_ctrl'. The actual TCU access is performed though the TCU external TDR mechanism based on the register selection through the LBIST TDR (LTDR). Expected LBIST signatures are kept in the Non-Volatile Memory (NVM). Through STCU programming the required signature is fetched from the NVM for comparison.

2.6. LBIST Clock and Reset Control

LBIST Clock Control: All LBIST clocks are controlled through the Magic Carpet Clock Gating Logic (MC_CGL) associated with each LBIST partition. The clock control by the MC_CGL is purely based on clock enables rather than the clocks generated by the LBIST IP. Figure 3 shows the modules relevant for LBIST clock control for one LBIST partition 'C0'.

The LBIST controller, as well as the blocks lbist_clock_control, lbist_cgl_control, and cgl_lake exist local to all eight LBIST partitions. The LBIST controller with its modified co_clock_control block is connected to the main lbist_clock_control module, that combines the shift and capture enable signals. The lbist_cgl_control block switches between the clock enables generated by the TCU and by the LBIST controllers depending on the mode setting. The clock gate inside the MC_CGL will generate the slow bist clock based on the enable provided by the LBIST IP. The LBIST clock control will provide punch out clocks, not 50% duty cycle clocks.

Slow Clock Generation: The LBIST slow clock ('slow_clock') is a punch out clock divided down from bist_clk (== fast_clk) using a programmable clock divider inside the 'sg_slow_clock_gen'. It is used to control several key LBIST functions, such as PRPG, MISR, pattern counter etc. The same slow clock divider is used to program the shift clock frequency. The default divider ratio of the 'sg_slow_clk_gen' module is set to 8 but can be reprogrammed via the LBIST control registers.

LBIST Reset Control: To control all resets within the LBIST partition, all resets must be routed through the LBIST reset control block. The block allows reset control for LBIST, while the system resets are not gated. This is to make sure, that a system reset is not blocked during device startup.

LBIST reset requirements are:

- All asynchronous resets of an LBIST partition must be routed through the LBIST reset control block.
- All functional resets must be in off state during LBIST execution.
- No LBIST partition output to MC_RGM/MC_RSL must have an influence on self-test / LBIST execution.

The original reset control logic provided by the LBIST controller IP is an active-high reset (clock) signal multiplexed into the functional reset path. With the non-blocking reset control, where the functional reset is not blocked by LBIST a new reset control is introduced replacing the original one. To pre-vent reset glitches from propagating into the LBIST partition in scan mode, the LBIST reset control must be bypassed by a scan mode reset. The non- blocking reset control dictates, that all functional resets are off during LBIST execution, otherwise the LBIST MISR becomes invalid.

2.7. Making the LBIST Partitions LBIST Ready

The interface of the LBIST partitions need special attention to ensure that there is no X poisoning into the LBIST partition. All critical signals causing problems in the standard X-bounding flow will be X-bound in RTL. Mentor Testkompress fault simulation is used to identify missing X-bounds. The decision on whether an input is to be X-bounded is taken based on the partition input signal categories shown in Table 2.

The X-bounds inserted in RTL will instantiate a MUX controlled by lbist_en from the LBIST controller IP. Whenever possible the partition outputs are used as inputs to the MUX. This increases coverage as it provides toggling and not constant inputs to the MUXes, while at the same time adding observability to the partition outputs.

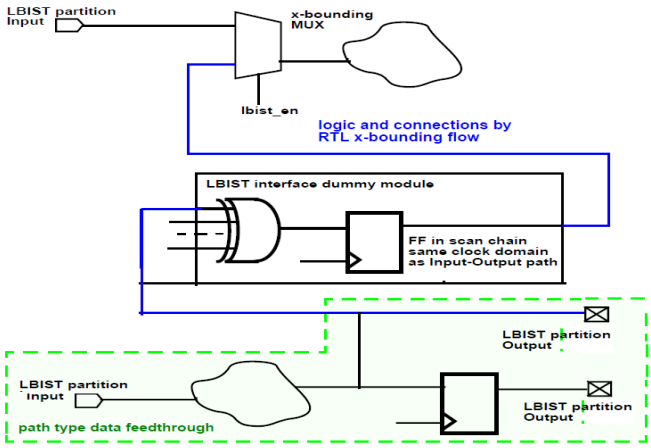

Figure 5: X-bounding to avoid multi-cycle path generation

Figure 5 shows a concept used to avoid multi-cycle path generation on known critical input – output combination. The LBIST interface dummy module will include several XOR gate FF combinations as shown below. The RTL X-bounding flow uses and connects these structures. In a later stage the automatic RTL x-bounding flow might also include instantiation of these structures instead of using predefined ones.

Table 2: LBIST partition input categories

Category	LBIST Control	Bound
Reset input	Via LBIST reset control	No
Clock input	Via LBIST clock control	No
Clock gate control	Via LBIST interface dummy	No
Common Digital Input		Yes
Selected Tied Digital Input		Yes
Unconnected Digital Input	None required	No
Digital Input from TCU – no influence on LBIST		yes
Digital Input from TCU – influence on LBIST	Constant from TCU	No
Bidirectional	NA	No
Analog/Special Nets	All hard IP in LBIST mode	No
LBIST Controls	From LBIST control IP	No

3. Implementation Details

LBIST scan chain insertion and concatenation to top level LBIST chains including lockup-FF insertion followed these basic steps in the DFT and physical flow.

1. DFT flow - Generated EDT controllers everything pos-edge based w/o lockup-FFs
2. DFT flow - Generated LBIST Controller and connected internal LBIST chains at the BIST controller to form ATPG scan chains. Modified LBIST controller to provide ATPG chain outputs with LBIST controller interface. Connecting ATPG chain inputs and outputs of LBIST controller to EDT controllers using IPXACT flow. (Assigned fixed value to EDT controller pins for remaining chains outside LBIST to protect them in synthesis)
3. Physical flow -One step scan insertion: Building LBIST chains, connecting them to the LBIST controller. Building ATPG chains for logic outside LBIST, connect-ed them to the

EDT controller using the pins with fixed value assigned by IPXACT.

4. Physical flow - Post processing step to insert lockup FFs, including required lockup-FFs in concatenated LBIST chains.
5. Checked for missing lockup-FFs on

a. change of clock name or clock polarity in scan cell report - DFT flow

b. clock hierarchy change - Physical flow

Figure 6 depicts concatenation of four LBIST scan chains to form one production chain with input and output available at the LBIST controller boundary for hook up to the EDT controller. Also shows where lockup FFs are placed by the physical flow.

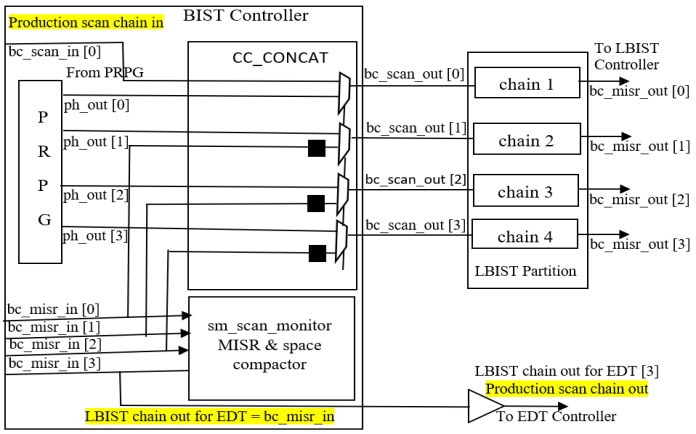

Figure 6: LBIST chain concatenation and lockup latch insertion

3.1. LBIST Dummy Netlist Integration at RTL

Integrating a dummy netlist in the design at RTL level with the same number of scan chains, scan clocks and scan resets is done. This dummy netlist should only be visible to the verification environment, in the LBIST testcases expect the MISR calculated for the dummy netlist.

Flow: Generate a dummy netlist (with scan chains) → Generate the MISR value for the same dummy netlist →Integrate this dummy netlist into the actual design RTL → run the testcases for verifying the complete start-up sequence. Details of each step are described below:

Step1: Generate a dummy netlist using "skeleton design creation".

create_skeleton_design -o lbist_for_verif -i skeleton_design.txt

Step2: Generate MISR for dummy netlist by doing fault simulation using LBIST Architect

*lbistarchitect -fault_simulation *
*lbist_for_verif.v -verilog *
*-lib skeleton.fslib -nogui *
-dofile lbist_for_verif.dofile

Step3: Integrate the dummy netlist into the lbist partition using "ifdef"

Step4: Perform RTL simulations for LBIST based start-up sequence using the com-pilation argument:

+define+LBIST_DUMMY_SIM

3.2. LBIST Direct Control Mode

For LBIST debug purposes there is a 'LBIST direct control' mode, where the different LBIST partitions can be run stand alone or in parallel. Which LBIST partitions are run, as well as LBIST parameters like pattern count, MISR start value etc., are programmed via JTAG. The LBIST Direct Test Mode Entry uses the LBIST Test Data Register (LTDR) to select the LBIST controllers, start the LBIST run. The following sequence shown in Table 3 is used in the Teskompress setup as well is in the Verilog stimuli for LBIST direct mode verification and pattern generation.

Table 3: LBIST direct mode entry

Step	Description
1	Common steps to TCU based mode entry
2	Load and update the Generic TCR
3	Load and update the RGMTDR to disable gating reset phase 3.
4	Load and update the CLK TDR to program the PLL0 clock source for LBIST execution
5	Set LBIST direct control: Load and update LTDR LBIST direct mode: tcu_lbist_testmode=1; tcu_lbist_direct_control=1;
6	Turn TEST mode on to be able to program LBIST Controllers
7	Program LBIST controllers Select the LBIST controllers: Load and update the LTDR: ipt_lbist_sel[4:0]=<controller id>Program controller settings like pattern start/end counter using the steps in Table V.
8	Deassert RESET and apply EXTAL clock pulses to get rgm state machine to stabilize.
9	Start LBIST run on selected controllers: Load and update LTDRipt_lbist_sel[3:0]=<selected controllers> and ipt_lbist_run=1.
10	2 cycles for LBIST finder PRPG and MISR recognition
11	Deassert RESET_B

The following Table 4 describes the sequence of Writing to / Reading from an LBIST controller register in LBIST direct test mode and Table 5 describes the sequence to read out the MISR values after completion of an LBIST run in LBIST direct test mode.

Table 4: Writing to / reading from an LBIST controller register

Step	Description
1	Write register address to LBIST controller dselect register: a. Load and update the LTDR to select dselect register: ipt_lbist_reg_sel=1 b. Send JTAG instruction 6'd5 to access external LBIST controller register. Write value to LBIST controller dselect register. E.g. '0110' to map pattern count end value into data register.
2	Write value to / read value from an LBIST controller data register a. Load and update the LTDR to select data register: ipt_lbist_reg_sel=0. b. Send JTAG instruction 6'd5 to access external LBIST controller register. Write value to / read value from LBIST controller data register

Table 5: Reading out MISR values

Step	Description
1	Read the LTDR to observe LBIST done flags lbist_done [3:0]
2	Turn off EXTAL before switching from bist_clk to TCK
3	Load and update LTDR: ipt_lbist_run=0. This switches from bist_clk to TCK
4	Read MISR registers a. Select the LBIST controller: Load and update the LTDR: ipt_lbist_sel[3:0] b. Read the MISR value using the steps in Table V.

4. LBIST verification results at RTL

Verification of all different partitions are carried out with four different testcases listed below running parallelly with respective MISRs generated during LBIST Fault simulation using LBIST Architect tool [18].

1. Testcase with PLL clock
2. Testcase with EXTAL clock
3. Scan chain mask decoder
4. MISR exposed on PADs

4.1. Testcase with PLL clock frequency

LBIST controller logic/integration reset and clocks of the respective partitions, mode entries are verified at lbist_fast_clk = 320MHz & lbist_slow_clk = 80 MHz frequencies. Figure 7 shows one of the issues identified for a partition.

- MISR mismatching is observed after pattern count value 237, expected MISR value is 415B3579F4B1C0DA, simulation result MISR value is DE2F87E1C111F4D1.
- Analysis: Capture window for pattern count value after 237 is as below but from waveform we can see along with below 4 clk_domain clk_domain_58 is also pulsed which is causing the MISR mismatch.

clk_domain_1 → pulse '10000000'
clk_domain_18 → pulse '00100000'
clk_domain_39 → pulse '00001000'
clk_domain_30 → pulse '00000010'

Figure 7: MISR mismatch issue caught during RTL verification

4.2. Testcase with EXTAL clock Frequency

LBIST controller logic/Integration reset and clocks of the respective partitions, mode entries are verified at EXTAL = 100MHz frequencies. As shown in Figure 8 MISR is observed after pattern count value 260, expected MISR value is B8D5_F506_668B_F517, simulation result MISR value is B8D5_F506_668B_F517.

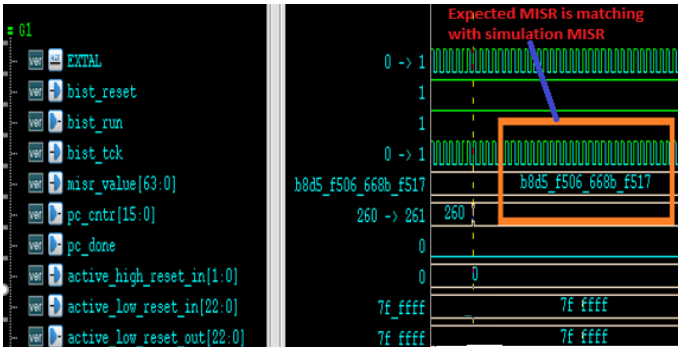

Figure 8: LBIST Verification with EXTAL clock frequency 100MHz

4.3. Scan Chain Mask Decoder Testcase

LBIST controller logic/Integration, reset and clocks of the respective partitions, verified at lbist_fast_clk = 320MHz & lbist_slow_clk = 80 MHz frequencies. As shown in the Figure 8 chain_0 is masked for every LBIST partition and pattern lbist_si[980:0] toggles for mask decoder lbist_si[980:1] and lbist_si[0] will be static 1.

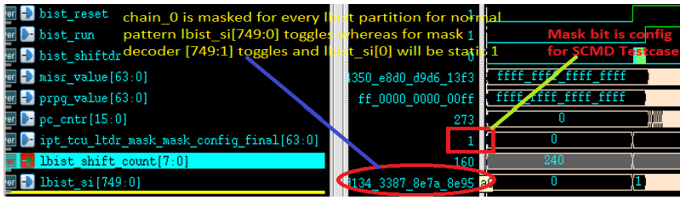

Figure 9: Scan chain mask decoder testcase result

4.4. MISR Expose at PAD Testcase

LBIST controller logic/Integration, reset and clocks of the respective partitions, verified at lbist_fast_clk = 320MHz & lbist_slow_clk = 80 MHz frequencies along with MISR value is exposed at PAD during end of the pattern count using lbist_misr_word_sel bit to expose 1st 32 -bit and later 32 -bit values respectively. As show in Figure 10 MISR value DCCF_7DA6_225C_9279 at program counter value 272 is exposed on PAD pins using lbist_misr_word_sel (0/1).

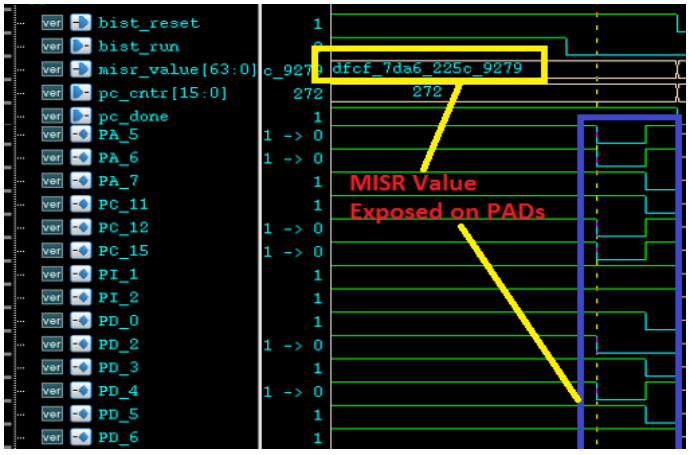

Figure 10: MISR exposed at PAD testcase result

5. Conclusion

The proposed methodology for verifying LBIST implementations at RTL in SoCs is not a replacement for gate

level verification of LBIST implementations, with this approach a significant effort and design cycle time can be reduced by moving the verification process early into the SoC design cycle. The results are proven with measurable improvements on real design where the flow/methodology was implemented and helped in identifying the bugs & fixing them before logic freeze, thereby avoiding ECOs.

ABSTRACT

Empathy is an attribute of importance between the nursing professional and the patient, where it influences the recovery of their health. Several studies carried out have shown worrying results where they reflect a great decrease in empathy during the formative academic years. The objective of the study is to determine empathy in nursing interns from three university institutions in Lima, 2019. The study is a quantitative approach, with a non-experimental, prospective, descriptive and cross-sectional design. The application of the Jefferson Medical Empathic Scale instrument for students in Spanish version S is proposed, where the data was entered into a matrix in the Microsoft Excel 2013 program, then the IBM SPSS Statistics version 24.0 is subsequently analyzed obtaining the percentage of empathy of the internal, also take actions to improve these variables. 216 nursing interns from three universities in Lima participated. 51.4% are from Universidad Norbert Wiener, 89.4% (n = 193) were women, 56.4% (n = 123) are from the ninth cycle, 42.4% (n = 91) they study and work, 58 nursing interns from Universidad Norbert Wiener representing 52.3% have a medium level, 34 nursing interns from the Universidad de Ciencias y Humanidades, representing 30.6% have a medium level and finally 19 nursing interns from the Universidad Privada del Norte representing 17.1% have a medium level. Universidad Norbert Wiener obtained a higher score prevailing the medium level.

1. Introduction

The definition of empathy over time has been modified and expanded, coming to recognize it more than a static trait, also a state or ability that flows, being susceptible to change according to personal experiences and cultural interventions [1]. Empathy in the nurse-patient relationship should be used on a day-to-day basis, since it may affect their work of caring for patients, the decrease of it may lead to the loss of ability that allows better communication in the opinion of the patient since this is considered a relevant factor in the recovery process [2].

The comparison of the three universities is very important since it is going to differ in the type of teaching that each university offers to nursing interns, in turn the ability of nursing interns to function in the clinical field, where His training will stand out depending on each intern willing to improve and be a successful professional.

These circumstances may be due to the educational system because it must be oriented to the service of society and the individual, which should be based on the needs and demands that are important for development and competent from the professional point of view [3].

To carry out a relationship between nurse and patient, health personnel provide empathetic treatment to the patient to not worse the situation of the patient's disease, thereby also giving the staff the development of attitudes, capacities and skills, giving a care of quality, that's why, different causes of the deficit are visualized in its application.

The health personnel with the longest service time and high hierarchy level are those that present the greatest decrease in the level of empathy [4].

*Corresponding Author: Brian Meneses-Claudio, Mr., +51 1 950159924 & bmeneses@uch.edu.pe

In a study on health students, "Evaluation of empathy in human medicine students from the private university of Peru" [5], they found that those students who think that their specialty is linked to Patient Care presented greater empathy with 66.9%, the same as those who reported having a professional model in patient contact with 72%.

In a research work [6] studies carried out in nursing and medical students, indicate that students have found variations in empathy in terms of specialty and clinical competence, being worrying because some of them reflect a decrease in empathy over the years of training, the score is from 0.0 to 140.0; the women with 118.7 obtained a higher level of empathy score than the men with 110.4 points, differences that were statistically significant.

In the research work "Concepts on empathy: development of an instrument for formative evaluation based on a teaching experience with pediatric residents of the Universidad de Antioquía" [7], indicates that a deficit in student training on the basis and practice of empathy, because the participants had misconceptions about empathy, where they adopted universal criteria for all their patients, believing that they had to make the patient's wishes come true, make the patient or family feel that are important in the decisions of health personnel, among others.

Currently, professionals who can work normally in the socio-labor context that allows them to function interpersonally are required, the variable empathy is essential in the deployment of a professional in different medicine and social fields that its performs, its importance is appreciated in the development of professional skills [8].

The objective of the research work is to determine empathy in nursing interns from three University Institutions in Lima, 2019 according to their three dimensions of compassionate care, perspective taking and putting themselves in the other's place. The implementation of empathy on a daily basis will help, also the mental state of the patient and the health personnel, to recognize and identify mental problems that could be going unnoticed, being a national research priority 2015-2021 established by the Instituto Nacional de Salud [9].

The technique to be used is the survey that will be through the questionnaire and data collection instrument the Jefferson Scale of Empathy (JSE) for students in Spanish version S, created by the Jefferson group, led by Mohammadreza Hojat, consisting of 20 evaluated questions on a 7-point Likert-type scale, the score ranges from a minimum of 20 to a maximum of 140 points, there are 10 items written in a positive sense and 10 in a negative sense, whose items explore the dimensions of perspective taking, compassionate care and ability to put yourself in the other's place. Permission has been offered to use the Jefferson Empathy Scale in 85 countries. The JSE has been translated into 56 languages[10]. After this, the data will be entered into a matrix in Microsoft Excel 2010, and then exported to the IBM SPSS Statistics Base 22 statistical package, in which it will be analyzed.

The following research work is structured as follows: In section II, the development of the used data processing will be presented. In section III, the results of the tables and figures of sociodemographic agreement, institution and dimensions will be shown. In section IV, it will present the discussions of the research work and finally in section V, the conclusions, as well as the future work that is intended to be wanted with the research work.

2. Methodology

2.1. Research type and design

The present research is of a quantitative approach because the variables were measured, statistical data was used generalizing the hypothesis, the methodological design is a non-experimental, prospective research because according to the planning of data collection, they are primary, cross-sectional because the measure is non-experimental, it was for a single occasion, descriptive because it consists of a single variable.

2.2. Population and sample

The study population is made up of 216 nursing interns from three private universities in Lima, enrolled in 9th and 10th semesters, who carry out their pre-professional practices and are in contact with the patient, during the period of 2019, according to the Population type are non-probabilistic type, selected according to the inclusion and exclusion criteria.

Inclusion criteria

University students of both sexes who are studying nursing at the time of data collection, nursing interns enrolled during the academic semester 2019 who are taking the 9th and 10th semesters who voluntarily participate in the interview or fill out the data collection questionnaire, nursing students who agree to sign the informed consent.

Exclusion criteria

Nursing students who are from the 1st semester to the 8th semester and nursing interns who have not signed the informed consent to carry out the study.

2.3. Technique and instruments

The technique used was the survey, in the form of the Jefferson Scale of Empathy in Spanish for students, containing general student data such as: sex, age and year of training that will be used to obtain information of the students who participate in the survey, specially designed to measure empathy in the context of patient care, whose items consist of 3 dimensions of perspective taking, compassionate care and ability to put yourself in the patient's place. It consists of 20 items which are evaluated on a 7-point Likert-type scale ranging from: Strongly Agree (7 points) to Strongly Disagree (1 point). The score is from a minimum of 20 points to a maximum of 140 points, the highest scores correspond to a high level of empathy. There are 10 items written in a positive sense and 10 in a negative sense (inverted score) [10].

"Jefferson Scale of Empathy" has been validated in many countries around the world, including Latin American countries and previously applied in Peru, it has construct validity; convergent, parts that comprise are related to each other; and discriminating, its parts are not related to topics different to empathy. In addition, it has the Chi X^2 that is 0.5 in its various versions and translations, which is a reliable measurement scale and each of the questions are correlated with each other and with the entire instrument [11].

2.4. Data collection procedure

- An authorization was presented to the Nursing faculty for the execution of the project in order to obtain the respective permission.
- Subsequently, the nursing faculty provided facilities for the execution of this research, also will provide a cover letter.
- Once obtained, it was presented to teachers and delegates of the ninth and tenth semesters informing the objectives of the project and the informed consent, in order to obtain their acceptance, support and collaboration in the application of the instrument.
- The evaluators met teachers and delegates of ninth and tenth semester to discuss the date and time of application of the instrument.

2.5. Application of data collection instruments

- The evaluators attended the classrooms of each semester, ninth and tenth, on coordinated dates and times.
- The students were informed of the importance of their participation, a brief explanation about the instrument.
- The informed consent form was distributed to be signed for the student and then the questionnaire.
- The questionnaire development lasted approximately 10 to 15 minutes.
- Then the instrument was collected, verifying that all questions are answered.
- In closing, the students were thanked for their participation and collaboration in the research.

As shown in Figure 1, nursing interns were presented and explained how to carry out the survey. The protection aspects of the research participants and bioethical principles were taken into account, likewise informed consent was applied after clear information given to the participants, the application of the instrument is important, it will help especially in the mental state of the patient and the health personnel themselves, to recognize and identify mental problems that could be going unnoticed, being a national priority, which asks them to collaborate in providing with certain data that will allow to get the study objective .

Figure 1: Teacher permission and approval to apply the survey to students.

After obtaining the approval of the teacher of the classroom, the survey was applied, where advice was given before and during the application because questions were raised by the students, most of them were just to clarify questions, as shown in Figure 2.

Figure 2: Advice before and during the survey application

2.6. Data analysis and processing techniques

The data collection process was carried out during May 2020, the data was initially entered into a data matrix designed in the Microsoft Excel 2010 program, then exported to the IBM SPSS Statistics version 22.0 program. There, they were analyzed, obtaining tables and graphs that were later described and interpreted in the results and discussion sections, respectively.

For the statistical analysis of each main variable involved in the study, descriptive statistical tests such as absolute frequencies, relative frequencies, and measures of central tendency were applied, in addition to some correlational tests to verify the study hypothesis.

3. Results

A summary table of the surveys carried out following the guidelines corresponding to the research work will be shown, in the study participants were 216 nursing interns of 9th and 10th semester from the three University Institutions, in the following table, it will present results of the sociodemographic data of the study participants.

Table 1: Sociodemographic data of empathy in nursing interns from three University Institutions in Lima, 2019 (N = 216)

Participant Information	Total	
	N	%
Total	**216**	**100**
University		
Universidad de Ciencias y Humanidades	64	29,6
Universidad Norbert Wiener	111	51,4
Universidad Privada del Norte	41	19,0
Gender		
Female	193	89,4
Male	23	10,6
Study semester		
9th Semester	123	56,9
10th Semester	93	43,1
Occupation Status		
Study	61	28,2
Study and eventually work	64	29,6
Study and work	91	42,1

Regarding the university, 111 nursing interns representing 51.4% are from Universidad Norbert Wiener, 64 nursing interns representing 29.6% are from the Universidad de Ciencias y Humanidades, and finally 41 nursing interns representing 19% are from the Universidad Privada del Norte.

Regarding gender, the female sex predominated with 193 students representing 89.4%, followed by the male with 23 students representing 10.6%.

Regarding the study semester of nursing interns, the ninth semester is 123 representing 56.9%, and the tenth semester, 93, representing 43.1%.

Regarding the occupation status of nursing students, 91 with (42.1%) cases study and work, followed by 64 with (29.6%) cases study and eventually work and 61 with (28.2%) cases only study.

Table 2: Empathy in nursing interns from three University Institutions in Lima, 2019 (N = 216)

			Universidad de Ciencias y Humanidades	Universidad Norbert Wiener	Universidad Privada del Norte
Empathy	**Low**	N	0	0	1
		%	0,0	0,0	100,0
	Medium	N	34	58	19
		%	30,6	52,3	17,1
	High	N	30	53	21
		%	28,8	51,0	21,2

In Table 2, it can see Empathy in nursing interns from three University Institutions in Lima, 58 nursing interns from Universidad Norbert Wiener representing 52.3% have a medium level, 34 nursing interns from the Universidad de Ciencias y Humanidades, representing 30.6% have a medium level and finally 19 nursing interns from the Universidad Privada del Norte representing 17.1% have a medium level. Universidad Norbert Wiener obtained a higher score prevailing the medium level.

Table 3: Empathy in relation to gender of nursing interns from three universities in Lima, 2019 (N = 216)

		Empathy			
		Low	Medium	High	Total
Student gender	Female Count	0	98	95	193
	% within Student's gender	0,0%	50,8%	49,2%	100,0%
	Male Count	1	13	9	23
	% within Student's gender	4,3%	56,5%	39,1%	100,0%
Total	Count	1	111	104	216
	% within Student's gender	0,5%	51,4%	48,1%	100,0%

Chi-square tests

	Value	df	Asymptotic significance (bilateral)
Pearson's Chi-square	8,958[a]	2	,011
Likelihood ratio	5,069	2	,079
Linear by linear association	1,649	1	,199
N of valid cases	216		

a. 2 cells (33.3%) have expected a count less than 5. The minimum expected count is ,11.

In Table 3, empathy is related according to sex, where women present a higher level of empathy (49.2%) than in men (39.1%), in which it was determined with the chi-square test of Pearson (X^2). The level of significance of the test obtained a value of 0.11 (p> 0.05) (X^2 = 8.958; d.f = 2). Therefore, an association hypothesis is not rejected, for which there are statistical data that verify the relationship between empathy and the sex of nursing interns from three universities in Lima.

In Table 4, we can observe the relationship between the dimension of perspective taking with the Universities of the nursing interns, in which it was determined with Pearson's chi-square test (X^2). The level of significance of the test obtained a value of 0.95 (p> 0.05) (X^2 = 3.512; d.f = 4). Therefore, an association hypothesis is not rejected, for which there are statistical data that verify the relationship between the perspective taking dimension and the universities of the nursing interns in the research. By which, we can interpret that the interns of the Universidad Nolbert Wiener have a high perspective taking (79.3%).

Table 4: Empathy in its perspective-taking dimension in nursing interns from three universities in Lima, 2019 (N = 216)

			Institution			
			Universidad de Ciencias y Humanidades	Universidad Nolbert Wiener	Universidad Privada del Norte	Total
Perspective taking	Low	Count	1	3	1	5
		% within Institution	1,5%	2,7%	2,5%	2,3%
	Medium	Count	19	20	8	47
		% within Institution	29,7%	18,0%	19,5%	21,8%
	High	Count	44	88	32	164
		% within Institution	68,8%	79,3%	78,0%	75,9%
Total		Count	64	111	41	216
		% within Institution	100,0%	100,0%	100,0%	100,0%

Chi-square tests

	Value	df	Asymptotic significance (bilateral)
Pearson's Chi-square	3,512[a]	4	,476
Likelihood ratio	3,398	4	,494
Linear by linear association	,981	1	,322
N of valid cases	216		

a. 3 cells (33,3%) have expected a count less than 5. The minimum expected count is ,95.

Table 5: Empathy in its compassionate care dimension in nursing interns from three universities in Lima, 2019 (N = 216)

			Institution			
			Universidad de Ciencias y Humanidades	Universidad Nolbert Wiener	Universidad Privada del Norte	Total
Beware with compassion	Low	Count	8	16	6	30
		% within Institution	12,5%	14,5%	14,6%	13,9%
	Medium	Count	26	54	16	96
		% within Institution	40,6%	48,6%	39,0%	44,4%
	High	Count	30	41	19	90
		% within Institution	46,9%	36,9%	46,4%	41,7%
Total		Count	64	111	41	216
		% within Institution	100,0%	100,0%	100,0%	100,0%

Chi-square tests

	Value	df	Asymptotic significance (bilateral)
Pearson's Chi-square	2,278[a]	4	,685
Likelihood ratio	2,285	4	,684
Linear by linear association	,138	1	,710
N of valid cases	216		

a. 0 cells (0,0%) have expected a count less than 5. The minimum expected count is 5,69.

In Table 5, we can observe the relationship between the dimension of compassionate care with the Universities of nursing interns, in which it was determined with Pearson's chi-square test (X^2). The level of significance of the test obtained a value of 5.69 ($p > 0.05$) ($X^2 = 2.278$; d.f = 4). Therefore, it is not possible to reject an association hypothesis, in which there is no statistical evidence in a significant relationship in the compassionate care dimension with the universities of nursing interns. By which we can interpret that the interns of the Universidad de Ciencias y Humanidades have a high compassionate care (46.9%).

Table 6: Empathy in its dimension, ability to put oneself in the place of others in nursing interns from three universities in Lima, 2019 (N = 216)

			Institution			
			Universidad de Ciencias y Humanidades	Universidad Nolbert Wiener	Universidad Privada del Norte	Total
Ability to put oneself in the place of others.	Low	Count	17	41	12	70
		% within Institution	26,5%	36,9%	29,2%	32,4%
	Medium	Count	41	54	25	120
		% within Institution	64,1%	48,6%	61,0%	55,6%
	High	Count	6	16	4	26
		% within Institution	9,4%	14,5%	9,8%	12,0%
Total		Count	64	111	41	216
		% within Institution	100,0%	100,0%	100,0%	100,0%

Chi-square tests

	Value	df	Asymptotic significance (bilateral)

Pearson's Chi-square	4,581[a]	4	,333
Likelihood ratio	4,607	4	,330
Linear by linear association	,068	1	,794
N of valid cases	216		

a. 1 cells (11,1%) have expected a count less than 5. The minimum expected count is 4,94.

In Table 6, we can observe the relationship between the dimension ability to put oneself in the place of others with the Universities of nursing interns, in which it was determined with Pearson's chi-square test (X^2). The level of significance of the test obtained a value of 4.94 ($p > 0.05$) ($X^2 = 4.581$; $d.f = 4$). Therefore, an association hypothesis cannot be rejected. In which, there is no statistical evidence in a significant relationship in the compassionate care dimension with the universities of nursing interns. By which it can be interpreted that the interns of the Universidad de Ciencias y Humanidades have a medium level of empathy (64.1%).

This dimension was the most affected, it makes understand that being nursing interns where the work of a professional is being carried out having a great responsibility, the first thing the hospital prioritize is the technological or the material and forget the emotional, the feelings; this makes understand that during academic training, it does not have a good empathetic training where it must be emotionally prepared and not as professional competitiveness among University institutions.

These results will be used as antecedents for future researchers to give greater emphasis to humanized treatment and improve the level of empathy at first base that are the students.

4. Dicussion

In the present study, an increase in medium empathy was found in nursing students where the level of empathy occurred more in women than in men, this is because women, because they are more emotionally sensitive, feel a more empathic concern, personal discomfort where concern for the care of the child, adult and older adults perceive themselves based on their understandings and at the same time on non-verbal language. Our findings are similar to the results of the authors M. Montilva and her collaborators in their study "Empathy according to the Jefferson scale in students of Medicine and Nursing in Venezuela", the average score of the EMed was 120.3, and the EEnf was 117.9; found a non-significant difference in the score with a higher level of empathy in women than in men [6]. The presence of empathy in the Peruvian population of three universities was 111, also have a medium empathy.

According to the study, empathy in nursing students according to their compassionate care dimension, it found with a high frequency, regarding the author M. Mejía and her collaborators in their study "Empathic behavior in science students of the health from Universidad de los Andes ", it is observed that there is not as much relationship since the students of the Universidad de los Andes are less compassionate [12].

In the found findings, it can observe that empathy in nursing students who carry out the non-medical internship, in its dimension perspective taking is high, which is related to the study of the author R. Lorch and his collaborators "a phenomenological study of nature of empathy ", which leads to the importance of developing empathy as an aspect of emotional competence, this study is related to the understanding that nursing students perceive and experience [13].

Another findings of empathy in health students, elaborated by J. Huancaya and his collaborators in their study "Evaluation of empathy in human medicine students of the private university of Peru", they found that those students who think their specialty was linked to patient care, they showed greater empathy, like those who reported having a professional role in patient contact, a higher percentage of the level of empathy in women was also found [5].

In the study by J. Blanco and collaborators in their study "Medical empathy in residents and medicine tutors of family and community. The vision of the professional and the patient "found that the health personnel, who have the longest service time, presented low levels of empathy compared to other professionals [14]. Regarding nursing students, it is observed that the majority have medium empathy, comparing with the mentioned study, the difference between them was that in the non-medical internship, there is a decrease in empathy.

It can be seen that there is a similar relationship in terms of gender, empathic levels in women are high, which indicates that women are superior to men.

5. Conclusions

It is concluded that empathy in nursing interns from three university institutions in Lima, 2019, medium empathy predominates. Regarding the dimensions of the three universities, the most affected dimension was putting themselves in the place of others the low level predominates, according to their compassionate care dimension, the medium level empathy predominates and, in the perspective, taking dimension the high level predominates.

In the bibliographic reviews of the national and international scientific databases, it was determined that there is not an adequate number of national scientific articles that involve this type of subject: Empathy in nursing interns and the comparison between different universities. Knowing that these students of the new generation must be prepared not only with scientific aspects but also with the human part. For this reason, the present research wants to complete this research gap.

The study contributes to the development and consolidation of the topic of research in empathy, and also introduces the concept of empathy in nursing interns through an instrument, which its new version is adapted to the field of nursing-patient. The results will contribute to the improvement of the humanized treatment of the patient.

Conflicts of Interest

The authors declare no conflict of interest

ABSTRACT

The results investigated in this work are toward the optimization of the photonic crystal structures in 1D and 2D scale. One-dimensional distributed Bragg reflectors (DBRs) have demonstrated substantial potential in various optoelectronic applications, due to the observed tunable optical band-gap. Herein, the use of DBRs in light trapping solar cells was simulated and validated, representing its effect as a back reflector structure. In terms of the layer thickness, material selection and number of layer, the optimized DBR structure was modeled and evaluated with respect to previously published numerical and experimental data. The proposed model is capable of designing photonic crystal structures with tunable band-gap varies from 400 nm to 700 nm while controlling the pass-band in both Visible and Near Infra-red regions. On the other hand, 2D grating structure has been simulated where the transmission spectra under various design dimensions have been investigated. Finally, thin film deposition is utilized for experimental validation to our proposed optical model.

1. Introduction

This paper is an extension of the work originally presented at the IEEE Conference on Power Electronics and Renewable Energy (CPERE) in 2019 [1].

Nowadays, new techniques of solar cells have shown a perfect solution to provide low cost alternative compared with conventional methods that used in solar cells [2-10]. These methods depend on using low cost active layer with less than 1 μm thickness and also minimizing the fabrication cost [2, 11-14]. By observing the literature, the reported structures showed low absorption in the active layer [15]. Based on that, the researchers began to find method to avoid the limitation in the absorption layer by using light trapping structures [8, 16, 17] (cf. Figure1). The light trapping structures can be divided into two main classifications, either by function or composition of the structure. The composition of the light trapping structure can be in the form of photonic crystal (PCs) [18] or plasmonics structures [1, 16, 17, 19-23]. The fabrication of PCs structures depends on the contrast between dielectric materials and semiconductor materials (refractive index contrast) which influences the optical properties of the structure [24]. This paper will discuss 1D PCs [25] as well as 2D grating structure for solar cells utilization

Additionally, other new generations of solar cells, namely dye sensitized solar cells and perovskites solar cells, showed enhanced performance with embedding two-dimensional colloidal crystal structures [26-29]. Such colloidal crystal structures are not only acting to enhance the photon capturing of the active layer of solar cells, but can be integrated for decorative purposes [29]. Over and above, light trapping techniques can have a positive role while harvesting diffused light in underwater applications [30, 31]

Light trapping structures can be applied in new technologies of solar cells, by trapping the light in the active layer through embedding nano-structures either above or below the active layer [8]. The technique of applying light trapping in the active layer depends on minimizing the reflected light in the upper layer by using anti-reflecting coating (ARC) while maximizing the reflected light in the back layer. The angle of reflection in the back reflector must exceed the critical angle, targeting total internal reflection in the active layer, which attributes to the absorption [8] (see Figure 1).

Additionally, other new generations of solar cells, namely dye sensitized solar cells and perovskites solar cells, showed enhanced

*Corresponding Author: Sameh O. Abdellatif, British University in Egypt (BUE), Cairo, 11387, Egypt, +201222194077, sameh.osama@bue.edu.eg

performance with embedding two-dimensional colloidal crystal structures [26-29]. Such colloidal crystal structures are not only acting to enhance the photon capturing of the active layer of solar cells, but can be integrated for decorative purposes [29]. Over and above, light trapping techniques can have a positive role while harvesting diffused light in underwater applications [30, 31].

The demonstrated optical model introduces an advanced optimization tool for 1D/2D PCs, seeking for maximum absorption in the active layer utilized in new generation of solar cells. Using Matlab scripting, the developed tool was essentially deployed and proved using a free optical simulator platform called "Open-Filter" [32], while absorption profiles were simulated numerically using Comsol multi-physics. The optimization procedure was applied on particular parameters such as the number of layers constricting the PC structure, the difference in refractive index and the layer thickness. The output results showed complete consistency with the literature data previously measured [20] and simulated [8, 17].

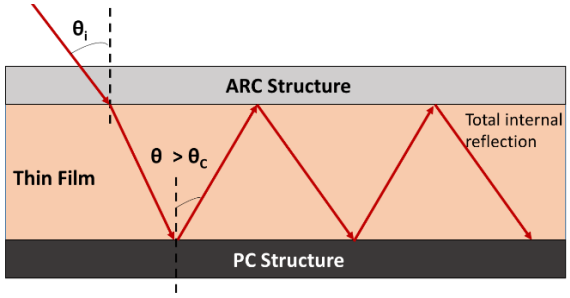

Figure 1: Schematic diagram of sandwiched light trapping structure for solar cells.

2. Optimization Model

2.1. Analytical modeling

The thin film optical modeling represented by characteristics matrix analytical method [33] is utilized in this paper. This method depends on Maxwell's equations which describe by electric field that cross continuously from medium to another. When the incidence of layer was given by electric and magnetic field, the field of both electric and magnetic can derived by matrix that given above [33]:

$$\begin{bmatrix} E_1 \\ H_1 \end{bmatrix} = M \begin{bmatrix} E_2 \\ H_2 \end{bmatrix} \quad (1)$$

where the intensity of electric and magnetic fields in the input medium are E_1 and H_1, while the electric and magnetic fields in the output medium are E_2 and H_2. Herein, M is given by:

$$M = \begin{bmatrix} \cos k_o h & i \sin k_o h/\gamma_1 \\ \gamma_1 i \sin k_o h & \cos k_o h \end{bmatrix} \quad (2)$$

and γ_1 is given by:

$$\gamma_1 = \sqrt{\frac{\varepsilon_o}{\mu_o}} \frac{n_1}{\cos \theta_i} \quad (3)$$

where h is thickness of thin film, k_o represented as propagation coefficient ($k_o = 2\pi/\lambda$), ε_o and μ_o are represented as air permittivity and permeability, refractive index of material called n_1, angle of incidence called θ_i.

A concatenation of layers can be referred to as a system matrix, represented by the multiplication of individual layer matrices. This matrix used to calculate the overall coefficients of reflection and transmission. Open-filters [32] is used as open source of analytic thin film optical modeling where we can validate our characterization matrix results.

Distributed Bragg Reflector (DBR) is a one-dimensional structure of simple photonic crystal. Optical band-gap is formed for Distributed Bragg Reflector as observed by solving Maxwell's equation (more detailed analytical solution for 1D and 2D photonic crystals can be accessed in [16]). The angle of incident and polarization should directly affect the width of band-gap. By incrementing the incidence angle to oblique, the TE modes band-gap becomes wider, while the band-gap of TM mode becomes narrower. This finding leads us to the independence of the band-gap from the polarizations and angle of incidence, as presented later in the discussion section. The photonic band-gap would exist, when contrast of dielectric occurred. In this manner, DBR could be shaped by layers of silicon with thickness 550 nm (n = 3.48) and SiO_2 of thickness 550 nm (n =1.46). The Lorentzian-Drude (LD) model introduced in [9] is used, which explain the absorption and dispersion of silicon as a wavelength dependent function.

2.2. Material modeling

The coefficient of dispersion should be calculated to modal dispersive and absorptive materials. Herein, Lorentzian-Drude (LD) model through FDTD simulations are enrolled [34]. The LD modal divided into two models. The Drude model is defined as the first model that, due to intra-band transitions, directly affects background absorption and dispersion. The second modal that represents dispersive media by multiplying resonant frequencies is the Lorentz model.

The model of semi-quantum reflects the electronic inter-band transitions. A material using the LD model's complex permittivity could be expressed by:

$$\varepsilon(\omega) = \varepsilon_{\bowtie} + \sum_n \frac{\sigma_n \omega_n^2}{\omega_n^2 - \omega^2 - i\omega\Gamma_n} \quad (4)$$

where $\varepsilon_{\bowtie}$ is the instantaneous dielectric response (DC), Γ_n and ω_n are the LD coefficients and σ_n is a position function that defines the power of the n^{th} resonance. Figure 2 shows the optical model for the DBR structure to be optimized. The optimization process is considering the number of DBR layers, reflective index (n_1– n_2), and the thickness of the layer (h_1, h_2).

2.3. Structure optical modeling using FDTD

The finite difference time-domain (FDTD) algorithm is used to make simulation of light interaction with various structure of layers [35]. The (FDTD) algorithm is considered as a standard numerical technique in classical electromagnetism. To simulate (FDTD) algorithm, open source algorithm is used called MEEP [36].The simulated volume is reflected on the required simulation time and RAM that required to make simulation on MEEP. A runtime of nearly 10 ns per pixel per time step of time is needed with RAM of almost 100 bytes per pixel [37].

MEEP was used to implement simulation of reflection and transmission of light by using different structure of light trapping. 10 μm × 10 μm is volume that used in simulation with unit step and resolution of 10 nm and 10 respectively. The wavelength is set as 550 nm to simulate sun irradiance for TM and TE modes. Figure 3, shows the modal with two detectors integrated for the calculation of transmitted and reflected field.

The maximum intensity of AM1.5G is determined to be 1000 W/m^2. Two identical Gaussian light sources with a width from 200 nm to 1500 nm and a mean wavelength of 550 nm, were utilized to represent TE and TM modes. It is important to model and integrate in MEEP the wavelength dependent variation in the real and imaginary parts of the refractive index for different materials used. Here, we integrate the published LD model to illustrate the complex refractive indices using the Lorentzian-Drude (LD) coefficients for the chosen materials with specific focus on Si as a semiconductor material. The compatibility of the LD model with MEEP is considered as the main reason for selecting it [38].

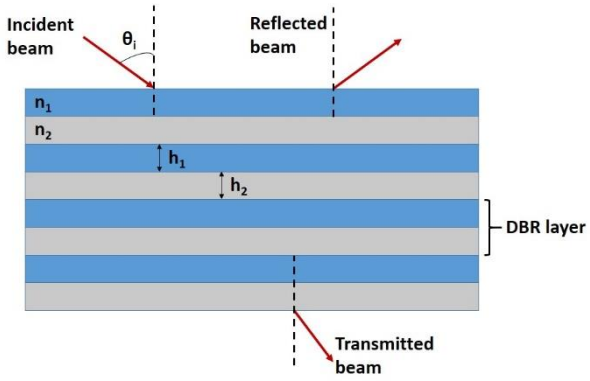

Figure 2: Schematic diagram of the structure of the DBR under test.

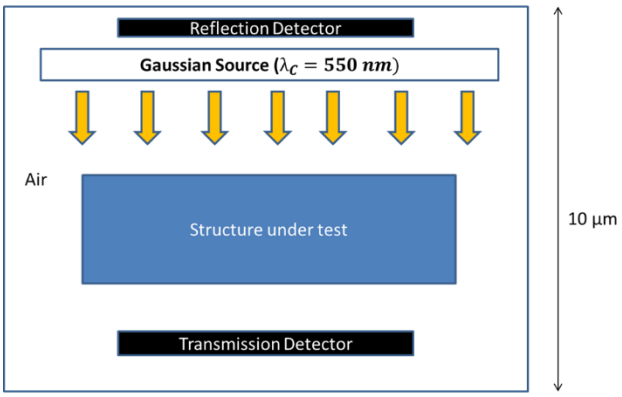

Figure 3: Schematic diagram used for the calculation of transmission and reflection spectra for the MEEP model.

2.4. 2D optical modeling using Comsol Multi-physics

Using the commercial simulator Comsol Multiphysics 5.0 [37], optoelectronic modeling is carried out. Comsol utilize finite element method (FEM) solver such that a tetrahedral mesh is selected based on the minimum feature length in the geometry under investigation. Various 2D optical structures devices could be simulated by optical and electromagnetic libraries and are modeled by the continuity, Poisson, drift-diffusion and Maxwell's equations assuming 2D solution. The targeted solar cells with light trapping structure are described as a p-i-n junction [39]. Consideration is also provided to the bulk, surface recombination, and contact effects. The primary governing equations are given by [8]:

$$-\nabla.\left(\frac{\varepsilon_o \varepsilon_r}{q}\nabla V\right) = -n + p + N_D(1 - f_D) - N_A(f_A) + \sum_j N_{tj}(\delta_j - f_{tj}) \quad (5)$$

$$\nabla.J_n - \sum_j R_n^{tj} - R_{sp} - R_{st} - R_{av} + G_{opt}(t) = \frac{\partial n}{\partial t} + N_D\frac{\partial f_D}{\partial t} \quad (6)$$

$$\nabla.J_p - \sum_j R_p^{tj} - R_{sp} - R_{st} - R_{av} + G_{opt}(t) = \frac{\partial p}{\partial t} + N_A\frac{\partial f_A}{\partial t} \quad (7)$$

where p and n are the excess hole concentration and minority-electron concentration with respect to equilibrium, N_A and N_D are the doping levels of acceptors and donors, J_p and J_n are the current density for holes and electrons, R_p and R_n represent the bulk recombination of holes and electrons, G_{opt} is the term for optical generation, R_{sp} represents the recombination of surfaces, and R_{av} and R_{st} are trapping recombination. The required optoelectronic parameters per each layer are captured from the simulation tool library and the optical generation term is calculated using an Matlab based optical model, taking into confederation a doping level of 10^{18} cm^{-3} in both the n and p sides [10].

Herein, the optical generation parameter G_{opt} plays a critical role in investigating the optical impact of the proposed photons management structure in enhancing the performance of the solar cell. The expected enhancement can be attributed to the elongation of the optical path length inside the active materials under simulation. This elongation is directly reflected on the generation term.

3. Simulation Results

3.1. Optimizing number of layer in DBR structure

Si-SiO$_2$ DBR structures have been simulated following the characteristics matrix analytical approach defined in the section two. Based on our previous work, these DBR structures were taken into account as an initial model to be optimized [8]. Firstly, the influence of the DBR layers on the presence of the optical band-gap was originally discussed in Figure 4. The spectra showing the reflectance are plotted and the structures of two, four and six DBR layers have been simulated. Here, the ratio between the the reflected light and the incident light is termed as the optical reflectivity (dimensionless unit), cf. Figures 2 and 3.

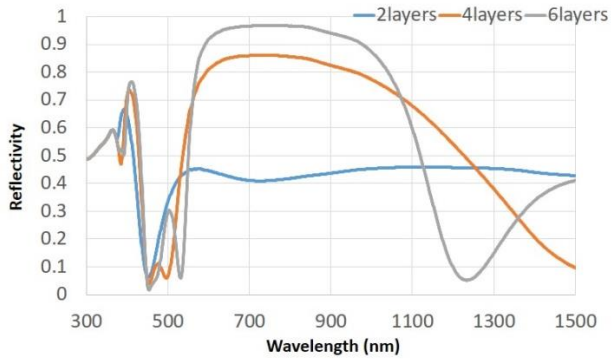

Figure 4: Si-SiO2 Reflectivity of DBR for different layer numbers.

It is evident from Figure 4 that the occurrence of the optical band-gap is associated to the number of layers constructing the one dimensional photonic crystal structure. 550 nm optical band-gap

(from 550 nm to 1100 nm) was formed with reflectively of around 0.95, while utilizing six DBR layers structures. In contrast, attention should be given to the trade in parameters concerned to the overall DBR dimensions and to the fabrication procedure sophistications. For instance, a sharper optical band-gap is anticipated by increasing the number of layers, more than six, however the complicity and fabrication cost will increase as well. Thus, the optimal structure in terms of layer count for such Si-SiO_2 DBR structure is the six layer DBR structure. It is worth noting that this layer number is not a global optimum, as the observation of the optical band-gap depends not only on the DBR layers count, but also plays the refractive index contrast plays an critical role.

3.2. DBR thickness optimization

Following the first optimization stage demonstrated in section 3.1, Figure 5 shows the influence of the thickness variance on reflectivity. The DBR structure of six layers optimized in section 3.1 is used. To reduce the variables included in the optimization problem under investigation, the thickness of both layers, SiO_2 and Si, are considered equal. Figure 5 examined 550 nm, 250 nm, and 125 nm reflectivity spectra. The nominated wavelengths are selected to fit the peak wavelength for the input source at 550 nm. Consequently, λ_o , $\lambda_o/2$ and $\lambda_o/4$ thicknesses have been simulated. As shown in Figure 4, the presence of the photonic-gap is associated at thin film thickness of $\lambda_o/4$. This is attributed to the maximum local point at which the maximum reflection occurs. The thin film thickness is nominated to be a 1/4 of the optical wavelength where maximum reflection is observed [14]. In view of the projection of a quarter wavelength layer of Si with a refractive index of n_1 and light on a wavelength layer of λ_o, the thickness h_1, which induces maximum reflection, is determined by [14]:

$$h_1 = \frac{\lambda_o}{4\, n_1} \quad (8)$$

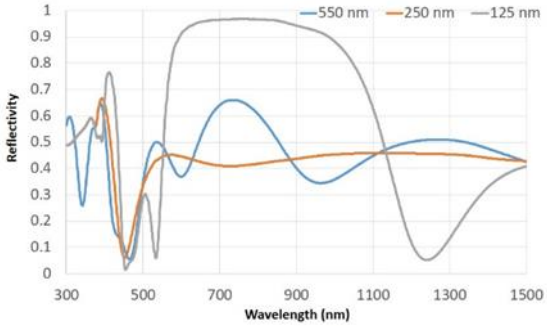

Figure 5: Six Si-SiO2 DBR reflectivity layers with various layer thicknesses.

3.3. Refractive index contrast optimization

Finally, Titanium dioxide is integrated as a direct substitution for Si, in order to examine the impact of refractive index contrast variation on the photonic-gap. TiO_2 is chosen as an easily prepared, low-cost and efficient n-type semiconductor material, knowing that we have already investigated its refractive index experimentally in [28]. Manual as well as automated Dr Blade screen printing can be utilized, as a sol-gel method, to deposit thin film of TiO_2 layer in micrometer range as previously discussed in [28]. In such context, diluted paste with isopropanol can be managed to tune the thin film thickness [27]. The large variation between the refractive index of TiO_2, nearly 1.78, and that of Si, around 3.9 [26], negatively contribute to the detected width of the band-gap. This narrowing can be observed in Figure 6, as a reduced, less sharp optical band-gap with maintaining the number of layers in both DBRs under test.

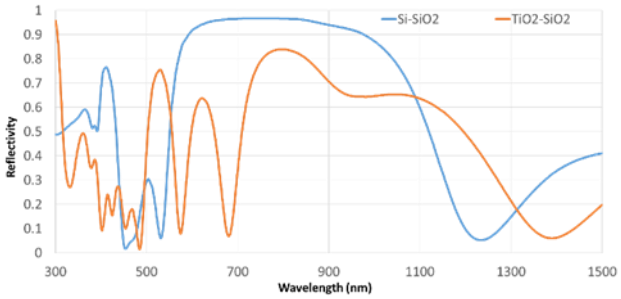

Figure 6: 125 nm, six layers Si-SiO2 and TiO2-SiO2 DBR reflectivity.

3.4. Absorption profile simulation

Towards more optical investigation in the DBR structure optimized in the previous versions, Comsol Multi-physics was utilized. Herein, six layers Si-SiO_2 DBR modeled in the previous section were simulated. The electric field components are used to describe the absorption profile following the Poyting vector method illustrated in [8]. The demonstrated optical absorption profile shown in figure 7, at 550 nm, illustrates the trapping functionality of the DBR structure to trap light inside the active material seeking for optical path length elongation. Accordingly an enhancement of nearly 38% is recorded in the optical generation term. The simulation has been conducted over an optical wavelength range from 200 nm (UV-range) to 2000 nm (IR-range) with a peak at 550 nm.

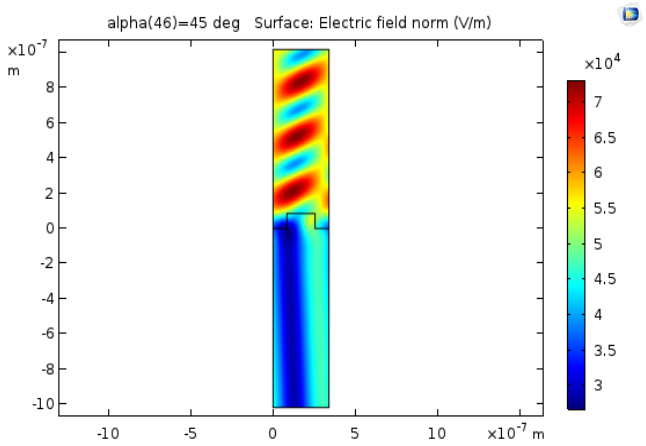

Figure 7: 125 nm, six layers Si-SiO_2 absorption profile.

3.5. Two-dimensional grating light trapping structure

As shown in figure 8a, a 2D grating is characterized as structures that are periodic with a periodicity L in two-dimensions, (e.g. x-direction and y-direction), and are uniform in only one dimension (z-direction). We consider the propagation of incident light in the xz-plane. Since the structure considered is two-dimensional, the reaction of the structures can be separately considered for the s-polarization, which has its electric field polarized along the y-direction, and for the p-polarization, which, as shown in figure 8b, has its magnetic field polarized along y-direction.

With a periodicity L of 1 µm, SiO_2 thickness d_2 of 100 nm, and an aspect ratio (a/b) of 1 (figure 8b), a 2D Si/SiO_2 grating structure is simulated. The minimum x-direction dimension b = 500 nm is used to allow such a device to be fabricated in an area of 200 µm x 200 µm. Furthermore, another experiment was carried out in order to simulate the same structure but with aspect ratio of 2.4. The reflectance of this structure is shown in Figure 9 in the near infrared region with an optical band-gap. With respect to the DBR structure, this shifting in the optical band gap structure is due to the scaling up of the minimum dimension length from 50 nm to 500 nm.

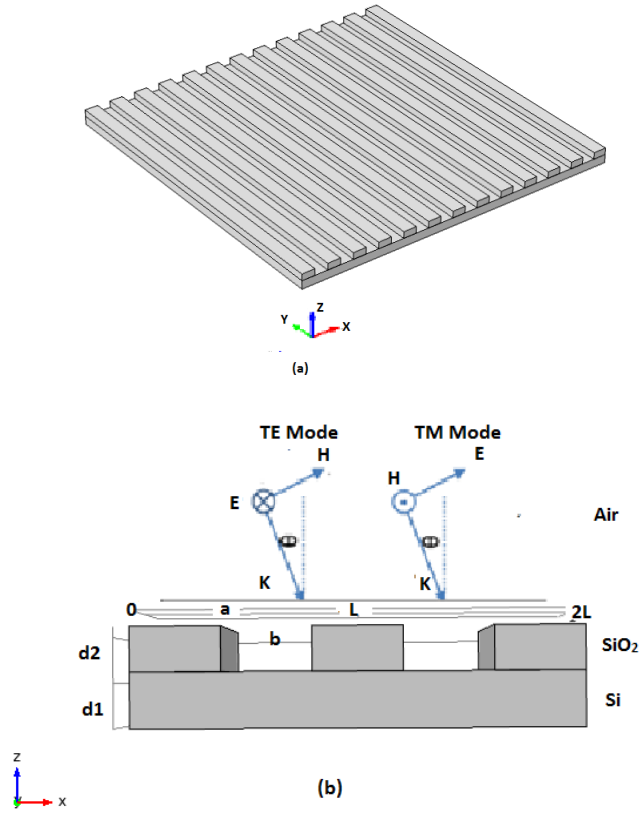

Figure 8: (a) 3D schematic for the structures of 1D grating. (b) X-Z cross section for 1D grating structure.

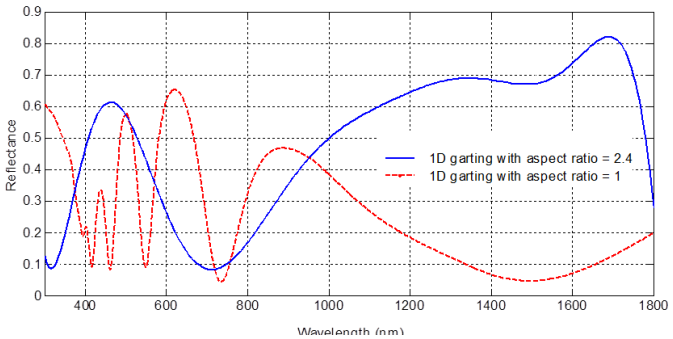

Figure 9: 1D grating structure with aspect ratio of 1 (red curve) and 2.4 (blue curve).

4. Fabrication Process

As mentioned in the introduction, one of our targets here is to fabricate thin film to validate our proposed optical model. Herein, thermal evaporator and spin coater are suggested to be used for this process, while UV-Vis spectrometer is used for the optical characterization purposes.

The thermal evaporator consists of different subsystems. One of the subsystems is the vacuum chamber, the control valves, the vacuum pumps are integrated to satisfy the vacuum itself, and the gauges is utilized to evaluate the pressure level in the chamber. Another obvious subsystem is the filament and the current source required to heat the filament and to control its temperature. Another subsystem measures the thickness of the deposited film so that we can know when the targets are evaporating and when the film deposition is complete. A more trivial subsystem is the framework used physically to hold the substrates and to control whether the evaporated material reaches the substrates.

The Spin coater is equipment enrolled in deposing thin films to flat surfaces substrates. A coating material, usually called suspension, is drooped in the center of the sample before starting the spinning process. The sample is then rotated either in one step or multi-steps with a certain rotating speed and acceleration. This rotation produces the thin film with the aid of centrifugal force.

The speed and the acceleration chosen play an important role in adjusting the thickness of the produced film. The used suspension is usually chosen to be easily evaporated and volatile. It is also worth to mention that not only the speed and acceleration of rotation tune the thickness but also the viscosity and concentration of the suspension. However, in principle, the faster the rotation speeds, the thinner the produced film. Typically, spin coater are used in deposing thin films of few nanometers thick to micrometers range such as the photoresist materials.

For optical characterization, the UV-Vis spectrometer used to scan the ultraviolet to near infrared regions including the visible portion of spectrum. The basic setup of the UV-VIS spectrometer is consisting of a light source which includes two lamps. The first is a tungsten-halogen lamp for the visible and the near infrared (NIR) region. For the UV region, the deuterium lamp is used A NIR and a visible light detector are used in detecting light. Finally, fibers optics cables are used to connect the source detectors and sample holder (cf. Figure 10).

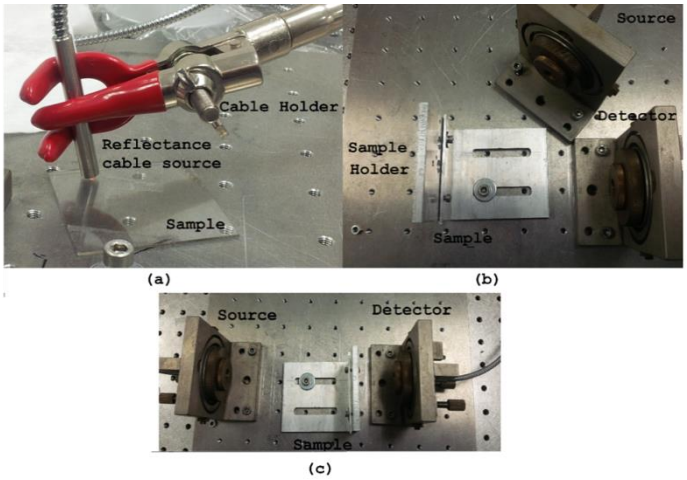

Figure 10: (a) Measuring reflectance using three terminals fibres cable. (b) Measuring reflectance using source/detector setup. (c) Measuring the transmission

5. Experiential validation

In order to validate order optical proposed model, experimental validation take place using thin film based samples. A thermal

evaporation process is used to evaporate a 70 nm of Ag on a highly P-doped Si wafer. The highly P-doped Si wafer is chosen to maintain its optical characteristics during the fabrication process. The thermal evaporation process is done under a current rate of 12% where the tooling factor was previously determined using a dektak profilometer and it was found to be 0.551. The output evaporation rate is 0.1 nm/sec. Then a characterization process takes place using UV-VIS spectrometer to measure the reflectance of the sample in the desired portion of the spectrum as shown in figure 10. The effect of adding the collimating lens is also considered here showing a more accordance with the simulation results than the without collimating lens results. The simulation results shown here are based on our optical numerical model described in the previous section.

The results shown in figure 11 is not only considered as a new validation step to our optical model but it can also be considered as a validation to the new suggested measurement setup of the UV-VIS spectrometer with adding collimating lens. The results show that the adjusted lens doesn't cause any undesirable effect in the wavelength portion of interest making it possible to use such a setup in measuring the reflectance of small area samples.

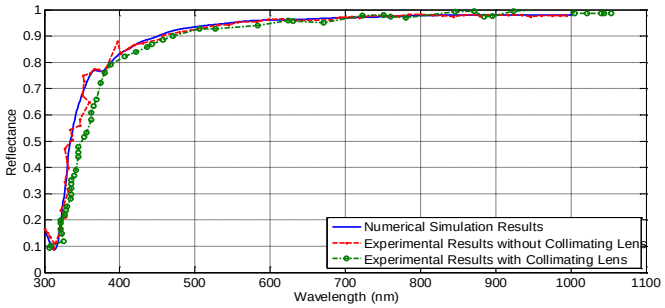

Figure 11: Comparison between the simulated and the measured reflectance of a 70 nm Ag thin film.

A 40 nm thin film of SiO_2 is deposited on a Si <100> wafer using thermal evaporator. The tooling factor is calculated and it was 0.1812 while the current rate is set to be 35%. It is observed that the current needed to evaporate SiO_2 is much higher than that used for Ag, this is due to the high evaporating temperature of SiO_2 with respect to that of Ag. The evaporation rate is varying around 0.01 nm/sec. The Reflectance of the thin film is measured using the UV-VIS spectrometer as observed in figure 12. The figure shows a high accordance between the numerical simulated and the measured reflectance. It was found that due to the high evaporating temperature of SiO_2 (about 1800 ^oC); it is not efficient to evaporate thin film of SiO_2 using thermal evaporation technique. As deposing thin film of SiO_2 must be done by more than one iteration, due to the very low evaporating rate, which causes a poor uniformity of the surface.

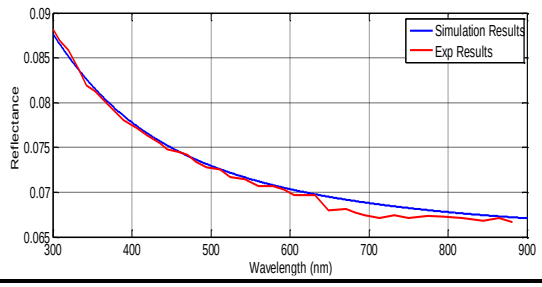

Figure 12: Comparison between the simulated and the measured reflectance of a 40 nm SiO_2 thin film.

It's worth to mention here that the optical validation process implemented on two sample of thin films behaving as optical filter showed perfect agreement with the data captured from our proposed optical model. However, the validation process demonstrated in this paper is limited to thin films samples due to constrain associated with photonic crystals fabrication. Accordingly, we consider the validation step with fabricated photonic crystal structure as a future extension of the current work.

6. Discussions

After the iterations used to optimize DBR structure the output for three steps of optimization that shown in section 3 and also take in consideration the previous measurement in [8], shown in figure 13. By our requested of optimization modal, it is shown the suitable match. Our represented structure is suggested structure to back reflector of thin film of solar cells. This model of structure lead to optical band-gap in near infrared and far visible region, (from 800 nm to 1100 nm) the low absorption occurred at the layer of Si. We attribute such extended band-gap to the refractive index contrast with respect to the DBR shown in figure 5. This structure showed below describe the performance of non-absorbed photons which cannot escape from active layer, after that the light trapping occurred inside material. It is worth to mention that the height (y-axis reflectance value) is inversely proportional to the optical band gap-width [16]. The higher the reflectance the lower the band-gap.

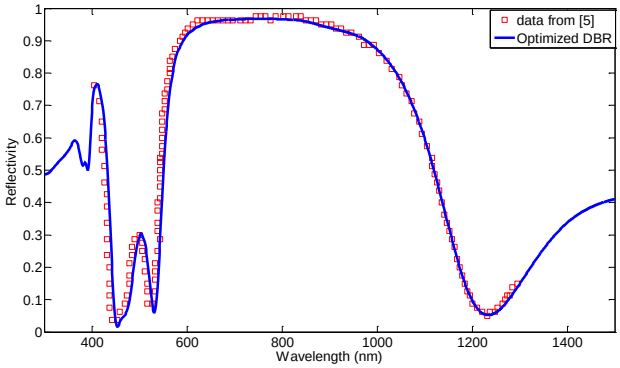

Figure 13: 125 nm, six layers Si-SiO_2 DBR verification with previously published data in [5].

A primary downside within the proposed silicon-slica DBR structure is that the nonappearance of metal which may act as a counter electrode. Consequently, another altered DBR structure with Indium tin-oxide (ITO) rather than Si can be suggested. Though, the proposed planned structure will lack of a condensed optical band-gap because of the less index of refraction distinction with the ITO-SiO_2 DBR with respect to the optimized Si-SiO_2 DBR structure. Additionally, the proposed ITO-SiO_2 DBR structure will show more refined fabrication process, particularly within the deposition of SiO_2 layer the thin ITO layer. Regularly the SiO_2 deposition is achieved by chemical vapor deposition (CVD) at moderately high temperature. Such testimony conditions might influence the ITO electrical properties yet as morphology.

Fundamentally, Nano-lithography technology can be essentially used to fabricate higher dimensions (2D and 3D) photonic crystal structure. In this manner, more refined manufacturing processes and costs would be expected. This specifically influences the cost of delivered energy (Wh/$) by TFSCs. An inclusive analysis showing the effect of the 1D, 2D, and 3D PCs structure in terms of cost versus increase in conversion

efficiency can be carried out as a future task. In principle, alternative low-absorption solar cells can be upgraded using the same light trapping process.

7. Conclusion

The optimization in DBR structure that represented in the paper depends on thickness of layers, refractive index contrast and number of layers. The optimization of DBR structure implement in two step, firstly analytical implantation by MATLAB and secondly verification by using Open-filter. In order to simulate the solar spectrum (AM1.5G), Gaussian sources and FDTD were used.

By using 6 layers of Si-SiO_2 of DBR as result of optimization, the band-gap occurred in 550 nm. This band-gap represents a massive potential in Si as reflected near-infrared of photonics and this reflection avoid light from escaping from material. After comparing between previous data that published and our simulation results, the suitable match was chosen. On another hand, TiO_2 was examined as alternative of Si to observe the effect of changing refractive index in the optical band-gap. At the end the effect of adding metal layer of ITO on Si as substitution was discussed in this paper and released the effect of it on the optical band-gap. Additionally, 2D grating structure was also examined based on the developed optical mode, where transmission spectra were simulated. Fabricated thin films were utilized to validate the optical model while a perfect matching was recorded.

The proposed optical model has showed a great potential in designing optimal 1D and 2D photonic crystal structures with a tunable optical band-gap varying from 400 nm to 700 nm capable of integrating in various solar cells applications. Moreover, the study investigates the optical absorption profile for various photonic crystals seeking for minimum parasitic absorption.

Acknowledgment

In this work, the authors would like to acknowledge the contribution and support of the STDF. As part of the STDF Project entitled, “Mesostructured Based Solar Cells for Smart Building Applications”, Project ID#33502. Additionally, the authors would like to thank the Centre for Emerging Learning Technology (CELT), directed by Prof. Hani Ghali, in BUE for providing all the fabrication facilities needed.

ABSTRACT

In this paper, a modified configuration of Single-Phase Seven-Level Packed U-Cell (PUC) Multilevel Inverter for solar photovoltaic system is presented & investigated for standalone operation. The Seven-Level MPUC Inverter comprises of six semiconductor switches & two DC links which generates seven voltage levels at the inverter output. The maximum amplitude of inverter output voltage is more than that of available maximum DC link value (i.e. sum of two DC link values). The voltage levels generated in the MPUC inverter is more with reduced number of components counts as compare to conventional multilevel inverter topologies like Cascaded H-Bridge (CHB) and Neutral Point Clamped (NPC). The proposed inverter finds application in PV System where green power is derived from two PV panels with different power rating and voltage rating connected to DC links. Several design considerations viz. the RMS value of inverter output voltage, switching frequency & voltage rating of semiconductor switches are taken into consideration to prove the advantages of the MPUC inverter. The simulation results of the MPUC inverter shows the appropriate operation of multilevel inverter.

1. Introduction

Owing to growing number of consumers in addition to large scale power industries, the power grid has experienced large energy demand from last decade. Traditional bulky transformers are significantly replaced by power electronic devices because a lot of research work is happening in power electronic field these days resulting in advancement of semiconductor device technology. Power converters are utilized as a conversion medium for transferring green power either for grid or a standalone load. Economic pricing of power semiconductor devices makes it beneficial to produce and allow them in competitive market. Recently, the use of a greater number of switches in the converter causes no significant rise in pricing. This is the reason that the traditional two-level converters having high harmonics and power losses are being interchanged by the multilevel inverters having less switching frequency [1, 2].

Now, the focus of researchers has moved towards developing various topologies of multilevel inverters and their control strategies. So, the foremost attention is to reduce the component counts in these inverters. Fewer the component counts, lower the cost and power loss [3]-[5]. The two most popular commercially available multilevel inverter (MLI) topologies are CHB and NPC inverter topologies [6].

Recently, the flooding of green power into the grid has become a prime concern [7]. Most of the countries have initiated to implement the solar power panels at broad scale to cater the local energy need. With the use of power electronic converters, the DC power is converted into AC power which is further transferred to the grid or a standalone load.

Thus, the improvement in conversion efficiency and reduction in power loss of these converters are tackled in several reports [8-9]. Conversion of DC voltage of PV system into AC waveform with low harmonics to be used by the grid or standalone load with high conversion efficiency and small size filtering requirement can be fulfilled by single-phase multilevel inverters (MLI) [10].

The key problem with most of the topologies are to use numerous isolated DC sources which makes it difficult for its practical implementation. An isolated DC source can be made by an AC transformer and diode bridge rectifier which is a costly affair and become bulky for manufacturing. Consequently, topologies having single DC source i.e. NPC (Neutral Point

*Corresponding Author: Kishan Bhushan Sahay, kishansahay16@gmail.com

Clamped) inverter and five-level PUC (PUC5) inverter [11] are commercially more viable than other new topologies. Nevertheless, some topologies e.g. CHB are utilized for very high-power applications owing to necessity of large number of DC sources.

In latest survey, seven-level PUC inverter topology was introduced which has many advantages like low component counts and numerous output voltage levels [12]. The key problem with PUC inverter is its maximum output voltage level which is actually the maximum available DC link value of the topology. In recent times, a seven-level modified PUC inverter topology has been presented which provides an alternative for those applications where several Photovoltaic panels are available for connecting it to isolated DC links. In [13], the authors demonstrated that Photovoltaic panels having different voltage rating & power rating can be coupled with two DC link of modified PUC inverter topology.

In this paper, modification of Seven Level Packed U-Cell inverter is done for solar PV systems. MPUC inverter topology is similar to CHB inverter having unequal DC sources where two cells produces seven voltage levels. The introduced inverter has a smaller number of semiconductor switches than the CHB inverter with equivalent performance. In MPUC inverter, two unequal DC sources (i.e. two PV panels with different power rating) are required to generate seven output voltage levels by means of reduced harmonic and uniformly distributed voltage levels. The maximum inverter output voltage level is sum of amplitudes of two dc sources. So, authors call it as Modified PUC Inverter (MPUC).

The seven-level PUC inverter is elaborated in section II. Subsequently, seven-level MPUC topology is described in section III. The rms value of seven level inverter output voltage for standalone operation is discussed in section IV. The results obtained from simulation of MPUC inverter has been given in section V. Conclusion is specified under section VI.

2. Seven-Level Packed U-Cell Inverter

The template is used to PUC inverter topology was first introduced by Al-Haddad in 2010 & later it was advanced by Hani Vahedi in 2015 [14]. PUC inverter is among the most promising multilevel inverters which takes advantages of both Flying Capacitor Converter (FCC) & CHB inverter. This topology is known as Packed U-Cell as the shape of each inverter unit is in U form. In Each U Cell, it contains two semiconductor switches & one DC voltage source. PUC topology work only with one DC source & a smaller number of active and passive components. Six semiconductor switches with anti-parallel diodes are used to achieve seven voltage levels which is evident from figure 1.

These 6 switches are divided into two legs having three switches in each leg. In one leg, there are three main switches (Q_1, Q_2 & Q_3) and in another leg, there are three complimentary switches of main switch ($Q_{1'}$, $Q_{2'}$ & $Q_{3'}$).

Various voltage levels are achieved either through DC voltage sources available or through their series opposition provided the amplitude of second DC source (V_2) is equal to one third of amplitude of first DC voltage source (V_1) i.e. $V_1 = 3V_2$. Thus, inverter output voltage has seven-voltage levels i.e. 0, $\pm V_2$, $\pm 2V_2$, and $\pm 3V_2$. From the Table I, it can be concluded that there are 3 positive voltage levels, 3 negative voltage levels and 2 zero voltage levels (viz. state 4 and 5). All eight switching states are shown graphically in Figure 2. Zero voltage level can be achieved only when the load is either shorted through main switches or through complimentary switches. Redundant zero voltage states are utilized by appropriate means just for reduction in switching frequency at the time when there are changeover in between positive & negative half cycles of AC signal.

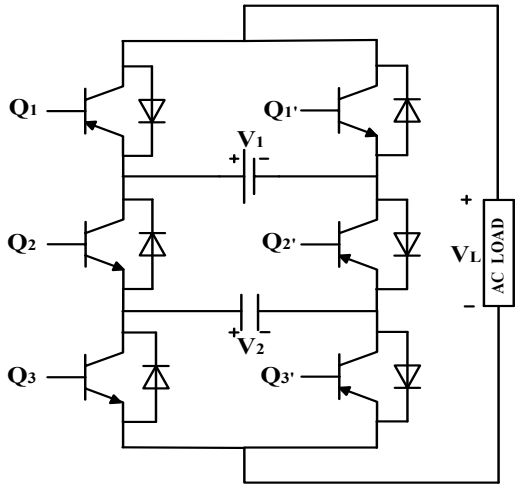

Figure 1: Packed U-Cell (PUC) Inverter Topology

Table 1: Complete Switching States & Voltage Levels

Switching States	Q_1	Q_2	Q_3	$Q_{1'}$	$Q_{2'}$	$Q_{3'}$	$V_{inv} = V_L$
1	1	0	0	0	1	1	V_1
2	1	0	1	0	1	0	$V_1 - V_2$
3	1	1	0	0	0	1	V_2
4	1	1	1	0	0	0	0
5	0	0	0	1	1	1	0
6	0	0	1	1	1	0	$-V_2$
7	0	1	0	1	0	1	$V_2 - V_1$
8	0	1	1	1	0	0	$-V_1$

From above switching states Table I, it can be concluded that irrespective of change in switching frequency and carrier frequency of adopted PWM technique, the switches Q2 & Q2' operate at line frequency (i.e. 50 Hz). This results in significant reduction of switching losses. Thus, the switches produce flow of current in the DC bus resulting in the use of a series diode for blocking the reverse voltage. To overcome this problem, an energy storage element i.e. Capacitor is used as a second DC source. The voltage across capacitor must be one third to that of V1 which can be achieved by various voltage balancing techniques. The current through the capacitor is in positive and negative parts which shows that there is charging and discharging in the capacitor [15]-[19]. Thereby achieving the desired voltage level for generating constant desired inverter output level. The biggest issue in using PUC inverter topology is its low maximum voltage level i.e. the maximum amplitude of the PUC inverter topology is maximum value of amplitude of the two voltage sources. Thus, the PUC inverter can't generate voltage more than the maximum value of the two voltage sources. So, it doesn't get application in medium or high-power applications [20]-[23].

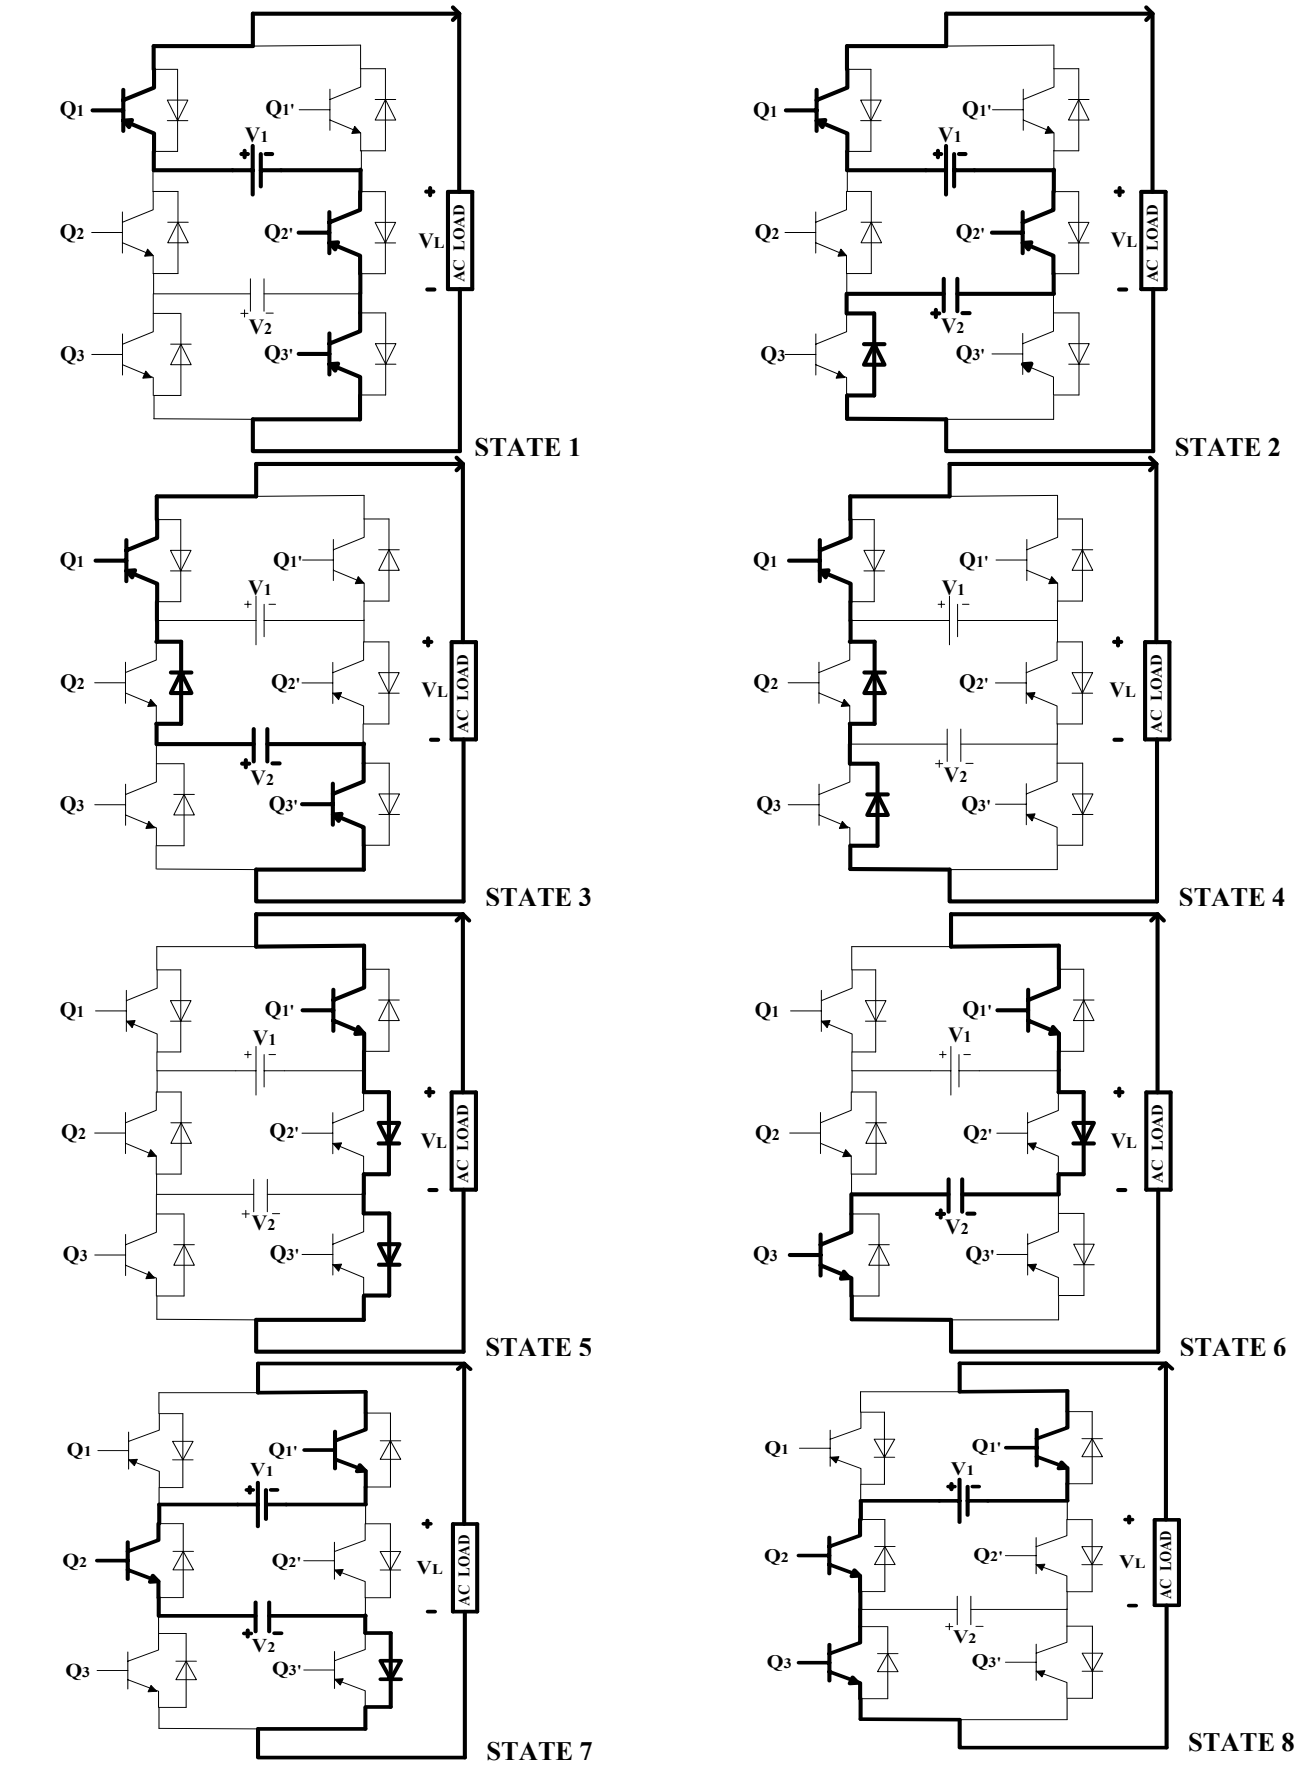

Figure 2: Switching States for PUC Inverter Topology

3. Seven-Level Modified Packed U-Cell Inverter

Due to recent advancement in solar panels and its economic cost, it becomes feasible to use number of PV panels as DC sources. Hence multilevel inverters using large number of DC sources are justified economically. The maximum output voltage in PUC inverter is not more than that of maximum DC voltage source magnitude. To solve this issue, the MPUC inverter topology is proposed as shown in figure 3. The DC source (V_2) is attached in reverse direction when compared to PUC inverter. So, the lower switches viz. Q_3 & $Q_{3'}$ have also been reversed to hinder current through diodes. Thus, with appropriate use of gate pulses, the path of current flow can be allowed or hindered. Various Switching states & output voltage levels for MPUC inverter is shown in Table II. From table II, it can be concluded that maximum inverter output voltage of MPUC inverter is nothing but total addition of two DC voltage sources i.e. V_1+V_2 which can be obtained by joining two voltage sources in series. Thus, we are getting more voltage amplitude by this proposed topology. It is evident that seven uniform voltage level is produced by MPUC inverter provided the second DC source (V_2) amplitude is two times the first DC source (V_1) amplitude i.e. $V_2 = 2V_1$. So, the output voltage levels have following levels: 0, $\pm V_1$, $\pm 2V_1$, $\pm 3V_1$. Thus, the maximum output voltage amplitude will be $3V_1$ while maximum DC source is equal to $2V_1$. The voltage level $3V_1$ is obtained by joining two DC voltage source V_1 & V_2 in series which appear on load. The voltage level $2V_1$ can be achieved by making second DC voltage source V_2 to be appear on the load. The voltage level V_1 can be achieved by making first voltage source V_1 to be appear on the load [24]-[26].

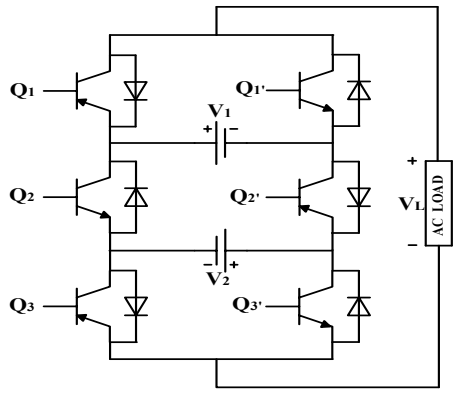

Figure 3: MPUC Inverter Topology

Table 2: Complete Switching States & Voltage Levels

Switching States	Q_1	Q_2	Q_3	$Q_{1'}$	$Q_{2'}$	$Q_{3'}$	$V_{inv} = V_L$
1	1	0	0	0	1	1	$V_1 + V_2$
2	1	0	1	0	1	0	V_2
3	1	1	0	0	0	1	V_1
4	1	1	1	0	0	0	0
5	0	0	0	1	1	1	0
6	0	0	1	1	1	0	$- V_1$
7	0	1	0	1	0	1	$- V_2$
8	0	1	1	1	0	0	$- V_1 - V_2$

Eight switching states are presented graphically in figure 4. Here are two redundant zero voltage states viz. state 4 and 5 which is used in the reduction of switching frequency. When zero voltage level is required to be generated at the output, the modulation technique selects the appropriate state in state 4 and 5 to give gate pulse to switches which gives less change in Turn-On & Turn-Off mode of operation resulting in significant reduction in switching frequency. From the switch states shown in table II, it can be concluded very clearly that irrespective of change in switching & carrier frequency, the two switches viz. Q_2 & $Q_{2'}$ operate at the line frequency i.e. 50 Hz.

4. Design Consideration of Standalone Operation

A mathematical analysis has been done for the standalone application of MPUC inverter supplying power to single-phase load. Here we aim to determine general expression for output voltage waveform of seven-level MPUC inverter based on figure 5.

The general expression for determining RMS voltage is given by:

$$V_r = \sqrt{\frac{1}{T}\int_0^T v_0^{\,2}(t)\,dt} \tag{1}$$

where Vr is RMS voltage, v_0 is time function of voltage and T is time period of the periodic function.

Thus equation (1) can be rewritten as follows:

$$V_r = \sqrt{\frac{1}{2\pi}\int_0^{2\pi} v_0^{\,2}(t)\,dt}$$

$$= \sqrt{\frac{1}{2\pi}\left[4\int_{\theta_1}^{\theta_2} V_1^{\,2}\,d\omega t + 4\int_{\theta_2}^{\theta_3} V_2^{\,2}\,d\omega t + 2\int_{\theta_3}^{\theta_4}\left(V_1+V_2\right)^2 d\omega t\right]}$$

$$= \sqrt{\frac{1}{2\pi}\left[4V_1^{\,2}\alpha + 4V_2^{\,2}\beta + 2\left(V_1+V_2\right)^2\gamma\right]} \tag{2}$$

Since $V_2 = 2V_1$

$$V_r = \sqrt{\frac{1}{2\pi}\left[4V_1^{\,2}\alpha + 4\left(2V_1\right)^2\beta + 2\left(3V_1\right)^2\gamma\right]}$$

$$= V_1\sqrt{\frac{2\alpha + 8\beta + 9\gamma}{\pi}} \tag{3}$$

where α , β and γ are angles at which reference signal crosses voltage levels as fixed lines between the carriers. The RMS value of output voltage can also be determined in term of modulation index (m_a) and maximum output voltage level ($V_{max} = 2V_1$) which is given as follows:

$$V_r = 0.725 \times m_a \times V_{max} \tag{4}$$

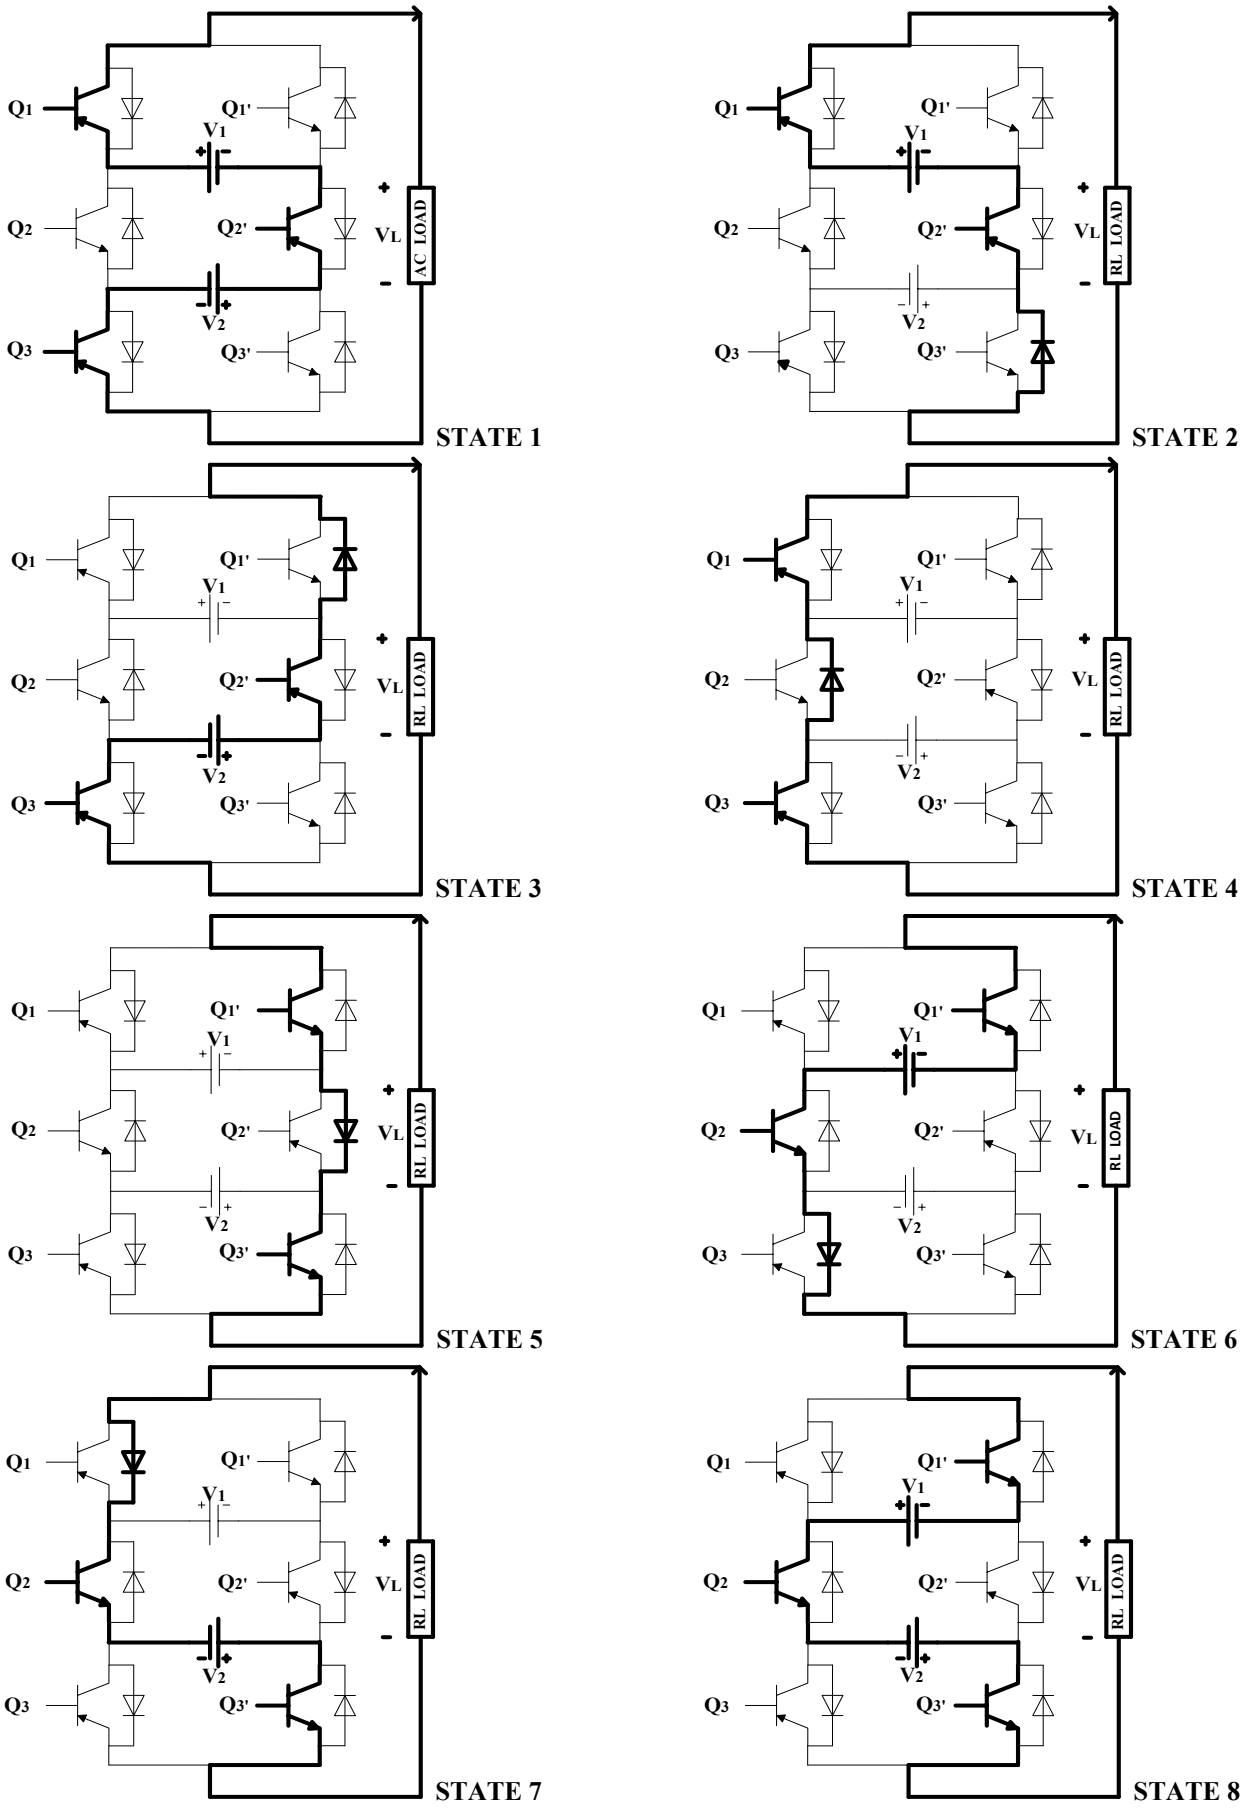

Figure 4. Switching States for MPUC Inverter

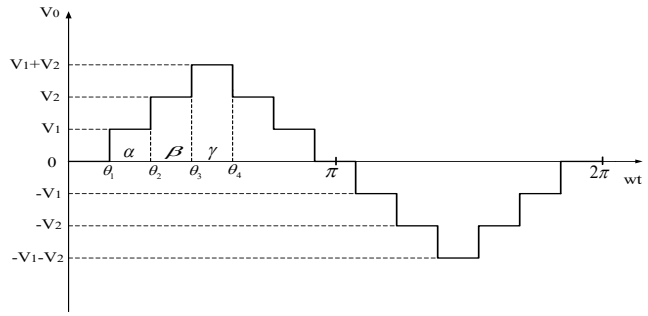

Figure 5: Seven-Level Inverter Output Voltage Waveform

5. Simulation & Results

The introduced MPUC inverter topology is simulated in standalone mode of operation to validate the above analysis. Six IGBT switches are taken in the simulation model. The switching algorithm adopted is elucidated in [16] where four level shifted carriers are used for modulating the reference signal. Thus, gate pulses are given to all the six pulses. Table III gives complete view of simulation parameters.

Here two DC sources viz. V_1 and V_2 are joined to different DC links of PV panels having different power & voltage rating and standalone load has been taken at the output. At higher switching frequency, passive components size reduces significantly.

Here the MPUC inverter is connected to RL load because most of the AC loads are inductive in nature. The parameters of RL load is specified into table III and results obtained from simulation has been given in figure 6.

The inverter output voltage waveform i.e. V_{inv} has seven uniform voltage levels having maximum of 120 Volt i.e. the total addition of two DC sources. The uniformly distributed & symmetric structure of inverter output voltage & current shows proper selection of modulation technique. THD of inverter output voltage waveform with no use of any filter is 23.96 % which is evident from figure 7. THD for output current waveform is 1.24 % which is evident from figure 8. Thus, the current THD is less than 5 % which is as per IEEE STD 519. Thus, the filtering requirement will be small and economical for MPUC inverter applications especially renewable energy.

For determining switching frequency of MPUC inverter topology, the inverter output voltage as well as gate pulses for switches Q_1, Q_2 & Q_3 has been shown for one time period of output voltage which is given in figure 9. Based on number of switching pulses for one cycle, we can determine the switching frequency of MPUC inverter switches which is given in table IV. Since each switch in one U cell operate in complimentary, so both the switches in a U cell will have same frequency. During switching time, the upper switches viz. Q_1 & Q_1, have to block voltage V_1 & lower switches viz. Q_3 & Q_3, have to block voltage V_2. So, the voltage rating of upper switches and lower switches are V_1 and V_2, respectively. The two middle switches viz. Q_2 & Q_2, have to suffer higher voltage than other switches i.e. V_1+V_2. So, the voltage rating of two middle switches are V_1+V_2.

The middle switches operate online frequency i.e. 50 Hz. So middle switches operating online frequency and high power are placed into middle U cell. Thus, a comparative study based on component counts is performed among popular Cascaded H-Bridge (CHB) inverter & MPUC inverter. The main limitation of MPUC inverter is that the unequal shading of Photovoltaic panels may cause deterioration of power balance between two DC links which may lose voltage control.

7-level MPUC Inverter	6	2

6. Conclusion

In this paper, the modified form of Packed U-Cell inverter topology has been presented and validated on MATLAB Simulink. The proposed MPUC topology can generate seven levels of inverter output voltage with acceptable harmonic contents. Unlike PUC topology, the proposed topology is capable to produce maximum output voltage level which is more than the available maximum voltage source. In this topology, the DC source amplitudes gets added so that it can supply more power at the output. The switching algorithm adopted in MPUC inverter is such that it can operate at less switching frequency. Furthermore, this topology is targeted for PV applications for delivering power from different voltage rating PV panels. To show this, simulation results are given to verify THD for inverter output voltage & output current. Likewise, the comparison of MPUC inverter & CHB inverter proved the suitability of proposed inverter for advantages like fewer component counts, economical manufacturing cost and compact package owing to reduced filter size.

ABSTRACT

Recognizing the human behavior and gesture has become important due to the increasing use of wearable devices. This study classifies hand gestures by creating sound in the inaudible frequency range from a smartphone and analyzing the reflected signals. We convert the sound using Short-Time Fourier Transform to magnitude and phase. We trained two types of data on Convolutional Neural Network model. And then we propose a method applying soft voting, an ensemble technique, to improve classification accuracy taking the average of two models' result. In this paper, the classification accuracy of the Mag model is 96.0% and the classification accuracy of the Phase model is 90.0% for 8 hand gestures. While the ensemble model showed 96.88%, which is better than Mag and Phase models.

1 Introduction

With the advancement of IT technology, the use of wearable devices such as smartwatches and IoT-based devices is becoming more popular. However, as devices become smaller for portability, there are some limitations, including the difficulty of controlling these devices using buttons or touches. To date, lots of studies are being conducted to overcome this limitation. Most studies collect and recognize data from sensors like cameras and controllers [1]–[4]. However, it is a fatal flaw that requires a sensor or product to recognize movement. Therefore, in this study, we propose a hand gesture classification using a smartphone without a separate sensor.

When the smartphone's speaker makes an inaudible sound, the microphone records this sound. A subject performs a hand gesture while recording is in progress, the signal hit by the subject's hand and reflected changes in frequency domain because of the Doppler effect. There are several methods to analyze a signal into time and frequency domain, among them, we analyzed the signal using the Short-Time Fourier Transform (STFT) [5]. This is because STFT converts the data into a 2D grid-like topology with time and frequency domains. It can be easy to input in 2D Convolutional Neural Network (CNN) [6]. In this way, the sound signal is transformed into magnitude and phase. We propose a method to increase the classification accuracy of the independently trained magnitude and phase CNN models by applying soft voting, an ensemble technique. As a result, the proposed method showed a classification accuracy of 96.88% for 8 hand gestures.

The rest of this paper is organized as follows. It introduces the hand recognition and classification research using ultrasound and ensemble technique in Chapter 2, describes the method proposed in Chapter 3, evaluates its performance in Chapter 4, and finally concludes this paper in Chapter 5.

2 Related Work

In this chapter, we briefly introduce how hand gesture recognition and classification are being used, and studies using ultrasonic signals and studies to improve the performance of a model using multiple CNN models are described.

First, the current status of research on hand gesture recognition and classification is introduced [7]. Data for hand gesture recognition and classification are collected from various sensors, for example, mount-based sensors, multi-touch screen sensors, vision-based sensors, and ultrasonic-based sensors. The collected data are trained on machine learning models used in various fields, such as human-robot interaction, virtual manipulation, sign language, and gaming.

Second, studies on recognizing or classifying hand motions using ultrasonic signals will be described. There is a study called

[*]Corresponding Author: Sunwoong Choi, Kookmin University, School of Electrical Engineering, 82-2-910-4416 & schoi@kookmin.ac.kr

FingerIO that uses smartphone and smartwatch to find fingers using the microphone and speaker [8]. In this study, they use sound in a inaudible frequency range and track the fingers' position by Orthogonal Frequency Division Multiplexing (OFDM). Other study proposes a deviceless gesture tracking scheme. This is called LLAP (Low-Latency Acoustic Phase) [9]. In this study, they use microphones and speakers that built-in on mobile devices to track hands and fingers. This study measures the phase changes that is formed by movement and converts the changes into the distance of the movement. There is a paper that classifies hand gestures using two smartphones [10]. One used as a microphone, while the other used as a speaker. In this paper, they used STFT. These window size is 500, and overlapped size is 475. The frequency resolution is 2,048. As a result, their proposed CNN model classified 8 hand gestures with a classification accuracy of 87.75%.

Finally, studies using multiple CNN models will be described. These two papers [11, 12] explained ensemble method. In paper [12], the performance of the model for classifying hand gestures was improved using the ensemble technique. They ensembled three types of classifiers: a polynomial classifier, a multi-layer perceptron, and a support vector regression. So, they obtained median recognition rates per moment in time of more than 86%. Another paper [13] is a paper that improves performance by fusion of GoogLeNet, VGGNet, and ResNet. The performance was improved by extracting feature layers (100-dimensional and 40-dimensional fully connected and softmax) to each model and attaching them. This paper implemented a model that recognizes the motions of a person in an image, and performance improved in order when only one of the three models mentioned above was used, when two were used, and when all three were used.

3 Proposed Method

Our system can be divided into three steps (data acquisition, data pre-processing and model training) like Figure 1. First, we collect sound data using our own application. Then, the data are pre-processed by STFT on MATLAB. Lastly, We train the pre-processed data on the proposed CNN model.

Figure 1: Overall system architecture.

3.1 Data Acquisition

We collected data with a smartphone application developed in Android Studio. This application produces a single frequency of 20 kHz on the smartphone's speaker. At the same time, the application starts recording on the smartphone's microphone. The speaker and microphone are activated for 3 seconds, and a subject makes a hand gesture within that time at a distance of 1–5 cm from the smartphone. The application stores the sound reflected by gestures. When collecting data, only one subject in the office performing hand gestures to reduce the noise.

3.2 Data Pre-processing

We have used STFT to convert sound data because STFT informs the change of frequency over time. A window size of 5,000, an overlap size of 4,750, and a frequency resolution of 2,048 are detailed information of STFT we used. The microphone recorded for 3 seconds, but the speaker only produced up to 2 seconds. So, we cut off the last second of the data. We also trimmed the data around 20 kHz to suppress the background noise and reduce the number of data. As shown in the Figure 2, the raw data graph represents amplitude value only, however the STFT spectrogram represents the signal intensity using color. STFT data contain magnitude and phase parts. Figure 3 shows magnitude of STFT data, and Figure 4 shows phase of STFT data. So, we pre-processed the sound data to magnitude and phase data.

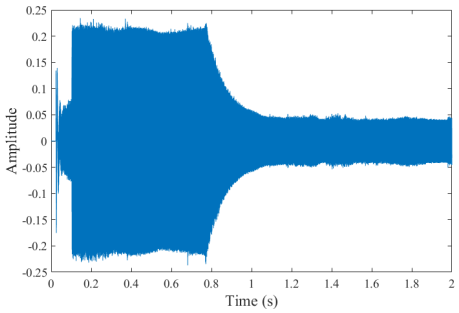

Figure 2: Recorded raw data amplitude graph.

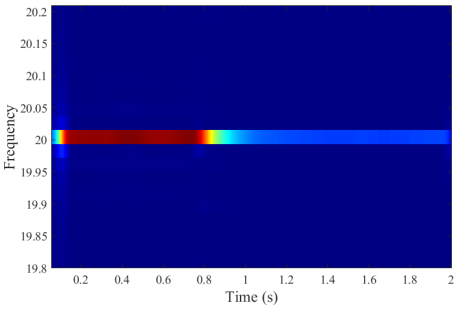

Figure 3: STFT spectrogram (magnitude).

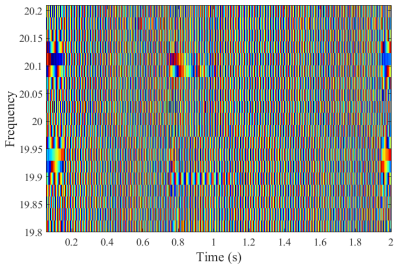

Figure 4: STFT spectrogram (phase).

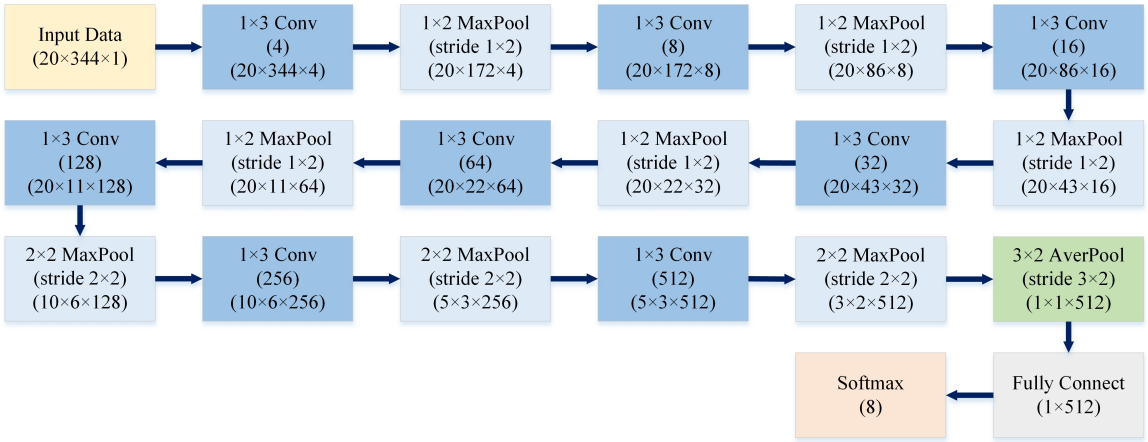

Figure 5: The structure of Mag and Phase models.

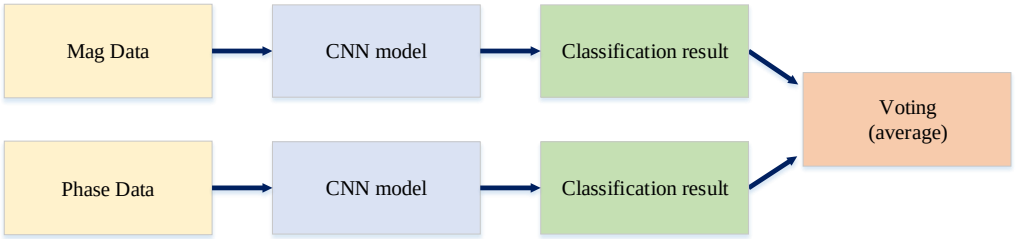

Figure 6: The structure of ensemble model.

3.3 Model Training

We propose two CNN models which called Magnitude (Mag) model and Phase model. Mag and Phase models have the same architecture. The models trained with one part of pre-processed data (magnitude or phase). The data were trimmed to the specific frequency range of 19.8–20.2 kHz through STFT. The models are largely composed of 5 parts: convolution layers, max pool layers, an average pool layer, a fully connected layer and a softmax function. There are 8 pairs of a convolutional layer and a max pool layer in the models to extract data feature. The filter size of the convolutional layer is 1×3, and the filter size of the max pool layer is 1×2 and 2×2. The output of pairs of the convolutional layer and the max pool layer passes through an average pool layer of 3×2 and then through a fully connected layer. Figure 5 shows the structure of our CNN models.

After that, the models were ensembled by taking the average of the softmax function outputs (soft voting). When Mag and Phase models train, the ensemble model not affected training but is only used when testing. Two results of softmax function are calculated by inputting magnitude data and phase data for one hand gesture into each model. The size of the softmax result of each model is the same as the number of classes, and a new softmax result is created by averaging two softmax results corresponding to each hand gesture. The operation is as (1). In this equation, S means the result of softmax funcion.

$$S^{ensemble} = \frac{S^{mag} + S^{phase}}{2} \quad (1)$$

Figure 6 shows how to progress the ensemble model. The magnitude part of the STFT is input to the Mag model and the phase part is input to the Phase model to calculate the average of the softmax matrix outputs from each model. The class that has the largest value among the values of the average matrix is the predicted class of the ensemble model.

4 Evaluation

4.1 Experiment Setup

In the experiment, we have collected the data to TG&Co.'s LUNA smartphone in an office where only one subject performed hand gestures. The application was developed in the Android Studio environment. The UI of developed application is as Figure 7. The smartphone was placed on a flat desk and recording started when the REC-START button was pressed. The application activated the speaker to produce a single frequency at 20 kHz and the microphone to start recording. After 3 seconds, recording stopped automatically.

The saved sound data were transferred from the smartphone to the computer. The data were converted to STFT on MATLAB R2019b. The models were implemented using the Tensorflow 1.6.0, and Python 3.4.8 for running the Tensorflow. Training and test were performed on a GPU server which operates CentOS 7.5 and uses Intel Xeon Silver 4114 CPU. The learning progressed about 4,000 epochs. Besides, a 5-fold cross validation technique was used to increase the reliability of the models.

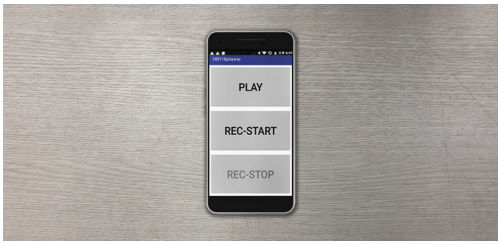

Figure 7: UI of developed application.

4.2 Gesture Dataset

In this study, 8 hand gestures were classified. Figure 8 shows 8 hand gestures that were used as a dataset. The subject gestured at a distance of 1–5 cm from the phone without touching the screen. This action was performed within 3 seconds and repeated 100 times per gesture. Through this process, we have collected a total of 800 data. The data were divided into training data and test data at a ratio of 8:2.

- Do nothing : Do not move the hand while recording.
- Block : Block the microphone with palm while recording.
- Move : With the palm open, record perpendicular to the screen. Place the hand at the beginning of the arrow and move it in the direction of the arrow while recording (to right, to bottom, to left, to top).
- Draw : Stretch only index finger and draw on the screen once in the direction of the arrow (circle and triangle).

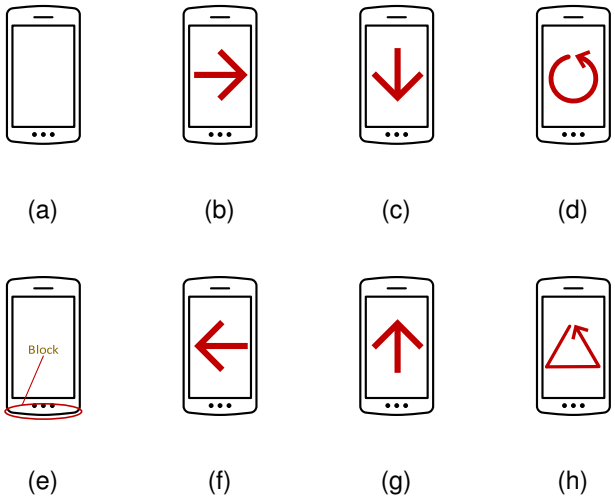

Figure 8: Used hand gestures.

4.3 Experiment Result

When performing STFT, the STFT result value also changes depending on the window size, so that we evaluated this. We tested the classification accuracy by increasing the window size from 2,000 to 8,000 in steps of 1000 using only magnitude data. In all window sizes, the frequency resolution and overlap size were unified to 2,048 and 95% during the evaluation. The classification accuracy by window size is shown in Figure 9. Therefore, the evaluations of the Phase and ensemble model were proceeded when window size is 5,000.

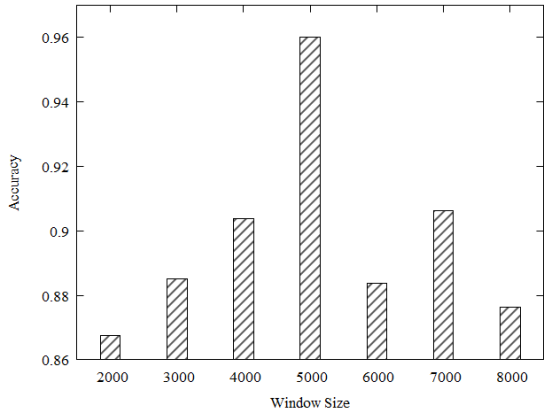

Figure 9: Classification accuracy by window size.

In conclusion, we presented the ensemble model that classified 8 hand gestures as 96.88% classification accuracy. We estimated Mag, Phase, and the ensemble model when window size is 5,000. Mag model showed 96.0% classification accuracy, and Phase model showed 90.0%, slightly lower than Mag model. However, when these two models were ensembled with our method, the performance improved, showing a classification accuracy of 96.88%. Not only classification accuracy but also various evaluation indicators were tested. Figure 10 shows precision, recall, F1-score, and accuracy of each model. It can be seen that the ensemble model better than the two models in all evaluation indicators.

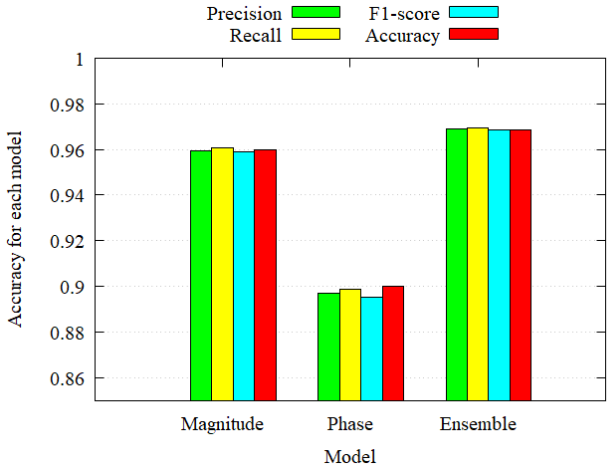

Figure 10: The performance comparison of each model.

We plotted the confusion matrices to also check the accuracy corresponding to each class. The confusion matrices are shown in figures 11– 13. Comparing the confusion matrices, it can be seen that the Mag and Phase models differ in the class that predicts well. For example, in Mag model, 'do nothing' gesture shows the highest accuracy, but not in Phase model. Since the accuracy of Mag model

is higher than that of Phase model, the ensemble model shows a similar pattern to Mag model. Also, almost classes of the ensemble model show better accuracy than Mag and Phase models.

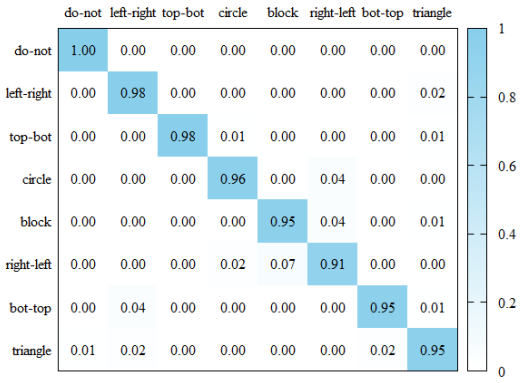

Figure 11: The confusion matrix of Mag model.

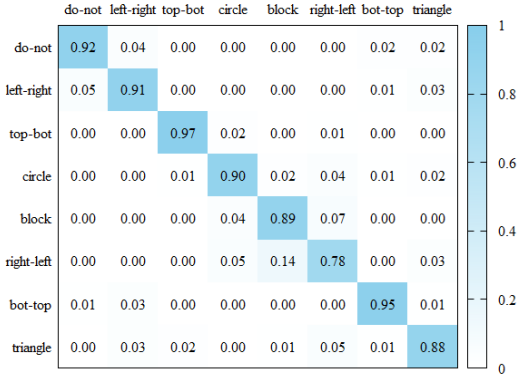

Figure 12: The confusion matrix of Phase model.

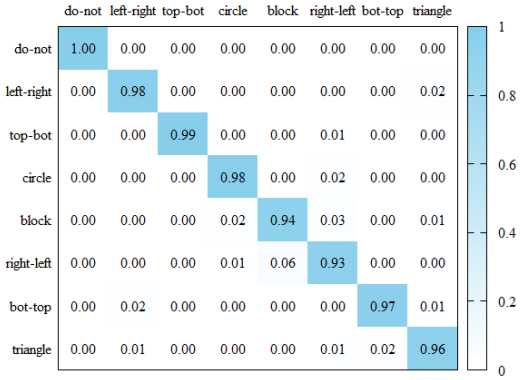

Figure 13: The confusion matrix of the ensemble model.

5 Conclusion

This study classified hand gestures using inaudible sound using a smartphone's speaker and microphone. We used our own application to produce and record 20 kHz sound while gesturing. The sound data were converted to STFT as magnitude and phase data. These data used for training and test in our CNN models. We proposed Mag and Phase models, and also suggested ensemble method using soft voting to improve classification accuracy. As a result, our model showed 96.88% classification accuracy for 8 hand gestures.

ABSTRACT

*This article proposes a cost-aware autoscaler for microservices-based applications deployed with docker containers. This autoscaler decreases the cost of the application deployment as it reduces computing resources. In elastic treatment, microservice resources are scaled when the used metric as the central processing unit (CPU) exceeds the threshold. In case of threshold exceeding, an autoscaler adds many instances of docker containers in order to satisfy the need of the application. In many studies, the autoscaler adds many containers without selecting the appropriate microservices for scaling and without in advance calculation of the adequate number of containers. This may lead to allocating additional resources to inappropriate microservices and a non optimal number of containers. For this reason, we propose our autoscaler "*Docker-C2A*" which identifies the adequate microservices to add resources. It also calculates the optimal number of needed containers. "*Docker-C2A*" analyses the state of the application, uses the execution history and uses a Particle Swarm Optimization (PSO) algorithm to identify the adequate microservices for scaling resources and to determine the optimal number of containers. As a result, "*Docker-C2A*" helps to reduce computing resources and to save extra costs. Experimental measurements were conducted on a microservices-based application as a concrete use-case demonstrating the effectiveness of our proposed solution.*

1 Introduction

Microservices is an architectural style of development consisting of a collection of small independent and loosely coupled components [2]. Nowadays, several companies like Amazon, Linkedin, Spotify and Netflix have migrated towards microservice architecture in order to increase the efficiency and the scalability of computing resources.

Currently, the most of microservices-based applications are deployed in docker containers [3] and orchestrated with kubernetes tool [4]. Docker is a container technology designed for creating, deploying and running applications using containers. The latter allow developers to package up an application with all needed parts such as libraries and deploy it as one package. Each instance of a microservice is a docker container. They are orchestrated and deployed in a cluster of VMs (Virtual Machines) configured by kubernetes, an open-source container orchestration system created by Google for automation of application deployment, scaling and management.

When there is a rise on the workload, microservices resources are overloaded and thus additional resources should be allocated. One of the most important stakes in Cloud environment is to minimize computing resources so as to reduce the deployment cost of the application. We can resolve this issue and optimize computing resources using autoscaling techniques. Over-provisioning of computing resources leads to allocating unused resources. Whereas, under-provisioning causes performance degradation of the application. Thus, an autoscaling technique should identify the needed resources for the application in order to allocate quasi-exact needed computing resources.

In literature, few autoscalers are proposed for containers and microservices-based applications, and most existing solutions have the same treatment as kubernetes autoscaler. The autoscaler of kubernetes is called Horizontal Pod Autoscaler HPA [5]. HPA scales the number of containers based on CPU usage. CPU threshold is

[*]Corresponding Author: Mohamed Hedi Fourati, ReDCAD Laboratory Sfax, Tunisia. Email : mohamed-hedi.fourati@redcad.org
This paper is an extension of work originally presented in [1].

specified by the user. When the application receives high workload due to the increase of requests number, many microservices are overloaded and the CPU threshold is exceeded. Consequently, kubernetes HPA adds one container instance to each overloaded microservice. If the threshold is still exceeded, the autoscaler continues adding other containers until reaching the normal state of the CPU or the maximum number of containers. This autoscaling process has several issues that allocate many resources and thus charge a high deployment cost.

The first issue is the usage of CPU metric. In fact, using CPU metric in autoscaling is not effective and may lead to allocating unnecessary resources. Indeed, it was proved in [6] that a high CPU usage means that the container instance is fully utilized, but it can still provide acceptable response time without adding more resources. So, it is possible to execute further requests and to have acceptable response time even if we have high CPU and high workload. This is also why many elastic solutions tend to use response time metric instead of CPU usage to benchmark their autoscaler. Moreover, it is highly recommended to use response time metric instead of resource metrics as CPU when launching autoscaling actions.

The second issue is that existing autoscalers do not select the adequate microservices for adding resources. In fact, the microservices of an application are in relationship, and an issue in a given microservice may be propagated to other ones. Similarly, if this issue is resolved for a microservice, it is automatically resolved for related microservices. Thus, an autoscaler should select and find the eligible microservices for scaling. To do that, the autoscaler should analyze the whole application with an overview of all microservices. Also, it should use the execution history of the application to find eligible microservices.

The third issue is that existing autoscalers do not calculate the needed number of containers for each microservice and do not react fast. For example, the autoscaler of kubernetes adds containers one by one until reaching the normal state. In this case, the normal state is recovered after a period of time, while in Cloud applications, the time constraint is critical and fast scaling actions are requisite. Then, the autoscaler should calculate and estimate the needed number of containers for each microservice from the beginning to launch fast actions. To do this, the autoscaler should analyze the application and its microservices to estimate the adequate number of containers for each microservice. Moreover, it should consider the execution history and the architecture of the application as the relationship between microservices to estimate the adequate number of containers. As a result, the autoscaler calculates precisely the needed number of container and launches fast actions. This leads to optimize computing resources and deployment cost.

This paper proposes "Docker-C2A" a **C**ost **A**ware **A**utoscaler for microservices-based applications deployed with docker containers. This autoscaler focuses on existing issues in order to optimize computing resources and reduce deployment costs. Firstly, "Docker-C2A" is based on response time metric instead of CPU metric. Also, it selects eligible microservices for scaling and calculates the optimal number of containers to be added to each microservice. To do this, during autoscaling treatment, "Docker-C2A" considers the architecture of the application and the relationship between microservices. In addition, it uses the execution history of the application and executes a PSO algorithm. As a result, "Docker-C2A" selects appropriate microservices for scaling and calculates the needed number of containers for each microservice. Experimental results conducted on a concrete use case demonstrates that we can satisfy high workload with minimum computing resources by allocating a small number of containers. Thus, "Docker-C2A" optimizes computing resources and reduces the deployment cost. And that is the main purpose of this autoscaler.

This paper is organized as follows: Section 2 presents the related work. Section 3 presents the motivating example of our autoscaler. Section 4 presents in details Docker-C2A autoscaler. Section 5 details the PSO algorithm in Docker-C2A. Section 6 discusses the experimentations. We conclude the paper in Section 7.

2 Related Work

Autoscaling is dedicated for optimizing resource allocation in order to avoid allocating unused resources and to reduce the cost of deployment. Few studies were proposed for the autoscaling of microservices-based applications focusing on containers. As it was explained in section 1, these solutions have many issues. In fact, most of these solutions focus on CPU metric. Also, the resource allocation is not accurate as many resources are allocated without selecting the adequate microservices for scaling and without previous calculating the needed amount of resources. This may lead to allocating unused and unnecessary resources and thus charging the user extra costs. In this section we review these studies and explain the shortcomings of each one.

In [7], the author designed a container-based autoscaling policy with a mathematical model dedicated for Iot applications based on containers and microservices. This autoscaler uses two main metrics, number of requests and resource related metrics as CPU or memory usage. Also, it uses the history of the application to take adequate actions for similar cases recorded in the history. After each scaling action, the autoscaler waits for a cooling period defined by the user to avoid launching other scaling actions until the application becomes stable. The main objective of this autoscaler is to minimize computing resources and the deployment costs. Using the history, this autoscaler calculates and estimates the optimal number of containers used to scale each microservice. Although this solution estimates the needed resources for allocation, it does not select the eligible components for scaling.

In [8], the author presented a message queue as a specific use case in IoT context. They considered metrics related to message queue mi- croservices. Two classes of microservices were considered, compute-intensive and I/O-intensive. In [9], the author aimed to adjust computing resources to the incoming load. In scaling process, a new container is added when the response time exceeds 1000 ms in a 15 s window. A container can be removed if it uses less than 10% of cpu. These two studies neither select containers and components for scaling nor calculate the adequate quantity of resources to be allocated.

In [10], the author proposed a genetic algorithm for resources allocation and elasticity management dedicated for microservices-based applications deployed on a containerized environment. The main objectives of the proposed solution is the container allocation

in VMs and elastic treatment of containers. This study models the whole system such as applications, microservices, the relationship between microservices, the required resources of each microservice, containers, the needed resources, physical machines and the network. Then, it optimizes this model using a meta heuristic genetic algorithm to get optimal results for resource allocation of containers and the number of containers for each microservice. This autoscaler considers the architecture of the application and the relationship between microservices in scaling process. However, it does not calculate the needed amount of resources for scaling.

In [11], the researchers developed an autoscaler called Microscaler for microservices-based applications which identifies the scaling-needed services using a customized metric called Service Power. When detecting a response time violation, Microscaler launches the process of detecting services that should be scaled using the customized metric Service Power. This metric is based on response time and used to identify the microservices that need to be scaled with additional resources. Besides, this autoscaler calculates the adequate number of containers to be added for each selected microservice. This autoscaler uses a Bayesian Optimization (BO) and an heuristic approach to determine the optimal number of instances for selected services. Although this autoscaler selects the appropriate microservices to be scaled and calculates the number of additional containers, it is strongly related to applications based on service mesh that make this approach not applicable in other contexts.

In this paper, we propose "Docker-C2A" autoscaler for microservices-based applications using docker containers. We focus on docker container technology because it is the most used in the context of containerization and microservices-based applications. This autoscaler is based on response time metric. Also, "Docker-C2A" selects eligible microservices for scaling and calculates the optimal amount of resources to be allocated. This autoscaler uses the execution history of the application and a PSO heuristic algorithm. The execution history helps to determine which of application microservices need to be scaled. Then, the PSO algorithm calculates the optimal number of containers to be added to each selected microservice.

"Docker-C2A" can be distinguished over existing solutions as it allocates the optimal amount of resources to the adequate microservices. "Docker-C2A" is a fast and accurate autoscaler that gives more precise scaling actions. This leads to optimizing application resources and deployment costs.

3 Motivating Example

To illustrate existing issues, we detail the behavior of kubernetes autoscaler on a concrete microservices-based application. We take the example of kubernetes autoscaler as most existing autoscalers have the same treatment. In fact, we consider Bookinfo [12] a microservices-based application. Figure 1 illustrates Bookinfo application composed of four microservices.

This application displays the data related to each book. It is similar to a unique catalog entry of an online book store. It displays book details as ISBN, number of pages, and book reviews. Bookinfo application is composed of four separate microservices: **Productpage** microservice calls details and reviews microservices to get the book data. **Details** microservice gives the book information. **Reviews** microservice contains the book reviews and calls ratings microservice. **Ratings** microservice contains ranking formation deducted from the book review. Reviews microservice has three versions as three types of instance : **Reviews v1** does not call Rating microservice. **Reviews v2** invokes Rating microservice and displays rating stars as 1 to 5 black stars. **Reviews v3** invokes Rating microservice and displays rating stars as 1 to 5 red stars. This application is deployed with docker containers and deployed on a kubernetes cluster.

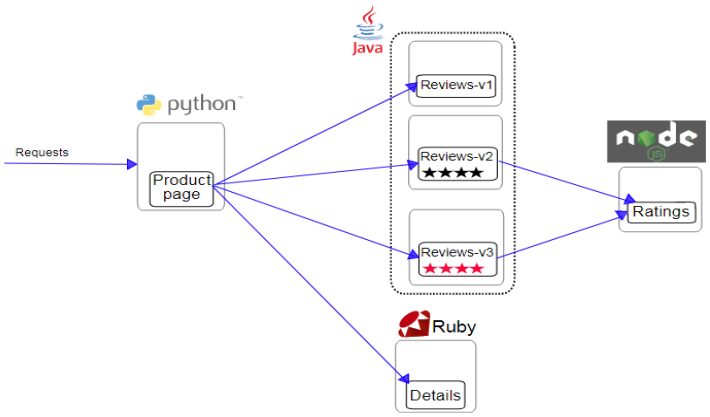

Figure 1: Bookinfo Application

Kubernetes is the most known and efficient orchestrator for docker containers. In the following, we use the pod concept of kubernetes. A pod in kubernetes is considered as a single docker container of a microservice. A microservice is composed by a set of pods (a set of containers). The elasticity controller of kubernetes is called Horizontal Pod Autoscaler HPA [5] and is based on CPU metric. It adds pods when the CPU threshold is exceeded. CPU threshold is specified by the user. If the maximum number of pods (containers) is reached, HPA autoscaler cannot add any more pods.

Many types of workload can be launched in this application. For example we can manage a workload that routes all incoming requests to Reviews v3 of microservice Review. Another example of workload routes incoming requests in 50% to Reviews v2 and 50% to Reviews v3. Technically, it is difficult to route requests flow to a specific container of a microservice. However, it is easy to manage the request flow with Istio [13] service. Istio is based on service mesh which facilitates the creation and management of the network of deployed services. Istio allows to manage network communication between microservices as well as the traffic of requests. In fact, it helps to create configuration rules for traffic routing in order to control the traffic flow between microservices.

In this paper we consider a workload that routes all incoming requests of microservice review to reviews-v3 instances. This workload launches a flow of 70 Req/s. It is not a very high workload but it saturates resources and generates overloaded microservices. This section presents the behavior of kubernetes HPA autoscaler using this workload.

Figure 2 shows the behavior of kubernetes HPA autoscaler using the presented workload with a request flow of 70 Req/s. Many pods were saturated and Kubernetes HPA launches autoscaling ac-

tions. Kuberenetes HPA adds 4 pods for productpage microservice resulting in a total of 5 pods. It adds also 1 pod to reviews-v3 microservice. From t=70, we have a total of 12 pods of reviews-v3. Ratings and details microservices were not saturated and we have no additional pods. The curves of ratings and details are superimposed as they have 1 pod all the time. The total number of pods required for this workload is 19 pods as 5 pods for productpage, 12 pods for reviews-v3, 1 pod for ratings and 1 pod for details. This autoscaler is based on CPU. If the CPU usage of a microservice exceeds threshold, the autoscaler adds many pods until recovering of the normal state.

However, as explained in section 1, using CPU usage in autoscaling treatment is not effective and may lead to allocating unnecessary resources. Therefore, we should also analyze the behavior of kubernetes autoscaler towards the response time. The red curve in Figure 2 illustrates the evolution of the response time in kubernetes autoscaler.

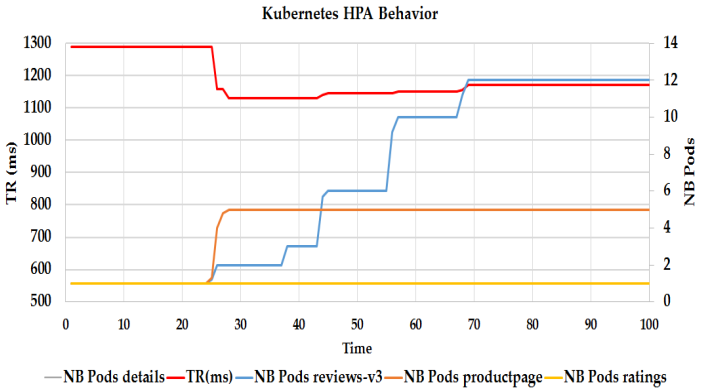

Figure 2: Kubernetes HPA Autoscaler behavior

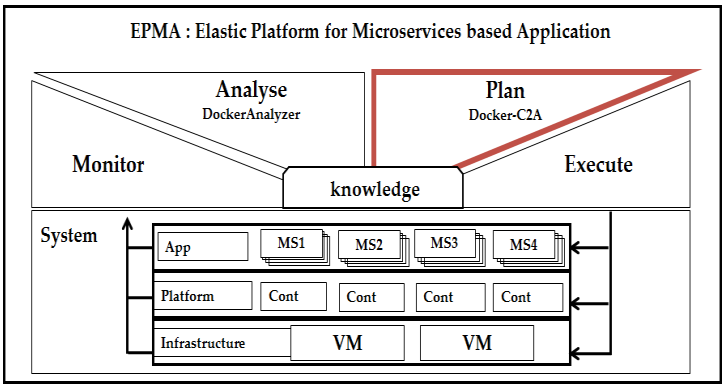

Figure 3: EPMA : Elastic Platform for Microservices based Application : Autoscaling Engine

Approximately, the response time starts with 1300 milliseconds (ms). At time t=25, we have 5 pods for productpage microservice and 2 pods for reviews-v3 microservice. We can notice a considerable evolution of the response time with approximately 1100 milliseconds. From t=37 to t=100, kubernetes autoscaler adds pods for the microservice reviews-v3 until reaching 12 pods. Following this addition, we notice no improvement in response time, but we can see a slight increase starting from t=43. It is concluded that during this interval of time, kubernetes autoscaler added 10 pods for reviews-v3 microservice, while the response time is not improved. So the added pods for reviews-v3 are not useful and kubernetes allocates unnecessary resources without any benefit.

With our autoscaler Docker-C2A, based on response time metric, we aim at optimizing the addition of resources and avoid allocating unnecessary resources. Docker-C2A uses PSO heuristic algorithm and the execution history of the application to optimize resource allocation. Using Docker-C2A, we can satisfy the same workload used in kubernetes example with a very small number of pods and with a better application performance.

4 Docker-C2A Autoscaler

4.1 EPMA platform

Docker-C2A is part of our EPMA platform (Elastic Platform for Microservices based Applications) illustrated in Figure 3. This platform is based on the autonomic MAPE-K loop proposed by IBM [14]. MAPE-K loop is composed of four components that share the Knowledge: Monitor, Analyze, Plan and Execute. EPMA manages the entire system with all levels: VM level, container level and microservice level. The analyze component DockerAnalyzer was previously presented [1] while this paper details the plan component Docker-C2A.

The monitor component collects data from different levels: VM, container and Microservice. This component collects metrics related to resources as CPU usage and memory usage and metrics related to the application performance as the response time. These parameters are filtered and correlated in order to determine symptoms that should be analyzed. As example of a symptom, an overload state caused by the CPU violation. If the monitor detects a symptom, DockerAnalyzer, the analyze component, is invoked to check whether this symptom is caused by a normal behavior as resource saturation or by an abnormal behavior as VM problem. If an abnormal behavior is detected, the analyzer had to check the root cause of the problem. Then, the plan component Docker-C2A generates the appropriate change plan describing the desired set of changes, and deliver the change plan to the execute component. The execute component applies the change plan and executes adequate actions for each layer. These four components share the knowledge containing particular data as policies and symptoms. This paper explains deeply the plan component Docker-C2A of EPMA platform.

Docker-C2A is based on the execution history of the application and a PSO heuristic algorithm. When the application state needs additional resources, Docker-C2A selects the best microservices for scaling and calculates the optimal amount of needed resources for each microservice.

4.2 Execution History

The main purpose of the execution history is to identify the microservices that should be scaled, and those that should not be scaled as there is no need to add resources. To do that, we attribute a score value for each microservice. The score value is a number varying from 0 to 5 depending on the utility of adding resources to the

microservice. For example, if we have a microservice that the addition of pods (containers) improves greatly the response time, the attributed score will be 5. If we have a microservice where adding pods will not improve the response time, the attributed score will be 0. As a result of the execution history, we generate the score value for each microservice. This helps to scale the appropriate microservices.

We account for the score attribution using bookinfo application with the same workload explained in section 3 which routes the incoming traffic of reviews microservice to reviews-v3 instances and uses a flow of 70 Req/s. Bookinfo application is composed of 4 microservices. We present in the following an extract from the history related to two microservices in order to demonstrate the score attribution.

NB Pods Productpage	NB Pods Reviews-v3	NB Pods Ratings	NB Pods Details	Response Time (ms)
1	1	1	1	1289
5	1	1	1	1134

Figure 4: An extract of Productpage history

In Figure 4, we change the number of pods in microservice productpage and we keep the same number of pods for other microservices. In the second row in this table of Figure 4, we have 5 pods of productpage and the response time has been improved considerably compared to the first line with 1 pod. The response time decreased effectively with 155 milliseconds. So requests are much faster with 5 pods than if we had 1 pod of productpage. In this case, we notice that adding pods to productpage microservice improves greatly the response time. We attribute the high score with value 5 for this microservice.

NB Pods Productpage	NB Pods Reviews-v3	NB Pods Ratings	NB Pods Details	Response Time (ms)
1	1	1	1	1289
1	5	1	1	1292

Figure 5: An extract of Reviews-v3 history

In Figure 5, we change the number of pods in microservice reviews-v3 and we keep the same number of pods for other microservices. There is no remarkable difference in response time between 1 and 5 pods. There is a very small increase in response time with 3 milliseconds, which is not profitable when we add 4 pods. In this case, we notice that adding pods to reviews-v3 microservice has no effect on the response time. Then, there is no change in the result. So we attribute the lowest score to reviews-v3 with value 0.

With the same process, we analyze the evolution of the response time when we add pods to ratings and details microservices. In fact, there is a weak improvement of the response time when we add pods to these two microservices. Then, we attribute the score value of 1 for ratings and details microservices while adding pods improves the results slightly.

As a conclusion for the execution history, we can admit that adding more resources to productpage microservice can effectively improve the response time of the application. Adding pods to reviews-v3 microservice has no effect on the response time. So adding pods to this microservice is unnecessary. Adding pods to ratings and details microservices improves the results slightly. They are not privileged in autoscaling treatment.

We illustrate the score values for each microservice in Figure 6.

	Microservice Index	Score value of scaling
productpage microservice →	0	5
reviews-v3 microservice →	1	0
ratings microservice →	2	1
details microservice →	3	1

Figure 6: Score value for each microservice

The execution history is very helpful when adding resources in scaling actions. In fact, it helps to select the appropriate microservices for scaling which leads to optimize resource allocation. After selecting eligible microservices for scaling, Docker-C2A calculates the optimal number of pods to be added to each microservice. To do this, Docker-C2A uses PSO algorithm to estimate the needed amount of resources for each microservice.

4.3 PSO Algorithm

Particle Swarm Optimization (PSO) is a computational technique based on the behavior of herds of animals that optimizes a given problem. It tries iteratively to improve candidate solutions with regard to a given quality measure. It was developed by Kennedy and Eberhart [15] in 1995 and widely used and researched ever since.

In PSO algorithm we define a particle which is analogous to a bird in a flock of birds. The flock of birds forms the search space. The movement of each particle is guided by the velocity vector. Each particle moves according to its best position pbest and the best position of the swarm gbest.

In this algorithm, we use a fitness function to measure the performance of each particle. In each iteration, the algorithm changes the velocity of each particle towards pbest and gbest positions. The algorithm stops when a stopping criterion is met or the number of iterations is reached. The velocity and positions equations are represented with Eqs. (1) and (2), respectively. The pseudo-code of the algorithm is presented in Algorithm 1.

$$V_i^{k+1} = wV_i^k + c_1 r_1 (pbest_i - X_i^k) + c_2 r_2 (gbest - X_i^k) \quad (1)$$

$$X_{i+1}^k = X_i^k + V_i^{k+1} \quad (2)$$

where

- w : inertia weight

- c_1 and c_2 : acceleration coefficients
- X_i^k : position of particle i at iteration k
- X_i^{k+1} : position of particle i at iteration k+1
- V_i^k : velocity of particle i at iteration k
- V_i^{k+1} : velocity of particle i at iteration k+1
- $pbest_i$: best position of particle i
- $gbest$: best position of the swarm

Algorithm 1 PSO Algorithm

```
Initialize a population of particles with random values positions and velocities from D dimensions in the search space
while Termination condition or Number of iterations not reached do
    for Each particle i do
        Update the velocity of the particle using Equation 1
        Update the position X_i of the particle using Equation 2
        Calculate the fitness value f(X_i)
        if f(X_i) < f(pbest_i) then
            pbest_i ← X_i
        end if
        if f(X_i) < f(gbest) then
            gbest ← X_i
        end if
    end for
end while
```

5 Docker-C2A : PSO Algorithm

Docker-C2A uses PSO algorithm to calculate the optimal number of pods (containers) to be added to each microservice. Two main objects should be defined in PSO algorithm: particle and fitness function.

5.1 Particle definition in Docker-C2A

In PSO algorithm, a particle represents a solution candidate of the problem. In our context, a solution is a particle that contains the adequate number of pods for each microservice. The dimension of the particle is defined by the number of microservices of the application. We consider the same example and workload explained in section 3. In this example, we use bookinfo application composed by 4 microservices: productpage, reviews-v3, ratings and details. In this case we define particles of 4 dimensions. Each microservice is referenced by an index. For example, we consider the productpage microservice with index 0, reviews-v3 with index 1, ratings with index 2 and details with index 3. We illustrate the particle model for bookinfo application in Figure 7.

	Particle_i	
	Microservice Index	Number of Pods
productpage microservice →	0	Nb_pods_ms_0
reviews-v3 microservice →	1	Nb_pods_ms_1
ratings microservice →	2	Nb_pods_ms_2
details microservice →	3	Nb_pods_ms_3

Figure 7: Particle model of bookinfo application

In Figure 8. below we present an example of two particles. Particle_0 contains 3 pods for productpage microservice, 1 pod for reviews-v3 and ratings microservices, 3 pods for details microservice. Particle_1 contains 1 pod for productpage microservice, 5 pod for reviews-v3 microservice, 1 pod for ratings details microservices.

Particle_0	
Microservice Index	Number of Pods
0	3
1	1
2	1
3	3

Particle_1	
Microservice Index	Number of Pods
0	1
1	5
2	1
3	1

Figure 8: Example of Particles

The PSO algorithm 1 evaluates each particle using the fitness function. The fitness value helps to decide about the best and which one is better than another by searching pbest and gbest positions as described in the algorithm.

5.2 Fitness function in Docker-C2A

The fitness function helps to evaluate particles and update pbest and gbest positions. We aim to minimize the fitness value to get the best solution. In Docker-C2A, the fitness function depends on the score based on the execution history as depicted in section 4.2 and the cost of the particle. We aim to maximize the score of particles in order to improve the response time and to minimize the cost of the particles to save deployments charges.

The fitness value of each particle P_i is calculated following equation 3 which is the cost of the particle divided by the score of the particle.

$$fitness(P_i) = \frac{Cost(P_i)}{Score(P_i)} \tag{3}$$

If we reduce the cost and increase the score then we minimize the fitness value and obtain a better solution. The particle with the lowest fitness value is the best particle, while it has a low cost with high score. The high score reflects a great improvement of the response time.

The score value of the particle is calculated following equation 4 which is the sum of the score of each microservice MS_k multiplied by the number of pods of the microservice.

$$Score(P_i) = \sum Score(MS_k) * NB_Pods(MS_k) \tag{4}$$

The cost of the particle is calculated according to equation 5 which is the sum of the cost unit of each microservice MS_k multiplied by the number of Pods of the microservice.

$$Cost(P_i) = \sum Cost(MS_k) * NB_Pods(MS_k) \quad (5)$$

5.3 PSO Example

In this section, we explain a concrete example of executing PSO algorithm. We consider the bookinfo application with the same workload presented in section 3 which routes requests of reviews microservice to reviews-v3 pods. In this example, we use 3 particles and 3 iterations. We follow the algorithm 1.

	Best position of the swarm gbest	Fitness value of gbest position
After Particle Initialization	Particle_1 Microservice Index / Number of Pods 0 / 2 1 / 2 2 / 2 3 / 1	Fitness = 0,538
After Iteration 0	Particle_0 Microservice Index / Number of Pods 0 / 3 1 / 2 2 / 2 3 / 1	Fitness = 0,444
After Iteration 1	Particle_0 Microservice Index / Number of Pods 0 / 4 1 / 2 2 / 2 3 / 1	Fitness = 0,391
After Iteration 2	Particle_0 Microservice Index / Number of Pods 0 / 5 1 / 2 2 / 2 3 / 1	Fitness = 0,357

Figure 9: Summarize of the execution treatment

In the first step, the algorithm initializes the number of pods needed to the 3 particles randomly. Initially, the best position of each particle pbest is the particle itself. The fitness value of each particle is calculated following the equation 3. When we calculate the cost in fitness function, we consider that all pods have the same cost as 1 unit of cost. In the first step, the fitness values of particles 0, 1 and 2 are ”0.75”, ”0.538” and ”0.714” respectively. The particle with the lowest fitness value is the best particle which is Particle_1 with a fitness value of ”0.538”. PSO algorithm selects Particle_1 as the best particle having the best position gbest in the swarm.

In each iteration, the algorithm calculates the fitness value for each particle, selects the gbest position and moves particles to new positions in order to ameliorate particle positions with better fitness values.

Figure 9. summarizes the execution treatment in this example. This figure illustrates the best position gbest after each iteration and its fitness value. We remember that we use 3 iterations in this example. It is clear that the fitness value of the best solution gbest is improved in each iteration, as the purpose of the algorithm is to minimize this value. In fact, if we minimize the fitness value, we guarantee that the particle position has the minimum cost with significant gain in response time.

At the beginning, the fitness value of gbest was ”0.538”, this value was decreased after each iteration, so our algorithm is improving the solution correctly with the decrease of fitness value. The lowest value of fitness ”0.357” is presented in the final iteration and it is the output of the algorithm. This particle has 5 pods for microservice 0 which is productpage, 2 pods for microservices 1 and 2 which are reviews and ratings microservices respectively, and 1 pod for microservice 3 which is details microservice.

In the next section, we discuss the results of our autoscaler Docker-C2A based on PSO algorithm and execution history using this example and we discuss the difference and the contribution compared to Kubernetes HPA autoscaler.

6 Experimentations

In this section, we discuss the impact of our autoscaler Docker-C2A compared to Kubernetes HPA autoscaler.

In our experimentations, we use a cluster Kubernetes composed by 4 virtual machines (VMs). Each VM runs on Ubuntu OS and contains 4 cores CPU, 8GB memory and 100 GB for disk storage. We use the same microservices-based application bookinfo detailed in section 3 composed by 4 microservices: productpage, reviews, ratings and details. Each microservice is deployed in Kubernetes cluster as a deployment containing a set of similar pods. We use the same workload used previously which routes the incoming traffic of reviews microservice to reviews-v3 instances with a flow of 70 Req/s.

Figure 10 illustrates the difference between Kubernetes HPA and Docker-C2A behaviors. At the time t=24, we launch these two autoscalers. Kubernetes behavior is illustrated in Figure 10a. We detailed the behavior of Kubernetes HPA in section 3 using the workload of bookinfo application. When Kubernetes HPA detects a high load it waits 15 seconds to launch autoscaling actions. In each period of 15 seconds, it calculates and launches the needed number of pods. Every period, it updates the number of needed pods and monitor the situation. Kubernetes HPA stops adding pods when the state of the application becomes stable or it reaches the maximum number of pods. As a result, HPA autoscaler launches 5 pods for productpage microservice, 12 pods for reviews-v3 microservice and 1 pod for both details and ratings microservices. So for this workload Kubernetes HPA launches 19 pods.

Whereas, with Docker-C2A autoscaler, based on the execution history and the PSO algorithm, we can manage the same workload with reduced number of pods. Docker-C2A behavior is illustrated in Figure 10b. When it detects a high workload, it waits 15 seconds and launches the action plan issued by PSO algorithm. In this example, the output of PSO algorithm is presented in Figure 9. The output is the gbest particle of the last iteration. This particle contains 5 pods for productpage microservice, 2 pods for both reviews-v3 and ratings microservices and 1 pod for details microservice. Docker-C2A

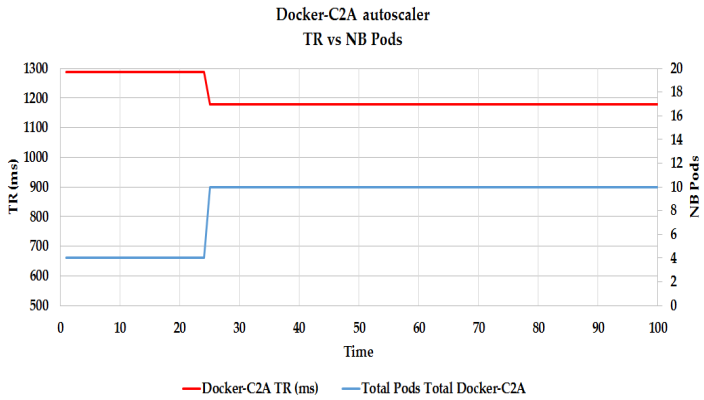
c

(c) Kubernetes HPA Response Time vs NB of Pods



d

(d) Docker-C2A Response Time vs NB of Pods

Figure 10: Kubernetes HPA autoscaler vs Docker-C2A autoscaler

launches in total 10 pods.

If we consider the response time of requests which is presented with red curves in Figures 10a and 10b, we notice that the response time is almost the same in Kubernetes or Docker-C2A autoscalers. While Docker-C2A launches only 10 pods which is 9 pods less than Kubernetes HPA that launches 19 pods. We summarize the number of pods and the response time of these two autoscalers in Figure 11. The response time of requests with Docker-C2A is 9 milliseconds higher than the response time with Kubernetes. This difference is negligible and is not considerable as the difference is appreciated if it is in the order of tens or even hundreds of milliseconds. So, we have certainly reached our goal with Docker-C2A using the execution history and the PSO algorithm which gives an optimized amount of resources with good performance.

Autoscaler	NB Pods Productpage	NB Pods Reviews-v3	NB Pods Ratings	NB Pods Details	Total NB of Pods	Response Time (ms)
Kubernetes HPA	5	12	1	1	19	1170
Docker-C2A	5	2	2	1	10	1179

Figure 11: Kubernetes HPA autoscaler vs Docker-C2A autoscaler

Also, Docker-C2A takes in average 60 milliseconds to generate the decision of scaling, which is a short period of time that does not disturb the elastic treatment. However, Docker-C2A uses a high amount of resources of about 1.2 cores of CPU to process the PSO algorithm. The high resource usage is the cost of problem optimization and among the weak points of our autoscaler. Moreover, to run our algorithm, it is recommended to execute up to 4 iterations as a maximum. Indeed, in our context, PSO algorithm generates erroneous results from 5 iterations.

7 Conclusion and Future Works

In this paper, we presented our autoscaler Docker-C2A a cost aware autoscaler for microservices-based applications deployed with docker containers. Docker-C2A is based on response time metric. It uses the execution history of the application and PSO algorithm. Docker-C2A selects appropriate microservices for scaling and calculates the optimal number of containers for each microservice. We clearly presented the effectiveness of our autoscaler compared to Kubernetes HPA autoscaler using bookinfo application as a real case study. We compared with Kubernetes autoscaler as most of existing autoscalers have the same issues. They neither select appropriate microservices for scaling nor calculate the optimal number of additional containers. As a result, Docker-C2A optimizes computing resources and reduces deployment cost. And that is the main purpose of our autoscaler. However, there are some

limitations of Docker-C2A. In fact, it consumes a high amount of resources to generate the solution. This fact is caused by the PSO algorithm which requires high resources and this is the case of several optimization algorithms.

In future work, we improved Docker-C2A to consume less resources, either by proposing another particle definition in PSO algorithm, or by integrating another optimization algorithm instead of PSO that consumes less resources and generates good results. Also, in future work, we improved the execution history using other performance metrics and more execution data in order to analyze the application behavior in each workload. This greatly helps to estimate the needed resources with more precision and allows better optimization of computing resources.

ABSTRACT

This paper covers a new topology, a synchronous wind turbine generator, and a solar photovoltaic generator. The Permanent Magnet Synchronous Generator is linked to the grid by back-to-back voltage source converters (BtB VSC), consisting of a two-stage rectifier and a five-stage Neutral Point Clamped inverter, operated by the Space Vector Pulse Width Modulation technique. A solar photovoltaic system has a direct interface with the capacitor of the DC link of the BtB VSCs, with no additional DC/DC conversion stage, while the efficiency of the system is maximized. This work features a Perturb and Observe algorithm Maximum Power Point Tracking for to extract the optimum power from both wind turbine and solar PV generator. The application of Space Vector Pulse Width Modulation control scheme is used for harmonics compensation THD. A proportional integral regulator is used to regulate the DC link voltage. A prototype is tested under various conditions, wind velocity variations as well as under several photovoltaic solar isolations. The present work has been treated using Matlab/Simulink. Simulation results proved efficiency provided by this controlling approach: reduced distortion of harmonic and increased power factor.

1 Introduction

Today, the major energy sources used for generating electricity are fossil fuel resources [1]. To reduce the dependency on fossils based energy it necessary for power generation to move towards the renewable resources including solar energy, wind power, hydroelectricity, and biomass. In literature, most of the distributed production systems are uniquely focused on one type of sustainable resource, e.g., a wind power like in [2] or solar power like in [3].

The combination and the penetration of the renewable resources, face considerable challenges due to growing power industry. The injection into the grid of the energy yielded by wind and solar photovoltaic generators, is proven to be one of the technological solution [4, 5]. Their combination offers additional benefits such as increasing the overall operational efficiency and power reliability, optimal use of lands resources, and improves the capital investments [5]. Grid-connected wind/Photovoltaic (PV) cogeneration is not largely discussed [6]–[7], whereas in literature, most of wind-PV hybrid systems are proposed for standalone off-grid applications [5]. The optimization method of generation of power using hybrid system used for battery charging is developed in [8], to increase the stability and efficiency. In [9], the author have proposed a small scale hybrid solar- wind power generation system to reduce Electricity shortage in Egypt.

Much research was conducted to track maximum power point (MPP) of the wind using methods based on Perturb and Observe (P&O) algorithm [6], neural network technique, or other approaches based on fuzzy logic. Due to the nonlinear voltage-current properties of PV solar panels, the necessity of MPP tracking has become apparent. MPP tracking schemescan be accounted for as perturb and observe (P&O), incremental conductance method, Fractional Open-Circuit Voltage, Neural Network, Fuzzy Logic Control, Current Sweep [10]. The combination of multilevel inverter and renewable energy sources are advantageous. In [11], the authors have proposed a hybrid cascaded nine level inverters for photovoltaic applications. The proposed system in [12] are based on Maximum Power Point Tracking (MPPT) combined with multilevel inverter to achieve the maximum power. In [6], the system comprises back-to-back voltage source converters with no extra dc/dc conversion stages to connect wind and photovoltaic generators to the power grid. Moreover, the control of the currents on the machine- and grid- side are carried out using hysteresis regulators, introducing higher harmonic contents

[*]Corresponding Author: Elamri Oumaymah, Email: oumaymahelamri@gmail.com

from the variable switching frequency. The objective in [13] is to realize a photovoltaic system with a MPPT linked to the 11 KV grid by employing a new control technique in order that it is possible to transfer maximum active power from the PV to the grid without injecting harmonics. The study proposes in [14, 15] a control strategy for a single-phase, three-phase photovoltaic system connected to a distribution network. The proposed technology is based on the modification of the conventional control in current mode to adjust the power factor of the photovoltaic system and control the voltage of the converter link.

This paper extends the work originally presented in ICEIT'4 [2], where the modeling and simulation of a wind turbine string, based on a vector-controlled five-level inverter, was presented. Its objective was the optimization of the energy produced, adjust the DC link and control power transferred into the grid. Motivated by advantages of hybrid production systems, presented paper covers a new topology to interface both is Permanent Magnet Synchronous Generator (PMSG)-based wind energy and PV generators with power grid. Note a blocking diode is series connected with each PV string to avoid reverse flow of current. Two P&O algorithms, namely P&O Wind and P&O PV, are used to optimize the energy extracted by turbine and solar system, respectively. Note that perturbations could impact correct operation of the receivers attached to the grid if the voltage output wave is not sinusoidal. To avoid this problem, we have implemented in this chain a two-stage rectifier followed by a five-stage Neutral Point Clamped (NPC) inverter regulated by the Space Vector Pulse Width Modulation (SVPWM) technique, without additional DC/DC conversion stages[16]. The converter control strategy is detailed in which the presented study was treated using Matlab/Simulink. Simulation results proved efficiency provided by this controlling approach: decrease distortion of harmonic and increased power factor.

2 Wind Photovoltaic Generator Side Model

2.1 Wind turbine model

Mechanical energy absorbed by a wind turbine is defined by [2]:

$$P_m = \frac{1}{2}.\rho.C_p(\lambda,\beta).V_v^3.R^2.\pi \tag{1}$$

where: C_p is the coefficient of the rotor that is a non-linear function of the tip speed ratio λ and the pitch angle of blades β, R and V_v are the radius of blades and the wind speed, respectively.

2.2 PMSG model

PMSG in the dq marker is modelised using these equations [2]:

$$V_d = -R_s.I_d - \frac{d\varphi_d}{dt} + \omega.(L_{sq}.I_q + \varphi_f) \tag{2}$$

$$Vq = -R_s.I_q - \frac{d\varphi_q}{dt} - \omega.(L_{sd}.I_d + \varphi_f) \tag{3}$$

The mechanical equation is as shown below:

$$J.\frac{d\Omega}{dt} + f_c.\Omega = C_r - C_m \tag{4}$$

Where: R_s and L_s are stator-winding resistance and inductance, respectively, I_d and I_q are the stator currents, Ω is Rotational speed of the PMSG, φ is stator phase magnetic flux, f_c and J are the friction coefficient and motor inertin, respectively. φ_f: the flux generated by the permanent magnets across stator windings, C_m is the mechanical torque .

2.3 Photovoltaic Generator

The model of the PV generator is presented in Appendix whereas it is modeled as following:

$$V_{pv} = -R_{dc}.I_{pv} - \frac{d\,I_{pv}}{dt}.L_{dc} + Vdc \tag{5}$$

The I_{op}-V_{op} characteristics of the PV array, there is an optimal operating point (I_{op}-V_{op}) corresponding to the maximum generated PV power, at any solar irradiance level.

3 Control Strategy

The suggested wind-PV system appliances two appropriate control techniques for machine-side Voltage Source Rectifier Control (VSRC) and grid-side Voltage Source Inverter Control (VSIC).The proposed system operates efficiently despite solar insolation changes and wind speed variability. The next section deals with control strategies.

3.1 Voltage Source Rectifier Control (VSRC)

Figure 1 visualizes the VSRC schema. Momentary torque is regulated through the application of the vector control schema. Vector Control technology treats the technique of control of AC machines. This control is based on eliminate the coupling between the inductor and the induced by dissociating the static current into two components (i_{sd},i_{sq}). So that, the reference direct axis current (i_{sd}) is controlled relative to desired flux, while reference quadrature axis current (i_{sq}) is adjusted according to the desired torque. Which allows for a function comparable to a dc machine, with separate excitement [4].

The Voltage Source Rectifier (VSR) equivalent circuit is presented in Figure 1. The control of the VSR is split over two parts. The first is the direct and quadrature reference current generation (i_{sdref} and i_{sqref}) and generation of switching signals for VSR.

3.1.1 Generation of i_{sdref} and i_{sqref}

In proposed system, the electromagnetic torque is controlled by controlling the current i_{sqref} while the current i_{sdref} is set to zero.

For each wind speed, the speed of the rotor has only one value for maximum wind power. Using MPPT P&O algorithm, the reference speed Ω_{ref} is generated.

Speed is regulated by the proportional integral (PI) speed controller, as illustrated in Figure 1, and its output is considered as i_{sqref}.

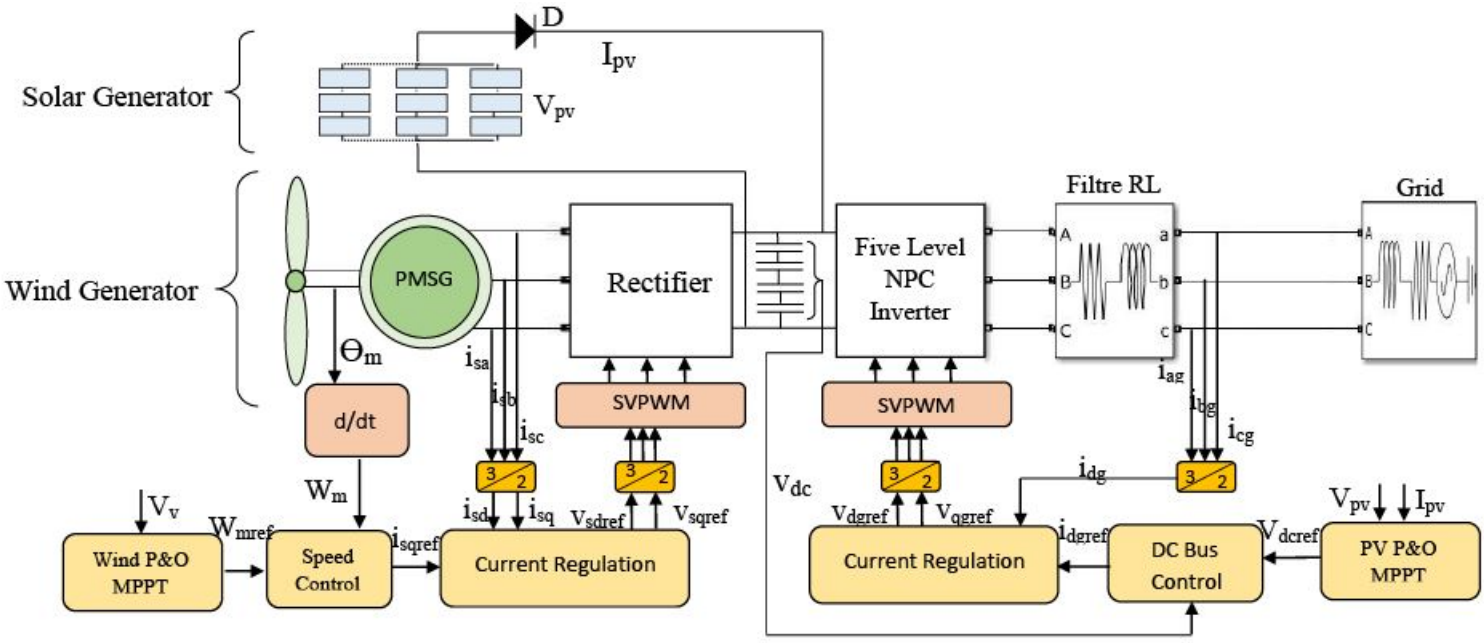

Figure 1: The proposed Wind-PV System Configuration

$$\begin{cases} i_{sdref} = 0 \\ i_{sqref} = \frac{2.Te_{ref}}{3.p.\varphi} \\ Te_{ref} = K_p.(\Omega_{ref} - \Omega) + K_i.\int(\Omega_{ref} - \Omega)\,dt \end{cases} \quad (6)$$

With: K_p and K_i are the proportion and integral coefficients of PI speed controller.

3.1.2 Generation of switching signals for VSR

The PI current controller is employed to ensure stator currents generated by PMSG correspond to references in (6), as shown in Figure 1 and (7).

$$\begin{cases} V_{sdref} = K_p.(i_{sdref} - i_{sd}) + K_i.\int(i_{sdref} - i_{sd})\,dt - \\ \Omega.L_s.i_{sq} \\ V_{sqref} = K_p.(i_{sqref} - i_{sq}) + K_i.\int(i_{sqref} - i_{sq})\,dt + \\ \Omega.L_s.i_{sd} + \Omega.\varphi \end{cases} \quad (7)$$

With: K_p and K_i are proportion and integral coefficients of PI current controller.

Three phase reference stator voltages (V_{saref}, V_{sbref}, V_{scref}) are generated from V_{sdref} and V_{sqref} using inverse Parks transform. They fed the SVPWM controller.

Voltage reference is determined using:

$$V_{ref} = \frac{2}{3}(V_{saref} + e^{-j2\frac{\pi}{3}}V_{sbref} + e^{-j4\frac{\pi}{3}}V_{scref}) \quad (8)$$

The rectifier delivers eight states, consisting of two zero vectors and six active vectors. The complex diagram is split by the active vectors in six sectors with 60 degrees forming each hexagon, with voltage reference vector corresponding to a pair of two active adjacent vectors (T_a, T_b) and a zero vector (T_0) of commutation time T_s [17].

Commutation times are determined by the equations below:

$$\begin{aligned} T_a &= T_s.m.sin(\frac{\pi}{3} - \theta) \\ T_b &= T_s.m.sin(\theta) \\ T_0 &= 1 - T_a - T_b \end{aligned} \quad (9)$$

$$\text{With: } m = \frac{(\sqrt{3})}{V_{dc}}|V_{ref}| \text{ modulation index} \quad (10)$$

3.2 Voltage Source Inverter Control (VSIC)

Figure 9 shows the Voltage Source Inverter (VSI) commutation configuration, uses the SVPWM strategy. VSI control is structured in two sections. The first section is the active power component i_{dgref} generation, the second is the VSI switching signal generation.

3.2.1 Generation of i_{dgref} and i_{qgref}

VSI system is regulated by using vector control scheme in which a phase locked loop (PLL) is applied to converter to synchronize it with power grid. Active and reactive power regulation are expressed by:

$$\begin{cases} P = 1.5(V_{dg}.i_{dg} + V_{qg}.i_{qg}) \\ Q = 1.5(V_{qg}.i_{dg} - V_{dg}.i_{qg}) \end{cases} \quad (11)$$

This control has the advantage of decoupling active and reactive control, whereas to regulate DC bus voltage V_{dc}, current i_{dg} is used and to regulate reactive power transited Q, current in quadrature i_{qg} is used. .

$$\begin{cases} P = 1.5V_{dg}.i_{dg} \\ Q = -1.5V_{dg}.i_{qg} \end{cases} \quad (12)$$

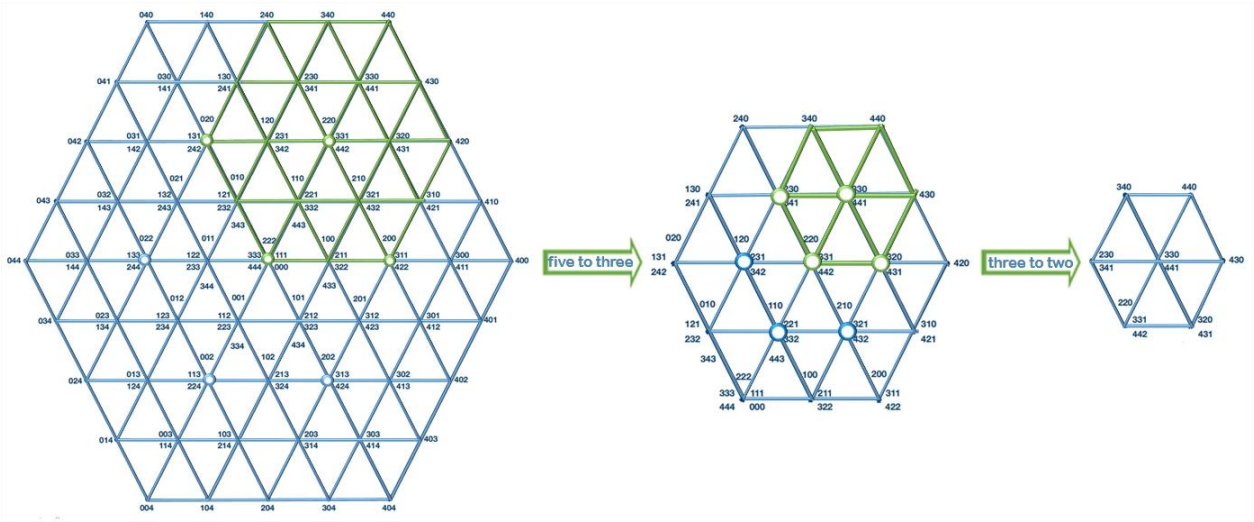

Figure 2: Decomposition of the five-level inverter vector diagram

We can therefore, through the imposition of reference currents, provide referencing for active power P_{ref} and reactive power Q_{ref} fixed in zero that maintains a unity power factor (PF), we have:

$$\begin{cases} i_{dgref} = \frac{P_{ref}.V_{dg} - Q_{ref}.V_{qg}}{V_{dg}^2 + V_{qg}^2} \\ i_{qgref} = \frac{P_{ref}.V_{qg} + Q_{ref}.V_{dg}}{V_{dg}^2 + V_{qg}^2} \end{cases} \quad (13)$$

The DC link reference (V_{dcref}) is obtained by the PV P&O MPPT algorithm as shown in figure 1, corresponding to its maximum PV power output voltage at various irradiation levels. The regulation of DC bus voltage is performed by PI regulator and its output is considered as the active power component i_{dgref}. The i_{dgref} is given as,

$$i_{dgref} = K_p.(V_{dcref} - V_{dc}) + K_i.\int (V_{dcref} - V_{dc})\,\mathrm{d}t \quad (14)$$

With: K_p and K_i are the proportion and integral coefficients of DC-bus voltage controller PI, respectively.

3.2.2 *Generation of switching signals for VSI*

The i_{dgref} and i_{qgref} are compared with i_{dg} and i_{qg}, respectivly, to obtain the currents error and are given as,

$$\begin{cases} i_{dge} = i_{dgref} - i_{dg} \\ i_{qge} = i_{qgref} - i_{qg} \end{cases} \quad (15)$$

The currents error are fed to PI controllers and the output of decoupled controller is given as:

$$\begin{cases} V_{dgref} = -K_i.\int i_{dge}\,\mathrm{d}t - K_p.i_{dge} + \\ \Omega_g.L_f.i_{qg} + v_{dg} \\ V_{qgref} = -K_i.\int i_{qge}\,\mathrm{d}t - K_p.i_{qge} + \\ \Omega_g.L_f.i_{dg} + v_{qg} \end{cases} \quad (16)$$

The three phase reference grid voltages (V_{agref}, V_{bgref}, V_{cgref}) are generated from V_{dgref} and V_{qgref} using inverse Parks transform.

This approach is founded on geometrically splitting of a vector diagram to several hexagons that represent low-level vector diagrams, as shown in figure 2 [18].

To attain this objective, two actions need to be completed:
- Depending of voltage reference vector position V_{ref}, one of six referenced hexagons is chosen;
- V_{ref} is moving to center of the hexagon selected in the first action.
Following these actions two times would reduce the five-level inverter's vector diagram to the two-level inverter's vector diagram. Next, we will employ the classical method of vector modulation of the two-level inverter, discussed in the section 3.1.2.

4 Simulation results

For the hybrid system, a simulation model shown at figure 1 has been modulated with Matlab/Simulink® in order to validate and evaluate system performance. Simulation parameters are as shown in the appendix A. Penetration of wind and PV energy is studied under different weather conditions.As shown in Figure 3 and 4, the wind speed increases from 20 to 8, and finally drops to 5 m/s, at t= 0.3 and 0.7s, respectively. Solar irradiance level increases from 400 to 1000, than drops at 500, and increases to 300 W/m, at t= 0.3, 0.5, and 0.7s, respectively.

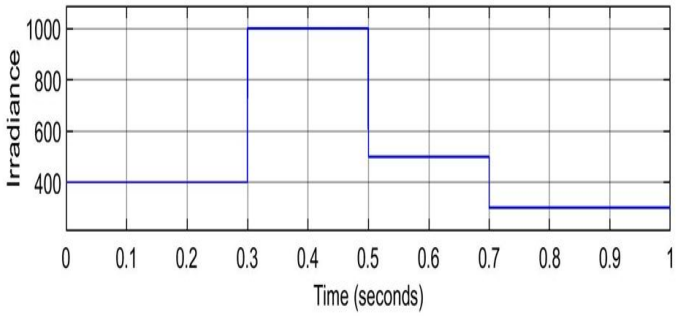

Figure 4: I_{pv} V_{pv} photovoltaic characteristics at different irradiation levels

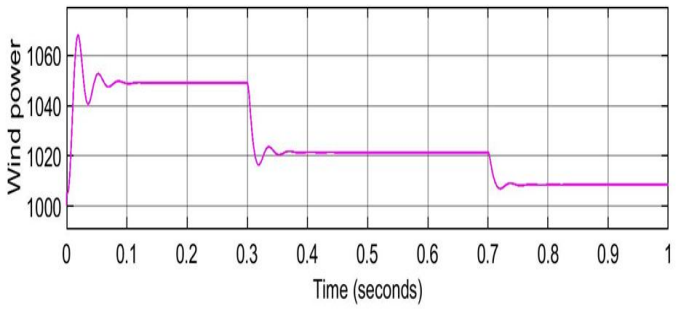

Figure 7: wind power

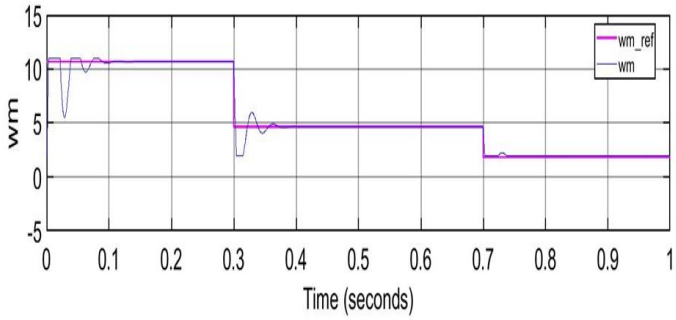

Figure 5: Generator rotation speed

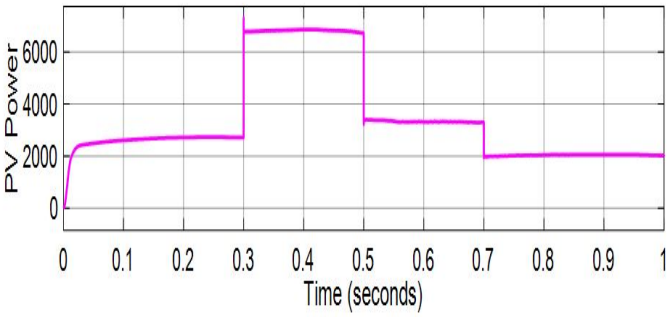

Figure 8: PV power

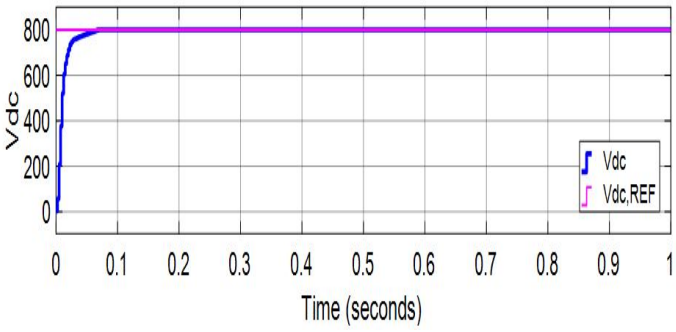

Figure 6: DC-link voltage

Optimal Ω_{ref} and V_{dcref} are generated by Wind and PV MPPT P&O, respectively. As depicted in Figure 5 and 6, the corresponding variables are then regulated.

Under these conditions, Ω_{ref} and V_{dcref} are both refracted on the corresponding PV and wind powers, as shown at figures 7 and 8.

Three-phase grid voltages before filtering are shown in figure 9, representing five-level inverter output voltage waveform obtained from capacitors. Economically, it is not interesting to use a rectifier for each capacitor, so it is necessary to ensure the balance of the continuous bus, as depicted in Figure 10 .

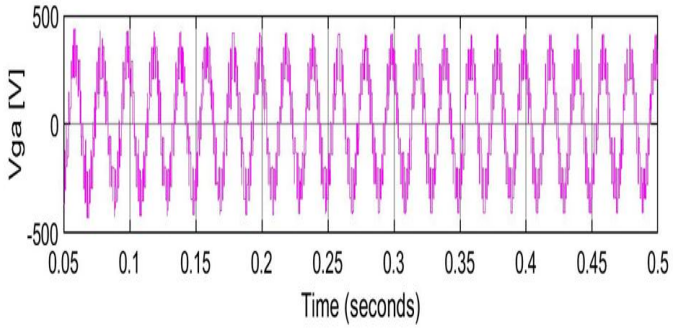

Figure 9: Output voltages of the three-phase inverter at five levels

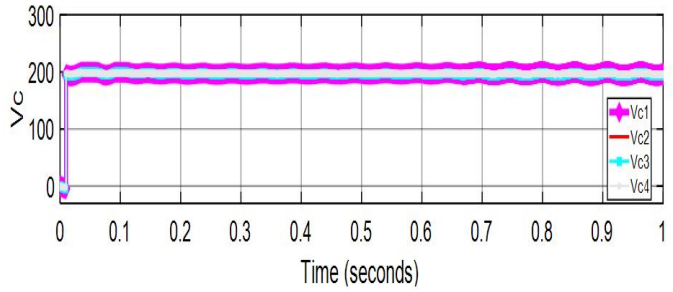

Figure 10: Capacitor voltage

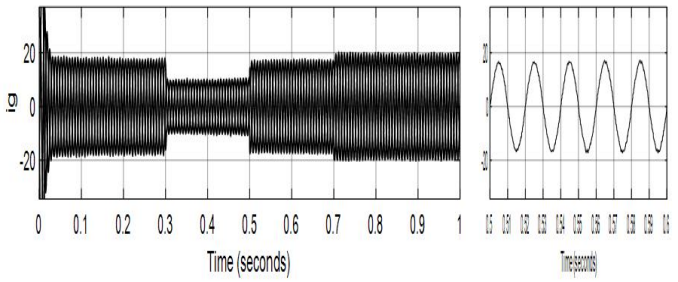

Figure 11: Grid current

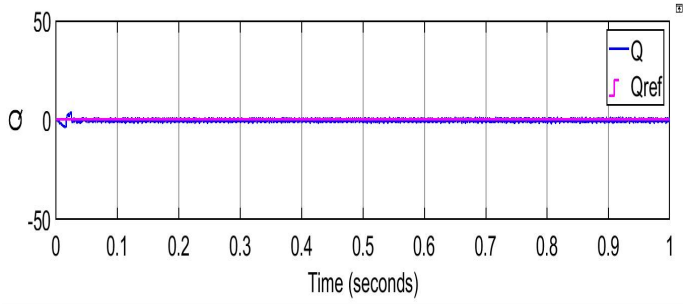

Figure 12: Reactive power

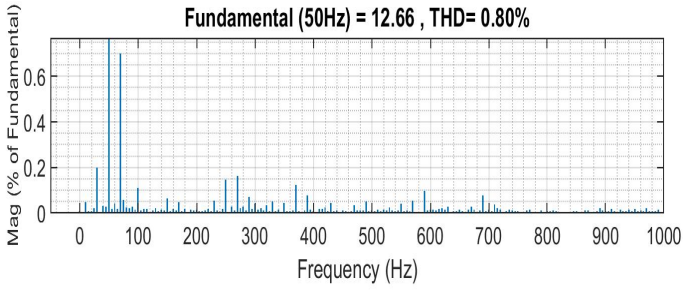

Figure 13: THD of grid currents injected

The AC current injected into grid is indicated in Figure 11. During entire operating range, the reactive power is set to zero, then a unity PF is maintained, as shown in in Figure 12.

The figure 13 illustrates the THD currents injected in the grid. According to THD analysis above, the total harmonic distortion at Fc=1KHz given THD=0.80%. Therefore, as the number of levels is increased, THDs are minimized in comparison with classical multi-level inverters [19].

5 Conclusion

In this paper, the modeling and simulation of wind-power hybrid systems connected to the grid, using vector control systems were presented.A hybrid system based on wind and photovoltaic energy was set up with a five-level inverter. The VSRC's purpose consists of extracting the maximum wind power, and the VSIC is responsible for extracting maximum PV power, and balance of dc-link capacitor in order to transfer produced power to utility-grid. This way, reactive power is fixed at zero, then a unity Power Factor PF is maintained. The proposed system has enhanced efficiency and reliability via a hybrid renewable energy system, the maximum power is extracted from independent MPPT using P&O algorithm, and reduces current THD. The results of the simulations showed the correspondence of the quantities assessed with the reference quantities and allowed the validation of the mathematical models.

ABSTRACT

This paper is an extension of a research work presented at ICSIoT 2019. An attack continuum against the insider attack in mobile money security in Ghana using a witness based cryptographic method proposed by Alornyo et al. resisted the service provider from peddling with users data for economic gains. Our improved scheme achieves a simultaneous benefit of digital signature in public key encryption (PKE). The adoption of signcryption cryptosystem in our scheme achieved a desired security property of EUF-CMA using the random oracle model.

1 Introduction

Ghana and other African countries have seen a tremendous growth in mobile money service patronage in recent times. The use of the mobile money services platform requires the use of a less-resource constraint mobile devices that do not require access to internet or mobile app for mobile payment. Thus, any mobile device that does not have access to internet but can access the mobile money service provider cellualr network can perform financial transactions and other utility payments. This and many other reasons has lead to the high patronage of mobile money services in Ghana. However, the mobile money system is not immune to data forgery and re-play attacks. The system model of our scheme is depicted in 1

Our research work is an extension of a publication presented at ICSIoT 2019. The construction presented at ICSIoT 2019 [1] considered the service provider as the adversary who could launch the insider attack. The service provider had access to users token information and transaction details and was possible for the service provider to peddle with users data via the following:

- The mechant receives valid transaction details such as transaction ID, td_{ID} and finds out the content M_1 as well as the token information td_{ID} from the transaction details TSD.
- The adversary (insider) attains the ciphertext CT_1 of a guessed message $M_1^{'}$ and token tdk_{ID}.
- The adversary checks if the test $Test(CT_1, TSD, td_{ID}^{'}) = 1$

In the above scenario, the insider wins the game if it succeeds in deriving the token information from the transaction details. However, the scheme utilized the witness based cryptographic primitive with an added pairing operation to resist the insider attack continuum.

In spite of their construction, there were a possible attack during data transmission such as forgery and re-play attacks in mobile money payment systems. To solve the problem, we propose a scheme using a signcryption cryptographic primitive to achieve the simultanoeus benefit of digital signature and PKE in mobile money systems deployed in Ghana (West Africa). This approach resist data forgery and re-play attacks.

The first generic construction of identity-based signcryption was unveiled [2]. Their work fulfilled a dual function of digital signature and public key cryptosystem (PKE). Other traditional approaches that employed signature-then-encrypt had a high cost computations as compared to [2]. However, the scheme [2] adopted data encapsulation method instead of key encapsulation method [3]–[6] to achieve confidentiality and unforgeability instantiation in the standard model.

Signcryption scheme unveiled in [7] did not propose a secu-

[*]Corresponding Author: Seth Alornyo, Koforidua Technical University, Computer Science Department, +233 554936729 & sabigseth@ktu.edu.gh

rity proof even though their construction were based on discrete logarithm assumptions. In view of this, several research in signcryption and signature schemes have been unveiled [8]–[15] with other functional extensions [16]–[19]. In 2011, a survey of identity-based signcryption cryptosystem was examined by Li et al.[20] to examine the security models as well as a comparative study of their security properties and efficiency. Analysis of other flavours of signcryption constructions [4], [11]–[13], [21]–[24], threshold signcryption [25]–[30], proxy signcryptions [31]–[37] and ring signcryption [38]–[42] have been proposed and constructed. Subsequently, Xiong et al. [43] did a cryptanalysis on the scheme [21]. The security notion of CPA in their work was diffused by Xiong et al. [43]. Hence, [43] showed that their scheme did not achieve chosen plaintext attack (CPA) security as they claimed.

Due to the need to resist the cloud server from peddling users outsourced data, efficient signcryption cryptosystem was unveiled in [44]. According to him, some existing signcryption schemes in [45]–[55] had certain lapses such as lack of data integrity, authentication and non-repudiation. Hence the need to construct a scheme to deny the insider adversary in the cloud from data peddling and modification for economic gains became paramount. Furthermore, the emergence of distributed computing and interconnected systems propelled [56] to unveiled a signcryption scheme in heterogeneous systems. Although in [57], the author earlier discussed the above problem, they could not construct a scheme to solve the problem of signcryption in heterogeneous systems. However, the constructions in [57, 58] and [59] achieved insider and outsider attack resistant respectively.

Recently, secure identity-based cryptosystem has been unveiled in [60]. Their security improvement was based on certain proposed signcryption algorithms [11]–[14], [61] constructed using the random oracle, and as well as schemes designed using the standard model [21, 23, 24, 62] with certain deficiencies such as IND-CCA2 and existential unforgeable chosen message attack (EUF-CMA). However, an attack was launched in [63] to unveil a new functional secure identity-based signcryption cryptosystem in [60]. A scheme to curtail an attack continuum in mobile money wallet system in Ghana to prevent message forgeability and re-play attack is still an open problem.

1.1 Our Contribution

By considering that the integrity, authentication and non-repudiation of the data in mobile money wallet system in Ghana, we proposed the mobile money wallet attack resistant scheme using the ID-based signcryption cryptographic primitive with equality test (known as MWAR-ID-SET) to achieve a simultaneous benefit of digital signature with public key encryption, and with equality test. Concretely, the formal definition, security model and concrete construction of MWAR-ID-SET are proposed in this paper. Further, our proposed scheme was shown to achieve the security property of existential unforgeable chosen message attack (EUF- CMA) by using the formal security proof.

1.2 Paper Organization

The rest of this work is organized as follows; In Section 2, our scheme outlines preliminaries for the construction and formulate the definitions of MWAR-ID-SET. In Section 3, the definitions of our scheme are outlined, section 4 outlines the security model of MWAR-ID-SET. Section 5 details the construction of our scheme, and proof the security in Section 6. Section 7 compares our work with existing schemes. Section 8 concludes our work.

2 Preliminaries

Definition 1: Bilinear Map. Let G and G_T be two multiplicative cyclic groups of prime order p. Suppose that q is agenerator of G. A bilinear map $e : G \times G \rightarrow G_T$ satisfies the following properties:

1. Bilinearity: For any $g \in G$, and $b \in Z_p$, $e(g^a, g^b) = e(g, g)^{ab}$.
2. Non-degenerate: $e : (g, g) \neq 1$.
3. Computable: There is an efficient algorithm to compute $e(g, g)$ for any $g \in G$.

Definition 2: Bilinear Diffie-Hellman (BDH) problem. Let G and G_T be two groups of prime order q. Let $e : G \times G \rightarrow G_T$ be an admissible bilinear map and let q be a generator of G. The BDH problem in (q, G, G_T, e) is as follows: Given (q, q^a, q^b, q^c), for random $c, d, f \in Z_p^*$, for any randomized algorithm. A computes the value $e(q, q)^{cdf} \in G_T$ with advantage:
$ADV_A^{BDH} Pr[A(q, q^c, q^d, q^f) = e(q, q)^{cdf}]$.

We say that the BDH assumption holds if for any polynomial-time algorithm A, its advantage ADV_A^{BDH} is negligible.

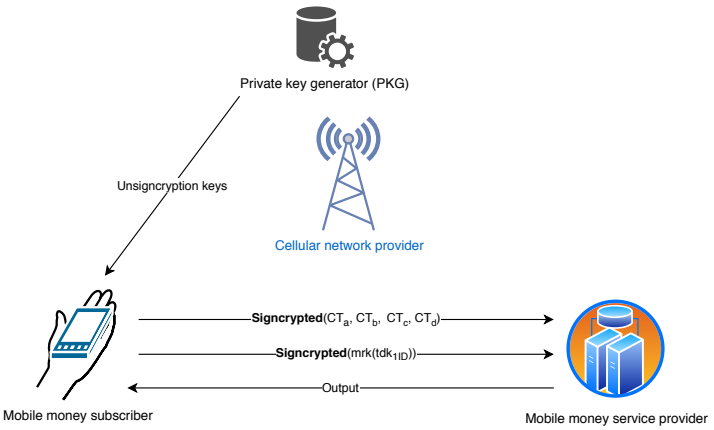

Figure 1: System model of our scheme

3 Definitions

In this section, the formal definition of our proposed scheme is outlined. MWAR-ID-SET achieves a formal security property of EUF-CMA. The construction specifies six(6) steps: $Setup$, $MW - Extract$, $TokenGen$, $MW - Signcrypt$, $MW - Unsigncrypt$, $MW - Test$. M_T and C_T are considered as the plaintext space and ciphertext space respectively.

1. $Setup$: The construction on input a security parameter k, output public parameter K with MSK as master secret key.

2. $MW - Extract$: The scheme on input MSK, $ID \in \{0,1\}$ arbitrary and gives out a message recovery key mrk corresponding to an identity.

3. $TokenGen$: With the input message recovery key mrk, arbitrary $ID \in \{0,1\}^*$ and it return token tdk_1 corresponding to an identity (ID_1).

4. $MW - Signcrypt$: The scheme on input $ID \in \{0,1\}^*$, random witness $w \in W$, a chosen plaintext $m_1 \in M_1$, and output ciphertext $CT_1 = (x_1, c_1)$ where $x \in X$ from generated witness $WInsGen(w) = x$ with the relation R satisfied [1].

5. $MW - Unsigncrypt$: On input the ciphertext CT_1, message recovery key mrk with a random chosen witness $w \in W$, the plaintext $m_1 \in M_1$ is uncovered provided CT_1 is deemed as a valid ciphertext derived from a witness relation R.

6. $MW - Test$: The scheme on input the ciphertext $CT_A \in CT_1$ with its corresponding receiver ID_A derived from the token tdk_{1_A} with its corresponding ID_A, the ciphertext $CT_A \in CT_1$ with its corresponding receiver ID_B derived from the token tdk_1 with its corresponding ID_B. The scheme respond 1, provided CT_A and CT_B have same message. Otherwise it respond as $\perp$.

4 Security Model

We assume $\sqcap = \{Setup, MW - Extract, TokenGen, MW - Signcrypt, MW-Unsigncrypt, MW-Test\}$ as the scheme and polynomial time algorithm adversary A. $MWAR - ID - SET$ achieves two main security notion of $IND - CCA2$ and $EUF - CMA$. However, our scheme adds the security notion of ID-based indistinquishability to IND-CCA2 and is coined as IND-ID-CCA2, similarly presented in [55] via the standard model..

1. $Setup$: The challenger A executes the security parameter k and outdoors K with a randomly chosen witness $w \in W$ and generates $x \in X$ of the relation R. It gives out the relation R to the adversary A.

2. Phase 1: The mobile merchant adversary A then issues $(\wedge_1, \wedge_2, ..., \wedge_{n-1})$. It is assumed that such query is of:

   - $MW-Query(ID_i)$: The merchant executes $H(.)$ and generates mrk_i which corresponding to ID_i as the identity. The recovered mrk_i is forwarded to A.
   - $TokenGen(ID_i)$: The merchant executes the $MW - Unsigncryption$ to generates tdk_i via the witness relation R. The algorithm then forwards tdk_i to A.

3. $MW - Challenge$: When the phase comes to an end, two messages (m_1, m_2) with equal-length and ID^* is submitted by A to the challenger and wishes to be challenged. But (m_1, m_2) were both not issued during signcryption and ID^* was never extracted during phase 1 section. Given this, the challenger randomly chooses $t \in \{0,1\}$ and returns $CT_1 = MW - Signcrypt(m_t, ID^*, w^*)$. Again, a challenge ciphertext token $mrk^* = (ID^*, x^*)$ is issued by the execution of $TokenGen$ phase $mrk^* \leftarrow mrk(tdk, m_t, x^*)$ and it output mrk^* to A.

4. $MW - Unsigncrypt$: The merchant executes an unsigncryption algorithm to unsigncrypt CT_1. The merchant obtains mrk_1 which corresponds to a public key of ID_i. The plaintext m_i is forwarded to A.

5. Phase 2: The merchant adversary issue the query $(\wedge_1, \wedge_2, ..., \wedge_n)$. The query is of the form:

   - $MW - Query$. A similar response as in phase 1 is given because $ID_i \neq ID^*$.
   - $TokenGen(ID_1)$. Given $x \neq x^*$, the merchant respond same as in phase 1.

6. Result. The adversary A does a guess v' of v. Since $v' = v$, then the adversary will win the game.

   The adversary advantage in breaking the scheme is noted as: $ADV_{MWAR-ID-SET}(k) = Pr[v' = v] - \frac{1}{2}$ as a negligible probability.

5 Construction

A detailed construction of our proposed scheme is outlined as follows:

1. On input a secured parameter k, the algorithm output public parameter K, with MSK as master secret key.

   - Two multiplicative group G and G_T are generated by the system with the same order of lemgth θ bits with a bilinear map $e : G \times G \rightarrow G_T$. The group generater $P \in G$ is selected.
   - The algorithm exploits keyed permutation $F : \{0,1\}^s \times \{0,1\}^n \rightarrow Z_p^*$ with a positive interger $D = k(i)$ and $L = b(i)$, it then activate a random value r_1 from $\{0,1\}^L$. Message authentication code (MAC), $MAC = GSV$. Thus, generate, sign, verify (GSV). After executing $G(i)$, it obtains r_2. It then set master token key as $MTK_1 = (r_1, r_2)$.
   - A hash functions $H_a : \{0,1\}^\tau \rightarrow Z_p^*$, $H_b : \{0,1\}^* \rightarrow G$, $H_c : A \times G \times G_T \rightarrow \{0,1\}^{\tau + r_1}$, where r_1 represent random numbers and τ as length of message. $(\tau_1, \tau_2) \in Z_p^2$ is randomly chosen and $R_v = P^{\tau_1}$, $R_m = P^{\tau_2}$. The paramrter $K = (A, \tau, G, G_T, P, R_v, R_m, MAC, H_a, H_b, H_c)$ is made public (published)

2. $MW-Extract$: With an $ID \in \{0,1\}$ as string, the system computes $Q_{ID} = H_b(ID) \in G$ and private key $mrk_{ID} = (Q_{ID}^{\tau_1}, Q_{ID}^{\tau_2})$. It should therefore be noted that (τ_1, τ_2) are secret value randomly chosen by the algorithm.

3. $TokenGen$: The algorithm with an input string $ID \in \{0,1\}^*$, the computation $Q_{ID} = H_b(ID) \in G$ is executed and the token $tdk_{1_{ID}} = (Q_{ID}^{\tau_2})$ is generated.

4. $MW - Signcrypt$: The algorithm with an input public parameter K, string ID, it executes $Q_{ID} = H_b(ID) \in G$ and a **signcryption** $m_1 \in G$ is triggered by choosing two random values $(q_1, q_2) \in Z_p^*$. The ciphertext is set as $CT_1 = (CT_a, CT_b, CT_c, CT_d)$ as :

$$CT_a = H_b(e(Q_{ID}, R_m)^{q_1}) \cdot m_1^{q_1}, \qquad CT_b = P^{q_1}$$

$$CT_c = P^{q_2} \quad CT_d = (m_1 \| w) \oplus H_b(CT_a \| CT_b \| Z \| e(Q_{ID}, R_v)^{q_2}).$$

The signature $Z \leftarrow S(r_2, CT_c)$ is used to signcrypt the ciphertext of the employed MAC. The signcrypted tag Z is used to verify signcrypted ciphertext CT_c

5. $MW - Unsigncrypt$: To **unsigncrypt**, the algorithm with an input the ciphertext CT_1, private **unsigncryption** key $mrk = (Q_{ID}^{\tau_1}, Q_{ID}^{\tau_2})$ with $CT_1 = (CT_a, CT_b, CT_c, CT_d)$ corresponding to an identity ID. The algorithm executes $(m_1 \| w^{'}) = CT_b \oplus H_b(CT_a \| CT_b \| CT_c \| e(CT_c, Q_{ID}^{\tau_1}))$. The algorithm do a check of $CT_a = (m_1^{'}) \| x^{'}$ and $CT_b = P^{q_1^{'}}$ to determine whether they are equal. If they are equal, the algorithm returns m_1, contrarily, it returns $\perp$.

6. $MW - Test$: With a given **signcrypted** ciphertext CT_{1_A} with trapdoor tdk_{1_A} and a different **signcrypted** ciphertext CT_{1_B} with a trapdoor tdk_{1_B}. The algorithm determines whether $m_{1_A} = m_{1_B}$ is equal or not. The algorithm does this by executing:

$$TD_A = \frac{CT_{a_A}}{H_b(e(CT_{a_A}, R_{m_A}))}, \quad TD_B = \frac{CT_{a_B}}{H_b(e(CT_{a_B}, R_{m_B}))}.$$

If the above equation holds, the algorithm then output 1 on success and 0 on failure.

Construction Correctness.
We assume that $CT_1 = (CT_a, CT_b, CT_c, CT_d)$.). Test algorithm executes:

$$CT_{1_A} = \frac{CT_{a_A}}{H_b(e(CT_{a_A}, R_{m_A}))}, \quad CT_{1_B} = \frac{CT_{a_B}}{H_b(e(CT_{a_B}, R_{m_B}))}$$

$$CT_{1_A} = \frac{H_b(e(Q_{ID}, P^{\tau_2})^{q_1}) \cdot m_{1_A}^{q_1}}{H_b(e(Q_{ID}, P^{\tau_2})^{q_1})}, CT_{1_B} = \frac{H_b(e(Q_{ID}, P^{\tau_2})^{q_1}) \cdot m_{1_B}^{q_1}}{H_b(e(Q_{ID}, P^{\tau_2})^{q_1})}$$

$$CT_{1_A} = m_{1_A}^{q_1}, \quad CT_{1_B} = m_{1_B}^{q_1}$$

Hence, $m_{1_A}^{q_1} = m_{1_B}^{q_1}$

From the above, the algorithm output 1 on success and 0 on failure.

Therefore:

$e(CT_{b_A}, R_{m_B}) = e(CT_{b_A}, R_{m_B})$.

$$e(CT_{b_A}, R_{m_B}) = (P^{q_1}, P^{\tau_2}) = e(P, P)^{q_1 \tau_2},$$

$$e(CT_{b_A}, R_{m_B}) = (P^{q_1}, P^{\tau_2}) = e(P, P)^{q_1 \tau_2}.$$

This implies that if, $m_{1_A} = m_{1_B}$, then

$e(CT_{b_A} = R_{m_B}) = e(CT_{b_A} = R_{m_B})$.

6 Security Analysis

In this section, we consider a formal security property of IND-CCA2 and EUF-CMA [60]. Our scheme adds the notion of ID-based indistinquishability to IND-CCA2 and referred to as IND-ID-CCA2.

6.1 IND-CCA2 Security

Our MWAR-ID-SET is $(SET_\varepsilon, t_s, q_{ks}, q_{ns}, q_{us})$-IND-CCA2 secure if $(\varepsilon_{mdbdh}, t_s) - mDBHDH$ assumption holds. Thus, H_1 and H_2 serves as (ε_{H_1}) and (ε_{h_2}) are both collision resistant hash functions, such that:

$$\varepsilon_{SET} \leq \varepsilon_{mdbdh} + \varepsilon_{H_1} + \varepsilon_{H_2} + \frac{q_{ks}+q_{us}+3}{p} + \frac{q_{ns}}{p^2}.$$

Where t_s refers to index period time, q_{ks} refers to number of extraction key queries, q_{ns} represent number of signcryption queries and q_{us} represents number of unsigncryption queries. Therefore, the security analysis with a collission resistant hash function proves our scheme secured.

6.2 EUF-CMA Unforgeability

Proof Theorem: This section outlines the security proof of unforgeability against adaptive CMA derived from the security constructions in Chow[41] ID-based **signcryption** cryptosystem. Thus, it is expected that the adversary can forge a ciphertextof a message m_1, if the assumption $CT_1 = (CT_a, CT_b, CT_c, CT_d)$ corresponding to a user identity ID holds. Thus, $CT_d = (m_1 \| w) \oplus H_3(CT_a \| CT_b \| CT_c \| e(Q_{ID}, R_v))^{q_2}$ is regarded as the signature of the message $m_1 \| w$, where $e(Q_{ID}, R_v)^{q_2}$ is regarded as the pairing of a corresponding user with secret **signcryption** key R_v. It is however noted that the difficulty of CDH problem makes the scheme unforgeable via the random oracle model.

6.3 Security Analysis of Token Key

Further details on the token security analysis can be accessed in [1]. The token security analysis experiment to our scheme is defined as: $EXP_{MWAR-ID-SET_A}^{IND-ID-CCA2}(k)$.

With a security parameter k, a master token key $MTK_1 = (r_1, r_2)$ and A adversary against token security. According to [1], the adversary A win the game if $b^{'} = b$, which shows that the output of the experiment is 1 on success and 0 on failure. Adversary A advantage in the experiment is defined as:

$Adv_{MWAR-ID-SET}^{IND-ID-CCA2}(w) = |Pr[Exp_{MWAR-ID-SET}^{IND-ID-CCA2}] - \frac{1}{2}|$

However, the probability for the adversary to win the game is negligible, hence proves our construction secured.

7 Comparison

A security strength comparison computations with existing **signcryption** schemes are outlined in Table 1. Constructions in ID-based **Signcryption** cryptosystem in [21, 23, 60, 64] are compared to with respect to security strength. The parameters for our comparison includes group multiplication, group exponentiation, inverse computations, pairing operation, test for equality, and support for EUF-CMA.

Table 1: The performance computational cost and Communication overheads

Scheme	G_{Mult}	G_{Exp_a}	$G_{T_{Mult}}$	$G_{T_{Exp_a}}$	$G_{T_{Inv}}$	Pr	IND-CCA2	EUF-CMA	ET
[21]	$2n_{u_a} + 2n_{m_a} + 1$	3	5	1	1	7(+2)	⊠	√	No
[23]	$2n_{u_a} + 2n_{m_a} + 1$	3	5	1	1	7(+2)	⊠	⊠	No
[60]	$2n_{u_a} + 2n_{m_a} + 1$	7	5	1	1	7(+2)	√	√	No
[64]	$2n_{u_a} + 2n_{m_a} + 3$	7	5	1	1	7	√	√	No
Ours	$2n_{u_a} + 2n_{m_a} + 1$	7	3	2	2	8	√	√	Yes

Legend: $''G_{Mult}$": multiplication in group G, $''G''_{Exp_a}$: exponentiation in group G, $''G''_{T_{Exp_a}}$: exponentiation in group G_T, $G_{T_{Inv}}$: inverse computation in group G_T, $''n_m, n''_u$: length of identity in bits string, $''Pr$": pairing operations in the form $x(+y)$ as in [23], $''ET''$: equality test, $''\boxtimes''$: not supportive, $''\surd''$: supportive .

Table 2: Running Times with Symbols

Symbols	Description	Times
G_{Exp_a}	G exponentiation operation	6.3937
$G_{T_{Exp_a}}$	G_T exponentiation operation	1.9518
T_{p_a}	Operation with pairing	11.4173
T_{h_a}	Hash functions	000853
G_{Mult}	Multiplication operation in G	0.047
$G_{T_{Mult_a}}$	Multiplication operation in G_T	0.0119

The Pairing-Based Cryptography (PBC) Library [65] is used to quantify the time consumption of signcryption, unsigncryption and test operations. We use the code of a program in VC++ 6.0 and executed on a computer (Windows 10 Pro, operating system), Capacity of Intel(R) Core (TM) i5-4460 CPU with 3.20GHZ and 4Gb RAM. The code was executed several times and average time of execution extracted (see Table 2). With respect to the scheme in [66], and other pairing-based constructions with a security level of 1024-bit RSA, a supersingular curve $z^2 = x^3 + x$ with an embedded degree of 2 is adopted. Also, $q = 2^{159} + 2^{17} + 1$ noted as a 160 bit Solinas prime noted as a $512 - bit$ prime. With regards to ECC-based schemes, an equivalent security level of Koblitz elliptic curve of $y = x^3 + ax^2 + b$ defined on a $F_{2^{163}}$ is used to provide the same security level in the ECC group. The computational units are in millisecond (ms) and bytes respectively. The execution times of each respective algorithm were calculated and Matlab program was used to generate Table 1 and computational results in Table 2.

Therefore, it is clear that our scheme support equality test as compared with other schemes without equality test. The computation of trapdoor and trapdoor delegation to the tester is equally achieved in our scheme. In terms of computational cost, our scheme has a lower computation cost as compared to existing schemes. Also, the support for IND-ID-CCA2 is featured in our sccheme as compared to other existing scheme with IND-CCA support. However, the inverse compuatation to recover the message achieves a ligh computational cost as compared to others in Table 1. This is pardonable due to the additional trapdoor computations featured in our scheme.

8 Conclusion

The construction $MWAR - ID - SET$ achieves a security improvement in mobile money service security in Ghana via the adoption signcryption cryptosystem. Data forgery and re-play attack is curtailed in our construction and the simultaneous benefit of PKE and digital signature is achieved in our scheme using the random oracle model. A desirable security property of EUF-CMA is achieved in our construction. In spite of other applications and extentions of identity based cryptosystem [67]–[70], our scheme achieves a remarkable achievement in indentity based cryptosystem.

Conflict of Interest The authors declare no conflict of interest.

Acknowledgment We will like to use this opportunity to thank the anonymous reviewers for their kind support and consideration.

Ant colony optimisation
Analog circuit design
Positive second-generation current conveyor

ABSTRACT

Ant Colony Optimization (ACO) algorithm, a well-known robust technique to solve easily both a simple and multiple objective optimization problems. This article presents an application of the ACO in order to achieve the optimal sizing of analog circuit. The proposed technique is employed to optimizing the sizing of a positive second-generation current conveyor (CCII+). Results show better objective functions than previously achieved by other optimization procedure. PSPICE simulations are used to confirm the validity of the reached optimal results and the accuracy of the proposed procedure.

1. Introduction

Current Conveyor (CC) represents the first construction block developed for current signal processing [1]. Two years later, in 1970, another variant of a CC, namely, Second Generation Current Conveyor (CCII) was published [2].

Recently, a Current Conveyor is seen as a good alternative for the voltage-mode. CC can be widely employed in different applications. The CCII is the most popular configuration [3].

Despite the number of positive proprieties ensured by the CCS [4], it seems that designing integrated CC circuits with high performance is in effect still open particularly in CMOS technology [5].

Currently, an important interest has been devoted to achieve the best sizing of the analog component efficiently and with high accuracy. Some (meta) heuristics were used in the scientific publications such as Genetic Algorithms (GA) [6, 7], Ant Colony Optimization (ACO) [8, 9], Particle Swarm Optimization (PSO) [10], Differential Evolution algorithm (DE) [11], Simulated Annealing (SA) [12] and Artificial Bee Colony Algorithm (ABC) [13, 14].

ACO algorithm is proposed in this work, with view to get an optimal design of positive second-generation current conveyor (CCII+). To this end, we applied three of the most important variants of ACO, specifically, the Ant System (AS), the Min-Max Ant System (MMAS) and the Ant Colony System (ACS). In fact, the ACO has already efficiently been used to treat real optimization problems, particularly in the analog circuit area.

A high performance CCII+ depends on the high-end cut-off frequency for the current waveform (F_{ci}) and the input impedance at port X. Hence, two objectives functions are taken into consideration: achieve a low input resistance R_X and a very high cut-off frequency F_{ci}. However, the suggested technique is a mono-objective one, to this end; the optimization process is treated using two distinct manners; firstly, each objective function is solved separately. In the second way, a mono-objective problem is considered by using a weighting technique.

This paper is organized in the following manner: The second section is about a detail description of the ACO technique. The third section proposes an example for the optimal sizing of CCII+. Then, a comparison with some similar works and simulation results are represented in the fourth section. Through the fifth section, the optimized CCII+ is exploited in order to form a current mode filter. Finally, the sixth section is the conclusion.

2. The ACO Technique Presentation

Ant Colony Optimization (ACO) is a nature-inspired algorithm, used to resolve various hard problems. The use of ACO has proved a capacity to deal with complex optimization problems successfully, for instance we can cite the traveling salesman

*Corresponding Author: Kritele Loubna, loubnakritele@gmail.com

problem (TSP) [15], vehicle routing problem [16], the quadratic assignment problem (QAP) [17].

The ACO takes inspiration from the real ant colonies behavior. The fundamental idea of this metaheuristic consists in simulating the social intelligence of ants in searching the shortest road from the nest and a source of food. In fact, real ants communicate indirectly through trails of chemical pheromone. Concretely, the agents of the colony deposit pheromone on the road to determine certain favorable route to be pursued by other ants [18].

2.1. Ant System

« Ant System » (AS) is the basic variant of the ACO. The modelling approach to resolve a given optimization problem is established as follows:

Ants choose the vertex to travel to by applying the state transition rule [19, 20]. Ant k in node a will move to vertex b according to the probability offered by (1):

$$P_{ab}^{k}=\begin{cases}\dfrac{(\tau_{ab})^{\alpha}\cdot(\eta_{ab})^{\beta}}{\sum_{l\in J_a^k}(\tau_{ab})^{\alpha}\cdot(\eta_{ab})^{\beta}} & \text{if } a\in J_a^k\\ 0 & \text{if } a\notin J_a^k\end{cases} \quad (1)$$

while J_a^k corresponds to the list of possible moves, which are possible for ants starting form vertex a, τ_{ab} represents the intensity of the trace associated to brink (a, b). α and β identify the relative impact of the trace intensity and the visibility value, η_{ab}.

where

$$\eta_{ab}=\frac{1}{d_{ab}} \quad (2)$$

The d_{ab} represents the distance between nodes a and b

The pheromone is updated by means of formula (3), when all agents of the colony construct their path:

$$\tau_{ab}=(1-\rho)\cdot\tau_{ab}+\sum_{k=1}^{m}\Delta\tau_{ab}^{k} \quad (3)$$

While ρ corresponds to the pheromone decay parameter, m represents the number of ants, and $\Delta\tau_{ab}^{k}$ is the amount of pheromone deposited by ant k on brink (a, b):

$$\Delta\tau_{ab}^{k}=\begin{cases}\dfrac{Q}{L_k} & \text{if } (a,b) \text{ belongs to tour done by k}\\ 0 & \text{otherwise}\end{cases} \quad (4)$$

Q is a constant; L_k represents the tour length built by ant k.

2.2. Min-Man Ant System

The Min-Max Ant System is an adjustment of the AS [21].

Min-Max Ant System (MMAS) is designed to attain the best result. To this end, only the optimal result is authorized to intensify the pheromone quantity. In fact, MMAS uses an instrument to border the trace intensity, and so that avoid the premature stagnation.

MMAS presents some new features and they are as follows:

- Only the ants that produced the best solution are allowed to update trails;
- To avoid stagnation, MMAS introduces upper and lower bounds so that the pheromone intensities lie inside the interval $[\tau_{min}, \tau_{max}]$;
- In each brink, the trail strength is initialized to τ_{max}.

2.3. Ant Colony System

The Ant Colony System (ACS) algorithm incorporates three main differences with respect to the AS algorithm:

- ACS algorithm uses a parameter q_0 ($0\le q_0\le 1$), which controls the tuning between exploitation and exploration. thus, the probability that ant moves to node b is given by this rule:

$$b=\begin{cases}\arg\max_{u\in B_a^k}\left[\left(\tau_{au}(t)*(\eta_{aB})^{\beta}\right)\right] & \text{if } q\le q_0\\ (1) & \text{if } q\succ q_0\end{cases} \quad (5)$$

where q is a random variable evenly distributed in [0, 1]

- The global pheromone update is applied only to edges that form part of the best solution, as in the following:

$$\tau_{ab}=(1-\rho)\cdot\tau_{ab}+\rho\cdot\Delta\tau_{ab} \quad (6)$$

where

$$\tau_{ab}=\begin{cases}1/L & \text{if } (a,b)\in best-global-tour\\ 0 & \text{otherwise}\end{cases} \quad (7)$$

- The updating of local pheromone is applied when each ant produce a solution:

$$\tau_{ab}=(1-\rho)\cdot\tau_{ab}+\rho\cdot\tau_{int} \quad (8)$$

The procedure of the ACO technique can be illustrated by means of the flowchart bellow:

3. Application of the ACO to the optimal sizing of CCII+

CCII is the most popular configuration of CCs; it replaces the conventional OPAMP in different applications as for example active filters, oscillators, and analog signal processing.

The CCII is three terminal devices; the current conveyor's response is illustrated by expression (9) [22]:

$$\begin{pmatrix}I_Y\\V_X\\I_Z\end{pmatrix}=\begin{pmatrix}0&0&0\\1&0&0\\0&\pm\beta&0\end{pmatrix}\begin{pmatrix}V_Y\\I_X\\V_Z\end{pmatrix} \quad (9)$$

The voltage at node X is duplicated from the voltage applied at node Y. Similarly, the current at Z port is copied from the current flowing through node X. A positive Z output current conveyor is considered when $\beta=+1$ and it is denoted CCII+. For optimal

circuit performance, it is desirable to have very high impedance on Y and Z nodes and small Rx, i.e. the resistance on X [22].

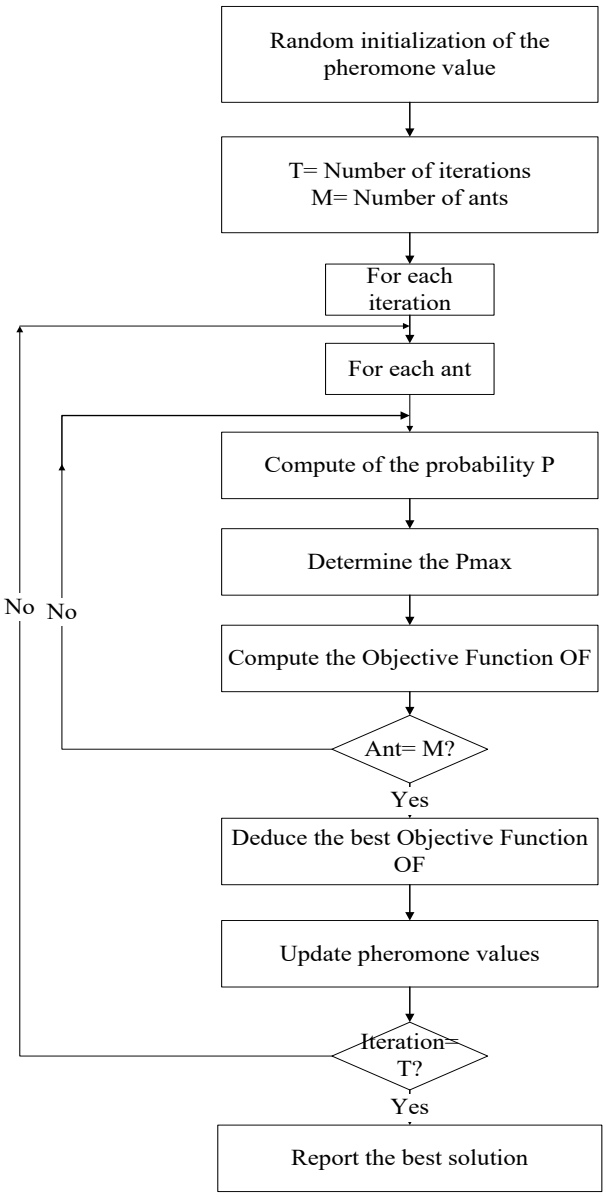

Figure 1: Flowchart of ACO

In this work, the ACO is used to optimize the performances of a positive second-generation CMOS current conveyor (CCII+) (figure2). Optimizing the most affecting parameters of the current conveyor is highlighted:

This optimization problem is resolved using two methods; in the first one, two mono objective function are considered. The objective functions are:

- Minimize the Rx, which represents the X-port input parasitic resistance

$$R_x \approx \frac{1}{gm_2 + gm_4} \tag{10}$$

- Maximize the Fci, which represents the current high cut off frequency

$$F_{ci} = \frac{1}{2\Pi}\sqrt{\frac{gm_5(gm_4 + go_4)}{Cgs_4(Cgs_5 + Cgs_6 + Cgd_4)}} \tag{11}$$

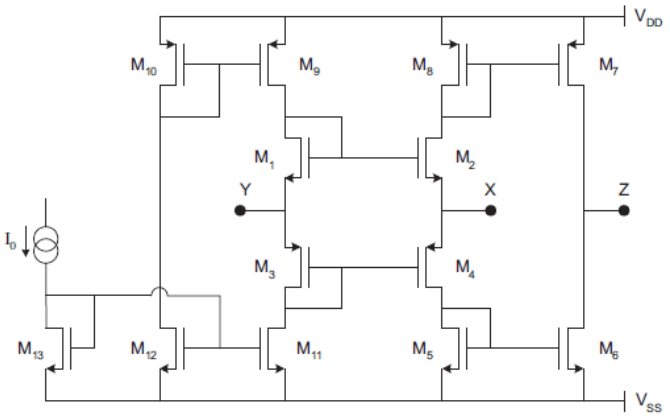

Figure 2: A positive second generation current conveyor

In the second method, the proposed objective function allows simultaneously minimizing Rx and maximizing Fci, and it is configured as:

$$f_{obj} = \frac{1}{F_{ci}} + R_X \tag{12}$$

The MOS transistors size represents the geometric variables that will be considered: the gates widths (WN and WP) and channels lengths (LN, and LP). The binding functioning conditions require that all the transistors of CCII+ must function in the saturation mode. So that, the main constrain of the optimization problem are presented by expressions (13) and (14):

$$\frac{V_{DD}}{2} + V_{TP} + \sqrt{\frac{2I_0}{\mu_N C_{ox}\frac{W_2}{L_2}}} \geq \sqrt{\frac{2I_0}{\mu_P C_{ox}\frac{W_8}{L_8}}} \tag{13}$$

$$\frac{V_{DD}}{2} - V_{TN} - \sqrt{\frac{2I_0}{\mu_N C_{ox}\frac{W_5}{L_5}}} \geq \sqrt{\frac{2I_0}{\mu_P C_{ox}\frac{W_4}{L_4}}} \tag{14}$$

where C_{ox}, μ_N, and μ_P are MOS technology parameters. V_{TN} and V_{TP} denote threshold voltages of NMOS and PMOS transistors respectively. The employed supply voltages are V_{SS}/V_{DD}= -2.5V/2.5 V and a bias current, Ibias=100 µA.

4. Results and Discussion

The proposed variants of the ACO technique were applied to deal with the optimal sizing of CCII+. The optimization technique works on C++ codes.

4.1. Optimization problem result using tow separated objective functions

The optimal values for the parameters of CCII+ achieved by the ACO algorithms and the circuit's performances linked with these values are indicated in tables 1 and 2.

Table 3 presents the performances provided by the AS, the MMAS and the ACS techniques versus to the ones ensured by Particle Swarm Optimization (PSO) and the Genetic Algorithm (GA) algorithms.

Table 1: the obtained results for RX

	LN (µm)	WN (µm)	LP (µm)	WP (µm)	$R_{X\text{-}min}$ (Ω)	
					Opt.	Sim.
AS	0.59	36.60	0.35	58.64	333.01	315.89
MMAS	0.60	36.34	0.35	59.00	335.63	318.69
ACS	0.59	36.68	0.35	59.00	**332.65**	**315.19**

Table 2: the obtained results for Fci

	LN (µm)	WN (µm)	LP (µm)	WP (µm)	Fci-max (GHz)	
					Opt.	Sim.
AS	0.55	5.48	0.35	9.52	1.795	1.739
MMAS	0.55	5.60	0.35	9.60	1.775	1.731
ACS	0.55	5.44	0.35	9.50	**1.801**	**1.754**

The results of the simulation under SPICE for Rx and Fci employing the optimal results acquired by the suggested techniques for CCII+ are exposed in figures 3 and 4. We can observe that simulation results are in good correspondence with theoretical values achieved by the ACO technique.

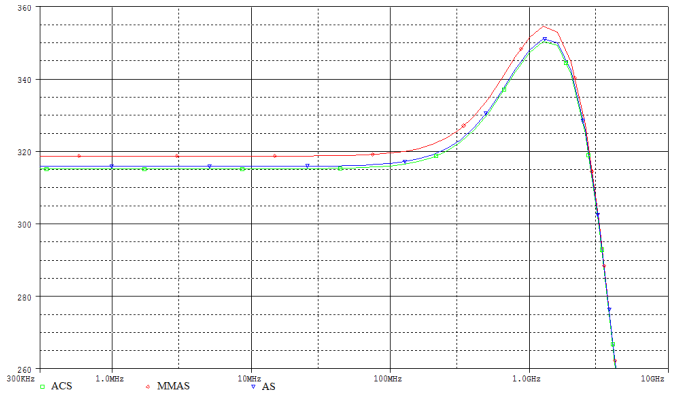

Figure 3: Variation of resistance (ohm) versus frequency (Hz) employing AS,MMAS and ACS

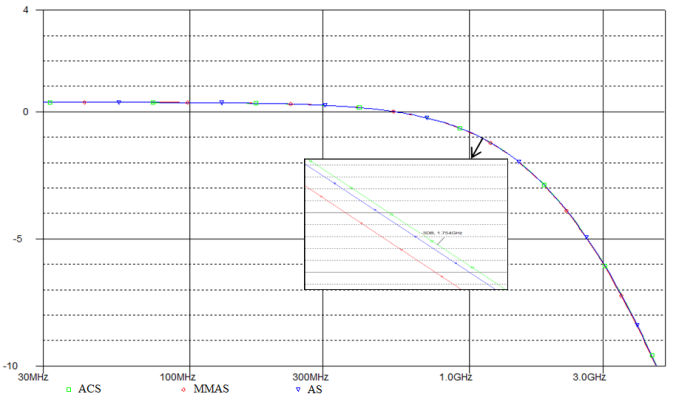

Figure 4: Current gain (dB) versus frequency (Hz) employing AS,MMAS and ACS

Table 3: Comparison results

	ACS	PSO[23]	GA[23]
R_{X}-min (Ω)	**332.65**	464	510
F_{ci}-max (GHZ)	**1.801**	1.751	1.541

It is shown that the three variants of the ACO algorithm offer similar results. The comparison with two techniques belonging to metaheuristics indicates that the ACS accomplished the greatest results with regard to objectives compared to Particle Swarm Optimization (PSO) and the Genetic Algorithm (GA) algorithms.

4.2. Optimization problem result using weighting approach:

The optimal physical parameters values of MOS transistors achieved employing the three variants of ACO algorithm are given in table 4. The comparison of the acquired results with those obtained by another metaheuristic namely, particle swarm optimization (PSO) algorithm, shows that ACS could reach a greatest F_{ci} value. However, PSO could achieve a smaller R_X value.

Table 4: Optimal parameter values and optimization results for R_X and Fci

	LN (µm)	WN (µm)	LP (µm)	WP (µm)	$F_{ci\text{-}max}$ (GHz)	$R_{X\text{-}min}$ (Ω)
AS	0.58	7.95	0.35	13.00	1.446	711.42
MMAS	0.59	8.08	0.35	13,00	1.420	708.75
ACS	0.55	7.53	0.35	12.97	**1.531**	721.08
PSO-2S [24]	0.52	14.30	0.35	23.62	1.358	**444**

The following table presents the simulation results:

Table 5: The optimal results for Rx and Fci

	F_{ci_max} (GHz)		R_{X_min} (Ω)	
	Opt.	Sim.	Opt.	Sim.
AS	1.446	1.495	711.417	825.896
MMAS	1.420	1.479	708.75	825.896
ACS	1.531	1.552	721.085	827.704

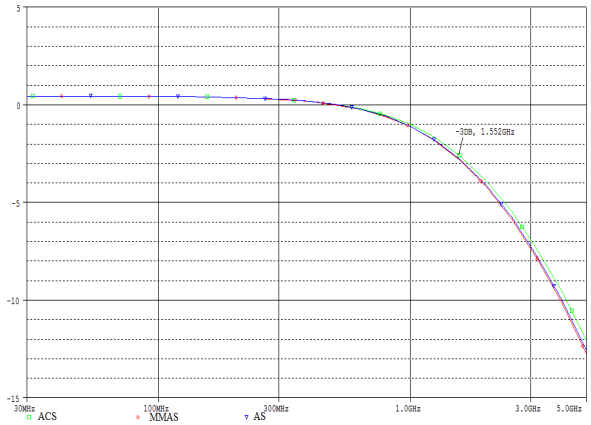

Figure 5: Current gain (dB) as a function of frequency (Hz) employing AS,MMAS and ACS

The figure 5 gives the SPICE simulation for current gain (in dB) as a function of frequency, and the figure 6 presents the SPICE simulation results for R_X (in ohm) as a function of frequency and this by employing the acquired optimal values by the three proposed variants of ACO algorithm for CCII+.

5. A Current Mode Filter based on the CCs

A second order filter can be implemented based on the use of simulated inductance [25]. In fact, Current conveyors present the basis of simulated inductance topology. Figure 7 shows a current mode active filter constituted of 4 current conveyors and two capacitors [26].

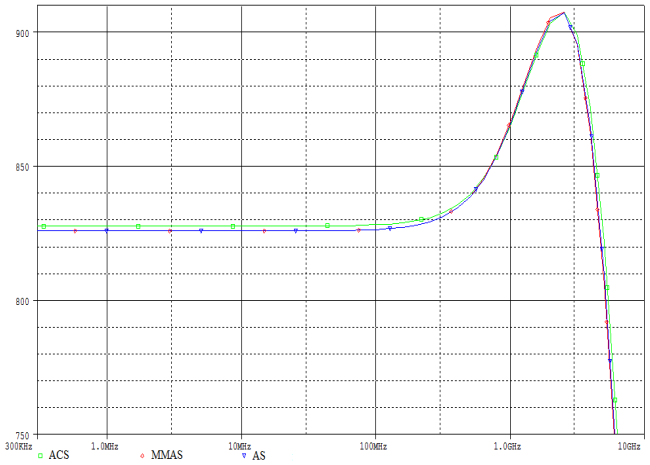

Figure 6: Variation of Rx (ohm) as a function of frequency (Hz) employing AS,MMAS and ACS

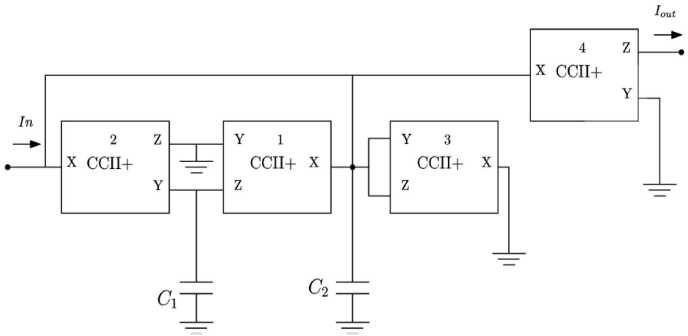

Figure 7: Current- mode pass-band filter

The quality factor and the resonance frequency of this filter are respectively presented by:

$$Q = \frac{R_G}{\sqrt{R_{X1}R_{X2}}}\sqrt{\frac{C_1}{C_2}} \tag{15}$$

$$f_0 = \frac{1}{2\pi}\frac{1}{\sqrt{R_{X1}R_{X2}C_1C_2}} \tag{16}$$

where:

$$\frac{1}{R_G} = \frac{1}{R_{X1}} + \frac{1}{R_{X2}} + \frac{1}{R_{X3}} + \frac{1}{R_{X4}} \tag{17}$$

R_{X1}, R_{X2}, R_{X3} and R_{X4} represent the parasitic resistances on port X of the considered CCII+.

The considered filter is simulated using SPICE, and it is designed based on the optimized CCII+ with optimal sizes determined by ACS for this cases:

a. Firstly, it is designed by employing the obtained CCII+ offering the maximum F_{ci}.
b. Secondly, it is designed by employing the obtained CCII+ offering the minimum R_X.
c. Finally, it is designed by employing the obtained CCII+ offering simultaneously maximum F_{ci} and minimum R_X.

The optimal parameters values of MOS transistors for the three cases are summarized in the table 6.

Table 6: Optimal physical parameters values of MOS transistors

	Minimum R_X	Maximum F_{ci}	Minimum R_X and Maximum F_{ci}
WN/ LN (µm)	36.68/0.59	05.44/0.55	7.53/0.55
WP/ LP (µm)	59.00/0.35	09.50/0.35	12.97/0.35

Figure 8 shows the SPICE simulation of the filter gain, where C1=C2=0.1pF.

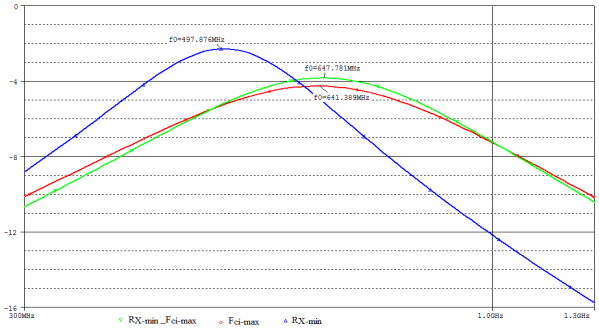

Figure 8: Resonance frequency of the second order current mode band-pass filter

The resonance frequencies reached by the ACS are presented in the following table; we can observe that the best resonance frequency of the current mode second order band pass filter is recorded in the third case.

Table 7: The obtained resonance frequencies

	$R_{X\text{-}min}$	$F_{ci\text{-}max}$	$R_{X\text{-}min}$ and $F_{ci\text{-}max}$
f_o (MHz)	497.896	641.389	647.781

6. Conclusion

In this work, the Ant System (AS), the Min-Max Ant System (MMAS) and the Ant Colony System (ACS), which are the most important variants of Ant Colony Optimization technique, are applied in order to optimize the sizing of conventional CMOS CCII circuit. The performances of a CCII+, especially the current high cut off frequency and the X-port parasitic resistance are optimized. The acquired results prove that the ACO algorithm offers a competitive optimizing capability for the design of CCII+. Then, the improved CCII+ structure was utilized as an elementary

block to build current mode band -pass filter. SPICE simulations and comparison with already published works were highlighted.

ABSTRACT

Computer vision is a technique used for processing images and videos which are increasingly becoming ubiquitous day by day. Technologies developed are revolving around human needs and demands high computational power as volume of data increases. The extraction of the necessary information for processing, that is independent of various scene complexity is a challenging task. Computation visual attention methods channelize a way to select the information using psychological studies on the human visual system. This work aims to develop a computational visual attention method to select the target in a scene. Feature Gate Top-Down model is proposed to filter the significant region of a target in the scene. The proposed model is extended as a choice-based system to detect target or salient movement in surveillance videos. Experimental analysis is performed on various scenes for detecting human as a target followed by the analysis on surveillance videos is evaluated. The metrics such as Kullback-Leibler divergence (KL div), Normalized Scanpath Saliency (NSS), Correlation Coefficient (CC) and similarity reveals that the proposed model is more adaptive in identifying the target region by suppressing other dominant objects.

1 Introduction

In this era of technology, many human activities largely demand on various kind of information processing by machines. The simplification and accessibility of devices make the accumulation of data that is increasing day-by-day. Consequently, modern computing methods focus on processing such voluminous data especially images and videos. The demand is to manipulate and maintain the data in an intelligent way and to extract the information whenever required. The computer vision methodologies provide a solution to the problem in terms of image labelling, classification and compression etc. Many applications focus on human-centric technology especially detecting the target in the image or video for further manipulation. Target detection is a challenging problem, due to variations in natural factors like background, illumination and posture of object. So the thrive for the robust target detection algorithm is continuing as an active area of research. In this work, the effectiveness of adapting visual attention technologies in target detection is proposed. Visual attention methods are derived by analyzing the behaviour of the human eye while processing the information that is in form of image or video. The computational models devised from the hypothesis of the visual system have often helped to improve and simplify the task of many vision applications. Visual attention model has been developed and studied through two approaches viz. Bottom-Up (BU) and Top-Down (TD) approach. BU approaches detects the salient region in the image and TD approaches detects the regions based on intention. As target search as intention in the scene, object may or may not be salient in the scene. Hence the proposed work is on TD computational model that identifies the significant regions of target in an image. The organization of the paper is as follows: Section 2 presents the preliminaries of the visual attention mechanism and human detection system. Section 3 proposes computational Top-Down model. Section 4 discusses experimental design and simulation results. Conclusion is given in section 5.

2 Related Work

The proposed method is demonstrated to detect the human as a target in the scene. In [1] surveyed many models that detect all moving objects and classified humans using features like shape, texture etc. The state-of-the-art human detection methods were analyzed in [2] and the advantages of each method with a guide to the choice for applications were briefly discussed. The proposed visual attention techniques detect both target in the scene as well as moving object. In psychological attention theories, the BU is handled by early vision regions where the component is fast and instantaneous. There are models developed to extract BU component by extending theories and image-based techniques. Saliency detection based on

*Corresponding Author: Aarthi Ramachandran, Email: r_aarthi@cb.amrita.edu

regional contrast that can simultaneously evaluate global contrast differences and spatial coherence was discussed in [3]. Histogram-based Contrast(HC) method [4] was used to define saliency values for image pixels using colour statistics of the input image. The method extended to Colour Co-occurrence Histogram (CCH) that captures saliency based on location information and statistics of image pixels were composed into a visually perceivable image. It was inspired by the behaviour of the human visual system and the fact that visual attention was driven by the low-level stimulus. The images were analyzed in various resolutions, then the maps were computed on multiple low-level features like intensity, colour, orientation, and texture. The top-down component was highly dependent on the task, the human visual system, attention could be focused volitionally to cues determined by the current task (e.g., looking for something). In [5], the author derived the TD (Top Down) map generated using the decision tree classifier on the test date. A fuzzy rule-based system was used in [6], [7] and [8], where the feature is used for the specific image property (Intentional features) introduced in fuzzy inference system on learned features. A Visual Attention System for Object Detection and Goal-Directed Search (VOCUS) [9] model derived the TD map by tuning the features of the target region in the map. The weights were calculated from the ratio of mean value between the Region of Interest (RoI) and the surrounding region. The contextual information of the object was used in many works as TD component. The method in [10] method used spatial information on global context information to detect the target. The gist of the scene was determined to categorize as indoor and outdoor and to perform the task based on that. In [11] learned the behaviour of human eye fixations while playing a video game mapped to scene as TD model. Natural Language Processing (NLP) and then interfaced with vision using Language Perceptional Translator (LPT) for parsing the sentence and to extract the corresponding properties of an object like location, colour, size and shape for the object. Few features that influence the visual search task were context, features and background [12]. Context was unimportant for the detection of human due to its dynamic behaviour in surveillance scenes. Features that are highly related to the target was elicited other than the distractor feature. Brain system had functional areas as a pre-attentive stage where the parallel processing of basic visual cues were performed and subsequently followed by the region where complex-operation such as recognition was performed [13]. In Top-Down model the location that satisfied the target features from inhibiting the other distracting region was favoured. Boolean map model [14] divided the region as selected and not selected by sequentially producing Boolean map considering one feature at a time. It combined the result of one feature that becomes the input for searching the other feature. The main contribution of this work is the development of computational visual attention method to select the target in a scene. We have proposed a model namely feature gate model using biological theories, that makes use of the influence of target features and integrates the distinctive features for filtering the target. Then the model is extended to video by integrating with moving object detection algorithm. The method is analysed with map generated without intention and prominence of a target concerning surrounding environment complexity. The proposed method is also compared with other existing models to evaluates its performance.

3 Feature Gate Top Down Model

Feature gate model [15], terms derived from visual attention system as gate control the flow of information from each level of the hierarchy to the next. The gating of each location depends on the features present. It is a fast and efficient method for inhibiting distractor locations in the search task. The specific aim of the work is:
1. Implement the Feature Gate model concept for effective feature combination of target detection.
2. Evaluating the influence of pre-learned feature extending to video processing. The results are analysed for visual target search application, where the choice for selecting the target region in frames is also included.

The system architecture is presented in Figure 1. The sequence of 'k' frames(fr) from fr_{i-k}, fr_{i-k+1},... fr_i are considered to be entitled as processed in the system. The ith frame (fr_i) in the video sequence is considered for finding static TD map. The low-level features like colour, orientation and intensity are tuned to pops out the target or salient region as static map. The proposed Feature Gate Top-Down model (FGTD) is discussed in subsection 3.1 and pop out the probable location of the target(human) as TD map. The 'k' frames are used for finding the potential region of moving target in the scene by entropy-based moving object detection discussed in section 3.2. The saliency map is calculated from low-level feature by procedure discussed in [16]. The model has the flexibility to select a specific target in the video or it can detect the potential salient moving object. Hence, the weights W_m and W_s is help to increase or decrease the proposition of selecting the target. The final map generated as discussed in subsection 3.3.

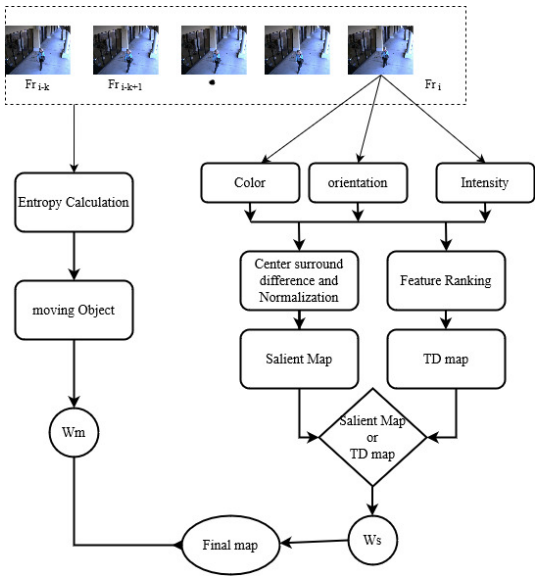

Figure 1: Overview of Proposed model

3.1 TD Map Generation

The human brain fires the neurons based on the task that need to be coordinated. In case of developing a TD model, it requires to enable the relevant low-level feature information. The feature related and necessary for the target passes through the open gate and other features are inhibited by the closed gate. The features that

are passed through the open gate will be kept in the output and others are restricted from appearing in the output. Some of the pre-defined set of local features are learned in the model. Color, intensity, and orientation play a significant role in determining the salient regions in images. The architecture for FGTD model is given in Figure 2. The details of the target and environment to be searched are given as input to the system. The visual feature and salient features are considered for evaluation of TD Information. These features are well suited for target search concerning various background. Features are expressed as a feature map and then combined to form conspicuity maps. Feature map is mapped to form a sub-conspicuity map. The features are learned from low-level features in different scales. The input image is broken down into intensity, colour and orientation maps. Four broadly-tuned color channels Red(R), Green(G), Blue(B) and Yellow(Y) are created. Gaussian pyramids R(s), G(s), B(s), and Y(s) are created from these four colour channels. Centre-surround differences (Θ) between a "centre" fine-scale c and a "surround" coarser scale s yield the feature maps as represented in equation 1. Scales are obtained from pyramid with center c= {2,3,4} and surround scale S= {3,4}. Feature maps across color, orientation and intensity are computed using Itti model [16]. Conspicuity feature map of intensity, color opponent as Red-Green (RG) in (1) and orientation in (2) of target region are also calculated. Three-level orientation feature for θ={0°,45°,90°,135°} of target region are calculated. Gabor filter is used to obtain different orientation features. The mean of features is extracted from the selected target region of the image to create training samples.

$$RG(c, s) = |(R(c) - G(c)) \ominus (G(s) - R(s))| \quad (1)$$

$$O(c, s, \theta) = |O(c, \theta) \ominus O(s, \theta)| \quad (2)$$

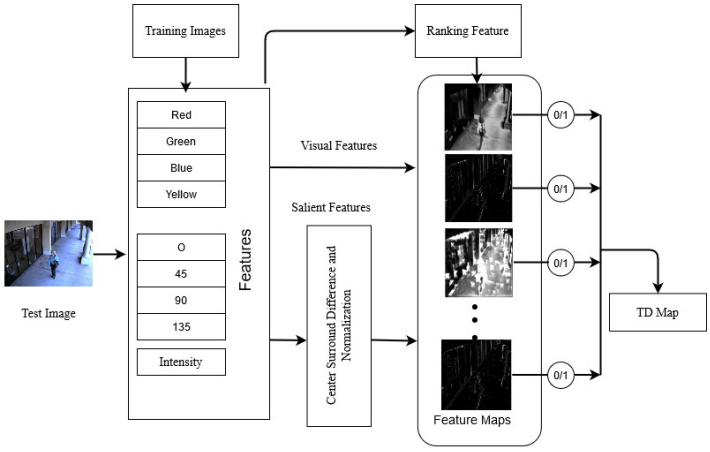

Figure 2: Architecture of FGTD map generation

In the learning phase, each feature is observed across different environments. The proposed FGTD Model combines the few relevant feature of the target as selecting weight as '1' (open) and other as weight '0'(close). Thus the features that are relevant to object are given uniform weightage and irrelevant features are removed. The target-specific local features are learned and used as cues while searching. The details of the target as features are given as training data to the system. The target features are learned and stored based on the dominancy as TD Information. Relief algorithm[17] is a successful attribute ranking method, which has been well studied and adopted for classification problems. The experimental analysis is performed by having the target as human in various scene from other background region. The mean value of the features are used to classify target from non-target. The algorithm used in this method is proposed in [17] as ReliefF to rank the features. Rather than single hit and miss while detection, the approach relies on parameter k that specifies the use of k-nearest hits and misses in the scoring update for each target instance. The features rank and weights are calculated based on scores. TD map has been generated based on combining the first 'n' ranked features. There are mathematical operations for combining the feature map. The summation is used to combine the feature from TD candidate map. Further the TD map on static images is combined with movie object map to extend to videos.

3.2 Moving Object Map

Visual saliency helps the human brain to select the most salient region in real-time. In human vision system apart from the static salient region, the moving object attracts attention in a sequence of images. To extend the method for video analysis, motion is an added feature required to process by analyzing the set of sequence of images, which gives moving object map. The map is obtained by the method in [18] that uses entropy calculation to detect the moving object map from every instance. It also eliminates the background noise like the movement of the tree, flag, elevator, fan, etc based on processing location information. The same procedure adopted to detect the moving object map(M) is given below,

Input:'k' successive frames(fr) in the video (fr_{i-k}, fr_{i-k+1} .....fr_i)
Output:Detection of moving object in ith frame as 'M'.

Step 1: Convert fr_i to gray scale and quantize into 'L' levels.
Step 2: Normalize the frame to the range [0, L-1].
Step 3: Calculate entropy by designing probability mass function for 'k' frames.
Step 3.1: Obtain the histogram integer values.
Step 3.2: Let R(x, y) is a local region in coordinate (x, y). The information content M(x,y) is calculated as (3)

$$M(x, y) = \sum_{\forall k} p(R(x, y), k) log_2 p(R(x, y), k) \quad (3)$$

Step 3.3: Eliminate the static elements by analyzing M(x, y).
Step 4: Continue the step 1 to 3.3 for the entire video sequence.

3.3 Final Map Generation

Regions related to TD Knowledge have higher saliency value than other regions. The contribution of features in the field is not uniform and its weights are varied between the targets. Assigning the appropriate weight to the feature channel pops out the target region. The weights help to determine the amount of feature that

Table 1: Metrics used for analysis

Evaluation method	Equation	Significance of value
Similarity: closeness between maps ground truth $S_h(i)$ and predicted values $S_s(i)$	$\sum_{i=1}^{n} min(S_s(i) - S_h(i)))$	'1' determines the results are same; 0 depicts it is different
Normalized Scan path Saliency (NSS): Average response value of human eye position in a model's saliency map	$NSS = \frac{1}{n}\sum_{i=1}^{n} \frac{S(x_h^i, y_h^i) - \mu_s}{\sigma_s}$	Score>1 saliency map shows significantly higher value than the human fixated location map
Kullback–Leibler(KL) Div.: KL divergence predicts the distance Between two distribution S(x) and h(x).	$D(s,h) = \sum_x s(x) log \frac{s(x)}{h(x)}$	It is non negative value, the score is 0 if distribution s=h
Correlation Coefficient (CC): Measures the strength of linear relationship between the model and human saliency map	$D(s,h) = \sum_x s(x) log \frac{s(x)}{h(x)}$	CC varies between -1 to 1. Positive values shows the better correlation in prediction than -ve values

Table 2: The Ranking of features by ReliefF

Features	**R**	**G**	**B**	**Y**	**I**	**RG**	**GR**	**BY**	**YB**	**0°**	**45°**	**90°**	**135°**
Ranking	10	8	6	12	13	11	3	1	9	4	5	2	7

helps to separate the target region from other regions. In this work, weights for moving object map (Wm) and static map (Ws) is used to fine-tune the result. Each intermediate feature map is multiplied by its corresponding weight to form the final map as in (4). The weight stands for the amount of information that is decided based on the required property on output. The weight can be within the range of [0-1], and according to the probability theory the sum of weight is '1'. To summarize, the FGTD model that uses biological inference to select the salient location of target pixels is given by,

$$Finalmap = Wm * (M) + Ws * (BUorTDMap) \quad (4)$$

4 Results and Discussion

In this section the experiments done on proposed FGTD model on static images followed by combining it with movie object map is discussed. The dataset is taken from various sources on internet having the target with different illumination and scale complexities. Experiments are done with the aim to find the influence of TD knowledge compared with map generated by without intention. The application of computer vision domain namely human detection having target as human are evaluated using metrics like similarity, NSS, KLdiv and CC of visual attention models. In Table 1, $S(x_h^i, y_h^i)$ saliency value of human fixation at ith position, mean μ_s and variance σ_s of saliency region, Cov(s,h) covariance of saliency(s) and human map(h). In Figure 3 gives the comparison of FGTD with BU Map. First Column is input image, followed by result obtained by BU model and proposed FGTD model and region of human target in the scene.

The FGTD model in section 3.1 is evaluated to detect the human target with dataset consisting of more than 200 images that were collected under varying illumination, scale and background. The features discussed in section 3.1 are learned, and relief method is used to rank the features. The ranking of features for human as target is given in Table 2. The TD map is generated for test image by combining first '5' features according to ranking starting from Blue-Yellow(BY), orientation 90° e.t.c. The sample result obtained for 6 images are presented in Figure 3. The first column shows test image and second column gives the result map without intention [16]. The result obtained by proposed FGTD is highlighted with red color square box and finally the expected target region is highlighted with red color oval shape.

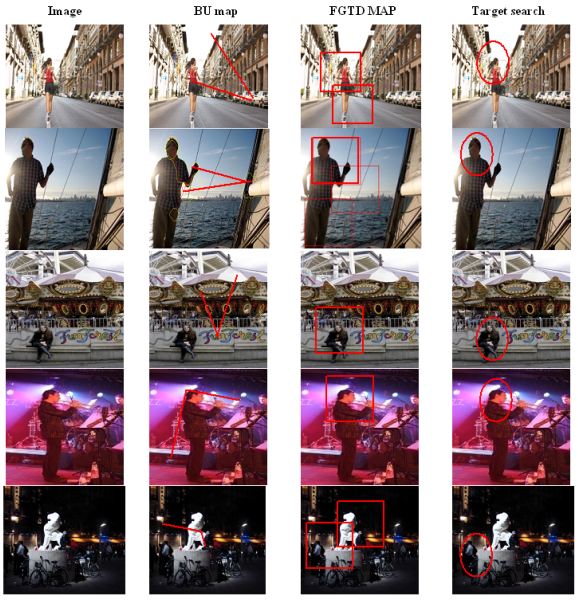

Figure 3: Comparison of FGTD with BU Map

A comparison between Map [16] and FGTD Map with target has been carried out to measure how the model helps to pop out the relevant region as it decreases in prominence in image. Hence the performance is compared with human perception without intention measures like similarity, Normalized Scan path Saliency (NSS), KL div and Correlation Coefficient (CC) in Table 1 used for analysis. Hundreds of image samples were collected under various environments, illumination and scaling conditions. In Figure 4, KL Div score is minimized in the variation of 0 ~ 10. NSS, CC and similarity score is maximized compared with map[16] Model. The scores improved especially in case of target in cluttered background. Observation shows that FGTD model helps to move closer to target region even if it uses minimum feature of the target object to filter out the irrelevant information from image. But, it shows similar performance of saliency map when the entire test image has the same feature as target. In Figure 4 the performance Analysis of FGTD model with map[16] metrics are compared with NSS, KL div, Similarity and CC, where the X-Axis in the graph is the image samples arranged according to the background clutter.

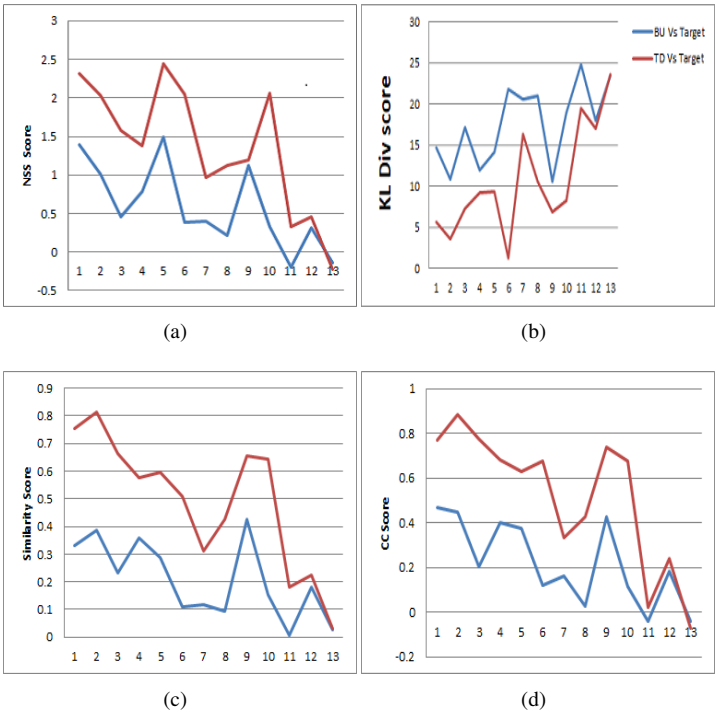

Figure 4: Performance Analysis of FGTD model with map[16](a)NSS, (b)KL div,(c)Similarity and (d) CC , where X-Axis in the graph images arranged according to the background clutter

The static map is further combined with moving object map to extend in video. The dataset consists more than 100 video clips collected from surveillance video of varying outdoor and indoor scene. The model can select Most Salient Region (MSR) as human or it can directly consider as salient region by BU model. The impact of selection between TD Map or salient map are analyzed by varying the weight parameter Wm and Ws are represented in Figure 5. The result obtained for indoor and outdoor scene with and without human presences are evaluated. The sample results obtained for 6 video frames are presented in Figure 5.

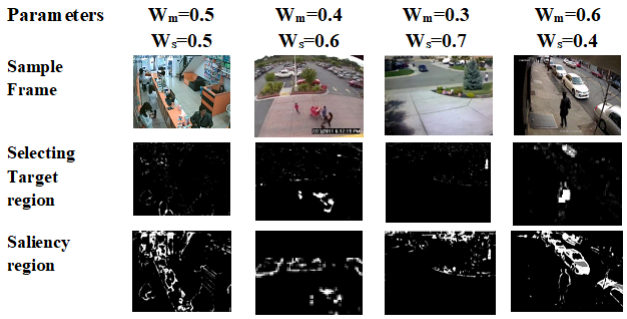

Figure 5: Comparison of BU model with TD map where First row weight parameters are given,second row has TD map with moving target and third row has BU map combined with Moving target

Hence the background distraction is minimum in indoor scene, the outdoor scene sample are highlighted. The first column represents an indoor scene, where other represent outdoor scene. In order to analyze the result, the result by selecting as human region (TD map) and saliency region (without intention) are presented. A comparison with Map [16] and FGTD Map with target Evaluated by factors prescribed in Table 1 are presented in Figure 6. Performance Analysis of proposed model with map[16] of NSS, KL div, Similarity and CC is represented. The X-Axis in the graph has samples arranged based on increasing complexity of scene.

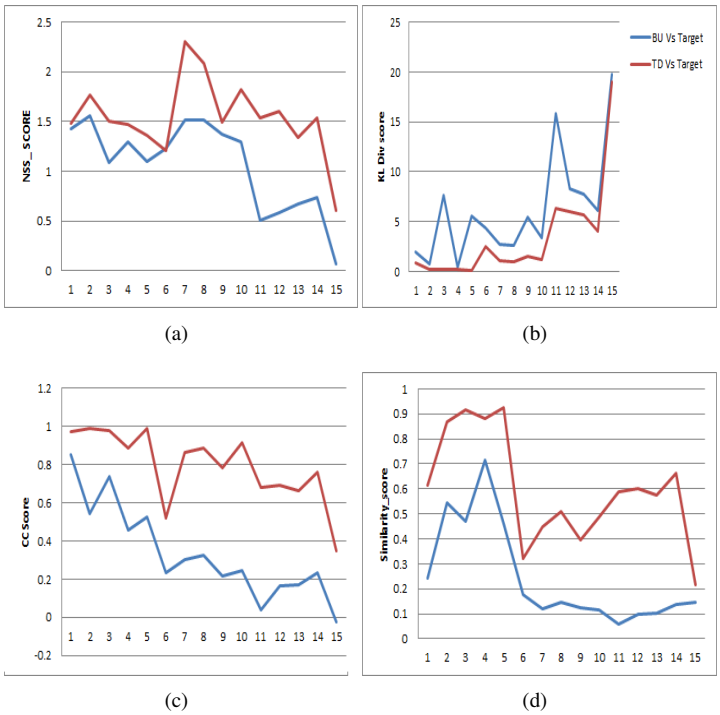

Figure 6: Performance Analysis of proposed model with map[16] (a)NSS, (b)KL div,(c)Similarity and (d) CC , where the X-Axis in the graph has samples arranged on increasing complexity of scene

In Figure 6, KL Div Score is minimized in the variation of 0.2 ~ 5. NSS, Similarity and CC Score is maximized in the variation of 0.02 ~1. The score shows reliable performance even in case of moving object that is not salient. The model is also compared

with moving object detection algorithms like optical flow [19] and dynamic background subtraction [20] methods. The existing algorithm detects all the movie objects in the scene. So, the evaluation is performed on the scene where the pedestrians or vehicle is present in the video. The analysis done more than 30 video sequence with frame rate of 30 to 45 frames per second. The average pedestrians speed varied from 3 km/hour to 5 km/hour and vehicle speed in the video varied from 40 km/hour to 80 km/hour. The performance metrics like True Positive Rate(TPR), False Positive Rate(FPR), True Negative Rate(TNR) and False Negative Rate(FNR) are listed in Table 3. It gives the average detection rates on all video clips. The proposed model shows better performance in compared with other methods.

Table 3: Comparison of FGTD method with existing techniques

Model	TPR	FPR	TNR	FNR
Optical flow method	80.56 %	15.11 %	82.89 %	17.44 %
Background Subtraction method	69.19 %	15.75 %	82.25 %	32.81 %
Proposed Model	85.75 %	73.19 %	26.81 %	24.25 %

5 Conclusion

The main contribution of this work is a TD model that binds the low-level features and pops out the target region. The FGTD model combines the features-based rank order derived by relief method. Further the model is combined with moving object map for analysing the performance in video processing. The weight based final map generation provides the significance of weight modulation in region detection. The method is evaluated with the computer vision problem to detect a human in a scene. The procedure has been extended to detect the target in videos and compared with existing methods. As compared with the scene perceived without intention, the proposed approach shows the capability of suppressing the dominant region of the image to pop out the target. The methods can be further extended to detect different targets in a real-world scene. It can be further extended to simultaneously detect multiple targets in the scene. The features like depth and texture can be included for better robotic navigation in the scenarios.

Conflict of Interest The authors declare no conflict of interest.

Water Quality Sensors

ABSTRACT

Recent technological advances allow us to utilize remote monitoring systems or real-time access of data. While the use of remote monitoring systems is not new, there are still numerous applications that can be explored and improved on, one such is groundwater level and quality monitoring. In the Philippines, the extraction of groundwater for both domestic use and industrial use are manually monitored by the government's concerned agency and is done at least once per year. With this current setup, the real and significant state of the groundwater is not reflected in a way that is most valuable to the government and to the community. This project aims to design and develop a remote real-time groundwater level and quality monitoring system. It is intended to provide quantitative data for policy makers in addressing recurrent water shortages in the Philippines. This paper discusses the designed system composed of three modules: power module, sensors and control, and data visualization. These three modules provide real-time data from far-flung locations while being energy-sustainable. Dry runs of the system in a controlled environment yielded excellent results — average data accuracy of 96.63% for all six (6) groundwater quantity and quality parameters namely: pH, temperature, electrical conductivity, total dissolved solids, salinity, and static water level (SWL), and 90.63% data transmission reliability. Initial deployment of the system on one of the groundwater monitoring well in Metro Manila, Philippines returned a 91.16% data transmission reliability. The system is currently installed in 20 groundwater monitoring sites all-over the Philippines and is scheduled for more installations.

1. Introduction

In the Philippines, the main freshwater sources are inland surface water and groundwater. These water sources are used by the agricultural, industrial, and domestic sectors [1]. For the domestic sector, the ideal setup utilizes the surface water as the main source and the groundwater as a reserve during a water crisis [2]. But in the current recurring water shortage crisis, it is inevitable that these groundwater reservoirs are tapped as additional water resources.

The monitoring of water supply and water quality using observation wells is paramount. There are calls for deployment of sensor systems for monitoring wells for dense communities with high water usage and industrial areas producing wastes and contaminants [2]. If the rate of potential groundwater recharge is lower than the rate of extraction, the extraction well could dry up. Additionally, water contamination will harm the consumers, including agricultural farms and livestock located downstream [3].

Regular monitoring of the water is crucial. There is a need for automated water quality monitoring systems that regularly gather data from observation wells at designated and crucial times of the day. This lessens manual collection of samples, particularly in hard-to-reach and dangerous areas [4]. The use of wireless sensor networks (WSNs), deployed on-site to transmit data back at specified intervals, has been found to be an efficient way of regularly monitoring and ensuring that water quality remains consistent and compliant with standards [5]-[7]. This setup provides needed information to relevant agencies that allow them to make well-informed decisions and guidelines for water conservation.

In full, this paper focuses on the design of the sensor system

*Carlos M. Oppus, Quezon City, NCR, Philippines, coppus@ateneo.edu

composed of three modules, namely: the power supply, sensor and control, and data visualization.

2. Overall System Overview

Figure 1 shows the overall framework of the groundwater monitoring system which is composed of: (A) Power Supply, (B) Sensor and Control, (C) Data Visualization, and (D) Monitoring Well. While the block diagram of the whole system and components for each sub-system are shown in Figure 2.

The power supply sub-system provides power to the sensor and control sub-system through a rechargeable battery. The battery and solar panel are both managed by the solar charge control to prevent unwanted voltage or current discharges during low sunlight or nighttime.

The sensor and control sub-system uses a microcontroller to fetch data from the sensor units. The sensor data collected are pH level (pH), temperature, electrical conductivity (EC), total dissolved solids (TDS), salinity, and groundwater level (static water level). These water parameters are listed under the water quality monitoring guidelines for groundwater from the Philippines' Department of Environment and Natural Resources Administrative Order No. DAO-2016-08 [8]. This set of sensor data is consolidated and sent to the cloud server using a GSM/GPRS module [9], [10]. This sub- system uses an on-site micro-SD card for data back-up in case of remote communication loss.

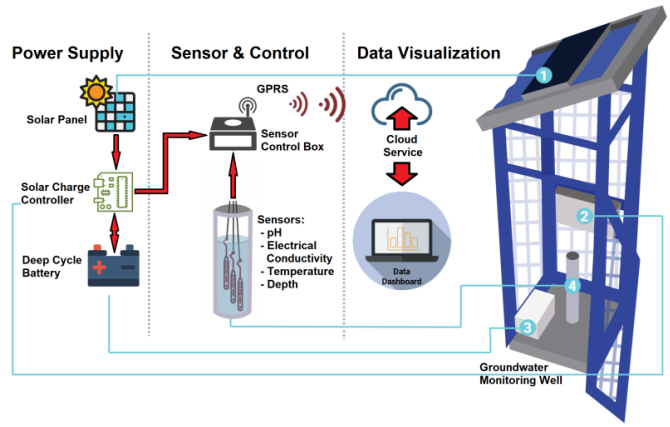

Figure 1: GMP System Framework

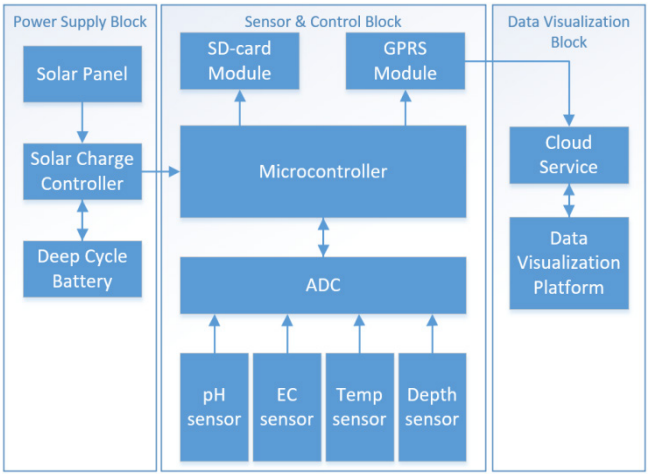

Figure 2: GMP System Block Diagram

Once the data is received by the cloud server, they are processed by the data visualization sub-system. The processed visualized data can be accessed through a dedicated website. The website includes a presentation of the project with its goals and partner institutions; a map showing the monitoring well sites with sensor systems; a view of available data; and a page on helpful information regarding water level and water quality parameters.

3. Design Implementation

3.1. Power Supply

It is essential that the system has a reliable power supply to operate and transmit data at required intervals. The system's power supply is composed of the solar battery, the solar panel, and the charge controller. Actual components used are shown in Figure 3.

The solar battery acts as the main source of power for the sensor system. It provides power while being rechargeable by harnessing solar energy.

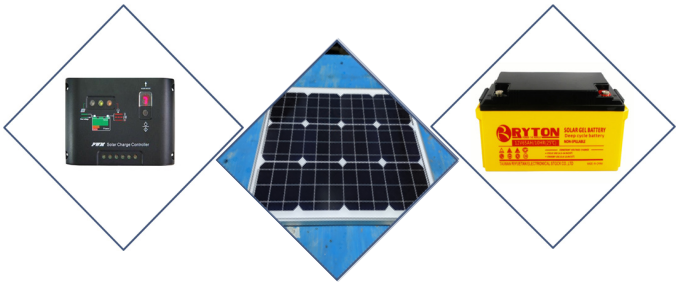

Figure 3: Solar charge controller (left), Solar panel (center), Deep cycle battery (right)

The solar panel charges the battery to keep it above the cutoff voltage. The solar panel harvests energy from the sun and converts it to electrical energy. To replenish the energy consumption of the system, the solar panel is located and properly positioned to be directly exposed to sunlight for at least 3 hours a day. Unable to meet the minimum exposure time might not guarantee full recharge of the solar battery. In this case, the sensor system will only work until the energy of the solar battery is depleted. The specification of the solar panel is shown in Table 1.

Table 1: Solar Panel Specifications

Type	Mono Crystalline
Power	50W
Open-Circuit Voltage	22.5V
Current at Max Power	2.75A
Material	Weatherproof Tempered Glass Aluminum Frame
Dimensions	70x54 cm^2

The solar charge controller maintains the proper recharging and disconnection of the solar panel and the battery. The solar charge controller disconnects the solar panel when the solar panel output voltage does not meet the minimum requirement for charging the battery. Also known as a solar charge regulator, it protects a solar battery's life by limiting the electric current allowed to the connected solar battery when charging, and from the solar battery while used to power a device.

The solar charge controller in the setup has 3 pairs of positive

and negative terminals where three types of devices can be attached: a solar panel, a battery, and a load. The load in this case is the sensor control box. A cutoff voltage is set to prevent the battery from fully draining itself. This allows the system to work for roughly two (2) weeks without sunlight exposure.

3.2. Sensor and Control

A Bluno Mega microcontroller is the central unit of the sensor system. It features enough serial ports to accommodate the various sensors and can be managed via Bluetooth communications for the calibration method. It collects sensor data before sending it using a GSM/GPRS module.

Figure 4: pH sensor probe (left), Submersible pressure sensor (center), and EC sensor probe (top right)

The sensor system measures groundwater quality by collecting the parameters pH, temperature, electrical conductivity, total dissolved solids, and salinity. A sixth parameter, static water level (SWL), is included to measure groundwater quantity relative to the ground level. The sensor system uses off-the-shelf environmental sensors from Atlas Scientific and a pressure transducer from Sendo Sensors. The sensor components are shown in Figure 4. The sensors used with the corresponding units are summarized in Table 2.

Table 2: Water Level and Water Quality Sensors

Sensor	Parameter	Unit
Atlas Scientific Industrial pH Sensor	pH, Temperature	pH °Celsius
Atlas Scientific Industrial Conductivity K 1.0 Sensor	Conductivity, Total Dissolved Solids, Salinity	microSiemens/centimeter ppm, ppt
Sendo Sensors Pressure Transducer	Static Water Level	meter

The Atlas Scientific sensor probes are interfaced with Atlas Scientific carrier boards for better electrical isolation. Each EZO™ circuit carrier board from Atlas Scientific contains calibration data and receives the analog sensor information to be sent to the Bluno Mega's serial ports as digital data. The system contains three EZO™ circuits: pH, temperature, and electrical conductivity. The pH sensor probe is also being used for temperature detection, hence it is connected to both the pH and temperature EZO™ circuit carrier boards.

The Sendo Sensors pressure transducer sends signal directly as current in milli-Ampere values. However, the Bluno Mega's Analog-to-Digital Converter can only read voltage signals. The sensor probe's 4-20mA current loop is connected in parallel to a resistor to convert the electrical signal as a corresponding voltage value. Since the maximum voltage the Bluno can read is 5-volts, we need a 250-ohm parallel resistor. The available single-resistor resistance value closest is 220 ohms. Therefore, our highest analog voltage reading peaks at 4.4 volts, and the pressure data is calibrated accordingly.

3.3. Data Visualization

For data telemetry, a minimum-standard 2.5G network is used for data transmission to cloud servers since there are areas in the Philippines that do not have access to even a 3G network and above. With this limitation, the Elecrow SIM800C GSM/GPRS module is chosen as the data telemetry module.

Since the GPRS module is designed for Arduino, minimal modification is required to interface it with the Bluno Mega. However, the pin assignments for software serial ports are different. The GSM module's default software serial ports are at pins 7 and 8. Since these pins are not usable as software serial pins for Bluno Mega, pins 7 and 8 of the GSM module are rewired to pins 10 and 11 of the Bluno Mega, respectively.

4. Results

4.1. The Sensors and Control Box

Figure 5 shows the setup of the system in a controlled environment, as well as the setup installed on some of the groundwater monitoring wells in Metro Manila, Philippines. The sensors and control box are tested for accuracy after calibration by comparing the sensor readings to that of the known values of several specified buffer solutions.

Note that prior to actual calibration, initial trend tests should show the sensor reacting to its specific parameter, e.g., pH level. Once the trend test readings show a correct trend, such as pH level sensor value increasing when dipped in higher pH level, the sensor is then accepted for calibration.

For calibration, the pH sensor is tested using pH buffer solutions 4, 7, and 10, being acidic, neutral, and basic solutions respectively. The sensor's electrical responses for each of the buffer solution are recorded. Then by using linear regression method on the three calibration points, any pH values outside the buffer solution range can be obtained. As for the electrical conductivity sensor, three-point calibration method is also used. The first point being the dry-state or 0µS (zero), second and third points uses standard electrical conductivity solutions 1,440µS and 12,880µS respectively from Atlas Scientific, with the higher value being the more conductive or saline solution. The same linear regression method is used to determine electrical conductivity values outside the calibration points. As for the pressure sensor, it is calibrated based on water depth and pressure relationship. The sensor is dipped in a container filled with water and with known depth. Two-point calibration is used for determining water depth with respect to pressure read by the sensor. To test the accuracy of the pH and EC sensors after calibration, the sensors are re-tested in parallel with a pH level digital testing stick, a litmus paper, and an EC testing stick.

Shown in Figure 6 are the results of the pH level test after calibration. The different instruments used showed almost consistent values with the pH solution, thus validating the performance of the system's pH sensor. This results in a computed general accuracy for the pH sensor of 95%.

Figure 5: Test setup in a controlled environment (top-left), the setup installed on some of the groundwater monitoring wells (top-right, bottom-left), and the team during one of the system installations (bottom-right)

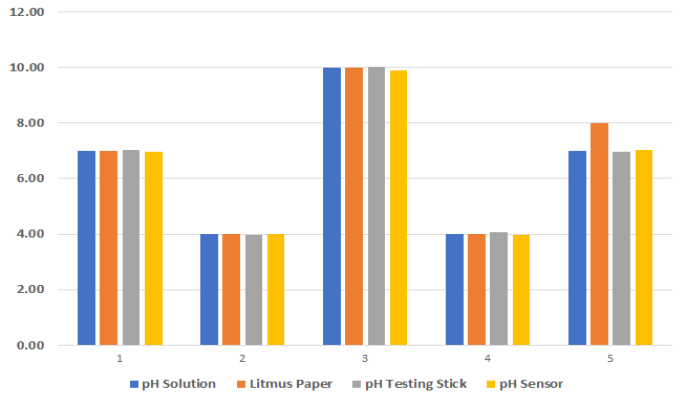

Figure 6: pH level test using litmus paper, digital tester, and the pH sensor

4.2. Test Setup and Initial Deployment

To further test the different sensors, the setup equipped with data telemetry capability was left in a controlled environment with distilled water for 4 days, as can be seen in Figure 5 (top-left). Table 3 indicates the summary of data gathered for 4 days: showing the minimum, maximum, and average values transmitted for each parameter; the accuracies of the transmitted values compared to the expected values; and the overall average accuracy. The accuracy for parameters pH, temperature, EC, TDS, salinity, and SWL are 92.14%, 94.69%, 97.26%, 99.06%, 100%, and 100% respectively, which then translate to an overall average accuracy of 96.63%. These accuracy values are very well comparable with the sensors' technical specifications which are listed at 95%-98% accuracy.

Table 3: Summary of Test Data from Controlled Environment

	pH	Temp	EC	TDS	Sal	SWL
Min	7.09	23.33	640	346	0.31	0.17
Max	7.95	29.82	763	412	0.37	0.19
Average	7.55	27.38	719.17	388.63	0.35	0.18
Expected	7	26	700	385	0.35	0.18
Accuracy (%)	92.14	94.69	97.26	99.06	100	100
Average Accuracy (%)	**96.63**					

After yielding promising results from the controlled test setup, the system was then deployed initially on one of the groundwater monitoring well in Metro Manila, Philippines, as shown in Figure 5 (top-right). The setup was left on the monitoring well for 31 days equipped with data telemetry and solar panel for power sustainability. Table 4 shows the summary of data gathered from the deployed system. Different with the data from controlled setup, data from the deployed setup were not compared with any expected values due to the nature of the setup being a monitoring system. Accuracy checks for sensor readings were done prior to installing the system on the groundwater monitoring well by comparing them with the values obtained using pH level and EC digital testing kits, as well as the manual measurement of the actual SWL.

Table 4: Summary of Data from initially deployed Monitoring System

	pH	Temp	EC	TDS	Sal	SWL
Min	9.06	36.05	1105	597	0.55	17.05
Max	11.82	36.37	1391	751	0.70	17.97
Average	9.83	36.23	1237.02	668.27	0.62	17.44

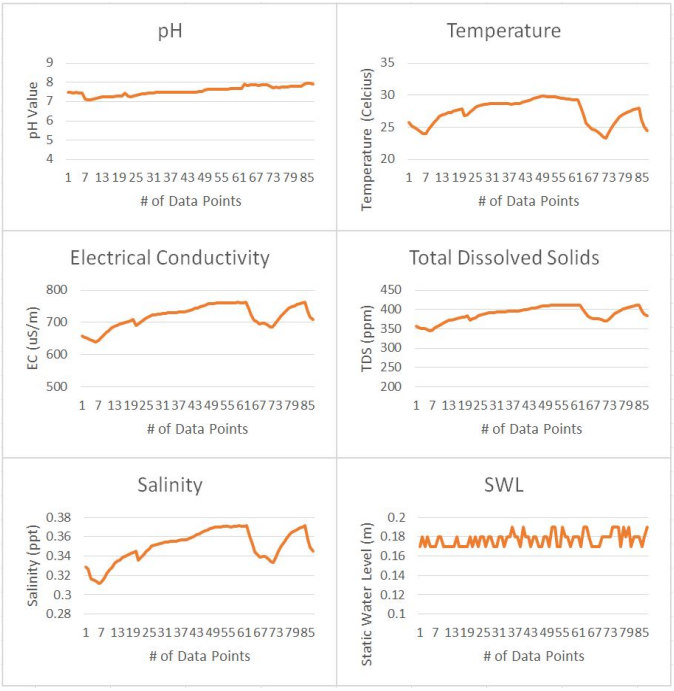

Figure 7: Sensor Test Results at 100 data points (x-axis)

4.3. The Telemetry

In terms of data transmission reliability, we have the system send data around every hour. In this paper, we define data

transmission reliability as the capacity of the system to transmit data to the remote server via GPRS communication [11]. Table 5 shows the summary for the data telemetry reliability. For the controlled-environment setup, the remote server was able to receive 87 data sets out of the expected 96 from the 4-day test setup, thus yielding 90.63% of data telemetry reliability. While for the field-deployed setup, the remote server was able to receive 650 out of the 713 data sets, for 91.16% transmission reliability. These reliability values also translate to about 21 data sets per day. The complete 87 data sets from the controlled-setup can be seen represented by the graphs shown in Figure 7.

Table 5: Summary for Data Telemetry Reliability

# OF DATA SET			
Controlled-Setup		**Deployed-Setup**	
Actual	87	**Actual**	650
Expected	96	**Expected**	713
Reliability (%)	**90.63**	**Reliability (%)**	**91.16**

4.4. The Power and Sustainability

A simple voltage divider circuit is installed in the control system for the Bluno to read the voltage level of the battery power source. This allows for remotely monitoring the power level of the system for its consumption and recharging cycles. In Figure 8, the battery voltage trend both for controlled- and deployed-setups having 87 data sets can be seen. The battery voltage for the setup under controlled-environment have a decreasing trend with the setup being in a laboratory setting where the battery is not connected to a solar panel or any charging source. While the voltage trend for the deployed-setup shows a cyclic trend for charging and discharging phases that signifies that the solar panel is decently exposed to sunlight.

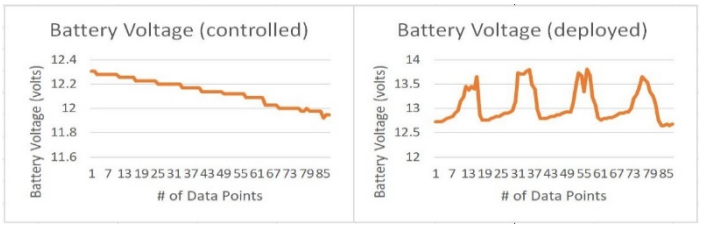

Figure 8: Battery voltage trend, controlled-environment (left), deployed-setup (right)

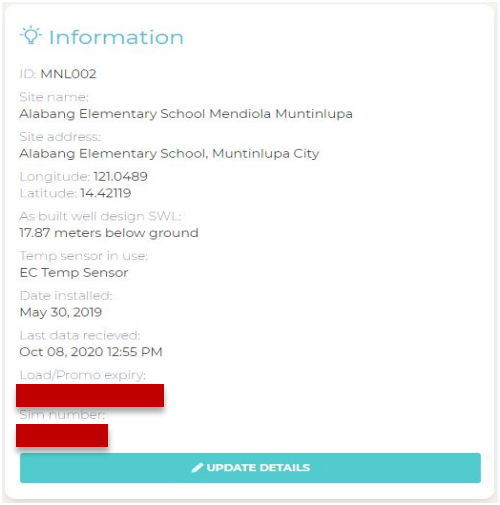

Figure 9: Screenshot of the Data Visualization Platform showing the information regarding the Monitoring Well

4.5. Data Visualization

After gathering these water quantity and quality parameters, the control box sends the data to a cloud server for visualization purposes in a web-based platform. These can be viewed publicly on the website of the project. The data are sorted according to location, data type (pH, temperature, EC, TDS, Sal, SWL), and in chronological order. A screenshot of the data visualization in Figures 9 shows the information about one of the monitoring wells in Metro Manila, Philippines, while Figure 10 shows the monitoring well's actual SWL readings for about a month.

Figure 10: Screenshot of the Data Visualization Platform showing actual SWL data

5. Conclusion

The research group is able to develop a fully-functional energy-sufficient remote monitoring system that can gather and record accurate groundwater quality and quantity data. The data can be transmitted reliably to a separate web-server. Further testing for robustness and accuracy during extended field deployments is recommended. In conclusion, the designed and developed system can operate with an overall average accuracy of 96.63% for 6 water quantity and quality parameters, and 91% data transmission reliability. Considering the data transmission requirement of at least 1 data set per day by the funding agency, it is therefore recommended for installation for the remaining groundwater monitoring wells all over the Philippines.

One of the challenges encountered during the designing and development of the system is the calibration of the sensors as there are occasions where the manufacturer's calibration kits are off. Worth mentioning is the pH sensor since its EZO^{TM} circuit is very sensitive to electrical static discharge and mishandling. It is also problematic to manually control its calibration offsets. The analog pH sensor is used instead. By mathematically computing for the calibration equations and offsets, more consistent readings of pH values are obtained.

Another challenge is the power consumption of the system. The sensors consume more power than the charging capability of the power sub-system due to unforeseen lower solar exposure. This is remedied by having the sensors undergo sleep mode majority of the time and varying the remote sending frequency of the system.

Acknowledgment

This research is a project implemented by the Ateneo de Manila University (ADMU), funded by the Department of Science and

Technology (DOST) - Philippine Council for Industry, Energy and Emerging Technology Research and Development (PCIEERD), National Water Resources Board (NWRB), and partially funded by the University Research Council (URC) of the Ateneo and the Ateneo Research Institute of Science and Engineering (ARISE).

ABSTRACT

The study aimed to understand and analyze the technological and innovation performance measures of the Nepalese cellular telecommunications industry from the customers' perspective. The measures like network service quality, signal strength and coverage, voice quality, and calls drop are used for technological performance, whereas measures like product/service innovation, process innovation, customization, competitive innovation, and marketing innovation are used for innovation performance. It followed a descriptive research design employing a structured questionnaire survey instrument. Two market leader companies of the Nepalese telecommunications industry (Nepal Telecom and Ncell) and their customers were considered as objects of the study. For this study, 391 respondents were selected by using the judgmental sampling technique. Targeted respondents of the study were postgraduate understudies, service holders, business persons, and freelancers. The survey instrument was set in three segments with 19 questions to collect and analyze information with the help of a statistical package for the social sciences and analysis of moment structures software. Two constructs with nine test variables found as the determinants of the technological and innovation performance of the Nepalese cellular telecommunications industry. The results of the study would provide helpful guidelines in understanding the key drivers of the technological and innovation performance in the Nepalese scenario.

1. Introduction

One of the most important inquires in business has been why some organizations succeed while others fizzle. Organizational performance is one of the most articulated concerns for all organizations, either profit or not-for-profit. It has been immensely important for stakeholders, especially for managers, to identify the components that influence an organization's performance so that they can initiate appropriate actions. However, describing, conceptualizing, and measuring organizational performance has never been an easy undertaking [1]. Various researchers have made an attempt to define and assess organizational performance, yet it remains an issue of debate among analysts [2]. Basically, organizational performance refers to the outcomes of daily administrative processes [3] that the organization intends to accomplish in the long-term [4]. The primary concern of the study of organizational performance is the suitability of various approaches to deal with the idea usage and its measurement [5].

Organizational performance is a multifaceted concept, and the use of a financial measures-based performance system alone is not sufficient to measure performance of organizations operating in highly competitive, innovative, and advanced technological environments [6]. As such, the contemporary business environment demands a multidimensional performance measurement system that can provide more information to stakeholders, more specifically managers. Out of several dimensions of the performance measurement system, the telecommunication industry's two inherent components are *technology* and *innovation* due to the fact that adoption of technological advancements through innovative actions distinguishes products/services or companies in the competitive market.

Although the determinants of technological and innovation performance are still unclear, accomplishing and sustaining superior organizational performance, especially in the cellular telecommunications setting has become a top priority today. The study therefore tries to find the measures to assess and quantify the technological and innovation performance of the Nepalese

Email: dahalrewan@gmail.com

cellular telecommunications industry. Alongside that, the study's objective is to examine the intensity of technological and innovation performance measures in the Nepalese scenario and initiate some theoretical and practical discussions for better organizational performance.

This study is extremely significant in the scenario of Nepalese telecommunications industry as the cellular telecommunications has been growing by leaps and bounds and gradually covering the broad spectrum of Nepali populace. As per [7], the number of Global System for Mobile (GSM) network subscribers has surpassed 3.5 million as of June 2020. The industry's main focus as it can be observed is on mobile phones and their primary functions, such as calling and hearing. Telecommunication companies are under persistent pressure to deliver creative items more rapidly, at lower cost, and with enhanced quality [8]. This shows that cellular telecommunications companies have a special relationship with the customer, and necessitates the assessment of organizational performance in order to strength that relationship by incorporating new features at lower cost with better services in the future.

2. Literature Review

The literature contends that technological and innovative performance measures are endogenous and are impacted by more profound organizational growth determinants. In today's knowledge-based economy, corporate growth is driven primarily by creative capacity, invigorated by the pertinent information and technological externalities, instead of gathering capital [8]. So, performance measures concerning technology and innovation stand at the point of convergence of organizational performance measurement system.

2.1. Technological performance measures

The world of technology is changing at a rapid pace, and telecommunications technology is not an exception. Over time, technological changes have a significant impact on the creation of marketing opportunities [9]. The preferences of customers change rapidly and pose numerous difficulties for any business [10]. Technological advances, especially in information and communication technology (ICT), make product/service innovation conceivable [11]. New technologies bring new challenges to business players and seek opportunities to offer customers innovative products/services to pursue long-term relationships [12] and distinguish them from other competitors [13]. Previous studies like [14]-[16], have analyzed the crucial role of technology in the performance and competitiveness of organizations. This study thus examined and evaluated some technological performance measures among the various customers.

Network and service quality has a significant role in organizational performance for telecom service providers [17]. In [18], [19], the authors acknowledged that network quality is one of the crucial factors that determine the organization's performance in evaluating its service quality.

Signal strength and coverage have always been essential criteria for selecting telecom services. Multiple studies demonstrate that signal strength and range positively affect consumers' satisfaction and the organization's image [20], leading to overall organizational performance.

Voice quality in telecommunications networks has been a fundamental part of service qualification. Because of the inherent characteristics of a converged voice and voice-over internet protocol (VoIP), administrators face specific problems such as echo, jitter, delay, side-tone, background noise, etc. Quick and efficient mitigation of VoIP issues to maximize call quality leads to better service provider performance [21].

Calls drop is another key performance indicator to assess the performance of operators' networks. It is expected to have a direct impact on customer satisfaction and retention [22].

Electronic customer relationship management (e-CRM) allows users to frequently communicate with one another and maintain their databases as clearly as possible while improving customer relationships [23]. Implementation and uses of e-CRM enhance organizational effectiveness and significantly connect with the overall performance [24].

2.2. Innovation Performance Measures

New methods of products, processes, and other components are being applied to organizations by innovation [25]. It transforms into a product/service as it is produced and bought by the customer and provides the vendors with financial benefits. Innovation performance measures introduce new strategic tactics, working environment and guidelines, decision-making techniques, and better external relations approaches [26]. Studies like [27], [28], [29], have been conducted to examine the crucial role of innovation on a firm's performance and competitiveness. Despite several dimensions of the innovation performance measures, the study secured just five general business criteria and assessed them from the customers' perspective.

Product/service innovation satisfies customers by turning the invention or idea into a product/service and enhancing company value at acceptable risk [30]. Innovation analyzes the needs of the customers and provides the products/services accordingly. Therefore, product/service innovation helps escalate customer benefits [29] tantamount to better organizational performance.

Process innovation refers to doing business in a new and innovative way [31]. Conversion of new technology into processes, especially in ICT based companies, has a significant impact on the performance of the firm. Process innovation therefore represents a type of service innovation that provides an immense advantage in creating new streams of value for better customer experiences, thereby enhancing a firm's competitiveness and overall performance of a company [32].

Customization is the process of making and changing something to the buyer's or user's needs. The telecommunication sector's service competitiveness, including variations of services and facilities and the degree of customization, influences technological and innovative performance. Additionally, customization capability encourages service systems to suit a specific customer within a particular use-circumstance and to make a unique value for that customer [33].

Competitive innovation is a strategy that organizations use to make a competitive advantage by developing products that

nobody else can, showing improvements over every other person, or presenting prevalent, less expensive, and quicker services [34]. It is a type of social design that focuses on creating and elaborating the best and practical thoughts originating from the best innovators for superior organizational performance.

Marketing innovation is implementing a new advertising technique, including significant changes in product design, placement, packaging, distribution, communication, promotion, and pricing strategy [35]. According to [36], improvisation, modification, augmentation, or transformation of existing trade channels using technology can reduce transaction costs that lead to better organizational performance. [37] also argued that companies developing innovative practices were more able to position themselves on the market against their competitors and achieve emphatic retention of customers.

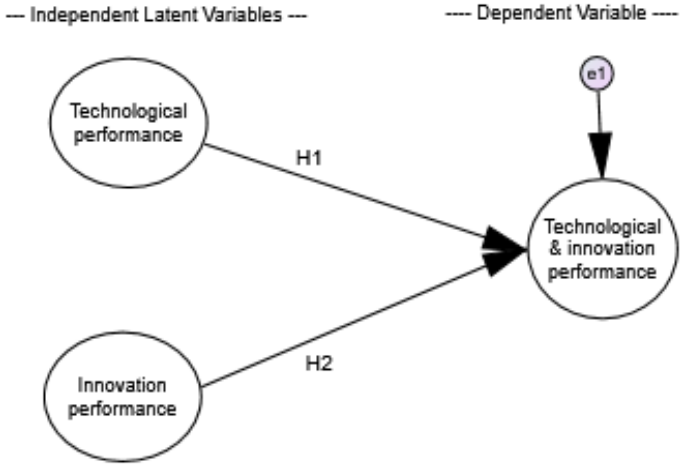

Figure 1: Conceptual framework of the study

2.3 Technological and Innovation Performance

Various metrics can be used to assess a firm's performance [38]. Technological and innovation initiatives are considered to be primary indicators of the cellular telecommunication industry. They allow the firm to improve capability to meet the demands of its evolving domestic and international market [39], thus giving the firm a lucrative outcome.

The overall technological aspect is multidimensional and can be decomposed appropriately from different perspectives [40]. Studies showed that technological advancement is a primary determinant of superior long-term success [41] and leads to better performance than rivals [42].

The overall innovation aspect allows better delivery of the services offered and a more significant impact of any campaign and promotes organizational changes standardizing certain activities [43]. In [44], the authors evidenced that in firms, where there is a willingness to innovate its products/services, there is a significant and positive impact on overall organizational performance.

3. Conceptual Framework and Hypotheses

Organizational performance shows the development and progress of an organization [45]. The analysis of organizational success is one of the most investigated variables. It is a criterion for management and tends to depend on the fitness between corporate systems and situational factors. Therefore, the study is driven by the contingency theory, which provides a practical perspective for examining and measuring different contingent variables.

Within the framework of prior literature and conceptual sketching, the study has the following two hypotheses:

H1: Technological performance positively and significantly affects technological and innovation performance.

H2: Innovation performance positively and significantly affects technological and innovation performance.

4. Methodology

The quantitative research strategy was employed to extract information for the study, and the required information was acquired through a structured questionnaire survey from the targeted respondents. The study used a statistical package for social sciences (SPSS) version 23 and analysis of moment structures (AMOS) version 21 software to dissect and decipher the information. The study's targeted populace comprised all the Global System for Mobile (GSM) customers of Nepal Telecom and Ncell. According to [7], the sample companies' customers possess more than 93 % of the Nepalese cellular telecommunications market share. The study employed a judgmental sampling technique because there was no proof of active and the dead Subscriber Identification Module (SIM) card issued with the sample organizations. Targeted respondents of the study were postgraduate understudies, service holders, business persons, and freelancers. A sampling plan was used as proposed by [46], [47] and ensured at least 385 respondents' responses. Therefore, the study employed 391 respondents' perceptions as sample.

The designed questionnaire for the survey comprised 19 questions and structured them into three segments. In the first segment, seven items were requested, relating to demographic and general information. In the second segment, 10 items mentioned about technological and innovation performance measures in various dimensions. In the last segment, two items inquired about the overall technological and innovation performance. The last two segments centered on the study variables with a series of close-ended questions to get the appropriate information. With a 6-point Likert-type scale of 1 = strongly disagree to 6 = strongly agree, all the survey queries of the study variables were estimated. The 6-point scale was picked because it excludes the undecided middle rating.

The researchers distributed the questionnaires through an online and a field survey. Based on the data provided by different colleges/universities, an online survey conducted among university graduates from the recent five years and who are working in Nepal's various parts. A total of 500 respondents approached during the 30-days of January/February 2020. Out of this, 143 responses were received from the online survey and recorded in SPSS for further analysis. On the other hand, the researchers themselves disseminated 500 questionnaires among Tribhuvan, Kathmandu, Pokhara, and Purbanchal Universities'

graduate students and their faculties to conduct the field survey. Out of them, 276 responses were collected during the period of 30 days in January/February 2020. From the collected responses through the field survey, 28 were rejected due to incomplete information. The remaining 391 responses were considered valid and were used in this study.

5. Reliability and Validity of the Survey Instrument

The study assessed the reliability and validity to confirm the constructs' suitability before evaluating the hypothesized model. The survey instrument's overall reliability statistics showed an excellent Cronbach's alpha ($\alpha = 0.819$) and the average inter-item correlation coefficient ($r = 0.312$) from the 10 test items. Despite having excellent values of the statistics, construct-wise Cronbach's alpha was also analyzed. The value of Cronbach's alpha of the technological performance construct having five test items (VAR_8, 9, 10, 11, and 12) was 0.775. The analysis found that the VAR_12 'the company alters and provides me all information through SMS' required to delete because of the higher value of alpha 0.807 if the item deleted. The variable VAR_12 also had a low correlation (0.317) to total correlation, while the rest were in the area of 0.576 to 0.680. Therefore, VAR_12 was also not relevant in the study and deleted from the analysis. None of the items were found to delete at the innovation performance construct. Thus, reliability statistics promoted nine variables within two constructs for further study. Table 1 presented the analytical result for the reliability statistics of each construct.

Table 1: Reliability Statistics

Construct	Cronbach's Alpha	The average inter-item correlation coefficient	Name of the items	No of items
Technological performance	0.807	0.512	VAR_ 8, 9, 10, 11	4
Innovation performance	0.765	0.394	VAR_13, 14, 15, 16,17	5
			Total no of items	9

The construct-wise statistics showed that both constructs had good alpha values, i.e., 0.7 or higher, as suggested by [48]. The innovation performance construct had good average inter-item correlation ($r = 0.394$) whereas the technological performance construct had ($r = 0.512$) slightly higher than the recommended ideal range of 0.15 to 0.50 by [49]. A higher value of the average inter-item correlation indicated that the measuring variables might be capturing a small bandwidth and tended to be very similar to each other.

The study had an adequate sample size concerning the validity issue since the Kaiser-Meyer-Olkin (KMO) value of 0.816 from nine test items was more significant than the threshold value of 0.5 as recommended by [50]. The significant value of Bartlett's test of sphericity (1035.011, $df = 36$, $p = 0.000$) indicated that the variables had some correlations to each other. The constructs' validity was assessed by using convergent and discriminant validity. Table 2 presented the validity statistics of the technological and innovation performance model.

Table 2: Validity Statistics

Constructs	Composite Reliability (CR)	Average variance extracted (AVE)	Max./Average shared variance (MSV/ASV)	Constructs	
				Technological Performance	Innovation Performance
Technological performance	0.79	0.49	0.212	**0.70**	
Innovation performance	0.77	0.40	0.212	0.47	**0.63**

Validity statistics showed that both constructs had a good value of composite reliability, i.e., greater than 0.7, as suggested by [51]. They stated that if the average variance extracted is less than 0.5, but composite reliability is higher than 0.70, the latent measures' convergent validity is adequate. In addition, in [52], the authors proclaimed that AVE values > 0.4 are considered acceptable convergent validity measures. In the case of discriminant validity, there was no multicollinearity problem since inter latent variables correlation ($r = 0.47$) was less than the threshold value of 0.7, as recommended by [53]. Similarly, as per [51] criterion, AVEs of the constructs were greater than MSV/ASV. The square root of the constructs' AVEs (presented in bold in Table 2) was higher than the correlation between the constructs for satisfactory discriminant validity. Therefore, the constructs were distinct and measuring the theoretically-driven facts. Besides, absolute values of skewness (- 0.515 to - 0.152) and kurtosis (- 0.949 to - 0.142) of the observed variables proved normality of the data as they were reported within the recommended ± 2 range [54]. The absolute value of standardized residual covariance of the variables (- 1.862 to + 1.589) within the recommended range of ± 2.58 [55] also indicated that the latent variables had a significant effect on the model.

6. Results and Analysis

By administrating the organized questionnaire to 391 cell phone users of Nepal Telecom and Ncell, the required information was accounted for, dissected, and deciphered. According to the sample encircled, responses were taken from understudies (56.7 %), service holders (38.9 %), business persons (2.3 %), and freelancers (2.0 %). Female (51.7 %) respondents were somewhat higher than the male (48.3 %) respondents. Even though the field study was conducted in Kathmandu valley, it covered all provinces of Nepal since the respondents regularly used to come to Kathmandu valley at one time or another. Demographically, the respondents were from: Province 1 (19.4 %), Province 2 (9.5 %), Bagmati (36.8 %), Gandaki (11.5 %), Lumbini (12.5 %), Karnali (4.6 %) and Sudur Pashchim (5.6 %). The study ensured almost equal participation from Nepal Telecom (50.1 %) and Ncell (49.9 %) and showed that 79.0 % of users carrying the pre-paid subscriber identity module (SIM) card exclusively. All the respondents had at least experience of five years or more in carrying the cell phone services in Nepal.

Descriptive statistics observed that all nine test variables except VAR_9 (signal strength and coverage) averaged more than 3.5 on a six-point Likert scale and revealed that all the test items within the constructs had the right intensity. The signal strength and coverage (VAR_9) was perceived to the lowest mean value of 3.21 (below the average mean of 3.5). Such a result indicated that cellular companies need to improve their signal strength and coverage. The respondents' response dispersions from the mean of all indicator items were quite similar.

The study applied structural equation modeling (SEM) to evaluate the significance of the hypothesized paths and the model's explanatory power by computing multiple correlation coefficients for each endogenous variable. Technological and innovation performance was measured by nine test variables within two latent variables, as presented in Figure 2, and the key parameter estimates of the model shown in Table 3.

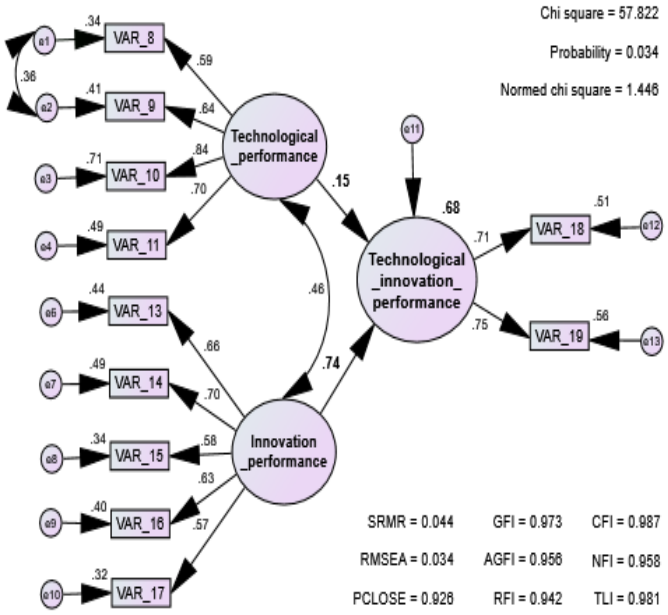

Figure 2: Technological and innovation performance model

Table 3: Parameter Estimates of the Technological and Innovation Performance Model

INDICATORS	URW	SRW	SE	CR	p-value
Technological performance					
---> Tech & innovation performance	0.142	0.152	0.061	2.326	0.020

*Note: URW = Unstandardized regression weights; SRW = Standardized regression weights; SE = Standard error; CR = Critical ratio; *** = Significant at 0.01 level*

As presented in Table 3, the technological and innovation performance model produced statistically significant critical ratios at $p \leq 0.05$ for all measuring test variables, covariance relationships between latent variables, and error terms. The testing model results produced standardized regression weights that were all significantly different from zero and above the 0.5 threshold level for a good fit, as recommended by [56]. The standardized regression weights indicated that innovation performance was a better predictor of technological and innovation performance ($\beta = 0.743$, $p < 0.01$) than technological performance ($\beta = 0.152$, $p < 0.01$). Various indices also observed to test the constructs' model fit, as presented in Table 4.

Table 4: Model Fit Indices of the Technological and Innovation Performance Model

Model fit measures	Cut-off value	Recommended by	Model of the study
Chi square (χ^2)	Smaller the better	Wan, 2002	57.822
Probability (p)	> 0.05	Wan, 2002	0.034
Normed chi square [χ^2/df]	≤ 3.00	Kline, 1998	1.446
Standardized Root Mean-square Residual [SRMR]	≤ 0.08	Hu & Bentler, 1999	0.044
Root Mean Square Error of Approximation [RMSEA]	≤ 0.08	Hu & Bentler, 1999	0.034
RMSEA Associated p Value [PCLOSE]	≥ 0.05	Garson, 2009	0.926
Goodness of Fit Index [GFI]	≥ 0.90	Bagozzi & Yi, 1988	0.973
Adjusted Goodness of Fit Index [AGFI]	≥ 0.90	Bagozzi & Yi, 1988	0.956
Relative Fit Index (RFI)	≥ 0.80	Hair et al., 2006	0.942
Comparative Fit Index [CFI]	≥ 0.90	Hu & Bentler, 1999	0.987
Normed Fit Index [NFI]	≥ 0.80	Bentler & Bonnet, 1980	0.958
Tucker Lewis Index [TLI]	≥ 0.90	Hu & Bentler, 1999	0.981

All the model fit indices were fallen in the range of recommended cutoff values and evidenced an excellent fit with the technological and innovation performance model. Exemplary values of the chi-square, normed chi-square, and probability as recommended by [57], [58], revealed the absolute and parsimonious fit of the model. Values of root-mean-square residuals, the root-mean-square error of approximation, associated p-value, and goodness of fit index as recommended by [59]-[61], further proved the absolute fit of the model. Values of adjusted goodness of fit index, comparative fit index, normed fit

index, and Tucker Lewis index as recommended by [59], [61], [62], supported the incremental fit of the model.

7. Discussion and Conclusion

Traditional financial measures-based backward-looking accounting systems' dissatisfaction led to a performance measurement revolution in the late 1970s [63]. Each organization has its reasons to measure performance. So, multidimensional performance measurement systems have been acknowledged since the 1990s. Scholars from different schools of thought have used the concept of subjective information to scale organizational performance. As the guidance of contingency theory, this study explores the subjective measures of technological and innovation performance in the Nepalese scenario. A literature review of the study identified 10 observed variables within two constructs to assess technological and innovation performance. The study did not accept the test variable e-CRM (VAR_12) as the determinant of technological performance in the Nepalese scenario though it was significant in the earlier studies like [23], [24].

The latent variable 'technological performance' was assessed from four observed variables: network and service quality ($\beta = 0.586$, $p < 0.01$); signal strength and coverage ($\beta = 0.643$, $p < 0.01$); voice quality ($\beta = 0.844$, $p < 0.01$); and calls drop ($\beta = 0.701$, $p < 0.01$) that directly influence the technological and innovation performance. Technology and information facilitate innovation in competitive markets [64]. As consistent with the past studies like [17]-[22], [65], the study confirms that network and service quality, signal strength and coverage, voice quality, and calls drops to have significant influence to choose the cell phone operators as the service provider. That means cell phone operators must ensure good and strong technological performance measures to satisfy their subscribers. Such evidences lead to an inference that technological performance at the Nepalese scenario was significantly associated with technological and innovation performance ($\beta = 0.152$, $p < 0.01$).

The latent variable 'innovation performance' was assessed from five observed variables: product/service innovation ($\beta = 0.663$, $p < 0.01$); process innovation ($\beta = 0.702$, $p < 0.01$); customization ($\beta = 0.584$, $p < 0.01$); competitive innovation ($\beta = 0.629$, $p < 0.01$); and marketing innovation ($\beta = 0.565$, $p < 0.01$). Service innovation influences customer satisfaction and retention [66] that eventually leads to better organizational performance. Process innovation applies a new method for doing something that helps an organization remain competitive and meets customer demands. Customization can govern the effectiveness of other capabilities and create higher competitive advantages [67]. Competitive innovation differentiates and adds competitive value to their products/services by adopting innovations and new technologies. Marketing innovation aims to give value to the customers and to improve competitive advantage. As consistent with previous research like [68]-[70], the study showed that the observed variables have a positive and significant effect on innovation performance. Besides, it supports the study conducted in [71] that innovation performance positively and significantly impacts technological and innovation performance. Hence, innovation culture has been pronounced as a pre-condition for improving organizational, marketing, and managerial entrepreneurship in a competitive environment [72]. In other words, the innovative capabilities have a direct and positive impact on organizational performance [69]. All the evidence lured that innovation performance in the Nepalese scenario was significantly associated with technological and innovation performance ($\beta = 0.743$, $p < 0.01$). As per the conceptual framework of the study, the overall model summary is presented in Figure 3.

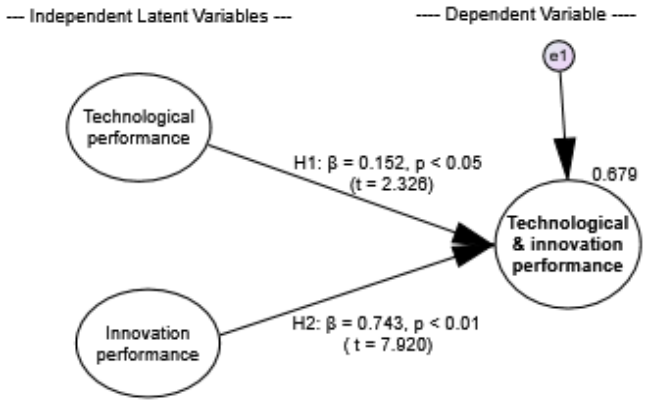

Figure 3: The model summary

The study outcomes inferred that each of the subjective performance measures provides a partial explanation of the synergetic impacts on organizational performance. The study observed nine contingent variables that quantified two response variables to measure technological and innovation performance. The technological and innovation performance depends on a fit or math between various contingent factors. Consequently, the study concludes that the model's validation and fit were vital because they provide empirical evidence for measuring non-financial organizational performance. More precisely, it offers the power of the Nepalese cellular telecommunications industry's technological and innovation performance measures. It is believed that the level of technological advancement with innovativeness is an essential determinant of organizational performance.

8. Limitations and Future Research

Studies of performance measurement systems cover several disciplines, and their methodological approaches differ considerably. It made a comprehensive examination extremely challenging. As a result, only two aspects of the performance measures, technological performance measures, and innovation performance measures have been considered in this study. The study variables were developed the most straightforward ways since they could be easily understandable and the respondents could mark the structured questionnaire's option precisely. The technological performance measures have been associated with the characteristics of mobile phone networks. In contrast, innovation performance measures have been associated with the business in general because a common respondent cannot grasp the technological essence of innovation performance measures in Nepal.

Although the analysis made for the study is rigorous and the findings significantly relatable, this study is a representative instead of a comprehensive effort. The key drawback was that the analysis used only the quantitative survey to collect the necessary

information with a structured questionnaire, using the terms accessible to ordinary users. The structured questionnaire denies the opportunity to discuss many of the relevant issues of the responses. Nonetheless, all the tests have been carried out to assess the authenticity and reliability of the information obtained. The reliability could depend on the number of participants that could have been further improved by a larger sample further emphasizing on the validity and generality of the findings.

The study examined new contingent variables in the cellular industry's organizational performance measurement system. The findings of the study will serve as a foundation for future studies to refine the theory. Researchers may consider more variables such as additional packages provided by operators, latency, security, etc. not covered in this analysis. Similarly, the ownership of firm can be integrated into the research model to identify whether the findings vary with various corporate holdings. On the other hand, future studies can concentrate on other sectors or other countries to address and compare related topics with this report. These results thus unravel the avenue for future research in various contingent variables to generalize the theory. Finally, this study hopes that the analysis findings will be useful for practitioners, researchers, or policy makers and will lead to related studies and future research as a guide.

9. Implications

Studies have shown that various performance assessment frameworks have been maintained across the world. In the case of Nepal, no corporation tends to make specific use of technological and innovative performance measures explicitly in the organizational performance process. Therefore, this study sought to analyze the effects of performance measures that could further improve the Nepalese cellular telecommunications industry's organizational performance. The consequences of this study have been divided into two parts: practical and theoretical perspectives.

9.1. Practical Implications

The study results would help telecommunications industry managers recognize the customers' perception of organizational success as a path to technical acceptance and innovation in the Nepalese scenario. The analysis provides more evidence for the various management decisions. Managers can focus on variables that obtained low weights from respondents. This study would also provide valuable guidance for identifying the critical driving variables of technical and innovative change and offer insightful knowledge on the system's strategic areas of organizational performance evaluation.

9.2. Theoretical Implications

The study is driven by the contingency theory, which provides a reliable lens to consider different variables and new ways to measure them. Every measure of a firm's performance has advantages and disadvantages, and provides a prospect of success for researchers. It endeavored to fill the literature gap and address the Nepalese scenario's issues not considered by previous researchers. On the other hand, the government can help companies innovate by leading and supervising their innovation efforts and by providing them with an amiable institutional environment.

SMEs
Analysts Skills

ABSTRACT

SMEs usually succeed in today market since they achieve unique things in the business market. Therefore, SMEs look to keep their business benefit by avoiding any regulation conducted of software. Executed software packaged at SMEs consequently provides obstacle concerning to misfits between software services process and SMEs business process. Hence software analysts' skills are a critical factor for successfully overcome obstacle relating to misfits. This study conducted a questionnaire by quantitative data to understand in-depth analysts' skills need during the process of software mismatch adjustment. Based on our analysis of the data gathered, we represented a list of skills that analysts applied to detect misfits between software service provided and SME's business process. This study, therefore, explains skills that analysts used to overcome the obstacle of software implementation at SMEs.

1. Introduction

In current years Small Software Vendors (SSVs) for Packaged Software (PS) is increased they are competitive by selling their products to large numbers of SMEs [1]. SSVs have, therefore activated to mark SMEs less complicated products that have developed [2]. SMEs are an essential business target many SSVs as mentioned by [3] SMEs "with less than 500 employees provided 51 per cent of all employment in the USA as of March 2004 and 64 per cent of all Canadian private sector employment in 2005. In the European Union, firms with 250 employees or less provided 67 per cent of employment" [3]. A study by [4] stated that SMEs subsidize to economic growing to a great degree and incessantly generating employ chances through the business. SMEs are an essential economies part, SMEs surface particular challenges once they are implementing a PS for their business [5, 6].

SMEs seem to remain different comparing to large companies in several points [7]. Some individual features of SMEs contain types of ownership, business structure, and target market [7]. Several studies have stated that SMEs have limited IT knowledge and resource regarding IT adaptation/adoption [7]. These obstacles lead to the implementation of PS presence a challenge for SMEs. Researchers of SSVs have found that they cannot conduct the process of implementing PS at a large business to SMEs [7]. Regardless of the importance of Packaged Software (PS) conducting it is recognized by these SSVs researchers, there is a little investigation to exploring these obstacles. In particular, considerations about SMEs hardly investigate in the SSVs literature and the question of how SSVs have overcome these obstacles and what are the analysts' skills to successfully conducted a PS at SMEs [2].

In [8], the author conducted research relating to the soft skills of software development staff across four significant parts of the world, which included North America, Asia, Europe, and Australia. researchers conducted on the belief that soft skills are complementary to technical skills, and thus essential attributes for IT staff to have [8] claimed that during different project stages, incredibly soft skills required. Therefore, various team members should have a variety of soft skills. Those skills were communication skills, interpersonal skills, analytical and problem-solving skills, organizational skills, innovative skills, adaptability to change, and the ability to work in a team and to work independently. Other study by [9] regarding analysts' communication skills a key factor for requirement gathering, they found that knowledge about business process of users' companies and domain knowledge different business are the most critical factor for requirements gathering.

It can claim that none of the previous studies related to analysts' skills focuses on any detail on how analysts manage software specificity and generality when implementing packaged software compare to bespoke software [10]. Hence, they do not provide any overview of what domain knowledge and estimation skills required from analysts implementing packaged software. Nor do they focus on the fact that there are pronounced differences

*Corresponding Author: Issam Jebreen, ijebreen@zu.edu.jo

between bespoke software and packaged software. Therefore, there is a need for an investigation of which domain knowledge and estimation skills are required when analysts manage software specificity and generality.

This study provides an overview of analysts' skills at small software vendors (SSVs) regarding PS conducted at SMEs. It explores this area from the perspective of small software vendors. In focusing on an understanding of analysts' skills at SSVs, we construct a questionnaire by quantitative data to represent high demand for skills used during the conduct of PS at SMEs. This study organized as follows: review literature; research method; results and discussed, conclusion and considers future work.

2. Study Background

The purpose of this section is to provide a perception of the theoretical concept of software packaged; analysts' skills and the processes involved, and packaged software implementation. In this section, we assumed that PS conducted at SMEs depend on a set of techniques such as software integrations, customization, adoption/adaption, and the identification of misfits between PS services and SMEs business process. Hence these processes require from PS analysts to interact with SMEs employees that require different skills. Additionally, in this section, during the review of previous studies relating to packaged software, we present and define several PS elements. There are several elements involved in the process of PS conduction such as PS customization, adaption, and adoption [11]. If the efficiency of these elements enhanced, this might lead to the increased success of PS conduction at SMEs.

The market of PS is the fastest rising business for small software vendors (SSVs), [12] study shown that PS market for SSVs is growing to $64.88 billion in 2009. Therefore, such procedures of software may be very targeted to viable SMEs business [12].

Small software vendors shape their business to developing small packaged software (SPS) instead of bespoke software. However, those vendors have faced new management development challenges [13], [14] recognized the lack of in research investigate dedicated to reviewing the packaged software area, he recognizing main differences between the packaged software development process and bespoke software. The study acknowledged variances at four levels that contain "industry forces, approaches to software development, work culture, and development team efforts". His argument of the conflicts increased by recognizing and discoursing the five different participant groups participate in both bespoke and PS development. In [14], the author stated that "custom IS are those made by either an organization's internal staff or by direct subcontract to a software house". The study goes on to classify ERP product as the wildest rising example of a packaged software product. PS requires wide modifying for their application, which regularly involves the help of variances parties such as training, consultants, and support staff [15-17].

When associating noticeable differences between bespoke and PS developing process, Sawyer states that time pressures are a main critical factor for PS development rather than software cost compare to bespoke software. Meanwhile, the successful implementation criteria for PS software is different compare to bespoke software, PS software assesses by software profit, several target markets, and famous the product. However, successful implementation criteria for bespoke software, that is measured by specific company satisfaction about the services provided by the software. Moreover, the PS development is relying on developers' experience of business domain knowledge, but bespoke software is depending on the needs of users.

In [14-17], and other research by [13] and [18], the authors stated that software companies treat PS as a product. Therefore, the effort is on carrying a product that can sell to many, and the product vision relying on releases planned. Meanwhile, bespoke software, the effort is on carrying on software development process in order to have a user's stratification. The primary assumption of these researchers is that the process of software development is different from PS and bespoke software, the most distinct is at software company structure level, the process of development regarding users' involvement, the culture of work, development effort by software teams.

In recognition of these concerns, systematic studies have been undertaken in the current year to increase the success of the method of packaged software creation [11]. For example, in order to understand the process of requirement engineering for PS, [14] researched the process and challenges of the requirement engineering process for PS in Swedish software companies. Many of the problems they exposed were exclusive to PS and not suitable for personalized applications. They therefore noted that specifications for engineering approaches carried out by a tailor-made software team might not be especially helpful in supporting the development process for PS. In another study by [10], it was reported that the personalized process of software requirement engineering and the methods used have inadequate utility for PS.

For analysts, these present a primary challenge in creating the preliminary software for future marketing. However, as possible consumers are accepted, they have become the primary source for the selection of requirements. Nevertheless, the original software / product specifications are typically generated by the creators of PS, who have used their thoughts on business goals, understanding of the business domain or a product vision [14]. This method makes it rational to assume that not all packaged software services and features are suitable for the business of SMEs [15]. In other words, there can be misfits between the business processes of PS services and SMEs. In order to minimize any unintended effects, SSVs and recognized SMEs should reduce the possible gaps (a skills require from analysts) in the PS to be effective.

Therefore, several studies conducted to investigate the critical success factors (CSFs) for PS implementation. Instead of that, [19] surveyed 86 organizations by an essential characteristic of success PS implementation to generate the most important critical success factors for PS implementation. They propose that the CSFs list may include assistance leaders of PS projects to better apply inadequate resources by using the CSFs that are existences at SMEs and have a primary effect on the PS success implementation. The study offers a brief clarification of critical success factors, along with an interpretation of the value of each aspect. (1) Management support, (2) product champion, (3) consumer

training, (4) expectation management, and (5) supplier / customer relationships are the leading five variables recognized.

The purpose of [17] is not only to test the accuracy of the top 10 list of [16], but to build on the list by theorizing some of the causal relationships between the individual CSFs. The research question was: (1)" Can the list of [16] helps to gain a deeper understanding of the root causes of success and failure in the implementation of ERP?" [17] agreed to evaluate the top 10 CFSs that have a mix of 'hard' and 'soft' success elements, and they noted that the most significant factors are: top management support, project team experience, interdepartmental cooperation, consistent expectations and goals, and project management. Any of the stuff on the top 10 list were originally ranked lower by [16]. Still, after feedback received from 52 company managers approached to provide input by [17], he moved the ranking up. In other IT literature related to implementation, many of the items on the top 10 list also seem to appear frequently.

In [4], the author reviewed in the words of SMEs, the most recent literature on the adoption and application of ERP systems in SMEs. Noting that ERP systems have now been almost universally implemented by large organizations, [4] said that ERP vendors have now begun to turn their attention to small-medium-sized organizations (SMEs). Although ERP systems can help small and medium-sized enterprises, "the risks for small and medium-sized enterprises of implementing an ERP system are different because small and medium-sized enterprises are likely to have limited resources and business features that are different from those of large organizations." In [4], the author provided insight into the areas missing from the current ERP adoption analysis in SMEs and provided expertise to assist 'professionals, suppliers and SMEs' while embarking on ERP projects.' In fact, 'Small and medium-sized enterprises (SMEs) recognized as fundamentally different circumstances relative to large enterprises'[18] have not published any relevant literature on the implementation process in SMEs [4].

The literature mentioned by [4] shows that academic research has shown a significant increase in the use of ERP in small and medium-sized enterprises, and that case studies and surveys are the most common methods used in research papers on this topic. They discovered that the implementation method was the most discussed in the literature on ERP use in SMEs. This result contributes to the crucial topics of literature debate within larger organizations on ERP systems. However, in the literature on the use of ERP in SMEs, the adoption decision, the acquisition process, and the use and maintenance step are also given acceptable levels of emphasis. The processes for which literature has been rather scarce or non-existent are ERP evolution and ERP system retirement [4]. Further suggested that only two published papers found 'in-house built systems' to be a viable option for small and medium-sized enterprises. At the same time, "normal ERP solutions could require straight lines and a lack of versatility for particular SMEs." It is therefore safe to say that, from the point of view of SSVs, the existing literature has paid little attention to the implementation of PS activities by SSVs.

In [5], the author make some more remarks about the existing literature after giving specific critical of the reviewed literature and suggest more avenues for research. First of all, they say that, even though 77 papers identified and examined, this was still a minimal number of documents to be conducted within ten years on the subject, considering the increasing significance of ERP technology in response to SMEs. They conclude that "in contrast with ERP in LEs, SMEs have not earned sufficient attention." "that include a lack of" ex-ante cost estimate, economic viability and investment appraisal studies of ERP ventures "research, a lack of contrast between" SME-specific ERP and general ERP systems " or "industry-specific ERP vs general ERP packages" studies.

In [4], the author found that only a few studies were performed on the growth of ERP systems in small and medium-sized enterprises, and no study on small and medium-sized enterprises discussed the implementation phase of an ERP system. Finally, while they found 77 articles related to ERP systems in small and medium-sized enterprises, [4] recorded that the majority of small and medium-sized enterprises were engaged in traditional manufacturing, and that it could be important to achieve results compared to different industries, or it could be beneficial if recent studies on the use of the ERP system in small and medium-sized enterprises were carried out. They also found that almost all research studies have found that businesses are concentrated in America, Australia, Europe, and Asia. There has been a shortage of studies that examine SMEs in Africa or the Middle East. Therefore, a one-sided viewpoint (in data collection) has been adopted by current literature, e.g. on the client-side, whereas other views might strengthen the perception of such phenomena. Any studies that examine instances of failed ERP implementations within SMEs are also absent.

After reviewing the literature on this subject, package software often created in many sequential releases but that there is intense competition among various formats within the packaged software industry. This is only one of the components unique to packaged software, which explains part of why the features of packaged software vary significantly from the elements of customized software. Alternatively, there are potential clients, an imagined group of people who may fit the profile of the product's intended customer. The elicitation of specifications from this group of users and customers is one of the tasks that separates bundled applications from bespoke. The elicitation of such requirements is primarily handled by ads, technical assistance, user groups and trade publication testers. Therefore, it seems reasonable to say that not all the applications functionalities will be appropriate for the customers' business requirements. In other words, when packaged software is implemented by tech firms, there would be inconsistencies between the features provided by packaged software and customers ' business requirements. Therefore, different skills are required from PS analysts in order to successfully implement a PS.

Packaged program development can be a massive undertaking that needs a substantial amount of time, effort and adjustments in the implementation organization. The implementation of the PS is often the single largest project ever launched by an organization.

3. Research Design

A survey questionnaire on the skills adopted was used to collect quantitative data based on [8-10] and shows the skills required in PS. The skills mentioned in the table below in terms of how analysts used them.

In cases where expectations of one's competence affect the way he or she interacts, the Self-report instruments are suitable [20]. Besides, claimed that people could have more contextual information about themselves than anyone else does, offering some encouragement for the use of such a system.

As show in table 2, our sample of software companies involved in this research covers the area of software development, integration of systems, and localization of software. A total of 60 participants presented, including analysts and developers. Seven of the participants made up of team leaders.

Table 1: Survey Questionnaire Sample

Skills	
Skills & Knowledge	Assessment Level
Communication skills	Low, Moderate, and High
Interpersonal skills	Low, Moderate, and High
Organizational skills	Low, Moderate, and High
Team Player	Low, Moderate, and High
Ability to Work Independently	Low, Moderate, and High

Table 2: Sample descriptions

Area	%Sample	Participants	Experiences
development	85%	Team Leader	12%
Integration	70%	Analysts & Developers	75%
localization	40%		
Experiences	12%	75%	

System analysts and developers were most of the participants at the same time. Most participants had a cumulative experience of 3-10 years in the industry, while a few had the experience of more than ten years. Most of the participants had experience working concurrently as researchers, designers, and developers. As analysts only, some participants had the expertise and some as developers only. Most participants had experience with software for company applications and software for database systems.

The data has analyzed as the percentage of participants answers regarding skills required for bespoke software and packaged software.

Table 3: Responses regarding software type.

Software type	#Responeses
Bespoke	27
Packaged	33

As show in table 3, it was 27 responses from bespoke software analysts and developers and 33 responses from packaged software. The top of questionnaire, the participants were chosen the type of software they would like to fulfill up the questionnaire for.

4. Result & Discussion

The table 4 below follows a list of skills adopted by [8-10] and shows the skills required in PS vs Bespoke software. The skills mentioned in the table in terms of how analysts used them.

It can be seen from the table 4 that the skills generally required of analysts practicing Packaged software implementation (PSI) are much the same as those required of analysts engaged in bespoke software, but that some of the skills are required to be practiced at a higher level or to use more often. There are some differences involved in terms of how skills are needed and practiced about skills and knowledge, development skills, software knowledge, business skills, problem-solving, and hardware knowledge.

Table 4: Skills Assessment Level

Skills		
Skills & Knowledge	**Bespoke software**	**PS**
Communication skills	High	High
Interpersonal skills	Moderate	***High***
Organizational skills	Low	Low
Team Player	Moderate	Moderate
Ability to Work Independently	Moderate	***High***

Desktop/PC	Low	***Moderate***
Devices/printers/storage	Low	Low

Note that the bolded italics in the PS column show the differences

Bespoke software requires the analyst to show a certain level of skills and knowledge related to communication skills, interpersonal skills, organizational skills, ability to work in a team, and ability to work independently. PSI requires the same kinds of skills, but some of these skills demanded at a different level as shown in figure 1.

For example, the analyst engaged in PSI will need to meet higher demands in terms of their development of interpersonal skills, and their ability to work independently.

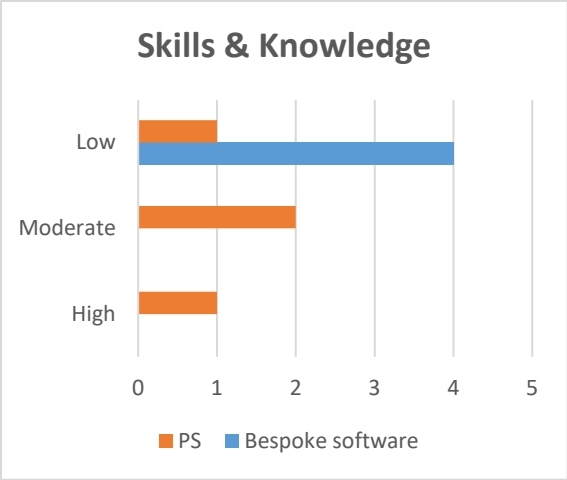

Figure 1: Skills & Knowledge

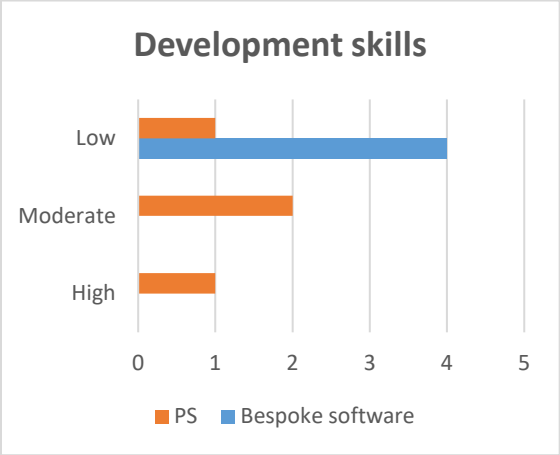

Figure 2: Development Skills

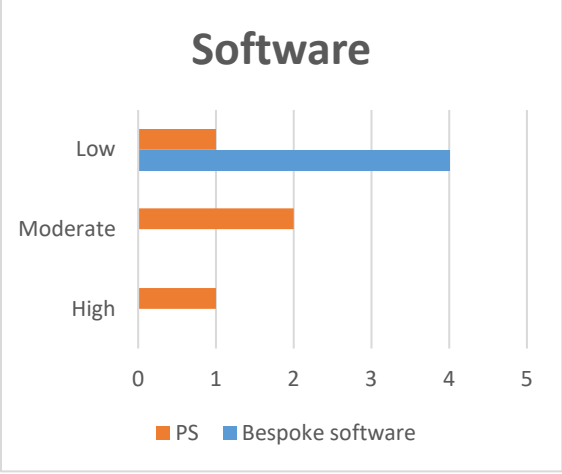

Figure 3: Software

When it comes to development skills as shown in figure 2, the analyst engaged in PSI will need to have a higher level of skill when it comes to dealing with software integration, quality assurance, and knowledge of technological trends. In bespoke software, these skills only required at a 'low' level. In PSI, the need for these skills categorized as 'high'.

When it comes to knowledge of software and the ability to use the software as shown figure 3, the skills required of bespoke software analysts and PSI analysts also differ. In Bespoke software, the analyst's knowledge about operating systems/platforms and packages only needed to be at a 'moderate' level. In PSI, these skills required to be at a 'high' level.

Bespoke software and PSI also require a different use of business skills as shown in figure 4. The analyst engaged in bespoke software needs a high level of knowledge about the business, as does the analyst employed in PSI.

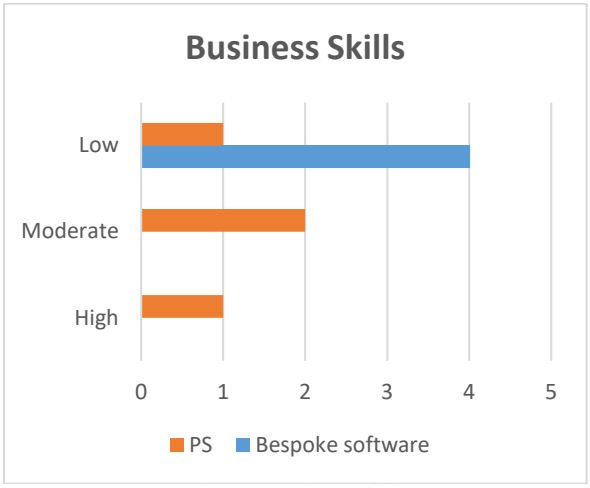

Figure 4: Business Skills

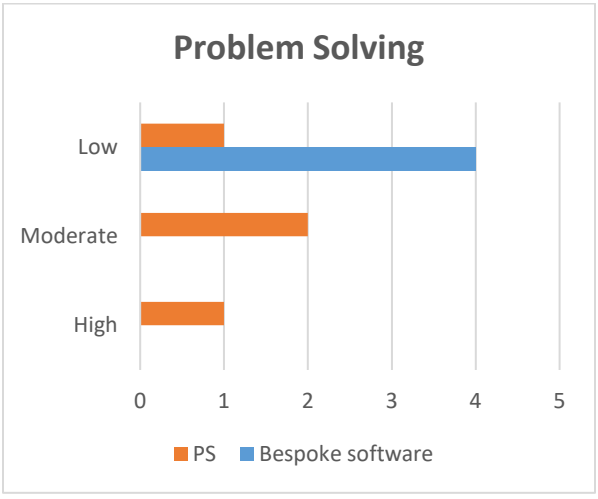

Figure 5: Problem Solving Skills

However, in bespoke software, the analyst needs only a 'moderate' understanding of specific functions. In PSI, this knowledge of particular procedures must be high. In bespoke software, the analyst's industry-specific and enterprise-wide skills are 'low', whereas, in PSI, they practiced at a 'high' level.

The skills related to 'problem-solving' also differ between bespoke software and PSI as shown in figure 5.

The ability to be adaptable or flexible required at the 'low' level in both forms of RE. Several other skills needed to differ in terms of use, however. For example, skills related to general problem-solving, technical expertise, the ability to be analytical, critical, or logical, and to engage in customer-oriented problem solving

practiced at a 'low' level in bespoke software. These same skills practiced at a 'high' level in PSI.

Lastly, analysts' skills related to hardware also differ as shown figure 6. The analyst doing bespoke software requires only a 'low' level of skills concerning general knowledge about hardware, knowledge about servers, desktop PCs, and knowledge about devices and storage. The requirement of these skills is slightly different for the PSI analyst. In PSI, the analyst has 'moderate' skills concerning general knowledge about hardware, desktop computers, and PCs. As in bespoke software, they need only 'low' knowledge about devices, storage, and printers. However, they will need to have a 'high' level of knowledge about servers.

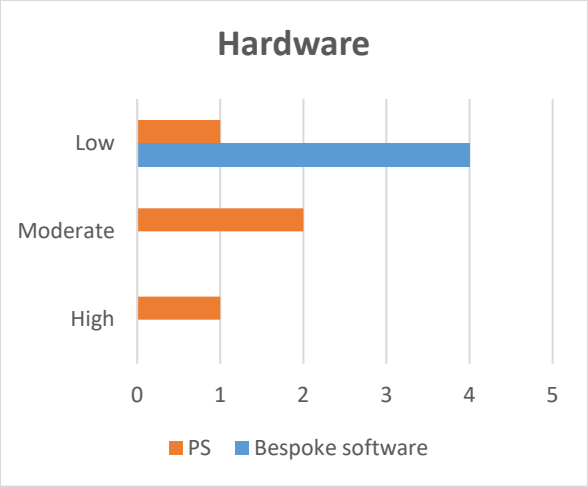

Figure 6: Hardware

5. Conclusion

This study provides an account of the distinction between the skills of analysts for packaged software and bespoke software with an emphasis on the activities of analysts. Through this report, we offer a detailed discussion of the skills of analysts required to be effectively implemented by PS and the challenges faced when implementing packaged software at SMEs. The numerous factors involved in seeking buyers, eliciting requirements and detecting misalignments, designing a packaged software product, and updating or adapting existing packaged software have been addressed.

The expertise and abilities of analysts to communicate with consumers should be considered as crucial factors when attempting to enhance the actions and results of the application of the PS. By enhancing their development skills, in particular integration, awareness of technical developments, and quality assurance skills, analysts will gain confidence, strengthen their critical thinking capabilities and problem-solving skills, and enhance their ability to connect, engage, and cooperate with the implementation of PS.

Business skills are the most important for understanding the business process of SMEs based on the responses of our 60 participants. In view of this, it is important to improve well-developed function-specific skills to minimize misunderstandings and increase the efficacy of such communication. In addition, the involvement of analysts with inadequate skills to work efficiently during the implementation of PS, showing weak or poorly performed interaction skills, may also lead to fragmented teams and disagreements between team members, resulting in an unsatisfactory experience for both users and analysts. This analysis of skills analysts in PS can help to shed light on areas of practice that can be focused on by an analyst to reduce the risk of problematic implementation of PS. Future studies will seek to establish a theoretical framework that describes the interaction techniques that analysts apply during the production and implementation of the PS, as this research is ongoing.

ABSTRACT

The presence of urban parks and green spaces in the city can play a role in maintaining urban residents' quality of life. Parks in Manila are located near main thoroughfares. Since people usually go to parks for recreation and relaxation it is important to have an idea of the concentration of criteria pollutants at these parks as they have great effects on people's health. Using portable sensors, one-hour average ambient concentration of O_3, NO_2, and $PM_{2.5}$ was measured once a month between 8 am to 11 am local time from May 2018 to April 2019 at three popular urban parks in Manila, namely, Arroceros Forest Park, Rizal or Luneta Park, and Manila Zoo. Mean concentrations of O_3 and NO_2 are highest in Luneta Park at 0.071 ppm and 0.032 ppm, respectively. In the case of $PM_{2.5}$, the mean concentrations at Luneta and Arroceros Park are the same at 0.070 mg/m^3. Manila Zoo had the lowest mean concentrations of the three criteria pollutants among the three urban parks. In terms of proximity to major thoroughfares, Luneta is closer and surrounded by four busy thoroughfares compared to Manila Zoo, and Arroceros Forest Park. It was also observed that measured concentrations of the three criteria pollutants were relatively higher during the cool dry months from October to February, with January 2019 recording the highest concentrations. Compared to a background site in Halang, Batangas, results of the measurement showed that the mean concentrations of O_3, NO_2, and $PM_{2.5}$ at the three urban parks are higher demonstrating the effect of proximity of the parks to vehicular traffic on the air quality inside the parks.

1. Introduction

According to the State of Global Air Report 2019, air pollution is the fifth leading risk factor for mortality worldwide with the Philippines ranking number 10 in terms of the highest mortality burden attributable to air pollution [1]. Exposure to short-term and long-term air pollution is associated with respiratory and cardiovascular diseases [2]. In highly urbanized places like the National Capital Region (NCR) in the Philippines, popularly known as Metro Manila, air pollution aside from urban heating is one of the region's major challenges [3]. In the latest National Emissions Inventory by source conducted in 2015, 88% of air pollution in Metro Manila comes from mobile sources, 10% from stationary sources, and a mere 2% from area sources. The increase in the number of vehicles is attributable to the increase in population to cater to the transport needs of the people [4]. In Metro Manila alone, there was an average increase of 7.77% in vehicular registration the year 2016-2018 (NCA, 2018). One of the 16 highly urbanized cities (HUCs) in Metro Manila is the City of Manila, the capital of the Philippines. It was the most densely populated among the HUCs with 71,263 persons per square kilometer in 2015 [5]. Criteria pollutants such as Nitrogen Dioxide

(NO_2), Ozone (O_3), and fine particulate matter ($PM_{2.5}$) mostly come from mobile sources [4].

The increasing population and vehicles make Manila an example of unsustainable urbanization [6]. Hence, the presence of urban parks and green spaces in the city can play a role in maintaining urban residents' quality of life. Urban green space, a category of land cover that includes public parks and other (public or private) vegetated areas in densely populated places plays a great role in improving not only human health and but also the air quality [7–11]. To date, there were no available data on the level of air pollution in urban parks in Manila. People come to public parks to exercise, sometimes have family picnics, and just for relaxation. Some urban poor and street-dwellers make parks as their temporary home. Measurement of air pollution level is important especially if the parks are located or surrounded by main thoroughfares where traffic congestions are always present. These can increase the potential of park users to be exposed to pollutants associated with vehicular emissions. Lam et al made a study in Hongkong urban parks, and they have shown that the air quality in urban parks is better compared to the roadside but not significantly different from that in the ambient conditions [12]. Three of the popular parks in Metro Manila are located within the City of Manila. These are Manila Zoo, Luneta or Rizal Park, and

Arroceros Forest Park. These three parks are located near the main thoroughfares, hence the proximity to vehicular traffic, which is the main source of air pollution in the city. There have been no air quality measurements in these parks as most static reference standard instruments are usually positioned near the roadside. The use of low-cost and portable air quality monitoring systems has become very popular as there is a need to provide a more accurate assessment of human air pollution exposure assessments [13]. In this study, the ambient concentrations of criteria pollutants such as nitrogen dioxide (NO_2), fine particulate ($PM_{2.5}$), and ozone (O_3) at these three public parks were measured once a month for one year using portable sensors. The measured ambient concentrations at the three parks are then compared to a background site in Halang, Batangas which is far from any vehicular traffic. The comparison between the urban parks and the background site will demonstrate the effect of vehicular traffic on the ambient concentrations of $PM_{2.5}$, NO_2, and O_3. Furthermore, this study will explore the usefulness of portable sensors to provide real-time determination and assessment of air quality in public areas so that people will know the quality of the air they are breathing and, once the air quality drops to unhealthy levels, people can be requested to vacate the area. This will also provide information to authorities if there is a need to place static reference standard air quality monitoring system in such public areas.

2. Materials and Methods

2.1. Sampling Sites

The study was conducted at the three urban parks located in the city of Manila. These are Arroceros Forest Park, Luneta or Rizal Park, and Manila Zoo. For comparison, a background sampling site was included, and this was located in Halang, Batangas which is about 70 km south of Manila. The location and addresses of the sampling sites are given in Table 1 and Figure1 shows the relative location of each sampling site. Yellow and white lines indicate roads for vehicular traffic. Permits were secured with the park administrators for us to conduct the measurements, which should be done only during office hours. Sampling Site 1 is the Arroceros Forest Park (AFP), also called as the "Last Lung of Manila". It is a 2.2-hectare (5.4-acre) manmade urban forest along Pasig River, at the foot of Quezon Bridge. The second sampling site is Rizal Park also known as Luneta Park or simply Luneta is a historical urban park in the Philippines and one of the major tourist attractions of Manila. It is approximately 16.24 hectares (40.01) acre and located along Roxas Boulevard, Manila, and also adjacent to Taft Avenue, Manila. The last urban park is the Manila Zoological and Botanical Garden or Manila Zoo. It is a 5.5-hectare (14-acre) zoo located in Malate, Manila, Philippines.

2.2. Measurement

The criteria pollutants measured in this study are $PM_{2.5}$, NO_2, and O_3. A DustTrak™DRX aerosol monitor (Model 8533, TSI incorporated) that used a light scattering technique to infer the mass concentration of particles was used for $PM_{2.5}$ measurement [14]. It was set on a 1-s time resolution at 3L/minutes. Before the start of each measurement, zero calibration was performed using a TSI 800663 zero filter. NO_2 and O_3 concentrations were measured by a real-time portable battery-operated gas sensor monitor AEROQUAL Series 500 with NO_2 and O_3 sensor heads. The sensor heads used gas-sensitive electrochemical (GSE) technology where it measures the concentration of a target gas by using oxidation or reduction reactions to generate a positive or negative current flow through an external circuit and the magnitude of this current is proportional to the gas concentration. The operating parameters of the sensor heads are as follows; O_3 (detection range 0–10 ppm; resolution and minimum detection limits 0.01 ppm; response time 60 secs; temperature 0 – 40°C; relative humidity 15 – 90%), NO_2 (detection range 0–1 ppm; resolution 0.001 ppm; minimum detection limits 0.005 ppm; response time 30 secs; temperature 0 – 40°C; relative humidity 15 – 90%). A 1-min time resolution was used during the measurement. Although the DustTrak and Aeroqual are not regulatory-grade monitors they are widely used in prior air quality research studies [13,15–24]. Measurements done for this paper were performed during the warranty period of the instruments. Being under warranty, instrument calibration and performance was within factory specifications. During the measurements, researchers observed the performance of the instruments, and temperature and humidity on the site were within their specified operating conditions. Simultaneous measurement on all sampling sites was not possible because only one set of instruments was available. Background measurement in Halang, Batangas was done on a Sunday, and the measurements at the three parks in Manila were conducted on the following weekdays if weather permits. The sampling dates are summarized in Table 2. To observe the same atmospheric and vehicular traffic conditions in the site, measurements were done on successive days in the morning between 8 am to 11 am local time for one hour, once a month for each sampling site for one year. Measurement was not conducted during bad weather conditions and sampling time was chosen to also avoid the effect of sunlight on O_3 concentration.

3. Results

One Way Analysis of Variance (ANOVA) was the statistical method used for identifying if there are any significant differences in the measured concentration of a particular criteria pollutant at the different sampling sites. If there's a significant difference, a Tukey honestly significant difference (HSD) test is then carried out to identify what sampling locations are significantly different, and then based on the mean concentration, the locations are ranked from highest to lowest concentration. RealStat (http://www.real-statistics.com/) Microsoft Excel Add-In was used to carry out the statistical calculation. An alpha value of 0.01 was used. To illustrate the variation of air pollution concentrations at each sampling site, Box and Whisker plots were used in terms of the lower quartile, upper quartile, median, mean, minimum, and maximum in each of the four study locations.

3.1. Ozone (O_3) Measurement

Shown in Figure 2 is the box plot of the O_3 concentrations from the four different locations from May 2018 to April 2019. Table 3a shows the result of the statistical analysis for O_3. In all the sampling months, there was a significant difference in O_3 concentration between each sampling site. The O_3 concentrations at the background site always have the lowest concentration on all sampling months. The DENR EMB National Ambient Air Quality Guideline Values (NAAQGV) for 1-Hour Averaging is 0.07 ppm [4], [25]. As shown in Figure 3, in some months, the measured O_3 concentration was 0 ppm at the background site

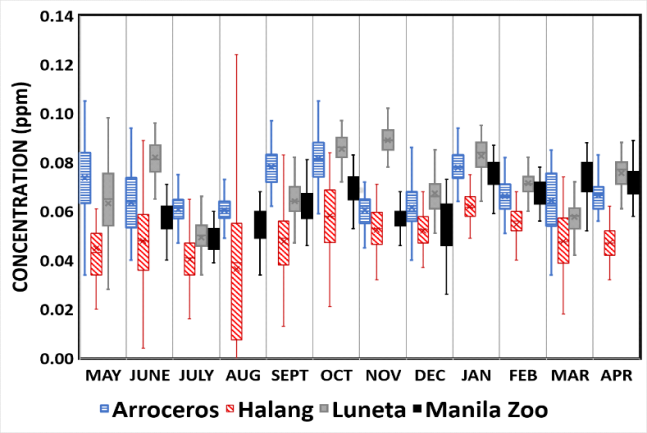

Figure 2: Box plot of monthly concentration of O_3 at the four sampling sites from May 2018-April 2019

For the whole year, as shown in Figure 3, Luneta had the highest concentration of 0.071 ppm and Arroceros was a close second at 0.067 ppm, followed by Manila Zoo at 0.063 ppm, and the background site at 0.050 ppm. A high concentration of O_3 exceeding the NAAQGV was observed for all sites except the background site in January 2019 which is one of the coldest months in the Philippines.

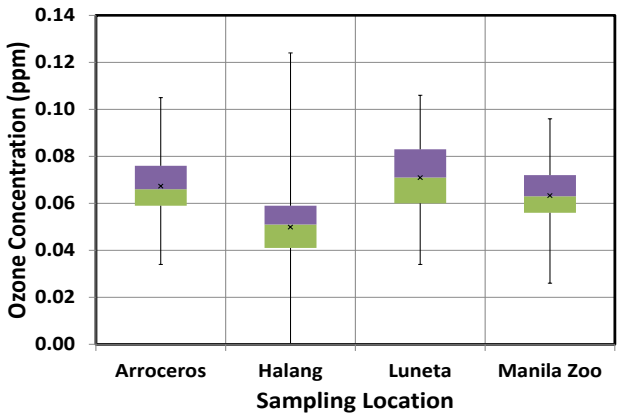

Figure 3: Box plot of the one year mean O3 concentration at the four sampling sites from May 2018-April 2019.

3.2. Nitrogen Dioxide (NO_2) Measurement

Shown in Figure 4 is the box plot of the NO_2 concentration from the four different locations from May 2018 to April 2019. Table 3b shows the result of the statistical analysis. In all the sampling months, there was a significant difference in NO_2 concentration between each sampling site. The NO_2 concentrations at the background site have the lowest concentration on all sampling months. On some months, the NO_2 concentration was 0 ppm indicating that the NO_2 concentration was below the detection limit of the NO_2 sensor. This was true most especially in the case of the background site where the lower quartile value was equal to the minimum value measured by the NO_2 sensor. For the whole year, as shown in Figure 5, there is a significant difference in all sampling locations. Luneta having the highest concentration of 0.032 ppm and Arroceros is a close second at 0.025 ppm, followed by Manila Zoo at 0.022 ppm and the background site at 0.017 ppm.. The National guideline value for NO_2 is 150 µg/Ncm (0.08 ppm) maximum for a 24-hour exposure [25]. As in the case of O_3, the coldest month of January and February 2019 registered higher NO_2 concentrations for all the urban parks except the background site.

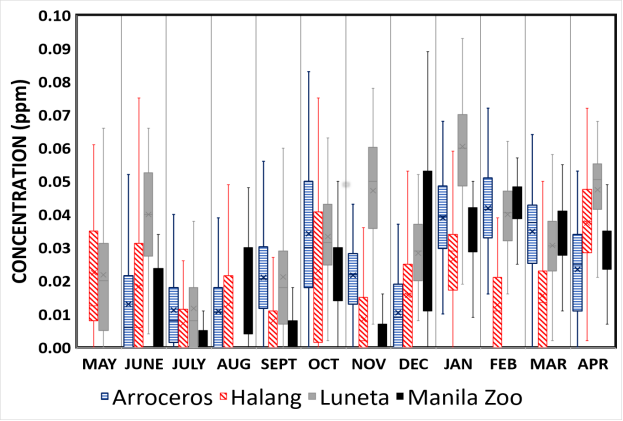

Figure 4: Box plot of monthly concentration of NO2 at the four sampling sites from May 2018-April 2019.

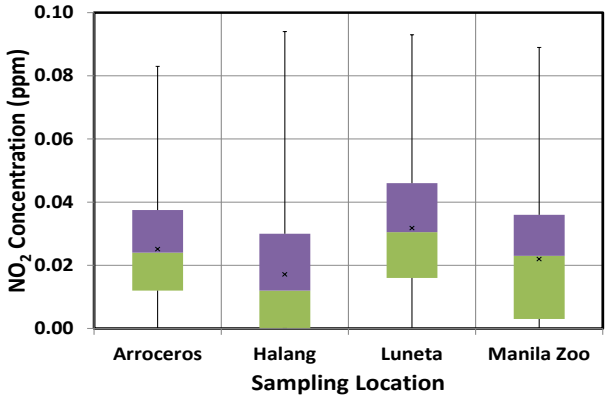

Figure 5: Box plot of the one year mean NO_2 concentration at the four sampling sites from May 2018-April 2019.

For Particulate Matter measurement, TSI DUSTTRAK DRX Aerosol Monitor 8533 was used and this can measure PM_{10}, $PM_{2.5}$, and $PM_{1.0}$ but only $PM_{2.5}$ will be presented. For statistical analysis, only $PM_{2.5}$ measurement will be used since all the other PM sizes follow the same trend. Furthermore, in terms of Air Quality Guidelines, $PM_{2.5}$ is the one that is reported. No air quality guidelines yet for $PM_{1.0}$. Shown in Figure 6 are the box plots of the $PM_{2.5}$ concentration measured by the DUSTTRAK. The lowest concentration of PM is in Halang, Batangas while Arroceros always gives the highest concentration. The result of One-way ANOVA indicates a significant difference in the PM concentration for all months between each sampling location. Arroceros always ranks the highest while Halang is the lowest. The WHO Air Quality Guideline values for $PM_{2.5}$ is 10 µg/m^3 annual mean and 0.025 mg/m^3 24-hour mean [4]. NAAQGV are 0.025 mg/m^3 annual mean and 0.050 mg/m^3 24-hour mean [4]. It can be seen from Figure 7 that the $PM_{2.5}$ concentration measured from TSI DUSTTRAK at the sampling locations in Manila exceeds the annual mean guideline values. However, please note that the instrument is not the reference instrument. Like O_3 and NO_2, it was also observed that in January 2019, high values of $PM_{2.5}$ concentration were measured at the urban parks exceeding the 24-hour mean NAAQGV.

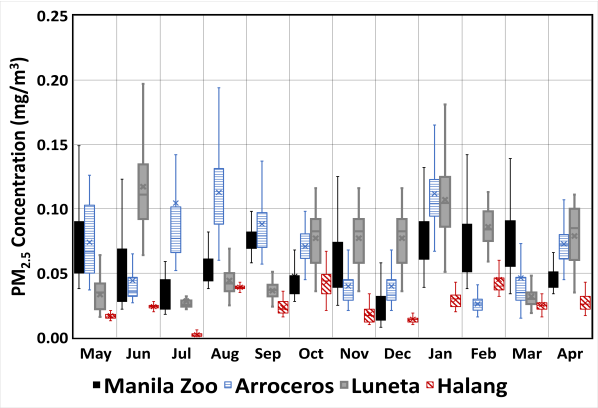

Figure 6: Box plot of monthly concentration of PM2.5 at the four sampling sites from May 2018-April 2019

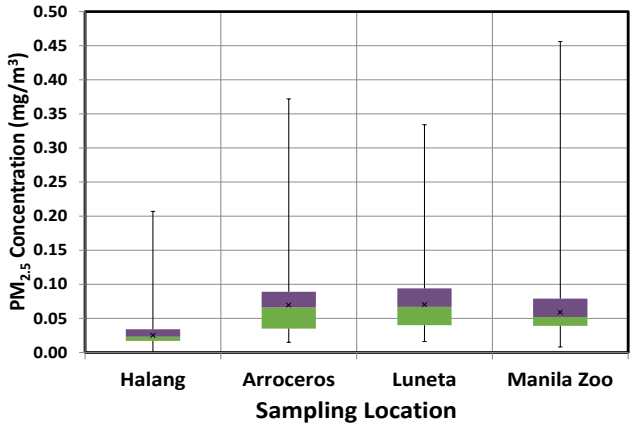

Figure 7: Box plot of the one year mean $PM_{2.5}$ concentration at the four the four sampling sites from May 2018-April 2019

With the unsustainable urbanization in Manila, the presence of urban parks can provide residence with quality of life. However, the location of these parks affects the air quality within the park. The measured values of O_3, NO_2, and $PM_{2.5}$ at the three well known urban parks in Manila are higher compared with a background site in Halang, Batangas. Using portable sensors, the

ambient concentration of O_3, NO_2, and $PM_{2.5}$ was measured once a month between 8 am to 11 am local time from May 2018 to April 2019 at three known urban parks in Manila, namely, Arroceros Forest Park, Rizal or Luneta Park, and Manila Zoo. Mean concentrations of O_3 and NO_2 are highest in Luneta Park at 0.071 ppm and 0.032 ppm, respectively. Among the three parks, Luneta is the one surrounded by major roads. For mean concentration of $PM_{2.5}$, Luneta, and Arroceros Park are the same at 0.070 mg/m^3. One of the main reasons is the proximity of the three parks to vehicular traffic. It was also observed that measured concentrations of the three criteria pollutants were relatively higher during the cool dry months from October to February. Although the instruments used were not the reference instruments, the result provides information on the necessity of monitoring the air quality within the parks. Many residents most especially people who cannot afford, and don't have time to go out of the city need these urban parks for relaxation and recreational activities.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The authors would like to acknowledge the support from Commission on Higher Education (CHED) project entitled UDM CHED DARETO "Using wireless environmental monitoring sensors in assessing the impact of megacity environmental pollution and local climate on butterfly diversity in Manila, Philippines" and CHED –Grant-In-Aid Project "Evaluation of Human Skin Analogues" and we also acknowledge ARCHERS, CENSER through EARTH lab and De La Salle University Research Coordination Office (URCO) 47 F U 2TAY18-2TAY19 for partially supporting this project.

ABSTRACT

The population living in the residential area in two villages, including Pohuwato village and Pohuwato Timur village, are mostly fishermen, who live under the poverty line, meaning that the people there have low income. The objective of the present study was to explore the living condition in terms of the physical, social, and economic aspects of the fishermen communities in Pohuwato Village and Pohuwato Timur Village, Marisa City, Gorontalo; it took into account the minimum service standard of a settlement area. The primary data was obtained by conducting field observations, interviews with fishermen, and Focus Group Discussion (FGD) forums; secondary data was obtained from the related literature, including books, research results and documentation as well as various articles. The quantitative analysis was implemented by scoring, in which the indicators and variables of slum will be assessed with the standards of the Ministry of Public of Works and Housing, Directorate General of Human Settlement. Living conditions in the slums spread in the studied villages were in the moderate category. Findings showed that, issues, such as the provision of lavatory, drainage system for wastewater, clean water supply, waste management, and fire protection system, were most visible. Developing a disaster management system for the settlement area is also crucial. Therefore, the fulfillment of basic needs was deemed essential as the solution to the sustainability of the fishermen community.

1. Introduction

The term "urbanization" is defined as the population shift from rural areas to urban areas, aiming at creating a better quality of life. This phenomenon can be found in many parts of the world, both in metropolitan cities and small cities, with a feasible livelihood option that people can find compared to the one in their previous settlement. In [1], the authors argue that urbanization has encouraged and attracted rural communities to move to urban areas. Marisa city, one of the small cities, has experienced a rise in its population numbers due to urbanization. The rapid advancement of industrial cities, in addition to other contributing factors, e.g., ease of access to infrastructures, education, health, and job opportunity, is cited as the cause of urbanization. However, the population growth is not accompanied by the initiative of the city government to provide basic infrastructure, include adequate or appropriate settlements, for the people; thus leading to socio-economic inequality. In [2], the authors claim that the inability to provide the infrastructures contributes to the rise in the number of slums with insufficient necessary infrastructures, and this problem is found in the fishermen's settlement in Marisa city.

The population living in the residential area in two villages, including, Pohuwato Village and Pohuwato Timur Village, are mostly fishermen. In those villages, the houses are adjusted to fit the needs of the fishermen so that the pattern of the settlement results in a linear shape, with wooden moorings and wild plants along the beach. Many people there live under the poverty line, meaning that they have low income. In [3], the authors propose that the settlement in those villages is mostly inappropriate houses with poor environmental conditions due to dense populations. In this research, the term "slum" refers to unsuitable building and/or high-density housing, which is inappropriately arranged, with

*Corresponding Author: Irwan Wunarlan, irwan.wunarlan001@gmail.com

below standard facilities and infrastructures. Another defining characteristic of a slum is that this area does not meet the spatial planning or housing standard. A slum is notoriously known for its settlement that has poor services; it is an overcrowded and unhealthy area with high criminality rates. In general, settlements located in a slum represents an area with poor quality in terms of the environmental aspect, overpopulated, and high-density housing, with below-standard public infrastructures.

Conditions in an abandoned small city could trigger some problems, such as the rise in the number of slums, poor development of the area, visually undesirable city, and a decline in the health of the population due to the absence of the health standard, as well as socio-economic problems. The present work discusses the life of the fishermen community residing in areas nearby a small city of Marisa, including Pohuwato Village and Pohuwato Timur Village; these areas are notable for their urban-rural characteristics and far from the activity center.

Based on the research background, the main question of the study is as follows: "how is the living condition of fishermen's settlement in the coastal area of Marisa City, Gorontalo province according to the minimum standard of services? Therefore, the objective of the present study was to explore the living condition of the fishermen's settlement. It focused on examining the physical, social, and economic aspects of the fishermen communities in Pohuwato Village and Pohuwato Timur Village, Marisa City, Gorontalo; it took into account the minimum service standard of a settlement area.

It is further expected that the study will contribute to: (1) broadening the insight regarding the living condition, facilities, and infrastructures of the fishermen's settlement in the coastal area of Marisa City, Gorontalo; (2) providing references and inputs for the government of Pohuwato regency in terms of the housing and settlement in the area, by which it helps their development program and the management of the coastal area in Marisa City, including the provision of housing facilities and infrastructures that fit the physical, social, and economic condition of the people.

2. Literature Review

2.1. Settlement

A settlement refers to a process of functional establishment underpinned by the pattern of human activities and the influence of the aspect of the physical and non-physical setting (which affects the activities and establishment process). In [4], the author infers that the setting is impactful on the physical environment that is shaped by the location and the community with its socio-cultural aspects. A settlement can be established through particular processes, with or without a plan. The processes are long-term and continuous. On the other hand, in [5], the author opines that the formation of a settlement pattern is the outcome of the distribution of a settlement area based on a particular geographical factor, e.g., a settlement in a coastal area or nearby a river and linear settlement.

According to the Law of the Republic of Indonesia, Number 1 of 2011 Concerning Housing and Areas for Settlement, the term settlement refers to a part of the environment, outside the protecte d areas, including both urban and rural areas serving as a residential area and a place that supports livelihood. The term settlement area, in this context, is defined as the residence of a person or a family, consisting of a house and yards. In [6], the author states that this notion later confirms that housing is among the components of a settlement area. Furthermore, In [7], the author mentions five major elements in a settlement area, namely (1) residential area, (2) workplace, (3) movement area, (4) recreational area, and (5) facilities and infrastructures.

In [9], (as cited in R.W. Diah [8] I.N Nasution, A. Syahreza), the author argues that issues revolving around settlement areas are notoriously complicated due to many underlapping factors that contribute to the concerns. As a living place, the settlement areas take into account several aspects other than physical and technical; those aspects include the socioeconomy and culture of t he residents. The problem concerning the provision of housing mostly occurs in urban areas. It blames the population migration from the rural areas to cities due to cities' appealing aspects and internal urges from the villages. Such a condition results in continuous increases in the urban population by which it is considerably impactful on the provision of land for housing. In [10], the authors point out that the growth rate in cities in many developing countries is accompanied by the growth in the number of population living in a slum. This is signified by the condition of people living with undesirable standards.

In [11], the author defines the condition of a building is seen from its age, density, and arrangement. Building's age is one of the factors causing damage and fires. In [12], the author describes an area becomes a slum due to the density of the building and the poor standard of the area of the construction. On top of that, the types of construction can determine the level of the building's durability. As mentioned in [13], the author states that most constructions in a slum are made of combustible materials, e.g., wood, zinc, fabric, iron, and bamboo.

2.2. Urban Settlement

A settlement develops along with the rise in the population number of an area. The constant condition of the land and the increase in the population number is the leading cause of the increase in the needs for settlement areas. For this reason, finding another land to create more suitable residential is a necessity.

Settlements in urban areas are generally categorized into three groups, namely: (i) well-arranged settlement with quality facilities, infrastructures, and utilities; (ii) unplanned settlement, i.e., areas where the housing is not in compliance with the regulation, and it has no facilities, infrastructures, and utilities that meet the standard, and; (iii) informal settlement, where the construction of the houses are not well-planned. In [14], the author explains that in the last group of the settlement, poorly arranged houses can be found amid well-constructed houses. The inability of spatial planning in urban areas to make ends meet results in improper management of the settlement areas; which also causes rapid growth of slums. In [15], the author states that these situations will, in turn, lead to a distortion in the environment in terms of the physical and social aspects.

A metropolitan city has people with different elements; this condition is the outcome of the high attractiveness value of the city. Some of the people have inhabited the city for a long time, and the others are newcomers who expect to earn a better living. One

inexorable trend of a metropolitan city near a coastal area or ship port is the presence of the fishermen community in the structure of the urban population. According to [16], the author reckons that fishers are among the components of society with the lowest financial well-being compared to other social groups. In the same tune, in [17], the authors state that the consequence of low-quality human resources in the fisheries sector is a declined productivity level, leading to the low earning and impoverishmen t among the fishermen.

2.3. Slum

The term slum refers to a settlement area with undesirable environment qualities caused by the gap between the rapid population growth and slow economic growth. A guideline published by the Directorate General of Human Settlements has established the criteria to identify a slum area. Indicators or criteria of a slum area based on the facilities and infrastructures include the condition of the road drainage system, clean water, wastewater, and waste management.

The slum area is an unplanned settlement area with inadequat e basic services, such as clean water and sanitation, and poor ownership security. Further, this area is infamous for its inapprop riate and dense housing, and unsafe construction of the houses. In [18], it considers that there are many terms associated with the slum area at the national and regional levels, such as informal settlement and squatter. In other words, the slum area represents a squalid and overcrowded area in many cities. The slum area is represented by many defining characteristics, such as inhabited by unemployment, high crime rate, and demoralization rate, inha bited by unemotionally stable residences with low purchasing power and income level, and squalid and unhealthy environment. Most of the population in this area are migrants from villages, and they are prone to serious health issues, such as malnutrition [19], since authors have limited access to the public facilities. In [20]-[22], the authors express the majority of the people here work in informal sectors as labor, and they live in informal houses.

According to [23], the author states that common problems revolving around a slum area include (1) overcrowded housing with poor health and social standard, (2) dense building, which is prone to fires, (3) lack of clean water, (4) insufficient electrical energy supplies, (5) poor drainage system, (6) bad roads, and (7) lack of lavatories. Preventions of slum conditions are possible if the development of the settlement area adheres to the regulations; one of the practices is by establishing a healthy housing standard. A slum area represents a residential area with low quality of housing and poor infrastructures with a constant decline in the environmental aspect. Despite these conditions, the residences of the area have guaranteed land ownership; this regulation encompasses legal protection for the owner of the land, a residence, or the landlord. In [24], the author states that slum refers to an area located in urban areas, in habited by marginalized communities that experience a drop in the quality of life.

2.4. Typology of Fishermen's Settlement Areas

The fishermen's settlement area in Pohuwato and Pohuwato Timur villages is positioned to adjust with the area, facing the coastline, i.e., a linear settlement. This adjustment is based on the fishermen's activities. In general, this typical settlement is categorized into two: (1) settlement area with houses facing towards the beach, and (2) settlement area with houses facing towards the street with access to the beach.

The settlement is regarded as a high-density area, thus leaving the impression that the settlement resembles a slum area with bad sanitation. Most of the houses are made of wood and bamboo, although there are some concrete houses with gable roofs. Furthermore, the materials of the roof of the houses in the area are zinc and thatch. Each house has a mooring. Currently, the two villages have no fishing ports that function as a port or harbor for landing and distributing fish.

Each fisher who owns a boat is accompanied by 25-30 subordinates who are helpful during fishing. They can catch 1.5 to 3 tons of fish per day.

As many as 1.5 to 2 tons of the catch are distributed to the tra ditional market in Marisa and Paguat for fulfilling the food supply of the population in the cities and nearby areas, while 3 tons of the catch is sold to the markets in the city center in Bitung, Gorontalo, Palu, and even to other islands, such as Kalimantan to earn more income for the community in Marisa city. Should the fishermen want to land their catches from their boat to the coastal area, they have no choice but to rent a smaller boat because the port in the area does not meet the standard.

Figure 5: Permanent house of a Fisherman in Pohuwato and Pohuwato Timur (Source: Authors, 2018)

3. Research Methodology

3.1. Research Sites

This study was conducted in the fishermen's settlement in Po huwato and Pohuwato Timur village, Marisa city, Pohuwato regency; the area of the settlement is 392.91 Hectares. (see Figure 6). In these densely packed villages, the majority of the population works as fishermen living in slums. Such a situation leaves the impression of an inelegant city since the fishermen settlement is located at the center of Marisa City.

3.2. Data Collection

The data involved primary and secondary data. The primary data functioned to gather information regarding the overview of the condition in the settlement area of the fishermen community in Pohuwato and Pohuwato Timur village, and information regarding the preferences and perceptions of related stakeholders in terms of the improvement of the quality of these two villages. Methods to obtain the primary data involved field observation, interviewing 148 fishermen (or 25% of the total population selected purposively), and Focus Group Discussion (FGD). Each closed-ended question (with responses using a Likert scale system) is intended to retrieve information regarding the condition of the fishermen settlement. The secondary data were collected from reviewing the literature, books, research report, documents, and articles that correlated with the present study.

3.3. Data Analysis

The data were analyzed quantitatively using a scoring system, where the indicator and the variables of slum area were examined based on the standard of Ministry of Public of Works and Housin g, Directorate General of Human Settlement; this was aimed at determining the living conditions in the fishermen's settlements in the studied villages.

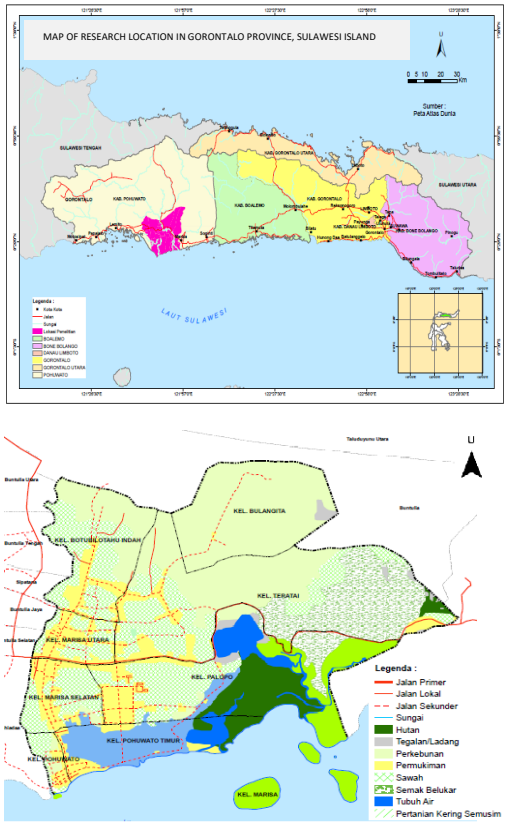

Figure 6: Research Site Map

4. Results and Discussion

4.1. Evaluating the living conditions in the fishermen's settlements

The population living in the residential area in two villages, including, Pohuwato village and Pohuwato Timur village, are mostly fishermen. The total population is 4333. The two villages share land borders with several areas. Palopo and Marisa Selatan villages are located in the north border of Pohuwato and Pohuwato Timur. On the east border and the southern border, the two villages share land borders with Maleo village, Paguat district, and Tomini bay, respectively. Bulili village, Duhiadaa district, is located on the east border of Pohuwato and Pohuwato Timur.

Table 1 shows the living conditions of the settlement area of the fishermen community in Pohuwato and Pohuwato Timur village.

Table 1: Living conditions in fishermen's settlements in Pohuwato and Pohuwato Timur village units

Number	Aspect	Conditions of slums in Pohuwato Village and Pohuwato Timur Village
1.	**Information of Population**	
	Total population	4333
	Number of the head of the household	867
2.	**Conditions of house**	
	Total houses	864 units
	Number of unorganized houses	529 units

	Number of houses that do not meet the standard	335 units
3.	**Environmental Condition**	
	Road width > 1.5 m.	6634 meter.
	Road width < 1.5 m.	1957 meter.
	Width of bad roads	1796 meter.
	Width of the road without canal	5519 meter.
4.	**Condition of Drainage System**	
	Width of the drainage canal	5034 meter
	Width of the bad drainage canal	3045 meter
5.	**Clean Water Services**	
	Number of households who has no access to clean water	651
	Number of households who has no access to clean water	651
6.	**Condition of Waste Water Management**	
	Number of houses without access to public lavatories	304
	Number of houses without standard lavatories	475
7.	**Condition of Waste Management**	Management of domestic waste in Pohuwato Village and Pohuwato Timur Village are yet categorized good since the officers do not take the waste to the garbage dump nearby.
8.	**Condition of Fire Protection System**	The villages have no fire protection systems; some locations are hard-to-reach areas, thus hindering the fire trucks from reaching the areas (the road is < 1.5m).

Source: Survey reports, 2018

According to the findings, the general information depicting the condition of the building in Pohuwato and Pohuwato Timur village based on eight main indicators of a slum area are as follows:

1. As many as 61% of the total houses in the two villages are categorized as informal housing, and the majority of them are not facing directly to the main road with a minimum width of 1.5m.
2. The percentage of houses that do not meet the standard is 38.64%. All of those buildings need to be repaired.
3. The width of some of the roads is less than 1.5m.
4. Other roads (83.19%) with a width of more than 1.5m have no drainage system.
5. As many as 33.89% of the drainage system is in bad condition, hampering the function of the system to flow the water.
6. Although the access to clean water for the community in the research sites has been provided by Indonesian Regional Water Utility Company (hereinafter referred to as PDAM) of Marisa city, 75.34% of the population in the two villages still have a problem regarding the clean water supply. As a result, they rely on public wells.
7. Regarding the wastewater management, the majority of the people in Pohuwato and Pohuwato Timur village have standard private lavatories, while others still use the public lavatories or defecate in the seawater.
8. The disaster management system in Pohuwato and Pohuwato Timur village is yet available. On top of that, some areas are hard to reach by a fire truck as the roads are too narrow (< 1.5m). The two villages also do not have sufficient disaster management systems (such as mangrove forest as shoreline protection) to keep the settlement area from abrasion and rob flood.

Figure 7: Simple fishermens' settlement in Pohuwato Village and Pohuwato Timur Village (Source: Authors, 2018)

Figure 8: Houses with mooring (Source: Authors, 2018)

Figure 9: Condition of roads (Source: Authors, 2018)

Figure 10: Daily activities of the fishermen (Source: Authors, 2018)

Two scoring methods were employed to determine the living conditions in the fishermen's settlement in the studied villages. Table 2 demonstrates the criteria and indicators of the slum area, along with its scoring, prepared by the Directorate General of Human Settlements

Table 2: Criteria score of living conditions in fishermen's settlements in Pohuwato and Pohuwato Timur village units

No.	Aspect	Criterion	Indicator and Parameter	Score
1.	Condition of building	Building irregularity	Building located in an irregular location	3
		Building density	High-density building that does not meet the standard	3
		The discrepancy with building	Building in a location that is not in compliance	5

		technical requirements	with the technical requirements	
2.	Condition of roads	Road coverage	Areas not covered by the roads	1
		Quality of the surface of the roads	Areas with poor-quality roads	5
3.	Condition of clean water supply	Availability of the access to clean water supply	Total population with no access to clean water	1
		Unfulfilled demand for clean water supply	Total population, whose demand for clean water supply, is not met	3
4.	Condition of the drainage system	Inability to manage water flow	Areas with >30cm of puddle, in > 2 hours, and > 2 times a year	3
		Unavailability of the drainage system	Areas with no drainage system	3
		A local drainage system that is not connected to the urban drainage system	A drainage system that is not connected with other systems	5
		Poorly-managed drainage system	Dirty and unpleasant smell	5
		Quality of the construction of the drainage system	Areas with a poorly-constructed drainage system	5
5.	Condition of the wastewater management system	The wastewater management system is not in compliance with the technical standard	Areas with a wastewater management system that is not in compliance with the technical standard	3
		Infrastructures in the wastewater management system are not in compliance with the technical standard	Areas with poor infrastructures in its wastewater management system	3
6.	Condition of waste management	Infrastructures in the waste management systems are not in compliance with the technical standard	Areas with poor infrastructures in its waste management system	5
		The waste management system that does not meet the technical standard	Areas with poor waste management systems	5
		Poorly-managed infrastructures	Areas with poorly-managed infrastructures	5
7.	Condition of the fire protection system	The availability of fire protection system	Areas with no fire protection system	5
		Unavailability of the fire protection system	Areas with no fire protection system infrastructures	5
			Slum criteria score	73
	Category	Moderate		

Source: Analysis Results, 2018

Description: Score 1 = 25% – 50%, Score 3 = 51% – 75%, Score 5 = 76 %– 100%, Low slum level = 19 – 44, Moderate slum level = 45 – 75, Severe slum level = 76 – 95.

The condition of an area with a disproportional number betwe en the total population, the availability of facilities, and infrastructures would evince the quality of a slum area. As a result, the provision of the facilities and infrastructures is considered as something that is likely over compelled.

Facilities and infrastructures found at the fishermen's settlement are discussed below.

- Lavatories

The needs of lavatories are something unavoidable for the fishermen community in Pohuwato and Pohuwato Timur village. According to the data, 31 units of the house (3.57%) are regarded unlivable, although those houses have lavatories. This condition urges a need for a public lavatory for the fishermen community, considering that 96.43% of the houses in the area have no private lavatories. Consequently, the majority of the people have no choice but to defecate in seawater or a river. Table 3 provides information regarding the distribution of public toilets in Pohuwato and Pohuwato Timur village.

Table 3: The Number of Public Lavatories in Marisa City, 2019

No.	Village	Total	Percentage
1	Pohuwato	21	67,74
2	Pohuwato Timur	10	32,26
Sum Total		31	100

Source: Village Profile, 2020

Table 3 shows that Pohuwato village has more public rest rooms totaling 21 units or 67.74% compared to Pohuwato Timur Village. Pohuwato Timur Village has the least lavatories (10 units, 32.36%) for its people. There are 31 public lavatories spread in the residential area and the settlement of the fishermen community at Marisa City. However, people's awareness to manage the cleanliness of the public facility is low. To worsen, the public lavatories in the two villages are far from satisfying the minimum standard. Such a condition demands the involvement of the people to start taking care of the cleanliness of this facility.

- Roads

Roads are crucial for the fishermen's settlement at Marisa city since these infrastructures connect the activities between the city and the village. The roads in the research site are mostly collector roads, residential streets, and pathways. In this context, the collector road and the residential street refers to a road that connects a group of houses with others, while the pathway connects one house with another.

Table 4: Roads in the fishermen's settlement, Marisa City, 2019

No.	Road classification	Height (km)	Width (m)	Existing condition	SPM (Minimum Service Standard)	Description
1	Collector	22.65	10	0.00522	0.0006 m/individual	Meet criteria
2	Residential street	9.56	8	1.59703	40-60/Ha	Does not meet criteria
3	Pathway	7.1	0.8-2	1.18608	50-110/Ha	Does not meet criteria

Source: Field Survey, 2020

Table 4 reveals that only the collector road that satisfies the minimum public service standard compared to other road types in Marisa city. The other two roads, however, urge the local government to improve, such as expanding new road networks and enhancing the quality of the roads to fulfill the standard.

- Wastewater system

According to [25], the author states that an urban drainage system is designed as flood control in a settlement. The drainage system in the residential area and fishermen's settlement in Marisa city is adjusted according to the model of the road. However, some of the current drainage canals cannot be used properly. The drainage systems that are properly functioned serve to manage the rainwater and domestic wastewater thus flow the water into a river and sea. Problems in some canals blame the rubbish heap covering the drainage surface. The rubbish clogs the rainwater, thus resulting in floods. For this reason, the maintenance of the drainage system is crucial in preventing the rise in the water level surface and flood during the rainy season. The types of drainage systems in the residential area and fishermen's settlement in Marisa city consist of arterial, primary, and secondary drainage.

Table 5: The drainage system in Marisa City, 2019

Number	Classification of Drainage System	Height (m)	Width (m)	Description
1	Primary	2108	1	Good
2	Secondary	514	0.9	Poor
3	Tertiary	326	0.7	Poor
Sum Total				

Source: Survey Reports, 2020

According to the interview with the people living in the residential area and the fishermen's settlement area in Marisa city, flood never hit their areas since the drainage canals can collect the rainwater, thus preventing puddles for two hours. On that ground, it could be argued that the drainage system in the residential area and the fishermen's settlement within Marisa city has met the minimum standard. Expansion of canals in the areas without the drainage systems allows the rainwater to flow into the point of final disposal.

- Clean water resources

In general, PDAM has provided affordable access to clean water for people in the residential area and fishermen's community in Marisa city. The following table provides brief information regarding the use of clean water of the people in the research sites.

Table 6: Clean water resources in Marisa City, 2019

No.	Village	Water source			Percentage		
		Dug well	Drilled well	Indonesian Regional Water Utility Company (PDAM)	Dug well	Drilled well	Indonesian Regional Water Utility Company (PDAM)
1	Pohuwato	15	0	0	4,76	0,00	0,00
2	Pohuwato Timur	300	0	10	95,24	0,00	100,00
Sum Total		315	0	10		100,00	0,00

Source: Village Profile, 2020

According to the results of Table 6, the clean water supply of the fishermen community in Marisa City includes 315 dug wells. PDAM contributes to ten units of water resource facilities. Pohuwato Timur Village has the most access to clean water resources (dug wells), totaling to 300 units or 95.24%, while Pohuwato village has limited resources with only 15 units or 4.76%. Resources provided by PDAM in Pohuwato Timur Village comprise ten units (100%). Both Pohuwato Village and Pohuwator Timur village, however, have no injection wells due to funding problems and the fact that the water from such wells contains salt, and thus it is undrinkable. Clean water resources are one of the primary needs for the fishermen community residing in the residential area and settlement area found within Pohuwato Village and Pohuwato Timur Village. From the above discussion, it can be said that 37.84% of the urban population has access to clean water, while the remaining 62.16% is the opposite.

Thereby, the local government is urged to provide facilities of clean water resources for 1000 houses in the fishermen's settlement; it is aimed at ensuring a healthy life of the fishermen community.

- Waste management

The residential area and fishermen's community in Marisa city has been perplexed by the issue of waste. Such a condition blames the lack of waste management and temporary waste dump sites (hereby referred to as TPS) in all residential areas and fishermen's settlement area in the city. As a result, the majority of the people have no choice but to litter and to burn their waste.

A survey conducted in the residential areas and fishermen's settlement in Marisa city reveals that some areas, such as temporary drainage systems, have been turned into a garbage disposal, thus resulting in the spread of diseases.

Provision of facilities, such as TPS, in a specific area that serves 100 units of the house per radius is, thereby, deemed essential. According to Table 7, the waste management system in the research sites is below the minimum standard, urging the stakeholders to design waste management planning.

Table 7: SPM of waste management

No.	Representing Parameter	Existing condition	SPM (Minimum Service Standard)	Description
1	TPS	0	Per 50-100 m	Below standard
2	Public waste container	0	Per 150m	Below standard
3	Domestic trash bin	26%	60-100%	Below standard
4	Frequency of waste collection	2 times	Every day	Below standard
5	Population served	20%	80%	Below standard

Source: Survey Reports, 2019

- Electricity

Electricity is the source of energy and lighting, which is crucial for all human activities in every sector, e.g., industry, commercial, and household. It also functions as the resource of energy for

electric supplies and industrial machines. There are no significant issues regarding the electrical distribution system in the residential area and fishermen's settlement in Marisa city since the system has been distributed within these areas. The only notable concern for the State Electricity Company (PLN) is the management of cable management for better power transmission to all houses.

- Fire Protection System

There were fires in the residential area and fishermen's settlement in Marisa city in 2008, 2016, and 2017, damaging the houses and public facilities, e.g., schools and regent's official residence, within the city. However, the issues had been addressed properly due to the preparedness of fire brigades in Marisa city, with four units of fire trucks.

The capability of the fire trucks to reach the area correlates with the road and the availability of water supply in every house within the residential areas and settlements in Marisa city. However, there are still some issues regarding the availability of hydrant and road conditions (the trucks are unable to reach the site due to narrow roads, such as in Pohuwato and Pohuwato Timur village). Another issue worth-mentioned is the density of building in the areas, in which it could hinder the officers from extinguishing the fire.

5. Conclusion

It can be concluded that the living conditions in the studied settlements are in the moderate category. Several issues, such as the provision of lavatory, drainage system for wastewater, clean water supply, waste management, and fire protection system, are most visible. Formulating coping strategies by the local government is necessary to address the problem in the areas. According to the living conditions in the studied slums, the fulfilment of basic needs is deemed essential for the sustainability of the fishermen community. This approach thus addresses the scarcity of lavatories and clean water supply, limited drainage system for wastewater, and poor management of waste. Developing a disaster management system for the settlement area is also crucial.

Oftentimes people residing in Pohuwato Village and Pohuwato Timur Village tend to build their houses in a vacant land without any legal permission. The houses can be found around the riverbanks, beaches, or nearby the workplace of the people and in the city center. The needs for housing and settlement areas for the fishermen in Marisa City are considered as their primary needs. Meanwhile, the provision of facilities and infrastructure of a settlement area is supposed to fulfill the spatial planning criteria, involving education facilities, health facilities, praying facilities, public services (office) and open spaces, roads, clean water system, drainage system, waste management (such as garbage dump), electrical energy, telephone network, and fire protection systems. For this reason, the government of Marisa City must strictly monitor the issuing of a building permit, since carrying out building work without such a permit is considered illegal and violate the regulation of urban planning.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

In 2020, a great change occurred around the world due to the covid-19 pandemic, daily activities were restructured and thanks to technological advance it has been an ideal means to carry out remote work. With regard to education in Peru, it was paralyzed for a long time and only obtained in later months the option of video offerings software for the interaction of teachers and students, given these new activities carried out. In schools, we are proposing a mobile application prototype that is adaptable to any school in Perú in order to facilitate the registration process of parents for their children due to the global crisis that we are going through. Parents will have a follow-up and ideal control for your children. The methodology that will help us to carry out this application will be the agile methodology with the scrum framework, since it adapts to the needs of the client, and to the constant changes in the development process of the mobile application. Since high student demand requires fast delivery of the application with cost and time efficiency. The mobile application to which students and tutors will be automatically transferred will have easy access to use it in the registration processes and in their academic controls. Our task is created in three points of view, student, tutor and teacher. The student was validated, with the registration or registration and login for the students already registered. Where the student can validate their personal data already registered and see their school monitoring, such as grades, attendance, courses, schedules and payments. The result obtained is the proposal of a productive approach, optimizing the license plate control processes, through a mobile application, where each agent can perform this function, and thus reduce the risk of contagion in these moments of pandemic. And so, in this way, interconnect all the enrollments, the benefactors in a system, saving their information and the data of the students. With these results, it will be of great benefit for the school to minimize the time and thus increase the competitiveness between the schools, also for the parents and for the students who despite the difficulties continue to progress in life.

1. Introduction

In December 2019, a large and growing outbreak of a new coronavirus was reported in Wuhan, Hubei Province, China [1]. The global COVID-19 pandemic spreads easily to people nearby, especially in crowds with mobile people (for example, city centers). A widely accepted strategy to mitigate its spread is social distancing, avoiding crowds [2].

One of the first broad-spectrum measures has been the closure of educational centers at all levels, which has affected 91.3% of the total number of students enrolled in the world: more than 1.5 billion people have been left without power attend their face-to-face classes, according to UNESCO [3].

Several methodologies were found for the construction of the mobile application, but in this case the Scrum methodology was used, which is a framework for agile software development that has expanded to other industries.It is a process in which a set of

[*]Corresponding Author: Alexi Delgado, kdelgadov@pucp.edu.pe

good practices are applied on a regular basis to work collaboratively, in teams and to obtain the best possible project results. The evolution of software development methods has taken place since 1970. The Agile Methodology also offers services to companies to create the right product that makes them aggressive in the market [4], [5]. The Agile methodology is considered one of the best approaches for the development of mobile applications [6]. Many unavoidable developmental changes could also be identified [7]. Finally, Balsamiq was chosen for the development of the design, as it is useful for communicating ideas [8].

This article uses the design of a mobile application to analyze the enrollment and school monitoring process in the Comas District [9], in order to allow parents to access enrollment without the need to go to schools. It will also include a search and database of school monitoring information per student.

The objective of this research work is to help parents maintain control of their children at school, using a tool that will be easy to use for the different processes that the institution handles. In addition, with the study of information that we carry out it will allow us to avoid spreading the coronavirus.

The present work is structured in the following way, in the next section number II the methodology used for the construction of the application will be described in detail. In section III the results obtained will be evidenced and finally in section IV the own results will be discussed and the conclusions will be presented.

2. Methodology

In this section we will detail what steps will be followed for the development of the mobile application, so we will use the Agile Scrum Methodology as shown in Figure 1 which explains in a general way the behavior of Scrum, using this methodology is advantageous due to the flexibility in the requirements and ease in adapting to changes.

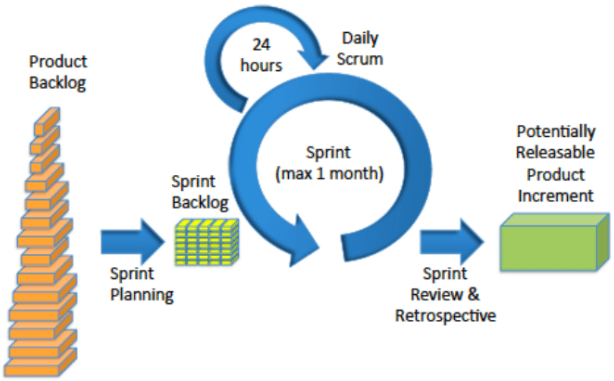

Figure 1: Diagram of the Scrum methodology

2.1. Analysis

Agile Scrum Methodology: As Troy Dimes wrote, scrum is like a lifeline for those companies that face difficulties in not even having a methodology to develop software. Scrum is a framework for creating complex software and delivering it on time in a much simpler way. Scrum is not a methodology; it is a reference framework within the agile software development methodology, which will enable it to create excellent software, through the application of a set of guidelines to be followed by work teams and the use of specific roles [10].

Scrum defines three roles: The Scrum master, the product owner, and the development team. The scrum master's role is to ensure that the team is adopting the methodology, its practices and values and norms; is the team leader, but does not manage development [11]. For its part, the development team is responsible for converting what the customer wants, the Product Backlog, into functional iterations of the product; the development team does not have hierarchies, and all its members have the same level and position: developer. The optimal team size is between three and nine people [12].

Sprint planning

This stage takes place at the Sprint Planning meeting where the activities to be carried out are defined. This activity takes eight hours for a month of Sprint. If Sprint is shorter, the time is allocated proportionally [12].

Development stage

At this stage, the sprint managers must guarantee that last minute changes that affect the objectives are not generated. In addition, they must ensure that they meet the established deadlines.

Sprint review

The Sprint Review occurs at the end of the Sprint and lasts for four hours for a one-month project (or a proportion of that time if the duration is shorter). At this stage: the project owner reviews what was done, identifies what was not done, and discusses the Product Backlog; the development team counts the problems it found and the way they were solved, and shows the product and how it works.

Feedback

Empirical process control is retrospective and not predictive, which would imply that decisions are made based on evidence and knowledge is nurtured in experience. The lessons to be learned in this stage will allow us to learn how sprints can be much more effective and agile.

2.2. Design and tools

Programming platform (Android Studio)

It is the official integrated development environment for the Android platform, is one of the most used IDES for the development of Android applications due to its intuitive interface for the arrangement of the elements used in the architecture of the project [13].

Database manager (Microsoft SQL Server)

The storage and management of data is mainly done through the database of the business management system, so it is very important to study the design and implementation of the database in the system [14].

Design Tool (Balsamiq Wireframes)

In this research, the Balsamiq Mockups tool is used as a tool that will facilitate the development of the project's prototypes [15].

2.3. Procedure

Product blacklog

The Product Backlog is a list, ordered by value, risk, priority and need of the requirements that the product owner defines, updates and orders. The list has as a particular characteristic that it is neveFinished, since it evolved during the development of the project [12].

Sprint backlog

It is the task list that contains selected tasks from the Product Backlog, in which it subdivides the user stories that describe the functionalities that make up the project. This listing is defined and estimated at the Sprint Planning meeting at the start of the iteration [16].

Sprint planning meeting

It is the Sprint planning meeting based on the Product Backlog and they participate: Product Owner (responsible for the subject) who prioritizes the tasks to include in the Sprint Backlog, the Scrum Master and the Development Team [16].

3. Case study

This section will develop what is the planning of the sprints of each of the modules and the estimates of the times in which it is being carried out in the mobile application development stage.

3.1. Sprint planning

- As a user you can enter the application through an account generated by the school.
- As a user you can view the courses with their grades, schedules and pensions.
- As a user, you may be able to register me once you have paid the registration fee.
- As a proxy you can know the names of the teachers with their respective courses that my son will take.
- As a proxy you can know the respective qualifications of my son with their respective states.
- As administrator, you can keep track of student pensions.
- As administrator you can generate detailed reports of each student.

3.2. Development Stage

Time estimation

In this phase we will see the duration of each of the sprints as shown in Table 1.

Product scope

This is the estimate of the time it takes for the equipment to be able to have the user's history points, for which the estimates of the scope of the equipment will be noted in Figure 2.

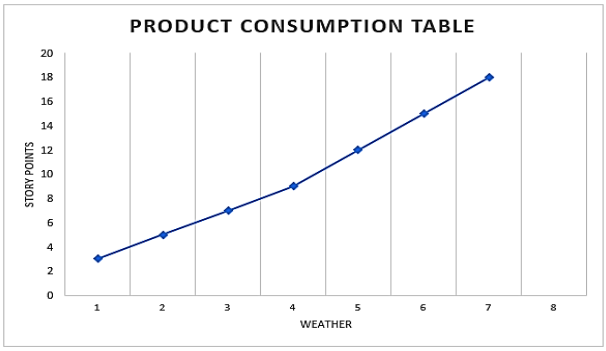

Figure 2: Product scope

Table 1: Duration of Sprints

Name	Duration	Start	Final
Mobile Application for the Enrollment Process	3 months	01/06/2020	01/10/2020
1. User Module	2 weeks	01/06/2020	15/06/2020
2. Enrolment Module	2 weeks	16/06/2020	30/06/2020
3. Schedule Module	2 weeks	31/06/2020	13/07/2020
4. Courses Module	2 weeks	14/07/2020	27/07/2020
5. Ratings Module	2 weeks	28/07/2020	10/07/2020
6. Pension Module	4 weeks	10/07/2020	10/08/2020
7. Reporting Module	5 weeks	11/08/2020	31/09/2020

3.3. Prototypes of the mobile application

In this stage we will see the creation of the mobile application design that we will carry out and we will detail the functions that each of the modules will have as we see in Figure 3 (a), Figure 3 (b), Figure 3 (c) and Figure 3 (d).

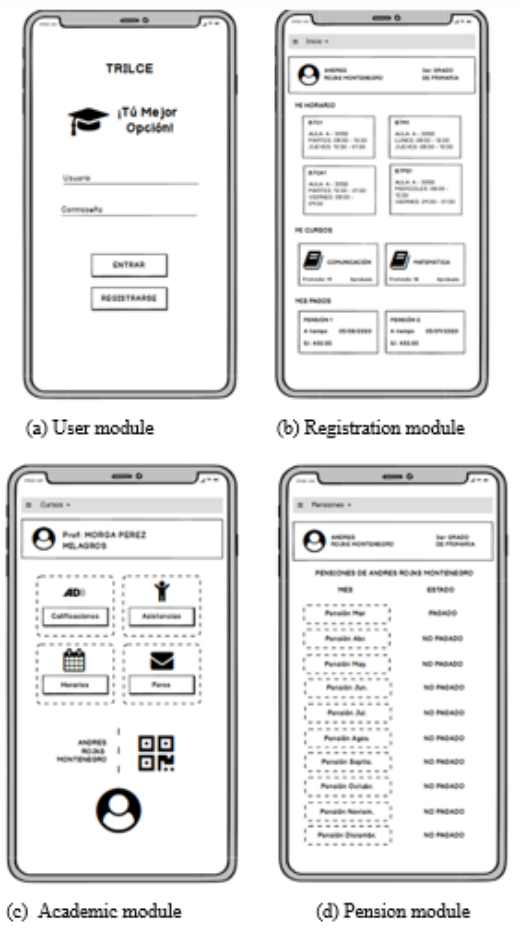

Figure 3: Prototype phase of the mobile application

Increment 1: Main Start

This increase shows the start of the application which, if we have a user already generated by the institution, we could enter the account that maintains personal data of the students Figure 3 (a).

Increment 2: Enrollment module

This increase shows the process that must be carried out to enroll each student, and as a requirement to proceed, they would have to pay the enrollment for the school year Figure 3 (b).

Increment 3: Detailed courses module

In this increase it will show the detailed course with its qualifications, assists, schedules and forums, in addition to having a QR code to download the report Figure 3 (c).

Increment 4: Pension module

In this increase it shows the pensions of each student, detailed by month and the state if it is already canceled or even just canceled Figure 3 (d).

4. Results and discussion

4.1. About the case study

Compared to other research works, we have observed the design of the work of an Android mobile application for an online Travel Agency, where the use of the NinjaMock tool is specified, where we can see that, on the contrary, its interface does not provides a professional visual finish, increasingly difficult to use [17].

The google API services will be used to obtain the latitude and longitude of the reported location [18]. The importance of the interface is a means for the user to interact with the software and hardware. The interface will help the user to interact with the system much easier than with the old method of giving a command at the command prompt. The following image is the Trusted Halal interface. Malaysia Cosmetic Products System Application [19] [20].

Due to the covid-19 pandemic, enrollment in Peru was 7,834,543, unlike last year, which was 8,024,672. Figure 4 extracted from the Ministry of Education [21] shows the number of enrollments in 2020 and a large decrease in enrollment is observed, therefore the proposal of this research will help students to enroll successfully using mobile applications.

URBANO		RURAL	TOTAL

4.2. About the methodology

The tool used in the present work, which is Balsamiq Mockups, is easier and more adaptable to any user, and that shows us a good effectiveness before its prototypes made. In Balsamiq Mockups, mobile applications are designed in a smarter and easier way [22]. We have observed as an important factor in a project and the first decision of the application is the development prototype therefore the prototyping software Balsamiq Mockups served as a benefit to be able to create our Wireframes easily and quickly [23].

Riadh proposed designing the notification system using GCM (Google Cloud Messaging) of the Android app and connecting to the website and providing information that helps instructor to select who will send notification [24].

In this project, the methodology to be used is Agile Scrum Methodology. Scrum is a lightweight project management framework with the ability to iteratively and incrementally control and manage all types of projects. Through use. The "Product

Owner" Scrum methodology will work closely with the team to detect and prioritize system functionality [25].

Differences in Methodologies: This part will detail the differences of using the agile methodology, as opposed to using other methodologies that exist. Table 2 will detail the differences that each methodology will have.

Table 2: Traditional Methodology vs Agile Methodology

Traditional methodologies	Agile methodologies
Predictive	Adaptive
Process-oriented	People-oriented
Rigid process	Flexible process
It is conceived as a project	A project is subdivided into several smaller projects.
Little communication with the client	Constant communication with the client.
Software delivery at the end of development.	Constant software deliveries
Extensive documentation	Little documentation

5. Conclusions

In this research we designed the proposal of a mobile application, helping to achieve a better solution at the time of registration of enrollment and monitoring of students.

This proposal does not try to meet one level but to seek a comprehensive solution in the short term and can be adapted to any educational institution as has been determined in Table 2 with respect to the duration of the Spring. This work can be improved and will be carried out when they go through the final users in which the satisfaction of the users will be determined with statistical data. We can conclude that the design proposal of the mobile application will be of great benefit to parents when registering their children and monitoring and controlling their daily activities, a proposal that is being promoted in schools in Lima, Peru.

In-situ LAI
MODIS Surface reflectance

ABSTRACT

The measurement of Leaf Area Index is of fundamental importance in agriculture and ecological research because it reflects plant growth. This study aims to estimate LAI from, NDVI derived from standard eight days composite MODIS surface reflectance, acquired during the rice growing period.

A two-stage model was developed to relate the LAI of rice to NDVI derived from MODIS surface reflectance. In the first stage, a correlation has been developed between 'MODIS NDVI' and 'in situ NDVI' derived from spectral reflectance measured with spectrophotometer, in rice field of Suphanburi Province, Thailand. In the second stage, correlation has been developed between in situ NDVI and, in situ LAI measured with handheld LAI-2000 instrument. Eventually, a model has been derived using these two relationships, which estimate LAI from MODIS Surface Reflectance, in an irrigated rice field, central Thailand.

1. Introduction

In agriculture and ecology, historically, the Leaf Area Index (LAI) concept is used for the estimation and evaluation of crop production and crop yield and the scheduling of irrigation and amendments during crop cultivation [1]. In order to assess growth and vegetation intensity across the globe, monitoring the distribution and change of LAI is significant. It is directly related to the interception and absorption of light by the canopy. It also influences heat balance and evaporation from the cropping field and thus, accurate assessment of LAI is necessary [2]. However, many factors are important if the reflectivity of the crop canopy is to be assessed. These include the complexity of canopy design, improvements to the internal arrangement of leaves and background effects of the soil [1].

Direct measurement of canopy LAI is accurate but extremely labor intensive and destructive [3]. Remote sensing techniques have been used to measure LAI on a landscape scale or even global scale. The benefit of the remote sensing technique is that it can collect plant canopy information on a global scale without interfering with normal plant growth [4, 5]. The introduction of simple NDVI-LAI relationships has yielded reliable results over a 12-year period in the estimate of green vegetation abundance [6]. There are two common approaches to estimate LAI using remote sensing [7]. The first one is associated with spectral vegetation index (SVI) and the second one, is by modelling approach [7]. In the first approach, an empirical relationship between a Vegetation Index (VI) and LAI has to be established. One major drawback of this method is that equation have to be established for each vegetation type. Thus, it requires substantial LAI measurements and corresponding remote sensing data [8]. This method is unsuitable for pixels of low-resolution remote sensing data enclosing a heterogeneous field. Another approach to estimate LAI is by using Bi-Directional Distribution Function (BRDF) models such as Spectral Absorption of Inclined Leaves (SAIL). These models usually consist of a set of equations that relate surface physical properties to observed signals as a function of wavelength. Physical properties may include soil reflectance, canopy architecture, optical properties and geometric configuration of sensing systems as well as illumination sources. . The input parameters needed for BRDF models are single-scattering albedo of individual leaves, leaf inclination distribution and anisotropic properties of both canopy and soil substrates. BRDF models can then be theoretically inverted to obtain the model parameters, and some vegetation parameters can be estimated [7].

The relationship between growth traits and Normalized Differential Vegetation Index (NDVI) to assess their potential use in estimating the growth of rice crops has been examined [9].

*Corresponding Author: Rushikesh Kulkarni, rushikeshk@sitpune.edu.in

Experiments were conducted at the Taiwan Agriculture Research Institute (TARI) experimental farm on loam soil during the first and second cropping seasons (1996-1997). Plants were sampled at two weeks intervals after transplanting till harvest and the LAI was computed at each new sampling date. A LI-1800 high spectral resolution portable Spectroradiometer (LI-COR Inc., Nebraska, USA) was used to measure the reflectance to calculate in-situ NDVI. Yang and Su then developed a correlation between the computed LAI and in-situ NDVI. A linear regression gave results with R^2=0.982 for SPOT HRV and R^2= 0.985 for Landsat MSS. As these spectral transformations are highly correlated, estimation of growth traits based on NDVI can be accurate for both in-situ NDVI and satellite-derived NDVI. Thus reflectance band of HRV and MSS sensors could be used as predictors of canopy characteristics [9].

In-Situ LAI and spectral reflection data were assessed for the 2004-2005 period in part of Suphan Buri, Thailand [10]. This was done in order to develop a relationship between LAI and NDVI at ground level. In 2004, the researchers developed a model to estimate ground based LAI from ground-based NDVI. This is a specific case, since the remote sensing data corresponding to the field data collection period was not available. It was assumed that NDVI from Landsat MSS and from SPOT VGT to be equal and thus, used the model developed by Yang and Su (1998) for MSS to estimate ground based NDVI from SPOT VGT [10]. Yang and Su's LAI - NDVI correlation estimated LAI in the range of 0.082 to 1.848 for SPOT VGT data which seemed too low compared to the LAI field data collected by Srinuandee in 2004-05, which were measured in the range of 0.0 to 7.15. Srinuandee's field based correlation estimated LAI in the range of 2.03 to 5.3002 for a pixel in SPOT VGT.

Srinuandee's model showed little improvement compared to Yang and Su's model however, impressive variation in result have not been observed. Improvements made by Srinuandee on Yang and Su's model are not proving conclusive. Thus, the main goal of this research was to estimate LAI from Moderate Resolution Imaging Spectroradiometer (MODIS) based NDVI with major changes on Srinuandee's efforts. Indeed, in-situ LAI data recorded by Srinuandee seems to be overestimated and BRDF effect has not been considered during data collection. BRDF effect is an important factor to be considered in case of low-resolution remote sensing data where satellite have wide swath since the measurements vary according to different viewing angles.

2. Materials and methods

2.1. Description of Study Area

The case study was conducted in rice field of Song Phi-Nong district, Suphan Buri Province, central part of Thailand during January' 2006 to April' 2006 which is the growing period of first crop in Suphan Buri province. The geographic location of study site as shown in Figure 1. Experiment was carried out in the homogeneous rice field which was detected using Landsat 7 ETM +, land use map and aerial photographs.

The topography of study area was mostly flat lowland terrain. Thus the rice fields in this area remains completely flooded during rainy season. The climate of the Province characterized mainly by three seasons: (i) rainy season from May to October (ii) cool and dry season from November to February (iii) hot and dry season from March to May. The average annual rainfall in the central plain is between 900-1300 mm, average solar radiation about 17 MJ $m^{-2}d^{-1}$ and temperature ranges from 33-34^{0}C to 23-24 ^{0}C.

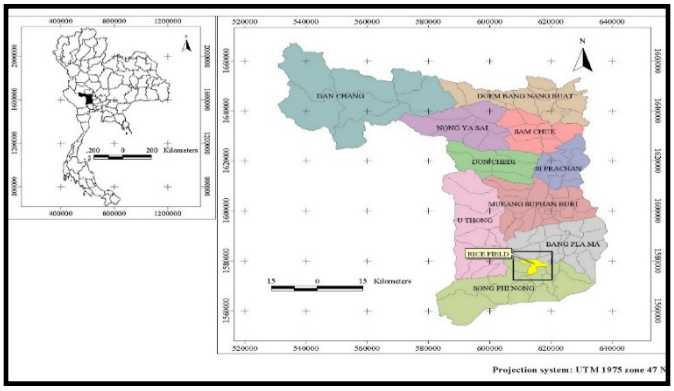

Figure 1: Location of study area in Suphan Buri Province, Central Thailand

3. Field Data Collection

The spectral reflectance and LAI were measured using a Spectroradiometer and a LAI-2000 Plant Canopy Analyser (PCA) respectively from the first stage of rice growth till the harvesting period. LAI was measured at 9:00 am to 11:00 am because LAI canopy analyser doesn't need direct solar radiation to measure LAI and LAI measurements should be done with low sun elevation angle which is in between morning time or in the evening time. Five different locations were sampled at each time of ground trothing.

In-situ spectral reflectance readings used to calculate NDVI have been recorded at five different angles in East and West directions separately in order to create similar circumstances as satellite data; since, satellite moves in North-South direction with acquiring reflectance in East-West direction. Each measurement was recorded with 15^0 intervals, starting from 0^0 to 60^0, marked on a simple handmade clinometer in order to examine BRDF effect in the field refer Figure 2. Five readings of spectral reflectance at each five different angles in East and West directions and five LAI readings, from five sampled locations were averaged for each day of ground truthing. Total eight readings of spectral reflectance at each five different angle and eight readings of LAI, were measured in field during the period of 12th February to 2nd April. The fibre optics wire of the spectrometer was clamped at each angle and spectral reflectance readings were recorded in both directions, so total ten readings of spectral reflectance has been measured each day of ground truthing. One end of fibre optic wire was at a height of 1.5 m from ground level and another end was connected to spectrometer which was further connected to computer through USB port. The spectrometer measures spectral reflectance in the range of 304 nm to 1135 nm with an increment of 1 nm. In order to compare in situ NDVI with MODIS data, average reflectance for red band was calculated from wavelength of 620 nm to 670 nm and that for near infrared band was calculated from wavelength of 841 nm to 876 nm.

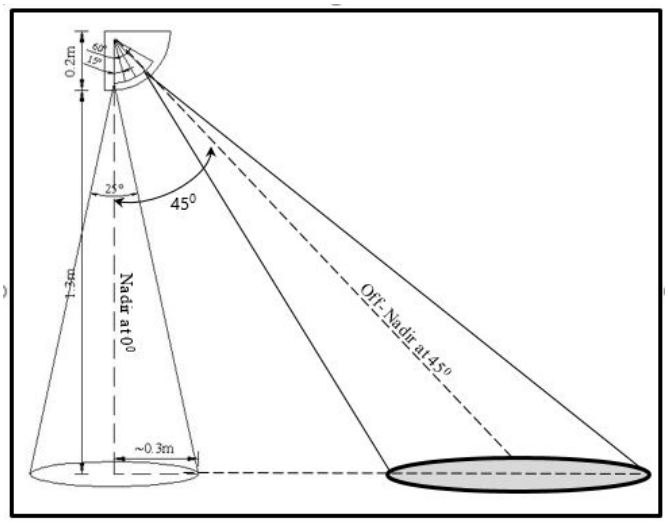

Figure 2: Schematic diagram of clinometer setup used to measure surface reflectance in the field with various angles.

In-situ NDVI estimated from field spectral reflectance measured in each week of data collection has been compared with NDVI estimated from 8 days composite MODIS surface reflectance acquired on corresponding week of ground thruthing, refer figure 5. Two field data collection dates, 26th Feb and 3rd March, are members of 8 days composite of 26th February to 5th March (Table 1).

The general flow chart of the methodology is shown in figure 3. The atmospheric corrected MODIS surface reflectance is obtained and compared to the field NDVI derived using a fiber-optic spectroradiometer.

The relationship between MODIS derived NDVI and LAI is established as shown in flow chart of methodology figure 3.

4. Results and discussion

4.1. Correlation analysis of in situ NDVI and NDVI derived from MODIS

Thus, eight values of in situ NDVI were compared with seven values of MODIS derived NDVI. NDVI derived from MODIS surface reflectance and in situ NDVI did not show the same pattern in early crop development.

Table 1: Comparison of field data collection dates and MODIS 8-days composite dates

Field Data collection dates	MODIS 8-days composite dates
12th Feb	10th Feb - 17th Feb
19th Feb	18th Feb - 25th Feb
26th Feb	26th Feb - 05th Mar
03rd Mar	26th Feb - 05th Mar
12th Mar	06th Mar - 13th Mar
19th Mar	14th Mar - 21st Mar
26th Mar	22nd Mar - 29th Mar
02nd Apr	30th Mar - 06th Mar

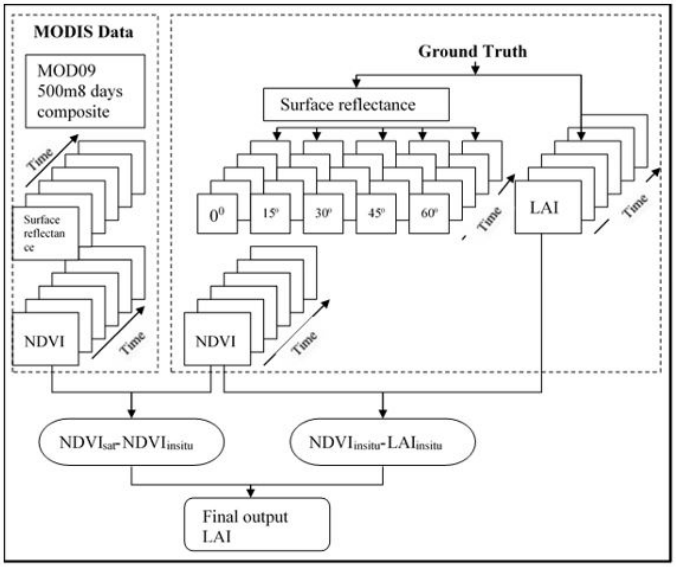

Figure 3: Overall methodology of model development

However, they agree in the full vegetative stage. In the field, early growing stage paddy has a dispersed pattern of newly germinated rice plants along with water, refer figure 4. In this case, muddy soil was easily visible at this stage, which induces canopy background contamination error. While in case of observation from MODIS, angular effect make the field looks different from the way it actually looks with naked eyes. Thus, angular effect was responsible for higher NDVI in case of MODIS observations. Difference between "true" NDVI, as would be measured at the surface, and that actually determined from the space are sensitive to attenuation by atmosphere and by aerosols [11]. In this case MODIS BRDF nadir adjusted 16 days composite data was compared with in situ NDVI figure 6. Similar growing pattern was obtained with in situ ground truth measurement measured at nadir. However, it was rather difficult to compare 16 days composite data with a data acquired on single day.

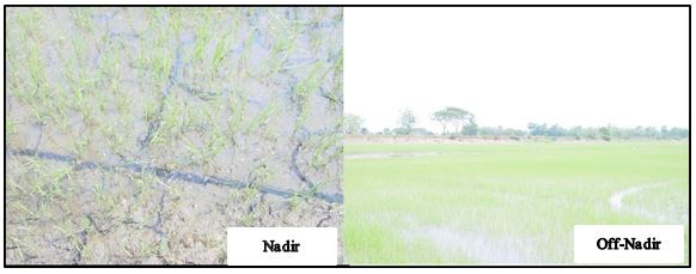

Figure 4: Photograph of paddy field taken at nadir and at off-nadir.

MODIS NDVI was compared with average in situ NDVI estimated from NDVI from all five locations in the field, in both directions i.e. East and West, for all five observation angles. Ground truth surface reflectance was collected in morning time from 9:00 am to 11:00 am.

Linear correlation coefficient (R^2) was calculated between in situ NDVI estimated in five angles and NDVI derived from MODIS surface reflectance,(Table 2). The results obtained were more or less seems to be equal in all cases figure 7[a-e]. The in situ NDVI was linearly interpolated to corresponding view zenith angle of MODIS.

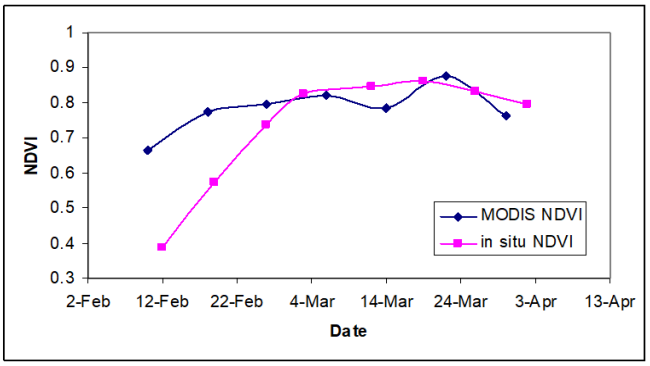

Figure 5: Plot between estimated NDVI in field at 00 viewing angle and NDVI from MODIS surface reflectance.

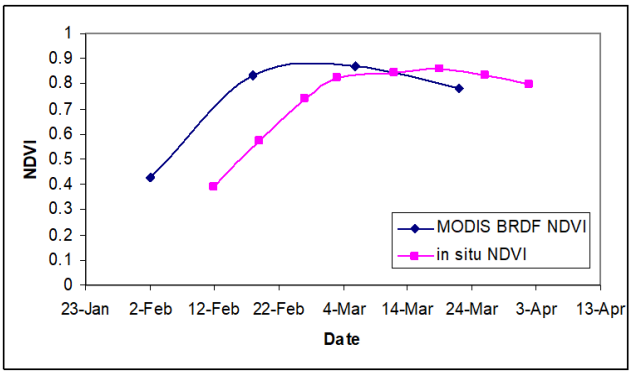

Figure 6: Plot of NDVI computed from MODIS Nadir adjusted data, NDVI estimated from field-collected data

Table 2: Linear relationships between in situ NDVI at different angle and MODIS NDVI

Observation angle	Relationship	R^2
0^0	y= 2.447x – 1.1838	0.65
15^0	y= 2.437x – 1.1793	0.66
30^0	y= 2.447x – 1.1838	0.65
45^0	y= 2.532x – 1.2469	0.67
60^0	y= 2.488x – 1.2068	0.68

$$\text{Model derived in-situ NDVI}_{at\,0^0} = 0.9586 * \text{NDVI}_{interpolated} + 0.024 \quad (2)$$

$$\text{Model derived in-situ NDVI}_{at\,0^0} = 2.2967 * \text{NDVI}_{MODIS} - 1.0727 \quad (3)$$

MODIS metadata file represents the specifications of the MODIS surface reflectance product. (Table 3). The in-situ NDVIS measured at various angles is interpolated to the corresponding zenith angle of the MODIS. The results are shown in Table 4.

Table 4: Interpolated in situ NDVI corresponding to view zenith of MODIS

Field data collection Day	Interpolated in situ NDVI
12 Feb	0.3794
19 Feb	0.5675
26 Feb	0.7362
03 Mar	0.8252
12 Mar	0.8642
19 Mar	0.8616
26 Mar	0.8492
02 Apr	0.7941

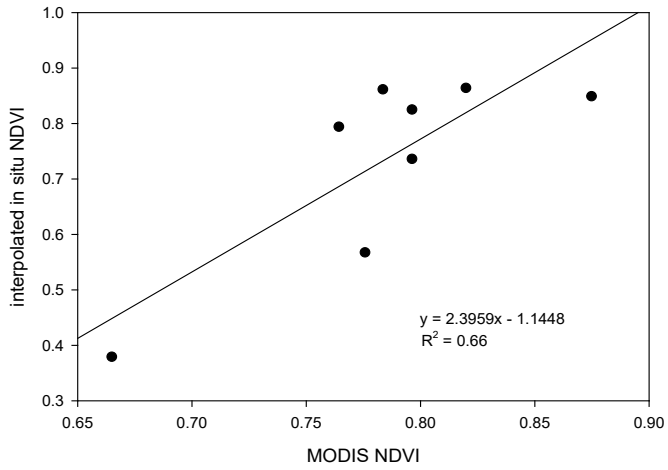

Figure 8: Relationship between MODIS NDVI and interpolated.

The interpolated in situ NDVI was adjusted to standardized form i.e. at nadir observation. Thus, the in situ NDVI was derived from MODIS NDVI in multistage approach.

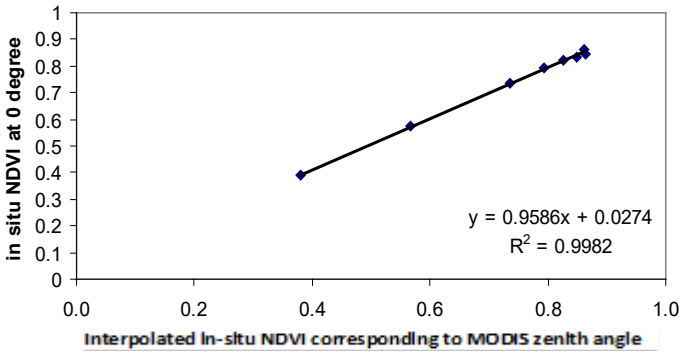

Figure 9: Plot of in situ NDVI estimated at 00 and interpolated in situ NDVI.

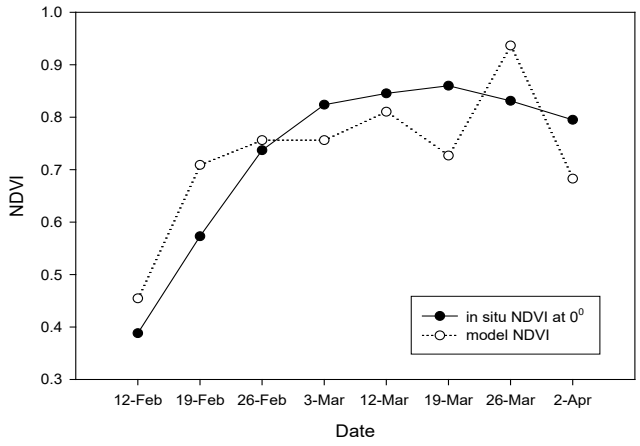
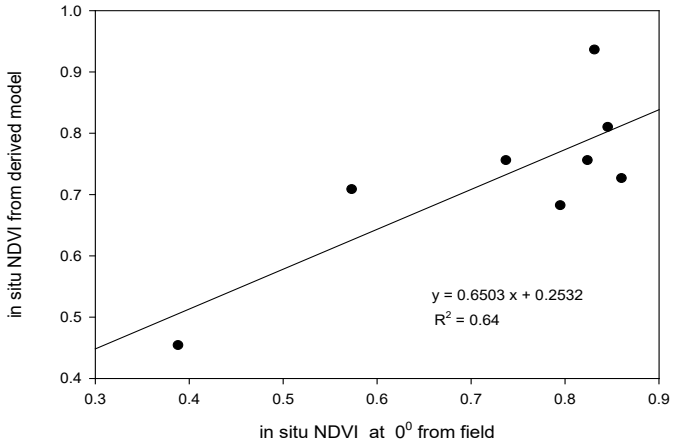


(a)



(b)

Figure 10: Comparison of in situ NDVI estimated at 00 in field and in situ NDVI obtained by derived model

The presence of clouds has been shown to have a major impact on the field data set. The remote sensing data collected on the day 19th March and 22nd March have lots of errors which induced errors in calculation of NDVI and LAI.

The field data collection in this study started with data collection from seven locations but due to proper care and maintenance of rice at two locations in the field, data collection from only five sites could be considered till the end of study.

5. Validation of Model

The derived NDVI from model showed nearly same pattern with an in situ NDVI estimated at 0^0 in the field, figure 10 [a-b]. In the beginning of rice growth, modelled in situ NDVI seems to be approaching to get better fitness with in situ NDVI. However, in the last stage of rice growth, few contaminations induced in remote sensing data were intending to the modelled in situ NDVI to oscillate from expected output.

6. Correlation analysis of in situ NDVI and in-situ LAI

In-situ NDVI and in-situ LAI were not linear together. The sensitivity of NDVI to LAI becomes increasingly weak with increasing LAI beyond a threshold value, which was typically between 2 and 3 [11]. NDVI increases almost linearly with increasing LAI and then asymptotic region was observed in which NDVI increases very slowly with increasing LAI. Ground surface was almost completely covered by leaves in asymptotic region.

A linear correlation coefficient (R^2) was calculated between in situ NDVI estimated at 0^0 and in situ LAI. However, most of the LAI measurements were in the range of 4 to 5. A non-linear correlation analysis between in situ NDVI and in situ LAI was used in this study.

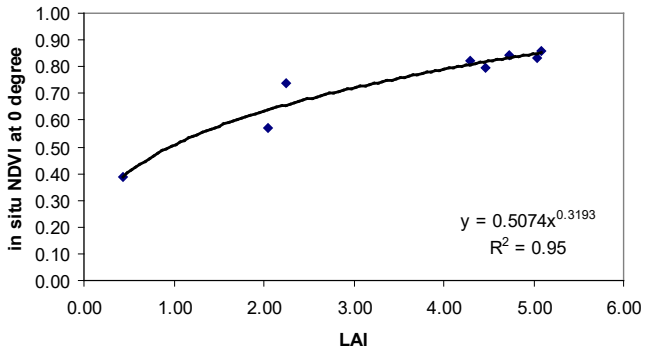


Figure 11: In situ NDVI computed at Nadir and in-situ LAI collected from filed.

Eventually the result obtained by non-liner correlation analysis between in situ NDVI estimated at 0^0 and in situ LAI is:

$$\text{In situ NDVI at } 0^0 = 0.5074\ \text{LAI}^{0.3193} \quad (4)$$

7. Final Model development

The final model involves two parts, the first one is a NDVI transformed from satellite to in situ and the second one from in situ NDVI to LAI. In the first part, similar variables (NDVI) were compared. In the second part, the spectral reflectance and an in-situ LAI were measured at the same location and at the same time in the rice field, which makes this multi stage modeling approach more realistic than single stage model. However direct relationship between MODIS NDVI and in situ LAI was not used in this study.

In situ NDVI was calculated with RMSE of 0.603 and that of for LAI was estimated at 2.120. The high RMSE could be induced because of the contamination error in the remote sensing data. The remote sensing data acquired on 22nd of March estimated higher value of NDVI which caused an error in LAI calculation.

$$\text{In situ NDVI at } 0^0 = 2.2967\ \text{NDVI}_{\text{MODIS}} - 1.0727 \quad (5)$$

$$\text{LAI} = (\text{NDVI}_{\text{in situ}} / 0.5074)^{3.1318} \quad (6)$$

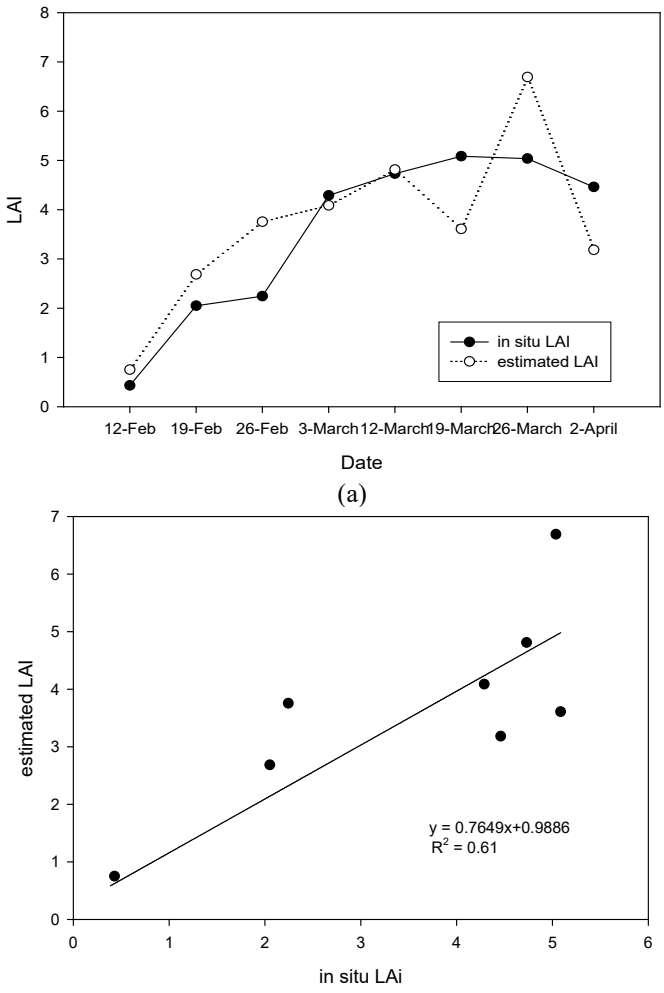

Figure 12: Validation of model LAI with in situ LAI

The LAI estimated with developed model grow similar as the in situ LAI measured. Coefficient of correlation (R^2) was found to be 0.61 which could be increased with increasing accuracy of remote sensing data.

8. Conclusions

In this study, field-based rice LAI is estimated from standard MODIS surface reflectance product. We proposed multi stage approach to derive LAI from MODIS surface reflectance. In the first stage, in situ NDVI is derived from MODIS NDVI and in the second stage, field-based LAI is derived from in situ NDVI. BRDF corrected relationship is considered in the first stage.

The angular effect in MODIS NDVI causes little higher values of modeled in situ NDVI than in situ NDVI estimated at 0^0. In the case of in situ measurements of surface reflectance small

area is sampled by fiber optics wire as compared to remote sensing data. If the number of locations in the site is increased more realistic result can be obtained. The data information of rice growth in a year definitely improves the result. The accuracy of the model could be increased with increasing in the field data collection for entire period of rice cropping cycle in a year.

The model could be used for regional scale with MODIS 250m and accuracy can be checked with MODIS 500m. The model can also be further developed for other crops like sugarcane, maize etc. The model could be improved for mixed pixel condition. The LAI could be estimated by using some other vegetation indices such as Soil Adjusted Vegetation Index (SAVI) and accuracy check can be done with the derived model in this study.

In order to enhance the applicability of LAI-NDVI relationship, more crops and more satellite remote sensing data sets should be assessed and checked. The use of multi-angular remote sensing for LAI estimation may be further tested and investigated using radiative transfer models.

Acknowledgements

We thank Ms. Kamal Thapa for her assistance and support during in-situ data measurement and also thankful to Thai research students from the RS-GIS Field of Study for helping as interpreter, Thai- English-Thai during field data measurement.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

This study is based on the challenges related to the low quality of education in Indonesia. One of the reasons for these challenges is the low ability of teachers to conduct professional tasks. Future demands for teachers' professionalization will be higher, considering the rapid development of society, science and technology, and current global competitiveness. In aspiring for improved quality education in the future, efforts are needed to optimize teachers' professional development, particularly for primary school teachers, through continuous and comprehensive education and training with broader access. Basing on this, the present paper analyzes a model and material of education and training programs which is believed to improve teachers' competence on a broader scope and ensures quality training outcomes. The research method study used was research and development. It has been used depending on the objectives to be achieved, which included developing a training model aimed at improving the mastery of cognitive abilities in the pedagogical competence of elementary school teachers. The preliminary study indicates that the implementation of the existing teacher education and training program is sufficient. However, further improvements are needed to reach a broader scope. Teachers' perceptions concerning their mastery of competencies required to perform their professional tasks indicated weaknesses regarding several aspects of the pedagogic and professional competencies. This exists because the of education and training teachers undergone which varies; yet, some teachers still have not had the opportunity to attain sufficient education and training. Identifying the needs of primary school teachers training and education program highlights the importance of developing a training and education model which optimizes modular material-based independent learning.

1. Introduction

The Indonesian Law No. 14 of 2005 [1] on Teachers and Lecturers requires teachers to have suitable academic qualifications, academic competence, teaching certificate, physical and mental health, and capability to realize the objectives of the national education system. The competencies a teacher must have, according to the law, include pedagogic competence, personal competence, social competence, and professional competence.

Possession of those four competencies is expected to facilitate a condition that allows teachers to perform excellently during work, serve their functions, and play their roles as accountable and professional educators. To ensure that teacher's services, tasks, and responsibilities as professional educators are implemented under the existing law. A Teacher's Performance Assessment System (or PK Guru) was developed and applied to every teacher in every formal education unit (schools) by the central government, regional government, or society. The result of Teacher's Performance Assessment (PK Guru) becomes the basis for determining the amount of credit obtained by the teacher for teacher's career development, as set in the Decree of the Minister of Administrative and Bureaucratic Reform No. 16 of 2009 [2] concerning Teachers' Functional Positions and Their Credit Values.

Then, the result of PK Guru is utilized to develop a profile of teacher's performance as an input for the obligatory Sustainable

Profession Development (PKB) program held for teachers in every academic year. This program intends to ensure that teachers are always able to satisfy the standard of competence and improve their competencies to anticipate future demands. This will make all teachers gain the appropriate image, respect, honor, and welfare because their competencies will promote the improvement and development of high-quality education services. The Sustainable Profession Development program is obligatory for teachers from the III/a level of position, in which they have to undergo self-development; teachers in the III/b level are required to publish academic and or innovative works. To move from IV/c level to the IV/d rank, teachers must do an academic presentation.

The Decree of the Minister of Administrative and Bureaucratic Reform No 16 of 2009 [2] mentions three elements of teacher's activities in Sustainable Profession Development (PKB) that earn them credit value, i.e., self-development, scientific or academic publication, and innovative work. Self-development is essentially an effort to improve teachers' skills and capabilities through, among others, functional training and education that may develop teachers' competencies and or profession. With such self-development, teachers will be able to perform their main and additional tasks and responsibilities. Functional training and education are some of the in-job training, implemented so that teachers can achieve the required competencies appropriate for their type and level of functional position (Government Regulation No 101 of 2000 concerning In-Job Training and Education for Civil Servants)[3]. The Minister of Education Regulation No 35 of 2010 [4] defines functional training and education as teachers' activities participating in education or training aimed to improve the teachers' profession in question over a specified period. As a consequence of this policy, all future teachers who have to develop their professional careers must have physical evidence of participating in Functional Education and Training.

The data from the Directorate of Educators (PMPTK) in the Ministry of Education shows that the Ministry is responsible for 2,607,311 educators from all levels of education in Indonesia. With this large number of teachers, it is impossible to provide Functional Training and Education for all of them in the current conventional way. An alternative, more progressive form of training, with broader access while maintaining a high level of quality, is needed so that all teachers can participate in functional training without leaving their places of work and their primary responsibilities at schools.

One of the alternatives to conduct such training and education for the development of teachers' competencies is by utilizing the concept of independent learning using modular material. Therefore, the study and development of a modular material-based independent training model are needed to promote sustainable professional teacher development functional training.

The professional career improvement of future teachers is highly dependent on the result of teachers' performance assessments (PK Guru), which require sustainable professional development (PKB) through in-job functional training. Several problems that often hinder the implementation of teachers' in-job functional training are, among others: (a) the materials provided in training are not the ones the teachers need; (b) the trainers often do not have more qualified knowledge and are not more experienced than the trainees; (c) the training is commonly held in the effective working hours when teachers are supposed to teach; (d) teachers generally view training as merely a requirement to have an efficiency report; and (e) the training organizers are usually too project-oriented, which means that they often focus only on the delivery of the training, not the quality. Another problem concerning teacher training is that the training is usually delivered in lecture form, which tends to provide a comprehensive understanding of the competencies needed by the teachers. These problems lead to the low quality of teachers' performances and, in turn, affect the result of students' learning.

Many aspects of the main competencies are understood incomprehensively by the teachers. Besides, teachers do not have enough opportunity to develop their understanding while performing their jobs. The training that teachers have participated in intend to be short and not optimal, as well as focus directly on practical skills only, leaving the other aspects untouched.

Identifying these problems warrant a scientific and empirical study to deal with the obstacles in teachers' competencies development through various alternatives embedded in the teachers' training model. In general, this study aims to answer the main problems of "what kind of model and training material is effective in developing teachers' competencies in a wider scope, with quality, and without requiring teachers to leave their primary jobs?" The questions to be studied to answer the main research problem include: (1) How are the implementation of the existing teacher training, the type of training, and the teachers' mastery of competencies? (2) What training model and material design can be developed to improve the ability of teachers' competencies? (3) How is the effectiveness of the implementation of a teacher training model using a modular material-based learning approach?

2. Literature Review

To be a teacher is to be a professional, meaning that the duties and responsibilities therein cannot be carried out effectively without appropriate training. A profession is a job or activity carried out by a person as a source of income that requires expertise and skills that meet specific quality standards or norms and require professional education and training. In-Law Number 14 of 2005 [1] on Teachers and Lecturers, it is stated that a teacher is a professional educator whose primary task is to educate, teach, guide, direct, train, and evaluate students through formal education in the levels of early childhood education, primary education, and middle education. However, according to Supriadi [5], the teacher's position is still a growing / emerging profession and has not yet reached the level of being a profession in the real sense.

Professional teachers must have various abilities. Sukmadinata [6] groups these abilities into three general dimensions: professional, social, and personal. Supriadi [5] assesses that capability is too ideal, so it is not easy to achieve and be evaluated by measurable criteria. Various training is needed to improve the ability of teachers. The real challenges facing the world of teacher training in the present and future according to Hasan (2001) are mainly related to improving the quality of teachers in terms of (1) mastery of subject matter being taught, (2) teaching ability, (3) vision and attitude towards the profession, (4)

ability to develop a profession, (5) ability to communicate with educators, experts, and the community, (6) community appreciation of the teaching profession, and (7) high competitiveness and professionalism. According to Evans and Brueckner [7], to become a qualified and professional teacher is strongly influenced by (a) professional preparation, (b) continuing education, (c) professional involvement, and (d) commitment.

Teacher training is being carried out by various parties, both government and private; it is considered as an effort to develop a systematic attitude, knowledge, skills, and behavior patterns needed by someone to have the ability to perform the task appropriately. It is also affirmed by Bramley [8] that "Training is a systematic development of the attitude, knowledge, skills and behavior pattern required by an individual to perform a given task or job adequately."

In training teachers, adult education methods (andragogy) must be applied. According to Abdulhak [9], the scope of the technique in adult learning involves: giving encouragement, revealing the growth of learning interest, delivering learning materials, creating a conducive learning climate, stimulating creativity, encouraging self-assessment, and identification and tackling weaknesses in learning outcomes. Considering that trainee teachers are adults, a methodological study of how to conduct adult training is more effective in optimizing intended outcomes.

Several approaches in training programs that apply self-instruction have received considerable attention in adult education [10]. These approaches include programmed instruction, individualized instruction, personalized system of teaching, learner-controlled instruction, correspondence study, and self-study.

The self-instruction approach in teacher training is related to the application of instructional technology concepts. According to Miarso [11], this instructional technology uses an isomorphic approach, which combines two complex concepts, technology, and instruction, in an integrated concept. Both academics and practitioners have now developed the science of learning technology in developed countries, especially the United States. The emergence of a book called "Instructional Technology: The Definition and Domains of the Field" is one proof of the development of scientific learning technology. Instructional technology "is defined as" the theory and practice of design, development, utilization, management, and evaluation of processes and resources for learning [12]." The application of learning technology in teacher training, according to Mukminan [13], comprises four primary characteristics: applying a systems approach, using learning resources as broadly as possible, and improving the quality of human learning, and orientation towards individual learning activities.

Programmed learning is a form of curriculum implementation in view of technological education. Lapp [14] notes that there are several advantages of this programmed learning: (a) providing positive immediate feedback and reinforcement for students (immediate positive feedback and support for the student), (b) releasing the teacher from "drill" type teaching, and (c) individual student progressions. The type of programmed learning developed by Crowder is better than that established by Skinner; however, it would be even more perfect if modified with other methods, in this case, with the tutorial learning method. Kemp and Dayton [15] put it that the "tutorial method attempts to emulate a human tutor. Instructions are provided via text or graphics on a screen. At appropriate points, a question or problem is posed. If the student's response is correct, the computer moves on to the next block of instructions. If the response is incorrect, the computer may recycle to the previous instruction or move to one of several sets of remedial instructions depending upon the nature of the error."

3. Methodology

The research method in this study uses research and development methods. It is following the objectives to be achieved that include developing a training model aimed at improving the mastery of cognitive abilities in the pedagogical competence of elementary school teachers. Research and Development (R&D) is essentially a process used to develop and validate learning products or prototypes of research-based learning tools [16]. The outcome in this research is a training development model that uses an independent learning approach to improve cognitive abilities in elementary school teachers. Research and development activities in this study are operationally carried out through three stages: the preliminary investigation, the development of a training model, and the validation test of the model. The detailed research and development procedures are described in Figure 1.

The study subjects were managers of the institutions/agencies that were given the task of organizing training of elementary school teachers in West Java Province and several elementary school teachers in cities across West Java province. Data collection techniques and instruments for gathering information on research points are adjusted to the three stages of the research activities. At the field study stage, the questionnaire was used as the data collection technique; in the limited trial stage, questionnaires and interview guidelines were used for the broader trial phase in addition to using questionnaires, and interview guidelines were used as comprehension test instruments. Finally, at the model validation test, the comprehension test instrument was used.

Data analysis techniques used were adapted to the stages of research and development carried out, the pre-survey, testing the application of the model, and testing the validation of the training model.

4. Results/Findings

4.1. Preliminary Study Results

The pre-survey results from the preliminary study were taken into consideration in developing the draft model of elementary school teacher training to address the problem in the focus of this study. The field pre-survey was conducted through interviews with the leadership of teacher training institutions. Information gathering was by questionnaire to elementary school teachers in the study sample in several districts/cities in West Java. Table 1 below sums up the results of the survey i56t7n teacher training institutions concerning the organization of teacher training.

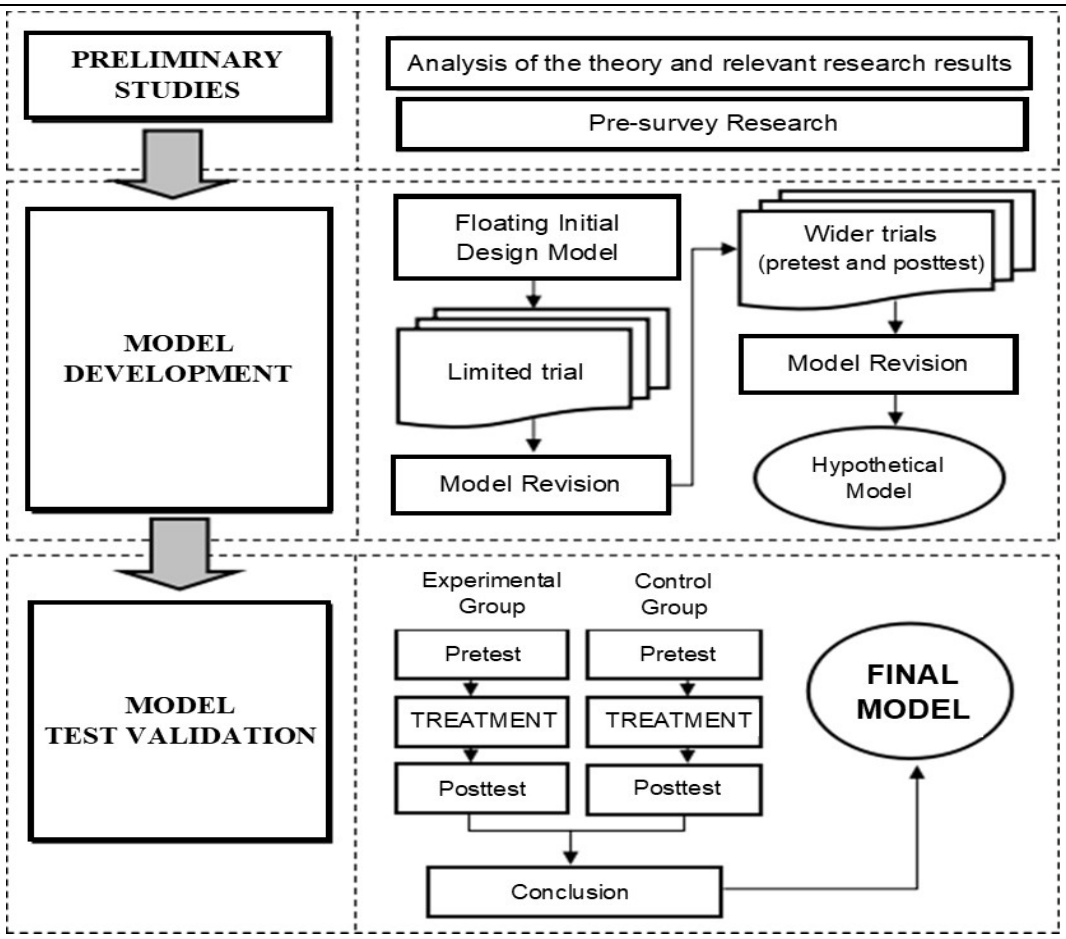

Figure 1: Research and Development Procedure

The following description is a synthesis of data obtained from the results of a survey of teachers as the basis for developing a modular model of teaching materials in elementary school teacher training. The study results on mastery of subject matter and pedagogical competencies can be seen in tables 2 and 3.

In table 2, almost all teachers stated that they had mastered teaching materials in the five primary subjects that were their responsibility. Only a small percentage of teachers still said they did not learn the teaching materials. There are no teachers who claim to be very ignorant of teaching material. However, there are only a few teachers who claim to be proficient in teaching material. With this description, according to perception, teachers, in general, have mastered the material in five elementary subjects.

If observed in table 3, it turns out that in general, teachers say that they have mastered the pedagogical competencies needed in elementary schools. A small proportion of teachers said that they had learned them. There are some interesting notes from the data above, where for the mastery of teachers relating to how to communicate with students, it seems that as many as 70% of teachers have reached the level of proficiency to master it.

However, in three cases it was revealed that there were still teachers who did not learn the necessary educational / teacher knowledge, namely relating to (1) how to develop curriculum, (2) how to utilize information and communication technology, and (3) how to carry out thematic learning.

In table 2, almost all teachers stated that they had mastered teaching materials in the five primary subjects that were their responsibility. Only a small percentage of teachers still said they did not learn the teaching materials. There are no teachers who claim to be very ignorant of teaching material. However, there are only a few teachers who claim to be proficient in teaching material. With this description, according to perception, teachers, in general, have mastered the material in five elementary subjects.

Table 1: Results of a survey on the implementation of elementary school teacher training

Teacher training aspects	Conclusion of survey results
1. Teacher training needs assessment	The needs assessment results are rarely utilized in determining and sending prospective trainees following the training institution's requirements.
2. Teacher training programs and materials	Teacher training programs and materials are developed at the level of the training institution based on field needs analysis results. The focus of the

	training program is on the development of subjects taught in primary schools.
3. Learning methods in teacher training	The training method applies the adult learning approach (andragogy) by optimizing the use of lecture and question and answer methods, simulation methods, problem-solving, practical activities, and field visits or practice.
4. Teacher training instructor qualifications and competencies	Teacher training instructor qualifications are determined based on competency or mastery of subjects, experience, and educational background following the items. The appointment of instructors is determined by the directorate and or the teacher training institution.
5. Recruitment of teacher training participants	Teacher training participants' recruitment is determined based on (a) direct appointment from the ordering party (directorate) and (b) based on training need assessment, although sometimes the local government with its authority determines itself without clear criteria.
6. Assessment of the impact of teacher training	Impact assessments are carried out by monitoring the progress of the participants, both in the form of visits, correspondence, questionnaires, and direct observation of schools.
7. Teacher training quality assurance program	Teacher training institutions do not explicitly develop quality assurance programs. It is usually done based on a review of various activities that are programmed.

Note: STM (still not mastered), TM (not mastered), CM (quite mastered), M (mastered), SM (highly mastered).

If observed in table 3, it turns out that in general, teachers say that they have mastered the pedagogical competencies needed in elementary schools. A small proportion of teachers said that they had learned them. There are some interesting notes from the data above, where for the mastery of teachers relating to how to communicate with students, it seems that as many as 70% of teachers have reached the level of proficiency to master it. However, in three cases it was revealed that there were still teachers who did not learn the necessary educational / teacher knowledge, namely relating to (1) how to develop curriculum, (2) how to utilize information and communication technology, and (3) how to carry out thematic learning.

Based on the results of capturing information from teachers, information/data obtained about the frequency of training activities that have been attended by elementary school teachers are closely related to the main task area as a teacher. There is a tendency in the past five years. The frequency of teachers attending training is generally only 1-3 times, and only a small proportion of teachers participated in more than four training activities. There are still many teachers who have not attended training in the past five years (17.52% of 304 respondents). Based on the data obtained about the teacher's assessment of the training activities that he had participated in, there were still many teachers who stated that the training was unclear, for example relating to training on process evaluation techniques and the results of instruction used.

As for the expectations of teachers in the implementation of teacher training in the future, including:

- The existence of training material packages that have the characteristics of 1) using language adapted to the features of the participants, 2) optimizing the use of supporting media, 3) equipped with pictures and illustrations that are appropriate and interesting, 4) containing statements that are packaged in the form of disclosure of teacher problems, 5) the facts that are raised are actual, and 6) some questions are directed to solve the problem.
- Training places, in the opinion of some teachers, should not need an exceptional location, so teachers do not need to come to the training venue and do not need to leave their primary tasks. The method of training is to use material packages that can be done alone. Thus, in such training activities, there just a few instructors/trainers, but with expertise in their fields.
- According to some teachers, training time could be at any time as long as the form of training uses material packages and individualized instruction approaches.

5. Model Generated

Based on the pre-survey results, it was found that there were some loopholes the learning system implemented in elementary school teacher training activities at the time. Thus, a teacher training model that is more individualized and requires training participants to learn actively with the following characteristics is essential : (1) flexible in the sense of not needing a particular place, (2) opportunity and time are not so binding on the teacher, (3) learning adapted to the ability of learner and teacher, (4) broad-reaching and able to overcome geographical obstacles, (5) relatively cheaper training costs (on a large scale), (6) teachers do not need to come to the training site and do not need to leave their main task at school, (7) able to overcome the limitations or availability of qualified instructors, (8) standardization of teacher quality; and (9) affect the independence, responsibility, discipline, tenacity, initiative, and creativity of teachers in carrying out their duties. The teacher training model's characteristics can be accommodated in training models that use programmable modular training materials.

The model design that resulted from this study was in the form of independent programmatic learning developed in elementary school teacher training, including planning design, implementation design, and assessment design, as illustrated in Figure 2.

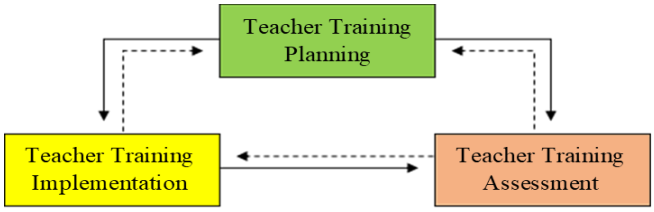

Figure 2: Teacher Training Development Model Design

5.1. Training Planning Design

The planning activity functions as a blueprint, providing an overview of what to do in teacher training activities. This model is an application of the concept of instructional technology in which the learning planning stage applies an approach that emphasizes systemic connectedness between various learning components. In this case, a systemic relationship means that all components in planning are integrated following their functions, related to one another, and form a unity. The training planning component consists of the objectives or competencies to be achieved, learning material, learning activities, and learning assessment. The training planning stage is illustrated in Figure 3.

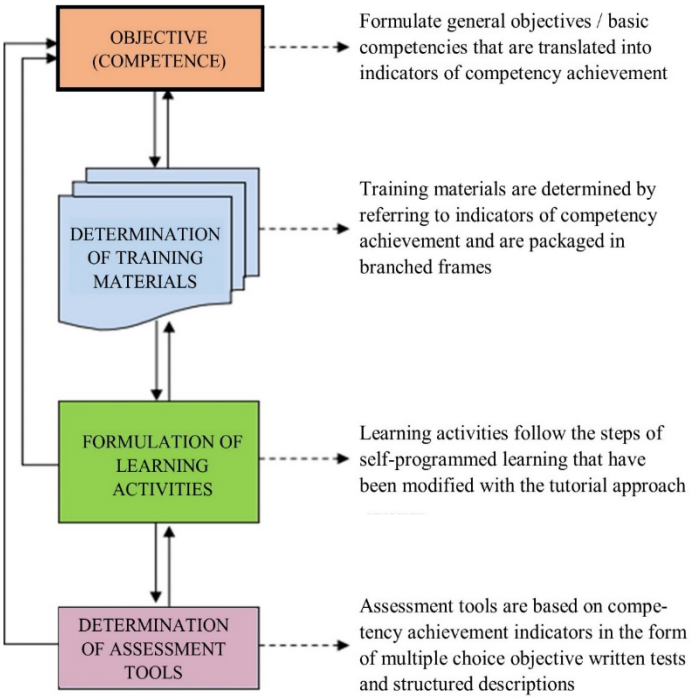

Figure 3: Teacher Training Planning Design

5.2. Training Implementation Design

The design of the implementation of learning developed in teacher training uses a self-instructional approach in which individual trainees carry out learning activities following prescribed instructions and procedures. The trainees actively interact with the training materials that have been packaged in such a way by reading instructions and presenting information, responding to questions, and seeing feedback on the alternative answers they choose. With this feedback, trainees without delay can determine whether the response given is correct or not, so mistakes can be corrected immediately. At the end of the activity, the trainees work on the tests prepared about the training objectives.

The amount of time spent by each participant in carrying out the training process may vary considerably. In this case, the trainees complete the learning at their own pace. Some participants can quickly complete, while slow participants can still finish even though not too fast. Adjustments are made in line with the principles of mastery learning.

The design of the programmed self-learning implementation developed as a modification of the model developed by Norman A. Crowder in 1962 called the Crowder's Intrinsic Program in the branching frame format. The characteristics of this type include: (a) broader and more information, (b) questions that are accompanied by several possible answers that can be chosen, and (c) checks that are accompanied by an explanation that explains why the answer/response true or false. Modifications to the learning model intended in this study emphasize improving the components or steps of the learning. The learning step applies the tutorial learning procedure developed by Allesi and Trollip [17] with the following eight stages: 1) Introduction, 2) Presentation of information, 3) Question of responses, 4) Judging responses, 5) Providing feedback about reactions, 6) Remediation, 7) Sequencing lesson segments, and 8) Closing. The procedure of implementing the self-learning program that must be taken by the trainees in this study follows the learning steps, as illustrated in Figure 4.

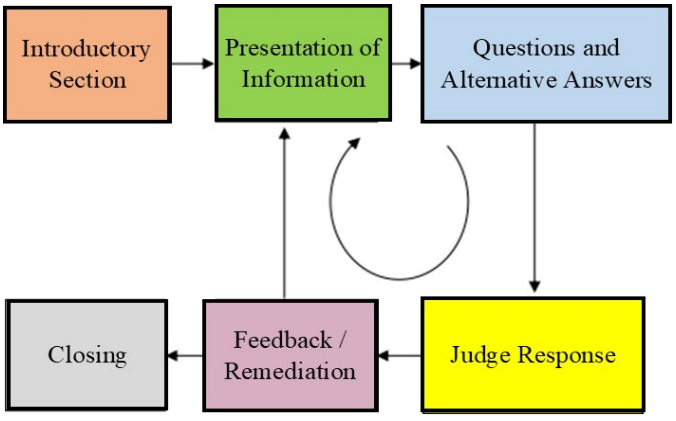

Figure 4: Design of Teacher Training Implementation

5.3. Teacher Training Assessment Design

Headings, or heads, are organizational devices that guide the reader through your paper. There are two types: component heads and text heads.

The assessment design used is guided by the learning planning developed in which the trainees must achieve some objectives/competencies. The characteristics of this model emphasize the ability and speed of learning of each trainee. Therefore, the assessment design used is more individualized and directed primarily to measure the cognitive abilities of trainees. The assessment takes the pretest and post-test procedures. The pretest determines the extent of training participants' abilities before studying the training material, while the final test determines the participants' abilities after investigating the training material. If the pretest demonstrates the trainees' mastery of the content presented, then there are several possibilities. For trainees who have mastered the entire learning material, there is no need to study the material. For trainees who have mastered some or part of the learning material, these participants do not need to learn it from the beginning. In this case, because the abilities of each participant differ, it is necessary to determine carefully, which participants must start from the beginning, which participants can begin in the middle, and so on.

The pretest (TA) and the pot-test (TF) in this model can be carried out with two variations. The first variation is when the two types of tests are carried out in each piece of training material (SM). In the second variation, the pretest is done before the trainee learns the presentation of the learning material. The post-test is done after the trainee completes the entire performance of the learning material. The type and form of assessment used are appropriate in measuring competence in cognitive aspects. Thus, the type of evaluation used is with an objective test and or structured description. The design of teacher training assessments can be seen in Figure 5.

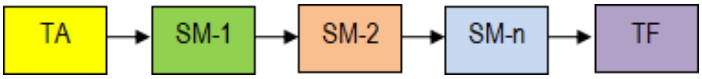

Figure 5: Teacher Training Assessment Design

5.4. The Effectiveness of the Teacher training Model

This teacher training model's effectiveness has been proven by a significant effect on improving cognitive abilities in pedagogical competence compared to conventional training models that are generally used today. To find out the description of the validity of the pretest and post-test treatment between the control group (trainees treated through the presentation with conventional procedures) and the experimental group (the trainees are given a treatment of serving with programmed modular teaching materials), the null hypothesis (Ho) proposed "there is no significant difference in ability between the control group post-test outcome variable and the experimental group post-test outcome variable." In contrast, the alternative hypothesis (Hi) proposed is that "there is a significant ability difference between the control group post-test result variable and the post-test result variable of the experimental group. "Acceptance of the null hypothesis (Ho) is done if the results of the calculation of significance are greater than 0.05 (> 0.05), and Acceptance of alternative hypotheses (Hi) is done if the results of the calculation of significance are less than 0.05 (<0.05). The calculation of the significance of the results of this post-test can be seen in table 3.

Table 3: Results of post-test calculation of control and experimental validation tests

	N	Mean	Std. Deviation	Std. Error	95% Confidence Interval for Mean		Min.	Max.
					Lower Bound	Upper Bound		
POSTTEST CONTROL	36	7.2769	0.65877	0.10979	7.0540	7.4998	6.27	8.50
POSTTEST EXPRIMENT	36	8.1944	0.66845	0.11141	7.9683	8.4206	7.00	9.00
Total	72	7.7357	0.80474	0.09484	7.5466	7.9248	6.27	9.00

	Sum of Squares	df	Mean Square	F	Sig.
Between Groups	15.153	1	15.153	34.406	0.000
Within Groups	30.828	70	0.440		
Total	45.981	71			

The significance calculation results are equal to 0.000, and F test results are 34.406. With the results of these calculations, the null hypothesis (Ho) is rejected. The alternative hypothesis (Hi) is accepted, meaning there is a significant difference between the control group's post-test outcome and the experimental group's post-test outcome variable. In this case, it can be concluded that the trainees who were given the treatment using the training development model using a modular programmatic model have higher abilities compared to the ability of trainees treated with ordinary procedures (conventional models).

The test results obtained instructions that the developed training material package can meet the requirements as an independent learning material that allows self-instruction. In reality, the use of training development models that are self-instruction is still a new thing that is considered relatively difficult to implement. Thus, an adaptation process needs sufficient time to provide awareness to the teacher training providers that training, which is more focused on acquiring cognitive abilities, does not always have to be done through face-to-face meetings with training instructors with a tight schedule and venue for training.

6. Discussion

Several assumptions underlying the choice of the teacher training model in this study include the following:

As a whole individual, the teacher inherently possesses self-learning capability by optimally utilizing his/her potentials. With sufficient time and opportunity, every teacher has the same chance to understand and master the knowledge and skills needed to perform his professional tasks.

Teachers are adults; therefore, the training model or approach should be relevant and based on adult learning theories and principles (andragogy learning). The implementation of an independent training model is essentially an implementation of adult learning theories and principles.

The self-instructional approach utilized in professional training is a better approach to develop human resources. It allows the trainees to self-instruct according to their own time and capabilities.

Learning with modular materials is a learning method or technology based on a system approach. It is primarily characterized by the progressive development of ideas to achieve the desired behavior. This approach's other characteristics include continuous evaluation, verification, and revision, varied and flexible delivery of easy-to-learn materials, and logistically easy to administer. Modular elements are equipped with various tasks and learning models, as well as continuous feedback. Slow learners will not lose their opportunity or be left behind, even if the materials get more complex and sophisticated.

6.1. Contribution of the Study to Teacher Training

In general, this study aims to analyze and develop a model for training primary school teachers using modular material-based learning. With new policies concerning the assessment of teachers' performance (PK Guru) and the sustainable profession development (PKB) and considering the vast number of teachers in Indonesia; makes it is impossible to satisfy teachers' needs for functional training using the existing conventional method. The development of a new model of teacher training is justified.

This study's significance and urgency on primary school teachers training using modular material-based learning are as follows:

The training model is based on the individual teacher's potential and skills. Thus, it will theoretically provide benefits for the development of future primary school teachers' training models.

This study's findings are expected to provide new principles for primary school teachers' training, based on the application of instructional technology concepts. These principles are expected to strengthen the benefit of self-instructional concepts in teacher training, which will help develop primary school teachers' competencies through maximizing independent learning without face-to-face learning.

This study's findings can be used to develop a model for initial teacher training in the future, mainly to develop the training system and materials. What is more, this training model will help improve teachers' mastery of their competencies because its learning is adjusted to individual learning characteristics and pace. They can learn the materials in training based on their capabilities, opportunities, and time.

For teachers living and working in remote areas, this model will free them from the geographical limitations to participate in competencies development training. Those teachers do not need to come to the training venue and do not have to leave their jobs at the schools.

For the primary school teachers training administrators, both at the regional and national level, this training model will go a long way in addressing various issues hindering the efforts of improving teachers' competencies and qualifications.

The dissemination and dissemination of new information or knowledge to develop teachers' competencies and improve teachers' professionalism and quality can be conducted on a broader scope. This model can reach more teachers, which will accelerate the development and equalization of primary school teachers' quality.

6.2. Output

The challenges and obstacles in future education, particularly at the primary school level, are expected to be more complicated than today. Therefore, it is essential to prepare teachers who are competent and able to understand their professional function and responsibilities to realize a high-quality education process. The targets to be achieved in this study are:

The profile of current primary school teachers training implementation, the types of training the primary school teachers, have participated in, and the level of teachers' competencies mastery.

The training model to improve primary school teachers' competency mastery consisted of the model of learning design, the model of learning implementation, and the learning assessment model.

Modular materials developed and used in the training model the dual-mode system.

Data and information concerning the effectiveness of the implementation of primary school teachers training model using the modular material-based approach, both in the aspects of comprehension and application.

The administration or implementation of primary school teachers' training focuses on the following aspects: Need assessment to compile data concerning various elements needed in teachers' training, supported by the result of teachers' competencies mapping as a measure of primary school teachers' competencies after the training.

The training program and materials are based on various aspects. The development of school subjects needs to focus on integrating those subjects with other essential skills. The learning method developed in primary school teachers' training should be supported by a more robust approach, focusing on adult learning principles.

Primary school teachers training in an uncoordinated training institution needs more proper management, including the recruitment and assignment of qualified instructors. The qualification of training instructors varies based on their competence/mastery of materials, experience, and educational background.

Training activities that can facilitate the improvement of competencies for numerous teachers require a significant amount of money. Teachers training with an independent learning approach can be a solution to widen access for teachers to participate in competency development training while reducing the costs.

Cognitive competencies of primary school teachers, including the mastery of the five primary subjects and educational/teaching discourses, are not comprehensively mastered by primary school teachers. This situation indicates the importance of a training system that develops teachers' motivation to learn those competencies according to their potentials. Decentralized training hinders teachers' mastery of competencies because they limit teachers' frequency and opportunity to participate and their time to master the competencies they need.

7. Conclusion

The implementation of primary school teachers' training has generally reflected the ideal condition of the efforts to improve teachers' competency. Further development to equalize the training opportunity for teachers is still needed. The obstacles to equalize the training and development opportunity include the discrepancy between the available training facilities and frequency of training with the number of primary school teachers whose competencies need to be improved.

The development of teacher training models should represent the interrelated nature of design, implementation, and assessment aspects as a whole system to improve teachers' cognitive, pedagogic, and professional competencies mastery. This training design utilizes a systemic approach that focuses on the interrelationship among the competencies to master, the training materials, the learning activities, and the learning evaluation. The designed training requires the trainees to perform the events based on defined procedures individually. The training design is more individual-oriented and aims at measuring teachers' cognitive skills in the pedagogic and professional competencies.

Wireless Communications

ABSTRACT

Advances in channel modeling allow wireless communication designers to accurately model and understand the channel's phenomena within different propagation scenarios. A precise channel model results in the wireless system's optimized performance while considering trade-offs due to the effects of the channel. The geometric-based stochastic channel model considers different interacting objects affecting the parameters using the indicated parameters measured, such as the delay, power profile, and angles of departure and arrival in MIMO wireless systems to multiple paths taken by the propagating signal. These different paths are known as multipath components (MPCs). Studies and measurements suggest that MPC appears in groups based on similarity or dissimilarity measures of the MPCs known as multipath clusters. The clustering of these MPCs can be done automatically and manually. The automatic approach clusters the measured or simulated data using an algorithm; on the other hand, the manual approach uses a visual representation and an expert evaluation to cluster the data. This paper aims to implement visual mapping of the multipath cluster dataset approach into parallel coordinates plot, t-SNE, principal component analysis, heatmaps, and dendrograms to find an optimal visualization of data to enhance the validation and interpretation of MPC further. The dataset is simulated and presented in a MATLAB environment.

1 Introduction

Wireless communication technology grows exponentially in connected devices and the data required in the modern information era [1]. The wireless communication system can be simplified to three main components, the transmitter, the channel, and the receiver. Both the transmitter and the receiver can be optimized based on the required use case. However, the channel is the challenging component since it varies in the environment and channel bands in which the channel cannot be engineered and manipulated easily [2]. System designers address the channel impairments through statistical modeling by acquiring parameters and effects to form the channel impulse response (CIR). Channel modeling is a broad research area that can be seen through literature, and these channel models account for different wireless propagation scenarios.

The development of the fifth-generation (5G) mobile communication standards takes into accounts the use cases with three major requirements [3, 4]. These standards require the wireless community to develop new enabling techniques and technologies to satisfy the stringent standards to provide the Quality of Service that the 5G demands. One key enabling technology is based on massive multiple-input multiple-output (MIMO) systems. Such a system has n number of antennas that are utilized at the transmitter and/or the receiver to provide trade-offs based on the use case as reliability, sensitivity, and high throughput. MIMO systems send out a multiplicity of signals going to the receiver. As these signals travel, different paths are taken by the signals known as multipaths that can create constructive or destructive combinations at the receiver. Multipath components (MPC) exhibit different parameters due to the channel state, where multiple objects that obstruct the signals can be reflected or dispersed [5]. The geometric based stochastic channel models account for these objects collectively known as scatterers. The MPC measured in different studies proves that MPC tends to cluster based on their similarity of parameters; furthermore, the clustering of these MPCs provides simple calculation while maintaining the channel model's accuracy, which can adequately measure the channel capacity and behavior.

Clustering has benefited different disciplines in analyzing mea-

[*]Corresponding Author: Aaron Don M. Africa, De La Salle University, 2401 Taft Ave., Malate, Manila, 1004, Philippines, +63(2)85244611 & aaron.africa@dlsu.edu.ph

sured data. It can also predict the future values or categories used in machine learning to analyze the data with multiple features or dimensions to be measured. Clustering measurement data also benefit the wireless channel modeling field [6]. Validating the clusters poses a challenge due to the limitation of the human eye's visual perception, especially for large datasets that crowds the common visual representation such as the 2 and 3 dimensional (2D, 3D) scatterplots. Therefore, techniques have been developed to mitigate these limitations by using dimensionality reduction techniques to embed the D- dimensional data sets to a 2D and 3D where it can be visually interpreted and analyzed.

The traditional identification of clusters was made manually through the visual analysis of the data, which provides a physical realism of the environment. However, the manual approach can be laborious due to large data sets to be clustered. This approach has changed through the development of cluster algorithms. The automated method of clustering is done through the power of computational algorithms. The measured data are fed to an algorithm and computes the clusters within the measured data, and the validity is tested using different Clustering Validity Index (CVI). However, the channel's physical realism does not account for automated clustering and relies on numerical computations [7]. Furthermore, different algorithms tend to focus on specific parameters that lead to unaccounted features of the MPC.

This study aims to project the MPC data using visual techniques to validate the cluster using visual representation, thus harvesting both the advantages of the manual and the automated approaches of clustering. The graphical representation aids the validation and interpretation of data by drawing insights and increase cognition of the wireless propagation clustered data. Proper evaluation of clusters of MPC leads to an accurate representation of the channel, thus enhancing the design and implementation of the wireless network within a given environment and specific propagation scenario.

This paper aims to map the wireless multipath cluster dataset to the state-of-the-art visualization techniques and impressively represent and analyze MPC clusters. The remaining parts of this paper are organized as follows: Section 2 presents related works for improving MPC clustering and studies in other disciplines that employ data visualization. Section 3 discusses the propagation channel reference, clustering, and data visualization principles with the methodology used in this study. Section 4 provides a comprehensive discussion of the data visualization techniques used in this work. Section 5 summarizes and analyses the results with future considerations, followed by Section 6, which concludes this work.

2 Literature Review

2.1 Multipath Clustering

Multipath clustering has been unfavorable in the past [2]; due to the algorithmic development of clustering, novel algorithms are used to determine the clusters in various propagation scenarios. This section provides a review of the literature that scopes manual and automated clustering approaches.

One of the earliest and popular indoor channel models is the Saleh-Valenzuela model [8]. It describes the time of arrival of the MPC in a 1.5 GHz indoor channel where a cluster of the measured rays is due to objects surrounding the transmitter and receiver. This model is for the Single input single output system (SISO). The author in [9], used a manual clustering approach in an indoor scenario in the MIMO 5 GHz band and identified 4 to 5 clusters in an area. In [10], the authors presented a framework for automating the clustering process that outperforms traditional visual identification clusters. The study was placed in an indoor environment and utilized the k-Means algorithm. The study also proposed the use of Multipath Component Distance (MCD), enhancing the clustering algorithm's performance. Simulation performed by Arias [11] used a cluster-based channel focusing on the angle of arrival (AoA) and the power delay profile (PDP) where the probability density function of the clusters was used to derive these parameters. The work presented in [7], the author used a middle-ground approach utilizing automatic and manual clustering to validate each of the results. The representation of data produced by automatic clustering poses crowding and overlapping data points in the scatterplot. This study was able to identify interacting objects along the wireless channel, thus real objects associated with the clusters in the channel. A proposed a framework in [12] focused on de-noising MPC data using a snapshot fusion method to address false MPC clustering. Simulation and measurement were also done, and concluded that the Fuzzy C-means algorithm was outperforming the K-means algorithm. A power-weighted Gaussian mixture model was used to cluster the measurements in a 28 GHz indoor channel reported in [13]. The clustering's focus is the elevation of arrival, delay, and the MPC's relative power. Moreover, the accuracy of K-Power Means was evaluated using the Jaccard Index [14]. The datasets used are from the COST2100 channel model, where the comparison has been visualized using angles of azimuth and elevation in contrast with the delay. One challenge of clustering is also to find the number of optimal clusters. Moreover, a graphical user interface (GUI) was developed in [15] to determine cluster counts by a factor weighing approach, and it was reported that the delay and angular data were effective weight factors in the indoor and semi-urban scenarios, respectively. The non-stationary and spherical waveform was considered parameters in [16]. They proposed considering these parameters for a broad array of antennas to improve the channel model's accuracy.

2.2 Data Visualization

In [17], the author provides a survey for visualization advances in the past decade. They also categorized the pipeline and workflow in visualizing data from data transformation, visual mapping, and the view transformation. This survey also shows that different interactions can be done by the user when visualizing data.

A GUI is presented in [18] named VISTA that provides a framework to validate the multivariate or multi-dimensionality of clusters interactively. Furthermore, in [19] the authors presented a cluster visualization web tool implemented using R. The web tool utilizes the heatmap and the Principal Component Analysis (PCA) visual tools. The ToxPi presented in [20] was developed using JAVA to explore and visualize data. The interface shows the user's good interactivity with the data resulting in a more efficient analysis and interpretation. Clustering methods with 30 CVI variables were implemented in R software presented in [21]. Another application of

visualization is finding the traffic patterns used to analyze data and improve the data-driven transport systems [22].

To summarize, studies on MPC clustering relies on the algorithms and corresponding CVI. The studies visualize datasets using scatterplots, providing the MPC parameter that is focused on the clustering procedure. Different propagation scenarios, measurement campaigns are also present in the literature, and to this point, no clustering algorithm performs best for all scenarios. Spatial parameters were also considered in [16] and resulted in increasing the measurement parameters that limit the visual representation of the 3D plot. Data visualization is also abundant in different fields, especially bioinformatics but rarely used in channel modeling. By addressing these issues as they relate to cluster identification, the authors' goal is to investigate optimal visualization techniques to draw the advantage of manual clustering as a post-process for automatic clustering.

3 Theoretical Consideration

3.1 Channel Modeling

Channel modeling is a crucial task in designing the wireless communication system. Channel models specify parameters that reduce the randomness in the channel. The parameters indicate essential features that affect the performance of wireless networks. In a MIMO system, the double-directional channel model reveals the propagation's fundamental parameters [23]. The double directional channel model parameters consist of the delay τ that corresponds to the length of the MPC going to the receiver, the azimuth of departure φ_{AOD}, the azimuth of arrivalφ_{AOA}, the elevation of departure θ_{AOD} , and the elevation of arrival θ_{AOA} , and power. These parameters can be seen graphically in Figure 1. The MPC appears in clusters based on the similarity and dissimilarity of the above parameters. This combination produces a six-dimensional vector of an MPC: $\boldsymbol{x}_\ell = [\tau_\ell \quad \theta_{\ell,\text{AOA}} \quad \varphi_{\ell,\text{AOA}} \quad \theta_{\ell,\text{AOD}} \quad \varphi_{\ell,\text{AOD}}]$. Where $\boldsymbol{x}_\ell$ represents the ℓ-th MPC. Each MPC observed or measured is stored in a matrix $\boldsymbol{X}$ which forms the set of one snapshot of the MPC. Given these parameters, the visual analysis of MPC is limited due to its multidimensional features. To improve the validation of the clusters in the channel model, the visualization addressing all the features is necessary.

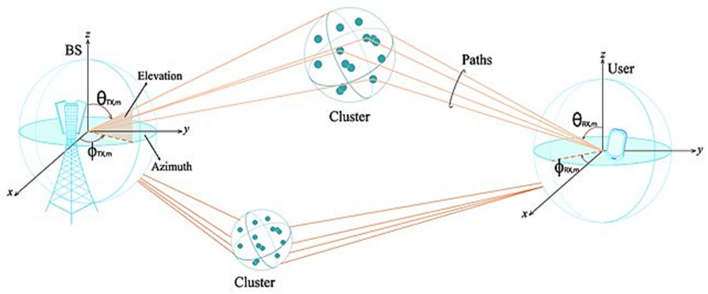

Figure 1: Parameters in the multipath wireless channel [24]

3.2 Clustering

Clustering is a process of separating and grouping the MPC into their respective similar or dissimilar parameters. Clustering allows the discovery of patterns in a given dataset. In terms of machine learning, clustering can be seen as an unsupervised learning problem [25]. When datasets are unlabeled, clustering algorithms label the data in their respective affinity based on the feature of the data specified by the algorithm. The clustering of MPC can simplify acquiring the CIR and obtain the effects of scatterer in the environment. The clustering of MPC was traditionally done using the manual visual inspection approach. Due to the manual approach's laborious and subjective drawbacks, [10] proposed an automatic framework for MPC clustering, which increases the impact on the research of clustering MPC. This work resulted in a plethora of literature that accommodates novel algorithms for specific propagation scenarios. The clustering method can be summarized into four steps: feature extraction, clustering algorithm, validation, and interpretation [26]. This work focuses on aiding the post-processing of the data, validation, and interpretation using data visualization techniques.

3.3 Data Visualization

Data visualization is a crucial method to interpret the MPC measurements. Visualization techniques unfold underlying patterns of clusters through visual analysis. Although, plots that can be drawn and perceive by the human eye for interpretation are limited to 3-Dimensional scatter plots. With the addition of colors, the designation or cluster membership of MPC can be identified. The rise of big data produced techniques to further improve the visualization of datasets to reveal patterns and clusters within the data. The methods developed reduced the features and embedded the dimension to a two-dimensional matrix, which can be visualized using a scatter plot. Dimensionality reduction techniques use a transformation to extract the essential details while preserving the features and the data [27]. The reduction techniques can be linear and non-linear. Data visualization has benefitted disciplines like bioinformatics regarding large data sets of gene expressions. Keim [28] states that to infer knowledge in a dataset effectively, it must include the human domain knowledge and interaction in the data exploration.

4 Design Consideration

This section presents a brief discussion of the main concepts of visualization techniques used in the MPC datasets in this work.

4.1 Parallel Coordinate Plot (PCP)

PCP is one axis based method for representing multidimensional datasets. The parallel plot maps all the data dimensions to parallel horizontal axes that displays the values of each data point to its respective feature. It can represent all the data dimensions and can be color-coded to show the cluster identification. The parallel plot's drawback is that large data sets crowd the graph resulting in visual clutter [29]. Another drawback is the overshadowing of values if one parameter has large magnitudes compared to others.

This disadvantage can be addressed by using data normalization before plotting. In this paper, the dataset used was normalized before visualization and mapping. The coordinate axes order can be re-arranged to uncover specific patterns and relationships among the features to interact with the data fully.

4.2 Dendrogram and Heatmaps

The dendrogram is a visualization technique that uses a tree-like structure representing clusters by nodes that interconnect similar multipaths. It uses distance metrics for computing, which among the measurements are closed to one another and projects a line graph to a node included in a more massive cluster. Heatmaps represent a colored data matrix representing the magnitude of parameters [30]. The clustergram function in MATLAB is used in this work. Hierarchical clustering is used to form the visual representation; hence, data interpretation must focus first on the dendrogram linkage of elements. This technique reorders the row elements based on the tree-like structure of the values.

4.3 Principal Component Analysis

Principal Component Analysis (PCA) is a reasonably old dimensionality reduction technique that captures multi-dimensional data variance [31]. The goal of the PCA is to construct principal components by computing the covariance matrix using the eigenvector and eigenvalues of the data. Upon applying PCAon a D-dimensional data, its principal components, each with a percentage on how it largely affects the variance. PCA projects a line in each dimension that captures the maximum variance of the data. Selecting a principal component with the highest variance score leads to an analysis of the multi-dimensional dataset. PCA projects the best fitting line is the highest scored principal component's dimension and minimizes squared distances of the points to the line in the respective dimension. The algorithm does the same for all the orthogonal dimension to the previous dimensions and readjusts the axes with respect to the projected line. Using PCA captures the global structure of the data linearly.

4.4 t-Distributed Stochastic Neighbor Embedding

t-SNE is a popular and relatively new dimension reduction technique developed in 2008 by van der Maaten [32]. It is a non-linear projection algorithm that computes the local structure data points indicated by a distance metric and is mapped to low dimensional space. t-SNE utilizes an optimized cost function to remove the crowding problem of data points and applies Student-t distribution instead of Gaussian. t-SNE requires a perplexity parameter that is a value of neighboring points the user wishes to preserve during transformation. In this work, the features of the MPC are the input variables for each of the multipaths. The t-SNE outputs matrices containing the joint probability of the L multipaths with the computed scores embedded to plot the data based on the stochastic neighbors. The plot of the t-SNE is a grouped scatter plot based on the perplexity given and groups the points with the nearest correlation. t-SNE preserves the local structure of the dataset and a powerful dimensionality reduction technique in a non-linear fashion. In MATLAB, the t-SNE function allows the user to define the distance metric to calculate the pairwise distance. In this work, the Euclidean distance metric is employed.

5 Results and Analyses

The data set used in this study is extracted from the IEEE data port presented in [33]. Datasets were first extracted from the COST2100 Channel Model [34]. The dataset was transformed from the spherical coordinates to rectangular coordinates using the directional cosine method resulting in a 7-dimension feature of each MPC. Whitening the data also converts the data into specific values to accommodate necessary adjustments. This transformation assumes that the cluster ID of the channel reference is considered the ground truth of each MPC. Two specific propagation scenarios were selected from the eight propagation scenarios in the dataset—the Indoor Line of Sight and the Semi-Urban Non-Line of Sight in a wideband channel. The dataset captures 29 and 911 multipaths for the indoor and semi-urban propagation scenarios, respectively. The visual technique's performance in drawing knowledge with the data can be observed using these two scenarios.

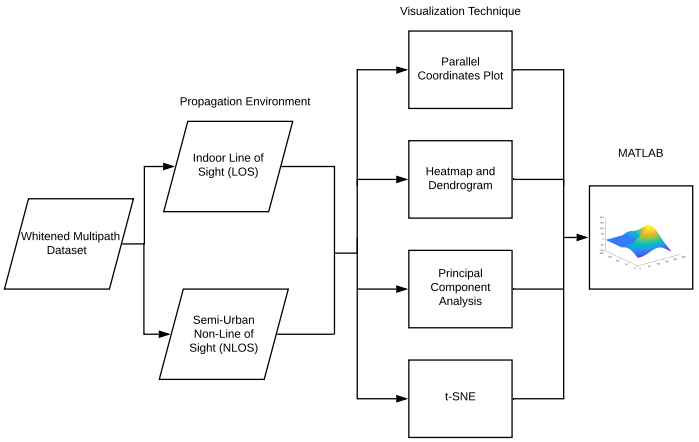

Figure 2: The methodology of the study

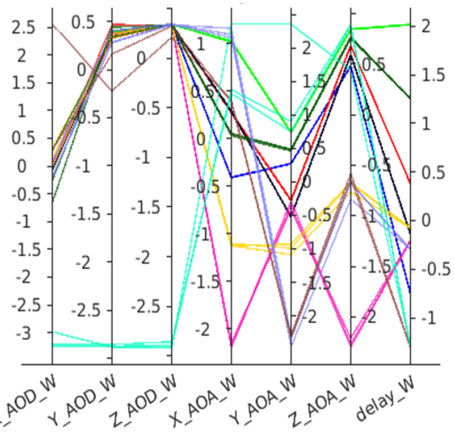

Figure 3: Parallel Coordinate Plot (Indoor)

The methodology in the implementation of this work is shown

in Figure 2. The datasets chosen are implemented in the MATLAB environment due to the availability of the previously discussed visualization techniques' tools and functions. The input data sets are stored, evaluated, and presented using visualization methods. The color represents each multipath's reference cluster in the graphs except for the heatmaps in Figure 3.

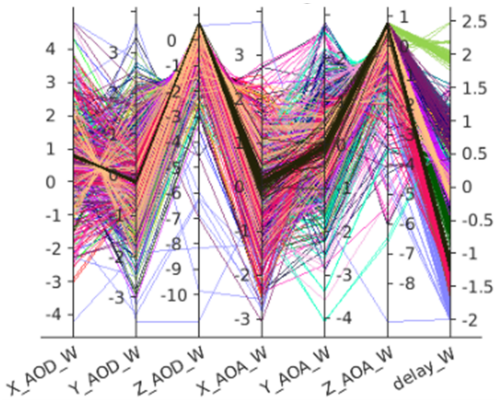

Figure 4: Parallel Coordinate Plot (Semi-urban)

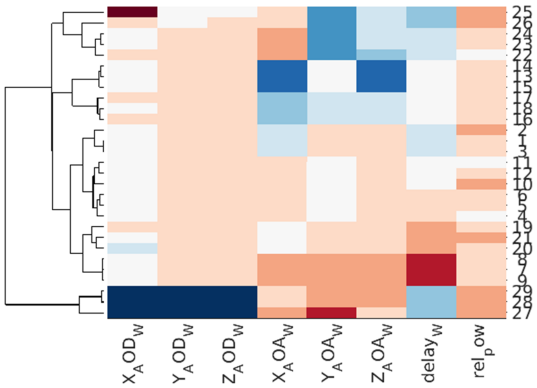

Figure 5: Heatmap and Dendrogram (Indoor)

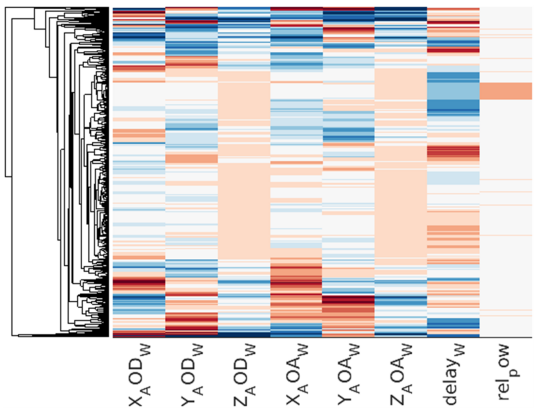

Figure 6: Heatmap and Dendrogram (Semi-urban)

The parallel coordinate plot is a useful technique in visualizing all dimensions of the data as it plots all the MPC dimensions all at once. A specific color represents the cluster ID based on the dataset. In the indoor scenario, more straightforward analysis is possible due to the small number of MPC, and the outliers can easily be observed with the light blue color cluster. The indoor scenario in Figure 3 shows the MPC clusters have the same AoD values but varies within the arrival angle and delay. This result shows the advantage of using a parallel plot for cluster analysis. As opposed to the indoor figure, the projection of the semi-urban environment in Figure 4 visually clutters the graph due to a large number of MPC data. To address the cluttering, the user can filter clusters that can be seen as validated clusters and use a density-based parallel plot as presented in [29].

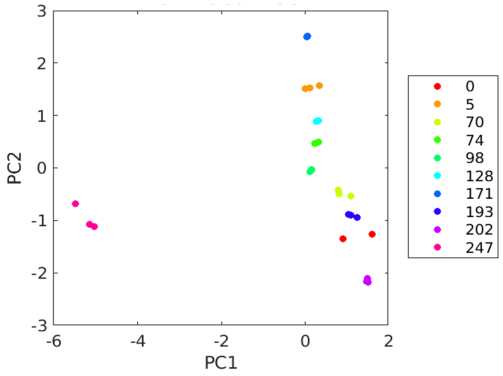

Figure 7: Principal Component Analysis (Indoor)

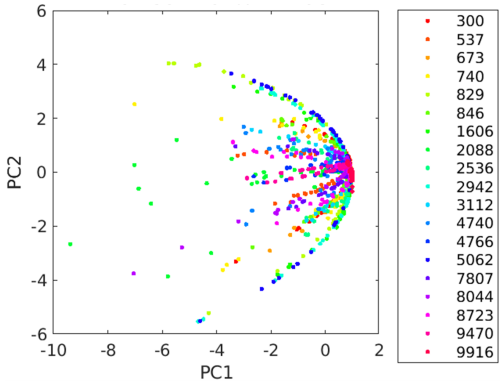

Figure 8: Principal Component Analysis (Semi-urban)

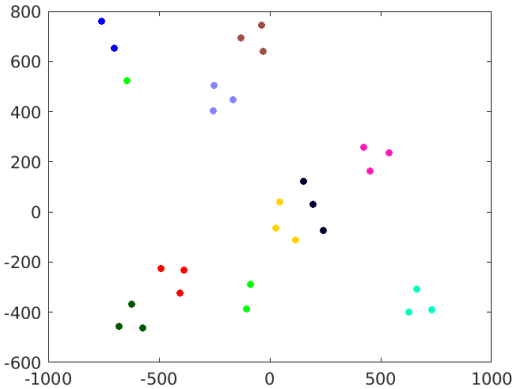

Figure 9: t-SNE (Indoor)

The clustergram function in MATLAB utilizes the linkage func-

tion and dendrogram that produces a hierarchical clustering result and is presented in a heatmap. The dendrogram in Figure 5 and Figure 6 show the cluster using a tree diagram that links the MPC with a close relationship in the lowest node and represents the high separation of the values with the upper branch. In contrast with the other tools in this work, this function is limited to presenting a heatmap of the reference cluster ID. The authors suggest creating a customized heatmap based on the computed cluster id and doing a dendrogram to compare the algorithm's performance and the hierarchical clustering.

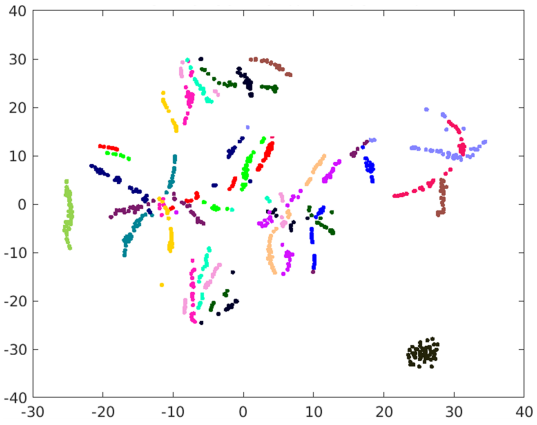

Figure 10: t-SNE (Semi-urban)

PCA outputs two principal components with the highest variance in the MPC dataset. MATLAB's pca function provides each principal component's scores with the two highest scores are projected to represent the dataset in a 2D scatterplot. These principal components are computed by matrix factorization using the singular value decomposition (SVD), including the eigenvectors. By truncating the matrix to the desired dimension, pca produces a low dimensional representation of the data using the principal components. The x-axis in Figure 7 shows the highest scored principal component that handles most of the variance. The increased value of data points in both axes shows the MPCs variance in the first and second principal components. The cluster with ID 247 indicates a low variance in both the principal components and can be interpreted as uncorrelated to the other clusters. On the other hand, the MPC in the semi-urban scenario clusters is grouped closely and signifies a high correlation as can be seen in Figure 8.

The tsne function in MATLAB from the extracted dataset, the cluster ID is removed from the dataset and later represents each cluster classification using colors. The features of the MPC, which is an $L \times 9$ matrix, is reduced to an $L \times 2$ matrix and plotted in a scatterplot. Given the pairwise distance of x_k and x_l MPC, the function computes the conditional probability that the kth MPC picks the lth MPC as its neighbor. The perplexity parameter value sets the number of neighboring points desired by the user. The t-SNE implementation can be varied by selecting the perplexity parameters. Furthermore, the number of iterations was set to the default value of the tsne function with 500 steps. In the indoor scenario in Figure 9, the perplexity was set to group the neighboring data points is maximized to 5 since the data set has 21 MPC. Based on visual observation, the grouping reflects the cluster properly, and each of the neighboring groups can be correlated to form a new cluster. In the semi-urban environment in Figure10, perplexity was set to 40 adjacent points, and observed overlapping clusters could be correlated with one another. Even so, the visual grouping by the t-SNE performs well and isolates clusters that have high dissimilarity with other clusters. The use of t-SNE for iteratively providing insight into the MPC clusters can help interpret the propagation environment's physical realism if the interacting objects are identified.

Due to the wide variety of data when measuring MPC in propagation scenarios, several algorithms are being investigated to correctly cluster the MPC. Using these visualization techniques, designers can quickly identify outliers produced by the algorithm and provide a physical realism within the data. It can be observed that the t-SNE can significantly identify natural clusters between MPC and can visually analyze the effectiveness of algorithms applied to measured MPC. With the built-in functions of MATLAB, the user can specify another column with another cluster ID that is the output of a clustering algorithm. These flexible parameters can compare the clusters from the ground truth of the data set.

Furthermore, visualization can be done as a pre-processing and post-process steps on clustering to observe the structure of data before using an algorithm and the effectiveness of the clustering algorithm with the MPC. Using t-SNE, which solves the crowding problem of the data set, the clusters in the plot can be easily used to identify specific scatterers with physical distance and have a high effect on the signals being transmitted. This work presents visualization to enhance the manual approach of clustering in parallel with the development and research of clustering algorithms.

The authors encourage the use of the variation and extensions of the visualization tools presented. The implementation of the visual techniques with algorithmic clustered datasets, both measured and synthetic, is also considered.

6 Conclusions

This study implements visualization techniques to wireless multipath clusters. It can be observed that these techniques aid the analysis in finding natural clusters and outliers of MPC visually. As measurement campaigns suggest increasing the parameters, MPC clustering then has more features than previously discussed. Since the optimal algorithm for clustering MPC is still an open topic for research, visual analysis can be drawn to enhance the clusters by visual representation further. The techniques used in this study considers the angular, delay, and relative power properties of the MPC and are visualized in one plot. The use of the parallel coordinate plot and t-SNE is effective in both the indoor and outdoor scenarios. The proper validation of clustering results in channel modeling can be improved by allowing users to visualize each feature of the data in the dimension provided by the parameters. The user domain knowledge and inputs based on the scenario can serve as a basis to improve the validity of these clusters, leading to an efficient and effective way of observing the effects of the wireless channel. Presenting the data in different possible ways aids cognition and infers knowledge in clustering the MPC. Furthermore, the execution of this work with more data analysis and the development of a GUI is considered for future work.

Conflict of Interest The authors declare no conflict of interest.

ABSTRACT

Phasor Measurement Unit (PMU) is an integral device for tracking, protection, and regulation of the power network. PMU gives synchronised calculations of actual-time data for voltage phasor, current phasor, and the frequency. Placing PMU in every node to observe the power network is not realistic from an economic standpoint and even for big data management. Thus, raising the number of PMUs in the node network to achieve optimum monitoring of the power network is a mandatory issue. In tracking the problem of optimal PMU placement, various methods have been proposed by various researchers in recent times. To facilitate understanding among the various approaches, this study classified the existing methods into two headings; heuristic and mathematical(conventional)methods. The study discusses the different existing optimisation approaches used to solve the optimal PMU placement problems. The benefits, as well as the drawbacks of each approach, is thoroughly examined and wind up the discussion that the heuristic approach is a fast knowledge-based methodology, which was used as the optimization solver for the IEEE 14, 30 and Nigeria national grid 28 and 52 bus system.

1. Introduction

Phasor measurement unit is an electrical instrument that measures the phase angle and magnitude of current and voltage in the power network system, using a synchronised time source provided by global positioning system, which can provide accuracy up to one microsecond [1]. To decide the condition of a power network, the estimations of the state variables (phase angles and voltage magnitude), of all system nodes should be known. Realising these values helps to calculate the flow of real and reactive power in the power network. It will be very strenuous to consider system nodes one of after the other most especial a large system, this is one area in which intelligent devices find application [2] in this case PMU estimations solve the problem effortlessly.

At a particular period, the voltage phase angle and magnitude and current sinusoidal waveforms are expressed as real and imaginary numbers that are known as a phasor. The value of the magnitude is dependent on the amplitude of the sinusoidal waveform, while the phase angle is gotten relying on the time position as presented in the figures. Figure 1a shows the sinusoidal waveform is behind as for the cosine reference, as it is behind, the phase angle will be negative, though, in Figure 1b, the sinusoidal waveform is ahead as for the cosine reference. Subsequently, the phase angle is positive. Since the phasor measurement unit is provided with the global positioning system, every phasor estimation is time-tagged, consequently, permitting phasor estimations gotten from the phasor measurement units in different positions in a system to synchronise.

PMU firstly receives signals in analogue form. The signal being received contains estimated voltages and currents from current and voltage transformer. The anti-aliasing filter then used in eliminating high-frequency factors surpassing the sampling limit of Nyquist. It will, therefore, suppress the frequency factors that exceed the Nyquist sampling rate. The phase-locked oscillator divides the global positioning system one pulse each second into the needed number of pulses as regards the sampling of the waveform. Through the use of a 16-piece accuracy analogue to a digital converter, the input signals will be digitised at sampling moments when the time signals are sampled from the phase-locked oscillator before feeding it to the phasor microprocessor. The microprocessor resamples the signals from the digitised sample information and estimates the positive succession. Then the

2. Optimal PMU Placement Problem Formulation

There are two main performances used in the analysis for observing power system; they are numerical observability and topological observability [4]. Numerical observability suffers from a lot of matrix computations; thus, it is not advisable to employ them for analysing power systems, especially large ones. Topological observability of a system is achieved when a full rank of traversing the tree is obtained. Some simplified and improved effective rules when topologically analysing a power system are illustrated below:

Rule 1: For a PMU-installed node, voltage phasor and the connecting branches current phasor are known as demonstrated in Figure 2. This measurement is known as direct measurement. In Figure 2, PMU is installed in node 1; consequently, the voltage phasor of the node is known, and the current phasor of the connecting line is also known following the first rule.

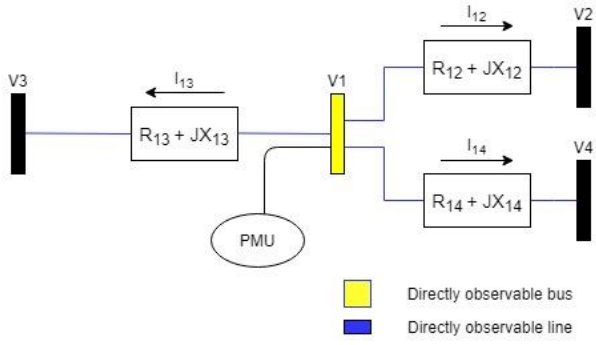

Figure 2: illustrating Direct measurement Rule 1

Rule 2: When the voltage phasor is known, and the current phasor at one end of the branch is also known, it guarantees that the other end is observable by determining the voltage phasor, as illustrated in Figure 3. This type of measurement is known as pseudo-measurement.

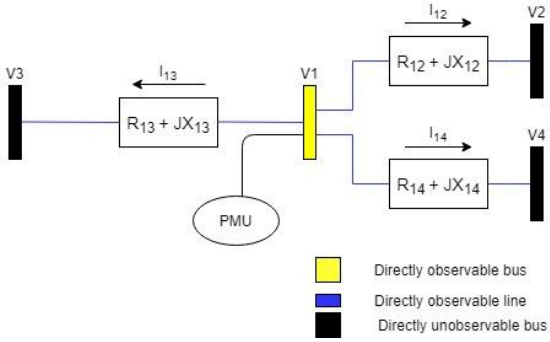

Figure 3: illustrating pseudo-measurement Rule 2

Since the value of the current phasors of the lines connected to node 1 is known, the value of the other nodes can be solved for by utilising Ohms law.

$$I_{12} = \frac{V_1 - V_2}{R_{12} + jX_{12}} \tag{1}$$

$$V_2 = V_1 - I_{12}(R_{12} + jX_{12}) \tag{2}$$

$$I_{13} = \frac{V_1 - V_3}{R_{13} + jX_{13}} \tag{3}$$

$$V_3 = V_1 - I_{13}(R_{13} + jX_{13}) \tag{4}$$

$$I_{41} = \frac{V_4 - V_1}{R_{14} + jX_{14}} \tag{5}$$

$$V_4 = V_1 + I_{41}(R_{41} + jX_{41}) \tag{6}$$

Rule 3: In a case where the voltage phasor for both ends is known, the current phasor of the connecting branch can be gotten as shown in Figure 4. Knowing the voltage phasor of node-1 and node-2, the current phasor of the connecting line can be calculated using Ohm's law.

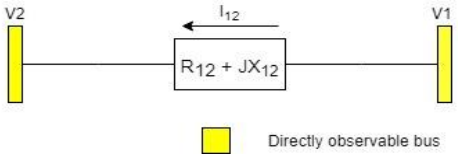

Figure 4: Illustrating observability of the branch current for rule 3

$$I_{12} = \frac{V_1 - V_2}{R_{12} + jX_{12}} \tag{7}$$

Rule 4: For a zero-injection node, knowing all the current of all connected branches, except one, calculating the current for the unknown branch can be achieved using Kirchhoff current law (KCL) this rule is demonstrated in Figure 5. node-3 is the zero-injection node, and current phasor of every branch is known except the current for the branch between node-3 and node-4.

Rule 5: For a zero-injection node where the voltage phasor is not known, if all the neighbouring nodes are known, the zero-injection node can be known through calculations, as shown in Figure 6. In the diagram, node-3 is the zero-injection node and the

voltages for the neighbouring nodes is known. By using node calculations, the voltage for node-3 is known.

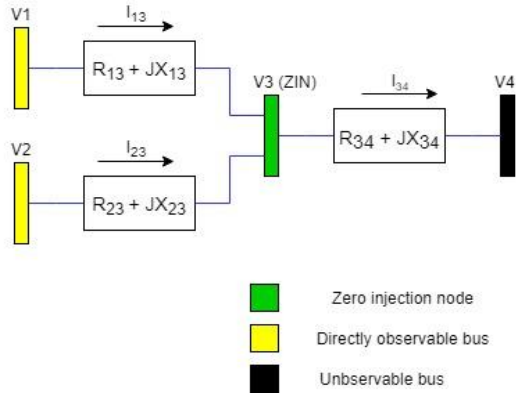

Figure 5: Model observability of zero-injection node for rule 4

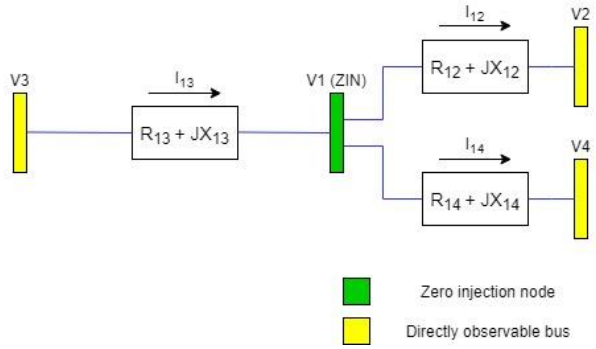

Figure 6 Modelling unobservable ZIN rule 5

$$V_3 = V_1 - I_{13}(R_{13} + jX_{13}) \quad (8)$$

$$V_3 = V_2 + I_{32}(R_{32} + jX_{32} \quad (9)$$

$$V_3 = V_4 + I_{34}(R_{34} + jX_{34}) \quad (10)$$

$$0 = I_{12} - I_{32} - I_{24} \quad (11)$$

Rule 6: For a group of neighboring zero-injection nodes that are not observable because the voltages are not known, but the neighboring nodes connected to the group of zero injection nodes are known. The unknown voltage phasors of the zero-injection nodes can be made known by using both Kirchhoff's current and voltage laws as illustrated in Figure 7. In this figure, the voltage of node-3 and node-4, but the voltages of the nodes connected to them are known.

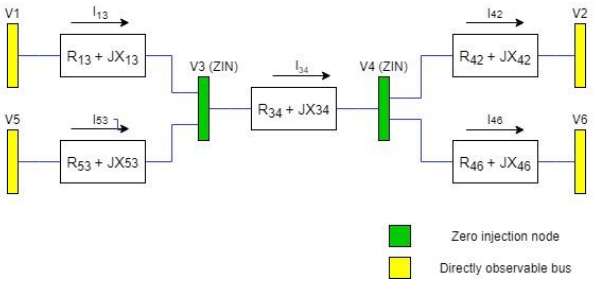

Figure 7 Modelling unobservable ZINs rule 6

Minimum number of PMU: One of the purposes of the optimal PMU placement problem is to resolve the minimum number of PMUs needed for a power system and their right allocation to make sure that the system is totally observable. This objective can be represented mathematically as shown:

$$\sum_{i}^{\text{N nodes}} A_{ij} \quad (12)$$

$$s.t\, B * A \geq 1 \quad (13)$$

$$I = [111 \ldots \ldots 1]^{T}_{N\,X\,1} \quad (14)$$

$$A(i) = \begin{cases} 1 & if\ PMU\ is\ installed\ on\ node\ i \\ 0 & if\ PMU\ is\ not\ installed\ on\ node\ i \end{cases} \quad (15)$$

$$B(i,j) = \begin{cases} 1 & if\ i = j \\ 1 & if\ nodes\ i\ and\ j\ are\ joined \\ 0 & if\ nodes\ i\ and\ j\ are\ not\ joined \end{cases} \quad (16)$$

3. Placement Methods

Several methods have been deployed for optimal location on power system network in different regards such as distributed generators and PMU [5,6]; in this section, several of the methods used to optimally site PMU are extensively reviewed.

3.1. Conventional Method

Two of the conventional methods that have been reported in previous studies are discussed under this subsection.

3.1.1. Integer Linear Programming (ILP)

Integer Linear Programming methods, also recognised as binary integer programming, considering both the system's injection and power measurement as well as PMU error calculation by state estimation. Integer linear programming algorithm is based on the individual vectors derived from the adjacency matrix of the transverse tree [7]. Upon decomposition, the PMUs are positioned ideally in the networks utilising the integer linear programming principle to reduce the deployment rate. Two types of ILP models are mixed integer linear programming (MILP) and binary integer linear programming (BILP) [8].

3.1.2. Integer Quadratic Programming (IQP)

Integer quadratic programming utilises the connectivity matrix that reflects the topology of the system to define the optimal PMU placement (OPP) problem. The quadratic function's objectives were structured, taking into account linear constraints and the vector of integer values. The method will decrease the number of PMUs by providing full network observability in standard operations as well as in outages [8].

In [9], the authors discussed factors that affect calculation precision, including measurements inconsistencies, number of PMU measurements, and quasi-power measurements implementation. Quasi-power uncertainty is determined by the propagation concept of uncertainty, and the optimum location of PMU is calculated by integer quadratic linear programming. Various types of state variables as well exhibited different sensitivities to different measurements [10].

3.1.3. Drawbacks of Conventional Methods

Usually, the conventional technique is utilised to model a network when the network is not so complex. Also, conventional

technique takes more computational time when compared with Heuristic techniques to solve a complicated network problem.

3.2. Heuristic Methods

Most of the Heuristic Methods that have been reported in previous studies are discussed under this subsection.

3.2.1. Genetic Algorithm

The foundation of genetic algorithm is to model natural selection which has no requirement for secondary functions like derivatives calculation. Some of the advantages of genetic algorithm which makes it more applicable to OPP problems are: the likelihood of the local minimum being trapped is reduced, Calculations are decreased from one state to the other, and the fitness assessment of each sequence directs the search [11].

In [12], they investigated optimally placing PMUs and communication links for distributed state estimation in distribution networks. They combined integer linear programming and genetic algorithm to find the least number of PMUs in a distribution network. A distributed state estimation system segmenting technique is created to minimise the burden it takes to compute and communicate [13]. The aim of the partitions is to balance the number of buses in subareas. By turning the network segmenting into the problem of assigning a centralised bus of each subarea, the scale-balanced partitioning scheme between subareas is obtained by applying genetic algorithms.

3.2.2. Particle Swarm Optimisation

Particle swarm optimisation is a similar technique to genetic algorithm, where population solutions are randomly assigned to a system firstly [14]. In [15], the authors described particles as entities that are hovering through multidimensions in space. For every particle, the best location is determined by the fittest position faced by that particle and its neighbouring particles. The process of the particle swarm optimisation begins with a primary point and velocity for every particle, where the velocity of each particle is restricted by reasons of not hovering in unusable space as well as overflowing forbiddance [16].

3.2.3. Tabu Search

The Tabu search algorithm is a combinatorial method, and it combines techniques such as conventional method and heuristic method. This method is majorly used in solving combinatorial optimisation problems in covering and scheduling. Tabu lists, which is a major element of tabu search, consists of numbers of states visited in recent times and unwanted states. Another major element of tabu search is the state definition and the encompassing area. The tabu search resets when it does not converge [17].

In [18], the authors solved the optimal PMU placement problem and achieved maximum observability of a system and maximum redundancy by utilising tabu search-based linear state estimation model [19]. This quick technique of topological observability analysis required a loss simulation function relying on the matrix of incidence to solve the optimal PMU placement problem. This technique also concerns the convenience and high speed to monitorable power network by manipulating integer numbers [20].

3.2.4. Differential Evolution

The method of differential evolution (DE) uses elements such as N-dimensional vectors to reduce progressing space functions. Mutation, fusion and choice are the key functions used in the global optimising process. Differential evolution approach is utilised extensively in various problems of cost function including multimodal, non-differentiable, and nonlinear functions. Certain advantages of this method include simultaneous computations, simple use, and strong synchronisation properties [21].

The researchers introduced multi-objective optimal PMU placement in [22] utilising a non-dominating filtering DE technique, that is an organic synthesis of the nondominated filtering procedure and DE technique Pareto. This theory put into consideration total measurement reliability and voluntary PMU failure to achieve complete observability of the network in addition to finding a solution to the optimal PMU placement problem [3] Using the differential evolution technique obtained from genetic algorithm contributed to the suggested method for the nondominated sorting differential evolution algorithm. It was stated that obtaining a particular and absolute Pareto front and having several Pareto ideal solutions was the improvement of this method.

3.2.5. Simulated Annealing

The simulated annealing method solves complex combinatorial optimisation where the existing solution is changed arbitrarily. The new changed solution is the worst change with a decreased probability as computing continues. The ideal outcome for a major problem of combinatorial optimisation requires an effective disturbance framework, cost function, space for the solution, and cooling plan for the simulated annealing to solve. Simulated annealing can be considered adequate by looking for a large-scale network and achieving good speed in seeking an ideal or near-ideal solution [23]

Authors in [24], investigated effective use of different PMU estimated values and exposure to extremely critical network data were put into consideration for the ideal deployment of PMUs to make the power system fully observable. A topological observability formulation based on the incidence matrix evaluated the original PMU arrangement to have a network with complete observability.

3.2.6. Ant Colony Optimization

A further concept used to present an optimisation problem solution is ant colony optimisation, which originally utilises the ant population. The function of the ant colony was to travel across neighbouring states of the problem by implementing an ideal controller for the stochastic local resolution, resulting in solving optimising problem. Evaporation of the pheromone trace and action of the daemon are procedures in ant colony optimisation. The use of ant colony optimisation to determine good paths across graphs will decrease computational issues [25].

Authors in [26], investigated on an enhanced ant colony optimization which was used to solve the ideal PMU placement problem for achieving a totally visible power network with the least number of PMUs and putting into consideration total measurement redundancy. The depth-first search as a conceptual

graph approach was used to create an estimation tree to evaluate if the power system was observable [27].

3.2.7. Iterated Local Search

The key viewpoint of iterated local search is to search for a subspace characterised by local optimal solutions rather than the entire solution space. By using an integrated heuristic, there is a series of solutions where the best option is achieved if repeated arbitrary tests of the heuristic were to be used [28].

The optimal PMU placement method introduced in [29] involves two phases which included an initial PMU dispensation to reach a visible network by using an iterated local search to decide the least number of PMUs required to make a system fully visible. Page rank placement formulation is utilised in this approach to determine the significance of every bus.

3.2.8. Mutual Information

Taking into account not only access to a system with maximum observability but also analysing irregularities in the network states that utilised mutual information between PMUs measurements values and system states, and information theoretical method to solve optimal PMU placement problems was addressed in [30].

3.2.9. Matrix Reduction

For the problems of placing PMUs, a distribution matrix occurs, whereby the graph indicates the distribution scope whenever a station is placed in different locations. The problem level is determined by the range of the distribution. The approach of matrix reduction aims to establish ideal placement by increasing the matrix of incidence. Using a formulation based on removing digital data, the matrix reduction technique was proposed to achieve the least number of PMU to reach observability of the network completely and reduce the computation process [31].

3.2.10. Imperialistic Competition Algorithm

Imperialistic competition technique is a new technique formulated to solve optimal placement problems. Just like other heuristic techniques, imperialistic competition algorithm begins with a first population named country which is a colony of two types. Competitiveness of the countries brings about the minimal of the problem. The effectiveness of the Imperialistic competition technique in wide area optimisation was evaluated on test buses and as confirmed [32].

3.2.11. Immune Genetic Algorithm

The Immune Genetic Algorithm was utilised to proffer solution to placing the PMU optimally utilising three impact vaccinations to create a topologically measurable power system. The two measures that occur in an immune genetic algorithm approach to defend against viruses and bacteria are vaccines and immunity alternatives. The vaccination basis is the combination of technical knowledge and previous data about the optimal PMU placement problem. Two operators, namely, crossover and mutation, were considered by the immune genetic algorithm, which was utilised to maximise the tests [33].

3.2.12. Biogeography Based Optimisation

The biogeography-based technique is a mathematical model for the movement of species from one region, which is known as a habitat to another region, rising and extermination conditions of species. This technique is used to provide solutions to the problem of optimisation through complex performance environments and to improve the efficiency of species migration and integration into the habitat [34].

3.2.13. Chemical Reaction Optimization

To find a solution to the OPP problems, a newly formed heuristic approach named population-based chemical reaction technique was implemented. Through modelling the behaviour and movement of gases in a chemical reaction, reaching a low energy steady state was the key goal of the chemical reaction techniques, which sought to achieve the least free energy level. High performance was demonstrated by the application of the chemical reaction technique to metrics and practical problems [35].

Using a new heuristic approach called chemical reaction technique and simplified chemical reaction technique model, optimal PMU placement problem solved to achieve a completely measurable power network considering the system with and without zero-injection nodes [36].

3.2.14. Artificial Bee Colony (ABC)

Artificial bee colony technique's key motivating criteria are food resources path, food resources range, and food resources performance information [37]. The developed formulation could be used in solving unimodal and multi-modal mathematical optimization problems. Also, a multiple objective optimal PMU placement algorithm, called binary-coded was implemented in solving the optimal PMU placement problem and obtain the least quantity of PMU and highest possible network redundancy. Consideration was given to eventuality constraint conditions like a one-line outage, and arrangements of the least quantity of needed PMUs were determined [37].

3.2.15. Bacteria Foraging Algorithm

Biological evolution propensity towards animal exclusion with weak feeding strategies that work to find, handle, and consume food and spread the genes of animal performance in feeding approaches as they are more probable to achieve productive results. Weak foraging approaches after several years are either discarded or revamped [4]. Four operators utilised in the developed bacterial foraging algorithm were chemotaxis, swarming, reproduction, and removal and distribution [38].

3.2.16. Cellular Learning Automata

Cellular learning automata technique is cantered on the use of training automaton to change cellular automaton state conversion likelihood. This approach begins by determining each cell's inner condition. Instead, on the basis of cellular learning automata law, the strengthening signal for every training automata is calculated. Maintaining this operation will achieve the intended state [39].

In [29], a CLA approach was used to examine the integration of two opposing objective functions like the least number of PMUs and total measurement reliability to achieve a completely measurable power network. This research put into consideration

the drawbacks of flexibility, including PMU/branch loss and traditional measurements and zero-injection nodes.

3.2.17. Hybrid Methods

Utilising a formulated hybrid genetic algorithm and simulated annealing, a solution was introduced in [38] to ideally place PMUs and remote terminal units for a large network of interconnected grids determined by a multiarea system state estimate. Using remote terminal units and conventional measurements, a PMU was incorporated into a power network to ensure the calculated state more precisely and reduce the expense of conventional measurement and cost of the remote terminal unit. Utility centre of one multiarea area to reach system measurements required a single PMU placement, as PMU measurement calculated the network node voltage. A criterion for the PMU was the node with the highest connecting line. The identification of faulty data was achieved by taking into account the vital measurement of each region.

A synthesis of least traverse tree technique with the optimised genetic algorithm is a hybrid method named MST-GA presented in [40] to achieve the least number of PMUs required to make a system fully observable and to consider optimising redundancy. This approach enhanced mutation operation taking into account grid topology information. As the key and side steps, fusion and mutation were used as an activity to create new entities, the outcome of the new analysis of this approach was a decrease in the number of PMUs required and a variety of solutions [41].

To easily capture the objectives and contributions of the previous studies with respect to methods/techniques deployed Table 1 is developed while Table 2 gives the comparison of conventional and heuristic methods with respect to four factors namely; the size of the problem, data requirement, accuracy, and effectiveness.

3.2.18. Drawbacks of Heuristic Methods

To efficiently implement the heuristic technique, it takes a specific level of expertise and experience [4,8]. Often these functionality specialists are difficult and costly to employ, particularly if they need domain knowledge. If the analysts are not included in the development, they may not be informed of the technical design constraints or why such design choices have been made [8]. Heuristic tests are poorly organized, and thus risk identifying one-time, low-priority issues. Lastly, heuristic assessments do not allow for an assessment of the performance of re-designs [3].

Table 1: Objectives and contributions of investigated studies

Author(s)/Reference Number	Objective	Technique	Considerations	Gaps	Benefits
B. Mallikarjuna, P. Gopakumar, M. J. B. Reddy and D. K. Mohanta [23]	Ideal positioning of PMUs to allow monitoring of incorrect data. simulated annealing technique is implemented with the stochastic new approach	Simulated Annealing	detection of critical measurements	Zero-injection nodes (ZIN)& Measurement Redundancy was not considered	Observability of the power network with critical measurements
C. Margarida, K. Xenia and V. Ana, [42]	Limiting the quantity of PMU allocation utilising stochastic simulated annealing algorithm	Stochastic Simulated Annealing	Detection of critical measurements is introduced as a consequence function	The algorithm was not Line loss, PMU the outage	Detection of critical measurements
Z. Zhida, Y. Hao, L. Peng, L. Peng, K. Xiangyu, W. Jianzhong and W. Chengshan [12]	Reducing the quantity of PMUs, and determining their geographical allocation, achieving a total network of measurable power. A genetic algorithm-based procedure is used, and PMUs are installed with current phasor measurements as the maximum quantity of simultaneous lines are highlighted in all network nodes	Genetic Algorithm	Connection of PMUs with the number of current phasors to be calculated	Quality of the result were not documented.	Needed channels for current in the optimisation problem
C. Peng, H. Sun and J. Guo. [43]	Limiting the quantity of PMUs and increasing the redundant measurements. In place of one optimal solution, Pareto-ideal solutions are presented	Non-Dominated SortingGenetic Technique	Zero-injection nodes & Measurement Redundancy	It was assumed that PMUs capacity is limitless. PMU channels limit was not considered	Offering Pareto-ideal facade forcontradictory objectives, solution repair
S. M. Mazhari, H. Monsef, H. Lesani and A. Fereidunian [39]	A multi-objective ideal allocation to minimise the quantity of PMUs and increase the accuracy of measurements. PMU allocation is also analysed by the implementation of a standardised observability function based on traditional non-synchronous	Cellular Learning Automata	Traditional measurements, PMU failure, Branch loss	This technique might not give the least quantity of PMUs to make the network observable	High performanceinelectrical net works on a large scale
A. A. Hany, Y. A. Almoataz and V. Mukherjee [25]	The ABC definition is used to attain the least quantity of PMUs to achieve a total measurable power network, fulfilling measurement redundancy	Artificial Bee Colony	One branch loss, zero-injection nodes	The pheromone variation span is restricted to interval [0, -1],	System viability and efficiency is shown by the comparison of the simulation results with the previous works

N. C. Koutsoukis, N. M. Manousakis, P. S. Georgilakis and G. N. Korres [19]	Two contending purposes involving the least quantity of PMU and maximum redundancy on the network	Tabu Search	Zero-injection nodes & Measurement Redundancy	Placement of PMU in ZINwas not allowed in the initialization.	Optimal problems solved with high precision and reduced calculation
R. Ramachandran and S. Karthick [44]	Limiting the quantity of PMU placement and developing a parallel tabu search formulation	Parallel Tabu Search	Communication restraint, Zero-injection nodes, and matrix condition of the state estimations	Traditional measurements, PMU failure, Branch loss was not considered	Reduced calculation period
M. Nazari-Heris and B. Mohammadi-Ivatloo [4]	Two contending purposes involving the least quantity of PMU and maximum redundancy	Clonal Algorithm	Total redundancy	ZIN enhancement of secondary voltage control operation was not considered	Maximum velocity of the procedure, achieving practical schemes
M. Zhou, V. Centeno, A. Phadke, Y. Hu, D. Novosel and H. Volskis [31]	Reducing the quantity of PMUs. Utilising pre-processing techniques and providing solutions using mathematical based methods	Matrix Reduction	Computer-generated data removal, Pre-processing technique and matrix reduction procedure, utilising Lagrangian relaxation	Quality assessment was not recorded because there was no other tested optimal placement set for the Brazilian network	Minimising the size of allocation model and the calculation exertion, employed in a large-scale network
S. Md, I. H. Md, M. Abido, A.-F. Taher and M. A.H [15]	Limiting the quantity of PMUs so as the power network can be fully observed. Developing a hybrid technique based on binary particle swarm optimisation	Binary Particle Swarm Optimisation	Increasing redundancy in the power network, one PMU and Multi-PMU failure	loss of PMU and branch loss were ignored	Maximum velocity of the procedure and reduced calculation period

Biplab [46]	Reducing the number of meters and PMUs Taking consideration of one line/meter loss and one line/PMU loss	Biogeography Based Optimisation	Zero-injection nodes, line loss, SCADA meter loss, PMU the outage, PMU/branch loss	Traditional measurements, PMU failure, Branch loss was not considered	using simulated node reduction method for decreasing the size of the network
M. Hurtgen and J.-C. Maun. [28]	Reducing the overall quantity of PMUs utilising PageRank placement technique and iterated local search	Iterated Local Search	PMU outage	Zero-injection nodes (ZIN)& Measurement Redundancy was not considered	Taking consideration of eventualities, simple comprehension and implementation
S. S. Noureen, V. Roy and S. B. Bayne. [8]	Limiting the quantity of PMUs. Observing guide nodes needed for secondary voltage control	Branch and Bound	Zero-injection nodes enhancement of secondary voltage control operation	PMU outage, branch loss, measurements redundancy, considered	Observing guide nodes for boosting speed of the voltage control system
Y. Zhao, P. Yuan, Q. Ai and T. Lv [22]	Reducing the quantity of PMUs to monitor both the overall network and fault in the power network	Differential evolution	Fault monitoring, Zero-injection nodes	The constraints utilized ignored some optimal solutions	Utilising PMUs for power network monitoring and fault detection

S. S. Noureen, V. Roy and S. B. Bayne [8]	Limiting means square error by achieving the least quantity of PMUs	Differential evolution	Taking consideration of incessant alterations in the power network's topology	Fault monitoring, ZIN was ignored	Integrating PMU allocation problem into state estimate.
A. Ahmadi, Y. Alinejad-Beromi and M. Moradi [16]	Limiting the quantity of PMUs, recommending new the rule for the network to be observed topologically	Modified binary particle swarm optimisation	Zero-injection nodes, PMU/Branch loss	Measurement redundancy was not studied, and the problem of local least affected the results	Establishing new rules of topologically Observable valuation for limiting the quantity of the needed PMUs
H. Mohammadi, G. Khademi, D. Simon and M. Dehghani [34]	Two contending purposes involving the least quantity of PMU and maximum redundancy	Multi-objective biogeography-based optimisation	measurements redundancies, zero-injection nodes.	The large amount of cost evaluations utilized made a little difference in the solution	The proposed technique generates well-circulated Pareto-optimal solutions
M. Nazari-Heris and B. Mohammadi-Ivatloo [4]	Multi-objective model, reducing the quantity of PMUs and increasing measurements	Genetic algorithm	Considering single branch/single PMU loss considered	ZIN enhancement of secondary voltage control operation was not ignored	Very little population and iterations needed are less
L. Qiao, C. Tao, W. Yang, N. Rohit, F. Franz and M. D. Ilić [30]	Reducing the quantity of PMUs utilising anInfo-theoretic approach	Mutual information	PMU outage, standard measurement	ZIN was not considered	Modelling the improbabilities in the network states
A. Bashian, M. Assili, A. Anvari-Moghaddam and O. R. Marouzi [11]	Reducing the quantity of PMUs needed for a total observable network and increasing measurements redundancy. A topologically observable rule of zero-injection nodes is also presented	Binary imperialistic completion algorithm	PMU outage, branch loss, measurements redundancy,	Cost considering ZIN was ignored	Quick integration, less deviance, competence of locating global optimal and zero standard deviation
S. Li and Z. Meng [37]	Artificial bee colony technique is implemented to attain least Quantity of PMUs to achieve total observability of the power network, a fitting measurement redundancy	Artificial bee colony	One branch loss and Zero-injection nodes	The technique in this study was only tested on small scale network	Viability and performance of the technique validated by comparison of the simulation outcomes with the related previous research

Table 2: Comparison of Conventional and Heuristic Technique

S/N	Properties	Conventional Technique	Heuristic Technique
1	Size of the Problem	Usually, the conventional technique is utilised to model a network when the network is not so complex.	Heuristic technique is a form of computation which tries to mimic human or animal capability in a very simplified manner in order to proffer solution to the problem of PMU allocation
2	Data requirement	The conventional method utilises physical principles to obtain network relationships, which are typically rightfully generalised with several assumptions and need a previous understanding of the nature of the data relationships.	The heuristic technique focuses on data based on the data only to decide the framework and variables to solve a network problem, with fewer assumptions about the network's nature.
3	Accuracy	As compared to Heuristic technique, because of several factors implemented, the conventional technique does not have a better degree of correctness.	Owing to very little possibilities of failure, Heuristic technique has higher precision.
4	Effectiveness	The conventional technique takes more computational time when compared with Heuristic techniques to solve a complicated network problem.	The heuristic technique can be used effectively in performing routine and tasks that consume time.

4. Results

According to the comparison in Table 2, heuristic technique did better in terms of complexity of the network, data requirement, and level of correctness and effectiveness as regards to time. For this research genetic algorithm is selected the optimization solver for optimal placement of PMUs on IEEE14, 30 and Nigerian 330KV (28 and 52 bus system) networks. It was selected in place of other heuristic algorithms because it is one of the pioneer evolutionary algorithms, simplicity and ease of implementation, and logical reasoning behind the use of operators like selection, crossover and mutation. The mutation operator is executed bit by bit after offspring is produced, for every node in the chromosome expression, an evenly appropriated random number is created between zero and one. If the number produced is lower than the likelihood of the mutation, then the corresponding bit will be

modified from zero to one or one to zero, thereby putting or eliminating the PMU on the appropriate node. Once all the offspring have been generated, the current population and the created offspring are categorized based on the decreasing order of the objective function provided, and a tournament selection is carried out to determine the new generation. Again, a difference is made based on the size on the problem, the top 10 chromosomes are chosen to utilize the tournament selection scheme and inserted directly into the current generation. The suggested approach is implemented to find a solution to the problem by taking consideration of these cases: Normal operation; and Case considering Zero Injection (ZIN)

4.1. Normal operation

In this case, the solution for the optimal PMU placement problem is obtained by ignoring ZIN.

Table 3: Normal operation

	IEEE14	**IEEE 30**	**NG 28**	**NG 52**
Number of PMU	4	10	11	17
PMU location Bus number	2, 6,7, 9	1, 5, 8, 11, 12, 19, 23, 26, 29	1, 3, 4, 12, 13, 17, 20, 21, 23, 24, 27	3, 4, 6, 8, 10, 16, 19, 24, 26, 27, 32, 35, 39, 41, 42, 46, 51

Table 3 shows PMU placement result for the IEEE 14, IEEE 30, Nigeria bus 28 and 52 considering normal arrangement of the bus.

4.2. Case considering ZIN

In this case, the solution for the optimal PMU placement problem is obtained by considering ZIN.

Table 4: Locations of the ZINs

Bus	**Zero Injection location**
IEEE-14	7
IEEE-30	6, 9, 22, 25, 27,28
NG-28	11
NG-52	-

Table 4 shows the location of the zero-injection node for each bus considered.

Table 5: Considering Zero Injection Node

	IEEE14	**IEEE 30**	**NG 28**	**NG 52**
Number of PMU	3	7	10	N/A
Bus PMU location	2, 6, 9	1, 2, 10, 12, 19, 23, 27	1, 3, 4,12, 17, 20, 21, 23, 24, 27	N/A

Table 5 shows PMU placement results for the IEEE 14, IEEE 30, Nigeria bus 28, and 52 considering zero injection node. When a zero-injection node is considered, the number of PMUs needed to observe a system is reduced because that particular bus is merged with a connecting node.

Table 6: System of Redundancy Index (SORI)

Bus	GA	ILP [54]	IQP [55]
IEEE14	NPMU: 4 SORI: 19	NPMU: 4 SORI: 19	NPMU: 4 SORI: 19
IEEE 30	NPMU: 10 SORI: 52	NPMU: 10 SORI: 50	NPMU: 10 SORI: 50
NG 28	NPMU: 11 SORI: 46	N/A	N/A
NG 52	NPMU: 17 SORI: 71	N/A	N/A

Table 6 shows a benchmark with previous studies that utilized a mathematical method considering a normal operation. The result is favourably compared with the previous work carried out on IEEE 14 and IEEE 30 bus system. However, the result obtained in this study is superior to the mathematical methods since it gives the same number of PMU and a higher quality of SORI. Based on this fact, Genetic Algorithm is recommended and is adequately fit heuristic technique for PMU placement which improved resilience of the system and enhanced its reliability.

5. Conclusion

The problem of placing PMU optimally was solved using GA heuristic technique and the quality of the result was compared to results of previous research, from the comparison as shown in the result, it can be observed that the system of redundancy index for the heuristic algorithm used did better than the mathematical programming method when implemented on the IEEE 30 bus system, and achieved the same quality for the IEEE 14 bus system. Methods such as conventional and heuristic techniques, exist to solve the optimal placement problems; this study presented a thorough review study on both techniques. Stabilisation and control of Optimal PMU Placement (OPP) have become a power network necessity. We covered a magnificent set of techniques in this study. This would give researchers a structure for classifying these methods and choosing the appropriate solution prior to applying for PMU placement. Analysis of optimisation techniques in this research shows that minimising the OPP would be a framework and help identify optimisation conditions for projections in time to come.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Human emotional states can transform naturally and are recognizable through facial expressions, voices, or body movements, influenced by received stimuli. However, the articulation of emotions is not practicable by every individual, even when feelings of joy, sadness, or otherwise are experienced. Biomedically, emotions affect brain wave activities, as the continuously functioning brain cells communicate through electrical pulsations. Therefore, an electroencephalogram (EEG) is used to capture input from brain signals, study impulses, and determine the human mood. The examination generally included observing a person's frame of mind in response to a given stimulus where the immediate results were inconclusive. In this study, the associated classifications were normal, focused, sad, and shocked. The raw brainwave data from 50 subjects were recorded by employing a single-channel EEG called the Neurosky Mindwave. Meanwhile, the assessments were performed while the candidates' minds were stimulated by listening to music, watching videos, or reading books. The Fast Fourier Transform (FFT) method was utilized for feature extractions, along with the K-nearest neighbours (K-NN) for classifying brain impulses. The parameter k had a value of 15, and the average classification accuracy was 83.33%, while the highest accuracy for the focused emotional state was 93.33%. The Neurosky Mindwave in conjunction with the FFT and KNN techniques is potential analytical solutions to facilitate the enhanced identification of human emotional conditions.

1. Introduction

The signal of the brainwaves has specific traits and characteristics of the person. The brainwaves cannot be imitated or interpreted by individuals so that there is no chance of resemblance. Identity recognition is essential to identify the features of the person [1].

Identity development is done using biometric technology, which aims at personality-implantation through the use of parts of the body or social behavior—application of Identity Recognition using Biometrics Technology for self-recognition by using parts of the body or human behavior [2-6]. In [7], the author has presented machine-learning algorithms to categorize EEG dynamics according to subject self-reported emotional states during music listening. Support Vector Machine was employed to classify four emotional states and obtained an accuracy of 82.29% across 26 subjects. Vanitha [8] has used Hilbert-Huang Transform (HHT) to remove artifacts and relevant time-frequency features from the EEG signal, and the extracted features are manipulated to detect stress levels using Support Vector Machine (SVM) Classifier on real-time stress detection.

EEG is used as a diagnostic tool by medicine. In comparison, a broader application of the EEG is to analyze a person's mental state, thought patterns, or emotional state [9]. The EEG signal's visual observation is real, given the very low amplitude of the EEG signal, and the pattern is very complex. In addition, EEG signals are strongly influenced by various variables, including emotional conditions, health, respondent activity, environment, electrical disturbances from other organs, and external stimuli.

*Corresponding Author: Anton Yudhana, eyudhana@ee.uad.ac.id

[10]. Conducting the introduction of the EEG signal requires a pattern of brain activity that is prominent and constant. This pattern emerged due to specific stimulation from volunteers. EEG signals are shown to provide more insight into the subject's emotional processes and responses. The recorded EEG signals will get the waveform, the duration, the orientation of the signal, and the signal rhythm. [11, 12].

The EEG signal pattern data's shape and position are not yet known because the signal pattern and response speed response of each individual's brain to the received stimuli are different [13]. Therefore, we need a signal processing method EEG that can pattern specific brain activity [14].

In this study, the Fast Fourier Transform (FFT) based spectrum analysis method converts the EEG signal from the time domain to frequency domain. The FFT results were classified by K-Nearest Neighbor (KNN) as a training data set to characterize the brain wave output from the EEG as a material for analyzing differences in brain waves in each emotional state studied.

2. Data Acquisition

2.1. Neurosky Mindwave Mobile

Neurosky Mindwave Mobile is a brain-computer interface (BCI) device that can be used wirelessly and connected to several devices such as computers and smartphones via Bluetooth connection to collect input from the human brain wave activity [15].

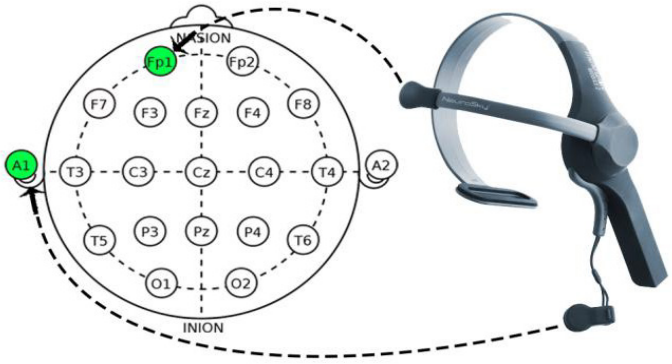

Figure 1: Neurosky Mindwave Mobile and electrode's position

Mindwave provided single-channel EEG in the form of an electrode and placed in the forehead or Fp1 position to measure the brain's electrical voltage and ear-clip on the left ear or A1 position as ground. With Neurosky's ThinkGear and eSense technologies, connected devices can receive a real-time visual representation of brain waves generated from the electrodes [16, 17].

2.2. Subjects

In this study, EEG data were recorded from 50 subjects aged around 20 - 22 years old who were in healthy condition. All of the subjects were undergraduate students and were informed about the purpose of this experiment.

2.3. Stimuli

The use of appropriate stimuli is needed to get better brain wave recording results where a psychologist has validated the stimulus used for this study. Respondents were given stimuli in the form of listening to music, watching videos, and mathematical calculations to influence brain wave activity in the subject to produce an emotional condition that was following the object to be studied [18, 19].

2.4. Procedure of Data Collecting

Before starting data collection, make sure that the respondent is in good health. The data collection process is carried out in a quiet and calm place to make subjects feel comfortable and reduce disturbances affecting data collection. We use the computer laboratory at Ahmad Dahlan University for this research.

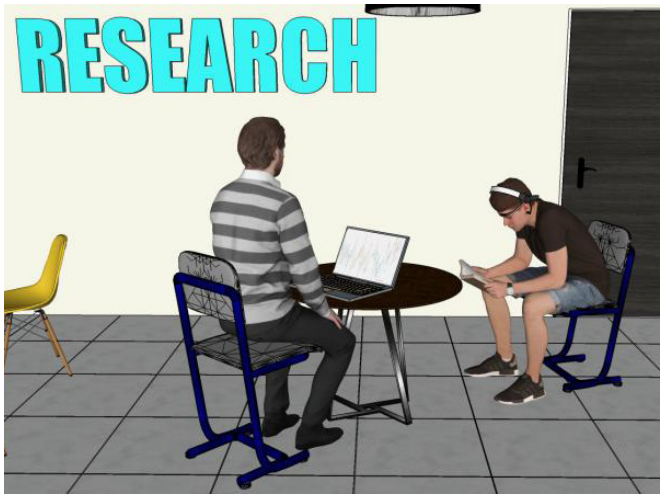

Figure 2: Illustration of the data collecting process

Data collection will be needed as much as 200 data with 50 respondents and carried out four times with a span of at least two days. The recording time for data collection is 7 minutes. When the recording begins, the respondent will be given a stimulus in instrumental music, video, and math questions [20].

3. Methods

3.1. Fast Fourier Transform (FFT)

FFT is applied in various fields,from digital signal processing and solving partial differential equations to algorithms to multiplicate integers in large numbers. FFT is an algorithm for calculating discrete Fourier transforms (DFT) quickly and efficiently. Because many signals in a communication system are continuous in the time domain, we use the Fourier transform to represent the frequency domain [21].

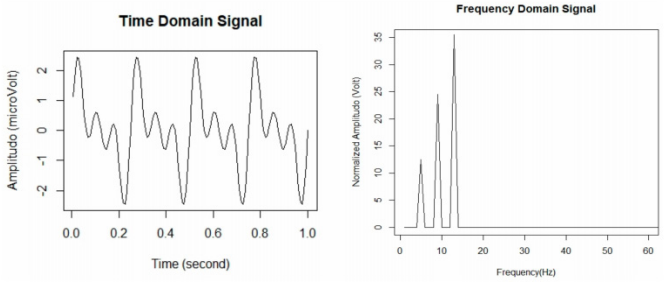

Figure 3: Time-domain signal and frequency domain of EEG signals

FFT is a reliable method for signal processing in the form of a sine wave as EEG signals, and it was proven in previous studies

related to real-time applications because of superior speed compared to other available methods. However, it is not suitable for the analysis of short EEG signals [22]. The FFT formula is defined in (1).

$$S(f) = \int_{-\infty}^{\infty} s(t) e^{-j2\pi ft} dt \quad (1)$$

$e^{-j2\pi ft}$

FFT algorithm is used to reduce the complex transformations performed by DFT. For comparison, when using DFT, then the transformation complexity is N2. Meanwhile, with the FFT algorithm and faster transformation times, the complexity of the transformation is too decreased to (N) log (N).

3.2. K-nearest neighbor

K-Nearest Neighbor is a method for classifying objects based on training data closest to the object. The data is then presented with a distance measure to be processed into a mathematical calculation. In this classification, the calculation is done by using Euclidean Distance. The training data with the closest distance are said to be neighbors and then sorted from the closest distance to the farthest distance. Each neighbor is different from one another or the like. Similar neighbors with the largest number among *k* neighbors correspond to the object being classified [23]. To find the neighbor, it uses distance metrics like euclidean distance as given in equation (2) .

$$D(x, y) = \Sigma_{k=1}^{N} \sqrt{(x_k - y_k)^2} \quad (2)$$

where *D (x, y)* is the distance between *x* and *y* facilities, x_k-y_k is the *x* and y coordinates of variable *k* (*k* = 1,3,5,… n). The value of k must be an odd number, and the number of training data is even to avoid ambiguity. This value is necessary to facilitate the achievement of classification results from the number of closest neighbors. When there is a class with the most neighbors, the test data will get that class result [24].

3.3. Hardware Design

The block diagram above shows that Neurosky Mindwave Mobile is a major component in this hardware system. Neurosky captures input from brain waves via electrodes attached to the FP1 area of the respondent's head and sends an EEG signal via a Bluetooth connection, which acts as a communication protocol between Mindwave and PC / Laptop.

Figure 4: Hardware system diagram

3.4. Software Design

The block diagram above explains that when raw EEG data is obtained from recording brain waves using Neurosky Mindwave on respondents who have been given a stimulus. Raw data taken in the signal pre-processing stage is cut 2 seconds early to minimize noise at the beginning of the recording, due to external interference such as a Bluetooth connection between the recording device and the application, or due to the imperfect installation of the device on the respondent's head. The next stage of feature extraction is carried out using the FFT algorithm to convert the EEG signal in the time domain into the frequency domain and extract all important frequency components from the EEG signal such as Delta waves (0.1 - 3 Hz), Theta (4 - 7 Hz.), Alfa (8 - 12 Hz), Beta (12 - 30 Hz), and Gamma (30 - 100 Hz) [25]. From the results of feature extraction, a huge amount of data is obtained, and data simplification must be done by not including data that is below the average value so that the classification results are more accurate for each emotion. Furthermore, grouping training data and test data are carried out using the KNN classification method in mathematical calculations with the Euclidean formula to calculate the closest distance to the results of the FFT feature extraction. The final step is to determine the accuracy of the KNN classification results on waves using the Confusion Matrix.

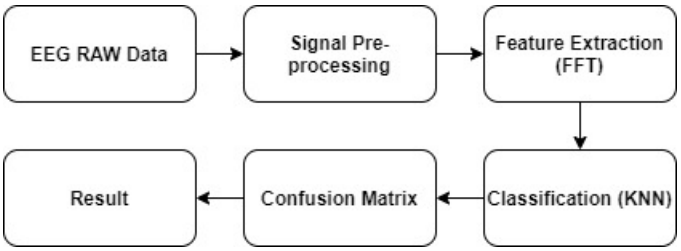

Figure 5: System design diagram

4. Result

In this research, several experimental stages were carried out. The first step is signal pre-processing to reduce noise in raw data, then feature extraction to change the form of RAW data from brain waves to the FFT spectrum. Second, monitoring the FFT results in each emotional state, followed by taking all the highest data from the FFT spectrum with a range of 0.2 Hz. Finally, KNN is used to classify emotions (normal, focused, sad, and shocked) and calculate accuracy using a confusion matrix.

4.1. Feature Extraction of Raw Data

As previously explained, FFT feature extraction with a sampling frequency of 512 Hz is used to convert the time domain signal from raw data to the frequency domain. We use MATLAB2016b software to do this process. The results of running the program can be seen in Figure 6 below.

The picture above shows the feature extraction program results, which produces two different forms of signal output with the same raw data input from subjects who have been given a stimulus in the form of listening to instrumental music. It can be seen that the signal in the time domain has data along with 2.13×10^5 ms with the highest amplitude of 631, which is in the range of 1.32×10^5 ms, while the signal in the frequency domain has data with a range of 0 - 50 Hz where the highest amplitude value is at a frequency of 2.26 Hz. These results will show a different value for each respondent due to different human brain wave activity against the given stimulus.

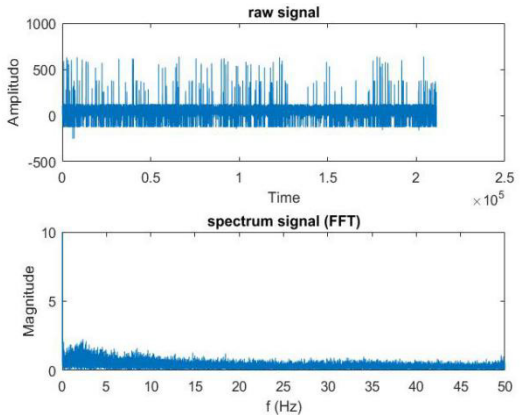

Figure 6: Feature extraction result of raw data

4.2. FFT Spectrum Comparison

In this stage, a comparison of four signal combinations resulted from FFT feature extraction that represented the subject's emotional condition. The results of running programs are shown in Figure 7.

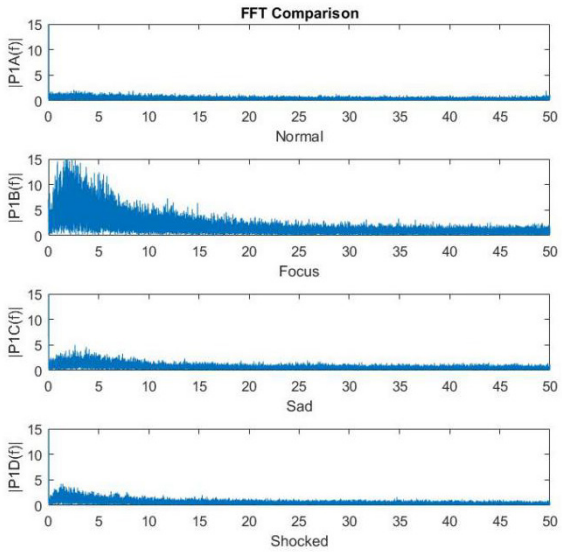

Figure 7: FFT spectrum of all emotional state

It can be seen that the spectrum of the FFT signal in four emotional states, namely Normal, Focus, Sad, and Shocked. When the spectrum is observed, there is a significant difference from the shape of the spectrum wherein the Focused and Normal emotional state, the difference in the form of the spectrum is very recognizable compared to the Sad and Shocked emotional states.

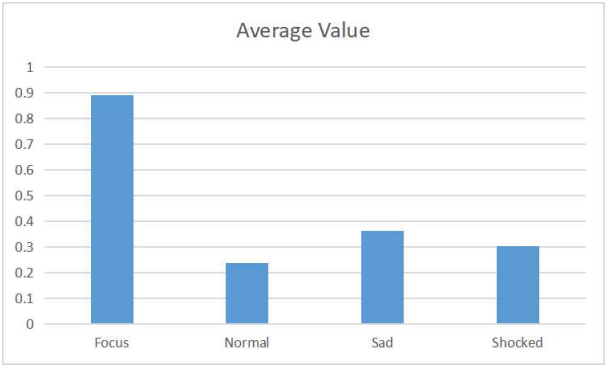

Figure 8: The average value of amplitude in the FFT spectrum

Then the amplitude value is compared to prove the truth of the observations. However, each spectrum with a frequency range of 0 - 50 Hz produces hundreds of thousands of data so that only the average value from data will be taken. Normal emotions get an average score of 0.2386, Focus 0.8904, Sad 0.3625, and Shocked 0.3044. Figure 8 shows the average value of the FFT spectrum.

From a comparison of the average values on each FFT spectrum, focus emotional state has the highest amplitude and lowest for Normal emotions, between Sad and Shocked emotions there is a small difference in the average results so that it can be proven the truth of observation result on the FFT spectrum.

4.3. Collecting Data Based on Spectrum Peaks

A reduction process is carried out at this stage at a frequency of 50 Hz to 10 Hz because the fluctuation of data values in the FFT spectrum always occurs at frequency range 0-10 Hz. Figures 9 to 12 show the results of the reduction process.

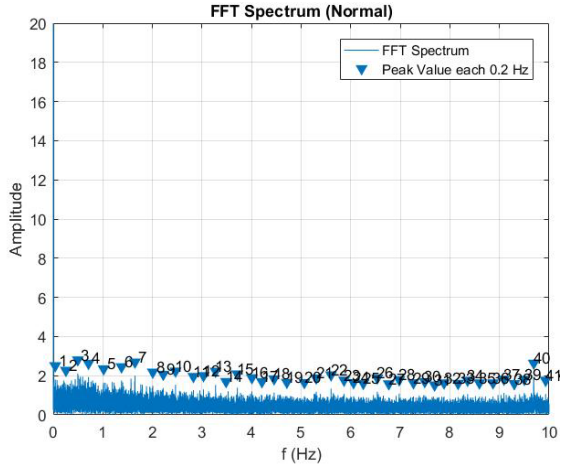

Figure 9: FFT Spectrum of Normal emotion

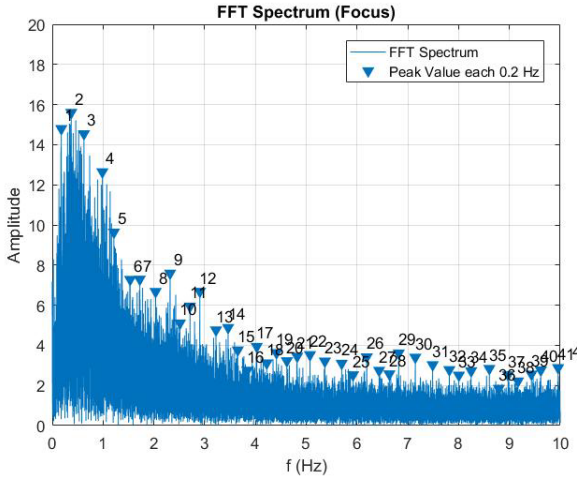

Figure 10: FFT spectrum of Focus emotion

The Values at the highest peaks of the marked frequency spectrum will be collected from the figure above. The frequency in the range 0 - 10 Hz produces 40 data by looking for the highest peak value every 0.2 Hz. Then, from 40 data, each 10 data's average value will be sought to produce four average values used

as material for the classification process. The results of the average value are shown in table 1.

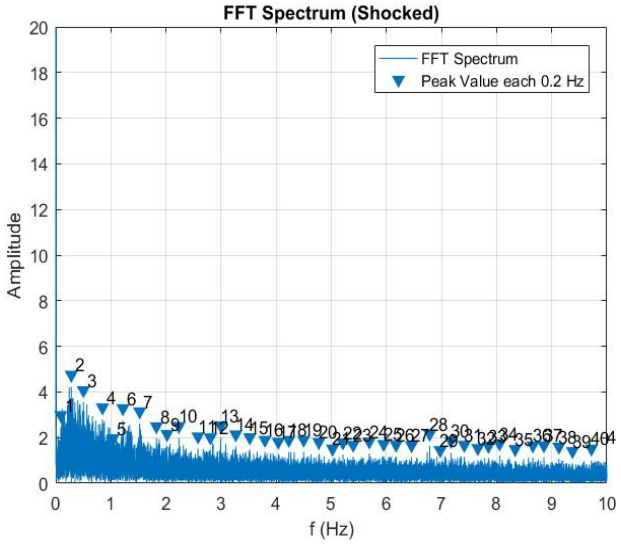

Figure 11: FFT spectrum of Shocked emotion

Table 1: Frequency average value

Focus	Normal	Sad	Shocked
8.891733187	1.908573527	4.199081623	3.059306615
3.371044125	1.2510798	2.052021058	1.633249441
2.851979474	1.124556395	1.583934658	1.250179144
2.597699756	1.202698894	1.554512291	1.136366638

If the reduction process is not carried out in the FFT spectrum, then based on the previous discussion (4.2), it is explained that the frequency in the range 50 Hz produces hundreds of thousands of EEG data and a minimum average value, which can complicate the classification process. We get between the results of previous observations and the current calculations to get very similar results from this process. It can be proven that the results of recording brain waves with the stimulus used to produce good data quality.

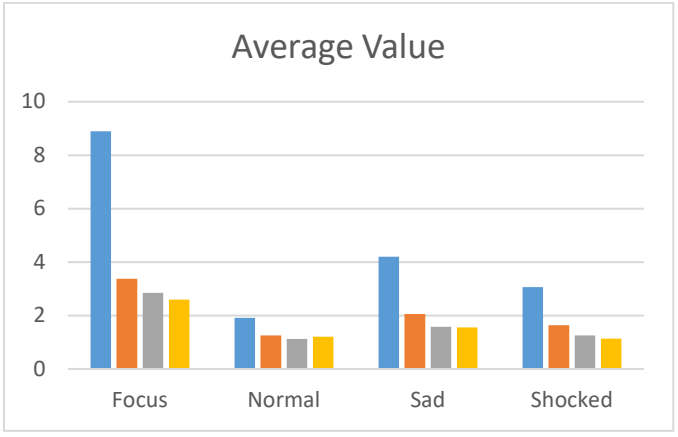

Figure 12: Average value of FFT based on spectrum peaks

4.4. KNN Classifier

In this process, 50 respondents studied and recorded brain waves four times obtained 200 data with 140 training data and 60 testing data. The KNN classification is then carried out to determine the results of the subject's actual emotional state from the 60-testing data.

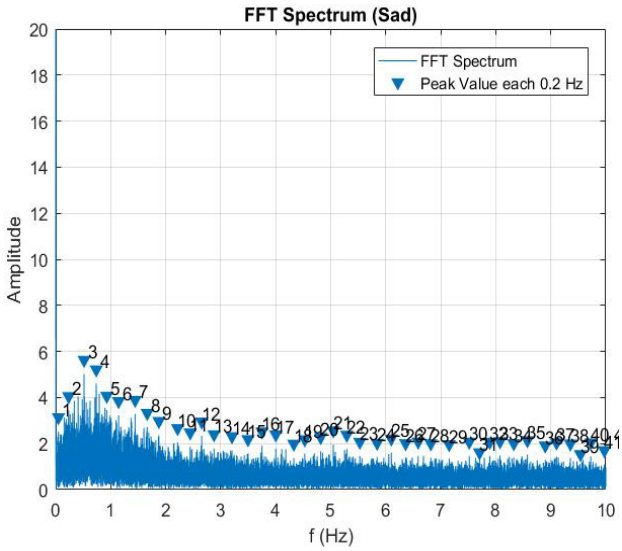

Figure 13: FFT spectrum of Sad emotion

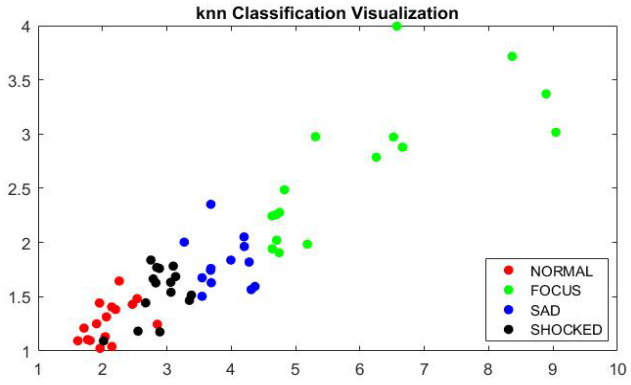

Figure 14: Visualization of KNN classification

The KNN classification results run through MATLAB2016b are displayed in a scatter chart and the coordinate points. It can be seen that each color at the coordinate point is a representation of the emotional condition of the subject, which forms a group based on the value obtained from 60 testing data. If observed, there are several color points whose coordinate values are closer to other neighboring groups. This indicates a change in the status of the color point. more clear results are shown in Table 2 below

Table 2: Result of KNN Classifier

	Match	Error	Match	Error	Match	Error
***k* Values**	**7**		**15**		**23**	
Normal	11	4	**13**	**2**	13	2
Focus	13	2	**14**	**1**	12	3
Sad	9	6	**12**	**3**	11	4
Shocked	12	3	**11**	**4**	12	3
Total	45	15	**50**	**10**	48	12

The table above shows that the KNN classification results using the k = 15 value are the best choice among k = 7 or k = 23. Sixty

test data produces 50 data that corresponds to the original emotional state status, and 10 data does not match. Then perform accuracy testing using the confusion matrix as in table 3 below.

Table 3: Accuracy result using confusion matrix

	Accuracy		
***k* Values**	**7**	**15**	**23**
Normal	73.33%	**86.66%**	86.66%
Focus	86.66%	**93.33%**	80.00%
Sad	60.00%	**80.00%**	73.33%
Shocked	80.00%	**73.33%**	80.00%
Average	74.99%	**83.33%**	79.99%

From the table above, the highest average accuracy is obtained from the results of the KNN classification using a value of k = 15 with a result of 83.33%, where the accuracy value of the focused emotional state gets the highest result of 93.33%, followed by a normal emotional state of 86.66%, 80% sad emotional state, and shocked get the lowest accuracy of 73.33%. Differences in accuracy results using the right stimulus dramatically affects the accuracy obtained. Regulations about sad emotions and focus are needed to help improve the accuracy of the results obtained.

5. Conclusion

This study aims to identify human emotions towards a given stimulus by applying the FFT method as feature extraction from the raw data generated by recording brain waves using the Neurosky Minwave mobile with the KNN method using the variable k = 15 to classify the FFT spectrum. Accuracy in each emotional state studied was performed using a confusion matrix where the best accuracy was obtained for Focus emotions as much as 93.33%, followed by Normal emotions 86.66%, Sad 80%, and Shocked getting the lowest accuracy results of 73.33%. The results of the average accuracy in the classification of brain waves were 83.33%. This research found that FFT and KNN can be used as alternatives in the EEG signal analysis method.

ABSTRACT

The 5G, as a new source of telecommunication infrastructure technology, has attracted many stakeholders to promote the progress of its standards and the development of its technology industry. The 5G reinforces new technologies and delivers vehicles for everything services (V2X) to drivers and passengers. It also offers several advantages. On the other hand, due to pervasive network connectivity, there are significant trust, security, and privacy issues for vehicles this affects the overall performance of 5G V2X. This paper provides a comprehensive review; and particularly; an overview of the mobile communication system and introduces the Next Generation (NG). additionally, the paper concentrates on the fifth-generation structure and its use cases. The 5G-V2X as a new field of communication requires more attention and focus, moreover, it aims to present the problems facing this new technology as well, and some future directions for research have been highlighted.

1. Introduction

Telecommunication changed radically in recent years, from traditional wired telephony oriented services to data-based services, from non-shrewd devices to smart handheld and versatile mobile computers.

Mobile ad hoc networks (MANET) formed a network without infrastructure because the mobile nodes in the network dynamically establish a path to transmit data packets. The strength of this network is its rapid development, robustness, flexibility, and mobility. With the rapid growth of this network and the massive focus on data creation through mobile phones and devices. Previous generations become unable to manipulate this data because they achieve their limits. For this purpose, a fifth-generation has been developed. The appearance of 5G has given several advantages to mobile involvement and some new technologies appear with it [1] to enhance communication between devices:

- Millimeter waves
- Small cells
- Massive multi-input multi-output (MIMO)
- Beamforming
- Full-duplex.

The 5G named also next-generation (NG), is emerging the network. Due to their capacity to handle large and diverse sets of devices, the NG is expected to bring a true wireless worldwide web (WWWW) which will have the ability to support massive data rates and a huge number of user applications and services. Moreover, it will reduce latency and will improve energy efficiency.

The 5G aims to create a networked society, where anyone can view and share information anytime from anywhere [2]. It will bring wireless connectivity for everything that is connected. Due to this fact, 5G faces some issues that can be summarized as follows:

- The number of connected devices has increased considerably;
- Traffic has increased significantly;
- Wide variety of applications with various characteristics and demands.

Our goal is to provide a detailed review where we will show the development brought to 5G and present some use cases and application of 5G, especially we will discuss the relation between 5G and V2X communication and application. This paper is an extension of an original work presented at the international conference of computer science and renewable energies (ICCSRE) [3]. In the previous article, we have shown that with the application of 5G the generation of data will increase. For that, it is essential to implement a dedicated storage method to manage this large

*Corresponding Author: Boughanja Manale, Salé,Morocco, 2126 68 81 32 32 & boughnja.manale@gmail.com

quantity of data. In this article, we will focus more on NG itself; explain the difference between 5G and prior generation, and some applications that allow generating this data. For this reason, our paper is organized as follows: In the first section, we will present an overview of the development of mobile networks. Then, we will introduce the 5G new radio access technologies in section two. We will provide some applications for 5G in section four. Further, in section five, we will introduce the 5G V2X application, and we will present the security issues that face the 5G V2X services. To address this security issue, we present some future directions for further studies to promote greater efforts on trust, confidence, assurance, and trustworthiness in 5G V2X services. Finally, we will conclude our paper.

2. Overview

So far, four generations of cellular communication systems have already been adopted [4]. Starting with the 1G that relies on an analog FM cellular system to 4G. With the huge interest in data creation and connected devices, the past generation achieved their limits. To deal with this problem the 5G has been created to solve the problem of the frequency spectrum cutting [5]. The 5G performances will develop later on with the progressive introduction of new technologies: use of millimeter waves, small cell, massive MIMO (or smart micro antennas), beamforming, and full-duplex [6], we will briefly explain those new advances.

- Massive MIMO: the concept was created in [7]. The purpose is to permit the system to achieve higher throughput. The massive MIMO can provide multiple services to various customers simultaneously in all directions.
- Millimetric waves: mobile wireless systems have been always in the band 300MHz - 3GHz. However, the spectrum becomes congested with the huge increase in mobile data traffic and the number of connected devices and the frequency band is coming to an end, creating a signal cutoff [8]. The proposed solution was to use millimeter waves. This latter refers to the wave between 30 and 300 GHz, and their wavelength varies between 1 and 10 mm [9].
- Small cells: are considered to be low-power radio switching equipment controlled by the administrator [10]. We can describe a small cell as a little power base station that will be very nearby to the usual towers and transmit the signal without having any break of connection or attenuation of the signal bypassing all obstacles.
- Beamforming: given the number of antennas used in 5G, the signal will be transmitted from the base station to the devices in an unmonitored manner [11]. This technique permits the orientating of the signal.
- Full duplex (FD): this technique brings to the device the capability to Send and get the data on the identical frequency band. FD improves the efficiency of the network.

The figure 1 summarizes those advances.

3. 5G new radio access technology

5G wireless is conceived to provide a connected environment, where information can be accessed and shared anywhere and anytime, by anyone and deliver a wireless connection for anything. However, with this requirement, the 5G will face several challenges like the volume of traffic the large variety of applications, and so on. To overcome this difficult task, 5G wireless access demands not just new functionality, but also a much more spectrum and larger frequency bands. The millimeter waves provide a huge spectral range, wide transmission bandwidth for the 5G [12]. The figure 2 shows the frequency spectrum.

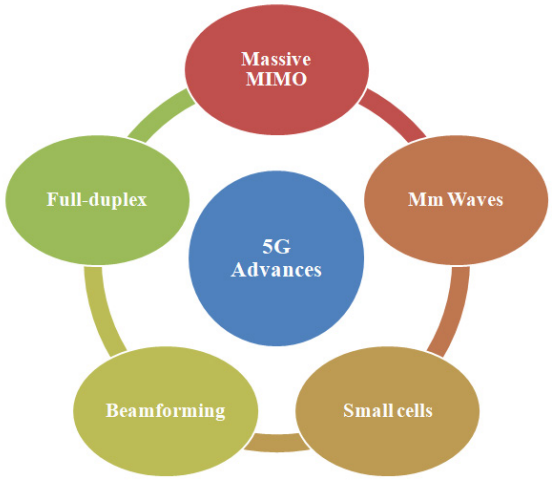

Figure 1: 5G Advances

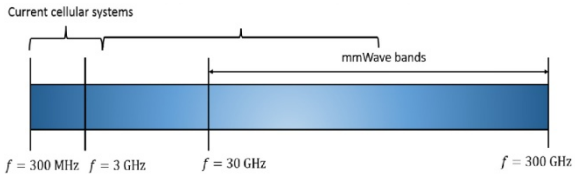

Figure 2: The frequency spectrum of the current and NG communication system

The past generations of cellular mobile systems were operating below 6 GHz frequencies, but with the implementation of the mm waves frequencies, much more spectrum is available and can deal with the huge amount of connected devices With the use of this principle in both 5G and Long Term Evolution (LTE), will have covered to have wireless access [13]. The appearance of 5G did not stop the evolution of LTE. LTE continues its evolution to meet the growing demand for 5G. This evolution is called the LTE evolution [14]. Figure 3 shows the LTE and 5G radio access.

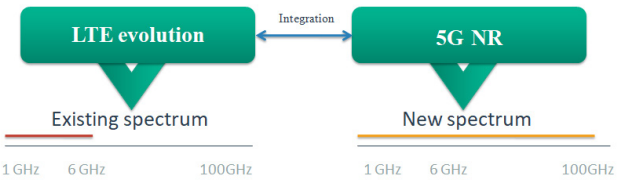

Figure 3: 5G radio access

3.1. Spectrum for 5G

Due to the lack of spectrum in the conventional mobile wireless band regulator started to envisage alternative approaches to manage the spectrum availability. For this reason, one of the major adjustments between the past generation of mobile communication and the fifth generation is the use of a higher frequency spectrum in the millimeter-wave interval [15]. It is about technological evolution and revolution, mixed to the spectrum. This approach is

made to make the spectrum more available with a higher frequency to exploit the frequency above 6 GHz and provide more bandwidth for mobile applications. The regulators have taken some measures for the proper functioning of the new generation among them:

- Spectrum sharing: technologies that will allow wireless broadband applications to operate bands assigned to multiple sites.
- Spectral efficiency: to minimize the bandwidth needed to supply a given quality of service level.
- Advanced MIMO: for higher modulation and lower signaling throughput.
- Densification: 5G communication system aims to get mobile customers closer to base stations, particularly by implementing a dense network of small cells.

All these developments reduce the amount of spectrum required for a single user, which indirectly leads to a greater spectrum availability to serve more users with an increased Quality of Services (QoS).

3.2. Use cases for 5G

5G will need to bring solutions for a variety of equipment running within a completely heterogeneous environment. The new human-centric applications include several fields: augmented reality, virtual reality, and gaming. This requires an extremely higher flow rate and reduced delay. In other words, we can differentiate two segments for machine-model communication:

- The Massive Internet of things (MIoT): which is categorized by a large number of low-cost device connections, in this case, a small amount of data supported by each device with extended battery lifetime and a wide range of coverage. This type is used more in the field of intelligent building, transport logistics, and agriculture.
- The critical internet of things (CIoT): shaped with highly dependable, extremely low-latency connectivity. For example, it can support autonomous vehicles, robotic surgery, and road safety.

Unlike previous products, 5G aims to bring improved support for a diversity of distinct services. 5G target three sets of use cases with very unique features:

- Enhanced Mobile Broadband (eMBB): This kind of use case is a direct extension of the conventional mobile broadband connection scenario based on the current mobile telecommunication standards. This set of boxes addresses broadband access everywhere, and in highly inhabited areas. This later provides the user with multiple services such as multimedia and 3D video [16].
- Large scale machine to machine communication (mMTC): with high latency and stability demands. This type of use case mainly relates machine to machine communication (MTC). It enables mobile communication with vehicles, this type requires simultaneous broadband and high mobility capacity. The problem with the mMTC that requires increased reliability and decreased latency [17].
- Ultra-Reliable Low Latency Communication (URLLC): the development of IoT is leading to a multiplication of wireless attached devices carrying TCM network traffic. It is intended that the expected number of these devices will soon surpass. The goal of mMTC is to provide the ability to connect a large set of equipment that may occasionally send a small quantity of data. mMTC devices are categorized by having long battery life and can be deployed remotely [16].

3.3. The key feature of 5G

The 5G was defined by the 3rd generation partnership project (3GPP) as a collection of key functionalities with associated parameters. In addition to the technological and protocolling environment and architecture inherited from the 4G system. We can summarize those technologies as follows:

- 3D MIMO: to ensure high performance in terms of spectral effectiveness. MIMO was firstly implemented in the LTE system was improved than the third generation [18]. The old system was composed of traditional antennas and composed of 8 to 10 elements stacked in a column, but with the evolution, restraint adjustments have been made and provide a downward tilt angle for network convergence. In this situation, the identical radio frequency (RF) pulses are delivered to everyone on the antenna. In such a manner, with the implementation of 3D MIMO, the signal will be simultaneously monitored in both the horizontal and vertical levels.
- Software-Defined Air Interface (IA): the fifth generation intended to handle various use scenarios and a broad range of the spectrum with a signal AI. For this reason, a unified framework was defined to handle different usage scenarios.
- User-Centric Network: to ensure the most suitable operator environment on the entire network, based on user requirements and the network conditions. Therefore, to provide a better user-centric experience the 5G network should handle a user context awareness where the network can serve the user more effectively when there is more information or expertise which means that the more information is loaded onto the network, the better the customer is served. Also, it should have the MEC functionality that includes traffic, security, transport isolation computing, and storage resources. Last and not least it should have a core network perspective to plan the use of the base stations.
- SDN/NFV: This technology enables the management and coordination of various network tranches on a shared physical infrastructure [19].

4. 5G applications

4.1. 5G and Mobile Ad Hoc Network

Mobile Ad Hoc Network (MANET) refers to a signal type of cellular network that contains mobile wireless nodes for communication [20]. These nodes are dynamically organized in random and volatile topologies. The utility to use the 5G for wireless communication in the field of MANET is to give more efficiency to the network. With the implementation of the NG, the MANET network achieves high levels of flexibility and intelligence. Figure 4 illustrates an example of MANET using the 5G connection.

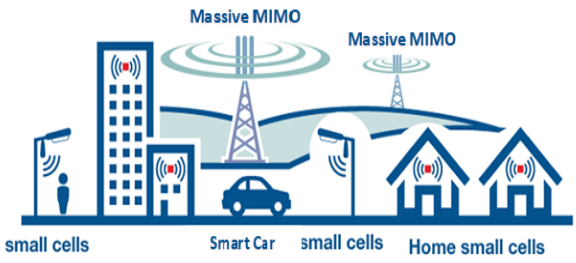

Figure 4: An example of MANET applied in 5G

The NG allows the connection of several devices and provides communication between multiple types of equipment. This communication can be classified into two different parts the device to device communication (D2D) and the vehicle for everything communication (V2X).

D2D communication: also known as proximity service communication (ProSe). The main objective of this functionality is to allow mobile devices to explore the presence of any other close devices within a radius of 500 meters and establish direct communication with it. The basic D2D procedures consist of three main steps:

- Device detection (ProSe discovery): detects if there are other devices nearby.
- Link parameters: establish a link between the associated devices.
- Data communication (ProSe communication): send or receive data via a set of links.

Figure 5 shows the D2D communication.

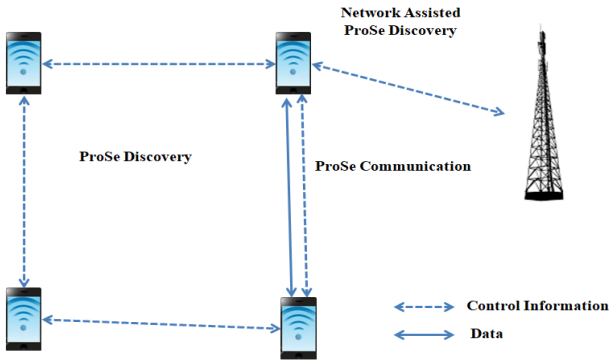

Figure 5: Basic ProSe procedure

V2X communication: are the exchanges between the vehicle and any device that may impact the vehicle, and the opposite. The X can for instance be on a different vehicle (V), an area of infrastructure (A/I), a pedestrian (P), a domicile (D), or any entity that communicates with the vehicle. We can summarize the cases of use of the vehicle with X as follows:

- Vehicular internet: user experience similar to that provided by their home and network.
- Pre-collision detection and mitigation: detect impending collisions and exchange relevant data from the vehicles involved.
- Cooperative vehicles: V2V and V2I communication to safely operate vehicles such as a train of autonomous cars on a highway.
- V2V information exchange: allows the vehicle to communicate on road to avoid any congestion.

5. 5G and V2X

The 5G mobile communication system will continue to emerge to meet unprecedented requirements beyond the capabilities of the past generations. The NG will not only be used for human interaction but also will be implemented in-vehicle communication. Therefore, the 5G has to support:

- Connection density: to handle million of demands and links across the square kilometer.
- Continuous latency from end to end.
- The density of road traffic volume: several dozens of terabytes created each second per square km.
- Mobility and maximum data rate.
- Network efficiency and high network capacity.

Continuous improvement and the increase in the number of applications have led to the development of new usages, in particular, that of connected objects. Vehicular communications or V2X communications allow vehicles to communicate in real-time with their environment to enhance road control, traffic performance, and energy savings. Figure 6 illustrates the different modes of communication, grouped under the term V2X.

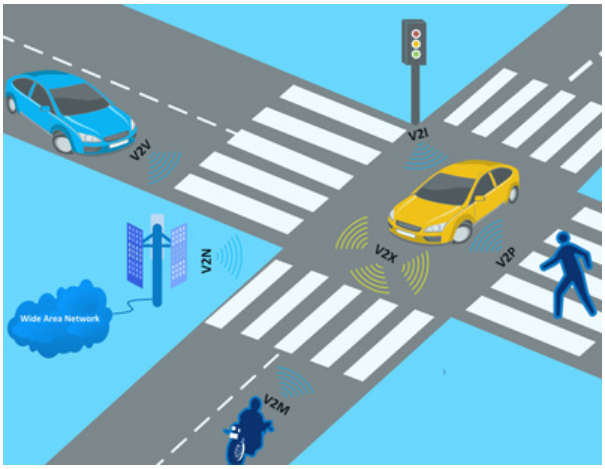

Figure 6: V2X communication modes

Embedded 5G will reform the experience of users in the transport sector (vehicles, subways, planes, trains, etc.), in particular by developing internet connectivity, which will make it possible to create an environment connected to the vehicle. V2X (Vehicle to Everything) communication technology will enable enormous changes the almost instantaneous exchange can be summarized as follows:

- Vehicle-to-vehicle (V2V): that permit inter-vehicle communication.
- Vehicle to infrastructure (V2I): it another type of communication that allows the vehicle to communicate with

its surrounding like the communication between the roadside unit and the vehicle.

- Vehicle to pedestrian (V2P); that permits the exchange between the vehicles and the pedestrian into the road.
- Vehicle to motorcycle (V2M): Communication between vehicles and motorcycles to decrease the high rate of collisions and deaths in motorcycle crashes.

The concept of a connected vehicle is based on sensors that operate in line-of-sight such as radars, cameras, or laser remote sensing. The 5G will play a key role in making road transport more efficient and safe. Indeed, the automotive industry will require a more robust, stable, and low-latency network.

5.1. 5G V2X architecture

The structure of the fifth generation and vehicle to everything architecture is based on four network levels:

- 5G Access Network;
- Network Edge;
- 5G Core Network;
- Data Network.

The 5G Access Network is composed of a Next Generation Radio Access Network (NG-RAN) or/and a non 3GPP access network, which interconnects the 5G Core Network and the User Equipment (UE). Figure 6 shows the 5G V2X architecture:

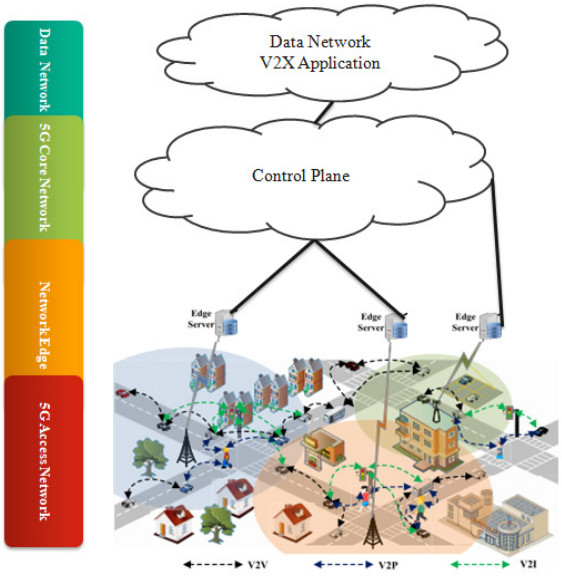

Figure 7: 5G V2X architecture

5.2. Security issues in 5G V2X services: problems and risks

Even though 5G guidelines are as yet being defined it will confront a few difficulties the moment of its implementation. The new radio (NR) will require a steady improvement in security. In this specified situation, portable security and oversaw security services are one of the most escalated areas regarding advancement, to react to the difficulties in the field of digital security inborn to computerized change for the communication service providers and their clients. Moreover, 5G vows to reshape services and advance development by providing an expanded transfer speed, multitenant edge processing, and a few creative services, high-data transmission networks, and high-bandwidth connectivity to machine learning and artificial intelligence (AI). The insurance of services in 5G V2X requires ground-breaking, versatile, and coordinated security. The implementation of 5G V2X brings with it several security threats. The attack on the vehicle can lead to serious problems and can affect all sides of the security requirement

- Attacks on availability: the attacks that focus on the availability of data are the riskiest in V2X communication since they have a real impact on the basic circumstances of well-being. We can find attacks such as the jamming attack which is a radio interference attack that can be carried out across any communication based on wireless technology.
- Attack on data integrity: where the attacker intercepts the data circulated into the network. the attacker can launch attacks such as GPS spoofing or even replay attacks.
- Attack on confidentiality: as an important security requirement in V2X communication and all sent data in the V2X should be secured. An attack such as eavesdropping and location tracking are launched in the network to break through the V2X confidentiality
- Attack on authenticity: Assuring authenticity consists of the process to verify that nodes are granted access to the network according to their identities using certificates and digital signatures. Some threats that infringed this requirement are certificate replication where the nodes use replicated certificates that were added to the blacklist. Moreover, the Sybil attacks where one node (the attacker node) pretends to be many identities in the road network.
- Attack on the non-repudiation: Non-repudiation is concerned with the ID of the effective node that is performing a particular behavior.

The table below shows some attacks that impact the security requirement:

Table 1: Threats of security for 5G V2X

Security Requirement	Attack	External	Internal
availability	Blackhole Grey hole	✓	×
	Flooding	✓	×
	Jamming	×	×
	Coalition	✓	×
data integrity	Messages Alteration	✓	×
	False messages injection	✓	×
	Replay	✓	✓
	GPS Spoofing	×	×
confidentiality	Eavesdropping	✓	×

	Location tracking	×	×
authenticity	Certificate replication	✓	✓
	Sybil	✓	✓
non-repudiation	Masquerading impersonation	✓	✓

5.3. Security solutions for 5G V2X communication

Vehicular communication experiences numerous difficulties, hence, guaranteeing safe communication is viewed as a complicated process due to the lack of safety features in both empowering innovations of the vehicle to everything interchanges, an additive safety scheme is required to secure vehicle networks. The fields of security for 5G V2X was not deeply discussed. In this section, we will try to gather the mean full strategy that has been implemented to secure the 5G V2X communication. In [21], they proposed a lightweight and protected navigation system for VANET. Each vehicle implements a cryptographic and digital signature to manage the secured correspondence process from the vehicle to the roadside unit (RSU). The system dealt with the replay attack and the man-in-the-middle attack. Another solution was proposed by [22], consisting of a trusted and smart forwarding protocol using double ciphering for data packets and implemented strong verification schemes to gauge the trust of the node. In [23], they proposed a new technique depends on a one-time Identity-Based confirmed asymmetric gathering key consent to make cryptographic blend areas that oppose malicious Eavesdroppers. There are several types of research have proposed potential solutions for 5G from a machine learning (ML) perspective. In [24], the authors suggested a monitoring system employing a Support Vector Machine (SVM) learning algorithm to prevent the replay attack. Also in [25] an anti-jamming methodology for auxiliary users to choose the correspondence channel and mobility. Another researcher [26], based on deciding the arrangements of conceivable interfacing neighboring vehicles, and design the boundaries reserving the joint V2V network. In [27], they have introduced a trusted and standard secure signature solution for collecting plain text for vehicle system applications. The authors in [28], have suggested an algorithm for VANET that delivers authenticate delivered messages. He gave oversight roles to some specified nodes referred to as verification nodes. The authors in [29], suggested a model framework as an IDS based on compartmental attacks. it addressed various attacks in VANET such as the black hole, wormhole, and Sybil attacks.

6. Discussion

This article presents the state of the art on 5G technology applied to transportation to make roads safer. The security of 5G V2X communication presents a great challenge, for this reason, a security layer should be added to strengthen security, and the communication must respect the CIA principle (confidentiality, integrity, and availability):

- Confidentiality concerns the condition under which the vehicle user has the right to know what information is sent by the On-Board Unit (OBU) and for how long this information exists.
- Integrity to verify that all data has been transferred.
- Availability, to ensure that the protocols must remain operational even in the event of a failure, and remains fault-tolerant and stabilize once the failure has been eliminated.

In addition to two other aspects: privacy, this technique implies the preservation of the privacy of the driver and the vehicle. Also, the authentication which consists of ensuring that the intended recipient receives messages from a real sender.

As we have already presented, many applications and solutions have been implemented to ensure the security of 5G V2X communication to preserve and maintain the security of users. We can summarize these in three categories:

- Identity-Based Cryptography (IBC): The concept of IBC is a cryptographic scheme very suitable for devices with limited computing resources. It has been presented in many articles, to encrypt and effectively sign the messages interchanged.
- Behavior-Based: The concept is quite simple this solution is based on the behavior of the attached vehicles communicating in the network and the messages transmitted by the RSU.
- Machine Learning-Based (ML): This provides threat and attack prediction based on suspicious network activities and anomaly detection. The implementation of ML enables automation, adaptability, and enables efficient orchestration and dynamic provisioning for scaled network resources cognition and prediction of mobility

Last and not least the security of such a network can be done depending on four parameters:

- Arrangement: shows if the model is mounted on a flat or cluster network.
- Structure: specifies if the model has used structured, distributed, or hybrid.
- Purpose: specify if the goal of the system is an IDS, the implementation of a safe route, or the protection of the message content.
- Targeted attacks: specifies the attacks handled in the model.

7. Open issues and future orientations

Open issues and future perspectives were highlighted in this section. Securing the 5G V2X is a quite difficult challenge, For this reason, both security solutions and possible cures for identified and unidentified menaces rely on 5G-V2X implementation approaches. We can divide two approaches for 5G V2X. The first one the V2X is implemented with non-autonomous-5G (NA-5G), possible assaults on LTE-V2X are real and can leverage 5G-V2X capabilities. However, with the second implementation Autonomous-5G (A-5G), the attack window diminishes and safeguarding from threats can be augmented. Network deployment plays a critical factor in the 5G-V2X security policy decision. for this purpose, we have encountered the security needs at two levels in the 5G V2X field:

- Secure network caching at the network edge: Storing commonly demanded data in the cache at the edges of storage is an important and effective way to decrease the delay of V2X operations. Yet, it is difficult to maintain the privacy of stored and buffered content, from which opponents can determine which are the relevant services for a given target. To ensure

network caching is secure, these key issues need to be resolved: knowing when and where to cache the desired data for a given vehicle, choosing trusted peripheral devices for data storage, and ensuring the confidentiality of buffered data when peripheral nodes are under attack. For this reason, cache placement could be well planned.

- Security-enhanced network slicing: The security and confidentiality of the grid segmentation have not yet gained a lot of attention. Therefore, it is essential to perform both authentication and authorization for a specified part of a network. For this reason, it is crucial to guarantee authentication with low latency to V2X services.

8. Conclusion and perspectives

Five generation and V2X services have expanded tremendously and have benefited our day-to-day lives. While providing a range of advantages to conductors and passengers on the road, 5G V2X's connectivity has as well raised several concerns about security, trust, and privacy. In this article, we have presented the fifth generation and its characteristics. Besides, we have identified the key challenges that face this new generation. We also briefly outlined the main issues in securing the 5G V2X by determining its issues of reliability, safety, and privacy. Finally, we brought some open issues and future orientations in this field. This latter should have more attention in the future our perspective is to build a system that will be able of securing the communication between the vehicle and everything basing on the 5G connection.

ABSTRACT

Forecasting the occurrence and development of thunderstorms near insured mobile objects, such as aircraft carriers, oil tankers, requires the usage of appropriate single-point monitoring systems (SPMS) of thunderstorm activity. These systems must be small and included in the equipment of the objects. A SPMS based on EH location finder meets the requirements of small dimensions. But the primary processing algorithms for them used to determine the location of the radiation source lead to errors in the calculation of the bearing per atmospheric discharge. This inevitably occurs due to the presence of an anomalous component of the magnetic field of an arbitrarily oriented dipole. The error depends on the orientation of the equivalent dipole of the radiation source. If the dipole moment is vertical, the error is minimal, otherwise the direction finding error is completely determined by the horizontal projection of the equivalent dipole and can be equal to π radians. Information of a thunderstorm activity collected by SPMS can be used by secondary processing algorithms to identify a real location of the thunderstorm foci. It is especially important when processing pre-storm radiation which consist of intra- and inter-cloud discharges. Secondary processing algorithms reduce errors by analyzing the parameters of all registered lightning discharges over a certain time interval. The proposed algorithms divide the entire space into a set of three-dimensional cells and determine the their grade of membership to a thundercloud or its projection. The presented methods for analyzing the location parameters of radiation sources defined across the entire set of received signals and ways to display them reduce the uncertainty of determining the coordinates of the thunderstorm location. Processing of pre-thunderstorm radiation is essential for predicting the development of thunderstorms.

1 Introduction

Predicting the occurrence and development of a thunderstorm near the insured object requires the development of appropriate single-point systems for monitoring thunderstorm activity. For mobile insured objects, such as aircraft carriers, oil tankers, these systems must be small and included in the equipment of the objects [1]. Primary processing algorithms which used to determine location of the radiation source can lead to errors in calculation the bearing of discharge. It inevitably occurs in a single-point monitoring systems (SPMS). The error depends on the orientation of the equivalent dipole of the radiation source. If the dipole moment is vertical then the error is minimal, otherwise the direction finding error is completely determined by the horizontal projection of the equivalent dipole and can be equal to π radians.

Information of a thunderstorm activity collected by a SPMS can be used by secondary processing algorithms to identify a real location of the thunderstorm foci. It is particularly critical when processing pre-storm radiation which consist of intra- and inter-cloud discharges. Secondary processing algorithms can reduce the uncertainty of determining the coordinates of the thunderstorm location by analyzing the location parameters of radiation sources that found for a time interval. This approach has been announced at "2019 Russian Open Conference on Radio Wave Propagation (RWP), Kazan, Russia" [2] in the field of study that deals with electromagnetic methods of lightning detection. This paper is an original extension of this work.

Each cloud and ground lightning flash consist of many individual physical processes. These processes can be associated with

[*]Corresponding Author: Anatoly Panyukov, Email: anatoly.panyukov@gmail.com

characteristic electric and magnetic fields. Lightning emits significant electromagnetic energy in the radio-frequency range from below 1 Hz to near 300 MHz. This electromagnetic radiation can be detected by lightning locating systems. Lightning data have utility in different areas of importance meteorological service organizations. Typically, meteorological organizations use this data to protect life and property. Commercial organizations use lightning data to provide weather warnings, forecasts to aviation, agriculture, energy, mass media.

There are plenty of lightning locating systems that uses different radio-frequency ranges, for example, the very low-frequency (VLF) range from 3 to 30 kHz, the low-frequency (LF) range from 30 to 300 kHz. Accurate lightning locating systems necessarily employ multiple sensors. But single-point passive monitoring system are also popular as they are inexpensive, mobile and do not require communication. Many companies are engaged in the production of such devices [3]–[6].

A challenging problem which arises in this domain is processing pre-thunderstorm radiation (that is before the first lightning flash). During the project ISTC 1822 [7] were recorded 2.5 million atmospherics and less than 10% were defined as a lightning discharge, the rest radiation were classified as pre-thunderstorm radiation. Algorithms used in multiple sensors systems require registration of the atmospherics by several sensors, it is not always possible. Otherwise, single-point systems generally filtered out this data or it processed incorrectly.

Algorithms to determine location of the radiation source uses the magnetic direction finding (MDF) technique to calculate the bearing of discharge. It works really well for multistation systems especially with combination with time of arrival (TOA) technique. But using MDF technique in SPMS leads to significant errors for the discharges whose equivalent dipole has an orientation different from vertical.

In general, the results of the project showed possibility of creating a new generation of passive thunderstorm detection systems to extend their functionality. One way to overcome these problems is not only revision of the technical characteristics of sensors, but also development of new mathematical models and algorithms for analyzing thunderstorm activity. The problem of identifying the position of thunderstorm foci is practically important to forecasting the development of thunderstorm. The registration of the cloud radiation by a single-point lightning protection system, for the purposes of forecasting thunderstorm development, can be reached by expansion of receiving hardware dynamic range and development of mathematical and software.

The standard model for the lightning discharge is based on a vertical dipole that cannot adequately represent all discharges. Modern methods of analyzing the electromagnetic radiation source (EMRS) field allow to determine the parameters of the EMRS location by many algorithms based on the dipole as a model of the EMRS [1], [8]–[10]. A more correct approach is to simulate a lightning discharge as a arbitrarily oriented dipole and it possible by using special a group of $E-H$ methods that allow arbitrary orientation of dipoles [11, 12]. These algorithms allow us to estimate the position parameters of this dipole: the distance to the radiation source and the pseudo bearing, and can be used for processing pre-thunderstorm radiation. In this case, signals from various sources of electromagnetic radiation are registered, the appropriate mathematical model of which is an arbitrarily oriented electric dipole. Processing signals from dipoles with a predominant horizontal projection leads to uncertainty in the estimation of the bearing on the [2, 12] discharge, which significantly reduces the quality of dipoles location detection. One way to reduce this uncertainty is to analyze the information received from all dipole sources.

The aim of the work is describing approach for the secondary processing of monitoring results of thunderstorm activity in VLF range, allowing to get plausible estimates of the location of a thunderstorm center based on its pre-storm radiation.

A review of the status of passive storm monitoring systems and the demonstration of the use of lightning-position detection systems for the passive radar of hazardous meteorological phenomena are presented in [8]. Modern methods for analyzing the field, allowing to determine the parameters of the EMRS, characterizing its location and orientation are presented in the works [12].

2 Primary processing of EMRS signal

Figure 1 shows the geometry of the problem: the earth's surface is plane Oxy, the observation point is origin O, the polar coordinates of the radiation source are r, ψ, θ , and the angular coordinates of the radiation source dipole moment are ψ_0, θ_0.

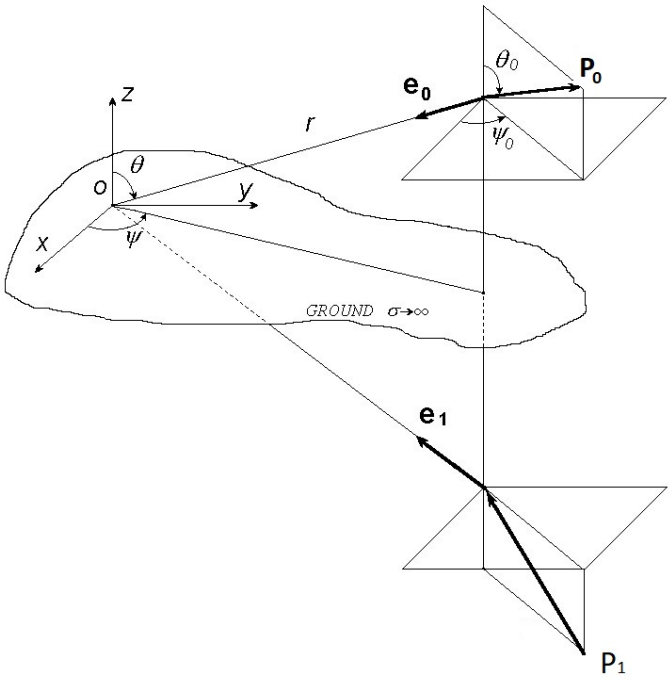

Figure 1: Geometry of the problem

There are a dipole $\mathbf{P_0}$ and an imaginary dipole $\mathbf{P_1}$ which is the mirror image of the dipole $\mathbf{P_0}$. $\mathbf{P_0}$ results a field $(\mathbf{E}, \mathbf{H})$ consisting of the field ($\mathbf{E}(\mathbf{P_0})$, $\mathbf{H}(\mathbf{P_0})$) of the source $\mathbf{P_0}$, and the reflected field represented by the field ($\mathbf{E}(\mathbf{P_1})$, $\mathbf{H}(\mathbf{P_1})$) of the $\mathbf{P_1}$.

The electric $\mathbf{E}$ and magnetic $\mathbf{H}$ components of the field in terms of the Cartesian system of coordinates with origin at the observation

point O and the O_z axis being the normal of the bounding plane have representation [9]

$$E_x = E_y = H_z = 0, \tag{1}$$

$$E_z = \frac{1}{2\pi\epsilon_0 c^2 r}\left\{p''[\cos\theta\sin\theta\sin\theta_0\cos(\psi-\psi_0) - \sin^2\theta\cos\theta_0] + \right.$$
$$\left. +(p'\alpha + p\alpha^2)[3\sin\theta\cos\theta\sin\theta_0\cos(\psi-\psi_0)]\right\} =$$
$$= \frac{w}{2\pi\epsilon_0 c^2 r}\left[p''u + (p'\alpha + p\alpha^2)(3u-2v)\right], \tag{2}$$

$$H_x = \frac{1}{2\pi c^2 r}(\sin\theta\cos\theta_0\sin\psi - \cos\theta\sin\theta_0\sin\psi_0)\,(p'' + p'\alpha) =$$
$$= \frac{w\sin\varphi}{2\pi c^2 r}\,(p'' + p'\alpha), \tag{3}$$

$$H_y = \frac{1}{2\pi c^2 r}(-\sin\theta\cos\theta_0\cos\psi + \cos\theta\sin\theta_0\cos\psi_0)(p'\alpha + p'') =$$
$$= -\frac{w\cos\varphi}{2\pi c^2 r}(p'\alpha + p''), \tag{4}$$

$$\alpha = \frac{c}{r}, \quad u = \sin\theta\cos(\phi-\psi), \quad v = \frac{\sin(\phi-\psi_0)}{\sin(\psi-\psi_0)}, \tag{5}$$

$$\tan\varphi = \frac{\sin\theta\cos\theta_0\sin\psi - \cos\theta\sin\theta_0\sin\psi_0}{\sin\theta\cos\theta_0\cos\psi - \cos\theta\sin\theta_0\cos\psi_0}, \tag{6}$$

c is speed of light in vacuum, ϵ_0 is permittivity of vacuum.

The values of the parameters r, φ, u, v are measured as a result of primary processing, for each pulse signal received from a radiation source [9]. The quality of estimating the location of an individual source is quite low. Really, a vertical dipole (that is when $\theta_0 = 0$) have

$$\varphi = \psi, \quad \sin\theta = u = \frac{1}{v}.$$

In other cases (that is for an inclined dipole) there is an uncertainty in determining the coordinates ψ and θ. As shown in the article in [9] they are bounded by

$$\arcsin u \le \theta \le \frac{\pi}{2}, \tag{7}$$

$$\varphi - \arccos u \le \psi \le \varphi + \arccos u. \tag{8}$$

The probability density for angles ψ and θ are

$$f_\psi(\eta) = \frac{s}{2\widehat{\psi}\,[s^2\cos^2(\varphi-\eta) + \sin^2(\varphi-\eta)]},$$
$$-\arccos u \le \eta - \varphi \le \arccos u, \tag{9}$$

$$f_\theta(\zeta) = \frac{su\cos\zeta\sin\zeta}{\widehat{\psi}\,(s^2u^2 - u^2 + \sin^2\zeta)\cdot\sqrt{\sin^2\zeta - u^2}},$$
$$\arcsin u \le \zeta \le \frac{\pi}{2}. \tag{10}$$

where

$$s = \left|\frac{1-vu}{uv}\right|, \quad \widehat{\psi} = \arctan\left(\frac{1}{s}\tan\arccos u\right). \tag{11}$$

It's easy to see that for $s < 1$, that is for θ_0 approaching the vertical,

$$\varphi = \arg\max_{\eta:\,-\arccos u\le\eta-\varphi\le\arccos u} f_\psi(\eta), \tag{12}$$

$$\arcsin u = \arg\max_{\zeta:\arcsin u\le\zeta\le\frac{\pi}{2}} f_\theta(\zeta), \tag{13}$$

in other words, the maximum likelihood estimates are the same as for the vertical dipole: $\psi = \varphi$ and $\theta = \arcsin u$; and for $s \ge 1$, that is for orientation with a significant horizontal component, poor angular resolution is gained.

An adequate mathematical model of the pre-thunderstorm EMRS is an inclined electric dipole with a predominance of the horizontal component. Processing signals from dipoles with a predominant horizontal projection leads to uncertainty in the estimation of the angle coordinates of the [2, 9] discharge, which significantly reduces the quality of dipoles location detection.

The multipoint system of passive monitoring of thunderstorm activity not only removes the uncertainty of location [9], but also allows to determine the orientation of the dipole [13, 14]. Nevertheless, the improvement of forecasting methods using single-point systems remains relevant [15, 16].

One way to reduce the uncertainty of thunderstorm location is to analyze the information received from all dipole sources for time T.

The purpose of secondary processing is to estimate the location of the thunderstorm center by information about all dipoles location parameters for time T.

3 Secondary processing of EMRS signals from thunderstorm foci

It is known that the Cartesian coordinates x, y of the possible position of the EMRS satisfy the condition [9]:

$$x\cos\varphi + y\sin\varphi = r\sin\theta\cos(\varphi-\psi) = ru, \tag{14}$$

which determines the OXY projection of the EMRS possible positions set. The coordinates of the possible location EMRS belong to the set of solutions of the system of equations

$$x\cos\varphi + y\sin\varphi = ru, \qquad x^2 + y^2 + z^2 = r^2. \tag{15}$$

Let S be set of all solutions of (15) system. In general, S is multiple.

Entire space divided into $4N^3$ cells:

$$C(i,j,k) = \left\{ (x,y,z) \;\middle|\; \begin{array}{l} i\Delta \le x \le (i+1)\Delta \\ j\Delta \le y \le (j+1)\Delta \\ k\Delta \le z \le (k+1)\Delta \end{array} \right\}, \quad k = 0,\,1,\,\ldots,\,N,$$
$$i,\,j = -N,\,-N+1,\ldots,-1,\,0,\,1,\,\ldots N. \tag{16}$$

The OXY plane is divided into flat cells

$$C(i,j) = \{(x,y):\; i\Delta \le x \le (i+1)\Delta,\; \Delta \le y \le (j+1)\Delta,$$
$$i,\,j = -N,\,-N+1,\ldots,-1,\,0,\,1,\,\ldots N\}, \tag{17}$$

and OZ axis of the coordinate system $OXYZ$ to be divided into segments

$$C(k) = \{z:\; k\Delta \le z \le (k+1)\Delta\}, \quad k = 0,\,1,\,\ldots,\,M.$$

In the future we will use the following notation:

$$C_{OXYZ}(r,u,\varphi) = \{(i,j,k) \mid C(i,j,k) \cap S \neq \emptyset\}$$

is set of cells in which the EMRS can be locate with a non zero probability;

$$C_{OXY}(r,u,\varphi) = \{(i,j) \mid \exists k:\ C[i,j,k] \cap S \neq \emptyset\}$$

is OXY projection of set $C_{OXYZ}(r,u,\varphi)$;

$$C_{OZ}(r,u,\varphi) = \{k \mid \exists C(i,j):\ C(i,j,k) \cap S \neq \emptyset\}$$

is OZ projection of set $C_{OXYZ}(r,u,\varphi)$.

For each cell containing solutions of the (15) system, we find the probability that the EMRS belongs to this cell when some hypothesis is fulfilled. In the future, we will use the found probabilities to build a three-dimensional map of the membership level of cells that are part of the thunderstorm center.

3.1 Hypothesis H_1: Uniform probability distribution on $C_{OXY}(r,u,\varphi)$

It is following from (15) that on the OXY plane, the valid points farthest from the origin of the coordinates are $(x_1,\ y_1)$ and $(x_2,\ y_2)$

$$x_{1,2} = r(u\cos\varphi \mp \sqrt{1-u^2}\sin\varphi), \tag{18}$$

$$y_{1,2} = r(u\sin\varphi \pm \sqrt{1-u^2}\cos\varphi, \quad z_{1,2} = 0. \tag{19}$$

The coordinates x, y for all possible ERMS positions belong to segment $[(x_1,y_1),\ (x_2,y_2)] \subset OXY$ between the points (x_1,y_1) and (x_2,y_2). The all possible radiation source locations can be represented in a parametric form as the set of points:

$$\mathcal{L}(r,u,\varphi) = \left\{ \begin{array}{c} x(\lambda) = ru\cos\varphi + \\ +r(2\lambda-1)\sqrt{1-u^2}\sin\varphi, \\ y(\lambda) = ru\sin\varphi + \\ +r(1-2\lambda)\sqrt{1-u^2}\cos\varphi, \\ z(\lambda) = 2r\times \\ \times\sqrt{\lambda(1-\lambda)(1-u^2)} \end{array} \middle| \ 0 \le \lambda \le 1 \right\}. \tag{20}$$

Let

$$\Lambda = \left\{0,\ \frac{1}{N},\ \frac{2}{N},\ \ldots,\ \frac{N-1}{N},\ 1\right\}.$$

It is following from (20) that points $(x(\lambda), y(\lambda)),\ \lambda \in \Lambda$ are evenly distributed on the segment $[(x_1,y_1),\ (x_2,y_2)]$, and

$$[(x_1,y_1),\ (x_2,y_2)] \quad \subset \bigcup_{(i,j)\in C_{OXY}(r,u,\varphi)} C(i,j).$$

If the hypothesis on uniform probability distribution on $C_{OXY}(r,u,\varphi)$ is accepted, there are equalities

$$C_{OXYZ}(r,u,\varphi) = \left\{(i,j,k)\ :\ i = \left\lfloor\frac{x(\lambda)}{\Delta}\right\rfloor,\ j = \left\lfloor\frac{y(\lambda)}{\Delta},\right\rfloor\ k = \left\lfloor\frac{z(\lambda)}{\Delta}\right\rfloor,\ \lambda\in\Lambda\right\},$$

$$C_{OXY}(r,u,\varphi) = \left\{(i,j)\ :\ i = \left\lfloor\frac{x(\lambda)}{\Delta}\right\rfloor,\ j = \left\lfloor\frac{y(\lambda)}{\Delta}\right\rfloor,\ \lambda\in\Lambda\right\}.$$

Let

$$N(i,j,k) = \mathrm{card}\,\{\lambda\in\Lambda\ :\ (x(\lambda),\ y(\lambda),\ z(\lambda)\in C(i,j,k))\},$$

$$N(i,j) = \sum_{k\in C_{OZ}(r,u,\varphi)} N(i,j,k), \quad .$$

Then, the probability of EMRS in cell $C[i,j,k]$ is equal to

$$\mathrm{P}_{OXY}(i,j,k) = \frac{N(i,j,k)}{N(i,j)\cdot N}.$$

3.2 Hypothesis H_2: Uniform probability distribution on $C_{OZ}(r,u,\varphi)$

It follows from (15) that the set of points of all possible locations of EMRS can be represented in a parametric form other than (20) :

$$\mathcal{L}(r,u,\varphi) = \left\{ \begin{array}{c} x(z) = ru\cos\varphi \pm \sqrt{r^2(1-u^2)-z^2}\sin\varphi, \\ y(z) = ru\sin\varphi \mp \sqrt{r^2(1-u^2)-z^2}\cos\varphi, \\ z:\ \ 0\le z\le \sqrt{r^2(1-u^2)} \end{array} \right\}. \tag{21}$$

Let

$$M = \left\lfloor\frac{\sqrt{r^2(1-u^2)}}{\Delta}\right\rfloor, \quad Z = \{0,\ \Delta,\ 2\Delta,\ \ldots,\ M\cdot\Delta\}. \tag{22}$$

It is following from (22) that points $z\in Z$ are evenly distributed on the segment

$$[0,\ \sqrt{r^2(1-u^2)}] \quad \subset \bigcup_{k:\in C_{OZ}(r,u,\varphi)} C[k].$$

If the hypothesis on uniform probability distribution on $C_{OZ}(r,u,\varphi)$ is accepted, there are equalities

$$C_{OXYZ}(r,u,\varphi) = \left\{(i,j,k)\ :\ i = \left\lfloor\frac{x(z)}{\Delta}\right\rfloor,\ j = \left\lfloor\frac{y(z)}{\Delta},\right\rfloor\ k = \left\lfloor\frac{z}{\Delta}\right\rfloor,\ z\in Z\right\},$$

$$C_{OXY}(r,u,\varphi) = \left\{(i,j)\ :\ i = \left\lfloor\frac{x(z)}{\Delta}\right\rfloor,\ j = \left\lfloor\frac{y(z)}{\Delta}\right\rfloor,\ z\in Z\right\}.$$

Let

$$M(i,j,k) = \mathrm{card}\,\{z\in Z\ :\ (x(z),y(z),z)\in C(i,j,k)\},$$

$$M(k) = \sum_{[i,j]\in C_{OXY}(r,u,\varphi)} M(i,j,k), \qquad k:\ k\cdot\Delta\in Z,$$

then

$$\mathrm{P}_{OZ}(i,j,k) = \frac{M(i,j,k)}{M(k)\cdot M}.$$

3.3 Hypothesis H_3: Uniform probability distribution on $C_{OXYZ}(r, u, \varphi)$

Since (20) and (21) give different representations of set $\mathcal{L}(r, u, \varphi)$, there are also two ways to represent a set of cells with a non-zero probability of having the EMRS:

$$C_{OXYZ}(r, u, \varphi) = \{(i, j, k) : \ \mathrm{P}_{OXY}(i, j, k) > 0\} = \\ = \{(i, j, k) : \ \mathrm{P}_{OZ}(i, j, k) > 0\}.$$

If the hypothesis on uniform probability distribution on $C_{OXYZ}(r, u, \varphi)$ is accepted, we have

$$\mathrm{P}_{OXYZ}(i, j, k) = \frac{1}{\operatorname{card} C_{OXYZ}(r, u, \varphi)}, \quad (i, j, k) \in C_{OXYZ}(r, u, \varphi).$$

3.4 Three-dimensional map of the level belonging of thunderstorm foci to space cells

So, for each cell containing solutions of the (15) system, we found the probability that the EMRS belongs to this cell when hypothesis $H \in \{H_1, H_2, H_3\}$ is fulfilled. Let us use the found probabilities to build a three-dimensional map of the membership level of cells that are part of the thunderstorm center when hypothesis H is fulfilled.

The set of discharges registered for the time period T is defined as $R(T)$. The cell grade membership to thunderstorm of the radiation source defined as the sum of all of radiation during this period.

$$\operatorname{grade}_H^{R(T)}(i, j, k) = \frac{\sum\limits_{d \in R(T)} \mathrm{P}_H(i, j, k)(d)}{\max\limits_{(l,m,n)} \sum\limits_{d \in R(T)} \mathrm{P}_H(l, m, n)(d)}. \qquad (23)$$

Further we demonstrate the possibility to estimate the thunderstorm center location by (23) formula applying simulation.

4 Simulation

Let's define two artificial thunderstorms $R_1(T)$ and $R_2(T)$ for modeling purposes. All discharges of the thunderstorms will have the same location $R = 60$ km, $\Delta = 10$ km, $\psi = \pi/4$, $\theta = \pi/3$.

Figures 3–8 demonstrate the observation point ($x = 0$, $y = 0$, $z = 0$) and the thunderstorm location cell is $C(i = 3,\ j = 3,\ k = 3)$ (marked with a blue square). Cell color shows the cell grade membership level to the thunderstorm (see figure 2).

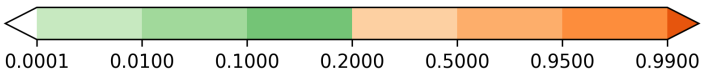

Figure 2: Scale of the level of belonging of a cell to a thunderstorm center

The $R_1(T)$ emits 256 pulse signals from dipole radiation sources with orientation $\psi_0 \in \{\pi k/16 : \ k = 1, 2, \ldots, 32\}$, $\theta_0 \in \{\pi k/8 : k = 0, 1, \ldots, 8\}$, that is EMRS are different incline dipoles, which is typical for a thunderstorm center. Location parameters values r, u, v, φ are calculated by (5)-(6) formulas.

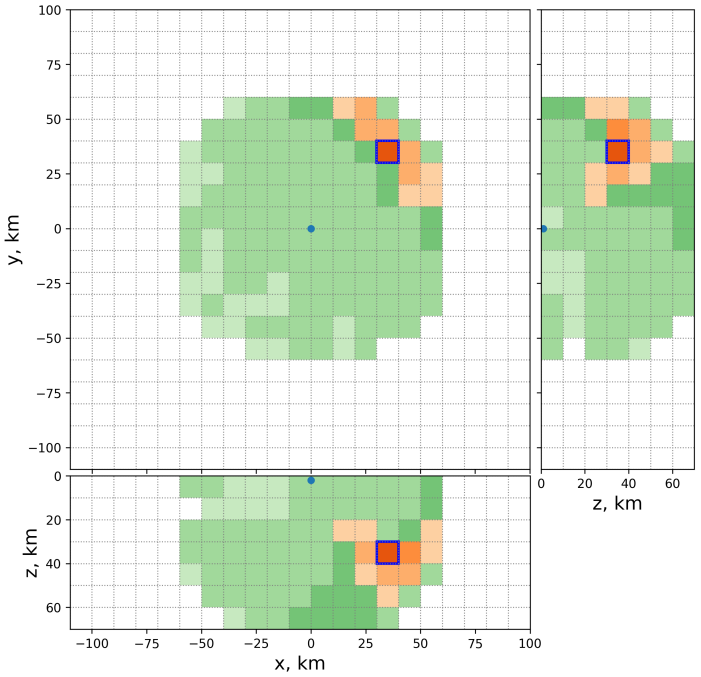

Figure 3: Map of $R_1(T)$ under hypothesis H_1

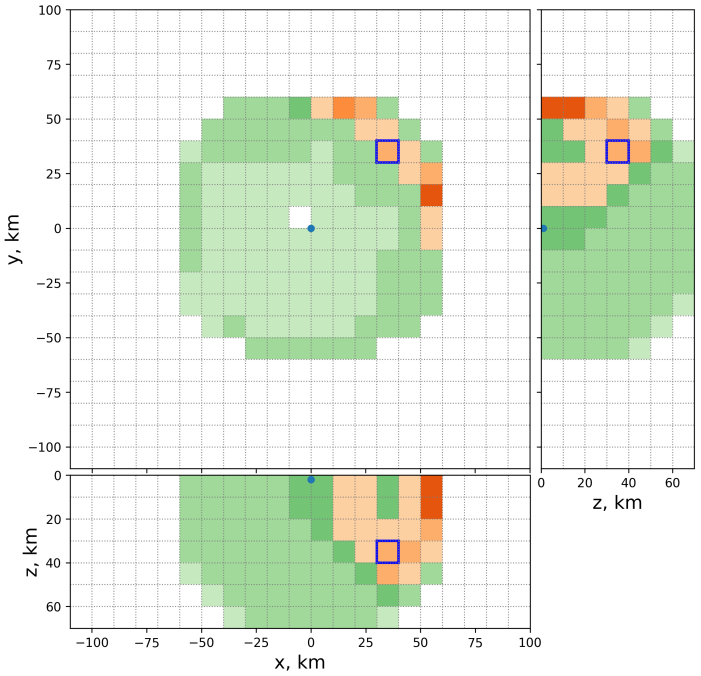

Figure 4: Map of $R_1(T)$ under hypothesis H_2

Figures 3–8 demonstrate three projections of the three-dimensional map of thunderstorm foci $R_l(T)$, $l \in \{1, 2\}$ level belonging to space cells under hypothesis $H \in \{H_1, H_2, H_3\}$

$$\operatorname{grade}_H^R(T)(i, j) = \sum_k \operatorname{grade}_H^R(T)(i, j, k), \qquad (24)$$

$$\operatorname{grade}_H^R(T)(i, k) = \sum_j \operatorname{grade}_H^R(T)(i, j, k), \qquad (25)$$

$$\text{grade}_H^R(T)(j,k) = \sum_i \text{grade}_H^R(T)(i,j,k). \quad (26)$$

Figure 3 demonstrates the belonging of desired cell to cell with maximum level of membership. Figure 4 demonstrates that the desired cell does not belong to cells with maximum level of membership. Figure 5 demonstrates the belonging of desired cell to cell with maximum level of membership.

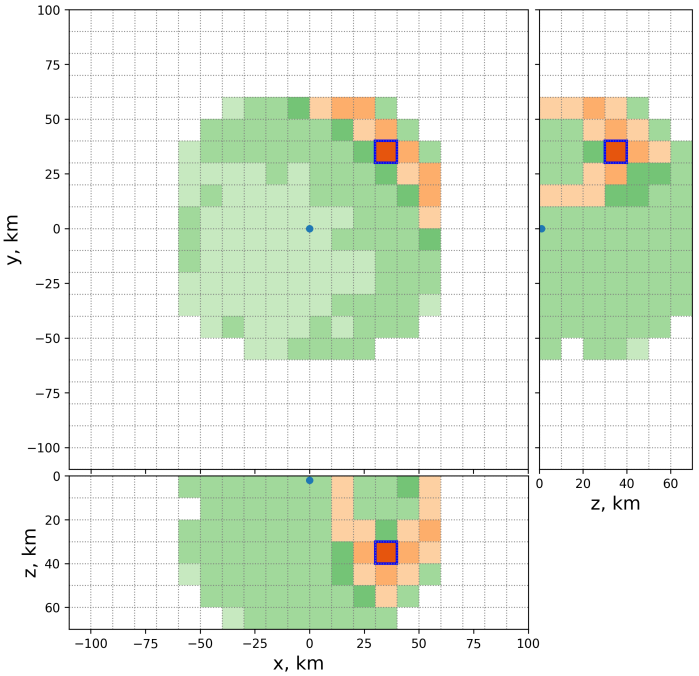

Figure 5: Map of $R_1(T)$ under hypothesis H_3

Figures 3, 5 make it possible to identify the desired cell $C(i = 3, j = 3, k = 3)$. Figure 4 does not allow to identify the desired cell at all.

Table 1 shows cells with grade membership level to the thunderstorm $R_1(T)$ no less 0.9 and similar to visual analysis of the projections hypothesis H_1 and H_3 found the desired cell.

Table 1: Cells with grade membership level to the thunderstorm $R_1(T)$ no less 0.9

Hypothesis	$C_{OXYZ}(r,u,\varphi) \cap \{(i,j,k) : \text{grade}_H^{R_1(T)}(i,j,k) > 0.9\}$
H_1	$\{(3,3,3),\ (3,2,3),\ (4,3,3)\}$
H_2	$\{(1,5,0),\ (1,5,1),\ (3,3,4),\ (5,1,0),\ (5,1,1)\}$
H_3	$\{(3,3,3)\}$

But the best hypothesis is hypothesis H_3, because it will allow to identify the cell with a thunderstorm center uniquely and accurately.

The $R_2(T)$ has the same location as $R_1(T)$ but emits only 100 pulse signals from dipole radiation sources with orientation $\psi_0 \in \{2\pi k/100 :\ k = 1,2,\ldots,100\}$, $\theta_0 = \pi/2$, that is EMRS are different horizontal dipoles, which is typical for a pre-storm center. Location parameters values r, u, v, φ are calculated by (5)-(6) formulas.

Figures 6–8 demonstrate three projections of the three-dimensional map of thunderstorm foci $R_2(T)$ level belonging to space cells under hypothesis $H \in \{H_1, H_2, H_3\}$.

Figure 6 demonstrates that the desired cell does not belong to cells with maximum level of membership.

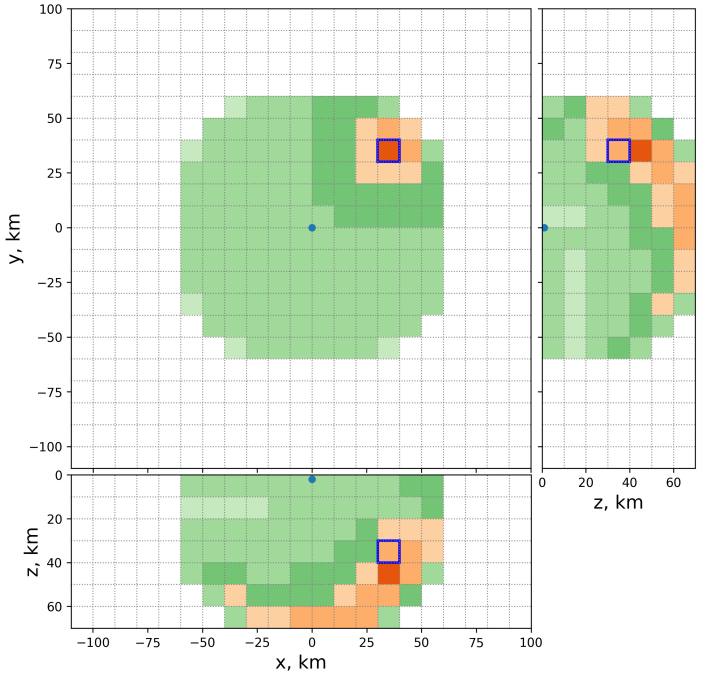

Figure 6: Map of $R_2(T)$ under hypothesis H_1

Figure 7 demonstrates that the desired cell does not belong to cells with maximum level of membership.

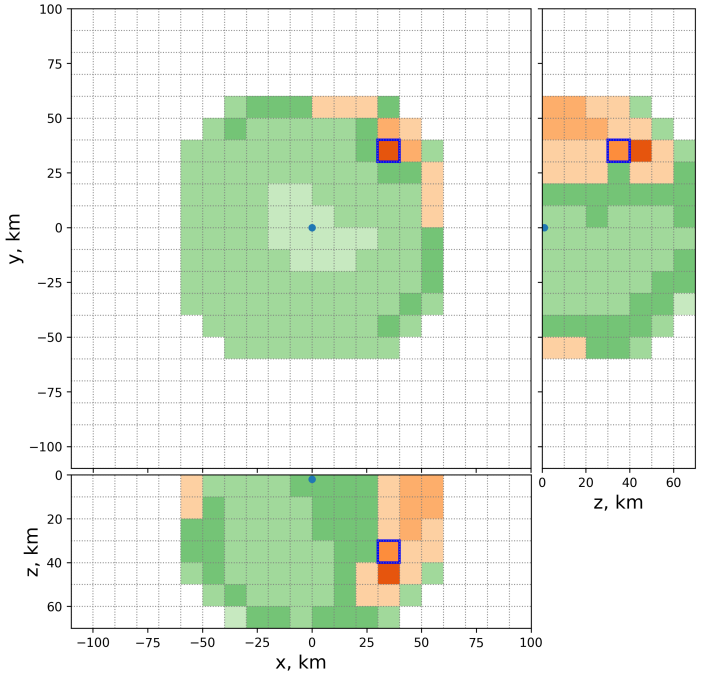

Figure 7: Map of $R_2(T)$ under hypothesis H_2

Figure 8 demonstrates that the desired cell belong to cells with maximum level of membership only.

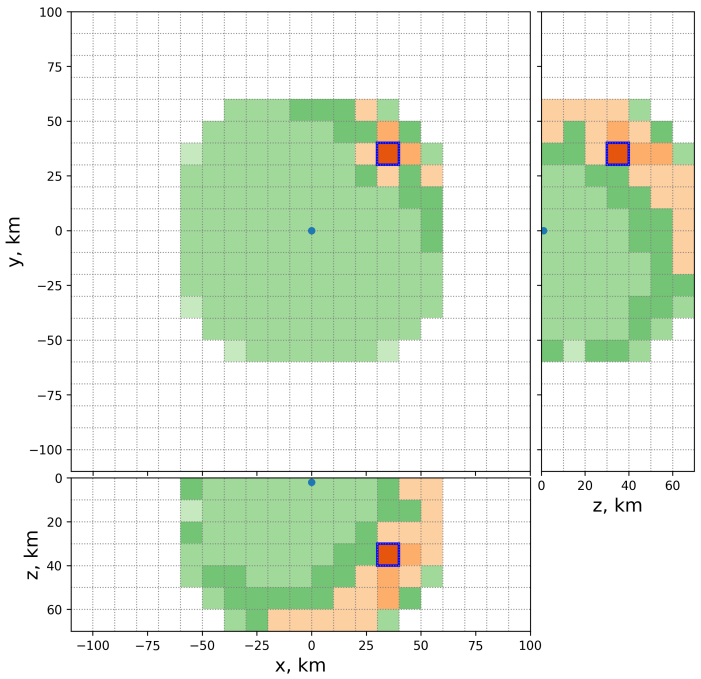

Figure 8: Map of $R_2(T)$ under hypothesis H_3

Table 2 also shows the best hypothesis is H_3. Hypotheses H_1 and H_2 maps do not contains the desired cell and does not allow to unambiguously establish the location of the foci.

Table 2: Cells with grade membership level no less 0.9 to the thunderstorm $R_2(T)$

Hypothesis	$C_{OXYZ}(r,u,\varphi) \cap \{(i,j,k):\ \text{grade}_H^{R_2(T)}(i,j,k) > 0.9$
H_1	$\{(3,3,4)\}$
H_2	$\{(3,3,4)\}$
H_3	$\{(3,3,3),\ (3,3,4)\}$

5 Conclusion

These findings provide a potential new technique to processing of the results of thunderstorm activity monitoring in the VLF range. The processing of all data from the SPMS during thunderstorm activity introduces a lot of uncertainty and makes it difficult to determine the real location of the thunderstorm center. The methods of analysis and visualization of the entire set of received signals presented in this paper reduce the uncertainty in determining the coordinates of the thunderstorm location. Processing of pre-thunderstorm radiation is significantly important to forecasting the development of thunderstorm.

The artificial single-point thunderstorm model described in the paper is a very simple, which is very convenient for research, however, a real thunderstorm can have a more complex structure, therefore it is important to carry out modelling with more complex models of thunderstorms, for example, check the proposed approaches for their ability to identification of multiple foci. This is an interesting topic for future work.

In future work, investigating another hypothesis of probability that the EMRS belongs to cell might be important.

ABSTRACT

The apple tree (Malus domestica) is an agricultural species of great importance in Morocco. Currently, it occupies about a quarter of the surface of fruit-bearing rosaceae. Apple tree production has evolved rapidly, stimulated by a buoyant market, a varietal range which is tending to diversify and a dynamic profession. The present study aims to determine the physico-chemical properties of soil and apple leaves in Beni Mellal-Khenifra region, Morocco. Data collection was consisted to sample the soils at different depths, three Pearson correlation coefficients were determined: i) Correlation between organic matter and soil mineral elements, ii) Correlation between clay content and soil mineral elements and correlation between CaCO3 content and soil mineral elements. The analytical results of soils were compared to reference values. The results show that there is no correlation between these mineral elements and the rate of CaCO3 and clay fraction. Analysis of the main components showed that the apple leaf contains more sodium, copper and zinc and less magnesium, phosphorus and potassium. The coefficient of variation (CV) of manganese content expressed as a percentage is significantly higher than that of the other elements, while the potassium content is the lowest, in particular for magnesium and sodium the coefficient of variation is zero. In apple orchards in the Middle Atlas, there are great variations in terms of yield levels, fertilizer inputs, soil richness in nutrients and their concentration at leaf level. These variations are due to differences in cultivation practices, in particular fertilization, because the relationship between apple yield and nutrient content at soil and leaf level is significant.

1. Introduction

The agricultural sector plays a key role in economic activities in Morocco. Likewise, it represents a strong support to the development of the country because it constitutes a higher percentage of 20% of the gross domestic product and employs about 40% of the active population [1, 2].

In Morocco, the apple tree (*Malus domestica*) is the species, which occupies the largest surface in terms of fruit rosaceae. Currently, orchards planted with apples total 32,000 ha, or about a quarter of the surface area of fruit-bearing rosaceae. Annual production is estimated at 560-600,000 tonnes, based on an average yield of around 20 T/ha [3]. However, Intensive agriculture and the search for new fertile land put pressure on the ecosystem, which in turn leads to reduced soil fertility [4, 5]. As a result, yields are relatively low and land productivity decreases. There are several types of soils in Morocco which have developed on different geological substrates and in various climatic, topographical and biotic contexts. These soils must be protected as a natural resource because it contains substances essential to the maintenance of ecosystems and human populations, such as essential minerals. this study is carried out in the Beni Mellal-Khenifra region which is characterized by a variety of soils and by the predominance of fertile types rich in organic matter which allows an important agricultural activity, in particular for apple trees [6]. So far, interpretation of soil and leaf analyzes for

*Corresponding Author, El Mahjoub Aouane, University Campus BP 133 Kenitra, Morocco. Email: aouane_mahjoub@yahoo.fr

Moroccan apple orchards has been limited. For this reason, the main objective of our study is to determine the physicochemical properties of soil analysis and apple leaves in the Beni Mellal-Khenifra region in Morocco. More specifically, i) Determining the correlation coefficients between organic matter and soil mineral elements, ii) Correlation between clay content and soil mineral elements and correlation between CaCO3 content and soil mineral elements.

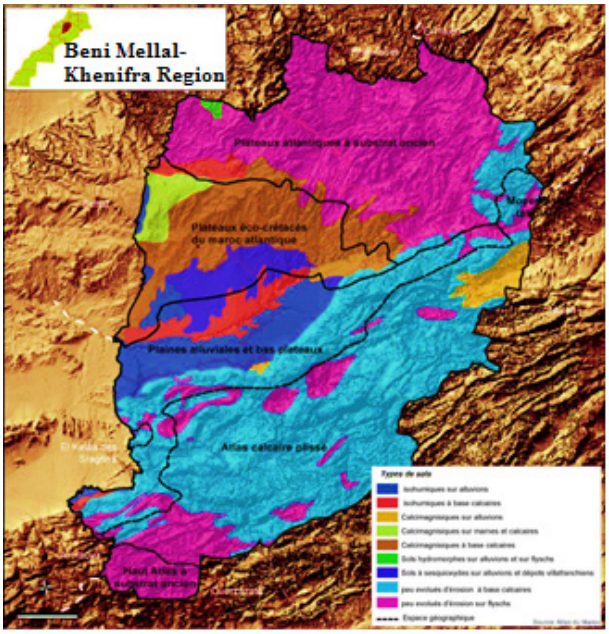

Figure 1: Geographical location and soil types in Beni Mellal-Khenifra region, study site [7].

2. Materials and methods

2.1. Presentation of the study area

The Beni Mellal-Khenifra region is a major contributor to national agriculture. From field crops to local products, its environmental diversity allows it to have a very varied agriculture. Between mountains, foothills and plains, the diversity of climates and soils offers the Beni Mellal-Khenifra region many agricultural opportunities. In addition to its environmental and natural wealth, this region has the advantage of having significant water resources unlike other regions of the Kingdom. The study area is part of the perimeter of the Beni Mellal-Khenifra region, which is made up of four large distinct geographic areas, which maintain relations of exchange, complementarity and forms of solidarity, particularly in the field of agriculture and extensive farming [7]. It has a total surface area of 2.8 million hectares, of which 960,000 hectares of useful agricultural area (205,000 hectares under irrigation and 700,000 hectares of rangelands). Moreover, the region has adopted a specific agricultural plan designed to remove the constraints that hamper agricultural development. It is a specific region, inserted between the Atlas Mountains and the Atlantic coastal provinces, with a much-contrasted physiognomy and a marked character. However, these contrasts, however clear-cut they may appear, present undeniable advantages for the implementation of mutually beneficial solidarity, the rich natural heritage (hydraulic and forest) which is highly diversified, the agricultural potential of the plain which is being reconverted (Beni Amir and Beni Moussa), the opportunities offered by mining activity, the major structuring projects (connecting infrastructures and agro-industrial and commercial platforms) and the hinge position in the national system [7].

2.2. Soil types in the area

The soils in the region are diverse due to the nature of the source rocks. They are shallow, shallow, and low in humus. Their water reserves are sometimes limited. Moreover, the dominance of holm oak, a very plastic species from an ecological point of view, confirms this situation when the ecological atmosphere is difficult. The substrates are colonized by thermo-xerophilic (*Aleppo pine*, thuja and red juniper) and xerophilic (*Thuriferous juniper*) species (Figure 1). Even at altitude, the soils generally remain shallow to shallow, humus and humid for a fairly long period of the year, allowing the establishment of friendly forest species (zene oak, cedar and holm oak) [7].

2.3. Soil sample collection

The study covered 19 observation sites (10 samples by site). Soil samples were taken at different depths (0-60 cm) using an auger on plots of apples. These samples were air dried overnight or longer and sieved through a 2 mm sieve to obtain a fine soil. The results of the soil analyzes were compared to limit values and reference standards. We also measured the electrical conductivity and pH of the main elements using the same techniques as below:

Table 1: Analysis technique.

Analysis	Methods
Granulometry	Sieving (2 mm to 45 µm sieve)
pH 1/ 2.5	pH to put
CE 1/5 25 °C	Granulometry
Cation exchange capacity CEC and exchangeable shares	Cationic exchange capacity CEC and exchangeable shares
Na+ and K+ Cations	Flame spectrophotometer
Ca++ and Mg++ Cations	Volumetric titration
Chlorides Cl-	MOHR method (silver nitrate precipitation in the presence of chromates)
Sulphate SO4--	Precipitation at BaCl2

2.4. Sampling of plant material

The foliar analysis of the apple tree (or foliar diagnosis of the apple tree), is the best way to determine the quantity and the type of fertilizer to give to the fruit trees. Thirty samples of healthy and homogeneous trees were chosen (70 to 90 days after full flowering (stage F2)) and the samples were representative of the plot. We chose the woody branches representative of the vigor and the average growth of the tree (eliminate the greedy ones), the leaf in the middle of the branch with its stem.

In total 200 sheets. The collected leaves are placed in new perforated plastic bags and awaiting transport to the analysis

laboratory; they are stored cool or cold at 4-5 ° C so that they retain all their characteristics. The analysis is carried out the day after harvest at the latest. It focuses in particular on the nitrogen content expressed as a percentage of dry matter (% DM). The results of soil analyzes were compared to values thresholds and reference standards specific to apple production (Table 2).

Table 2: Reference thresholds [8].

	N (% MS)	P (% MS)	K (% MS)	Ca (% MS)	Mg (% MS)
Apple	2.2-2.4	0.22	1.13 à 1.75	1.25	0.22 à 0.3
Prunes	2.4 -3	0.14-0.25	1.6 - 3	1.5 – 3	0.3 - 0.8

2.5. Statistical methodology

Statistical analysis was performed using SPSS software. Descriptive statistics were used and analyzes of variance and comparison of means were performed at a probability level of $p<0.05$.

3. Results

3.1. Physico-chemical characteristics of the soil studied for each site

The results of the particle size analysis of the studied soils are presented in table 3. On the samples analyzed, the texture tests did not reveal significant clay contents except for site 2, which showed values barely greater than 45%. The clay content of the studied soils varies between 26% and 46.57%. Under these conditions, the deep migration of nutrients is slow and leaching losses are low. According to the Texture Triangle (FAO), which is used to determine the textural class of soils, the study area mainly has loamy clay soils. Considering also that apple trees prefer healthy and deep loamy-clayey-loamy soils with a permeable subsoil, it can be assumed that the studied soils are favorable for this apple crop.

Table 3: Physical constituents of the soils studied.

Observation sites	Depth	Granulometry (%)

19	0-40	41	43.5	15.5

The pH is an important parameter of soil dynamics, the degree of acidity or basicity plays a very essential role in the absorption of nutrients by the plant. The average pH of the soil samples studied is eight, which shows that the majority of sites are basic with an alkaline tendency (Table 4).

Table 4: General Statistics of different physico-chemical characteristics of the samples studies.

Characteristics	Min	Max	Median	Average		Standard deviation
				Statistique	Erreur std	Statistique
MO	0.48	3	2.00	1.71	.187	0.772

CaO meq/100g	12	6850	1388.00	3217.27	689.230	2669.376
MgO meq/100g	0	380	320.00	269.53	36.272	140.479

The soils studied exhibited an organic matter content in the range 0.48-3%. Analysis of the elements of Iron, zinc and copper revealed average contents of 6.5 mg/kg, 3 mg/kg and 1 mg/kg respectively. For all the soils studied and sampled at different depths, three Pearson correlation coefficients were determined: one between the different soil types and CaCO3 content, the second between the different soil types and the percentage of organic matter, and the third between the different soil types and the clay content. The coefficients of determination obtained show

that variation of soil types and their sampling at different depths explains 12% of the variation of clay content, 11% of CaCO3 and 8% of the material content. In terms of physico-chemical characteristics, descriptive statistics are the set of methods and techniques that allow us to present, describe and summarize, numerous and varied data; they allow us to know the characteristics of our sample.

For all variables, the standard deviation is more or less low, so the dispersion of the measurements around the mean is narrow. The results are therefore consistent, except for the last three variables, namely the K2O, CaO and MgO content, where the standard deviation is very high, which shows that there is a wide dispersion of the results for these contents (Table 5,6 and 7).

Table 5: Correlation between organic matter and soil mineral elements

In order to study the relationship between the mineral element content and the CaCO3, MO and clay fraction, we calculated the Pearson correlation coefficient (Figure 2). The results show that there is no correlation between these mineral elements and the rate of CaCO3 and clay fraction. The results for the organic matter content show that the latter explains 57% ($p<0.05$) of the variation in K2O content.

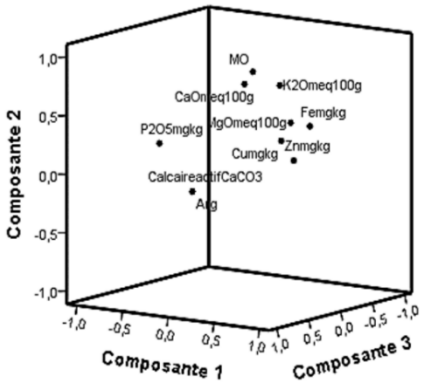

Figure 2: Principal component analysis of the physico-chemical properties of the soils sampled

The ANOVA test application, to compare the average characteristics of 19 sites (without distinction of depths) is presented in the table above. It shows that in the different sites studied, the difference in mean is insignificant for the parameters pH, organic matter, CaCO3 content, clay content, B, CaO; it is also insignificant for the silt and sand variables, so the null hypothesis H0 is accepted as long as there is no difference in the means. For the variables Fe, Zn, Cu, P2O5, K2O, MgO the difference of the means is significant and, in this case, the null hypothesis H0 is rejected.

3.2. Physico-chemical properties of apple leaf soil

The differences in the average composition of the three varieties are shown in the table 8. The apple leaf contains more Na, Cu and zinc and less Mg, P and K. The coefficient of variation (CV) of the manganese content expressed as a percentage is much higher than that of the other elements, and the coefficient of variation (CV) of the potassium content is the lowest, especially for magnesium and sodium the coefficient of variation is zero (Figure 3).

Table 8: Global apple leaf nutrient content statistics.

	Average	Standard deviation	CV	Min	Max
Magnesium, Mg (%)	0.1900	0	0	0.19	0.19
Phosphorus, P (%)	0.2200	0.01732	7.873	0.20	0.23
Potassium, K (%)	0.553333	0.0152753	2.761	0.5400	0.5700

4. Discussion

The apple tree represents in Morocco an agricultural species of great importance. Growing apples requires a long period of vegetative rest to meet its cold needs; it also requires very specific conditions with regard to the various production factors, in particular for the soil / irrigation water combination. The main areas of apple plantations in Morocco are; Meknes, Midelt, Khenifra, Haouz Marrakech, Fes, Ouarzazate. Our study was carried in Beni Mellal-Khenifra region. The results of the granulometric analysis of the studied soils showed that the samples have a silty clay texture, which is often very favourable for apple tree cultivation. A good yield could therefore be obtained if the mineral elements provide the essential and important quantities for the good development of the crop. According to the literature review, the physicochemical properties of the soil play a major role in the yield of apples, in particular the pH [10,11]. It should be noted that apple trees generally prefer slightly acidic soils with a pH between 6.5 and 6.8 [12]. However, the soil samples analyzed recorded rather average alkaline pH values of up to 8.85. Despite the measured pH, qualified as alkaline, the yields obtained on the farm are very satisfactory. Indeed, even if we often talk about an optimal pH for a particular plant, in fact the pH does not meet a physiological need of the plant. It is the action of pH on the physical, chemical and biological properties of the soil that creates a more favourable environment for mineral nutrition and plant growth. In fact, plants are most often able to cope with a pH difference of up to one unit. Most plants grow very well in soil with a pH of 6.5 [12]. Doucet in 2006 states that agricultural species that grow at pH 6 most often prefer a pH of 6.5 and that all plants that grow in neutral soil with a pH of around 7 can tolerate a pH of 6.5 [13]. Regarding active limestone, apple tree fears soils with a high content of active limestone. This is not the case for our study soil with variable proportions which can sometimes be very high or even twice the tolerated standards. This can easily lead to iron deficiency. Furthermore, the more abundant the total CaCO3 rate in the soil, the greater the risk of blocking trace elements and phosphorus, hence the need to take these constraints into account

when developing fertilization programs. For a good interpretation of the rate of organic matter, it is necessary to take into account the quantity, but also the quality of this organic matter, the ventilation, humidity and temperature conditions. According to the guide reasoned fertilization in fruit arboriculture, presented by the Chamber of Agriculture of Tarn-et-Garonn, the value of the desirable organic matter content according to a clay content> 30 % must be between 2.5 and 3%. However, the organic matter content in the present study is generally low, with contents varying between 0.48% and 3 %. Nevertheless, it is therefore necessary to add MO to the soil. As long as the OM content is high, the production potential of the soil is great. In addition, it will improve the physical properties (structure, porosity, water and air circulation, water retention capacity) and chemical (cation exchange capacity, reversible anionic bond, release of trace elements. by decomposition in the soil) [15]. Compared to the interpretation standards given by the INRA (National Institute of Agronomic Research) for Contribution to the establishment of standards of fertilization of apple trees in the Middle Atlas. According to Dr. Rachid Razouk (researcher, CRRA Meknes), the optimal levels of nutrients found in clay-loam soils (the case of the study) are classified as low for phosphorus, in the “sufficient” class for potassium and in the "high" class of Ca and Mg [16]. However, for K2O, the values found correspond in fact to the optimum intakes for a high apple yield. Internationally, experts agree that 1.5% is the theoretical critical limit, below which fertility declines rapidly. It is often desirable to aim to maintain a minimum rate of 2.5% and even 3.5 to 4% in heavy soils [13]. A similar study was carried out to assess the quality of agricultural soils in the northeastern area of the plain Tadla (Morocco).The results indicated that 1.12% of the study area has poor suitability for sustainable intensive agriculture due to their unsuitable texture and low salinity, while about 77% of cultivated soils are adapted to agricultural production [17]. According to Barakat et al, 2017 the diagnostic of the quality of agricultural land in Beni-Moussa, Tadla plain (Morocco), showed that about 1.69% (1324.38 ha) of studied area are classified in the clas ‘excellent suitable’, 17.14% (13449.81 ha) in ‘good suitable’, 75.70% (59393.30 ha) in ‘medium suitable’ and 5.47% (4293.11 ha) in ‘poor suitable’ for sustainable intensive agriculture. Reading the results of the leaf analysis and their comparison with international standards for the nutrient content of apple leaves shows that for the elements phosphorus, calcium and magnesium, their concentration levels in the leaves are too satisfactory. On the other hand, the nutrient potassium has levels in the leaves below the desired limits compared to the required reference standards. A slight potassium deficiency is probably due to excessive nitrogen fertilization, as nitrogen-induced vegetative growth generates high potassium requirements. In general, leaf levels of N, P, K, Ca, and Mg are significantly correlated with their levels in the soil. However, foliar analysis is an effective tool for assessing the nutritional status of trees and for readjusting fertilizer requirements taking into account factors that can affect nutrient availability and root uptake.

5. Conclusion

The soils studied and sampled at different depths (0-60 cm) have a clay-loam texture. They are relatively poor in organic matter, the content of organic matter and major elements are not sufficient to optimize the optimum yield of the apple tree culture. The study shows a correlation between apple yield and nutrient content in the soil and leaves. The nutrient deficiencies observed can be corrected by the application of fertilization and adequate maintenance. However, further studies are needed to fully understand other variables such as the nature of rootstocks, the varieties cultivated and the method of irrigation which strongly influences apple tree production and yield. A prospect may be distant; indeed, it would be very interesting to generalize our paradigm to other sectors related to apple growing. As well as tackling research on phytosanitary techniques in order to move from the conventional vision to the integrated vision. Further research could also focus on other crops.

ABSTRACT

Despite that groundwater is an important and vital water resource, it is not well managed; depletion of aquifers around the world due to overexploitation is of serious concern especially in arid regions where the situation is much more alarming. Tafilalet plain in Morocco which belongs to this type of environment is certainly no exception and is viewing its groundwater disappearing. Artificial aquifer recharge (AAR) is found to be appropriate to such an urgent issue. Thus, the objective of this paper is the exploration of suitable sites to process Artificial aquifer recharge in Tafilalet plain by the joint use of remote sensing (RS), geographic information systems (GIS), and the analytic hierarchy process (AHP) method. For doing so, eight parameters were considered as groundwater influencing parameters such as slope, soil, geology, land Cover/land Use, depth to the water table, aquifer transmissivity, electrical conductivity and drainage density. The laters were integrated and processed in a GIS, their thematic layers were created, and their relative weights were generated by The AHP method based on their significance in recharging the aquifer. Afterward, thematic layers were reclassified and assigned their weights, so the GIS overlay tool was used for inferring artificial groundwater recharge potential regions in the study area. 47 % were identified as suitable while only 12 % were identified as unsuitable. Such studies facilitate groundwater management for stakeholders and water managers because important decisions may be taken in a record time which will preserve water resources and prevent them from being in an alarming situation.

1. Introduction

Groundwater is a valuable natural resource and constitutes a significant freshwater reservoir as it accounts for 30 % of the earth's freshwater while surface water accounts for just 0.3 % [1, 2]. Besides, groundwater offers a multitude of benefits in different forms. In fact, groundwater meets the need for drinking water to relatively half of the world's population [3, 4] and around 38 % of the world's irrigated lands are supplied by groundwater [5], not to mention its contribution to the industry sector and its paramount role for the environment. Nevertheless, there is growing evidence that groundwater is under threat of numerous difficulties such as climate change impacts, contamination, pollution in addition to depletion [6–10]. Actually, many aquifers throughout the world suffer from groundwater depletion [11–17] and this situation is much more serious in arid regions since groundwater constitutes their main source of water supply. Mismanagement and namely over-exploitation are considered as its major cause alongside many other factors. In fact, rapid population growth, agricultural and industrial activities that require a considerable availability of water together with climatic conditions notably of arid environments consisting of high evapotranspiration rates, low precipitation, and low vegetation cover are placing greater pressure on limited aquifer resources which has led to their intensive extraction in many parts of the world [9, 12, 17–25]. Moreover, If this abstraction is greater than the natural groundwater recharge, it is referred to as an overdraft; so, groundwater levels will drop sharply over time, triggering depletion [8, 9, 14, 17, 25–30], which can make the situation complicated as the replenishment of the aquifers

*Corresponding Author: Aicha Ousrhire, Email: aicha.ousrhire@gmail.com

to the original levels takes a lot of time [3] and it is more complicated in cases of fossil or compacting aquifers because of their irreversible and non-renewable character [14, 31]. In such a way, countless negative impacts and many political, social, environmental, and economic issues, such as conflicts, land subsidence, degradation of groundwater dependent ecosystems, deterioration of water quality, aquifers drying and obviously water scarcity will take place particularly in countries which are groundwater dependent [10, 11, 14, 23–25, 27, 28, 32–39].

The above situation has been a major point of concern of water researchers, water managers, and water decision-makers, seeing that in many parts of the world a lot of measures have been taken to properly manage their groundwater resources and to prevent the worsening of the situation. The implementation of monitoring networks to control groundwater levels, the establishment of groundwater laws, and the setting up of exploitation rules for regulating its use, in addition to the organization of awareness-raising companies to urge on the importance of water and also education on water conservation are a good illustration of the undertaken measures [9,37,38,40,41], but even so, the decline of groundwater resources levels has been noticed and is still ongoing in many places around the globe. This is especially due to the violations of the established rules and the intensive mining of underground water notably in case of droughts. Added to that, the natural recharge of aquifers by streams, precipitation, rivers, pond seepage, reservoirs, irrigation canals, and lakes has become overwhelmed by the intensity of groundwater withdrawals [25] and has become difficult to occur especially in urbanized areas [42], because the presence of impervious surfaces such as roads, sidewalks, driveways and parking lots has led to many modifications to natural processes like impeding the infiltration of water. Thereby, the natural recharge of aquifers has proved to be insufficient to fill the quantity of water coming out of the aquifers in many parts of the world. Given these trends, water researchers, water managers, and water decision-makers have been prompted to think about solutions and innovative scientific analyses in order to bring better and sound management strategies that may address this groundwater issue and guarantee its sustainable use. If decreasing discharge and regulating abstraction has not brought important results, then this depletion can only be alleviated by increasing and boosting recharge.

Thus, artificial or managed aquifer recharge is a promising solution to this problem. Actually, artificial aquifer recharge (AAR) or managed aquifer recharge (MAR) is defined as an intentional human intervention arranged to enhance groundwater resources through processes implemented to heighten and improve the replenishment of depleted aquifers or depleting aquifers [22, 43–47]. The (AAR) has many gains and benefits, the major ones are the restoration of groundwater balance and the revival of the overexploited aquifers [11, 19, 25, 39, 48, 49], the other ones are enhancement and raising the water table which will cut down its operating costs, improving groundwater quality and prevention of seawater intrusion in the case of coastal aquifers [28, 46, 49, 50], alleviating floods adverse impacts given that during strong storms aquifers can be managed to play the role of a water storage reservoir which will mitigate the magnitude of flooding [22, 45, 51–53], besides (AAR) can limit the loss of land covered with surface water storage structures and limit the loss of water by evaporation in dams, ponds, and other surface reservoirs by storing it in aquifers [12, 39]. In order to artificially recharge aquifers, treated wastewater, floodwater, or water pumped from another aquifer can be used and redirected across the land surface. So, a variety of ways and systems have been developed such as infiltration basins, canals, ponds, ditches, sprinkler systems, rills, and irrigation furrows where the surface water is put on and subsequently infiltrates into the soil and moves downward to recharge aquifers or simply artificial recharge can be achieved by injecting water directly into the aquifer through injection wells especially in case of confined aquifers and each of these ways is implemented according to specific conditions. Applying the (AAR) needs some criteria to be met notably, the presence of highly permeable geological formations allowing percolation of recharge water, endowed with high capacity of water storage (unsaturated zone thickness should be deep enough to increase the piezometric level) and have high transmissivity. Moreover, the presence of a water source ensuring volumes of water needed for the recharge such as dams, stormwater runoff, wastewater treatment station, and desalination station besides, the water intended for artificial groundwater recharge as well as those of receiving aquifer must be of good quality and meet a certain number of standards and also good knowledge of the climatic characteristics of the region is essential in (AAR) projects (temperature, evaporation, rainfall, frequency of floods, periods of drought, snowmelt, etc.). Consequently, performing the (AAR) requires a suitable place whose selection depends on solid scientific analysis. Actually, selecting optimal sites for (AAR) involves integrating several parameters proved to have an influence on the infiltration of water to aquifers. To do this, a combination of geospatial technologies and multi-criteria decision analysis (MCDA) is used in this study.

Tafilalet plain was chosen as the study area in the present study as it is one of the Moroccan regions calling for urgent intervention and requiring important measures to be taken at all levels, including the environmental one; it suffers from enormous environmental difficulties mainly scarcity and poor water quality, due essentially to long periods of drought that has affected the region in recent years, combined to severe nature of the climate which makes groundwater resources the main source of water supply in low-flow periods. In 1967, the Hassan Addakhil dam was constructed in the north of Errachidia city and located at a distance of about 80 km from the Tafilalet plain, it was built on wadi Ziz in order to regulate floodwaters and, simultaneously, it serves a variety of goals, ranging from irrigation to water supply for domestic and industrial uses and remarkably it helps to establish a certain balance of groundwater of Tafilalet aquifer both quantitatively and qualitatively, but in front of considerable population growth and an agrarian-based economy resulting in increasing the number of wells notably prived ones, the exploitation of groundwater resources is proceeding at a very fast pace which has lead to their overdraft, so the implementation of artificial aquifer recharge in this region is essential to recover its overexploited groundwater.

Thus, the prime focus of the current paper is to delineate the artificial groundwater recharge potential regions in Tafilalet plain (Morocco), using the analytic hierarchy process (AHP) method which is a forme of Multiple-criteria decision analysis (MCDA) and geospatial technologies represented here by remote sensing (RS) and geographic information systems (GIS).

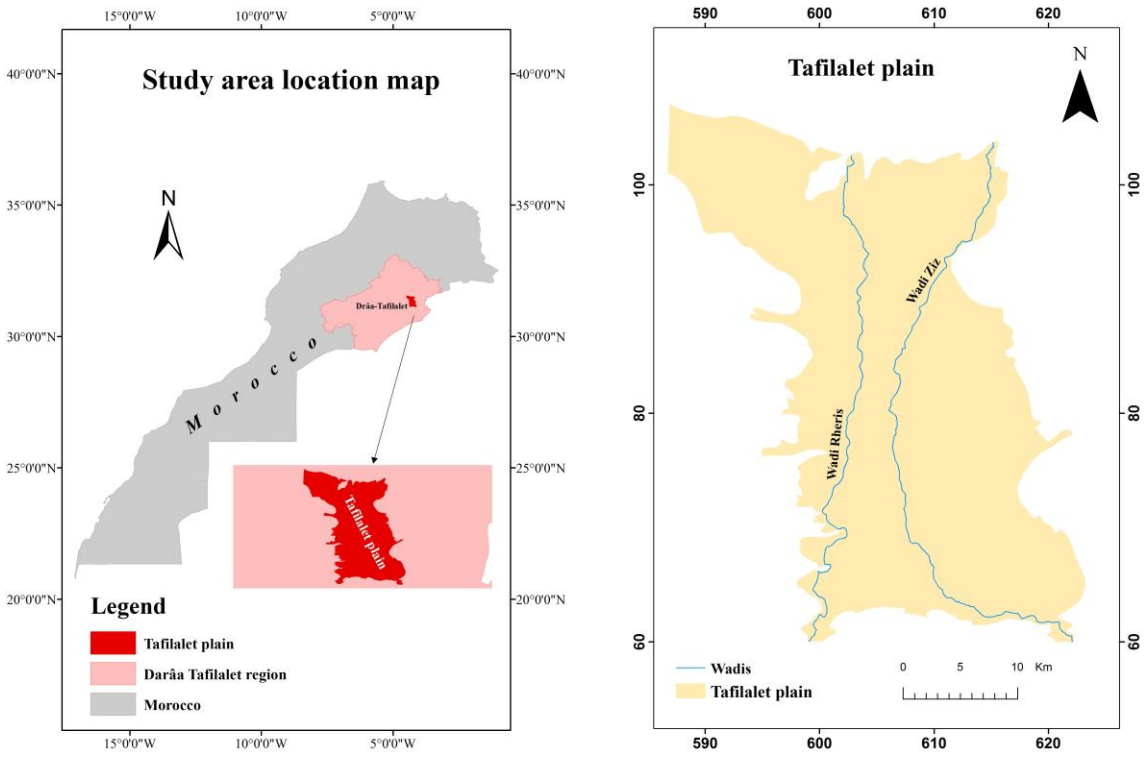

Figure 1: Study area location map

After this introduction, the following parts are organized in five sections, the first one is an overview of the study area, the second one is a presentation of the materials and definition of the methods used, the third one is a description of the major results, the fourth one is a discussion about the outcomes and the last one is a conclusion of the main ideas of this study.

2. Study Area

Tafilalet plain belongs to the pre-Saharan region located in the extreme southeast of the kingdom of Morocco, particularly in the Drâa-Tafilalet region, at an altitude of 700 to 800 m, it lies in between the coordinates of projection system Lambert zone Morocco (Zone I) X = 580000 m to X = 630000 m and Y = 50000 m to Y = 120000 m (Figure 1), covers an area of about 700 km², and the majority of its population are rural. Besides, Tafilalet plain is part of the quaternary basin of Tafilalet; it is an erosional depression arising out of the secondary and tertiary coverage clearing during the quaternary era, the bottom of this depression was, afterward, covered by the alluvium of wadis Ziz and Rheris. In fact, it constitutes the zone of gathering and accumulation of alluvial deposits, conveyed by surges of the Ziz and Rheris wadis and their tributaries. Moreover, Tafilalet plain extends over three different geological formations, it is enclosed by the High Atlas in the north, it crosses the pre-Africain furrow and is surrounded at the south by the old massif of the Anti-Atlas domain as well as overlying an impermeable Palaeozoic and pre-Cambrian substratum.

Concerning the climate, Tafilalet plain is dominated by an arid to semi-arid climate, typified by a great rainfall scarcity as the average annual precipitation barely reaches 70 mm all over the area, this is mainly due to the presence of Atlas reliefs in the north which constitute a barrier to oceanic influences. The climate is also characterized by a great irregularity of the temperature, rising to very high values in summer (about 40 degree C ° especially in July) and dropping to very low values in winter (surroundings 0 degree C ° especially in January), this great difference in temperature brings out two seasons: a hot season from May to October and a cold season from November to April so, in the Tafilalet plain, The dry periods last almost all the year with extremely hot summers and highly cold winters which is mainly due to its openness on the Sahara. In addition, The mean annual evapotranspiration is close to 500 mm which is higher than the mean annual rainfall, this means that Tafilalet plain suffers from water deficit all over the year. Adding to that, the dominant winds are commonly known as Chergui, they are characterized by their hotness and dryness and they blow from the southeast to the northeast.

Regarding the water resources, Tafilalet plain is, on the one hand, underlain by confined and unconfined aquifers, the north of the region encloses the infra Cenomanian aquifer which is a totally confined aquifer, whereas the entire area is almost occupied by an unconfined, shallow and very extensive aquifer named as "Tafilalet aquifer" which is the aquifer targeted in this study. In fact, this aquifer is not very thick and the water below the ground surface is 2 m to more than 30 m in some places, its shape matches the slightly convex shape of the plain and its slope is very weak. Consequently, this makes the water of this aquifer sensitive to hydrological and atmospheric conditions such as pollution and evapotranspiration. The spatial distribution of Tafilalet aquifer transmissivities indicates dispersed values ranging from 10^{-2} m²/s

to 10^{-4} m²/s and groundwater flows mainly from the north-east to south-west, south, and south-east characterized by an average hydraulic gradient that declines from upstream to downstream [54]. From a lithological point of view, the base of the aquifer is constituted by conglomerates and lacustrine limestones including gravelly levels and at the top of the aquifer, there are sands, gravel, and pebbles, covered with unevenly distributed powerful silts. Moreover, the main sources of groundwater recharge of the Tafilalet aquifer are essentially from the High Atlas mountains surrounding the plain in the north, from surface runoff including rivers, mainly Ziz and Rheris wadis, as well as irrigation water which infiltrates to the aquifer, and without forgetting precipitation and dams contribution. Conversely, the Tafilalet aquifer discharges mostly by evapotranspiration, by extraction from wells, and by Khettarats and springs. On the other hand, Tafilalet plain is crossed by many ephemeral wadis, the major ones are wadi Ziz in the center, wadi Rheris in the west. Besides, the region holds some springs resulting from the emergence of groundwater resources to the surface, such as Aïn Dolla-Attrouss and Aïn Chorfa.

Furthermore, the heart of the Tafilalet plain is made up of a very large palm grove, which occupies most of its surface so, a great part of the plain is devoted to agriculture, especially irrigated agriculture, making it the main economic activity in this region and is the main source of income for a large population. Because of climate aridity, the majority of crops are water-demanding which implies a strong mobilization of water notably during the months of June and July and due to the scarcity of surface waters in the region, growers are turning to groundwater exploitation to fill this water gap and meet their water needs. This has made the groundwater balance in aquifers of Tafilalet plain quickly in deficit.

3. Materials and Methods

The overall process followed in this study of the artificial aquifer recharge site selection has been schematically presented in (Figure 2).

3.1. Influencing factors Selection reason

The prediction of suitable sites for artificial aquifer recharge depends on a number of parameters that have an influence in either a direct or indirect way on the process of aquifer recharge. The selection of these factors was based firstly on a deep review of studies of artificial recharge carried out in other areas in the world, secondly on a complete understanding of the characteristics and specificity of the study area "Tafilalet Plain" and thirdly on the point of view of experts. Thus, eight factors were revealed to have control over the recharge of the Tafilalet aquifer, including slope, soil, geology, land cover/ land use, depth to the water table, aquifer transmissivity, electrical conductivity and drainage density as mentioned in (Table 1).

- Slope: The slope is one of the essential factors influencing the artificial aquifer recharge because the slope directly affects the penetration of water into the soil. Actually, the flatter the ground, the more time the water has to sink in, unlike the steep slopes where the water runs over the ground rather than entering it [25, 55–57]. However, the penetration of water is not guaranteed even if the slope is suitable because it depends on the soil's nature.
- Soil: Soil is a factor of significant importance in aquifer recharge because soil's nature determines the percolation ability of the soil as well as the water infiltration quantity and eventually governs the recharging capacity of the bedrock [58]. Moreover, soil acts as a purificator of water [29] that is why it should contain high rates of loam and sand to avoid groundwater contamination and to ensure a high infiltration rate.
- Geology: Taking into consideration geology in artificial aquifer recharge site selection is of major importance because geological formations which must be selected should enjoy high permeability so that water can flow seamlessly downward towards the groundwater besides, they should have adequate transmissivity and high water storage capacity.
- Depth to the water table: Depth to the water table or unsaturated zone thickness is the distance from the ground surface to the groundwater, it is another major factor to consider in artificial groundwater recharge site selection since, the deeper the water table, the greater the amount of groundwater storage, and the more efficient the artificial aquifer recharge will be Moreover, the deeper the water table, the more purified the water will be, because it will pass through a very large layer of soil, which is called soil aquifer treatment (SAT) [19, 29]. Acceptable depth is about 3 m consequently, sites, where the depth is less than 3 m, should not be considered [59].
- Transmissivity: transmissivity is an important hydrodynamic parameter of an aquifer which makes its consideration paramount in the selection of suitable sites for artificial groundwater recharge. Actually, transmissivity determines the rate of water flowing per unit width of the fully saturated thickness of an aquifer under a unit hydraulic gradient [25, 60–62] so, to avoid the excessive formation of groundwater mounds that interfere with the infiltration process, aquifers should be unconfined and sufficiently transmissive to allow the lateral flow of infiltrated water well away from the recharge zone [49].
- Drainage density: Drainage density is defined as the total length of streams of all orders per unit area and provides an indication of the watershed draining state. Drainage density was heeded as another factor of artificial aquifer recharge site selection because it indirectly signals the suitability of a site. In fact, high drainage density allows less penetration and more surface runoff and areas with great infiltration capacity are endowed with low drainage density [25, 39, 51, 58, 63–68] hence appropriate to artificial aquifer recharge.
- Electrical Conductivity: Groundwater quality is a paramount parameter that should be investigated in the artificial aquifer recharge projects because it is a determinant factor of the future usage of that water. Usually, the water intended for artificial aquifer recharge is of good quality but when it penetrates across a geological formation and mingles with different dissolved materials in it, its quality may get altered. Electrical conductivity (EC) is considered in this study because its variations have similar trends to those of total dissolved solids (TDS) as shown in the following formula :

$$EC = TDS / 0.65 \quad (1)$$

In fact, the higher the electrical conductivity, the poorer the water quality and vice versa [69]. Thus, the quality of groundwater will be assessed through the EC in the artificial aquifer recharge site selection.

- Land Cover / Land Use (LCLU) : (LCLU) is one of the important aquifer recharge influencing factors, it affects both the infiltration capacity and the water restraining of the land. Actually, areas with an important density of vegetation cover are appropriate for undertaking artificial aquifer recharge projects because the denser the vegetation cover, the more the runoff is slowed down and the more water infiltration takes place and also the less evapotranspiration and soil surface erosion will occur. In addition, organisms present in the soil and plant roots form openings in the subsoil, allowing water to infiltrate easily, unlike in areas without vegetation and in built-up areas, where the soil is mostly impervious, which favors runoff and prevents infiltration.

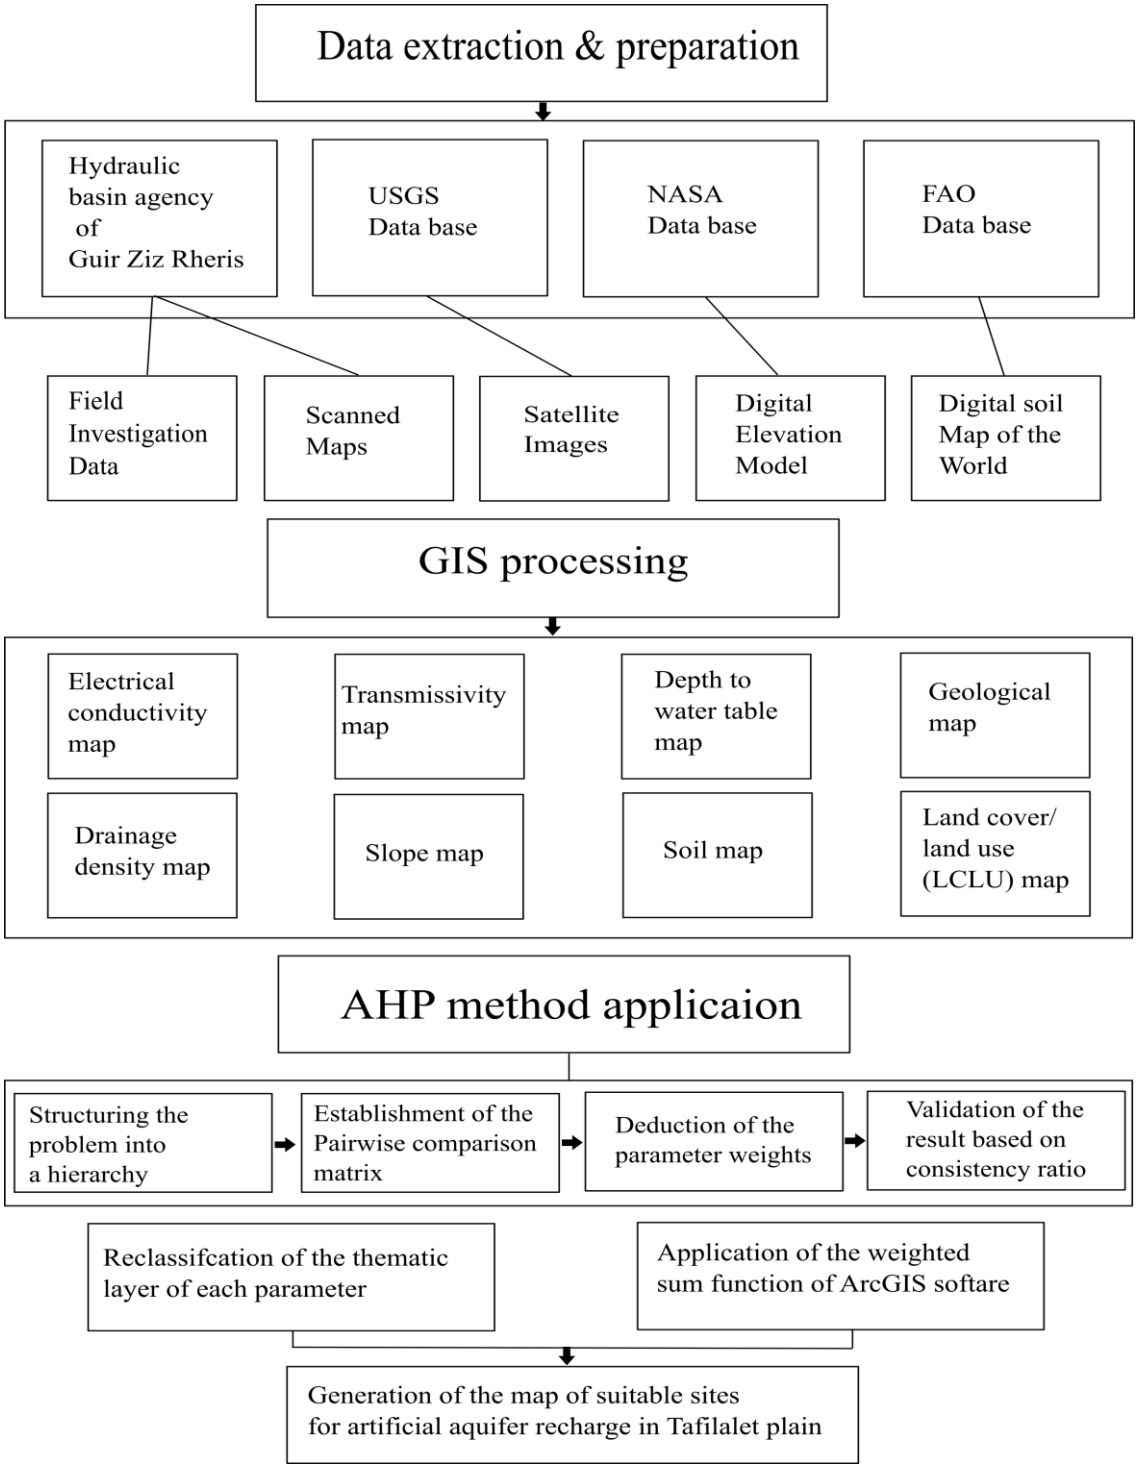

Figure 2: Methodology workflow

Table 1: Data Extraction and Preparation

Data	Origin format	Data source	Acquisition mode	Output
Slope	ASTER DEM at 30 m	National Aeronautics and space administration (NASA) website	Extraction	Slope map of Tafilalet plain
Soil	Digital soil map of the world	Food and Agriculture Organization of the United Nations (FAO) website	Extraction	Soil map of Tafilalet plain
Geological data	geological map of Tafilalet-Taouz (1/200000 scale)	Hydraulic basin agency of Guir Ziz Rheris	Digitalization	Geological map of Tafilalet plain
land Cover/land Use (LCLU)	satellite image (Landsat 8)	United states geological survey (USGS) institute website	Classification	LCLU map of Tafilalet plain
Depth to the water table	Excel sheet of field investigation data	hydraulic basin agency of Guir Ziz Rheris	Interpolation	Depth to the water table map of Tafilalet aquifer
Transmissivity	Excel sheet of field investigation data	hydraulic basin agency of Guir Ziz Rheris	Interpolation	Transmissivity map of Tafilalet aquifer
Electrical conductivity	Excel sheet of field investigation data	hydraulic basin agency of Guir Ziz Rheris	Interpolation	Electrical conductivity map of Tafilalet aquifer
Drainage density	ASTER DEM at 30 m	National Aeronautics and space administration (NASA) website	Extraction of the hydrographic network then application of Line Density	Drainage density map of Tafilalet plain

3.2. Data extraction, preparation, and GIS processing:

Given the interdisciplinary nature of groundwater, using remote sensing (RS) and geographic information systems (GIS) techniques are required because RS is a technology that provides important and information-rich geospatial data, especially for unreachable and very large areas. Moreover, GIS is commonly known for its usefulness to handle, analyze, integrate, and process various thematic geospatial data.

Therefore, in order to get the geographic data related to the above-mentioned factors, various data sources were used: FAO database, NASA database, USGS database, and other data were given by the hydraulic basin agency of Guir-Ziz-Rheris as detailed in Table 1. Furthermore, in order to process and to analyze those data, the geographic data processing functions of the ArcGIS software were used. In fact, as indicated in Table 1, slope and hydrographic network were extracted from ASTER DEM at 30 m, then the drainage density was formed by applying the Line Density function to the hydrographic network, the soil was extracted from the digital soil map of the world taken from the FAO database, geology was digitized from the geological map of Tafilalet-Taouz (1/200000 scale), electrical conductivity, transmissivity and depth to the water table were taken from field surveys carried out with the hydraulic basin agency of Guir-Ziz-Rheris and land cover/land use (LCLU) was classified from satellite image (Landsat 8) drawn from USGS database. Thus, a geospatial database was constructed and filled with the aforementioned data. Afterward, using ArcGIS software a thematic layer of each factor was created (Figure 3) and each thematic layer has been converted to raster format and reclassified into five classes pertaining to its importance for artificial groundwater recharge (Figure 4), each class is translated to a category and each category has assigned a score as it is detailed in Table 2. Actually, the five categories adopted are very good, good, moderate, poor, and very poor in accordance with a specific evaluation scale (Table 3).

3.3. AHP method application

After reclassification of all the thematic layers, appropriate weights were generated by the analytic hierarchy process method (AHP).

Indeed, AHP is a multi-criteria decision analysis method and a mathematically-based technique [70], the mathematical underpinnings and the philosophy of which were developed in the seventies of the last century by the mathematician Thomas L. Saaty [71], AHP involves breaking down a convoluted multi-criteria decision problem into a hierarchy also called decision modeling in order to organize and better understand the problem and analyze the decision to be made.

Table 2: Classes of each parameter and assigned categories

Parameter	Class	Category	Score
Slope (%)	0 - 3	Very good	9
	3 - 6	Good	8
	6 - 9	Moderate	5
	9 - 15	Poor	2
	> 15	Very poor	1
Soil	Calcisols	Very good	9
	Fluvisols	Good	8
	Leptosol	Moderate	5
Geology	Primary	Very poor	1
	Early quaternary (Regs, crusts)	Moderate	5
	Early quaternary (Puddingstone, Lake Limestone, Sandstone)	Good	8
	Late quaternary	Very good	9
LCLU	Sand	Very good	9
	Vegetation	Good	8
	Buildings	Very poor	1
	Bare ground	Poor	2
Depth to the water table (m)	2 - 5	Very poor	1
	5 - 10	Poor	2
	10 - 20	Moderate	5
	20 - 30	Good	8
	> 30	Very good	9
Transmissivity (m^2/s)	0.00004 - 0.005	Very poor	1
	0.005 - 0.015	Poor	2
	0.015 - 0.025	Moderate	5
	0.025 - 0.05	Good	8
	> 0.05	Very good	9
Electrical conductivity (µs/cm)	880 - 1000	Very good	9
	1000 - 5000	Good	8
	5000 - 10000	Moderate	5
	10000 - 30000	Poor	2
	> 30000	Very poor	1
Drainage density (km/km^2)	0 - 1	Very good	9
	1 - 2	Good	8
	2 - 3	Moderate	5
	3 - 4	Poor	2
	> 4	Very poor	1

After structuring the problem in such a way, the second step is to evaluate, compare and prioritize in a pairwise comparison matrix, based on decision-makers' judgments each criterion against the others pertaining to their importance in the problem decision making. To represent the magnitude of judgments, Saaty's fundamental scale should be used (Table 4), in doing so, relative weights of each criterion is deduced using Saaty's eigenvector technique and the generated weights must be validated because judgments are subjective and can typically be made with errors, so Saaty defined an index for measuring the degree of inconsistency which is the consistency ratio C. R. and it should be computed.

Table 3: Adopted evaluation scale for reclassification

Category	Very poor	Poor	Moderate	Good	Very good
Score	1	2	5	8	9

Actually, C. R. is a way of measuring the number of "errors" created when making the judgments, the rule-of-thumb is that if the C.R. is below 0.1, the errors are relatively small, thus the final estimate is acceptable [70,72–76].

The above-explained concept of AHP could be explained mathematically as follows:

Suppose $c_1, c_2, \ldots, c_n$ are n criteria influencing a decision with respect to a given problem, the pairwise comparisons matrix $B=[b_{ij}]$ of that problem is an $n \times n$ matrix and it may be represented as follows :

$$\begin{array}{c} \\ c_1 \\ \vdots \\ c_n \end{array} \begin{array}{c} \begin{array}{ccc} c_1 & \cdots & c_n \end{array} \\ \begin{bmatrix} 1 & \cdots & b_{1n} \\ \vdots & \ddots & \vdots \\ 1/b_{1n} & \cdots & 1 \end{bmatrix} \end{array}$$

comparing the n criteria in pairs should comply with the following conditions:

$b_{ij}>0$ and $b_{ij}=\frac{1}{b_{ji}}$ *for all i and j* which means that B should be a positive and a reciprocal matrix. Besides, the values that can be attributed to b_{ij} *for all i and j* must be on the scale of intensities defined by Saaty (Table 4).

Table 4: The fundamental Scale

Intensity of importance	Definition	Explanation
1	Equal importance	Two criteria contribute equally to the objective
3	Moderate importance	one criterion is slightly favored over another
5	Strong importance	one criterion is strongly favored over another
7	Very strong importance	one criterion is highly favored over another
9	Extreme importance	one criterion is extremely favored over another
2,4,6,8	Intermediate values	when compromise is needed
Reciprocals	if criterion i has one of the above values assigned to it when compared with criterion j, then j has the reciprocal value when compared with i.	

Deriving the weights $w_1, w_2, \ldots, w_n$ relative to the n criteria $c_1, c_2, \ldots, c_n$ can be done by Saaty's eigenvector technique when judgments are inconsistent. Saaty's eigenvector technique stipulate that weights can be computed as the principal right eigenvector of the matrix B:

$$BW = \lambda_{max} W \tag{2}$$

where λ_{max} is the maximum eigenvalue of the matrix B, or

$$w_i = \frac{\sum_{j=1}^{n} b_{ij} w_j}{\lambda_{max}} \quad for\ all\ i = 1, 2, \ldots, n \tag{3}$$

After generating the weights, the consistency of the matrix should be measured by C.R. as explained above but first consistency index C.I. should be computed by the following formula:

$$C.I = \frac{\lambda_{max} - n}{n - 1} \tag{4}$$

because C.R. is the ratio of C.I. to R.I. :

$$C.R = \frac{C.I}{R.I} \tag{5}$$

with:

R.I. is the random index and is defined for each size of the matrix which is illustrated in Table 5.

C.R. must be less than 0.1 to consider the result as acceptable, larger values require the decision-maker to revise judgments in order to reduce the inconsistencies.

Therefore, for the current study, application of the AHP gives firstly the hierarchy structure illustrated in Figure 5, secondly, the pairwise matrix (Table 6) was developed by comparing pairs of factors with the help of expert point of views and using the fundamental scale of Saaty (Table 4) to translate judgments into values. Comparisons were done with regard to the relative influence of each factor on aquifer recharge and on implementing the (AAR) technique in Tafilalet plain. R.I. used is 1.41 because the dimension of the pairwise matrix of the current study is 8×8 (Table 6) so, after computation, the obtained C.R. is equal to 0.041 which is less than 0.1 and according to the AHP method this result is satisfactory and the generated weights are acceptable.

Based on the generated weights, geology is the highest eigenvector while drainage density is the lowest (Table 6). In fact, geology, soil type, depth to the water table, and transmissivity are the factors that were given the highest weights. This was expected because, according to the analysis that was made during pairwise comparisons, the first thing to look out for in a project for artificial recharge of an aquifer suffering from overexploitation is the geological formations, which must be sufficiently permeable and transmissive, the soil, which must have a high infiltration capacity and the groundwater which must be deep enough to provide sufficient space for water storage to allow the water table to regenerate its level.

3.4. AAR index generation

After generating the relative weights for each factor by the AHP method, the reclassified thematic layers of the factors were multiplied by their weights and finally added up using the weighted sum function of ArcGIS software.

Thus, the potential sites for the artificial aquifer recharge map was produced by calculating the AAR index according to the following formula:

$$I_{AAR} = \sum_{i=1}^{n} F_i w_i \tag{6}$$

where:

-I_{AAR} is the AAR index

-n is the number of factors influencing (AAR) which is eight in the current study

-F_i stands for factor

-w_i stands for weight

Table 5: Random inconsistency index

n	1	2	3	4	5	6	7	8	9	10
R.I.	0.00	0.00	0.58	0.90	1.12	1.24	1.32	1.41	1.45	1.49

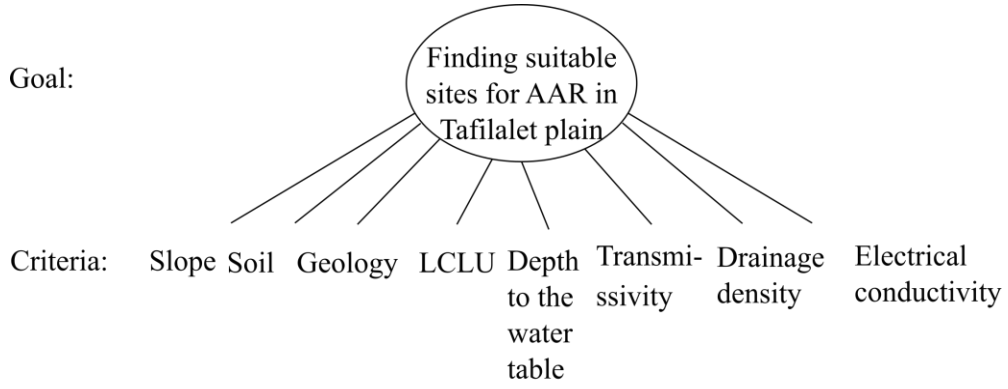

Figure 5: Hierarchy structure of the current study

Table 6: Pairwise matrix developed for the current study

Criteria	Slope	Soil	Geology	LCLU	Depth to the water table	Transmissivity	Electrical conductivity	Drainage density	Generated Weights
Slope	1	1/2	1/5	1/3	1/2	1/2	1	5	0.07
Soil	2	1	1/2	2	1	1	3	6	0.15
Geology	5	2	1	4	2	3	2	6	0.28
LCLU	3	1/2	1/4	1	1/2	1/2	2	5	0.10
Depth to the water table	2	1	1/2	2	1	1	3	7	0.16
Transmissivity	2	1	1/3	2	1	1	3	6	0.15
Electrical conductivity	1	1/3	1/2	1/2	1/3	1/3	1	5	0.07
Drainage density	1/5	1/6	1/6	1/5	1/7	1/6	1/5	1	0.02

4. Result

The map of potential sites for artificial aquifer recharge which is illustrated in Figure 6 was produced as explained above and then reclassified according to five categories which are: very poorly suitable, poorly suitable, moderately suitable, suitable, and very suitable. It indicates that the most suitable areas for the artificial groundwater recharge of Tafilalet aquifer are located notably in the northeast and in the west of the plain. Statistically, About 47 % of the study area is suitable for artificial aquifer recharge and about 40 % are moderately suitable. Thus, those results can be used to formulate an efficient groundwater management plan for sustainable utilization of these limited resources because identified areas will be prioritized in the implementation of artificial aquifer recharge projects.

Based on the produced map of potential sites for artificial recharge of Tafilalet aquifer (Figure 6), most suitable zones are underlain by high permeable geological formations that mostly belong to the late quaternary and covered with soils with high infiltration capacity most often constituted by alluvium and basic aeolian reliefs rich in meteoric materials and located in areas where the water table is very deep more than 20 m deep in addition the slope of the plain is generally not too steep and the above-mentioned description of the Tafilalet aquifer revealed that it is an alluvial and unconfined aquifer so, the artificial aquifer recharge technique most conducive with regard to the aforementioned conditions is infiltration basins nevertheless, the climatic characteristics of the region known by very high evapotranspiration rates will constitute a big challenge because more water will be lost by evaporation so less water will infiltrate unless the artificial aquifer recharge is conducted just during wet seasons when evapotranspiration rate decreases. Thus, several other factors must be taken into account when deciding whether a specific (AAR) system is suitable to be implemented, even if the appropriate locations are identified.

5. Discussion

The present-day situation of Tafilalet aquifer should urge water managers to work hard to avoid its worsening so, great efforts in risk mitigation need to be greatly accelerated and they should be centered on a range of scientific and engineering-based solutions. The current study presents one of those solutions which is the (AAR) and how to identify, in a scientific way, the most suitable locations for its implementation. In fact, A GIS-based multi-criteria analysis was performed, using eight thematic maps in order to produce an appropriate map for the identification of sites for (AAR) in Tafilalet plain. The resulting map shows that the most suitable areas are identified in the northeast and in the west of the region while inappropriate locations are limited to small portions in the northern, southern, and eastern parts of the study area. This result is extremely important because it will help taking appropriate decisions for mitigating the overexploitation problem of the Tafilalet aquifer that is why the scientific approach should be taken into consideration in such important projects because it gives nearly accurate results and it brings time savings.

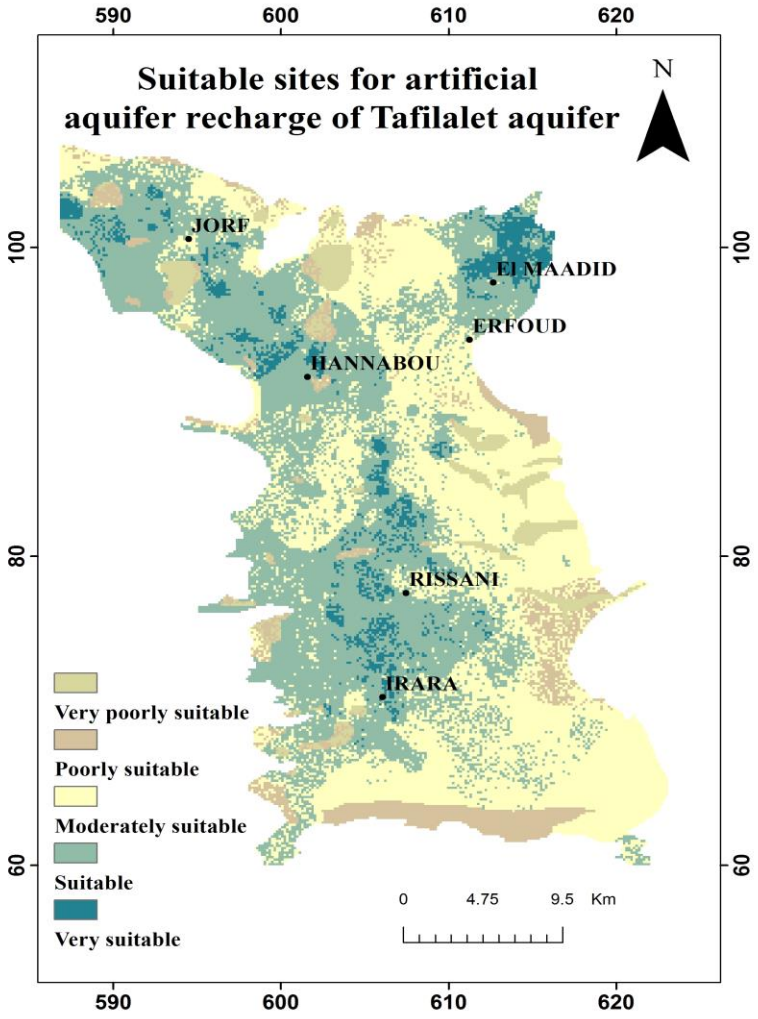

Figure 6: Potential artificial aquifer recharge sites map

The (AAR) will certainly sort out the problem of depletion of groundwaters in the Tafilalet aquifer as it was proved in some other aquifers in Morocco and in other countries. In fact, the (AAR) has already initiated and applied to some aquifers suffering from the same problem in Morocco such as the Charf El Akab aquifer in the region of Tangier, the Haouz Mejjate aquifer in the region of Marrakech, the Souss aquifer in the region of Agadir and the Berrechid aquifer located in the south of Casablanca, those aquifers have already started to reap its benefits. Even if the (AAR) practices in Morocco are still very much in their infancy, the technology is beginning to be recognized at the national level as having a value in tackling groundwater depletion issues.

Some attempts have been made in Tafilalet plain by the hydraulic basin agency of Guir-Ziz-Rheris in this regard and artificial recharging techniques have already begun to emerge on the plain, such as the construction of dikes or sills in the bed of the wadi Ziz in order to slow down the speed of the water and increase the wetted areas along the bed of the wadi, however, if the working field is extended to other locations that must be well chosen, these locations must be identified by means of scientific decision-making like GIS and multi-criteria analysis taking into consideration several criteria such as geological, pedological, hydrogeological, and many other factors to make sure that they are suitable for artificial recharge, in doing so, other artificial recharge techniques can be performed and can better and quickly restore the groundwater level situation of Tafilalet aquifer to its normal stage.

6. Conclusion

The aridity of the climate together with the excessive need for water is putting pressure on groundwater resources of Tafilalet plain so, the water level of the Tafilalet aquifer is declining to a threateningly low level which may undermine its productivity and causing its depletion, problems which are more likely to have irreversible adverse effects may occur like imperiling groundwater-dependent ecosystems, human activities as well as economic development of the region. Thus, the core objective of this study is to investigate suitable places for artificially recharge the Tafilalet aquifer to restore its levels to normal and fill the gap caused by overexploitation. For this purpose, thematic layers of factors that control groundwater recharge like depth to the water table, drainage density, electrical conductivity, slope, aquifer transmissivity, geology, soil, LCLU were prepared mapped, and reclassified in a GIS (ArcGIS software), after that, AHP method

was applied to compute weights of each factor and the map of appropriate sites of artificial groundwater recharge was generated by the application of weighted sum tool of ArcGIS software. The result has revealed that around 47% of the study area has been identified as a high potential zone for groundwater recharge which is a very important outcoming. However, identifying suitable places is essential but not sufficient for implementing (AAR) because as mentioned above even if infiltration basins are estimated as the appropriate (AAR) system to implement in Tafilalet plain, there are other factors to consider like climatic conditions of the region, need for periodic maintenance of the basin in order to sustain infiltration rates over the long term because organic matter build-up, silting and/or clogging can make the surface of the basin impervious and the capacity of infiltration will decrease over time in addition to the existence of a good quality water source nearby that will ensure the supply of water to be put into the basin and many other conditions that if not met will render the project impractical. Lastly, the present study has shown an example of the benefits of coupling multi-criteria analysis with GIS and remote sensing techniques in taking relevant decisions to better manage and protect groundwater resources.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The authors wish to record their deep sense of gratitude and profound thanks to all the employees of hydraulic basin agency of Guir-Ziz-Rheris for their warm welcome and their support to bring this work to fruition.

ABSTRACT

This research presents the outcomes of thin layer convective drying of ginger rhizomes with different treatments using the ARS-0680 environmental chambers for the drying process. TD 1002A – Linear Heat Conduction Experimental equipment was used in measuring the thermal conductivity of the ginger samples at varied temperature levels ranging from 10°C – 60°C and drying time of 2 – 24 hours. The result of this experiment shows that the average moisture content for 2 hours drying at 60°C was 70.6% while at 24 hours drying was an average of 7.55% which is close to the range of 4 – 7%. The drying rate at drying times of 24 hours was 0.889/°C and 0.4437/°C for 2 hours drying, giving 50% by moisture reduction rate. While the lowest moisture content (5.98%) is obtained for unpeeled ginger and the highest (9.04%) at 24 hours drying at 60°C, the analysis shows the variation in the temperature varied as the ginger shrinks when subjected to heat.

1. Introduction

Thin layer drying can be utilized in removing volatile liquid from porous materials such as foodstuffs, ceramic products, wood, and so on. Porous materials have microscopic capillaries and pores which allow for the simultaneous transfer of both moisture and air when subjected to heating or cooling. The drying of moist porous solids involves concurrent exchange of heat and mass. Moisture is eliminated simply by evaporation into an unsaturated gaseous phase. Drying is fundamentally essential for the preservation of crops for prospect usage. Crops are usually conserved by removing sufficient moisture from them to evade decay and deterioration. Reducing the moisture content of ginger rhizome to a very low level will discourage the growth and multiplication of microorganism which could decompose the rhizome. Nevertheless, the drying process could cause the enzymes present in ginger rhizomes to be destroyed.

Thin-layer drying studies provide the basis for understanding the unique drying characteristics of any particular food material. The results of such studies have been extensively employed in the simulation of dryers under deep-bed drying conditions and for quantifying parameters for the design of specialized drying equipment. In thin-layer drying, the moisture content of a bio-material exposed to a stream of drying air of known relative humidity, velocity, and the temperature is observed over a while. Several mathematical models have been developed to simulate moisture movement and mass transfer during the drying of many agricultural products [1]. The porous material that will be used for this study is ginger. The physicothermal properties of ginger will be obtained and used in the resulting mathematical equations.

Ginger rhizomes are popular in most countries throughout the world [2]. Ginger rhizomes are edible spices of tropical origin, though it can thrive in humid regions. It is harvested in different seasons depending on the region. In Nigeria, the harvesting period is usually in July, while in areas like Hawaii and the USA harvesting season is in December. Gingers grows up to 125cm high under conducive environments and it is an annual crop [3, 4].

Figure 1: Raw materials for the experiments (Ginger Rhizomes) [1]

*Corresponding Author: Gbasouzor Austin Ikechukwu, Email: unconditionaldivineventure@yahoo.com

It is grown for its pungently aromatic underground stem or rhizome which is an important export crop valued for its powder, oil, and oleoresin, all of which have both food and medicinal value [5].

Ginger is an herbaceous perennial plant known as *Zingiberofficinale*, which belongs to the order *scitamineae* and the family *zingriberaceae*

Nigeria is presently the fifth top producer of ginger in the world and one of the principal exporters of ginger [6] The most important form in which ginger enters international trade is as a dried product; next in importance is as preserved product, and least important is as fresh product [7].

The quality of fresh ginger produced in Nigeria is the best in the world. However, it has been observed that the quality of its dried ginger has been declining due to the low level of mechanization of ginger production and processing [8]; with the attendant mold growth and loss of some important ginger qualities because of which Nigerian ginger attracts the cheapest price in the world market [9].

The aforementioned issues formed the basis for this work. Attention will be directed towards the use of a thin-layer drying process to determine the drying characteristics of thin layered ginger in a convective environment.

The drying of the porous material was conducted experimentally under free and forced convection environmental conditions. Ginger rhizomes used were peeled, unpeeled, split, and then cut into slices before drying at elevated temperatures in the environmental chamber [10]. The heat and mass transfers were studied using available correlations of boundary layer equations.

The economy of Nigeria had since the mid-1960s of oil boom deviated from agriculture to petroleum. This has placed undue pressure on the oil reserves in the volatile Niger Delta region and agriculture and its produce have been neglected. Therefore, any adverse influence on oil both locally and internationally affects the economy of Nigeria drastically. The present administration of President Muhammad Buhari has promised Nigerians better days, change in all sectors, and improved agricultural outputs. Nigeria needs to process its agriculture produce to derive the desired benefits available in the international markets. This research seeks to find solutions to the prevailing low quality of dried ginger in Nigeria.

Most researches done on ginger rhizomes were focused on the effects of cutting, solar-drying, and particle size of Ginger (Zingiber officinale Roscoe) pigment and powder [11]; configuration of volatile oil [9]; biochemical variations in ginger during storage [12]; and advances of ginger processing technologies [8, 13, 14, 15-17]. The goal of this work is to analyze experimentally the drying characteristics of thin layered ginger rhizome in a convective environment.

This study on the thin layer drying characteristics of ginger rhizomes produced in Nigeria will be experimental and analytical. It will not delve into production methods, harvesting techniques, and marketing strategies. For this study; four different treatments were carried out on the ginger. They are blanched, unblanched, peeled, and unpeeled treatments [18].

The ginger rhizomes obtained for the study required minimum duration of six to eight months of planting and will be dried to 7 – 15% moisture content. The ginger samples used in this study were obtained from one region. It is assumed that most ginger produced in Nigeria have similar quality and characteristics.

2. Materials and Method

The ginger samples utilized in this study were supplied from Kachia in Southern Kaduna in the Kaduna State of Nigeria and were preserved at room temperature before being used for the experimentations. The experiments were carried out at the Electronic Manufacturing Engineering Laboratory (ERMERG) Hawkes building, University of Greenwich, Maritime Kent, UK.

Variously treated ginger samples (peeled, blanched, unpeeled and unblanched) were used in the experiments. The variously treated ginger samples were cut into slices of 30mm diameter and 18mm thickness by scoopers designed for this purpose. ARS – 0680 Temperature and Humidity Chamber were used to dry the samples. The chamber houses the samples and temperature is controlled by an electric heater. The ginger drying experiment was conducted according to ASAE Standard S352.2. Before the commencement of the experiment, the whole apparatus was operated for at least 15-30 minutes to stabilize the humidity, air temperature, and velocity in the dryer.

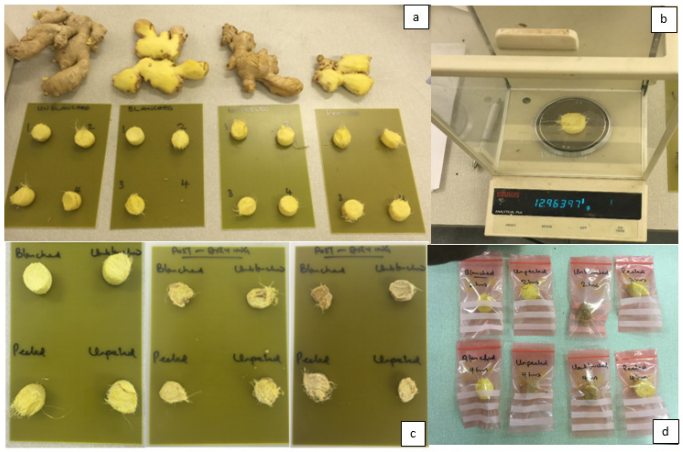

Figure 2: Schematic representation of ginger samples (a) Samples of fresh ginger (b) Sample in the electronic balances (c) Samples after drying; and (d) Bagged ginger samples after drying.

Drying started by 08:00 hours and lasted till the specimen attended the final moisture content. The weight loss of the sample in the environmental chamber was recorded during the drying period of 2 and 24 hours with an electronic balance (EK-200g, Max 200±0.01g) see figure 2c. At the end of drying, the thermal conductivity of the dried sample was measured with the aid of linear heat conduction equipment, TD1002A - Linear Heat Conduction Experiment Unit (LHTEU) [19].

3. Mathematical Modeling and Theoretical Principle

3.1. Determination of the most suitable model for drying

Thin-layer drying always requires a good understanding of the regression and correlation analysis. Linear and non-linear regression analysis are used to ascertain the relationship between variables MR and t in thin layer drying for selected drying models.

The recommended models chosen for applications were further validated using correlation analysis, standard error of estimate (SEE) and root means square error (RMSE) analysis respectively. The major indicator for selecting the best models is the determination coefficient (R^2). The highest determination coefficient and lowest standard error of estimate and RMSE values are used to determine the goodness of fit [20, 21, 22]. The determination coefficient (R^2); standard error of estimate (SEE) and root mean square error (RMSE) calculations can be performed using the following equations [23]:

$$R^2 = \frac{\sum_{i=1}^{N}(MR_i - MR_{pre,i})\sum_{i=1}^{N}(MR_i - MR_{exp,i})}{\sqrt{\left[\sum_{i=1}^{N}\left(MR_i - MR_{pre,,i}\right)^2\right] - \left[\sum_{i=1}^{N}\left(MR_i - MR_{exp,i}\right)^2\right]}} \quad (1)$$

$$SEE = \frac{\sum_{i=1}^{N}\left(MR_{exp,i} - MR_{pre,i}\right)^2}{d_f} \quad (2)$$

$$RMSE = \left[\frac{1}{N}\sum_{i=1}^{N}\left(MR_{pre,i} - MR_{exp,i}\right)^2\right]^{1/2} \quad (3)$$

where N is the number of observations, $MR_{pre,}\ I\ ith$ predicted moisture ratio values, $MR_{exp,i}\ ith$ experimental moisture ratio values, and d_f is the number of degree of freedom of the regression model.

3.2. Moisture Content (%) Calculation Formula

The moisture content of the materials can be calculated by using two methods: wet or dry basis

i. The wet basis is calculated as follows:

$$M_{wb} = \frac{w(i) - w(j)}{w(i)} \quad (4)$$

where

$M_{wb} = Moisture\ Content, wet\ basis\ (\%)$
$w(i) = mass\ of\ the\ sample\ before\ drying\ (g)$
$w(j) = mass\ of\ the\ sample\ after\ drying\ (g)$

The dry basis is calculated as follows:

$$M_{db} = \frac{w(t) - d}{d} \quad (5)$$

Moisture content, dry basis $\boldsymbol{M_{db}}$, is the amount of water per unit mass of dry solids (bone dry) existing in the sample

Where

$M_{db} = \text{Moisture Content, dry basis (\%)}$
$w(t) = \text{mass of wet materials at instant t (g)}$
$w = \text{mass of wet material (g)}$
$d = \text{mass of dry material (g)}$

Note that the two moisture contents are related by the following equation:

$$M_{db} = \frac{M_{wb}}{1 - M_{wb}} \quad (6)$$

3.3. Determination of the effective diffusivity and activation energy

The effective diffusivity of agricultural products can be determined using Fick's Second law for slab geometry [17, 18]. The common geometries were considered during the analytical solution of Fick's Second law for the infinite slab is expressed as:

$$MR = \frac{8}{\pi^2}\sum_{n=0}^{\infty}\frac{1}{(2n+1)^2}exp\left(-\frac{(2n+1)^2\pi^2 D_{eff}t}{4L^2}\right) \quad (7)$$

where n is a positive integer, L is the half-thickness of samples (m), D_{eff} is the effective moisture diffusivity (m^2/s), t is time (s), MR is the fractional moisture ratio.

Eq (7) can be modified in a logarithmic form as:

$$ln\ (MR) = \ln\left(\frac{8}{\pi^2}\right) - \left(\frac{\pi^2 D_{eff}t}{4L^2}\right) \quad (8)$$

The effective moisture diffusivity can be obtained by plotting $ln(MR)$against drying **time**; this gives a straight line with a slope (K) expressed as:

$$K = -\left(\frac{\pi^2 D_{eff}}{4L^2}\right) \quad (9)$$

The relationship between the effective diffusivity on temperature is described by the Arrhenius equation as [17-19]:

$$D_{eff} = D_0 exp\left(-\frac{E_a}{RT}\right) \quad (10)$$

Eq. (10) can be expressed in the logarithmic form as:

$$\ln D_{eff} = \left(-\frac{E_a}{RT}\right) + \ln D_0 \quad (11)$$

where D_0 is the pre-exponential factor of Arrhenius equation (m^2/s); E_a is the activation energy in (kJ/mol); R is the universal gas constant $8.314 J/molK$, and T is absolute air temperature (K).

From equation (11), plotting of $\boldsymbol{\ln D_{eff}}$ against $\boldsymbol{(T)^{-1}}$ would lead to the evaluation of activation energy for the diffusion of moisture during drying and $\boldsymbol{E_a}$ isobtainedas:$-(\boldsymbol{slope} \times R) = \boldsymbol{E_a}$, where ($-E_a/R$) is the slope of equation (18).

The average drying rate of the ginger in terms of initial and final moisture content could be evaluated using following equation [24].

$$\left(\frac{dM}{dt}\right)_{avg} = \frac{M_o - M_t}{t} \quad (12)$$

where $dm/dt\ is$ the average drying rate (kg/kg), t is the time (min), M_o is the initial moisture content ant and M_t is final moisture content [24].

The air velocity and temperature effect on the drying rate could be determined using appropriate statistical method. The overall drying rate of the ginger could be evaluated considering the total drying time as:

$$\left(\frac{dM}{dt}\right)_o = \frac{M_o - M_F}{t_1} \quad (13)$$

The evaluation of moisture content considering the dry basis could yield values more than 100% because the excessive moisture that could be present in some ginger rhizomes. The dry basis might be used to approximate the percentage moisture content as the moisture-free material. However, the wet basis moisture content is usually recommended for usage [25].

4. Results and Discussion

Tables 1 – 13 show the experimental results obtained during the whole experiment. This study considered two important features of thin-layer drying of ginger rhizomes:

- moisture content characteristics
- thermal conductivity of each sample at varying drying time and temperature with the aid of linear heat conduction's experimental unit in a convective chamber [26].

Table 1 shows the results obtained for moisture ratios and thermal conductivities of the variously treated ginger at a drying temperature of 10°C. The moisture ratios of the variously treated ginger samples decrease as the drying time increases. This implies that moisture is eliminated from the samples over time. Blanched treated samples recorded the least moisture ratio of 41.13. Also, the thermal conductivities for the various treatments decrease with the drying time. As expected, a decrease in moisture will not encourage faster moisture reduction.

Tables 2-6 present the results obtained for moisture ratios and thermal conductivities of the variously treated ginger at drying temperatures of 20°C, 30°C, 40°C, 50°C, and 60°C respectively. Both moisture ratios and thermal conductivities decrease with drying time. The least values were recorded at a drying time of 24 hours. The results of the variation of moisture ratios with drying time were plotted in figures 3 to 8 for various drying chamber temperatures,

The drying behavior of variously treated ginger rhizomes were studied using experimental drying curves. Drying curves for drying period of 2 –24hours at drying temperatures of 10°C to 60°C with step of 10 were considered. The results were employed to investigate the thermal conductivity content for the various treatments. The effect of moisture ratio on thermal conductivity with time was examined

4.1. Experimental Results at Temperatures 10°C

Table 1 shows the results obtained for moisture ratios and thermal conductivity of the variously treated ginger samples at a drying temperature of 10°C

Table 1: Moisture ratio (%) and thermal conductivity (W/m.K) at drying temperature of 10°C

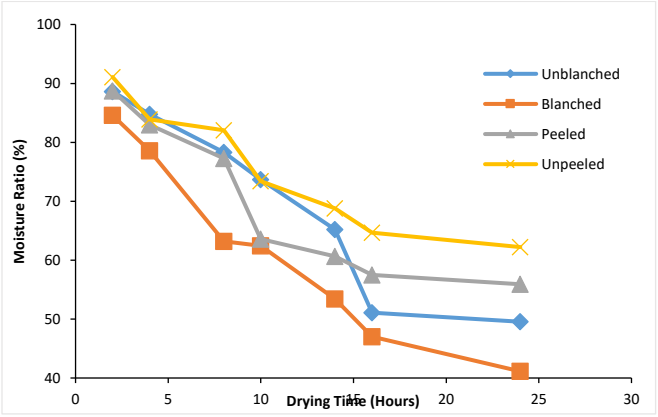

Figure 3: Variation of Moisture Ratio with Drying Time at 10^0C

Figure 3 shows the variation of moisture ratio with drying time at a temperature of 10°C for variously treated ginger samples. The unblanched ginger sample had a moisture ratio of about 88.64% before drying commenced, it lost moisture smoothly until 14hours where the moisture ratio reduced to 65.22%. It then drops abruptly to 51.1% within two hours and continued smoothly till 24hours. The blanched ginger sample had an initial moisture ratio of 84.58%; it lost moisture gradually till the end of the drying process with a final moisture ratio of 41.13%. It lost about 43.45% of moisture within twenty-four hours. Peeled and unpeeled treated samples lost 32.87% and 28.86% of moisture respectively within the twenty-four hours of drying. From figure 3, it could be deduced that the blanched ginger sample lost the highest amount of moisture with time while the unpeeled lost the least amount of moisture within the drying duration. Generally, the moisture ratio decreases with time for the variously treated ginger samples.

4.2. Experimental Results at Temperature of 20°C

Table 2 shows the results obtained for moisture ratios and thermal conductivity of the variously treated ginger samples at a drying temperature of 20°C

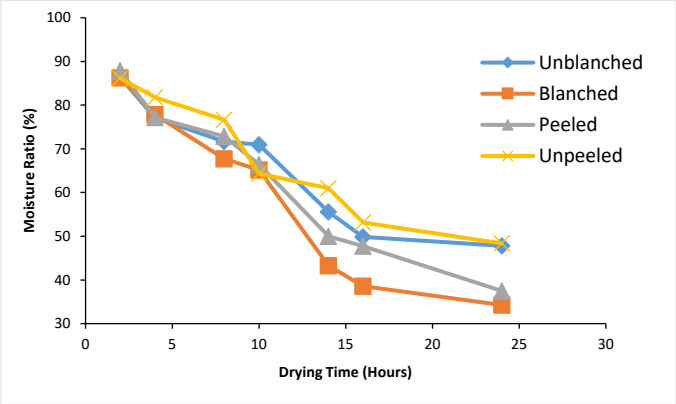

Figure 4: Variation of Moisture Ratio with Drying Time at 20^0C

Figure 4 presents the variation of the moisture ratio of the variously treated ginger sample with drying time at a temperature of 20°C. All the samples had almost the same initial moisture ratio of about 86%. The unblanched treated ginger sample lost about 38.54% of moisture, the blanched treated sample lost about 52.03%, the peeled treated sample lost about 50.36% and the unpeeled treated sample lost about 37.81%. As previously observed at drying temperature at 10°C, also at a drying temperature of 20°C blanched treated ginger sample lost the highest amount of moisture and the unpeeled treated ginger sample lost the least amount of moisture.

4.3. Experimental Results at Temperature of 30°C

Table 3 presented the results gotten for moisture ratios and thermal conductivity of variously treated ginger samples at a drying temperature of 30ºC

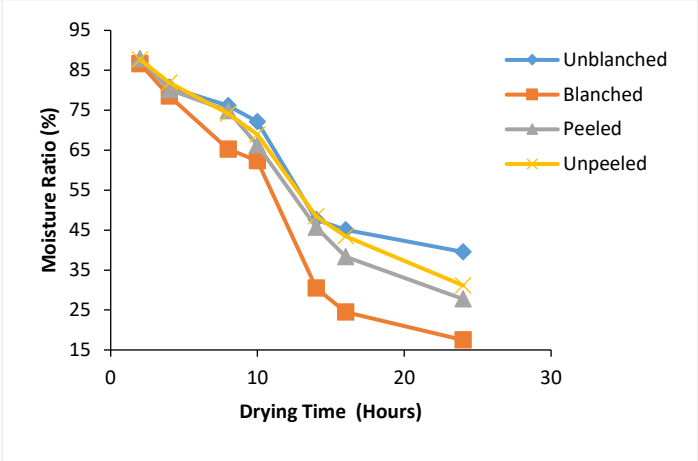

Figure 5: Variation of Moisture Ratio with Drying Time at 30^0C

Figure 5 presents the variation of the moisture ratio of the variously treated ginger sample with drying time at a temperature of 30°C. All the samples had almost the same initial moisture ratio of about 87%. The unblanched treated ginger sample lost about 47.79% of moisture, the blanched treated sample lost about 69.17%, the peeled treated sample lost about 60.16% and the unpeeled treated sample lost about 56.56%. The blanched treated ginger sample has the highest amount of loss while the unblanched treated ginger sample has the least amount of loss.

4.4. Experimental Results at Temperature of 40°C

Table 4 shows the results obtained for moisture ratios and thermal conductivity of the variously treated ginger samples at a drying temperature of 40ºC

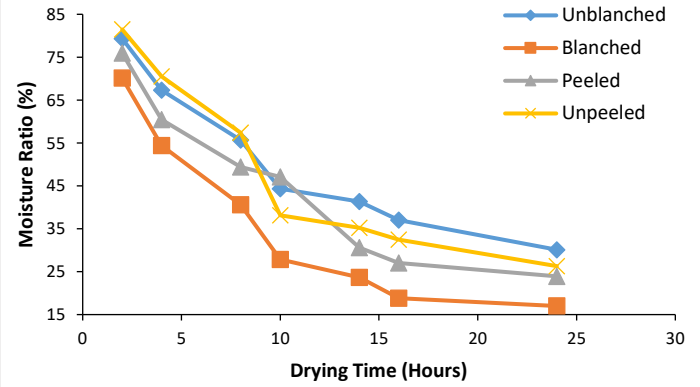

Figure 6: Variation of Moisture Ratio with Drying Time at 40^{0}C

Figure 6 presents the variation of the moisture ratio of the variously treated ginger sample with drying time at a temperature of 40°C. The unblanched treated ginger sample lost about 49.20% of moisture, the blanched treated sample lost about 53.11%, the peeled treated sample lost about 52.01% and the unpeeled treated sample lost about 55.16%. It can be observed that the unpeeled treated ginger sample experienced the highest moisture loss, but the blanched treated ginger sample attended the lowest moisture ratio of 17%.

4.5. Experimental Results at Temperature of 50℃

Table 5 shows the results obtained for moisture ratios and thermal conductivity of the variously treated ginger samples at a drying temperature of 50ºC

Table 5: Moisture ratio (%) and thermal conductivity (W/M. K) at a drying temperature of 50°C

Figure 8 presents the variation of the moisture ratio of the variously treated ginger sample with drying time at a temperature of 60°C. The unblanched treated ginger sample lost about 67.53% of moisture, the blanched treated sample lost about 54.07%, the peeled treated sample lost about 62.19% and the unpeeled treated sample lost about 68.38%. It could be observed that the unpeeled treated ginger sample experienced the highest moisture loss.

The respective ginger rhizome samples were dried at temperatures of 10°C to 60°C, at step of 10. Figures 3-8 present

the drying curve behavior of the variously treated ginger rhizomes at drying time of 2 - 24 hours and the effect of temperature on the different treatments. It could be observed that as the drying time increases, the moisture ratio decreases. Nevertheless, caution must be exercised to avoid excessive heating resulting from high temperature. Drying of ginger at excessive temperature could result in severe quality loss and shrinkages. Drying at above 60°C could result to quality loss and minor discoloration of the samples.

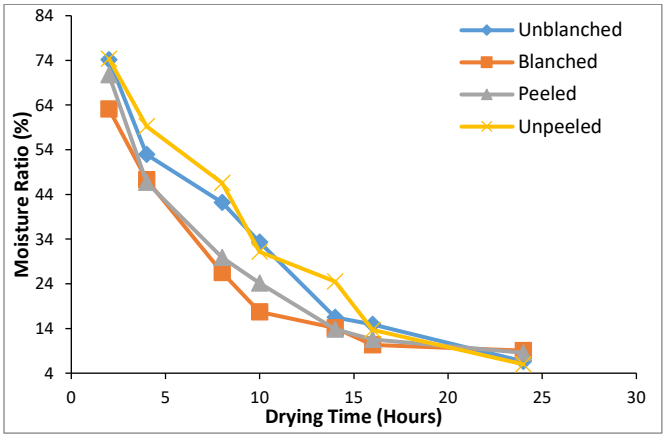

Figure 8: Variation of Moisture Ratio with Drying Time at 60^0C

The thermal conductivity decreases with the moisture ratio as the drying time progresses as shown in Tables 1-6. In Figures 3-8 the moisture ratio of the blanched ginger samples decreased the most when compared to other ginger samples while the unpeeled decreased the least. This could be as a result of the morphology of the ginger samples.

4.7. Drying Rate of Ginger Rhizome

Equation 12 shows that the average drying rate for ginger samples could deduct from Figures 3-8. The drying rate is the gradient of the graph of moisture ratio versus drying time. The values of the rate of drying for the various samples at different temperatures level were presented in Table 7; also, the averages for the various treatments of the samples were presented in Table 7. The negative value for the drying rate is a result of a loss of mass as the water content of the ginger escapes during drying. The blanched samples recorded the highest average drying rate indicating that it dries faster than the other samples, while the unblanched samples recorded the least average drying rate.

Table 7: Average Drying Rate for Variously Treated Ginger Samples

Samples	**dM/dt**						
	10^0C	20^0C	30^0C	40^0C	50^0C	60^0C	**Average**
Unblanched	-1.967	-1.839	-2.433	-2.177	-2.37	-2.98	**-2.2943**
Blanched	-2.026	-2.568	-3.495	-2.365	-2.683	-2.366	**-2.5838**
Peeled	-1.598	-2.341	-2.956	-2.359	-2.547	-2.614	**-2.4025**
Unpeeled	-1.351	-1.844	-2.768	-2.554	-2.339	-3.126	**-2.3303**

The sliced treated sample exhibited the highest drying rate, which might be attributed to diffusion behavior of the surface. The moisture travelled faster to the surface and evaporated than other treatments. Similar research showed that blanching increases the drying rate [27]. The various treatments exhibited different drying behaviors at lower drying temperatures; but as the drying temperature increased to 50°C, the difference becomes minimal. These variances could arise since blanching moderately exposed the sample to hot water and some cells might be slackened; which could cause the moisture diffusion to be higher and as consequently, resulting to higher the drying rate. The effect of this becomes conspicuous at drying temperature of 40°C - 50°C. Similar results were presented for red chili [28] and pear fruit [29]. External and internal factor have been reported to be responsible for controlling drying mechanisms in agricultural products. [30, 31]. The results indicated that the use of environmental chamber for drying purposes has minimized the drying time when compared with available reports on drying of peeled and unpeeled ginger which hitherto took 11 days to attain a moisture content of 17% using the open sun drying and 7.8% with the solar dryer [32]. Although samples in the solar dryer dry faster than those in the open-air sun, the convective drying methodology is a better time-saving measure. This observation agrees with some published reports [33-35].

4.8. Effect of Drying Time on Thermal Conductivity

Drying time is an important factor in the agro-based industrial process. Most agriculture products come in wet conditions and need to be dried to required standard moisture content at a given time interval. Variations in thermal conductivity of the variously treated ginger samples at various drying temperatures for drying time are shown in tables 8 to 13. Figures 9 to 14 present the effect of drying time on the thermal conductivities of the variously treated ginger samples.

Table 8: Variations in Thermal Conductivity of the Variously Treated Ginger Samples at Drying Temperature of 10°C

Time (Hour)	Thermal Conductivity (unblanched) $\left(\frac{W}{m.K}\right)$	Thermal Conductivity (blanched) $\left(\frac{W}{m.K}\right)$	Thermal Conductivity (unpeeled) $\left(\frac{W}{m.K}\right)$	Thermal Conductivity (peeled) $\left(\frac{W}{m.K}\right)$
2	0.4064	0.329	0.3397	0.3768

24	0.1607	0.14	0.1713	0.1449

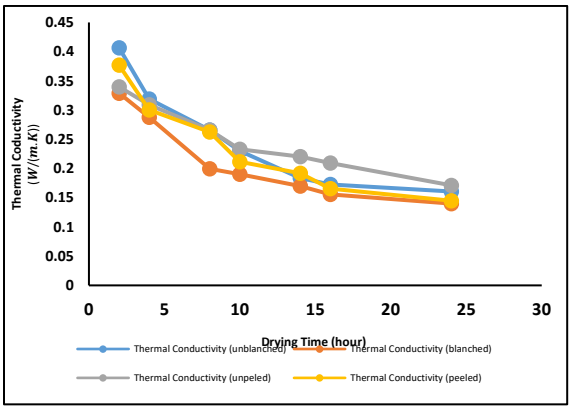

Figure 9: Variations of Thermal Conductivities of the Ginger samples at a drying temperature of 10^0C

Figure 9 presents the variation of thermal conductivity with drying time at a drying temperature of 10°C. The best fits to the data were logarithmic and polynomial of the second-order trend. The thermal conductivities for the variously treated samples decrease with time, which implies that as time progresses, less amount of moisture is lost. The thermal conductivity of the unblanched treated sample reduced from 0.4064W/mK to 0.1607W/mK within the twenty-four drying time. The thermal conductivity of the blanched treated sample reduced from 0.3397W/mK to 0.1713W/mK within the twenty-four drying time. The thermal conductivity of the unpeeled treated sample reduced from 0.329W/mK to 0.14W/mK within the twenty-four drying time. The thermal conductivity of the peeled treated sample reduced from 0.3768W/mK to 0.1449W/mK within the twenty-four drying time.

Table 9: Variations in Thermal Conductivity of the Ginger Samples at Drying Temperature of 20°C

Time (Hour)	Thermal Conductivity (unblanched) $\left(\frac{W}{m.K}\right)$	Thermal Conductivity (blanched) $\left(\frac{W}{m.K}\right)$	Thermal Conductivity (unpeeled) $\left(\frac{W}{m.K}\right)$	Thermal Conductivity (peeled) $\left(\frac{W}{m.K}\right)$
2	0.4064	0.2919	0.3454	0.3768
4	0.3188	0.2527	0.3343	0.3238

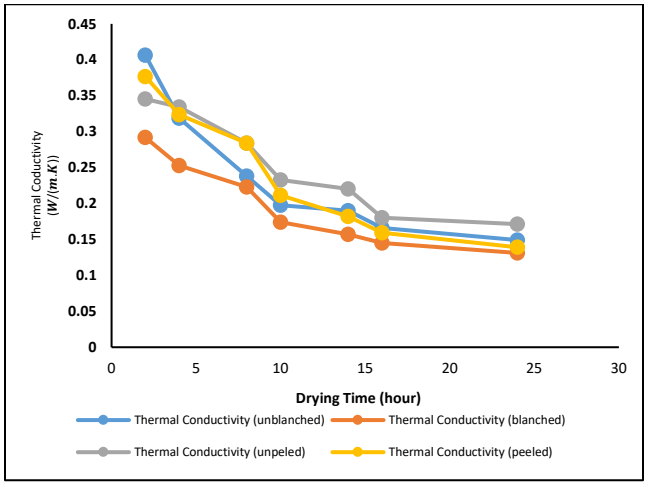

Figure 10: Variations of Thermal Conductivities of the Ginger samples at a drying temperature of 20^0C

Figure 10 presents the variation of thermal conductivity with drying time at a drying temperature of 20°C. Also, the best fits to the data were logarithmic and polynomial of a second-order trends. Also, the thermal conductivities for the variously treated samples decrease with time. It could be seen that as time increases, the thermal conductivity of the blanched treated sample is reduced as low as 0.1312W/mK.

The variation of thermal conductivity with drying time at a drying temperature of 30°C is shown in figure 11. Also, the best fits to the data were logarithmic and polynomial of a second-order trend. As expected the thermal conductivities for the variously treated samples decrease with time. It could be seen that as time increases, the thermal conductivity of the unpeeled treated sample is reduced as low as 0.0611W/mK.

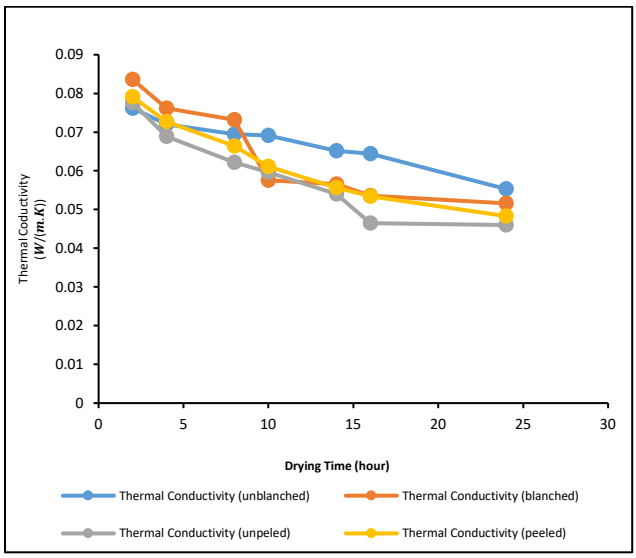

Figure 14: Variations of Thermal Conductivities of the Ginger samples at a drying temperature of 60^0C

Figure 14 presents the variation of thermal conductivity with drying time at a drying temperature of 60°C. The best fits to the data were found to be logarithmic and polynomial of a second-order trend. The thermal conductivities for the variously treated samples decrease with time. Also, the initial thermal conductivities for the various treatments decrease with temperature. The thermal conductivity value recorded was highest at drying time of 2 hours and then drops meaningfully until it reaches a drying time of 24 hours. This trend was prominent at drying temperatures of 10°C - 20°C and became insignificantly at drying temperatures of 30°C - 60°C for the variously treated samples.

The drying characteristics of Nigerian ginger rhizomes investigated shown that the drying route employed might be hastened only during the initial stages of the drying process where the movement of mass and air and are external factors that influence the rate of drying. The unpeeled and blanched treated ginger rhizomes are similarly influenced by the presence of moisture barriers like the unpeeled skins. As the studies reveal, drying of ginger rhizomes at low temperatures of 10°C-20°C does not have much significance on drying behavior as it maintains high initial moisture content and high thermal conductivity. However, as the temperature increases above 60°C ginger rhizomes becomes sensitive to temperature both in texture and color. The author opines that the drying of ginger rhizomes could be accomplished at temperatures between 50°C to 60°C to maintain the desired drying criteria.

5. Conclusion

The following conclusions were drawn from this study:

- It was gathered that ginger rhizomes might be dried at various temperatures. But ginger rhizomes dried at lower temperature might not reduce the effects of pest and bacterial infections, while drying at high temperatures say 60°C will considerably reduce the effects of pest and bacterial infecting connected with moist ginger rhizomes.
- The drying rate at drying time of 24 hours was 0.889/°C and 0.4437/°C for 2 hours drying time, giving about 50% reduction in moisture content. The interception which theoretically gives the initial moisture content of 0°C is lower at 24 hours drying (59.33%) compared to 95.12% on dry bases at 2 hours drying time, as expected. The average drying time for the variously treated ginger sample is about 2.4hours.
- The result of this study shows that the lowest moisture content of 5.98% was obtained for unpeeled ginger while the highest value of 9.04% was gotten for blanched sample for drying time of 24 hours and drying temperature of 60°C.
- The average moisture contents were 70.6% and 7.55% for 2 hours drying time at 60°C and 24hours drying time at 60°C respectively. The moisture content of 7.55% is close to the range of 4-7% desired for this research. This is an improvement to the result of 22.54% obtained at 50°C under blanched condition drying for 32 hours. [36, 37] as reported earlier the principal processing of ginger rhizomes involve sorting, washing, soaking, splitting, or peeling and drying to moisture content of 7-12%.
- The importance of drying ginger for a long time at temperatures close to 60°C has been shown in this work. At higher temperatures, ginger shrinkage and surface discoloration may occur. As can be seen, good results are attainable at a temperature of 60°C to maintain the quality of the products.
- The average effective moisture diffusivity and the average activation energy for the variously treated ginger rhizome samples are $5.49 \times 10^{-10} m^2/s$ and 22.63kJ/mol respectively.

MDVRP

ABSTRACT

The heath-care sector has confronted significant difficulties in the past few years due to several issues such as insufficient human resources, budget cuts, and shortage of equipment and drugs. The logistics in the health-care sector take an extensive part of the budget, especially since it is the main axis to provide the hospital's pharmacies with goods (drugs and materials).The delay in the delivery of drugs, inappropriate transport conditions, and quality are the main challenges for the health-care supply chain.

These issues will affect the user and hospital satisfaction and product quality during transportation/storage. The Geo-Distributed storages play a considerable role to provide equipment and drugs faster, thus, routing and scheduling method and also clustering method for geographic data is needed for defining regions and areas to be served by distributed storage. Having multiple storages to severe multiple health-care facilities it can be presented as Multiple Depot Vehicle Routing Problem (MDVRP) which can be solved using metaheuristics, however, the MDVRP cannot take into account the nature of the context (health-care), priority, and capacity of the facility to serve which is in this context the hospital bed capacity (HBC).

This paper presents a new smart logistic method for the health-care sector to provide a better drug pulling system, by using the clustering method to provide a suitable location for new pharmacies and using genetic algorithm to perform routing and scheduling for Multi-Depot Vehicle Routing Problem (MDVRP) in the health-care context to feed the hospital's pharmacies with goods. This approach considers planned routes from the depot (central/regional pharmacy) to hospitals, as chromosomes, and groups the chromosome based on geographic distance and hospital bed capacity as a cluster. This method provides results with minimal computing power and resources and less calculation time.

1. Introduction

Logistics play a major role in sustaining hospitals and health-care facilities as motioned in [1], from operating rooms to patient bed and health-care units, they are all supplied by hospital pharmacies with drugs and equipment. As shown in figure 1, those pharmacies are supplied by health-care warehouses or in other words central pharmacies, in the same case, the goods can be sent to another warehouse (regional pharmacy) to provide a more accessible warehouse to the hospital. Each regional pharmacy is responsible for serving hospitals and facilities in a region; those Hospitals vary greatly geographically and demographically. This has a significant impact on how health-care logistics practices can be applied in each region. As a result, the drug takes time to be delivered and low quality of transport, which causes the patient to be unsatisfied, and that affects the service quality. Also, the quality can be affected by other factors such as the drug needs and bed capacity in each hospital (HBC).

Figure 1: Drug's supply chains in health-care

The regional pharmacy needs to store a specific number of drugs based on hospital needs. Therefore, a drug pulling system is needed. The idea to build regional pharmacies for each region is unrealistic, due to the limit of the construction budget, human resource, and infrastructural factor. That is why an alternative solution is building a regional pharmacy that can serve multi-region hospitals. In this case, the system needs to cluster health-care facilities based on each region's needs to determine the suitable set or regions that can be served by the selected pharmacy, with the proposition of the nearby position for pharmacy construction. However, in many cases such as pandemic disease period and urgent situation, the region pharmacy has to serve multiple hospitals at once or even serve other hospitals in other nearby region's hospitals, which can be presented as routing and scheduling issues of the drugs to hospitals from regional pharmacies. In this case, an intelligent transportation system (ITS) approach needs to be applied to provide routing and scheduling solutions.

Nowadays, researchers use clustering methods besides Artificial Intelligence to solve similar issues related to routing and scheduling problems. The genetic algorithm is an optimization technique based on a parallel search mechanism which makes it more efficient than other classical optimization techniques. It reflects the process of natural selection, using the genetic operation as crossover and mutation to escape the local optimum by selecting the fittest individuals to reproduce a new population.

This paper will discuss at first section Multiple Depot Vehicle Routing Problem and the mathematical formulation, in the second section will present the approach of clustering region by geographic distance and hospital bed capacity, with a comparison between three well-known clustering methods. The third section is dedicated to the routing and scheduling method using genetic algorithm for drug delivery between Regional pharmacies and hospitals based on drug demand

2. Literature Review

Multi-Depot Vehicle Routing Problem is considered one of the well-known problems in the research field currently for solving the delivery of goods in multi-depot instead of one depot as VRP, the goal is to optimize cost and exchange between multiple sources and destinations. As proposed in [2], the author presents an approach using a model MDGVRP (MD green VRP) based on an ant colony with a solution to route the optimal path while considering the capacity of the vehicle and fuel capacity.

An ordinary algorithm can resolve vehicle routing problems. However, Multi depot vehicle routing problems cannot be resolved without consuming high computing power and resources, and the precision is still questionable. To get better precision, the genetic algorithm (GA) can be used in this case, because of the stochastic properties and efficiency of GA, also MDVRP can be resolved by using those techniques. In [3] author measure the MDVRP efficiency with and without GA, the result can be concluded to good impact on MDVRP while using the GA in term of performance, Also in [4] the author described an approach to resolve the MDVRP based on clustering algorithms, the authors proposed two algorithms, first one is the 'Minimum Distance', after sorting the distance from suppliers to depots, the supplier with the minimum distance is selected for the nearest depot without exceeding the depot capacity, and repeating the process until all supplier have been assigned. The second algorithm is 'Minimum Distance with Balancing Depot ', the first supplier located nearest to the depot will be chosen to be assigned, after. each unassigned depot will be assigned to the closest supplier sequentially provided that their supply does not exceed the depot's capacity. In [5] the author developed a new method based on machine learning with a combination of GA for solving problems related to VRP, this method learn to classify the coordinates into regions which drive to divide to routing calculations into regions, this method provides many benefits over previous research and traditional solutions used by companies by 25.68% of routing cost, and 8.1% over classical GA methods[4], also the ML side of this algorithm can predict of future customer regions which give new behavior to resolve the problem.

Clustering has been used to solve problems in diverse fields as bioinformatics, data mining, several methods, and clustering algorithms have been proposed to define hospital clusters. William Thomas has contributed several times for clustering and identifying hospitals with a methodology of clustering communities and hospitals simultaneously, which led to a geographically connected area of populations served by a common cluster of hospitals [1-6]. The State of Michigan has applied the Thomas methodology. In [7] the author explains an approach based on disease-specific hospital networks with considering similarity among disease symptoms, k-mean is among the most popular clustering algorithms [8], K-means is an unsupervised algorithm for non-hierarchical clustering, making it possible to group in K distinct clusters the observations of the data set. Thus, similar data will be in the same cluster. Moreover, an observation can only be found in one cluster at a time (exclusivity of belonging). The same observation, therefore, cannot belong to two different clusters. In [9] the author audited similarity in geographic location and patient utilization to create health-care facilities clus0ters by using two steps k-means clustering. In [10] the author uses cluster analysis to group health-care facilities based on the distribution of health-care spending across service categories with k-means as a clustering technique. On the other hand, by comparing centralized and decentralized pharmacies structure. In [11] author used the Weighted k-Means Algorithm to cluster Text, in [12] author showed that in the case of centralized pharmacies, the cost of transport is reduced, which makes the logistics chain less expensive. The transportation of goods — which, in this case, are drugs and equipment — are linked to the routing and scheduling, these two factors can give satisfaction for the consumer, in our cases, it is the hospitals and patients. Many studies have been proposed to solve the routing and scheduling problem, in 1995 [13] the author introduced the MDVRP. In [14] the author proposed two solutions for the MDVRP problem based on Genetic algorithms. Both authors in [15] and [16] tried to solve the problem with exact methods. However, the author of [17] demonstrated that both techniques are not effective. In [18] proposed an approach to solve for Priced MDVRP, which the vehicle visits customer only if it is profitable, they propose two methods: the heuristic method to solve the MDVRP and mixed-integer linear programming (MILP), and conclude that heuristics give better results. In [19] author

solved the MDVRP with separate delivery by proposing a heuristic based on integer programming.

3. Positioning the Contribution

As mentioned above, transportation is a main part of health-care. Costs invested in logistics can exceed 50% [20] of the hospital budget. In addition to the coasts, there are infrastructural issues. Those kinds of issues can cause slow delivery and affect the patient's satisfaction. The good's quality can also be affected by several aspects, such as the delivery condition especially if the central pharmacy or regional pharmacies are located in another region or distant region, caused by the lack of structure and construction of pharmacy, or pharmacies that are not well distributed or centralized in some specific region based on a political decision. Besides infrastructural issues, the organization is also involved, especially for routing and scheduling, to distribute drugs, regional pharmacy needs to prepare and send a vehicle with the quantity or equipment of specific drug without exceeding the vehicle capacity, but also there are some cases when other regional pharmacies can serve other region's hospitals. Especially if the vehicle capacity and the distance (the hospital in the same pharmacy region are near to other region's hospitals) can afford the delivery or in urgent cases. This challenge can't be resolved by the traditional VRP (Vehicle Routing Problem), because in this case, we are facing a multi-depot routing (Multi-regional pharmacies).

Our contribution/model allows solving the above issues and challenges, by proposing locations for the construction of future regional pharmacies, based on the number of newest pharmacies, geographic distance, and hospital bed capacity in each cluster (a group of hospitals). Also, the model improves the routing and scheduling for drug delivery, while allowing regional pharmacies to serve other regional hospitals in specific cases without overlap between pharmacies for serving the targeted hospital. The proposed contribution has been applied to solve a recent challenge pointed by the Ministry of the health of Morocco. In this paper, we propose a solution to improve the creation of new centralized pharmacies and determine the methodology of good's (drugs and equipment) delivery to regions, by clustering regions who will be served by regional pharmacies as the first step based on Performance indicators shared by the same ministry [21]. The second step is to project the MDVRP problem to the logistic chain of health-care by making the hospital (or set of hospitals) as a customer and centralized pharmacies as a depot.

4. Vehicle Routing With Several Pharmacies

4.1. Background

The distribution of goods based on routing paths is one of the most important challenges of logistics currently. In general, the cost is associated with the distance. Costs invested in transportation exceed 50% of the total cost of a supply chain [20]. The objective then is to minimize the cost of combined routes on Multi-depot vehicle routing problems (MDVRP) by minimizing the distance traveled by a group of vehicles exposed to different requirements. However, MDVRP is a non-deterministic polynomial-time (NP-Hard) for deciding the courses of several vehicles of several depots to a group of customers simultaneously and return to the same deposit without surpassing the capacity limit of each vehicle.

The Vehicle Routing Problem (VRP) as illustrated in figure 2, is a class of operational search and combinatorial optimization problems. The aim is to determine the routes of a fleet of vehicles to deliver a list of customers or to carry out tours of interventions (maintenance, repairs, and checks) or visits (medical visits, commercial, etc.). The main idea is to minimize the cost of delivering goods. This problem is a classic extension of the traveling salesman problem. It is an employee who is responsible for distributing products (or services) on behalf of one or more employers.

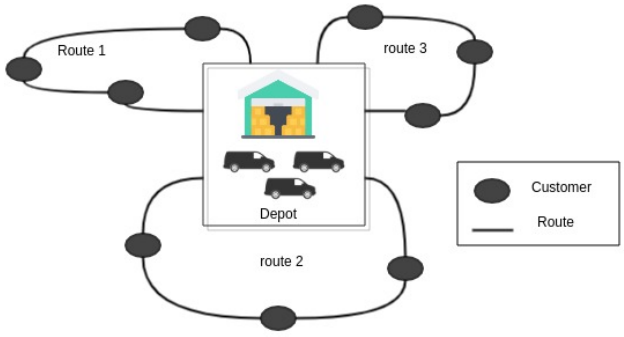

Figure 2: Illustration of Traditional VRP

MDVRP is a VRP with Multi depots from which the vehicle can serve its customers. If customers are grouped around repositories, then the distribution problem must be modeled as a set of independent VRPs. However, if clients and repositories are intertwined or for specific needs the delivery must be from another depot, the problem of multi-depot vehicle routing needs to be resolved. As shown in figure 3, the MDVRP processes several numbers of deposits. Each vehicle or set of vehicles is assigned to a single depot, which is usually both the origin and destination of the vehicle route

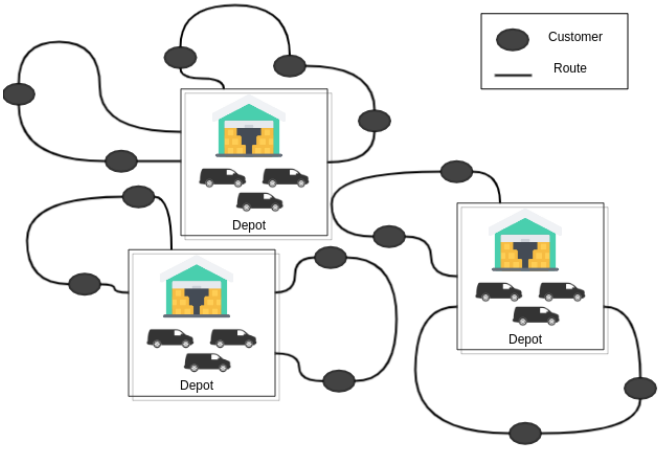

Figure 3: Illustration of MDVRP

We can group the approaches to solve the VRP into two doctrines: Exact algorithms and heuristics algorithms. Obviously, the MDVRP is more complex to solve than a simple VRP. Consequently, propose an optimal solution for an NP-hard

problem takes a long time, and maybe impossible with an exact algorithm. Both authors in [15] and [16] tried to solve the problem with exact methods. However, the author in [17] demonstrated that both techniques are not effective. In [18], the author proposes an approach to solve for Priced MDVRP, which the vehicle visits the customer only if it is profitable, they propose two methods: heuristic method to solve the MDVRP, and mixed-integer linear programming (MILP), and conclude that heuristics give better results.

It is unrealistic to use Linear Programming (LP) to solve large instances of the problem [22]. The intelligent algorithm is more widely applied, so the proposition is GA as a heuristic algorithm and one of the most promising hybrid intelligent methods for optimization problems. Distribution logistics encompasses all activities related to the supply of finished products and goods to customers. The central point of distribution logistics is the transportation of goods from the manufacturer to the consumer.

In our case, the manufacturers are a set of centralized pharmacies, and consumers are presented as hospitals' pharmacies. The idea of this contribution is to project the MDVRP model into the need for pharmacy logistics, representing centralized pharmacy as a single depot and hospitals as customers (or set of customers in cases of delegated hospitals to another hospital or health center). In some cases, one central pharmacy (CP) is not enough for some regions, also grouping/clustering phase is needed for our proposition, the grouping approach focuses on grouping hospitals and provides a suitable geographical place to consider building regional pharmacy while taking into account both distance and bed availability as a performance indicator in each region and hospitals which will be described in the next section.

4.2. Mathematical formulation

We can present our MDVRP mathematically as follows: $G = (V, E)$ is a graph where V is the set of vertices partitioned into two collections.

$V_c = \{V_1, V_2, \ldots, V_n\}$Represent the list of the hospitals.

$V_p = \{V_{n+1}, V_{n+2}, \ldots, v_{n+m}\}$ represent the collection of centralized pharmacies,

E set of edges connecting two points.

A Cost matrix $D = (D_{ij})$ is the length of arc (v_i, v_j) (corresponding to distance)

Expecting D symmetry, and the distance between sets of three points satisfies the triangle inequality.

Each centralized pharmacy $V_{n+m} \in V_d$ has the same model. k_m(The number of vehicles at the CP) are identical in term of vehicle (model, capacity Q, shape).

We consider the following:

Each vehicle starts from a centralized pharmacy (CP), serving a set of hospitals, at the end of the route or when Q is not enough to serve the next Hospital, the vehicle must return to the starting CP to refill.

Every hospital is visited only once by one vehicle, we consider in this example that a route can be done only by one vehicle.

The total demand for each route does not exceed the vehicle capacity Q

The vehicle cannot exceed the vehicle capacity Q, and the number provided by each CP is limited.

Centralized Pharmacies cannot serve each other's (CP cannot serve another CP).

The main objective for MDVRP, in this case, is to link hospitals into the proper CP with minimization of distance traveled by vehicle across the network.

n hospitals are grouped to form m clusters. Each cluster consists of $n_1, n_2, \ldots, n_m$ number of hospitals.

The number of vehicles based at a CP is k_m.

$k_j$is the group of hospital linked to a vehicle

Based on [23], MDVRP formulation for finding x which is the minimizes can be described as following:

Decision variables X and Y:

$$x_{ijkm} = \{\text{hospital j else } 0\}$$

$$y_{ikm} = \{\text{CP m else } 0\}$$

$$\text{MIN} = \sum_{p=1}^{m} \sum_{q=1}^{k_p} \sum_{i=1}^{n} \sum_{j=1}^{n} d_{ij} x_{ijqp} \quad (1)$$

Subject to:

$$\sum_{i=1}^{n} q_i y_{iqp} \leq Q \quad (2)$$

$$0 \leq n_{jq} \leq n_j \quad (3)$$

$$\sum_{q=1}^{k_j} n_{jq} = n_j \forall j = 1 \text{ to } m \quad (4)$$

$$\sum_{j=1}^{m} n_j = n \quad (5)$$

$$\sum_{p=1}^{m} \sum_{q=1}^{k_p} y_{iqp} = 1 \quad (6)$$

$$x_{ijqp} = 1 \vee 0 \quad (7)$$

$$y_{iqp} = 1 \vee 0 \quad (8)$$

The objective function according to Equation (1) minimizes the total delivery distance and cost of each vehicle within a CP. (2) limits capacity Q of the vehicle, (3) indicates the hospitals served by every vehicle must not overtake the number of the hospital a CP can deliver to. (4) shows the sum of the hospitals served by the whole route should be the sum of the hospitals served by CP m. (5) shows every hospital served by a CP. (6) guarantee that every hospital must be visited only once by vehicle. (7)(8) is the value bound of the decision variables.

5. Clustering Algorithms with Multiple Health-care Facilities

5.1. Clustering based on distance and HBC

Clustering is organizing objects (data) into homogeneous groups based on specific characteristics (data points) so that similar objects are kept in groups, while dissimilar objects belong to different groups or in other cases ignored.

Clustering algorithms are used in many fields such as image segmentation to group similar regions, insurance fraud detection, document clustering based on topics keywords, identifying crime-prone areas, customer segmentation for grouping customers based on behavior and needs, and public transport data analysis.

With 12 administrative divisions as regions, Morocco is the most north-western country in Africa. The construction of centralized pharmacies is for serving the hospitals pharmacies in defined regions, several approaches have been proposed to cluster hospitals [1, 6, 7, 9, 10]. We propose in our work clustering by Performance indicators of regions instead of hospitals. The data provided are grouped by regions.

The performance indicators in our case are Hospital Bed Capacity (HBC) by region. Table 1 shows the HBC in Morocco by region with latitude and longitude for each region. Table 1 presents the old territorial division based on 16 regions besides the HBC

Table 1: The HBC by Region in Morocco for 2015

REGION	ID	HBC	Geo-Position
Oued Ed-Dahab-Lagouira	A	53	(22.733, -14,286)
Laâyoune-Boujdour-Sakia El Hamra	B	313	(25.443 -13,174)
Guelmim-EsSemara	C	322	(28.708 -9,545)
Souss-Massa-Draa	D	2199	(31.120, -6,067
Marrakesh-Tensift-El Haouz	E	2347	(31.562, -7,959)
Meknes-Tafilalet	F	663	(31.905, -4,727)
Tadla-Azilal	G	964	(32.004, -6,578)
Doukkala-Abda	H	2872	(32.599, -8,660)
Chaouia-Ouardigha	I	1343	(33.047, -7,265)
Fes-Boulemane	J	1474	(33.187, -4,233)
Oriental	K	1739	(33.419, -2,145)
Grand Casablanca	L	826	(33.520, -7,568)
Rabat-Sale-Zemmour-Zaer	M	2884	(33.817, -6,237)
Taza-Al Hoceima-Taounate	N	1506	(34.258, -4,233)
Gharb-Chrarda-BeniHssen	O	757	(34.543, -5,898)
Tangier-Tetouan	P	813	(35.262, - 5,561)

The above table contains different data about regions and bed capacity in each classified by region. The order in this table is random, there is no order by any indicator, and each region has a specific geographic and demographic diversity.

Morocco is bordering the Mediterranean Sea and the Atlantic Ocean each region in a vertical shape as shown in figure 4.

Each dot in the above figure shows the location of a region presented in the previous table with their id to simplify the graphical presentation of the clustering operations.

5.2. Clustering algorithms to determine construction regional pharmacies area

One of the major challenges is to determine the most appropriate place to install the central pharmacy to serve a region or a set of regions and ensure the connectivity between these latter. The cluster appears to be the remedy to similar issues in a larger area. We aim to find the location of CP by using a range of clustering algorithms as k-means, DBSCAN, and Weighted K-means. All clustering algorithms are implemented using Python with numpy to calculate distance and matplotlib to display results as shown in map figures. The simulation of the clustering algorithms is done in an Alienware 32Gb RAM and i7 CPU (the execution of the scripts was in CPU level and not the GPU).

Figure 4: Old Territorial Division Based On 16 Regions of Morocco.

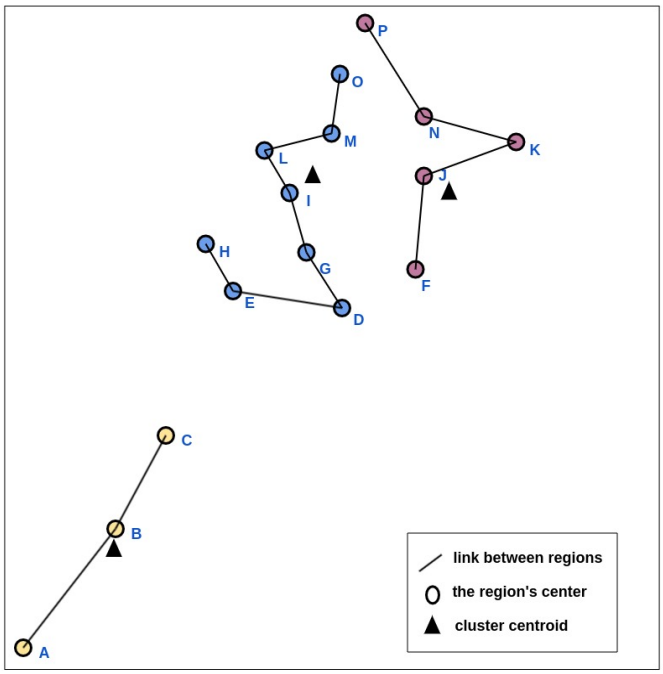

Figure 5: Geographic result as clustering with k = 3 using k-means.

5.2.1. Clustering with K-means

K-means is an unsupervised algorithm for non-hierarchical clustering, making it possible to group in K distinct clusters the observations of the data set. Thus, similar data will be in the same cluster. Moreover, an observation can only be found in one cluster at a time (exclusivity of belonging). The same observation, therefore, cannot belong to two different clusters.

We present each center of the region characterized by latitude and longitude as points in the cluster. Figures 5 and 6 present the result of clustering with k-means with 3 and 4 clusters in map shape.

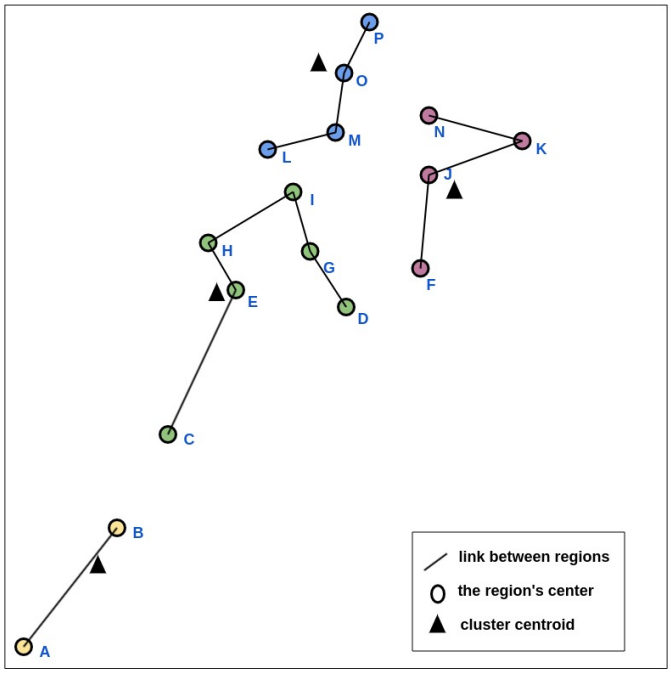

Figure 6: Geographic result as clustering with k = 4 using k-means.

The results of using k-means for 3 clusters show a favoring result for cluster 1 with a total of 15192 HBC and less than half for a cluster with 6195 HBC, for cluster 3 the HBC more minimal than the other clusters. Therefore, this method doesn't present equality or equilibrium between clusters, it shows a considerable imbalance between all three clusters. We can also notice the same disproportion for clustering with 4 clusters with different variations of total in every 4 clusters

5.2.2. Clustering using DBSCAN

DBSCAN is less popular than the k-means algorithm, based on the concept of density: cluster is an area of space where the density of observations is important. At the output, the algorithm generates as many clusters as areas of the high-density space. Isolated points are considered noise. The DBSCAN algorithm uses 2 parameters: the distance and the minimum number of MinPts (minimum number of points required to form a dense region) points to be in a radius for these points to be considered as clusters. The input parameters are therefore an estimate of the density of points of the clusters. The basic idea of the algorithm is then, for a given point, to retrieve its radius-neighborhood and check that it contains MinPts points or more. This point is then considered part of a cluster. We then go through the radius-neighborhood closer to find all the points of the cluster. Using the same data presented for k-means (without giving the number of clusters), the result was as following (Figure.7):

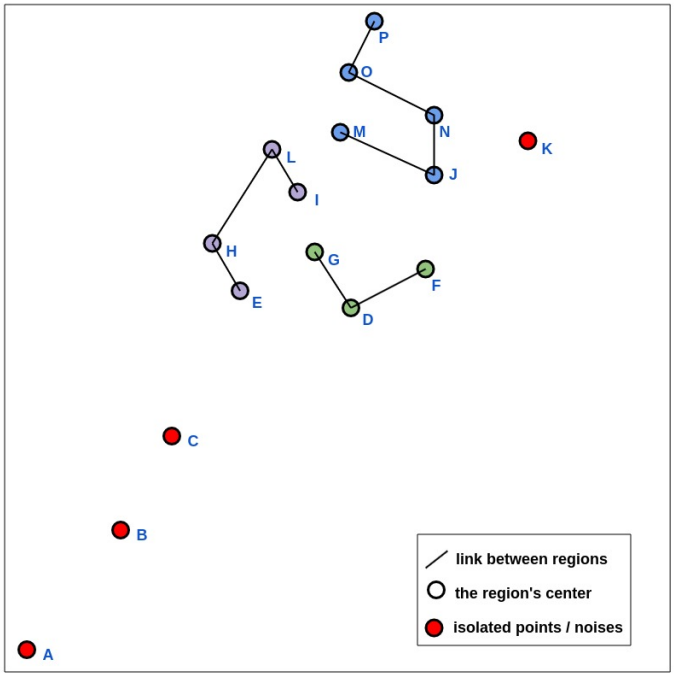

Figure 7: The result of clustering by using DBSCAN.

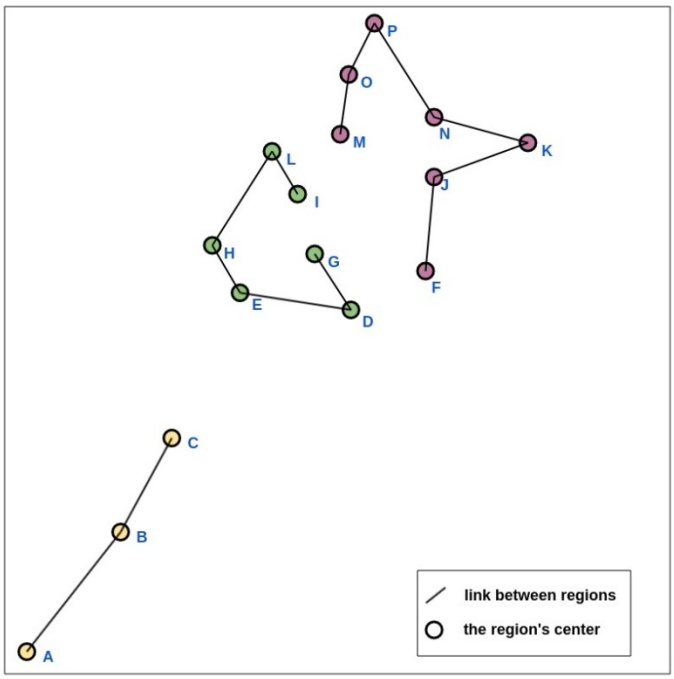

Figure 8: The result of weighted k-means for 3 clusters.

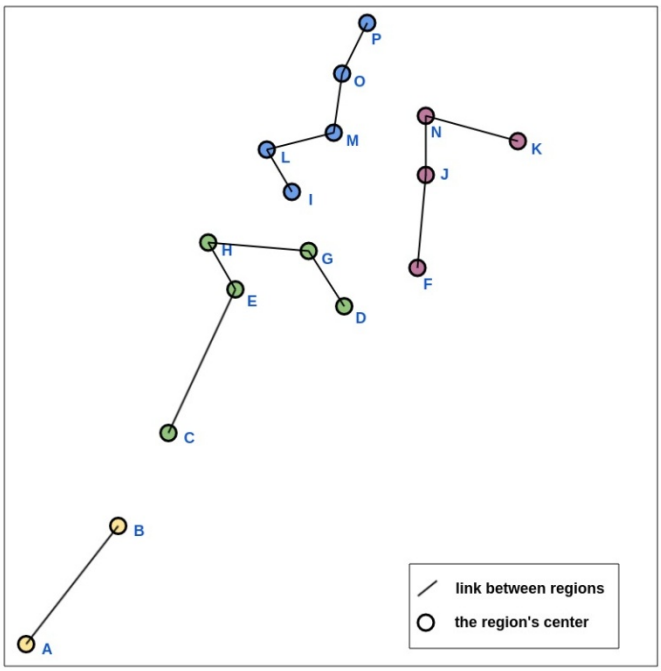

Figure 9: The result of weighted k-means fork = 4.

The result provided by this approach introduces the creation of 3 clusters where the density is outstanding. However, 4 regions are designed to be noise instead of points linked to a cluster, these are points that do not belong to any group/cluster. Noises or points that do not fit into any cluster are also significant at least in our case they present regions that need to be served, as they can represent a problem or rare event in data clustering, which we need to consider because it represents HBC in an isolated area, especially in epidemic cases, also this method cannot handle the number of clusters needed, the nature of DBSCAN consists on given number of clusters as a result which is not suitable in our case for decision making.

5.2.3. Clustering with weighted k-means

K-means algorithm groups data by assigning all points to the nearest clusters, and determining the cluster means. The algorithm repeats previous steps until points assemble. Weighted k-means automatically calculates the feature weights in a cluster, adopting the idea that features can have different degrees of relevance from other features. Figure 8 and 9 present the result of the current method for 3 and 4 clusters.

The result shows equilibrium between the two first clusters in the case of three clusters (first 11551, second 9836), and another equilibrium between the three first clusters in the case of four clusters (first 7623, second 5382, third 8704). Each cluster is unbiased in terms of HBC, south regions make an exception in this case because the points that represent the southern regions are far from the other points, which is tolerable since the integration of these regions with other regions will raise the costs of the transport.

Examination with k-means, DBSCAN, and weighted k-means shows progressively suitable results for weighted k-means. the method does not present an equilibrium between the clusters. However, clusters are unbiased, which the other clusters methods can't afford.

6. Genetic Algorithm

The Genetic Algorithm is a stochastic optimization technique based on a parallel search mechanism which makes it more efficient than other classical optimization techniques such as branch and bound, Tabu search method and simulated annealing. The main idea of GA is to avoid getting trapped in local optimum by genetic operators, crossover, and mutation. GA maintains a population of possible random solutions representing chromosomes that can evolve through a generation. The chromosomes are evaluated for fitness in each generation. The best-fitting chromosomes have a high probability to be selected for genetic operations such as crossover and mutation for the creation of the next generation.

GA is the most widely class of heuristics methods used as an application to the MDVRP problem, that why GA has received great attention from many authors, In [24] the author present a comparative study of different types of GA's applied to MDVRP, in [14] the author propose two solutions for the MDVRP. The first one is an implementation of the GA for solving the issues. The second one is a hybrid method with Clarke and Wright saving

method and nearest neighbor, and he proved that the last method performs better than the first one.

Initial population: or the first chromosome is formed based on the routes, CP and hospitals according to the clustering method we use in the first section (grouping, routing, and scheduling). Consider an MDVRP instance with 5 hospitals and 0 represent CP. If the path representation for this instance is (0 2 4 1 0 3 5 0), then two routes are required by the vehicles to serve all the hospitals. The first route: departs from the CP at 0 and travels to hospitals (2 4 1) as soon as the vehicle has returned to the CP. Second route: leaves the CP 0, serves hospitals 3, 5, and returns to the CP.

Evaluation: evaluate each chromosome by measuring the fitness value, the main function in MDVRP is to optimize the delivery time and decrease spending cost in n CP. The operation starts in every CP simultaneously, that's why it's normal that some vehicles in the network can achieve the objective (finish the delivery to the set of hospitals) while others can achieve the same objective later. In our context we consider fitness score calculated based on a total of cost route CR_{mk} of each vehicle (k) in every CP (m). The cost formula will be mathematically presented as the following:

$$\text{cost} = \sum^{m}\sum^{k} CR_{mk}$$

The cost for one vehicle of the i CP is calculated as the following:

$$CR_{i1} = D(d_i, c_1) + \sum D(c_j, d_i) + D(c_n, d_i) \text{ for all j } \in n_{jq}$$

Selection: for each generation, the best chromosome (based on fitness value) is selected for the mating pool and reproduction for the next generation, to generate new individuals in the population approach used in [14] use roulette wheel selection operation, while others use tournament selection [23]. The selection strategy is based on fitness evaluation, chromosomes will be selected with generated probability measured by the fitness function, the fittest individual we are selected for the next step.

Genetic operation: the mutation and crossover used in GA as genetic operation, both mutation and crossover affect the selected chromosomes with genetic operations rate.

Crossover: consists on combine genetic information from two genomes to a new generation. In [25] the author developed a technique for crossover based on BCRC - Best Cost Route Crossover - oriented to the vehicle routing problem with time windows (VRPTW). The classical order crossover is used by [14] to perform crossover into MDVRP. The aim is to combine the genetic information of exactly two parents to create new information

Mutation: consists of swapping two distinct customers i and j randomly selected, there are many propositions of mutation methods, and we can group them into two classes, heuristic mutation and inversion mutation. The effect is to flip a chromosome substring to create an offspring, mutation works on only one chromosome. The creation of the initial population will be projected as a chromosome with hospitals and regional pharmacies, hospitals presented as numbers while0_a, $0_b$are CP.

1	2	3	4	5	6	7	8	9	10	0_a	0_b

Grouping: We used the weighted-k means to cluster regions into the hospital's groups. Usually, in the same region, the geographical obstacle is not considerable. Also, the HBC for each hospital is not available. Therefore, in the grouping section, we use only Euclidean distance, however, if the space is large and can be affected by the shape of the globe, we can add haversine as distance instead of normal Euclidean one. The chromosome will be two sets of the group each group has its own pharmacy.

CP_A1, 2, 3, 4, 5. CP_B6, 7, 8, 9, 10.

The figure below (Figure 10) presents a flowchart to describe the initialization of parameters and the iteration on GA algorithm:

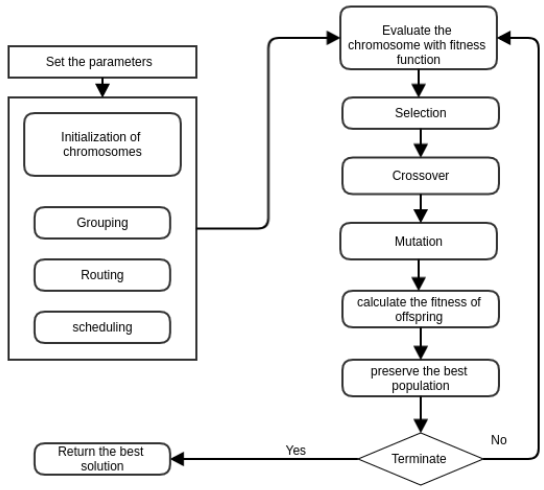

Figure 10: Flowchart of GA implementation.

7. Methods and Results

For the simulation, we used a list of hospitals by region from the Moroccan administration Open Data website, and we added demand for drugs to be served for the Casablanca region. Some of those health-care facilities use call for tender instead of begging to serve from CP based on category. For the purpose of this simulation, we consider all the facilities in table 2 are served by centralized pharmacies. Also, we consider three CP in the region only for the demonstration:

Table 2: The list of healthcare facilities in the grand Casablanca region.

ID	HOSPITAL	COORDINATE	DRUGS UNIT
1	Sekkat (Salam)	33.54631, -7.5884	30
2	Centre de Léprologie	33.55384, -7.59255	40
3	Mohamed V	33.58945, -7.55146	10
4	Med Bouafi	33.55874, -7.60972	15
5	Ben M'sick	33.55225, -7.5782	22
6	IbnRochd	33.58125, -7.61976	41

7	My Youssef	33.60274, -7.63226	13
8	20 Aout 1953	33.57474, -7.6199	8
9	Hôpitald'enfants	33.58088, -7.62111	21
10	Al Hassani	33.55849, -7.68736	26
11	Tit Mellil	33.54937, -7.48586	50
12	My Abdellah	33.69778, -7.38551	14
13	SidiOthmane	33.55804, -7.57312	7
14	Prince My Hassan	33.60457, -7.63394	13
15	Al Mansour	33.6078, -7.50362	30

Consider three CP with coordinate: CP1 {33.58212, -7.6594}, CP2 {33.57125, -7.5813}, CP3 {33.58200, -7.5289}

The capacity of each vehicle is 50 units, the population size is 10 chromosomes. In our demonstration we followed the standard GA for MDVRP mentioned by [23] after performing our clustering method mentioned above. The operation was simulated using C# as programming language on an Alienware aurora R2 CPU i7 and RAM 32 GB.

The grouping will give us three set CP1, CP2 and CP3:

CP1: [6-7-9-14-1-2-4] CP2: [5-8-10-11-13] CP3: [3-12-2015]

The bellow table (table 3) shows the simulation for weighted-k means by generations with their set of groups. The group here means the route that each vehicle needs to do to de starting from the source (CP in our case) which is presented as 0. Each 0 means a go back to CP to load drugs for the next route.

Table 3: Result of simulation for weighted-k means.

Generation	Fitness	Group	Path
Initial Generation	60000>	CP1	0-3-15-0-12-0
		CP2	0-1-13-0-11-0-10-5-0-8-2-0-4-0
		CP3	0-14-0-6-0-7-9-0
Generation 1	55986	CP1	0-3-15-0-12-0
		CP2	0-1-13-0-11-0-10-5-0-8-2-0-4-0
		CP3	0-6-0-14-7-9-0
Generation 20	51848	CP1	0-12-15-0-3-0
		CP2	0-8-10-0-1-0-11-0-4-5-13-0-2-0
		CP3	0-6-0-9-7-14-0
Generation 100	49948	CP1	0-12-15-0-3-0
		CP2	0-4-1-0-10-5-0-11-0-2-13-0-8-0
		CP3	0-14-7-9-0-6-0

Due to the mutation and crossover, each generation has its own fitness, a part of the above table presents an example of fitness by several generations (initial, 1, 20, 100). Figure 11 presents details of the evolution of fitness score by generation. The fitness is calculated based on several visits for the CP in each group, the figure also presents the comparison between k-means method used in [3] with the distance clustering and weighted k-means proposed in this paper. Both methods have the same initial data.

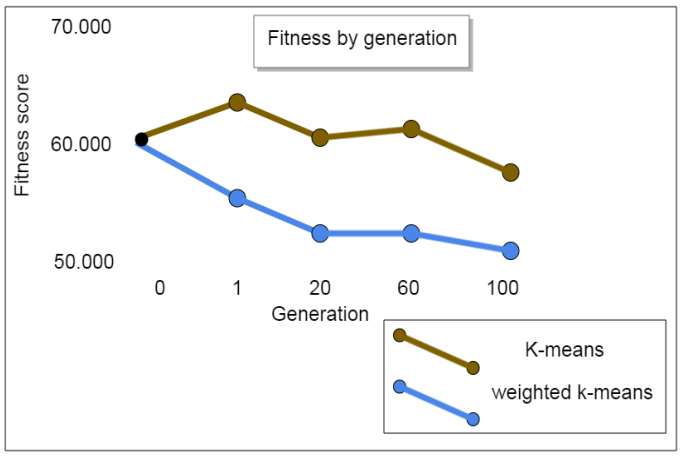

Figure 11: Fitness time for each generation.

Results show considerable regression in fitness score, which means acceptability of solution in newer generations in both clustering methods. Both methods have been improved over each generation, and the results shows that generation 100 is more fit in comparison with the others. However, the fitness score reached by weighted-k means is more acceptable than k-means.

The time simulation for each generation had shown a regression that can be presented in figure 12 as a chart for both methods. The time by minutes is calculated based on the distance crossed from each node of the set in each group with the visits of CP.

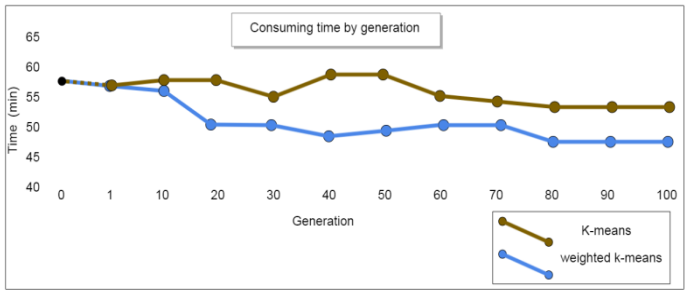

Figure 12. Consuming time for each generation.

In terms of time, the total consumption time from generation to generation is considerably changing in both methods. For the weighted k-means, the first generation shows better results in terms of time (less time-consuming means better results) in comparison with the initial random population (generation 0). At generation 40, the result is considered as the "better result", before time rises again. However, results show better results at generation 80 to 100 which means an escape from local minima to new global minima due to the use of crossover and mutation in GA and that shows less time in comparison with the normal k-means method.

Thus the result shows a less distance traveling between nodes (figure 11) and a faster route for each group using the weighted k-means in comparison of k-means (figure 12). Note that k-means has been improved over generations but not more fit then weighted k-means, which can impact the traveled cost by distance, the figure

13 shows the comparison between our proposed GA and the GA proposed by [3].

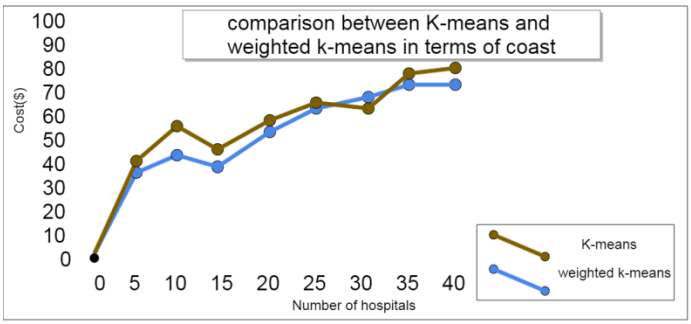

Figure 13: Comparison between K-means and weighted k-means in terms of cost.

The cost in weighted k-means is more efficient in comparison with traditional k-means, the figure 13 shows that the result using our proposed solution is competitive with k-means proposed by [3], however, the k-means solution can be more efficient if the hospitals' area in large number, which in our case not realistic due to the nature of the problem that we are resolving, the hospitals cannot exceed a large number in comparison with the CP and population in a specific region.

8. Conclusion and Future Work

Health-care and hospitals suffer from drug delivery delay and distribution due to the lack of infrastructure and distributed central/regional pharmacies. Our contribution is the adoption of clustering methods to locate the appropriate placement to set new central/regional pharmacy and group hospitals to favorable pharmacy based on hospital bed capacity, and using an algorithm based on genetic algorithms to set routing and scheduling plans for drug distribution at the level of one region or a set of regions. The MDVRP besides clustering is rarely adopted in the resolution of similar matters. The most relevant algorithm to adopt is weighted k-means one that showed favorable results, at least in our case. Also, even if this solution appears to be specific to the health-care sector, this work can concern further fields like agriculture and food-processing.

As an additional feature/improvement to the current model, it can be helpful considering applying parallelization and prediction for the GA algorithm and taking into consideration the conditions of transportation and providing an access to the result beside the transportation process with transparency.

Recommender systems

ABSTRACT

There is currently an overload of information on the internet, and this makes information search a challenging task. Researchers spend a lot of man-hour searching for journals related to their areas of research interest that can publish their research output on time. In, this study, a recommender system that can assist researchers access relevant journals that can publish their research output on time based on their preferences is developed. This system uses the information provided by researchers and previous authors' research publications to recommend journals with similar preferences. Data were collected from 867 respondents through an online questionnaire and from existing publication sources and databases on the web. The scope of the research was narrowed down to computer science-related journals. A hybrid model-based recommendation approach that combined Content-Based and Collaborative filtering was employed for the study. The Naive Bayes and Random Forest algorithms were used to model the recommender. WEKA, a machine learning tool, was used to implement the system. The result of the study showed that the Naïve Bayes produced a shorter training time (0.01s) and testing time (0.02s) than the Random forest training time (0.41) and testing time (0.09). On the other hand, the classification accuracy of the Random forest algorithm outperformed the naïve Bayes with % correctly classified instance of 89.73 and 72.66; kappa of 0.893 and 0.714; True Positive of 0.897 and 0.727 and ROC area of 0.998 and 0.977, respectively, among other metrics. The model derived in this work was used as a knowledge-base for the development of a web-based application, named "Journal Recommender" which allowed academic authors to input their preferences and obtain prompt journal recommendations. The developed system would help researchers to efficiently choose suitable journals to help their publication quest.

1. Introduction

The overload of information available through the world wide web today has created a lot of challenges for information seekers. Researchers who are in need of journals related to their research area sometimes find it difficult to access and keep track of the relevant journals or research materials of their interest including searching for relevant journal to publish research outputs.

Conducting a very good research could be very stressful and searching for the right journal to publish it could even be more stressful. Academic authors are therefore faced with making their decision based on a number of competing preferences such as the scope of the journal, the access type, article processing charge, speed of the review process, impact factor, indexing and ranking just to mention a few. A simple approach used in searching for such journal publishers is to randomly surf the web by typing some specific keywords predetermined by the author. Results obtained from using this style may not be too beneficial as it is probability-based and highly dependent on the searching skills and maneuvering abilities of the author. Some authors, also, make their journal selection decision by checking out the reference lists form existing related journals available to them. This style is also limited in scope and it depends fully on related journals currently available to the author. Moreover, some potentially useful journals may be difficult to access by authors. It is also a fact that the article processing charge of some accessible journals may be too expensive especially for authors from low income countries where

access to research grants and funding are also a major challenge. There is, therefore, a need for a recommender system that can assist in solving the highlighted problems.

Recommender systems are described as information filtering systems that are designed to solve the challenge of information overload by filtering a large amount of information according to the user's observed behaviour, interest, preferences and producing very useful and vital information fragment as output [1]. Recommender systems have the ability to predict the choice of its user based on their past preferences. In this work, the use of a journal recommender systems to automatically suggest relevant journals to the researchers based on some initial information provided by the users and other information from journal publishing sites, was developed. To provide more relevant recommendations, the developed recommender system would incorporate the list of journals, the type of journal access whether it is an open access or restricted access, free or article processing fee, research topic, the field of study, indexing and rating. It is also specific to the field of study, which is Computer science-related journals.

This work resolves information overload problem to academic authors; whereby a researcher would want his/her authored works to be published, this might take a more extended period because the scope in the popular bibliographic database is vast. Also, in this age, when there is high proliferation of academic journals, getting the right journal to publish an article could turn out to be a huge task. A recommender system for guiding researchers when searching for journals to publish their articles promptly was developed in this work. This would make their publication quest easier and effective.

2. Literature review

In this section, some relevant literature tied to the research were reviewed and some closely related works were also presented.

2.1. Recommender Systems

The increasing use of internet services has resulted in a massive amount of data and information available on the internet. The nature of this data is so dynamic as well as diverse that it becomes difficult for one to look for the kind of data that matches the requirements. This challenge has aroused the development of new technology to assist Internet users to cope with information overload and indecisions on a product, service and items. They are called Recommender Systems. According to [2], recommender systems are applications that filters users' preferences, suggesting the most suitable items to specific users based on similar information about the users, the items, and their relationships. Solving the problem of information overload and filtering out the most important items, products and services are considered to be the primary purpose of recommender systems. Personalized recommendations could be generated by analyzing the behaviour of a user and other similar users to suggest user's interests and preferences [3]. Recommender systems are very useful in diverse domains such as education, commercial, entertainment, for example, movies, music and others. This work focused on deploying the recommender system in the academic domain in order to facilitate the search for useful educational web resources such as Journals, more comfortable to find, thereby helping researchers enhance their publishing process by getting access to very useful journal recommendations leading to faster publication time.

2.2. Techniques of Recommender Systems

The main recommendation techniques include traditional methods such as content-based, collaborative filtering-based, hybrid-based (a combination of content-based and collaborative filtering methods) and knowledge-based methods [4]. Other recently appearing variants in the literature are trust-based, group-based, fuzzy set-based, context awareness-based and social network-based methods. The most acceptable and widely used out of all are the traditional recommendation methods. Content-based is further divided into tag-based and descriptive-based. Collaborative filtering's subdivisions are Model-based and Memory-based, under model-based are Clustering, Association, Bayesian networks while for Memory-based are User-based and Item-based.

In content-based recommendation methods, items similar to items previously preferred by a specific user are usually recommended [5]. More on the basic principles, techniques, strengths and limitations of content-based recommender approaches can be found in [5]-[7]. On the other hand, collaborative filtering is a process of filtering information or pattern based on the opinion of other users, or the similarity between items [6]. This approach makes recommendation by finding similar users having a rating history similar to the new user. This implies that user preferences, in this case, are compared with the other users [7]. More information on the collaborative approach, its characteristics, techniques, strengths and drawbacks can be found in [6]-[10]. A hybrid recommendation system is an approach that deals with the combination of different recommendation models to evolve a more efficient and effective technique that would outperform the traditional stand-alone recommendation techniques. This is done to overcome the weaknesses of stand-alone recommendation techniques while combining their power and strengths to achieve better recommendation. There are seven main combination approaches for building hybrid recommendation system, and they are also grouped into three designs which are Monolithic, Parallelized and Pipelined. More details on hybrid recommendation systems, adapted in this work, could be obtained from the works of [4], [10] and [11].

2.3. Related Works

Apart from some of the previous works done by authors [12] and [13] on the exploration of recommender systems in the education sector, some other related works are also presented here. The authors considered only one algorithm in their implementations. A knowledge-base of product semantics recommender system was built by [14]. The recommender system was capable of determining semantic attributes of products, thereby helping the authors to understand the customer's taste. In order to learn the attributes of the product descriptions found on retailers' websites, supervised and semi-supervised learning techniques were applied to the system. The system was able to map products to an abstract layer of semantic features by recommending other items in the same class of products that

matches the user's model and understand the customer taste and also recommend items across categories. This approach is believed to enhance the user experience and build the user's confidences in the recommendations. The work of [14] focused on narrow classes of products from retailers' websites. A recommendation system based on collaborative filtering approach using Convolution Deep Learning Model was proposed by [15]. The convolution deep learning model used was based on the Label Weight Nearest Neighbor with three categorizations. The authors in [15] concluded that their proposed system outperformed the other traditional recommendation algorithms in terms of efficiency and effectiveness.

In [16], a product recommender system based on a hybrid recommendation technique was presented. The system focused on books as the product, and in order to recommend more accurately, a personalized book recommendation algorithm was used. It was based on the time-sequential collaborative filtering and content-based filtering. Essential factors such as time sequence of purchasing books of different users in the database and content of the user profile were considered in the system, and it is expected to satisfy users by providing best and efficient book recommendations. The accuracy of recommendation results in this work was low and this was due to the small volume of books used as the experimental dataset. The authors in [17] were able to predict fake information and fake Facebook accounts using a machine learning-based recommendation approach, which can also work on online social network. The limitation of the work was the low prediction accuracies recorded. In [18], a collaborative filtering job recommender system was developed, which was executed by exploring and analyzing Google employees' features to match the qualifications of job seekers and, thereafter, recommending Google to job seekers. The classification algorithms used were SVM, Naïve Bayes, Neural Networks and Decision Tree. The low F1 score and the few number of companies with few features was the limitation to the work.

3. Methodology

This section presents the research methodology, which includes the techniques used in the recommendation system and the design of the hybrid recommendation system.

3.1. Data collection and description

The primary aim of this work is to develop a system that recommends computer-related journals to academic researchers and authors. Two sets of data were used for the study. First primary data was collected through an online questionnaire prepared through google form and broadcasted across the web. Secondary data was also collected directly from major journal databases and indexing organizations available online. The sources of the data were obtained from bibliographic databases, journal publishers, and their journals, some of them are, Science Direct, Scopus, Researchgate, Elsevier, Google Scholar, DOAJ just to mention a few. The selected journals from these databases were specific to the field of computer science, and the topics selected covered every aspect of computer science including Computer programming, Big data analytics, Software engineering, Computer Architecture, Artificial Intelligence, Cybersecurity, Decision trees, Encryption, Data Mining, Recommendation systems, Human-Computer Interaction, Robotics and Cloud computing just to mention a few.

The questionnaire, used to collect the data was administered online using Google Forms, with eight hundred and sixty-seven (867) respondents, who are researchers that have published at least one article in a standard journal responded to the survey. There were three major sections in the online questionnaire. The first section contained the "Demographic data of the respondents". The second section contained "Questions on Articles Already Published by Respondents in Learned Journals" and "Questions on Publishing Preferences". The first section consisted of five questions. The second and third questions consisted of ten questions, each making a total twenty-five questions altogether. The demographic section contained five questions that required answers about the target audience which included their optional full names, institution, gender, highest academic qualification and work status of respondents. In summary, the majority (71%) of the respondents were males, and the remaining 29% were females. 76% of the respondents were PhD holders, and most (73%) of the respondents had published at least two articles in learned journals.

3.2. Attribute Representation and Categorization

Four major attributes were used for the recommendation in this work. They are Area of Research Interest (ARI), Journal Access Type (JAT), Article Processing Charge (APC), Indexing and Ranking (IAR). All the data were stored in Microsoft Excel and saved as a comma-separated (.CSV) files. The attributes used were assigned labels represented by three-character nominal values to make the data suitable for classification. These attributes represent preferences of future authors that will be matched in the journal recommendations model built from preferences selected by previous authors and secondary data obtained from publishing sites.

Eighty-one ARI was identified in Computer Science. They are Artificial Intelligence, Adaptive computing, Big Data Analytics, Bioinformatics, Biometric Technology, Classification, Cloud Computing, Clustering, Computational Biology, Computer Forensics, Computer Security, Computer Vision, Content Management Systems, Crowdsourcing, Cryptography, Cybernetics, Data Security, Data Management, Data Warehousing, Data Mining, Decision Support Systems, Decision trees and forests, Distributed systems, E-Commerce, E-Government, E-Learning Technologies, Embedded Systems, Evolutionary computing, Genetic Algorithms, Global Positioning System (GPS), Global System for Mobiles (GSM), Geographical Information Systems (GIS), Green Computing, Grid Computing, Human-Computer Interaction (HCI), Image processing technologies, Information systems, Internet Telephony, Intrusion Detection Systems, Knowledge based systems, Knowledge Management Systems, Machine Learning, Management Information Systems, Mobile agents, Mobile Computing, Multi-agent systems, Network Security, Artificial Neural Networks, Open Source Technology, Parallel Computing, Computer Architecture, Parasitic Computing, Pattern Recognition Techniques, Pervasive Computing, Proactive Computing, Real-time information systems, Recommender Systems, Robotics, Social Networks and Online Communities, Soft Computing, Support Vector Machines (SVM), Theoretical Computer Science, Internet of Things, Virtual Reality, Visualization, Voice Over Internet Protocol, Web-mining, Network Topology, Biosystems & Computational Biology, Cyber-Physical Systems and Design

Automation, Computer Engineering, Database Systems, Computer Education, Computer Graphics, Process Mining, Operating Systems, Programming Systems, Scientific Computing, Security, Theoretical Computing, Networking and Deep Learning. The JAT was divided into two categories, which are Open Access (OA) and Restricted Access (RA). Table 1 shows the distribution characteristics of the preferences of the respondents concerning JAT. The majority (62.51%) of the respondents preferred to publish in open access journals.

Table 1: Journal access type preferences

JAT	Frequency	Percentage (%)
OA	542	62.51
RA	325	37.49
TOTAL	867	100.00

APC was sub-divided into three other categories, which are low, medium and high with low having highest percentage (83.04%) preferences among the respondents, as shown in Table 2.

Table 2: Journal Article Processing Charge Preferences

Category	APC	Frequency	Percentage (%)
BELOW 500USD	LOW	720	83.04
500 - 1000 USD	MEDIUM	92	10.61
ABOVE 1000 USD	HIGH	55	6.34
	TOTAL	867	100.00

Furthermore, few (23.07%) of the respondents did not care about indexing and ranking of the journal while the majority (76.93%) considered ranking and indexing as the most crucial factor for publishing their articles in a journal (Table 3).

Table 3: Journal Indexing and Ranking Preferences

IAR	Frequency	Percentage (%)
YES	667	76.93
NO	200	23.07
TOTAL	867	100.00

3.3. The Design of the Recommender System

This section gives an accurate description of how the proposed system was designed. Unified Modeling Language (UML) was used to understand the flow of this system, and it shows the functions the users can do. The users of the system are represented as actors of the system, and the actions performed are called the use-case. There are two primary users of the system, the admin and the user. Figure 1 shows the use-case diagram for the Admin and User of the system. The Admin will normally log in as the system administrator. The System Admin can add journals and make it accessible to the system users with all the required details attached to it. The details are its Title, Topic category, Publisher, Its type of access, Its article processing fee, Issues per year and its link for easy access. System Admin can also add the category of a journal which also means the field of the journal, Publishers of Journals into the system and can View, Edit, Update and Delete Journals details. The User, on the other hand, can register and login to the system, search for Journals, Publishers, Categories with the use of keywords, view system recommendations regarding journals selected and generated by the system based on particular preferences.

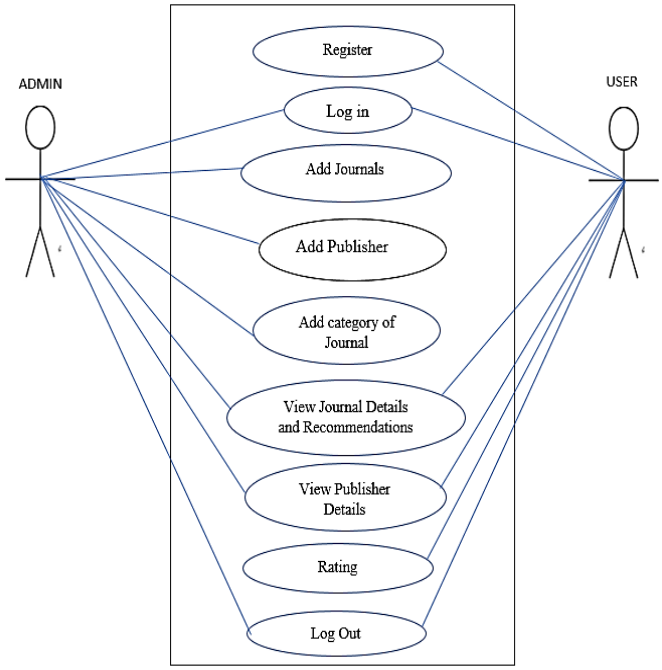

Figure 1: The Use-Case Diagram for the Recommendation System

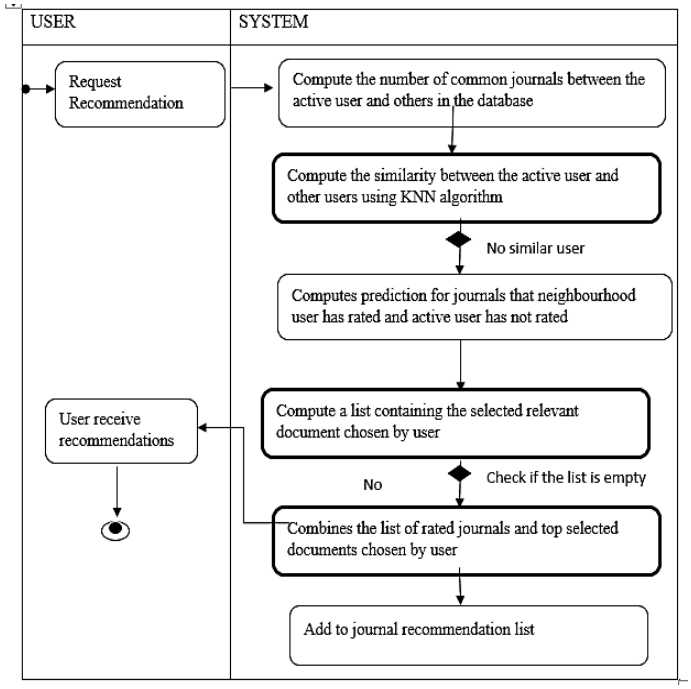

Figure 2: The Hybrid Filtering Recommendation Activity Diagram

3.3.1. Description of the hybrid filtering recommendation activity diagram

In a hybrid recommendation model shown in figure 2, recommendations were based on content-based filtering and collaborative recommendation combined using a monolithic feature augmentation approach. It also employed the combination of Naïve Bayes and Random forest algorithms for searching the desired journal. This model combined the results of collaborative and the result of content-based views the results to the users**.**

3.3.2. Description of the register process activity diagram

The activity diagram in Figure 3 shows that for a user to make use of the system, the user has to be registered with valid registration details. The user views the blank registration form and fills in personal details such as name, email address and phone number and other details the system requires. As the user begins to fill the form, the system simultaneously stores the information. The user is also expected to fill the preferences details such as the user's research topic, the type of access to journals, and field of study. Then the account form as part of the registration is the authentication using passwords. After the user has filled all the dialogue boxes for registration, the user's account is successfully created, and the account is active.

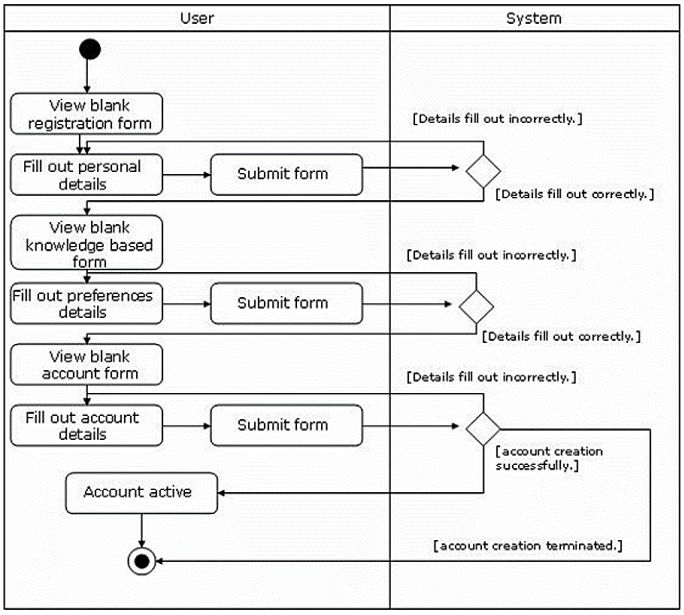

Figure 3: The Register Process Activity Diagram

3.3.3. Description of the search process activity diagram

The activity diagram in figure 4, shows the search process of when a user decides to search for a journal by using its name, publisher and the category, type of access, issue per year. A user can also make use of keywords as an alternative for the searching process, for example, searching for the word " Inter" for "International". The user selects the search form and fills it, the system checks for the search result, filters, sorts and views multiple lists of results to the user. The system can also inform the user when there are no matches of the searched journal. Every user can search as many as they require for journals of their interest.

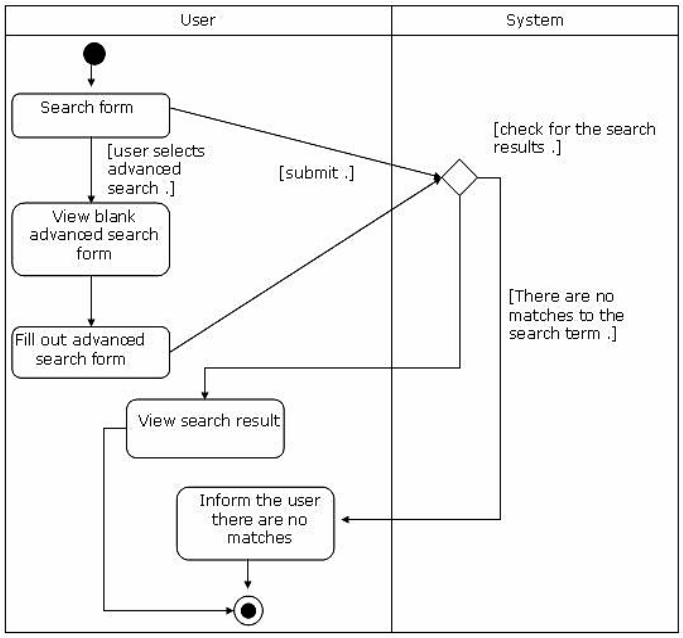

Figure 4: The Search Process Activity Diagram

4. Implementation and Results

This section provides the details of implementation followed by the discussion of the results.

4.1. Implementation

The WEKA Explorer version 3.9.4 was used for the training of data and implementation. This was done based on the data generated from the respondents' preferences discussed in section three. Naïve Bayes and Random Forest algorithms were used for the classification of the data and training of the model. The model generated was used as a knowledge-base for the development of the web-based journal recommender application. The data was saved in comma-separated values (CSV) format as required in the WEKA explorer and preprocessed by converting it into the *.arff* format, which is the format recognised by WEKA for a classification of this type. The preprocessed data were trained using the Naïve Bayes and Random Forests without any splitting. In classifying the data, accuracy was based on predicting the journal preferences class labels in the training data. Naive Bayes classifier is a major classifier that is very useful in Collaborative Filtering based Recommendation Systems. Naïve Bayes uses machine learning and data mining techniques to filter the information and use it to predict future occurrences. Naive Bayes algorithm can handle both continuous and discrete data. It requires less training data, can make probabilistic predictions, requires less training data, easy to implement and fast. Random Forest algorithm can be used for both classifications and regression task. It provides higher accuracy than other classification algorithms. Random forest classifier will handle the missing values and maintain the accuracy of a large proportion of data. If there are more trees, it will not allow overfitting trees in the model. Random Forests was chosen over decision trees and other classification methods because it is easy to interpret and make for straightforward visualizations, the internal workings are capable of being observed and thus make it possible to reproduce work, it can

handle both numerical and categorical data, and performs well on large datasets and are extremely fast.

4.2. Results and Discussion

Results of data training and classification carried out in WEKA explorer using the two ranking algorithms is presented in this section.

4.2.1. Results from Classification with Naïve Bayes Algorithm

Figure 5 shows the results of data training and model generation and with Naïve Bayes algorithm in WEKA explorer. Eight hundred and sixty-seven instances of the data and five attributes were trained using the 'Use training set' option.

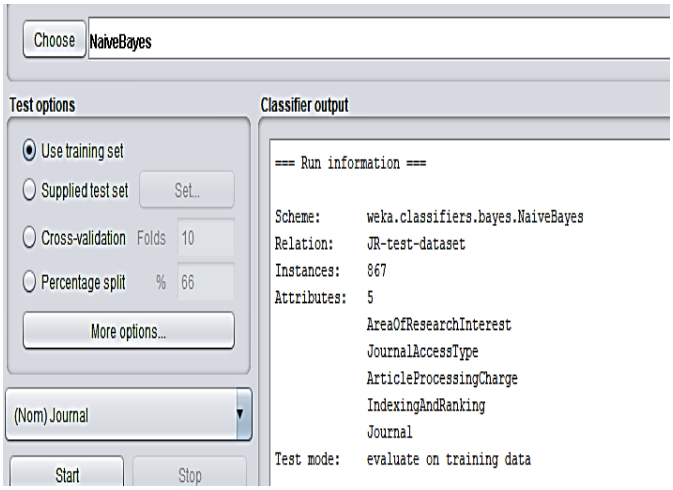

Figure 5: Details of Classification with Naïve Bayes Algorithm

Results from the classification using Naïve Bayes algorithm are shown in Figure 6. Time taken to build the model was 0.01 seconds. Time taken to test the model on training data was 0.02 seconds. There were six hundred and thirty (72.66%) correctly classified instances and two hundred and thirty-seven (27.34%) incorrect classified instances. Mean Absolute Error (MAE), which is a measure of the average magnitude of the errors in a dataset without considering their direction, was 0.0225. This result implied that the error associated with this classification was minimal and insignificant. Root Mean Squared Error (RMSE), which is a measure of the average magnitude of the error, was 0.0943. In this study, RMSE was larger than MAE, which implied that there was variance in the individual errors of the dataset. This is consonance with the standard as RMSE is always larger than or equal to the MAE. Kappa statistic, which measures the agreement of prediction with the actual class was 0.714. This showed a higher agreement between the predicted and the actual class. The evaluation measures that also showed the accuracy of the model are given as True Positive (TP) Rate, False Positive (FP) Rate, Precision, Recall, F-Measure, MCC, ROC Area and PRC Area. TP signifies the correct predictions. From the results obtained using Naïve Bayes classification, TP was an average of 0.727, which implied that more of the class labels were predicted correctly. False Positive (FP), which is the number of instances predicted positive that was negative, was an average of 0.014, which implied that fewer instances were not predicted correctly. Precision was an average of 0.789, which meant that many cases that were predicted positive are positive. The recall was an average of 0.727, which indicated that more of the positive instances were predicted positive. F-measure was an average of 0.760, which indicated that the precision and recall were evenly weighted. MCC was an average of 0.765. ROC Area was an average of 0.977. PRC Area was an average of 0.785. The high values obtained for MCC, ROC Area and PRC indicated that the model was predicting with a very high level of accuracy.

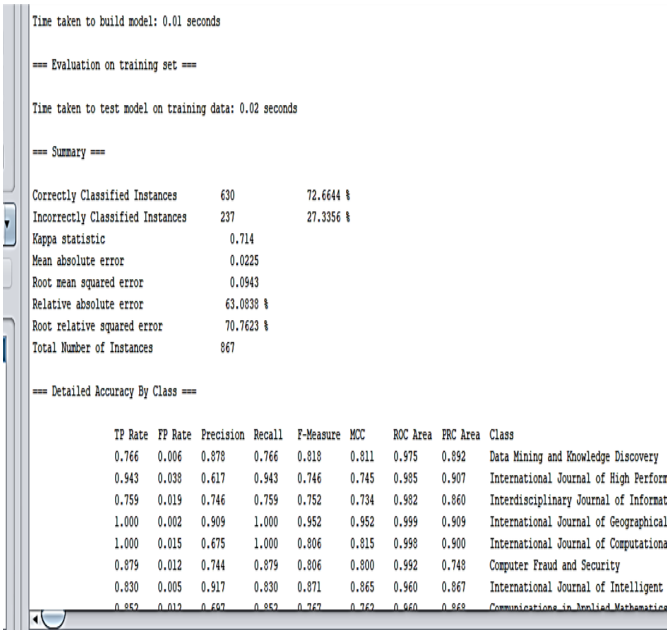

Figure 6: Results from Classification with Naïve Bayes Algorithm

4.2.2. Results from Classification with Random Forest Algorithm

Figure 7 shows the results of data training and model generation and with Naïve Bayes algorithm in WEKA explorer. Eight hundred and sixty-seven instances of the data and five attributes were trained using the 'Use training set' option.

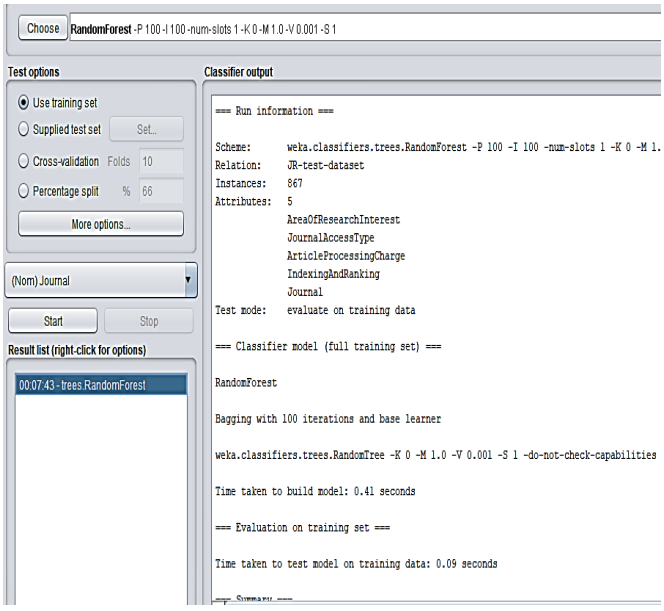

Figure 7: Details of Classification with Random Forest Algorithm

Results from the classification are shown in Figure 8. Time taken to build the model was 0.41 seconds. Time taken to test the model on training data was 0.09 seconds. There were seven hundred and seventy-eight (89.73%) correctly classified instances and eighty-nine (10.27%) incorrect classified instances. Kappa statistic was 0.893, which represents a higher agreement between the actual and the predicted class. MAE was 0.0061 and RMSE was 0.0526. which implied that there was variance in the individual errors of the dataset. Other evaluation measures that also showed the accuracy of the model are TP, which was an average of 0.897, which implied that more of the class labels were predicted correctly. Fewer instances were incorrectly predicted with FP as 0.004. The recall was an average of 0.897 and precision was an average of 0.900, which meant that many cases that were predicted positive are positive. F-measure was an average of 0.886, which indicated that the precision and recall were evenly weighted. ROC Area was an average of 0.998, PRC Area was an average of 0.912 and MCC was an average of 0.892. The high values obtained for ROC Area, PRC and MCC showed that the prediction accuracy of the model was very high.

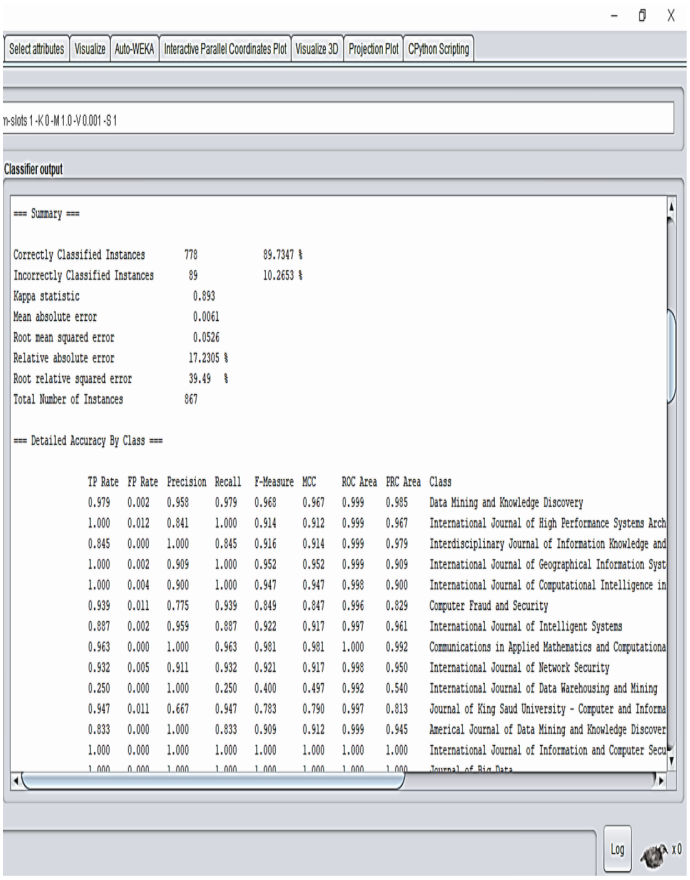

Figure 8: Results from Classification with Random Forest Algorithm

4.2.3. Comparing Results of Classification with Naïve Bayes and Random Forest Algorithms

The performance metrics for comparing the data training and model generation of the Naïve Bayes and Random Forest algorithms are shown in Table 4. The Naïve Bayes classification was faster than Random Forest in model building and testing. On the other hand, the Random Forest algorithm outperformed Naïve Bayes in terms of classification accuracy, Kappa statistics, true positives, ROC Area and all other performance metrics measured in this work.

Table 4: Results of Classification Using Naïve Bayes and Random Forest Algorithms Compared

PERFORMANCE METRICS	NAÏVE BAYES	RANDOM FOREST
Training time (s)	0.01	0.41
Testing time (s)	0.02	0.09
Instances correctly classified (%)	72.66	89.73
True positive	0.727	0.897
False positive	0.014	0.004
MAE	0.0225	0.0061
RMSE	0.0943	0.0526
Kappa Statistics	0.714	0.893
ROC Area	0.977	0.998
PRC Area	0.785	0.912
F-measure	0.760	0.886
Avg_Precision	0.789	0.900
MCC	0.765	0.892

4.2.4. Evaluation of Results

In this section, the results obtained from the study were compared with existing methods, which were already discussed in section two. After comparing the classification accuracies, the classification accuracy derived in this work (89.73%) outperformed four related works [13], [16]-[18].

Table 5: Results of Classification Using Naïve Bayes and Random Forest Algorithms Compared

Reference	Year of Publication	Algorithm Used	Classification Accuracy (%)
13	2019	C4.5	78.84
16	2017	Time sequence-based algorithm	60
17	2018	CNN	75
18	2015	Neural Network	63
This work	2020	Random Forest	89.73

4.3. System Interface

The section describes the features of the developed recommender system. The most important pages are described here and in the following subsections. The system's interface was built with HTML, CSS, PHP, Java scripts and AppServe. The interface for the application was thoroughly tested to ensure that it complies with the requirement of the recommendation system. The home page (Figure 9) is the first page a user is presented once the application loads. It shows the labels Home, Categories, Journals, Publishers, Recommendations, Register, Login and Search icons.

For example, users will click the 'Journals' menu to access the list of journals in the system and likewise click 'Recommendations' menu to make necessary recommendations after answering a few questions by selecting their options. The

'categories' menu shows the various fields of computer science available for searching.

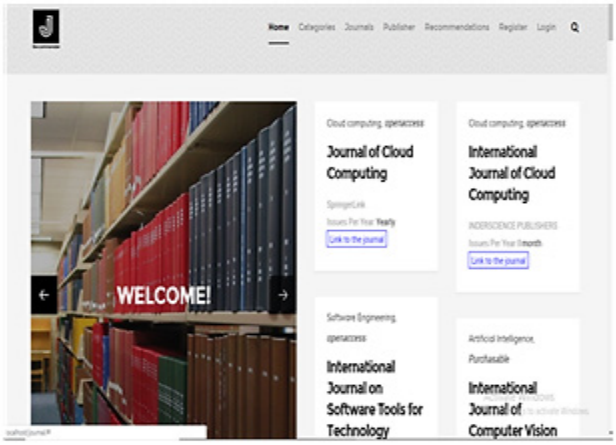

Figure 9: The home page of the 'Journal Recommender'

4.3.1. The Registration Page

The 'Registration page' is the page where a user creates an account. In this page the system requests for Name, Phone number, Email address, the type of user, Research topic, Selection of the field of study, the type of the Journal access he/she is interested in patronising, that is, open access or purchasable. The Registration Page (Figure 10) is significant because recommendations are generated from preferences any user inputs into the system, and the information supplied here helps to build the system's database with more robust information useful for future suggestions or recommendations.

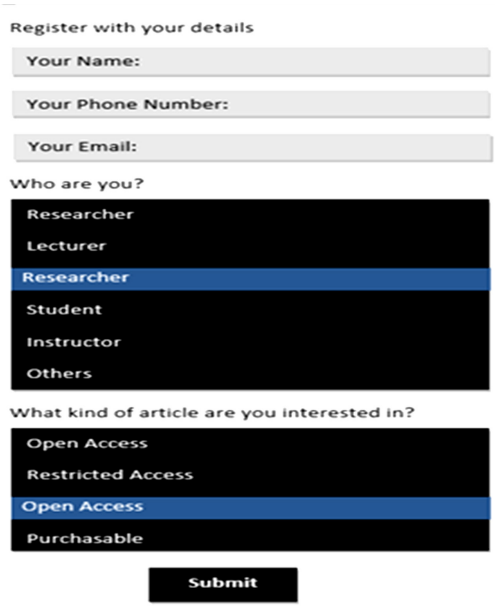

Figure 10: The Registration Page

4.3.2. The Journal Page

The 'Journal page' (Figure 11) is a direct link to all the journals available in the recommender system, and it gets updated from time to time.

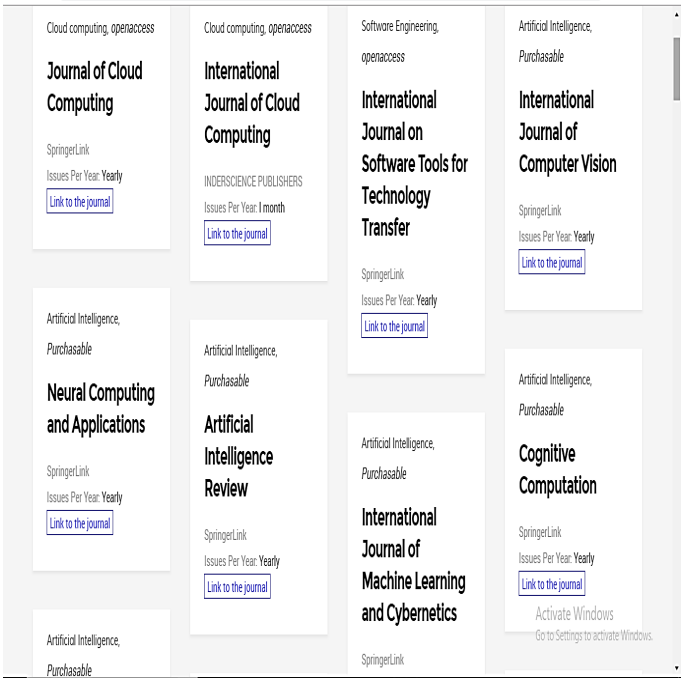

Figure 11: The Journal Page

4.3.3. The Publisher's Page

This 'publisher's page' (Figure 12) consists of the complete list of journal publishers and the journals each of them contain in the developed system.

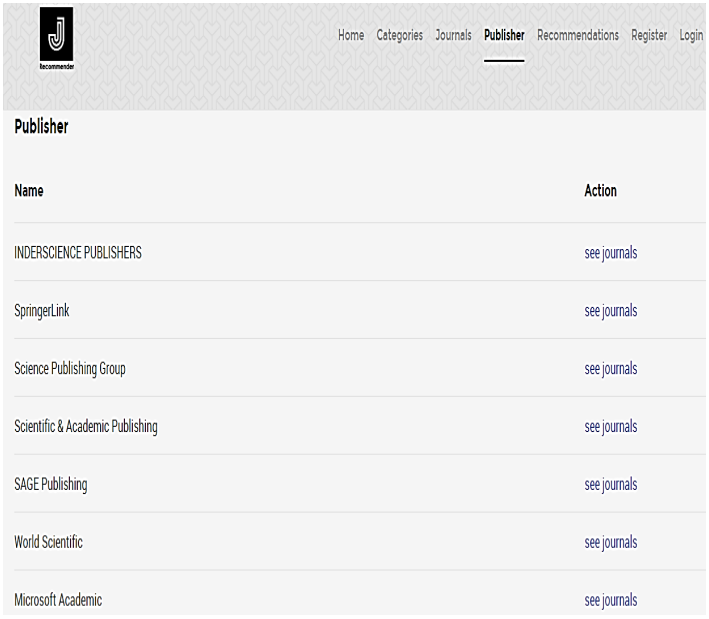

Figure 12: The Publisher's Page

4.3.4. The 'Get Journals Recommendation' Page

The 'Get Journals Recommendation' Page (Figure 13) is the main page displayed to the user when the "Recommendations" link is clicked. It requires the user to fill in the recommendation form, which is based on user's interests and selection of options. Some of the options that determine the final recommendation are the type of Journal Access, the kind of journals that serves user's interest,

the research topic, the amount of article processing fee that is charged and a few others. The user is expected to fill the form.

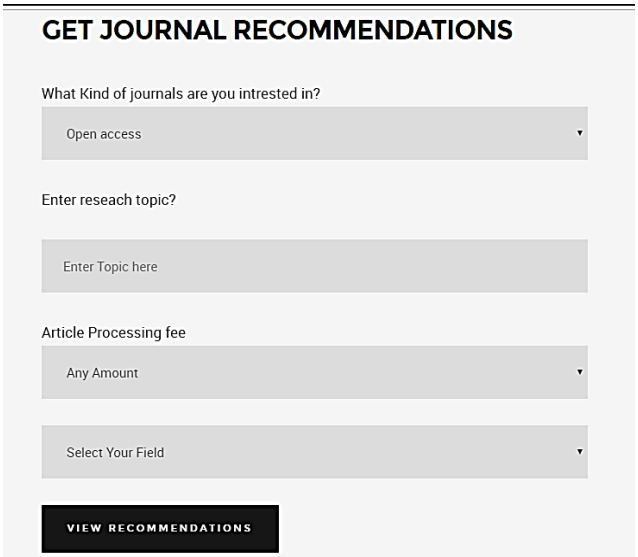

Figure 13: The Get Journals Recommendation Page

In Figure 13, the field "What Kind of Journals are you interested in?" refers to the type of journal access the user wants. Some journals are accessible to view, that is, open access, and others have to be purchased before viewing. The user is given a choice to choose the type of journal access he/she is interested in. Also, the field, Article Processing Fee', is also known as publication fee, which is charged to authors to make their work available in either the open access but free or restricted access and paid versions. This information is usually included in the Authors Instruction page of most journals. The range used for the purpose of the recommendation carried out in this work is from free, one to one-hundred USD, one hundred and one USD, two hundred and one to three hundred USD, three hundred and one to four hundred USD, four hundred and one to five hundred USD and five hundred USD & above. The category field defines what field of computer science the user is interested in. Examples of the fields in the drop-down list are Software Engineering, Information systems and Artificial Intelligence, just to mention a few. The rating field is used the system's feedback mechanism based on the user's acceptance of the recommendations. It has just two options, which are "Very Helpful" if the user is satisfied and "Not Helpful" if the user is dissatisfied with the recommendations from the system. This information is handy as the system makes use of it to self-improve itself from time to time.

4.3.5. System's extendability

The System Admin.'s page allows the flexibility and extendability of the system. The admin can add and update more publishers, more journals, more publishers, new users, review article processing charges and several other functions that extend the system's robustness and effectiveness.

5. Conclusion

An academic researcher can be an author who wants his or her article, papers or life's work to be published in journals through publishing groups. Over the years, the amount of information on the internet is enormous, and this causes information overload problem to researchers during their publication quest to finding the right journals to publish their works. This study proposed a solution that applied a monolithic hybrid recommender system with feature combination and augmentation along with two algorithms, which are Naïve Bayes and Random Forest. Data used in this work were computer science-related journals, collected from pre-existing data that are readily available on academic web sites and repositories. Five attributes were used as preferences for the recommendation of journals. They are the fields of study, type of journal access, research topic, article processing fee and rating of the journals. These attributes were trained and modelled in a machine learning tool, WEKA, and the model generated was used to develop a front-end interface application where prospective academic researchers and authors can enter preferences and view journal recommendations directly generated by the developed system. This system was tested and was found to make recommendations with high levels of accuracy. The recommender system, developed in this work, will help researchers and authors to quickly and dynamically determine which journal is best suitable for their ready-to-be published articles. It is highly recommended that universities, researchers, authors could start adopting the system to improve publishing speed and output. Future works will involve the use of ensemble machine learning algorithms. A comparative analysis would also be done to test the best method under different scenarios. Finally, future works would also include recommendations of other significant disciplines aside from computer science.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The authors appreciate the Department of Computer Science's laboratory, Redeemer's University, Ede, Osun State, Nigeria for providing a convenient environment for the analysis.

ABSTRACT

The filter bank multi-carrier (FBMC) technique is being considered as the major candidates for the 5G schemes. The orthogonal frequency division multiplexing (OFDM) technique is used in 4G but it has drawbacks such as higher Out-of-Band (OOB) power reduction, and higher peak to average power ratio (PAPR). OFDM uses cyclic prefix (CP) extension to overcome on inter symbol interference (ISI) problem but reduces the spectral efficiency (SE). Wireless networks often suffer from extreme mobility that results to inter-carrier interference (ICI) and degradation of the performance system. In a previous work symbol time compression (STC) - Shaped system was proposed for the OOB power reduction, PAPR reduction, ISI reduction and removes the extension of cyclic prefix (CP). This paper will modify the STC- Shaped system for completely ICI cancellation due to high mobility with keeping of OOB power reduction, PAPR and ISI reduction as well as CP removal. Comparative study between this proposed scheme and FBMC will be also presented. As the windowing concept is applied to mitigate OOB, PAPR, ISI and ICI problems, it is implemented on overall symbol of the proposed scheme. A significantly transmitted power saving of this scheme would be achieved to be about -4.3 dB compared to the OFDM transmitted power. This recommends the system to be in satisfactory agreements with the 5G green communication needs. The system performance measurements have been fulfilled using cumulative distribution function (CDF), power spectral density (PSD) and bit error rate (BER). In this paper, the mathematical model of the proposed modified STC-Shaped technique will be introduced. Finally, the analysis of ICI power will be covered in this paper.

1 Introduction

The OFDM is the key technique for 4G networks, and it can effectively transform a frequency-selective (FS) channel into multiple frequency-flat channels at different sub-carriers, allowing easy one-tap channel equalization to alleviate the multi-path effect [1, 2]. Nonetheless, OFDM also has drawbacks, such as large side lobes in spectrum, large PAPR, higher adjacent channel interference and higher power radiation OOB. While OFDM uses the CP to mitigate the ISI problem but reduces the overall spectral efficiency [3]–[6].

OFDM main drawback [7] is its sensitivity to frequency offsets, also known as carrier frequency offset (CFO). This problem can be divided into two situations: (i) the frequency mismatch in the oscillators of the transceiver, and, (ii) the Doppler Effect as the transmitter and the receiver move relatively. The CFO is classified into two types: the integer offset frequency (IFO) and the fractional offset frequency (FFO). IFO causes the sub-carriers to shift on the receiver side, which causes a major deterioration of the bit error rate (BER) output but does not damage the Orthogonality between components of the sub-carrier frequency; therefore ICI does not appear. With FFO, its presence will demolish the orthogonality among the sub-carriers [8]. Therefore, the time varying channel deteriorates the BER performance of OFDM systems. ICI mitigation schemes for high mobility OFDM systems can be classified into two categories.

The first category is the receiver ICI cancellation schemes [9]. The second category is ICI self-cancellation schemes [10]. The receiver ICI cancellation schemes require estimation the characteristics of time varying channel to mitigate the interference of each sub-carrier to adjacent sub-carriers (ICI). This category handles normalized Doppler frequency up to $\epsilon_d = 0.3$ but suffers from less accuracy, Large computational complexity due to large number of iterations and needs extra BW due to pilots. The ICI self-cancellation scheme is based on the difference between the ICI coefficients of two consecutive sub-carriers is very small. Thus, the main idea is to

*Corresponding Author: Mohamed Yasin Ibrahim Afifi, mohamedyasin869@azhar.edu.eg

modulate the input data symbol onto a group of sub-carriers with predefined coefficients such that the generated ICI signals within that group cancel each other hence the name self-cancellation. The ICI self-cancellation schemes are not spectral efficient because redundant data in the transmitter. It suffers from reduction 50% of the system throughput, and it mitigates ICI up to $\epsilon_d = 0.2$.

Therefore, a half-time OFDM-STC is needed. The STC scheme raises the spacing of the sub-carrier twice, thus reducing the Doppler frequency by 50 percent and then improving the efficiency of the BER compared with OFDM. STC model is applied by distributing input information streams and combining them. STC has been significantly overcoming both of ICI and CFO [11, 12]. During an OFDM symbol duration expose time varying channel in high-speed mobile environments, thus being orthogonality disrupted resulting in ICI and therefore, the system efficiency is diminished [13].

Many other non-orthogonal filtering-base waveform have currently been introduced to satisfy the 5G specifications. With regard to the filtering's granularity, these waveform candidates can be categorized into two kinds: sub band filtering and sub-carrier filtering. FBMC [14, 15] is a sub-carrier filtering waveform. FBMC, theoretically, the frequency localization C/C's resulting from the long-length filters's prototype will make CFO more robust; it is hard to design a prototype filters with low OOB to mitigate ISI and ICI. In this paper, the FBMC scheme [16] will be implemented and compared with the proposed system.

This paper's key contribution is to address some of the problems in wireless communications networks that adopt 5G technology based on STC scheme. STC model compresses symbol duration of OFDM into the half. This paper would leverage the 50% symbol interval compression obtained by using the STC strategy by extending the duration of the symbol without degradation of the system's throughput. In this paper, the STC-Shaped system will be modified for completely ICI cancellation due to high mobility with keeping of OOB power reduction, PAPR reduction, ISI reduction and CP removal [17].

The proposed modified STC-Shaped system is achieved by using symbol extension, symbol shaper in the transmitter side and combiner process in the receiver side. The symbol extension will repeat the compressed OFDM symbol data in the transmitter side. Therefore, the entire OFDM symbol is composed of N data coefficients from $\frac{-N}{2}$ to $\frac{N}{2} - 1$. The first half of the entire OFDM symbol includes data from the STC accompanied by its repeater. Next, the shaper of symbol will be applied using the suggested raised cosine function (RCF). Then, data is transmitted via linear time varying (LTV) channel. The useful information and its repeater with using a symbol shaper will ensure proper retrieval of data in receiver. The combiner is attained at the receiver side.

This Paper contributes the following

- The proposed system decreases OOB power radiation for traditional OFDM system which is very near to the needs of 5G such as FBMC.
- And though, CP is removed, in multi-path environment the scheme is more rigorous against ISI.
- PAPR is also reduced in this method as opposed to traditional OFDM and FBMC.
- The performance of the proposed scheme is investigated for BPSK modulation technique in DVB-T2 system under COST 207, typical rural fading channel environment. The performance measurements are the ICI power and bit errors rate (BER). It is demonstrated that, under normalized Doppler frequency, the proposed modified STC-Shaped scheme significantly improves the BER efficiency.
- Also, the proposed scheme decreases the ICI power compared to OFDM and FBMC. A significant power saving of the proposed scheme is aimed during the system development and implementation.

The substance of this paper is structured as follows: The FBMC transceiver is presented in section two. The OFDM system in high mobility was presented in Section three. The proposed modified STC-Shaped model has been covered in Section four. Analysis of ICI power is demonstrated in Section five. The obtained simulation results are shown in section six. The complexity of the proposed system is introduced in section seven. Finally, Section eight indicated the conclusion of the proposed system.

2 Overview of Filter Bank Multi-Carriers

In the QAM modulator, the stream from a binary source is converted to parallel data streams. IFFT algorithm is applied for conversion to time domain. The output stream of IFFT is suitable to the FIR filter Poly-phase Network (PPN) at an overlap factor K=4. This transmitter-side PPN filters are known as synthesis filters. These filters output are again converted into serial pattern for transmission. The mathematical basis for the design of the PHYDYAS project synthesis filters has been obtained in Eq.1. Fig.1 displays the FBMC transmitter block diagram [16].

$$G(F) = \sum_{l=-(k-1)}^{k-1} \left(G_l \frac{\sin\left(\pi \left[\frac{f-l}{m_k}\right] N_k\right)}{N_k \sin\left(\pi \left[\frac{f-l}{m_k}\right]\right)} \right) \tag{1}$$

where:

Coefficient	Value
G_0	1
$G_{(\pm 1)}$	0.97196
$G_{(\pm 2)}$	$\frac{\sqrt{2}}{2}$
$G_{(\pm 3)}$	0.235147

At the receiver side of Fig.1, $y(n)$ denotes the received signal of Eq.2 where $t(n)$ is the transmitted signal and C is the channel impulse response, $w(n)$ symbolizes the AWGN added to the signal.

$$r(n) = C * t(n) + w(n) \tag{2}$$

The signal is transmitted through the RF down conversion, where it has been divided into parallel streams. The PPN is the analytic filter in the receiver-side, and then Fast Fourier Transform converts the signal into frequency domain. And finally OQAM is

converted to QAM which leads to recovery of initial bits of data. The block diagram of the overall FBMC system is shown in figure 1.

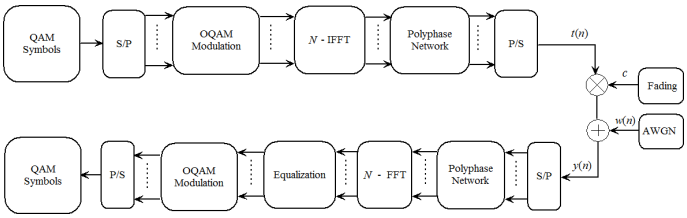

Figure 1: Block diagram of FBMC System[16].

3 Conventional OFDM Model Under Time Varying Channel

On the transmitter side, the following equation is described as a discrete OFDM symbol after IFFT [12, 13]:

$$x(n) = \frac{1}{N}\sum_{m=0}^{N-1}\left(X_m e^{\left(\frac{j2\pi nm}{N}\right)}\right) \quad -N_{cp} \le n \le N-1 \tag{3}$$

The n^{th} received symbol of OFDM through multi-path time-varying channel after CP removal is as follows [12, 13]:

$$y(n) = \sum_{l=0}^{L-1} h_n^{(l)} X_{n-\tau^{(l)}} + W_n \quad 0 \le n \le N-1 \tag{4}$$

where:

Parameters	Symbolize
n	Index of time
x_n	Symbol of OFDM at the n^{th} sample
N	Total number of useful sub-carriers in OFDM symbol
N_{cp}	The duration of CP
X_m	The complex transmitted data symbols on the m^{th} sub-carriers ($m = 0, \ldots, N-1$)
L	The total number of channel paths
$h_n^{(l)}$	The l^{th} path channel impulse response at the n^{th} sample
$\tau^{(l)}$	Delay spread of the l^{th} path
w_n	The additive white Gaussian noise (AWGN) with zero mean

The received OFDM symbol at the m^{th} sub-carrier is written as follows [12, 13]:

$$\begin{aligned} Y_m &= \frac{1}{N}\sum_{l=0}^{L-1} y_n e^{\left(\frac{-j2\pi nm}{N}\right)} \\ &= \underbrace{H_{n.m}X_m}_{\text{desired signal}} + \underbrace{\sum_{m'=0}^{\frac{N}{2}-1}\sum_{m'\neq m} H_{m.m'}X_{m'}}_{\text{ICI terms}} + \underbrace{W_m}_{\text{AWGN}} \end{aligned} \tag{5}$$

where;

$H_{m.m'} = \frac{1}{N}\sum_{l=0}^{L-1} e^{-j2\pi\frac{m'}{N}\tau^{(l)}} \sum_{n=0}^{N-1} h_n^{(l)} e^{-j2\pi\frac{n}{N}(m-m')}$ does not vary during OFDM symbol duration, that is $0 \le n \le N-1$, thus there is no ICI terms. In contrast, if $H_{m,m'} \neq 0$ for $m' \neq m$ ICI occurs due to time variation of each complex path gain $h_n^{(l)}$, within one OFDM symbol $0 \le n \le N-1$. In the next section, the proposed modified STC Shaped scheme will be discussed and implemented.

4 The Proposed Modified STC-Shaped System

The proposed scheme is based on STC process, symbol extension and symbol shaping at the transmitter side, while only combining process at the receiver side. The desiring steps of the proposed method are followed;

In the transmitter side

- Input data streams are entered into STC stage.
- After STC process, the number of sub carriers decreased into half.
- Symbol extension process is proposed by repeating the compressed OFDM symbol in front of the useful part.
- The symbol shaper is suggested by using modified raised cosin function.
- Finally, the transmitted data has been sent to the LTV channel.

In the receiver side

- The received data are entered to the proposed combining stage for retrieving compressed OFDM symbol, which the extended part is combined to the corresponding information part.
- Finally, the STE stage is used to recovery the original input data streams.

The block diagram of the overall proposed system is shown in figure 2. After STC process, the number of sub-carriers becomes $N_c = \frac{N}{2}$ [17]. After IFFT, the n^{th} compressed OFDM symbol is expressed by modifying Eq.4 as follows:

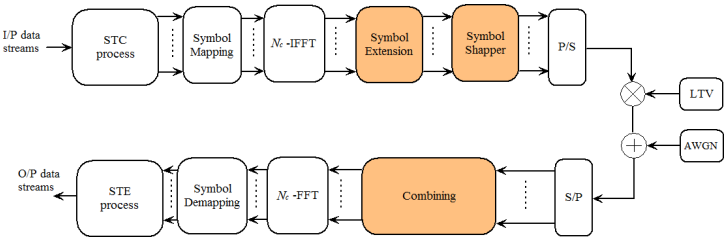

Figure 2: Block diagram of the proposed modified STC-Shaped System.

$$x_n^c = \frac{1}{N}\sum_{m=0}^{N_c-1} X_m^c e^{\left(\frac{j2\pi nm}{N}\right)} \quad 0 \le n \le N_c - 1 \tag{6}$$

Thus, after STC process, the transmitted signal as shown in figure 3

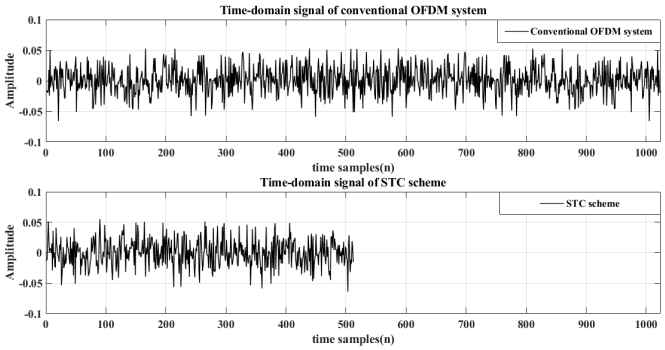

Figure 3: Time domain signal of the STC scheme and OFDM [17].

The symbol extension process is achieved by repeating the compressed OFDM symbol X_m^c in front of the useful part as shown in figure 4.

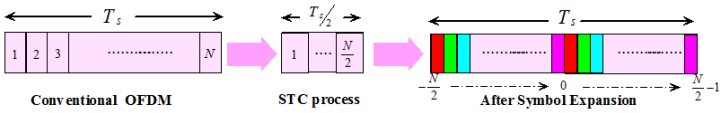

Figure 4: Symbol Expansion process in the transmitter for proposed system.

Thus, the time domain after symbol extension process becomes:

$$z_n = \frac{1}{N_c}\sum_{m=-N_c}^{N_c-1} X_m^c e^{\left(\frac{j2\pi nm}{N}\right)} \quad -N_c \le n \le N_c - 1 \tag{7}$$

The symbol shaper is achieved by using the raised cosine was proposed in [17], but with minor modification makes the raised cosine function (RCF) is symmetric around zero with keeping on the complementary concept for the negative part and positive part.

Thus, the modified symbol shaping is expressed as follows:

$$f_n = \frac{1}{2}\left[1 - \cos\left(\frac{2\pi(n+N_c)}{N}\right)\right] \quad -N_c \le n \le N_c - 1 \tag{8}$$

The proposed modified RCF is showed in figure 5. After symbol shaper, the transmitted OFDM symbol becomes:

$$\begin{aligned} z'_n &= z_n * f_n \\ &= \frac{1}{2N_c}\sum_{m=-N_c}^{N_c-1} x_m^c - x_m^c \cos\left(\frac{2\pi(n+N_c)}{N}\right) e^{\left(\frac{j2\pi nm}{N}\right)} \\ &\quad -N_c \le n \le N_c - 1 \end{aligned} \tag{9}$$

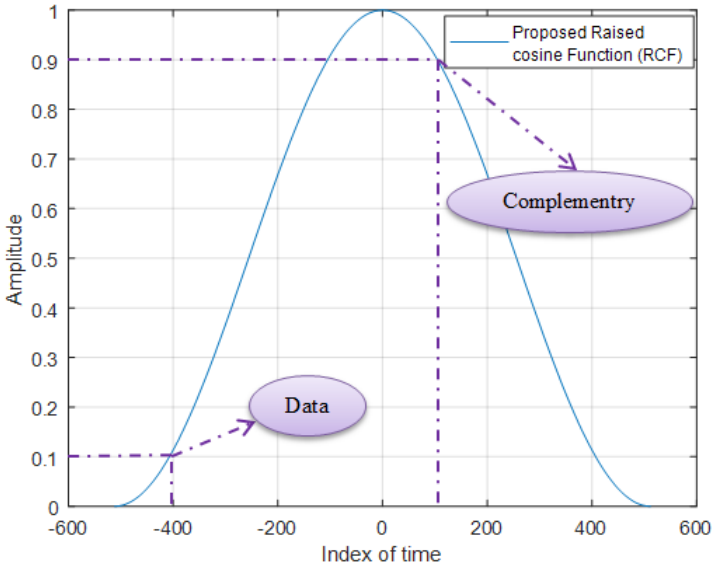

Figure 5: The proposed modified raised cosine function.

In this paper, the channel is assumed to be linear time varying channel (LTV) during OFDM symbol as follows:

$$h_n^{(l)} = 1 + j\left(\frac{\pi\epsilon_d n}{N}\right) \quad -N_c \le n \le N_c - 1 \tag{10}$$

$$\epsilon_d = \frac{d_f}{\Delta f} \tag{11}$$

Where:

Parameters	Symbolize
X_m^c	Compressed OFDM symbol at n^{th} sub-carriers
$h_n^{(l)}$	The l^{th} path channel response at time instant n
ϵ_d	The normalized Doppler frequency
f_d	The maximum Doppler frequency
Δf	The sub-carrier spacing

Thus, the received signal over LTV multi-path channel is expressed as follows:

$$r_n = \sum_{l=0}^{L-1} h_n^{(l)} z'_{n-\tau^{(l)}} + W_n \quad -N_c \le n \le N_c - 1 \tag{12}$$

The proposed receiver for modified STC-Shaped system is achieved by only combining process. This stage is used to retrieve compressed symbol of OFDM in the receiver side. However, the extended part is combined to the corresponding information part. The combined time domain signal is derived as follows:

$$y_n = r_n + r_{n-N_c} \quad 0 \le n \le N_c - 1 \tag{13}$$

By substituting Eq.10 into Eq.11, the combined signal is expressed as follows:

$$\begin{aligned} r_n = &\sum_{l=0}^{L-1} h_n^{(l)} z'_{n-\tau^{(l)}} + \sum_{l=0}^{L-1} h_{n-N_c}^{(l)} z'_{n-N_c-\tau^{(l)}} \\ &+ W_n + W_{n-N_c} \quad -N_c \le n \le N_c - 1 \end{aligned} \tag{14}$$

Therefore, the equivalent channel time variation of the proposed modified STC-Shaped scheme is turned into flat with constant gain. As a result, the overall channel time variation is completely canceled without throughput loss.

5 ICI Power Analysis

In this section, the ICI power analysis of the proposed modified STC-Shaped scheme in high mobility will be discussed. The performance of the proposed modified STC-Shaped scheme is evaluated by computing the ICI power of the system. The ICI power of proposed modified STC-Shaped scheme is computed as follows:

$$\begin{aligned} p_{ICI} = &\frac{1}{N_c^2} \sum_{m'=0 m' \ne m}^{N_c-1} \sum_{l=0}^{L-1} p^{(l)} \sum_{n=0}^{N_c-1} \sum_{n'=0}^{N_c-1} E\left\{h_n', h_n'^*\right\} \\ &e^{\left(-j2\pi \frac{(n-n')(m-m')}{N_c}\right)} \end{aligned} \tag{15}$$

Where:

Parameters	Symbolize
$E\left\{h_n', h_n'^*\right\}$	The correlation function of Rayleigh fading channel of the l^{th} path of the channel
$P^{(l)}$	The power of the l^{th} channel path

The equivalent channel time variation after applying the proposed modified STC-Shaped scheme is expressed as follows:

$$h_n' = (f_n * h_n) + (f_{n-N_c} * h_{n-N_c}) \quad 0 \le n \le N_c - 1 \tag{16}$$

Thus, the time correlation function of the equivalent channel time variation in Eq.15 is expressed as follows [18] :

$$\begin{aligned} E\left\{h_n', h_n'^*\right\} = &\left(z_n' z_{n'}' + z_{n-N_c}' z_{n'-N_c}'\right) E\left\{h_n, h_{n'}^*\right\} \\ &+ z_n' z_{n'-N_c}' E\left\{h_n, h_{n'-N_c}^*\right\} \\ &+ z_{n-N_c}' z_{n'}' E\left\{h_{n-N_c}, h_{n'}^*\right\} \end{aligned} \tag{17}$$

where:

$$E\left\{h_n, h_{n'}^*\right\} = J_0\left(2\pi f_d T_s \frac{n-n'}{N_c}\right)$$

$$E\left\{h_n, h_{n'-N_c}^*\right\} = J_0\left(2\pi f_d T_s \frac{n-n'+N_c}{N_c}\right)$$

$$E\left\{h_{n-N_c}, h_{n'}^*\right\} = J_0\left(2\pi f_d T_s \frac{n-n'-N_c}{N_c}\right)$$

6 Simulation Results

In this paragraph, some numerical results for simulation are provided to analyze the performance of the proposed modified STC-Shaped model. The proposed modified STC-Shaped scheme is investigated in DVB-T2 OFDM system parameters in Table 1.

Table 1: Simulation system parameter [16, 17].

Parameters	Specification
OFDM sub-carriers N	1024
CP length N_{CP} in OFDM	256
CP length in proposed system	None
Modulation type	BPSK for (OFDM – STC)
	OQAM for (FBMC)
Overlapped factor K in FBMC	4
No of symbols	10000

The proposed modified STC-Shaped scheme is investigated under multi-path Rayleigh fading environment. The power delay profile of COST 207 rural area (RA) environment channel model which is summarized in Table 2.

Table 2: Power Delay Profile [10, 15].

	Delay ($\mu S\, ec$)	**Power**(dB)
tap 1	0	-3
tap 2	0.2	0
tap 3	0.5	-2
tap 4	1.6	-6
tap 5	2.3	-8
tap 6	5	-10

The proposed model is simulated by Matlab 2019 m-files software using intel Core i7-8550U CPU @1.99 GHz, 16.0 GB RAM, x64 Operating System for Windows 10 ultimate version. The results show the implemented model using Matlab M-file with respect to the theoretical results. The following paragraphs include demonstration ICI performance, BER, sidelobes suppression, and PAPR performance.

6.1 ICI Power Performance

Therefore, the time varying channel deteriorates the BER performance of OFDM systems. The proposed scheme will use proposed windowing technique for all symbol transmitted via channel, while OQAM-FBMC used a sub-carrier windowing waveform. Figure 6 is dedicated as illustrative graph for eight Consecutive OFDM sub-carriers in cases of without shaping and with shaping.

It is observed from figure 6 that, the symbol shaping reduces amplitude at sub-carrier index, so the ICI power will be reduced. figure

7 illustrates the ICI power of conventional OFDM, OQAM-FBMC and the proposed modified STC-Shaped schemes versus normalized Doppler frequency ϵ_d. figure 7 shows that the ICI power of the proposed modified STC-Shaped scheme is less than the OQAM-FBMC and conventional OFDM system for different normalized Doppler frequencies.

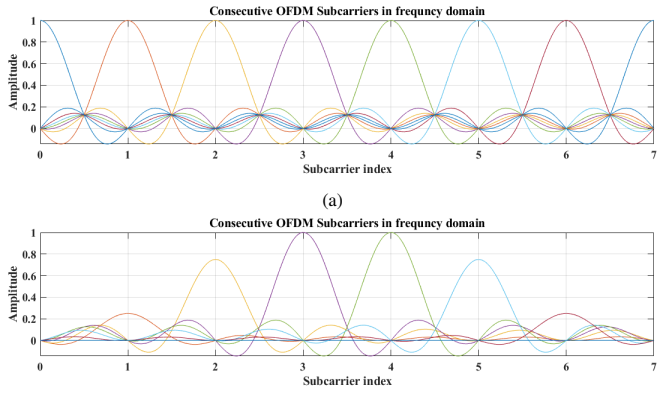

Figure 6: Consecutive OFDM subcarriers of (a) Without Shaping and (b) With Shaping.

At ϵ_d= 0.19 , the ICI power of the proposed modified STC-Shaped scheme is - 29.43 dB but the ICI power of OQAM-FBMC scheme is - 6.074 dB and the ICI power of conventional OFDM scheme is - 12.62 dB. Thus, the ICI power reduction using the proposed modified STC-Shaped scheme is 16.81 dB compared to OFDM and 23.36 compared to FBMC. As a result, the proposed scheme significantly reduces the ICI power compared to the OFDM and FBMC schemes. The simulated ICI power results of the proposed modified STC-Shaped scheme conform to the theoretical results.

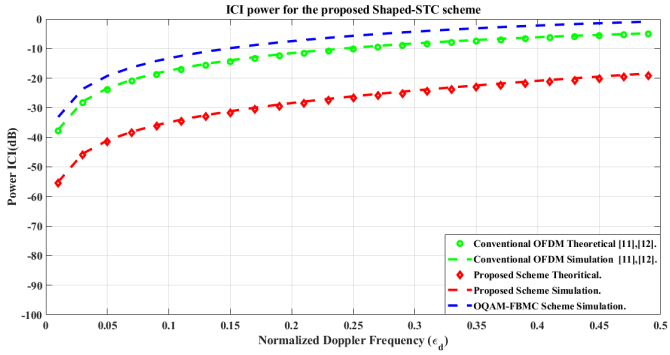

Figure 7: The ICI power of the proposed scheme versus ϵ_d.

6.2 Combined ISI & ICI Performance

This section evaluates the performance of OFDM system in time varying channel due to high mobility. The proposed modified STC-Shaped system is proposed for ICI reduction caused by high mobility. It is investigated in 2k mode DVB-T2 OFDM system parameters. It is evaluated under AWGN and multi-path Rayleigh fading channel for BPSK modulation scheme at 600 km/hr traveling mobile speed which corresponds to ϵ_d= 0.19. figure 8 and figure 9 show the BER performance of BPSK modulation scheme for the proposed modified STC-Shaped scheme compared to the conventional OFDM and OQAM-FBMC systems under AWGN and Rayleigh fading in high mobility respectively.

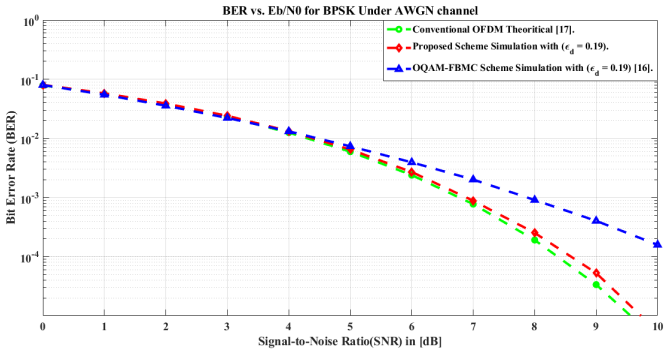

Figure 8: The BER under AWGN channel at ϵ_d=0.19.

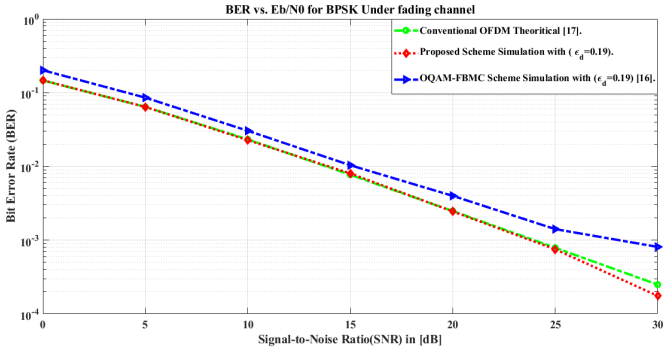

Figure 9: The BER performance under multipath fading channel at ϵ_d= 0.19 .

6.3 Side-lobe Suppression Performances

A comparison with the proposed system is discussed with the conventional OFDM, and FBM. figure 10a, figure 10b and figure 10c respectively depict the PSD for the traditional OFDM, the proposed modified STC-Shaped system and OQAM-FBMC.

6.4 PAPR Efficiency

The disadvantage of OFDM multi-carrier systems is a higher peaks of the coherently non-constant envelopes added [19]. The OFDM signal has addition of N sub-carriers. If N is large enough, a resulting signal is near a complex Gaussian model. This means that Gaussian is distributed for both its imaginary and real parts, and that its envelope and energy satisfy Rayleigh and exponential distributions respectively. PAPR is expressed as a discrete version of X[n] [20, 21].

$$PAPR(x[n]) = \max_{0 \le n \le N-1} \frac{|x[n]|^2}{E\left[|x[n]|^2\right]} \quad (18)$$

Figure 11 shows the calculated cumulative distribution function of proposed modified STC- Shaped system without CP. It has the

performance of PAPR which is referred to as 3dB better than the traditional OFDM and 4dB better than the OQAM-FBMC.

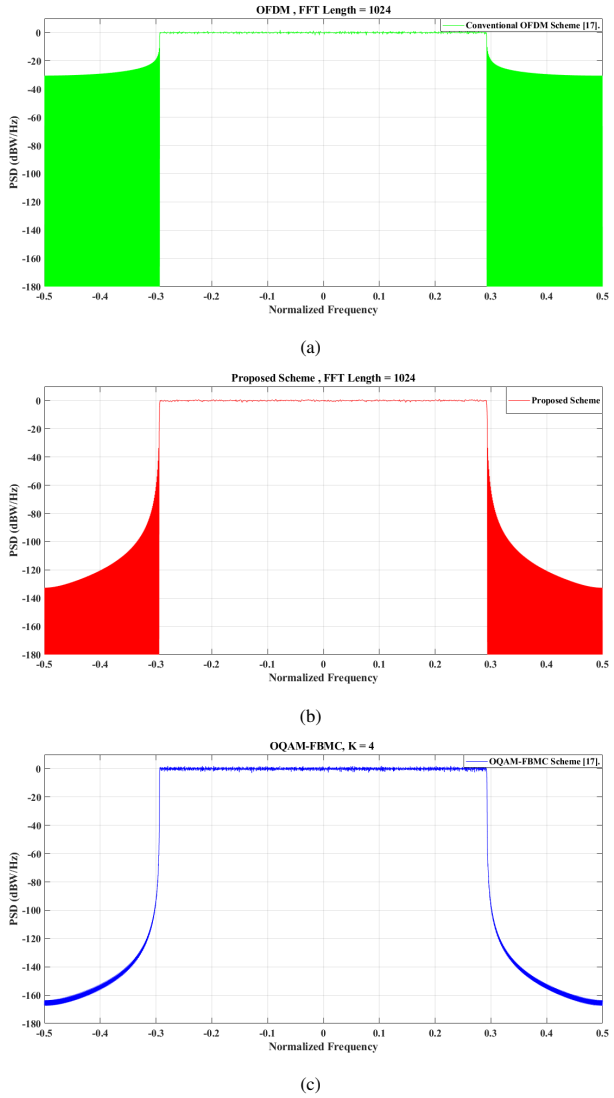

Figure 10: PSD of (a) traditional OFDM scheme[22], (b)proposed modified STC-Shaped system scheme and (c) FBMC scheme [23, 24].

6.5 *Power Saving*

The transmitted power for OFDM symbol after shaping can be estimated as follows:

$$\begin{aligned} P_T &= \frac{1}{N}\sum_{n=0}^{N}|h(n)|^2 .\hat{P} \\ &= \frac{\hat{P}}{N}\sum_{n=0}^{N}\left|\frac{1}{2}\left(1-\cos(\frac{2\pi n}{N})\right)\right|^2 \\ &= \frac{3}{8}\hat{P} \end{aligned} \tag{19}$$

where: P_T is the transmitted average power after shaping, $h(n)$ is the filter response and $\hat{P}$ is the power for symbol without shaping. The factor of $|h(n)|^2$ can be calculated from Eq.8 which is estimated by $\frac{3}{8}$. So, the transmitted after shaping is reduced by $\frac{3}{8}$ value of the power before. Thus, the proposed scheme would be saved to around -4.3 dB of the conventional OFDM transmitted power. Power amplifier rating could therefore be reduced by the estimated factor (-4.3 dB).

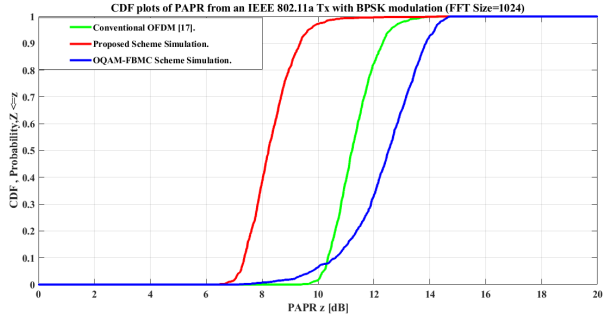

Figure 11: PAPR for OFDM, FBMC and proposed modified STC-Shaped systems.

7 Computational Complexity Analysis

For this paragraph, it is possible to obtain the computational complexity of the proposed modified STC-Shaped system in terms of number of multiplications as well as the number of additions compared to traditional OFDM, and OQAM-FBMC schemes as shown in Table 3.

Table 3: Comparative analysis of both the number of multiplication as well as addition processes.

Method	number of multiplications	number of additions
Traditional OFDM [18]	$2Nlog_2(N) - 2N$	$3Nlog_2(N) - N$
FBMC [25]	$2kN^2 + 3N$	$2N(NK-1)+3N+N-1$
Proposed modified STC-Shaped scheme	$2Nlog_2(N)$	$\frac{3}{2}Nlog_2(N) - \frac{N}{2}$

Finally, for the suggested scheme, the computational complexity is proportional to $Nlog_2(N)$, while FBMC has been used in 5G proportional to N^2. The proposed modified STC-Shaped model can thus fulfill very low computational complexity 5G requirements compared to FBMC requirements.

8 Conclusion

The optimal performance of mobile 5G green communications has been introduced and satisfactory implemented. An efficient performance STC based on time symbol modification has been suggested to increase the utilization factor of the band width as well as the reduction in band capacity. The shaped-STC will be adapted to an efficient STC-Shaped scheme for completely ICI cancellation due to high mobility with keeping of OOB power reduction in addition to PAPR, ISI reduction and CP elimination. The simulation

results compare the proposed scheme performance with OFDM and OQAM-FBMC.

The proposed modified STC-Shaped scheme is investigated under AWGN and multi-path Rayleigh fading channel for BPSK modulation scheme at ϵ_d=0.19. The proposed STC scheme has been achieved improvement on the BER performance compared to the conventional OFDM and OQAM-FBMC systems. It has been provided around -3 dB PAPR reductions about conventional OFDM, while for PAPR reduction -4 dB PAPR reductions compared to OQAM-FBMC. It had also offered a significant -80 dB lower than OFDM OOB radiation. The system results have been revealed a better performance throughout the computational complexity. The theoretical ICI power of the proposed STC scheme is computed. Finally this scheme has been saved the transmitted power to around -4.3 dB compared to the conventional OFDM transmitted power. The simulation results of the ICI power and BER performance were in a satisfactory agreement with the theoretical results.

The future work could cover latency, throughput, and higher order compression technique to meet the 5G requirements.

ABSTRACT

This paper proposes a photovoltaic (PV) integrated shunt active power filter (SAPF) for reactive power compensation, uneven loading and compensation of harmonic current. The control of SAPF is implemented by using adaptive based current estimation algorithm to maintain power factor near to unity and source current sinusoidal at source side. The weights are calculated online by recursive least mean square algorithm once the three-phase load current is detected. Secondly, the unit vector templates (UVT) are multiplied with these weights and thus the load current with fundamental active component is derived. PV system enhanced by Maximum Power Point Tracking (MPPT) plays the role of maintaining the dc link voltage constant. Finally, a current control scheme based on hysteresis is used for converter switching and thus the source current to follow reference current precisely. The superiority of the proposed method of compensation of harmonic current and reactive power using SAPF with Recursive Least Mean Square (RLS) algorithm is proved by the simulation results based on MATLAB/SIMULINK.

1. Introduction

The pervasive use of converters based on power electronics has given rise to increasing use of non-linear and inductive loads. The adjacent loads are negatively affected by the voltage variation at point of common coupling (PCC) caused by the harmonic current component of non-linear loads linked to the same network [1-4]. The increased demand of reactive power diminishes the flow capability of active power, and increases feeder losses, whereas the ordinary operation of transformer and generator are adversely affected by the unbalanced system. IEC-61000 and IEEE-519-2014 standards are put into practice to minimize such problems. The introduction of custom power device technology such as unified power quality controller (UPQC), dynamic voltage regulator (DVR), distributed static compensator (D-STATCOM) are effective for the electrical distribution network that faces these issues (unbalanced load, reactive power and harmonics). It is found that SAPF is suitable to efficiently compensate the afore mentioned issues [5].

The control method used to determine the efficacy of the SAPF presented. It mainly relies on the fundamental current extraction algorithm and converter switching generation using extracted reference currents.

The concept here to is to separate load current into three constituent factors. They are fundamental active (i_{Lfp}), reactive(i_{Lfq}) and harmonic(i_{Lh}) components of load current. References [6-9] have reported the low pass and band pass filter (LPF-BPF) based fundamental active current extraction scheme, per phase computation, scheme based on neural network, instantaneous reactive power (IRP) theory, rotating reference frame and instantaneous symmetrical components. Artificial neural network-based extraction scheme requires training of load current datasets for different load conditions which makes system complex and suitable for very specific loads. IRP theory works very well under sinusoidal supply voltage but fails to separate out working and wattless components of the load current under distorted supply condition.

Adaptive filtering techniques are proposed in latest literature because of its merits such as robustness, instinctive monitoring and tracing, less real-time calculation and a fast-dynamic response even under complex load conditions [10-11]. References [12-16] propose various adaptive filtering techniques such as adaptive notch filter, improved sinusoidal notch filter, fuzzy based adaptive control and synchronous adaptive filters. Reference [17, 18] presents least mean square (LMS) based fundamental active current extractor scheme. Least mean squares (LMS) algorithms has the least difficulty and most effectively applied versatile

[*]Corresponding Author: Ragam Rajagopal, ragamrajagopal@gmail.com

algorithms. The disadvantage of using LMS algorithm is its slow convergence rate. Excellent performance and prominent fidelity make the recursive least square algorithm (RLS) superior, however they accompany expanded intricacy and computational expense. In adaptive filtering applications, RLS approaches Kalman filter with reduced computational complexity in the signal processor. At the cost of requiring more computations, the RLS approach has quicker convergence characteristics compared to LMS algorithm and less error with respect to the unknown system. Reference [19] have reported PV integrated system-based voltage source converter (VSC) to keep a constant voltage at dc link. The development of PV technology has given motivation to the concept of combining clean and free solar energy for SAPF.

This paper proposes a PV integrated 3-phase shunt active filter with recursive least mean square based extractor scheme for fundamental active current extraction by recursively updating the weight of the input signal. The recursive approach finds the filter coefficients that minimize a weighted linear least squares cost function relating to the input signals. Minimization of the total weighted squared error between the desired signal and the output is the main objective of this approach.

It also uses variable forgetting factor to get fast merging rate and less steady state error. The usage of forgetting factor makes the de-emphasis of previous old data as compared to the new data. Moreover, PV system is integrated to keep the voltage of dc link constant. The performance analysis of RLS based SAPF reveals IEEE standard 519 compliant functionality under various operating conditions.

2. System Configuration

The Shunt active filter which act as voltage source converter is coupled to PCC through interfacing inductor L_f. The key functions of the SAPF include a) the elimination of harmonic component of load current thereby maintaining sinusoidal nature of source current with THD<5% b) maintaining source current in phase with pcc voltages achieving near unity pf and c) unbalanced load current compensation by maintaining source currents balanced irrespective of load conditions. The implementation of SAPF requires accurate connection of interlinking inductors, capacitor in the dc link, current and voltage sensors. The control algorithm must be fast enough for the successful functioning of the SAPF. The adaptive RLS algorithm used in this work has higher convergence rate as compared to other variants of least mean square algorithms. Figure 1 indicates the typical illustrative figure of 3-phase SAPF. Notations used in Figure 1 are described in section 2.1.

Three phase (i.e. a, b and c) load currents are determined by means of current sensors. Similarly, source currents, i_{sa}-i_{sb}-i_{sc} are measured. Three voltage sensors are used to measured three phase voltages v_a-v_b-v_c at PCC. PLL will determine θ, based on PCC voltages which in turn is used to generate UVTs for the three phase system. Fundamental active current extractor which makes use of RLS based adaptive algorithm as illustrated in figure 2 utilize this θ, to determine i_{Lfp}.

The product of UVT and i_{Lfp} results in the production of the reference source currents, i_{saR}-i_{sbR}-i_{scR}, [19]. These reference source currents along with the instantaneous values of the three phase source currents are fed into the hysteresis controller for the production of gate signals. These gate signals are in turn fed to voltage source inverter (VSI) for the generation of compensating currents which are injected into the system. DC link voltage is regulated by means of the PV array. Economic reliability is enhanced since the VA rating of photovoltaic panel used need not be very high as required for the injection of active power since the compensating currents injected need to provide only for harmonic currents and reactive power.

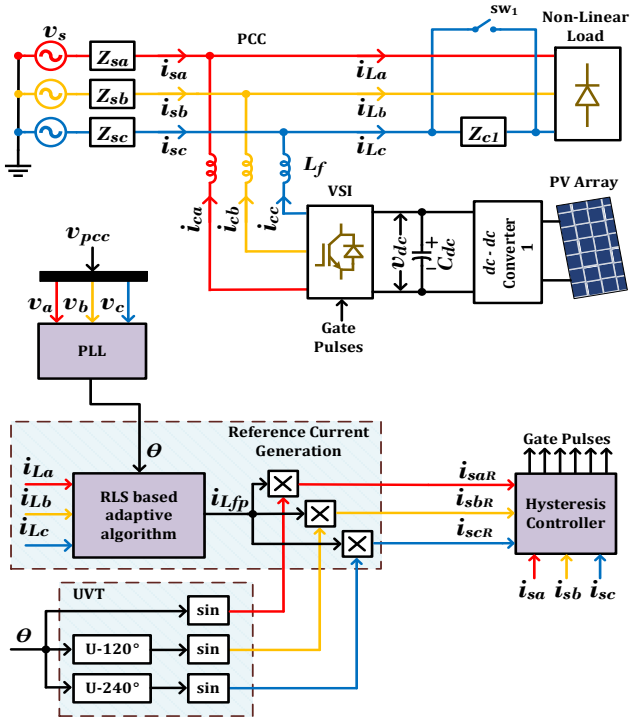

Figure 1: Block diagram of 3-phase SAPF

2.1. Nomenclature

a,b,c : Three Phases

v_{sa}-v_{sb}-v_{sc} : Supply voltage

v_a-v_b-v_c : PCC voltages

θ : instantaneous phase angle of fundamental component of supply voltage

Z_{sa}-Z_{sb}-Z_{sc} : Line impedances

i_{Lh},i_{Lfp},I_{Lfq}, : Harmonic load current component, Fundamental active and reactive components of load current

i_{La}-i_{Lb}-i_{Lc} : Load currents

u_{pa},u_{pb},u_{pc} : Unit vector template

i_{ca}-i_{cb}-i_{cc} : Compensating currents

i_{saR}-i_{sbR}-i_{scR} : Reference source currents

v_{dc} : DC link voltage

C_{dc} : Capacitor at dc link

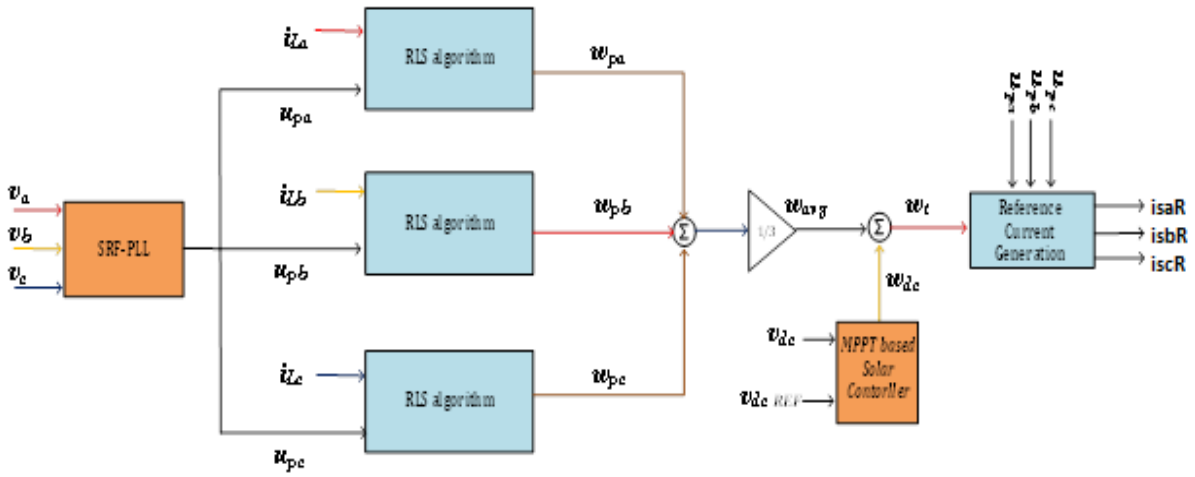

Figure 2: Control diagram for 3-phase SAPF

i_{Lp} : Fundamental active load current component's peak value

i_{Lq} : Fundamental reactive load current component's peak value

i_{Lm5}, i_{Lm7} : Peak value of 5th and 7th harmonic components of load current

i_{c1} : Fundamental compensating current component's peak value

i_{cm5}, i_{cm7} : Peak value of 5th and 7th harmonic components of compensating current

i_{sm1} : Fundamental source current component's peak value

i_{sm5}, i_{sm7} : Peak value of 5th and 7th harmonic components of source current

3. Control Scheme

The LS estimate of the filter coefficient w(n-1) at iteration n-1 is the basic technique behind RLS algorithm. This type of algorithm is known as recursive least mean square algorithm. This algorithm may be viewed as a special case of Kalman filter. Recursive filter is implemented by using the available starting conditions and then update the weight based on new arrived data. This leads to the minimization of cost function, where observed data's variable length is notated as n.

Cost function $J(n) = \sum_{k=1}^{n} w_n e^2(n)$ where w_n is weighting factor and e(n) is error.

This error e(n) can be expressed as,

$$e_j(n) = i_{Lj}(n) - i_{sj}(n) \quad (1)$$

where, j=a, b and c phase

$$e_j(n) = i_{Lj}(n) - w^T(n-1)x(n-1) \quad (2)$$

Weight updating equation for RLS control is given as,

$$g(n) = P(n-1)x(n)[\lambda + x^T(n)P(n-1)x(n)]^{-1} \quad (3)$$

$$P(n) = \lambda^{-1}P(n-1) - g(n)x^T(n)\lambda^{-1}P(n-1) \quad (4)$$

$$w(n) = w(n-1) + e(n)g(n) \quad (5)$$

where P(n) and g(n) represent the inverse input correlation matrix and Kalman gain vector. For algorithm learning, the term λ which is the forgetting factor plays a very major role, whose value is between 0 and 1.

The value of forgetting factor is closely related with convergence rate and tracking capability. In fixed forgetting factor based RLS algorithm, as λ increases and its value moves closer to 1, convergence rate increases and at the same time tracking speed will reduce. To improve the tracking capability of the algorithm λ value must be small which will diminish the convergence rate. These conflicting requirements are met by the usage of a variable forgetting factor RLS algorithm.

3.1. Generation of switching pulses for the operation of SAPF

Based on the three phase supply voltages, the control scheme shown in figure 2 will determine θ. This θ generates the three unit vector templates for the system. This UVT along with three phase load currents are the inputs to the control algorithm. The algorithm will generate weights corresponding to the three phase components of active power.

The mean weight magnitude equivalent to the components of active power (w_{pa}, w_{pb} and w_{pc}) from figure 2 is obtained by,

$$w_{avg} = \frac{w_{pa} + w_{pb} + w_{pc}}{3} \quad (6)$$

The dc bus voltage is sensed with the aid of a voltage sensor. This in turn is compared with the set point voltage of the dc bus (v_{dc}), and leads to the generation of the error signal (v_e). The MPPT based PI controller's tuned output (w_{dc}) ensures the steady maintenance of the dc bus voltage at its desired value.

The output of the PI controller at nth sampling instant is indicated below,

$$w_{dc}(n) = w_{dc}(n-1) + k_p(v_e(n) - v_e(n-1)) + k_i\, v_e(n) \quad (7)$$

where the gains of PI controller are notated as k_p and k_i

The sum of mean weight (w_{avg}) and PI controller's tuned output (w_{dc}) is utilized to find the active component of load current's weight.

$$w_t = w_{avg} + w_{dc} \quad (8)$$

UVT is used to calculate the reference source currents and denoted in (8) can be represented as,

$$i_{saR} = w_t u_{pa}, i_{sbR} = w_t u_{pb}, i_{scR} = w_t u_{pc} \quad (9)$$

The computation of VSC compensating current is carried out by subtracting the reference source currents (9) from load currents.

4. Performance Validation

MATLAB/SIMULINK platform is used to manifest the performance of the RLS based control algorithm. For various load conditions, validity of the proposed scheme has been checked as mentioned in the next section. The simulation parameters are detailed in Table 1. The SAPF comes into play at t=0.1 sec and the results of the three phase SAPF are as displayed in Figure 3.

Case 1: Steady state performance for Load-I

As shown in the Figure 3, from t=0.1s to 0.2s, undistorted v_{PCC}, supplies Load–I which has a Total Harmonic Distortion (THD) of 1.53% and RMS value of 230V. THD and max. value of load current is 27.16% and 1.84 A respectively.

Current harmonics is controlled by forcing peak value of fifth and seventh harmonic of compensating current to take a value as shown in Table 2. This will lead to a reduction in THD to 3.05%. Hence peak value of fifth and seventh harmonic of source current are found to be negligible. By ensuring source side pf at unity, enforcement of reactive power compensation is done by controlling the max. value of the compensating current's fundamental component to be at 0.17A. Allowing for a p-p ripple of 0.2 V, voltage at dc link, v_{dc} is maintained at a mean value of 220.2 V.

Table 1: System Parameters

System Parameters	Value
v_{pcc}(undistorted)/phase	230V, 50Hz
Load – I:	3-phase rectifier having load : (140+j31.42) Ω ;S_w closed; balanced load
Load – II:	3-phase inductive load having (90+j31.42) Ω ;S_w closed; balanced load
Load – III	3-phase rectifier having (90+j31.42)Ω ;S_w open; unbalanced load
Unbalanced load, Z_{c1}	(10+j3.14) Ω
Source impedance, Z_s	(0.02+j0.0314) Ω
DC link voltage, V_{dc}	220 V
Interfacing Inductor, L_f	4mH

Case 2: Dynamic performance under step change of load

Figure 3 manifests step load change from I to II at 0.2 sec, which demonstrates the SAPF performance under the condition of dynamic load change with the RLS control algorithm. From figure 3, peak value of source current under the transient condition is 2.02A. Values of all parameters in the new steady state condition with Load II is as indicated in Table 2. Compensation ensures that THD becomes well within the limit and also pf being improved to unity.

Under the sudden step load changing condition, voltage at dc link, v_{dc} droops to 215.8 V. The action of PV integration along with the MPPT control algorithm make sure that within 0.07 sec, voltage at dc link is restored to its set point value. The presented algorithm displays a satisfying performance by efficient tracking of the fundamental load current component, i_{Lfp} change from 1.28A to 1.90A.

Case 3: Steady state performance for unbalanced loading condition

Figure 3 shows the steady state unbalanced loading condition performance of 3-phase SAPF operating with RLS control scheme. Switch S_w is open at t=0.3sec to introduce the unbalanced loading scenario. The values related to unbalanced load currents and compensating currents for each phase are as indicated in Table 3. Unbalanced loading results in unbalanced compensating currents for the three phases. Each phase caters to the harmonic current and reactive power requirement set forth by the load. Once the load currents under unbalance are compensated, the source currents will automatically become balanced. The THD and max. magnitude for the source's currents i_{sa}, i_{sb} and i_{sc} are 3.21% and 1.61 A. The voltage at dc link, v_{dc} with p-p ripple of 0.21 V is sustained at a mean value of 221V. Also, the source power factor is kept at unity. This set up ensures unbalanced load compensation by the 3 phase SAPF with the presented control algorithm.

The results for the three cases are summarized in Table 2. From the table, it can be clearly understood that $i_{cm5} \cong i_{Lm5}$ and $i_{cm7} \cong i_{Lm7}$. This reveals harmonic current compensation with source current THD maintained well below the 5% limit. Unity power factor is well kept at supply end via reactive power compensation which is evident from the fact that $i_{cm1} \cong i_{Lq}$. Also unbalanced load current compensation is achieved by the algorithm which ensures that source current is balanced even under unbalanced load conditions. Thus the presented control scheme of 3 phase SAPF based on adaptive RLS algorithm is providing the necessary compensating currents, reactive power and unbalanced load compensation which leads to THD kept within 5% limit and unity power factor (UPF) at supply end.

From table 3, it is clear that convergence time, % steady state error and % THD is less for RLS based algorithm compared to LMS algorithms. Computational complexity is high for RLS algorithm since it considers the estimate of previous samples of output signal, error signal and filter weight. To include the effect of losses, distortion power should be taken into account because of the harmonic inducing nature non- linear loads connected to grid side. Thus the product of displacement power factor and distortion power factor gives the true power factor.

Table 2: Performance of the SAPF with the proposed control algorithm

Case	Category of load	v_{pcc}	i_L (A)				i_c (A)			i_s (A)			%THD	
			I_{Lp}	I_{Lq}	I_{Lm5}	I_{Lm7}	I_{cm1}	I_{cm5}	I_{cm7}	I_{sm1}	I_{sm5}	I_{sm7}	i_L	i_s
1	Load – I (balanced)	Undistorted (THD=1.53%)	1.22	0.14	0.25	0.13	0.16	0.24	0.13	1.28	0.01	0.01	27.16	3.05
2	Load – II (balanced)	Undistorted (THD=1.53%)	1.93	0.31	0.41	0.27	0.33	0.41	0.26	1.90	0.0	0.0	23.20	2.30
3	Load – III (unbalanced)	Undistorted (THD=26.5%)	1.78	0.21	0.28	0.34	0.25	0.27	0.34	1.61	0.01	0.01	31.6	3.21
			1.33	0.31	0.37	0.36	0.35	0.37	0.36	1.61	0.01	0.01	34.9	3.21
			0.45	0.2	0.13	0.31	0.40	0.12	0.31	1.61	0.01	0.01	34.8	3.21

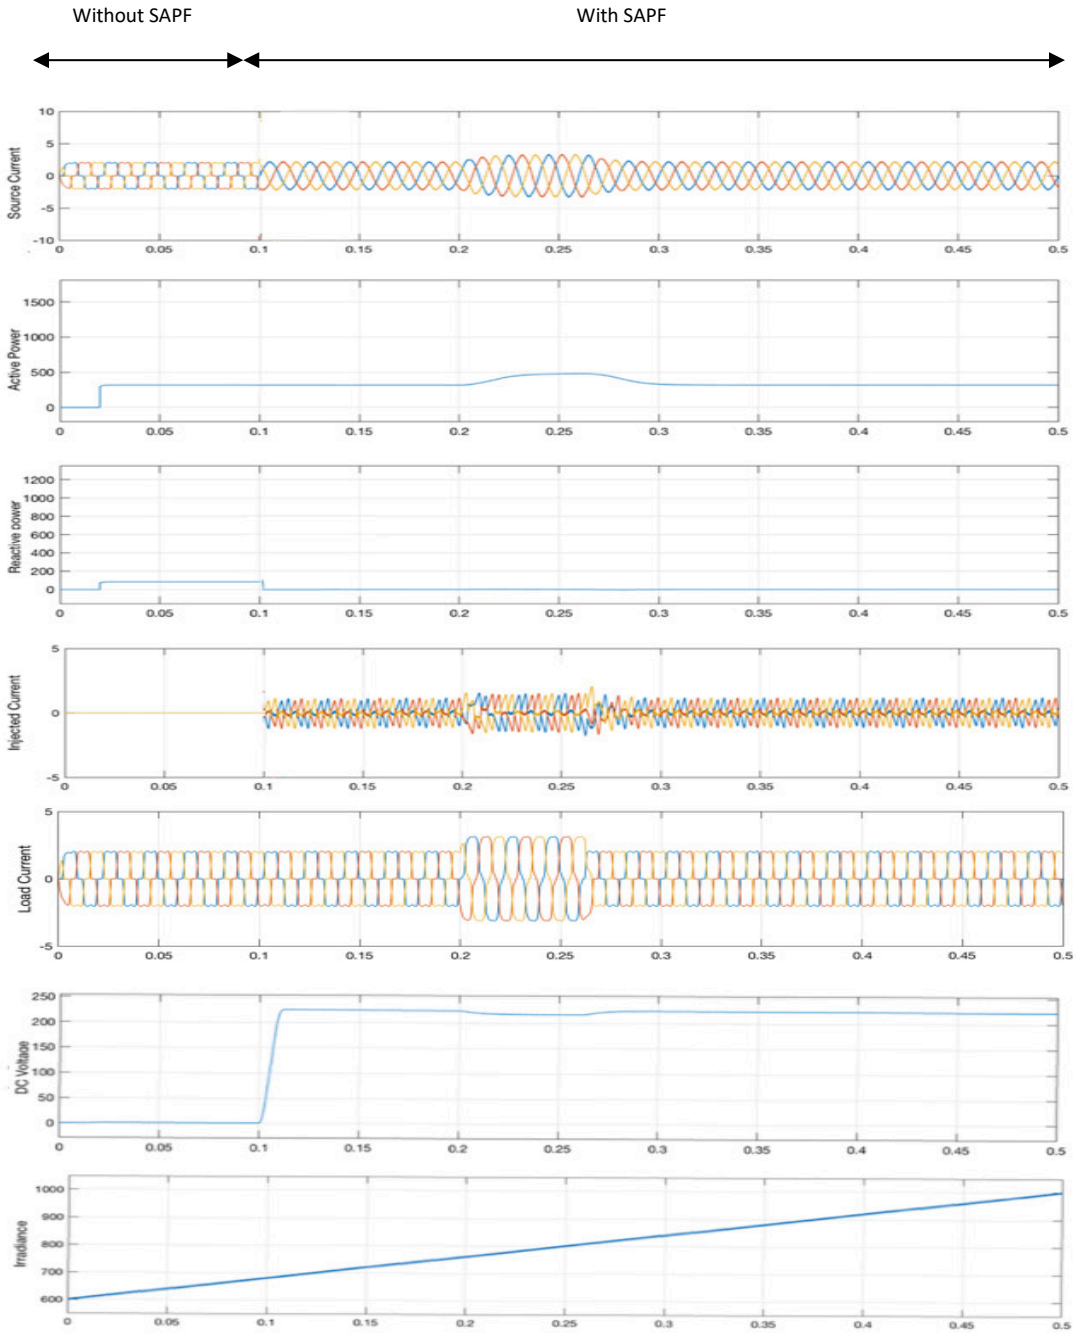

Figure 3: Simulation results for operation of the three phase SAPF with proposed algorithm

Table 3: Performance comparison of RLS algorithm with LMS algorithm [18]

Function	NLMS	VSSLMS	RLS
Convergence time	0.3 sec	0.12 sec	0.06 sec
Steady state error	2.11	0.85	0.56
THD	4.32	2.13	1.48
Complexity	Less	Less	High

Table 4: Power factors under varying load conditions

Case	Load	Distortion Factor	Displacement factor	True Power Factor
1	Load – I (balanced)	0.9995	0.9998	0.999
2	Load – II (balanced)	0.9997	0.9997	0.999
3	Load – III (unbalanced)	0.9995	0.9998	0.999

The equations (10-12) implies that the overall power factor gets diminished by the term cos γ. This leads to the conclusion that the average power transferred to the load gets diminished by cos γ, which depends on harmonic distortion induced in load current by the non-linear loads.

$$DF = \cos\gamma = \frac{I_{1(rms)}}{I_{(rms)}} \tag{10}$$

$$DPF = \cos\phi_1 = \frac{P_1}{S_1} \tag{11}$$

$$\begin{aligned} Power\ \ factor &= \frac{P}{S} = \frac{VI_1\cos\phi_1}{VI} \\ &= \left(\frac{I_1}{I}\right)\cos\phi_1 = \cos\gamma \times \cos\phi_1 \end{aligned} \tag{12}$$

The proposed SAPF configuration, maintains displacement power factor at 0.999 and the distortion power factor at near unity, for all the analysed load conditions. This leads to a magnitude of 0.999 for the true power factor. Table 3 manifests the true power factor under varying load conditions considered here.

5. Conclusion

This paper illustrates the performance aspects of PV powered RLS based shunt active power filter control utilizing the MATLAB/SIMULINK platform. Fundamental active components reference from the load currents are separated by the control law, based on the load currents, phase angle and reference currents of the previous sample. Load current's fundamental active component is only drawn from the source side and this is performed by the control system by ensuring that source currents track the reference currents with minimum steady state error. This makes the SAPF satisfy the reactive and harmonic power requisite of the considered non- linear load. Even under unbalanced loading condition, the source currents are in perfect balance. The put forward theory is validated by the results which shows that the source currents are drawn at UPF and they comply with the IEEE standard 519. Also, it is shown that dc voltage is maintained constant using PV integration into the network. With RLS algorithm, the 3-phase SAPF ensures sinusoidal and balanced supply currents which are maintained at UPF at various load conditions along with THD maintained under the 5% limit.

ABSTRACT

Cyberattacks such as spear phishing and malspam pretending to be companies, institutes, and government officials are increasing and evolving. Malware has a variety of purposes, such as collecting personal information and illegal access to the system. New types of malware are increasing every day, and many malware programs spread all over the Internet, causing severe problems. To analyze such malware effectively, analysts first need to understand the inner structure of the malware. They can try to analyze malware manually and automatically. However, attackers who create malware use many different kinds of techniques, such as anti-reverse engineering, to hinder and delay analysis. They also extend malware life through a combination of different techniques, such as social engineering and anti-debugging. These techniques make the malware more sophisticated; thus, it is hard for an analyst to detect the malware. Anti-debugging, one way to protect malware, is a deadly poison to malware analysts because it makes the analysis more difficult by detecting a debugger or debugging environments. Therefore, this paper describes malware's anti-debugging techniques and how to defeat them through anti-anti-debugging mechanisms. It applies its findings to analyze a sample program, packed files, and actual malware with anti-debugging modules and performs various experiments to verify the proposed techniques. After the experiments, it confirms whether its countermeasure is useful for malware analysis.

1. Introduction

In the past, the development of malware was mainly used for malware programmers to show off. However, malicious software(*malware*) such as virus and keylogger in recent years illegally accesses server systems in various ways to steal personal and financial information and computing power. Fatal damage, such as the theft of essential data of institutes, corporations, public institutions, and personal user information, occurs. The malware damage can take many forms, from stealing personal information such as a user's financial information to destroying industrial facilities such as Stuxnet [1]. According to Symantect's "Internet Security Threat Report 2019", financial Trojans accounted for 16% of the many malware programs spread in 2018. In addition, Trend Micro's "Unseen Threats, Imminent Losses" said that a vulnerability was found in the Supervisory Control And Data Acquisition (SCADA) system, one of the industrial systems' components. Also, attackers can penetrate the system through malware that attacks this vulnerability and illegally controls the SCADA system.

New types of malware appear every day and spread over the Internet, causing serious problems frequently. The malware also uses anti-reverse engineering techniques such as Self-Modifying code, code compression, packing, and anti-debugging methods to hide internal code structures and interfere with the analysis. This paper is an extension of work initially presented in the *International Conference on ICT Convergence* [2] to solve these kinds of problems. It is challenging to analyze malware with these anti-reverse engineering techniques accurately and requires considerable time. Security experts reinforce security by using anti-virus software and various equipment types to minimize malware damage, while analysts scrutinize malware using various techniques, it is more likely that anti-virus software or an automated analysis tool fails to detect it. The workflow of malware analysis is as in Figure 1. Usually, when an analyst analyzes malware, an analyst gets information from automated and static tools [3]. For example, if malware has anti-reverse engineering analysis. After static analysis, the analyst analyzes malware behavior through dynamic analysis and investigates its behavior in more detail through advanced analysis. However, anti-debugging techniques are hinder all analysis steps especially advanced

*Corresponding Author: Mi-Jung Choi, 305 Hanbit-Gwan, 1 Gangwondaehakgil, Chuncheon-Si, Gangwon-Do, 24341 Repblic of Korea, mjchoi@kangwon.ac.kr

analysis. Most of the tools in the advanced analysis are insufficient to deal with anti-debugging techniques. The relevant APIs and structures such as PEB and HEAP could be modified to defeat anti-debugging techniques as soon as advanced analysis begins. This step makes it more convenient for analysts to analyze malware, and it could be analyzed more quickly because the malware interference is gone.

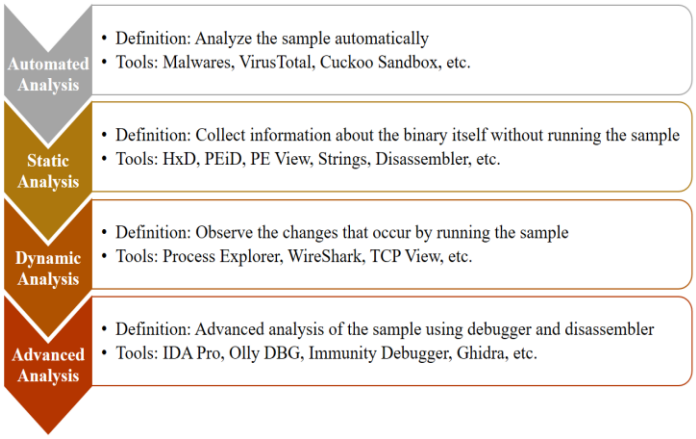

Figure 1: Workflow in safe and accurate analysis of malware

When analyzing malware in virtual environments such as QEMU, VMware, and VirtualBox, the virtual environments can be constructed similarly to the physical environments. The virtual environment analysis has advantages that are vastly similar to the actual execution, and does not have to worry about infecting a physical computer while performing malware analysis. However, there is a disadvantage in that analysis may be disrupted through the anti-VM (Virtual Machine) techniques. Anti-VM techniques disable malware analysis using CPU emulators or virtualization tools. The Dynamic Binary Instrumentation (DBI) tool can bypass anti-debugging by inserting or replacing code chunks into the operation command [4]. However, DBI has a disadvantage because it is not convenient, and it cannot execute huge or complex programs correctly.

The static analysis uses tools such as a decompiler and disassembler to analyze the binary or code of malware to infer the type of malware. However, this approach becomes more difficult and complicated by evasion techniques such as code obfuscation and packer [5]. A dynamic analysis examines the behavior of the target file. However, dynamic analysis tools cannot provide both accuracy and convenience when analyzing complex malware. The debugger, widely used to analyze malware dynamically, can examine changes in the machine's state while executing each command. However, the disadvantage of using a debugger is that there are anti-debugging techniques that can detect and interfere with the debugging process. Thus, if analysts can defeat anti-debugging techniques that interfere with the debugger, it becomes one of the most powerful methods for analyzing malware. Therefore, this paper introduces anti-debugging techniques that attack a debugger's vulnerabilities to interfere with analysis, and explains how to bypass analysis. In addition, it proposes anti-anti-debugging techniques that can defeat anti-debugging techniques, and verify the proposed method applying them to a sample program, packed files, and actual malware with anti-debugging modules. This paper aims to give direction for researchers who analyze malware or those who dream of being analysts to develop their methods or scripts that can defeat anti-debugging techniques when using a debugger.

This paper is organized as follows. Section 2 introduces research related to anti-debugging. Section 3 proposes anti-debugging techniques based on artifacts and time and describes correspondent anti-anti-debugging mechanisms. Section 4 presents the experiments performed and verifies anti-anti-debugging techniques with a sample program, packed files, and actual malware. Section 5 concludes the study.

2. Related Work

Analysts have continuously reviewed malware detection and binary code analysis. On the other hand, anti-reverse engineering research does not draw much attention from researchers except for some category topics [6], [7]. There are various topics in anti-reverse engineering such as anti-debugging, anti-VM, and code encryption. To understand anti-analysis, first, malware analysis must be briefly described. There are two different types of malware analyses, namely static analysis and dynamic analysis. Static analysis is a method of analyzing codes or binaries without executing them. Analysts can observe the file's operation code with a decompiler or disassembler and analyze the program flow and internal structure. Dynamic analysis probes its behavior by executing them using a sandbox, debugger, or emulator. Debugging refers to the process of detecting and eliminating errors or bugs when a process operates unexpectedly or crashes. A debugger is a tool or software that helps with this, therefore, it is a useful tool for understanding malware's inner workings. It likewise helps to observe changes in registry, memory, and stack closely while executing instructions in the target file (*debuggee*) line by line. Also, analysts use debuggers because they can manipulate elements such as code, environment, and memory. The sandbox case runs the file to record and analyze the process and network changes over a while [8].

However, malware developers use anti-analysis techniques against each analysis. Therefore, anti-debugging techniques delay malware detection and increase its life span by bypassing the anti-virus software. Anti-analysis is a series of techniques in which malware remains concealed, prevents detection, interferes with analysis, and makes analyzing it challenging. It is analyzed 6,222 samples of malware and studied how malicious behaviors differed in an environment with virtualization and a debugger [9]. As results, they found about 40 percent malware in an environment with a debugger performing less malicious behavior. Also, only two percent of the samples in a virtual environment showed malicious behavior when executed. This study shows malware with anti-VM and anti-debugging can bypass dynamic malware analysis tools such as a debugger, sandbox, and emulator.

Examples of anti-analysis techniques that interfere with static analysis include packer [10]-[12], code obfuscation [5], [13], [14], and opaque constants [15]. Packer is a technique that compresses the executable file and creates a new program entirely different from the original program. However, the new packed file has the same or similar behavior with various techniques such as Portable Executable (PE) relocation and anti-analysis. In the case of code obfuscation and opaque constants, these are the process of encrypting text, binary data, or code to make it difficult to understand. For these reasons, the malware detection method

based on signature became ineffective. Thus, dynamic analysis emerged to solve these kinds of problems. Debugging, which analyzes malware, carefully examines details such as behaviors, registers, and stacks while executing malware instructions by line. However, dynamic analysis using the debugger suffers from anti-analysis, such as anti-debugging, anti-VM, code compression, Self-Modifying, and blocking input devices. Among the anti-analysis, anti-debugging is an attempt by the debuggee to find or detect evidence of an analysis environment or debugger's presence. It is provided an overview of the analysis disruption techniques used by malware such as anti-debugging, anti-VM, and obfuscation [16]. Shang Gao and Qian Lin gave an overview of Windows's debugging mechanism, categorized according to the debugging methods used by the debugger, and explained the debugging functions and anti-debugging through exceptions [17]. It is classified general malware, targeted malware to attack specific systems and investigate how many anti-debugging techniques applied to it [18]. Most malware had anti-debugging techniques, however, it is found that the general malware had more anti-debugging techniques than targeted malware.

To defeat anti-analysis techniques, analysts can defeat most anti-debugging techniques using many CPU emulator and virtualization tools. However, these tools are not suitable for analyzing malware because they can analyze only a specific process or program. Dynamic Binary Instrumentation (DBI) framework can insert, modify, and delete code at the arbitrary address during the program's running [4], [19], [20], [21]. Therefore, the DBI can bypass the anti-debugging techniques by code insertion. However, analysis is inconvenient, and some DBIs cannot execute complex programs correctly [22]. Recently It is proposed the Apate framework to analyze malware [23]. Apate is a framework that hides the debugger from anti-debugging. The spectrum of powerful anti-debugging techniques is analyzed and classified into 79 attack vectors and six categories.

Apate is designed to defeat anti-debugging techniques by: (1) performing just-in-timed disassembling based on single-stepping and; (2) monitoring the execution flow of the debuggee and modifying the state of the debuggee to hide WinDbg. It is defined anti-debugging rule sets and proposed replacing the matching part of the binary with other instructions. The method proposed and modified the part that calls the anti-debugging functions in the debugger to other instructions [24], [25]. It is proposed a new framework for classifying, detecting and bypassing reverse engineering prevention techniques used by malware and protecting systems [9]. It is proposed UBER, a new system to neutralize anti-sandbox [26]. Sandbox has many artifacts of analysis environment. The anti-sandbox looks for various system artifacts expected to exist in the system for identifying the sandbox environment. UBER does not replicate artifacts or folders in use or directly simulate user behavior. Instead, it generalizes the user's computer usage pattern with an abstract behavioral profile, adopts the profile to simulate user and artifact creation operations, and then replicates the system with the created artifacts into a sandbox. Through this, UBER can defeat the anti-sandbox (i.e., usage artifacts analysis), while malware in the Windows or macOS malware is increasing. Since the tools for analyzing macOS based on malware are very limited. It is proposed Mac-A-Mal, a framework for analyzing Mac based malware [27]. It is developed a kernel extension to monitor malware behavior and bypass several evasion prevention techniques used in the wild, which uncovered 74 unknown malware programs.

3. Defeating anti-debugging techniques

This section first finds out how anti-debugging techniques work in Windows. Afterward, it explains how to defeat them [28].

3.1. Process Environment Block (PEB) Structure

The Process Environment Block (PEB) structure is a data structure in the Windows NT operating system. Each process has this structure and it contains each process information. Malware can detect the presence of debugger without using a specific function such as `IsDebuggerPresent`(). If implemented manually, there is no way to detect this in a static analysis or initial analysis. The anti-debugging based on PEB structure protects programs not only by malware but also many by many packers such as `PECompact`, `ASPack`, and `ASProtect` [29].

It confirms the `BeingDebugged`, `NtGlobalFlag`, and HEAP structure to perform anti-debugging among many PEB structure members. `BeingDebugged` is set to 0x0 if not debugged, and 0x1 if debugged. `NtGlobalFlag` has a value of 0x0 if not debugged, and is set to a value of 0x70 if debugged. Table 1 shows the flags of `NtGlobalFlag` while debugging. Not only the PEB structure, but HEAP structure can also detect the presence of a debugger.

Table 1: Flag configurations of `NtGlobalFlag` member in the PEB structure

Flag	Value
FLG_HEAP_ENABLE_TAIL_CHECK	0x10
FLG_HEAP_ENABLE_FREE_CHECK	0x20
FLG_HEAP_VALIDATE_PARAMETER	0x40

Table 2: Flag configurations of `Flags` member in the HEAP structure

Flag	Value
HEAP_GROWABLE	0x2
HEAP_TAIL_CHECKING_ENABLED	0x20
HEAP_FREE_CHECKING_ENABLED	0x40
HEAP_SKIP_VALIDATION_CHECKS (only in Windows XP or under)	0x10000000
HEAP_VALIDATE_PARAMETERS_ENABLED	0x40000000

Table 3: Flag configurations of `ForceFlags` member in the HEAP structure

Flag	Value
HEAP_TAIL_CHECKING_ENABLED	0x20
HEAP_FREE_CHECKING_ENABLED	0x40
HEAP_VALIDATE_PARAMETERS	0x40000000

Anti-debugging can detect debuggers using the `Flags` and `ForceFlags` members of the HEAP structure. `Flags` has a value of 0x2 if not debugged. It has a value of 0x50000062 in Windows XP or 0x40000062 in Windows 7 or later versions, if debugged. `ForceFlags` has a value of 0x0 if not debugged, and 0x40000060 if debugged. Table 2 shows the configuration flags of `Flags` and Table 3 shows the configuration flags of `ForceFlags`. To bypass anti-debugging based on PEB structure, analysts can defeat anti-debugging by modifying each member to an appropriate value, such as 0x0 in `BeingDebugged`.

3.2. IsDebuggerPresent()

IsDebuggerPresent() is the function in which software can easily detect the presence of a debugger. Malware and general software use this function to protect itself from reverse engineering. This function is also one of the anti-debugging techniques that most packers such as UPX and PECompact can apply to the original program. This function returns the BeingDebugged member of the PEB structure. To defeat this function, one must modify the code to return 0x0 or change the value of BeingDebugged member of the PEB structure. This paper uses PUSH and POP instructions to store 0x0 in the EAX register, shown in Figure 2. The original code of IsDebuggerPresent() is the left side of Figure 2, and the modification code of IsDebuggerPresent() is the right side of Figure 2.

```
MOV EAX,DWORD PTR FS:[18]          MOV EAX,DWORD PTR FS:[18]
MOV EAX,DWORD PTR DS:[EAX+30]      PUSH 0
MOVZX EAX,BYTE PTR DS:[EAX+2]      POP EAX
RETN                               RETN
```

Figure 2: The original code (left) and modification code (right) of IsDebuggerPresent()

```

```

Figure 3: The original code (left) and modification code (right) of CheckRemoteDebuggerPresent()

3.3. CheckRemoteDebuggerPresent()

CheckRemoteDebuggerPrenset() function takes the Process Identifier (PID) of a particular process to detect whether it is debugged or not. It calls the NtQueryInformationProcess() function from inside to perform anti-debugging not only on malware but also on general software, and some packers use it to prevent debugging. The code on the left of Figure 3 is the original code of CheckRemoteDebuggerPrenset() and as shown on the left side of Figure 3, it calls NtQueryInformationProcess() from inside. There are two ways to defeat this function. Firstly, defeat the function called NtQueryInformationProcess() internally. Secondly, store 0x0 in the EAX register to make it always return 0x0.

This paper stores 0x0 in the stack using the PUSH instruction, as shown on the right side of Figure 3. It then stores 0x0 in the EAX register with POP instruction and terminates the function using RETN. There are three essential things to defeat this function. First, three existing instructions from the top of this code must be maintained. The second is to store 0x0 in the EAX register and return it. Last is to save the return address stored in the stack to the EBP register with POP instruction, then end with RETN. Otherwise, the flow of the debuggee gets tangled, and the analysis cannot proceed further.

3.4. ZwQueryInformationProcess()

The developer uses ZwQueryInformationProcess() functions for various reasons, such as finding a process path not only for anti-debugging. However, this section, only describes anti-debugging based on ZwQueryInformationProcess(). Figure 4 is a parameter for ZwQueryInformationProcess(). Among these parameters, ProcessInformationClass is the type of process information to be retrieved. It performs by set a specific value to the ProcessInformationClass parameter. If ProcessInformationClass is set to 0x7 which means ProcessDebugPort, it can determine whether it is debugged or not. In case of debugging, it returns 0xFFFFFFFF (-1). If not, it returns 0x0. Not only ProcessDebugPort, this function can executes anti-debugging bypassing 0x1E, which means ProcessDebugObjectHandle or 0x1F, which means ProcessDebugFlags to the parameter ProcessInformationClass. In the case of ProcessDebugObjectHandle, this function returns 0x000000B4 if debugged, and it returns 0x0 if not debugged. In the case of ProcessDebugFlags, this function returns 0x0 if debugged, and it returns 0x1 if not debugged. The code on the left of Figure 5 is the original code of ZwQueryInformationProcess().

```
NTSTATUS WINAPI ZwQueryInformationProcess(
    _In_      HANDLE              GetProcessHandle,
    _In_      PROCESSINFOCLASS    ProcessInformationClass,
    _Out_     PVOID               ProcessInformation,
    _In_      ULONG               ProcessInformationLength,
    _Out_opt_ PULONG              ReturnLength
);
```

Figure 4: Parameter of ZwQueryInformationProcess()

```
MOV EAX,0EA                        PUSH 100000

                                   RETN
                                   MOV EAX,DWORD PTR SS:[ESP+C]
                                   PUSH 0
                                   POP DWORD PTR DS:[EAX]
                                   XOR EAX,EAX
                                   RETN 14
                                   MOV EAX,DWORD PTR SS:[ESP+C]
                                   PUSH 0
                                   POP DWORD PTR DS:[EAX]
                                   XOR EAX,EAX
                                   RETN 14
                                   MOV EAX,DWORD PTR SS:[ESP+C]
                                   PUSH 1
                                   POP DWORD PTR DS:[EAX]
                                   RETN 14
```

Figure 5: The original code (left) and modification code (right) of ZwQueryInformationProcess()

In order to bypass ZwQueryInformationProcess(), three things are crucial: (1) the first two instructions from the top of the original code must be executed; (2) it must return an appropriate

value; (3) it should not interfere with the flow of the debuggee. It needs a new virtual memory that must be allocated to handle the number of cases and consider non-anti-debugging cases. Also, `ZwQueryInformationProcess()` enters the kernel area through `KiFastSystemCall` and `SYSENTER` instructions. Since the debugger cannot enter the kernel, one can bypass these powerful instructions by writing new instructions in allocated virtual memory, as shown on the right of Figure 5. It determines whether the received `ProcessInformationClass` parameter is 0x7 (`ProcessDebugPort`), 0x1E (`ProcessDebugObjectHandle`), or 0x1F (`ProcessDebugFlags`). In each case, it jumps to the address with the specific instructions. Otherwise, it returns to the original instruction with `RETN`. The reason for returning to the original function is not to disturb the flow of the debuggee.

Figure 7: The original code (left) and modification code (right) of `FindWindowW()`

3.5. *FindWindow()*

The family of `FindWindow` functions can find the name of the specific window. It consists of `FindWindowW()`, `FindWindowA()`, `FindWindowExW()`, and `FindWindowExA()`. These are anti-debugging techniques that confirm the debugger's window name to see if the debuggers are running on the operating system. Figure 6 shows the parameters of `FindWindowA()` and `FindWindowW()`. The `lpClassName` gets a specific class name, and the `lpWindowName` gets a specific window name when calling these functions. If it finds the name of a specific window, it returns the handle of the window. If not, it returns 0x0. If malware calls these functions, it passes a particular debugger's window name to the `lpWindowName` parameter for anti-debugging. However, the analysts can defeat it always to returns 0x0.

The code on the left of Figure 7 is the original code of `FindWindowW()`, and the code on the right of Figure 7 is the code to defeat it. This study allocates a virtual memory and writes new instructions to disable anti-debugging techniques. After moving to the allocated address through the `PUSH` and `RETN` instructions, one must execute the existing `CALL` instruction. Next, it needs to get the debugger's window handle and compare it with the `EAX` register using `CMP` instruction. If it is the same, it jumps by `JE` instruction and stores 0x0 in the `EAX` register. Otherwise, it jumps by `JMP` instruction and restores the return address to the `EBP` register. The analysts can defeat this anti-debugging technique by writing new instructions in virtual memory. In Figure 7, the address of virtual memory is 0x00220000. However, this address must point to empty virtual memory.

3.6. *GetCurrentProcessId(), BlockInput()*

The commercial packer such as `Yoda's Protector` uses the two functions described in this section. The malware packed with `Yoda's Protector`, it calls `CreateToolHelp32Snapshot()` to obtain the PIDs and process all running processes' information. Next, it uses the `GetCurrentProcessId()` to get its process information and then compares the two results. If the parent process is a debugger, it interrupts analysis by terminating the process. Therefore, to defeat this anti-debugging technique, `GetCurrentProcessId()` always returns the PID of a debugger or analysis tool by modifying the PID of the debugger and debuggee to be the same. Analysts can defeat this technique. The code on the left side of Figure 8 is the original code of `GetCurrentProcessId()`, and the code is modified the same as on the right side of Figure 8 to defeat this function. To match the PID of the debugger and debuggee, it stores the PID of the debugger (0x0EA0 in Figure 8) in the `EAX` register and returns it. At this point, `NOP` instruction fills the remaining space of memory.

```

RETN 4
```

```
NOP
NOP
⋮
NOP
NOP
RETN 4
```

Figure 9: The original code (left) and modification code (right) of `BlockInput()`

The `BlockInput()` blocks the input events such as keyboard and mouse. When software calls this function, the computer blocks all events from input devices. By blocking all input devices' events, signals from devices do not affect the input queue's synchronous key state and asynchronous key state. If the software calls this function while running, the computer blocks the input devices' events, and there is no solution until the software calls again. The malware exploits this. If malware calls this function while debugging, the computer blocks all events from input devices, and

analysis stops. The only solution is to reboot the computer and analyze the malware again from the beginning. This function has a BOOL value as a parameter. If the parameter is TRUE, the computer blocks the events. If FALSE, the computer unblocks the events. This function returns to non-zero if it ends with no errors. The corresponding code is the left code of Figure 9. The way to defeat this technique is more straightforward than others. As shown on right side of Figure 9, this is defeated by modification with NOP instruction, which does nothing.

Figure 11: The original code (left) and modification code (right) of timeGetTime ()

3.7. GetTickCount(), timeGetTime()

The anti-debugging techniques described so far are anti-debugging based on artifacts. Those are techniques in which malware detect analysis signs, analysis environment, or debugger. The anti-debugging based on artifacts is the most common and useful technique for malware to evade analysis. If a debugger runs the program, there are differences from normal execution. The anti-debugging based on artifacts confirms the debugger through these differences.

However, the anti-debugging described in this section is slightly different from the previous ones. The anti-debugging described in this section uses time elements. The anti-debugging based on time measures the time between a particular routine. It compares the execution in the real system and the execution analysis environment and indirectly detects the debugger. It measures the time stamp counter cycle before and after starting a particular routine in a program to confirm a debugger's presence because the analysis using a debugger takes a long time.

GetTickCount() starts counting after Windows boots. Through this function, malware or software can easily determine how long it has been since the computer booted up and got time value every time stamp counter cycle. The return value is the 32-bit form to keep the count for up to 49.7 days. Many developers use this function to measure elapsed time, and malware developers use it as well. The code on the left in Figure 10 is the original code of GetTickCount(). To defeat this, it must return the same value by hard coding. Hard coding is the way to develop software by embedding data directly into the source code or memory. In this way, it stores a meaningless value in the EAX register. Therefore, the return value of GetTickCount() is always meaningless value which hard coded. In other words, the measured time for a specific routine is always same.

timeGetTime() has less overhead than timeGetSystemTime(), because timeGetSystemTime() uses a MMTIME structure, which contains timing information for different multimedia data types. However, timeGetTime() uses a DWORD structure. Moreover, timeGetTime() reacts directly to timer interruptions and returns the time in milliseconds that have elapsed since the Windows booted, thus GetTickCount(). The debuggee can determine the presence of the debugger by using precise functions such as timeGetTime(). Disabling this is not much different with GetTickCount(). To defeat this function, one must to return the same value all the time. The code on the left of Figure 11 is the original code of timeGetTime(). However, if modified as the code on the right side of Figure 11, debuggee fails to detect the presence of debugger because it always returns the same value.

4. Experiments

This study implemented a sample program which includes anti-debugging techniques for the *(i) Sample-ex* experiment. The sample program has various anti-debugging techniques such as the PEB, and HEAP, among others. The sample program printed the return value to verify the results of the anti-anti-debugging intuitively. In the second experiment, *(ii) Packed-ex*, packed programs were used for packed malware or packed software. This study confirms the effectiveness of the proposed anti-anti-debugging mechanisms using these programs. Finally, real malware was employed in the in *(iii) Malware-ex* experiment. The anti-anti-debugging proposed in this paper works well with benign files, packed files, and actual malware through the step by step experiments.

Table 4: Anti-debugging techniques of each packer

Packer	Anti-Debugging Techniques
PECompact	IsDebuggerPresent()
Armadillo	IsDebuggerPresent()
ACProtect	IsDebuggerPresent()
	ZwQueryInformationProcess()
Themida	IsDebuggerPresent()
	ZwQueryInformationProcess()
Yoda's Protector	IsDebuggerPresent()
	GetCurrentProcessId()
	BlockInput()

Table 5: Information of real virus

File Type	Win.32.EXE
Virus Type	Worm/Win32.Abuse
MD5	068c3b80106b3300548bv6vv673a3db5
Anti-Debugging Techniques	`GetTickCount()`
	`FindWindowExA()`
	`FindWindowA()`

4.1. Experimental Data

This paper implemented a sample program including various anti-debugging techniques for *(i) Sample-ex* experiment, as shown in Figure 12. This program prints different results depending on the presence of a debugger. Next, sample files used in the *(ii) Packed-ex* experiment, packed the calculator program provided by Windows 7 (32bit) into five packers or protectors. The common feature of used packers or protectors is that they protect the original software by applying one or more anti-debugging techniques. Five packers called `Yoda's Protector`, `Themida`, `ACProtect`, `Armadillo`, and `PECompact` for *(ii) Packed-ex* experiment were used. These packers apply one or more anti-debugging techniques to protect original program against reverse engineering. Table 4 shows the anti-debugging techniques applied by each packer.

Among these, the most commonly used function is `IsDebuggerPresent()`, and the unusual cases are `GetCurrentProcessId()` and `BlockInput()` used by `Yoda's Protector`. Table 5 shows information about one of the malware samples collected from VirusShare[**], which is for the *(iii) Malware-ex* experiment. This malware sample uses `GetTickCount()`, `FindWindowExA()`, and `FindWindowA()` functions for anti-debugging. However, it is impossible to analyze some samples using different anti-debugging techniques such as `RDTSC` instruction and Self-Modifying technique.

`RDTSC` is an instruction that reads the current time-stamp counter variable. Unlike function such as `timeGetTime()`, `RDTSC` is executed as a single instruction. In order to bypass this instruction, it is necessary to modify the debuggee. However, modifying the debuggee requires careful attention. Self-Modifying is one of anti-analysis techniques. It is a technique to alter its own codes while the file is executing. Therefore, an analyst fails to identify the real instructions before executing Self-Modifying. Thus, `RDTSC` and Self-Modifying are out of our research scope and this paper does not handle these techniques.

4.2. Experimental Results

Figure 13 shows the results of analyzing sample data in the debugger in *(i) Sample-ex*. In the case of Figure 13 (a), all of the anti-debugging techniques used in the sample program detected a debugger. All of these anti-debugging techniques returned and printed artifact or evidence which indicates the presence of a debugger. However, an analysis was made again using anti-anti-debugging, and the results were confirmed, as shown in Figure 13 (b). It showed a completely different artifact or evidence and message against Figure 13 (a).

This research primarily confirmed that the anti-anti-debugging works successfully. Next, it conducted *(ii) Packed-ex* and analyzed using different data. The analysis from this point shows that the results of the analysis are limited. Therefore, the actual memory address and instructions were shown. Figure 14 (a) is the loaded file with `Yoda's Protector` in the debugger. The number series on the left correspond to each address, and instructions on the right correspond to the original code. Figure 14 (b) shows the new code to defeat `GetCurrentProcessId()`. It stored the PID of the debugger, which is 0x0B5C in the `EAX` register, to make it the same as shown in Figure 14 (b). This study also confirmed the results of `ZwQueryInformationProcess()` used by `ACProtect`, as shown in Figure 15. Figure 15 (a) is the original code and address of `ZwQueryInformationProcess()`, and Figure 15 (b) is the new instructions to defeat it. At this time, 0x003E0000 is the address of the virtual memory. Through this, whether the anti-anti-debugging is effective even in packed samples was secondarily ascertained.

`Self-Modifying`	X	X	X	X
Success Rate	87.5%	68.8%	62.5%	56.3%

Finally, this paper collected and experimented with malware, which has anti-debugging techniques for *(iii) Malware-ex*. As a result of the *(ii) Packed-ex* experiment, this paper listed the address and instructions in Figure 16, which shows the loaded malware sample results used in *(iii) Malware-ex* on the debugger and the results of defeating its anti-debugging techniques. Figure 16 (a) is the original code of `FindWindowExA()`, and Figure 16 (b) is the new code that defeats it. This study wrote a new code that was occupied in 0x00190000 virtual memory to defeat the function. Figure 16 (c) is the original code of `FindWindowA()`, and the code that defeats it is Figure 16 (d). This study occupied and wrote the new code on the memory address 0x00170000 to defeat this. As mentioned before, virtual memory addresses cannot always be the same and must occupy the memory with empty space. The last anti-debugging technique is `GetTickCount()`. Figure 16 (e) is the original code of this function, modified as in Figure 16 (f), in which malware failed to detect the presence of a debugger, and the malware analysis could proceed. Thus, this study experimented and confirmed step by step that the anti-anti-debugging proposed in this paper is effective.

Table 6 shows the experimental results for 16 anti-debugging techniques. The Binary Substitution [25], which shows the lowest success rate among each work, changes debuggee's binary. It requires special attention. Pin [4] is an excellent analysis tool, but it cannot defeat the anti-debugging techniques used by `Yoda's Protector`. Apate [23], which has a similar success rate to Pin, has also been unable to defeat the anti-debugging techniques used by `Yoda's Protector`, and it can defeat fewer anti-debugging techniques than Pin. As shown in Table 6, most anti-debugging techniques are based on APIs, PEB, and HEAP structures. However, there are far more anti-debugging techniques, and their research is needed for future works.

Among the many samples, there were some that this paper failed to analyze. Because this work can defeat some APIs and PEB structure-based anti-debugging techniques, the anti-debugging using different artifacts could not be defeated, such as `RDTSC` instruction, Memory Breakpoint, Self-Modifying, and Single-Step Detection [22].

5. Conclusion

Malware as well as commercial packers use various anti-debugging techniques to protect themselves from the analysis by reverse engineering. Anti-debugging techniques can bypass or neutralize debugging analysis. An analyst needs an advanced debugger and related knowledge in order to analyze malware with anti-debugging techniques. Thus, this study proposed an anti-anti-debugging against the anti-debugging techniques. In order to explain the anti-anti-debugging, we expounded the anti-debugging techniques used by malware and packers. Also, it set up a step by step experiment for verification. It implemented, experimented, and analyzed sample files, and packed files with anti-debugging techniques. Finally, it experimented with the actual malware with many anti-debugging techniques. As a result of a step by step experiment, it found that proposed anti-anti-debugging can defeat the anti-debugging techniques and deal with actual malware. It did not interfere with program execution flow as less as possible by minimizing the debuggee's direct modification. Of course, the method proposed in this paper cannot defeat all anti-debugging techniques. Nevertheless, the method serves an essential part in analyzing malware with a debugger. Furthermore, it improves the ability to handle sophisticated debugging evasion techniques.

Also, debuggees, such as `Yoda's Protector`, can call the anti-debugging techniques more than once to interfere with the analysis. However, the anti-anti-debugging proposed in this paper has the advantage of being able to defeat the anti-debugging

technique that is called multiple times by only modifying it once. There are several tools and methods to disable anti-debugging techniques, however, none elaborate on how to disable it or explain with assembly code. Thus, this paper aims to discover for analysts new ways to defeat anti-debugging techniques and help researchers develop their scripts for research and analyze malware.

Data Availability

The script file used in the experiments is available at https://github.com/goldbear564/antiantidebugging.

Conflict of Interest

The authors declare no conflict of interest.

Digital transformation

ABSTRACT

The pressing and most urgent challenge for most of the Posts in Southern Africa is to transit from its historical reputation of being a snail-paced, inefficient, loss-making and ineffective service provider to an agile, innovative, solution-driven and highly competitive service provider that strive for excellence. In this context, adoption, and diffusion of technology and digital transformation by Posts should deliver the necessary traction to steer the digital transformation journey of the postal industry in Southern Africa with the necessary velocity while cognizant and mindful of the appropriateness of the technology in the African context in the light of a VUCA (Volatile, Uncertain, Complex and Ambiguous) world. The traditional technology adoption models are characterized by "linearity" which is the opposite of a dynamic setting characterized by "causality" which is the fundamental principle of a system thinking approach. The multi-stakeholders in the postal sector with often competing interests renders a linear approach defunct and requires a system approach to digital transformation and technology adoption. The conceptual framework developed from the critical review of literature offers considerable leverage to postal sector in developing countries and to Southern Africa in particular. The proposed conceptual framework integrates dimensions such as Postal Industry 4.0 Envisioning, Strategy, Institutional factors, Organizational factors, Individual factors, Industry 4.0 environment and outcomes.

1. Introduction

This paper is an extension of "Postal Development: Literature Review into Adoption Models" presented at IEEM 2019 Conference in Macau by authors in [1]. The rise of digitalization powered by a digital revolution of the 21st century ushered by the Fourth Industrial Revolution and personified by Industry 4.0, has prompted the postal sector across the world to expand their services well beyond the original service of postal operators (POs) which was delivery of physical mail in the form of letters and post cards.

In [2], the authors propose that although there are Posts in different nations that are struggling to keep afloat due to economic and political turbulence there are other Posts that are trailblazers in postal digital transformation which is underpinned by digital innovation which leads to digital disruption. It comes as no surprise that Swiss Post, The Netherland Post, Deutsche Post, La Poste, and Japan Post are trailblazers in digital innovation.

In [3], the authors postulates that societal anatomy is rapidly changing, and that the digital age shepherded changes in consumption patterns which has resulted in the evolution of the customer of the future with unique needs and expectations that industries should meet. A systems (holistic) approach is required to comprehend a new world that is driven by volatility, uncertainty, complexity, and ambiguity (VUCA). VUCA world is categorised by the traits of volatility, uncertainty, complexity and ambiguity [4]. In [5], the authors argue that Volatility, Uncertainty, Complexity and Ambiguity (VUCA) explains the competitive ecosystem of the digital economy in which corporations ought to acclimate business process to match up briskly shifting and more complex dynamic settings.

In [6], the authors propose that in the current Volatile, Uncertain, Complex and Ambiguous (VUCA) world, organizations and employees are faced with a plethora of challenges that overly dynamic and totally different from the challenges of the past. In [6], the authors further argue that there are several of drivers that propel these changes, and that

*Corresponding Author: Kgabo Mokgohloa, mokgok@unisa.ac.za

technology, accessibility to information, a fast shifting global economy, the establishment of a global consumer society and a very insistent customer with unique and diverse requirements are only some influences that have shaped an extremely complex and ambiguous world.

In [7], the authors advance that organizational and societal systems in the digital era encompass characteristics of volatility, uncertainty, complexity, and ambiguity; and as a result a systems approach to digital transformation and technology adoption is a key success factor for Posts in Southern Africa.

1.1. Problem statement

The crises that has befell on the Designated Postal Operators (DPOs) in Southern Africa has precipitated the near collapse of the postal logistics sector due poor performance on the four performance indicators of the 2IPD and consequently losses except for a few Designated Postal Operators making a profit, this is characterized by the scores respective Post in Southern Africa obtained on the 2IPD.

The underperformance by SADC DPOs is fuelled by a plethora of dynamics including inflexible or rather outdated business models that are not adapting to the technological changes that are disrupting current business models immensely, the archaic business models cannot compete in the 21st century and this result in majority of Postal Operators in Southern Africa posting losses year in year out. The unsustainability of the DPOs leave the State in respective countries with no option but to bail out these institutions. This performance is contrary to the first-tier countries who occupy pole positions on the integrated index on postal development (2IDP).

1.2. Research question

Can a technology and digital adoption framework in the context of postal industry 4.0 be developed for Posts in Southern Africa?

1.3. Concluding remarks to introduction

The paper is divided into (a) Introduction which introduces the phenomenon under study as well as articulating the problem statement and the research question which guided the research study. (b) Literature review which delved into the postal landscape, articulation of the Integrated Index on Postal Development (2IDP) which is a global measure of performance of the postal sector globally, and with specific reference to the top 5 performers on the 2IDP and digital readiness index. The literature review further delved into the phenomenon of industry 4.0, technology adoption, digital transformation, reductionist vs systems approach and capability maturity models. The report then detailed the research methods adopted, the discussion and findings that included the development of the theoretical framework, deductions and upcoming research concludes the study.

2. Literature review

2.1. The Postal landscape

In [2], the authors articulates an international view point of the Postal Industry, accentuating that the postal network encompasses a worldwide grid of over 677 000 retail offices, 5.3 million members and substantial infrastructure comprising 192 nations.

In [8], the authors hypothesizes that imperfect internet connectivity, inadequate investment and/or recapitalization of the network infrastructure, deprived value of service, restricted interoperability and connectivity among the systems of value chain participants, as well as uncertainty in postal industry characterisation in southern Africa are the foremost motives for the snail-paced advancement.

In [9], the authors argues that the regional scenery of the postal industry in southern Africa encompass 50 mail centres and a distribution infrastructure of 16, 064.394 deliverance points. Of these, South Africa has a lion share of 26 mail centres and 14, 106.896 delivery points. The postal industry in Southern Africa comprise of fourteen designated postal operators in South Africa, Botswana, Zambia, Eswatini, Seychelles, Democratic Republic of Congo, Malawi, Comoros, Madagascar, Mauritius, Tanzania, Lesotho, Mozambique, and Angola.

2.2. The Integrated Index on Postal Development

In [3], the authors note that most Posts are performing disappointingly on the Integrated Index for Postal Development (2IPD). In [3], the authors further proposes that measuring the multiple facets of postal development is no insignificant task, and hypothesize that in order to surmount this difficulty; the Universal Postal Union (UPU) has been tapping on abundance of postal big data to appraise the performance of Posts globally. One of the most important sequels of these endeavours was the development of the Integrated Index for Postal Development commonly known as the 2IPD. In [10], the author argues that 2IPD gauges the performance of Posts in the four vital aspects of postal advancement which are known as the 4Rs (reliability, reach, relevance and resilience).

In [11], the authors outlines the four aspects of postal advancement (development) as follows: (a) Reliability is a fusion of excellence of service delivery, including certainty across all categories of postal delivery service; it eventually gauges the level of postal operational efficiency (b) Reach is fusion of worldwide postal connectedness at intercontinental level across all categories of international postal delivery services, it ultimately gauges the level of globalization of the postal services (c) Relevance encompass the strength of demand for the full range of postal services in each postal section; it eventually gauges the level of attractiveness of the postal market (d) Resilience encompass ability to innovate, deliver wide-ranging postal services and assimilate sustainable development targets in postal business models; it ultimately gauges the level of adaptableness of postal business models.

In [3], the authors advances that a total of 172 countries were analysed for the development of the 2019 global ranking (based on complete data for 2018). Table 1 depicts the top 5 countries in alphabetical order with their corresponding scores on the 2IDP and are as follows: France, Germany, Japan, Netherlands, and Switzerland. In [12], the authors postulates that these top 5 DPO's are performing outstandingly on the 2IDP because they have steadily build dependable, well-connected, appropriate and agile postal services. The report further highlights that other DPOs

especially in developing countries are underperforming relative to the 2IDP indicators.

Table.1: Top 5 Designated Postal Operators performance on Integrated Index for Postal Development, adapted from [12]

Country	2IPD Score 2018	2IPD Score 2019
France	83.3	86.86
Germany	91.3	90.79
Japan	91.6	87.19
Netherlands	93.7	93.67
Switzerland	100	100

The analysis of performance on the 2IPD points to Posts in developing countries (Southern Africa included) as laggards' when compared to the top performing DPOs on the 2IPD. Table 2 lists the SADC (Southern African Development Community) Designated Postal Operators with their corresponding 2IPD scores.

Table.2: Southern African Development Community Designated Postal Operators performance on Integrated Index for Postal Development, adapted from [12]

Country	2IPD Scores 2018	2IPD Scores 2019
Angola	21.22	30.54
Botswana	23.72	21.00
Comoros	11.29	11.76
Democratic Republic of Congo	15.87	17.01
Eswatini	24.72	15.80
Lesotho	14.09	13.44
Madagascar	30.96	30.63
Malawi	24.78	13.74
Mauritius	49.17	40.53
Mozambique	4.95	6.28
Namibia	31.28	27.52
Seychelles	30.68	24.00
South Africa	33.34	33.34
Tanzania (Republic)	31.81	39.12
Zambia	7.73	8.75
Zimbabwe	19.53	12.74

In [13], the authors explains that the industrial sector has always been critical to the economic development of countries. Since the end of the 18th century, businesses have gone through enormous modifications that revolutionized a way how goods are produced and has yielded numerous benefits, predominantly related to efficiencies and productivity. In [14], the authors argues that presently, after three preceding industrial revolutions, the combination of advanced technologies and the internet age is completely transfiguring the industrial landscape and it is labelled the Fourth Industrial Revolution or its personification known as the Industry 4.0. The postal sector is not immune to these fast-paced technological revolutions that continue to chance the postal landscape daily.

The rise of digitalization brought upon the digital age has prompted the postal industry globally to enlarge their services further than the traditional mail delivery service of Posts. In [15], the authors hypothesise that with the global adoption of digitalization and digitization at an exponential rate, stakeholders are progressively demanding to interact directly with the postal service via digital networks.

2.3. Industry 4.0

In [13], the authors elucidates that the industrial sector has always been critical to the economic development of countries. Since the end of the 18th century, businesses have gone through enormous modifications that revolutionized a way how goods are produced and has yielded numerous benefits, predominantly related to efficiencies and productivity. In [14], the authors argue that today, after three preceding industrial revolutions, the combination of advanced technologies and the internet age is completely transfiguring the industrial landscape.

In [16], the authors argue that the aim of Industry 4.0 is to digitize and incorporate processes vertically across the entire value chain of the organisation, from conceptualization all the way to sales and after-sales support. Data throughout the value chain is available instantaneously, backed by augmented reality and optimized in a unified network Industry 4.0 is a farsighted initiative of the German State that traditionally supports advancement of the German industrial sector. In [17], the authors support this view and propose that in this sense, Industry 4.0 can be viewed as an action towards nurturing Germany's posture as one of the most leading technologically advanced nation.

In [18], the authors postulate that Industry 4.0 is envisioned at the fixated assemblage and application of prompt data and information by means of linking all individual rudiments of a system, with a view of reducing the intricacy of processes, while raising the efficacy and value of operations.

Figure 1 presents the Industry 4.0 framework and associated technologies at which the core of Industry 4.0 is based on the concept of the three underlying fundamentals which are:

- Digitalization and amalgamation of vertical and horizontal value chains
- Digitalization of offerings
- Digital industry models and client access

In [16], the author notes that the underpinnings to industry 4.0 could be elaborated as follows:

- Digitalization and amalgamation of horizontal & vertical value chains comprise of two features; The initial feature comprises amalgamation of processes vertically across the entire firm and entails all business processes from conceptual

design all the way to delivery of the product or service to the customer or end-user.

- Digitalization of offerings incorporates the extension of current offerings which includes the addition of smart sensors that could be utilized with data analysis tools as well as development of new digitized offerings. The ability to analyze big data could benefit firms to better respond to changing customer demands.
- Digital industry models and client access encompasses enlargement of offering by supporting disruptive digital solutions. Disruptive digital industry models have potential to create new revenue streams by responding with speed to the changing customer demand changes in a dynamic setting.

In [16], the authors argue that big data and data analysis tools are the principal competences of Industry 4.0 and is enabled by technologies such as smart sensors, advanced algorithms, Internet of Things, location technologies, and many other technologies that support the digital revolution.

Figure 1 presents the Industry 4.0 setting in which an argument is advanced that the crucial significance to Industry 4.0 is its ability to communicate with other smart "things" such as the digital capabilities of smart transportation, smart electrical grid, smart supply chain management, and other smart infrastructure. In [18], the authors argue that the linkage between social web and business web is of critical importance and will see further radical transformation in the future and will further reduce the digital divide between business and society at large as technology develops and becomes accessible to society.

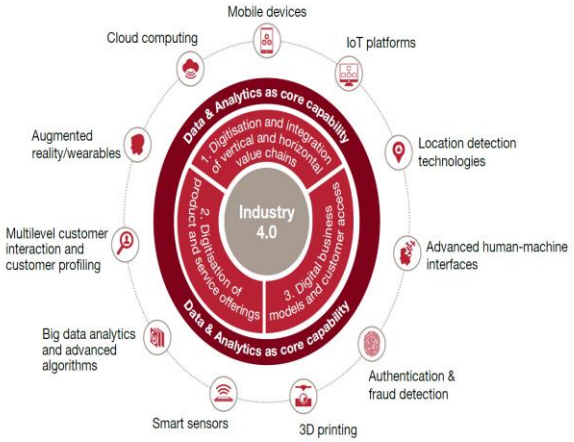

Figure 1: Industry 4.0 framework and contributing digital technologies [16]

In [19], the authors suggests that the important elements that outline the notion of Industry 4.0 are:

- Cyber-physical system (CPS), the term that describes the amalgamation of cyber with physical systems. CPS incorporates devices which can assemble and transmit data through the internet.
- Internet of things (IoT) facilitates the interaction with other systems and between systems and ultimately with the users.
- The ability to assemble data and analyze the data into useful information instantaneously is an important feature of a CPS and enables decision makers to make informed decisions.

In [20], the authors advocates that the concept of Industry 4.0 is underpinned by six design principles that are pertinent to its efficacious implementation in respective industries which are interoperability, virtualization, decentralization, real-time capability, service orientation and modularity depicted in Figure 2.

	Cyber-Physical Systems	Internet of Things	Internet of Services	Smart Factory
Interoperability	X	X	X	X
Virtualization	X	-	-	X
Decentralization	X	-	-	X
Real-Time Capability	-	-	-	X
Service Orientation	-	-	X	-
Modularity	-	-	X	-

Figure 2: Design principle for each of the main 4 Industry 4.0 components [20]

The Fourth Industrial Revolution and its application as espoused by Industry 4.0 offers both challenges and opportunities for the postal sector, the major challenge is that Posts can no longer operate using business models of the past because digitalization of the Post is something that is not optional but mandatory if the Post still must survive another 100 years.

In [21], the authors argue that today, the concept of the internet is often reflected as "given" due to its omnipresent manifestation and quickening effect on the ways in which humanity relates. The world is changing rapidly because of the digital revolution. In [22], the authors argue that one such manifestation of the digital revolution is the IOT (Internet of things) with which digitization is no longer a simulated reality. IOT links several "things" through the internet and allows them to communicate information amongst each other. In [23], the authors propose that the Internet of Things (IoT) is sensor technologies that enable physical objects to gather and transmit data through the Internet in instantaneously. It is one of the latest advances taking hold in many industries and most appropriate for the postal sector due to its possible applications in the postal value chain.

In [24], the authors propose that the IoT architype is envisioned at devising a sophisticated system with the combination sensors and associated technologies with ability to communicate in real-time. Contrarywise, assembling data and preserving the privacy of users, and then taking cognizance of confidentiality and internet security specification in IoT remains a significant concern amongst stakeholders in the IoT space.

In [23], the authors suggests that the current rise of IoT applications is fuelled by a conjunction of issues such as omnipresent connectivity and the diminishing expenditure and enhanced performance of measuring devices (sensors) and analytics. These technology developments relate to expanding consumer requirement for more data on the products and services they purchase. The flow of information is crucial to the "flow of things".

The United States Postal Service has embodied the Internet of Things (IoT) and coined the Internet of Postal Things (IoPT). In [23], the authors articulate a postal standpoint and reason that IoT can be better pronounced as "Things on the Internet" which are

unified webs of distinctively recognized physical "things" embedded with sensors that amass, converse, and act upon a widespread diversity of data such as locality pin-pointing, temperature, and movement. These "smart objects" amass and transmit data that can be scrutinized for improvement of business processes across organizations and for improved solutions to customer demands. Figure 3 depicts the chief elements of the IoT value-chain.

In [23], the authors argue that IoT unwraps new opportunities for various organizations and in particular entities like the postal service which has a geographic reach that surpass many industries. In [25], in the authors propose that the postal service world-wide has a widespread network of over 677,000 post offices, 5.32 million staff and physical network of buildings encompassing 192 countries and asserts that the postal sector performs a significant socio-economic role in society at large.

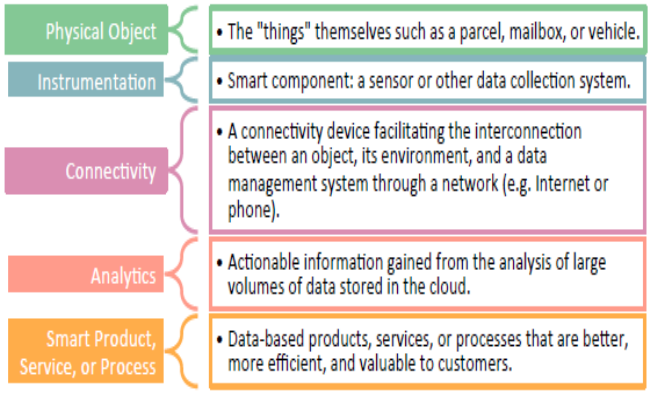

Figure 3: IoT value chain [23]

Posts could significantly profit in implementing Industry 4.0 fundamentals in the quest to adapt to challenges and opportunities presented by the digital era, and could greatly improve service delivery to new market demands and improve their sustainability (both economic, social and environmental). Applications of Industry 4.0 fundamentals can significantly improve sustainability of Posts in Southern Africa.

2.4. Innovation Diffusion Theory

In [26], the authors postulates that the most noticeable and dominant attempt to dissect the dynamics influencing the adoption and diffusion practices was pioneered by [27], however the authors argue that the framework is appropriate for conceptualization of adoption and diffusion from a qualitative point of view as opposed to quantitative prediction of adoption of innovative practices. In [28], the author argues that diffusion is the process by which an invention is conversed through networks over time amongst the participants of a network. In [29], the authors argue that technology adoption is a developed area of research in information systems (IS).

In [30], the authors articulates the difference between innovation and technology which is often confused and argues advance that technology is concerned in resolving real social problems to advance humanity. In [31], the authors argue that innovation on the other hand comprises of the creation of an innovative concepts and development of the concept into new offerings resulting in economic development. In [32], the authors argue that innovation is not merely creativity, research and development, invention, bright ideas or fancy gadgets. In [33], the authors argue that innovation is rather a development of new resources or new resource capacity that are able to create wealth. In [34], the authors argue that innovation is a complex, organization-wide effort, that demands a set of procedures and activities to shape, coordinate, and promote it.

In [28], the authors investigates drivers that define the speed of acceptance (adoption) of innovations and argues that the following factors regulate the degree of adoption. (a) Apparent characteristic of innovation affected by considerations such as relativity of the advantage to adopt, compatibility of adoption to current systems, complexity of the innovation, trialability of the innovation, and observability of the results. (b) Innovation choice, which is driven by issues such as is the innovation optional or mandatory (c) Type of societal structures including a component such as the degree of linkages of the societal structures; and (d) The effectiveness and efficiency of transformation (change) champions in advocating transformational change.

In [11], the authors suggests that each invention has distinctive attributes that affect the dispersion (diffusion) process. These attributes can be broken-down into five elements:

(a) Relative advantage is the extent to which an invention is understood as being superior to the concept it succeeds, typically stated as cost-effectiveness, societal stature, or other advantages.
(b) Compatibility as recognized by participants in society is constructively related to the level of acceptance (adoption) and influences the way customers act towards an invention.
(c) Complexity is the extent to which an invention is understood as comparatively complicated to comprehend and utilize.
(d) Trialability is the extent to which an invention may be tested on a restricted basis. The trialability of an invention is certainly related to the pace of acceptance (adoption).
(e) Observability is the extent to which outcomes are observable to the user and to others.

2.5. Technology Adoption Theory

In [35], the authors argues that Theory of Reasoned Action (TRA) is the early notion that attempted to explain user adoption of technology. TRA describes user behaviour from a social point, and with a specific aim of pin-pointing the causes of conscious behaviour. In [36], the authors propose that the model (Technology Acceptance Model- TAM) was developed from TRA as its basis but further refined.

In [37], the authors argues that the basis of TRA is that behaviour is predicted by intention (I) and further highlights that intentions are conjointly driven by two factors (a) Attitude (A) towards the act which is a function of attitudes about effects of this conduct and (b) subjective norms (SN) defined as a person's viewpoint of whether stakeholders key to the person consider the actions should be implemented. Attitude towards the behaviour is defined as the individual's negative or positive outlook about executing the behaviour.

In [38], the authors propose that TRA contends that views influence mindsets, which lead to intent and as a result engender behaviour. The TRA is graphically illustrated in Figure 4.

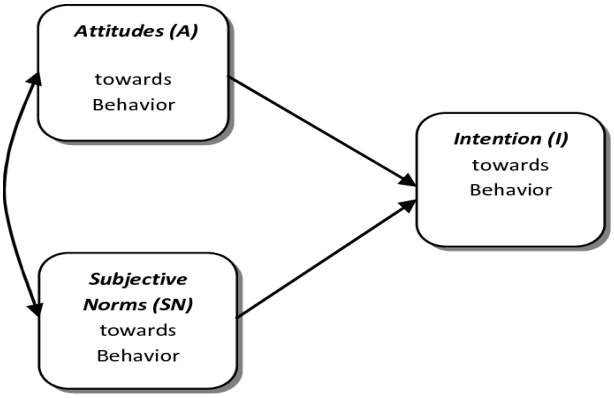

Figure 4: Theory of reasonable action. Source [37].

In [39], the authors state that consumer rationale to accept and adopt a technology could be explained by perceived usefulness (PU), perceived ease of use (PEU) and attitude towards the system. In [39], the authors hypothesize that attitude of a user towards the system was the core factor to determine if the user will accept or reject the innovation, and that attitude is directly influenced by (a) Perceived Usefulness (PU) and (b) Perceived Ease of Use (PEU); and concludes that apparent ease of use unswervingly influence perceived usefulness.

In [38], in the authors argue the concepts in the earliest TAM (see Figure 5) as follows: Perceived Usefulness (PU), Perceived Ease Of Use (PEOU), Attitude, and Behavioural Intention to Use. Among the constructs, PU and PEOU establish a user's confidence on a technology and consequently predict his or her stance on the technology, which in turn foresees its approval.

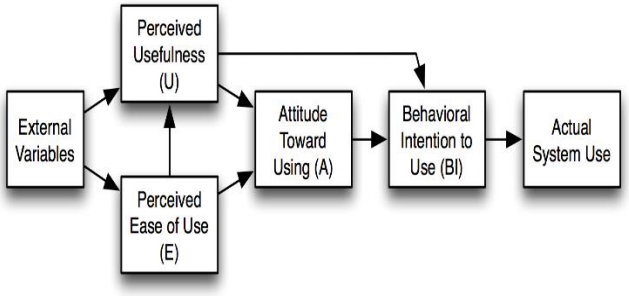

Figure 5: Technology Adoption Model. Source [38]

In [40], the authors maintains that while the TRA was intended to illuminate essentially any human behaviour, the TAM on the other hand was intended to offer an clarification of the factors of computer acceptance throughout a comprehensive range of end-user computing technologies and user populations. In [37], the authors subsequently contends that according to the TAM, actual system usage is directly defined by behavioural intention (BI) to use. BI is in turn swayed by the user's mindset towards utilizing the system and perceived usefulness. Attitude is propelled by perceived usefulness (PU) and perceived ease of use (PEOU) of the system. Both PU and PEOU are influenced by external variables, such as individual variations, situational constrictions, organizational traits, and system attributes.

As the TAM progressed past its initial positioning, several researchers established shortcomings in the model which required to be tackled. The outcome of research that was conducted by several researchers ensued in adjustments to TAM. In [37], the authors suggest that the adjustments entailed the establishment of additional variables and concepts resulting in TAM2 as depicted in Figure 6.

In [37], the authors argue that the major additions to the TAM that were introduced by TAM2 were the inclusion of societal influence activities (subjective norm, voluntariness, and image) and mental method procedures (job relevance, output quality and results demonstrability).

TAM2 theorizes that users' mental assessment of the match between considerable goals at work and the subsequent effects of executing tasks using the system provides a basis for establishing views concerning the usefulness of the system. The results of the research by uncovered that TAM 2 performed well in both voluntary and obligatory environments.

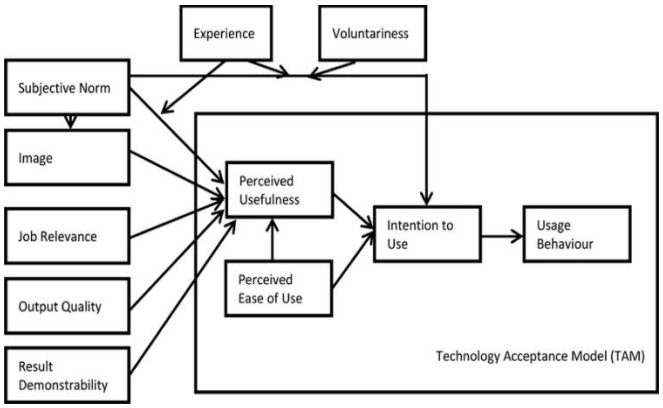

Figure 6: Technology Adoption Model 2. Source [42].

In [37], the authors argues that the succeeding foremost addition to TAM was the Unified Theory of Acceptance and Use of Technology (UTAUT), the author further proposes UTAUT was framed, with four fundamental determining factor of intention and usage and up to four moderators of crucial relations. The theory proposed that four important concepts perform a significant part as direct factors of user acceptance and usage behaviour: (a) performance expectancy (b) effort expectancy (c) social influence and (d) facilitating conditions. The UTAUT is presented in Figure 7.

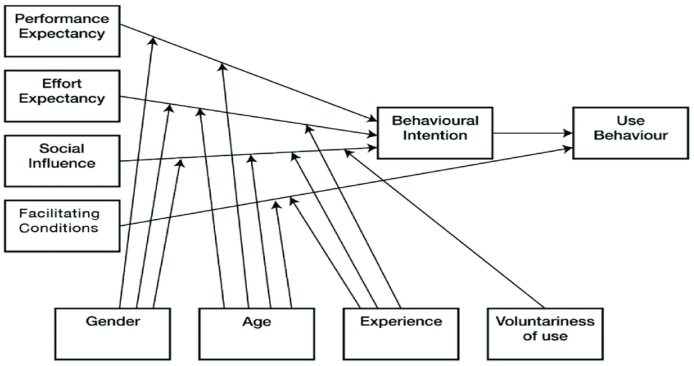

Figure 7: Unified Theory of Acceptance and Use of Technology (UTAUT. Source [43].

In [37], the authors propose that UTAUT advocates that facilitating conditions would unswervingly impact usage, while the remaining three concepts would influence Behavioural Intention (BI). In [44] the authors argue that the model describes facilitating conditions as the extent to which a person deems that organizational and technical infrastructure exists to support the utilization of a system they are accepting (adopting). In [45], the authors argue that the UTAUT further extended the concepts in the earliest TAM through the recognition of the vital role of endeavour in performing the new task and the role support structures determines adoption in organizations.

In [46], the authors argues that TOE (Technology-Organization-Environment) framework entails three categories of settings that may influence technological innovation adoption and implementation process. TOE is premised on the three context which are technological, organizational, and environmental. In [47], as represented in Figure 8, the authors explains that technological setting defines the internal and external technologies suitable to the organization, while organizational setting denotes descriptive actions about the organizational scope, size and structure; finally, environmental setting is the arena in which an organization conducts its business.

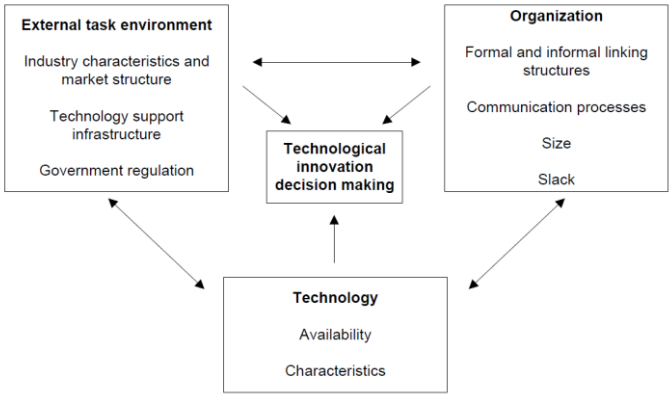

Figure 8: Technology, organization, and environment framework

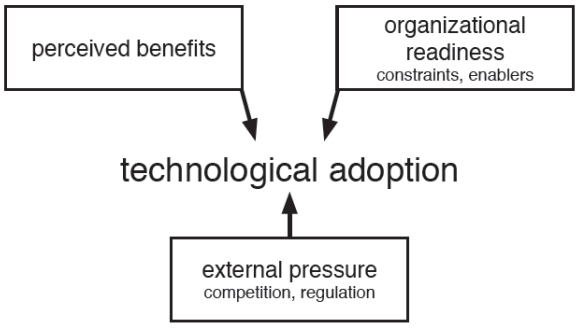

Figure 9: BOE Model [48]

In [48], the authors postulates that the TOE model defines the dynamics for technological adoption, focusing on the external stresses (e.g. market forces and governmental regulatory requirements), organizational structures, and technological availability; in addition the BOE model was originally developed to understand the adoption of EDI (electronic data interchange) technology, but has since been used as a general technology adoption model. The BOE model comprises three factors: external pressure, organizational readiness, and perceived benefits.

In [48], the authors advance that by distinction, the BOE model as illustrated in Figure 9 (Benefits, Organizational Readiness and External Pressures) integrates the organization and technology context of TOE into organizational readiness and augments a perceived benefit aspect for viewing at adoption of technology.

In [26], the authors argue that the Adoption and Diffusion Outcome Prediction Tool (ADOPT) was developed as a tool to encourage application in project planning and implementation of sound insight of the social and economic factors affecting acceptance (adoption) of agricultural innovations. In [49], the authors proposes that ADOPT focuses on factors that have demonstrated to impact the pace and/or highest point of adoption within a population. These are (a) attributes of the innovation, (b) attributes of the population, (c) tangible relative advantage of employing the innovation, and (d) learning of the actual relative advantage of the technology. In [26] the authors proposes that the variables of the theoretical context can be divided into two main categories: (a) those that relate to traits of the target population, and (b) those that relate to traits of the practice. These elements are presented in Figure 10.

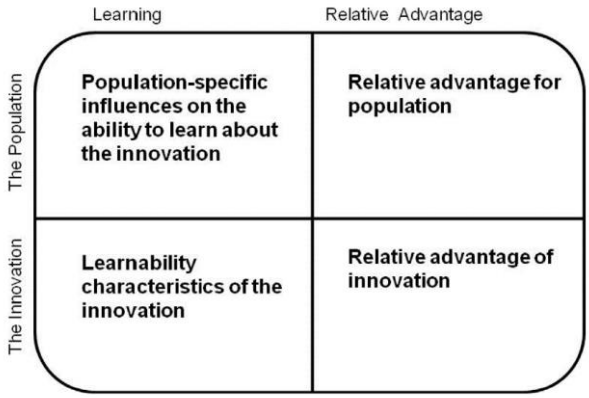

Figure 10: Conceptual characterization of factors included in ADOPT

2.6. Capability Maturity Models

In [50], the authors states that the original Capability Maturity Model (CMM) was developed in the software engineering space to support advances in the dependability of software development organizations, that is, in their aptitude to deliver software within time, performance, cost and quality. More specifically, it was "intended to assist developers to choose process-improvement strategies by defining their existing process maturity and finding the most critical issues to improving their software quality and process".

In [51], the authors describes the five maturity levels and further emphasize the basic process changes made at each level:

- Initial: The process is described as ad hoc, and sporadically even anarchic. Limited processes are defined, and accomplishment depends on individual effort.
- Repeatable: Fundamental business processes are established to track expenditure, plans, and functionality.

- Defined: The business processes are documented, standardized, and integrated.
- Managed: Detailed measures of the business processes are collected. Business processes are quantitatively understood and controlled.
- Optimizing: Continuous process improvement is enabled by quantifiable feedback from the business process.

The CMM provides a framework for shaping these incremental steps into five maturity levels that lie down consecutive grounds for continuous process improvement. These five maturity levels characterize an ordinal scale for evaluating the maturity of an organization's processes and for appraising its process capability. The levels also help an organization highlight its improvement endeavours. The steps above are graphically presented in Figure 11.

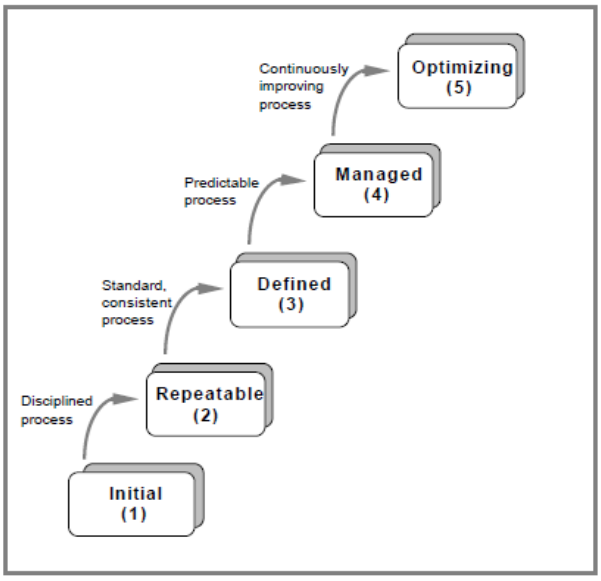

Figure 11: The five levels of software maturity [51]

In [52], the authors argue that capability maturity models are used in three ways; (a) Descriptive use which focuses on (1) To assess the 'as-is' state of specific organizational capabilities (2) As an analytical diagnostic tool (3) To communicate maturity levels to internal and external stakeholders (b) Prescriptive use which focus on (1) To ascertain desired maturity level and receive guidance on how to continuously improve from current to desired level (2) To follow specific and detailed sequences of action (3) Comparative use which emphasizes on comparing the performance of the specific organisation through internal or external benchmarking (best practices).

In [53], the authors affirms that one of the barriers to industry's wider headway in digital transformation is the absence of a vivid industry focused blueprint. The report proposes that the Digital Maturity Model presented in Figure 12 is a valuable instrument to offer guidelines for a vivid pathway throughout the transformation journey.

The five core dimensions underpinning the model are:

- Customer, this facet is focused on offering an understanding where consumers perceive the organization as their digital collaborator utilizing their desired networks of interaction to control their connected future on and offline
- Strategy, this facet stresses on how organizations transform or operate to enhance its competitive advantage through digital projects; it is entrenched within the whole organizational strategy
- Technology, this facet emphasizes the success of digital strategy by enabling the creation, processing, storage, securing and transmission of data to meet the needs of customers effectively and efficiently.
- Operations, this facet is premised on executing and evolving processes and tasks by leveraging on digital technologies to drive strategic management and enhance business efficiency and effectiveness
- Organization and culture, this facet focuses on identifying and cultivating an organizational culture with governance and talent management processes to boost advancement along the digital maturity curve, and the ability to realize expansion and invention (innovation) goals.

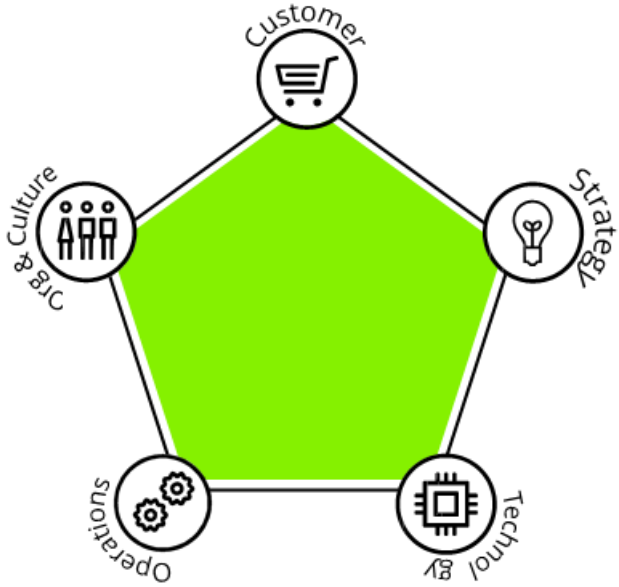

Figure 12: Deloitte Digital Maturity Model [53]

Figure 13 crystalizes the sub-dimensions that are associated with the five core dimensions presented in Figure 12. The sub-dimensions elucidate and unpacks each of the five core dimensions that are critical to digital transformation, these dynamics are such as customer engagement, customer insight and behaviour, brand management, finance & investment, connected things, data & analytics, real-time insights & analytics, agile change management, organizational culture, leadership & governance, organizational design & talent management, workforce enablement, automated resource management, stakeholder management, ecosystem management, strategic management, customer trust & perception, market & customer, network, security technology architecture and innovation management are key towards a successful digital transformation journey.

In [52], the authors propose a Digital Maturity Model which consists of four stages. The stages proposed in their model are (a) Initiate (b) Competent (c) Purposeful and lastly (d)

Transformative. The key attributes of businesses related to each of these maturity stages are presented in Figure 14.

Customer	Strategy	Technology	Operations	Organisation & Culture
Customer Engagement	Brand Management	Applications	Agile Change Management	Culture
Customer Experience	Ecosystem Management	Connected Things	Automated Resource Management	Leadership and Governance
Customer Insights & Behaviour	Finance & Investment	Data & Analytics	Integrated Service Management	Organizational Design & Talent Management
Customer Trust & Perception	Market & Customer	Delivery Governance	Real-time Insights & Analytics	Workforce Enablement
	Portfolio Ideation & Innovation	Network	Smart and Adaptive Process Management	
	Stakeholder Management	Security	Standards & Governance Automation	
	Strategic Management	Technology Architecture		

Figure 13: The 5 core dimensions divided into 28 sub-dimensions [53]

In [54], the authors suggests that the use of maturity models to the Industry 4.0 phenomenon could potentially aid corporations to assimilate this practice into their ethos and argue that the Industry 4.0 vision portrays a completely new approach to business process and a completely new business model. They propose a three-step systematic process to guide organizations in their respective Industry 4.0 journey to find footing and determine their vision which is precursor for strategy.

In [54], the authors proposes that the three-stage process comprise of (a) Envision 4.0 which relates to defining a tailor-made Industry 4.0 vision and it requires companies to develop their comprehension of the generic Industry 4.0 concepts with company-specific proficiencies and resources (b) Enable 4.0 starts with the significant Industry 4.0 vision developed in the previous phase, and based on this vision, the organization defines the digital portfolio and proficiencies required to provide support to the new products or services identified. (c) The enact phase is characterized by a well-timed, directed and multi viewpoint plan of the overall strategy towards the Industry 4.0 vision that fosters the strategic setting for tangible measures and outcomes.

In [54], the authors further argue that in order to employ maturity models to execute the three-staged process described earlier in the context of Industry 4.0, the maturity gauges (scales) for the three-stage model are described as follows: (a) Level 1 represents "initial" level where there is no industry 4.0 vision in place, (b) Level 2 represents "managed" level whereby a Roadmap of industry 4.0 strategy is in place, (c) Level 3 represents "defined" level whereby customer sections (segments), value intention (proposition), and significant (key) resources and competencies are clearly defined; (d) Level 4 which represents "transform" level whereby strategic imperatives are transformed into tangible projects, and lastly (e) Level 5 which represents "Detailed Business Model" level whereby the business model is completely transmuted in line with Industry 4.0 objectives.

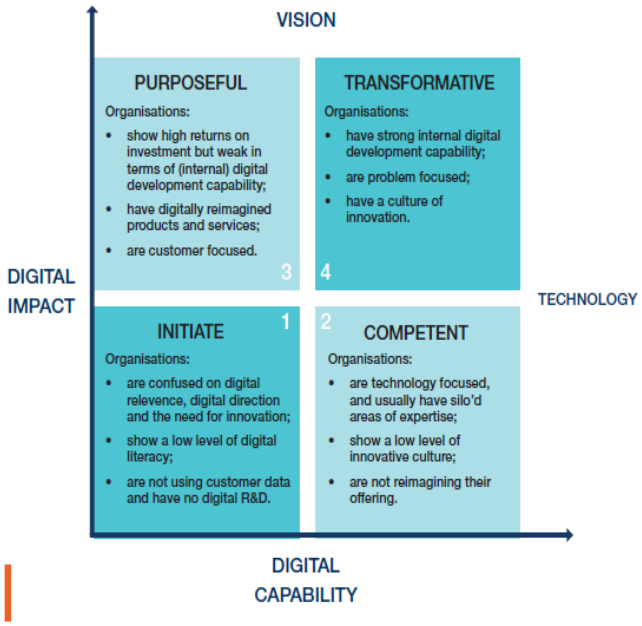

Figure 14: Stages of Digital Maturity and Key Attributes of Businesses in Each Maturity Levels [52]

2.7. Barriers towards movement to digital Post

In [15], the authors articulates the top five barriers (obstacles) towards movement into digital Posts by Region and for purposes of this study only the top performers (Industrialized countries) and Africa will be considered. These barriers are tabled in Table 3.

Table 3: Barriers for digital adoption and diffusion in the postal sector [15]

Geographic area	**Barriers**
Globally	Resource constraints
	Transition towards a digital culture
	Limitations of IT infrastructure
	Lack of adequate inhouse expertise required for development of digital services
	On-time custom clearance capability and capacity
Industrialized countries	The time taken for the corporation to shift in the direction of a digital culture
	Slow overall consumer embracing of digital postal services
Africa	Limited resources
	Lack of IT infrastructure
	Poor digital culture
	Lack the internal resources to develop digital services
	Slow overall consumer embracing of digital postal services

Clearly, Africa is faced with a plethora of challenges as depicted in Table 3, and Southern Africa as a Region in Africa suffers from the same challenges. In [8], the authors hypothesises that inadequate internet connectivity, inadequate capital outlay and

or recapitalization of the network infrastructure, meagre excellence of service, inadequate interoperability and connectivity among the business value chain and vagueness in postal sector definition in Southern Africa are proposed as foremost motives for the low advancement of the Region in embracing technologies associated with the digital revolution.

In [15], the authors affirms that the best ranking designated operator when it comes to digital readiness achieves a normalized score of 1, while the lowest possible performer obtains a normalized minimum score of 0. All normalized scores can be understood as the gap of any given designated operator with respect to the best (score 1), the midway (score above 0.5) or the worst (zero score) global performer. Table 4 represents the postal digital readiness of the industrialized countries with Switzerland leading with a full score of 1 while Table 5 portrays Southern Africa as a region and South Africa leads with a score of 0.46 which is just below the intermediate score of 0.5 while the worst performing countries are Madagascar and Democratic Republic of Congo which are both at 0.05. The distance between the worst performer and the best performer stands at a mammoth gap of 0.95. Clearly Southern Africa is faced with enormous challenges to realize a digital Post.

Table 4: Digital readiness score of Industrialized countries [15]

Country	Normalized score 2019
France	0.81
Germany	0.81
Japan	-
Netherlands	0.62
Switzerland	1.00

Table 5: Digital readiness score of Southern Africa countries [15]

Country	Normalized score 2019
Angola	-
Botswana	0.32
Comoros	0.14
Democratic Republic of Congo	0.05
Eswatini	-
Lesotho	0.19
Madagascar	0.05
Malawi	0.08
Mauritius	-
Mozambique	0.11
Namibia	0.27
Seychelles	-
South Africa	0.46
Tanzania (Republic)	0.22
Zambia	-
Zimbabwe	0.14

The literature has pointed out that adoption of technology of organizations in general or digitalization (Adoption of digital technologies) of the Post is a complex non-linear phenomenon with a variety of drivers and barriers. Adoption and diffusion barriers and drivers reveal a systemic character, which demands an all-inclusive approach to managing the complex nature of adoption and diffusion barriers and drivers that involve exploration of interactions between adoption and diffusion barriers and drivers as well as management of the casual relationship between the drivers and barriers of adoption and diffusion of technology/digitalization.

2.8. From reductionist to system thinking approach

In [55], the authors explains that reductionism is understood as the conventional means of tackling problem solving and is widespread throughout numerous fields. Reductionism also goes under many names including 'stepwise enhancement', 'disaggregation' and merely 'breaking problem into sub-problems'. Reductionism inclines to refer to comprehension instead of problem-solving but the latter seems more appropriate in this case. In [56], the authors argue that reductionism as the opposite of holism and systems thinking agrees with the view that all objects or systems are breakable to lower levels in the hierarchy of their composition.

In [57], the authors contends that in accordance with reductionist thinking "The whole can be broken down into its parts and put back together from its parts. Parts are related through a simple cause-effect relationship; Thus, its defining characteristics exist in its parts." However, there are limitations to a reductionist thinking approach because systems most often defy the reductionist analysis because by focusing on the system's parts, researchers miss the whole, which frequently took on a form that was not distinguishable from the reconstructed parts. This view can be interpreted that it assumes that for a system to perform effectively and efficiently, its components (parts) should perform effectively and efficiently.

Conversely, systems are complex and as result the interaction of the components (parts) in a dynamic setting invariably affect performance of the entire (whole) system. Therefore, effective, and efficient technology adoption must focus on the dynamic setting (interaction) of drivers and barriers rather than on their separate actions. In [58], the authors argue that system is a unified set of components that are logically organized in a way that achieves a particular objective. In [59], the authors proposes that a system is a sequence of intermingling components organised to achieve stated goals.

In [60], the authors suggests that there are key dissimilarities in behaviours of reductionist thinkers when contrasted with systems thinkers and the crux of the differences is that while a reductionist approach simplifies the problem to its smallest essence to enable resolution of the problem through analytical methods; a system thinking approach on the other hand seek to understand the bigger picture and how elements of the problem interact in a dynamic setting. Because organizations are complex due to many interacting dynamics and forces, it is probable to propose that postal sector in Southern Africa lags in adoption of innovative technologies due to its reductionist thinking approach rather than a system thinking approach.

In [61], the authors propose that an event-oriented viewpoint is logical, action-oriented, irresistibly uncomplicated and frequently narrow-minded. Figure 15 portrays this thinking as a concept. In [62], the authors further argues that this event-oriented mind-set

signifies a conviction that challenges are irregular, emanating from overwhelming events in the outside world and that life is unpredictable. He argues that this mind-set has a conviction that events pop out from nowhere or at least there is no time to worry about their causes, what is important he argues, is to fix the problem as soon as possible. The typical thinking is characterized by linearity whereby problems are events and solutions as fixes.

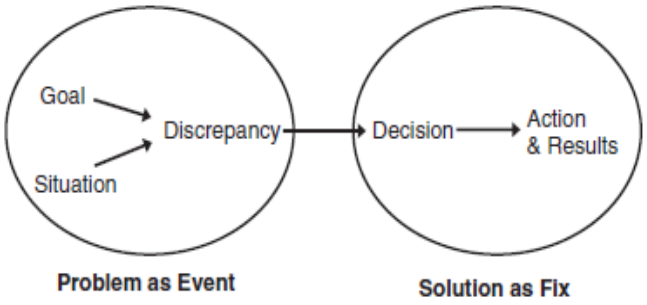

Figure 15: Event oriented worldview [62]

In [62], the author contends that feedback systems thinking is paradigm shift, a new approach of understanding the world, and a remedy to narrow thinking; and further advances that problems and solutions are viewed as intertwined as depicted in Figure 16.

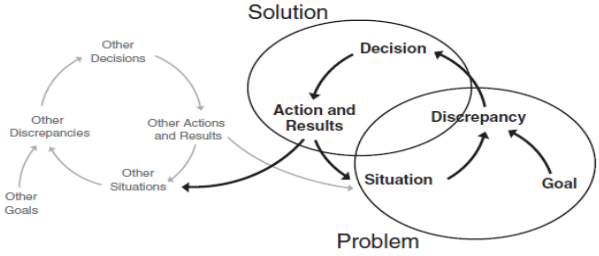

Figure 16: A shift of mind: A feedback perspective [62]

In [61], the authors contends that the change is the ultimate constant, and that change confronts conventional traditions, methods, and values. Important, most of the changes we battle to grasp occur as after-effects, deliberate, and not deliberate. In many cases, well-intentioned exertions to resolve unrelenting problems often lead to policy resistance, where policies are overdue, weakened, or thrashed by the unanticipated reactions of other people or of nature. This is a frequent challenge in the postal sector globally, in Africa and for purposes of this study in Southern Africa where for instance the digital age has brought unintentional consequences of the archaic postal business models that are putting in peril the very survival of postal operators.

In [63], the authors affirm that a system thinking approach is different from a reductionist approach, the reductionist approach focuses on analysis which is about dissection of complexity into manageable components or an event-oriented approach which has the conviction that problems emanate from nowhere. This approach clearly fits into the linear and mechanistic worldview, where the world and problems are fragmented into parts. Diametrically opposed to a reductionist approach of "analysis" is systems thinking approach which relies on synthesis rather than analysis. Fusion (synthesis) relates to comprehending the whole and the fragments (parts) simultaneously, alongside the relationships and links that constitutes the dynamic setting of the whole.

In [57], the authors supports this notion and argues that the whole emanates because of the interfaces between its components or fragments and proposes that fragments are related through intricate multiple effects. Thus, its defining attributes do not live in its fragments but in the whole. In [60] the authors suggest that systems thinking means the aptitude to distinguish and analyse the inter-connections within and between systems.

In [64], the authors contend that system thinking is a strong approach to deal with the system of innovation. In [64], the authors defines systems thinking as a field for observing aggregates and a context for spotting interrelatedness rather than things, for spotting patterns of change instead of stagnant snapshots. In [65], the authors define system thinking as the capability to epitomize and measure dynamic intricacy (e.g., behaviour that develops from the interface of a system's agents over a period), of systems.

In [66], the authors maintain that systems thinking is a set of harmonious diagnostic competencies used to enhance the ability to discover and comprehend systems, forecasting their conducts, and developing adjustments to them to create the anticipated effects. These competencies act as a system. In [63], the authors suggest that systems thinking is a process of examining and improving mental models and its core is based on four fundamental concepts (a) connectedness (b) Synthesis (c) Feedback loops, and lastly (d) Causality

In [60], the authors suggest that Systems Thinking requires recognition that systems designed by humans, recurrent occurrences or relations originate from systemic constructs which emanate from mental models. In [60], authors further propose that the Iceberg Model (Depicted in Figure 17), is a fundamental aspect of systems thinking. The Iceberg Model contends that actions (events) and patterns (which can be observed) are triggered by universal (systemic) structures and mental models, which are usually not observable.

In [60], the authors further propose that systemic constructs as in structures are the structural pyramid; societal order; interrelatedness; instructions and techniques; establishments and endorsement levels; process flows and methods; enticements (incentive programme), reward (compensation), aims, and system of measurement (metrics); manners (attitudes); responses and the incentives and qualms that cause them; organizational culture; feedbacks and interruptions (delays) in a dynamic setting; and fundamental forces that occur in organizations. Behaviours develop from these complex interactions, which exist because of mental models.

In [67], the authors argue that system dynamics, a subset of systems thinking signifies variations in a complicated system, and is beneficial for mimicking the stock-flow-feedback processes that usually trigger the behaviour of intricate systems. In [68] the authors argues that the modelling approach depend on the following crucial elements. "Stocks" exemplify the rise of something; "flows" exemplify the rate of flow into or out of a stock.

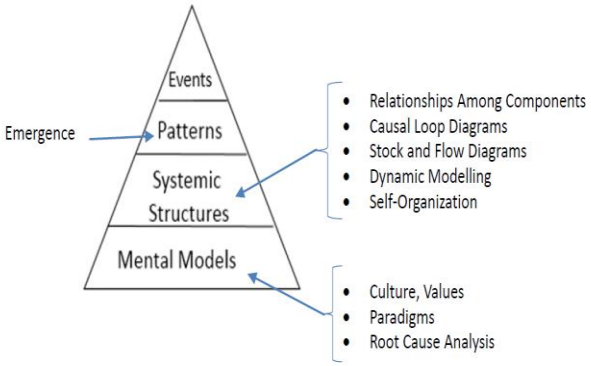

Figure 17: Integrated Model of Systems Thinking [60]

Stocks and flows, and variables characterises a system of linked non-linear differential equations, which can be modelled over a period to ascertain how stocks shift over time. In [69] the authors argues that one benefit of application of system dynamics approach over more conventional models is the addition of feedback consequences. Feedbacks ensure that a model's output is precise and uncovers intricacy that could be unobserved in other modelling approaches. Therefore, decision-makers can more definitely distinguish the interrelatedness of the model in a dynamic environment.

In [69], the authors argue that learning is a response (feedback) process. In [67], the author argues that as decisions are made these action modify the real world, and information feedback about the real world is received; and applying new insights, interpretation of the world is adjusted and becomes nearer to the goals.

This observation is principally valuable in the context of postal sector in Southern Africa which is overwhelmed by multiple stakeholders with multiple interests including policy directions internationally (Universal Postal Union), continentally (Pan African Postal Union), regionally (Southern African Postal Operators Association as implementing Agency of Southern Africa Development Community) and lastly nationally where individual postal operators operate. In this research the enablers and impediments that play in the adoption and diffusion of technology are identified including feedback loops that associate the several factors involved in the adoption and diffusion of technology process.

3. Methodology

In [70], the authors advances that research design can be classified in three categories which are (a) Exploratory research studies; (b) Descriptive and diagnostic research studies, and (c) Hypothesis-testing research studies. This study adopted the qualitative research design approach which is exploratory in nature.

In [71], the authors suggest that the idea behind qualitative research is to tenaciously hand-pick partakers or locations (or records or graphic materials) that enables the researchers to comprehend the conundrum (problem) and the research question. This fundamental feature of qualitative research design resulted in the in collection of specific secondary data that provides insight to the researcher to comprehend the phenomenon under study.

In [72], the author argues there are diverse forms of review methodologies; systematic, semi-systematic and integrative approaches and argues that each approach is appropriate depending on the purpose of analysis. This study adopted an integrative approach to literature reviews. An integrative approach is characterized by tenets which are articulated in Table 6.

Table 6: Tenets of an integrative approach to literature reviews

Tenet	Integrative Approach
Typical rationale	Critique and integrate
Research questions	Narrow or broad
Exploration approach	Usually not methodical
Sample attributes	Peer reviewed articles
Evaluation	Qualitative
Examples of contribution	Classification (Theoretical models or frameworks)

The data was collected from archival data from literature and industry reports, this data focused on a variety of drivers and barriers common in adoption of technology in organizations as well as characteristics of factors that drive or impede technology adoption in organizations and as well as in the postal sector.

This exploratory, qualitative research design using integrative approach was aimed at answering at great length the first research question which is, "Can a generic framework for technology and digital transformation adoption be developed for Posts in Southern Africa?

In [71], the author avows that "The data collection steps include setting the boundaries for the study, collecting information through unstructured or semi structured observations and interviews, documents, and visual materials, as well as establishing the protocol for recording information". In [71], the author further argues that the objective of qualitative research is to tenaciously choose members or sites (or documents or visual material) that will assist the investigator to fully grasp the challenge and the research question. The study purposefully selected relevant literature from Universal Postal Union, the different postal operators, specific literature that deals with technology adoption, ICT adoption and digital transformation with the view of comprehending the problem and the associated research question.

4. Discussion and findings

The literature review accentuates the significance of not only dealing with barriers and drivers to adoption of technology and Industry 4.0 technologies but highlights the fact that these barriers and drivers are not linear but intermingles with each other in a dynamic setting. Literature divulges that adoption and technology diffusion processes are very complex and entails multiple interdependent drivers and barriers which are very dynamic involving numerous feedback processes that demonstrate nonlinearity characteristics.

Literature details the postal sector landscape, and reflects on the digital panorama globally, continentally and in the region

(Southern Africa) and points to serious challenges faced by developing and less developed countries from a digital ecosystem point of view. These challenges are reflected in several barriers that need to be overcome and drivers that needs to be leveraged on in a dynamic setting.

Literature points to vast variances in digital adoption readiness between developed countries and developing countries, with specific reference to Southern Africa as depicted in Table 4 and Table 5 respectively and graphically depicted Figure 18 and Figure 19, respectively.

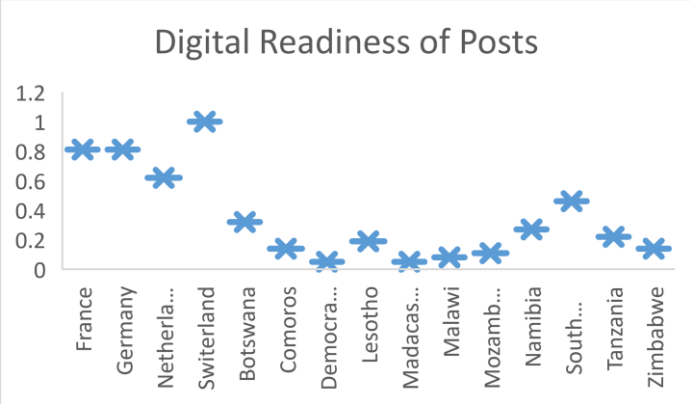

Figure 18: Digital readiness score of Posts

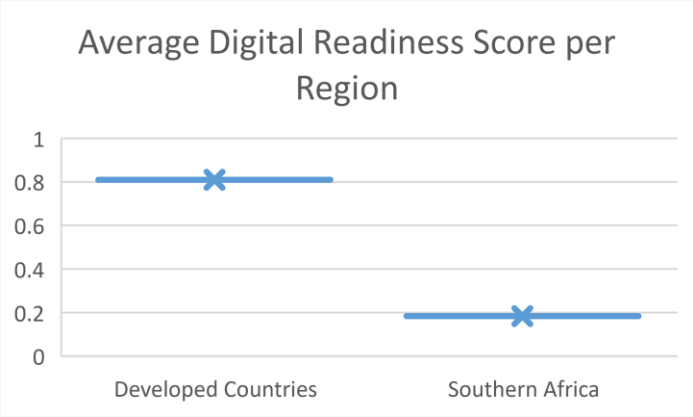

Figure 19: Average Digital readiness score per Region

The digital readiness score illustrates that Switzerland scores 100% and this is further supported by the performance of Switzerland on the Integrated Index on Postal Development in which it scores 100%. Switzerland is followed by both Germany and France scoring 81% and The Netherlands scoring 62%. The average of the four leading countries stands at 81%.

Southern Africa ranges from maximum of 46% which represent the performance of South Africa to a minimum of 5%, the variation within Southern Africa cumulatively results in an average of 18%. The performance of Southern Africa should be seen in the context of a plethora of challenges facing the continent and the Southern Africa in the context of this study. These challenges require a concerted effort by Posts and respective national governments and regional bodies to address the legacy of colonialism but also the problems that occurred post-independence that continue to halt prospects of development.

Literature also points to Technology Acceptance Models TAM, TAM2, TRA, UTAUT, TOE, BOE, and ADOPT are among the most popular which highlight factors related to system users; however, there is a literature knowledge gap in these models handling other stakeholders who are directly or indirectly affected by the adoption process and the interaction of drivers and barriers in a dynamic setting. These technology acceptance models lack the important aspect of feedback systems which are at the core of systems thinking approach.

TRA, TAM, TAM2, and UTAUT are significant pioneers in the technology adoption space by elucidating the aspects that perform a prominent role in the process of technology adoption. The evolution from TRA to UTAUT is exemplified in Figure 20.

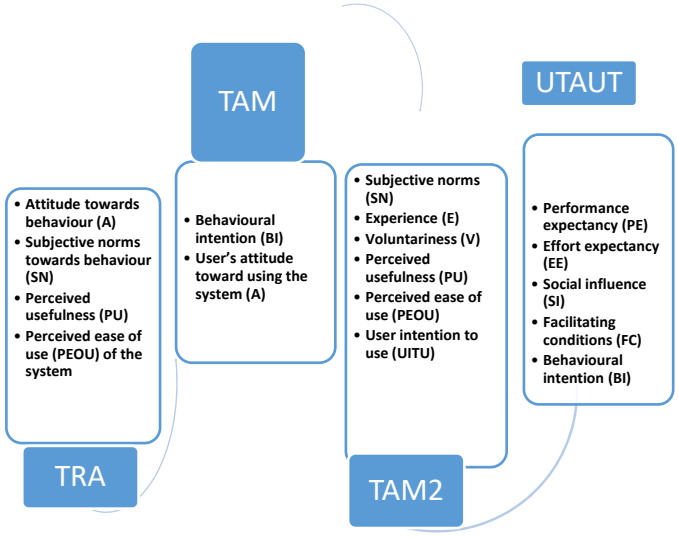

Figure 20: Evolution of technology adoption models

The factors elucidated in Figure 20 directly determine the user adoptability potential of technology, however they are applicable to individuals rather than organizations. The BOE and TOE attempts to address the limitations of TRA, TAM, TAM2 and UTAUT which are only applicable to individual's adoption of technology through articulation of constructs that are applicable to organization-wide adoption of technology. The constructs of BOE (Perceived Benefits, Organization Readiness and External Pressures) are depicted in Figure 21 and TOE constructs (Technology, Organization and External Environment) are depicted in Figure 22.

These factors associated with both TOE and BOE are an attempt to integrate organization-wide factors and external factors that are at play in the context of organization-wide adoption of technology adoption as opposed to the traditional technology adoption models in the form of TRA, TAM, TAM2 and UTAUT which are relevant to individual adoption of technology or new innovation. While TOE and BOE attempts to integrate factors associated with organization-wide adoption of technology and new innovation, they both lacked "causality" which is at play in a dynamic setting resulting in new emergence of patterns and mental models due to interacting factors that inhibit or enable adoption

and diffusion of technology in a dynamic setting which result in even greater complexity. BOE and TOE are therefore not sufficient to explain nor explore the complex nature of interacting factors in the dynamic setting of the postal sector in Southern Africa.

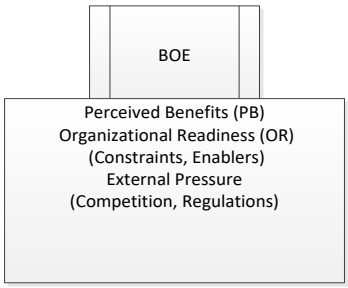

Figure 21: Constructs of the BOE model

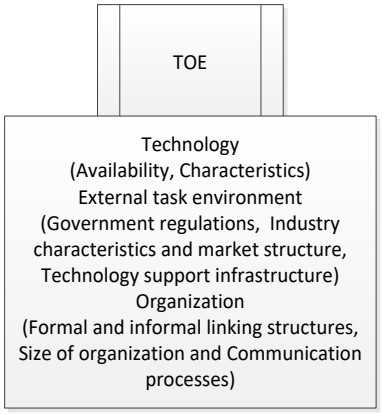

Figure 22: Constructs of the TOE model

The purpose of this research is to explore how best to close the limitations of the "linear" technology adoption models through the application of a holistic or systems thinking approach to identify systemic issues in technology adoption within Southern African context by considering the complete stakeholder system a "system of stakeholders" with their corresponding interests giving rise to various dynamic settings that could impede or enable technology adoption and digital transformation in the postal sector in Southern Africa.

The System Thinking approach which inherently integrates feedback systems is suitable for complex phenomenon like adoption of technology and digital transformation in the postal sector which is underpinned by multiple stakeholders with often opposing interests. A systems approach in comparison to traditional "linear" technology adoption models (TRA, TAM, TAM 2, UTUAT, TOE, BOE and ADOPT) was found to be the most appropriate and suitable for managing the interaction of barriers and drivers that are at play in a dynamic setting in the context of the postal sector in Southern Africa.

The literature suggests that Industry 4.0 is centred on digital transformation of business models. At its core is digitalization and integration of vertical and horizontal value chains, digitalization of offerings (products and services) and digitalization of business models and customer access. Of which, data and data analytics are core competencies interacting with digital technologies such as wearables and augmented reality, IoT platforms, mobile devices, big data and advanced algorithms, location detection technologies, 3D printing and other related Industry 4.0 technologies.

The critical review of literature explicates that the foundation to digital transformation is a systematic approach that is directed from a digital vision envisaged by the organization, the model proposed in [52] where the authors argues that the transformation requires organizations to move from level 1 (Initiate), to level 2 (Competent) to level 3 (Purposeful) and finally to level 4 (Transformative). The levels start from chaotic and no ambition or culture for innovation (level 1) to structured, systematic and innovative (level 4).

In [54], the authors articulates the three-stage model of envisioning of Industry 4.0, enablement of Industry 4.0 and lastly enacting of Industry 4.0. The three-staged model proposes 5 levels of digital maturity ranging from the lowest level (Level 1) in which the Industry 4.0 vision is not defined to the highest level (Level 5) in which there is complete business model transformation. The insights and inferences that could be drawn that without a solid vision and an underpinning strategy which acts as a roadmap for organizations with demonstrable projects; the adoption of technological innovation and digital transformation is set to fail.

In [53], the authors proposes the five dimensions that underpins digital transformation journey and are (a) Customers, (b) Strategy, (c) Technology, (d) Operations and (e) Organization and culture are key towards digital transformation journey that is structured to ensure success.

The proposed technology and digital adoption conceptual framework as presented in Figure 23 espouses the insights drawn from the critical review of selected literature.

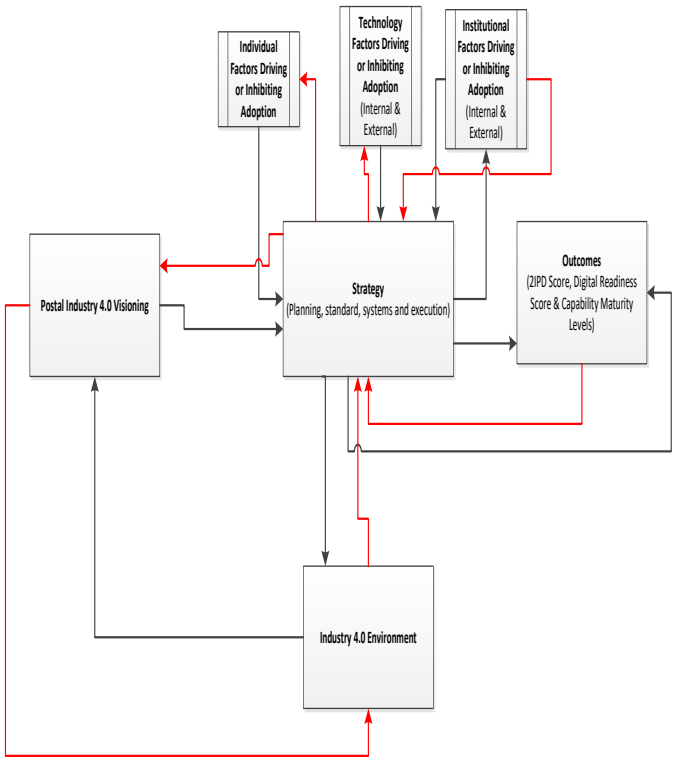

Figure 23: Proposed postal industry 4.0 adoption framework

The framework proposed commences with the visioning dimension which is a key critical success factor in adoption of digital technology and digital transformation. It sets the agenda for digital transformation of the Postal Sector in Southern Africa and without a vision for postal industry 4.0, the digital transformation process is bound to fail. The visioning dimension is supported by the strategy which integrates aspects of planning, systems relating to Industry 4.0, standards relating to Industry 4.0 and execution of strategic imperatives into concrete programmes and projects.

This dimension of strategy interacts with factors that inhibit or enable digital technology adoption and technology adoption broadly. These factors that either inhibit or enable adoption of digital technology and technology broadly are technological, institutional, and individual focused. These factors should be factored in during the strategy development phase and take cognizance of Industry 4.0 standards and systems prevailing. The strategy dimension also feedforwards to the Industry 4.0 environment which is meant to facilitate the core capabilities of Industry 4.0 which are data and analytics, aimed at supporting the core fundamental goal of Industry 4.0 which are: Digitalization and integration of horizontal & vertical value chains, digitalization of products and service offerings includes the expansion of existing products; and lastly, digital business models and customer access.

The execution of the vision for postal industry 4.0 through execution of strategy is envisaged to improve outcomes in the form of an improved 2IPD score, improved digital readiness score and improved capability maturity for the postal industry in Southern Africa.

The technology and digital objectives are underpinned by 5 strategic objectives which are:

1. Adoption of Industry 4.0 in the postal sector (Postal Industry 4.0)
2. Digital transformation readiness
3. Improvement of digital readiness by Posts in Southern Africa through capability maturity modelling
4. Adoption and diffusion of technological innovation
5. Improvement on the 2IPD score

A system approach is represented by feedback systems that are represented as red lines and arrows. Feedback systems are the foundation of the proposed approach as they mimic a dynamic setting due to interaction of a plethora of factors and outcomes.

The critical findings of this study can be summarized as:

(a) The traditional technology adoption models are particularly relevant to individual level rather than organizational level

(b) The TOE (Technology, Organization and Environment) model is the first attempt to incorporate organizational-wide adoptability of technology. However, the approach is linear in nature rather than systemic as feedback systems which are at play in a dynamic setting are lacking.

(c) That there is a big variation in performance on the 2IPD and on digital readiness index between the first-tier countries and Southern Africa. This variation is driven by digital culture which is lower in Southern Africa as compared to top-tier countries (Switzerland, The Netherlands, Germany, France, and Japan).

(d) Visioning and strategy drive digital transformation, without a robust visioning and strategy (including digital culture), the outcomes in terms of performance on both 2IDP and digital readiness index will always be below expectation.

(e) A linear approach to digital transformation and technology adoption fails to capture the complexities associated with interaction of factors in a dynamic setting resulting with even greater complexity.

5. Conclusions

Universally, the postal sector is faced with a plethora of challenges regarding the ever-changing world that is driven by volatility, uncertainty, complexity, and ambiguity (VUCA). This research presented the postal landscape with specific reference to performance of Southern Africa as a Region against the top 5 postal operators on the Universal Postal Union's Integrated Index on Postal Development.

The limitations of the technology adoption models were presented and discussed in context of their "linearity" or rather, a reductionist approaches to technology adoption as opposed to a systems approach which was presented and discussed in detail together with its respective tenets of which feedback systems are fundamental cornerstone to a system approach where the paradigm is "causality" rather than "linearity".

The conceptual framework that incorporates a system approach was presented and discussed in detail, with its respective tenets derived through insights obtained from critical review of literature. In [1], the authors presented a theoretical model at IEEM 2019. The proposed conceptual model as depicted in Figure 23; it is an enrichment of the earlier theoretical framework presented. It is a build-up towards the final goal of developing a dynamic model towards technology and digital adoption in the postal sector in Southern Africa. The conceptual framework answers the research question which was the guiding ingot to the critical literature review.

The research gap identified in this study is the failure of traditional technology adoption models in driving digital transformation agenda. The linearity fails to capture adoption dynamics in a dynamic setting as opposed to the proposed adoption model with build-in feedback loops to better understand interaction of drivers and barriers in an evolving dynamic setting as in the real world.

Future research will be the development of a conceptual framework using system dynamics where the drivers and barriers identified in the research are modelled in a dynamic setting to understand patterns that emerge from their interaction. The developed system dynamic conceptual model will be rigorously tested by selected participating Posts to further refine the model until it closely represents reality. The validated model could be used by Posts to model different drivers and barriers with a view of mitigating against barriers that would enable Posts in Southern Africa to fully adopt a digital transformation journey in order to be sustainable now and in the future.

6. Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

The emergence of the COVID-19 pandemic earlier this year destabilised the operations in the education sector, particularly in institutions of higher learning. Most of these institutions are now expected to teach online, assess their students using non-venue examinations and offer remote laboratory practical and experiments. However, many of these institutions were not prepared for such dynamic change in a such short space of time. Consequently, most of the institutions moved their mid-year examinations to the October/November period. In addition, they are finding methods to conduct laboratory practical and experiments. Prominent researchers agree that institutions of higher learning are challenged by the current dispensation where academics are expected to implement new pedagogical approaches and take advantage of information and communications technology (ICT) for teaching and learning. Every module requires a specific teaching method, as a result, academics need to know about various methods available. Generally, the sciences and engineering modules are taught within the classroom environment and require experiential platforms to solidify the theoretical knowledge gained. The current study is aimed at assessing the evolution of teaching approaches and technologies in distance education regarding online delivery particularly in science, engineering and technology. Various search engines such as Google Scholar, Scopus, Sabinet, ProQuest and EBSCO were used to obtain relevant literature to depict popular teaching approaches and the relevant technologies. In order to access relevant literature, various key strings were used. The findings of the study revealed problem-based, apprenticeship and experimental, and competency-based learning as the most popular teaching approaches, particularly between 2010 and 2020. Project-based learning, case-based learning and communities of practice equally share the third position followed by integrative learning. Students and academics show that instant feedback provided by virtual labs yielded encouraging results. This shows that many students and their academics prefer the introduction of the virtual labs in their learning environment, especially from 2012 until recent. The literature further confirms the current findings that institutions of higher learning need to equip academics to be able to integrate technology within their teaching methods for students to continue to learn at ease.

1. Introduction

This paper is an extension of "Online Learning Approaches for Science, Engineering and Technology in Distance Education" presented at the IEEM 2019 Conference in Macau [1]. Higher education institutions are currently endorsing online courses as a business reality since their budgets are now linked to their enrolments [2]. The introduction of an online learning environment has become a long-term business strategy [3] for many institutions worldwide, to the extent that the proportion of students taking at least one online course has increased from 1 in 10 to nearly one-third in 2010 [3]. The accessibility of the internet of things (IOT) in universities worldwide caused them to invest in e-learning systems to enhance their teaching activities to improve their students' learning experiences and performance [4]. Online teaching and learning environments have brought some mixed feelings to students who believe that video lecturers slightly outperform face-

*Corresponding Author: Rendani Wilson Maladzhi, maladrw@unisa.ac.za

to-face lecturers [5] and some students feel interactive online videos are even better [6]. In addition, others feel that online homework is as effective as paper and pencil [7], [8] and intelligent tutoring is seen to be as effective as human tutors [9]. The dynamics above describe how teaching and learning have evolved over the years with reference to five generations of distance education.

The transition through the five generations of distance education has, over the years, witnessed a change in the use the delivery media of teaching and learning that ranged from text and images, sound and video, live television broadcasting to Web 2.0 interactive online technologies such as podcasts, video conferences, virtual spaces etc. [10]-[12]. Based on the above stated transition, the exchange of information between academics and students remained key, but the mode of delivery and the technological tools made all the difference. Hence, various disciplines require different teaching methods accompanied by various technological tools, as is the case with the current research that focusses on the science, engineering and technology sector. Teaching science, engineering and technology in an online environment has been considered an impossible mission for several years [13]. It is a fact that the sciences and engineering disciplines customarily require laboratory work where students perform their practicals to demonstrate their understanding of the theoretical knowledge.

In another instance, an Engineering Graphics Online Course was first introduced in Tianjin University, where 20 colleges and universities participated to cater for almost 1500 students. As a result, this online environment enabled educational resources to be shared in different areas while quality teaching of engineering graphics was made possible [15].

Laboratory classes are an essential component of most science and engineering courses with the potential to achieve several practical and theoretical objectives [16]. Arguably, students must not only learn manipulative techniques, but also link theory to practice, solve different kind of problems, interpret data, interact with staff and other students, and successfully navigate the lab [16]. Learning in this situation can be greatly assisted by academics who are able to guide students through this complex process. However, the effectiveness of laboratory classes is often not achieved to their full potential [16].

The emergence of the COVID-19 pandemic brough along uncertainties for the institutions of higher learning regarding teaching activities and practical and laboratory experiments. On the other hand, it presented distance education institutions with an opportunity to introduce non-venue-based assessments and remote practical and laboratory experiments. The traditional teaching and learning platform greatly benefited by the development of internet and ICT capabilities [17]. Virtual labs afforded students an opportunity to revive their curiosity and creativity while learning from their own respective spaces [18]. The mode of teaching such as synchronous and asynchronous modes made it possible for teaching and learning to take place at a distance. As such, students taught through the asynchronous mode displayed higher cognitive achievement while those taught through the synchronous e-learning mode displayed improved skills acquisition [19]. Hence, the importance of academics understanding the engineering, science and technology (SET) environment to better equip the students appropriately. A synchronous mode of delivery facilitates teaching and learning in real time, whereas an asynchronous mode requires self-paced teaching and learning activities that make use of email, blogs, wikis, discussion boards, web-supported textbooks, hypertext documents, audio or video courses, and social networking using Web 2.0. [19]. The emergence of Massive Open Online Courses (MOOCs) has made it possible for students all over the world to access free credible multimedia resources utilised by academics from recognised universities across the world [20].

Theories about teaching methods do not exist, particularly in post-secondary level, but apprenticeships that resemble learning by teaching, do exist [21]. However, other researchers viewed apprenticeship or experiential learning or learning by doing as an opportunity for SET learners to engage in active learning while reflecting and putting into practice what they learned in the classroom or outside of the classroom [22]. Traditionally, SET experiential learning methods such as laboratory work, workshops; apprenticeships; problem-based learning; case-based learning; project-based learning; inquiry-based learning; and cooperative learning [21], were mainly found within the SET environment. Additive manufacturing [23], augmented reality, virtual labs, online teaching modules and educational aids (Kit) [24]; modelling activities by 3D printers [25]; Engineering Graphics Online Course [15]; online tutorial system [30]; flipped classroom [23]; virtual simulation teaching [26]; virtual reality; the Digital Engineering module were all transformed it into an online teaching environment.

The purpose of this paper is to determine teaching approaches in SET that are gaining popularity due to the evolution of technology within the online environment to improve students' performance. The technological advances over the years contributed positively in turning traditional teaching approaches in science, engineering and technology into suitable online learning.

2. Literature Review

Teaching and learning have evolved over the years due to technological advancements and knowledge transfer between academics and students. It is a fact that teaching modalities also depend on various disciplines offered in various institutions of higher learning.

Experiential learning took a form of learning by doing and as such, is preferable in the SET environment [21]. However, its successful implementation particularly in an online environment requires virtual technologies. As a result, literature that covers teaching methods and respective technologies are viewed as follows: integrative, apprenticeship and experiential learning, problem-based learning, project-based learning, case-based learning, inquiry-based learning, competency-based learning and communities of practice. It has now become apparent that technologies that enhance teaching and learning be exposed to the world for the benefit of the SET sector.

2.1. Integrative approach

The integrative approach is regarded as an innovative practice due to its ability to introduce a concerted approach to mathematics

and science academics in the teaching and learning environment [27]. It permits students to learn about life's origin, then life's evolution, and thereafter about the future of life and humankind in the Earth and Life Sciences, Mathematical modelling concepts, such as the modelling cycle, solves problems regarding real-life situations [27]. Some of the characteristics of the interactive approach are like those in seminars and tutorial [27]. The emergence of distance learning through online environments calls for teaching activities to be conducted differently. In other instances, the teaching of mathematics education in engineering spaces is enriched through modelling activities by 3D printers [25]. As a result, academics should be provided with technological skills to function better and teach effectively.

Virtual learning systems (VLSs) in the academic fraternity play a similar role as enterprise resource planning systems (ERPSs) in the administration arena [28]. Virtual learning systems are known for their role in the teaching and learning avenues that coordinate activities such as learning objectives, class exercises, quizzes and tests in both synchronous and asynchronous communication [29]. The introduction of online tutorial systems within the Australian universities has seen a tremendous increase in the number of students entering the universities [30]. It is a fact that the new developed online teaching approaches introduced a diverse background of skills, motivations and prior knowledge. In addition, the online tutorial system was found to be instrumental in modules such as engineering physics and mathematics, and as such, students did not only pass their examinations, but it also improved the retention rate of first-year engineering students with the financial benefit to the institution [30].

2.2. Apprenticeship and experiential learning

The teaching approaches such as apprenticeship, experiential learning, cooperative learning and adventure learning are commonly used in the fields of SET. They are preferred for their capability to provide students with prospects to experimentally practice their learned experiences [21]. Learning by doing was traditionally instrumental in the mechanical, civil, electrical and electronics vocational fields [21], [27]. However, its transition towards online experimentation and remote/virtual labs presented learners with vast opportunities to control real or virtual equipment at a distance in order to perform scientific experiments [20]. It appears that different researchers refer to virtual laboratories differently; some view it as simulation-based learning, remote experimentation and remote inquiry-based learning [18], [31], [32].

Lack of reputable laboratory experiments contributed negatively to engineering education and resulted in students utilising outdated experiments [18]. The introduction of virtual laboratories gave students an opportunity to make use of good laboratory facilities operated by trained academics as they made use of remote experimentation [18]. It should be noted that virtual laboratories allow students to take ownership of the experiments and the quality control thereof [18]. Virtual laboratories become a multi-institution and yet multidiscipline initiative aimed at benefiting the students within the engineering fields [18]. In its nature, it addresses the issue of lack of good laboratories facilities, as well as trained teachers, by making remote experimentation possible [18]. It provides students with an opportunity to take ownership of teaching and learning space while academics provide minimal guidance. According to [18] and [31], Virtual Laboratory reached over 100 000 students, and are accessible after hours [18,31].

It has been proven that virtual experiments are proven to be more beneficial for teaching and learning [33].

Factually, learning is currently shifting from synchronous in-class settings to asynchronous online platforms so that education can be accessible to a wider audience [34]. It is believed that engineering education always requires laboratory work and hands-on practical components that are not possible to conduct online. However, it was only made possible by the introduction of simulations in fluid mechanics laboratories [34].

Virtual reality (VR) puts the user into a computer-created world that seems real [35]. In addition, VR creates an environment in which the user feels and seems to be moving inside a computer-created virtual world in the same way people move in and around a natural environment; while immersed in the virtual world, the user cannot perceive the real one which still surrounds him [36]. The findings on the study conducted by Luo depicted that students enjoyed taking measurements in the laboratory. However, other students on the other hand were sleeping around with nothing to show. As a result, virtual practicals are preferred as opposed to the traditional way of conducting practical work [26] for mechanical, electrical, civil engineering and other qualifications.

Augmented reality (AR) utilises smart devices and applications such as smart phones, tablets, wearable headsets and immersive technologies that enhance information in real-time to become intelligent [37]. It contemplates real-world events with computer-generated digital information by allowing the user to experience the interaction of the two worlds [38]. AR is capable of making required information available, presented and experienced by users 'augmenting the real world with digital information [39]. The practical application of augmented reality proved itself to be economically and technically viable for societal usage [39]. Hence, it is preferred within the mechanical, industrial, electrical, civil and other engineering disciplines.

2.3. Problem-based learning

Problem-based learning (PBL) enables the students to gain knowledge about and apply it to different problems they investigate [40]. As they seek solutions for the problems at hand, students have an opportunity to argue and debate based on their own understanding and the acquired facts [40]. PBL teaches students not to depend on their lecturers for information but to rather resort to other sources to make informed decisions. It is important to note that PBL is more suited for student-centred and community-based learning environments [41].

Additive manufacturing (AM) is the preferred technology of teaching used by academics to introduce topics that are industry and academic experts, laboratory and final engineering projects. AM is a PBL in nature due to its innovative features dealing with devices for people with disabilities. Other PBL-related projects include the development of an opener for medicine containers, a device for pouring liquids for people who have Parkinson's disease, and a 3D puzzle for people who have visual impairments.

[23]. It has the capability to encourage students' creativity, learning motivation and engagement [23].

The flipped classroom (FCM) has emerged as a learning model that increases students' active learning, collaboration and scaffolding during the learning process through better allocation of teaching time [43]. As such, the FCM method recognises that teaching activities within face-to-face environment should not be about academics teaching but should rather focus on creating an environment for students to effectively collaborate with each other while guided by the academics through scaffolding methods [44], [45]. It is believed that digital technologies have made it possible for teaching and learning to take place without students being confined to a classroom, and that learning can take place from anywhere as long as study material, videos, online quizzes etc. are available.

The FCM method is preferred by both practitioners and researchers in various subjects such as Mathematics, ICT, Social Studies, Humanities etc. [46]-[50], [89].

The results from various studies further confirmed the FCM method is an effective technology that raises the performance of students who face difficulties in face-to-face educational contexts, and equally assists academics and institutions to improve learning conditions [51]. The FCM's nature affords academics an opportunity to scaffolding and create an enabling environment for engagement with hands-on practices [51].

Traditionally, the Digital Engineering lectures were limited to the face-to-face mode of delivery where students only listened to the lecturer delivering the lecture [24]. It was indeed a tremendous challenge since there was no point of demonstrating the application of electronic circuits, digital electronics and high logic circuits for students to apply in industry [24]. The introduction of online teaching methods utilising the Proteus software to enhance skills of learners began to make a difference [24]. Both problem-based learning and competency-based learning suited the Digital Engineering module. This is due to the application of the software that demonstrates teaching and learning activities to students, which also requires both online and off-line learning with computer-based learning assistance [24].

Arguably, teaching practical science at a distance has been a challenge for a while in most institutions across the world. However, in July 2013, the Open University (OU) launched the Wolfson Open Science Laboratory (OSL), which offered a variety of practical science experiences to their distance learning students [13]. With this initiative, students are provided an opportunity to observe, investigate, gather and analyse data. In fact, numerous studies confirmed the effectiveness of PBL because it fostered active learning.

2.4. Case-based learning

Case-based learning (CBL) is an interactive group learning pedagogy preferable in various disciplines including business, law, health [14], [52] and in sciences [53]. Case-based learning is defined as an educational approach that allows students to work in small, collaborative groups to solve problems [54]. It is gaining popularity at a faster pace within the online fraternity [14]. (2018: 283-300). Furthermore, it stimulates students' thinking and discussions amongst students [14]. It is paramount to mention that the case presentation teaching method is frequently utilised in medicine [52].

Case-based is predominantly used where complex and interdisciplinary themes openly discussed [27]. Application oriented teaching platform became a reality in various university through online course construction [17].

According [55], civil engineering requires modern teaching methods such as hybrid, project, case and discussion into the classroom while utilising engineering examples to enhance teaching and learning.

2.5. Project-based learning

Project-based learning (PJBL) is a twenty-first century innovative learning approach that teaches various strategies to ensure students' success [56], particularly in higher learning environments. With this approach, students are afforded an opportunity to experience the reality of the real-world while boosting their communication skills and interdisciplinary learning [57]. However, PBL places more emphasis on learning through internal rather than external projects. Industrial collaboration projects build partnerships and provide opportunities to work on real problems, often seeking multidisciplinary approaches. This study explores and suggests the benefits that students derived from their participation in an external research and consultancy project at a University in Oman [57].

In 2016, Ralph conducted a research study looking into the post-secondary project-based learning in science, technology, engineering and mathematics [58]. The findings indicated that students benefitted from the project-based method regarding content knowledge, and interdisciplinary skills. Their learned skills would be instrumental in their future classes and career settings. However, most students did not enjoy the teamwork that PJBL brings but some learned from other group members [58]. All in all, the findings recommended that PJBL should be implemented institutionally rather than per discipline.

Typically, students using the project-based learning method work together as a team in order to solve the given problem by developing the product and development process [59]. PJBL is found to be an efficient teaching method in the twenty-first century as it promotes critical thinking, problem-solving skills, interpersonal communication, information and media literacy, collaboration, teamwork and leadership, creativity and innovation [60].

Other researchers conducted a study on Reform Practice of Engineering Drawing Courses in Chinese Colleges in 2019 [61]. The findings highlighted amongst others the emergence of the MOOC platform of outcomes-based education for engineering education models. All mechanical drawing courses implemented project-based teaching methods that were suited for the online environment. The MOOC platform catered from various online learning engagement models for a variety of questions, discussions sessions and projects [61].

2.6. Inquiry-based learning

The inquiry-based instructional approach is learner-centred and requires the learner to observe, generate questions, discover existing gaps and find appropriate resources to overcome these

gaps [62]. These students take charge of their own learning by planning, monitoring and evaluating their progress made [63]. In 2017, researchers conducted a research study about preparing teacher-students for the 21st century. An inquiry-based teaching method was utilised when 110 physics and chemistry teachers were involved. In their tasks, they managed to successfully explore and analyse the problems and formulated hypotheses and conducted their experiments. ICT applications were integrated by means of smart phones with cameras, laptop computers and software applications. As a result, the experiments were fruitful as they worked together with one common purpose [63].

It is a fact that in an inquiry-based phenomenon, students become their own teachers and take lead in the teaching and learning processes. The emergence of technology makes it easy for students to access their laboratory through the internet of things without them being in the physical laboratory [64-66]. It is imperative to note that virtual laboratory makes things bearable and cost-effective as compared to traditional laboratories as they are easy to maintain and safe to use. The science, engineering, and technology students find virtual laboratories user-friendly as they interact in inquiry-based classes where they can implement and analyse their own experiments and learn by using virtual objects and apparatus [67]. This teaching method also equips students with critical thinking, and innovative and team skills, which are valued for the twenty-first century job market [67]. A previous study initiated the STEM build website to coordinate online teaching and learning where instructors, markers, researchers, and Universal Design for Learning experts can easily interact [68].

Previously, engineering drawing was hand-based, now, online tutors are currently assisting these students. The utilisation of artificial intelligence makes it possible to provide real-time human-like feedback to students [69].

The emergence of the COVID-19 epidemic has seen the closure of campuses for schools and universities to ensure the safety of their students. As a result, online teaching and learning has become the reality in the 2020 academic year [70]. Online teaching and learning were found to be conducive for teaching students about circuits in electronic engineering [70] (Hu, 2020).

2.7. Competency-based learning

Over the past years, competency-based learning has rapidly gained momentum within the higher education space [71] and has been supported by ICT [74]. It is noticeable that over 896 institutions (universities and colleges) across the world prefer the competency-based learning method in their teaching and learning activities [71, 72]. Within competency-based learning, students depend more on their competency levels than on other people [21, 73]. Competency-based learning enables students to return to one or more competencies that are not yet mastered to avoid having to repeat courses as a result of failing [74]. Competency-based learning equips students with explicit and transferable learning objectives that provide them with personalised support and formative feedback so they can foster critical-thinking, problem-solving, communication and collaboration skills [74]. Competency-based models are dependent on measurable assessments linked to the related learning outcomes [75]. In most cases, competency-based learning is demonstrated through both formative and summative assessments [75]. However, at the Minnesota State University, both assessments methods (summative and formative) were successfully utilised for the Honors Program to assess the competency level of the students over time through electronic portfolios. As such, this assessment method replaces the standard research thesis required in numerous traditional Honors Programs [76].

In most instances, the competency-based method is used by professional bodies to measure the level of acquired competencies of graduates regarding their required training expected in industries [77]. Employers like to state to the institutions of higher learning what competencies they expect from the graduates. Hence, the importance of institutions of higher learning to always consult the companies based on what they expect their graduates to possess is imperative [78].

2.8. Communities of practice

The communities of practice approach combine experiential learning, social constructivism and connectivism, which allows people to work together and give each other moral support [79] and compassion [80] as they study. This method permits students to put their skills into practice and largely share their experiences [10, 81]. Communities of practice (COP) allow the combination of experiential learning, social constructivism and connectivism can while demonstrating the limitations of classifying learning theories. In addition, COP allows group of engineers to work together in order to solve general challenges [81-84]. It is argued that for teaching and learning to effectively take place, precedence should be on cognitive, social and teacher presence [85].

3. Research Methodology

As mentioned before, the current study aims to determine teaching approaches in SET, which are gaining popularity due to the technological evolution over the years. It also aims to ascertain the state of distance education evolution with reference to technology adoption within the Science, Engineering and Technology qualifications in the institutions of higher learning. As mentioned earlier, engineering students were traditionally afforded opportunities to experientially practice learned knowledge in a laboratory setup. It is therefore of vital importance to assess the literature if science, engineering and technology students in higher education are to continue receiving laboratory experiments while studying in an online environment. The study targeted literature from 2010 to 2020 to determine teaching approaches that are gaining popularity in SET within an online environment. The reviewed literature was obtained from various search engines such as Google Scholar, Scopus, Sabinet, ProQuest and EBSCO.

The following search strings were used to search the open-journal sites:

- Teaching approaches for science, engineering and technology
- Teaching approaches for distance education
- Teaching technologies for SET in distance education
- Integrative approach for distance education in the SET
- discipline
- Apprenticeship and experiential learning for distance

- education in SET
- Problem-based learning for distance education in SET
- Project-based learning for distance education in SET
- Competency-based learning for distance education in
- SET
- Inquiry-based learning for distance education in SET
- Case-based learning for distance education in SET
- Community of practice-based learning for distance
- education in SET
- AR in SET
- VR in SET
- Virtual laboratory in SET

The research study concentrated only on journals that focussed on institutions of higher learning within the SET discipline. All other journal papers focussing on primary schools and industry were excluded from the study. The results of the reviewed literature were presented in both table and graph formats for appropriate analysis. Pareto analysis was conducted to determine teaching methods and their respective technologies preferred in the SET qualifications in an online environment.

4. Research Findings and Discussion

Theories such as cognitive behaviour, social constructivism and connectivism formed the basis of the different approaches discussed in the current study. It is clearly indicated that teaching approaches for SET always pay attention to the practical implications on what students theoretically learn in a class setup. The evolution of distance education has seen traditional teaching approaches such as competency-based learning, project-based learning, problem-based learning, inquiry-based learning, case-based learning, and apprenticeship and experiential learning as becoming relevant in the twenty-first century through technologies such as VR, AR, virtual laboratories, AM, FCM, Proteus software, Wolfson Open Science Laboratory, Virtual Microscope etc. It should be noted that the findings of this study are entirely based on the reviewed literature sources. The results in Table 1, depict how different approaches transited from traditional face-to-face to online virtual practical so that students could continue putting their knowledge into practice.

The results from both Figure 1 and Table 1 show the popularity of these teaching approaches in an online environment emerging from 2010 until recently. The results also display that problem-based, apprenticeship and experiential learning, competency-based learning and inquiry-based learning are more popular in an online environment, particularly in SET. It suffices to mention that all highlighted teaching approaches are preferred in SET within online space but differ due to their popularity over the years.

Figure 1 elaborates on the popularity of teaching approaches suitable for online teaching and learning as per the author's contributions. The study results show that problem-based learning has gained popularity and exceeded all the other approaches, followed by apprenticeship and experiential approaches. The third important approach was found to be competency-based. However, case-based, project-based and community of practice-based approaches shared the fourth position for popularity. Last, but not the least, integrative approach proved to have less popularity. It is important to emphasise that all these approaches are applicable in an online environment within SET disciplines. It is evidence that from 2009,2010, 2011, 2012 these various teaching approaches were utilised mainly in face-to-face institutions. However, the emergence of the internet of things made it possible for utilising them for open and distance education, particularly 2017, 2019 and recently. In recent years as from 2015 until recent Virtual labs, virtual reality gave problem-based, apprenticeship and experiential learning as well as competency-based approaches impetus within the science and engineering space as seen in the table below. It is evidence from Figure 1 and Table 1 that other technologies such as LMS, FCM in education, 3D printers and AM in the manufacturing spaces continued to gain recognition as from 2016 and prominently in 2019. The study rightfully, depicted the gap in open and distance learning environment where similar teaching approaches in science and engineering where applicable.

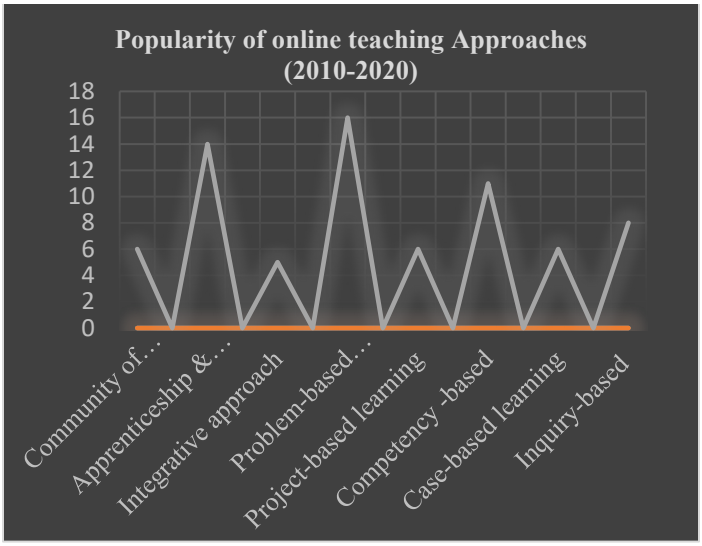

Figure 1: Popularity of teaching approaches

Table 1: Authors who endorsed teaching approaches

Authors endorsed these approaches	Learning Approaches & Preferred technologies	Used in SET	Online Learning delivery
[2011],[2015] [2017],[2018] [2019],[2019]	Community of Practice learning **Technologies:** Learning management system (LMS)	(6)	Yes
[2011][2012] [2013][2013] [2014][2015] [2017][2018] [2018][2018] [2018][2019] [2019][2020]	Apprenticeship & experiential **Technologies:** Virtual labs, AR, VR, LMS,	(14)	Yes

[2016][2017] [2018][2018] [2019]	Integrative approach **Technologies:** Virtual learning Systems; 3D printing	(5)	Yes
[2010][2017] [2017] [2017][2018] [2019][2020] [2020]	Inquiry-based learning **Technologies:** LMS	(8)	Yes
[2012][2014] [2014][2015] [2015][2017] [2015][2016] [2016][2017] [2017][2018] [2018][2018] [2019][2019]	Problem-based learning **Technologies:** AM; FCM; Proteus software; Wolfson Open Science Laboratory; Virtual Microscope	(16)	Yes
[2010][2016] [2016][2017] [2019][2020]	Project-based learning **Technologies:** FCM and LMS	(6)	Yes
[2015][2015] [2016][2016] [2016][2016] [2015][2016] [2017][2019] [2020]	Competency - based **Technologies:** FCM and LMS	(11)	Yes
[2011][2016] [2018][2018] [2019][2019]	Case-based learning **Technologies:** FCM and LMS	(6)	Yes

5. Conclusion

The emergence of the COVID-19 pandemic has provided an opportunity to many institutions to introduce various technologies to enhance teaching and learning activities for students and academics. Much more importantly, many institutions were not ready to offer non-venue-based examinations and remote laboratory practical. As a result, some institutions forged ahead and offered mid-year non-venue-based examinations while other institutions postponed all their examinations to October/November 2020. However, the issue of credible examination remained a concern to these institutions. These institutions want their students to write non-venue-based examinations, which are remotely invigilated by means of proctoring system to maintain their quality standards.

Equally important, institutions which offered campus-based practical experiments opted for alternative practical such as video-based and virtual practical to their students. Many of the institutions are only considering virtual practical now, as the COVID-19 situation does not show any sign of coming to an end soon. Hence, the importance of the current study so that institutions across the world can see various teaching approaches and technologies suitable for the online environment.

Traditionally, all practical experiments in science, engineering and technology institutions were conducted in physical laboratories. As such, most distance education institutions across the world collaborated with other campus-based institutions for their students to conduct laboratory work at those institutions, see Figure 1 and Table 1. However, such institutions always complained of the quality of practical work done in other institutions. In most cases, the Engineering Council of South Africa (ECSA) was concerned about the teaching and learning activities pertaining to engineering courses offered by distance education and those that were conducted online. ECSA, is a professional body that accredits all engineering qualifications in South Africa. They were more concerned about the practical work and the credibility of the assessments would ensue. Hence, the importance of the current study to publicise what other institutions across the world are doing regarding the virtual spaces utilising AR and VR technologies.

The findings of the current study indicate that virtual laboratories are the solution for most of the SET institutions operating in an online environment. The traditional teaching methods for civil engineering courses were no longer appropriate due to technological advancements [86]. Hence, the adoption of online courses for efficient learning. The introduction of micro-videos and final assessment methods made it possible for students in other areas to be involved [86]. Notably, most of the distance education institutions are already employing teaching approaches such as problem-based (16), apprenticeship and experiential learning(14), competency-based learning (11), inquiry-based learning (8), community of practice learning (6), case-based learning (6) and integrative-based learning (5).

Education technology has made it possible for students to learn outside of the classroom when they are at home. Both synchronous and asynchronous learning allows students to access teaching materials in their own comfortable space [87]. The study confirmed that many students in the engineering discipline developed an interest in teaching and learning where they were exposed to various assessment methods, linking theory for practice and case discussion [86]. This statement shows that the introduction of new technologies within the institutions of learning are enabling students to perform better, see Figure 1 and Table 1. The usage of different teaching methods plays an important role towards students' performances [88].

Both students and academics show that instant feedback provided by virtual laboratories yielded encouraging results [67]. Virtual laboratories began to gain popularity as early as 2012 and increasingly so in this digital era. This shows that many students and their academics prefer the introduction of the virtual laboratories in their learning environment. The institutions of higher learning are challenged by the current dispensation where

academics are expected to implement new pedagogical approaches and take advantage of ICT for teaching and learning, as can be seen in both Figure 1 and Table 1. As a result, these institutions need to equip the academics to be able to integrate technology within their teaching methods so that students continue to learn at ease. It is affirmed that the world-wide education system should incorporate the twenty-first century skills into curricula [63]. The current study acknowledges the challenges brought by the COVID-19 pandemic into the online institutions of learning, but the introduction of various teaching methods along with various technologies might bring relief if implemented correctly. Institutions are confronted with an opportunity to assess their current resources and equip their academics appropriately so that they can structure their assessments and practicals accordingly.

The current study proposes that a future study assess the implementation of various teaching approaches along their suitable technologies within the SET institutions in the southern Africa region.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

Performance Analysis

ABSTRACT

The Internet of Things (IoT) application has been experiencing increasingly progressive demand, especially for embedded devices (ED). However, the ED has limited capabilities, low power consumption resources, and low bandwidth in connecting to the Internet by using Wireless Sensor Networks (WSNs). Therefore, the WSNs form creates a necessity for new technologies and protocols for the IoT implementation. Thus, IPv6 Low Power Area Network (6LoWPAN) was designed by the Internet Engineering Task Force (IETF) to overcome the Internet Protocol (IP) based communication that allows direct communication between each ED. Nevertheless, the communication between ED using 6LoWPAN becomes challenging in designing routing protocols to achieve the efficient performance Quality of Service (QoS). Among the existing protocols for the 6LoWPAN network, RPL is considered effective for the 6LoWPAN system. However, the Power Consumption (PC) and routing overhead of RPL is high when it was implemented in a real scenario. Therefore, HRPL was proposed to enhance the RPL by introducing the rebroadcast technique in order to minimize the routing overhead at the same time reduced the PC usage. Thus, this paper is an extended version, in which 6LoWPAN Smart Home Testbed (6LoSH) was developed to investigate the impact of the number of nodes on PC usage for both protocols (HRPL and RPL) in a real scenario. The result shows for this instance, HRPL has succeeded in reducing the use of PC for both experiments (simulation and 6LoSH). On the other hand, the number of nodes had given an impact on PC usage. For further work, we plan to use multiple topologies and the different number of nodes to explore the HRPL for some performance metrics such as convergent time and latency.

1. Introduction

This paper is an extended version of work published in [1]. We are making this version available in order to have more results and discussions in comparison to its short version.

The 6LoWPAN was introduced by IETF to support a huge number of IP-based embedded devices that are connected to the Internet with a low power network capability. Moreover, the rapid development of the Internet of Things (IoT) ecosystem in multiple areas [2] such as healthcare, smart building automation [3], vehicle [4], etc. had made the embedded device to be in high demand [5]. The embedded devices are categorized as limited power usage, limited cost, limited bandwidth, and small memory usage [6]. Meanwhile, the development of IoT devices become a serious problem to enable interoperability and scalability among devices and systems [7,8]. Thus, the 6LoWPAN protocol was designed to complete and complement the technological constrain as an essential part of the IoT development application and ecosystem. 6LoWPAN that enables the ED which are mainly sensor nodes to connect to the Internet over IEEE 802.15.4 in Physical (PHY) layer and Medium Access Control (MAC) sublayer. Figure 1 presents the 6LoWPAN stack where the adaptation layer was added between the data link physical layer and network layer. 6LoWPAN is a wireless embedded internet [9]

*Corresponding Author: Nin Hayati Mohd Yusoff, nin6699@gmail.com

that integrates IPv6 with WSN [10] that allows the IP-based ED to connect and exchange information directly with other devices on the Internet [9]. Due to this matter, the energy used for connectivity will save, and for this condition, 6LoWPAN network becomes an essential part of the IoT deployment [11].

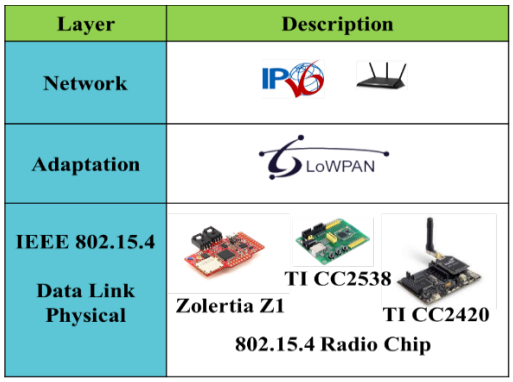

Figure 1: 6LoWPAN Stack

However, the infrastructure of IPv6/6LoWPAN and how IPv6 can integrate heterogeneous technology (system, tool, application, etc.) towards a new embedded application protocol (6LoWPAN) for IoT ecosystem become a challenging issue. This because the current standard of 6LoWPAN is limited to 250 kbps, and 127 bytes of frame length compared to IEEE 802.15.4 packet size is 1280 bytes. As a result, it is critically affected for the routing algorithm to optimize the path formation. Indirectly, it will degrade the interoperability of 6LoWPAN devices/applications. Besides, the implementation, integration and evaluation for large scale deployments of sensors networks in buildings, the potential heterogeneous combination of wireless and wired need to optimize the energy consumed by the system itself.

In addition, the 6LoWPAN protocol develops to optimize the routing scheme for converging cast traffic patterns for low power nodes [12]. One of the 6LoWPAN routing protocols is Protocol Over Low-Power and Lossy Networks (RPL) as defined in RFC6550 [13]. Based on previous research, the RPL protocol in 6LoWPAN is effective in terms of delay and Packet Delivery Rate (PDR). But, it can be further improved in terms of overhead as the original value is very high [14] [15]. According to Feschel, Huhn, & Schwetlick in 2012, the fragmentation of the frames should minimize the routing overhead and power consumption in order to save network lifetime that is a critical parameter to 6LoWPAN nodes. On the other hand, to optimize network performance, the routing overhead must be reduced. At the same time, the 6LoWPAN system offers the scalability and as well as interoperability between nodes. Therefore, this research project addresses algorithmic, networking, and application development using the 6LoWPAN CC2538 module in improving the 6LoWPAN protocol to achieve efficient performance QoS of the network in terms of PC. The proposed algorithm is implemented and tested using a simulation study and validated with the experimental approach by developing the 6LoWPAN Smart Home testbed (6LoSH). The initial phase of this study focused on a literature review that has been done in [17] to address the two (2) following challenges: i) Comparative analysis of existing systems and solutions and ii) Comparative analysis of existing standards and protocols. As a reminder of this paper, we present our work as follows. We describe a methodology used in Section II follows by Section III present the experiment setup. Then, Section IV describes the evaluation results. Finally, we emphasize the contribution of this paper and future works.

2. Methodology

The methodology is divided into three parts, as presented in Figure 2. The first part is the development process, followed by implementation, and the last part is testing and validity.

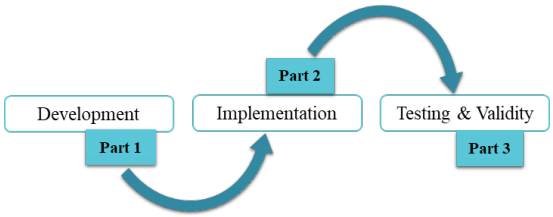

Figure 2: The Methodology Design

2.1. Development

The development of 6LoSH involves three (3) important aspects. First, the integration between the 6LoWPAN system requirement and building infrastructure with different technologies like sensors, actuators, and mobile devices. Figure 3 presents the proposed 6LoSH network design, which implements a simple node architecture [11], [9], [18]. 6LoWPAN nodes communicated with each other through border router, and share a backbone link to connect to the Internet. This allows all the 6LoWPAN nodes remain the same as the IPv6 prefix. Besides, 6LoWPAN connects to another IP network via a border router. At the same time, the border router is handling the 6LoWPAN compression and Neighbor Discovery (ND) for 6LoWPAN nodes. According to [11] the power consumption usage using simple architecture remain low when the intelligent objects are idle, and increases the data rate in both host and router mode. The end-users will be able to interact with the system by running several applications from their PCs, mobile phones, notebooks, and voice. These applications will make use of the services provided by the building system. They will allow end-user to obtain information about the state of the building and switched off/on the application over the Internet.

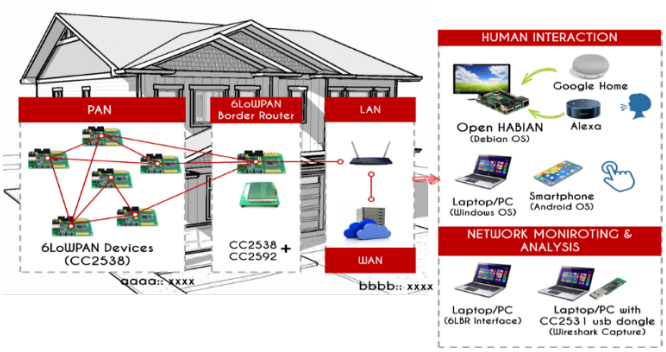

Figure 3: Simple 6LoWPAN Nodes (CC2538 Module) Architecture for 6LoSH

Second, the 6LoWPAN node, other hardware, and software requirements towards a new embedded application in developing 6LoSH. Table 1 shows the list of the equipment required for the implementation of the 6LoSH physical deployment. We used the TI CC2538 module [19] as a 6LoWPAN node and border router because it is a very low power wireless module for IoT applications [20], Figure 4. In contrast, Raspberry Pi 3 Model B is used for running the 6LoWPAN Border Router (6LBR). We observed 6LoWPAN packets by using a CC2531 traffic sniffer and the Wireshark packet capture tool with baud rate 115200. Besides, the Contiki OS [21] [22] by performed COOJA simulator is used to set up the CC2538 program and running simulation of the 6LoWPAN network.

Table 1: The equipment required for the implementation of the 6LoSH physical deployment

Hardware and Software Requirement		
Equipment	Count	Types, and Description
Node	10	• The CC2538 Texas Instrument
Border Router	1	
Sniffer	1	• CC2531 USB Dongle
Raspberry Pi 3	1	• Running 6LoWPAN Border Router (6LBR) • Model B (Debian OS)
Contiki OS (Cooja Simulator)		• Perform simulation testing • Writing a program for CC2538 module
Wireshark		• Packet capturing and analyzing the OTA packet

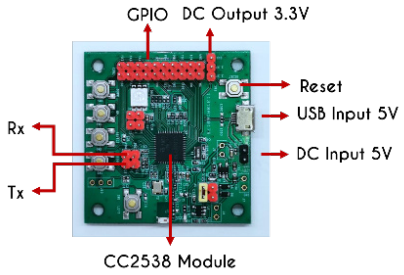

Figure 4: CC2538 Board

Finally, a novel algorithmic models and scalable solutions for the 6LoWPAN system. The on/off an application for embedded devices has been designed and flashed onto the CC2538 board, namely 6Node. The real-time arrangement of the 6Node setup is shown in Figure 5. Table 2 presents the proposed 6Node protocol parameter setup. The default trickle algorithm [15] is used to control the amount of DIO message in routing traffic by setting the parameter of DIO Interval Min as 12ms and DIO interval doublings as 16ms. To achieve the best Packet Delivery Ratio (PDR), the Minimum Rank with Hysteresis Objective Function (MRHOF, RFC6719) with Expected Transmission Count (ETX, RFC 6551) metrics are used as path selection mechanism [23]-[24].

Figure 5: Real-Time Arrangement of CC2538 setup

Table 2: System Parameter for CC2538 Protocol

Parameter	Algorithm/Coding

Trickle Algorithm	case RPL_TRICKLE_T_TIMEOUT:
	rpl_trickle_handle_t_timeout();
	break;
	case RPL_TRICKLE_I_TIMEOUT:
	rpl_trickle_handle_i_timeout();
	break;

Nodes rank	#define RPL_OCP_OF0 0 In #define RPL_OCP_MRHOF 1
RPL_Dio Interval Min	#ifdef RPL_CONF_DIOINTERVALMIN #define RPL_DIOINTERVALMIN RPL_CONF_DIOINTERVALMIN #else #define RPL_DIOINTERVALMIN 12 #endif
DIO interval doublings	#ifdef RPL_CONF_DIOINTERVALDOUBLINGS #define RPL_DIOINTERVALDOUBLINGS RPL_CONF_DIOINTERVALDOUBLINGS

2.2. Implementation

The implementation process involves the deployed hardware infrastructure, physical network, and integrated with software services for managing and controlling the hardware. Dealing with devices and technologies, it has explored existing platforms and solutions that could be relevant for 6LoSH to achieve effective communication (interoperability) between the nodes and systems [7], [8]. The home appliances are connected to nodes through a relay which in turn is connected to another digital pin of the board as illustrated in Figure 6. Figure 7 present the 6Node prototypes and Figure 8 show the development of 6Node prototype activities.

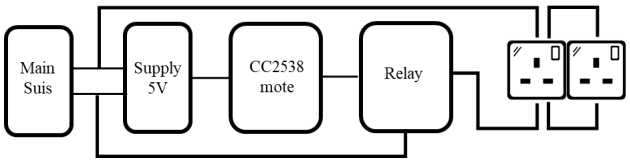

Figure 6: The Block Diagram of CC2538 Application (6Node)

2.3. Testing and validity

The performance of the 6LoSH platform has been evaluated and validated through simulation and calibrate the simulation result using an experiment to ensure the 6Node reach the efficiency of QoS. The HRPL protocol introduced in [1] and RPL

standard was used to assess the effectiveness of 6Node in reducing routing overhead toward new embedded applications for the 6LoWPAN environment.

Figure 7: The 6Node Prototypes

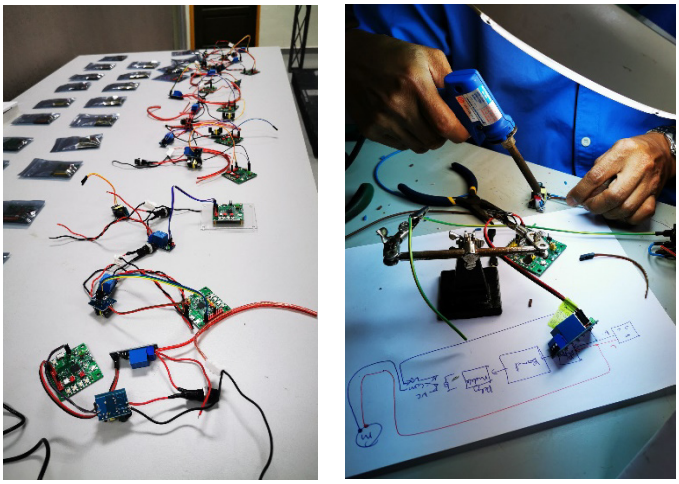

Figure 8: The development of 6Node Prototype Activities

3. Experiment Setup

Figure 6 shows the testing design and Table II describes a summary of the evaluation parameter setting for both experiments that was adapted from the existing model in [25] [26,27]. The comparative study in terms of power consumption has been done by using standard HRPL and RPL protocol to investigate the scalability and interoperability communication between devices (6LoWPAN appliances) and network performance. To be fair, the open-source implementations run on the same operating system (OS) which is Contiki OS. The HRPL and RPL protocol was simulated using the Cooja simulator [28,29] (Testing 1). Then, we compared the simulation results with the evaluation of HRPL and RPL through testbed experiments (testing 2). We created similar scenarios for both experiments. Lastly, we evaluated the performance of the HRPL protocol based on defined metrics. Figure 10 present the real-time arrangement of 6LoSH testing.

3.1. Simulation (Testing 1)

Tmote Sky CC2420 was used as a platform. The set of simulation scenarios (4, 6, 8 and 10 nodes) used in this study as shown in Figure 11. Firstly, the implementation of the RPL protocol from the standard examples of RPL collects file that contains source code of sink and sender nodes are simulated. We set a sink node in the middle of the network and deploy the sender node randomly. We set a transmission range (Tx) to 20m and interference range (INT) to 20m at Unit Disk Graph Model (UDGM) [30]. The radio messages were enabled to capture the traffic and saved as a pcap file. The saved pcap file would be used to analyze the network using Wireshark network analyzer. Then, the standard RPL collect file is modified by changing RPL library to HRPL library, in both source codes of sink and sender nodes. Next, the HPRL protocol is simulated in the same scenario. Lastly, the result between RPL and HRPL is compared with four types of power consumption: CPU Power, Transmit Power, Listen Power, and Low Power Mode (LPM). The simulation results will be evaluated for the different number of nodes (4, 6, 8, and 10 nodes).

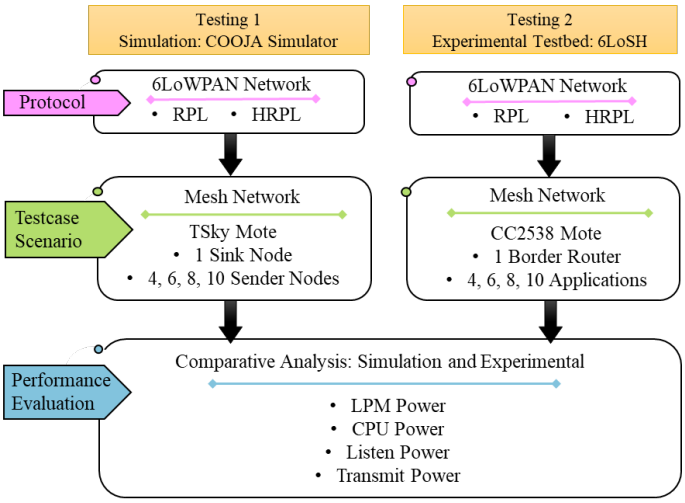

Figure 9: The 6LoSH Testing Design

Table 3: The Summary Parameter Seting for 6LoSH Testing

Method	Testbed (6LoSH)	Simulation
Protocol	HRPL	HRPL
Transport	UDP/IPv6	UDP/IPv6
Mote Type	CC2538 Module	Tmote Sky
Reception Ratio (Rx) and Transmission ratio (Tx)	-	100% & 100%
Packet Size	160bytes	160bytes
Queue	150 packets	250 packets
Transmission Power	-17dBm	0dBm
Transmission range	20m	20m
Network Scale	4, 6, 8, 10 nodes	4, 6, 8, 10 nodes
Length	60 minutes	60 minutes
Packet Capturing	Pcap (Wireshark)	Pcap (Wireshark)

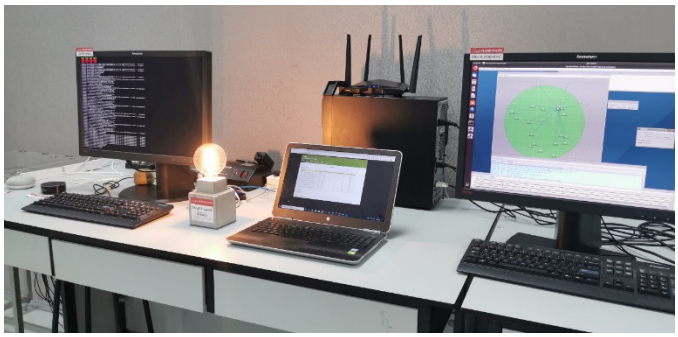

Figure 10: The Real-Time Arrangement of 6LoSH Testing

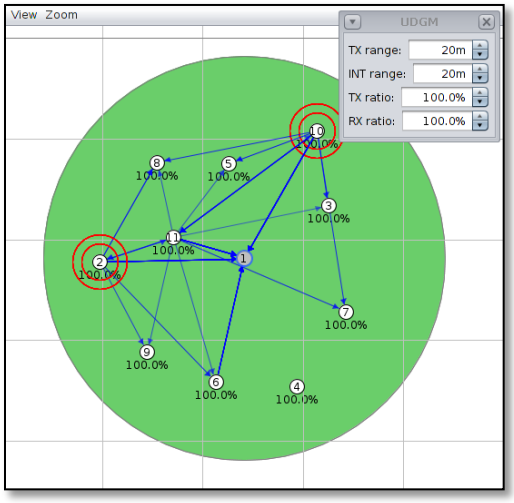

Figure 11: The Set of Simulation Scenario

3.2. Testbed (Testing 2)

The testbed results are used to calibrate the simulation results and also to validate the performance of HRPL in a real-scenario. In this scenario, one border router (6LBR) is located in the center and the different number of applications (4, 6, 8, and 10 nodes) were deployed randomly on the first floor in one of the houses in Malaysia, as presented in Figure 12.

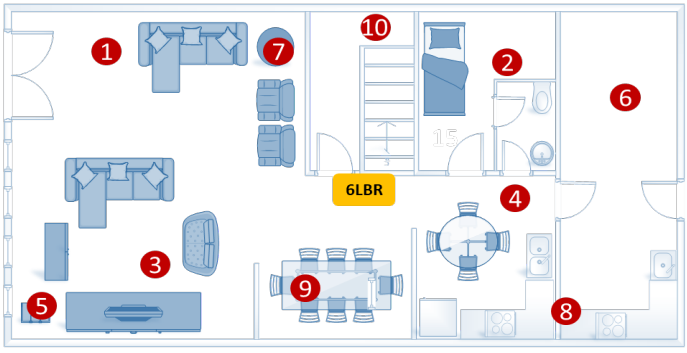

Figure 12: The 6Node Deployment

3.3. Performance Metric

The power consumptions are monitor in both experiments through the development of the Powertrace application in the Contiki operating system. There are four types of power are measured:

- CPU Power,
- Low Power Mode (LPM) Power
- Transmit Power and
- Listen Power.

CPU power refers to the power of computation required by the node in active mode while LPM power refers to the power used by the nodes in CPU sleep mode. Meanwhile, the energy used by each node to transmit the data package to the neighbors is called transmit power, and listening power refers to the energy required by each node in ready mode to receive the data package.

4. Results and Discussion

We assumed our experiment a random topology where the nodes were deployed randomly in an area of 20m x 20m (simulation) and 20m x 20m (testbed). We put the sink node in the center of the network. In order to enable interconnection between all the sender nodes, we set up each node with multi-hop transmission distances from the border router. For both experiments, we considered the DAG root at the border router. Then we set up the nodes to generate packets 1 packet/min randomly in a fixed interval time. We derived this analysis using a script to determine when all nodes had printed to the simulator output (simulator) and web interface (testbed) that they joined the DAG.

Table 4: Analysis of Total Power Consumption

Number of Nodes	Testing 1 (Simulation)			Testing 2 (6LoSH)		
	RPL (mW)	HRPL (mW)	%	RPL (mW)	HRPL (mW)	%
4	0.995	0.629	36.8	1.576	1.0405	34.0
6	1.015	0.641	36.9	1.607	1.0515	34.6
8	1.021	0.650	36.3	1.623	1.07225	33.9
10	7.239	3.175	56.1	7.906	4.1099	48.0

Figure 13 shows the results obtained from the analysis of HRPL and RPL power consumption usage in different nodes (4, 6, 8, and 10) for testing 1 and testing 2. By comparing the four different nodes, it is evident that the power consumption usage for Number of Nodes (NoN) = 4 is the lowest followed by NoN = 6 then NoN = 8 while NoN = 10 is the highest power consumption usage. The result shows that HRPL is better in all NoN and managed to reduce the overall power consumption by 36.8% (NoN=4), 36.9% (NoN=6), 36.3% (NoN=8) and 56.1% (NoN=10) lesser than RPL in testing 1. While in testing 2 HRPL has obtained a better result that can reduce power consumption by 34.0% (NoN=4), 34.6% (NoN=6), 33.9% (NoN=8) and 48.0% (NoN=10) lesser than RPL. In this instance, according to the observation, the HRPL had generated a smaller power consumption, and due to the number of nodes, however it had managed to obtain the increases of power consumption in real time scenario (6LoSH) compared in simulation. It is figured out which the power consumption value would have effect under different platform even used the same scenario and system setting. The cooja simulator enable the node which make a simple network and doesn't requirement gateway to connect to the internet. But

different condition in 6LoSH, raspberry pi (powered by battery) used as a 6LBR to deploy the node for physical network and this condition increase the radio transmission power received by each node. Besides, the retransmission activities detected leading to higher power consumption in real scenario.

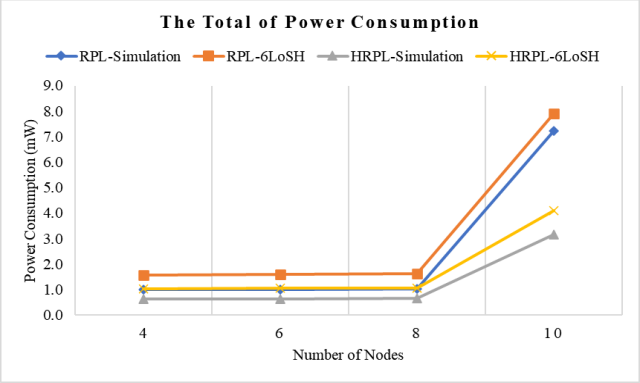

Figure 13: The Total Power Consumption for Both Experiment.

Table 5 presents the analysis of each type of power consumption for testing 1 and testing 2. The CPU Power, LPM Power, Listen Power, and transmit Power values obtained for each of the experiments were presented in Figure 14-17. It is observed that for NoN = 4 gave a minimum value of LPM Power, CPU Power, and Transmit Power. However, the value of Listen Power is the highest in comparison with others. Based on observation, the node turns on its radio during all its idle slot when it's set as a parent. This condition not only becomes the listening power increase but also wastes their energy for the whole network. Interestingly, the computation of each node is increased due to the way the node determines the best route from the source node to the destination node[31]. Meanwhile, the T-Sky CC2420 module that is used in simulation has less power compared to the CC2358 module that is used in 6LoSH.

Table 5: Analyses of Power Consumption for Testing 1 (Simulation) and Testing 2 (6LosH)

Types of Power	Number of Nodes	Testing 1 (Simulation)		Testing 2 (6LoSH)	
		RPL (mW)	HRPL (mW)	RPL (mW)	HRPL (mW)
CPU Power	4	0.332	0.209	0.453	0.285
	6	0.349	0.213	0.487	0.309
	8	0.357	0.218	0.514	0.328
	10	0.376	0.228	0.586	0.362
LPM Power	4	0.153	0.101	0.224	0.156
	6	0.153	0.104	0.218	0.143
	8	0.153	0.105	0.224	0.145

5. Conclusion

6LoWPAN system enables the ED to communicate with each other using the IEEE 802.15.4 wireless network. Due to this matter, 6LoWPAN had become a priority network for IP-based communication for ED. However, the design of the 6LoWPAN system in the real-world scenario has become a challenging issue, such as interoperability, scalability, and integration among the nodes, and network. Thus this study aims to develop the 6LoWPAN smart home system (6LoSH) to evaluate the performance of HRPL and compared the result with RPL. The result of this study shows the PC of nodes reached its most minimum for NoN =4 scenarios, while low link quality is linked to NoN = 10 scenarios respectively for both experiments. These results confirm that the 6Node (6LoSH) reaches an efficiency of QoS and HRPL reliability to reduce the PC. The routing overhead for the number of nodes increases significantly with the increase of the PC. The main contribution of this study, the present result shows that HRPL outperforms the RPL standard of PC in both experiments. However, these results were derived from a limited number of nodes, the Transmission Range (Tx) is 5m, and it was tested for random topology. Further research should be conducted to investigate large-scale networks in multiple topologies for different distances and metrics.

ABSTRACT

The fifth-generation (5G) wireless system was implemented due to the massive connectivity, especially Internet of Things (IoT) including industrial automation, Vehicle to Everything (V2X) communications, which is shelter an extensive range of applications services and use cases and Intelligent Transportation Systems (ITS). A cellular Non-Orthogonal Multiple Access (NOMA) based on radio resource allocation schemes need to be carefully designed to serve and support the diversity of applications and services, through increased safety and traffic efficiency usage of connected vehicle and ranging from infotainment services. In this paper, we develop a novel scheduling and resource allocation algorithm for vehicular communications named Priority -based Scheduling Algorithm for NOMA integrated V2X (PSA). The novel scheme could make the limited radio Resource Blocks (RB) to be assigned in a more efficiently manner to the different traffic classes (safety and non-safety traffic) imposed by V2X exigency, in order to improve the performances of the system in terms of average throughput, Quality of Service (QoS), Average Blocking Rate (ABR) and to ensure fairness criteria between Vehicular User Equipments (VUEs). The performance of PSA is shown for urban macro-cell and rural macro-cell scenarios and we compared it with the conventional OMA and some recent works for NOMA based allocation.

1. Introduction

New 5G technologies supporting vehicular communications considered as a promising and vital role in the blueprint of Intelligent Transportation Systems (ITS), assisting to solve the main problems of transport engineering, improves road safety, traffic efficiency and comfort and infotainment services, try to prevent any fostering and dangerous situations investments in the automotive market [1-3].

V2X connectivity has been developed as a potential concept for 5G which strive to give communication models that can be supported by vehicles in several application contexts including vehicle-to-vehicle (V2V), vehicle-to-infrastructure/network (V2I/N) and vehicle-to-pedestrian (V2P) [4].

V2X will include two complementary sets of specifications for direct transmission which are 802.11p and cellular V2X (C-V2X) standards. The first one is proposed as the lower layers of Wireless Access in the Vehicular Environment (WAVE), it is standardized for V2V defined in USA and recognized as Dedicated Short-Range Communications (DSRC). 802.11p is also designed as the lower layers of the ITS-G5 standard in Europe. It is based on OFDM and which is known as the case of fourth generation (4G) technology LTE (Long Term Evolution). However, the adoption of DSRC has been delayed due to its Medium Access Control (MAC) and physical layer designs that have been planned for Wireless Local Area Networks (WLAN) and its poor scalability and the high-mobility environments that impose communication challenges, and lack of QoS guarantee. In addition, 802.11p indicates that it's restricted range, reliability and undefined performance especially in urban propagation scenarios when scaling up the number of transmitting VUEs [4].

Cellular-V2X is proposed to innovate and deliver an evolution path to 5G and it comes to handle the challenges of 802.11p. The main advantage of C-V2X that is based on a technology originally optimized for high-speed mobile services, which has been enhanced specifically for safety and automotive applications. C-V2X is outperformed 802.11p due to modulation and coding enhancement, to support a better communication range, greater capacity, better congestion control in denser environments with lower packet error rate, higher reliability and superior Non Line-of-Sight (NLoS) performance [4].

*Corresponding Author: Ala Din Trabelsi, trabelsi.ala93@gmail.com

Accordingly, 27 use cases for V2X communications are designed by third-Generation Partnership Project (3GPP) in Release 14 that including two categories of service requirements as safety related applications, like car platooning, autonomous driving, vulnerable road user warning, etc and non-safety related uses cases exemple, dynamic digital map update, mobile hot spot, mobile high data rate entertainment, office, home, etc [5].

More recently, 5G networks anticipate an explosive demand for massive connectivity driven by the ever-increasing number of connected vehicles, Internet of Things (IoT) and the explosive proliferation of mobile Internet, over limited radio resources [6].

The limitation of OMA-based scheme that it has not been efficiently and fully assigning the limited radio resource blocks causing to serious problems as lack of QoS guarantee for NLoS environment. This defiance can be exemplified with the following scenario, consider a single User Equipment (UE) with mediocre channel condition needs to be scheduled for fairness purposes, example this UE has superior priority information or has not been scheduled for a long time. This causes that one of the limited bandwidth resources is only allocated by this UE. In addition, the limitation of the conventional OMA is the number of users that can be served simultaneously. Towards these challenges, 3GPP is motivated to develop new technologies in order to maximizing the achievable throughput. Among various solutions, non-orthogonal multiple access (NOMA) is a very promising access technology. It has been envisioned and recognized as an innovation for 5G mobile networks to increase the number of links, enlarge the spectral efficiency and to ensure the high data rate necessity. It provides enhancements in terms of high reliability, low latency and communication's range for vehicular environments [7].

Using non-orthogonal radio resource allocation, make NOMA to multiplex more than a few users with different power levels into a same frequency resource and time to transfer information. Not only does NOMA support users with good channel conditions but also it serves both others with poor channel conditions and those operate in the same bandwidth resources [8][9].

To enable V2X communications, radio resource management is a vital specification of the MAC layer of the eNodeB, that aims to optimize the use of the limited availability of the spectrum while meeting the requirements of QoS and insure efficient resources scheduling, resource allocation and interference management. Even in 5G networks, a resource allocation technique requires to be carefully developed to satisfy different QoS requirements to achieve target throughput and to maximize spectrum efficiency for several V2X traffics and services.

The paper contributions are as following:

- Taking into account traffic classification, such as Safety Traffic (ST) and Non Safety one (NST) are considered
- A resource allocation algorithm called Priority -based Scheduling Algorithm for NOMA integrated V2X (PSA) is proposed.
- Adding a scheduling priority which is determined according to the channel condition for each VUE, users with higher priority will be selected for NOMA sharing.
- Due to the diversity and multitude of the propagation scenarios, various simulations are presented for performance evaluation for rural macro-cell and urban macro- cell, to demonstrate the efficiency and the applicability of the proposed PSA algorithm for any propagation scenarios.
- Validate the proposed PSA algorithm with several Matlab simulations showing the aggregate throughput, the fairness index and the ABR among different VUE traffic classes.
- Compare the proposed algorithm with the conventional OMA
- Evaluate the PSA algorithm with some recent works for NOMA based allocation.

This paper is presented as follows we study same proposed method as related works in section 2. We detail our approach in section 3. In the section 4 and 5 we portray its different steps. We evaluate and analyze the performances of the developed scheduler in section 6. Finally, in Section 7, we determine our work by conclusion and perspective as future work.

2. Related Work

The radio resources management task to enable V2X communications has been investigated in several research works such as:

In [10], the authors developed a novel resource allocation algorithm to maximize the number of scheduled V2N communications while satisfying the required latency for the several priority classes of the V2V links (two class of priority are defined, where the messages in the class 1 are more critical and aware to the latency comparing to messages in the second one). They perform the power allocation for potential resource reusing. Then, they selected the finest reusing pattern by employing the Hungarian scheme. However, this method does not take NOMA systems in consideration and the performance evaluations focused only to present the average latency.

In [11], the authors studied the resource allocation process when the periodic messages are not all at the same size in cellular V2X networks. They addressed an optimization problem for maximizing number of vehicles that can be allocated simultaneously without interfering each other. Then, they provided the same algorithm to solve optimization problem then evaluate its performance by increasing number of vehicles when a trade-off between range and density of vehicle is guaranteed. However, NOMA scenarios issue was usually ignored in design of the resource allocation algorithm.

In [12], the authors developed a novel resource allocation scheme for Power domain based a cooperative multi-cell network by using the cellular mode. This algorithm aims to improve the spectral efficiency of the system and achieves the desired QoS. They assume a communication scenario for two pairs of users sharing the same sub-carrier to transmit their information, where the primary users characterized by delay-sensitive communication that requires stringent QoS exigency as well as the minimum transmission rate, share the same radio RB with the secondary users which support non-delay sensitive or elastic traffic and exploit the physical resources of the network in a best-effort manner. Successive convex approximation (SCA) method is the

best solution to solve general optimization issues, they adopt the successive convex approximation (SCA). Furthermore, they investigate the computational complexity of the designed approach and they compare our work with existing transmission methods based on Orthogonal Frequency Multiple Access (OFDMA). However, this approach does not hit the V2X links requirements.

Some recent research has begun to explore efficient energy NOMA design were given in [13-16]. They presented a general overview of NOMA techniques and seek to optimize the power allocation problem in order to improve Energy Efficiency (EE). Then, they proposed a low complexity power allocation approach. However, those algorithms do not cover V2X links, traffic classifications and heterogeneous QoS requirements for each VUE link.

In [17], the authors focus on the problem of clustering users in groups of different size, and assigning RB to each cluster based on Power-Domain (PD-NOMA) scheme. Clustering and RB allocation are performed as stated by Proportional Fairness (PF) technique with the main objective that obtaining high cell throughput, low complexity and guaranteeing NOMA relevance. The performance evaluation of the clustering algorithm proposed Relevant Clustering (RC) compared with two other algorithms named Ordered Clustering (OC) and Disparity Clustering (DC). However, traffic classifications such safety information for the V2X links is not considered in this algorithm.

In [18], the authors improved proportional fair scheduling scheme for NOMA system, called a spectrum resource and power allocation algorithm with Adaptive Proportional Fair (APF) user pairing with low complexity. This algorithm aims to maximize system throughput and considers the fairness among UE by selecting the user pairing with higher priority expressed by the channel gain. For the optimizing the power allocation, they explore different power allocation schemes which focusing on the proportional rate constraint so as to ensure the best throughput performance. The limitation of this approach that does not considering V2X traffic classifications.

In [19], the authors have addressed and investigated the power allocation problem in downlink Multiple Carriers Non-Orthogonal Multiple Access (MC-NOMA) systems for maximizing Weighted Sum Rate (WSR) by considering imperfect successive interference cancellation, in order to present an iterative power allocation with low-complexity algorithm. Moreover, they have presented a joint user scheduling and power allocation scheme for the MC-NOMA systems. The proposed methods can achieve an optimal WSR performance and user fairness improvement compared to OMA and other existing schemes. However, the system model only considered each sub- channel can be multiplexed by two users no user priority and service classification are treated.

In [20], the authors investigated the benefits of 5G technologies based on NOMA to support massive connections services to group and assign the required sub-channel of the internet of things equipment. To show how the quality of experience requirements of IoT links affect the needed number of physical RBs in real time, they developed a novel method to improve spectrum distribution and to control IoT links mobility by using Non-Orthogonal Multiple Access technique for autonomous vehicles. The designed solution aims to maximize throughput, to contribute QoS improvement and exploiting k-means grouping to reply to the dynamics of the system and minimize the complexity of re-arranging NOMA clusters. The regrouping of IoT connections according to distance while considering the maximum supported devices by group. Therefore, they determined the requisite set of RB for each group of UEs based on the QoS requirement. However, IoT equipments are clustered without considering their type of traffic.

In [21], the authors is introduced an over view on optimization problems of scheduling and NOMA approaches. They planned a novel scheduling and resource allocation scheme based on NOMA-enhanced cellular network for device-to-device (D2D) communications called Tree-based Search power allocation Algorithm (TSA). This scheme is compared and evaluated with several statistic models for user scheduling algorithms, users selection problems for the D2D communications underlying cellular network based on NOMA technology and power allocation strategies such as FRPA (FRactional Power Allocation) and FIPA (FIxed Power Allocation algorithm) where their mean objectives are mitigating computational complexity of the algorithm, increase network capacity, guarantying the QoS and maintaining a better system throughput. The simulation results clearly demonstrate the superiority of TSA compared with traditional algorithms. However, the proposed algorithm does not consider V2X links and traffic classification (ST and NST).

In [22], the authors designed a new method entitled proportional-fairness based user pairing and power allocation algorithm for NOMA uplink transmission. This method is introduced to serve two scenarios: the first one is when user equipments are only distributed in the coverage area of the cell and the second one which is the more complex that is when the interference users are distributed outside of the cell. For scenario one, to optimize the problem they decoupled the User Pairing (UP) part and Power Allocation (PA) part. In the power allocation part, they classify the pairs of users by considering their channel condition and SINR constraint and they developed different power allocation techniques. While in the user pairing part, they designed a probability-based tabu search user-pairing algorithm (PTS). For scenario two, they carried out a prediction-based particle swarm optimization (PBPSO) power allocation algorithm with a low computational complexity to obtain a good proportional fairness performance under the constraints of outage probability. Then, they combine PBPSO and PTS to achieve high system performance in terms of average throughput and outage probability. However, this algorithm assigns the RB for the pairs of users independently of their type of traffic class.

In [23], the authors investigated the global throughput maximization for two UE with timeliness transmission over fading channels for partial and full Channel State Information at the Transmitter (CSIT). This approach supports certain level of fairness and the minimum average throughput constraint. In the full case of CSIT case, the dynamic resource allocation method was optimally determined by using lagrangian dual decay, while in the partial CSIT one, the power allocation technique was proposed focused on investigative results. However, the limitation of this algorithm that does not takes into account the demanded QoS requirements for users and the traffics classifications. The simulation results are investigated with limited parameters setting.

In addition, the required bandwidth to enable ST V2X services in NOMA has not been studied.

In [24], the authors are introduced an over view on the optimization scheduler problem joined with NOMA techniques. They developed and simulated some statistic models for user scheduling strategies and power allocation approaches which aim to achieve the different objectives as minimizing the computational complexity of the algorithm, satisfy the required QoS and obtaining a better system performance in terms of average sum rate and equity criteria. Also, they select Proportional Fairness (PF) and Round-Robin (RR) as a shared model of scheduling and NOMA techniques, to evaluate the optimization problem of power allocation for combined NOMA and round-robin scheduling scheme and proposing an optimization strategy for joint NOMA algorithms and Proportional Fairness scheduling which assure the required QoS. However, the proposed scheme doesn't reflect on the V2X link environments and traffic classifications.

The table 1 illustrates all the mentioned algorithms above. All related work mentioned above doesn't take charge the traffic classifications while seeking the throughput performance gain. Nevertheless, the benefits of V2X ST class at the road cannot be exploited successfully by these algorithms. Despite the existing literature, there is a lack of priority constraint-based scheduling scheme that marked the transmission ranking to each connection but it restricted just by the Channel Quality Indicator (CQI). In addition, diverse algorithms presented above didn't balance cell throughput, equity index and take the system-level QoS for V2X links, new solutions must be provided.

3. System model

The used input and variable parameters are given below.

3.1. System Model

In order to evaluate our proposal work, we consider NOMA scheme consists of a single base station and N connected VUEs denoted by I = {1,....j,…,N}. We suppose that the number of available RBs in the cell is M where the resource blocks set U = {1,…i,…,M}. To assure the required capacity of the N vehicular connections, we suppose that PD-NOMA (Power-Domain NOMA) technique linking by the base station. NOMA is a scheme used to appreciate multiple accesses by utilizing power domain in a spectrally resourceful way and can schedule multiple vehicular user equipments in the same radio resource. This can be maintained by assigning dissimilar power levels to VUEs. Moreover, NOMA scheme is expected to allocate more power level to the VUEs with poor channel qualities. Denote the power of VUE_j on subcarrier k by $P_{j,k}$, satisfying $\sum_{j \in N} P_{j,k} \leq P_j^{max}$, where $P_j^{max} = P$ is the maximum power constraint allocated for VUE_j. Therefore, we assume that $N \geq 2M$ for dense environment and each vehicular user assign to one RB in the same Transmission Time Interval (TTI) while the entire other not scheduled vehicular users are not allocated. In addition, we assume that the distribution and the position of links are supposed random in the coverage area.

To maintain the improvements of V2X link, radio resource allocation and Transmitter -Receiver selection are managed by the eNodeB in each TTI.

Table 1: Comparison between different algorithms studied above

Table 2: Notations

Symbol	Description
N	Connected VUEs.
I	Set of vehicular uses equipments.
M	Available RBs.
U	Set of resources blocks

P_{ST}, P_{MT}, P_{IT}	Percentage of safety, management and infotainment class of traffic.
N_{ST}, N_{MT}, N_{IT}	Number of active VUEs for each class of traffic.
φ, ψ	Set of safety and non safety VUEs.
$N_{NST}= N_{MT}+N_{IT}$	Number of NST VUEs.
Ć, Ŕ	Set of ST and NST VUEs candidates that can be served to different resource.
P_{factor}	The power level for VUE.
H_ST	Channel coefficient of safety VUE.
H_NST	Channel coefficient of non-safety VUE.
thr_min_safety	Minimum throughput for safety traffic requirement.
H_safety	Matrix contains the channel coefficient of safety VUEs.
H_nonsafety	Matrix contains the channel coefficient of non- safety VUEs.

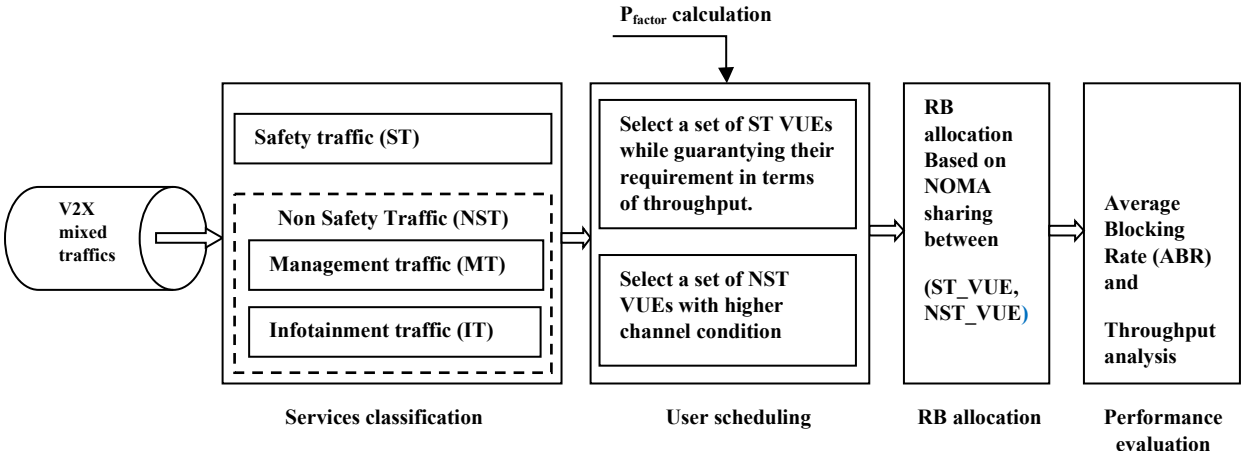

Figure 1: PSA system model

Using NOMA system, the eNodeB superimposes the message waveforms with different assigned power level for its selected users. At the Rx, successive interference cancellation (SIC) schemes are employed to cancel multi-user interferences and each user detects its own signal. The receivers with higher channel gain apply SIC for signal decoding. Therefore, those the modulated symbols are subtracted and removed from the united data until the associated UE obtains the desired message [6].E.g., consider two Tx: VUE_{j1} and VUE_{j2} occupying the RB_i in the current TTI transmitting to receiver VUE_m satisfying $P_{j1,k}^{(i)} \left|H_{j1,m,k)}^{(i)}\right|^2 < P_{j2,k}^{(i)} \left|H_{j2,m,k}^{(i)}\right|^2$, where $P_{jn,k}^{(i)}$ representing the transmit power of the transmitter VUE_{jn}, n $\in\{1, 2\}$. $H_{j2,m,k}^{(i)}$ presentes the channel coefficient of the subchannel k which allocated for the vehicular user VUE_{jn} in the RB_i. The receiver VUE_m deals the signal of the great channel condition VUE_{j2} as a noise, first, detects and remodels the signal of the inferior channel gain of VUE_{j1}, then, exploits the SIC technique to cancel or withdraw the signal of VUE_{j1} which has the mediocre channel condition to get signal of VUE_{j2}.

Generally, the signal x_k, transmitted by the eNodeB at a certain sub-band k is a simple power multiplexing of the symbols generated by the scheduled users.

$$x_k = \sum_{j\in N_m} x_{j,m,k} = \sum_{j\in N_m} \sqrt{P_{j,k}^{(i)}}\, s_j^{(i)} \quad (1)$$

Denotes $N_m=\{1 \le j \le N \mid \max (SINR_{j,m}^{(i)})\}$: presents the set of VUEs inside receiver vehicular UE m's communication range of interest. $P_{j,k}^{(i)}$ is the power allocated to user j at sub-band k and $S_j^{(i)}$ indicates the transmitted signal of Tx VUE_j.

The received signal vector corresponding to the time slot i can be defined by:

$$Y_{m,k}^{(i)} = H_{j,m,k}^{(i)} x_{j,m,k} + n_m^{(i)}$$
$$= \sum_{j\in N_m} \gamma_j^{(i)} \cdot \mu_{j,k}^{(i)} \sqrt{P_{j,k}^{(i)}} H_{j,m,k}^{(i)} S_j^{(i)} + n_m^{(i)} \quad (2)$$

where:

$\gamma_j^{(i)}$: Binary variable denotes that RB_i is assigned by the BS to VUE_j.

$\mu_{j,k}^{(i)}$: Binary variable indicates that subchannel k is assigned by the eNodeB to VUE_j.

$H_{j,m,k}^{(i)}$: presents the channel coefficient of subchannel k between Tx_j and Rx_m in RB_i.

$n_m^{(i)}$: CN~$(0,\sigma^2)$ is the additive white Gaussian noise (AWGN) for reciever VUE_m, and σ^2 is the noise variance. Furthermore, the channel gain can be defined as:

$$H_{j,m}^{(i)} = G \cdot h_{j,m,k}^{(i)} \cdot \beta \cdot \left(d_{j,m}^{(i)}\right)^{-\alpha} \quad (3)$$

Denotes:

G: Constant power gain factor implied by the amplifier and antenna.

$h_{j,m,k}^{(i)}$: Complex Gaussian variable CN (0,1) indicates the rayleigh fading.

β: Shadowing fading.

$d_{j,m}^{(i)}$: Distance between VUE_j and VUE_m.

α: Path loss exponent.

3.2. Propagation Scenario

Many covered propagation scenarios are detailed in [25] and [26]. It is indispensable to extend such modeling and measurement efforts to various environments that are also very important for V2X communications, mainly when safety applications are supported. Moreover, modeling a radio channel has been one of the most challenges in the mobile radio system design, and it is based on measurements specifically made for an intended communication system. Propagation models are the base for channel modeling, as they try to describe the way a radio signal changes during its travel distances from the Tx to the Rx and to mitigate interference. Also, radio propagation has a significant impact on the performance of cellular mobile radio systems due to increased data rate, bandwidth, mobility and QoS.

Then more, the trajectory between the Tx and the R can differ from a simple Line Of Sight (LOS) to a line that is obstructed by mountains, buildings, or foliage, named Non line of sight (NLOS).

The main characteristics of the radio channel - such as path loss, fading and time-delay spread and the parameterization vary from each scenario to an other one similar environments.

The macro-cell propagation can be divided into two classes as urban macro-cell propagation and rural macro-cell one. As the surrounding building heights, the density of obstacles and the number of users is very high in urban area, the cellular network is more robust and complicated where one macrocell antenna serves many microcells and picocells to ensure a better service compared to rural area because of the presence of less buildings and obstacles in the area [26].

For our work, we focus on rural macro-cell and urban macro-cell senarios with vehicles travelling on multiple lanes and on random position in the cell, including other pedestrians. Since we are considering the network-controlled allocation under independent Rayleigh fading channel and the line of sight (LOS) propagation properties of the vehicular networks, without loss of generality, we only incorporate the effect of the distance dependent path loss between the eNodeB and each VUE into analysis. Therfore, Path-loss models play an important role in the design of cellular systems to specify key system parameters such as antenna heights, frequency, transmission power and so on.

According to [26], The path-loss models are parameterized and controlled using results from a wide-ranging set of measurement campaigns, and they are extensively used and accepted.

Path loss (PL) is a measure of the average radio frequency attenuation suffered by a transmitted signal when it reaches the receiver, after traversing a path of several wavelengths [25]. It is defined by:

$$PL=\alpha*\log10(d[m])+B+C*\log10(fc[Ghz]/5) \quad (4)$$

Were, the fitting parameter α includes the path-loss exponent, B is the intercept, C describes the path loss frequency dependence and fc is the center frequency.

However, the path loss frequency dependencies model used in our scenarios are defined below:

$$PL_{Rural}[dB] = 40*\log10(d[m])+10.5-18.5*\log10(h_{BS}[m])-18.5*\log10(h_{MS}[m])+1.5*\log10(fc*1e-9/5) \quad (5)$$

$$PL_{Urban}[dB] = 40*\log10(d[m])+13.47-14*\log10(h_{BS}[m])-14*\log10(h_{MS}[m])+6*\log10(fc*1e-9/5) \quad (6)$$

where, h_{BS} and h_{MS} are the antenna heights at the base station and the mobile station respectively. d denotes the distance between the Tx and the Rx.

4. Proposed Algorithm

This proposed technique aims achieve a higher cell throughput, consider the heterogeneity of VUEs channel gains and the equity criteria. This algorithm trys to increase the number of served safety V2X links in the cell while a minimum requirement must be guaranteed on terms of throughput and to maximize the average data rate of the NST VUEs.

Our proposed algorithm named Priority -based Scheduling Algorithm for NOMA integrated V2X (PSA), can be considered as an assignment solution that aims to obtain an efficient and optimal spectrum allocation for VUE. Firstly, we begin by services classification, also, the incoming links of the VUE are classifyed according to their types of services as: safety traffic and non safety traffic . The NST is divited into two type of services as Management Traffic (MT) and Infotainment Traffic (IT).

Then, we assign the physical resources blocks to the pairs VUEs which can occupy the same spectrum by taking into account the channel condition of the transmitters on each RB. The designed approach enhances the equity index in the processus of resource allocation among diverse VUEs class of services. In fact, if the selected VUE has already assigned to an RB during the current TTI, this one will have't another radio resource block in the same TTI while all the selected users are not served. This, at the same time, raises the spectral efficiency and the capacity of the system inside the coverage area, and ensures a better compromise between the average throughput and the fairness index.

Once, the RB allocation is performed, a power control process is used to treat the interference and minimize the binary error rate by calculating per each resource block the P_{factor} that allows the safety user to obtain the needed throughput as well as maximizing throughput of the non-safety user, also, each VUE can attain on the allocated RB without minimizing its achieved throughput. The non-scheduled safety VUEs in the present TTI will be selected with the superior priority to be served for the subsequently TTI. The scheduling algorithm of our system is shown in Figure 1.

The mean objective of our proposed algorithm PSA is maximizing: the cell throughput, the number of served VUEs, the number of served safety VUEs, the sum rate of non-safety communications. We try to minimize the interference inter VUEs using the same RB by imposing a power constraint for different vehicular UEs.

5. Description of the Proposed Algorithm

In this part, we present more details for all steps of our proposed strategy.

5.1. Step 1: Service Classification

NOMA resource allocation schemes need to be designed to serve the ever-increasing number of vehicles that are connected for different services, such as safety features and passengers multimedia amenities.

V2X services are a real time traffics and arrive with strict exigency on throughput, reliability and latency. Also, we consider two types of service classes as Safety Traffic (ST) that imposes timeliness requirements, network scalability, and stringent reliability and refers to the case when the transmit signals need high QoS and requires to be selected almost momentarily in order to minimize road accidents, such as traffic condition warning, curve speed warning, vulnerable road user warning and emergency vehicle warning [27].

The NST (Non Safety traffic) included two categories of services: MT and IT. The Management traffic required to be scheduled with most importance thanks to their significance which aims to enhance traffic flow by minimizing traffic congestion and travel time, examples traffic information and recommended, intersection management, regulatory speed limit and automated parking system [28].

Infotainment Traffics are characterized by the delay tolerance and provides convenience applications and comfort for VUEs to improve their driving experience, exemples media downloading, vehicle software update and data provisioning [28].

The idea of the first step is to sort the arriving vehicular links according to their type of service that are: ST, MT and IT.

5.2. Step 2: User Scheduling

Scheduler functionality is to allocate the RBs to the UEs according to their requested requirements and their radio conditions at every TTI. So, the available resources blocs are very limited and it has to be allocated with an optimal manner that highest cell throughput and equity index are ensured among all VUEs, applications or service classes.

The system comprises two categories of V2X communications. Let $\varphi=\{1\ldots j,\ldots N_{ST}\}$ the set of Vehicular users with Safety Traffic (VST) and $\psi=\{1\ldots j',\ldots N_{NST}\}$ the set of VUEs with Non Safety Traffics (VNST), where $\{\varphi, \psi\} \in \{I\}$.

Moreover, the purpose of this step is: firstly, to select a set of VST by $\acute{C} \in \{\varphi\}$ while guarantying their requirement in terms of throughput. The idea is to search the combination (VST_j, RB_i) where $1 \leq j \leq N_{ST}$ and $1 \leq i \leq M$, with the highest metric on the RB_i. This metric expresses the channel gain between the VST_j, $j \in N_{ST}$ and the receiver m on subcarrier k, denotes by $\left|H_{j,m,k)}^{(i)}\right|^2$, which includes both small-scale Rayleigh fading and large-scale path loss.

Secondly, to select a set of VNST by $\acute{R} \in \{\psi\}$ that will be shared the same $RB_i$with VST. The selection of VNST is based on the higher channel condition expressed by the estimated SINR which corresponds to the CQI (Channel Quality Indicator) index sent by the VNST to the eNodeB.

Also, priority users scheduling considered as an important tasks to enhance the network performances in terms of aggregate sum rate and equity index before the resource allocation.

5.3. Step 3: RBs Allocation

The third step is designed based on NOMA to maximize the aggregate throughput of the system by assigned the limited physical RB to pair of VUEs (VSTj, VNSTj') selected in the above step. Exploiting the knowledge on vehicle positions and propagation characteristics at the eNodeB, this latter allocate the resources to guarantee the required quality of service and maximize the network capacity. Moreover, the proposed RB allocation method is divided on two processes. Starting with the RB allocation for ST communications which aims to allocate the candidate $\acute{C} \in \{\varphi\}$ safety users to different resource blocs and set a minimum requirement must be guaranteed for those. Then, the RB allocation for VNST candidate $\acute{R} \in \{\psi\}$

The proposed scheme offered superior priority to the safety links than others type of traffics because they can't tolerate delay and must be scheduled and served immediately without forgetting to taking into considiration the equity index. Moreover, in this step the scheduler checks if each VST has the minimum requirement in terms of throughput. In fact, if the VUE is't satisfied, for the scheduler, this vehicular user is reselected to transmit for the next TTI. This allows us to maximize the served VUEs number by trying to give each one his requested requirement. The algorithm for RB allocation is summarized as following.

Algorithm 1: RB allocation

```
{Initialization};
// select the set B safety VUE candidates can be served to
different resource blocs;
Check each line of the matrix H_safety and calculate the
matrix rb_acceptable_safety : if a single allocation is
acceptable that is used (where an allocation can be used is '1'
or can't be used is '0');
at_least_one_allocated = true;

While i=1 to N at_least_one_allocated do
    at_least_one_allocated = false;

    For i=1 to all the vehicle of safety traffic do
        if sum(rb_acceptable_safety(i,:))==1 then
            Find the best VUE candidate to be served at the
            rb_to_allocate;
            Select the best VUE candidate to be served at the
            rb_to_allocate;
```

```
        Store the number of selected VUE corresponds to
        the index the rb_to_allocate which granting the
        minimum requirement in terms of throughput;
        at_least_one_allocated = true;
      end
    end
  End
  // Allocate the different RBs for the selected Ć safety
  VUEs.
  While sum(sum(rb_acceptable_safety(:,:))) > 0 do
    Calculate H_safety matrix of the channel coefficient per
    each selected VUE at the rb_to_allocate;
    Find (ue_to_allocate,rb_to_allocate) = max h_matrix
    (ue_to_allocate,rb_to_allocate), with
    (ue_to_allocate,rb_to_allocate) ∈ Ć X U;
    Selecting the best VUE with highest channel gain;
    Remove the ue_to_allocate row from h_matrix;
    Assign rb_to_allocate to ue_to_allocate ;
    Update U: U = U \ { rb_to_allocate };
    Update Ć: Ć = Ć \ { ue_to_allocate };
  End
```

We define an indicator defined by a variable s_j^i , (i∈M, j∈N) which indicates if the i^{th} RB is assigned to j^{th} VUE or not.

$$S_j^i = \begin{cases} 1 & \text{if } RB_i \text{ is used by } VUE_j \\ 0 & \text{otherwise} \end{cases} \quad (7)$$

This step is designed to maximize non safety vehicular users throughput (for both management and infotainment VUEs) by prioritizing the users with good channel condition and not to starve others with bad channels condition.

Specifically, the SINR at the receiver Rx with the highest channel gain which can cancel the interference is computed as:

$$SINR_{j,k} = \frac{s_j^{(i)} P_{factor}^{(i)} P \rho_{j,m,k}^{(i)}}{1 + \sum_{l \in L_n, l \neq j} (1 - P_{Factor}^{(i)}) P \rho_{l,m,k}^{(i)}} \quad (8)$$

where Ln represents the subset of the interfered VUEs when the receiver m exploiting the resource block for the transmission.

5.4. Step 4: Performance Evaluation

To collect the benefits of the output of our proposed scheme, certain performance evaluations are need to be addressed such as cell throughput and average blocking rate.

Algorithm 2 briefly describes this process.

Due to the unavailability of radio resources, ABR is a typical constraint for VUE with safety traffic (VST) in PSA which aims to maximize served VST thanks to their high priority, great QoS requirement and due to better road utilization and surroundings. The average blocking rate is calculated as following:

$$ABR = \frac{\text{Number of blocked transmitters}}{\text{Total number of VST}} \quad (9)$$

Algorithm 2: Throughput calculation

```
For i=1 to N do
  RBi is used by safety VUE then;
  Determinate the channel coefficient H_ST of the selected
  safety VUE;
  Determinate the channel coefficient H_NST of the selected
  non safety VUE;

  If H_ST > H_NST then
    % safety is the primary VUE that cancels the
    interference
    Calculete P_factor;
    P_factor= (N0/(P*H_ST))*(2^(thr_min_safety/Bw_rb)-
    1);
    % N0: Additive White Gaussian Noise (AWGN);
    Calculate the throughput of safety VUEi;
    thr_user_safety=(Bw_rb)*log2(1+(P*(P_factor)*H_ST/(P
    *(1-P_factor)* H_ST + N0)));
    Calculate the throughput of non safetyVUEi;
    thr_user_nonsafety= (Bw_rb)*log2(1+(P*(1-P_factor) *
    H_NST / (P * P_factor * H_NST+N0)));
  else
    % safety is the secondary VUE that cannot cancel the
    interference;
    P_factor= (2^(thr_min_safety/Bw_rb)-1)*(P*H_ST+N0) /
    ( 2^( thr_min_safety / Bw_rb)*(P*H_ST));
    Calculate the throughput of safety VUEi:
    thr_user_safety=(Bw_rb)*log2(1+(P*(P_factor)*H_ST/(
    P*(1-P_factor)*H_ST+N0)));
    Calculate the throughput of non- safety VUEi;
    thr_user_nonsafety = (Bw_rb)*log2(1+(P*(1-P_factor)*
    H_NST / N0 ));

  end
end
```

In this step we calculate per each resource block the Pfactor that allows the safety VUE to obtain the needed throughput and to maximize the sum rate of non-safety VUE at the same time. Indeed, the objective is to take into account power split between the two vehicular users which share the same RB to minimize the interference.

The achievable data rate obtained from VUE_j over sub-channel k at the RB_i can be mathematically formulated as:

$$R_{j,m,k}^{(i)} = B_W \log_2 \left(1 + \frac{s_j^{(i)} P_{Factor}^{(i)} P \rho_{j,m,k}^{(i)}}{1 + \sum_{l \in L_n, l \neq j} (1 - P_{Factor}^{(i)}) P \rho_{l,m,k}^{(i)}} \right) \quad (10)$$

6. Simulation Results

In this section, simulation results based on Matlab are presented and performed to demonstrate and validate the efficiency of the developed PSA schemes. We assume that the position and the distribution of vehicular users are randomly in the

coverage area for the current TTI. Simulation results provide a better insight of various issues i.e. average throughput, BER and fairness analysis. In addition, we vary the percentage of ST and NST services, we take as an example three scenarios that are mentioned in table 3where scenario 1 is oriented Non Safety Traffic (NST), scenario 2 is marked by equity of percentage of traffic and the last one is oriented Safety Traffic (ST), in order to evaluate the system performance and show that our algorithm is efficient and applicable for any scenarios. So the objective of these scenarios is to highlight the effect of the priority on the average blocking rate, the cell throughput and the equity index. Moreover, the performance results of the developed algorithm are compared with the conventional OMA based allocation which is detailed in [29] and some recent works for NOMA based allocation to demonstrate the benefits of our proposed approach.

Table 3: Parameter setting

Parameter	Value		
Bandwidth	10 MHz		
Available resource blocks	50		
connected VUEs in the cell	[100, 150]		
eNodeB in the coverage area	1		
Transmitted power	15 dBm		
Number of VUEs allocated the same spectrum	2		
TTI	1 ms		
	Scenario 1	Scenario 2	Scenario 3
Percentage of ST services	30%	50%	70%
Percentage of MT services	40%	30%	20%
Percentage of IT services	30%	20%	10%

The used parameters for simulation results are announced below in Table 3.

6.1. ABR Analysis

ABR is an important Key Performance Indicators (KPIs) [30]. It is presenting the ratio between the number of blocked transmitter VUEs due to the limited spectrum and the total number of vehicular users defined for each scenario. Moreover, the average blocking rate achieved by the PSA algorithm was calculated by their average values for all scenarios and traced as illustrated in Figure 2.

While increasing the number of connected vehicular UEs in the coverage area, the average blocking rate raises a little or will be perpetually starved in scenario 1 due to the limitation of radio resource blocks. We mark that the raise of average blocking rate is less important for safety traffic in scenario 1 than the others one, those explain that the RBs are assigned based on the type of traffic connections. Scenario 1 is oriented NST traffics, so the number of VST is less than the number of VNST. In addition, the main objective of the proposed approach is to maximize the number of vehiclar users served by assigning a physical RB to two VUEs and by giving more priority to the safety links which must be served immediately due to their timeliness requirement. In scenario 1 and 2, the user with good channel condition can guarantee the minimum required QoS, has a superior priority to be scheduled while VUE with a mediocre channel gain waiting their access, which conducts to a equity problem and high latency. PSA aims to allocate multiple VUEs with diverse channel qualities simultaneously. Moreover, it can supply an enhancement by ensuring massive connectivity as indicated in Figure 2.

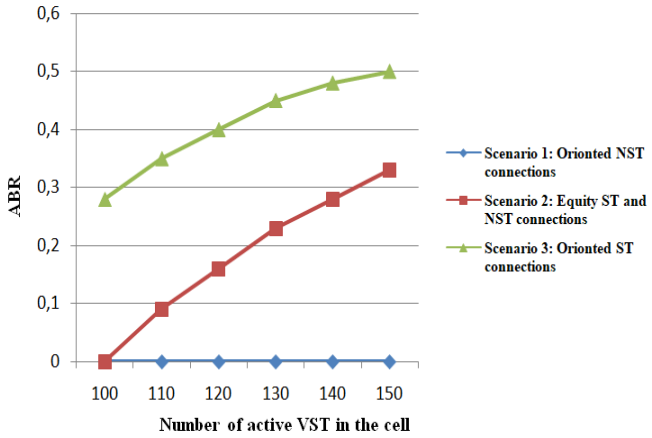

Figure 2: ABR analysis for ST communications

6.2. Cell Throughput

Maximizing average throughput is the principal goal of our algorithm. Figure 3 illustrates the performance of PSA scheme in terms of overal throughput for the three already mentioned scenarios versus the number of connected links in the cell.

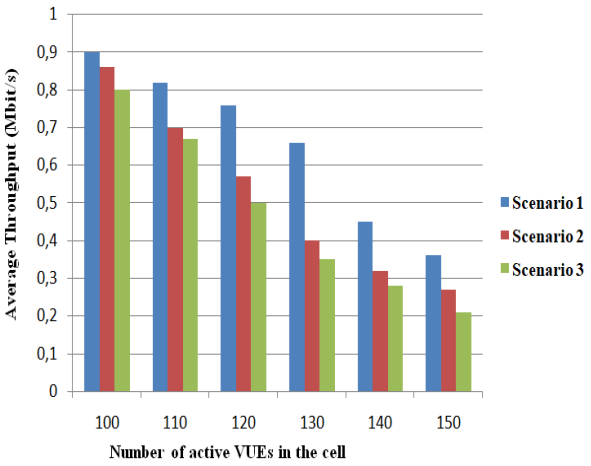

Figure 3: Average throughput analysis for NOMA (Rural Macro-cell)

We show that the raise in cell throughput is more better for scenario 1 than for scenario 2 and scenario 3 which is less efficient. From the Figure 3, it is observed that the total throughput of the proposed algorithm gradually decreases when the number of VUEs increases. This is due to the large demand on resources blocs. Since the proposed algorithm cancels the waste of the RBs by updating the metric before each new allocation and by maximizing the use of available RBs. Indeed, the proposed algorithm achieve 0,9 Mbps (scenario 1) when the targeted active VUEs in the cell is

equal to 100. This scenario oriented to be NST, while this type of traffics needs a high throughput to provide desired QoS. On the other hand, scenario 3 is oriented safety traffic. Taking into account the type of communications, this increase affects the throughput because in real world scenarios not all V2X connected links are safety communication and not all VUEs are close to the base station. ST connections often requires stringent exigency as will as low latency and high reliability. Indeed, safety traffics representing small data packets compared to non safety traffics. For ST connection like control loss warning, pre-crash sensing warning, forward collision warning and queue warning, the short transmit packets have a size of 50-300 Bytes [31] [32]. Figure 3 shows that the acheived throughput for ST can support several packets sizes. So, PSA allows exchanging packets size along to 120 Bytes when the average sum rate is equal to 0.9 Mbps. Moreover, the results satisfy the recommendation which is imposed by 3GPP organization when the lowest message size is 50 Bytes.

Indeed, Figure 4 shows how the cell throughput varies according to the number of active connections in the coverage area for the conventional OMA.

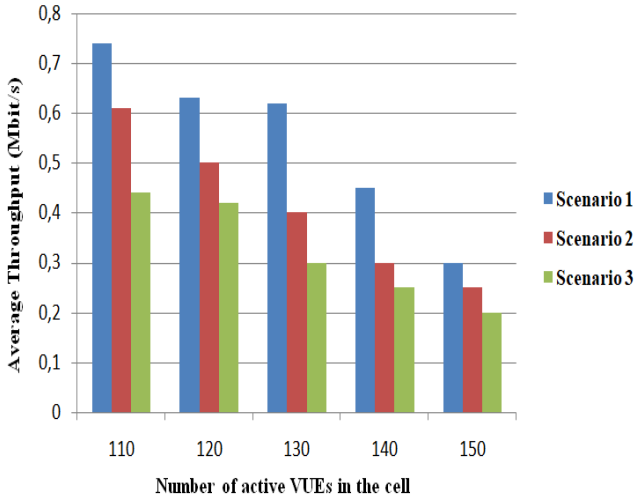

Figure 4: Average throughput analysis for OMA (Rural Macro-cell)

It's obvious that overall throughput decreases when VUEs increases. From that, it is clear that NOMA outperforms OMA even in all scenarios, which verifies that PSA based on NOMA can attain a higher cell throughput than OMA which has a gap to the greatest attainable cell throughput due to it uselessness on active V2X links selection. So, our proposed algorithm out performs OMA-based scheme due to a better resources allocation.

This is because PSA effectively preserves user diversity by its RB allocation metric. Unlike OMA scheduler, NOMA can simultaneously ensure optimal use a huge number of VUEs as well as performing better QoS requirements.

System model of our proposed algorithm does not consider only rural propagation scenario but also urban environment. Figure 5 illustrates the average throughput varies with the number of connected vehicular users in the cell for urban macro-cell propagation scenario evaluated for three different scenarios.

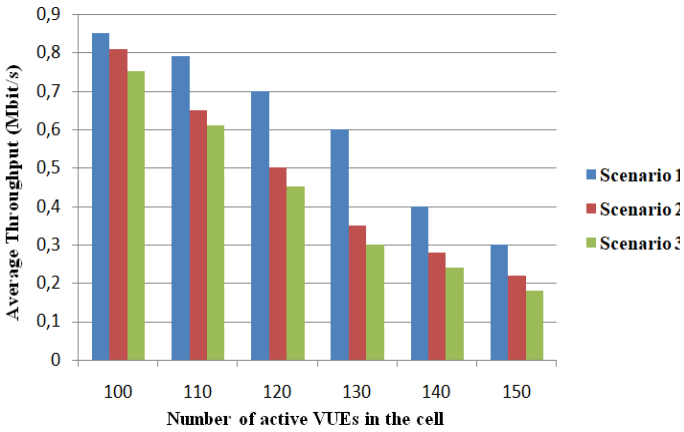

Figure 5: Average throughput analysis (Urban Mcro-cell)

Urban macro-cell propagation will face much path loss due to various properties, such as diffraction, reflection, refraction, absorption, free space loss, coupling loss and aperture-medium compared to the rural macro-cell propagation. This is confirming that the average sum rate for rural macro-cell outperforms the urban macro-cell average throughput as shown in figure 5. Moreover, all propagation scenarios based on NOMA algorithms are much better compared to OMA one, which confirming the convergence and stability of our proposed algorithm and verifying that NOMA can obtain a higher system throughput than OMA.

In addition, Figure 6 displays the system throughput of the developed resource allocation approach PSA compared with the attainable system throughput in [21] versus of the number of vehicular UEs in the system. Our algorithm is compared to [21], already detailed in related work section, because we find that this reference present the most high throughput compared to other studied related works.

Tree-based Search power Allocation algorithm (TSA) can both solve the link selection problems, user scheduling and power allocation with a low computational complexity for Device to Device underlaying cellular network based on NOMA techniques to increase the average throughput [21].

For FIxed (channel-Independent) Power Allocation algorithm (FIPA), the set of users is sorted in the decreasing normalized channel gain order, the system reaches to assign more power level to users experiencing high channel qualities based on the fixed weighted sum of the instantaneous throughput [33].

For FRactional Power Allocation (FRPA), the transmission power control depends on channel condition variations among users. Respective users must be informed by allocated power through explicit control signaling, which differentiates this allocation from the fixed power allocation [33].

For our proposed PSA algorithm and TSA defined in [21], the cell throughput increases with a varying speed that increasingly slows down due to increasing the number of connected VEUs in the system.

From Figure 6, the increment of the average throughput, PSA is better than TSA and therefore outperforms the other three algorithms FRPA and FIPA.

Figure 6 also clearly demonstrates the superiority of PSA that outperforms the compared scheme in terms of sum rate since the proposed algorithm takes into account the service classification and the channel gains of the respective non-orthogonally multiplexed VUEs.

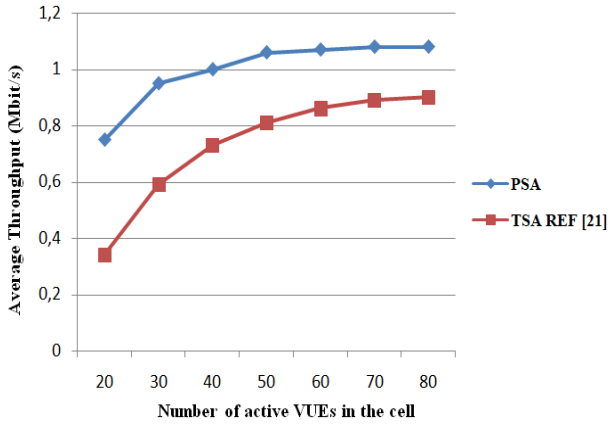

Figure 6: Average throughput analysis

6.3. Fair Index

The developed solution focuses on priority management to serve users fairly and increase the number of served VUEs. Fairness is a key factor for evaluating the simulation results of scheduling and resource allocation schemes, its calculates the equity index among VUEs. As PSA aims to maximize the minimum achievable instantaneous data rate, this can ensure fairness among users. To measure the equity of the system, we exploite the well-known techniques, it is Jain's fairness index [34] given by equation "(11)".

$$f(D_1, D_2, D_3, \dots D_K) = \frac{\left[\sum_{K=1}^{N_s} D_K\right]^2}{N \sum_{K=1}^{N_s} (D_K)^2} \quad (11)$$

where N_s is the number of served VST users and D_K is the throughput of the Kth VST.

We can observe on Figure 7 that the designed scheme has a good level of equity index for VST because it maximizes the use of the available RB between different V2X communications. Moreover, PSA tend to minimize the rate gap among scheduled users, thus maximizing fairness among them. Comparing with OMA algorithm, the proposed algorithm achieves not only higher system throughput but also better fairness between subscribers.

It was shown that the fairness index of the proposed resource allocation scheme with NOMA system is higher than others paper [18]. The equity of all algorithms decreases when the number of connected links raises. The authors simulate this factor of performance with limited active connections in the system. This demonstrated that the proposed algorithm can ensure the best fairness performance by the different number of connected vehicular users comparing with resultas shown on [18].

Simulation results have illustrate that the proposed algorithm PSA has various proprieties that maintain remarkable enhancement in terms of average throughput, Average Blocking Rate (ABR) and to guarantee fairness index between different class of VUEs comparing to the conventional OMA assisted relay scheme and some recent work for NOMA based allocation. According to [31] and [32], the simulation results guarantee the 3GPP recommendation when the minimum small packet size is 50 bytes. Hence, our proposed algorithm is capable to support variable packets sizes meeting the requirements imposed by 3GPP standard.

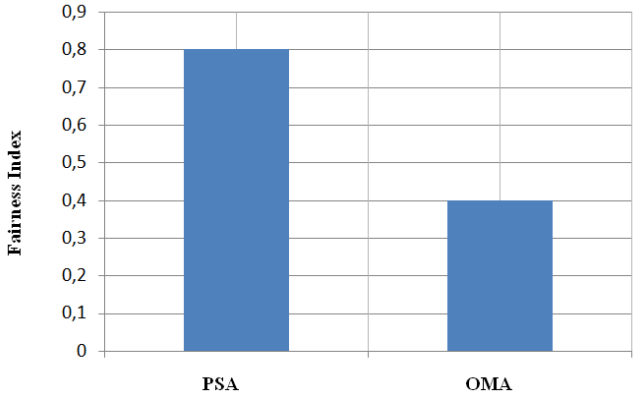

Figure 7: Fairness index analysis for ST connections

7. Conclusion

This paper, presents a novel scheduling and resource allocation approach named PSA for NOMA systems. PSA aims to maintain the highest average throughput by considering the heterogeneity of channels quality of each V2X link. The proposed work increases the number of served safety V2X links in the cell while a minimum requirement must be guaranteed on terms of throughput and maximize the average throughput of NST VUEs. The simulations results verify the optimality of our proposed algorithm in comparison with conventional scheme OMA that lack of caring fairness between vehicular users. The proposed scheme performs amelioration in term of throughput compared to other studied publication papers. A better compromise between cell throughput and fairness index has been achieved. As perspective for this research work, we plan to study the possibilities offered by Quanser platforms for reel environment implementation. In fact Quanser is an open-architecture system integrating plants with realistic dynamics sufficient for physically-relevant testing, real-time computation, and modeling for rapid testing of algorithms and concepts in MATLAB/Simulink and LabVIEW environments. We can also adopt such improvement to optimize the proposed scheme in terms of complexity.

ABSTRACT

The role of creativity techniques in the design of prototypes is of particular interest given its potential for innovation. At same time, despite the efforts of decades in terms of policies and programs of action, humanity has not yet come close to global sustainability. Sustainability design must involve society and creatively employ all available knowledge sources for creating sustainable software. This paper proposes a prototype design approach rooted in employing creativity techniques, while being guided by the dimensions and principles of the Karlskrona Manifesto. This approach is applied to the development of a multidisciplinary aggregator for the optimization of social services. As a result. guidelines for the use of creativity in requirements engineering will be presented, as well as on how to include sustainability issues, namely the Sustainable Development Goals and the five dimensions of sustainability in the design of prototypes.

1. Introduction

This work is an extended version of the paper [1] originally presented in 15th Iberian Conference on Information Systems and Technologies (CISTI 2020).

The software industry has become extremely competitive. Often, a choice is made between multiple software systems that strive to meet the needs of users in the same application domain. Therefore, in order to be sustainable and grow in the market, a software product needs to differentiate itself from other similar products and captivate users with new and useful features. Given such context, the use of creativity techniques is a determining factor for those who develop software. In Grady Booch's opinion [2], the nature of the systems we build continues to change and as they cross collectively in our lives, we must take into account not only the technical elements of software development, but also human needs. The use of creativity techniques allows requirements engineers to deal with new problems and domains, unique contexts, new applications and a combination of existing methods and techniques [3], [4]. However, research on how the application of creativity occurs has been neglected. Various creativity techniques, such as Brainstorming, scenario generation and simulations, and ad hoc design can be used to support and promote creativity in the requirements engineering process [3].

The Karlskrona Manifesto [5] and other authors [6]-[11] gave visibility and increased awareness of the importance of sustainability in software and Information Systems (IS). Specifically, the Karlskrona Manifesto for Sustainability Design (KMSD) serves as a guide for designing and developing sustainable software systems. Thus, the study of sustainability in the area of software development and IS is of extreme importance in promoting good sustainability practices and the integration of the 17 Sustainable Development Goals (SDGs) defined by the United Nations [12].

This study aims to describe the Creative process and techniques to be used in the design of integrative prototypes for a Social Organization, taking into account sustainability issues and the SDGs.

The paper is organized into five sections. After the introduction, the fundamentals and motivation for using creative techniques in the design of software prototypes are presented, as well as the principles of the Karlskrona Manifesto. Section three

[*]Corresponding Author: Clara Silveira, Polytechnic of Guarda, mclara@ipg.pt

describes the proposed approach. Next, section four presents a case of applying the approach to a social organisation as well as the proposal for a prototype in relation to the specificity of the problem. Finally, in the last section, the conclusions are presented, as well as the perspectives of future works, showing the spaces still open in the field of work development.

2. Creativity and Sustainability Design

2.1. Creativity in Requirements Engineering

The field of software engineering, especially requirements engineering, is extremely creative. However, professionals and researchers seem to have different perceptions about creativity, making knowledge transfer difficult [13]. The types of knowledge that we find in the literature that impact creativity from the perspective of software engineers are classified as [14]: previous knowledge, analogies and dynamic knowledge.

Prior knowledge ensures useful information about previous projects for the early stages of ideas generation. This background information provides a starting point or motivation to start with ideas for solving the problem. Analogies help software engineers create a link between two objects in the same or another domain and create new ideas. Dynamic knowledge refers to the knowledge embedded in the tools and available at any time.

We also emphasize that knowledge itself is creative [15] and, therefore, should be encouraged to develop. Results from various experiments show that creativity during the design phase can be improved with the help of analogies [16]. Robert Sternberg [17] defines creativity as the ability to produce work that is simultaneously new (i.e., original and unexpected) and appropriate (i.e., useful and adaptable).

It is also considered that the design of the prototype must contemplate aspects of creativity, including also the concern with the level of comprehensiveness of the information in face of the organizational reality. One concern focuses on the excessive coverage underlying duplication of information [18]. Such a situation can occur when there are duplicates in the individual sources.

In this sense, prototypes must be created to stimulate the creativity of the actors. It may be useful to think about the possible causes of prototype coverage [18], when compared to the target population. Therefore, it is considered essential that a prototype is developed based on research, knowledge, analogies, creative techniques, sustainability factors and, ultimately, validated to answer if it works as specified [19].

Thus, given the specificity of the organization used in this study (of a social nature), it is considered that the purpose of a prototype [19], is to create a semi-realistic representation of something in order to be able to interact and be tested with end users. Its main function is to identify problems and opportunities for improvement long before implementation begins. As it is an agile and efficient method, prototyping will help to define and include more assertiveness in problem solving.

Within the scope of the works related to the thematic area and considering the objective of the paper, practical works developed in organizational context are cited, ([1], [3], [4]).

2.2. Sustainability Design for Software Development

The concept of sustainability is often extrapolated to software engineering with the KMSD [5]. The KMSD principles cover several aspects of sustainability, serving as a point of reference and guide during the software design process [20].

The KMSD manifesto appeared at the Third International Workshop on Requirements Engineering for Sustainable Systems (RE4SuSy), held in Karlskrona, Sweden. It is considered a guide to design and develop more sustainable software systems. The KMSD includes nine principles ([5], [21]):

- **P1.Sustainability is systemic**: Sustainability is never an isolated feature. Systematic thinking should be the main focus to include interdisciplinarity.
- **P2.Sustainability has multiple dimensions**: Advocates the inclusion of the five dimensions (Table 1) in our analysis to be able to understand the nature of sustainability in any situation.
- **P3.Sustainability transcends multiple disciplines**: Sustainability exceeds several disciplines, working on challenges from several perspectives.
- **P4.Sustainability is a concern independent of the purpose of the system**: Regardless of the system's development context, sustainability must always be included.
- **P5.Sustainability applies to both a system and its wider contexts**: Concerned with considering at least two spheres in the design of the system: the sustainability of the system itself and how it may affect the sustainability of the context of the entire system.
- **P6.System visibility is a necessary precondition and enabler for sustainability design**: Concerned with sharing the vision of the system and its context in different perspectives and with the various levels of abstraction, allowing an informed choice. In this principle, it is important to cite the application of the *SharedClearVision* pattern [22].
- **P7.Sustainability requires action on multiple levels**: Consists of researching measures for sustainability that are considered the most effective way to intervene in comparison with other alternative actions.
- **P8.It is possible to meet the needs of future generations without sacrificing the prosperity of the current generation**: Sustainability innovation can play a key role in defining present and future needs. Thus, it is possible to make options that benefit both the present and the future.
- **P9.Sustainability requires long-term thinking**: Assess, in the long term, the possible impacts, costs and benefits of decisions made.

The manifesto presents general and abstract principles as well as values of sustainability. The KMSD Manifesto also includes the dimensions (five) shown in Table 1.

Table 1: Karlskrona Manifesto - Sustainability Dimensions [5], [21]

Dimension	Focus
Human	It focuses on the well-being of the individual.
Social	Refers to social issues like groups of people and organizations in a community. Social

	responsibility, justice, job, and democracy are essential elements.
Economic	Economic sustainability aims at maintaining capital and added value.
Environ-mental	The main mission of environmental sustainability is to improve the well-being of the person, protecting natural resources and ecosystems.
Technical	Concerned with the longevity of information, systems, their evolution, maintenance and innovation.

The KMSD principles and commitments provide an overview of the various dimensions of sustainability and their relationships. In this way, we consider that they show the impact that concerns with sustainability can have in the design of an information system. We added a new vector, combining creativity with the various dimensions of sustainability, allowing to preserve the environment and achieve new technological innovations in social organizations.

3. Creative Approach in Prototype Design

In this section, we describe the creative approach used in prototyping within the framework of a more comprehensive methodology for requirements engineering. Among the various creativity techniques that can be used to support and promote creativity in the design of prototypes, the following were selected by the creativity expert [2], namely: Brainstorming, Brutethinking, Reversal and Ideabox. The selection of these techniques took into account the author's accumulated experience in conducting workshops.

Brainstorming is an idea generation technique, which consists of a meeting designed to encourage the full release of mental activity without restrictions. This technique works so well because, among many other reasons, "ideas call ideas". Other people's ideas are sometimes starting points for our best ideas [3].

The Brutethinking technique [3] is characterized by being a simple process, which develops in four stages: choosing a random word; choose things/elements associated with the randomly chosen word; force a link between the word and the problem and between associations and the problem; relate the ideas obtained and analyze them.

The Reversal technique originates from the transformations that generate ideas. In some cases it is better to think first about the negative and then invert the negative, indicate "the worst" and then revert to "the best" [3]. One of the ways is double inversion: initially the reversal identifies the ways to make the situation worse by realizing what can aggravate the problem, instead of improving it. Then, you make an inversion again, identifying the paths that can lead to the improvement of the situation.

IdeaBox is a tool that allows you to combine the parameters (characteristics, factors, variables or aspects) of a challenge (it can be a prototype) into new ideas.

In the creative approach, it is proposed to integrate multiple existing paradigms, in which the creative contribution results from the integration and combination of different approaches that can interrelate, in the search for the integration, in a single proposal, of different forms of thought about a phenomenon [23]. On the other hand, still in the context of the creative process, it is essential to mention the importance of the characteristics of the creative product, the different views on the models of creative processes, the role of the field of application, the personal characteristics found in highly creative people and, finally, the socio-organizational aspects involved [24].

And we have to note that [23] the multiple views of creativity are complementary and not mutually exclusive. This suggests that future models of creativity can integrate different sources and diverse individual perspectives. The creative approach proposed here is included in a more comprehensive methodology [3] and focuses on the step "Understanding user requirements and sustainability factors", which aims to apply Brainstorming, Brutethinking and reversal creative techniques to: identify the requirements of the user in a process of seeking a creative and sustainable solution; interaction with stakeholders to identify their needs and find out what needs to be built.

In this approach, existing applications and prototyping are used as a source for collecting and validating requirements. Sustainability principles and commitments are incorporated [5]. The preliminary list of requirements is drawn up, as well as the design of exploratory prototypes. In the analysis of prototypes it is proposed to use the Ideabox creativity technique.

4. Prototype Design in Social Organization

The Parish Social Center of the Parish of São Sebastião is a Social organization, founded in 1998 that develops strong intervention in the São Domingos Community (SDC). In his daily intervention integrates food distribution programs, monthly food aid (food products given by individuals and companies), distribution of clothing and hygiene products [25].

4.1. SDC Characterization

The organization under study, previously presented, has been the subject of work in the thematic area, contributing to the optimization of established practices [7]. In this sense, a brief characterization of the SDC (Figure 1) is presented to frame the problem.

Figure 1: SDC Characterization [7]

From the meetings between the Project Manager and the SDC Manager and also with the participation of the Software Architect, the organization's current situation was made. The development of the project also had the online collaboration of the Requirements Engineer element.

Figure 1 shows the various aspects that the prototype must include in Housing, Skills, Health, Training, Volunteering for the objective of Social Integration of the Citizen.

In view of the problem under study and the specificity of the social organization under analysis, the team used the Brutethinking technique, in three iterations, to identify the problem, the main objective, the primary causes, the actors of the system and their objectives, the functional and non-functional requirements, creative and non-creative requirements. The Reversal technique was used to prioritize requirements. The team also used the techniques of debate and Brainstorming, in order to evaluate and review artifacts and solutions found. In order to aggregate the information underlying the organization's activity, Figure 1 was conceived in order to highlight the themes involved in a transversal logic of support to the citizen inserted in a community, which, by its nature, has the collaboration of several official entities.

The development of the prototype for SDC was based on a multiple perspectives in order to describe each individual in the various components and taking into account the collaboration of several partners.The valence of volunteering has greater prominence (Figure 2) given the importance of collaboration / interaction of people in the community.

Figure 2: Volunteering characterization

Next, the other objectives and components of Figure 1 are characterized [26]:

- Social Center - support to activities –
  - Objective: aggregating skills and knowledge, so that the Social Center can offer high quality and integrated services. The objective is to provide a platform to the various actors, enabling them to access certain SDC data, depending on their access profile;
  - Characterization: the platform will allow: managing citizen profile, volunteer members, health professionals; nursing treatments; medication, physical activities; sharing goods and resources; share vehicle and register availability on the platform for volunteering.
- Official Entities – Partnerships
  - Objective: to list the entities with which they will establish partnerships, namely: parish council, health center, Public Security Police, Foreign Service and Borders. Collaboration with official entities will enable more effective responses to SDC people;
  - Characterization: the entity and the manager are identified, the mission, location, preferred contacts, partnership/protocol, association with other stakeholders are described.
- Experience - knowledge kills -
  - Objective: an SDC member's life experience (or that of their caregiver), can be valuable information to enhance cooperation with the SDC. Each member's level of literacy is also important so that their skills can be developed, culminating in the sharing of knowledge;
  - Characterization: the things a person did throughout their life; the things they like to do and would like to do; the activities they would like to participate in: these can be assessed from one's life experience.
- Resource/car sharing
  - Objective: to allow the sharing/donation of consumer goods or resources (equipment) and car sharing. Reducing carbon emissions and fuel consumption is promoted;
  - Characterization: application with resources and goods and availability; places and times to car sharing;
- Health and well-being
  - Objective: the aim is to thoroughly characterize the health status of community members, to help with specific and necessary care;
  - Characterization: in the various health valences, the importance of aggregating by areas is emphasized: health situation, rehabilitation/physiotherapy, motricity/biomechanics, medical and nursing care, taking medication.

The detailed characterization of the information previously exposed allows to present a multidisciplinary and aggregating vision in order to enhance the provision of services by the Social Center, corresponding to the expectations of its users.

4.2. Prototypes

The Social Center, as an entity that aggregates all information and considering the specificity of its mission and its social context, presents needs for collaboration with various entities.

The exploratory prototypes that were presented were conceived using the creative approach, namely the following techniques: Brainstorming, Brutethinking, Reversal and Ideabox. The following principles of the KMSD (described in section 2.2) have also been incorporated: P1; P2; P3; P4; P7 and P9.

Figure 3 shows the exploratory prototype for the main aspects of the Social Center. The prototype multidisciplinary enhances the aggregation of information. The project aims to define an access profile considering data protection concerns within the National Data Protection Commission, an entity that regulates citizens' access to and data protection in Portugal. Figure 3 presents as one of its components Partnerships representing the various entities

involved in the process, namely the Foreigners and Borders Service in order to support the organization of the process of inhabitants residing in the SDC district. The partners' name is also relevant in this context is social security since there is a regulatory and legal framework in Portugal that enhances the analysis of the economic and professional situation of citizens and families in order to enhance the creation of subsidies, namely the Social Income of Insertion. In this context, the prototype is of particular interest since it aggregates the information in various valences for each citizen and his family.

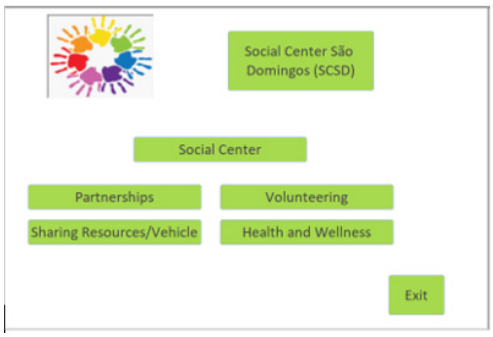

Figure 3: Main menu prototype

The Social Center São Domingos includes a low-level, low-economic community, mainly made up of elderly people with low economic levels, as they are retired people from the manufacturing environment. However, SDC also includes families with adolescents and children with economic needs. Thus, the creation of a prototype of this nature can enhance the centralization of community information in order to allow the delineation of support strategies. Figures 4 present prototypes for Citizen Profile.

Figure 4: Prototype Citizen Profile

The Citizen Profile characterization aims to collect and keep up to date a set of information referring to each citizen and his family in order to aggregate the various valences. Thus, it is intended a comprehensive characterization with regard to personal data in order to support the various sharing of information in order to create better living conditions. The medication and Health Problems includes the valences of improving the health care of each person, but also knowing the medication necessary to each person in the sense that in case of need the Social Center São Domingos provide its acquisition. Another of the concerns of the Social Center São Domingos is the mobility and conviviality of the elderly in which the Life Experience is an appeal to the sharing of knowledge promoting initiatives that allow to enhance the enormous knowledge of the elderly with other elderly and younger age groups through the organization of workshops and other events. Another aspect of the project focuses on recording in detail the Academic and Professional Training in which the practical experience of each one is emphasized by fostering this sharing through events. This need and also willingness to collaborate and explore the accumulated knowledge has allowed the create of availability for volunteering since it allows the taking of older people from home, enhances collaboration among community members increases the feeling of being useful and actively contributing in their community. Sometimes this collaboration is carried out in exchange for perishable and non-perishable goods increasing also of this were the resources of the family.

The regard to Volunteering - Actions to be promoted - it includes the concerns of involving SDC citizens in concrete voluntary actions. Particularly about the elderly, the objective is to enhance the coexistence and sharing of knowledge. The aspect willingness to receive volunteer support is carried out in actions such as: small reparations in housing, receiving non-perishable goods or other needs that are identified. In view of the sustainability concerns that are intended to be fostered, it is considered that in this context and in view of the specificity of the SDC Sharing – Resources/Vehicles has a view to promoting sustainability by appealing to the implementation of SDGs practices, in particular with regard to the re-use of resources and optimization of car sharing. Regarding Activities - Health and Well-being is intended to promote mobility and active life, as well as to have assertive monitoring particularly with regard to the senior population.

4.3. Discussion

The characterization of the SDC is of particular interest in the sense of having the opportunity, within the scope of a partnership, to study a community in order to test the applicability of the creative approach, contributing to the design of the prototype to meet the needs of the organization, although innovative and appropriate.

The prototype underlies the feedback from the team that includes the SDC manager. The creativity techniques Brutethinking, Reversal and Brainstorming were considered adequate for the design. The application of creativity techniques and the incorporation of concerns about sustainability allowed the inclusion of new services: car sharing; resource sharing; take medicine; volunteering; prototype integrating several valences and entities. This corroborates with the authors, in which the involvement and decision of the interested parties in the software project is an integral part of the constructions of software for effective use.

It is considered that the proposed prototype is an aggregator of information based on a multidisciplinary approach allowing the collaboration of several entities taking into account the specificity of intervention of each one so that the Social Center provides a more complete and integrating service.

In terms of sustainability concerns, it is noteworthy, for example, that volunteer actions allow contributing to SDGs as shown in Figure 5.

Figure 5: SDGs in the context of volunteering (adapted from [12])

The main contributions to the SDGs are highlighted [12]:

- SDG 4: The prototype under development aims to enhance the participation of young people from the Community of São Domingos to the extent that by getting involved in the various activities they acquire relational and technical skills in the context of their collaboration, even promoting their participation as entrepreneurs;
- SDG 5: The aim of this area is to promote women's empowerment by advocating a set of initiatives. A set of strategies have already been delineated, including short courses on the use of ICT and a financial education course in order to raise women's awareness of the importance of assertive management suggesting in this context the use of ICT to control expenditure;
- SDG 10: The Community of São Domingos has as its strategy inclusive policies given the multicultural provenance of its inhabitants. In this sense, it organizes social events serving the various cultures and religions existing in the neighbourhood.
- SDG 11: The Community collaborate in promoting efforts to protect the world's cultural and natural heritage organizes events;
- SDG 12: Aiming to promote sustainability policies, the Community of São Domingos promotes the distribution of non-perishable goods: clothing, specific health equipment such as wheelchairs and articulated beds and furniture. The Community not only aims to contribute to the well-being of its inhabitants, but also to promote the re-use and recycling of goods;
- SGD 14: Given its geographical location, the Community of São Domingos organizes awareness-raising actions about pollution mainly regarding the Sado River.

It should be noted that the SDGs cannot be analyzed in isolation, since the improvement of one SDGs will have a positive and/or negative impact(s) on another SDGs [27]. Integration adds valuable knowledge that can help society meet the SDGs [28].

5. Conclusions

This work presents a proposed approach to the design of prototypes using creativity techniques. It includes a study of a social nature, which contains a set of assumptions that constitute a challenge. Throughout the development of the work, conditions were created for the application and validation of techniques, namely in the field of creativity in IS. In this sense, Brainstorming, Brutethinking, Reversal and Ideabox techniques were applied. Another technique applied in the work was collaboration, where software engineers shared their ideas and thoughts with others. They build on each other's ideas and provide constructive feedback. In this way, it was possible to fill the knowledge gap of each one, creating a group. On the other hand, the principles of the Karslkrona Manifesto have already been applied in several areas [11], [27]-[31].

In this research was possible to apply the theoretical references mentioned to study a real problem, proposing an integrative and multidisciplinary solution in order to enhance the activity of the Social Center in the São Domingos Community in order to provide better services to its community.

As discussed in section 4.3, the results obtained show that creativity techniques can play an important role in transforming of existing Information Systems, bringing innovative and unexpected solutions, which without removing functionality or performance from Information Systems can make them more sustainable.

Therefore, in this context, the understanding that there is an important role to be played by creativity techniques in promoting SDGs and contributing to the development of more sustainable IS is reinforced.

The process was applied in another context [26] and a significant contribution was perceived in the field of sustainability, in the areas: social, individual, economic, environmental and technical [7].

As future work prospects, the case of the chosen Social Organization will be replicated in other communities/institutions in order to contribute to their sustainability. Also, the development of an application to make available to the Social Center is recommended, underlying concerns of a graphic nature, screen design, usability and accessibility. In this sense, solutions are being studied that address the specificities and constraints, particularly financial constraints implicit to social organizations. Thus, the choice of the platform for the development and hosting of information, licenses and maintenance are concerns about the importance of keeping the solution in full operation over time. For the validation of the application we´ll use inspection techniques, usability tests and accessibility.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

This research presents an effectively autonomous method that can save time and increases productivity for an assembly line in industry by using a 6DOF manipulator and computer vision. The objects are flat, aluminum type and randomly stacked in a box. Firstly, 2D color image processing is performed to label the object, then using 3D pose estimating algorithm, the surface normal, angle and position of an object are calculated. To reduce the burden time of 3D pose estimation, a voxel grid filter is implemented to reduce the number of points for the 3D cloud of the objects. As known the 3D image object was obtained by camera in bin often involves both heavy noise and edge distortions, so to prepare for the assembly a manipulator will pick and place it at sub position then a 2D camera is used to estimate the pose of the object correctly. Through implement experiment, the system proved that it is stable and have good precision. Installing time and maintaining is fast and not complicated. It is applicable in production line where mass product is produced. It is also the good foundation for other deep researches.

1. Introduction

For many reasons, such as people, productivity, management and working environment; the robots gradually replace the people to carry out the tasks flexibly, accurately and safely. The tasks such as assembling and disassembling a machine part, arranging large quantities of goods requiring a lot of effort. In addition to exposure to hazardous environments, the risks of machinery such as billet cutting machines, corrugated iron stamping, turning, heavy chemical containers, grippers and leveling of embryos when welding can be dangerous to humans. Therefore, the participant of intelligent robot is indispensable because The robot can recognize the surrounding environment and objects correctly by the sensors as well as very high performance. Currently, there are many researches in the world about automatically supplying embryos in the factory or especially the task of picking up objects occluded each other inside a bin and placing it in the assembly area or welding. This task is called "Bin Picking". Casado and Weiss proposed method to apply algebraic relations between the invariants of a 3D model and those of its 2D image under general projective projection for estimating object 3D poses [1-2]. However, because of the occlusion, pose estimation using 2D image matching only works when their poses are limited to a few cases especially in automatic random bin-picking systems. Ban and Xu et proposed a laser vision system consists of using a projector and a fixed camera to project vertical and horizontal lines, thereby using the camera to determine the X, Y, Z coordinate and direction of objects to pick [3-4]. Chang recommended attaching a laser and projector on the hand of the mobile device to reconstruct the 3D image of the workspace and objects [5]. However, the system [3-5] has limited speed because it requires waiting times for projector operating and also of process complex images. Recently, the work has been done to use the stereo vision system to view the work area and to calculate the position and normal vectors of the gripping objects or using both stereo vision, projector and CAD models to determine the position and coordinates of the object to be picked up in a box [6-9]. However, CAD models of objects in actual production are often not provided. Recently, the structured-light vision system and Point cloud are also recommended as Schraft proposed an algorithm to calculate the position and coordinate of the object based on the structure light system and a sample point cloud [10]. After obtaining 3D working area point cloud the system will compare with the sample point cloud to determine the location of an object. The system has the disadvantage that the model points must be saved at first as a data system so the algorithm will take a lot of time to compare with this sample data point cloud. More over the database will be huged and complicated. Bousmalis [11] and Mahler [12] use the learning method to identify the object to be picked, but the algorithm is

*Corresponding Author: Le Duc Hanh, Email: ldhanh@hcmut.edu.vn

limited because the object is randomly stacked, so the objects can overlap each other [11-12]. When the algorithm performs learning, it will also learn the black overlap region, so the amount of data learned is very large and when performing the pick-up, the robot will have a lot of difficulties due to these black shadows data. Over past decade, deep machine learning has also been applied to object recognition such as Tuan which uses large data collection and neural network to identify and take rectangular objects in containers [13]. Chen re-modeled the 3D object to be picked up, simulating and training the position and gripping position of the object to be picked [14]. However, the technique of [13-14] need to be retrained the database if using other objects and training data is very large.

This research is different from discussed above. A Kinect sensor, in addition to returning the location data of the pixel, also produces the color of each location, so combining the location and color data will improve the algorithm accuracy. Firstly, all the point cloud information consists of pixel location and its RGB image are converted to 2D image for labeled data and then converted again to point cloud data. Secondly, the 3D pose of object is roughly estimated. The data is then transmitted to a Manipulator to perform a grasping task. The object will be placed on the V-groove and the system uses a 2D camera to process the image to refine the object's pose.

2. Segmentation

2.1. 2D image processing

Watershed is an algorithm used in image segmentation [15]. Algorithms are popular in fields such as biomedical and medical processing, computer vision. Firstly, due to the high density of 3D data acquired from Kinect, the location of point cloud inside the registered range are kept by using pass-through filter algorithm. By using filer algorithm, the number of points in cloud reduced from 307200 points to about 30000 points. After filtering, all the point cloud information consisting of pixel location and its RGB image are converted to 2D image. The canny and the distance image transform algorithm are applied to find the contour of the object. After that the watershed algorithm is applied to label object. The labeled objects contained pixel locations and labeled colors are then converted back to 3D point cloud data as shown in Figure 1.

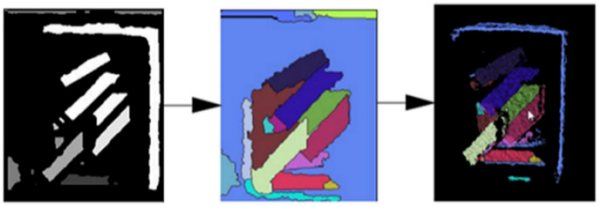

Figure 1: Watershed algorithm and colors assigning to Point cloud.

After objects are labeled, the data remains as unorganized objects data and will be segmented into each planar surface which represents for object cloud called cluster.

2.2. 3D image processing

When using 3D devices, the collected data often appears to be hovering and not in any plane. These points usually appear near the interface between surfaces, or near the edges of an object and. These points need eliminating, so the outlier filter is applied by considering the number of neighbor points K and the radius R of each point. If any point in point cloud whose number of neighbors in sphere of radius R is not greater than a threshold number, that point will be removed from point cloud. After that normal vector and the cluster segmentation are calculated. Normal vector is the most important point feature that distinguishes between different 3D cloud. the normal vector is the normative vector of a plane estimated from a given set of points. The problem of determining the normal to a point on the surface is approximated by the problem of estimating the normal of a plane tangent to the surface. To determine a plane equation in space, it is necessary to determine an x point in that plane and its normal vector $\vec{n}$. The point x is determined by focusing on nearby points.

$$x = \overline{p} = \frac{1}{k}\sum_{i=1}^{k} p_i \tag{1}$$

As discussed in [16], the solution for $\vec{n}$ is given by finding the eigenvalues and eigenvectors of covariance matrix $C \in R^3$ of P^k with:

$$C = \frac{1}{k}\sum_{i=1}^{k} \xi_i (p_i - \overline{p})(p_i - \overline{p})^T \tag{2}$$

The eigenvectors $\vec{v}_j$ form an orthogonal frame, corresponding to the principal components of P_i^k

$$C\vec{v}_j = \lambda_j \vec{v}_j, \quad j \in \{0,1,2\} \tag{3}$$

If $0 < \lambda_0 < \lambda_1 < \lambda_2$ the eigenvector $\vec{v}_0$ corresponding to the smallest eigenvalue λ_0 . Therefore the approximation of $\vec{n}$ is $\vec{n} = \{n_x, n_y, n_z\}$ or $-\vec{n}$. The calculation of the normal vector at the center will have errors, so to increase the reliability for the estimated vector, the maximum allowed error between the normal vector at the center and the normal vector at the adjacent point satisfy the following conditions:

$$\theta_{\overline{xi}} = ar\cos(\vec{n}_x \vec{n}_i) \tag{4}$$

Through conducting experiment, the $\theta_{\overline{xi}} = 5\ ^\circ$ is found to be appropriate.

Although the Kinect was placed perpendicular to the bin, the barrel edge point cloud still existed and connected to the real object in the bin formed an unexpected object in bin. When calculating the normal vector, the program will consider the barrel edge and the object are one object then the normal vector calculation and the position of the real object are not correct. Therefore, based on the normal vector, it is possible to separate the sides of the barrel with the idea that the angle between the two normal vectors on the side and the bottom edge will be larger than threshold value α. From experiment, the angle $\alpha = 50^0$ is appropriate. The results are shown in Figures 2 and 3.

The Euclidean clustering algorithm basically used to segment cluster and based on their neighbors [17]. Therefore, to estimate the normal vector to recognize that they belong to one plane, the Clustering procedure are through the following steps:

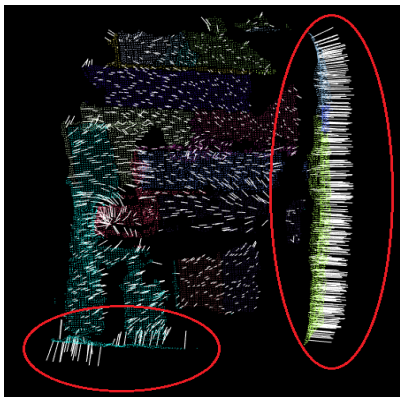

Figure 2: Normal vector of points

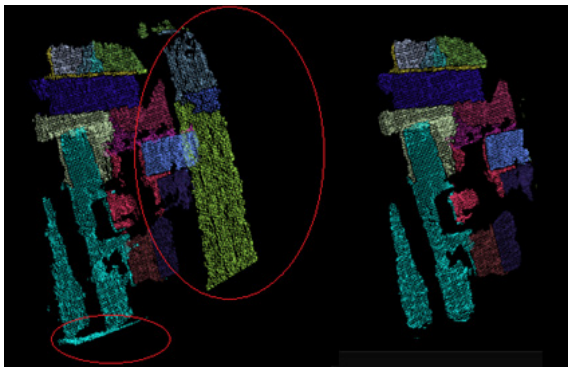

Figure 3: Image before and after removing barrel edge.

- Normal calculation of point cloud.
- Apply Kd-tree algorithm by define radius searching to find nearby points.
- Create list of cluster C and list of points to handle L.
- For every point p_i in P, do the following step:
- Add p_i in to L
- Search the list of neighbor n of p_i within a sphere of radius r using kd-tree algorithm.
- For every neighbor n_i, check if point exists in L. If it exists we skip to the next neighbor, otherwise we apply the following check.
- Calculate the angle between 2 point p_i and its neighbor n_i

$$\theta_{ij} = a\cos(\vec{p}_l, \vec{n}_l) \tag{5}$$

- Determine the color difference of 3 channels R, G, B of 2 points:

$$\left|R_p - R_n\right| + \left|G_p - G_n\right| + \left|B_p - B_n\right| < \text{Threshold} \tag{6}$$

- if the point p_i and its neighbor n_i satisfies (5) and (6) then add n_i to L, otherwise skip to the next neighbor.
- After checking all the points in L, put L into C and reset L.
- If the number of points in the cluster are in the range (Min_clust, Max_clust), it will save the cluster. Among the cluster that meet the conditions of color, normal, size, the cluster will be selected if it has the highest height as shown in Figure 4.

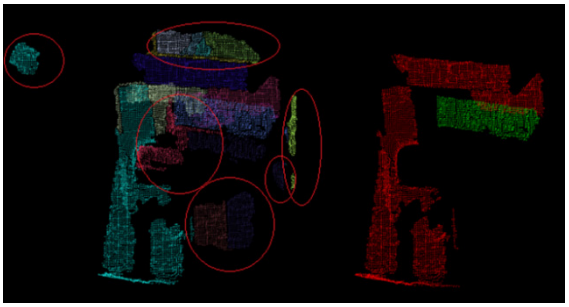

Figure 4: Image before and after extract cluster.

In Figure 4, the area circled to the left is the cluster having a smaller number of points than the Min_clust. Therefore, they were removed. Finally, the result is shown on the right with the green cluster which has the highest height. The robot will use this cluster to calculate the position and direction.

3. Manipulator and camera calibration

Because it is hard to determine the position of the camera coordinate that corresponds to the coordinate of the manipulator; therefore, using the method of measuring the distance from the manipulator to the camera will not give accurate results. Therefore, this research uses intermediate positions with known coordinates in both camera coordinates and manipulator to find transfer matrices. Suppose we have any point M in 3D real space, the coordinates of this point M in the camera coordinate system is denoted M_C and in the robot coordinate system is M_R, then we have the formula to transfer coordinates from the camera coordinate system to the robot coordinate system as follows:

$$M_R = RM_C + T \tag{7}$$

Where R is a rotation matrix and T is the translation matrix containing the translational vector from the robot origin to camera origin. If $M_R = \begin{bmatrix} X & Y & Z \end{bmatrix}^T$ and $M_C = \begin{bmatrix} x & y & z \end{bmatrix}^T$ then (7) becomes:

$$\begin{bmatrix} X \\ Y \\ Z \end{bmatrix} = R \begin{bmatrix} x \\ y \\ z \end{bmatrix} + T$$

$$\begin{bmatrix} X \\ Y \\ Z \end{bmatrix} = \begin{bmatrix} r_{11} & r_{12} & r_{13} \\ r_{21} & r_{22} & r_{23} \\ r_{31} & r_{32} & r_{33} \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix} + \begin{bmatrix} t_1 \\ t_2 \\ t_3 \end{bmatrix} \tag{8}$$

From (8), there are 12 variables to find, so it is necessary to have 12 equations corresponding to 12 variables, each point coordinates can only provide 3 equations so we need to take 4 points to be able to find two matrices R and T. After getting the necessary points, the system is solved as linear equation

$$A = BX \Leftrightarrow X = B\text{-}1A \tag{9}$$

With Kinect cameras, both 2D and depth images have a resolution of 640x480 and each pixel in 2D images corresponds to a point obtained from the depth camera. Kinect's true coordinate

system is defined to coincide with the color camera's coordinate system, so when the pixel coordinates of a point in an RGB image are obtained, the x, y, and z values of that point can be retrieved in the camera coordinates. So, the method to get coordinates is as follows: Use the Hough Circle algorithm to determine the center of a circle. From the pixel coordinates of the center of the circle in the color image, the center of the circle in the camera coordinate system is retrieved as shown in Figure 5a. Then, use the Teach-pendant to control the manipulator's head to the center of the circle to get the coordinates of this point in the robotic coordinate system. The work head needs to be small enough to increase accuracy Figure 5b. The data table of this process and error checking are shown in Table 1 and Table 2

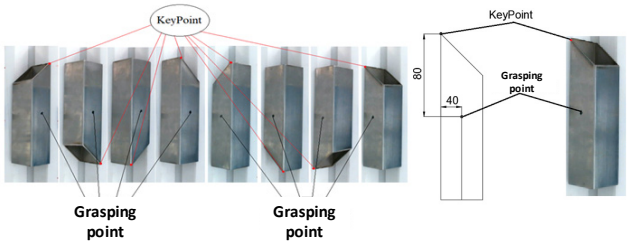
Mean error (mm)		1.3033	1.2865	1.1130

After identifying separated object, object is grasped and placed on the V-groove and there are eight case of placing as shown in Figure 6a. Since it is placed on a notched groove, the position of the object just changes along the axis of the groove. To determine the position O for grasping, it is only necessary to determine the coordinates of one point called the key point on the object as shown in Figure 6b and then using the dimension of the object to calculate the O position.



(a) (b)

Figure 6: (a) eight cases placing on V-groove, (b) Key point and grasping point.

To determine the key point, Firstly, the template matching algorithm are performed then the Hough Line detection applied to find the line equation. Then based on line equation, the intersection point coordinate of each two lines are calculated. By combining each case result of template matching and calculated points, the appropriate coordinate of the key point is determined.

4. Experiment

Working space for experiment includes one RGB-D camera fixed above the working space, a monocular camera 2D attached at the end effector of Manipulator, the 6DOF Nachi Manipulator and pneumatic suction cup with maximum 1 kg payload and the V-groove for fine tuning location of object as shown in Figure 7. The 3D Camera is the Microsoft Kinect v1 with a resolution 640x480 combined with 2D camera Logitech. Both of them are parallel fixed with table surface having rectangular box objects. The specification of computer is: Laptop, RAM 16GB, Core I7, CPU 3.1GHZ. Six objects, representing for six random cases, are aluminium type and randomly stacked inside the box. They will be picked up and put at registered position.

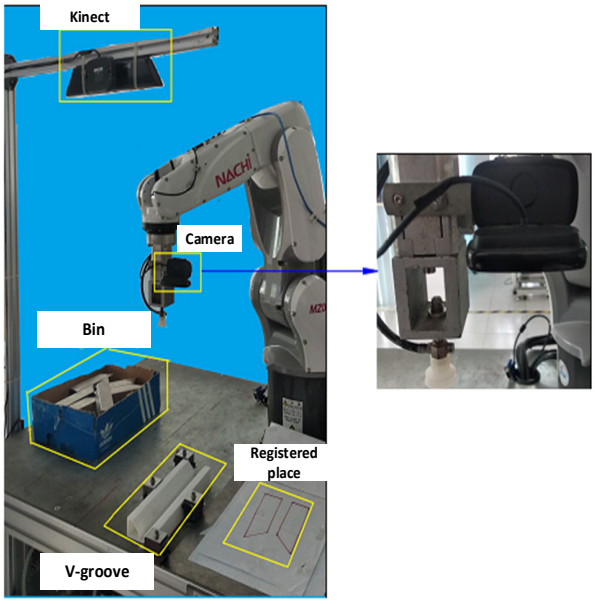


Figure 7: Experiment apparatus

By using 2D and 3D image processing discussed above, the positions of the objects are calculated as shown in Fig.8. The cluster having the highest height, green colour, is chosen to be grasped

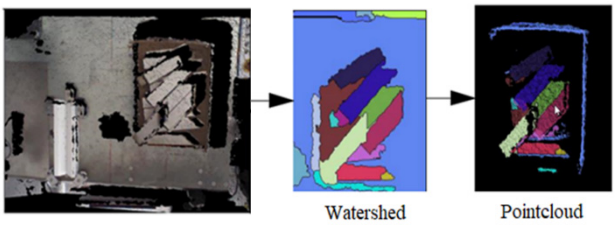

Figure 8: Image processing procedure

After having the coordinates and directions of object in the bin, the manipulator will perform the grasping task and then place it on the V-groove for the fine-tuning step Figure 9. After placing the object in the V-groove, the robot will use the second monocular camera to take the image to find the location and side of object to be picked Figure 10. Then the robot will put it to the registered position as shown in Figure 11.

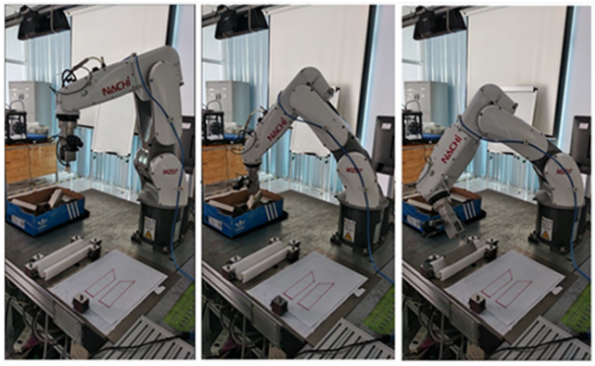

Figure 9: Process of grasping the object in the bin and putting it on V-groove

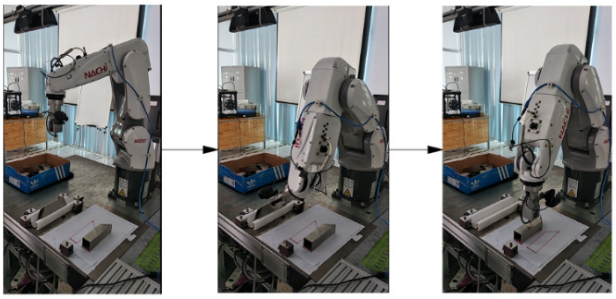

Figure 10: Process of grasping object on V-groove and putting it at registered

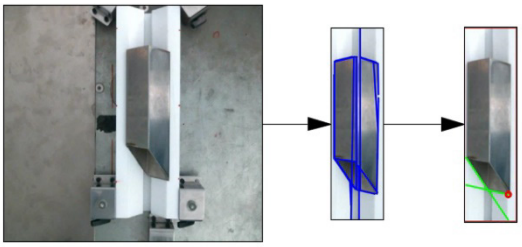

Figure. 11: Finding the key point of the object

After finish grasping task, the angular error, position error of the objects and the desired position are compared as shown in Figure 12. The real position of objects is obtained by reading the coordinate value on teach-pendant when moving robot manually. From that position the error of angle and position are calculated. The data are taken many times to calculate the mean error of the system as shown in following Table 3. The processing time is also calculated Figure 13

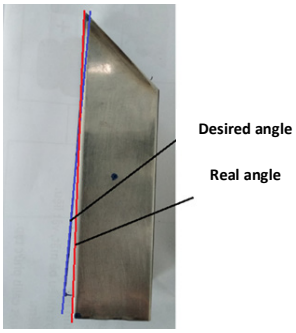

Figure 12: Desired position and real position

Table 3: Error position and angle calculation

No	Position Error (mm)			Angle error (degree)
	X	Y	Z	
1	1.00	1.73	0.08	1.1243
2	1.25	1.62	0.11	1.6973
3	1.01	1.52	0.19	1.0981
4	1.18	1.91	0.36	1.8352
5	0.50	1.15	0.34	1.9559
6	1.61	1.27	0.52	1.0600
Mean Error	1.0917	1.533	0.2667	1.4618

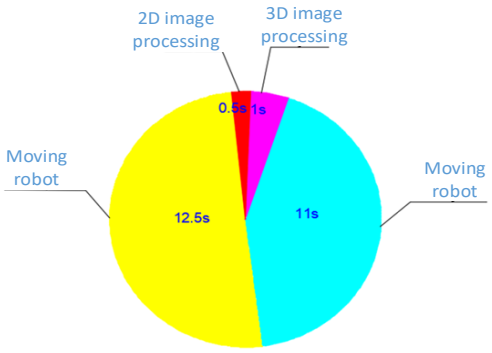

Figure 13: Processing time of system

From Table 3 it can be seen that the error of angle and position compared to the desired position is small and acceptable. The time to move the robot takes up most of the time by 23 seconds. Time to process images and data transmission is small about 1.5 seconds. The total time of implementation is 25 seconds, which is less than 30s. The image processing time is just about 6% of total time. To improve speed of system, the speed of robot could be increased to 100%. But for safety reasons it should only be done at 50% speed.

5. Conclusion

The paper proposed an effective method for the bin-picking problem. The image processing time is small and the accuracy is high. The method consists of two steps: the first step is to use the

3D camera and to combine 2D and 3D image processing for object segmentation and the second step is to use 2D camera for fining the grasping task. The effectiveness of the proposed approach was confirmed by a series of experimental results. The proposed method is also easy for installation and maintenance and applicable for assembly task in real industry. The comparing performance of proposed system and existing ones which are discussed in the introduction section are summarized in below Table 4.

Table 4: Comparing performance of Systems

	Proposed System	Existing system
Complexity	Not complicated	Very complicated
Time executing	Fast	Time consuming
Quality	Good and stable	Good and stable
Quantity	Mass product	Mass product
Setup	Easy	Complicated

Atmospheric pressure plasma

ABSTRACT

Atmospheric pressure plasma was used to treat polypropylene (PP) surfaces. Optical emission spectroscopy (OES) was used to determine the chemical species formed in the plasma as well as the electron temperature and density of the plasma. The flux of species (O and OH) produced during the plasma treatment interact with the polymer surface creating polar groups on the PP surface, which were evaluated by X-ray, Raman, and Attenuated total reflectance-Fourier transform infrared spectroscopy (ATR-FTIR) analyses. Moreover, the thermal properties of PP were investigated by thermogravimetric analysis (TGA) and differential scanning calorimetry (DSC) analysis. The plasma treatment increased the crystallite size and microhardness. This enhanced effect was produced from high concentrations of O and OH that induced functional polar groups containing C–O, C=O, and C=O–OH bonds appended to the PP surface. The polar groups produced by the air plasma can be attributed primarily to the oxygen radicals in the air plasma hitting the PP surface and to heat-induced oxidation rather than the incorporation of oxygen radicals or UV-induced oxidation from the plasma. The increase in hardness is attributed to the introduction of carbonyl and hydroxyl groups, cross-linking, annealing effects, and chemical etching.

1. Introduction

Atmospheric pressure plasma discharge treatment has become important because of its relatively simple process, low cost, easy operation, and applicability to vacuum-incompatible materials and processes compared with the low-pressure plasma process [1]. Typically, two categories of plasmas exist based on their gas temperatures: thermal and nonthermal (cold) plasmas [2, 3, 4]. In thermal plasmas, electron temperature is very close to those of heavy particles (both charged and neutral), and therefore, it cannot be used for the surface modification of heat-sensitive materials. However, nonthermal plasma electrons have a temperature that is 2–3 orders of magnitude higher than the temperature corresponding to the random motion of the background gas molecules. As a result of the very low heat capacity and density of electrons, plasma temperature is almost the same as room temperature. Subsequently, the ions remain rather cold, and a nonthermal plasma does not produce any thermal damage to the treated surfaces [2-4]. These characteristics are particularly advantageous for the treatment of heat-sensitive and fragile materials, such as polymers [5, 6].

Surface modification can be applied either directly or indirectly. Direct surface modification methods are used to modify an inert surface with free radicals for specific applications, whereas indirect surface modification methods are based on polymer grafting [5, 6]. The efficiency of plasma treatment methods depends on surface type, the gas phase of the plasma, and treatment conditions such as discharge type, pressure, frequency, discharge voltage and current, and treatment time. To modify surface properties without any change in the bulk material, it is essential to use successful surface modification methods such as atmospheric pressure plasma [5, 6].

Surface modification of polypropylene (PP) has been extensively studied to improve its properties, such as wettability (surface free energy), hydrophilicity, biocompatibility, and adhesion, using different atmospheric pressure plasma reactors [5,

*Corresponding Author: Oscar Xosocotla, Email: hm@icf.unam.mx

7-11]. However, only two studies have shown PP hardness improvement: the first study [12] involved beta irradiation at several doses, showing substantial changes in PP structure and mechanical and micromechanical properties, and the second study [13] utilized atmospheric pressure plasma treatment by diffuse coplanar surface barrier discharge using ambient air as the working gas. They observed no significant changes in the mechanical properties of the films after plasma treatment. Therefore, the purpose of this study was to characterize and test the impact of the commercial plasma device on the PP surface. Therefore, optical emission spectroscopy (OES) was used to investigate chemical species that cause plasma surface modification, electron temperature (T_e) and density (n_e) were used to characterize the plasma, differential scanning calorimetry (DSC) was used to determine the melting points of materials, thermogravimetric analysis (TGA) was used to evaluate the degradation of materials subjected to plasma treatment, X-ray diffraction (XRD) was employed to analyze crystallite orientation and size, Raman spectroscopy and Attenuated total reflectance-Fourier transform infrared (ATR-FTIR) spectroscopy were performed to investigate the conformations of polymer chains, and atomic force microscopy (AFM) with a micro-durometer was used to study the morphology of the surfaces and determine the microhardness of PP.

2. Experimental

2.1. Plasma Source

A schematic illustration of the APC 500 plasma torch source (Diener Electronics, Germany) used for surface modification is shown in Figure 1. The plasma source [14] was operated at a voltage of 20 kV, discharge current of 25 mA, frequency of 40 kHz, and gas pressure of 1500 torr. The plasma gliding discharge was generated by two electrodes. The discharge extended from the electrode region because of air flow, and the active plasma covered an area of ~10 cm^2. The samples were placed in the most homogenous region, which was at the center of the gliding plasma. OES was used for optical characterization of the plasma. For OES measurements, an Ocean Optics spectrometer (model HR2000CG-UV-NIR) was used in the spectral range 200–1100 nm, and the data were obtained with a step of 0.35 nm and an optical resolution of 1.0 nm (FWHM).

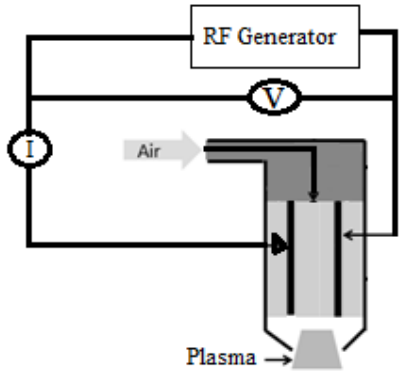

Figure 1: Diagram of the radio frequency atmospheric plasma generator

2.2. Materials

A commercially available isotactic (Lyondell Basell) PP cylinder with a density of 0.91 grams per cubic centimeter (g cc^{-1}) was cut into 1.5 × 1.5 × 0.5 cm^3 pieces. One side of each PP sample was polished to achieve uniform roughness using silicon carbide sandpaper with a grain size of 1,500. The samples were then washed in an ultrasonic bath for 20 min. To remove the residual liquid, the samples were placed in an oven at 30 °C for 30 min.

2.3. X Ray analysis

The XRD patterns of PP samples were recorded by a Rigaku D MAX-2000 diffractometer using Cu K_α (λ = 0.154 nm) radiation with 2θ in the range 10°–20° using a step size of 0.06° and step time of 10 s. The diffraction patterns of untreated and treated PP samples consisted of well-defined peaks. The high-intensity peaks were chosen to estimate the crystalline size and lattice strain using Scherrer's formula and Williamson–Hall (W–H) model [15, 16].

2.4. Raman analysis

Raman spectra were obtained using a SENTERRA II spectrometer (Bruker). The characteristic peaks of the crystalline and amorphous phases in the spectra of treated and untreated PP samples were then evaluated. The Raman spectrometer was equipped with a 785-nm laser and was operated at a power of 100 mW. The integration time was 1,000 ms.

2.5. DSC and TGA

DSC and TGA were performed to analyze the thermal properties of the samples, which were placed in aluminum specimen holders. To correct for their thermal histories, the treated PP samples were heated from 10 °C to 250 °C at a rate of 10 °C/min in a nitrogen atmosphere.

2.6. ATR FTIR analysis

The chemical compositions of the PP surfaces were analyzed before and after plasma treatment using a Spectrum 400 ATR-FTIR spectrometer (PerkinElmer). The vibrational modes appearing in the ATR-FTIR spectra were consistent with those reported in the literature [17-20].

2.7. Roughness

A NX10 atomic force microscope (Park) was used to quantitatively analyze the surface roughness of the PP samples due to plasma treatment [21-23].

2.8. Microhardness

A micro-durometer (Matsuzawa) was used to measure PP microhardness under a 300 g load. The penetration time was set to 20 s, and five indentations were made on each PP surface to obtain an average value [12, 24].

3. Results and analysis

3.1. Plasma characterization

The efficiency of plasma treatment depends on the surface type and treatment conditions. Therefore, the plasma discharge

was produced by applying a voltage (V) of 10 kV, and the electrodes were separated by a distance (d) of 2 cm. The resulting electric field strength (E) was equal to V/d. E was calculated to be 5.0×10^3 V cm^{-1}, and E/P was equal to 6.58 V cm^{-1} torr^{-1}.

The electron drift velocity (v_d) and E/N, where N is the number density, were obtained from the literature [25], considering the experimental conditions used. We obtained a v_d of 3.2×10^6 cm s^{-1} and E/N of 0.19 Td (1 $Td = 10^{-17}$V cm^2). Thus, N is 2.63×10^{19} cm^{-3}.

The electron density (n_e) was estimated from the measured current density (J) [26]:

$$n_e = \frac{J}{e v_d}. \quad (1)$$

The electron density was found to be $(1.95 \pm 0.24) \times 10^{12}$ cm^{-3}, and the order of magnitude was consistent with reported values [27, 28]. The electron density, n_e, was assumed to be equal to the ion density n_i in the plasma bulk [29].

3.2. Optical emission spectroscopy (OES)

OES was performed to characterize the plasma discharge. The OES spectrum obtained from the discharge is shown in Figure 2. It is well known that atomic and molecular transitions emit photons with specific wavelengths and energies that correspond to the difference between the upper and lower energy levels involved in the transitions. The OH($A^2\Sigma^+ - X^2\Pi_i$) molecular emission near 309 nm indicated that the plasma was not in equilibrium because of strong transitions and trace amounts of water vapor in the air. It is often difficult to prevent water from affecting the plasma. The peak at 337 nm was due to a $C^3\Pi_u \rightarrow B^3\Pi_g$ transition in N_2 and was the most intense peak in the region of 330–530 nm. Moreover, the first negative system, N_2^+ ($B^2\Sigma_u^+ \rightarrow X^2\Sigma_g^+$) generating a 0–0 band between 388.5 and 391.5 nm was observed together with two low-intensity peaks at 777.19 and 844.71 nm, which were attributed to O ($^5S^0 - {}^5P$) and O ($^3S^0 - {}^3P$) transitions, respectively.

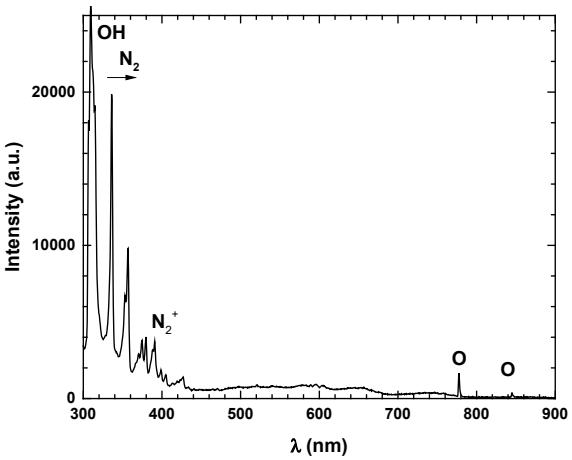

Figure 2: Optical emission spectroscopy (OES) spectrum.

OES is often used to determine the energy of electrons in the gas phase [30-33]. Thus, it can be applied to plasmas that are not in equilibrium at atmospheric pressure, which is often the case during the analysis of complex mixtures. The optical characterization of the discharge was based on the ratios of the O atomic line intensities in the emission spectrum. The electron energy was found to be (0.36 ± 0.04) eV, which was consistent with the results of previous atmospheric plasma studies [34-36]. The electron temperature (Te) can be several orders of magnitude higher than the temperature of the ions (Ti) or the neutral gas (Tg). Therefore, the heavy particles stay close to ambient temperature (27^0C) [29, 37, 38].

The species observed by (OES) in the plasma are formed due to electrons are accelerated by the electric field and can induce electron impact excitation, ionization and dissociation of the primary gas phase (humid-air containing 79% N_2/20% O_2/ 1%) reactions, these are:

$$e + N_2 \rightarrow N_2^* + e, \quad (2)$$
$$e + O_2 \rightarrow O_2^* + e, \quad (3)$$
$$e + N_2 \rightarrow N_2^+ + e + e, \quad (4)$$
$$e + O_2 \rightarrow O_2^+ + e + e, \quad (5)$$
$$e + N_2 \rightarrow N + N + e, \quad (6)$$

The formation in OH• radicals and H species during the plasma treatment may be attributed to the fragmentation/decomposition of H_2O molecules:

$$e + H2O \rightarrow H + OH + e \quad (7)$$

or

$$e + O_2 \rightarrow 2O + e \quad (8)$$
$$O + H_2O \rightarrow OH + OH \quad (9)$$

whereas the formation of atomic oxygen may be due to the dissociation of oxygen molecules by reaction (8).

3.3. X-Ray Diffraction analysis

The XRD patterns of the treated and untreated PP samples are shown in Figure 3. The peak characteristics of the α phase were observed at (2θ) 14.02° (110), 16.8° (040), and 18.44° (130), and between 20.80^0 and 22.40^0 for (111), (131), and (041). The same peaks appeared in the patterns of the treated PP samples, indicating that the plasma had no effect on the crystalline structure of PP. However, the peak intensity of the untreated sample at 16.8° differs from those of the treated samples.

The XRD patterns were used to calculate the crystallite size and orientation of planes in each sample.

The size of crystallites (D) in each PP sample based on the (110) and (040) planes was calculated using the Scherrer equation [16]:

$$D = \frac{0.9\lambda}{\beta \cos\theta}, \quad (10)$$

where λ is the wavelength, β is the full width at half maximum (FWHM), and θ is the maximum angle of dispersion.

The crystallite size (D) was compared with the values obtained from the Williamson-Hall (W–H) model, where the total peak broadening is represented by the sum of the contributions from crystallite size (D) and strain (ε) in the material. Assuming that the strain present in the material is uniform and considering the isotropic nature of the crystal, the W–H equation [15, 16] is given by

$$\beta \cos(\theta) = \frac{0.9\lambda}{D} + 4\varepsilon \sin(\theta). \quad (11)$$

The estimated values of the strain and crystallite size are given in Table 1.

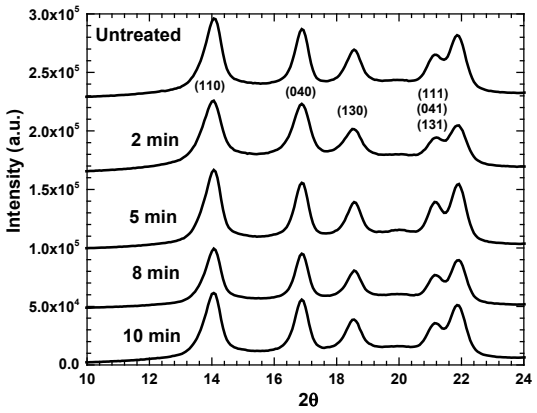

Figure 3: XRD patterns of PP samples subjected to plasma treatment for various periods.

Table 1: Geometric parameters for PP as a function of treatment duration.

Treatment duration	Scherrer´method	Williamson-Hall method	
min	D (nm)	D (nm)	ε (10^{-7})
0	11.7	10.7	4.4
2	10.5	8.0	9.9
5	12.4	10.5	5.6
8	12.9	11.9	3.4
10	12.5	11.8	2.8

We observed that increasing the treatment duration increases the crystal size, except for 2 min of treatment, which may be due to the rearrangement of the orientation parameters of the crystal planes due to the introduction of polar groups on the PP surface by the plasma treatment. In addition, the strain at 2 min of plasma treatment increases almost 100% and then decreases as the treatment duration increases. That behavior may be attributed to dislocations that increase the volume of grain boundaries (increase in the crystal size) due to the plasma treatment and incorporation of the polar groups on the surface of PP.

To evaluate the orientation parameters of the (040) crystal plane, A_{110} (040), and (110) crystal plane, C_{040} (110), we used Zipper's equation, which takes into account the intensities of the peaks observed [39-41]:

$$A_{110}(040) = \frac{I_{110}}{I_{110}+I_{111}+I_{131+041}}, \quad (12)$$

$$C_{040}(110) = \frac{I_{040}}{I_{110}+I_{040}+I_{130}}, \quad (13)$$

where I_{110}, I_{111}, I_{104}, I_{040}, I_{130}, and $I_{131+041}$ correspond to the peak intensity of the respective crystal plane.

Figure 4a shows the orientation indices of A_{110} (040) and C_{040} (110) crystal planes as a function of treatment duration. The orientation indices appear to increase as the duration of plasma treatment increases due to the surface functionalization by the plasma treatment. Changes in crystallite sizes in the (110) and (040) planes during plasma treatment are illustrated in Figure 4b. Crystallites of the samples became smaller during the first 2 min of treatment. The crystallite size increased as the duration of plasma treatment increased. It can be explained because the plasma treatment acts as a nucleating agent on the PP surface, which promotes the formation of perfect crystals [12, 39-41].

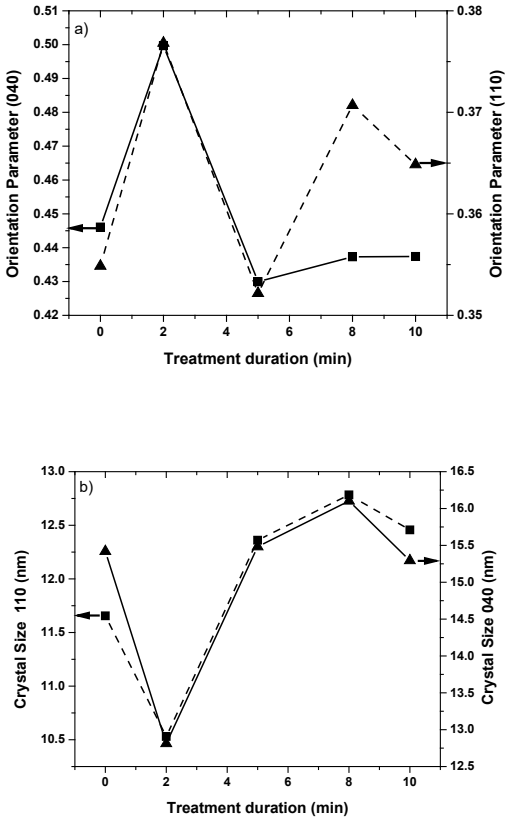

Figure 4: Crystallographic parameters of the treated PP samples. 4.a) Orientation indices of the crystal planes and 4.b) crystallite size.

3.4. Raman analysis

Raman spectra from 809 to 841 cm^{-1} are shown in Figure 5. The peak attributable to the crystalline phases in the PP samples was observed near 809 cm^{-1}, and the peak near 841 cm^{-1} was ascribed to the phases that contained helical chains with isomeric defects [17, 25, 42, 43].

The intensities of the observed peaks (I_{809} and I_{841}) were used to evaluate dispersion changes that were not related to crystallinity. The sum of the intensities ($\bar{I} = I_{809} + I_{841}$) was

independent of crystallinity within the range of measurement. The crystallinity of the treated PP samples was estimated using equations 14 and 15. The proportions of phases with defects and crystalline are denoted by x^b and x^c, respectively [40, 41]:

$$x^b = \frac{I_{841}}{\bar{I}}, \tag{14}$$

$$x^c = \frac{I_{808}}{\bar{I}}. \tag{15}$$

Variations in the proportions of phases with defects (x^b) and crystalline phases (x^c) in the samples are shown in Figure 6. Plasma treatment for 10 min increased the crystallinity of the PP samples, although the x^c values of samples treated for 2, 5, or 8 min slightly decreased. Variations in the proportions of phases with defects indicated that phase defects were associated with crystallinity. Regular chains in the samples subjected to plasma treatment for the greatest amounts of time reorganized to generate helices and local order. The amorphous phases contained irregular atactic chains that could not be reorganized into helices because of the random orientations of their side groups. Those changes are correlated with the increase in crystallite size and orientation parameters due to the plasma treatment and the functionalization of the PP surface [12, 21, 22, 25, 39-43].

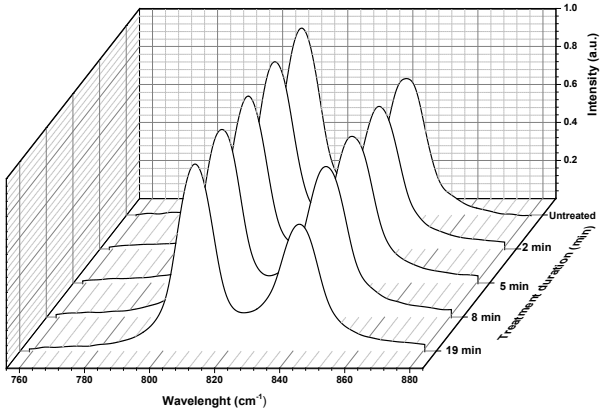

Figure 5: Raman spectra as a function of treatment duration.

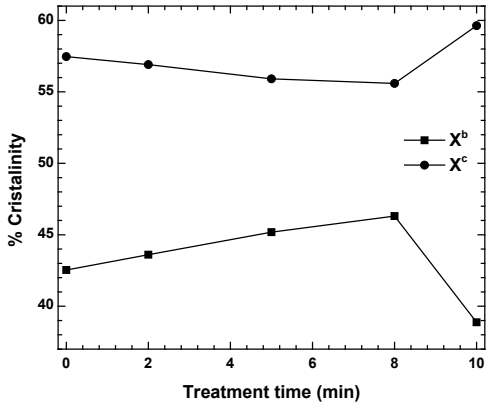

Figure 6: % crystallinity as a function of treated time.

3.5. DSC and TGA analysis

Changes in the thermal properties of the treated PP samples were Changes in the thermal properties of the treated PP samples were analyzed via DSC and TGA. Degradation is shown as a function of temperature in Figure 7. Plasma treatment did not affect mass loss under a nitrogen atmosphere because the percentages of mass lost by the untreated and treated samples did not differ. The first derivative of each mass loss curve indicated the largest change in mass. The highest rates of change in the weight loss curves of PP samples treated for 2 or 5 min occurred at 404 °C. In the weight loss curves of the untreated samples and samples treated for 8 or 10 min, the highest rates of change were observed at 416 °C (Figure 8).

Structural and compositional transformations in a polymer due to plasma treatment can be analyzed by evaluating the changes in its properties at different temperatures [39]. The DSC thermograms of the treated and untreated samples are shown in Figure 9. The untreated sample and samples treated for 8 or 10 min melted at 165 °C, whereas the samples treated for 2 or 5 min melted at 167 °C. Therefore, the melting points of the treated and untreated samples did not differ significantly [24].

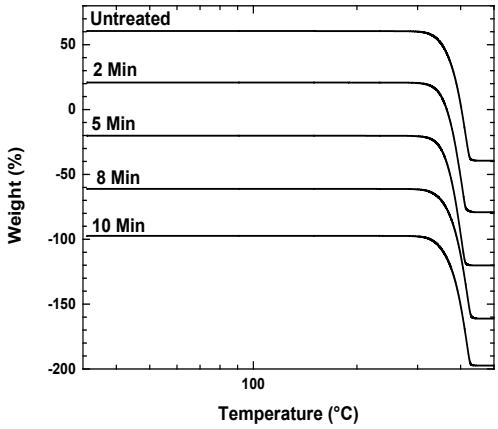

Figure 7: TGA thermograms of the treated and untreated PP samples, the curves have been shifted vertically for better comparison.

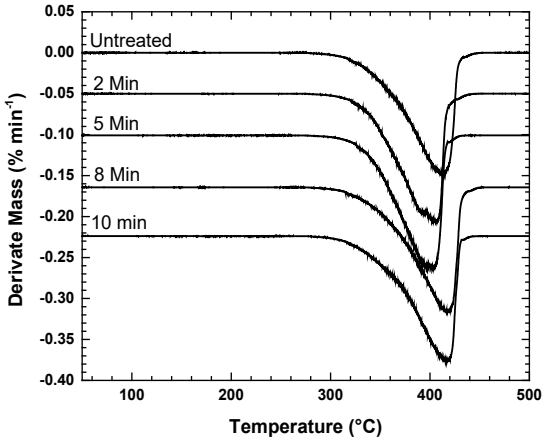

Figure 8: Weight loss curves of the treated and untreated PP samples, the curves have been shifted vertically for better comparison.

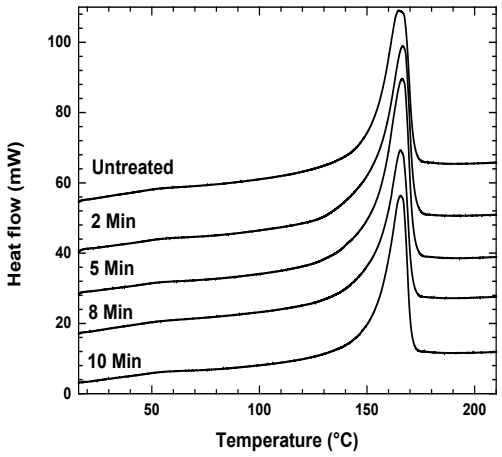

Figure 9: DSC thermograms of the treated and untreated PP samples, the curves have been shifted vertically for better comparison.

3.6. ATR-FTIR analysis

The FTIR spectra of the untreated and treated PP samples are shown in Figure 10. Chemical differences in the surface properties of the plasma-treated PP samples can be observed in Figure 10, indicating changes in their surface chemical compositions. The spectra confirmed the introduction of polar groups into all treated samples. Vibrational bands attributed to carbonyl (C=O) groups appeared from 1,500 to 1,700 cm^{-1} [18-21]. Moreover, the carbonyl (C=O) band was observed at 1,720 cm^{-1} in the spectra of the samples treated for 5 and 10 min but did not appear in the spectra of samples treated for 2 or 8 min. It means that the C content decreases, and the O content increases on the surface because of the plasma treatment. Additionally, the peak around 3400 cm^{-1} corresponding to the hydroxyl (–OH) group was produced by the plasma treatment. The relative intensities of all absorption peaks observed by FTIR were enhanced, indicating the increases in the carbonyl and hydroxyl groups on the surface [44]. In the present treatment, large amounts of O and OH polar groups were appended to the surface of PP because of the plasma treatment, improving the crystallinity and microhardness of PP.

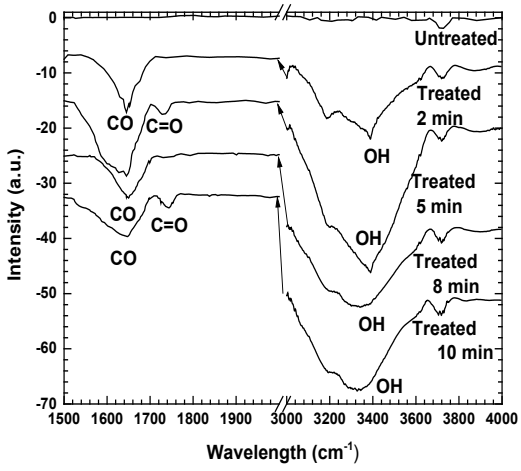

Figure 10: ATR-FTIR spectra as a function of treatment duration.

3.7. Roughness

The AFM images of the untreated and treated samples at 5 min are shown in Figures 11 and 12, respectively. The morphologies of the samples treated by plasmas were smoother than those of the untreated sample. Those figures were used to study the changes in the morphology of the PP samples, and the RMS roughness found for the untreated sample was 0.554 ± 0.064 pm, whereas for the samples treated at 2, 5, 8, and 10 min, the surface roughness values were 0.153 ± 0.031, 0.136 ± 0.013, 0.111 ± 0.024, and 0.090 ± 0.008 pm, respectively. The sample treated at 8 min shows the lowest value of RMS roughness. Those morphological variations may be due to the removal of the top few monolayers of the PP samples produced by the bombardment of plasma particles on the PP surface [13, 18], reducing the surface roughness and improving the microhardness of PP. Although their surfaces were smoothed, the ATR-FTIR spectra of the treated samples indicated that the introduction of polar groups was possible [13, 18-20, 22]

3.8. Microhardness

The microhardness values of the treated and untreated PP samples are plotted in Figure 13. The hardness values of the treated samples were higher than those of the untreated sample, and the hardness of the sample treated for 10 min increased by nearly 56%. An increase in hardness is attributed to annealing effects and chemical etching produced by the plasma treatment [45]. Also, the hardness increase may be related to either the hardening of interlamellar regions due to the polar group penetration or the hardening of the crystals themselves caused by the surface attachment of polar groups, as observed by Raman and ATR-FTIR. Plausible changes on the PP surface caused by the plasma treatment include cross-linking and oxidation. Cross-linking is due to the formation of tertiary carbon radicals. Tertiary hydrogen abstraction generates carbon radicals, which react with radicals in the nearest molecular chain. Oxidation primarily affects secondary carbon atoms. The introduction of oxygen-bearing groups, including –C–OH, –CO–OH, and –C=O moieties, occurs when the bonds between hydrogen and secondary carbon atoms on the PP surface are broken during the plasma treatment [13, 22-23].

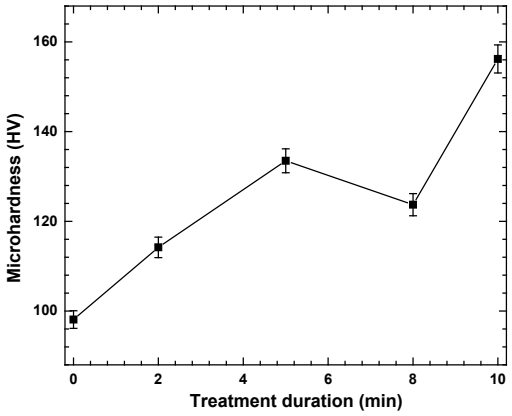

Figure 13: Microhardness values of the samples before and after plasma treatment

4. Conclusions

A commercial plasma device was used for the surface modification of PP. Using OES, we determined the chemical species formed in the plasma. High concentrations of OH and O radicals were observed in the plasma, and they led to the formation of functional polar groups, C–O, C=O, and C–O–OH bonds, on the PP surface. The plasma treatment increased the crystallinity size and microhardness. This enhanced effect is attributed to the formation of polar groups produced by the air plasma due to the oxygen radicals in the air plasma hitting the PP surface. The formation of polar groups in the PP surface was corroborated by Raman and ATR-FTIR spectroscopies. DSC and TGA indicated that plasma treatment had no effect on the thermal properties of PP. AFM analysis showed that plasma treatment for extended periods reduced the surface roughness of PP. Finally, the increase in PP hardness is attributed to the introduction of carbonyl and hydroxyl groups by the plasma treatment, cross-linking, annealing effects, and chemical etching produced by the plasma treatment.

ABSTRACT

Advances in the world of communications and information technology, as well as the urgent necessity to monitor particular areas and regions, have led to a considerable and influential development in the world of wireless sensor nodes. As they are small, low-cost multi-purpose nodes with limited energy and capabilities. The most important points that deserve research and solution is the problem of energy conservation and increasing the lifetime of the network as a whole. Whereas, many routing protocols have been proposed in the wireless sensor network, some of which are based on homogenous networks while others are not, some are location-based, some are based on hierarchical orientation, some are based on the hybrid approach and many more. Despite the long time that has passed since the discovery and activation of the Low Energy Adaptive Clustering Hierarchy (LEACH) protocol, it and its descendants still have the lion's share of attention, research, and development. In this research, we will be presenting the most prominent routing protocols while pointing to some pros and cons of each protocol.

1. Introduction

"This paper is an extension of work originally presented in "11th International Conference on Information and Communication Systems (ICICS). IEEE, 2020" [1].

Wireless sensor networks (WSN) can be defined as collection of thousands or hundreds of thousands of small self-configuring sensor nodes that bond together and collaborate to aggregate information and send it to a central station. The purpose simply is to get rid of the human aspect [2]. Usually, (these nodes being distributed randomly by aircrafts to serve military interests, detecting natural disasters like fires and earthquakes, also it plays a huge role in some peaceful applications such as detection of a specific disease in a specific crop, health care, electronic sales, and others [2]. On the other hand, routing is defined as the process of exactly determining the path from the main source to the final destination, and it must be fast and reliable as well.

As a reminder, these nodes are thrown from aircraft randomly and to places that are difficult for humans to reach, so they must remain functional as long as possible. Unfortunately, the only energy source for them is the battery and it is known that the battery depletes quickly and the node dies at that time. Therefore, the most important challenge is to keep the nodes alive as much as possible and distribute the total energy wisely, and not lose their energy, especially in the early stages. Researchers have provided a massive number of routing protocols and classify them on several levels, considerations, and parameters [1].

The rest of our research is split into the following sections: in section II the problems of routing are presented. In section III. Most important WSN routing methods. In section IV. Furthermore, Low energy adaptive clustering hierarchy (LEACH), the before the last section V. Different routing protocols based on (LEACH) protocol, the last VI. Conclusion and future work subsequently reference.

2. The Problems of Routing

In WSN, routing protocols can be considered to be dependent on the application, the data to be collected, and the good use of limited energy. A good routing protocol is a protocol that has several advantages, including simplicity, ability to know its energy level, ability to expand and adapt under the limited capabilities of the nodes, to name a few: power, memory, computation capabilities, and bandwidth allocated to the network according to [3]. The main purpose of the network design is to

*Corresponding Author: Nour Najeeb Abdalkareem Qubbaj, Email: nou20188107@std.psut.edu.jo

deliver all the information from the deployed nodes to the base station (BS) with the lowest possible power. This design faces several obstacles, including [1,3]:

2.1. Deployment of nodes

Deployment of nodes relies on the type of application that massively affects the efficiency of the routing protocol. Where the deployment of the sensor nodes may be random (self-organizing), by plane, for example, or be in a specific and thoughtful place. The node may be fixed, not moving, and it may be mobile, or all of them are stationary and the main station is mobile.

Location and movement play an important bit part in energy efficiency.

2.2. Conservation of energy

Data and information are transmitted by radio through the network, the power of the radio is inversely proportional to the square of the distance traveled, and the power consumption will be affected in the event of obstacles. Therefore, it is better to use the multi-hop approach rather than one-hop. It is worth noting that the one-hop orientation is suitable for a network with a small number of nodes and close to each other, which confirms that energy is affected by the paths that you take.

2.3. Tolerance of Faults

Error tolerance can be described as the ability of the network to continue its operation in the presence of obstacles. Such as the nodes death. For example, the routing protocol must quickly find an alternate route to cancel an insufficiency of information to the main (Base) station.

2.4. WSN Scalability

The number of nodes in the target area to be monitored will exceed hundreds or thousands. Thus the routing protocol must be able to accommodate this large density of nodes.

2.5. Constraints on hardware

All components of the nodes including, the power unit (battery), the processing unit (memory and the microprocessor unit), the sensor unit (sensor), and the radio communication unit, must be smaller in size, less expensive, and energy-consuming.

2.6. The surrounding environment

The node must be prepared for the difficult conditions in which it will monitor.

2.7. Transmission Media

From the name (WSN), we find that the mean of communication is wireless communication, as it is vulnerable to the rate of error and greatly influences the correct operation of the network.

2.8. Models for data delivery

Delivering the data to the main station is related to the type of application, it may be continuous, where all the data is sent to the station continuously and periodically. While if the connection is related to an event, the node sends its data when a specific event occurs. The communication may also be inquiry-oriented, so that when the station needs to inquire about a specific piece of information from the nodes, and the connection may be a hybrid connection consisting of two or more of the mentioned methods. Finally, it's worth pointing that the routing protocol being influenced by the type of that connection significantly.

2.9. Information aggregation (fusion)

The cluster head (CH) collects data from more than one node, so there is a possibility of duplicating data, especially adjacent nodes, so CH does this data fusion process to minimize the volume of the transmitted data to the main station.

2.10. Capacity of node

The capacity of a node this means that it is possible to assign a specific sensor node to one of the functions(tasks) (relaying, sensing, aggregation) according to the application, instead of giving the node all the functions(tasks) together to avoid consuming excess energy.

3. Most Important WSN Routing Methods

Route pathways may be defined in one of three forms i.e. reactive, proactive, or mixed, the reactive paths calculate the paths when the actual necessity of them. While the proactive route precedes the occurrence of the real event and stores the possible paths in a table for each node, it is heavy-duty due to the huge number of network nodes. The last type is the combination of the characteristics of both proactive and reactive see Fig 1.

Based on the design of network flow, the routing protocols are classified into flat-routing, hierarchical and location-based routing. In flat-based routing, all nodes execute the same task such that data is transferred from each sensor node with a strong data repetition [3].

Hierarchical Protocols, the clusters are formed in this type to raise energy efficiency and accommodate a large number of nodes and cover a larger area of the network with better efficiency by applying two main steps. The first one is determining the head of the cluster. The second is the path from the head of the cluster to the main station. [3].

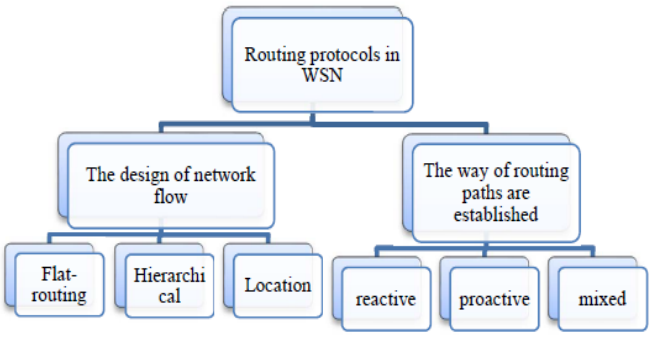

Figure 1: Routing protocols kinds [1].

Location-based protocols, some applications may require the

location of the node to calculate the distance between the nodes. There are several ways to calculate this, including (Global Positioning System) GPS or other ways [3]. See Fig 1.

The most rudimentary way to transfer data from the nodes to the base station is that each node does this by itself without an intermediary, which is known as Direct Transmission (DT), as it is considered one of the flat and simple protocols. And another example of it too is Minimum Transmission Energy (MTE). Whereas, the nodes that are farther from the base station and the nodes with a large volume of data require more energy than others. Therefore, the hierarchical protocols are distinguished from the flat and simple protocols, such as the ones mentioned.

The working principle of the clustering methods of WSN, is based on dividing the entire network into groups called the clusters, and in each cluster, there is a header that gathers data from the rest of the nodes, merges them, reduces their size, and sends them at once to the Base Station (BS) and the role of this head is exchanged with the rest of the nodes in the clustering according to the followed protocol [4]. Cluster formation has several characteristic and advantages, so it excels over flat protocols, including [5]:

- Easily handle the complexity of the network: The network is composed of nodes that act as the head of the cluster and that communicate directly with the main station on behalf of all the nodes of the cluster, and other nodes that collect data from the surrounding environment and send it to the head of the cluster that does not have another load, thus the master station receives data from a small number of nodes rather than all of the cluster members and thus facilitates control of the network as a whole see Figure 2.
- Aggregation / Fusion of information: Where the CH integrates and collects information from the rest of the members and reduces its size before sending it to the base station, the base station receives data from a small number of nodes rather than all of the cluster members.

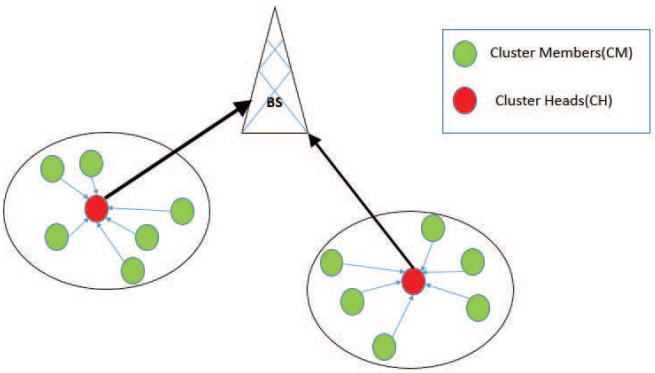

Figure 2: Creation of clusters [6].

- The life of the network is stronger and longer: By rotating the head of the cluster in every round to distribute an equal distribution of energy among the network members.
- Reducing collisions and traffic: In a WSN with a flat communication model, all the nodes must send their information to the main station at the same time. In the clustering organized, the communication with the main station is limited only to the head of the clusters.

4. Low Energy Adaptive Clustering Hierarchy (LEACH)

It is the parent protocol for hierarchical routing based on Clustering proposed by W.B. Heinzelman [7]. As has been reported, the clustering protocols have proven effective in distributing energy consumption among members and increasing the life of the network as a whole.

LEACH works on the principle of dividing the network into random groups (clusters) and then choosing a node from each group to be the head node to represent its group while connecting to BS. The role of the cluster head rotates to keep the energy consumption distributed among the network members. It's worth pointing that the head nodes have the heading role as an additional role to their original tasks (tasks of the non-cluster head nodes). It is also a kind of one-step approach (one-hop routing) to the BS. The LEACH principle is divided into several rounds, and each round contains two basic stages: One is the Setup stage, and the other is the Steady stage as shown in Figure 3.

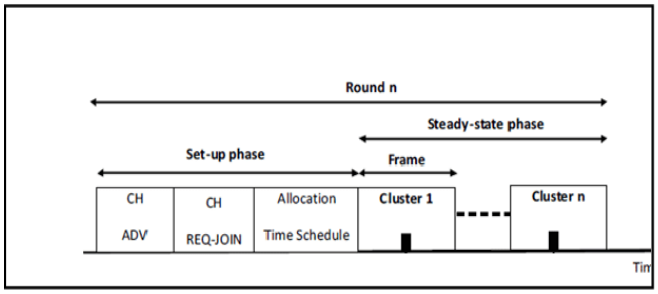

Figure 3: Operation of LEACH [8].

The node must initially pick a random number (n). If this number (n) is less than the threshold specified in the first equation T(n), then the node is selected as the cluster header (CH).

$$T(n) = \begin{cases} \dfrac{p}{1 - p.\left(r \bmod \frac{1}{p}\right)} & if\ n \epsilon\ G \\ 0 & otherwise \end{cases} \quad (1)$$

while p is the possibility of a cluster head (CH), G is a list of nodes that will never be chosen as cluster-head (CH) nodes until the 1 / p level.

After selecting the heads of the cluster according to the number (n), each cluster head will broadcast its status to all other nodes via CDMA (Code Division Multiple Access). After receiving broadcast messages from CHs, each normal node uses the Received Signal Strength (RSS) to determine which CHs are closest to it. Then the CH creates TDMA (Time Division Multiple Access) to divide a schedule for members of the same group (cluster) so that the normal node is activated and connected to CH at the time allotted to it according to the TDMA schedule. It will

be inactive at other times to preserve its energy, which means that CH deals with all nodes from the same cluster and is the only one who deals with BS from cluster members [9]. Note that the period of the Steady stage is longer than the Setup stage.

The significant drawbacks of LEACH are the following, according to [1,2,10]:

- Since LEACH (one-hop routing) to the BS is never suitable for a large network of sensors.
- Not suitable for time-compulsory applications due to delays.
- Unacceptable distribution for cluster heads: as have been stated earlier, a random selection of CH that is not based on clear criteria such as the distance between CH and BS, causes an imbalance in the power consumption of the network and this is considered a significant drawback.
- Unacceptable selection of cluster head: The randomness in choosing the head of the cluster so that the primordial energy of each node is not taken before it is considered as the head of the cluster.
- Note that the types of data delivery to the base station may be continuous, event-related, directed to an inquiry, or a mixture between them. The LEACH protocol is more appropriate with continuous delivery only.
- Different sizes for each cluster: The randomness of choosing the cluster causes the existence of large-numbered clusters and other small-number without specific study due to randomness only.

Several routing protocols have been proposed to solve some of these problems faced by the LEACH protocol, the most prominent of which will be presented in section Five.

5. Different Routing Protocols Based On (LEACH) Protocol

5.1. Low Energy Adaptive Clustering Hierarchy Centralized (Leach-C)

LEACH-C is one of the LEACH versions, which is a centralized protocol. It is divided into several rounds as the LEACH protocol and each round into two basic stages. This protocol assumes that each node can communicate directly with the BS and can calculate its energy and current position.

Unlike LEACH, LEACH-C take into consideration the distance from the node to the base station. The base station determines who is the CH in this round based on its energy and the distance between the node and the base station.

Where in the setup stage all nodes send their energy and location to the base station, the station calculates the average value of the energy values, and the node that contains energy higher than the average value is elected as CH for this round. In the Steady stage, the non-head nodes send their information to the head of their cluster, and the head of the cluster, in turn, collects the data and sends it back to the base station [5].

5.2. LEACH-Balanced (LEACH-B)

The LEACH-B protocol overcomes the original LEACH protocol by taking into account the remaining energy of the node and also strives to maintain the optimum number of cluster heads per round of the protocol. The optimum value for the number of cluster heads varies from 3 to 5% based on what was mentioned in [11]. Thus reduce energy consumption, it is a decentralized protocol, LEACH-B has improved energy performance compared to the parent LEACH protocol see Figure 4.

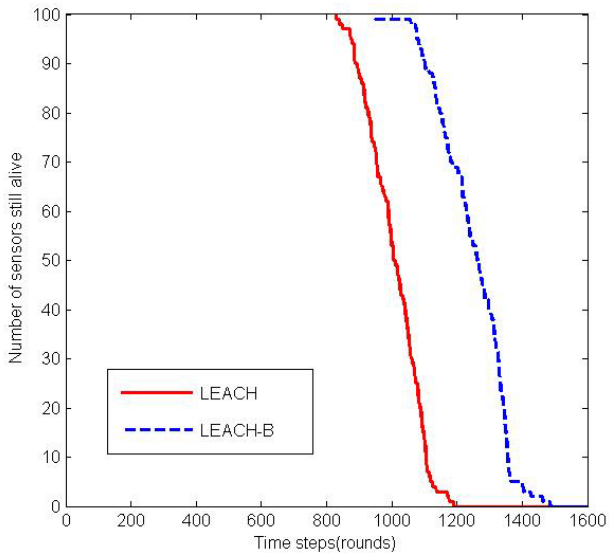

Figure 4: System life of LEACH and LEACH-B [11].

5.3. Fixed Number of Clusters LEACH (LEACH- F)

This protocol is a centralized approach, like the LEACH-C protocol. clusters are set, and rotation is just for the CH inside the same cluster. The steady-state is identical to the original LEACH since the number of clusters has been determined in advance, the energy wanted for re-clustering is saved. It is not elastic in the case of extension, elimination, or death of a sensor node [12].

5.4. Advanced Low Energy Adaptive Clustering Hierarchy (A-LEACH)

As a result of the overload on CH, it is likely to die early before the other nodes, A-LEACH prolongs the duration of stability (the time before the death of the first node). It worth mentioning mention that A-LEACH is a heterogeneous protocol.

Its working principle is as follows: Every sensor knows how to continue each round utilizing the synchronized clock. Let's assume that the total number of nodes is (n), and (m) is the number of nodes that contain more power than others (also called (CGA) nodes that chosen as gateways or CH), so the number of nodes other than nodes can be found using equation 2, see Fig 5.

$$head = (1 - m)\,.\,(n) \qquad (2)$$

A-LEACH is defined as a Distributed Algorithm because the selection of clusters is independent of the base station. CAG nodes can start to transmit data even when all the non-cluster head nodes collapse [12].

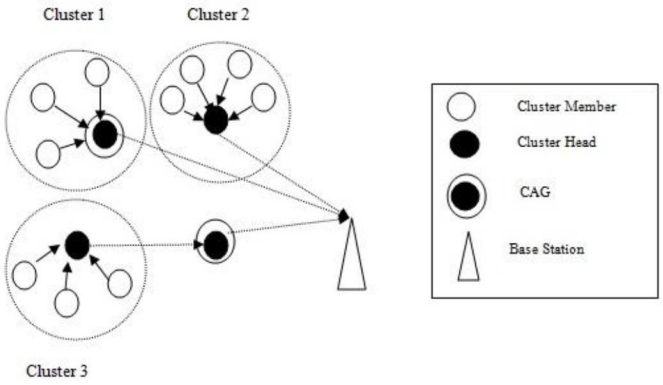

Figure 5: LEACH -A system [1].

5.5. Energy Low Energy Adaptive Clustering Hierarchy (LEACH-E)

E-LEACH is a variant of the LEACH protocol that takes into account the residual energy of a node selected as a cluster head. So the node with the maximum and most appropriate energy is chosen. In other words, E-LEACH is concerned with the number of CHs where the large number of cluster heads consumes higher energy while the small number of cluster heads will cover a greater distance. If the nodes are scattered away from the BS, it will consume more energy. The most appropriate number of cluster heads should be determined, their location and energy. The minimal spanning tree of cluster heads is used in the E-LEACH see Figure 6 [1,2].

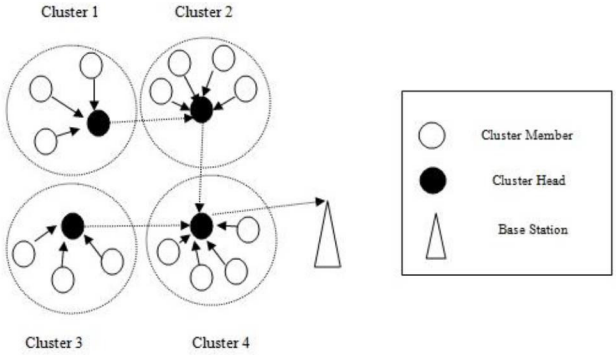

Figure 6: LEACH -E system [1].

5.6. Vice Cluster Head LEACH (V- LEACH)

V-LEACH is another version of the LEACH protocol. It is known that the load on the cluster head is greater because it aggregates data from the rest of the nodes and performs simple operations to reduce its size and transfer it to the main station.

If the CH energy is reduced, it will die thus, the whole cluster is useless because it does not communicate its information to the main station. V-LEACH suggested that the presence of a deputy head of the cluster in the event of his death. The vice-CH is responsible for transferring the information to the main station thus, the whole cluster remains connected with the main station, but in case of death of the vice-CH, there is no solution in this protocol see Figure 7 [10].

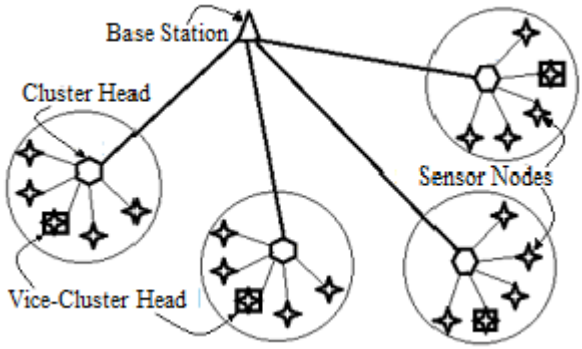

Figure 7: LEACH -V system [13].

5.7. I-LEACH

A new algorithm, I-LEACH, has been proposed, which takes into account the following: the geographic location of the CH, the number of neighbors, and the residual energy to improve network performance and lengthen its life. So the node with the most residual energy and closest to the BS is chosen. This protocol overcame a set of drawbacks of the original LEACH protocol some of them: Different size for each cluster, Unacceptable distribution for cluster heads, and Unacceptable selection of cluster head.

I-LEACH has been evaluated and proven to be effective in average energy consumption, the number of data packets received, and the flexibility to change the location of the BS in the network. Where it reduced energy consumption by approximately 62%, increased the percentage of data packets received by approximately 56%, and increased the life of the network each by 65% at least [14].

I-LEACH, has some of the following assumptions:

- All nodes have the same primary energy, are not rechargeable, and in the same random position when the nodes are thrown from the airplane. They remain in place and never move.
- All nodes have their identifier and can know their exact location and the remaining energy in its battery.
- It is known that each node contains a processing unit and a memory unit, and it can also define the sensed and the aggregated data.
- A node can sense different types of data.
- Each node can communicate directly with the BS and has the power required for this.

5.8. Cell Low Energy Adaptive Clustering Hierarchy (Cell-LEACH)

Cell-LEACH is another version of the LEACH, as in the original LEACH protocol, the entire network is split into groups (clusters). Here too, the network is divided into groups where each group is divided into 7sub-groups called cells. Each group has a cell head whose task is collecting the information from the members of the cell and communicates directly with the head of the cluster. The cell is randomly assigned and then chosen based on its remaining energy to be cell head see Figure 8 [15]. Cell-LEACH has proven its ability to lengthen the network life without

reducing efficiency as can be seen in Figure 9.

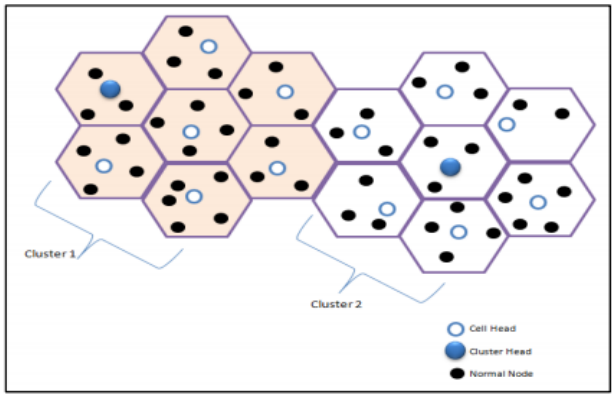

Figure 8: LEACH -Cell system [16]

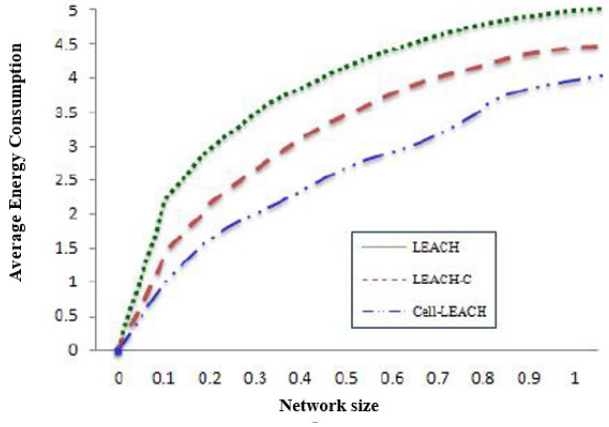

Figure 9: Average power consumed with network size [15].

5.9. Multi-Hop LEACH

5.9.1. TL-LEACH (Two levels LEACH)

Two levels LEACH) was suggested in [17]. Instead of aggregating and transmitting data in one hop, the data in CH being aggregated at a certain level and transferred to a closer CH level to BS thus, reducing the transmission power, which enhances energy efficiency, and extending the network life. To illustrate the idea further, we have Fig 10 that shows that there are 3 CHs at the top level is closest to BS and also 5 CHs on the second level closest to the normal nodes sensor, and the other 10 SN (Sensor Node) normal nodes at the final level. It has been shown that TL-LEACH increases network life by nearly 30 percent and also increases the percentage of packets received by 20 percent [17].

5.9.2. Multi-Hop LEACH:

Due to the disadvantage in " LEACH (one-hop routing) to the BS", and as mentioned earlier, the task of the cluster head is to transfer the collected data from the non-head nodes to the BS. This implies that if the distance is large, then the energy of the cluster head runs out quickly. So a midway cluster head has been considered to reduce distance, thus reducing energy consumption this is known as multi-hop communication [6].

SN	**Sensor Nodes**
CH_{ij}	**Cluster Head to second level**
CH_i	**Cluster Head to first level**
BS	**Base Station**

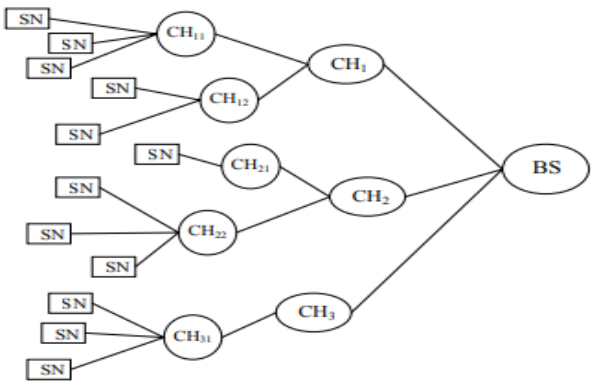

Figure 10: The TL-LEACH network format after the setup phase [17].

The original LEACH protocol does not take into account the primitive energy of the head of the cluster, CH may lose its energy more quickly than others and die, and this cluster loses its connection with the main station. Therefore, it has been proposed to amend the basis of CH selection to take into account energy.

A term was added to the original formula for the original LEACH protocol as in Equation 3 [6].

$$T(n) = \begin{cases} \dfrac{p}{1 - p.\left(r \bmod \frac{1}{p}\right)} \cdot \dfrac{E_{rem}}{E_{totnet}} & if\ n \epsilon\ G \\ 0 & otherwise \end{cases} \quad (3)$$

while p is the possibility of a cluster head (CH), G is a list of nodes that will never be chosen as cluster-head (CH) nodes until the 1 / p level. E_{rem} is the remaining energy level of the node, E_{totnet} is the total energy network. This happens in the setup phase.

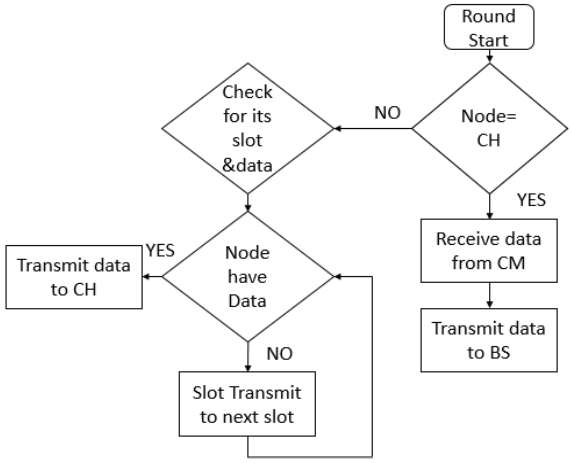

Fig 11: Freshly revised TDMA description [6].

In several protocols associated with an event, the most appropriate thing to do is to take advantage of the free time of the nodes. For example, when a node does not have information to send to the main station, an allocation technique activates to allocate the time assigned to the free node in the TDMA schedule to another node that has information to send. Thus, reducing energy and time consumption as well, as can be seen in Fig 11 [6].

5.10. Clustering Process Based on Fuzzy Logic

Fuzzy logic simulates human decision-making and experience to judge things and deals with decisions better than probabilistic approaches. Also, it is more suitable for real-time applications [18]. Due to the suspicion and doubt in the WSN environment, some protocols use Fuzzy Logic technology, as it simulates human logic less than others, which include computational complexities and the need for memory. Fuzzy Logic protocols used to choose CH more effectively and flexibly due to its flexibility and error tolerance choose CH more. The Fuzzy Logic model requires four steps to accomplish, namely:

- Fuzzification: In it, the inputs are inserted with clear values and are distorted into a fuzzy group, and this happens in the fuzzifier.
- Rule evaluation (Fuzzy Rule base): This is storing Rule IF-THEN.
- Fuzzy Inference Engine: This engine handles both input and law IF-THEN to produce a fuzzy group.
- Defuzzification: Converts the fuzzy group to clear values.

These steps are shown in Figure 12. Most of the Fuzzification methods use Mamdani's Method Fuzzy Inference technique to select the CH.

This block is called fuzzy logic controller (FLC). Not too long ago, the authors began leveraging Fuzzy Logic (FL) and incorporating it into WSN to lengthen the life of the network and improve the method for selecting the appropriate CH. Some of the popular Clustering Process Based on Fuzzy Logic will be featured in this section:

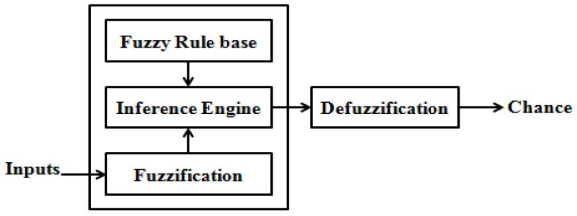

Figure 12: The Fuzzy Inference Process structure diagram.

5.10.1 Cluster Head Election using Fuzzy Logic (CHEF):

In this type, CH is chosen by entering two inputs: power and local distance. (The local distance is the total distance between the temporary CH in that round and the cluster members (normal nodes) within a predetermined fixed competition radius) [19]. So that the likelihood of the closest and more energy nodes to be selected as CH is higher than others, As the experiments of [18] show that CHEF is 22.7% more effective than LEACH.

However, some of the disadvantages of this type are that not all sensor nodes have a GPS device and sometimes are not able to know their geographical location [18]. Besides, this type is not suitable for network sized about 200m × 200m or more [19,20]. clusters closer to BS, run out of energy faster because traffic becomes congested the closer to BS, so an unequal clustering has been suggested to balance energy consumption [19].

5.10.2 Energy Efficient Unequal Clustering (EEUC):

This type divides all nodes into clusters that are not equal in number so that the clusters close to the BS contain fewer nodes. The distant clusters contain a greater number because the closer we get to the base station, the congested the traffic becomes, causing the closest nodes to consume more energy from the farthest [21]. As in the LEACH, the choice of CH is random here is random as well, a random number between 0 and 1 assigned for each node. The number indicates whether the node is going to be a CH or not [19]. Experiments proved that EEUC is more efficient than LEACH see Figure 13.

5.10.3. Energy-Aware Unequal Clustering with Fuzzy (EAUCF):

Battery level goes down to the CH [19]. In other words, when the residual energy of the temporary CH and the distance to the BS is large then the competition radius is large and vice versa [21]. Let us say that each temporary CH will forward its remaining energy and also if it is within the competition radius of this CH, another temporary CH will be compared between their energy, and the least energy will be out of competition and not CH [20]. In the experiments. It has been proven that EAUCF is more efficient than LEACH, CHEF, and EEUC see Figure 13. While this type does not pay attention to the degree of the node, it means the density of the internal cluster, as the density of communication inside the cluster costs energy and reduces the life of the wireless network as a whole [20].

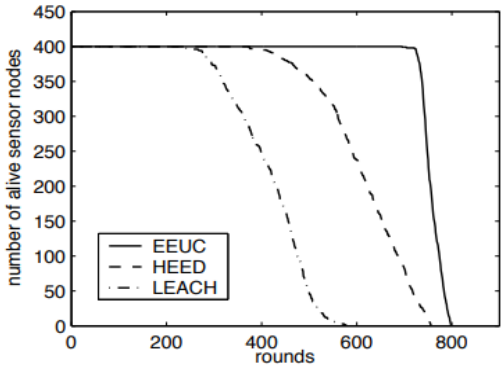

Figure 13: Over time, the number of live sensor nodes [22].

5.10.4. Fuzzy Cluster Head Selection Algorithm based on LEACH:

The authors of [16] noticed that when more than one entry is taken into account to determine one output (appropriate CH selection), Fuzzy Logic, is more accurate and appropriate than others. This type requires three fuzzy input variables. The first variable expresses the number of surviving neighbors, the second

variable expresses residual (remaining) energy, the last variable expresses the distance to BS. The one variable of fuzzy output is named a chance [20] as shown in Figure 15. The CH is selected with the most living neighbors, the highest residual energy, and the least distant to BS [20].

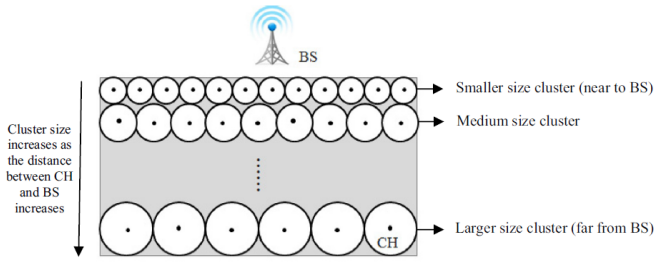

Figure 14: Unequal clustering architecture at WSN [22]].

Table 1: At round 250, the total remains energy for each algorithm [19]

Algorithm	Total Remaining Energy (J)
LEACH	27.14
CHEF	43.66
EEUC	44.78
EAUCF	46.41

Just like the LEACH, in each cycle, every node picks a random number between 0 and 1, and if the number was chosen is less than the threshold T, then it becomes within the Concurrent CH. Then each Concurrent CH node calculates its chance from the output of the Fuzzy and shares it with the rest of the Concurrent CH who are within its competition radius. Consequently, each Concurrent node CH has a list of all CH node and its chance, where the highest is elected as CH node, and the rest within the competition radius is a normal node and the elected CH node joins. Also, as usual, the elected CH node is required to create a TDMA schedule and to publish it to the rest of the cluster. The normal nodes send their information to the selected CH node in the time allotted to them and turn off their transmitter device at other times to conserve energy [20]. Compared to LEACH, this form improves network life by 58.38 percent see Table 1.

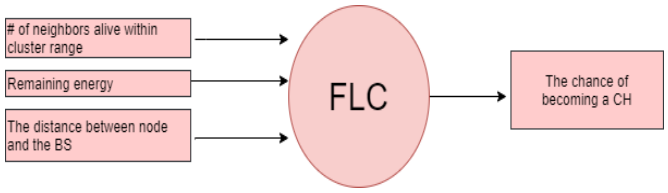

Figure 15: The Fuzzy-Logic system which controls the clustering

5.10.5. A Fuzzy-Logic based Energy-Efficient Clustering algorithm (FLEEC):

The authors of [21] noticed that when more than one entry is taken into account to determine one output (appropriate CH selection), Fuzzy Logic, is more accurate and appropriate than others. It should be noted that the process of calculating the distance between the node and the BS is done based on the Received Signal Strength (RSS).

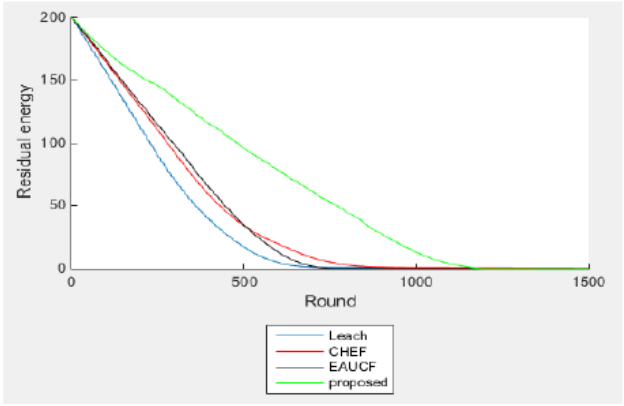

Figure 16: The full remaining energy of every cycle [20].

If clusters of the same size are created without taking into account the distance to the BS, then a "hot spot problem" begins to arise. As was evident from Figure 14, it requires more energy for the cluster closer to the BS. To create uneven clusters, the first fuzzy logic controller (FLC) is constructed, which takes two inputs (The distance to the base station and Node Density), and one output (cluster Radius) see Figure 15. Then the head of potential clusters measures the total distance of the neighbors that are in their radius [21]. The total distance to the CH and Residual energy are inputs to the second FLC, and the output is the probability of each node to be CH. The node that has the highest likelihood to become CH is when the node has the largest residual energy and more neighbors.

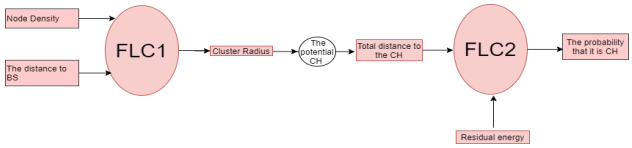

Figure 17: The Fuzzy-Logic system which controls the clustering in (FLEEC)

FLLEC is composed of three major stages [21]:

- Determination of cluster size process: First of all, the BS node broadcasts a welcome message to every node in the region, and then each node would like to calculate its distance from BS via Received Signals Strength (RSS). Each node sends to the BS node an ACK message, which contains its ID, residual energy, geographic distance from the BS node. Then the BS computes the density distribution from the information it obtained from every node. Here comes the role of the first FLC by calculating the corresponding cluster radius for each sensor node, and this information is saved in the memory of each node.
- Determination of likelihood to be a cluster head process: After the cluster radius determined successfully, all nodes would like to broadcast a message of exploring the neighbors around it, and each would like it to receive that message followed an ACK message. After that, the nodes calculate the total distance of their neighbors according to RSS. Here comes the role of the second FLC to calculate the likelihood to be CHs depending on the fuzzy rules reserved in the fuzzy rules base.

- Determination of CH process: Each Node broadcasts the HELLO message to all of its neighbors within the competition radius that it has both CH and its ID. During this information exchange process, the CH that has the greatest probability is the one who becomes CH and the rest is a normal node. CH broadcasts an advertisement message (ADV). If the normal node receives more than the ADV, then it determines the most suitable one that will belong to it, then each node sends a request message to the most appropriate CH.

Comparing FLEEC to LEACH (the main clustering algorithm) and CHEF (the main fuzzy-logic-based algorithm) algorithms. As can be seen from Figure 18, the results showed the superiority of FLEEC over both LEACH and CHEF, especially in the issue of energy consumption.

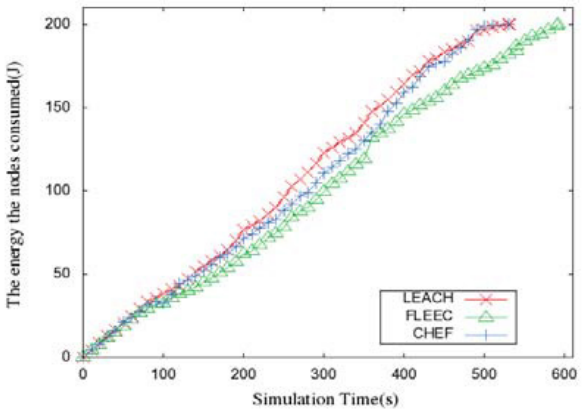

Figure 18: The energy consumed by the three main algorithms is comparable [21].

6. Conclusion and future work

Due to the emergence of nanotechnology and the persistence of multiple computing fields, the field of WSN and the optimal management of node energy remains a fertile field for research and experiment. This study covered two main topics, presenting and discussing some of the most paramount routing protocols and describing their key types and issues, and going through the most prominent hierarchical protocols and their development process.

We concluded from this research that the clustering design is one of the most energy-saving designs. Where we noticed that Multi-Hop LEACH saves energy because it reduces the distance over the CH and also excels and the fuzzy logic strategy based on clustering is superior to other clustering strategies because it is in line with human logic and its ability to convert more from one input to one output, and as it was presented in the research, it was saving more energy than any other algorithms.

In future work, machine learning with the wireless sensor network can be studied to further rationalize energy consumption and merge data before sending it to BS.

ABSTRACT

In 1980, an application was developed to track, manage and store documents in electronic format. Scan technology has enabled organizations to digitize papers for easier document storage and tracking. Document management tools have since developed by introducing new functionalities, related to security, users services, workflow and audit. Our research is part of the context of improving the efficiency of document processing by proposing an approach using information traceability retrieval and content recognition techniques through machine learning. In this sense, we started by proposing the exploitation and extraction of relationships between documents based on the traceability links and the calculation of similarity using information retrieval. Then, in order to improve the processing of documents, we proposed a contribution of the use of recognition of content techniques by machine learning approaches. Thus, the visualization of the results, according to user profiles, motivated us to offer recommendations dedicated to the document management system. A Big Data environment is proposed because of the exponential growth of data and also to our needs concerning the analysis and the distributed calculation of the voluminous masses of data.

1. Introduction

The definition of a document according to ISO (International Organization for Standardization); "Is the set consisting of an information medium and the data recorded on it, in a generally permanent form and readable by humans or by a machine". A document in electronic format is a file created, modified and readable by a dedicated computer application; it can be an audio, an image or any data file. Electronic documents are the precious treasure and the important part for the reuse and preservation of valuable data in storage based on operators of compression, decompression, encryption and decryption [1], [2]. From these definitions, we notice that any document, no matter how electronic or classic, it keeps two important properties; the information which represents the content processed at the document level and the metadata part which offers the possibility of introducing the notion of object at the level of the design of a document [3]. In the Information Technology (IT) domain, traceability is becoming an obligation for companies offering applications, systems or services that meet market requirements. At the IT project level, changing needs is essential in order to develop a good product that meets all customer requirements, in which case traceability is an essential element for managing changes as well as analyzing its impacts. However, traceability must be proposed to show that a methodological development process has been respected and to justify that the developed tool is ready for use [4]. Using what we have called traceability information retrieval, for the purposes of this article, is a process of producing a list of relevant documents as a response to a user's request by comparing the request to an automatically generated index of the content of documents in the tool [5]. These documents can be consulted subsequently to be processed in the same tool. Today everyone uses tools and applications using information research techniques, for example the search engines Google, Yahoo and Bing.

Nowadays, organizations are constantly seeking to be more flexible and optimized to cope with the revolution in the digital world. Each organization aims for organizational excellence through different means to satisfy either the project teams or their customers or their suppliers [6]. To meet expectations, an effective policy and a strategic vision must be created in a clear way through the structuring of processes, documents and resources. According to management standards [7], the updating of documents plays a very important role in the continuous improvement of the

*Corresponding Author: Othmane Rahmaoui, Hassan II University, ESTC RITM Lab., ENSEM, Casablanca, Morocco, othmane.rahmaoui@gmail.com

company, because the documentation, updated, guarantees optimal efficiency unlike documentation that discards outdated information and so that will make it obsolete. Documentation management is one of the important levers for building quality management; it allows the organization of a set of information, documents and records used in projects or in the various departments of the 'business [8]. A document can be in paper or electronic format.

In order to protect and ensure the validity of easily accessible data as well as keep traceability on the operations and activities carried out, we have thought of improving the processing of documents. However, we started by researching and formalizing methods and procedures necessary and sufficient to control the information and documents useful for the entire organization (entity, service, project, etc.) as well as the technologies that can be used in this direction. The proposed approach targets important issues in order to limit the risks of loss of documents and to make work collaborative with the sharing and capitalization of resources as well as communication between employees and accessibility to information, without forgetting security and reliability as well as traceability management [9], [10]. Our approach saves time in the search for information or documents, increases efficiency, increases the satisfaction of project teams (users) as well as reduces paper volumes, while using modern and efficient techniques through which we called ; IR Traceability Recommendations: Recommendations based on data traceability and information retrieval. Our approach deals with the case of document management that concerns the business domain, as we can generalize it in order to apply it to any sector and in any organization.

For electronic document management, improving the flow of documents has been widely studied in several research works based on the integration of one or more techniques through the implementation and proposal of tools for monitoring and storage as well as document management. The document management administrator is always required to monitor and control the flow of documents processed [3], [11]. Few works offer tools for automatic and incremental improvement of electronic document management. These contain unstructured data and are difficult to operate in another system and even the creation of relationships between information from different documents is difficult to manage, which is why we sought to propose a transformation of documents into data in order to facilitate the processing and development as well as the analysis of data and therefore improve the management of documents in an automatic manner.

In recent years, Big Data with information retrieval has become a more popular area of research [12]. Big Data is a collection of heterogeneous unstructured and structured data. The heterogeneity, volume and speed at which data is generated make the processing and analysis of big data problematic [13]. The traditional database system, warehouses and analysis tools fail to process this type of data [14]. Big Data with information retrieval techniques is an emerging approach not only because of the sheer volume of data, but also because of the kind of unstructured nature. Data related to the user's request should be retrieved with information research. According to experts, employees spend around 11 hours a week dealing with document-related issues, resulting in low productivity and poor customer service. Hence we came up with the idea of harnessing the potential of machine learning, so that companies can revamp and improve the traditional document management system. Machine learning can also be a powerful data mining tool [15], [16]. Using this technology, companies can develop a way to help their employees extract relevant data, classify and process documents automatically, improve data quality and analyze data. Document management by machine learning will therefore save a lot of time and effort. Recommendation techniques also provide new opportunities for the search for personalized information on this work. The recommendation, on the other hand, also serves to reduce information overload, which is a very common problem in information retrieval tools and allows users to have access to services or products that are not readily available to users on the tool [17]-[19].

In this article, we present an improvement of a proposed document management system using traceability and information retrieval with content recognition techniques in a big data context.

Our contribution consists in the improvement of document management systems. The remainder of this article is organized as follows ; The Sect. II presents a state of the art about document management, traceability information retrieval and content recognition through machine learning research area. The literature made was chosen based on recent research and discussion of important topics related to document processing, in order to be useful in relation to the objective of our proposed approach. We present the use of traceability and information retrieval in a big data environment in Sect. III. Machine learning techniques and recommendation are described in Sect. IV. The Sect. V describes the suggested document management system and we conclude in Sect. VI.

2. State of the art

2.1. Document management system

Document management is defined as "the set of techniques for organizing, managing and distributing documentary information in electronic form" [20]. Document management is actively developing especially within companies, because it covers the administration of the document flow within all departments of the company. In the literature [11], [21], [22], we can define document management system as seamlessly automating the document lifecycle process and providing tools to securely manage a large range of documents. Document management system uses statistical algorithms to classify and search documents. Document Management is actively developing especially within companies, because it covers the administration of the document flow within all departments of the company. The objective of this work is to propose techniques to improve the efficiency of document management on the one hand and to minimize the total cost of selecting and recommending documents on the other hand. For document management, improving the flow of documents has been widely studied in several research works based on the integration of one or more techniques through the implementation and proposal of tools for monitoring and storage as well as document management [8], [1].

2.2. Information retrieval based on traceability

In the world of computer science research, traceability is a modern and very recent term, in dictionaries this term appeared

only around the year 2000 while traceability has been known for a long time, its definition differs according to the fields and sectors (Industry, Food, Production, Logistics ...) [23]. The ISO-9001 standard of the international organization for standardization, defines traceability as: 'the ability to trace the history, application, use and location of a product or its characteristics using data from 'recorded identification', Indeed, this definition generates two important phases: the first concerns the identification of the item by a notation and the second concerns the existence of a recording of the data relating to this item on a support which has itself a traceability. The literature shows that there are problems related to the definition and understanding of traceability. the definition of which changes depending on the way it has been proposed. According to the dictionary, traceability is the "possibility of identifying the origin and reconstructing the journey of a product, from its production to its distribution". Researchers say that traceability is not a new concept but a practice that we must implement in order to respect the norms and rules of law [24]. However, in recent years, it has become a necessity in areas where the safety and security of consumers have challenged, particularly in the medical and food sectors [25]-[27]. Traceability is not a new concept but it represents the necessity of results which imposes the replacement of papers and pens by means and techniques more reactive and especially more efficient, traceability comprises two essential elements; tracing and tracking; The purpose of traceability is to provide proof at all times of the conformity of an element and its components as well as of its origin. Tracking represents the way to be able to save and know the paths of elements at the level of the data flow and the tracing is the fact of identifying the origin of a specific data at the level of the flow.

Information retrieval is a field allowing the search for relevant information from any type of data (audio, video, document, article or image). Traditional methods of finding information involve breaking down data into subsets or clusters across dimensions depending on the given problem. The Information Retrieval (IR) approach reduces the effort and time prescribed to create traceability links between artifacts [28] [29]. A search engine is an example of using the IR approach; it can search billions of web documents to answer a very specific query. Information retrieval techniques make it possible to solve several problems related to the processing carried out in a particular domain as well as to its optimization [30]. We have, in our case study, a large remarkable mass of documents and objects, and therefore to find an element adaptable to a need for information expressed by a user using a search query, we have thought of using the algorithms of the traceability information retrieval with recovery of traceability links.

2.3. Machine learning and recommendation

Machine learning has become one of the key words in recent research, machine learning represents an influential source of applications to automate the tasks of information retrieval. the latter offers several features that would fit into machine learning, but really what drives applications of machine learning to IR is not so much developments in machine learning technology as changes in our work and environment which requires new modes of operation [31]. Machine learning is an important discipline due to the digital transformation which has led to the production of large volumes of data of different types and formats. Machine learning can be seen as a branch of artificial intelligence. Indeed, a system which finds it difficult to learn can hardly be considered intelligent. The ability to learn from experiences is essential in a system designed to adapt to an environment that changes often. Artificial intelligence, defined as 'the set of techniques used to build machines capable of demonstrating behavior that can be described as intelligent' [32], also calls on cognitive sciences, to logic, to engineering to electronics, and much more. Artificial intelligence measurements are used by different tools and applications to collect and process and also to communicate and share useful information from datasets. Arthur Samuel defined machine learning, in 1959, as a "field of study that gives computers the ability to learn without being explicitly programmed" [33]. Machine learning (ML) is a concept that allows a computer program to be learned as well as to adapt to new information and new data without any human intervention. With the gradual use of technologies like cloud computing and advanced storage capabilities, the huge amount of data becomes easily accessible and available. Machine learning is the discipline of the computer science that concerns the analysis and interpretation of models and data to enable learning and processing as well as reasoning and decision making without thinking of human intervention. In a simple way, machine learning allows the user to feed an immense amount of data into an algorithm and ask the machine to analyze and make decisions as well as recommendations based on the entered data [34]. If corrections are identified, the algorithm can incorporate this information to improve future decision making. Decisions about data are increasingly making the difference between staying up to the competition and falling behind. Machine learning can be the key to unlocking the value of business data and customer and make decisions that allow a company ahead of the competition.

2.4. Literature and related work

Several works talk about traceability or information retrieval and also about content recognition through machine learning in a big data context, in literature we are finding :

About documents classification in [35], author proposed a review about a wide variety of methods on document classification task for German text with an evaluation of different approaches; Perceptrons, Discrete Naïve-Bayes, MC4, 3 Nearest-Neighbors, Racchio Centroid and Support Vector Machines. In [36], the author have proposed a framework for modeling link distributions by using a structured logistic regression model capturing both content and links in order to improve text classification. In [37], the author have presented TRAIL (TRAceability lInk cLassifier) as an approach for maintaining traceability information (traceability links between pairs of artifacts) to train a machine learning classifier which is then able to classify the links between any new or existing pair of artifacts as valid or invalid (two artifacts are related or no). So, document classification is an example of machine learning in the form of natural language processing (NLP), in the real world numerous more complex algorithms exist for classification such as support vector machines (SVM), Naïve Bayes and Decision Trees. There are also works that use information retrieval with several traceability methods; in [38], the author have presented a study to analyze the equivalence of information retrieval methods for automated traceability link recovery; Jensen-Shannon (JS), Vector Space Model (VSM),

Latent Semantic Indexing (LSI) and Latent Dirichlet Allocation (LDA). The result show that while JS, VSM and LSI are almost equivalent. In [39], the author have proposed an approach for improving requirements tracing based on framing it as an information retrieval (IR) problem, they have started with a classical vector space model algorithm but they found that this algorithm does not outperform analysts or existing tools in terms of recall or precision. In [40], the researchers describe a new technique called DROPT (Document Ranking Optimization) developed for documents retrieved from a corpus with respect to document index keywords and the query vectors, the purpose of DROPT id to reflect how human users can judge the context changes in IR result rankings according to information relevance. In [41], the author represent an algorithm based on classical mathematical expressions for calculating similarity between groups, known as the cosine, jaccard and dice formulas. In [42], an application of information retrieval to software maintenance and in particular to the problem of recovering traceability links between the source code of a system and its free text documentation by using an IR method (Vector Space), and in [43] a source code parser has been described to create a syntax tree as a processing step for information retrieval to recover traceability links between source code and documents. Several works of recovering of traceability links between documentation and source code by using Latent Semantic Indexing (LSI) like an information retrieval technique.

About the use of Machine learning, in [44] the author have proposed a predictive model for classifying potential traceability links in a system as either valid or invalid, by using a Machine Learning approach and features such as text retrieval (IR), rankings and query quality (QQ) metrics. In [45], the author also uses a machine learning approach for generating requirements traceability relations, this approach is based on a learning algorithm that produces traceability rules which are able to capture link between requirements statements specified in natural language and object models.

3. Improving document management using traceability and information retrieval in a big data environment

3.1. Context

The main goal of this work is to build a scalable model for classifying documents and extracting information from them. In a corpus of documents, the model extracts the text from each document and applies vectorization to it. Vectorization consists of counting the number of occurrences of each word appearing in a document. The vectorized representation is then entered into the model for prediction. Vectorization includes several algorithms and techniques in order to extract as much information as possible. Once this information is extracted and after dividing the data into a test set and a validation set, we apply different classification models on the data (VMS, KNN and decision trees). With arbitrary tests, the measurements showed very attractive results: precision, recall and F-measure between models, but the best result was recorded using TF / IDF with an accuracy of 0.934, an accuracy of 0.942, a recall of 0.905, and an F measure of 0.921.

When a user initiates a query, the query has multiple terms, and some of those terms may be more important than others. TF-IDF is a popular technique for measuring and getting an idea of the importance of a term in relation to a document. The TF is used to measure how often a word appears in a document. The IDF measures the importance of a word (Table 1). The TF-IDF value increases if a term appears in the document a number of times while taking into account the number of existing documents in the corpus that contain the same term.

Table 1: Example of frequency of appearance of a term in a document

	Document 1	Document 2	Document 3
Term 1	5	2	1
Term 2	1	0	0
Term 3	3	1	0
Term 4	0	4	3

The following formula will allow us to calculate the weights of the terms in each document:

$$\mathrm{Poid}(t_i, d_j) = \mathrm{TF} * \mathrm{IDF} \quad (1)$$

with:

$$\mathrm{TF} = \frac{f(t_i,d_j)}{N} \quad (2)$$

$f(t_i,d_j)$ is the number of occurrences of the term t_i in the document d_j and N is the total number of terms in the document d_j.

and

$$\mathrm{IDF} = \frac{\log\left(f(t_i, d_j)\right)}{M} \quad (3)$$

$f(t_i,d_j)$ is the number of occurrences of the term t_i in the document d_j and M is the total number of documents in the corpus.

We say that two objects are similar if their vectors are confused, so the similarity used in our work is the cosine similarity, this measure uses the complete vector representation based on the frequency of objects or words. The formula is defined by the ratio between the scalar product of the X and Y vectors and the product of the norm of X and Y:

$$\mathrm{Sim}_{\cos}(X, Y) = \frac{\sum_{i=1}^{n} x.y}{\sqrt{(\sum_{i=1}^{n} x^2)}.\sqrt{(\sum_{i=1}^{n} y^2)}} \quad (4)$$

A document is made up of a joint agreement of terms that have various patterns of occurrence. Text classification is an important task especially for document processing, but with the expenential growth of data, there are algorithms that can improve classification efficiency while ensuring the high precision desired. The purpose of classification is to organize documents by sets of documents that are similar, and theoretically the documents are said to be close. This phase aims to classify documents for the sake of research and extraction of useful information in an efficient manner. In this phase we propose to use VMS with the KNN (K Nearest Neighbor) algorithm and the decision tree algorithm in parallel, which makes it possible to put a document in a dominant set among its k nearest neighbors. A similarity measure makes it possible to determine the documents closest to the request launched by the user or, in the

case of classification, to determine the sets closest to the document to be classified.

KNN is a popular algorithm in the field of classification. Its use as well as its results place it among the best classification techniques in [46] [47]. As for the decision tree, it is an algorithm that makes it possible to perform an iterative partitioning of the entire feature space; The tree predicts the same label for each lower category and each category is chosen by selecting the best division from a set of possible divisions, which maximizes the information gain at a tree node [48]. However, a decision tree in the sense of our work will allow to classify data or observations already labeled as well as the visualization of the processed data; The tree starts with a source, where there are all the observations, then several branches in series show the nodes and at the end we find the leaves which represent the classes to be predicted. The major goal of a decision tree is to produce user-understandable classifications.

When we have a request, we must find the relevant objects, however the way to evaluate a document, whether relevant or not, is to calculate the similarity between the request and the object. Before calculating the similarity, it is important to index, clean and format all the contents of all the documents by using the techniques of the recovery of the traceability of the data (links, who, when, how, where ... etc.) as well as the classification using a machine learning. The vector representation will also allow us to facilitate the use of the requests made where each element of the vector represents the weight of each term or concept in the document or in the query. The objective is to extract all the terms (t) or concepts from our corpus and for each document (d) we build a vector (v) which represents it, if a term exists in the document we calculate its weight, otherwise we put 0, at the end of the operation we will have a vector for each document to calculate the similarity between the documentation and the purpose of the research done.

The traceability processed in this work represents an entire history of the operations carried out on the documents. Once an operation is performed by a user, this action is tracked (consultation, modification, deletion…). The traced data makes it possible to know, at any given moment, the life cycle of the documents as well as the associated operations. Each document with unstructured data must be converted into a format that can be analyzed in order to structure it and extract useful information. The content of a document can be represented as a set of terms such as words, sentences or other entities, each term will have its weight, which gives its utility in relation to this document. The main objective of document exploration is then to allow administrators to extract information from textual resources and to manage operations such as retrieval of traceability links and classification.

3.2. Traceability Information retrieval

In terms of our approach, we take into consideration any operation, any action and any event such as a trace stored in the database. We present a traceability link by a triple (source document DS, target document DC and similarity S). In order to apply IR techniques for the proposed approach, we consider all artifacts as a text document first. The IR allowed extracting all terms from a DS source document by calculating the similarity to another DC target document, depending on the document type and after processing, in order to extract the information. The high similarity between two documents suggests a potential link between them. For each DS, preprocessing done according to the type of document (image, video, text, etc.) for which we have thought of using machine learning techniques, we will generate the necessary traceability information in the database.

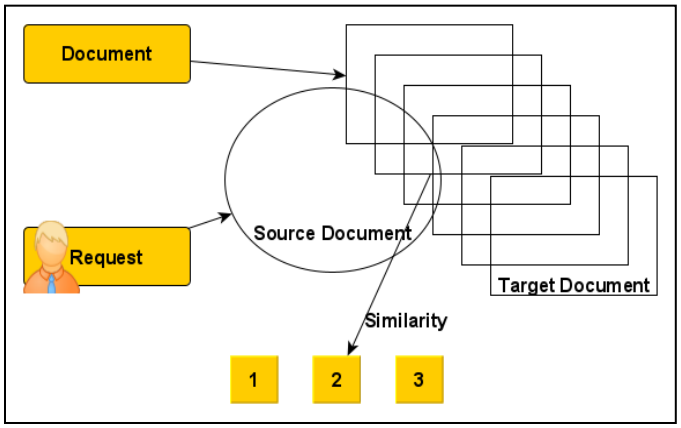

Figure 1: Similarity calculation and recovery of traceability links

We take as input, the construction of a matrix which concerns the terms per document (m × n), with m the number of all the terms appearing in the documents and n the number of documents. For each cell c_{ij} of the matrix, with i represents the term number and j the document number. We calculate the weight of each term and by applying the IR we calculate the similarity between two documents. The traceability links are created for each two documents with the value of their similarity. The latter is calculated by the positive cosine. For the recovery of traceability links, we aim to trace everything related to documents, even the traceability links in the document itself if it is divided into several parts.

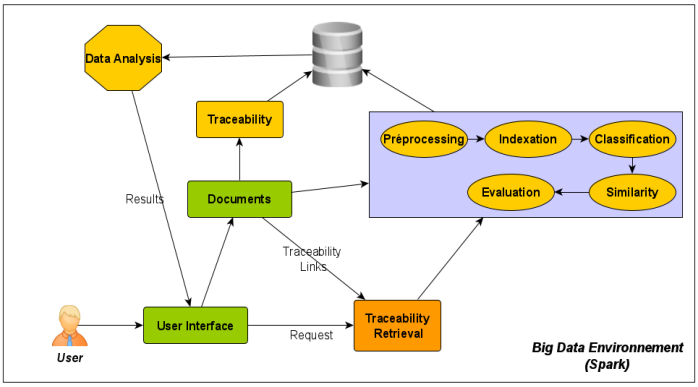

Figure 2: Process of the proposed approach

The interest in the need in Big Data is increasing day by day. In the age of big data, variety dominates volume and speed. Several difficulties and challenges may arise in acquiring, storing, processing and retrieving data. Companies like Google, Amazon, Facebook and YouTube have an advantage over others in personal development and competition due to their large amount of data. It should be remembered that processing data and finding information is as important as storing data. At the enterprise level, information can be structured or unstructured. In the first case, the information is presented in the form of a database and in the second case; the information is presented in the form of documents. Documents capable of keeping secrets that sometimes occupy special confidentiality in the company.

The architecture of the proposed approach is represented as shown in Figure 2.
