Nose of The Aircraft

ABSTRACT

The paper examines the impact on the product life cycle of reducing the duration of the development stages of aviation technology through the use of multi-criteria optimization. The subject of the study is the nose of a supersonic aircraft and the process of linking it. This example describes in detail the application of a comprehensive design methodology for aircraft components using top-level criteria as a way to significantly reduce the development time and the risks of obtaining negative test results when entering a full-scale sample.

1. Introduction

The great Russian aircraft designer Pavel Osipovich Sukhoi said: "We must not stop at what we have achieved, but must constantly move forward. After all, what was new and advanced yesterday will only be satisfactory tomorrow." This statement is still relevant until now because to take leadership positions in aviation, engineering, Economics, and business, you must constantly work ahead of time and your competitors. The current trend in the field of mechanical engineering is a significant (from 10-15 to 5-8 years) reduction in the development time of new aircraft systems due to the use of mathematical modeling, high unification and the use of scientific and technical reserve. The use of complex design techniques is one of the elements based on scientific and technical groundwork and allows you to reduce the design time.

2. Aircraft product life cycle

Within the lifecycle of the aircraft as a product, the aircraft goes through the following stages (gates):

Figure 1 shows the typical life cycle of an aircraft product, which is divided into internal and external design stages. The focus of the current work is optimization of internal design stages, so we will analyze them in more detail.

It is worth noting that key technical decisions are made at the stages of the preliminary project and preliminary technical design. The work is carried out by a relatively small number of OKB employees, the minimum amount of financial resources from the project budget is used, and the maximum number of technical decisions is made as shown in Figure 2. According to the results of these stages, the appearance of the designed aircraft is fixed.

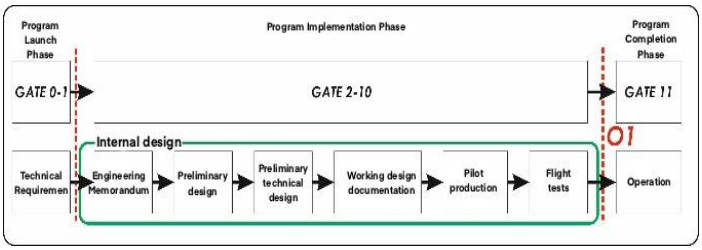

Figure 1: The typical lifecycle of the aviation system

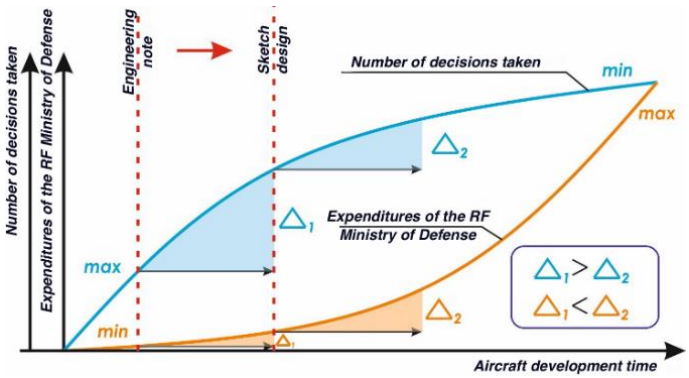

Figure 2: Dependence of the number of decisions made and the customer's costs on the project implementation time

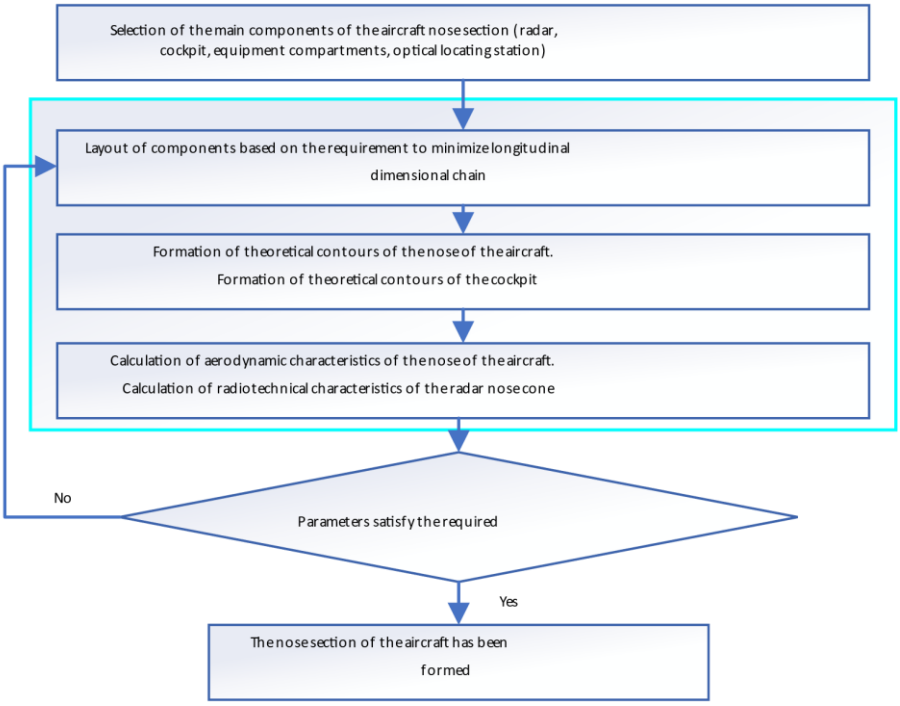

Figure 3: Typical algorithm for developing the nose of the aircraft

Thus, the stages of project initiation are the most effective in terms of cost and number of technical decisions:

$$\left.\begin{matrix}\Delta_i^{expenses}\\ \Delta_i^{time}\end{matrix}\right\} \rightarrow \min(opt)$$

However, these stages have the greatest technical risks, and errors in the technical decisions made may become fatal for the further fate of the project.

As can be seen from Figure 2, the initial stages of project implementation are the most effective in terms of the ratio of the customer's costs to the number of decisions made. Simultaneously, the technical decisions taken at these stages determine the further technical appearance of the project and can significantly affect its results.

Figure 3 shows an algorithm for linking the nose of the aircraft, consisting of sequential operations and, in case of errors, having an iterative character.

To complete the formation of the theoretical contour of the head part of the aircraft it must validate the obtained electronic and aerodynamic characteristics of the selected form of the radio waves fairing requirements to ensure the characteristics of the radar. Meanwhile, the speed and range characteristics of the aircraft will depend on the aerodynamic characteristics in the future, and the potential capabilities of the locator will depend on the radio technology. Thus, such a seemingly insignificant thing as the shape of the nose of an aircraft can determine its key characteristics of combat use. Moreover, the shape of the nose part of the minimum resistance and the shape of the maximum radar-transparency of a thing are incompatible because the best radio-technical characteristics are usually of small elongation nosecone (the ratio of the square of the length of the nosecone to the area of the initial cross-section), such a shape allows you to ensure the uniformity of the distribution of the angles of incidence of the electromagnetic wave front on the surface of the nosecone wall, the best aerodynamic characteristics on the contrary have the body with maximum elongation, it allows reducing significantly the resistance at supersonic flight speeds, see Figure 4:

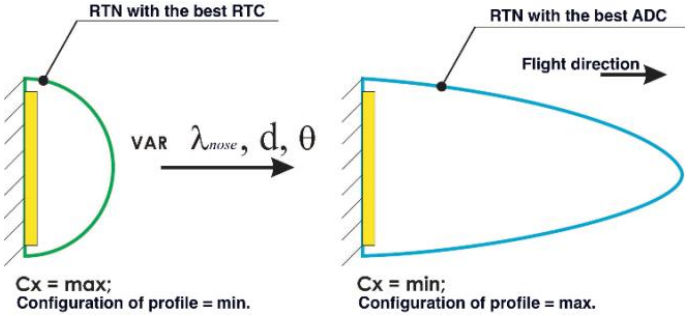

Figure 4: Comparison of nosecone shapes of the aircraft

From Figure 4 we can conclude that the final shape of the nosecone will be a compromise between the two shown in the figure. In this case, the wrong form at this stage may lead to the need to repeat the whole cycle of flight tests in case of its change after the construction of prototypes (stages of pilot production and flight tests).

3. Optimization of the aircraft life cycle

The scientific novelty of the work consists in carrying out multi-criteria optimization of the geometric parameters of the studied RPO using the Russian-made LOGOS software product and in terms of functions, which is an analog of the FLUENT product. The results of mathematical modeling and evaluation of aerodynamic characteristics have been validated with existing empirical methods, and the software product itself is widely used in Russian industrial projects.

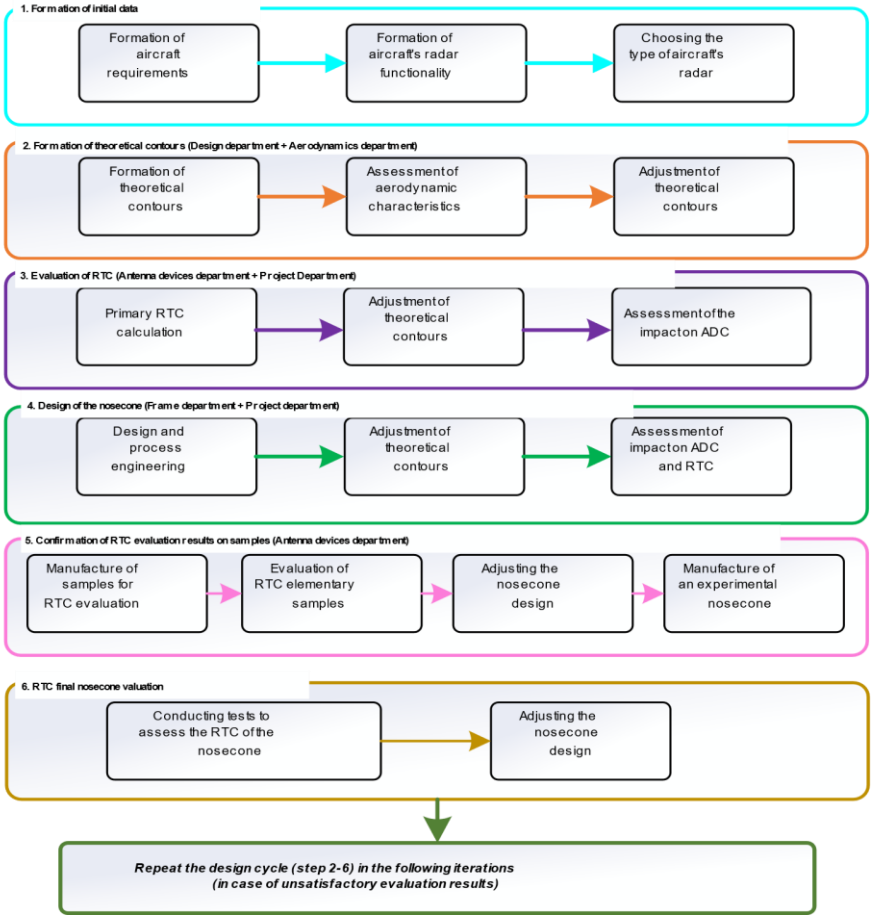

Figure 5: The existing algorithm for the development of the fairing

Reducing the timing of development work can be achieved by reducing the development and testing of the aircraft complex. Concurrently, correct and timely technical decisions made at the development stage will also reduce the time required for ground and flight tests. Let's look at an example of optimizing the development stages of a nose radio-transparent fairing (RPO). The current state of the RPO design algorithm is shown in Figure 5.

After analyzing Figure 4, we can conclude that the design of the radio-transparent fairing according to the existing methodology does not meet the requirements for the development of new aircraft systems. To meet the customer's requirements for the development of new AK in 5-8 years, it is necessary to significantly optimize this algorithm. To do this, you must: To optimize this algorithm, it is necessary:

1) In accordance with [1], [2] select a comprehensive criterion for evaluating the characteristics of RPO radar, both in terms of radio engineering (RTC) and aerodynamic (ADC) characteristics;

2) Form a research algorithm, in which to establish the relationship between the parameters of the shape of the fairing and its ADC and RTC.

3) Based on the results of the study, formulate technical recommendations for choosing rational parameters of the fairing shape, depending on the initial data and technical requirements.

As a complex criterion of the upper level (1), having analyzed the scientific and technical background in the field of research of radio technical characteristics (RTC) [3] and aerodynamic characteristics (ADC) [4], [5], [6], it is possible to take the ratio of the criterion of the first level of aerodynamic characteristics to the criterion of the first level of radio engineering characteristics:

$$X^{*} = ArgMax\left(\frac{ArgMax(RTC)}{ArgMin(ADC)}\right) \quad (1)$$

In this case, we will choose as the criterion of the first level for RTC nosecone its transmission coefficient (TC)—a dimensionless value equal to the ratio of the radiation flow through the medium (nosecone) to the radiation flow to its surface. The first level criterion for ADC is its drag coefficient (Cx), a dimensionless value reflecting how the body (nosecone) reacts with the environment (air).

According to this criterion, it is necessary to conduct research on possible options for the geometric appearance of the fairing and choose rational parameters that meet all the requirements. The algorithm for conducting these studies is shown in Figure 6.

Based on the results of the above studies, the method for selecting the geometric parameters of the fairing will allow optimizing the stages of RPO development. Adjusted according to the results of the optimization algorithm for the design of the fairing is presented in Figure 7.

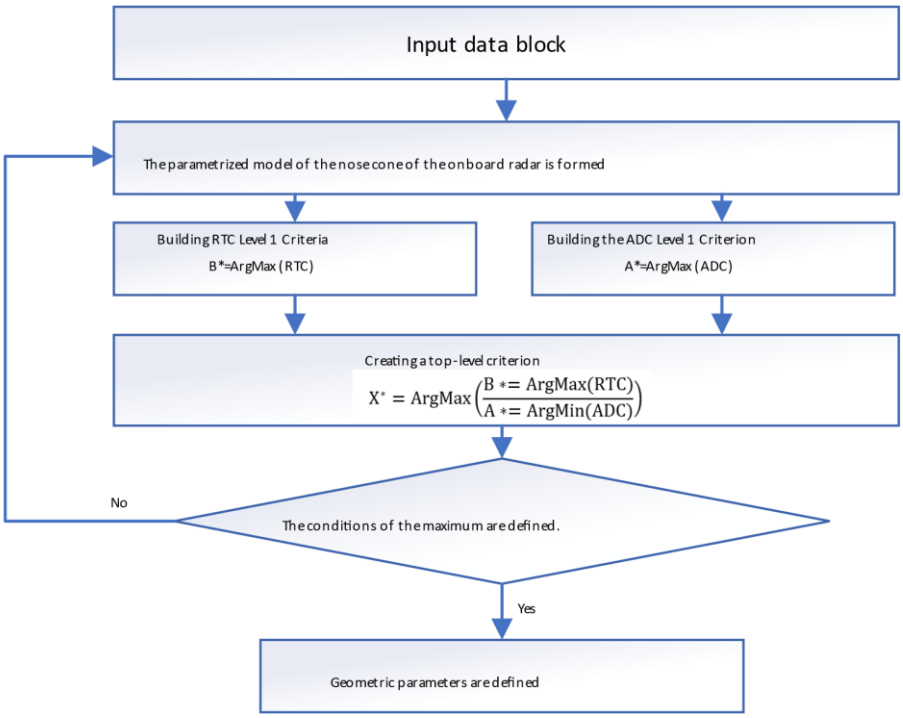

Figure 6: Algorithm for studying geometric parameters of RPO

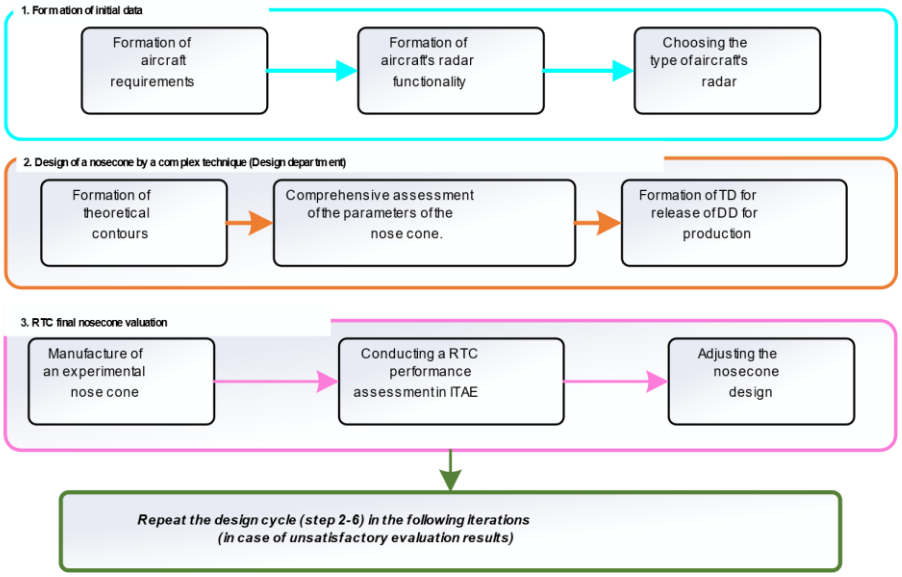

Figure 7: Adjusted the algorithm design of the fairing

Thus, the development of such methods for designing aircraft components can significantly reduce the number of design stages, as well as the involvement of company personnel, which in turn reduces the time and cost of product development.

4. Forming an optimal fairing with minimal drag

A typical example of multi-criteria optimization of an aircraft component to significantly reduce the product life cycle is the optimization of the geometric parameters of the radio-transparent fairing in order to obtain a body of minimal resistance. For this optimization, you must:

Firstly, to choose a complex criterion for evaluation of aerodynamic characteristics;

Secondly, to make up an algorithm for solving this problem and determine a method for evaluating aerodynamic characteristics that will have the required level of sensitivity to changes in key geometric parameters and the required accuracy;

Third, using the selected algorithm, to conduct research and, using a complex criterion, select rational geometrical parameters of the nose section of the aircraft for a given flight mode.

4.1. Choosing a comprehensive criterion

As noted earlier in this work, the issue of selecting rational geometric parameters for the nose section of the aircraft for the supersonic cruise mode is under consideration $M \sim 1.5$. To select the main criterion of aerodynamic characteristics of the nose

section, it is necessary to analyze the existing aerodynamic characteristics of the aircraft components as a whole.

According to [7], there are three main criteria for the aerodynamic characteristics of an object: C_x – aerodynamic resistance coefficient, C_y – lifting factor, Δmz_0 – component contribution to the longitudinal static torque of the aircraft as a whole:

1) Coefficient C_{xnose} as shown in Part 1. The introduction is one of the essential parts of the aerodynamic drag coefficient of the pressure of the aircraft as a whole $C_{xfpressure}$ in particular for $M > 1$.

2) In doing so C_{ynose} does not make a significant contribution to is not more than 0.1% of the total C_y as a whole.

3) It should be noted that the nose part of the aircraft can be shaped as a body rotation, and as a body of complex shape in the cross section. So for the body of rotation the contribution to Δmz_0 the aircraft as a whole tends to 0, and for a complex body it requires deep analysis and has a significant impact due to the large removal of the aerodynamic focus of the fore part of the aircraft from the center of the masses, which leads to losses on balancing and reduction of fuel efficiency of the aircraft in cruising mode of flight. Because for the current work is considered a cruise flight of the aircraft in the mode of $M \sim 1.5$ let's look at the fore part in the shape of a rotational body.

Thus, it is possible to draw an unequivocal conclusion that the criterion of a choice of rational geometrical parameters of a nose part of an airplane is the minimum value of the aerodynamic resistance coefficient, depending on basically geometrical options. This criterion can be written mathematically as follows (see (2)):

$$A^* = ArgMin\,(C_{x\,nose}(\lambda_{nose}, d, \theta)). \quad (2)$$

4.2. Selection of performance evaluation method

At the present time a significant scientific and technical reserve has been accumulated in the field of research of aerodynamic characteristics of bodies of various shapes and geometry, the main branch institute and center of competence of aerodynamics in the Russian Federation is the Central Aerodynamic Institute named after Professor N.E. Zhukovsky (TsAGI). Based on TsAGI's extensive work to determine the aerodynamic performance of various components of the aircraft, empirical dependencies of the AP on a few geometric parameters were obtained. These methods and dependencies are presented in [7] and are used to determine the AP (C_x and C_y) of the main components of the aircraft (wing, fuselage, plumage) and build integral AP of the aircraft. The empirical approach is widely used by the country's leading aviation and missile companies.

However, because these dependencies have been obtained from numerous wind tunnel experiments on wind tunnel models, there are certain assumptions in the wind tunnel estimates due to model manufacturing tolerances and measurement errors.

The trend formed in the XXI century of constant toughening of requirements to newly developed aircraft complexes (ACs) by the State Customer, related to ensuring competitive edge over foreign ACs, requires minimization of design reserves in the development of AKs and a more accurate assessment of the AP of both components and the aircraft as a whole.

In recent years, the main trend and element of product life cycle management in the aircraft industry is the digitalization of the life cycle stages in a single information space, including various types of tests [8] and the creation of electronic twins of the aircraft, including aerodynamic, through the application of mathematical simulation of geometry flow by finite element method [9]. The models received by results of similar digital tests are verified and possess necessary sensitivity to change of geometrical characteristics, are shown as algorithm in Figure 2, also allow to receive result with high accuracy and can be parametrized that essentially reduces terms of research.

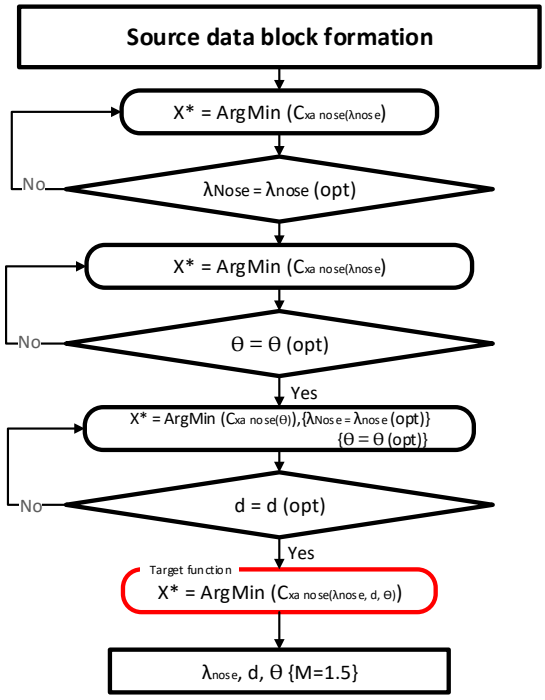

Figure 8: Algorithm for solving the problem of determining the rational parameters of the aircraft fuselage nose section

4.3. Problem solving algorithm

For effective solution of the problem within the framework of this work it is necessary to apply methods of mathematical modeling with the use of parametrized mathematical models of the surface, where the main geometrical parameters of the fore-body indicated earlier are used as variables of parametrization.

Main calculation parameters are accepted as a block of input data: altitude and speed parameters of flight, values of angles of attack, roll and slide, as well as atmospheric parameters at a selected altitude and speed.

The problem is solved iteratively, and at the first stage is the optimal value of the parameter of elongation of the nose part of the aircraft (λ_{nose}) as a most comprehensive parameter. Next, for an optimum elongation value, the optimum angle of tangent to the forming curve is selected (θ) and the final step is to determine the optimal value of the discriminant in the formation curve. (d).

It should be noted that for each stage a mathematical model of the investigated surface is built, and the range of parameter values can change based on the conditions of ensuring the smoothness of the fore-body surface (absence of double curvature) [10], [11].

4.4. Selecting the number of settlement cases

Calculated flight conditions are shown in Table 1. During the calculation the atmospheric parameters are accepted in accordance with the international standard atmosphere.

Table 1: Calculated conditions for solving the problem

	Parameter	Value
1	Estimated number of M flight	1.5 M
2	Estimated flight altitude	11 000 m
3	Calculated Flight Angle of Attack (α)	2^0
4	Calculated sliding angle (β)	0^0
5	Calculated roll angle (γ)	0^0
6	Atmospheric parameters	In accordance with the ISA

The calculation is performed in the selected calculation conditions for each of the values of the parametrization variables and in accordance with the algorithm presented in Part 4. The range of values of the parameterization variables and the step are shown in Table 2.

Table 2: Value range of variables

Parameterization parameter values								
λ_{nose}			$\theta_{,0}$			d		
min	max	step	min	max	step	min	max	step
2	5	1 (0.5 from 2 to 3)	20	45	5	0.5	0.8	0.1

The total number of settlement cases for the calculation is determined by formula (3):

$$N = n_\lambda + n_\theta + n_d, \quad (3)$$

Where n_λ – fuselage fore-nose extension parameter number, n_θ – number of angle values of the tangent curvature parameter, n_d – discriminant parameter number of the constitutive curve.

Thus, to solve the problem it is necessary to make 15 calculation experiments.

In accordance with the research algorithm (see Figure 8), a cycle of computational experiments to determine the dependence of values has been performed in this work $C_{x\,nose}$ the nose of the aircraft from its extension (λ_{nose}), the results of calculations are recorded in Table 3, the dependence of parameters is shown in Figure 9.

Table 3: Results of the dependency calculation C_{xnose} on λ_{nose} .

	θ	d	λ_{nose}	$C_{x\,nose}$
1	25^0	0.5	2	0.21
2			2.5	0.15
3			3	0.11
4			4	0.06
5			5	0.04

As can be seen from Table 3 and Figure 6, there is an inverse relationship between λ_{nose} and C_{xnose} for the nose section of the aircraft, so that the body with elongation has minimal aerodynamic resistance $\lambda_{nose} = 5$.

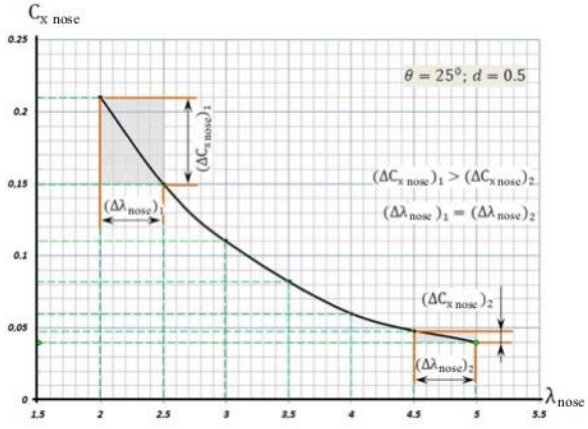

Figure 9: Dependency C_{xnose} on λ_{nose}

Taking into account these results in accordance with the algorithm (see Figure 8), we have estimated the change in the value of C_{xnose} change angle θ . In this case, to increase the sensitivity of the model to changes in the angle of tangent in the geometric model of the object surface, a spherical blunting of the spout with the $r = 15\,mm$ in this case the influence of the coefficient appears for the model $C_{xattenuation}$ in case of blunting, which is for M = 1.5 $C_{xattenuation} = 0.68$, and for $r = 15\,mm$ $C_{xattenuation} \sim 0.22$. The results of calculations are given in Table 4, the dependence is shown in Figure 10.

Table 4: Results of the dependency calculation $C_{x\,nose}$ on θ .

	λ_{nose}	d	$\theta_{,0}$	$C_{x\,nose}$
1	5	0.5	20	0.062547
2			25	0.062555
3			30	0.062565
4			35	0.062575
5			40	0.062587
6			45	0.062598

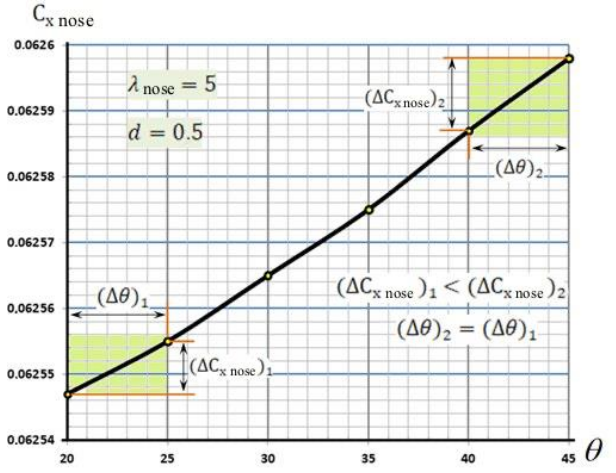

Figure 10: Dependency $C_{x\,nose}$ at θ

As can be seen from Table 4 and Figure 10, the aerodynamic resistance of the nose of the aircraft increases when the angle of tangent to the forming nose part of the aircraft. However, the difference between $C_{x\,nose}$ for $\theta = 20^{O}$ and $C_{x\,nose}$ for $\theta = 45^{O}$ at $\lambda_{nose} = 5$ not exceeding 1%. Based on these results, it can be concluded that the angle θ does not significantly affect the aerodynamic resistance of the nose section of the aircraft at $M = 1.5$. For the next phase of the study, we will accept $\theta = 20^{O}$ as a parameter with minimal aerodynamic resistance.

The next step in the study of the dependence of aerodynamic characteristics of the nose section of the aircraft on its geometrical parameters is to determine the dependence of $C_{x\,nose}$ from the curvature of the constituent – d. To determine the effect of curvature on the $C_{x\,nose}$ aircraft, a comparative analysis of the conical nose AP and the parabolic nose (at d=0.5) in determining the dependence of the $C_{x\,nose}$ on λ_{nose}. The results of this analysis are listed in Table 5, the dependencies are shown in Figure 11.

Table 5: Comparison $C_{x\,nose}$ at d.

	λ_{nose}	$C_{x\,parabola}$	$C_{x\,cone}$
1	2	0.21	0.23
2	2.5	0.15	0.17
3	3	0.11	0.13
4	4	0.06	0.08
5	5	0.04	0.059

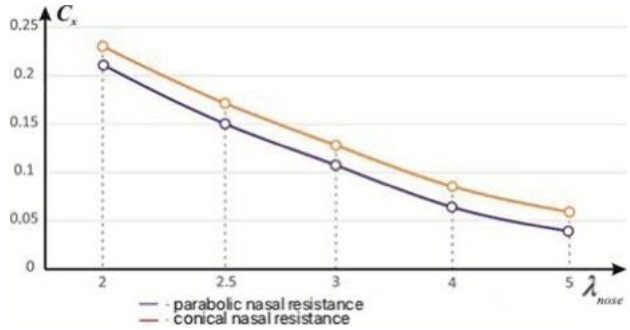

Figure 11: Comparison of nasal AP with conical and parabolic forming parts

As can be seen from Table 4 and Figure 8, both for conical and parabolic forming dependencies obtained in Figure 6 are fair. However, for the parabolic formative level $C_{x\,nose}$ lower than conical for all values λ_{nose}. Based on these results, it can be concluded that the nose section of the aircraft with parabolic formation has the lowest aerodynamic resistance.

To determine the rational value of the curvature forming within the framework of this work the dependence analysis has been performed $C_{x\,nose}$ at d for the nose section with the previously selected rational parameters λ_{nose} and θ, the results of this assessment are shown in Table 5, the dependence is shown in Figure 12.

Table 6: Dependency $C_{x\,nose}$ at d parabolic forming.

	λ_{nose}	θ	d	$C_{x\,nose}$
1	5	20^0	0.5	0.062547
2			0.6	0.062551
3			0.7	0.062558
4			0.8	0.062564

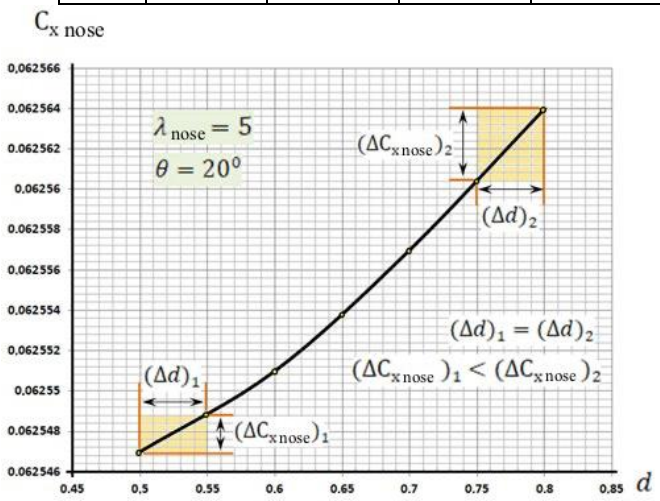

Figure 12: dependency $C_{x\,nose}$ at d

As can be seen from Table 5 and Figure 12, when the curvature of the aircraft nose increases, the aerodynamic resistance of the nose part increases. However, the difference between $C_{x\,nose}$ at $d = 0.5$ and $C_{x\,nose}$ for $d = 0.8$ at $\lambda_{nose} = 5$ and $\theta = 20^{O}$ not more than 1%. Based on these results, it can be concluded that parameter d does not significantly affect the aerodynamic resistance of the nose section of the aircraft at $M = 1.5$. As a rational value d at $M = 1.5$ take d =0.5 as a parameter with minimal aerodynamic resistance.

4.5. Optimal parameters

Within the framework of the work performed by the methods of mathematical modeling the dependences of aerodynamic resistance of the nose part of the aircraft on the main geometrical parameters varying in the selected range were obtained for supersonic cruise of the aircraft at $M = 1.5$. The following conclusions can be drawn from these studies:

1. Parameter of elongation of the nose of the aircraft λ_{nose} has a significant impact on the aerodynamic characteristics of the nose section of the aircraft. Dependence $C_{x\,nose}$ from λ_{nose} is reversed: when the parameter value is increased λ_{nose} level $C_{x\,nose}$ is decreasing. Reasonable value λ_{nose} to ensure minimum aerodynamic resistance in the selected flight mode is $\lambda_{nose} = 5$.
2. The parameter of the angle of tangent curvature to the forming nose part of the aircraft θ does not have a significant impact on the aerodynamic characteristics of the nose section of the aircraft when $M = 1.5$. Dependency $C_{x\,nose}$ for θ is direct: when the parameter value is increased θ level is increasing $C_{x\,nose}$. Rational importance θ to ensure minimum aerodynamic resistance in the selected flight mode is $\theta = 20^{o}$.
3. The nose section of the aircraft with a parabolic formation has a lower level of aerodynamic resistance than the nose section with a conical formation 3.

4. The parameter of curvature of the forming nose part of the aircraft d does not have a significant impact on the aerodynamic characteristics of the nose part of the aircraft at $M = 1.5$. Dependency $C_{x\,nose}$ from d has a direct character: when the value of parameter d increases, the level $C_{x\,nose}$ increases. The rational value d for minimum aerodynamic resistance in the selected flight mode is $d = 0.5$.

Thus, based on the conclusions (1–4) can be concluded that the main geometric parameter of the nose of the aircraft, which determines the level of its aerodynamic characteristics, for $M = 1.5$ is an extension of the nose of the aircraft λ_{nose}.

The nose section of the aircraft with rational geometrical parameters has minimal aerodynamic resistance: $\lambda_{nose} = 5$, $\theta = 20^{\circ}$, $d = 0.5$.

5. Conclusion

The main conclusion from the materials presented in this paper is that optimization of the development cycles of aircraft components leads to optimization of the product life cycle as a whole. The considered example of forming an optimization basis for choosing rational geometric parameters of RPO clearly showed a significant reduction in the RPO design cycle due to the use of complex techniques.

In this work, a total of about 90 computational experiments were performed, with an average labor intensity (if there is free computing power) of ~5 h/h. Thus, using the results of this work in the design of a new supersonic aircraft will save ~450 h/h of research work, which is ~2.5 months of work for one specialist of the organization.

The introduction of such an integrated approach in all industries and for all types of products will make it possible to make a new leap in the field of mechanical engineering in the shortest possible time. [12].

Probe Mark Discoloration
Fluorine Contamination
Wafer Storage

ABSTRACT

In this report, a probe mark discoloration with donut/circle shape was found. The corrosion formed on Aluminum bond pads. The SEM/EDS, TEM/EELS & AES surface techniques were used to identify this corrosion product. All these material analysis results pointed out the role of fluorine to this discoloration. The HAST testing, all the chip samples obtained from wafer center/middle area, were simulated to have been exposed in air for 1 year. HAST test result showed no fluorine source came from the center/middle zones of impact wafers. Another full wafer-level FOSB storage test showed the source of corrosive fluorine came from wafer itself. EDS mapping results, from extreme wafer edge zone, indicated the fluorine element distribution. The mechanism of this novel discoloration was proposed. However, more evidences were necessary for understanding the formation of donut discoloration corrosion.

1. Introduction

In order to obtain semiconductor device electrical performance, the circuit probing (CP) tests were performed by pin probing on bond pad before device package process. The typical bond pad materials are Aluminum (Al) with low content of silicon and copper to improve the resistance of electron migration. The interconnection from aluminum pad surface to external interface frame play a critical role in semiconductor package process. It is well known the Aluminum would form corrosion protective oxide film in oxygen condition. However, in the past three decades, the formation of fluorine (F) corrosive film on aluminum bond pad surface [1,2] and non-stick on pad (NSOP) failure issue that induced broad quality issues concern were reported by some researchers before. [3-7] These corrosive film was found to suffer semiconductor reliability. The early researches indicated two main root causes for these fluorine contained contamination. One is the fluorinated silicone glass (FSG) film could release fluorine into closed spacing, and then contaminate the bond pad surface. [1] The FSG layer is still an important low K dielectric layer used in device process, so the F leakage from FSG layer is still a unavoidable issue in semiconductor dielectric layer process. The second fluorine source is the fluorine embedded on Al pad surface, and the fluorine residue from previous pad etching and cleaning gas. [9] So the fluorine source for contamination divided into two groups, direct F embedded on Al top surface, and the indirect F from FSG layer. Therefore, the wafer storage become an important factor for fluorine contamination. The early F-induced contamination studies focused on the morphology and mechanism to induce corrosion product. No probe mark and electric testing effects were reported before. P. Chang [8] had stated the early probe mark discoloration study of yellow discoloration Al bond pad corrosion. However, the probe mark discoloration had not been fully report yet. [10, 11] In this paper, the donut/circle discoloration corrosion and a compressive study would be present.

In the beginning of this case, the probe mark discoloration was found at the stage of blue tape. All the impacted wafers finished all the CP tests, and stored in the Front Opening Shipping Box (FOSB) for more than two months. There are two types of probe mark discoloration forming on the bonding pad surface. Figure 1 (a) and (c) show these typical circle/donut discoloration optical microscope (OM) photos. The special feature of discoloration morphology is that probe mark is the center of cyclic/donut center. The OM inspection for discoloration corrosion indicated most of the corrosion was cyclic, and only few was donut shaped. Figure 1 (b) show that two touchdown would not induce two discoloration. The size of cyclic discoloration is not constant, however, the largest diameter of a suffered wafer, up to 35 um, is nearly the same. With the help of full wafer dice Auto Vision Inspection (AVI), most of the corrosive dice locate near the wafer edge zone. The worst fail rate would reach up to 15-18% of all the available dice.

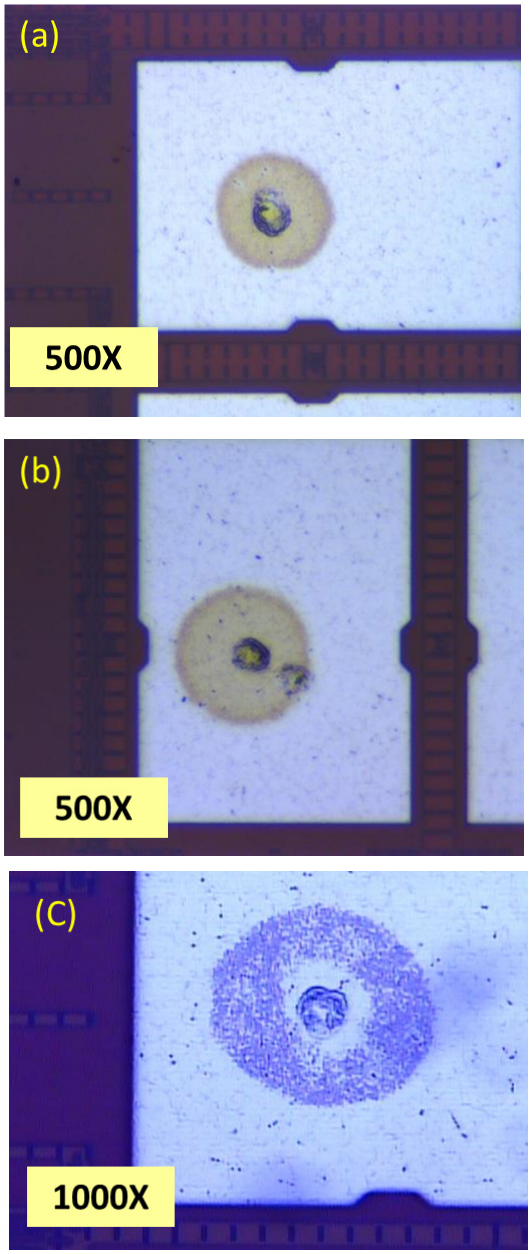

Figure 1: (a) show the typical probe mark discoloration OM image. (b) show the formation of discoloration on Al pad under dual pin touch down. No second discoloration is found. (c) show donut-shaped probe mark discoloration. To clearly show donut shape discoloration, (c) was magnified to 1000X, that is larger than Figure 1 (a) & (b).

2. Experiments and Results

In this study, the samples were checked in plane-view & cross-sectional approaches. The Scanning Electron Microscopy (SEM) images was obtained by 5 KeV electron energy. And the Energy Dispersive Spectrum (EDS) result was obtained by 10 KeV electron energy. Transmission Electron Microscopy (TEM) operated at 200 KeV with Electron Energy Loss Spectrum (EELS). SEM and TEM could get the information of morphology and corresponding EELS analysis for the normal and abnormal locations. Auger Electron Spectroscopy (AES) is a traditional surface analysis technology for bond pad corrosion case. So AES depth profile results would be included.

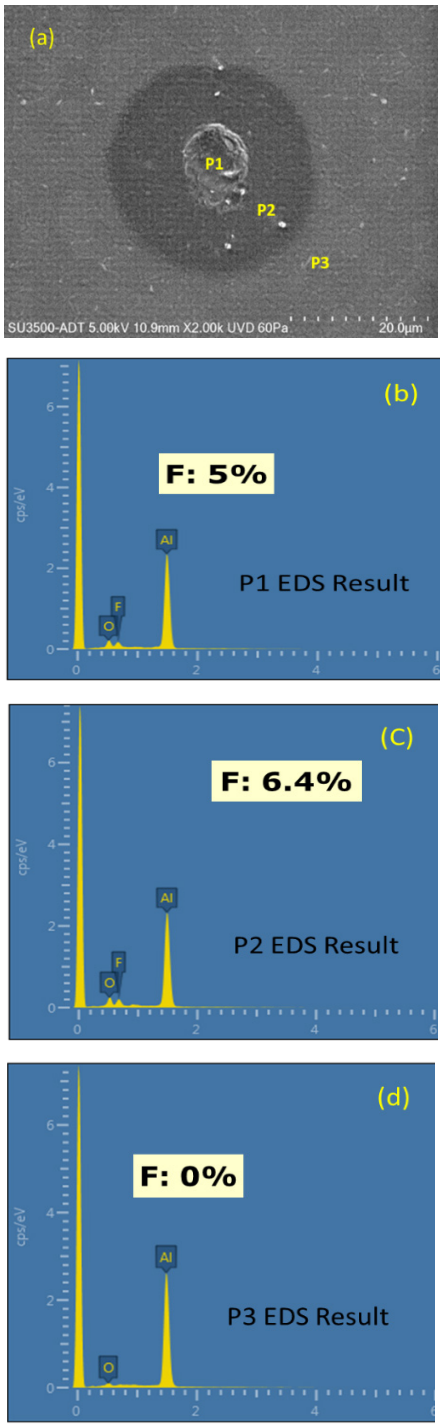

Figure 2: (a) is the SEM micrograph of probe mark discoloration corrosion. P1 is the zone of probe mark. P2 is the discoloration zone. P3 is the normal Al pad surface. (b),(c) & (d) the corresponding EDS analysis result of P1 to P3 various zones on Al pad surface. The oxygen element was found for each locations. The Fluorine was only found at the discoloration zones.

Based on the literature review, the various storage conditions would impact corrosion behavior. Highly Accelerated Stress Test (HAST) was applied with test conditions of temperature at 130ºC and RH 85% for 21 hours. This test is to simulate all the bond pad exposed in air without Nitrogen Cabinet storage or Moisture Barrier Bag (MBB) storage for 1 year. This test would be helpful to evaluate the impacted dies corrosion behavior. The secondary storage test, full wafer deposited in the regular FOSB, is to identify

the standard FOSB storage effect, and find out the source of F element.

2.1. SEM/EDS Analysis Results

Figure 2 show the top-view SEM photo and corresponding EDS analysis results of various feature locations on Al pad surface. The SEM photo clearly show the boundary of discoloration boundary on Al pad surface. Based on the SEM inspection, the rough size of this discoloration was more than 25 micro meter. The probe mark and corresponding discoloration zone were easily identified. The SEM photo also show various morphology of probe mark surface deformation. According to the EDS results of discoloration zone, the P1 & P2 of Fig. 2(a), where fluorine and oxygen contents are found on the center and middle of circle region. No Fluorine element was detected for normal P3 Al pad surface. The content of fluorine element, 5-6 %, is noted. That is, the probe mark discoloration is a kind of aluminum-fluorine-oxygen corrosion. As for the normal zone, aluminum oxide form on Al pad surface. Since this novel corrosion product has not been fully reported before, the EDS analysis is helpful to improve the key role of fluorine element.

Figure 3 show the OM photo and its corresponding EDS result. P1 to P4 of Figure 3(a) are the various locations of donut-shaped discoloration on Al pad surface. P1 is the probe mark zone. P2 is the cyclic annular zone without discoloration. P3 is the cyclic annular zone with discoloration corrosion. And P4 is the normal Al pad surface. The EDS result clearly indicate fluorine element is only found at the discoloration corrosive zone. No fluorine is found at P1- probe mark, P2- cyclic annular without discoloration, and P4 - normal Al pad surface zones. Based on these donut-shaped discoloration EDS results, the root cause of the discoloration event is due to fluorine contamination. However, due to the basic characteristic of high energy electron stopping power, the X-ray signal of EDS analysis is collected not only from Al pad top surface, but also the larger undersurface bulk volume. The distribution of fluorine element could not be identified by this EDS analysis. TEM and AES are necessary for further identification.

2.2. TEM/EELS Analysis Results

The cross-sectional TEM inspection is helpful to identify the thickness variation of corrosion film. Figure 4 show the full cross sectional TEM inspection photo of discoloration area. The thickness of discoloration corrosion film is just a few nm. Therefore, it could not be clearly identified by Figure 4. The magnified TEM photo indicate the thickness of discoloration film is uniform except for probing mark zone. Figure 5 show the High Angle Annular Dark Field (HAADF) TEM image of discoloration film structure. The HAADF image indicate the thickness of circle shape discoloration is within 5 nm. The corresponding Electron Energy Loss Spectrum (EELS) line scan results show the F & O distribution of this Al-O-F film. The fluorine is found on the top surface of corrosion film. No F & O could deeply penetrate into the Al. Figure 4 show the corrosion film of probe mark is complex. Figure 6 show the high magnification cross-sectional TEM image and its corresponding EELS data of probe mark oxidation. The variation of corrosion film thickness might be up to over 10X. The thicker film formed on probe mark zone is also the AL-O-F compound as other discoloration zone. The EELS fine structure analysis indicate discolored Al_2O_3 spectrum is a combination of

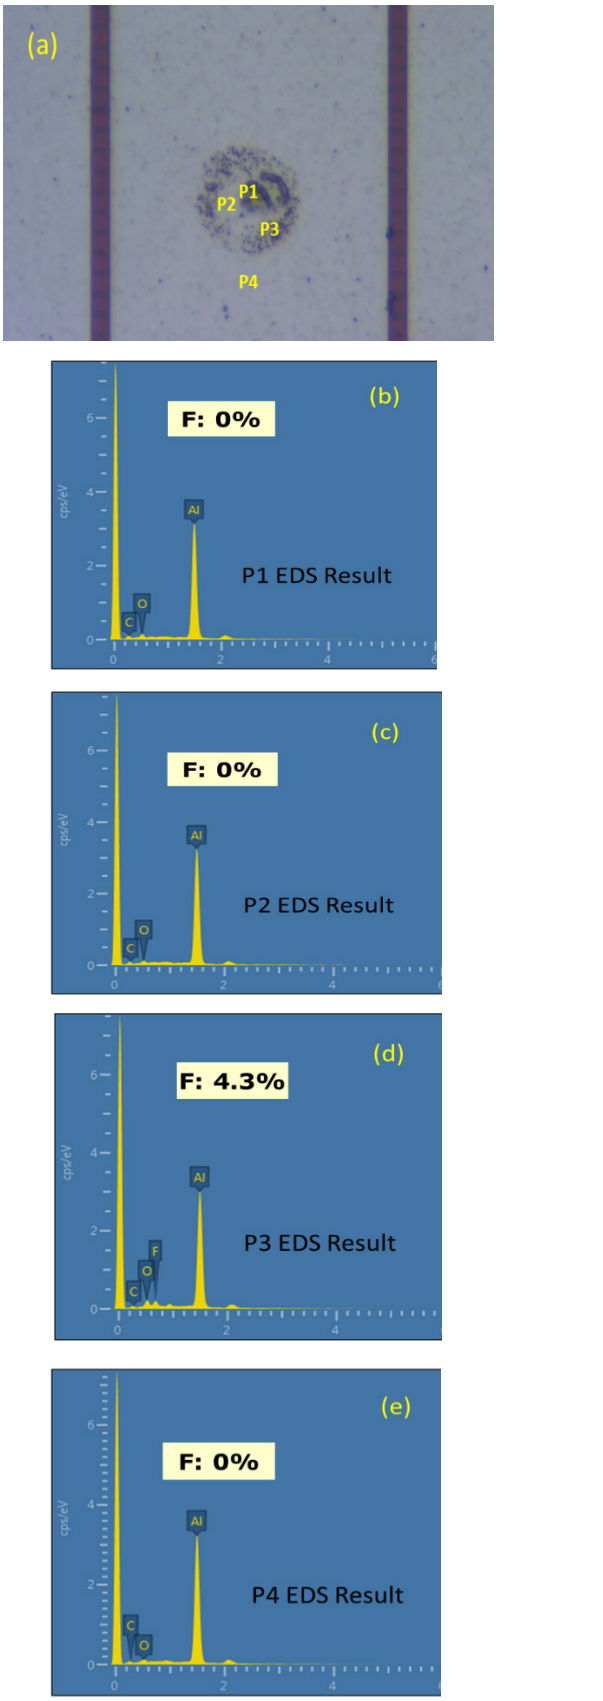

Figure 3: (a) is the OM image of donut-shaped probe mark discoloration. P1 is the zone of probe mark. P2 is the annular zone without discoloration. P3 is the annular zone with discoloration. P4 is the normal Al pad surface. (b), (c), (d) & (e) the corresponding EDS analysis results of various zones on bond pad surface. Fluorine is only found at the cyclic annular discoloration zone.

pure Al_2O_3 with OF_3. That is, the fluorine diffuse into the Aluminum oxide film. F atom form a new bonding to replace O bonding. These new formed Al-O-F must be less protective than original Al_2O_3 film.

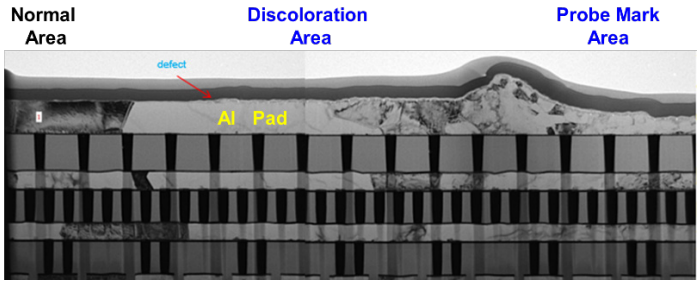

Figure 4: The low magnification full cross-sectional TEM image of discoloration defect corrosion.

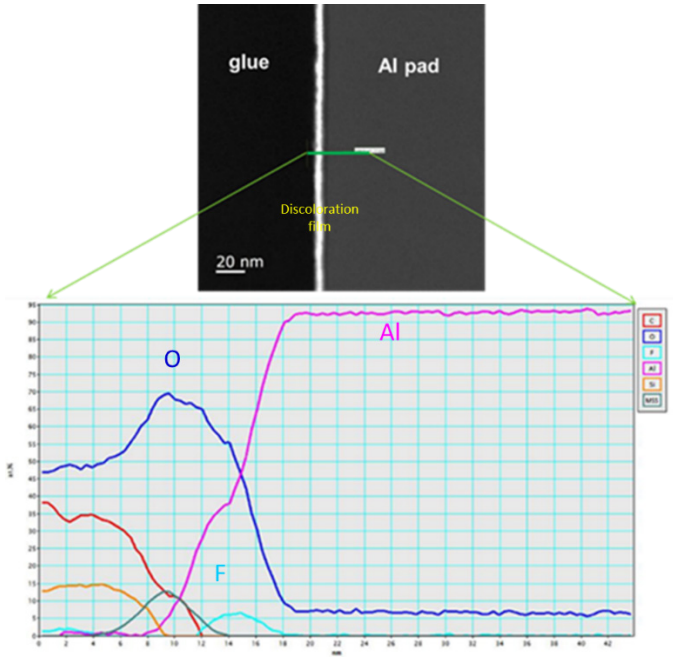

Figure 5: The cross sectional HAADF TEM image of discoloration zone and its corresponding EELS line scan result. The line scan result clearly show the distribution of fluorine and Oxygen just on the Al pad top surface.

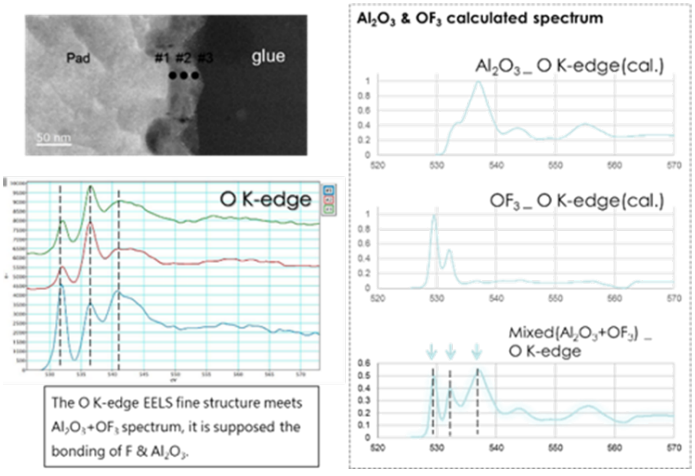

Figure 6: The TEM image and EELS data of probe mark discoloration defect film & its corresponding simulation EELS spectrum.

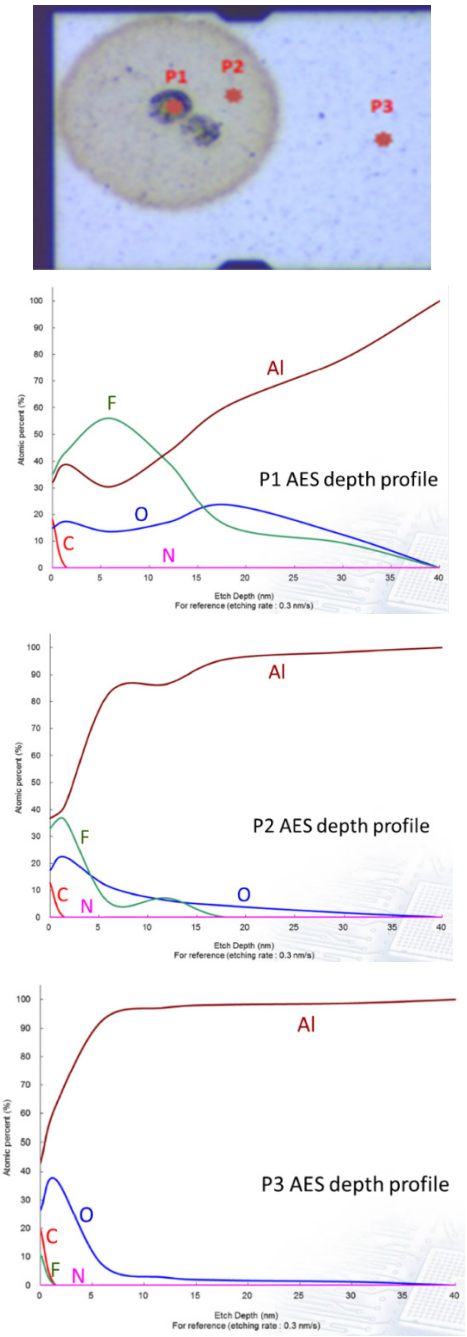

Figure 7: The OM photo and the corresponding AES depth profile of P1, P2 & P3, the P1, P2, & P3 are marked on discolored Al pad surface. P1 is the probe mark zone. P2 is the discoloration zone. P3 is the normal Al pad surface. The F element is found to co-exist with Al_2O_3 at discoloration zones.

2.3. AES Analysis Results

For a long time, the AES analysis is treated as the standard technology for Al pad surface contamination. Figure 7 (b) to (d) show the specific Auger Electron Spectrum (AES) depth profile result of normal/discoloration area of bond pad surface. The AES result indicate the main elements of probe mark and cyclic discoloration area are Al, F, and O. That is the same as previous EDS & EELS results. The AES depth profile results, P1, P2 & P3 of Figure 7, show the discoloration corrosion film is the F element co-existed with AlxOy. BTW, X-ray Photon Spectrum (XPS) is also an available surface analysis technology for oxidation state of

Al compound. However, due to the X-ray focusing capability limitation, XPS is not used in this bond pad case. The Secondary Ion Mass Spectrum (SIMS) analysis meet the similar limitation.

Two key factors decide the success of this contamination Failure Analysis. The first one is to identify the component of the corrosion product. The second one, sometimes it is more critical in probe testing FAB daily operation, is to find out the corrosion/contamination source, and then to stop this event.

Based on previous material analysis finding, the probe mark discoloration contamination is a special type of Al-F-O corrosion. Since the nature protective Al-O film would automatically form on bond pad top, therefore, the fluorine element play an important role in this corrosion event. Where do the fluorine come from? How do this discoloration develop?

The fluorine induced corrosion on Al bond pad is not an new issue[1,2]. The source of fluorine might come from wafer itself or external environment. The fluorine come from wafer itself is supposed to be the etching residue on Al pad surface.[9] The F-contained etching gas, like CF4, is broadly used in Al pad process loop. The fluorine element is supposed to easily residue on Al pad top surface after etching. Generally speaking, the 5 % fluorine residue on Al pad surface is regarded as a safe margin. However, the previous AES depth profile data indicate no fluorine element is found below 1.5nm of top surface on no discoloration area of Al pad. The source of fluorine need to clarify. Therefore, two various storage tests are necessary to find out the fluorine source. The first storage tests, HAST, the dice-level test is a high temperature corrosion accelerated test. The second test, FOSB storage test, is a full wafer-level test under daily standard storage operation. The experiment results show as below:

2.4. HAST Storage Test Result

In order to clarify the effects of long time storage and probing touchdown number on this corrosion. Four groups of various die samples were applied for the HAST. The nine discolored and nine normal dice were the first and secondary groups for HAST. The nine dice, with five and twenty probing touchdowns, set as the third and the forth groups. Therefore, in this HAST, total four groups dice obtained from impacted wafers were tested. The HAST testing preformed at the condition of temperature 130ºC and RH 85% for 21 hours. All the dice samples simulated to have exposed in air without N2 cabinet storage or MBB bag storage for 1 year. Table 1 consolidate the result of HAST storage test. The result of group one and two indicate that there is no visual change, by 100% OM inspection, after HAST storage simulation testing. No probe mark discoloration corrosion size increase after HAST. The secondary group data indicate no probe mark discoloration would form. The result of third and four group imply that the heavy deformation on Al pad surface would not automatic induce discoloration corrosion. According to the previous analysis, the fluorine is necessary for the formation of discoloration. The HAST result show no extra fluorine source exist in HAST tested dice.

Table 1: The HAST testing Result. Four various samples were tested. The size of all samples are die level. The discoloration dice show no deterioration after the test. No other tested dice show clear change. In this table, Y means discoloration; and N means no discoloration.

Group	1	2	3	4
Samples	Discolored 2 touchdown	Normal 2 touchdown	Normal 5 touch down	Normal 20 touch down
Dice Quantity	9	9	9	9
Discolored Before	Y	N	N	N
Discolor After	Y	N	N	N
Result	Discolor no deterioation	No Discolor	No Discolor	No Discolor

2.5. FOSB Storage Test Result

Based on the previous HAST result, all these dice were obtained from wafer center or middle area, and no extra fluorine was found. The FOSB storage test preformed for the full wafers deposited in normal FOSB at room temperature. The Ardentec AVI inspection was applied for the tested wafer before FOSB storage testing. Then these wafers, after some storage time, would be viewed by Ardentec standard AVI checking to identify the discoloration behavior on the same Al pad. After 4 weeks' storage time, obvious variation was found. Figure 8 clearly indicate the variation of two OM photos. The probe mark discoloration would deteriorate in FOSB storage test. That is to say, the fluorine-induced corrosion in the FOSB volume would be continuous. It is a manifest evidence the source of F element enhancing discoloration corrosion is due to the full wafers FOSB storage. The HAST result indicated no extra F was found from wafer center and middle area. Therefore, the source of F element of FOSB test is highly suspected to be the wafer edge or wafer extreme edge area. The EDS mapping was an excellent technology to show the various element distribution of semiconductor top surface. It would be helpful to identify the distribution of fluorine element of abnormal wafer extreme edge area.

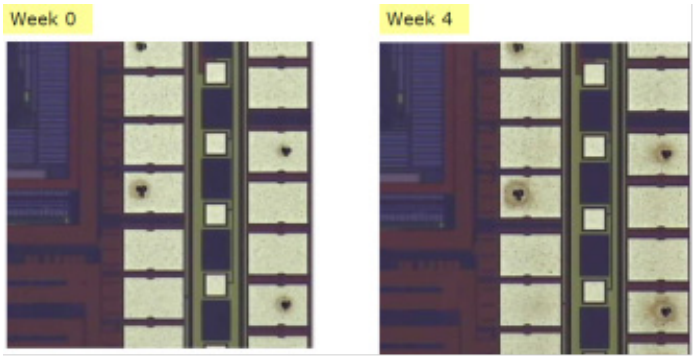

Figure 8: show the OM inspection result after FOSB storage test. The original probe mark discoloration is the OM micrograph on the left. After 4 week's FOSB storage, the size of probe mark discoloration became larger. The right hand side OM photo clearly show this deterioration.

Figure 9 show the EDS mapping result of extreme edge area of discoloration wafer. The EDS data clearly show the distribution of F, Al and other main elements on semiconductor wafer top surface. And the original location of this EDS mapping, the right hand side OM photo of Figure 9, was obtained at the extreme edge of full

wafers. There is a clear boundary between extreme edge, the upper part of OM image, and the internal die area. The fluorine-induced corrosion source is clearly identified from extreme edge of full wafers. It is supposed that the FSG layers exposed to FOSB space would be the F source of this corrosion.

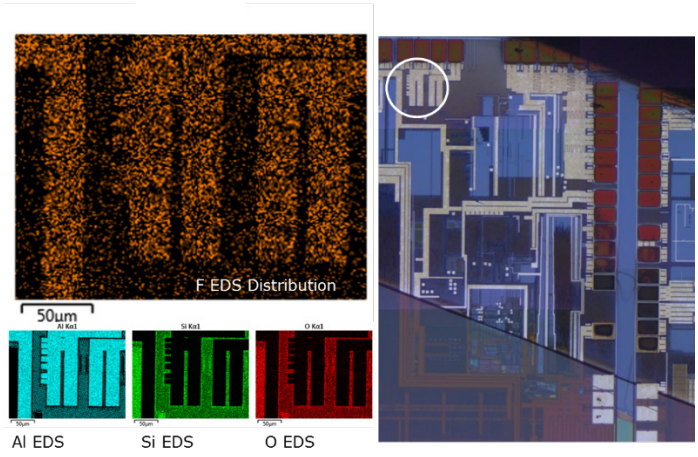

Figure 9: The EDS mapping result of Al pad on the discoloration wafer extreme edge area. The left hand side EDS mapping result show the distribution of F, Al, Si and O. The white circle area of right-hand side OM image shows the location of this EDS area of the wafer.

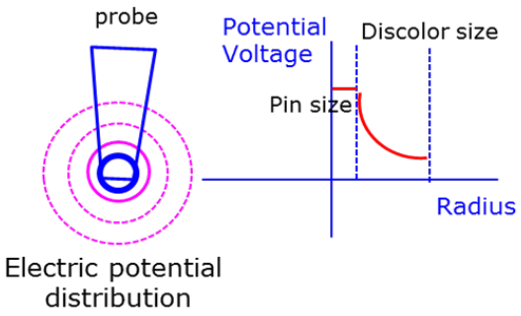

Figure 10: The critical CP testing and electrical testing potential field effect on Al bond pad surface.

The mechanism of this probe mark discoloration was proposed as follow: The CP testing would activate the embed fluorine. The formation of fluorine-contained oxide film induce this special discoloration.

The special point of this novel discoloration is the corrosion morphology with probe mark as its center. Some factors inducing the fluorine activation would spontaneously lead the probe mark as the discoloration cyclic center. In the beginning, the CP probing action would induce a permanent mechanical damage on the Al bond pad surface. This damage produce great deformation and heavy strain on the Al pad top surface, and this deformation and strain region, chemical activated, would be full of dislocation-like defects. The second mechanical effect was that probing test itself would break down the original protective Al-O film, and then create large amount of fresh aluminum surface. Both the mechanical effects would induce extremely active sites on Al pad surface. These would be easily for fluorine to react with Aluminum. The other impact of the probing action is the corresponding electric field potential, built by Circuit Probing test, would have an effect on the surrounding area of probe mark under the voltage/current variations. Under certain temperature, like the temperature of 125ºC setting at CP testing, and humidity, the fluorine contamination would be excited. Here the water is supposed to play an important role, leading to forming of hydrogen and oxygen, and after serial chemical reaction with fluorine, the AlxOyFz compound form. This kind of AlxOyFz compound is the discoloration by OM inspection. The threshold activation energy for all the chemical reactions was limited by electric potential field built by testing program, therefore, electric potential field introduced the circle shape discoloration region centered by probe mark. Figure 10 show the electric potential field distribution build by probing test.

The formation of probe mark discoloration on Al pad surface was not just due to single factor. There are three complex factors to induce this corrosion. The first factor is the sufficient fluorine supply in wafer storage environment. The fluorine might come from bond pad top surface or wafer inter metal dielectric layer. The second one is the environmental condition. The suitable temperature and enough humidity are critical to accelerate the fluorine corrosion reaction. The third factor induce probe mark discoloration formation was the probing touchdown and its sequential current and electric field. According the early study [3], the Al-O-F compound on Al pad surface show different morphology as this corrosion event. No previous report had pointed this Al-O-F compound discoloration morphology with probe mark as its circle center. Therefore, the characteristic of this contamination closely related to electric probing test condition. Then this novel probe marked discoloration need to combine all the above corresponding factors. These factors are materials property, wafer testing/storage environments and probing testing. Figure 11 show this idea.

According to the above mechanism, the formation of probe mark discoloration could stop in some ways. The material itself decide the source of fluorine. Therefore, the content of fluorine embedded on bond pad top surface or the distribution of fluorine on wafer edge is an important index to find the fluorine source. Since in CP and FT daily operation, no fluorine contained chemical materials are used. The CP & FT Fab is better to take them into regular monitor index for future discoloration event.

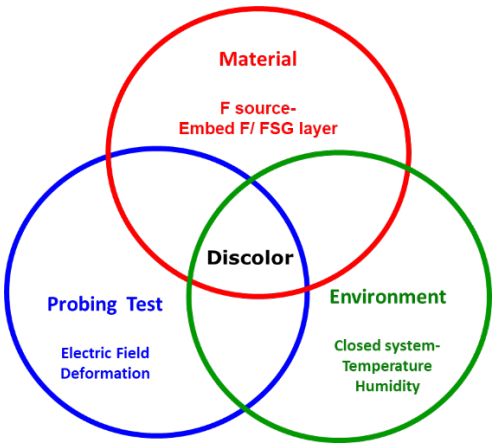

Figure 11: The factors to induce bond pad probe mark discoloration. These critical factors are material property, probing test and environment.

In the previous discoloration mechanism, the formation of donut shaped discoloration corrosion would be a weak point. Since the material analysis of donut discoloration indicate the fluorine

contained discoloration would only form on the ring zone, and no other discoloration would form on the other Aluminum pad surface. Therefore, the idea, discoloration originally form at probe mark area, and then fluorine diffusion to deteriorate discoloration, would not fully explain the formation of donut-shaped discoloration corrosion film. The EDS analysis result of donut-shaped discoloration imply that no fluorine exist at probe mark area. This impressive result also indicate the probe mark area with heavily deformation and high dislocation density would not spontaneously form corrosive fluorine contained Al-O-F film. The limitation of fluorine supply might be the key factor for this donut-shaped discoloration. There is no enough fluorine to form Al-O-F film on probe mark area, but enough fluorine to form Al-O-F film on annular area of Al top surface. In this system, there are two fluorine source, the embed fluorine and leakage form FSG. It is supposed that the embed fluorine would spontaneously form Al-O-F during CP testing under suitable electric potential activation. The fluorine supply from FSG leakage would be slowly deteriorate the corrosion due to diffusion into spacing is a time consuming process. That is to say, discoloration might be separate into two stages. In the first stage, embed fluorine play the key role in Al-O-F corrosion film formation. As for the secondary stage, the fluorine accumulation, leakage from FSG, and diffusion to Al-O-F interface play the key role. The secondary stage is a time consuming stage, therefore, storage environment is the controlled factor at this stage. The formation of cyclic discoloration corrosion would be that there is enough embed fluorine on the Al bond pad surface, and following with enough fluorine from FSG layer. As for the donut shaped discoloration, it would be that no enough embed fluorine on bond pad surface, so there is no complete cyclic discoloration formation. The key factor for donut-shaped discoloration formation is the supply of fluorine. No fluorine to react with Al metal. This explain that no Al-O-F film form at probe mark area and the formation of annular corrosion film. The possible root cause for donut discoloration might due to fluorine source complete consumption. However, no experiment would prove this proposal now.

3. Conclusions

- A new donut/circle shaped discoloration on Al bond pad is reported.
- Based on SEM/EDS, TEM/EELS and AES analysis results, the novel discoloration is due to form an Aluminum fluorine-oxide compound. The fluorine plays a key role in the formation of probe mark discoloration.
- With the help of HAST, FOSB storage test, and EDS mapping, the source of fluorine of this case is found.
- Since probe mark is the center of circle for discoloration, the formation of this corrosion is closely relative with the CP electric field.

Conflict of Interest

The authors declare no conflict of interest for this work. Formal "Conflict of Interest" document file is attached.

Acknowledgment

The authors would like to thank Polly Liu and Alex Si for their long time effort on discoloration impacted wafer management, and Berton Hsieh and Wei-Cheng Chen for their long time supporting on FA analysis.

ABSTRACT

Technologies are growing with the passage of time and providing solutions for the existing problems. One of such problems is to manage the crowd according to available capacity. Especially when the crowd density is dynamic because of dynamic position of the persons (Pilgrims). Not only dynamic position of the pilgrims makes crowd capacity dynamic but also special events increase and decrease in number of pilgrims that affect the capacity in a specific place. Therefore, it is not an easy job to estimate the available capacity according to the dynamic position and event. To overcome such problems of dynamic position and event-based crowd management different techniques and approaches are adopted. To solve the above-mentioned problem, this paper proposes a proactive approach to estimate the space occupy by the pilgrims in different positions in a zone or level. Maximum capacity in each zone and level is define on the basis of each position. On the basis of maximum and occupy capacities, available (remaining) capacity has been estimated in a zone and level according to the events such as Pilgrimage, Ramadan, Jummah etc. The occupied and available capacities in a zone, level or in the whole building can be estimated with the help of technologies such as Wireless Sensor Network (WSN), cloud computing, Internet of Things (IoT) and sensor topologies according to position and event. Simulation shows different scenarios according to the zones and different levels of building to prove the proactive approach. According to the results, it is concluded that zones, levels and point of entrances should be allocated to the pilgrims to avoid the congestion problems. Further for massive crowd and large area multi sink solution is better than single sink solution to estimate available capacity.

1. Introduction

Capacity estimation plays a vibrant role to maintain equilibrium among the maximum, occupied, and remaining capacities so that number of the persons can be allowed to enter in a zone, level or in a building [1]. Number of the persons permitted to enter an area directly dependent on the remaining capacity [2]. Although image-based method does not depend on the crowd to carry any type of device and counting can be performed without handling of device by the crowd. But the crowd counting done on the basis of images, does not provide result in case of dark or fade environment [3]. To provide the population awareness globally, crowd analysis can be done on the basis of video imagery to calculate and estimate the density of the crowd. It is considered an important tool of analysis for crowd density estimation at public places. Other methods also involve counting by performing the detection method or by using the clustering method for crowd estimation. Due to the more crowded environment one of the recent ways is regression. It has the capability to handle large crowded area [4]. The proposed proactive approach for capacity estimation is to calculate the number of the persons entering and exiting from the certain area. It is estimated according to the maximum capacity on the occasion of different positions and events. The sensor devices have the capability to sense and collect data at a given zone, level, building or an area [5]. In a specific scenario, data may include person ID (pilgrim ID), device ID, zone and level number, date and time for entry and exit etc. The sensed data then can be forwarded to the cluster head, then to a sink or

[*] Corresponding Author: Naeem A Nawaz, Ummal Qura University, nanawaz@uqu.edu.sa

server at each level and finally to central cloud storage location in order to calculate the remaining capacity of the areas. For different statistics, cloud computing can play a vibrant role to use the stored data. With the help of IoT data can be forwarded to different stakeholder for timely information to manage the crowd according to the position and events.

To overwhelm the problem of estimation of the capacity in different position and event, proposed proactive approach is one of the efficient solutions to provide advantages including:

- Counting number of pilgrims without human intervention
- Set the maximum capacity for different positions (Prayer, Walking, Sitting, Standing)
- Capacity estimation for different zone, Mataf area and on each level
- Capacity estimation according to Extreme crowded events such as, Jummah prayer, Ramadan, Eidain, Pilgrimage
- To restrict the pilgrims if they already performed Umrah so that remaining pilgrims can get opportunity
- Lost pilgrims can be traced within the coverage area

One of the central pillars of Islam is also Pilgrimage. Approximately 3.5 million pilgrims assemble to perform pilgrimage in the holy city of Makkah [6]. In the month of Ramadan millions of people gather to perform Umrah and other prayers [7]. Pilgrims perform different supplications at different places and time to achieve the Pilgrimage or Umrah requirements. To perform the Umrah during Ramadan people persist around the Masjid Al-Haram. The estimation of available capacity inside the Masjid Al-Haram, may be calculated by number of pilgrims in a specific zone, or level minus maximum threshold of the capacity. It has been observed that it is problematic to estimate capacity for a massive dynamic crowd, the number of pilgrims entered in Masjid Al-Haram and what is the remaining capacity inside? When it exceeds to maximum capacity? In this paper, we try to solve the above-mentioned problem by exploiting WSN. We proposed a proactive approach to process the data for different zones and levels to estimate available capacity. As I myself perform the Jummah Prayer many times, The Holy Masjid Al-Haram was so much overcrowded that it became difficult to perform Sajood and Tashahud. It is because of wrong capacity estimation of zone or level.

This paper is an extension of our previous work accepted in The International Arab Conference on Information Technology ACIT'2019 [1]. The extension includes capacity estimation of dynamic position, event, study of sensor topologies and proactive approaches.

1.1 Paper Layout

In section 2, we briefly discussed the technologies used in our proposed proactive approach that includes the technologies such as cloud computing, IoT, clustering and WSN. In Section 3, there are briefly given the approaches or strategies at present used for capacity estimation. Section 4 depicts the proposed proactive approaches according to zone, level and for the whole building. Section 5 elaborates the use case, section 6 offers comparison between existing and proposed capacity estimation, section 7 defines the algorithms, section 8 simulation and results, section 9 gives discussion and section 10 conclusion and future directions.

2. Technologies for Proposed Framework and Proactive Approach

2.1. Cloud Computing

Cloud computing is one of the most important technologies for proposed proactive approach. In cloud computing, cloud resources are located at different physical places. But via internet cloud computing makes efficient cloud services available globally to a large number of consumers located on many geographical locations [8], [9]. In a cloud computing environment, wearable devices are suggested for supportive communication between wearables and cloud server. Wearable device can be accessed remotely via the Internet [10]. Moreover, its everything-as-service-model (XaaS) impacts its clients and creators with many benefits [11]-[13]. Cloud computing is cost effective for the customers and uses the strategy "pay as you go" [14][15]. To process and access information in a more accurate way, cloud based software architecture has been proposed [16], [17]. Sensors, actuators and many other embedded devices are considered as a data generation source that provide help to enable IoT edge computing to process data [18]. Cloud can store the data according to the position, event and zones for future planning to control the massive crowd.

2.2. Internet of Things (IoT)

IoT lets people/anybody and things/devices connect anyone, anything, anytime, anywhere, for any service. Although it is flexible, complex and dynamic network infrastructure as given in [19]. In many fields such as healthcare, smart homes, smart cities, retail, traffic, security, and agriculture, IoT offers multiple solutions [20]. With the help of an IoT we can monitor the elements such as wind, crops, soil, atmosphere, lights and water over a big area [21]**.** For the growth of the IoT, there is a need of plentiful resources for the development of the intelligent devices and the WSNs. The core building blocks are the same for network communication in between devices to build an Internet of the Things setup [22]. With up to date development and advancement in the field of information and communication technologies, it also brought positive changes in the advancement and development of IoT. Through low-cost electronic devices and communication IoT paradigm improves human collaboration in the physical world [23], [24]. In the same way, it is also increasing the importance of WSNs to integrate and make connections with the Internet to develop different commercial and industrial applications [25]. In order to achieve different objectives, updated information is required efficiently during pilgrimage and Umrah. To achieve the above goal, IoT can play a vital role to get updated information as needed at a particular zone or level. Information received from IoT may be used by the management such as security management, and resource management (water, chairs, Quranic scripts etc…). So that necessary actions can be performed according to updated information on time in proactive way.

2.3. Clustering and WSN

There are some limitations in WSN such as energy limitation, coverage area, network lifetime, and bandwidth. These limitations

can be overcome with the help of some clustering schemes to get efficient solution [26]. Amongst the other factors, clustering is one of the most important factors. Clustering can also play an important role to control the performance of a network [27]. Wearable devices provide help to sense and disseminate information, such as physical activities, blood pressure, blood sugar level, heart rate) [28]. To monitor diverse environmental situations such as humidity, temperature, sunlight, and pressure, a smart sensing platform based on NodeMCU-ESP8266 microcontroller board has developed and given in [29]. With the implantation of WSN data can be sensed, stored, disseminated and processed to estimate the capacity [30], [31]. As an industrial IoT is an important infrastructure, WSNs play a crucial role in it. In IoT applications, efficiency balanced verification scheme for WSNs becomes a big contest, due to the resource limitation feature of sensor [32].

A proactive approach and framework can play an important role to enable reliable and an efficient management for WSN. One of the examples is Web Services based on clouds and lightweight cross-layer design [25].

2.4. Sensor Topologies

The topologies can differ in complication from a single node connected to a collector node to fully meshed network covering a large area. Flat or hierarchical architecture are used to design sensor topologies. In flat (peer-to-peer) architecture, each node either can be a sink or sensor node that has the same communication and computational abilities in the network. In hierarchical architecture, the nodes link with their particular cluster head in close proximity. Normally, cluster heads own more storage capacity and processing power as compared to any ordinary sensor node. Commonly line, star or bus topologies are used by the sensor networks that are physically wired together [33].

In Figure 1, point-to-point, Bus and linear topologies are given. A hardwired connection between two points is called a permanent point-to-point topology. A switched connection is a type of point-to-point connection in which control can be transferred between end nodes.

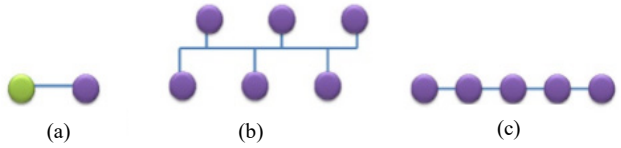

Figure 1: (a) Point-to-point, (b) Bus, and (c) Linear Network Topologies

In Bus topology, nodes are associated with a communication bus for communication. The advantages of the Bus topology are that it is simple and easy to install. But disadvantage is that the failure of central bus is the failure of the whole network, which is called a single point of failure. In Linear Topology, there is a two-way connection between the nodes. Only two terminating nodes has a single connection to their neighboring nodes at the end of the network, but all other nodes have link or connection to left and right nodes. In case of failure of a node, there is a disconnection from the network of any node connected to that node.

In Figure 2, ring, star and tree topologies are given. Network set up in a circular fashion is called ring topology. Each node in this configuration is connected to precisely two other nodes. Direction of flow of data is from the source to each node in clockwise or anticlockwise until it reaches to the intended recipient. In order to overcome this issue, a second communication ring is added by many networks that can transfer data in the opposite direction. In star topology, each node or device is connected to a single central device called hub or switch. Star topology has advantages such as easy to plan, implement, and add or remove the nodes. An intelligent node is needed as all data traffic flows through the central node. Entire network fails as a result of the failure of this node. In Tree topology, single “root node” is at the top of the hierarchy and other nodes are connected to the lower level in hierarchy in a tree manner structure. Many levels of nodes can be contained by a tree topology. This topology is extendable, and identification of the fault is easy and can be fixed easily because of simple structure. With the growth of the tree networks, it becomes more difficult to manage it.

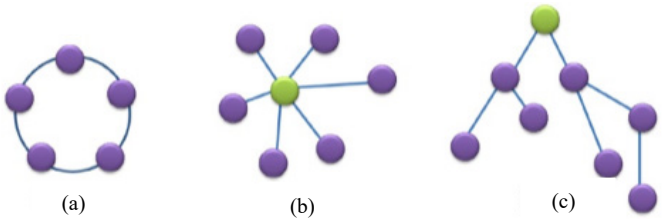

Figure 2: (a) Ring, (b) Star, and (c) Tree Network Topologies

In Figure 3, partially and fully mesh topologies are given. There are two arrangements of mesh topology: partially mesh and fully mesh. In partially mesh, some nodes are connected to more than one other node is called a partially connected mesh, while in fully mesh, every node is connected to every other node.

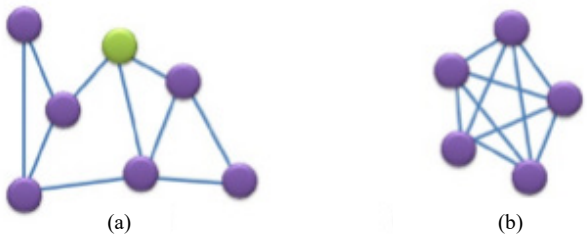

Figure 3: (a) Partially Connected and (b) Fully Connected Mesh Network Topologies

Cluster Tree topology consists of a single cluster or a multi-cluster network. Only one cluster-head (CH) is contained by a single cluster network. When all the nodes are connected to the cluster-head with single hop, the network topology becomes a star topology. More than one cluster-heads are contained by a multi-cluster network. An upper level sub-network is formed by all the cluster-heads. Nodes in different clusters communicate among themselves via their cluster heads but cannot directly talk to each other. Figure 4 illustrates the cluster tree topology, which has hierarchy architecture with the cluster-head network at the upper level and the clusters nodes at the bottom level [34]. The sink behaves as an entrance to the sensor nodes, gathering and updating the information. The sink plays a role as an interface among WSN, the external network and Internet, where the data are disseminated and processed. Sink can be single or multi sink depending upon the

requirement of the application. The goal of the single sink formation is to minimize the forwarding time and route information in the direction of a unique sink. Multi sinks are utilized for applications where tasks are distributed to different sinks. Multi sinks are used where there are high density crowd, large coverage area, redundancy, high latency, and possible high energy consumption [35]. In our scenario cluster tree or hierarchical cluster structure is suitable to collect the data from zones and levels during different positions and events.

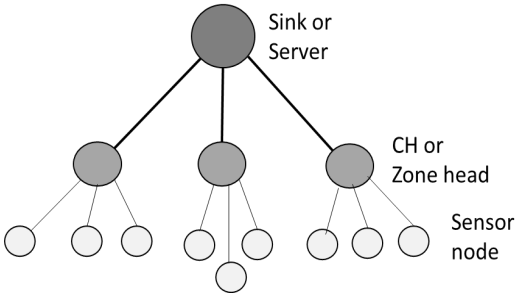

Figure 4: sensor cluster tree

During the events of Pilgrimage, Ramadan and Umrah the Holy city of Makkah (KSA) is crowded. Especially, to perform Umrah during the Ramadan all activities are around the Masjid Al-Haram, therefore it is need of the hour to organize, control and manage the crowded area smartly. The above objective can be achieved by proactive approach in smart way with the support of WSN, IoT, cloud computing and the management phases.

3. Present Capacity-Estimation Approaches

At present, capacity estimation is being done by management by taking view from the cameras or by the observation inside the Masjid Al-Haram. By cameras they discover the empty zone or level and update to the security officers to transfer the crowd to the empty or less crowded zone or level. They use the wireless system to give instructions to the security officers. By observation, the security officers check the capacity is available or not in an area where they are assigned. But they do not have auto capacity estimation approach so that they can measure how many pilgrims can be allowed in an empty space. They have just rough estimation of the available capacity. If the Zone or a level is reached to maximum capacity, the remaining crowd is diverted to the less crowded zone or level. If the Masjid Al-Haram is full then gates are covered with barrier and security officers do not permit pilgrims to get in, but they can make exit. No entry sign is turned on outside the gates. After that zones outside the Masjid Al-Haram are occupied. Sometimes zones and levels are overcrowded, and pilgrims face problem to perform the prayers or Tawaf. But currently, they do not have the smart estimation of the available capacity in a zone, level or in the whole Masjid Al-Haram. If there is smart capacity estimation with proactive approach, then pilgrims can be allowed according to the capacity available. Otherwise security stops the pilgrims at the gate and move to specified waiting area so that they do not overcrowd Masjid Al-Haram and do not cause any casualty.

4. Proposed Smart Capacity Estimation Framework and Proactive Approach

The Figure 5 represents the proposed smart capacity estimation proactive approach and framework. It provides help to estimate the capacity for zone and level to accurate the management. In order to ensure the smart capacity estimation in specific zone or level, the architecture uses WSN so that available capacity can be estimated for management automatically. The architecture provide help to understand the flow of data that is required to estimate the available capacity. It provides help to pilgrims to find out a specific zone or level where capacity is available. Figure 5 shows the overall picture of proposed framework and proactive approach for smart capacity estimation with the help of WSN, cloud storage and interaction among users by IoT for dynamic crowd management. It includes different phases: First phase involves smart capacity estimation according to time and preferable activity by pilgrims in a zone. Second phase involves smart capacity estimation according to time and their preferable activity by pilgrims at a level. Third phase involves smart capacity estimation according to time and their preferable activity by pilgrims at different levels, in order to calculate overall capacity occupied and available capacity in all zones or levels.

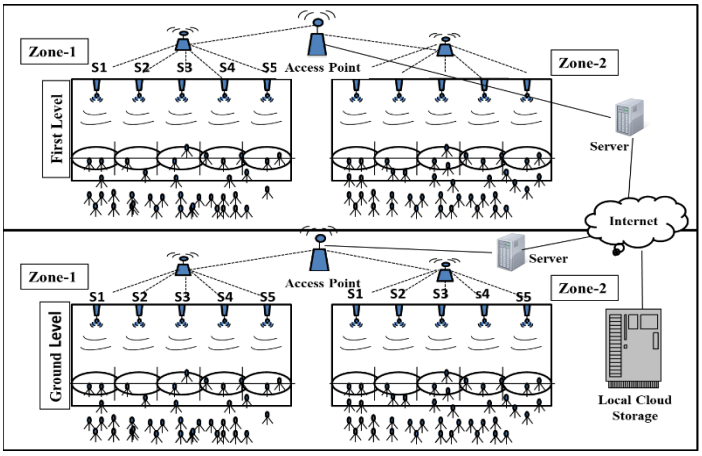

Figure 5: Proposed smart capacity estimation framework and proactive approach [1]

In the first phase, the calculation for the maximum capacity, capacity occupied by pilgrims and available capacity in the zone is done. In the second phase, head nodes or access point nodes fixed on the different zones at different levels will collect the data and forwarded to the server of different levels as update. In the third phase, data from each level from servers will be forwarded to the local cloud storage for further processing and management tasks. Detail of each proactive approach is given in subsection 4.1.

4.1. Proactive Approaches at Zone and Different Levels

Proactive approaches use to estimate the maximum, occupied and available (remaining) capacity with respect to zone, level and in a building.

The proactive approach for smart capacity estimation of zone is given as:

1- The Figure 6 depicts the steps to estimate the capacity based on a zone.

- Sensor nodes are fixed on each entry and exit point for each zone that can collect data about number of the pilgrims getting in and out of the zone.

- This information is updated to the zone access point or head node and from zone access point, it is forwarded to the level's server.
- The capacity occupied by pilgrims inside the zone can be calculated by number of pilgrims has entered minus number of the pilgrims exit.

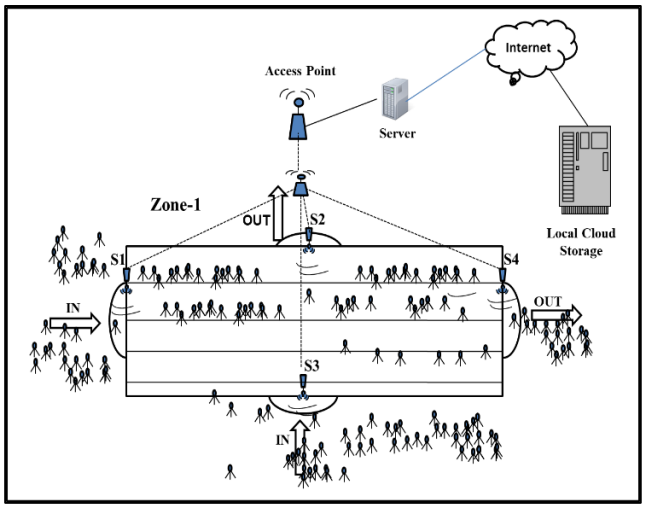

Figure 6: Smart capacity estimation of zone inside building [1]

Capacity occupied by pilgrims inside zone = number of pilgrims entered - number of the pilgrims exit

Z.IN=Entered to the zone
Z.OUT= Exit from the zone

$$Zone\ Capacity\ (Occupied) = \sum_{i=1}^{n}(Z.IN)i - \sum_{j=1}^{k}(Z.OUT)j \quad (1)$$

- The available capacity of the zone can be calculated by the maximum capacity of the zone minus total number of pilgrims inside.

The remaining capacity = maximum capacity of zone - (total number of pilgrims inside the zone).

Maximum Zone Capacity = Max (Z.C)

$$Zone\ Capacity\ (Available) = Max(Z.C) - \left(\sum_{i=1}^{n}(Z.IN)i - \sum_{j=1}^{k}(Z.OUT)j\right) \quad (2)$$

2- Proactive approach to estimate capacity at Ground Level is depicted in Figure 5.

- On each zone, sensor nodes will collect the data for pilgrims getting in or out. Afterward, it adds up or subtracts the number of the pilgrims got in and out from the head node or access point.
- The number of pilgrims getting in or out from all zones will be added up or subtracted by head nodes and then updated by the ground level server.
- If a pilgrim moves to the first level from ground level, then it will be subtracted from the ground level server but added into the first level server and vice versa.

L-IN=Entered to the level
L-OUT= Exit from the level

$$Level\ Capacity\ (Occupied) = \sum_{i=1}^{n}(L.IN)i - \sum_{j=1}^{k}(L.OUT)j \quad (3)$$

- From head node data can be forwarded to server to estimate the available capacity for ground level. If the ground level reaches to maximum capacity, then the ground level mentions no entry. Because ground level is full, it will be disturbance for the pilgrims if the pilgrims from outside entered into ground level and move to the first level. Therefore, security officers move the crowd to the first level from outside gate without entering into ground level and vice versa.

Maximum Level Capacity = Max(L.C)

$$Level\ Capacity(Available) = Max(L.C) - \left(\sum_{i=1}^{n}(L.IN)i - \sum_{j=1}^{k}(L.OUT)j\right) \quad (4)$$

3- Proactive approach to estimate capacity at First or at different levels is depicted in Figure 5:

- If the pilgrims move directly into the first level from outside gates, then there will be an addition to the ground level server and vice versa.
- If the pilgrims move into the First level via ground level, then it will be subtracted from the ground level but added into the first level and vice versa.
- From head node or access point data can be updated to the server to estimate the available capacity for first level. If the first level reaches to the maximum capacity, then at first level no entry appear at entrance. A message of maximum capacity is generated to the security officers by using IoT. The security officers move the crowd to second level from outside gate without entering into ground level or first level and vice versa.
- To avoid disturbance, pilgrims are allowed first to fill up top level then second and first level respectively. In this way first and second level pilgrims will not be disturbed.
- The data from each level forwarded to the local cloud storage to calculate the available capacity for the overall building. The data can be analyzed for different positions and events such as Ramadan, Pilgrimage, Jummah etc.

At present, most of prevailing wireless sensor devices are restricted because of memory, processing speed, efficiency and capabilities of communication. The above reasons are because of technology and economic limitations [36]. Low-power, low-cost, a multifunctional sensor device has been developed and designed by various industries for different applications, with high attention. Amongst the sensor devices one of the big issues in WSN is to classify and produce an organizational structure [37]. On behalf of clustering topologies, the processing of sensor devices can be improved which in turn improve the processing time. As a result, performance of capacity estimation will increase [38]. The collection of data will provide help to update information at zone, level, building and at crowded areas during Pilgrimage, Ramadan and Umrah for management.

The cloud storage, IoT and telecommunication play an important role in order to collect, assignment and process data locally and globally for smart capacity estimation [39]. To get results for different applications and different analysis, enormous amount of data can be sensed, stored and processed by the deployment of large number of sensor devices, cloud storage and IoT connections [40]. Detail of sensor topologies is given in section (2.4).

5. Use-Case for Smart Capacity Estimation

Data related to the pilgrims have been collected long time before by management and companies (travel agents) for pilgrimage, Umrah and visit. On the completion of e-visa process, management and companies receive information about pilgrim's residence in different sector or region. The information includes route of travel, reservation (city, hotel) and number of days to stay in different places. Pilgrims can be allocated the zones and levels according to their point of entrance according from their sector or region. As in Masjid Al-Haram, pilgrims have different positions therefore; capacities vary according to the different positions such as standing, sitting, walking and prayer positions. Capacity also depends on the events. Hence, it is important to measure the capacities according to each position and event.

5.1. Positions and Capacity

Capacity of the area is also depending on the position of the pilgrims such as standing, sitting, walking (performing Tawaf and Saee) and prayer position as given in Figure 7 and 8.In case of standing position space required for a pilgrim is less than as compared to the other position therefore, in standing position the available capacity will be maximum but in case of sitting, the pilgrim require more space than the pilgrim standing, therefore, in sitting position maximum available capacity will be reduced. In case of walking, the pilgrim required more space than sitting and standing position therefore, the maximum available capacity will be reduced as compared to sitting and standing maximum capacities.

In case of prayer position, the pilgrim needs more space than the standing, sitting, and walking position as the prayer position are dynamic such as standing (Qeyyam), sitting (Tashahud) and Sajood. Roughly, if we consider the standing position as the standard measurement then space ratio between standing and sitting position is measured as [5:9]. In case of walking position, the space ratio in between standing, and walking position is measured as [10:13]. In case of prayer position, the space ratio in between standing, and prayer position is as [1:3]. By calculating the capacities according to the crowd position, the crowd maximum capacity can be set according to standing, sitting, walking and performing prayer. At the time of prayer, the capacity will be minimum as compared to standing, sitting and walking position but in case of standing the capacity will be maximum as compared to sitting, walking and prayer position.

We can divide the sector for standing, sitting, walking and prayer. If crowd has different positions such as standing, sitting, walking and prayer within one sector or zone then we can calculate the average capacity. In case of The Holy Masjid Al-Haram, pilgrims want to see Baitullah (Kaaba), they can be managed on first, second and on top level near the balcony wall so that they can see the Kaaba in standing position. Sitting position is required when pilgrims want to recite the Holy Quran or Dhikr of Allah (Mention of Allah). They can be managed behind the Mataf area. Walking position is required in the Mataf or circular area on first, second and at top level. Prayer position can be at any sector but before prayer we need to calculate the capacity available for prayer and crowd inside the Masjid Al-Haram.

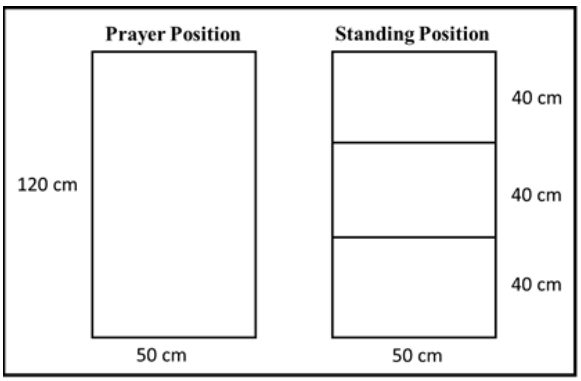

Figure 7: Capacity for prayer and standing positions

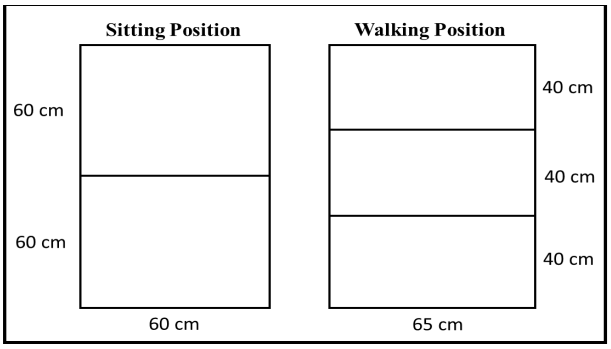

Figure 8: Capacity for sitting and walking positions

As we roughly calculated the space taken by the different position are given in Figures 7 and 8:

Standing = 40 x 50 = 2000 Sq CM

Sitting = 60 x 60 = 3600 Sq CM

Walking = 40 x 65 = 2600 Sq CM

Prayer = 120 x 50 = 6000 Sq CM

5.2. Stop and Wait

Calculate the average number of pilgrims entered in an area (Zone or sector) in unit time for example in one minute or in an hour. Average will provide help to calculate after how much time it is expected that the sector or zone will reach to its maximum limit. In this way we can control the crowd before it exceeds to its maximum limit. Usually it is observed that some time crowd exceeds the maximum limit and at prayer or Tawaf time pilgrims face a big problem which can lead to a stampede.

5.3. Move and Enter in the Zone

Rate of in and out to manage after maximum capacity, when zone and level reaches to its maximum capacity. Many pilgrims stay outside waiting for space availability. The space available for waiting pilgrims can be calculated by maximum capacity minus number of the pilgrims making the exit (going out). The space availability can be in a sector or zone or in whole area.

Table 1: Comparison between existing and proposed capacity estimation

S.No.	Existing Capacity Estimation	Proposed Capacity Estimation
i.	Initial capacity estimation is roughly calculated on the basis of previous experience and best guesses.	Initial capacity estimation will be calculated on the basis of data collected from central storage system.
ii.	Each zone capacity is calculated by the security officers or by computerized camera's system.	For each zone, automatically real time zone capacity will be estimated by zone sensors and sensor head.
iii.	Capacity available in a zone is controlled manually not automatically by security officers with the help of wireless system.	Capacity available in a zone will be calculated and automatically displayed. Zone security officer will manage the zone according to the available capacity.
iv.	There is no assurance about the exact maximum capacity estimation. Wrong estimation of maximum pilgrims' capacity can overcrowd the zone or level.	Maximum capacity for ach zone or level is already set therefore; maximum capacity alert will be generated automatically for no entry without any delay.
v.	According to dynamic positions and events there is no proper capacity records for zone and level.	Security officers can get records from local cloud storage system for future planning for each zone and level according to positions and events.
vi.	Real time capacity available cannot be calculated therefore capacity available can only be roughly estimated.	Real time capacity available will provide help to allow exact number of pilgrims to enter into a specific zone or level.
vii.	Difficult to estimate capacity available during different positions, events during prayer time and Tawaf time as each activity has different capacities that is number of pilgrims.	Capacity available during different positions, events during prayer time and Tawaf time is automatically estimated because prayer time and Tawaf time maximum capacity threshold can be set automatically according to activity.
viii.	There is no automatic way to trace out the lost pilgrim because existing system only support to manual capacity estimation and for security purpose.	Pilgrim lost can be traced out on the bases of the sensor device location with help of IoT.
ix.	CCTV cameras implementation provide help to observe and control the act of misconduct but there is no automatic way to identify the pilgrim (mis-conductor).	If the act of misconduct is done, then pilgrim (mis-conductor) will be identified on the bases of information stored on sensor device and on the cloud storage with the help of IoT.
x.	There is no such application to provide schedule, when the capacity is available for a specific building, sector and region.	Application can be developed on the basis of IoT to provide the schedule for visit to Masjid Al-Haram according to building, sector and region.

5.4. Evacuation or Exit from the Zone

In any case if the capacity exceeds to maximum limit in a zone or level, it can be managed in another zone or level. In worst case the pilgrims have to evacuate to the waiting place and put into high priority to get in when space will be available.

6. Comparison between Existing and Proposed Capacity Estimation

In the section 3, capacity estimation about existing system is described. It consists of manual capacity estimation, wireless system and computerized camera's systems. The proposed capacity estimation is discussed in the section 4. The comparison and preliminary analysis between existing and proposed smart capacity estimation systems are given in Table 1.

7. Algorithm for Proposed Capacity Estimation

We have taken the simple scenario to design the algorithms at different zones, different levels and in the whole building.

7.1. Algorithm for Zone Capacity Estimation

In zone capacity estimation, we simply check the available capacity in zone. If maximum zone capacity is greater than the number of pilgrims has entered in a zone minus number of pilgrims have exited from the zone. If the condition is true, then display the GREEN sign and also display the available capacity for pilgrims in waiting position. Otherwise display RED sign that zone is full and there is no entry.

Algorithm 1: Zone capacity estimation

```
Step-1   Begin
Step-2   GET value for Max(Z.C)
Step-3   If (Max(Z.C) > (Z.IN)-(Z.OUT))
Step-4      Display LED Turn(Green)
Step-5      Display Zone Available Capacity
Step-6   Else
Step-7      Display LED (RED)
Step-8   Endif
Step-9   End
```

7.2. Algorithm for different Level Capacity Estimation

In different levels capacity estimation, we simply check the available capacity in a level. If maximum level capacity is greater than the number of pilgrims has entered in a level minus number of pilgrims have exited from a level. If the condition is true, then display the GREEN sign for available capacity. Also display the zone number and level number where capacity is available for pilgrims in waiting position. Otherwise display RED sign that level is full and there is no entry.

Algorithm 2: Different level capacity estimation

```
Step-1   Begin
Step-2   GET value for Max(L.C)
Step-3   If (Max(L.C) > (L.IN)-(L.OUT))
Step-4      Display LED Turn(Green)
Step-5      Display Zone Number & Available Capacity
Step-6   Else
Step-7      Display LED (RED)
Step-8   Endif
Step-9   End
```

Cluster verification algorithm [31], represents the scenario of verification of cluster members (CMs) in cluster form. It discusses the number of verified and unverified CMs in a cluster. But in capacity estimation algorithm, it verifies and count the number of the pilgrims getting in or out from zone, level or in a building. All CMs remain within the cluster head transmission range for verification. But in capacity estimation algorithm, the pilgrims in the range of entry and exit sensors are verify when they make entry or exit from zone or level. CMs can enter to different clusters but in capacity estimation, it is not allowed to enter other than allocated zone or level. Zone and level are allocated so that pilgrims enter from the gate that is near to their zone and level. In this way crowd will be distributed in different zones, as a result a single path and zone will not be crowded. In the cluster verification, the number of the CM verify are listed out but in capacity estimation, it tells the available capacity for a zone and as well level and building. Cluster verification represents the number of CMs supported by a cluster head but in capacity estimation, the number of the pilgrims can be managed according to the available space in a zone or level or building. In cluster verification more than one CM can be verified. But in capacity estimation, the verification and counting of the pilgrims is done at entrance and exit one by one. In cluster verification, cluster head generate the signals for verification and in response CMs generate signals for their identification. But in capacity estimation, pilgrims (sensor devices) generate signals (that is an event driven approach) for verification and in response zone sensors verify and count the number of pilgrims getting in or out from zone.

8. Simulation and Results

Contiki OS is a lightweight open source operating system for sensor network. It was designed by Adam Dunkels, at the Swedish Institute of Computer Sciences. C programming language is used in both Contiki OS and its programs. Contiki is flexibly portable OS and it has been ported to different platforms. Texas Instruments MSP-430 in addition to Atmel AT mega series of microcontrollers are the most often used platforms. Contiki employs event-driven programming model to deal with concurrence. It is Contiki's main advantage that all processes share one stack, allowing savings of memory. In order to utilize this model Proto threads. Unconditional blocking wait is provided by Proto threads to save the state when it blocks. It jumps back to the next instruction on resumption of Proto thread. It also employs Rime stack that is a stack for sensor networks for lightweight communication. The main purpose of Rime stack is to support code reusing and simplify the implementation of sensor networks. Contiki is used in several systems, such as electric meters, alarm generating systems, remote control of house, radiation detection and streetlights control. Cooja is Java based Contiki network simulator with a graphical user interface (GUI). It is a trial system given by Contiki, and additionally empowers with original instrumentation before running it on the real target hardware. It integrates to simulate with the external tools to provide additional features to the large and small networks. Motes can be emulated, which is faster and allows simulation of larger networks, or at the hardware level. Two emulator software packages are contained by this tool: Avrora and MSPSim. Cooja can emulate multiple platforms like: TelosB/SkyMote, MicaZ mote, Zolertia Z1 mote, ESB, Wismote [41].

The Figure 9 shows full screen view of Contiki/Cooja simulator. Network simulator "Contiki/Cooja" is separated into small windows such as: Network Window, Notes Window, Simulation Control Window and Mote Output Window.

Network Window is employed to draw the WSN in random manner, linear, ellipse or manual positions. Notes Window is employed to write down the information or detail about the simulations and detail of its results. In order to start, stop, pause or reload the simulations, simulation control Window is used. The results for data packets have transmitted and received is provided by Mote Output Window. For our scenario, we use the Tmote Sky platform. Tmote Sky is one of the high data rate platforms work with low power consumption. It works well for many months to years without replacing the battery. Therefore, it is one of the most demanding wireless sensors. It is notable that options are best used in a selection manner, as the window can become disordered with too many selected options. The number for each mote is displayed by Mote IDs. Mote Output window can be used for analyzing and filtering results. On the simulated motes, LEDs are beneficial in order to observe the LED lights.

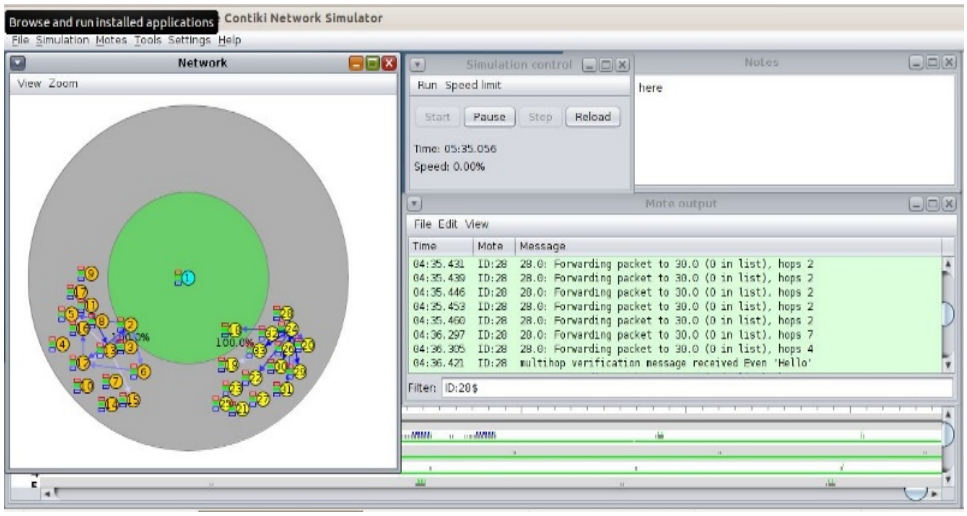

Figure 9: Full view of the Contiki/Cooja simulator

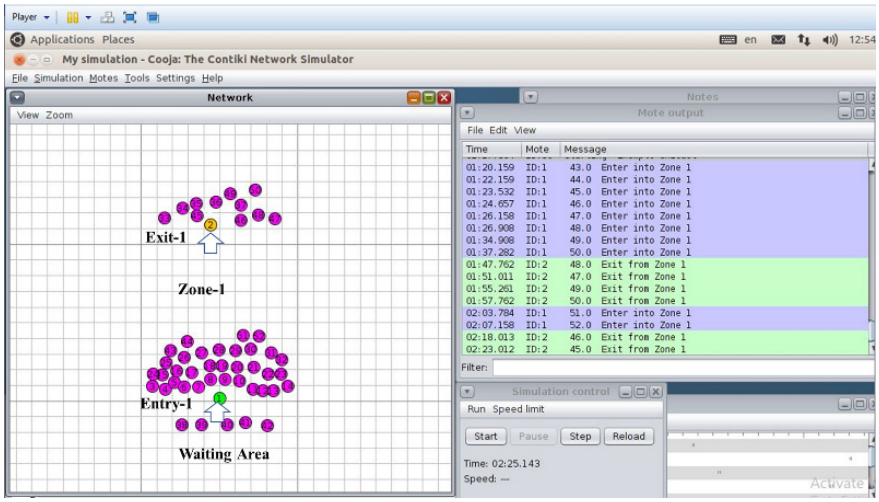

Figure 10: Single zone having maximum capacity 50

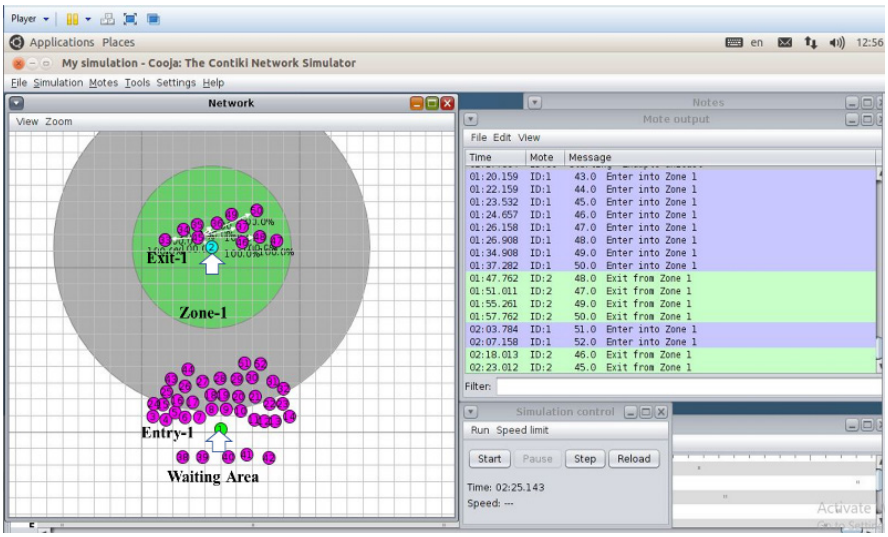

Figure 11: Single zone having maximum capacity 50 with coverage

We took the simple scenario to make understanding of the flow and function of each node as given in Figures 4 and 8. Head node function is to keep the record and status of CMs and forward record to the server for update. The status of the CM can be waiting to enter, enter and exit. Since the log file generated by the Contiki/Cooja simulation tool, we extracted the data for single and double zone in a level. For each zone we calculated the number of the pilgrims entered, exited, zone capacity occupied and available capacity for pilgrims. From this datum we can calculate the capacity for different positions and events. We also draw the table and graph for better understanding.

8.1. Single Zone Scenario

In single zone scenario, we consider one entry point and one exit point. We also set the maximum value for zone then we allow the specific number of the CMs to enter the zone and some of them allowed to exit from the zone. The simulation is shown in the Figures 10 to 18 and data is given in the Table 2. To make clarity of the figures, we consider the complete figure and then divided into its small parts (network, mote output and simulation control windows).

The simulation for maximum capacity 50 pilgrims is shown in the Figures from 10 to 14 and data is given in the Table 2.

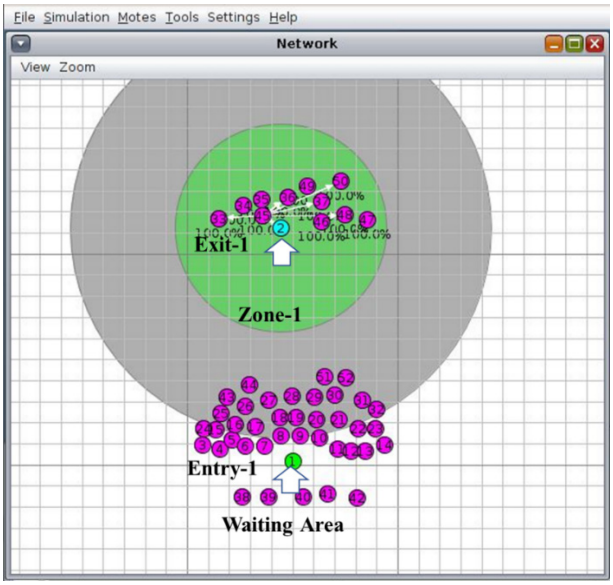

Figure 12: Network window from Figure 11

The Figures 10 and 11 represent the single zone having maximum capacity of 50 pilgrims. Figure 10 shows the capacity without coverage area while Figure 11 shows the capacity with coverage area in circular form.

The Figure 12 represents the network distribution of sensor nodes, entry point and exit point nodes in single zone having maximum capacity of 50 pilgrims. It also shows the number of nodes in waiting, occupy and exit position to calculate the available capacity.

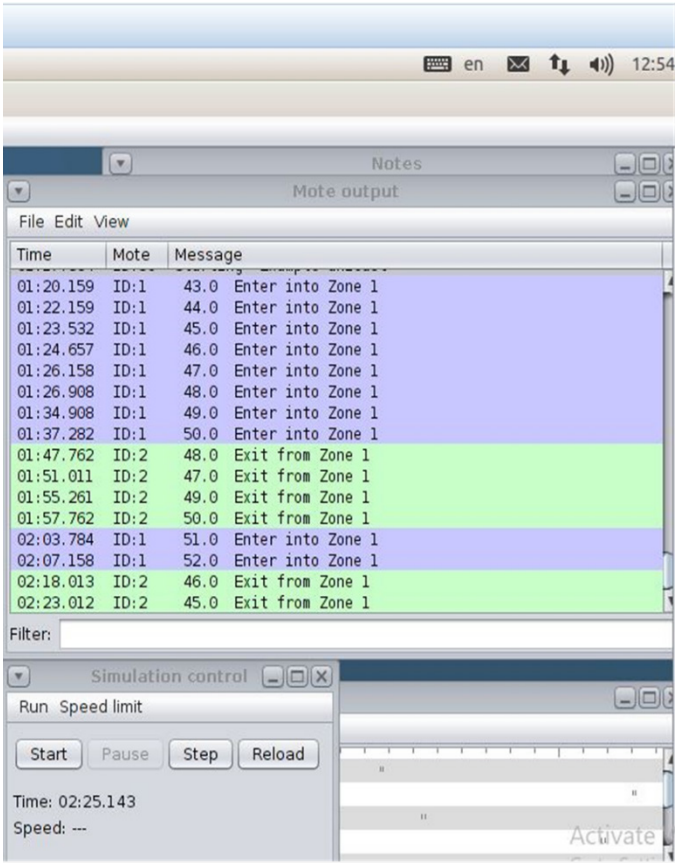

Figure 13: Mote output and simulation control windows from Figure 11

Figure 13 represents the most output with time, mote ID and its status enter or exit. The mote output is saved in the log file from where we can estimate the available capacity in a zone.

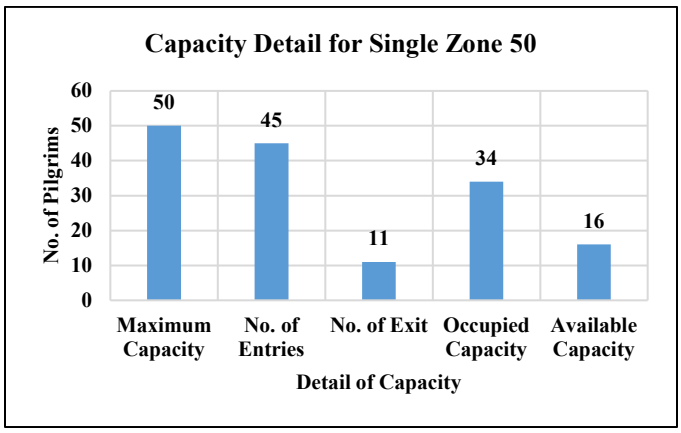

Figure 14: Capacity detail for single zone having maximum capacity 50

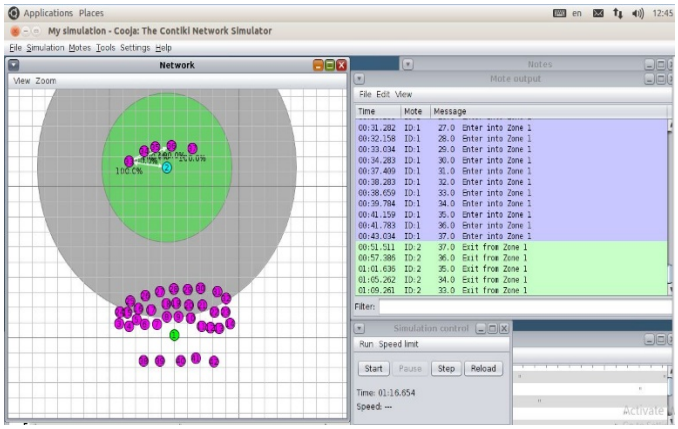

Figure 15: Single zone having maximum capacity 40 with coverage

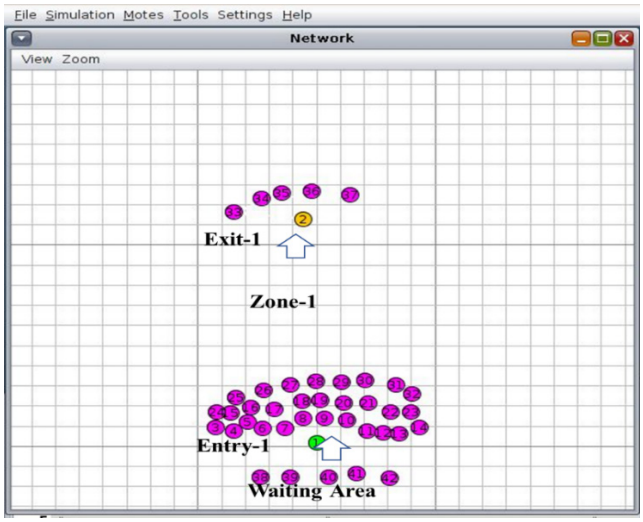

Figure 16: Network window from Figure 15

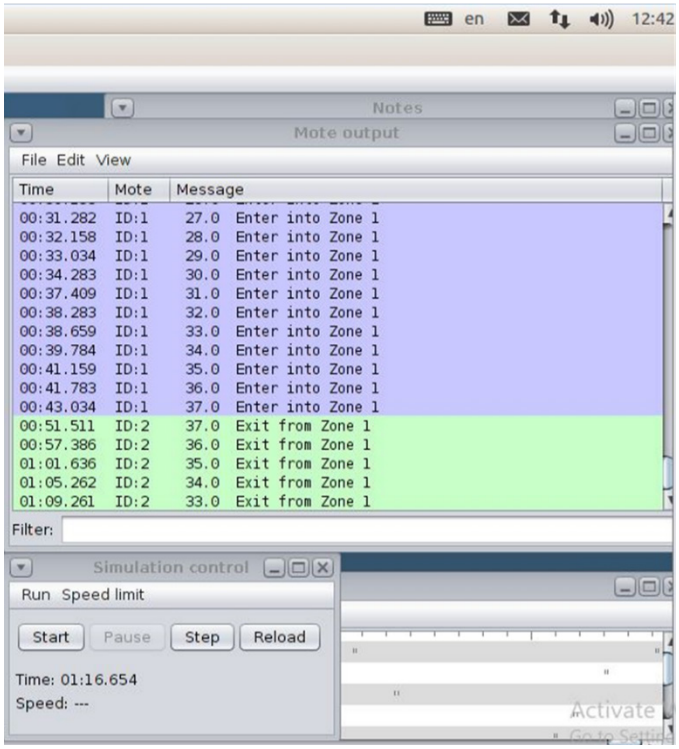

Figure 17: Mote output and simulation control windows from Figure 15

Figures from 10 to 14 considered that the maximum capacity for zone is 50 Pilgrims. Graph in Figure 14 shows that 45 of them have entered and 5 are in waiting position. 11 pilgrims have made the exit, occupied capacity in the zone is 34 and available capacity is 16.

The simulation for maximum capacity 40 is shown in the Figures from 15 to 18 and data is given in the Table 2. To make clarity of the figures, we consider the complete figure and then divided into its small parts (network, mote output and simulation control windows).

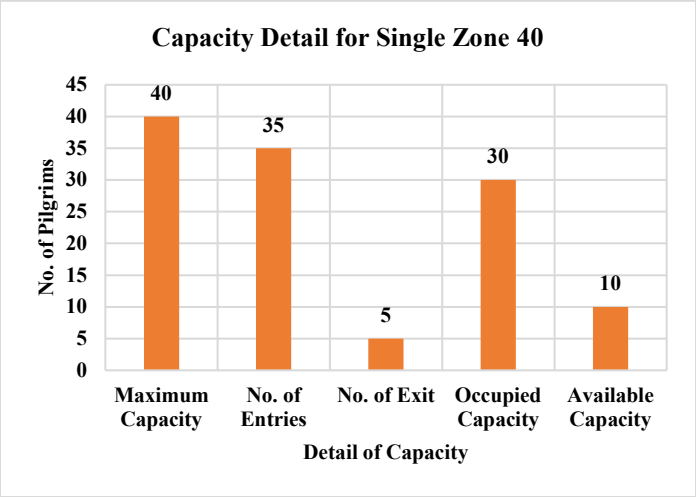

Figure 18: Capacity detail for single zone having maximum capacity 50

Figures from 15 to 18 show the maximum capacity for zone is 40 Pilgrims. Graph in Figure 18 shows that 35 out of 50 pilgrims have entered and 5 are in waiting position. 5 pilgrims have made the exit, occupied capacity in the zone is 30 and available capacity is 10.

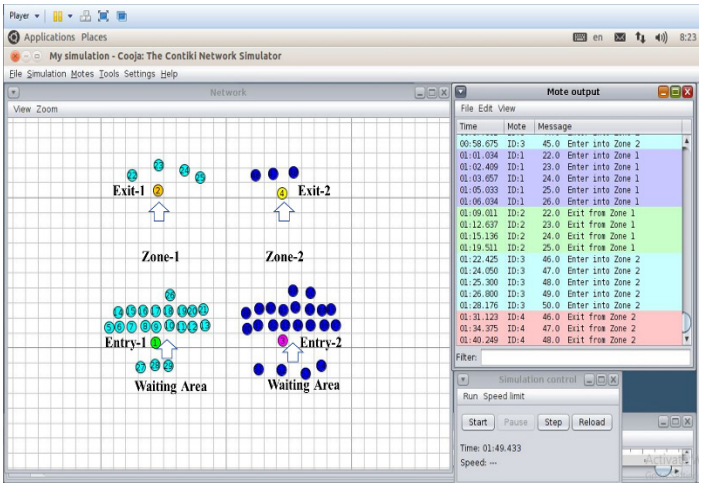

Figure 19: Each zone has maximum capacity 25 but total 50

8.2. Different Levels and Double Zone Scenarios

In different levels and double zone scenarios, we consider one entry point and one exit point in each zone and also consider that each level has double zone. We also set the maximum value for each zone and each level. We allowed the specific number of the nodes to enter in each zone and some of them allow to exit from each zone. The simulation is shown in the Figures 19-32 and data are given in the Table 2.

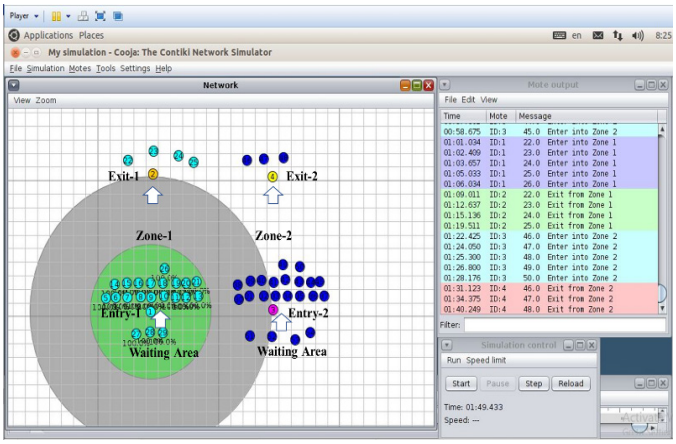

Figure 20: Each zone has maximum capacity 25 but total 50 with coverage

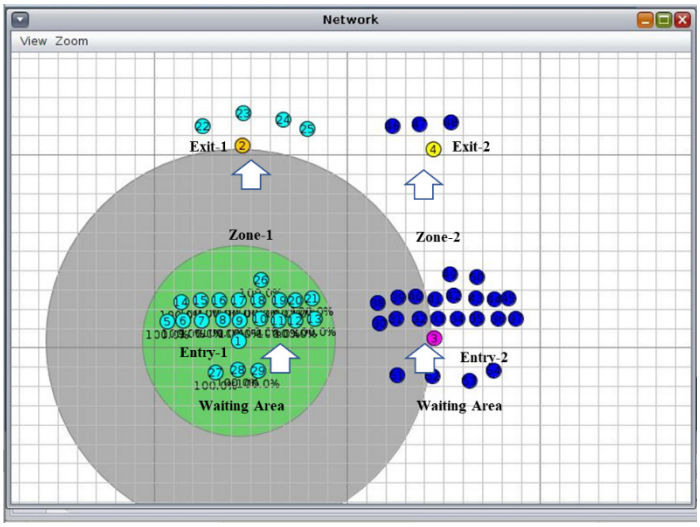

Figure 21: Network window from Figure 20

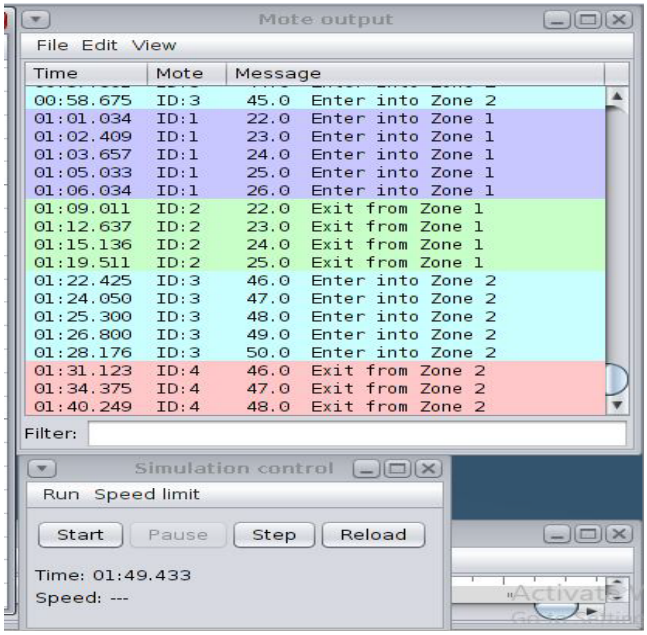

Figure 22: Mote output and simulation control windows from Figure 20

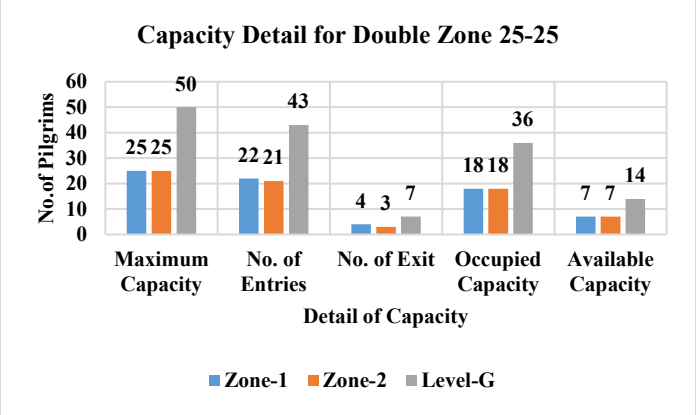

Figure 23: Capacity detail for double zones having maximum capacity 25 in each but Level-G has maximum capacity 50

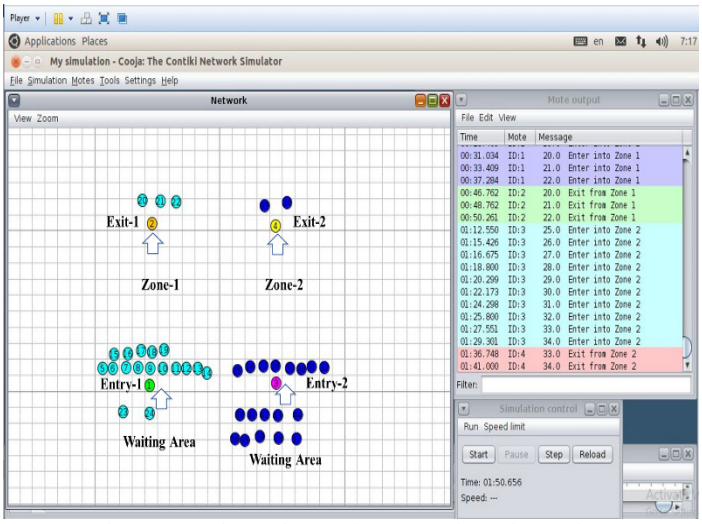

Figure 24: Each zone has maximum capacity 20 but total 40

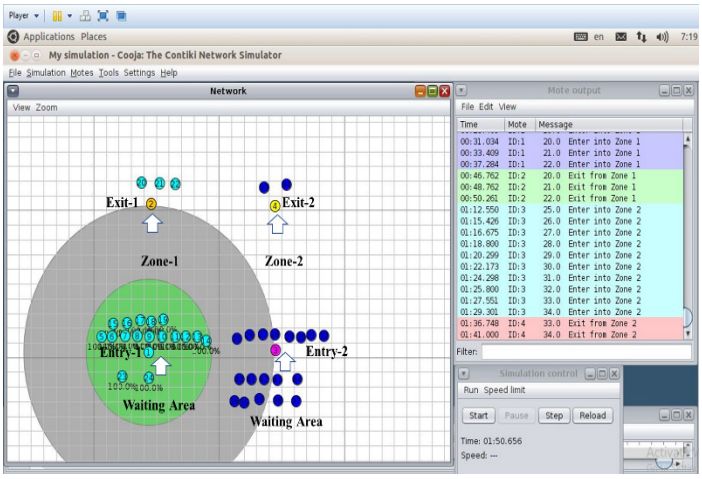

Figure 25: Each zone has maximum capacity 20 but total 40

In Figures 19 to 23, it is considered that the maximum capacity for zone-1 and zone-2 is 25. Zone-1 and zone-2 made the level-G and total capacity is 50 Pilgrims. In zone-1, 22 have entered and 3 are in waiting position. 4 pilgrims have made the exit, occupied capacity in the zone is 18 and available capacity is 7. In zone-2, 21 have entered and 4 are in waiting position. 3 pilgrims have made the exit, occupied capacity in the zone is 18 and available capacity is 7. From the log file or zone-1 and zone-2, we calculated the capacities for Level-G. Level-G has maximum capacity 50 pilgrims. 43 have entered and 7 are in waiting position. 7 pilgrims have made the exit, occupied capacity in the zone is 36 and available capacity is 14.

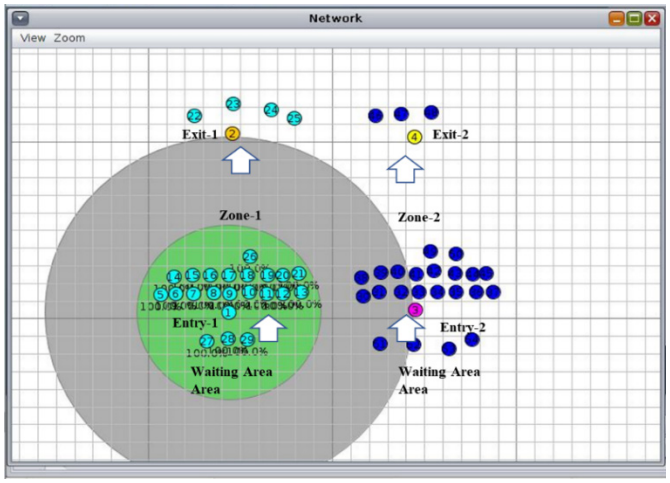

Figure 26: Network window from Figure 25

In Figures 24 to 28, it is considered that the maximum capacity for zone-1 and zone-2 is 20 pilgrims. Zone-1 and zone-2 made the level-1 and total capacity in level-1 is 50 Pilgrims. In zone-1, 18 have entered and 2 are in waiting position. 3 pilgrims have made the exit, occupied capacity in the zone is 15 and available capacity is 5. In zone-2, 10 have entered and 10 are in waiting position. 2 pilgrims have made the exit, occupied capacity in the zone is 8 and available capacity is 12. From the log file or zone-1 and zone-2, we calculated the capacities for Level-1. Level-1 has maximum capacity 40 pilgrims. 28 have entered and 12 are in waiting position. 5 pilgrims have made the exit, occupied capacity in the zone is 23 and available capacity is 17.

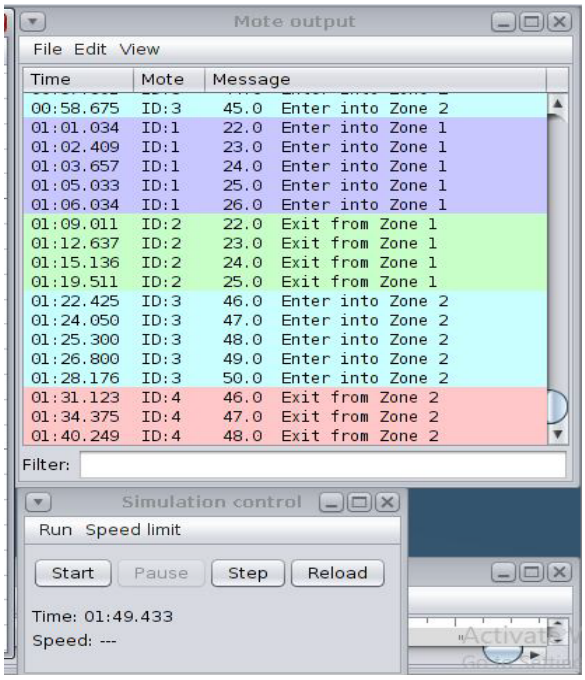

Figure 27: Mote output and simulation control windows from Figure 25

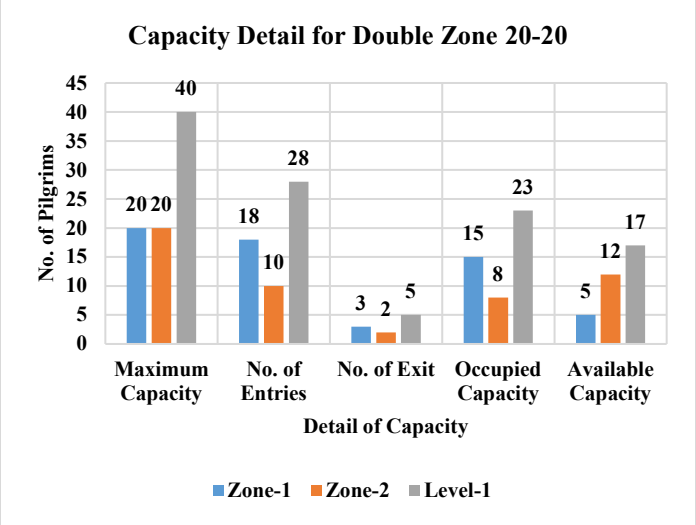

Figure 28: Capacity detail for double zones having maximum capacity 20 in each but Level-1 has maximum capacity 40

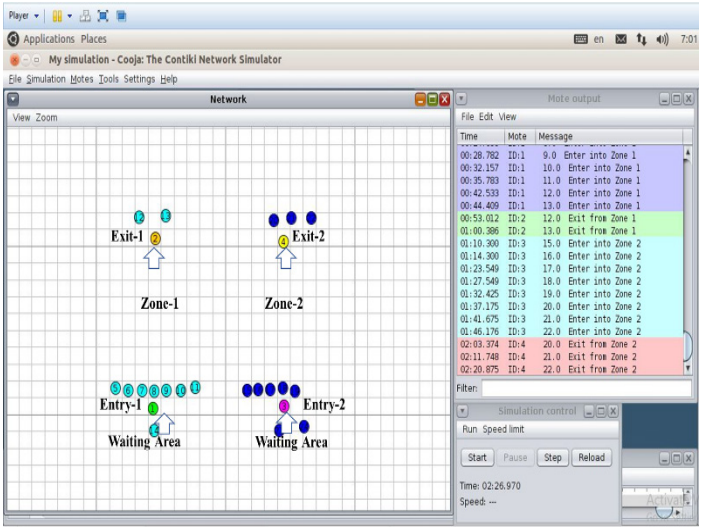

Figure 29: Each zone has maximum capacity 10 but total 20

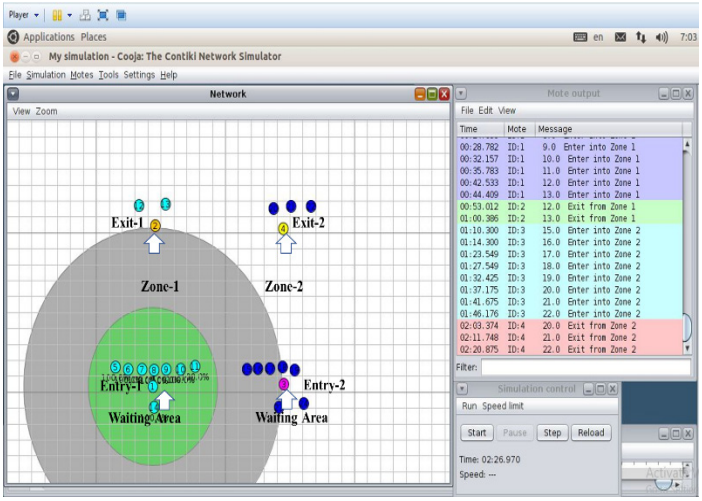

Figure 30: Each zone has maximum capacity 10 but total 20 with coverage

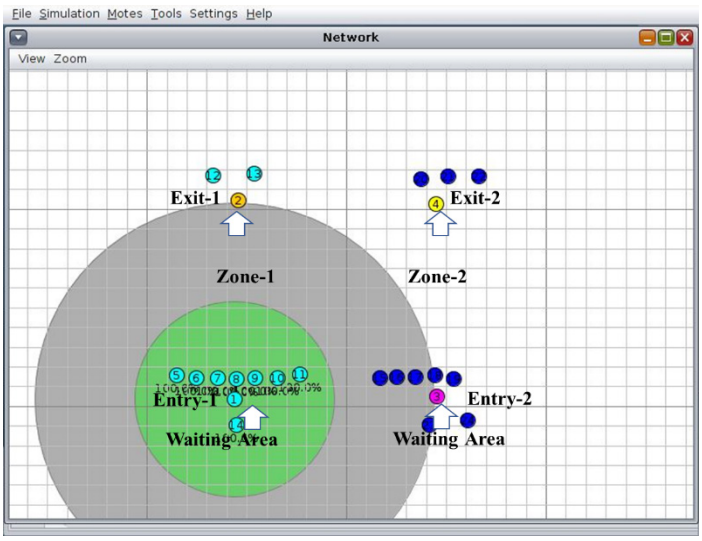

Figure 31: Network window from Figure 30

In Figures 29 to 32, it is considered that the maximum capacity for zone-1 and zone-2 is 10 pilgrims. Zone-1 and zone-2 made the level-2 and total capacity in level-2 is 20 Pilgrims. In zone-1, 9 have entered and 1is in waiting position. 2 pilgrims have made the exit, occupied capacity in the zone is 7 and available capacity is 3. In zone-2, 8 have entered and 2 are in waiting position. 3 pilgrims have made the exit, occupied capacity in the zone is 5 and available capacity is 5. From the log file or zone-1 and zone-2, we calculated the capacities for Level-2. Level-2 has maximum capacity 20 pilgrims. 17 have entered and 3 are in waiting position. 5 pilgrims have made the exit, occupied capacity in the zone is 12 and available capacity is 8.

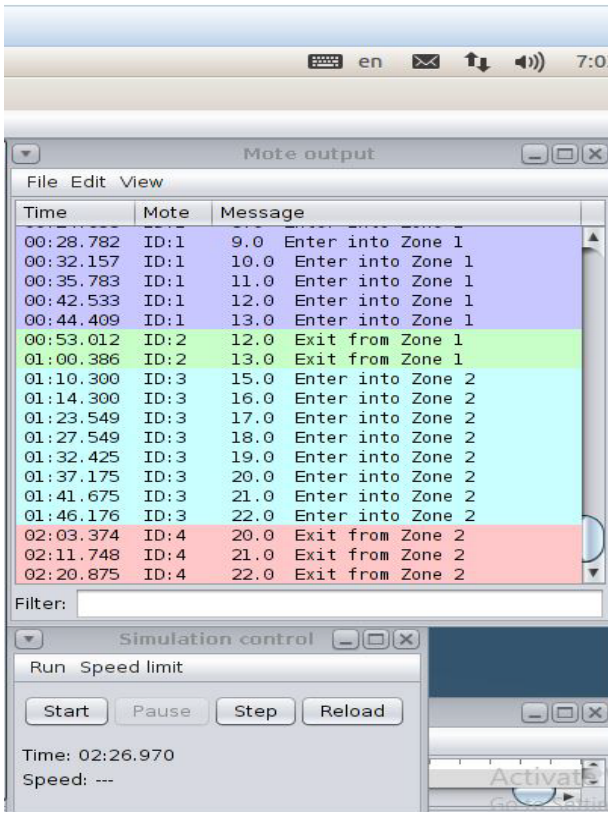

Figure 32: Mote output and simulation control windows from Figure 30

Table 2: Zones and Levels and capacities

Zone/Level	Maximum Capacity	No. of Entries	No. of Exit	Occupied Capacity	Available Capacity
Single Zone	50	45	11	34	16
	40	35	5	30	10
Level/Double Zone					
Zone-1	25	22	4	18	7
Zone-2	25	21	3	18	7
Level-G	50	43	7	36	14
Zone-1	20	18	3	15	5
Zone-2	20	10	2	8	12
Level-1	40	28	5	23	17
Zone-1	10	9	2	7	3
Zone-2	10	8	3	5	5
Level-2	20	17	5	12	8

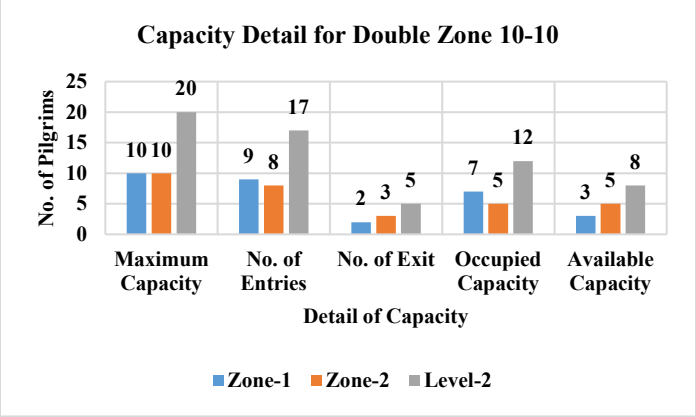

Figure 33: Capacity detail for double zones having maximum capacity 10 in each but Level-2 has maximum capacity 20

9. Discussion

The present analysis deals with capacity estimation for pilgrims at crowded place. The prime focus is on the allotment of zone and level number. This is performed according to moving status and events, single or multi sink, entry and exit point.

The concern of discussion is the allotment of zone and level number to pilgrims. According to discussion allotment of zone and level number to pilgrims should be specific (fixed) or flexible for dynamic position and events accordingly. Specific zone and level number according to dynamic positions and events is preferred because it is noticed if allotment is flexible then some zone and level number are more crowded than available capacity while others remain empty or less occupied. Furthermore, prayer position requires more area than standing and sitting position comparatively as given in section (5.1). As compared to routine days, pilgrimage, Ramadan and Jummah needs more area. The above mention reasons lead to non-uniform distribution of crowd. What is more, pilgrims having flexible zone and level move in different directions. It can result in congestions (bottleneck) that can lead to stampede. But in particular case, pilgrims are allotted the specific tracks to approach their zone and level number, that is why, chances of bottleneck and stampede are lessened or minimized. In flexible case, pilgrims are unable to move flexibly from overcrowded to less crowded zone or level (where capacity is available). This is because they have right to enter any zone and level number. But in particular case, pilgrims are allotted by the zone and level number. They can only move into allotted zone and level number. As allotment is performed considering maximum capacity of zone or level (a proactive approach), the zone or level does not get overcrowded. Place can be occupied within the zone on the basis of first come and first serve.

Entry point and exit point is the second point of discussion. In case of flexible, the pilgrims can enter and exit from any one of the points. Again, some entry points become more crowded than the other and cause bottleneck and there are chances of stampede. Moreover, pilgrims' attempt of entry and making exit from same location also causes bottleneck and stampede. But in specific case, each zone and level have particular point of entry and exit. In this way, chances of problem of bottleneck and stampeded can be overcome. Furthermore, pilgrims can conveniently access the transport of their residential area.

Third point of discussion is that there should be a single or multiple sink for WSN system. Massive crowd, scalability, latency, reliability, and network lifetime are the numerous challenges that may be created by the design of WSNs. The question whether sink should be single or multi sink is dependent upon its application. In the case of single sink and massive crowd, single sink has to control all traffic. The streaming of data traffic will be in one direction which causes congestion. There are probabilities that single sink is ineffective to control massive amount of data which causes the drop of data. This drop of data will cause the high latency rate. However, there are separate solutions to control the massive crowd and data in case the multi sinks are used. In the case of multi sink, data flow will be in multiple directions rather in one direction. Probability of congestion can be minimized in this way. In order to avoid the congestion and to distribute the task among sinks different type of data traffic or task can be allotted to different sinks. If the data is dropped on one path, it can be received on the alternative path. In this way latency rate can be minimized. When

data is received from different paths and sinks, it will provide the data redundancy. Single sink solution is not appropriate in case of long-distance communication because transferring data to long distance with the support of sensor nodes means consumption of energy to a lot degree. This consumption of energy will lead the sensor node die early and hence it will shorten the network life span. But in case of multi sink, the sensor nodes will get the shortest path as multi sink will divide the path and will consume less energy by increasing the network life span. Increasing of lifetime of network and receiving of data from multiple courses increase the reliability of the network. In our case, as data is massive, crowd is large, dynamic, and on large area therefore WSN required the multi sinks solution.

10. Conclusion and Future Directions

This paper provides an overview of a dynamic positions and events, proactive approach with framework and its implications towards smart capacity estimation using WSN and cloud computing in the IoT paradigm.

We discussed the framework and proactive approach in the context of dynamic position and events for smart capacity estimation. We examined how smart capacity estimation automate and minimizes time to manage available capacity in a zone or level by using framework and proactive. Explanation is done by use-case of masjid Al-Haram for smart capacity estimation for crowd management. We also compared the existing capacity estimation and smart capacity estimation systems. We also defined the algorithms with respect to Zone and Level. We also ran different simulation scenarios and also discussed the results. In future we will calculate the capacity according to the different position. The dynamic capacity can be calculated on the basis of time frame and capacity can be maximized and minimized according to time frame. In future algorithms can be defined how to maintain social distancing, how to calculate the capacity with social distancing and find the empty space with direction? Algorithms devised how to define the exit plan to move out without facing the congested path. Smart capacity estimation with Sensor and without sensor. Without sensor, capacity of pilgrims can be counted by putting the manual counter. If proposed proactive approach and framework for smart capacity estimation is commercially applied, it can provide help in different application developments, such as: 1. Capacity available in a zone or at a level can be calculated precisely. 2. To estimate the occupied and remaining capacity in a building or in an area. 3. Alert generation before the zone or level reached to its maximum threshold. 4. Positions and Events based capacity estimation. 5. Capacity estimation on the basis of social distancing. 6. Calculation of the social distance. 7. Drinking water estimation to supply the water in different zones and levels. 8. On the basis of wheelchairs' requests, wheelchairs supply plan according to demand in different zones and levels. 9. Estimation of the Holy Quran scripts according to different languages. 10. If water, chairs or the Holy Quran scripts are not enough in a zone or level then generate the alert to workers for supply. 11. Sharing of zone capacity data with different zone security officers to manage the crowd capacity. 12. In case of emergency, provide path for evacuation from affected zone or level to outside.

ABSTRACT

Teaching tax-related regulations have always been a challenge due to the inclusion of external variables that hinder the learning process, such as the high complexity of tax systems and legislation variability. Universities have sought different alternatives to support the teaching process both outside and inside the classroom, ranging from recreational activities to active learning. This article will show the experience resulting from using a chatbot to support learning in accounting students for the teaching of tax regulations related to the Chilean tax system, comparing two types of tools, on the one hand, a free conversation chatbot using natural language processing versus a rule-based chatbot driven by a decision tree. The experimentation process was carried out with 50 higher education students, divided into an experimental group and a control group, in two different courses. The results obtained demonstrated in both cases greater effectiveness of the use of the chatbot in learning the tax matter, both in the free conversation chatbot where the experimental group obtained a 15.7% improvement versus the control group that obtained a 1.05% improvement, as in the chatbot that applied decision tree where the experimental group obtained a 32% improvement versus the control group with 5.2%. Considering the complexity of the content in tax matters and the little innovation in the existing teaching subjects in the area and that the students improve learning using both chatbot tools compared to other learning techniques, is considered a relevant contribution to teaching innovation.

1. Introduction

This article is the continuation of a lengthy investigation developed in courses on the subject of taxation [1], which seeks to generate support for learning the Chilean tax system through the use of a chatbot with an automated conversational system technique; these technological systems aim to establish new mechanisms that have a direct impact on student learning, especially on issues such as the tax regime of a country, an area characterized by the complexity in the application of tax regulations.

Significant studies have taken place about the behavior and learning of students [2], [3], where motivation has been one of the key factors due to its direct impact on the perception and predisposition that students have towards the teaching activities delivered by teachers [4]. In this sense, the lack of motivation is one of the most critical causes when studying the failure and dropout of educational systems [5]. Socioeconomic and health factors also influence learning processes [6], [7], as well as the design problems of the different learning resources created by teachers [8], [9]. However, what research mostly agrees with is that this is a cross-cutting problem in society [3], [10], [11].

One technique that has become a common factor is the use of technology and software to support the teaching process and enhance the students learning [12], [13]. The integration of technologies in the classroom is a constant challenge that teachers and educational communities must face, but it is necessary based on the global demands on students' development of skills [14]. Based on this, there are numerous innovations, but the most outstanding and most attractive to students are those related to digital credentials, virtual assistants, and blockchain [15], [16].

This work puts into application in educational innovation, the use of a chatbot for learning theory, and application of Chilean tax regulations. The learning processes of tax regulations are always a

*Corresponding Author: Rafael Mellado-Silva, Pontificia Universidad Católica de Valparaíso, +56 32 2273340, Email: rafael.mellado@pucv.cl

great challenge for education and tax entities [17], [18]. In the case of Chile, the last ten years have seen critical structural changes in the tax system related to income tax, the reforms of which have been analyzed and studied [19], both due to the complexity that the tax system has acquired well as the particular characteristics defined for corporate taxes, which have direct effects on the economies of the countries [20]. Because of the above, different investigations have revealed the importance of teaching correctly and innovatively the subject of taxes [21]. With this, it is that innovative teaching mechanisms must be sought to produce effective learning in students.

The research objective is to compare the effectiveness in the learning of tax regulations in students of accounting careers through the use of two chatbot techniques, that is, one, through an automated conversational system and, two, based on a tree decision. This article presents the result of applying chatbots linked to the study of the tax system regulations, which cannot be exempt from applying, integrating, and using information technologies in their learning process [22].

Considering the complexity of the tax systems and the constant legislative variability produce an effect of obsolescence in the subjects, affecting the students' rejection towards these subjects and, consequently, very high rates of failure and dropout [23]. To address this problem, there were two chatbots with knowledge of tax matters. The first with a free communication with the students as applied in [1] and the second using a decision tree. The study was carried out in an N=50, dividing the students into an experimental and control group, in the accounting career in a Chilean higher education institution. The results obtained are promising, where, in the case of the free communication chatbot there is a difference of 14.65% in favor of the experimental group and in the case of the decision tree chatbot there was a difference of 26.8% in the results in favor of the experimental group.

For this article, we will consider a chatbot as a software tool that allows users to have a conversation between a human being and an artificial entity [24]. One of these technology precursors is Joseph Weizenbaum, with Eliza [25] applied to psychoanalysis with promising results [26]. As the winners of the Loebner [27] contest point out, chatbots have evolved from simple pattern matching systems to increasingly complicated patterns of computer interaction and reasoning, being applied in education [28], entertainment [29], health [30], among others. The rise of chatbots has occurred in customer service, such as Hennes & Mauritz AB, which seeks to replicate a human conversation to facilitate information collection by a customer [31]. The purpose of chatbots is to automate the process of communication and support for people [32].

At an educational level, there have been various applications to chatbots with mixed results, but most of them agree that an improvement in learning and student satisfaction is evident [33], [34], generating greater interest in the subjects test [35]. For this reason, three main factors stand out to determine their participation, the performance expectation, the effort expectation, and the habit [36], which indicates that the commitment is linked to the benefits versus the effort to which the students are subjected by supplementing your learning with a chatbot system. This is why it is critical to innovate in non-traditional areas and that the effect has a direct application in business, accounting, and auditing matters.

The research questions posed are in line with determining the effectiveness of the two tools applied and their impact on effective learning:

- Does the use of the two chatbot techniques positively contribute to learning tax regulations?
- Is learning through a chatbot more effective than through the use of gamified activities and e-learning videos?

Based on the above, we established as a research hypothesis:

Incorporating a chatbot, independent of the applied technique, for the learning process of tax regulations in higher education provides better results due to the students' academic performance.

Due to the above, a null hypothesis is also established:

The inclusion of technological tools, particularly chatbots, does not improve effective learning on tax matters compared to traditional methodologies or e-learning.

Concerning the structure of this paper, the theoretical framework that will deliver the definitions and general aspects that must be taken into account is presented below; later, other experiences applied in the matter will be seen, and then proceed with the experimental design and case study for the two techniques to be compared. This article ends with the results obtained and their corresponding discussion.

2. Related Works

Australian work by [46] shows that a significant number of accounting schools resist the adoption of new technologies in their training processes. The reasons are the lack of interest in implementing technologies with an extra workload, the little support, and the lack of resources, but the most relevant is the lack of educators' time to learn and develop skills and competencies to adopt new technologies in education systems efficiently. The work recommends considering a new model that reflects the current innovative technological nature to provide education, anywhere, anytime, and for anyone.

As far as tax learning is concerned, the work of [47] mentions how tax education faces significant challenges in the 21st century and delivers results to change current educational paradigms, prompting a more effective teaching practice based on conceptual knowledge over technical ability. In [48] it is explained how the subject of taxes is elementary to complement other subjects within accounting programs, and it seeks to find effective teaching methods using computer software, which, although it presents good results, its use is not every day. In [49] the work to support the understanding of tax systems and the effect on the systemic change that arises when different organizations are willing to learn from each other is presented. For this, real case studies are used in the companies Oxfam and Unilever. In Spain, there is the work of [50], which analyzes part of the challenges that exist for teaching tax law, considering students who are studying in a highly multidisciplinary degree; and in [51] whose economic concept is the distribution of the tax burden between buyers and sellers, it is

suggested that collaboration between teachers is more effective than the lesson study model. The work of [52] demonstrates how tax learning is necessary even in non-accounting programs, relating the interest of professionals in learning tax matters and the needs of companies.

As mentioned in [53], chatbots as learning tools are still in their infancy. The study carried out in [54] suggests that although initially arousing considerable interest in behavior, some tasks may not be interesting enough to impact subsequent interest in the broader domain of the study; for this purpose, in [55] a four-phase model of lasting interest development. In [56], it is stated that digital tools can provoke feelings of isolation and detachment caused by the lack of interaction with teachers, which is approached through the design of a hybrid-chatbot. Finally, it must be guaranteed that a chatbot's novelty does not define the end-user experience, although it is undoubtedly part of the initial interactions with these types of tools [54].

3. Solution Design

The solution was thought of in accounting students from a Chilean university, where the learning approach is related to tax regulations. In this context, it is essential to point out the Chilean tax system's difficulty due to its complexity, variability, and a very extensive law [57].

The proposed solution's objective was the implementation of two chatbots with pedagogical resources, which, using an automated conversational system and decision trees, could be applied to the context of tax regulations at the university level.

To respond to the proposed objective, two chatbots were designed, one through an automated conversational system and the other based on a decision tree, both focused on knowledge of tax regulations under the Chilean legal context. Also, the different tests and activities were designed to demonstrate the interaction and verify the effectiveness of the tools in the learning process.

The chatbot architecture is fundamental to explain its operation, and, as is well known, there are several architectures [37], [38]. In general, there is a standard operation that can be divided into three stages, as seen in Figure 1, where the user interacts with the voice manager through a device, where the analysis and generation of the query are carried out under the work context, considering that the bot must generate a response without considering the sense of intention. Finally, the generation of messages includes the planning of words, sentences, and coherence to deliver. With these aspects defined, we can establish that the user writes a question in his application, which must be answered by the chatbot and with greater complexity and volume of knowledge, then a more significant number of interactions between a bot and user [40], [41].

Decision trees are highly complex data structures sharing binary trees [42], [43]. This type of tree is characterized by storing its different nodes in a hierarchical and orderly manner under a defined criterion based on the problem addressed. Compared to linked lists, queues, or stacks, in this case, the data is not stored linearly [44].

In this case, the constraints to be applied to the decision tree have characteristics of an N-ary tree with single essential control used in binary search trees. The walkthroughs and handling of the decision tree structure are handed over to the natural language processing engine. The algorithm used by the classification and interpretation engine conforms to a conditional inference tree; consider that the Recast.ai engine handles the classification of intentions automatically, so no changes were made to it in this research.

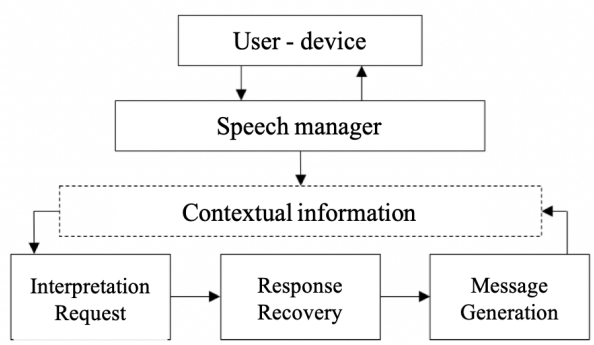

Figure 1: General chatbot architecture [39]

In this case, we start with a single node and then branch out into possible results based on the intent analysis of the natural language processing engine [45]. The decision node will represent the intention in which the user's interaction will be classified, giving rise to the existence of a terminal node that will show the result of the intention. The first node will correspond to the concept of tax and the last to specific answers.

4. Method

4.1. Pedagogical context

The learning context of this research's tax regulations focuses on the career of auditor accountant (public accountant) of a Chilean university. Thus, teaching and learning the rules that regulate tax regulations is a constant challenge, especially to achieve effective learning. The different indicators of the courses approval do not generate significant delays in the students' curricular progress. The professional profile for graduating the auditor accountant career (public accountant) considers the development of specific competencies that are directly related to the work performed:

- Generic fundamental training competencies: proactivity and responsibility; carries out its work with professional ethics.
- Specific disciplinary competencies: understand the conceptual framework of the current internal fiscal tax legislation.
- Specific professional competencies: apply the conceptual framework of the current internal fiscal tax legislation; apply the general, and special regulations of the tax legislation of the taxes levied on business income.

4.2. Learning Objectives

The Taxation courses of the auditor accountant career (public accountant) have a content structure that contributes to the learning results; in this way, the contents associated with this experiment are: (1) Understanding of the examination regulations, their practical application in the taxpayer's life cycle; (2) Understanding of the corporate tax structure.

For the technique through an automated conversational system, the learning outcomes associated with the experiment and the course are [1]:

- OL1: Recognizes basic concepts related to corporation tax to apply them to the company.
- OL2: Identify basic concepts of the different corporate taxes to compose tax returns.
- OL3: Applies basic concepts of the tax object to calculate taxes.

For the decision tree-based technique, the learning outcomes associated with the experiment and the course are:

- OL4: Defines the types of tax examination to identify the procedure applied in each of them.
- OL5: It includes the indirect control rules for their correct application in the taxpayers' life cycle.
- OL6: It includes direct inspection rules to identify the rights that assist taxpayers.

4.3. Methodology

For methodological purposes, we worked with the Taxation 1 and Taxation 3 courses of the auditor-accountant career, where the main subject of these courses is the regulations on audit and corporate taxes, respectively. The experimentation process for both chatbots is considered the same methodological steps are shown in the BPMN diagram in Figure 2.

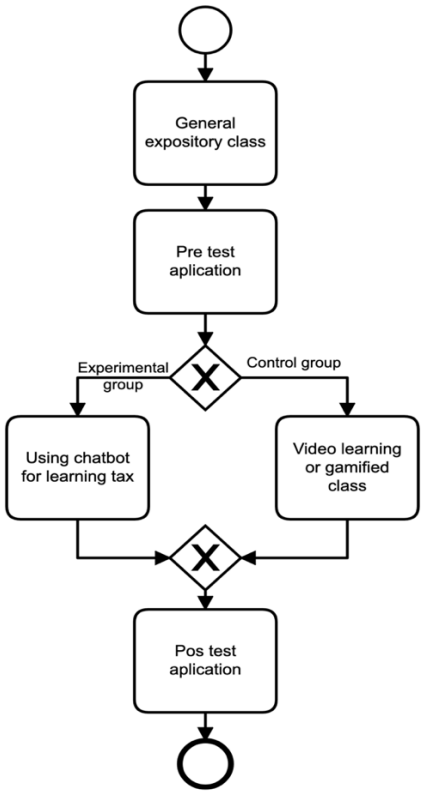

Figure 2: Stages of the methodology

First, a class of theoretical contents is held in both courses with all students without differentiating or separating individuals. This class is face-to-face and in a classroom with a projection. After that, a pre-test is applied to all students based on the contents taught in the face-to-face class of the Tax 1 and Tax 3 courses. Both courses are then divided into two groups, which we will call the experimental group and the control group. In the case of the Taxation 1 course, the use of videos through the *Moodle* platform was applied to the control group, and in the case of the experimental group, the use of the chatbot based on the decision tree technique was applied. In the case of the Taxation 3 course, the control group was given playful activities in the classroom led by a teacher, and in the case of the experimental group, the use of the chatbot with the technique was applied through an automated conversational system. A post-test is applied to both courses to measure the difference generated in the learning process. In this way, the results obtained in the tests by each of the groups of both courses will be compared, and the effectiveness of using the chatbot with the two techniques will be shown. Finally, it should be noted that, in the Taxation course, 1 of the of 16 students, eight remained in the experimental group and 8 in the control group. In the case of the Taxation course, 3 of 34 students, 18 remained in the experimental group, and 16 in the control group.

As mentioned above, two tests were applied to each course, one that was developed before dividing the group and another afterward to measure effective learning. An example of interaction in the evaluations is presented in Figure 3, using Google Forms.

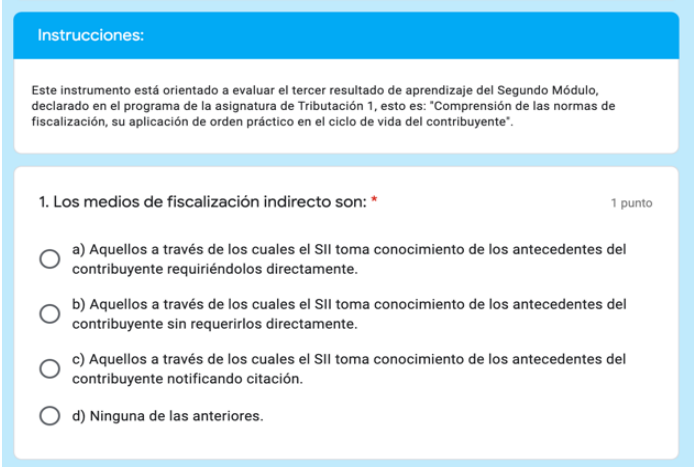

Figure 3: Example evaluation rendered by the student

4.4. Mechanics

In the Tax 1 course, the students belonging to the control group saw explanatory videos with the contents. For the experimental group, a guide to questions to be solved was delivered with the bot's support. The chatbot used was called Tribuchat, and it was linked to a Telegram chat, with which the students who made use of their mobile devices interacted under the guidance of the chatbot. Figure 4 shows an example of interaction with the bot.

In the case of the Tax 3 course, the students belonging to the control group did playful activities that included the themes addressed in the planning. The teacher-guided these activities. For the experimental group, a guide to questions to be solved was delivered with the bot's support. The chatbot was called Tribubot, and it was linked to a Facebook Messenger chat, with which the students, using their mobile devices, freely interacted with the chatbot. Figure 5 shows an example of interaction with the bot.

It is important to note that feeding both bots was carried out, in which the teachers in charge of the subjects generated the expert knowledge base on the subject and thinking about the interaction with the students, which was loaded into the tool SAP Recast.ai. Finally, interaction actions were included to measure a formative nature's learning through questions asked by the same bot to the students.

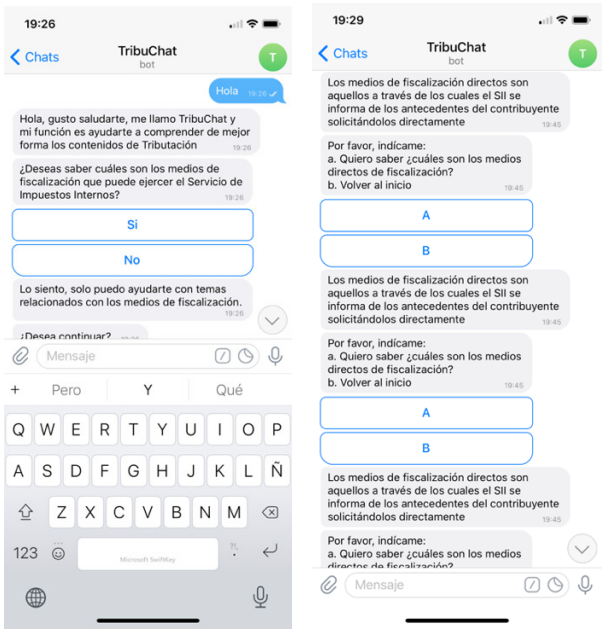

Figure 4: Chatbot group 1 interaction example

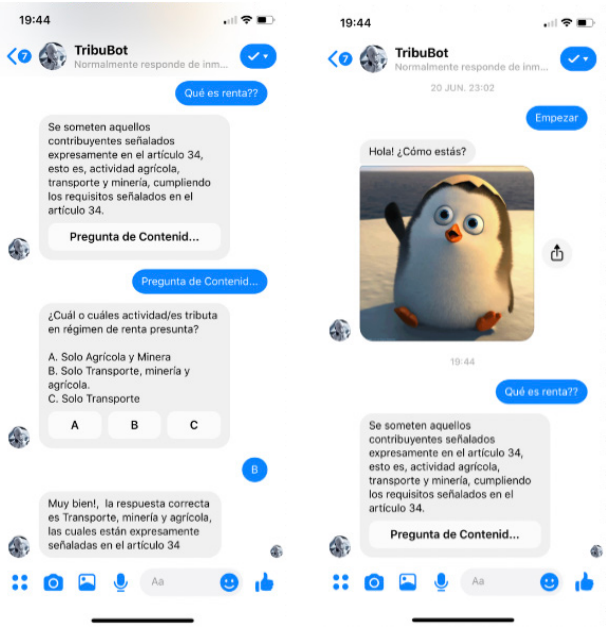

Figure 5: Chatbot group 2 interaction example

5. Results

The display of results obtained will be classified in the general results, later categorizing by gender, and finally according to performance. Table 1 shows the results obtained in the tests applied to the Taxation 1 and 3 courses, and the averages of correct, incorrect, omitted answers, and the percentage of correct answers that were.

Table 1: General Results

Course	Group	Clasification	Pretest	Postest
Tax 1 course	Control	Correct	7	7,125
		Wrong	5	4,875
		% correct	58,33%	59,38%
	Experimental	Correct	6,125	8
		Wrong	5,875	4
		% correct	51,0%	66,7%
Tax 3 course	Control	Correct	6,88	7,5
		Wrong	4,01	4
		% correct	57,3%	62,5%
	Experimental	Correct	6,56	10,39
		Wrong	4	1,87
		% correct	54,6%	86,6%

In Table 2, we can see the characterization and results in the test of the groups of Taxation 1 and 3 courses based on composition according to gender.

Table 2: Characterization by gender

Course	Tax 1 course		Tax 1 course	
Group	Control	Exp.	Control	Exp.
N	8	8	16	18
Male	25%	37,5%	43,75%	50%
% Improvement	0%	27,8%	5,7%	60,32%
Female	75%	62,5%	56,25%	50%
% Improvement	2,3%	32,3%	13,4%	58,21%

Table 3 shows groups' behavior according to the average of the Tax 1 and 3 course; for this, those below the average, equal and above, are grouped in their categories of the experimental and control groups.

Table 3: Behavior of groups according to the average

	Test	Group	Ref. $\bar{x}$	%<$\bar{x}$	%=$\bar{x}$	%>$\bar{x}$
Tax 1	Pretest	Control	7	12,5%	75%	12,5%
		Exp.	6,125	25%	62,5%	12,5%
	Postest	Control	7	25%	37,5%	37,5%
		Exp.	6,125	0%	25%	75%
Tax 3	Pretest	Control	6,88	6,25%	68,75%	125%
		Exp.	6,56	5,56%	77,78%	16,66%
	Postest	Control	6,88	0%	81,25%	18,75%
		Exp.	6,56	0%	0%	100%

In addition, to statistically validate the results, some tests were applied. Because the new experiment points directly to tax course 1, then as the results were analyzed, we begin with Table 4, where the samples' normality is appreciated through a Shapiro-Wilks Test. As can be seen, for the sample of the experimental group in the post-test, normality was rejected with a high level of significance, so that we will use non-parametric tests for the comparison of means.

Table 4: Results of Shapiro-Wilks test.

Group	Test	P-value
Control	Pretest	0,6877
	Postest	0,2993
Experimental	Pretest	0,1842
	Postest	**0,02066**

Table 5 shows the result of applying the Wilcoxon test for paired data. In this case, the difference in means for the control group between each test is not statistically significant; on the contrary, in the experimental group, it is observed that the mean of the post-test is higher with a high level of statistical significance (0.0001526 < <0.05).

Table 5: Wilcoxon test for paired data

Samples/Group		P-value
Control Pretest	Control Postest	0,08052
Experimental Pretest	Experimental Postest	**0,0001526**

In this first investigation, the data concludes that the research hypothesis is accepted, giving a difference between groups of p=9,722e-06. Specifically, the experimental group results were statistically much higher than those shown by the control group; therefore, the chatbot was more effective than the other method used.

Regarding the comparison of the two tools, only the sample data of each experimental group were taken. The research hypothesis is addressed: "The students' performance is different given the applied chatbot". To do this, first, a difference in proportion test was applied, where this test analyzes whether the percentage or proportion of a sample is statistically significance concerning another. Table 6 represents the data of the experimental group students who obtained a performance higher than the global average (control + experimental) in each post-test and the total sample of students of the experimental group.

Table 6: Proportion difference test by course

Students	Tax 1 course	Tax 3 course
Above average	7	15
Totals	8	18

Furthermore, with a p-value = 1, it can be concluded that this proportion is the same in both groups, and we cannot find a significance difference.

Finally, the result changes since the hypothesis focus only on a one-sided inequality and the test; therefore, a significance mean difference can be accepted and affirmed that the first chatbot students had a better performance (p = 0.04418). Also, it is noticeable that course 1 was much higher than those of course 2, but there was also a larger sample in that case (a little more than twice as many students), so that although the inequality between chatbots could be maintained. With the above, we have ruled out the null hypothesis.

6. Discussions

Due to what is stated in Table 1, it is evident that the control group of the Tax 1 course presents an advantage of 12.56% over the experimental group in the pretest, which was reversed in the posttest, leaving a 10.97% in favor of the experimental group; which leads us to deduce in the first instance that if the performance of the students in the experimental group is compared with the control group, the chatbot tool produced an evident improvement in learning to the detriment of the control group that took explanatory videos. This justifies the first research question about contributing positively to learning the contents related to the Chilean tax system, which is characterized mainly by the complexity of its normative structure.

The above also allows supporting the second research question on the effectiveness in the use of the chatbot. Indeed, the differences between incorrect answers and errors made are evident, where the control group presents discrete performance compared to the experimental group.

In the case of Table 1 related to the Tax 3 course, it is evidenced that the control group also presented an advantage of 4.94% over the experimental group in the pretest, reversing the situation in the posttest by 27, 82% in favor of the experimental group. The evidence is also significance when comparing the wrong questions that did not decrease.

If the behavior by gender in Table 2 is studied, it is essential to note that in the Tax 1 course, the men belonging to the control group did not show improvement (0%) versus the men in the experimental group (27.8%). In women's case, the improvement in those belonging to the control group is only 2.3% versus 32.3% in the experimental group. In the case of the Tax 3 course, the result in Table 2 is not so different compared to the Tax 1 course. Indeed, it can be found that men who make use of the chatbot show more than a 60% improvement in its results; on the other hand, those who do not use the chatbot improve by 5.7%; in the case of women, the difference is also greater, because those women who use bot the percentage of improvement is greater than 58% but those who do not use it improve 13.4%.

If the behavior is analyzed according to the means in the Tax 1 course, as shown in Table 3, the control group goes from having 75% in the average to 37.5%, leaving 37.5% above the average versus the initial 12.5%. In the case of the experimental group of 62.5% who were in the mean, only 25% remained, and those who were above the mean grew from 12.5% to 75% of the group, which together with finally remaining 0 % below the mean, then the effect of the tool applied in the experimental group is greater than that of the control group since many students being below the mean or within it rose to be at or above it. The above is a critical case to highlight and take into account for later statistical analysis. Finally, as shown in Table 3 about the Taxation 3 course, initially, 5.56% of the students who use chatbot were below the average; after using the chatbot, that number decreases to 0%, which shows a positive impact of the tool. It is not minor to identify that the control group also improves the results after applying the gamified activities.

7. Conclusions

It is already known that the teaching of tax matters is a constant challenge that expert teachers in the matter must face daily, especially considering the complexity of the contents and the repeated modifications of the legislation in the last ten years.

Throughout this paper, we have been able to see different experiences that try to improve effective learning, comparing two chatbot techniques, that is, through an automated conversational

system and another based on a decision tree, showing that independent of the technique of the chatbot used has better results than guided learning through videos or gamification techniques. The results showed that, in all cases, students who use a chatbot, regardless of the technique used, perform better than other tools, justifying their effectiveness according to what was raised in the research questions. The results show that the performance of the students of the experimental group produced an evident improvement in the learning of the contents related to the Chilean tax system, which is characterized by its complexity, derived mainly from the withdrawn legislative reforms in the last ten years.

As future work, the perspective should be taken to analyze and quantify the impact of the use of this type of tool and the cognitive load that it generates in students. Besides, it would be essential to study the change suffered by the levels of frustration of students compared to the different techniques that exist in novel and impact studies, directly related to emotionality and the application of algorithms. In this sense, an artificial emotion can be implemented as a synthetic abstraction derived from the observation of human emotions, which allows improving the effectiveness of the decision made [58]. It is also relevant to test other techniques and tools such as ROL-type games [59], gamification techniques [60], or the application of multilingual verbal communication with a focus on human-robot interaction.

Finally, it should be noted that through this research, it is shown that a chatbot improves the results in learning subjects related to tax regulations and, therefore, it is necessary to continue with studies that cover other aspects of effective teaching and learning.

ABSTRACT

This paper describes methods of eliminating Unmanned Aerial Vehicles (UAV) non-destructively, using Electronic Warfare Methods. The aim is to introduce certain methods of UAV detection and elimination in a complex environment and terrain, e.g., in an urban and battlefield environment, that will result in finding the control device position and the UAV itself. Neural networks, cyber penetration elements, and wireless network scanning programs are all used to address this issue. The output of this article is a new concept of a comprehensive solution, which can be implemented into the existing complex system of electronic defence against UAVs, e.g., within the allied base. Conclusions will be also used to further improve the above-mentioned topics at the authors' workplace, within the frame of long-term projects and specifically as a part of solutions applicable to the force protection of combat support units, namely field artillery, which is described here in detail.

1. Introduction

This paper is an extension of the work originally presented in proceedings of the "2019 International Conference on Military Technologies" (ICMT), Brno, Czech Republic [1]. The original material was enriched by the proposed concept applied in the urban area. The whole section proposing a possible concept applicable to artillery units was added.

A very dynamic development of Unmanned Aerial Systems (UASs) is becoming highly visible as they are used in all areas of human activities [2].

With the gradual widening of the UASs complexity and complementing other features, there is a demand for more complex security. The reason is that both military forces and terrorists have increasingly used Unmanned Aircraft Systems to plan, prepare, and execute attacks on ally and partner's forces and on "soft targets" in the civilian sector. Preventing, protecting, and recovering from such attacks require a cross-governmental approach, bridging the different efforts that Allies, partners, NATO, other international organizations, industry, and academia are making on this topic, both in the military and in the civilian domain. The threat description, probable scenarios, and protection models concepts are well described now by several trustworthy documents, e.g., in [3].

In another word, simultaneously with UASs development, we have been witnessing the counter-UAS (C-UAS) systems rapid improvement as well. Moreover, the C-UAS systems development concerns not only the direct defence against flying apparatuses themselves, but this also applies to the whole loop of the air defence system: detection, command-control system and elimination itself. The whole engagement process is now a highly complex, sophisticated, and, from a scientific point of view, multidisciplinary one.

Thus, after transforming from simple radio-controlled machines into sophisticated, "smart", digitally-controlled UAVs, an opportunity was developed to combat the whole UAS not only with standard methods, but – apart from another ones - also with cybernetic methods. Contemporary modern UAV can be seen as a small computer or a mobile phone with the ability to fly. This connects the current IT security issues and air defence issues together with the UAVs.

During the next development, it will be necessary to take into account the possibility of anti-aircraft defence congestion caused by the high availability of micro UAVs at a very low affordable price. Therefore, the developed means should be able to operate a large number of UAVs at the same time and at a minimum cost.

2. Methods of Cyberattack Applied to UAVs

In today's digital age, the growth of cyberattacks can be seen not only on personal computers, servers, and mobile phones, but also with the introduction of "internet of things", on any device that is able to connect and communicate over the network. This opens the possibility of cyberattacks on most types of UAVs too. Cybernetic methods of attack, like conventional methods, can be divided into two basic groups according to the expected effect. These methods are non-destructive and destructive.

2.1. Non-destructive Methods of Cyberattack

Non-destructive cybernetic methods of combat are understood as methods in which there is no direct destruction of any particular component of the affected system. This group includes the most contemporary cyberattacks. We can further divide these attacks into several subareas (in detail: [4]). Graphical representation of non-destructive cyberattack methods on UASs is depicted in Fig. 1.

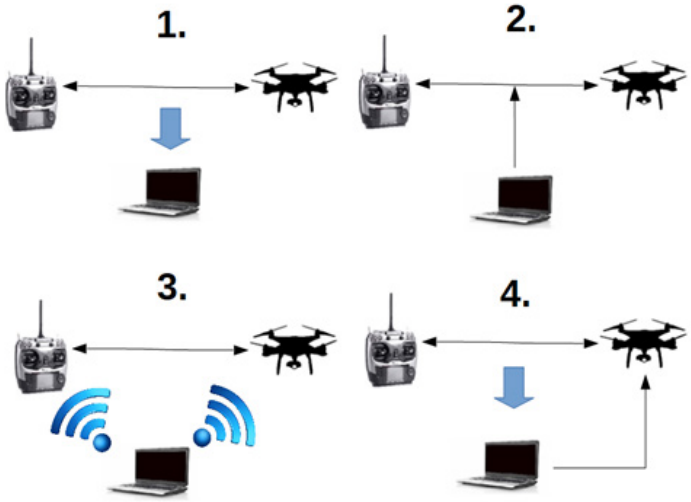

Figure 1: Graphical representation of non-destructive cyberattack methods applied to UAV´s

1) Leakage of Information

This type of attack results in disclosure or leakage of protected information. The advantage is its detection difficulty and in most cases the speed of attack. In UAVs, this attack is about getting the downlink channel information providing the UAV's mission or about getting the data to find the password for Wi-Fi communication.

2) Disturbance of Integrity

This subgroup includes attacks where the UAV's data are destroyed, damaged, or changed. This type of attack is very well detectable, but in most cases until after its accomplishment.

3) Denial of Service

Denial of Service (DOS) attacks make it impossible to use a particular service or system of UAS. The C-UAS defender will focus on a particular access channel or a specific service and will disable real-time activity by systematically sending requests (see DoS attack below). This attack is very visible and is usually suppressed quite quickly.

4) Unlawful Use of Information

These attacks focus on using the obtained information to access non-public parts of the system or to use certain services without authorization. In UAVs, for example, the acquired password can be used to decrypt the intercepted communication or to take over its control.

2.2. Destructive Methods of Cyberattack

The destructive C-UAS cybernetic methods of combat have a direct impact on the part of the attacked system that is physically irreversibly damaged as a result of this activity. These methods mainly use the vulnerability in the lower layers of the OSI (Open Systems Inter-connection) model and focus primarily on individual hardware components that are used in multiple systems. The operation of these methods is primarily based on a mechanical damage. For example: the cybernetic attack induces a collision of mechanically moving components or the cybernetic attack forces a battery or some other component to overheat and thus damage themselves.

3. Signal Detection of the UAV

When combatting mini and micro UAVs, one of the biggest problems is the detection and identification of the UAS itself, especially in an urban densely built area. Using radar or other detection methods with optical equipment (in the visible or IR optical band) is often considerably complicated by many fixed obstacles [5]. Methods using specific acoustic characteristics of the UAVs are also limited due to the interfering ambient noise [6].

The best choice in such environments is, therefore, the detection and localization of signals transmitted by the UAV itself or its control station.

These signals can be relatively well detected and identified due to their known specific transmission frequencies and known encoding.

However, this detection becomes considerably harder if the UAV is managed only by Wi-Fi in an electronically complex environment. Contemporary modern cities are full of devices that use the same Wi-Fi standards, and that hides the UAV' control signal among the other Wi-Fi networks within its range [7].

3.1. Localization Position of the remote control station or UAV

An UAV recognition method can be used, utilizing the MAC address to locate the position of the control station or the Wi-Fi standard to locate the position of the connected UAV itself. Each producer has a certain range of initial MAC address characters, which makes it uniquely identifiable. However, a problem occurs when the Wi-Fi module is modified or if the UAV MAC address is changed by software. Both of these methods are realizable by at least an average capable IT man.

3.2. Analysis of Data Flow Using Neural Network

One of the progressively evolving technologies is the technology of neural networks (NN). The main domain of these networks is their relatively rapid analysis of a large volume of data and the data subsequent evaluation. Neural networks, unlike algorithmic solutions, do not use serial computations. The task is solved simultaneously with several layers of neurons that interact

with each other. Neural network inputs can also be parameters of the UAS Wi-Fi traffic, such as the number of frames, their size, and generally the data flow over time.

Thanks to NN advantages, especially in the field of data processing, i.e., their ability to take in a lot of inputs, process them to infer hidden as well as complex, nonlinear relationships, NNs are playing a big role in signal characteristic recognition. Based on these features, the NN should be able to recognize which device it is both the UAV itself and the control station as well. Thus, the next part is devoted the NN application to the UAS detection and identification.

4. The UAS Signal Detection Using Neural Network

Neural networks can be used in the process of data mining. This is currently an increasingly inflected term. In general, it can be understood as a process aimed at discovering dependencies or finding the required information in a large volume of usually experimentally obtained data. The output is a certain knowledge that can be used in solving a decision problem, predicting values for other new data, or simply understanding a certain phenomenon or context. [8]

In principle, three methods can be used to identify UASs using 802.11 standards. UAS can be identified by the SSID, which is the name of the access point. However, this can be changed very easily. Furthermore, we can use the identification according to the MAC (Media Access Control) address, because in the MAC address the first six characters identify the manufacturer. This method is already suitable for use, but the MAC address can also be changed. The third method is based on the analysis of the data flow and the creation of the so-called fingerprint. For this purpose, a neural network can be successfully used, which has the task of analysing the data flow to decide whether it is intercepted traffic originating from UAS communication or not.

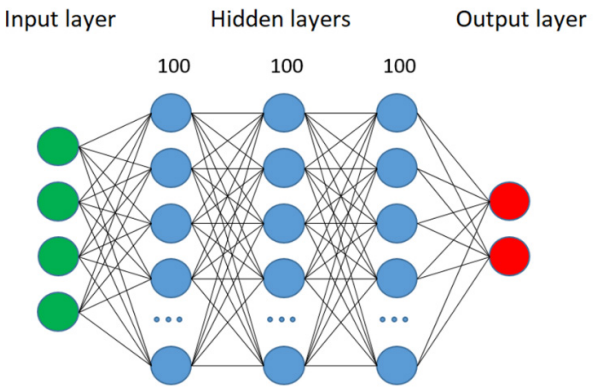

Figure 2: Topology of the created neural network

Input data is a key element in training neural networks. The ability of the network to learn and evaluate, or rather to evaluate with sufficient accuracy, depends on the appropriate selection of individual parameters and the input data set.

The selection of input parameters was made on the basis of knowledge obtained by analysis of data flows originating from the tested UAS and several other applications (e.g. Skype, YouTube). Analysis of data streams revealed that one of the determining parameters is the number of unique frame sizes in a given sample. This is due to the nature of the transmitted stream, where certain activities or communications create a larger number of unique frame sizes than others. The second determining parameter is the number of frames transmitted per second. This is mainly related to the overall data flow, but it also in some way represents the disposition of the intercepted communication. The average frame size was chosen as the third parameter. It expresses whether the captured traffic contains rather smaller or larger frames. The size of the frames is affected by the disposition of the transmitted data. The last parameter was the ratio of the number of frames with a size greater than 100 B and less than 100 B. This value was chosen mainly based on the analysis of all data streams, where different operations have this ratio different. The topology of created neural network is depicted in the Fig. 2.

Based on these parameters, the neural network can distinguish whether it is UAS operation even when masking the SSID or changing the MAC address of the transmitted frames.

5. Possibilities for UAS Elimination Using EW Methods

5.1. Possibilities of Penetration into the UAV Communication Channel

In general, the resilience of security depends on several factors, of which the quality of the encryption used and the length of the password usually have the greatest influence. Specifically, WPA2 security uses the CCMP (Counter Cipher Mode Protocol) algorithm based on the Advanced Encryption Standard (AES) encryption algorithm. The length of the password that can be used with WPA2 is between 8-63 characters. Security resilience depends not only on the length of the password, but also on the character set used. It is also advisable to choose passwords that are not contained in dictionaries, or that do not contain word forms or diminutives [7].

Brute force Attack and Dictionary Attack by Cloud Computing

Brute force Attack and Dictionary Attack can be amplified by using Cloud Computing. In the case of a brute force attack, it is necessary to test all possible combinations in the set given by the specified parameters. Any known information about password parameters significantly speeds up the successful use of this attack. Brute force Attack will certainly find a password in the future, but it is better to use a dictionary attack first. Dictionary attack is based on creating as big as possible a dictionary of known words, which increases the chance of an earlier password being discovered. Commonly used high-performance computer sets can test even with a GPU (Graphic Processor Unit) of only 400 KHps (Kilo Hash per second) when used for WPA2 encryption. The way to amplify computing power is called Cloud Computing. With these services, it is possible under certain circumstances to break relatively long passwords in short or real time. These services can be rented from technology companies such as Google or Amazon, from 10 minutes for the duration of the rental [9].

Rainbow Table

In some cases, the "Hashing Function" format is used for encrypted communication. This function recalculates the password entered by the user and the output is "Hash", which is a transformation of a string to a given number of characters. These

hashes are precalculated within the "Rainbow Table" to make it easier to crack the password [10].

DoS Attack

Denial of Service attack is an attack which transmits recurring deauthentication frames that result in disconnection of communicating devices on 802.11 [11].

KRACK Method

The Key Reinstallation Attack (KRACK) method is one of the relatively newly discovered methods focusing on a certain vulnerability of the Wi-Fi standard. It uses a four-way authentication process, in which communication is established between the AP (Access point) and the client. Simply put, it works on the principle of delaying the response to the third message during the four-way authentication sent to the access point. As a result, the AP sends a new 3rd message with an increased "counter number". When it receives the 3rd message for the first time, the client installs the GTK (Group Transient key) and PTK (Pairwise Transient Key) keys and sends the 4th message, which is then held. Upon receiving a retransmitted 3rd message with an increased counter number, the client reinstalls the previously installed GTK and PTK keys and resends the 4th message. Subsequently, both 4th messages are left to pass to the AP. Knowledge of changing the original and later reinstalled GTK and PTK keys can then be used to decrypt the communication [12].

5.2. Options after Successful Penetration into the UAV System

From the attacker's point of view, there are several ways to penetrate the system, differing in danger and enabling different goals to be met [1].

Secret Observation

The most inconspicuous way to start a penetration is a simple observation of the video stream or telemetry data, which are received by the UAS control station. This makes it possible to identify the equipment of the UAS with specific sensor (measuring) devices or to identify the operator' area of interest.

Sending Unobtrusive Commands

The operator' control can be affected by sending confusing or conflicting commands. Such an effect on the UAS may lead to the termination of the UAS task, as the operator will think it is a technical fault.

Complete take over the UAS

For the complete takeover of the UAS, it is necessary to disconnect the original RC and prevent it from being reconnected. To do this, you need to know the password and the ability to change it in real time as well. Successful takeover largely depends on the manufacturer of the individual components or the UAS model itself.

6. The Proposed Concept of the EW C-UAS System

6.1. Basic principles and functioning of the proposed concept

The basic principles of system operation are clearly shown in the Figure 3. The whole system is divided into one main and two support sections, each of which brings a different ability, or added value. The proposed concept [6] may represent the addition of another element of complex defence against micro and mini UAS.

The concept includes devices to detect signals and record Wi-Fi data in passive mode and send deauthentication frames in active mode. Within one computer and control centre, information are collected from one or more devices.

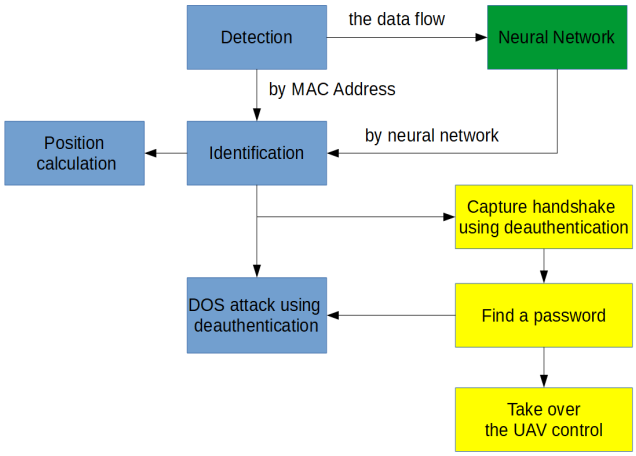

Figure 3: The proposed neural network

Detection, Identification, Position calculation and DoS Attack Using Deauthentication

The main section (shown in blue) provides the basic capabilities of the system and is the only one that can act automatically in a limited way. It contains 4 blocks providing initial signal detection (capture), device identification according to MAC address, position calculation based on information from one or more sensors and, if necessary, the DOS attack itself. Upon successful capture and identification of an unwanted UAS, we are able to send a deautentication frame to the nearest sensor to disconnect communication between the RC and the UAS or between the RC and the display device. After sending only one or a few deauthentication frames, the connection is established automatically, but if the deauthentication frames are still sent, the connection will not be established. [9]

Neural Network

The first support section (shown in green) evaluates the intercepted data stream using a neural network (explained in more detail in Section 4) and, based on the results, identifies the type of device or the type of traffic in the intercepted communication. This information is passed on to the main section for subsequent specification [6].

Possibilities to Find Password

The second support section (shown in yellow) aims to bring the ability to take control of the UAV. The process usually begins by sending a deauthentication frame and then capturing a 4-way handshake. This provides a signal pattern to perform the password retrieval process. After successfully finding the password, it is possible to take over the control, either completely or partially, or penetrate into the communication system. [6]

6.2. The proposed concept applied in the urban area

For practical use in urban areas, e.g., the device *Alfa AWUS036ACM* (see Fig. 4) can be used as a sensor and

transmitter, providing sufficient omnidirectional range, supporting 802.11 a / b / g / n / and ac standards, and operating in the 2.4 GHz and 5 GHz frequency bands, respectively. Another indisputable advantage of this device is its low price in combination with normal commercial availability [6].

Figure 4: Device *Alfa AWUS036AC*

Figure 5 shows an object with a marked critical defence point (red circle), access roads (3, 5), high-rise areas (1,2,4), and a low building (6), which poses the greatest risk due to the possibility of direct visibility to defended point

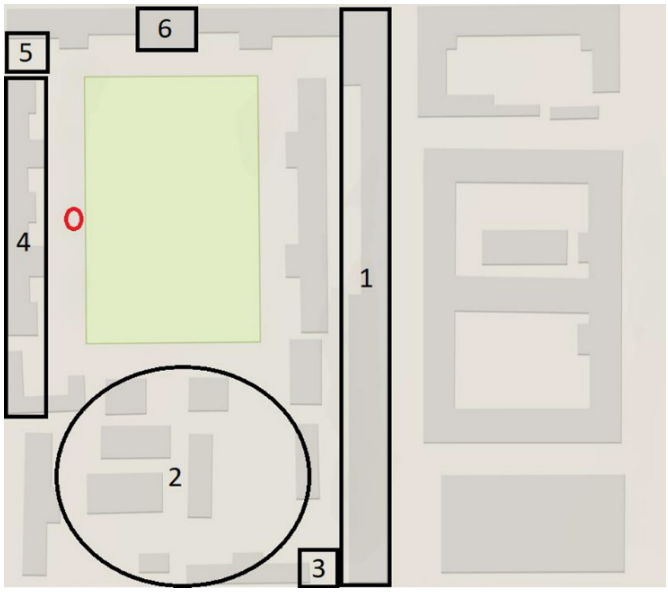

Figure 5: Defended critical point

It is advisable to place the sensors so that they cover most of the area and selected places outside the area from which the UAS control could be performed. The Alfa AWUS036AC device, which is connected to a certain small computer, e.g. *Raspberry Pi*, is taken as a sensor. All sensors would then be connected to a central point where evaluation and control would take place.

Despite of this that the quantity of sensors seems to be a little considerable, by using low-price hardware mentioned above, we are able to cover the protected area completely. Connection to the EW C-UAS system proposed in subsection 6.1 can sustain full control of this defended critical area.

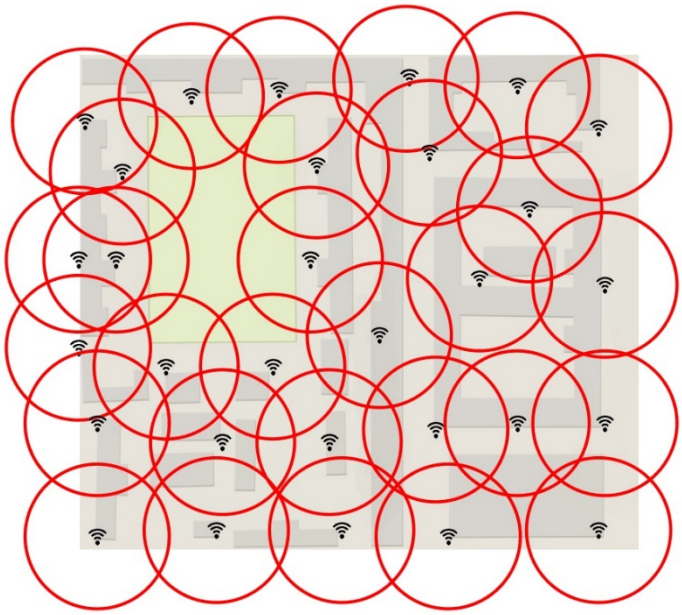

Figure 6: Defended critical point

6.3. Partial conclusion of Section 6

The previous parts described the general principles and division of cyber-attacks and the operation of the 802.11 standard of interest. To detect UAS using this standard was developed by applying the neural network and the concept in which it is embedded. However, instead of a neural network, it would be possible to use other methods of genetic programming, but the use of a neural network is suitable for this task.

Within this theoretical concept, the use of an existing HW and its deployment on the example of a defended object in a non-war area was also proposed. The use of the system in the military field is dealt with in the following section.

7. The proposed concept applied to artillery units

Based on knowledge from current conflicts, especially from the war in Ukraine and Syria, it is clear that UAVs - small, light, and cheap unmanned aerial vehicles pose a great risk to all combat units. The availability of these tools, which are available for small amounts of money, together with their capabilities makes them an ideal means of conducting aerial reconnaissance.

Findings from the conflicts in Ukraine and the Middle East clearly show that these instruments, when applied to fire support units, specifically artillery, can be used very effectively, especially for:

- reconnaissance (uncovering the battle group),
- target acquisition,
- artillery fire control,
- evaluation of the effectiveness of fires,
- perform attacks using explosives,
- perform attacks, using weapons s of mass destruction (chemical, biological, and possibly also radioactive "dirty" bombs).

In recent years, we can find countless combat situations, where small UAVs have successfully performed the tasks mentioned above. To illustrate this, several examples of the use of small UAVs are given in the table No 1.

Table 1: Examples of small UAV attacks

Year	Example
2005	Al-Qaida used Chinese made remote control model airplanes to recon Pakistan security forces prior attacks. It was also weaponized with IED.[13]
2014	Islamic state used small quadcopters for recon missions of Syrian military bases prior to ground attacks. [13]
2015	Drone attacks on military bases in Ukraine. Each drone was equipped with one grenade (ZMG-1 type). [14]
2015	Several attacks on ammunition depots at Svatovo, Ukraine. Drones were equipped with grenades. [14]
2016	Two French Special Forces soldiers were injured and an exploding ISIS drone killed two Kurdish fighters. [14]
2019	Drone attacks struck two key oil installations inside Saudi Arabia [15].
2020	Pro-Kremlin mercenaries use an unmanned aerial vehicle to drop a rocket-propelled grenade on Ukrainian emplacements. [16]

These examples clearly show the possibilities of using small UAVs and their ability to cause significant losses. The use of small commercial UAVs in combat operations can provide the enemy with key information about the positions of our own troops and their manoeuvres. In combination with explosives or weapons of mass destruction, it is possible to cause significant losses in technique and manpower. For this reason, it is necessary to be prepared for this variant and be able to defend effectively against these types of attacks.

7.1. Artillery units in the regular operations and proposed concept of application

In a peer-to-peer war, all kinds of military forces and resources are involved in combat operations. For simplicity, examples of the application of the proposed concept of protection against small UAVs are reduced only to artillery units. However, a similar approach can be used for all types of units and their specializations wherever there is a real possibility of attack by these UAVs.

The artillery battalion (battery) is conducting its operations within a given position area of artillery (PAA) within the zone of attack (defence) of the brigade (task force). Part of this PAA are also battalion (battery) Fire Direction Centres (FDC). Fig. 7 gives an example of PAA [17].

The danger emerging from the use of small UAVs is, in particular, the possibility of uncovering a combat formation and subsequent directing fire on firing units and command posts, and attacks using explosives placed on the UAV or attacks using weapons of mass destruction. Artillery units are usually deployed in a hidden position, outside the firing positions, when they do not conduct fires. Weapon systems occupy firing positions only when they are firing. Firing positions and firing points are usually in the open space. At this point, they are vulnerable and easy targets.

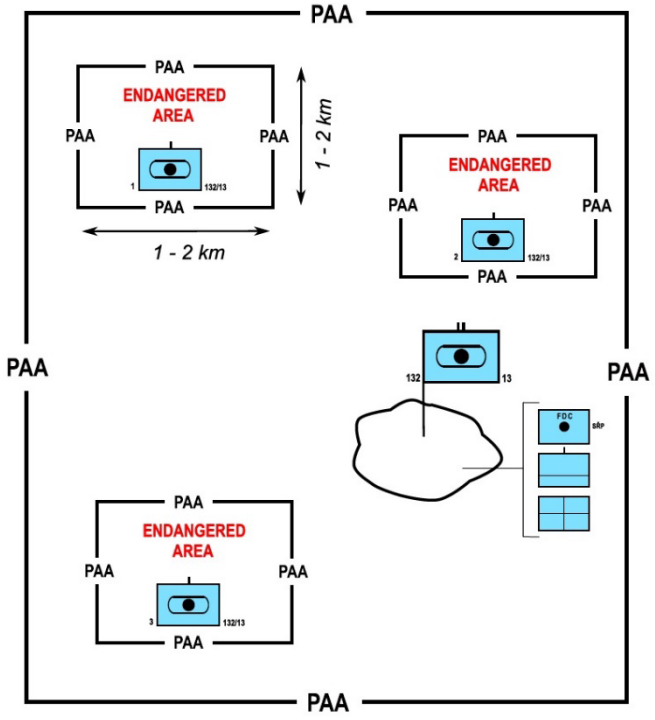

Figure 7: The position area of artillery [18]

One of the main risks the artillery is facing is the counterbattery fires. Artillery units are always priority targets and it is necessary to avoid the risk of detection, which precedes the implementation of counterbattery fire. The tactic of using small UAVs by enemy reconnaissance and diversion groups has always been a danger. In connection with the development of capabilities and possibilities of using not only military, but also small commercial UAVs, new risks are emerging and their frequency may be higher due to their massive spread and availability.

With a standard time of one fire mission and time to leave the firing position, the probability of successful counterbattery fire is low. In the case of proactive counterbattery activity, where artillery units are actively searched for and neutralized without unmasking themselves by firing, the probability of success is much greater than in the case of reactive counterbattery fire when it is reacted to firing artillery. The enemy gains an advantage by knowing the coordinates of the firing positions and starts the fire mission when the cannons are taking up firing points to conduct fire. It is this key information that can be easily obtained using small UAVs. They are able to uncover a combat formation, detect individual artillery weapon sets and already in the phase of the manoeuvre into the firing position, warn the enemy, and provide sufficient information for the preparation and execution of fire. At the same time, they can provide a detailed evaluation of battle damage assessment (BDA) after firing.

Another variant is the use of UAVs as carriers of explosive devices, which can be used to destroy targets. In the case of artillery, a suitable target are FDCs. Destruction of them will

eliminate the entire firing battery from combat for a period of time. Alternatively, it is possible to destroy individual artillery weapon sets, which cause a deficiency in fire support.

Based on these findings, the proposed concept of detection and neutralization of UAVs is a very effective tool for reducing the risk of detection by these means and the subsequent elimination of artillery units by enemy counterbattery fire, or explosive devices. From the point of view of the effective use of the proposed concept, it is necessary that the established measures reflect the tactics and procedures of artillery fire units. The biggest restrictions will be mainly area requirements. The firing battery of self-propelled cannon howitzers is deployed in the area of firing positions, usually 1 - 2 x 1 - 2 km, depending on the position conditions and the combat task [19]. This space must be covered with the ability to neutralize the UAV - this can be achieved by using a directional antenna with sufficient gain or power, which will ensure the required range. The individual antennas should be connected to an automated system, from which their focus and modes of operation will be controlled.

Firing units are most exposed to observation at the moment of performing fire missions, when they are deployed in firing positions. A suitable variant is the placement of equipment for neutralization of UAVs on vehicles of artillery reconnaissance/survey units, or on artillery weapons sets [20]. To a minimal extent, it would be sufficient to place this device on the lead gun of fire platoons, or vehicle of the platoon commander. However, this depends on the possibility of increasing the scope of the opportunity of neutralizing the enemy UAV within the proposed solution. At command points (FDCs), it would be sufficient to place the equipment on one vehicle of FDC.

7.2. Artillery units in asymmetric operations and proposed concept of application

The use of artillery in an asymmetric conflict has its specifics. Firing units are usually located on permanent or forward operational bases and provide fire support to units performing framework operations in the area of responsibility. They do not manoeuvre and are constantly at the firing points. In an asymmetrical operation, the risk of counterbattery fire is minimal according to current experience. However, commercially available UAVs can radically change this state if used correctly [21]. The danger of the UAV being used by the enemy lies mainly in the possibility of uncovering the combat formation, finding out the position of the firing point of individual artillery weapon sets, and possibly leading an attack on them using explosives placed on the UAV. In an asymmetrical environment, this way of conducting combat is one of the few ways to put the fire units located in the base area in danger. A coordinated attack can cause significant technical losses and limit the ability to provide artillery fire support in the area of operations. It is therefore appropriate to consider how to defend against such an attack and to provide protection for the artillery fire support units and other base personnel. Placing the defence EW device on the base in such a way, which achieves coverage of the base perimeter, is a suitable variant of solving the problem. In the event of a breach of the base perimeter, the operator is able to ensure the protection of base members and prevent the UAV from flying over the base within the proposed method.

7.3. Partial conclusion of Section 7

This concept of protection against small UAVs will ensure that units are not attacked or uncovered and the risk of losing artillery fire support will not increase. At the same time, the simplicity of the proposed solution will not place excessive demands on interventions in the construction of vehicles or buildings. The solution can be applied to all types of troops and its specialization, wherever the risk of using small UAVs in the combat activities of the enemy can be assumed.

8. Conclusion

UAV defence in a cyber environment combines elements of cyber security and air defence. The development of new methods for attack and defence is necessary due to the dynamics of the development of these areas, which is confirmed by current knowledge from the fighting in Nagorno-Karabakh, where unmanned aerial vehicles and artillery play a major role. One of the possible ways is the proposed solution for penetration into UAS control systems.

The methods described in this article focus on supplementing and extending existing complex solutions of UAV defence models. Their application clearly achieves an increase in capability in the implementation of defensive measures and the fight against the UAV opponent. Simplicity and ease of materials and new inexpensive technical means represent an advantage for application in practice, e.g. in the military environment, as described and suggested by the examples of artillery units.

As the main achievement, authors consider a practical demonstration of the possibility for identifying the device based on the characteristics of the data frames. For this purpose, a neural network was developed which, based on the entered parameters, can evaluate whether the intercepted traffic comes from UAV communication.

As all the UAS defence systems are usually aimed at a certain type of opponent, this concept is not universal. It focuses on complementing the existing comprehensive defence model with more options, thus creating the ability for the defence institutions to fight more effectively with highly sophisticated adversary means.

Subsequent research in this area could be aimed at expanding the input parameters of the neural network and output neurons. The neural network should then be able to identify not only the device or the type of data stream transmitted during UAV operation, but also other types of operation. The whole system could then be used for overall monitoring - for the purpose of using Wi-Fi networks in the area of interest. However, extending this system to such a level could mean a significant intrusion on the privacy of individual users. If implemented in practice, this problem would be forced by the author to solve both at the technical and legal level.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

This paper presents an integrated solution for a fault-tolerant three-phase permanent magnet synchronous motor (PMSM) field-oriented control drive subjected to an open-phase fault (OPF) integrated with effective fault-tolerant detection methodology. The fault detection methodology is based on model predictive current control (MPCC), which is easy to apply, detect OPF in a range of microseconds, and robust under-speed or load transient. On the other hand, the fault-tolerant compensation is based on a neutral point connection together with stator current regulation to maintain the magneto-motive force (MMF) unchanged under open-phase failure. Controlling the motor phase currents in the post-fault condition ensures a rotating magnetic field similar to that produced during healthy conditions thus, reducing the saturation impact and ensuring the reliability of the control operation. The proposed integrated fault-tolerant drive is validated using MATLAB simulation that ensure the effectiveness of the proposed solution in steady state and during transients under different loading and rotor speed condition.

Nomenclature

v_a, v_b, v_c	The *abc* stator voltages
v_d, v_q	The *dq*-axis stator voltages
i_a, i_b, i_c	The *abc* stator currents
i_{ds}, i_{qs}	The *dq*-axis stator currents
P	The number of pole pairs
R_s	The stator resistance
L_d, L_q	The *dq*-axis stator inductances
L_{ls}	The leakage inductance
ω_e	The rotor electrical speed
λ_m	The permanent magnet flux linkage
T_e	The electromagnetic torque
N	The winding turns
θ_r	The electrical rotor position angle

1. Introduction

Permanent magnet synchronous motor (PMSM) is employed when high torque density/volume is needed, including systems with high safety requirements [1], [2]. As the more complexity of the electrical drives become, the possibility of system faults and failures increases which are hard to be prevented and can lead to severe effects. Fault-tolerant (FT) capability is the main requirement of motor drives in various applications such as electric vehicles, aerospace and spacecrafts, as the reliability of the motor drive system is very critical [3]. Such a system should identify faults, locate their origin, and, if possible, continue to operate after the fault happens. The Fault-tolerant control scheme involves fault detection and compensation. The open-circuit fault may not cause instantaneous damage and can even remain undetected for long periods thus leading to secondary failures [4]. The open-phase fault (OPF) happens in electrical machine drives when a winding phase is disconnected or one inverter leg fails or even due to a protection system isolating a short-circuit condition. In this situation, a large ripple of electromagnetic torque is created and serious mechanical vibration may happen. Fast and accurate methods of detection and fault-tolerance are therefore urgently needed to identify, isolate the fault early, and prevent the destruction of the whole system [5].

Among the numerous techniques for identifying faults by sensing waveforms is the Machine Current Signature Analysis (MCSA) which is based on Fast Fourier transform (FFT) stator

current analysis but is limited to steady-state process and requires stator current monitoring for at least one or more electrical post-fault periods before detecting the fault successfully. It also needs substantial processing energy and memory resources. Another technique known as Park's vector approach relies on the analysis of stator current in the rotor reference frame [6]. The current trajectories have a circular shape in normal conditions, the trajectories shape changes to the ellipse in the case of open phase fault (OPF). Modifications and developments of this technique are presented in [7]. These methods are much simpler and faster than MCSA, but during transient speed and load, they are subject to false alarms. In [8], a model reference adaptive system (MRAS) detection technique has been presented which relies on voltage monitoring and model current calculation when a fault happens in the steady-state; the threshold value of the detection was estimated empirically. The model predictive current control (MPCC) that has been presented for fault diagnostic in PMSM [9], [10] is employed here, where it relies on the stator current prediction and estimated error. MPCC scheme for the fault detection is found to be fast, requires minimum processing effort and robust under transient conditions.

Fault-tolerant control (FTC) compensation techniques for OPF PMSM drives have been introduced in two major forms depending on whether reconfiguration in hardware is needed or not. Methods with reconfiguration [11] are most applicable due to the fact that single-phase operation of the method without reconfiguration [9] even with modifications applied has the probability of matching the system mechanical resonance frequency at low speeds. One of the reconfiguration methods with extra inverter leg connected to the neutral point of PMSM is presented in [12], however still the main drawback of this method is the extra complexity of the power converter and additional cost and size. In [13] the authors employed a fourth leg in a manner that it replaces the faulty leg, yet the same drawback of extra complexity and additional cost and size remains the same. In [14] fault-tolerant systems of five-phase permanent magnet motor drive was studied. However, the multiphase machines are not a suitable solution in some application owing to the extra weight and costs. In this paper, the FTC compensation methodology implemented is targeting a lower cost compensation methodology [15], however, the magnitude of the phase current is limited to its permissible limit in order to minimize saturation impacts and ensure a sustainable motor drive fault-tolerant operation [16].

It is commonly found in literature research efforts that are dedicated for the fault detection [6]- [9] and others that present the fault compensation methodology [11]-[15], while it is rarely presented in the literature papers that provide complete solution from the instant of open phase fault, it is detection until applying the fault compensation methodology

In this paper the authors are introducing an integrated solution for a field oriented controlled PMSM drive that incorporates the benefits of fast open phase fault detection using a methodology based on MPCC and a reconfiguration fault compensation method that utilizes minimum additional hardware achieving a balanced operation with balanced current in magnitude thus dramatically reduces the torque ripples and consequently the ripples in the rotor speed as presented in [15]. In contrary to using a pulse width modulator in [15], the authors here deduced the required transformation to apply a space vector modulator which provides less harmonic distortion.

The paper is arranged as follows, Section 2 presents the modeling of PMSM, Section 3 presents the concept of the field-oriented control (FOC) of PMSM, Section 4 presents the concept of the MPCC used for OPF detection, Section 5 describes the proposed FTC compensation strategy and Section 6 shows the simulation results. Finally, Section 7 provides the conclusion of this work.

2. PMSM Mathematical Model

The electrical dynamic equations of the PMSM in the abc stationary reference frame can be written as [15], [17]:

$$\mathbf{V}_{\mathrm{abc}} = \mathbf{R}_{\mathrm{s}}\mathbf{I}_{\mathrm{abc}} + \mathbf{L}_{\mathrm{abc}}\frac{\mathrm{d}\mathbf{I}_{\mathrm{abc}}}{\mathrm{dt}} + \omega_e\,\mathbf{I}_{\mathrm{abc}}\frac{\partial\mathbf{L}_{\mathrm{abc}}}{\partial\theta_{\mathrm{r}}} + \omega_e\,\boldsymbol{\psi}_{\mathrm{abc}}$$

$$\boldsymbol{\psi}_{\mathrm{abc}} = \lambda_m\begin{bmatrix}\cos\theta_r\\ \cos\left(\theta_r-\frac{2\pi}{3}\right)\\ \cos\left(\theta_r+\frac{2\pi}{3}\right)\end{bmatrix} \tag{1}$$

Where $\mathbf{R}_{\mathrm{s}} = \mathrm{diag}(R_s)$, $\mathbf{V}_{\mathrm{abc}} = [v_a \quad v_b \quad v_c]^T$,

$\mathbf{I}_{\mathrm{abc}} = [i_a \quad i_b \quad i_c]^T$ and the terms of the matrix $\mathbf{L}_{\mathrm{abc}}$ are

$$L_{hh} = L_{ls} + \left(\frac{L_d+L_q-2L_{ls}}{3}\right) - \left(\frac{L_d-L_q}{3}\right)\cos[2(\theta_r+\alpha)]$$

$$L_{kh} = L_{hk} = \frac{-1}{2}\left(\frac{L_d+L_q-2L_{ls}}{3}\right) - \left(\frac{L_d-L_q}{3}\right)\cos[2(\theta_r+\gamma)]$$

$$\gamma = \begin{cases}-\frac{\pi}{3} & (h,k)=(a,b)\\ \pi & (h,k)=(b,c)\\ \frac{\pi}{3} & (h,k)=(a,c)\end{cases},\quad \alpha = \begin{cases}0 & h=a\\ -\frac{2\pi}{3} & h=b\\ \frac{2\pi}{3} & h=c\end{cases} \tag{2}$$

For the mechanical part:

$$T_e = J\frac{d\omega_r}{dt} + B\omega_r + T_L \tag{3}$$

T_L is the load torque, B is the damping coefficient, ω_r is the rotor mechanical speed and J is the moment of inertia.
The electromagnetic torque can be represented as in (4):

$$T_e = \lambda_m P[\,(i_a - \tfrac{i_b}{2} - \tfrac{i_c}{2})\cos\theta_r + \tfrac{\sqrt{3}}{2}(i_b - i_c)\sin\theta_r] \tag{4}$$

For the loss of one phase, the current in the lost phase becomes equal to zero keeping a single-phase current circulating in the remaining two phases.
For the post fault operation with the neutral of the star-connected three-phase windings of the PMSM connected to the center point of the DC link, the PMSM equations can be re-written as in [15]:

$$\mathbf{V}_{\mathrm{ij}}(\mathrm{t}) = \mathbf{R}_{\mathrm{s}}\mathbf{I}_{\mathrm{ij}}(t) + \frac{\mathrm{d}\boldsymbol{\lambda}_{\mathrm{ij}}(\mathrm{t})}{\mathrm{dt}} \tag{5}$$

$$\boldsymbol{\lambda}_{\mathrm{ij}}(\mathrm{t}) = (\mathbf{L}_{\mathrm{S}} + \mathbf{L}_{\mathrm{Mij}})\mathbf{I}_{\mathrm{ij}}(\mathrm{t}) + \mathbf{M}_{\mathrm{ij}}\lambda_m \tag{6}$$

where, (i,j)=$\begin{cases}(b,c)\ phase\ a\ open\\ (a,c)\ phase\ b\ open\\ (a,b)\ phase\ c\ open\end{cases}$

$$\mathbf{V}_{ij} = [v_i \quad v_j]^T \qquad \mathbf{I}_{ij} = [i_i \quad i_j]^T \qquad \boldsymbol{\lambda}_{ij} = [\lambda_i \quad \lambda_j]^T$$

$$\mathbf{L}_S = \begin{bmatrix} L_{ls} + \left(\frac{L_d + L_q - 2L_{ls}}{3}\right) & \frac{-1}{2}\left(\frac{L_d + L_q - 2L_{ls}}{3}\right) \\ \frac{-1}{2}\left(\frac{L_d + L_q - 2L_{ls}}{3}\right) & L_{ls} + \left(\frac{L_d + L_q - 2L_{ls}}{3}\right) \end{bmatrix}$$

$$\mathbf{L}_{Mij} = -\left(\frac{L_d - L_q}{3}\right)\begin{bmatrix} \cos[2(\theta_r + \beta_1)] & \cos[2(\theta_r + \beta_2)] \\ \cos[2(\theta_r + \beta_2)] & \cos[2(\theta_r + \beta_3)] \end{bmatrix}$$

$$\mathbf{M}_{ij} = \begin{bmatrix} \sin(\theta_r + \beta_1) \\ \sin(\theta_r + \beta_3) \end{bmatrix} \tag{7}$$

β_1, β_2 and β_3 are selected under the condition of open phase fault, as defined in (8):

$$(\beta_1, \beta_2, \beta_3) = \begin{cases} \left(\frac{-2\pi}{3}, 0, \frac{2\pi}{3}\right) & \text{phase } a \text{ open} \\ \left(0, \frac{\pi}{3}, \frac{2\pi}{3}\right) & \text{phase } b \text{ open} \\ \left(0, \frac{-\pi}{3}, \frac{-2\pi}{3}\right) & \text{phase } c \text{ open} \end{cases} \tag{8}$$

The torque consists of two-component: reluctance torque (T_{er}) and excitation torque (T_{em}) that is expressed in (9) and (10):

$$T_e = T_{er} + T_{em} \tag{9}$$

$$T_e = \frac{P}{2}(\mathbf{I}_{ij}(t))^T \frac{\partial \mathbf{L}_{Mij}}{\partial \theta_r}\mathbf{I}_{ij}(t) + P\lambda_m(\mathbf{I}_{ij}(t))^T \frac{\partial \mathbf{M}_{ij}}{\partial \theta_r} \tag{10}$$

3. Field oriented control (FOC) of PMSM

The FOC method used for AC electrical machine is concerned to let the AC machine behaves like the dc machine in terms of decoupled torque and flux control. A FOC control algorithm is manipulating the stator current vector in a d-q reference frame attached to the rotor. The torque equation of the PMSM in a d-q reference is given as:

$$T_e = 3P(\lambda_m i_{qs} + (L_q - L_d)\, i_{ds}\, i_{qs})/2 \tag{11}$$

Keeping the direct component of the stator current vector equals to zero results in a torque that is controlled through the manipulation of the quadrate component of the stator current vector. λ_m is the permanent magnet flux linkage resembling the flux in the DC machine so the torque can be expressed as:

$$Te = \frac{3P\lambda_m i_{qs}}{2} = K_t i_{qs} \qquad , \; K_t = \frac{3P\lambda_m}{2} \tag{12}$$

FOC has the advantage of having a fast response and little torque ripple.

4. MPCC method for OPF detection

The model predictive current control (MPCC) applied for fault diagnostic relies on the stator current prediction and estimated error to detect the abnormal situation. The current prediction is derived from the stator voltage equations in the $d-q$ reference frame of the machine attached to the rotor (rotor field) as given in (13) and (14) [9], [10].

$$v_d = R_s i_{ds} + L_d \frac{di_{ds}}{dt} - \omega_e L_q\, i_{qs} \tag{13}$$

$$v_q = R_s i_{qs} + L_q \frac{di_{qs}}{dt} + \omega_e L_d\, i_{ds} + \omega_e \lambda_m \tag{14}$$

By simplifying the derivation of the predicted current from (13) and (14), justified by the short sampling interval of Δt, the rotor speed ω_e can be considered to be quasi-constant, and linear change of stator currents during the short sampling interval [9].The PMSM equations can, therefore, be discretized with Euler approximation, resulting in the prediction of stator current at the sample t_{i+1} as given below:

$$i_{ds(t_{i+1})} = i_{ds(t_i)} + \frac{\Delta t}{L_d}(v_{d(t_i)} - R_s i_{ds(t_i)} + \omega_{e(t_i)} L_q\, i_{qs(t_i)}) \tag{15}$$

$$i_{qs(t_{i+1})} = i_{qs(t_i)} + \frac{\Delta t}{L_q}(v_{q(t_i)} - R_s i_{qs(t_i)} - \omega_{e(t_i)} L_d\, i_{ds(t_i)} - \omega_{e(t_i)} \lambda_m) \tag{16}$$

The objective function is chosen at the sampling time t_i, as the sum of the squared errors between the predictive values of d- and q-axis currents and their corresponding actual values as expressed in (17) [10]:

$$E = (i^*_{ds(t_i)} - i_{ds(t_{i+1})})^2 + (i^*_{qs(t_i)} - i_{qs(t_{i+1})})^2 \tag{17}$$

where E is considered to be the fault indicator. Under normal conditions and without system failure, E is relatively small within the expected range, once a fault occurs, the value of E will increase in magnitude exceeding the error threshold E_{th}. The chart in Figure 1 shows how the proposed algorithm differentiates between actual fault condition and transient operation condition. In this algorithm, the condition of having one of the phases with zero measured current and zero predicted current fulfills the condition of OPF. Few sampling intervals are sufficient to detect the fault. The proposed solution has the following advantages:

1) The OPF can be identified rapidly, in a range of few sampling intervals that are in the order of µsec.
2) No considerable processing power is needed.
3) Effective during transient speed and load.

5. The fault-tolerant compensation topology

Between many configurations, the minimum level of fault-tolerance in a three-phase drive for an OPF can be accomplished by isolating the faulty element, opening the corresponding motor phase, and connecting the motor stator neutral point to the mid-point of the inverter dc bus [15], as shown in Figure 2. During the OPF, after the system detects the abnormal condition (OPF) the system firstly disconnects the faulty phase leg by disabling the PWM signals to the corresponding switches of the inverter to avoid its impact on drive behavior after applying the post fault strategy, then fault compensation technique should begin and can be split into two steps as follows:

a) Connect the PMSM neutral to the mid-point of DC bus by firing TRn to continue the machine operation as a two-phase motor as illustrated in Figure 2.
b) Apply the post-fault current regulation technique as will follow in this section.

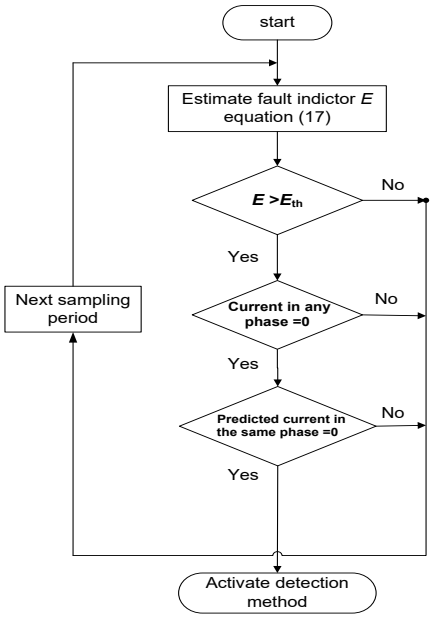

Figure 1: Flow chart of MPCC

For the PMSM FOC drive, in the healthy operation, the stator phase current has two components i_{qs}, i_{ds}, representing the torque and the flux components, respectively. During the post-fault stage, the motor neutral to the mid-point of the DC link split the machine phase currents into two currents where the zero-sequence component of the phase current becomes active, i.e. $\Sigma I_n \neq 0$. The fault-tolerant control strategy [11], [15] targets to maintain the same magneto-motive force (MMF) of the three-phase healthy operation and balance the unbalanced open-phase fault operation. This can be achieved by the following transformations to obtain the set of reference voltages for the remaining two healthy phases as follows:

$$\mathbf{V}^{u}_{\alpha\beta} = \mathbf{A}\mathbf{V}_{ij}(t) \quad (18)$$

$$\mathbf{V}_{\alpha\beta} = \mathbf{B}\,\mathbf{V}^{u}_{\alpha\beta} \quad (19)$$

$$\mathbf{V}^{r}_{qd} = \mathbf{R}_{v}\mathbf{V}_{\alpha\beta} \quad (20)$$

Also, similar matrices **A**, **B**, and $\mathbf{R_I}$ instead of $\mathbf{R_v}$ are used to transform the phase currents.

Where, $\mathbf{A} = \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}$ $\quad (\mathbf{A})^{-1} = \frac{1}{2}\mathbf{A}$

$$\mathbf{B} = \begin{bmatrix} \left[2\cos\left(\frac{\beta_1-\beta_3}{2}\right)\right]^{-1} & 0 \\ 0 & \left[2\sin\left(\frac{\beta_1-\beta_3}{2}\right)\right]^{-1} \end{bmatrix}$$

$$(\mathbf{B})^{-1} = \begin{bmatrix} 2\cos\left(\frac{\beta_1-\beta_3}{2}\right) & 0 \\ 0 & 2\sin\left(\frac{\beta_1-\beta_3}{2}\right) \end{bmatrix}$$

$$\mathbf{R_V} = \begin{bmatrix} \cos(\theta_r+\beta_2) & -\sin(\theta_r+\beta_2) \\ \sin(\theta_r+\beta_2) & \cos(\theta_r+\beta_2) \end{bmatrix} = ((\mathbf{R_V})^{-1})^{T}$$

$$\mathbf{R_I} = \frac{1}{3}\begin{bmatrix} \cos(\theta_r+\beta_2) & -3\sin(\theta_r+\beta_2) \\ \sin(\theta_r+\beta_2) & 3\cos(\theta_r+\beta_2) \end{bmatrix}$$

$$(\mathbf{R_I})^{-1} = \begin{bmatrix} 3\cos(\theta_r+\beta_2) & 3\sin(\theta_r+\beta_2) \\ -\sin(\theta_r+\beta_2) & \cos(\theta_r+\beta_2) \end{bmatrix}$$

And **S** is the transformation between the balanced alpha-beta frame and the alpha-beta reference frame of the SVPWM given as:

$$\mathbf{S} = \begin{bmatrix} \cos(\beta_2) & -\sin(\beta_2) \\ \sin(\beta_2) & \cos(\beta_2) \end{bmatrix}$$

Then the resulting two-phase post fault currents will increase to $\sqrt{3}$ of the healthy phase current with phase angle shifted 60° away from each other [11], [12]. This is illustrated by the phasor diagram in Figure 3 for an OPF in phase (a).

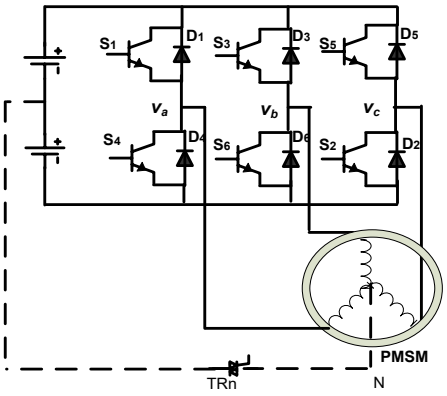

Figure 2: FTC motor drive configuration

This ensures the same rotating magnetic field and thus the same stator flux linkage by maintaining the same MMF between healthy and fault-tolerant conditions. The compensation of voltage drops due to the variation of stator resistance [11] was also applied to remove their effect during the fault-tolerant operation as shown in Figure 4. The flow chart in Figure 5 summarize applied post fault compensation methodology.

6. Simulation results

In this section, MATLAB simulation results are presented from a MATLAB Simulink model developed for the PMSM drive system in Figure 4 with proposed fault detection and fault-tolerant techniques under different modes of operation (healthy, during an open-phase fault, fault-tolerant compensation). Four cases under the different conditions and with different speed and load conditions as presented in Table 2. The PMSM parameters are listed in Table 1.

Table 1: Three Phase PMSM Parameters

Parameter	Value
Rated power	0.47 kw
Rated torque	2.2 N.m.
Rated current	2 A
Rated speed	1000 rpm
The number of pole pairs (p)	3
Moment of inertia coefficient	0.000198 kg.m^2
Stator Resistance (R_s)	5.95 Ω
d-axis Inductance (L_d)	12.5 mH
q-axis Inductance (L_q)	12.5 mH
The PM flux linkage (λ_m)	0.2955556 Wb

Table 2: Test cases

Cases	Description
A	In this case phase b is disconnected, detection method (MPCC) is disabled; reference speed 1000 rpm, and load torque 0.5 N.m.
B	In this case phase b is disconnected, detection method (MPCC) is disabled, reference speed 500 rpm, and load torque 1 N.m.
C	In this case phase b is disconnected, the detection method (MPCC) enabled, reference speed 400 rpm and load torque 1 N.m.
D	In this case of phase, b is disconnected, detection method (MPCC) is enabled, with transient speed change from 400 rpm to 800 rpm and load torque 1 N.m.

A. phase b is disconnected, detection method (MPCC) is disabled; reference speed 1000 rpm, and load torque 0.5 N.m.

The PMSM is first driven at healthy operating conditions. An OPF at phase *b* is then applied at t=0.1 sec with the fault detection subsystem being disabled for illustrating the error signal that is used for detecting the fault when the integrated fault detection, fault-tolerant compensation technique is fully applied. At t = 0.2 sec, The FTC current regulation technique is allowed to start thus, connecting the neutral point to the mid-point of the DC link and applying the required modification for the current control to return back the magneto-motive force to its value during the healthy operation as explained in section 5. Figure 6 shows the stator currents during the OPF in phase b at t = 0.1 sec, the phase *b* current falls to zero while the other two-phase currents have the same value of the current, but with opposite polarity (phase-shifted 180°). When the FTC compensation is applied at t = 0.2 sec, the currents of the remaining healthy phases is increased in magnitude by 1.73 and shifted 60° apart from each other.

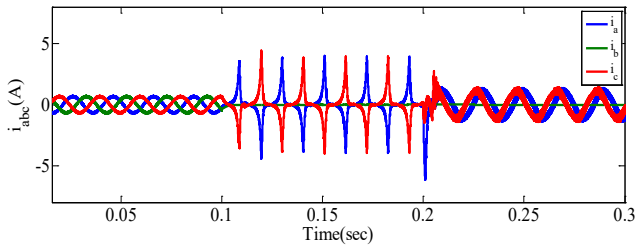

Figure 6: Stator currents before, during the fault and after FTC compensation (case A)

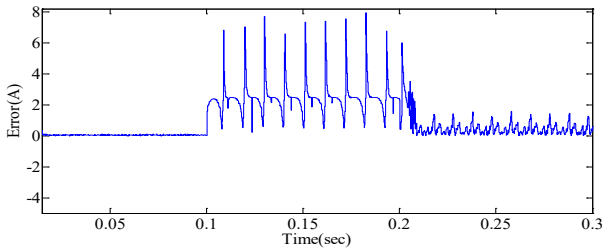

Figure 7: Fault detection error magnitude before, during the fault and after FTC compensation (case A)

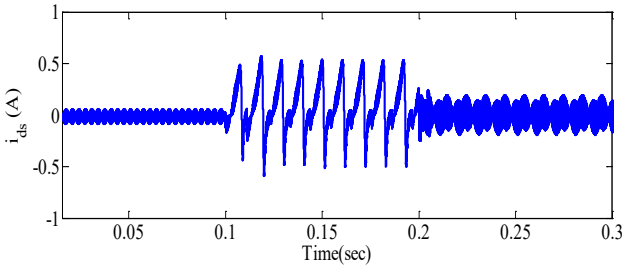

Figure 8: d-axis current before, during the fault and after FTC compensation (case A)

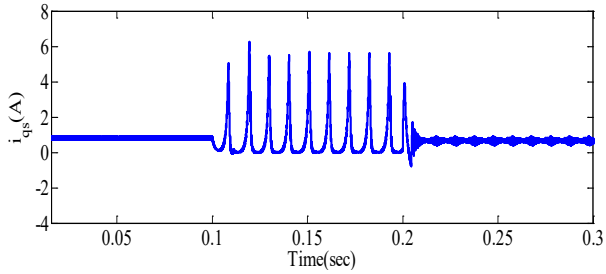

Figure 9: q-axis current before, during the fault and after FTC compensation (case A)

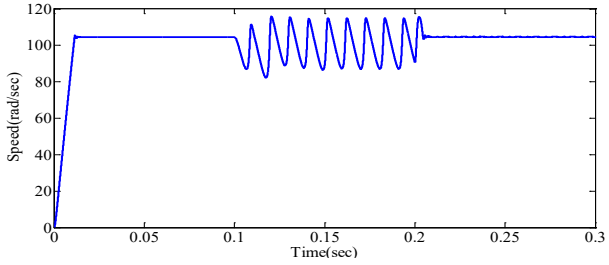

Figure 10: Rotor speed before, during the fault and after FTC compensation (case A)

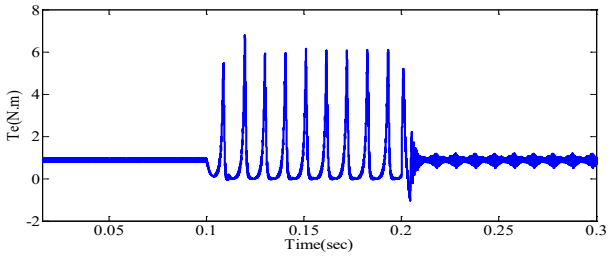

Figure 11: Electromagnetic torque before, during the fault and after FTC compensation (case A)

During the OPF the error magnitude increases due to the OPF (t = 0.1sec – 0.2 sec) then back to the acceptable range after the FTC technique is applied (t = 0.2sec - 0.3sec) as presented in Figure 7. The dq currents, speed, and torque ripples severely increase during the fault due to the OPF operation, then the FTC technique constrained it as shown in Figure 8, Figure 9, Figure 10, and Figure 11.

B. Phase, b is disconnected, detection method (MPCC) is disabled, reference speed 500 rpm, and load torque 1 N.m.

During single-phase operation (OPF occurs at t= 0.1 sec) without enabling the detection technique (MPCC), the system cannot identify the fault and this leads to the PMSM stop and cannot continue its operation. Until the FTC compensation is applied at (t=0.2 sec), PMSM can return back to work with the remaining two phases at t=0.2 sec a Shown in Figures 12, 13 and14.

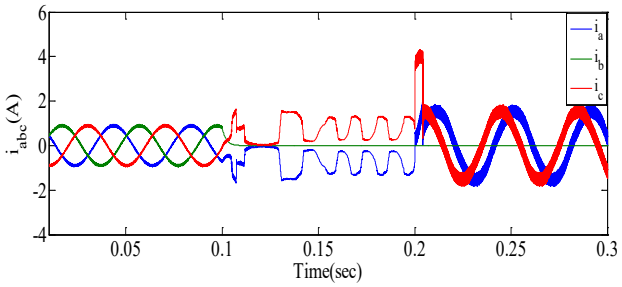

Figure 12: Stator currents before, during the fault and after FTC compensation (case B)

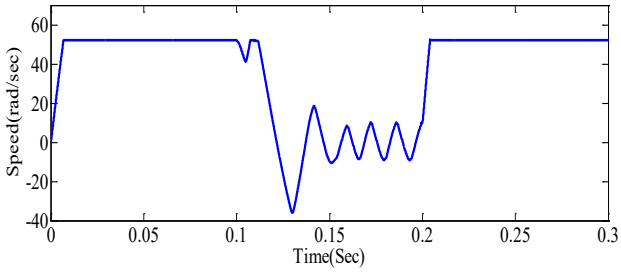

Figure 13: Rotor speed before, during the fault and after FTC compensation (case B)

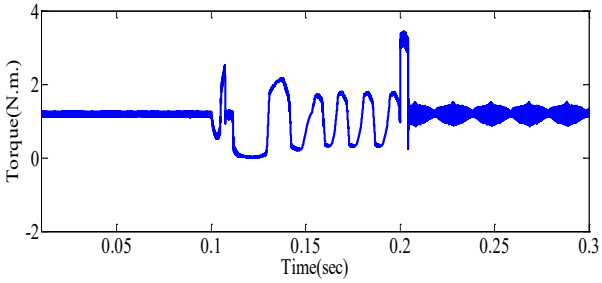

Figure 14: Electromagnetic torque before, during the fault and after FTC compensation (case B)

C. phase b is disconnected, the detection method (MPCC) enabled, reference speed 400 rpm and load torque 1 N.m.

Phase b is opened at 0.1 sec with the fault detection technique (MPCC) enabled. The function of the fault detection method is to detect the OPF and trigger the FTC-compensation for operation. It is obvious from Figures 15 to 20 that the detection of the OPF is only in a few µsec depending on the error indicator. In normal operation (t = 0 - 0.1sec) the error as given in (17) is close to zero, at the instant of fault at (t= 0.1 sec) the error magnitude is increased and the MPCC detects it quickly before the error value becomes high. Once the fault detection takes place it activates the FTC which returns back the error value to an expected range (t=

0.1 - 0.3 sec) as shown in Figure 16. The stator currents are depicted in Figure 15. As shown in Figure 17 and Figure 18, the balance in the resultant MMF can be easily observed by obtaining the same average torque and speed as in the healthy operation at the instant the fault is detected and FTC is activated. i_{ds} and i_{qs} are depicted in Figure 19 and Figure 20, respectively. Comparing case C to case B, it can be concluded that the fast response of the fault detection prevents the drive from halting at low-speed operation.

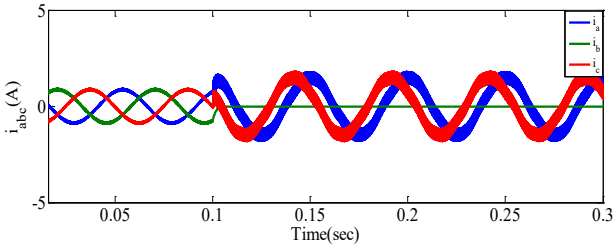

Figure 15: Stator currents in the healthy and post-fault operation

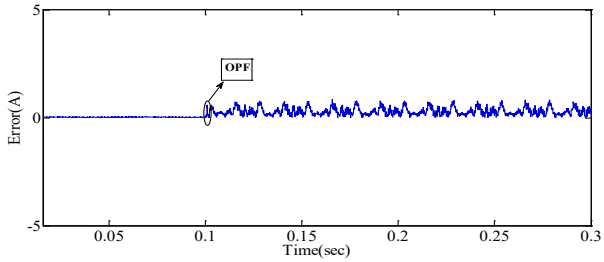

Figure 16: Fault detection error magnitude in the healthy and post-fault operation

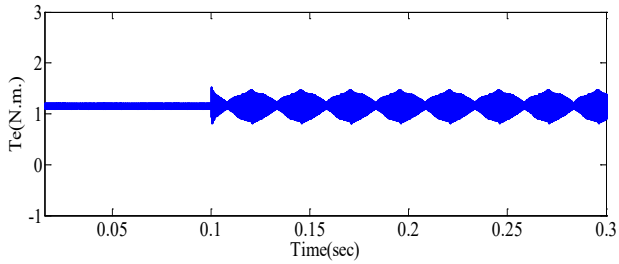

Figure 17: Electromagnetic torque in the healthy and post-fault operation

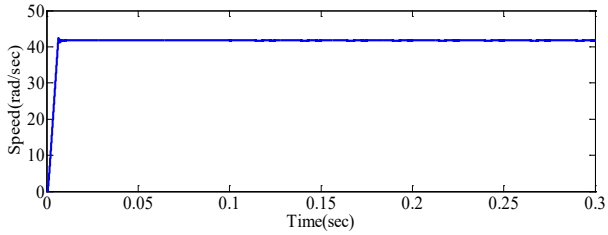

Figure 18: Rotor speed in the healthy and post-fault operation

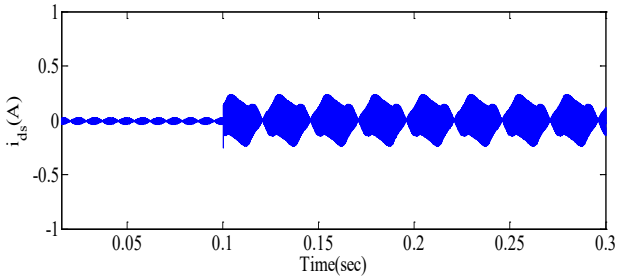

Figure 19: d-axis current in the healthy and post-fault operation

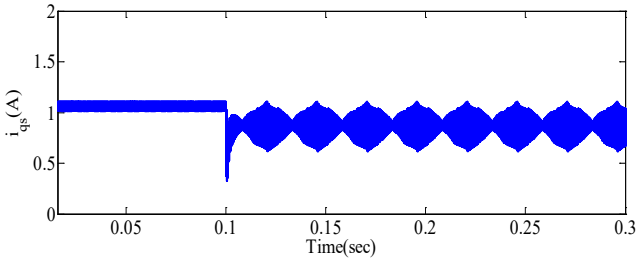

Figure20.: q-axis current in the healthy and post-fault operation

D. phase, b is disconnected, detection method (MPCC) is enabled, with transient speed change from 400 rpm to 800 rpm and load torque 1 N.m.

In this test case, the selective and discriminative performance of the fault detection method is examined under healthy, fault during transient and transients while operating in post-fault conditions. Figures 21-23 show the case where during the healthy operation the speed was changed from 400 rpm to 800 rpm while the detection algorithm being activated. A large error is observed by the fault detector similar to a fault condition however due to the presence of actual and predicted current, the algorithm takes no action. On the other hand, Figures 24-25 illustrate the same case for Figures 21-23 however during the transient change, an OPF of phase b is introduced (at t= 0.053 sec). The fault detection method observed the fault condition and takes the proper action for transferring the operation to the post-fault algorithm allowed to a balanced two-phase maintaining the same MMF as for the healthy condition with minimum torque ripples.

Moreover, the FTC-compensation strategy is tested to prove the robustness of the system during post-fault by changing the reference speed from 400 rpm to 800 rpm as indicated in Figure 26. It is obvious that the PMSM speed is totally able to follow the reference speed. Figure 27 and 28 illustrate the two-phase currents and the electromagnetic torque in the post-fault operation during the steady-state and transient conditions of the step change in the speed.

7. Conclusion

An integrated fault-tolerant system for open-phase fault in PMSM field-oriented controlled drive has been presented. This drive system consists of a MPCC technique for the fault detection, which is reliable, fast as only a few sampling intervals are sufficient to identify the OPF during steady-state and effectively under transient conditions, together with a fault-tolerant control (FTC) compensation method which utilizes the neutral point to split the single-phase current into two-phase currents that are 60° phase-shifted and equal in magnitude (increased to $\sqrt{3}$ of the healthy phase current) with minimum hardware. This guarantees the balance in the resultant magneto-motive force allowing for the current vectors regulation returning the operation with almost the same average torque.

The simulation results show the smooth transition from the healthy operation to the post fault operation immediately at the time the fault occurs without loss of machine torque and consequently the speed control. Moreover, the fault detection method is robust enough to discriminate between a real OPF and a normal operation transient condition.

The results obtained under different testing conditions show the robustness and precision of the proposed fault detection and fault compensation methods which makes the proposed integrated fault-tolerant is suitable for PMSM drives used in industrial processes to ensure the reliability of the whole system operation even in the event of OPF.

Conflict of Interest

The authors do declare that there is no conflict of interest.

ABSTRACT

One of the open domain challenges for Spoken Dialogue System (SDS) is to maintain a natural conversation for rarely visited domain i.e. domain with fewer data. Spoken Language Understanding (SLU) is a component of SDS that converts user utterance into a semantic form that a computer can understand. If we scale SDS open domain challenge to SLU then it should be able to convert user utterance to a semantic form even if less data is available for the rarest visited domain. The SLU reported in literature incorporate classifiers for the task of identifying the domain of user utterance, understanding the intent of the user, and filling slots-value pair. Thus, to address open domain challenges, classifiers in SLU must be robust to scarce training data. This paper presents investigations to improve the performance of SLU to convert user utterance into semantic form even if less training data is available. Eleven classification algorithms from machine learning have experimented under deficient data. The evaluation matrices used are accuracy, f-score, and inter cross-entropy. Comprehensive experimentation is carried out on the two publicly available datasets DSTC2 and DSTC3 were carried out.The accuracy for Support Vector Machine (SVM) , Stochastic Gradient Descent (SGD) and Decision tree are 0.940, 0.960 , 0.955 for DSTC2 and 0.916, 0.900, 0.901 for DSTC3 database respectively. The F-score for SVM, SGD and Decision tree are 0.855, 0.868, 0.849 for DSTC2 dataset and 0.725, 0.715, 0.700 for DSTC3 database, respectively. The ICE for SVM and SGD are 1.191,1.100 for DSTC2 dataset and 3.180,2.999 for DSTC3 database, respectively. The performance of SLU based on SVM and SGD was found to be the best among all. The worst performance in terms of all three evaluation metrics was displayed by SLU incorporating Automatic Relevance Determination (ARD) and Relevance Vector Machine (RVC) classifier.

1. Introduction

Spoken Dialogue System (SDS) interacts with the user in the most natural form of communication. It helps the user to achieve a goal through a series of interactions. SDS is moving to the open domain now. In the open domain, SDS has to maintain natural conversation even if data are scarce. Recently a lot of work is reported in the literature for open-domain Spoken Language Understanding (SLU) where it should be able to convert user utterance to semantic form even if less data is available. SLU reported in literature incorporates classifiers at different levels. The first level classifier in SLU will classify utterance to a domain example restaurant, flight booking, and tourist information. The next level classifier will classify user intend within domain example for example finding a restaurant or flight.

Subsequent levels in SLU should fill the slots such as time, date, etc. Filling slots will allow the flow of conversation to achieve the user goal. Thus, the robustness of the classifier to infer the output even if training data is less is important. There is a need for investigation of the robust classifier for SLU, which can convert user utterance to semantic form even if less training data is available. The work in the paper investigates a robust classifier. This research is broadening of work initially reported in the conference paper [1] The work is extended by incorporating CNN

*Corresponding Author: Sheetal Jagdale, Email: sheetal.jagdale2@gmail.com

for feature extraction and investigating eleven classifiers from literature. Comprehensive experimentation was done on the DSTC2 dataset and the DSTC3 dataset. The evaluation was done on two domain datasets. DSTC2 datasets for the restaurant domain and DSTC3 datasets for the tourist domain were used for evaluation.

Classification is an important task in many applications as image processing, spoken dialogue systems, etc. Choosing the right classifier for an application is a very important task. A lot of work is reported in the literature for investigating a robust classifier for a particular application. The work [2] has predicted error rates of k-neighborhood, SVM, and decision tree classifiers for the application of computer-aided diagnostic (CAD). The evaluation of the classifiers is done on a small training set. Later the work was extended to three tasks in CAD. The task was detecting cancer, identifying high or low-grade and-later the work was extended by adding more features [3] Another work investigates classifiers for text classification [4] The Paper investigates Rocchio Classification, K Nearest Neighbor, Naïve Bayes Classification, SVM Classification, and Regression-Based Classification for the task of classifying text. The paper concludes with a study stating that the right choice of dimension reduction algorithm and classifier can improve the performance of text classification. One more paper [5] refers to the classifier investigation for the task of text classification under limited data. A naive Bayes classifier is also investigated for text classification [6] The work combines the dimension reduction method with a classification algorithm for text classification under limited training data. The study was reported in [7] Paper [8] tackles the issue of imbalance data under training data. They tackle the issue by a stable space for testing data proposed using a metric algorithm. The effect of training size on the neural network classifier is also demonstrated in the literature [9] Recently a work [10] reported classifiers for clinical treatment. The study also includes data augmentation techniques along with classifiers Thus, a lot of classification algorithm investigation for different applications is done. This paper investigates a robust classifier for the slot filling task of SDS.

To improve SLU's performance for classifying utterance to predefined slots, different classification algorithms from machine learning were investigated. The purpose of the work is to:

1) Extend a robust classifier algorithm in machine learning to the semantic decoder in spoken language understanding for the task of converting user utterance into a semantic form of dialogue act and slot-value pair.
2) To demonstrate the impact of data scarcity on SLU incorporating different classifiers.
3) Comprehensive experiment on SLU incorporating eleven classifiers on two public datasets DSTC2 and DSTC3. The metrics used for evaluation are accuracy, f-score, and item cross-entropy.

2. Related Background

2.1. Decision Tree [DT]

DT is a popular classifier and is used in various machine learning applications such as data mining, image processing, statistics, etc. It uses if and then rules and follow the top-down method. In paper [11] decision tree is used for mining applications. A decision tree is used to extract information from huge data. Another work discusses the framework for decision tree algorithm, splitting criteria, and pruning methods [12] The paper also discusses extended decision trees such as obvious tree s decision trees, incremental tree, tree inducers, and fuzzy trees. A decision is also used as an inductive inference system [13] The decision tree algorithm consists of a set of rules called a decision. It extracts knowledge from example. Thus, it resembles the machine learning principle of learning from examples. In a research work presented in paper [14], the IDA decision algorithm is proposed. The ID3 decision algorithm is also discussed and compared with IDA.ID3 algorithm uses entropy for finding the uncertainty of classification output. While IDA uses divergence for classification. As reflected in the results, the IDA algorithm performance displays its effectiveness over ID3. Another paper [15] proposes an improved ID3 algorithm. It incorporates the Taylor series in ID3 to improve the classifier. One of the popular applications of the decision tree is data mining [16]

2.2. Multilayer Perceptron [MLP]

One of the most powerful classifiers used in machine learning is the MLP classifier. It uses a supervised learning and feedforward network. One of the applications reported for MLP is for recognizing a number in the Bengali language [17] For numbers recognizing pre-processing techniques such as feature, the selection is also incorporated. Another application reported is for the inference of liver cirrhosis [18] However, it is very difficult to tune the parameter of a multilayer perceptron. To overcome this difficulty a methodology is proposed in the paper [19] The methodology can find the number of epochs to get the best performance which is optimal.

2.3. Gaussian naïve Bayes

Gaussian naive Bayes classifier is a probabilistic classifier applied to many applications. Bayes theorem is used for classification. One application is discussed in [20] for breast cancer classification. A framework consisting of data pre-processing, feature selection, and classifier is proposed for breast cancer classification.

2.4. Gaussian classifier

Gaussian classifiers are used in many applications such as language identification [21], spectrum recognition [22] and dialogue representation [23] The work in paper [24] discusses the parametric Gaussian classifier. In this work, a Gaussian classifier incorporating a neural network is discussed. The results demonstrate the effectiveness of the parametric approach applied to Gaussian distribution. The Gaussian classifier is also analyzed for limited training data [25] The work discusses the impact of limited data on the decision boundary of a classifier.

2.5. AdaBoost classifier

In literature AdaBoost are used for detecting objects[26] ,detecting faults in gearbox [27] and detecting hands [28] In another paper, AdaBoost is used in mobile intelligent terminals for security level classification [29] Various modified AdaBoost algorithms are were analyzed for classification margin[30]

Further, in the same paper, generalized error for eight variants of AdaBoost was reported. Personalized AdaBoost which is a variant of AdaBoost as reported in the paper has the least generalization error

2.6. Relevance vector machine

Relevance vector machine (RVM) is a probabilistic model used for classification and regression. The prediction of the output of RVM is probabilistic. RVM is used for the classification of hyperspectral images using wavelet kernel [31] As reported in the paper, training speed was improved by RVC incorporating wavelet kernel. Another application was reported for RVM for the detection of clustering in mammogram [32] For mammogram classification, RVM was able to maintain better classification with less computation complexity

2.7. Stochastic gradient (SGD)

It is a linear classifier that incorporates SGD learning. These classifiers are used in classifying emotions in Hindi text [33] In the Hindi emotion classification model, first pos tagging is done on the text and then features are extracted from the text. Extracted features are used to train the SGD classifier or random forest classifier. The results were improved by incorporating reduced features to SGD. Another application for SGD in literature is for the categorization of Bangla text [34] The results for Bangla text classification was improved using SGD.

2.8. Support Vector Machine [SVM]

It is a linear non-probabilistic classifier. It uses Platt's model to predict the output. One of the applications in literature is big data automated selection [35] The quality of data affects the classification performance of SVM. Results in the paper showed that optimizing the SVM parameter can improve the performance. SVM is also used for skin disease classification [36] In this work, the Image was flattened to get an array of pixel intensities. This array of labeled data was used to train SVM. Recently SVM using field programmable gate array is used for knowledge discovery.

2.9. K-nearest neighborhood [KNN]

It is a supervised classifier based on distance measurement. It is widely applied to data mining for the classification task.In recent work[37], KNN is used for saving energy for the home. KNN is used here for appliance classification. The KNN classifiers were able to detect home appliances in a short time. Lot variants of KNN such as dynamic KNN, weight-adjusted KNN and distance weighted KNN are proposed to speed up the learning process [38]

2.10. Random Forest [RF]

It is an algorithm based on a decision tree. In a paper [39], RF is used for Android malware detection applications. The framework proposed in the paper was evaluated on the android feature dataset. RF was used for the classification task of identifying applications as benign or malicious. Misclassification error for classifying malware was least for the random forest. Recently in a paper, RF is used for identifying and classifying applications for network traffic detection. The algorithm used for comparison were random forest, SVM, and logistic regression. RF outperformed all the classifiers in terms of accuracy and f-score.

2.11. Variational Relevance Vector Machine [VRVM]

A variant of RVM is proposed in paper [40] known as variational relevance vector machine. This method is RVM with variational inference. VRVM is applied for RVM multi-dimension array classification. Another application for VRVM is discussed in the literature for the classification of table data such as blocks of image [41] VRVM was found more robust then RVM.

3. Block diagram of SLU

SLU is an important component of the SDS system which converts user utterance to a semantic form consisting of dialogue act and slot value pair. Figure 1 shows the block diagram of SLU.

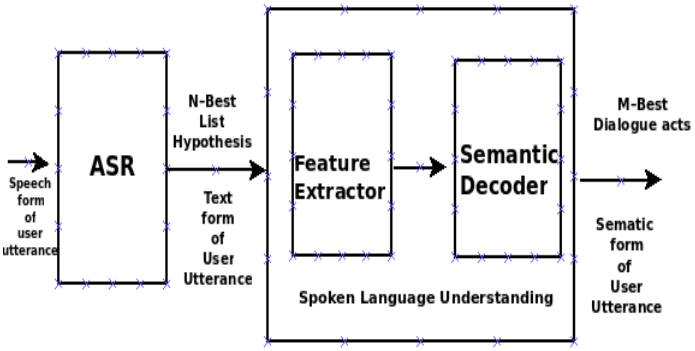

Figure 1: Structure of SLU

SLU plays a very important role in understanding user intent. User utterance is given to the Automatic Speech Recognition (ASR) system which converts speech into text form. The text input is given to SLU. It extracts features from text utterance. The features are fed to a set of classifiers to extract dialogue act and slot-value pair from features. The dialogue act and slot-value pair are combined to form a semantic representation of user utterance. Semantic representation is further analyzed to understand user utterance.

4. Implementation of SLU

Figure 2 represents a semantic tuple classifier for the task of semantic classification which is described in the paper [42]

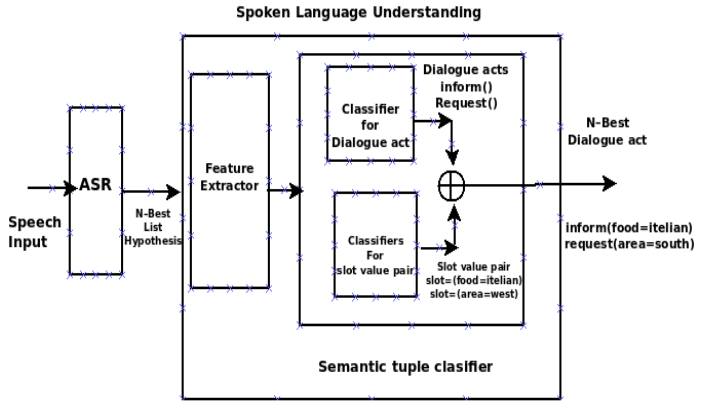

Figure 2: SLU incorporating classifiers for dialogue act and slot-value pair

The speech input is given to ASR. The ASR converts speech input to text form which is the N-best list. The features are extracted from the text. The feature extraction method in paper [42] is extended by incorporating CNN. The deep extracted feature is fed to the classifier. The first classifier classifies user utterance to dialogue act such as to inform (), request (), and bye (). This will help to understand the goal of the user. The next set of classifier identifies the slot-value pair for user utterance. The semantic form of user utterance consists of dialogue act and slot- value pair. Next, eleven classifiers from machine learning are investigated for dialogue act classification and to find slot–value pair. The classifiers investigated on SLU are support vector machine, stochastic gradient descent classifier, AdaBoost classifier, decision tree, relevance vector classifier, random forest, *k*-nearest neighbor classifier, multi-layer perceptron classifier, automatic relevance determination classifier, Gaussian naive Bayes classifier, and variational relevance vector machine. The experimentation was performed with a different amount of training data. The performance of SLU was studied and compared incorporating different classifiers under limited training data on DSTC2 and DSTC3 databases. The experimentation for measuring robustness on limited training data was conducted by training the model on 25% training data and then testing the model on entire testing data. Later experimentation was repeated for 50% training data, 75% of training data, and 100% training data. The evaluation was done on metric Inter Cross-Entropy (ICE), accuracy, and F-score.

5. Results and Discussion

5.1. Datasets

Experimentation is done on two public datasets DSTC2 and DSTC3. The DSTC2 dataset for the restaurant domain. It consists of 1765 dialogues for training data, 441 validation data and 1117 dialogue for testing data. The DSTC3 dataset is for the tourist domain. It consists of a total of 2265 dialogues. The training data used for the experiment is 1265 dialogues and 250 dialogues for validation. The testing data for the experiment is 750 dialogues.

5.2. Evaluation metrics

The framework is evaluated with three metrics: Inter Cross-Entropy (ICE), accuracy, and F-score. The ICE is cross-entropy between the probability density from the confidence and the optimal density given by delta functions at the correct values [43] In the paper, it was demonstrated ICE gives a consistent performance ranking for both the confidence scores and the overall correctness of the system. A lower ICE metric indicates good dialogue confidence performance. Accuracy and F-score are in range 0 to 1 and higher values indicate good performance. ICE metric is highly correlated with the performance of SDS. Accuracy and F-score will reflect the performance of the SLU model. Thus for the evaluation of model in the experiment is done with ICE, f-score, and accuracy.

5.3 Baseline Method

The framework used for experimentation is an extension of the semantic decoder [42] The decoder is extended by incorporating CNN for feature extraction. The extended framework experimented with incorporating eleven different classifiers from machine learning. The framework was evaluated on DSTC2 and DSTC3 datasets. The framework was also investigated for robustness for less training data.

5.4 Experimental setting 1

The first set of experimentation was carried out on the DSTC2 dataset. The experiment was conducted on a deep semantic decoder by incorporating 11 different classifiers. For each classifier, the robustness was evaluated by training the model with different quantity of training data and then testing using the entire set. The different quantity of training data was 1765 dialogues (100% training data), 1323 dialogues (75% data), 882 dialogues (50% training data), and 441 dialogues (25% training data). Testing of SLU for all different quantity of training data was done on 1117 testing dialogues. The classifiers investigated on SLU are SVM, SGD, AdaBoost, DT, RVC, MLP, RF, *k*-neighbourhood, ARD, Gaussian naive Bayes, and VRVM.

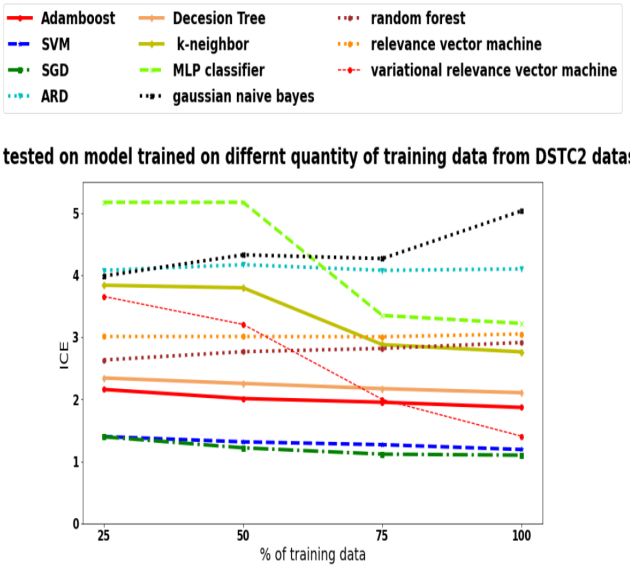

Figure 3: ICE for a model trained on 25% training data, 50% training data, 75% training data, and 100% DSTC 2 training data.

Figure 3 shows the experimental results for ICE measured on the dSTC2 dataset for different quantity of training data. Results show ICE is directly proportional to training data. Almost all classifier ICE was high when training data was less. This indicates the overall quality of distribution was least for 20% of training data and most when 100% training data. Their set of classifiers displaying the best performance are SVM, SGD, and VRVM at 100% data. SVM and SGD displayed the least variation in ICE at the different quantity of training data. The variation in VRVM and MLP was most for different quantity of training data. The set of classifiers displaying the worst performance are ARD, RVC, and MLP. The classifier which had an overall good performance for all quantity of training data and full data is SGD.

The testing accuracy results of the experiment on the DSTC2 dataset are shown in Figure 4. The measurement accuracy is for correct classification of user utterance to semantic form consisting of dialogue act and slot value pair. The classifiers whose topmost semantic hypothesis was correct are SVM, VRVM, decision tree, and SGD. These classifiers were also able to predict the semantic hypothesis for testing data even if the training data was less.

VRVM was not able to maintain its performance for limited training data. Thus SVM, decision tree, and SGD were able to maintain its performance even if training data was scarce. The classifiers displaying the least performance are ARD, RVC, and random forest. The VRVM's testing accuracy measured for 20% training data is 0.827 and for training 100% data it is 0.939. Thus, it is not able to maintain its performance under a scarcity of data. Similarly, MLP and k– neighborhood classifiers were also not able to maintain its performance under data scarceness.

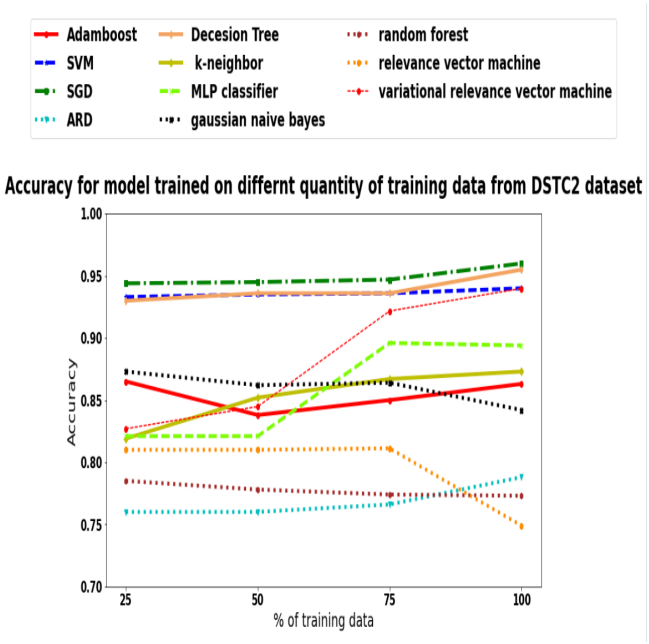

Figure 4: Testing data accuracy for a model trained on 25% training data, 50% training data, 75% training data, and 100% DSTC 2 training data.

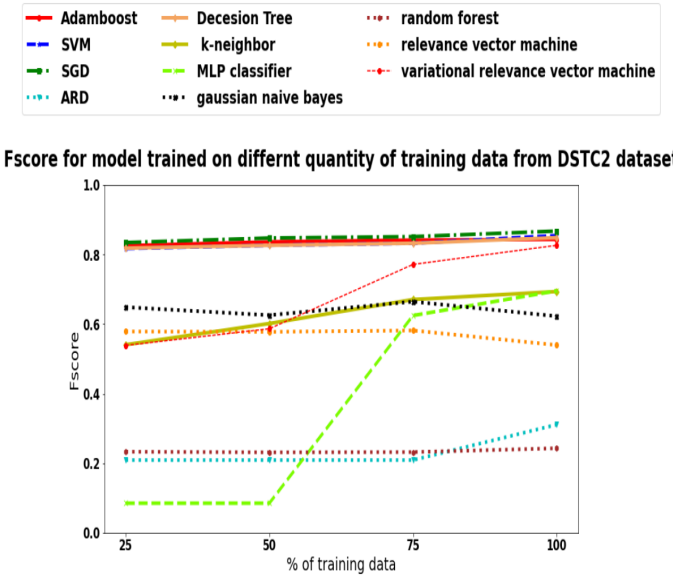

Figure 5: Testing data F-score for a model trained on 25% training data, 50% training data, 75% training data, and 100% DSTC 2 training data.

F-score for testing data DSTC2 is presented in Figure.5. A high value of the F-score will indicate a low false-negative and positive value of the semantic hypothesis. A high F-score was displayed by SLU incorporating Decision Tree, SVM, VRVM, and SGD. SLU's robustness for limited data was increased with these classifiers. VRVM again failed to show robustness for limited data. Low F-score was displayed by random forest and RVC. SLU incorporating MLP also had a lot of variation in F-score for different quantity of training data.

5.5. Experimental setting 2

The second set of experiments was carried out on DSTC3. The different quantity of training data was 1265 dialogues (100% training data), 925 dialogues (75% training data), 600 dialogues (50% training data), and 300 dialogues (25% training data). The testing data consist of 750 dialogues. The eleven classifiers included in an experiment setting 1 is also included in experiment setting 2 as well.

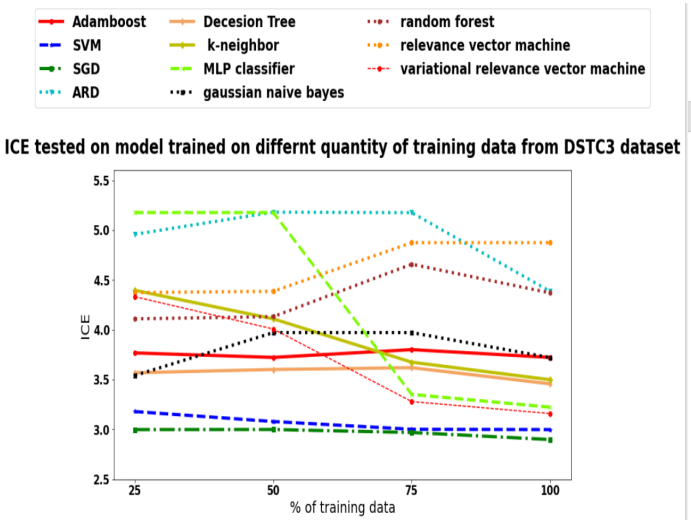

Figure 6: ICE for a model trained on 25% training data, 50% training data, 75% training data, and 100% DSTC 3 training data.

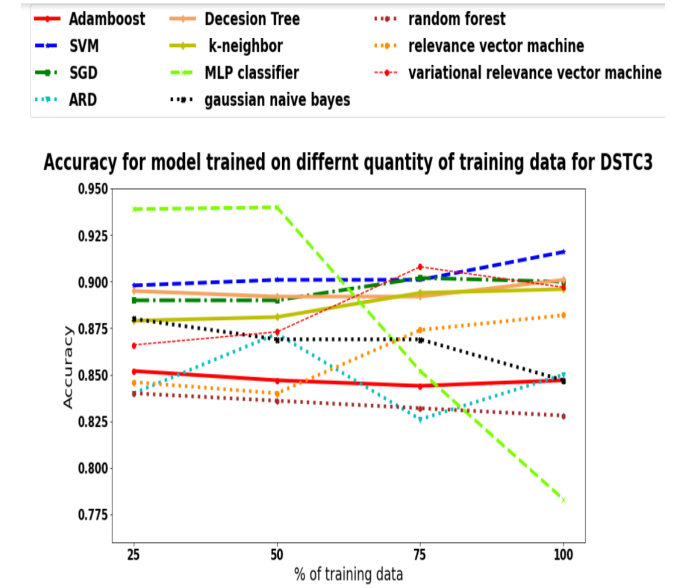

Figure 7: Testing data accuracy for a model trained on 25% training data, 50% training data, 75% training data, and 100% DSTC 3 training data

Figure 6 shows the ICE readings for the different quantity of training data for DSTC3 datasets. The results are similar as found for the DSTC2 experiment. The SLU incorporating the set of

classifiers displaying good results are SVM, SGD, and VRVM. Variation in ICE for different quantity of training data was minimum for SVM and SGD. Variation in ICE was more in VRVM. The SLU incorporating a set of classifiers displaying the worst results are ARD, RVC, and RF. The maximum variation in ICE was displayed by MLP, RVC, and K-neighbourhood.

Testing accuracy for the SLU model for different quantity of training data for the DSTC3 dataset is shown in Figure 7. Again, the results are in line with DSTC2 results. The classifiers which were able to classify user utterance to semantic form most accurately were SVM, SGD, and decision tree. The classifiers performing well under data scarcity are SVM, SGD, and decision tree. The worst performance in terms of data scarcity was showed by the MLP classifier. In terms of accuracy worst performance was shown by ARD, RF, and RVC.

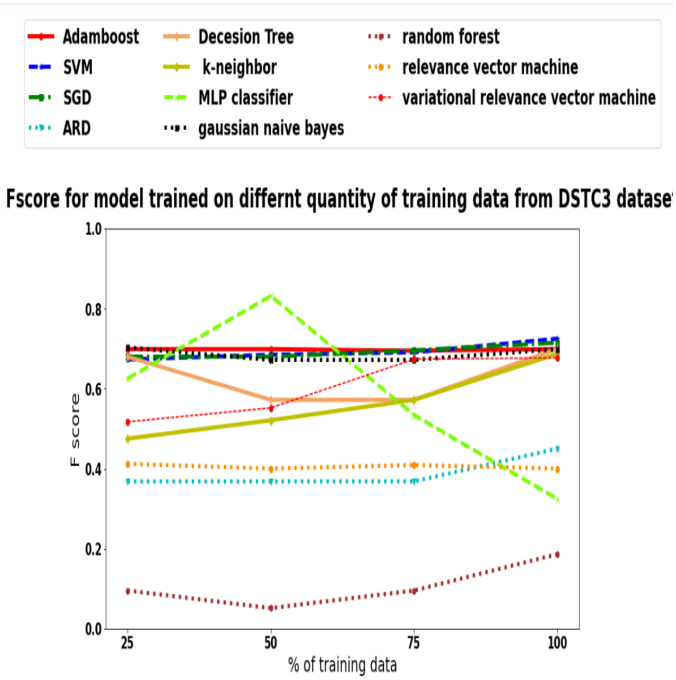

Figure 8: Testing data F-score for a model trained on 25% training data, 50% training data, 75% training data, and 100% DSTC 3 training data.

The results for SLU model performance on the DSTC3 dataset are shown in Figure 8. The results are again similar to the DSTC2 dataset. F-score was high for SLU when incorporated SGD, SVM, VRVM, and decision tree. Low F-score was displayed by SLU when incorporated RVC, RF, and ARD.

Variation in ICE for SGD and SVM when SLU is trained for least and highest train data is 0.296 and 0.209 for the DSTC2 dataset and 0.190 and 0.190 for the DSTC3 dataset, respectively. The least variation in ICE was found for SVM and SGD. Thus, the set of classifiers showing robustness under limited training data for ICE metrics are SVM and SGD. Variation in ICE for MLP and Gaussian naive Bayes when SLU is trained for least and highest train data is 1.95 and 1.45 for DSTC2 and 2.251 and 0.18 for DSTC3 dataset, respectively. The highest variation in ICE was found for MLP and Gaussian naive Bayes. Thus set of classifiers showing the worst result for ICE are MLP and Gaussian naive Bayes.

Table 1: Results on DSTC2 dataset

S.No	Classifier	ICE	Accuracy	F-score
1	Adamboost	1.861	0.863	0.848
2	SVM	1.191	0.940	0.855
3	SGD	1.100	0.960	0.868
4	ARD	4.02	0.788	0.311
5	Decision Tree	2.107	0.955	0.849
6	k-neighbor	2.765	0.873	0.694
7	MLP classifier	3.224	0.894	0.696
8	gaussian naive Bayes	5.03	0.842	0.623
9	random-forest	2.916	0.773	0.243
10	RVC	3.053	0.799	0.540
11	VRVM	1.405	0.939	0.827

Table 1 shows the results for the DSTC2 dataset. Table 2 shows results for the DSTC3 dataset for the tourist domain. Comparison of accuracy, F-score and ICE from table 1 and table 2 can be studied.

Table 2: Results on DSTC3 dataset

S.No	Classifier	ICE	Accuracy	F-score
1	Adamboost	3.723	0.847	0.699
2	SVM	3.180	0.916	0.725
3	SGD	2.999	0.900	0.715
4	ARD	4.380	0.850	0.450
5	Decision Tree	3.458	0.901	0.700
6	k-neighbor	3.499	0.896	0.687
7	MLP classifier	3.780	0.783	0.324
8	gaussian naive Bayes	3.721	0.847	0.699
9	random forest	4.179	0.828	0.186
10	RVC	4.375	0.884	0.400
11	VRVM	0.311	0.897	0.677

The results from table 1 and table 2 are analyzed to find the classifier performing best and worst. The lowest ICE results are obtained by SLU incorporating SGD and SVM when evaluated on both DSCT2 and DSTC3 datasets. The highest accuracy is obtained by SLU incorporating SVM and SGD for DSTC2 and DSTC3. The highest F-score is obtained by SLU incorporating SVM and SGD for DSTC2 and DSTC3.

6. Conclusion

The work extends the classification algorithm in machine learning to the semantic decoder in SLU. Experimental results on both the DSTC2 database for the hotel domain and the DSTC3 database for the tourist domain had similar findings. The SLU's robustness for data scarcity was measured by three evaluation

metrics: accuracy, ICE, and F-score. The SLU model was trained at 25% data (least training data), 50% data, 75% data, and 100% data (highest training data). The work indicates three important findings from the results obtained from experimentation. The first finding is that both the databases are displaying variation in SLU performance for different classifiers indicating SLU performance is influenced by the selection of proper classifiers. The second finding is that there is variation in ICE for least and maximum training data for all the classifiers indicating ICE is highly influenced by the quantity of training data used to train the SLU model. The third finding is the amount of variation in ICE displayed by each classifier is different indicating the robustness of SLU to work under data scarceness is influenced by the right choice of the classifier.

Variation in ICE, accuracy and F-score for SLU incorporating SVM is 0.209, 0.007, 0.035 for DSTC2 database and 0.190, 0.018, 0.052 for DSTC3 database, respectively. Variation in ICE, accuracy, and F-score for SLU incorporating SGD is 0.296, 0.016,0.033 for DSTC2 database and 0.190, 0.010, 0.035 for DSTC3 database, respectively. Thus, the overall performance of SLU, maintaining good performance for all the three evaluation metrics, is by incorporating SVM and SGD. The overall low performance is displayed by SLU incorporating ARD, RVC, MLP, Gaussian naive Bayes, and RF.

ABSTRACT

In a radial distribution system, component failure leads to service interruption and subsequent disconnection of a few load points. An abnormal variation in the voltage levels and high power loss gives rise to reliability issues. In this work, feeder reconfiguration is performed to improve reliability, minimize voltage deviation and power loss. A Binary Particle Swarm Optimization based search function handles the reconfiguration. The goal of this search function is to identify the optimal tie switches which minimize the multi-objective function. The search algorithm based on Binary Particle Swarm Optimization is utilized to handle the reconfiguration which identifies the optimal tie switches for minimizing the multi-objective function. The effect of the various algorith parameters on the convergence rate is studied. The proposed algorithm has been tested on Standard IEEE 33 and 69 test systems and the obtained results show a boost in the system reliability.

1 Introduction

Electric distribution system (EDS) are exponentially evolving due to the increasing demand and the changing sensitivity of customers loads. An interruption in electric power supply to the customers is caused by many events such as equipment failure, faults at substations, trees and much more. These interruptions cause a severe impact in the load equipment apart from the obvious financial losses and inconvenience. It is proclaimed that the failures in the distribution system causes nearly 80% of the interruptions. The customers of the electric utility desires an interruption free reliable power supply at the end of the day, emphasizing the need for calculating the reliability of EDS.

Reconfiguration is opening and closing of sectionalizing and tie switches. The former is normally closed whereas the latter is normally open switches. The alteration of the status of the switches under normal conditions or during contingencies results in change in topology of the feeders. It reduces the cost of implementation of various protective devices while satisfying the constraints such as maintaining radial condition of the system and feeding all the buses. It has become a practice nowadays to implement distributed generators along with reconfiguration to obtain better results [1]-[3]. But implementing Distributed Generation (DG) increases the overall cost of the EDS. Implementing reconfiguration will ensure that the customer does not face outages by rerouting the required power thereby enhancing reliability of the system. Voltage fluctuation of can be endured only for a brief stretch. If not, the impairment instigated in the equipment connected to the EDS would be high [4]. So reconfiguration is used to maintain the same within limits. Reconfiguration contributes to proper distribution of load and hence lower magnitude of current in the branches thereby reducing the power loss. This increases the loadability of the feeder thus contributing to the enhancement of reliability of the system.

There are several documented ways to solve for the optimal system reconfiguration, namely, heuristic, meta-heuristic and deterministic methods. Deterministic models hold no uncertainity and the output only depends on the intial state of the system and the value of the system parameters. Heuristic techniques are often greedy algorithms pursuing a local optimum instead of a global optimum even though they are problem dependent. Meta-heuristic

approaches are independent of the problem and not greedy, allowing them to perform and in-depth search of the workspace to get an optimum solution. In most cases, the parameters of interest are power loss, voltage profile and reliability. From the extensive literature cited in this work it is seen that employing meta-heuristic methods are techniques has been a recent trend in the research field.

In [5]-[14] an objective function has been developed consisting of both reliability indices and loss in models with and without a DG while [15]-[18] involve loss reduction and voltage profile improvement. Since 1980, Genetic algorithm(GA) which is classified as an evolutionary algorithms is widely used as an optimization tool [5], [8], [19] and [20]. But it is a slow algorithm [19] as it requires decent sized population and a number of generations to see good results whereas Particle Swarm Optimzation (PSO) entails small quantity of ciphering time not counting the better accuracy in results in contrast to GA. In [8] an Enhanced GA is presented that can resolve the reconfiguration of the feeder proficiently and sturdily with fewer iteration and time. A novel Micro genetic algorithm with reduced number of efficient solution which works well for multi-objective functions is presented in [6].

The technique shown in [7] adopts an Analytic Hierarchy Process for decision making with multiple criteria analysis. In the work presented in [9], Dynamic programming is used to find minimal cutsets and a search based technique for reconfiguration to attain the ideal set of switches has been articulated for RDS using DG. In [11] reconfiguration is solved using a novel Imperialist Competitive Algorithm which intensifies the exploration ability.In [14] the randomness in the reliability data is taken into account and has introduced a robust approach. In [3] a CRO algorithm to deal with complex network reconfiguration with DG present is taken. Different versions of Particle Swarm Optimization (PSO) is used in [10], [15], [17], [19], [21]–[24] where [15] and [23] takes another step by hybridizing PSO with Ant Colony Optimization and Evolutionary Programming respectively, for reconfiguration for various objectives. This algorithm provides better results faster in comparison to the other algorithms.

The contribution of this paper is the enhancement of reliability indices by performing an optimal reconfiguration of the distribution system using a modified version of PSO. The objective function involves minimization of Reliability index SAIDI, Voltage Deviation and Power loss. Four other reliability indices are calculated as well. The influence of certain parameters in PSO are determined using a MATLAB simulation environment and the results prove the validity of the proposed concept.

2 Problem Formulation

Reliability is the ability of a distribution system to provide uninterrupted power supply to customer [25]. Reliability indices are the benchmark parameters for evaluating reliability of the distribution system and performance of the utility. There are five standard reliability performance indices: System Average Interruption Frequency Index (SAIFI), System Average Interruption Duration Index (SAIDI), Customer Average Interruption Duration Index (CAIDI), Average System Availability Index (ASAI) and Average System Unavailability Index (ASUI) which are briefed below.

2.1 Reliability Indices

SAIFI is the average frequency of interrupt occurences that a customer experiences,

$$SAIFI = \frac{\sum_i \lambda_i \times N_i}{N_i} f/yr \tag{1}$$

where,

λ_i - failure rate(failure/year) of i^{th} load point

N_i - Number of customers at point i.

SAIDI is the average duration of interrupt a customer experiences,

$$SAIDI = \frac{\sum_i U_i \times N_i}{N_i} h/yr \tag{2}$$

where,

U_i - product of failure rate and repair rate of i^{th} load point.

Failure rate (λ_i) and Repair rate (r_i) are called load point indices and are calculated using Cutset Approach as the systen is a series-parallel system.

CAIDI is the average interruption time a consumer is affected by interruption per year. It is related to SAIFI and SAIDI indices.

$$CAIDI = \frac{SAIDI}{SAIFI} \tag{3}$$

ASAI represents the percentage of time during a year that the average customer have power.

$$ASAI = \frac{N \times 8760 - \sum_i U_i \times N_i}{N \times 8760} \tag{4}$$

It is the average system unavailability index is the contrary of ASAI and is given by,

$$ASUI = 1 - ASAI \tag{5}$$

2.2 Voltage Deviation and Power Loss

A stable voltage profile alongside low power loss is important as it directly benefits the electric utility operation and subsequently increases customer satisfaction. For this reason, it is embedded into the objective function. Voltage deviation and power loss can be calculated as follows,

$$V_DEV = \sum_{i=2}^{N} (1 - |V_i|)^2 \tag{6}$$

$$P_LOSS_i = \frac{R_i(P_i^2 + Q_i^2)}{|V_i|^2} \tag{7}$$

$$P_LOSS = \sum_{i=1}^{N} k_i P_LOSS_i \tag{8}$$

where,

P_LOSS_i is the power loss of branch i, P_LOSS is the total power loss, P_i and Q_i are the real power and reactive power of branch i, R_i and is the branch resistance, V_i is the voltage at bus i, N is the total number of branches and k_i is the status of branch i (1=close, 0=open)

2.3 Constraints

2.3.1 Failure and Repair rate constraints

$$\lambda_{i,min} \leq \lambda_i \leq \lambda_{i,max} \tag{9}$$

$$r_{i,min} \leq r_i \leq r_{i,max} \tag{10}$$

2.3.2 Real and Reactive power constraints

$$P_{G,min} \leq P_G \leq P_{G,max} \tag{11}$$

$$Q_{G,min} \leq Q_G \leq Q_{G,max} \tag{12}$$

2.3.3 Voltage constraint

$$V_{i,min} \leq V_i \leq V_{i,max} \tag{13}$$

2.3.4 Radial topology constraint

$$\varphi(L) = 0 \tag{14}$$

$\lambda_{i,min}$, $r_{i,min}$, $\lambda_{i,max}$ and $r_{i,max}$ are the limits of the values of failure and repair rate. $P_{G,min}$ and $P_{G,max}$ are the vectors of lowest and highest available real power generation whereas $Q_{G,min}$ and $Q_{G,max}$ are the vectors of lowest and highest available reactive power generation. $V_{i,min}$ and $V_{i,max}$ are the limits of the branch voltages and $\varphi(L)$ is the number of loops in the system.

2.4 Objective Function

$$Minf = w_1 \times \frac{SAIDI}{SAIDI_T} + w_2 \times \frac{V_DEV}{V_DEV_T} + w_3 \times \frac{P_LOSS}{P_LOSS_T} \tag{15}$$

Since reliability improvement is the major objective of the work, w_1 is given higher value such that,

$$w_1 + w_2 + w_3 = 1 \tag{16}$$

As the objectives have different dimension they're conveter to per-unit values. $SAIDI_T$,V_DEV_T and P_LOSS_T are the initial case values of SAIDI, Voltage deviation and Power Loss respectively. Thus multiple objectives are unified into a single objective resulting in reduced optimization load. The system condition before reconfiguration is taken as the base.

3 Proposed Method

This section presents the basics of PSO and the formulation an intelligent search method depending on PSO. All the feasible configurations of the distribution system that satisfy the objective function is presented.

3.1 Particle Swarm Optimization

PSO is a meta heuristic population based technique with its genesis from the observation of social behaviour associated with birds flocking. It can be applied to both continuous and discrete systems. In the presented problem, the switches are chosen from a discrete set for different bus systems and therefore discrete PSO is applied in this case.

The algorithm develops a population of particles each of which are a viable solution for the problem. Initially each particle is assigned a random position, velocity and objective function, X_i, V_i and F_i respectively. The evaluation is carried out using positional coordinates and population size as the input. Each particle has a follow up of its position and the best value acquired so far and is stored in P_{best}. . In the meantime the overall best value produced so far by any particle is stored as G_{best}.

$$w = w_{max} - \frac{w_{max} - w_{min}}{iter_{max}} \times iter \tag{17}$$

The interia of the particles has an impact on the future velocities of the particles. Experimentally it is observed that decreasing the value of inertia over the iterations causes exploration and exploitation to occur linearly. Number of particles in the swarm is represented by n. Smaller value takes large number of iterations to converge whereas high value cause a rise in computational complexity and time consumed. So a suitable value is chosen.

$$v_{ij}^{t+1} = w \times v_{ij}^t + c_1 r_{1j}^t [P_{best} - x_{ij}^t] + c_2 r_{2j}^t [G_{best} - x_{ij}^t] \tag{18}$$

where,

v_{ij}^t - particle velocity

x_{ij}^t - particle position

c_1 - cognitive parameter

c_2 - social parameter c_1 and c_2 represents the weights of the stochastic acceleration term that pulls the particles towards P_{best} and G_{best} respectively.

r_1 and r_2 are random values in the range [0,1].

The particles coordinates are updated using the sigmoidal equation,

$$s_{ij}^t = \frac{1}{1 + e^{-v_{ij}^{t+1}}} \tag{19}$$

The *ciel* of the function converts the continuous to discrete values. It is further modified according to the problem at hand to choose the values from a particular set of values. In our work, the set of values corresponds to the switches that are to be opened for reconfiguration from the array of switches from each loop of the bus system if the tie lines are closed.

3.2 Algorithm

1. Add Load bus data, line data maximum iterations and switch value matrix. Initialize population, position, random velocities, P_{best}, G_{best}.
2. Calculate inertia, update velocity and particles coordinates.
3. Check radiality constraint and calculate fitness. Power loss and voltage deviation are calculated from load flow solution. Reliability is calculated using the concept of cutsets.

Backward Forward Sweep Algorithm is used as the load flow solution.

4. Update P_{best} if the fitness function is lesser than the previous value.
5. Update G_{best} if the fitness function is lesser than the previous value.
6. If there is no criteria match, update particle velocity using the previous velocity, distance to P_{best} and distance to G_{best} in the equation
7. Update particle position from provided switches.
8. Terminate if the maximum iterations is reached. Go to step 3. The flowchat of the proposed algorithm is shown in Figure 1.

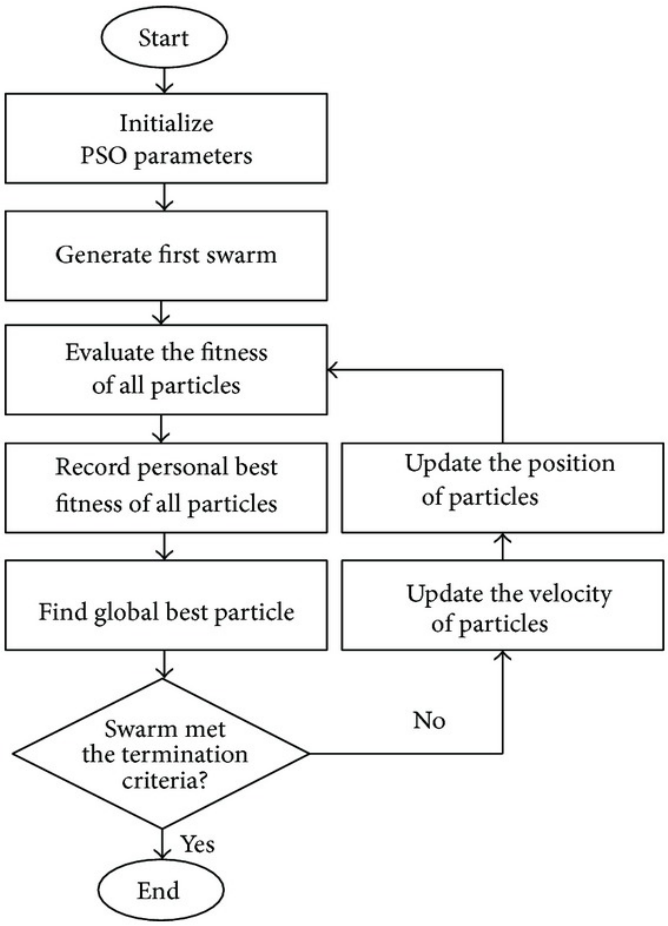

Figure 1: Flowchart of Proposed PSO

4 Results and Discussion

The IEEE 33 and 69 bus system data is presented in [10]. The failure rate and repair rate for the same is presented in [20]. The proposed method is implemented on the test cases and and the effectiveness is tested for the given objective function. Each load point is assumed to have one customer. Four different cases is made out of the objective function presented in Eq.15 with different weightage to each objective but with heighest weightage to SAIDI.

1. Case 1: $w_1 = 1.0$, $w_2 = 0$ and $w_3 = 0$
2. Case 2: $w_1 = 0.75$, $w_2 = 0$ and $w_3 = 0.25$
3. Case 3: $w_1 = 0.75$, $w_2 = 0.25$ and $w_3 = 0$
4. Case 4: $w_1 = 0.5$, $w_2 = 0.25$ and $w_3 = 0.25$

4.1 33 Bus System

It has a voltage rating of 12.7kV with a constant power load of (3.715 +j2.3) MVA. It is generally used to evaluvate the distribution reconfiguration problem. Figure 2 shows the single line diagram for a 33 bus system. In the base configuration, the solid lines represent the NC switches (1 through 32) and the dotted lines represed the NO switches (33 through 37).

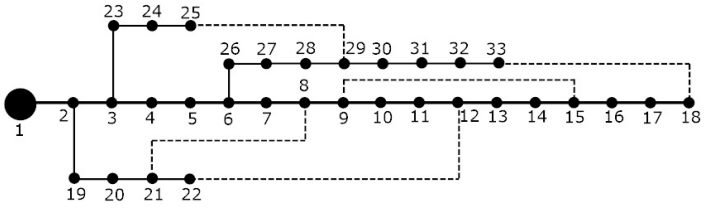

Figure 2: 33 bus system before reconfiguration

4.1.1 Case 1

The main objective of this case is to minimise the reliability index, SAIDI, which is used to find how reliable the system is. The algorithm is trained using this test case in order to find optimal solutions in the upcoming cases for the multi-objective function. For comparison purposes, the values of the indices of the base case is calculated.

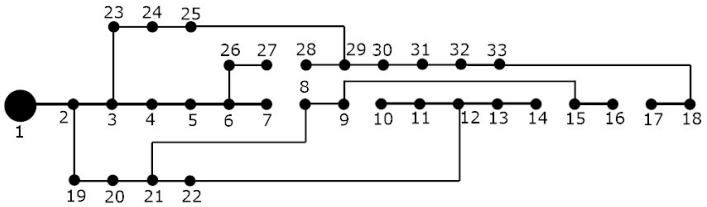

Figure 3: 33 bus system after reconfiguration (Case 1)

Figure 3 shows the bus system post reconfiguration. In this case a drop of 0.8769 p.u for duration index which is a 40% reduction from the original value making the system highly reliable. The Table 1 shows the best possible values, w_{min}, w_{max} and population size. A value of population swarm between 40 and 50 reduces the convergence time. The fitness function converges in the 6_{th} iteration when population is randomized and in the 8_{th} iteration when inertia is randomized.

Table 1: PSO parameters - 33 bus system

Parameter	Value
w_{min}	0.2
w_{max}	0.9
Population	48

The Voltage deviation and power loss have shown a reduction of 24% and 55% for the reconfigured system even without giving weightage to the same as shown in Table 2. Power loss and voltage deviation has shown drastic reduction in its values in spite of not giving weightage to them in this case thus concluding on the fact that all the three objectives are interrelated.

4.1.2 Case 2

The values of the parameters, inertia weight (minimum and maximum) and population of the swarm, are fixed for cases 2, 3 and 4. From Table 2 it is clear that with a 0.5% sacrifice of SAIDI, the voltage deviation and power loss values have been lowered by additional 4% and 2% respectively in comparison with the results of case 1. As shown in Figure 4 the system is radial post reconfiguration.

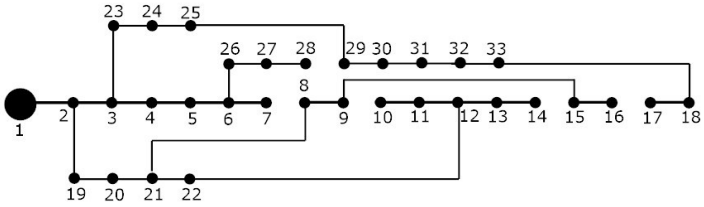

Figure 4: 33 bus system after reconfiguration (Case 2)

4.1.3 Case 3

It was found that the results of Case 3 is identical and hence the single line diagram is not repeated. The loss is reduced by an additional 4% when compared to case 1 while giving up only a 0.5% in SAIDI value with respect to case 1.

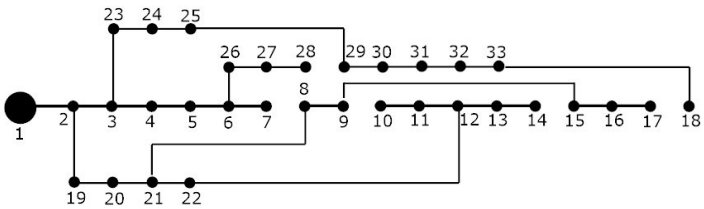

Figure 5: 33 bus system after reconfiguration (Case 4)

4.1.4 Case 4

It can be seen that a further reduction of 4kW power loss in comparison to the previous two cases. Voltage deviation has also reduced by an extra 2% when compared to the past two cases along with the betterment of minimum voltage in the system. Hence it is proved that the system is highly reliable with power loss and voltage deviation improved drastically. Figure 5 displays the bus system configuration after reconfiguration. Due to space issues, Voltage profile and Convergence graph of the final case is alone shown in Figure 6 and 7 to picturize the improvement in the voltage profile and the efficacy of the proposed method.

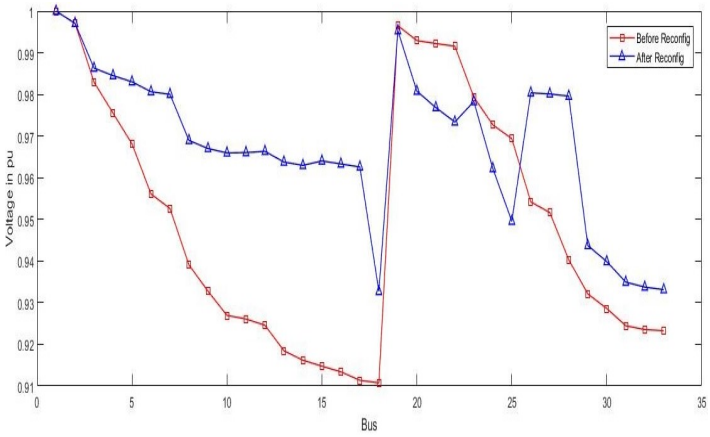

Figure 6: Voltage Profile pf 33 Bus System (Case 4)

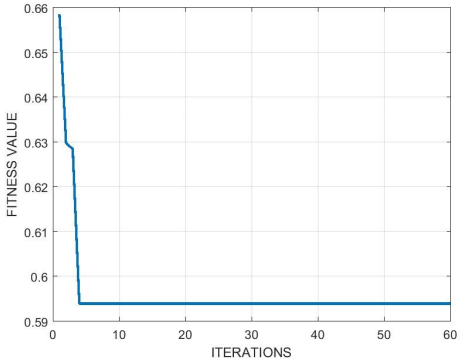

Figure 7: Convergence graph of 33 Bus System (Case 4)

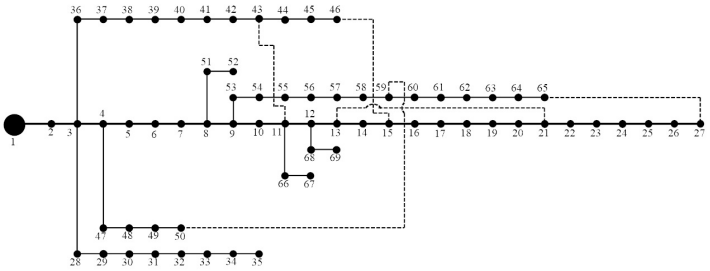

Figure 8: 69 bus system before reconfiguration

4.2 69 Bus System

The proposed topology is tested on a IEEE Standard 69 Bus system. This system has a rated voltage of 12.7kV.NO switches are 69 through 73 as in Figure 8. The reliability indices before reconfiguration are recorded by applying the algorithm to the base case of the 69 bus system. Other than the zero injection buses, each load

Table 2: Consolidated Results of 33 Bus System

INDICES	BASE CASE	CASE 1	CASE 2	CASE 3	CASE 4
TIE SWITCHES	33,34,35,36,37	7,9,14,16,27	7,9,14,16,28	7,9,14,16,28	7,9,14,17,28
SAIFI	2.5741	2.2675	2.258438	2.258438	2.308125
SAIDI	2.2291	1.3522	1.362656	1.362656	1.405469
CAIDI	0.86597	0.59633	0.603362	0.603362	0.608922
ASAI	0.99975	0.99985	0.999844	0.999844	0.99984
ASUI	0.00025446	0.00015436	0.000156	0.000156	0.00016
V_DEV (%)	2.8945	1.3137	1.20724	1.20724	1.137742
P_LOSS (kW)	202.7142	154.2636	150.2211	150.2211	146.3066
V_MIN (p.u)	0.9131	0.9276	0.9291	0.9291	0.9327

point is assumed to have one customer. The Inertia and Population are randomized separately and run hundreds of iterations to arrive at the best values. The values obtained as shown in Table 3 further implicate that w_{min}, w_{max} should be chosen with a difference of 0.5 for accurate results and reaffirms that population value within [40,50] holds the best results.

4.2.1 Case 1

Apart from SAIFI and SAIDI other indices such as CAIDI, ASAI and ASUI are found for base case in order to compare the results of all the cases. The switches that are to be opened post reconfiguration are {14, 18, 56, 64, 69}. When the switches are compared with the failure and repair rate, it is found that the branches with maximum failure rate are opened so that the values of the indices drop according to the Eq. 1 and Eq. 2. Table 4 shows that there is a major cutback of 0.7431 p.u which is 28.8% for SAIFI and 0.3804 which is 22.28% for SAIDI. Values of all the indices are shown as well. The power loss and voltage deviation is determined for the reconfigured system. Loss before and after reconfiguration presents a substantial drop of 47.11%. Voltage deviation has reduced by 71.2%. Figure 9 represents the 69 bus system after reconfiguration maintaining radial topology and its load evened out.

4.2.2 Case 2

In this case duration and voltage deviation are optimized. SAIDI plummeted by a 21% while voltage deviation which was given a weightage of 0.25 in the objective function dropped by 2.49 p.u which is nearly 74% with respect to base improving the voltage profile substantially and thereby improving overall reliability of the power system. Power loss for the above configuration was 119.6465kW which an improvement from the previous case highlighting the impact of better voltage profile on power loss. Figure 10 represents the 69 bus system after reconfiguration maintaining radial topology.

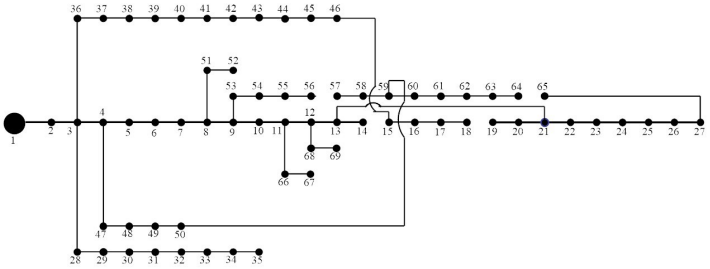

Figure 9: 69 bus system after reconfiguration (Case 1)

Table 3: PSO parameters - 69 bus system

PARAMETER	VALUE
w_{min}	0.2
w_{max}	0.7
Population	46

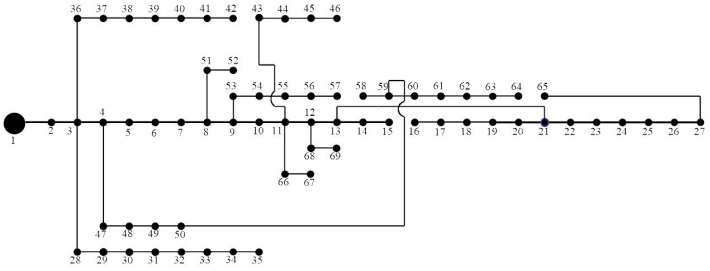

Figure 10: 69 bus system after reconfiguration (Case 2)

4.2.3 Case 3

This case involves optimizing SAIDI and Power loss with a weightage of 0.75 and 0.25 respectively. Table 4 shows the result after

reconfiguration and it is found that loss has reduced to 106.7573kW even though SAIDI raised by a value of 0.04. The voltage deviation calculated after reconfiguration was 0.8958 which is just a 0.02 p.u rise while the loss has reduced considerably. The minimum value of voltage has improved due to minimized power loss. This helps the sensitive equipment from falling a prey for low voltage conditions and hence improves the reliability of the system. Figure 11 represents the 69 bus system after reconfiguration maintaining radial topology.

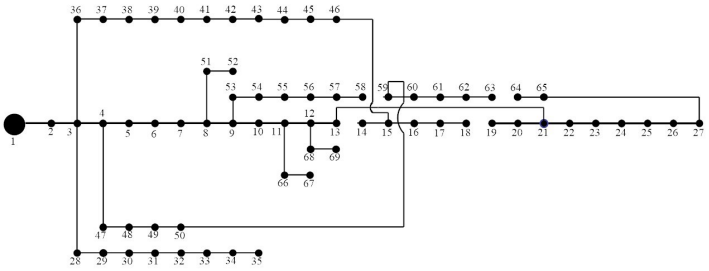

Figure 11: 69 bus system after reconfiguration (Case 3)

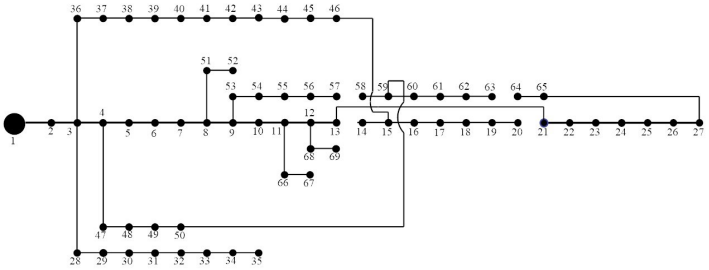

Figure 12: 69 bus system after reconfiguration (Case 4)

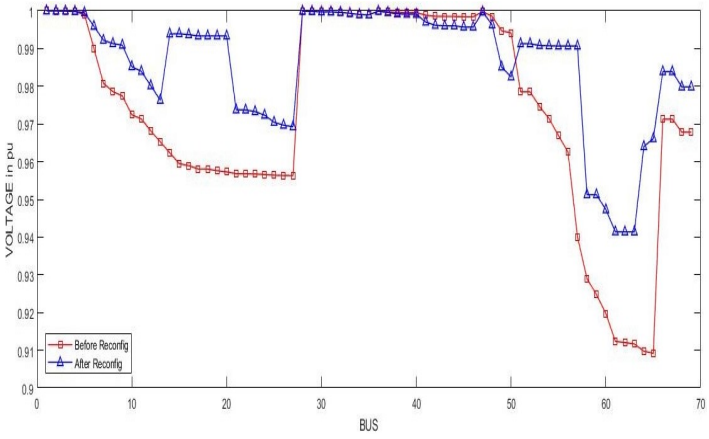

Figure 13: Voltage Profile of 69 Bus System (Case 4)

4.2.4 Case 4

This case includes all the three objectives with equal weightage to voltage deviation and power loss of 0.25 and reliability index SAIDI holding higher importance with weightage of 0.5. It is clearly seen from Table 4 that all three objective functions have their values reduced from case 3 giving us the best possible combination of switches under the above condition. The minimum voltage stays the same as previous case but overall voltage profile has improved. In comparison to the base case there is a drop of 20.4%, 73.45% and 52.57% in SAIDI, Voltage deviation and Power loss respectively as shown in Table 4. Figure 12 sketches the 69 Bus System with loads distributed and following the radial topology constraint. Figure 13 shows the pictorial representation of the improvement in voltage profile while Figure 14 supports the claim of high convergence rate in the proposed method.

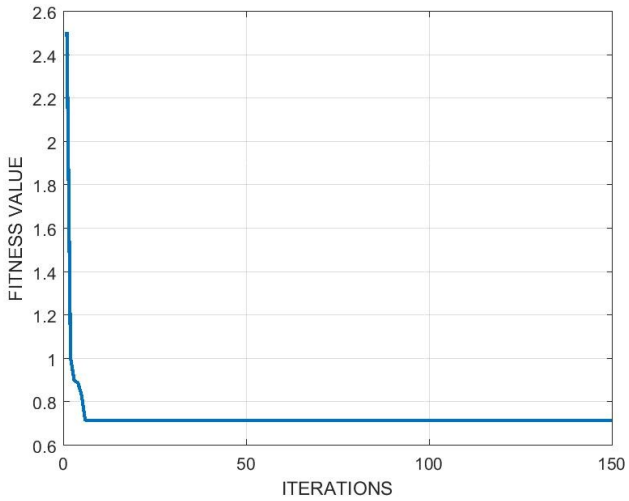

Figure 14: Convergence graph of 69 Bus System (Case 4)

5 Conclusion

This work presents a method for reliability improvement of Radial Distribution System through feeder reconfiguration. It is constructed based on Particle Swarm Optimization. The radial topology is conserved using the graph theory function in MATLAB. The load point indices such as failure rate and repair rate are calculated using Cut-set concept. The reliability indices are calculated using theoretical formulae. Power loss and Voltage deviation is computed by utilizing Backward-Forward Sweep algorithm.

The Inertia weight and Population values in the proposed algorithm clearly influences the accuracy of the results and the time to taken to obtain the same as it regulates the exploration and exploitation of the search space.

In single objective function, the switch selection for reconfiguration solely depends on the values of the load point indices (λ_i & U_i) and hence switches with highest values of the indices are opened. This results in cutting down the number of load points in the longest branch and distributing them to other branches.

In multi objective function, the switch combination chosen not only depends on the failure rate and repair rate of the load points but also on the voltage and power loss. This results in minor increase in the SAIDI and other reliability indices but it improves the voltage profile aiding the loads connected the system. It takes some demand of the utility system due to reduced power losses.

ABSTRACT

Sign language is a form of communication language designed to link a deaf-mute person to the world. To express an idea it requires the use of hand gestures and body movement. However, the bulk of the general population remain uneducated to understand the sign language. Therefore, a translator is required to facilitate the communication. This paper wishes to extend the previously proposed Convolutional Neural Network (CNN) model for predicting American Sign Language with a MobileNetV2-based transfer learning model. The latter model effectively generalized on a dataset which is around 18 times larger with 5 additional groups of hand signs. Over 98% of the recognition accuracy had been reported. Because of its relatively fewer parameters and less intensive computational operations compared to other deep learning architectures, the model was also ideal to be implemented on mobile devices. The model will serve as the key to deploying a sign language translator software on smartphone to enhance communication efficiency between the deaf-mute person and the general public.

1 Introduction

This paper is an extension of work originally presented in conference IEEE International Conference on Signal and Image Processing Applications (ICSIPA) 2019 [1]. The work was enhanced in the following aspects:

1. Dataset: Previous study used only 4800 images with 24 groups of self-collected images except for letters J and Z, since both signs require movement. Furthermore, all images were taken from a fixed distance, which is not generally the case when it comes to actual application. The sign performer can appear at different distances from the smartphone camera. In this paper Kaggle's dataset was used. Each sign has variations in capturing distance and brightness. There are a total of 87,000 images with 29 classes. In addition to the 26 classes belonging to letter A-Z, there are an additional 3 classes for SPACE, DELETE and NOTHING. As per the description of the dataset, these 3 classes are found to be useful in real time application and classification.
2. Method: Previous proposed shallow network failed to generalize well with this new ~18x larger dataset. Instead, transfer learning using MobileNetV2 was implemented. Unlike other deep learning models, the MobileNetV2 gives high prediction accuracy without penalizing too much on computational cost and memory. This met our original intention to have this model deploy as a mobile application in the future.

Spoken language binds a significant section of the population. The spoken language would not, however, support the deaf and mute population. Statistics from the World Health Organization (WHO) shows there are at least 5% or 466 million of people suffer from hearing impairment [1]. An individual with hearing impairment may have a distorted speech or may not speak at all. This creates a barrier to contact between them and the society.

Fortunately, sign language comes to help for this special group of people. It is a kind of visual communication language that uses a combination of hand gesture, facial expression and body posture. It helps the hearing-impaired communities to express their feelings and addresses the general communication issues within their communities.

The sign language is completely different from spoken language. It has its own syntax and the way it expresses itself. For the general population this may be difficult to understand and practice [2].

[*]Corresponding Author: Kin Yun Lum, Department of Mechanical Engineering, Faculty of Engineering and Technology, Tunku Abdul Rahman University College, Kuala Lumpur, Malaysia, lumky@tarc.edu.my

Moreover, most general public are illiterate to sign language. Unless they are surrounded by a deaf-mute person, most appear to be uninterested and disregard the meaning of sign language. This presents a real barrier of contact between the deaf-mute community and the rest of society, as a issue which has yet to be completely resolved.

Innovations of technology in the area of sign language recognition try to break down this communication barrier. To date, it addresses the issues mainly with two different approaches: 1) Sensor based system 2) Vision based system [3].

The sensor based system is a wearable device which utilizes various sensors to capture motion, spatial positions and velocity of the hand. For example, cyber glove is a wearable device that employs flex sensor to detect fingers movements and Inertial Measurement Unit (IMU) sensor to track the hand motions [4]. There are also invasive and non-invasive electromyography (EMG) wearable sensors system to measure human muscle's electrical pulses and collect the bio-signal to detect fingers movements [5, 6]. These wearable system can be costly, cumbersome, inconvenient, heavy and uncomfortable for daily use.

Vision based system has recently become increasingly popular because there is no need to attach sensors physically to the human. There are attempts to use Leap Motion Controller [2] and Microsoft Kinect which have depth sensor [4, 7, 8] to construct the sign language recognition system. However, such technology is not widely accessible and it can be expensive to the users. Furthermore, the systems were implemented using desktop or laptop computer, which is impractical because of its weight and size.

Since hand sign gestures are perceived through vision, computer vision can be a subject of profound interest. One of the solutions is to build a vision based sign language recognition system with the commonly available smartphone camera. Vision-based systems are historically prone to reliability issues. Background noise, colours, and lighting are greatly varied under actual environment. This would result in a lower rate of detection. The latest advance in computer vision and machine learning technologies has shown considerable progress in the classification of images [9, 10]. In the competition for image classification, the algorithm called Convolutional Neural Networks (CNNs) and its derivative networks such as AlexNet, GoogleNet and ResNet achieved more than 90% accuracy [11]. Conventional machine learning relies on manual features extraction. Instead of creating complex handcrafted features, CNNs will automate the feature construction process. That would significantly reduce human error and increase the accuracy of detection.

There are several studies using CNN for the identification of American Sign Language (ASL) but the findings are not satisfactory [12]. Furthermore, while some deep networks may offer high classification accuracy, a large number of parameters and heavy mathematical operations limit their application in smartphones.

Our aim is to develop a computer vision system that can use mobile camera to recognize sign language, so that it can be used everywhere and anywhere. Previous attempt to create a CNN network to recognize 24 classes of sign language has demonstrated a detection accuracy of 95% experimentally. This paper extends the work to draw on a much larger dataset in order to enable greater generalization. The larger dataset contains 5 more classes than the previously used dataset. It included all 26 alphabets and another 3 classes for the sign of SPACE, DELETE and NOTHING to make the whole sign language model more complete. In addition, this dataset has also images which were captured at different distance from the camera, which may reflect a real-life application more closely. Transfer learning using MobileNetV2 was implemented to further improve the model accuracy to more than 98%.

The remainder of this paper is structured as follows: the relevant works will be discussed in Section 2. Followed by the section 3 concept and theory that will address the different CNN architectures and put emphasis on MobileNet, which is the transfer learning model to be implemented in this paper. Dataset description and preprocessing will be described in the methodology in Section 4. Then we will detail our model architecture and setup of experiments. The section ends by showing some evaluation metrics that we used to measure the performance of our model. Section 5 addresses experimental findings with discussions. Lastly, Section 6 ends with the conclusions of this paper with some suggestions for future study.

2 Related Works

The works related to vision based sign language recognition system can be categorized into two, which are non-CNN and CNN approaches. The non-CNN approaches were mainly the traditional methods which involved manual feature extraction and classification. The involved classification algorithms were k-nearest neighbors (KNN) and Neural Network [13, 14]. These approaches normally had lower reported prediction accuracy. On the other hands, the CNN approaches that had better reported results were either proposing their custom CNN models [7, 8, 15] or implementing transfer learning [11, 12, 16, 17]. There was also literature which compared both their custom CNN model and transfer learning [18].

For custom CNN models, Vivek Bheda et. al. used a deep convolutional network to classify ASL with alphabets and digits. The proposed network had 3 cascaded convolutional layers and 1 max-pooling layer. There are two hidden layers with dropout before connecting to the output layer. Accuracy of 82.5% had been reported [7].

Ameen. S. et. al. separated the image and depth information from Microsoft Kinect input and used two convolution layers to perform feature extraction on each of them. Both extracted feature maps were combined in the second stage of convolution before passing to the classifier. The reported precision and recall were 82% and 80% respectively [15].

Similar architecture was used by Pigou. L. et. al. to extract hand features and upper body features separately from Microsoft Kinect dataset. Each CNN was three layers in depth. They had reported an accuracy of 91.7% [8].

For transfer learning, Das, A. et. al. used Inception v3 on custom processed static gesture images and obtained an average validation accuracy of 90% [16]. Alashhab. S. et. al. tested on VGG16, VGG19, ResNet, Xception, Inception V3, MobileNet and SqueezeNet. They were dealing with hand gestures detection instead of sign language. There were 5 classes of hand gestures used. The highest accuracy of transfer learning usign MobileNet was 99.45% [11]. Kania, K.et. al. build a network to recognize ASL with reference to the Wide Residual Networks. Data augmentation was used to increase the number of training sets and reported a high-

est accuracy of 93.3% [12]. Garcia and Viesca used GoogLeNet architecture to recognize 24 classes of sign language with only 70% or reported accuracy [17]. As far as our literature, there was only one work to compare custom CNN model and transfer learning done by Bousbai, K. and Merah, M. Their training set had 1815 coloured images with black background collected from five volunteers. Their custom CNN had a reported efficiency of 98.9%, slightly surpassed the transfer learning model with 97.06% accuracy [18].

In general summary, transfer learning can perform better than most of the custom CNN model when come to pure image recognition. Custom model is only needed usually to cater for the extra input like depth information. Transfer learning model specially designed based on pure images dataset like ImageNet might not doing as good as the custom model. Other than this reason, transfer learning is a more appropriate solution to develop a well performing model. Therefore, it is being used in this paper to enhance the results of our previous work.

3 Concept and Theory

3.1 Convolutional Neural Network (CNN) Architecture

Convolutional Neural Network (CNN) has proven to be very effective to handle image classification problems. It is in use by many industry leaders such as Amazon, Google and Facebook [8]. The convolution layers in the CNN perform multiple discrete convolutions on the input with defined number of trainable weights filters. The filters' weights were updated during training. After applying filtering on each channel, it will capture the image features such as lines, edges, colors and other visual elements. The deeper the network goes, more complex features like shapes and patterns can be generated. Combining all these features together with the activation functions can produce feature maps which can then pass to the ordinary neural network classifier to correctly classify the object.

Due to significant progress has been achieved in image classification, there were various CNN architectures introduced such as VGG16, ResNet and Inception Net. These models were trained and verified on large-scale annotated datasets like ImageNet and proven to be effective. Instead of constructing the CNN from scratch, leverage on the transfer learning on these architectures can significantly reduce the time required to produce a working model for a particular problem. Moreover, since these models were trained on ImageNet which consists of 1.2 million categorized natural images of 1000+ classes. Using the trained weights as a starting point will definitely help the model to converge faster as compared to training from scratch. As discussed by Shin, H. C. et. al, even though there is a disparity between the ImageNet and our sign language images, the deep architecture which is trained comprehensively can as well generalize on other specific domain problem with only minor fine-tuning training [19]. Among different CNN architectures, MobileNet was employed in this paper because it is an efficient network architecture designed to run on any computationally limited platform.

3.2 MobileNetV1

MobileNet had been introduced as a small networks and it is optimized for latency to match the restricted resource application such as in mobile devices, robotics and self-driving vehicles. These application platforms are not as powerful as a general purpose computer, but still requires comparable recognition accuracy under a timely computation.

Unlike other network architectures use shrinking or compression to reduce its size and in return to improve on computational costs, MobileNet was completely rebuilt using depthwise separable convolutions. Depthwise separable convolution is a form of factorized convolutions which decomposes a conventional convolution into a depthwise convolution and a pointwise convolutoin. This factorization ends up reducing computation cost and model size drastically. The rationale behind this is to reduce the costly convolution process due to multiple multiplication as explained below [20].

Examine a standard convolution process, let an input image, F of dimension $D_W \times D_H \times M$ where D_W and D_H correspond to the spatial width and height of the input image and M is the number of input channels (depth). There are N numbers of square filters, K with size of $D_K \times D_K \times M$ where $D_K$is the spatial dimension of the kernel. An example of standard convolution with an input matrix with channel, $M = 3$ and N number of 3×3 kernels is illustrated in Figure 1a. All the convolution processes discussed in this section are assumed to have stride of one and padding. This standard convolution between F and N numbers of K will have a computational cost of:

$$J_c = N\left[(D_W \times D_H) \times (D_K \times D_K \times M)\right] \tag{1}$$

The MobileNet addresses this issue by splitting the convolution process into two steps, namely depthwise convolution and pointwise convolution. The whole process is called depthwise separable convolution. In the depthwise convolution process, instead of using kernel with depth M, single layer kernels are applied on each input channel as showed in Figure 1b. This results in a computational cost of:

$$J_d = M\left[(D_W \times D_H) \times (D_K \times D_K)\right] \tag{2}$$

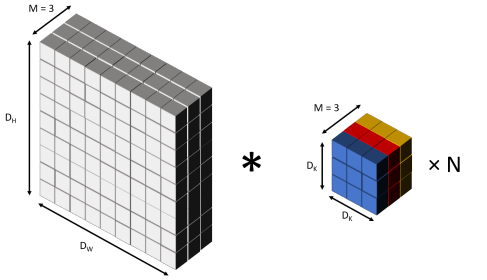
Then, pointwise convolution is performed on the output of the above depthwise convolution feature map. Pointwise convolution is being done by N number of 1×1 kernels with depth of M. This process is also called linear combination since the output matrix is of summation of linear scaling multiples. An pictorial illustration of this process is shown in Figure 1c. The computational cost of the pointwise convolution is:

$$J_p = N\left(M \times D_W \times D_H\right) \tag{3}$$

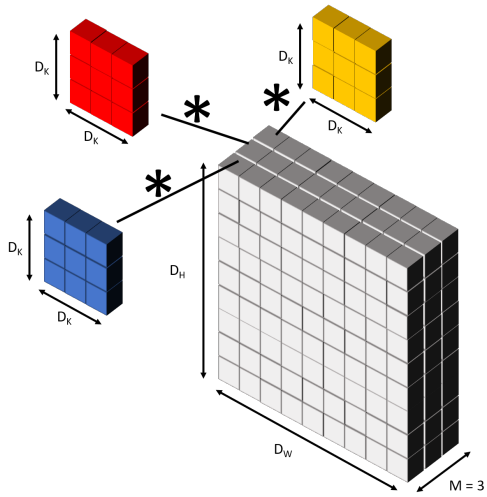
The total computational cost of a complete depthwise separable convolution is $J_{dp} = J_d + J_p$. Comparing to the standard convolution, there is a reduction factor of:

$$J_r = \frac{J_{dp}}{J_c} = \frac{1}{N} + \frac{1}{D_K^2} \tag{4}$$

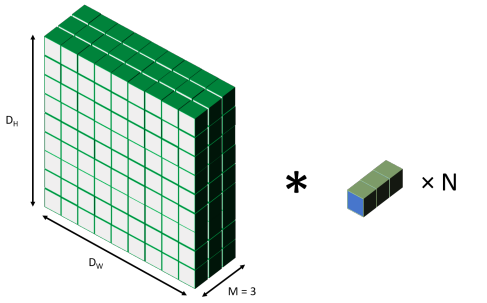
For a depthwise separable convolution with 3×3 kernels used, the computational cost can be 8 to 9 times lesser with only minor trade-off in accuracy [20].



(a) Standard convolution



(b) Depthwise convolution



(c) Pointwise convolution

Figure 1: Comparison between (a) Standard convolution (b) Depthwise convolution and (c) Pointwise convolution

3.3 MobileNetV2

MobileNetV2 is an improved version of MobileNetV1. MobileNetV1 or most deep convolution network uses the Rectified Linear Unit (ReLU) activation function defined by

$$f(x) = \begin{cases} x, & \text{if } x \geqslant 0 \\ 0, & \text{if } x < 0 \end{cases} \tag{5}$$

The ReLU activation function disregards any values smaller than 0. This non-linear transformation is argued to result in the loss of information, especially on input with a lower number of channels. ReLU may have less impact on input with lots of channels because the missing information in particular activation might still be preserved by other channels [10].

To tackle this issue, MobileNetV2 uses a narrow -> wide -> narrow approach in its inverted residual block. The low-dimensional input is first expanded by using a pointwise 1×1 convolution to produce a higher dimensional space which can cater for the information loss caused by the ReLU activation. Then, spatial filtering using depthwise convolution with ReLU activation was implemented in this higher dimensional feature map. Finally, another pointwise convolution was performed to project back to a lower dimensional output feature map. For the last step, linear activation instead of ReLU was used to preserve more information when encoding to a lower dimensional output map. This idea was called linear bottleneck by the authors. The non-linear transformation only happened in the internal expanded higher dimensional space inside the block. When come to lower dimensional output, linear transformation was used [10].

Besides, a skip connection similar to residual block is added between the input and output of the inverted residual block to allow gradient flow during backpropagation. This approach is essential to build a deep network. One last minor adjustment is the use of ReLU6 in this inverted residual block which capped the maximum output to 6 as defined by:

$$f(x) = min(max(0, x), 6) \tag{6}$$

The complete inverted residual block discussed in MobileNetV2 is shown by Figure 2.

4 Methodology

4.1 Dataset

Figure 3 shows the American Sign Language (ASL) for all alphabets. In the previous article, dataset was produced by smartphone camera captures [1]. There were a collection of 4800 images with 24 classes of gestures. The signs for character J and Z were excluded due to dynamic. All the images were taken from at a fixed camera distance with little lighting variation as displayed in Figure 4.

The challenge of developing a usable sign language recognition model lies in the variation in size, position, and shapes of the input image [15]. In real life applications, the sign language performer might stands at different distance relative to the smartphone camera. Provided data augmentation which is widely adopted in training CNN with limited dataset, which introduces more variations with scaling, rotating, flipping, shifting, shearing, etc. However, this image augmentation failed to reproduce the realistic perspective variations as discussed by Wenjin Tao et. al [4].

To extend the work, the dataset from Kaggle named "ASL Alphabet" was used [21] . Each sign has variations in distance capture and illumination. An example of sign B was shown in Figure 5. There are a total of 87,000 images in 29 classes. Besides the 26 classes belong to the letter A - Z, there are three additional classes for SPACE, DELETE and NOTHING. As per dataset description, these 3 classes are found to be helpful in real time application and classification.

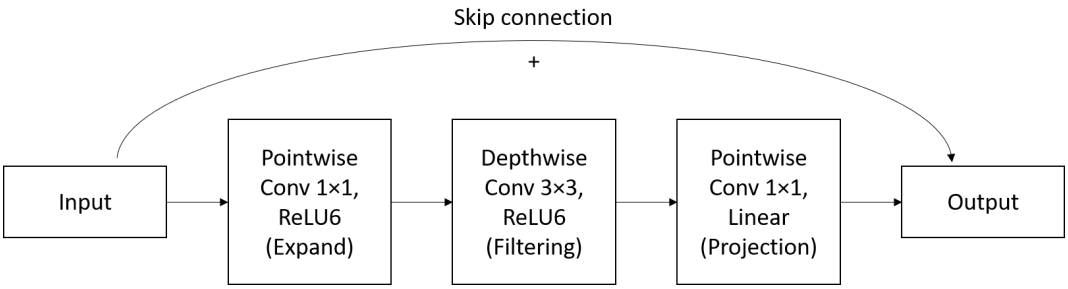


Figure 2: Inverted residual block

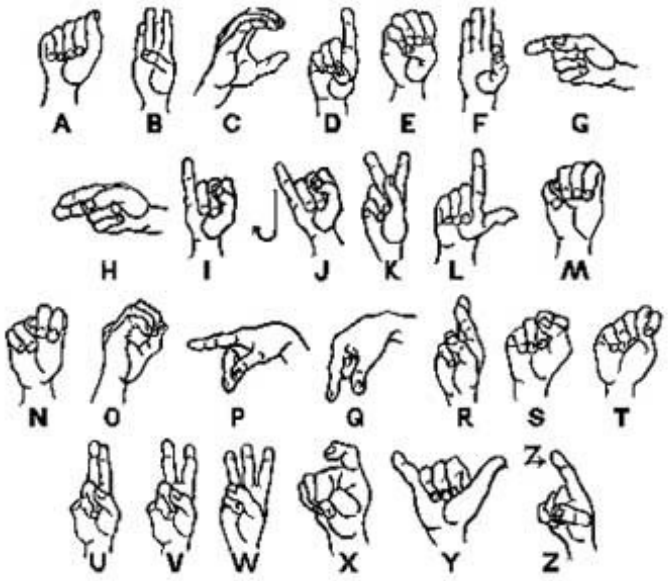

Figure 3: American Sign Language for all alphabets

Figure 4: Example self-captured dataset from previous article. From left to right (top) A, B, C and (bottom) D, E, F [1]

4.2 Model Architecture

The new dataset in this paper is approximately 18 times larger than the previous dataset. The previous proposed CNN network which had only two cascaded convolution layers failed to generalize to this dataset. The model was therefore being reconstructed using transfer learning with MobileNetV2. This CNN architecture was optimized for mobile devices to give high prediction accuracy while keeping the parameters and mathematical operations low. Compared to MobileNetV1, the MobileNetV2 is about 30 - 40% faster when tested on Google Pixel phone due to 2 times fewer mathematical operation and 30% lesser parameters. Not only that, it outperforms MobileNetV1 in terms of recognition accuracy [18].

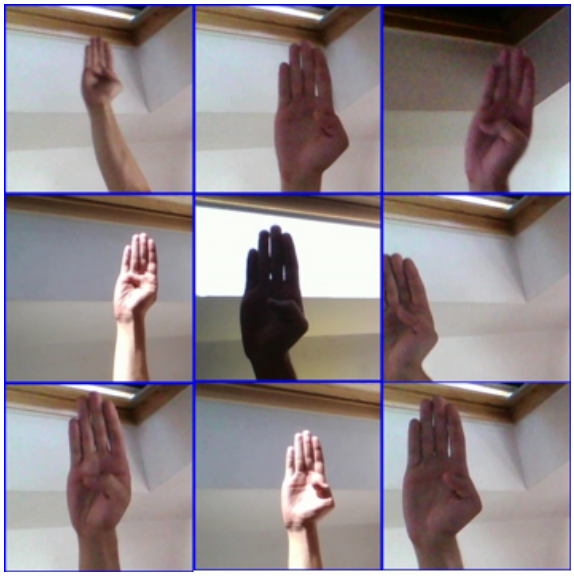

Figure 5: Example sign for letter 'B' under different capturing distance and lighting condition

All 29 classes had been used in this work. The images were resized to 224×224 pixels as suggested in the article by Samer Alashhab. et. al. [11]. Among different input sizes, 224×224 pixels gives best performance by experiment. The inputs were shuffled randomly and normalized. The images were divided into training and validation sets using a ratio of 80:20. The training set has 69,600 images while the validation set has 17,400 images. In view of the larger dataset, no data augmentation was carried out.

The built architecture is shown in Figure 6. The MobileNetV2 was preloaded with weights trained by ImageNet. Average pooling layer was added to the MobileNetV2 output feature map. Continued with a dense neural network layer of 1000 neurons. The activation function for this dense network was standard ReLU. A 50% dropout layer was added after that to prevent overfitting. Final layer was the dense layer that provides classification for 29 classes of images. It had a softmax activation function as defined by:

$$\sigma(z)_j = \frac{e_j^z}{\sum_{k=1}^{K} e_k^z} \tag{7}$$

The model was compiled using categorical crossentropy loss function. The model had about 3.5 millions training parameters. The optimizer used was RMSprop with a learning rate of 1×10^{-4}. Since the sign language images are differ from the ImageNet dataset, all the layers were unfreezed and retrained. Experiments were all conducted on a computer with Intel Core i5 CPU, 12 GB RAM and a NVIDIA GeForce GTX 1060. All of the steps mentioned in this section were performed using Keras deep learning framework with TensorFlow as the backend.

4.3 Performance Metrics

The performance metrics used to evaluate the build model are defined below, where TP stands for True Positive (correct prediction), TN is True Negative (correct rejection), FP is denoted as False Positive (incorrect prediction) and FN is defined as False Negative (incorrect rejection).

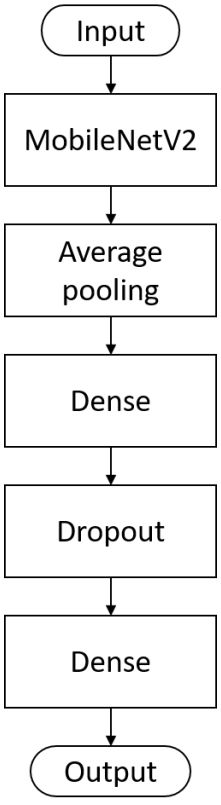

Figure 6: Model architecture

1. Accuracy - the overall correct prediction of the model

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \tag{8}$$

2. Precision - ratio of correct prediction over all the predicted values of a particular class.

$$Precision = \frac{TP}{TP + FP} \tag{9}$$

3. Recall - ratio of correct prediction over all predicted values that are supposed to be positive.

$$Recall = \frac{TP}{TP + FN} \tag{10}$$

4. F1-Score - weighted average of precision and recall. It tells the balance between precision and recall.

$$F1\ score = 2\left[\frac{Precision \times Recall}{Precision + Recall}\right] \tag{11}$$

5 Results and Discussion

The highest overall accuracy obtained by this model was 98.67%. The confusion matrix is shown in Figure 7. For each of the sign, 28 out of 29 were recorded with accuracy higher than 95%. The highest single class accuracy was 100% and the lowest was 85.67%. Lowest accuracy was recorded for the letter Q. There were only 514 out of 600 images were correctly predicted. The rests were all being predicted as P. This was believed to be the similarity existed in these two signs, where the index finger and thumb are both pointed out.

Looking at the precision, recall, and f1-score for each class as shown in Table 1, most of them obtained a score of 95% and above. The precision of letter P and recall of letter Q was lower due to the above mentioned similarity. Hence it also lowered the f1-score for these two classes. The second lowest recall was the sign for letter X which scored 92.83%. Some of them were being wrongly classified as either S or U due to the similar rounded fist shape.

Table 2 shows the comparison with some previous works. To have a fair comparison, only those works implementing transfer learning were compared. In the comparision, there was only one study done by Alashhab. S. et. al. had slightly better accuracy then this work, but they were not working with ASL and there were only 5 classes of hand signs used. Other than that, this work showed better results than the prior works. For a similar MobileNetV2 transfer learning architecture for ASL, there is also a marginally improvement over the work did by Bousbai, K and Merah, M.

Table 1: Precision, Recall, F1-score for each class

6 Conclusion and Future Work

This paper presented a model that was able to recognize American Sign Language with 98.67% accuracy. It is an extension of the work originally presented in ICSIPA 2019. Besides the improvement of the model accuracy, the following additional highlights are listed:

1. A much bigger dataset was used with additional 5 classes to make the ASL more complete. That allowed a better generalization of the model. In addition, this distance varying images given in the dataset could also make the model less sensitive to the difference in distance between the ASL users and the camera.

2. Even with the deep transfer learning network used, we still maintained our original intention to make the model suitable for running on mobile devices in order to use the smartphone camera for the convenience of users.

The model was less computational burdening since it had fewer parameters and lesser mathematical computations. With the implementation of the model as an smartphone app, it is believed to be able to improve the quality of communication between the deaf-mute person and the general public.

To offer more usability, this work can be continued with real-time video based sign language recognition. To reduce the effects of ambient noise, there is a need for real-time video processing, such as region of interest segmentation and hand tracking. Apart from that, the image occlusion has yet to be investigated. This can be a challenging issue when part of the performing signs is blocked.

Acknowledgment I wish to acknowledge Tunku Abdul Rahman University College for sponsoring this research.

Unknown Rotor Winding Resistance
Adaptive control projection operator
Lyapunov Theory

ABSTRACT

In this study, an adaptive nonlinear sensorless controller for doubly fed induction generator (DFIG) driven by a wind turbine is proposed. The aim is to maximize the extracted power by tracking the wind turbine optimal torque-speed characteristic without the need for rotor speed measurement. This controller ensures a satisfactory tracking of both stator flux and rotor speed. It considers the detailed model of DFIG in an arbitrary (d–q) rotating frame without any simplifying assumption. An observer provides the rotor speed estimation incorporated in the control loop. To guarantee the system stability under parametric uncertainties like the aerodynamic torque and the rotor winding resistance, which harms the efficiency and the robustness of the controller, update laws are established to estimate the uncertain parameters. Lyapunov's theory is used to prove the system stability. The proposed adaptive sensorless controller validity is demonstrated by simulation in Matlab/Simulink environment. The robustness of the controller is confirmed by the comparison between the same controller with and without adaptation.

1. Introduction

Recently, using wind energy to produce electricity has been gradually grabbing the attention of many researchers, thanks to its cleanliness and dependability. Because of its smaller power electronic components rating and its wide speed operation range, the DFIG is seen as the most used wind turbine generator [1–3]. The DFIG rotor windings are connected to the electrical grid via rotor and grid side converters (RSC and GSC) and RL filter, whereas the stator windings are immediately related to the electrical grid as illustrated by Figure 1. In the last decade, many researchers giving much focus and interest to the field of sensorless control of DFIG-based wind turbine (DFIG-WT)[4–7]. In this control strategy, the DFIG-WT systems operate without the need to use the speed sensor, which lowers the whole system cost and enhance its overall reliability by minimizing the number of components that are susceptible to failure.

There has been some research about sensorless control using proportional-integral (PI) loops such as [8,9]. The latter mainly relied on assumptions that the flux or stator voltages are constant, and the stator resistance is negligible. However, these assumptions are useless under grid faults or load variations. Furthermore, the small resistance of the stator may cause an incorrect damped dynamics of the stator flux [10].

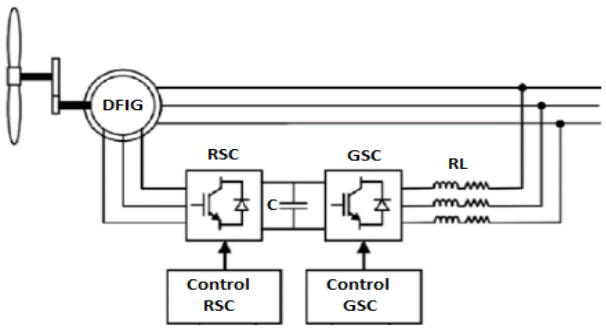

Figure 1: Schematic representation of grid connected DFIG-WT system

For the most control strategies, if the actual values do not correspond to the parameters and variables of DFIG-WT used in the control law, it could result in a failure of the closed-loop control. So, when some parameters and variables are difficult to be measured, some strategies based on estimation theory are important to generate a pertinent control. The frequency, the

*Corresponding Author: Radouane Ourhdir, radouane.ourhdir@edu.umi.ac.ma

temperature and the magnetic saturation may cause the change of DFIG parameters [11]. Therefore, the online parameter estimation or disturbance observer is compulsory to have high precision control.

Much research has addressed the control of DFIGs during parameter variation [12–14]. On the other hand, the modeling and the control of WT is not an easy task, particularly when large scale WTs, in megawatts, are considered [15,16]. Hopefully, to minimize the drive train vibration and to develop the quality of the extracted power, some works use the estimation theory in order to take into consideration the uncertainties arose from the aerodynamic torque, particularly in the stage of the maximum power point tracking (MPPT) [17].

The main focus of this work is to elaborate an adaptive sensorless control for the rotor side converter (RSC), this controller takes into consideration the detailed model of DFIG. Update laws in real-time are established to deal with the parameter uncertainties. To preserve the objectives of the MPPT without the need to use rotor speed sensor , a speed observer is incorporated in this controller. The remaining of this research paper displays as follows: The second section revolves around the model of the DFIG-WT system. The third section puts forward the suggested nonlinear controller: For the start, we present the proposed rotor speed observer. Afterward, we introduce our sensorless controller design, and we point out to the control laws of DFIG, and update laws for the speed observer, as well as the estimated rotor resistance and aerodynamic torque, which are competed using the Lyapunov theory. The last section considers simulation results and discussion. At last, we wrap up by drawing some concluding remarks.

2. DFIG-WT model

2.1. Wind turbine model

Based on wind turbine aerodynamic[18], The power captured from the wind can be expressed as :

$$P_t = \frac{1}{2}\rho\pi R^2 C_p(\lambda,\beta) v^3 \tag{1}$$

where ρ is the air density, R is the blade radius and v is the wind speed. The wind power coefficient $C_p(\lambda,\beta)$ depens on the design the blades; is a function of pitch angle β and tip speed ratio λ (TSR).
where:

$$\lambda = \frac{R\,\omega}{G\,v} \tag{2}$$

In which ω is the mechanical generator speed and G is the gearbox ratio. In the basis of the wind turbine design [18], the expression of power coefficient is:

$$C_p(\lambda,\beta) = c_1\left(\frac{c_2}{\lambda_i} - c_3\beta - c_4\right)\exp\left(-\frac{c_5}{\lambda_i}\right) + c_6\lambda \tag{3}$$

where:

$$\frac{1}{\lambda_i} = \frac{1}{\lambda + 0.08\beta} - \frac{0.035}{\beta^3 + 1}$$

The coefficients c_1-c_6 are listed in Table 1.

Table 1: Values of coefficients c1-c6

c_1	c_2	c_3	c_4	c_5	c_6
0.5176	116	0.4	5	21	0.0068

When the pitch angle β remains unchanged, there is an optimum tip ratio $\lambda = \lambda_{opt}$ that maximizes the power coefficient C_p, In this study, we assume that $\beta = 0$ .So the MPPT is achieved by the control of the generator speed. Conforming to (2) the mechanical speed that optimize the extracted power is:

$$\omega^* = \frac{G\lambda_{opt}}{R_t} v \tag{4}$$

2.2. Induction generator model

Employing the flux-linkage and voltage equations of the induction generator [19], the state variables of DFIG in an arbitrary reference frame rotating at speed ω_0 include d-q rotor currents and stator fluxes i_{dr}, i_{qr}, $\varphi_{ds}, \varphi_{qs}$, and generator speed ω .The considered 5th-order state-space representation of DFIG can be expressed as:

$$\begin{cases} \dfrac{d\varphi_{ds}}{dt} = u_{ds} - \alpha\varphi_{ds} + \omega_0\varphi_{qs} + \alpha M i_{dr} \\ \dfrac{d\varphi_{qs}}{dt} = u_{qs} - \alpha\varphi_{qs} - \omega_0\varphi_{ds} + \alpha M i_{qr} \\ \dfrac{di_{dr}}{dt} = \dfrac{1}{\sigma}u_{dr} - \dfrac{R_r}{\sigma}i_{dr} - \alpha\beta M i_{dr} + (\omega_0 - \omega) i_{qr} \\ \qquad - \beta u_{ds} + \alpha\beta\varphi_{ds} - \beta\omega\varphi_{qs} \\ \dfrac{di_{qr}}{dt} = \dfrac{1}{\sigma}u_{qr} - \dfrac{R_r}{\sigma}i_{qr} - \alpha\beta M i_{qr} - (\omega_0 - \omega) i_{dr} \\ \qquad - \beta u_{qs} + \alpha\beta\varphi_{qs} + \beta\omega\varphi_{ds} \\ \dfrac{d\omega}{dt} = -\dfrac{f}{J}\omega + \dfrac{T_t}{J} - \mu\left(\varphi_{qs} i_{dr} - \varphi_{ds} i_{qr}\right) \end{cases} \tag{5}$$

with:

$$\sigma = L_r\left(1 - \frac{M^2}{L_r L_s}\right), \quad \beta = L_r\frac{M}{\sigma L_s}, \quad \mu = \frac{M}{JL_s}, \quad \alpha = \frac{R_s}{L_s}$$

T_t is the mechanical torque. The rest of the parameters of DFIG-WT system are given in Table 2, Appendix B.

3. Control design

3.1. Speed observer

Achievement of MPPT strategy requires a quick convergence of the mechanical rotor speed to its optimal value. An observer is proposed to estimate the actual rotor speed of DFIG.

$$\dot{\hat{\omega}} = -\frac{f}{J}\hat{\omega} + \frac{\hat{T}_t}{J} - \mu\left(\varphi_{qs} i_{dr} - \varphi_{ds} i_{qr}\right) + \eta \tag{6}$$

Measurement of the rotor currents and the stator fluxes are compulsory for the latter observer; it relies also on the estimated aerodynamic torque $\hat{T}_t$ and the term η which will be elaborated by the means of the Lyapunov approach.

3.2. Reference Signals

Supposing that; the d-q rotating frame is aligned with the stator flux vector as in [20]. In our case, we consider that the stator flux vector is associated with the d-axis of the d-q reference frame giving:

$$\varphi_{qs} = 0;\ \varphi_{ds} = \Psi^* \tag{7}$$

Based on the assumption (7) illustrated by Figure 2, the expressions of the reference signals in the steady-state condition of DFIG can be established:

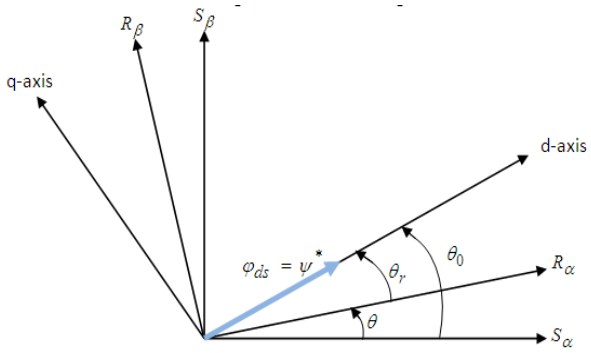

Figure 2: Determination of angles for the DFIG in d-q reference frame

Taking into consideration the latter assumption (7), and according to the first equation of (5), the reference of the direct rotor current can be expressed as follows:

$$i_{dr}^* = \frac{\Psi^*}{M} - \frac{u_{ds}}{\alpha M} + \frac{1}{\alpha M}\frac{d\Psi^*}{dt} \tag{8}$$

From the 5th equation of the system (5), the reference of the quadratic rotor current is established by replacing the aerodynamic torque by its estimate and incorporating a feedback saturation function [21], which relies on the estimated and reference rotor speed:

$$i_{qr}^* = \frac{1}{\mu\Psi^*}\left(-k_\omega sat\left(\hat{\omega} - \omega^*\right) + \frac{f}{J}\omega^* - \frac{\hat{T}_t}{J} + \frac{d\omega^*}{dt}\right) \tag{9}$$

where:

$$sat(y) = \begin{cases} 0.1 & if \quad y \geq 0.1 \\ y & if \quad -0.1 \prec y \prec 0.1 \\ -0.1 & if \quad y \leq -0.1 \end{cases}$$

The saturation function sat(y) has a finite limit at infinity; it is a linear, odd, and differentiable function in a neighborhood of the origin. To satisfy the assumption (7), the d-q reference frame must rotate at a specific speed ω_0 which is expressed using the second equation of (5):

$$\omega_0 = \dot{\theta}_0 = \frac{u_{qs} + \alpha M i_{qr}^*}{\Psi^*} \tag{10}$$

3.3. Control and update laws

The rotor speed sensor has some weak points concerning robustness, maintenance, cost, and cables linking the speed sensor and the control block. Any incorrect value provided by the rotor speed sensor may significantly harm the defined control targets and it can also destroy the system stability. Besides, accurate modeling of the aerodynamic torque is not an easy task, and the rotor winding resistance may vary up during operation due to the heating of the generator. That is to say that it constitutes uncertain parameters for the model which can affect the system stability. Yet, to ensure the system stability and maintain the control objectives in the presence of uncertainties and without needing to measure the rotor speed, the system closed-loop stability is examined to extract the expressions of the additional term η used in the speed observer, and the update laws of the estimated rotor resistance and aerodynamic torque. In this study, we assume that the aerodynamic torque and rotor resistance are unknown and vary slowly with time and should be estimated. To this purpose, the error variables can be introduced as follows:

$$\begin{cases} \tilde{\omega} = \omega - \omega^* \\ \tilde{\varphi}_{ds} = \varphi_{ds} - \Psi^* \\ \tilde{\varphi}_{qs} = \varphi_{qs} \\ \tilde{i}_{dr} = i_{dr} - i_{dr}^* \\ \tilde{i}_{qr} = i_{qr} - i_{qr}^* \\ e_\omega = \hat{\omega} - \omega \\ \tilde{R}_r = R_r - \hat{R}_r \\ \tilde{T}_t = T_t - \hat{T} \end{cases} \tag{11}$$

Using equations (5), (6), (7), (8), (9), (10) and (11) the system of the error dynamics can be expressed as follows:

$$\begin{cases} \dot{\tilde{\varphi}}_{ds} = -\alpha\tilde{\varphi}_{ds} + \omega_0\tilde{\varphi}_{qs} + \alpha M\tilde{i}_{dr} \\ \dot{\tilde{\varphi}}_{qs} = -\alpha\tilde{\varphi}_{qs} - \omega_0\tilde{\varphi}_{ds} + \alpha M\tilde{i}_{qr} \\ \dot{\tilde{i}}_{dr} = \frac{u_{dr}}{\sigma} - \frac{R_r}{\sigma}i_{dr} - \alpha\beta M i_{dr} + (\omega_0 - \omega)i_{qr} \\ \qquad - \beta u_{ds} + \alpha\beta\varphi_{ds} - \beta\omega\varphi_{qs} - \frac{di_{ds}^*}{dt} \\ \dot{\tilde{i}}_{qr} = \frac{u_{qr}}{\sigma} - \frac{R_r}{\sigma}i_{qr} - \alpha\beta M i_{qr} - (\omega_0 - \omega)i_{dr} \\ \qquad - \beta u_{qs} + \alpha\beta\varphi_{qs} + \beta\omega\varphi_{ds} - \frac{di_{qs}^*}{dt} \\ \dot{\tilde{\omega}} = -\frac{f}{J}\tilde{\omega} + \frac{\tilde{T}_t}{J} - \mu\tilde{\varphi}_{qs}i_{dr} + \mu\tilde{\varphi}_{ds}i_{qr} + \mu\Psi^*\tilde{i}_{qr} \\ \dot{e}_\omega = -\frac{f}{J}e_\omega - \frac{\tilde{T}_t}{J} + \eta \end{cases} \tag{12}$$

In order to have a compact error dynamic system, the error variables e_d and e_q are considered instead of $\tilde{i}_{dr}$ and $\tilde{i}_{qr}$:

$$\begin{cases} e_d = \tilde{\varphi}_{ds} + \frac{\tilde{i}_{dr}}{\beta} \\ e_q = \tilde{\varphi}_{qs} + \frac{\tilde{i}_{qr}}{\beta} \end{cases} \tag{13}$$

The error dynamics in (12) becomes:

$$\begin{cases} \dot{\tilde{\varphi}}_{ds} = -(\alpha + \alpha\beta M)\tilde{\varphi}_{ds} + \omega_0\tilde{\varphi}_{qs} + \alpha\beta M e_d \\ \dot{\tilde{\varphi}}_{ds} = -(\alpha + \alpha\beta M)\tilde{\varphi}_{qs} - \omega_0\tilde{\varphi}_{ds} + \alpha\beta M e_q \\ \dot{e}_d = \dfrac{u_{rd}}{\beta\sigma} - \dfrac{\tilde{R}_r}{\beta\sigma} i_{dr} + \left(\varphi_{qs} + \dfrac{i_{qr}}{\beta}\right)e_\omega + \eta_{0d} \\ \dot{e}_q = \dfrac{u_{rq}}{\beta\sigma} - \dfrac{\tilde{R}_r}{\beta\sigma} i_{qr} - \left(\varphi_{ds} + \dfrac{i_{dr}}{\beta}\right)e_\omega + \eta_{0q} \\ \dot{e}_\omega = \dfrac{f}{J} e_\omega - \dfrac{\tilde{T}_t}{J} + v \end{cases} \quad (14)$$

where:

$$\eta_{0d} = -\frac{\hat{R}_r}{\beta\sigma} i_{dr} - \alpha M i_{dr}^* + (\omega_0 - \hat{\omega})\frac{i_{qr}}{\beta} - (\hat{\omega} - \omega_0)\varphi_{qs} + \alpha\Psi^* - u_{ds} - \frac{1}{\beta}\left(\frac{\dot{\Psi}^*}{M} - \frac{1}{\alpha M}\frac{du_{sd}}{dt} + \frac{1}{\alpha M}\frac{d^2\Psi^*}{dt^2}\right)$$

$$\eta_{0q} = -\frac{\hat{R}_r}{\beta\sigma} i_{qr} - \alpha M i_{qr}^* - (\omega_0 - \hat{\omega})\frac{i_{dr}}{\beta} + (\hat{\omega} - \omega_0)\varphi_{ds} + \omega_0\Psi^* - u_{qs} - \frac{1}{\beta}\left[-\frac{\dot{\Psi}^*}{\mu\Psi^{*2}}\left(-k_\omega sat(\hat{\omega} - \omega^*) + \frac{f}{J}^* - \frac{\hat{T}_t}{J} + \dot{\omega}^*\right) + \frac{1}{\mu\Psi^*}\left(-k_\omega \frac{d}{dt} sat(\hat{\omega} - \omega^*)(\dot{\hat{\omega}} - \dot{\omega}^*) + \frac{f}{J}\dot{\omega}^* - \frac{\dot{\hat{T}}_t}{J} + \ddot{\omega}^*\right)\right]$$

The expression of the stator direct voltage derivative $\frac{du_{sd}}{dt}$ is detailed in Appendix A. we construct a Lyapunov function for the system (14) as:

$$V = \frac{1}{2}\left(\tilde{\varphi}_{ds}^2 + \tilde{\varphi}_{qs}^2 + z_d^2 + z_q^2\right) + \frac{1}{2}\lambda e_\omega^2 + \frac{\gamma}{J} e_\omega \tilde{T}_t + \frac{\gamma^2}{\lambda J^2}\tilde{T}_t^2 + \frac{1}{2}\delta\tilde{R}_r^2 \quad (15)$$

where λ, γ and δ are positive design parameters given in Appendix B. The derivative of V along with the time gives

$$\dot{V} = -\alpha\left[\tilde{\varphi}_{ds}^2 + \tilde{\varphi}_{qs}^2\right] - \alpha M\beta\left[\tilde{\varphi}_{ds}^2 + \tilde{\varphi}_{qs}^2\right] + \alpha M\beta\left[e_d\tilde{\varphi}_{ds} + z_q\tilde{\varphi}_{qs}\right] + \tilde{T}_t\left[v\frac{\gamma}{J} - \frac{2\gamma^2}{\lambda J^2}\dot{\hat{T}}_t\right] + \tilde{R}_r\left[-\frac{e_d i_{dr}}{\sigma\beta} - \frac{z_q i_{qr}}{\sigma\beta} - \delta\dot{\hat{R}}_r\right] + e_\omega\left[e_d\left(\varphi_{qs} + \frac{i_{qr}}{\beta}\right) - e_q\left(\varphi_{ds} + \frac{i_{dr}}{\beta}\right) + \lambda v - \frac{\gamma}{J}\dot{\hat{T}}_t\right] + z_q\left[\eta_{0q} + \frac{u_{qr}}{\sigma\beta}\right] + z_d\left[\eta_{0d} + \frac{u_{dr}}{\sigma\beta}\right] - \frac{\lambda f}{J}e_\omega^2 - \frac{\gamma}{J^2}\tilde{T}_t^2 - \left[\frac{\lambda}{J} + \frac{\gamma f}{J^2}\right]\tilde{T}_t e_\omega \quad (16)$$

It's obvious that:

$$\left(\frac{e_d}{2} - \varphi_{ds}\right)^2 + \left(\frac{e_q}{2} - \varphi_{qs}\right)^2 \geq 0 \quad (17)$$

From (17), we can get the following inequality:

$$\left[-\tilde{\varphi}_{ds}^2 - \tilde{\varphi}_{qs}^2 + e_d\tilde{\varphi}_{ds} + e_q\tilde{\varphi}_{qs}\right] \leq \frac{e_d^2 + e_q^2}{4} \quad (18)$$

The control laws are derived as:

$$\begin{cases} u_{dr} = -\sigma\beta\left[\dfrac{\alpha M\beta}{4} e_d + \eta_{0d} + k e_d\right] \\ u_{qr} = -\sigma\beta\left[\dfrac{\alpha M\beta}{4} e_q + \eta_{0q} + k e_q\right] \end{cases} \quad (19)$$

We define the dynamics of the rotor resistance as

$$\dot{\hat{R}}_r = \Pr oj\left[-\frac{1}{\delta}\left[\frac{e_d i_{dr} + e_q i_{qr}}{\sigma\beta}\right], \hat{R}_r\right] \quad (20)$$

where $\Pr oj[g, \hat{R}_r]$ is the projection algorithm[22], which is specified in our case by

$$\dot{\hat{R}}_r = \begin{cases} g & if\ \ R_{rm} \leq \hat{R}_r \leq R_{rM} \\ g & if\ \hat{R}_r < R_{rm}\ \ and\ g \geq 0 \\ g & if\ \hat{R}_r > R_{rM}\ \ and\ g \leq 0 \\ g\left[1 - \dfrac{R_{rm}^2 - \hat{R}_r^2}{R_{rm}^2 - (R_{rm} - \varepsilon_1)^2}\right] & if\ \ \hat{R}_r < R_{rm}\ and\ \ g < 0 \\ g\left[1 - \dfrac{\hat{R}_r^2 - R_{rM}^2}{(R_{rM} + \varepsilon_1)^2 - R_{rM}^2}\right] & if\ \ \hat{R}_r > R_{rM}\ and\ \ g > 0 \end{cases} \quad (21)$$

with R_{rM} and R_{rm} are the upper and the lower bound values of R_r, respectively, and ε_1 is an arbitrary positive constant such that $R_{rm} - \varepsilon_1 \geq 0$.

We define the update laws of the additional term and the aerodynamic torque as

$$\eta = \begin{cases} \varsigma = \dfrac{2}{\lambda}\left[e_q\left(\varphi_{ds} + \dfrac{i_{dr}}{\beta}\right) - e_d\left(\varphi_{qs} + \dfrac{i_{qr}}{\beta}\right)\right] & if\ \hat{T}_t \leq T_{tM} \\ \varsigma = \dfrac{2}{\lambda}\left[e_q\left(\varphi_{ds} + \dfrac{i_{dr}}{\beta}\right) - e_d\left(\varphi_{qs} + \dfrac{i_{qr}}{\beta}\right)\right] & if\ \hat{T}_t > T_{tM} \\ & and\ \dfrac{dP(\hat{T}_t)}{dt}\varsigma \leq 0 \\ \dfrac{\varsigma}{1 + P(\hat{T}_t)} & Otherwise \end{cases} \quad (22)$$

$$\dot{\hat{T}}_t = \begin{cases} \chi = \dfrac{J}{\gamma}\left[e_q\left(\varphi_{ds} + \dfrac{i_{dr}}{\beta}\right) - e_d\left(\varphi_{qs} + \dfrac{i_{qr}}{\beta}\right)\right] & if\ \hat{T}_t \leq T_{tM} \\ \chi = \dfrac{J}{\gamma}\left[e_q\left(\varphi_{ds} + \dfrac{i_{dr}}{\beta}\right) - e_d\left(\varphi_{qs} + \dfrac{i_{qr}}{\beta}\right)\right] & if\ \hat{T}_t > T_{tM} \\ & and\ \dfrac{dP(\hat{T}_t)}{dt}\chi \leq 0 \\ \dfrac{1 + P(\hat{T}_t)}{1 + P(\hat{T}_t)}\chi & Otherwise \end{cases} \quad (23)$$

where:

$$P(\hat{T}_t) = \frac{\hat{T}_t^2 - T_{tM}^2}{2\varepsilon_2\hat{T}_{tM} + \varepsilon_2^2} \quad (24)$$

with T_{tM} is the upper bound value of T_t and ε_2 is an arbitrary positive constant. Substituting (18), (19), (21), (22) and (23) in (16), the time derivative of (15) becomes:

$$\dot{V} \le -\alpha\left(\tilde{\varphi}_{ds}^2 + \tilde{\varphi}_{qs}^2\right) - \underbrace{\left[k - \frac{\alpha\beta M}{4}\right]}_{C}\left(e_d^2 + e_q^2\right) - \lambda\frac{f}{J}e_\omega^2 - \left(\frac{\lambda}{J} + \gamma\frac{f}{J^2}\right)\tilde{T}_t e_\omega - \frac{\gamma}{J^2}\tilde{T}_t^2 \quad (25)$$

The time derivative of (15) can be written in the following way:

$$\dot{V} \le -\min\{\alpha, C\}\left(\tilde{\varphi}_{ds}^2 + \tilde{\varphi}_{qs}^2 + e_d^2 + e_q^2\right) - \lambda\frac{f}{J}e_\omega^2 - \left(\frac{\lambda}{J} + \gamma\frac{f}{J^2}\right)\tilde{T}_t e_\omega - \frac{\gamma}{J^2}\tilde{T}_t^2 \quad (26)$$

Since $\tilde{T}$ and $\tilde{R}_r$ has been designed using a projection algorithm (bounded), from (15) and (26) we can establish that the functions $\tilde{\varphi}_{ds}$, $\tilde{\varphi}_{qs}$, e_d, e_q and e_ω are bounded on $[0, \infty)$. Consequently, from (14) it's clear that $\dot{\tilde{\varphi}}_{ds}$, $\dot{\tilde{\varphi}}_{qs}$, $\dot{e}_d$, $\dot{e}_q$ and $\dot{e}_\omega$ are bounded on $[0, \infty)$. So the functions $\tilde{\varphi}_{ds}$, $\tilde{\varphi}_{qs}$, e_d, e_q and e_ω are uniformly continuous on $[0, \infty)$, as a result, from(13) it can be seen that $\dot{\tilde{i}}_{dr}$, $\dot{\tilde{i}}_{qr}$, $\dot{\tilde{i}}_{dr}$ and $\dot{\tilde{i}}_{qr}$ are bounded, and the functions $\tilde{i}_{dr}$, $\tilde{i}_{qr}$ are also uniformly continuous on $[0, \infty)$.

The closed loop of the system (14) is determined based on (19), (21), (22) and (23) as:

$$\begin{cases} \dot{\tilde{\varphi}}_{ds} = -(\alpha + \alpha\beta M)\tilde{\varphi}_{ds} + \omega_0\tilde{\varphi}_{qs} + \alpha\beta M e_d \\ \dot{\tilde{\varphi}}_{qs} = -(\alpha + \alpha\beta M)\tilde{\varphi}_{qs} - \omega_0\tilde{\varphi}_{ds} + \alpha\beta M e_q \\ \dot{e}_d = -\left(k + \frac{\alpha\beta M}{4}\right)e_d - \frac{\tilde{R}_r}{\sigma}e_d + \frac{\tilde{R}_r}{\sigma}\tilde{\varphi}_{ds} \\ \qquad + e_q e_\omega + \frac{i_{qr}^*}{\beta}e_\omega - \frac{i_{dr}^*}{\sigma\beta}\tilde{R}_r \\ \dot{e}_q = -\left(k + \frac{\alpha\beta M}{4}\right)e_q - \frac{\tilde{R}_r}{\sigma}e_q + \frac{\tilde{R}_r}{\sigma}\tilde{\varphi}_{qs} - e_d e_\omega \\ \qquad -\left(\Psi^* + \frac{i_{dr}^*}{\beta}\right)e_\omega - \frac{i_{qr}^*}{\sigma\beta}\tilde{R}_r \end{cases} \quad (27)$$

We can put the last five equations of (27) in the following form:

$$\begin{aligned} \dot{x}(t) &= [A(t) + B(t)]x(t) + C(t)z(t) \\ \dot{z}(t) &= Dz(t) + Ex(t) + Fw(t) \\ \dot{w}(t) &= Gx(t) \end{aligned} \quad (28)$$

where:

$$x(t) = \left[\tilde{\varphi}_{ds}, \tilde{\varphi}_{qs}, e_d, e_q\right]^T \; ; \; z(t) = \left[e_\omega, \tilde{R}_r\right]^T \; ; \; w(t) = \tilde{T}_t$$

and

$$A(t) = \begin{pmatrix} -(\alpha + \alpha\beta M) & \omega_0 & \alpha\beta M & 0 \\ -\omega_0 & -(\alpha + \alpha\beta M) & 0 & \alpha\beta M \\ 0 & 0 & -\left(k + \frac{\alpha\beta M}{4}\right) & 0 \\ 0 & 0 & 0 & -\left(k + \frac{\alpha\beta M}{4}\right) \end{pmatrix}$$

$$B = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ \frac{\tilde{R}_r}{\sigma} & 0 & -\frac{\tilde{R}_r}{\sigma} & e_\omega \\ 0 & \frac{\tilde{R}_r}{\sigma} & -e_\omega & -\frac{\tilde{R}_r}{\sigma} \end{pmatrix} \quad C = \begin{pmatrix} 0 & 0 \\ 0 & 0 \\ \frac{i_{qr}^*}{\beta} & -\frac{i_{dr}^*}{\sigma\beta} \\ -\left(\Psi^* + \frac{i_{dr}^*}{\beta}\right) & -\frac{i_{qr}^*}{\sigma\beta} \end{pmatrix}$$

$$E = \begin{pmatrix} 0 & 0 & \frac{2}{\lambda}f_1\left(\varphi_{ds} + \frac{i_{dr}}{\beta}\right) & -\frac{2}{\lambda}f_1\left(\varphi_{ds} + \frac{i_{dr}}{\beta}\right) \\ 0 & 0 & -f_2\frac{i_{dr}}{\delta\sigma\beta} & -f_2\frac{i_{qr}}{\delta\sigma\beta} \end{pmatrix}$$

$$F = \begin{pmatrix} -\frac{1}{J} \\ 0 \end{pmatrix} \; ; \; D = \begin{pmatrix} -\frac{f}{J} & 0 \end{pmatrix}$$

$$G = \begin{pmatrix} 0 & 0 & f_3\frac{J}{\gamma}\left(\varphi_{qs} + \frac{i_{qr}}{\beta}\right) & -f_3\frac{J}{\gamma}\left(\varphi_{ds} + \frac{i_{dr}}{\beta}\right) \end{pmatrix}$$

with $f_i, i = 1,2,3,$ are bounded functions such that $0 \le f_i \le 1$

Since the functions $\tilde{\varphi}_{ds}, \tilde{\varphi}_{qs}, e_d, e_q, e_\omega$ are bounded, so for all $t \ge t_0$ $A(t), B(t), C(t), D(t), E(t), F(t)$ and $G(t)$ are bounded, with $\|A(t)\| \le A_M$, $\|B(t)\| \le B_M$, $\|C(t)\| \le C_M$, $\|D(t)\| \le D_M$, $\|E(t)\| \le E_M$, $\|F(t)\| \le F_M$, $\|G(t)\| \le G_M$

From (15), the function $V(t)$ can be put into the following inequation:

$$\alpha_1\left(\|x\|^2 + \|z\|^2 + \|w\|^2\right) \le V \le \alpha_2\left(\|x\|^2 + \|z\|^2 + \|w\|^2\right) \quad (29)$$

The time derivative of $V(t)$ (26) can be written in the following way:

$$\dot{V} \le -a_3\|x\|^2 - a_4\|w\|^2 + a_5\|w\|\|z\| \quad (30)$$

with:

$$a_3 = \min\{\alpha, k\}, \; a_4 = \frac{\gamma}{J^2}, \; a_5 = -\left(\frac{\lambda}{J} + \frac{\gamma f}{J^2}\right)$$

According to the proof of lermma 2.1 in [23], the origin $x = 0, z = 0; w = 0$ of (28) is locally exponentially stable.

4. Simulation Results

Simulation of the detailed model of 3MW DFIG-WT using the proposed adaptive nonlinear sensorless controller is performed in MATLAB/Simulink environment, the parameters and characteristics of the latter DFIG-WT along with the design parameters are given in Table 2, and Table 3, Appendix B.

The estimation and tracking performance of the adaptive sensorless controller is shown using a variable wind speed of $(8.5\ m/s)$ mean value as depicted in Figure 3. To show the robustness of the proposed adaptive sensorless controller against the aerodynamic torque and the rotor winding resistance variation the tracking performance for both the sensorless controller with [24] and without adaptation at constant wind speed $(9\ m/s)$ has been compared in Figure 4. The simulation is performed with the variation of the mechanical torque and the rotor winding resistance described by:

$$T_t = \begin{cases} T_t & for\ t \le 20s \\ 0.5T_t & for\ t > 20s \end{cases} \quad (31)$$

$$R_r = \begin{cases} R_r & for\ t \le 10s \\ 1.5R_r & for\ t > 10s \end{cases} \quad (32)$$

From Figure 3 (a) and 3 (b) the actual rotor speed varies in accordance with the wind speed, which confirms the effectiveness of the MPPT. Figure 3 (c) shows a good tracking performance of the stator quadratic current. According to Figure 3(d) it can be noticed that the estimated torque recovers the applied unknown torque. Similarly, from Figure 3(e) it can be observed that the estimated rotor resistance quickly converges to its true profiles. In Figure 4 the adaptive nonlinear sensorless controller performance is shown by the comparison of the proposed adaptive sensorless and the sensorless controller proposed in [24]. From Figures 4 (a) and 4 (b) it is noted that the stator flux and the rotor speed tracking errors sustain small perturbations caused by the unknown rotor resistance and the unknown aerodynamic torque, but they converge to zero quickly as soon as the estimates of R_r , and T_t converges to their actual values. Whereas in the case of control without adaptation Figures 4 (c) and 4 (d) the rotor speed and the stator flux don't track anymore their references after variation of the rotor resistance and the aerodynamic torque.

When the actual values do not correspond to their references, the closed loop system is exposed to failure, which destroys the control objectives. These results confirm the robustness of our controller regarding to the rotor resistance variation along with the aerodynamic torque.

5. Conclusion

This paper presents an adaptive nonlinear sensorless controller for DFIG-WT to maximize the wind energy extracted under parametric uncertainties and unknown rotor speed. The simulation performed in Matlab/Simulink environment illustrates the good results provided by the controller regarding the good tracking capability of the rotor speed and stator flux, in addition to correct estimation of the unknown rotor speed, aerodynamic torque, and the rotor resistance. Also, the comparison result between the same controller with and without adaptation shows the effectiveness of this work.

Appendix A. Frame transformation and u_{ds} derivative

The direct and quadratic components of the stator voltage in the (d,q) reference frame can be expressed as follows:

$$\begin{pmatrix} u_{ds} \\ u_{qs} \end{pmatrix} = \begin{pmatrix} \cos\theta_0(t) & \sin\theta_0(t) \\ -\sin\theta_0(t) & \cos\theta_0(t) \end{pmatrix} \begin{pmatrix} u_{\alpha s} \\ u_{\beta s} \end{pmatrix} \quad (A.1)$$

where (α, β) stand for the fixed reference frame and θ_0 the electrical angle of the (d, q) rotating reference frame to the (α, β) one, see Figure 2. The components of the stator voltage in (α, β) are:

$$\begin{pmatrix} u_{\alpha s} \\ u_{\beta s} \end{pmatrix} = \underbrace{\sqrt{\frac{2}{3}} \begin{pmatrix} 1 & -\frac{1}{2} & -\frac{1}{2} \\ 0 & \sqrt{\frac{3}{2}} & -\sqrt{\frac{3}{2}} \end{pmatrix}}_{T} \begin{pmatrix} u_{as} \\ u_{bs} \\ u_{cs} \end{pmatrix} \quad (A.2)$$

In which T is the Concordia matrix transformation, and u_{as}, u_{bs} and u_{cs} are the 3-phases stator voltage giving by :

$$\begin{pmatrix} u_{as} \\ u_{bs} \\ u_{cs} \end{pmatrix} = V_m \begin{bmatrix} \sin(\omega_s t) \\ \sin\left(\omega_s t - \frac{2\pi}{3}\right) \\ \sin\left(\omega_s t + \frac{2\pi}{3}\right) \end{bmatrix} \quad (A.3)$$

Using the conventional derivative proprieties for scalar, vector and matrix, we can obtain the direct stator voltage component derivative $\frac{du_{ds}}{dt}$ used in (14). From (A.1) the expression of the direct stator voltage is:

$$u_{ds} = \begin{pmatrix} \cos\theta_0(t) & \sin\theta_0(t) \end{pmatrix} \begin{pmatrix} u_{\alpha s} \\ u_{\beta s} \end{pmatrix}$$

From (A.2), (A.3) and (10), the derivative of u_{ds} is given by:

$$\begin{aligned} \frac{du_{sd}}{dt} = {} & \begin{bmatrix} u_{as} & u_{bs} & u_{cs} \end{bmatrix} T^T \frac{u_{qs} + \alpha M i_{qr}^*}{\Psi^*} \begin{bmatrix} -\sin\theta_0(t) \\ \cos\theta_0(t) \end{bmatrix} \\ & + \begin{bmatrix} \cos\theta_0(t) & \sin\theta_0(t) \end{bmatrix} T \omega_s V_m \begin{bmatrix} \sin\left(\omega_s t + \frac{\pi}{2}\right) \\ \sin\left(\omega_s t - \frac{\pi}{6}\right) \\ \sin\left(\omega_s t - \frac{5\pi}{6}\right) \end{bmatrix} \end{aligned} \quad (A.4)$$

$$\cos\theta_0(t) = \frac{\varphi_{\alpha s}}{\sqrt{\varphi_{\alpha s}^2 + \varphi_{\beta s}^2}} \text{ and } \sin\theta_0(t) = \frac{\varphi_{\beta s}}{\sqrt{\varphi_{\alpha s}^2 + \varphi_{\beta s}^2}}$$

ABSTRACT

The fight against poverty in the Peruvian Andes is a complex task in which various professionals, such as engineers, economists, anthropologists, among others, participate. The uncertainty of the decisions taken today, no matter how appropriate they may seem, such as million-dollar investments in irrigation infrastructure, can result in over-production and, therefore, in economic recessions. For this reason, a new mathematical simulation model is proposed using system dynamics to predict recession phenomena that can occur in months or after a few years of auspicious economic growth, and that can cause sales prices to be below production costs. The author has developed the conceptualization of the production system of irrigation improvement projects in several years of multidisciplinary work in the Cusco region of Peru. The primary objective of irrigation projects is to improve the socio-economic conditions of the farmer. Techniques as the fulfillment of goals have been used to quantify qualitative dimensions such as strengthening organizations and trainings that are key to guaranteeing irrigation improvement projects' sustainability in the long term. Therefore, it has been possible to identify the variables and relationships of this type of socio-economic system. To validate the model, we verified that the simulated data are consistent with the historical data collected. Likewise, if the values of the various proposed models' variables are adequately modified, these can be applied to other types of production systems under different market conditions. The dimensions addressed, such as supply, demand, sale price, land, production volume, public budget, etc., enhance the research's importance, making the simulation model formally expressed also acquire nuances from economic theory for the fight against poverty-based on water. One of the study's conclusions is to understand the production systems, it is necessary to see them in the context of their regional economy's behavior.

1. Introduction

One of the most important policies in the fight against poverty of the Peruvian government is implementing irrigation improvement projects. In this paper, we will address issues in greater depth about the experience of Plan Meriss Inka (PEPMI) to deal with the social component. We will highlight the characteristics that make this research an economic theory of water perspective that could not be exhibited in work originally submitted in the 2019 IEEE World Engineering Education Conference (EDUNINE) [1].

The primary nature of the irrigation improvement projects implemented by PEPMI is multidisciplinary, in which professionals of different natures such as engineers, economists, biologists, anthropologists, among others. One of the characteristics that stand out from this type of project is the high social component [2]. Since the first projects' implementation, it was observed that, despite providing rural communities with modern irrigation infrastructure. Farmers were reluctant to use it. A situation that has required social partners to decipher this peculiar impasse. Anthropologists' role in these cases has been essential to understanding the farmer's idiosyncrasy in terms of the intervention of new irrigation projects in their communities it refers.

From work carried out, it was concluded that the resistance to using the new irrigation infrastructure was because the farmer only uses the irrigation infrastructure that they have built and, therefore, they consider it as their own. So, not having participated in constructing this new irrigation infrastructure donated by the government, they did not consider it their own. To overcome this

*Corresponding Author: R.A. Romero-Flores, Urb. Chanu Chanu III S10, +51951885805, rromero@unap.edu.pe

problem, Community participation is incorporated as part of the project's financing, which consists mainly of the farmers' workforce's valuation in the construction of the irrigation infrastructure [3]. Similarly, there are cases of projects in which it has been possible to significantly improve water resources available without the need to build new irrigation infrastructure; it was only required to improve water management and irrigation techniques to increase agricultural productivity. This experience leaves an important lesson for professionals who are not from the social area, which is that, to achieve the objectives of the projects, they should improve their communication skills and understanding of the farmer idiosyncrasies in the area [3]. The social component is just one of the many problems. It gives an idea of the complexity of understanding and managing irrigation improvement projects in the fight against poverty in the Peruvian Andes. The ability and experience to face these peculiarities have made the PEPMI to be considered as a model project in South American by the German donors German Technical Cooperation (GTZ) and the State Development Bank of the Federal Republic of Germany (KFW).

In this understanding, the primary objective to be achieved with social intervention projects is their sustainability in strengthening the organization of farmers and profitability. In other words, farmers must manage their own resources without the accompaniment of PEPMI staff and only through its own organization and self-financed by the profit that results from the sale of their products.

In the Peruvian Andes, there is the occurrence of weather phenomena such as droughts and frosts that cause the loss of crops. The main effect of having adequate irrigation infrastructure is to ensure cultivation; firstly, supplying water in case of droughts and making it possible to recover plants from frosts. So that at least one harvest per year can be ensured. This is also known as crop safety. It is possible to increase the number of agricultural seasons per year by up to two in the best cases. Then, water administration is a strategy ancestrally used since the Incas to face unpredictable climatic changes and to guarantee food for the population [4].

To overcome these problems, millions are invested in infrastructure and training. But in the projects implemented in the Chumbivilcas-Espinar provinces, it has been shown that this does not always happen. Due to the overproduction of dairy products, there was a regional recession. A phenomenon in which supply exceeds demand and produces a drop in prices. In this case, prices fell even below production costs. So, the right short-term decisions can lead to long-term problems [5].

In this research, we are concerned with developing a production model to understand the factors that participate in it. The model simulation process has allowed the model to be validated. However, to know if the production process is profitable. It is required to evaluate it in the environment of its regional economy.

Therefore, it is also necessary to conceptualize and formulate economic factors. This gives greater importance to our research as it analyzes the Andes' economy from a perspective of fighting poverty. The methodology used to achieve our objectives is mainly system dynamics, as it includes the methods of thinking of systems and servomechanisms. The same ones that are suitable for complex systems.

As a result of the research, we have obtained the formulation of the different production sub-systems such as training, investment, available water, infrastructure, and others. And we have also managed to formulate the subsystems of the regional economy such as supply, demand, sale price, competition, etc. This makes it possible to project over time the impact of the irrigation improvement projects' anti-poverty policies. It also allows us to carry out a sensitivity analysis to know if the decisions we make in implementing the project are the correct ones, mainly to avoid regional recessions or falls in products sales prices [1].

2. Related Works

2.1. System dynamics

System dynamics is a popular simulation methodology developed by J. Forrester at the Massachusetts Institute of Technology (MIT). This simulation methodology is based on the theory of servomechanisms and feedback. It is also related to areas such as general systems theory and cybernetics. It also uses methods to study complex systems that act as an interlocutor between engineering methods and the methods for social systems [6]. One of the most important applications of System Dynamics is the world model published in 1970. A simulation of the behavior of society is shown under current "unplanned" growth conditions. The results of the simulation of the model show an over-exploitation of resources and a drop in population. The more population, the more waste is generated, and the more waste, the more diseases are generated is one of the conclusions of the model [7].

In the work of Fifth Discipline, considered to impact the business world greatly, revalues Forrester's systems dynamics. The author in [5] considers important for the understanding of modern organizations the study of dynamic systems, identifying the system's environment, and feedback mechanisms with it. He does not consider essential to arrive at the formulation of mathematical models. As a conclusion to his studies, he proposes the following disciplines: systems thinking, personal mastery, mental models, the construction of a shared vision, and team learning.

For irrigation research, dynamics can also be applied to the study of water management jobs, as demonstrated in the proposal for an optimization model for irrigation management in Australia [8]. In [9], the authors also developed a simulation model for China's water transport problem. In both works, positive results have been obtained using system dynamics.

2.2. Systems thinking

Systems thinking is the fifth discipline; the importance of systems thinking lies in being the body that unites the other disciplines of intelligent organizations. This job is incisive in pointing out that one of the factors for the failure of projects is the lack of systems thinking in their implementation [5]. Systems thinking is based mainly on the method of extension or synthesis. This becomes a premise for troubleshooting, where it is recommended to first view the system as part of a bigger system [10]. In this regard, we must comment that the classical scientific method, as we know, uses the analytical or reductionist method,

which, contrary to the synthetic method, what it does is studying the system in its components. The author in [11] categorically considers as a limitation of the scientific method. However, one of the most renowned authors on epistemology comments that systems thinking is an unfounded fashion issue and cannot generate scientific knowledge [12]. The author in [10] refuted this position, who maintains that the analytical and synthetic methods do not replace each other. On the contrary, they complement each other. In the present work, we show that it is possible to generate knowledge in the scientific method's formal language, between the system and its environment (exogenous variables) and the feedback mechanisms for adjusting the endogenous variables.

2.3. Fight against poverty

Thus, water is the engine for the economy of the Andes, although its cost is relatively low given its usefulness. To highlight the importance of water, we will mention the water-diamond paradox that tries to explain the low cost of water concerning diamonds that cannot generate life. This explains that, although the marginal utility of diamonds is much greater than the marginal utility of water, water's total utility is always greater than the total utility of diamonds [13].

To eradicate poverty, the author in [14] comments that the financial system has been saved on a global scale; for example, in Mexico, the banking system has been saved. Consequently, the cost of helping the poor is much lower and, in financial terms, more profitable if they are to be part of the aggregate demand. And, despite extreme poverty, we seem to have plenty of resources. At the same time, another study concludes that almost a billion people go to sleep hungry every day. In comparison, another billion people suffer from obesity, and 30% of food production is wasted, even from its mismanagement in harvest, sales, and post-consumption [15].

3. Methodology

The experience that served as inspiration for this work was that of the irrigation improvement projects in the Chumbivilcas-Espinar provinces that, due to their height (over 3820 m.a.s.l.) and geography, these are areas where low temperatures predominate (even below zero), all this leads to the existence of extreme poverty in the area [16]. Conditions that, in the first instance, made interventions in the so-called “high” provinces impractical. However, initially, they gave unexpected positive results thanks to the experience of the PEPMI and the adaptation of strategies that consisted, mainly, in cultivating imported pastures that resisted low temperatures and that were the main engine of the livestock industry and its derivatives in the area. Which brought the economic growth of the area. Despite this, after a few years, there was overproduction that manifested itself in the drastic decrease in sales prices. Therefore, it is necessary to manage uncertainty, the consequence of the decisions we make, and that, at first, seem the correct ones in the medium and long term, can become counterproductive. The explanation for this phenomenon was that an adequate market study was not carried out. Thus, to understand the interaction of the multiple factors, it was necessary to understand the behavior of the market and the mechanisms by which the sale price was mainly obtained. In an economic theory, appears the next components: consumers, producers, the market for goods and factors, and government intervention [13]. To formulate the simulation model of the production system, all these dimensions have been taken into account. Therefore, in this document, we will extend the original work to a perspective of economic theory whose main engine is water. In Figures 1 and 2, we can see the Sutunta lagoon and the dam built to store 4 million cubic meters to irrigate 6000 hectares.

Figure 1: Location map of the Sutunta lagoon in the province of Espinar-Cusco over 4000 m.a.s.l.

Figure 2: The dam built in Sutunta lagoon

In the conceptualization and formulation of the new production model, the systems dynamics methodology was used. The same one is based on the general theory of systems proposed in [11], the author that deals mainly to provide a general framework for science. To do this, it recognizes the concept of equilibrium or homeostatic point. The same that we must reach in the interaction of supply and demand in the market model also proposed [1]. Nash’s equilibrium abstracts the theory of non-cooperative games that involve sellers' participation, sets of strategies, and profits [17].

In the conceptualization phase, approximately 285 variables have been identified. The same ones have been organized in the dimensions of investment, training, organization, water for irrigation, irrigation infrastructure, production, market, environment, public budget, and water supply. As mentioned

above, the organizational dimension is primarily qualitative, and techniques have been used to allow it to be considered and provide qualitative information. This dimension has been adequate to be considered in the proposed production model. Another characteristic is that the production model allows obtaining a production volume that is considered supply and considering the existence of competition. Therefore, it is not an empirical model for educational purposes [6]; otherwise, it can provide information in a real environment. The number of variables and the peculiarities described makes it different from the authors' production models in [18], who propose a model of positive mathematical programming for models of regional production in agricultural-environmental programs and the classic spider web model [13].

The simulation of the production model has been carried out in the VENSIM program; the simulation results have served to validate the model. For validation, the Anderson-Darling normality test was used, whose results have been superior to $\alpha = 0.05$. As a result of the optimization model, non-linear programming with restrictions has been used to develop an optimization model that allows us to find the global optimum (profit maximization, cost minimization, and equilibrium point). Likewise, an analysis was carried out on the optimization model using nonlinear programming and genetic algorithms to determine the selection operators' efficiency in restricted non-linear problems.

4. Discussion

4.1. Conceptualization of the elements of the economic system for the fight against poverty based on water

In South America, the Inca culture developed. One of the most important cultures in the world whose cultural richness was based on values such as community work, also known as the "ayni" and the "minka". The Incas built large hydraulic works with the primary purpose of supplying food to the entire population. The importance of institutions like the PEPMI lies in need to revalue the cultural richness that, in some way, was being forgotten. In the field of intervention, they can be observed as problematic situations: inadequate irrigation infrastructure (inland canals that filter water), little farmer organization, and little knowledge of irrigation techniques [4]. This situation can even be complex if the following characteristics exist: conflicts, undefined access rights to water, water scarcity, and geological problems [3].

To solve these problematic situations, PEPMI implements irrigation improvement projects whose objective is to provide the population in the project area with the possibility of improving production and, therefore, improve their quality of life through access to more and better education, health, etc. services.

4.1.1. Production systems modeling in irrigation improvement projects

Consistent with the fifth discipline [5], a work in which the author concludes that one of the causes of project failure is the lack of a systems approach. If we review the experience of the projects implemented in Chumbivilcas-Espinar, in which there were problems of regional recession, after a few years of economic growth, it can be seen that, as part of the bigger system, the "market" is an exogenous component that is always present in the environment of the system. So, it is necessary to carry out an adequate market study and, for simulation purposes, to determine its feedback mechanisms. In figure 1, it can be seen through a block diagram, the main identified subsystems. Given the complexity of these projects' implementation, approximately 285 variables and 90 feedback loops have been observed and properly grouped into subsystems, as shown in Figure 3 [1].

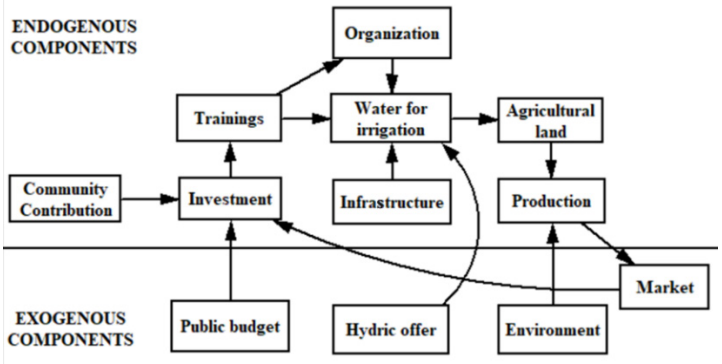

Figure 3: Block diagram of the proposed model for the agricultural production system

Figure 1 also identifies the necessary elements that participate in an economic theory (producers, consumers, goods markets, state intervention, etc.), having, in this case, water as the engine for the fight against poverty [13] or as "Theory of the economic and social value of water" states in a perfect market where there are several buyers and sellers, each commodity in the economy will be given its value [19]. As previously mentioned, the sustainability of projects is based on the strengthening of organizations and profitability. It is, then, necessary to know the profitability to identify the elements that participate under the economic theory defended by various authors [13].

4.2. Formulation and validation of the simulation model

The first objective of the work is to know the future behavior of the production system of the irrigation improvement projects implemented by the PEPMI. So, the planners will have a tool that allows them to know if they are making the right decisions or if the millionaire investments in infrastructure can cause short-medium or long-term adverse effects such as a recession. These phenomena have occurred in the provinces of Chumbivilcas-Espinar and the northern mountain range of Lima [20]. The causal diagrams made in the conceptualization phase have to be converted to mathematical logic models based on Forrester diagrams. For which the Vensim Personal Learning Edition (PLE) software has been used.

4.2.1. Subsystems formulation

Each of the subsystems shown in figure 1 are explained below:

A. Water supply

Determining the future supply of water is one of the main tasks to know. This to guarantee the water supply at the head of the plot. To achieve this, the historical information of the Pampaconga project has been considered. After analyzing the information, it has

been considered to perform a probability function for each month, using discrete probability distribution functions based on histograms. Requirements for the Monte Carlo simulation method [21]. Due to the limitations of Vensim Personal Learning Edition (PLE), the treatment of each probability function has been carried out in Excel and the results added in lookup functions in the implemented model.

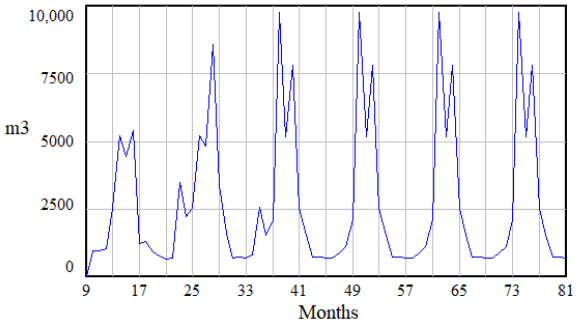

Figure 4: Projection of water availability due to rainfall

As shown in Figure 4, the hydrological year in Peru begins in September (month 9), and the high peaks represent the El Niño phenomenon. With climate change, this phenomenon will be increasingly present in the Peruvian Andes. When this occurs within the project's scope, the loss of production, and even irrigation infrastructure and all kinds of infrastructure is almost inevitable [22].

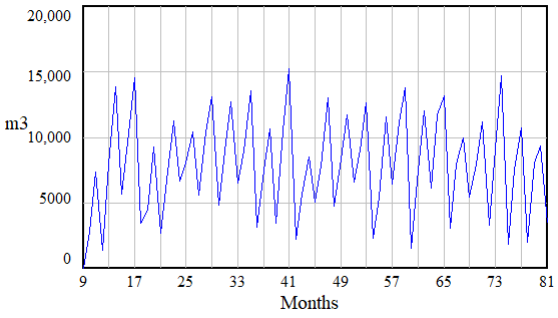

Figure 5: Projection of total water availability

The total water availability is made up of the rains and the flow of the rivers. These are exogenous variables that cannot be influenced. The projection of water availability is shown in Figure 5.

B. Investment

This subsystem is born from the public budget and external debt. For external indebtedness, there is German technical cooperation. According to the experiences of the first works implemented, the farmers showed resistance to change, to use and manage the modern irrigation infrastructure implemented by PEPMI. In addition, there is also the possibility of conflicts between communities over access to water and/or land. This demonstrates the high social component of the irrigation projects implemented [3]. Sometimes the engineer has to act as a sociologist to meet its goals [12]. To overcome these problems, the multidisciplinary team includes anthropologists, professionals who serve as important interlocutors between farmers and PEPMI.

In conclusion, the resistance to the change presented to use the new and free irrigation infrastructure was due; because farmers only use the infrastructure in whose construction they have participated. Therefore, project financing includes the community contribution, which is approximately 15 to 20% of the total project budget. This amount guarantees the participation of community members in the works to be built [3].

Another characteristic to take into account is that the Peruvian government considers irrigation improvement projects as social programs. And, given the appearance of economic problems, as the global pandemic caused by Covid-19, these programs are the first to reduce the public budget.

In the conceptualization of the production model in its interaction with the market, the investment subsystem receives feedback from the market, specifically, of the profit obtained from the sale of the products and the availability of financing that predisposes the advance of trainings and irrigation subsystems infrastructure.

C. Trainings

Training is an essential component to guarantee the sustainability of the project in its component of strengthening organizations and in terms of increasing productivity in the components of water management and the application of irrigation and cultivation techniques.

The PEPMI, being a state project, depends on the monthly budget. According to the monthly budget, it has the necessary factors to carry out the training: operational equipment, material, and workforce.

Figure 6 shows the Forrester diagram that explains the availability of resources to conduct the trainings.

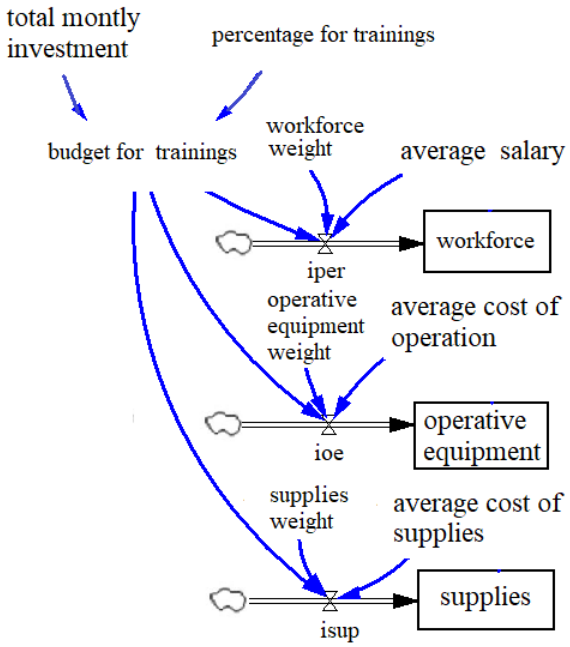

Figure 6: Forrester diagram: Availability of resources for training

The equations that govern the Forrester diagram in Figure 6 are as follows:

$$IPER = (BT*WW)/AS \quad (1)$$

where:

IPER: Personal ratio.

BT: Budget for trainings.

WW: Workforce weight = 0.5.

AS: Average salary = S/ 2000.00.

Percentage for trainings = 0.15.

$$IOE = (BT*OEW)/ACO \quad (2)$$

where:

IOE: Operative equipment ratio.

BT: Budget for trainings.

OEW: Operative equipment weight = 0.3.

ACO: Average cost of operation = S/ 1000.00.

$$ISUP = (BT*SW)/ACS \quad (3)$$

where:

ISUP: Supplies ratio.

BT: Budget for trainings.

SW: Supplies weight =0.2.

ACS: Average cost of supplies = S/ 300.00.

The trainings are carried out according to the availability of resources. The progress ratio is calculated according to the input targets programmed versus those available. And the total training per month predisposes the increase of water management, efficiency in the application of irrigation techniques, efficiency in the application of cultivation techniques, and strengthening of organizations that are governed by the following equations:

$$WM = 0.065*TPM \quad (4)$$

$$EAIT = 0.06*TPM \quad (5)$$

$$EACT = 0.07*TPM \quad (6)$$

$$SO = 0.065*TPM \quad (7)$$

where:

TPM: Trainings per month (the objective is 4 per month).

WM: Water management.

EAIT: Efficiency in the application of irrigation techniques.

EACT: Efficiency in the application of cultivation techniques.

SO: Strengthening of organizations.

As can be seen in Figure 7, in month 28, approximately the objective is achieved. This indicates that the trainings have made the farmer achieve 100% adequate water management. Similar behavior is observed in the variable's efficiency in applying irrigation techniques, efficiency in applying cultivation techniques, and strengthening organizations.

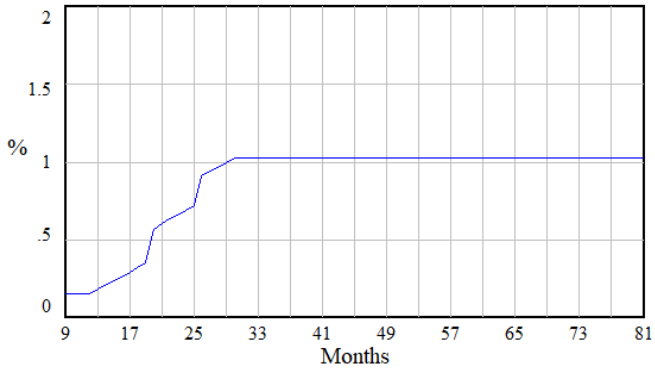

Figure 7: Advancement in water management

D. Irrigation infrastructure

Irrigation infrastructure is the component with the highest cost, depending on the size of the project. Its importance lies in the possibility of transporting water for kilometers without loss due to seepage and optimizing its storage and availability through dams and reservoirs. Advantages that the channels made on land do not have due to the high filtration rate. Irrigation infrastructure is also important to face adverse weather phenomena such as droughts, as it allows managing water scarcity, guaranteeing harvest (crop safety) and counteract adverse weather phenomena such as frost and hailstorms, since having a permanent water supply crops can recover, and, in areas where optimal conditions exist, the number of crops per year can be increased. What is also known as an increase in land use, which is the first step to fight poverty.

Then, the countries need to provide adequate irrigation infrastructure to manage the scarce water resource. This is because the imminent effects of climate change will affect primary sectors such as fisheries and agriculture, such as by 6% to the Peruvian GDP for the year 2030. One of the author's conclusions in [23] is that the emission of polluting gases and, therefore, the effects of climate change will continue. This situation evidently increases the total utility of water as part of managing scarcity and climate variability. Then, new efficient irrigation techniques such as dripping and sprinkling should also be considered. These aspects are already being considered in the making of water and irrigation laws.

Figure 8 shows the Forrester diagram that explains the availability of resources to carry out the irrigation infrastructure.

The equations that govern the Forrester diagram in Figure 8 are as follows:

$$Percentage\ for\ infrastructure = 0.85$$

$$ITS = (BI*TSW)/TSS \quad (8)$$

where:

ITS: Technical stuff ratio.

BI: Budget for infrastructure.

TSW: Technical stuff weight =0.06.

TSS: Technical stuff salary = S/ 2000.00.

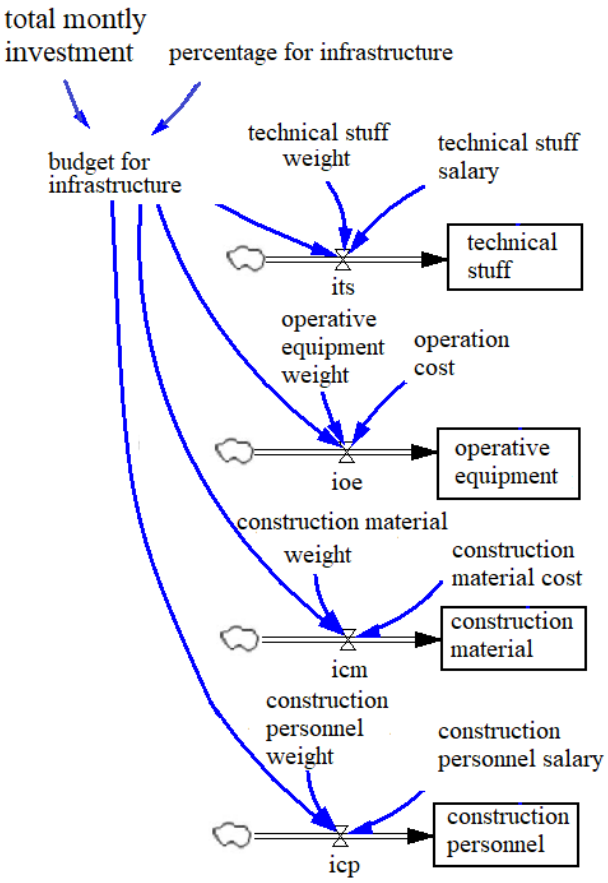

Figure 8: Forrester diagram: Availability of resources for irrigation infrastructure

$$IOE = (BI*OEW)/ACO \quad (9)$$

where:

IOE: Operative equipment ratio.

BI: Budget for infrastructure.

OEW: Operative equipment weight = 0.24.

ACO: Average cost of operation = S/ 4000.00.

$$ICM = (BI*CMW)/CMC \quad (10)$$

where:

ICM: Construction material ratio.

BI: Budget for infrastructure.

CMW: Construction material weight =0.11.

CMC: Construction material cost = S/ 15.00.

$$ICP = (BI*CPW)/CPS \quad (11)$$

where:

ICP: Construction personnel ratio.

BI: Budget for infrastructure.

CPW: Construction personnel weight =0.59.

CPS: Construction personnel salary = S/ 800.00.

Once the necessary resources are in place to carry out the irrigation infrastructure, the progress of the works depends on the availability of resources versus what is programmed and the weather conditions that allow the construction to continue. The construction progress is shown in Figure 9.

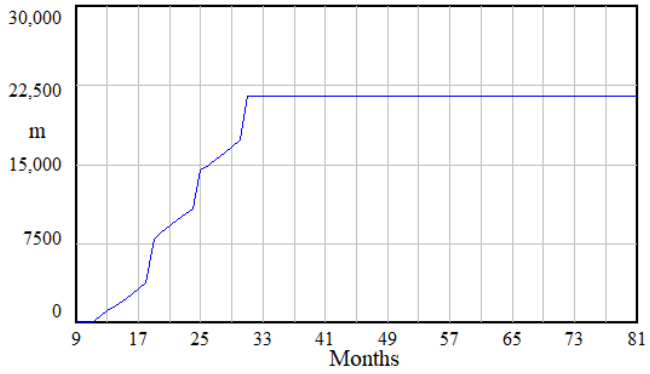

Figure 9: Progress in the construction of irrigation infrastructure

E. Water for irrigation

According to the progress of the irrigation infrastructure and the administration of water, the water for irrigation is determined according to the water demand calculated in the study phase. Figure 10 shows the Forrester diagram that explains the interaction of variables that determine the availability of water for irrigation.

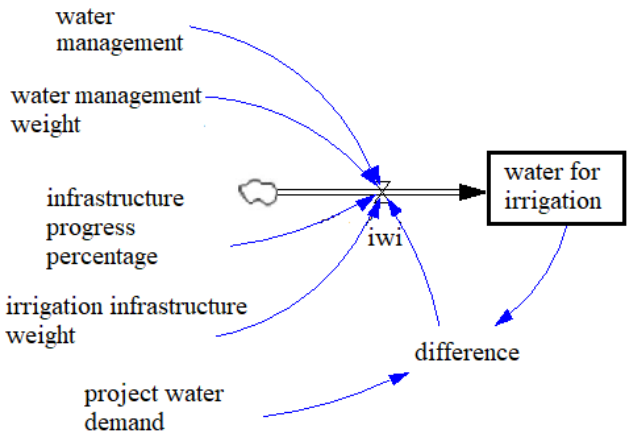

Figure 10: Forrester diagram: Water for irrigation

The equations that govern the Forrester diagram in Figure 10 are as follows:

$$IWI = [(D*WMW)*WM] + [(D*IIW)*IPP] \quad (12)$$

where:

Project water demand: 17,172.00 m3

D=PWD-WI

PWD: Project water demand.

WI: Water for irrigation.

WMW: Water management weight

WM: Water management.

IIW: Irrigation infrastructure weight

IPP: Infrastructure progress percentage

$$Water\ for\ Irrigation\ (t) = \int IWI(t)dt \quad (13)$$

where:

IWI: Water for irrigation rate

Figure 11 shows the increase in irrigation water until the project water demand is met, an important parameter that also serves to design the irrigation infrastructure (channels, reservoirs, canoes, rapids, etc.). The expansion of the agricultural frontier has a similar behavior within the project's scope as planned.

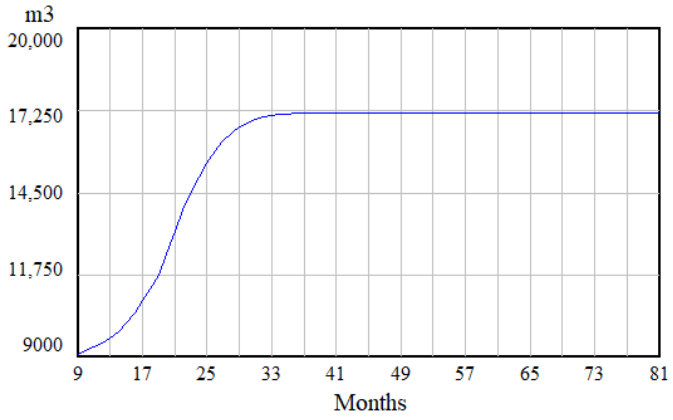

Figure 11: Increase in water for irrigation

F. Production function

The proposed simulation model for production in irrigation improvement projects includes the variables of water, supplies, training, machinery, and the human factor, whose interaction determines the quality and quantity of the cultivated land [1]. This is expressed in equation 14:

$$Adequate\ land\ for\ cultivation = \quad (14)$$

$$\begin{cases} 0 & ; WF \leq 0 \\ [WF*WWF+SF*SFW+TF*TFW+MF*MFW+HRF*HRFW]*PL & ; WF > 0 \end{cases}$$

where:

WF: Water factor.

WWF: Water factor weight (0.6).

SF: Supply factor.

SFW: Supply factor weight (0.1).

TF: Trainings factor.

TFW: Trainings factor weight (0.15)

MF: Machinery factor.

MFW: Machinery factor weight (0.1).

HRF: Human resource factor.

HRFW: human resource weight (0.05).

PL: Production land.

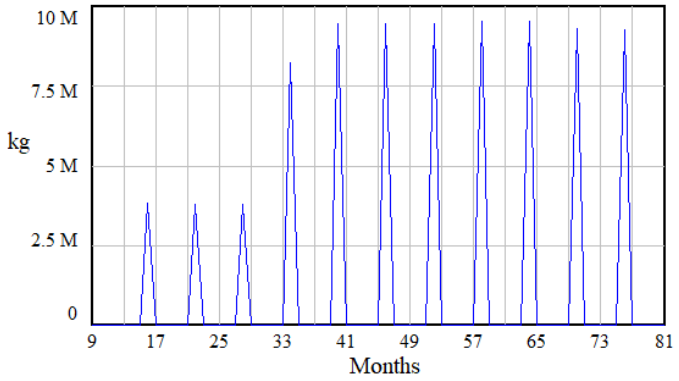

Figure 12: Production volume

G. Market

Once the production model has been obtained to determine the sustainability of the project, we must determine if there is a profit for the farmer due to sales in local markets. At this point, the proposed work requires to know the behavior of the market whose proposed model is of perfect competition [13].

Therefore, the present research becomes a broader study of the regional economy and an economic theory approach to fighting poverty, in this case, based on water as the main engine. Whose total utility in the medium term will allow farmers to access better living conditions such as health, housing, education, etc. Among these factors, we must highlight the greater and better access to education of the Andean population, as it will allow access to better economic income. About education, the winner of the last Nobel Prize in economics, in his work in Kenya,

concludes that better innovations must be made that allow more people to benefit economically from education [24].

H. Price determination

The interaction of supply and demand (which we have considered dividing into current demand and potential demand) and the seasonality of both allows us to know the product's sale price. Compared to the original work [1], in the present, we are going to present a new model described in equation 15.

$$Price = AP + [AP*(1-(SM+SMF))] \quad (15)$$

where:

AP: Average price.

SM: Satisfied market.

SMF: Stocks in the Market Factor.

$$Satisfied\ Market = Production\ volume / Current\ demand \quad (16)$$

Figure 13 shows the sale price behavior, in which it can be seen that the price reaches S/ 1.23 in times of scarcity and S/ 1.00 when there is overproduction. To carry out a sensitivity analysis, a scenario was constructed. The project's production increases by 30%, and due to market capacity (demand) occurs overproduction and, therefore, the sale price drops to S/ 0.66 per kg. These results, in a real environment, could occur in a few months or years. Note that the simulation is for 72 months, and, during the year, there are various seasons. This has been considered from the conceptualization of production and the market model. It represents an advantage and differentiates our proposal in relation to other production and market models such as the spider web.

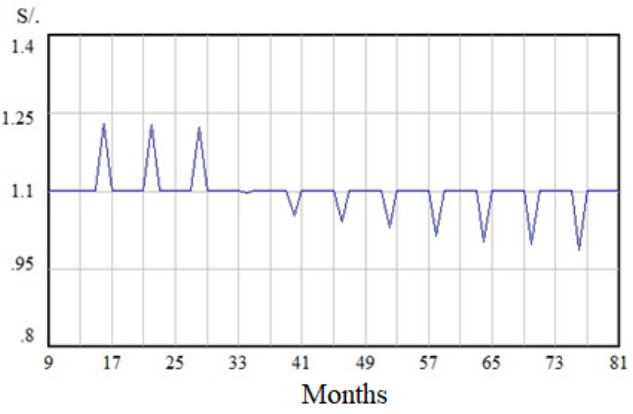

Figure 13: Sale price behavior obtained in simulation

4.3. Production optimization

Another aspect contemplated in economic theory is the maximization of producers' profits, who need to maximize the difference between total income and total cost. The break-even analysis allows us to know the minimum level of sales we must reach to avoid losses. Regarding the minimization of costs, the author in [25] recommends that this is the area we should focus on because it is difficult for producers to influence the sale price. Who governs us and defines the sale price is the market. Therefore, it is essential to reduce costs by implementing modern management techniques within organizations to obtain greater benefits. To define the optimization models, as observed through this work, we have the great restriction of the market (competition, seasonality, weather conditions, etc.). Therefore, it has been determined that the optimization of production is a restricted problem of the non-linear type. The objective function to maximize utility is shown in equation 17.

$$Max\ Z=16\varepsilon X_1 X_2 - 11.14X_1 \quad (17)$$

Subject to:

$X_3 \leq 3600+16X_1$; *Stock on the market*

$X_3-16X_1 \leq 3600$

$X_2 \leq AP+AP*[1-16\ X_1/X_3+X_4]$; *Sale price*

Replacing and solving:

Being: AP = S/ 1.10 (Average price)

$X_2 \leq 2.2-17.6X_1/X_3+1.1X_4$

$X_1 \leq 400$; *Arable area*

$X_4 = 0.1$

Solving, it is obtained that the maximum profit is S/ 5 784,000.00 and the sale price results S/ 1.6 (X_2).

5. Conclusions

The new proposed simulation model allows for understanding the behavior of the production process of irrigation improvement projects. In this paper, the systems dynamics methodology has been used mainly for its formulation. The new model allows the projection of data in the future and, in this way, determine the impact of the decisions that are made and if they do not lead to long-term problems. In the conceptualization phase, it has been possible to identify endogenous and exogenous variables; Among the exogenous variables, the behavior of regional markets stands out, determining the sale price of products. For the validation of the model, the Anderson-Darling normality test has been used for all the identified subsystems (training, strengthening of organizations, irrigation water, farmland, etc.). We obtained from the normality tests values higher than $\alpha = 0.05$.

The production factors that we identify for irrigation improvement projects are water, inputs, training, machinery, labor, and land. The respective weights can be seen in equation 14. The irrigation infrastructure and water management determine the availability of water. All these factors in the model determine the amount of cropland and the production volume to obtain. However, to measure the profitability of production, it is necessary to know its efficiency concerning the regional economy. That's why we formulate models that allow understanding of the market's behavior and sales prices in the region. The proposed models also make it possible to carry out sensitivity analyzes and

detect the appearance of regional recession phenomena. All these models have been expressed in a formal language, a requirement of epistemology for the generation of knowledge. Then our study becomes a perspective of economic theory for the fight against poverty based on water and its correct use.

For the formulation of optimization models, the nonlinear programming techniques based on objective functions and restrictions have been considered. The dimensions evaluated were: profit maximization, cost minimization, and breakeven point. The proposed production and market models have become constraints or objective functions as appropriate in the optimization model. To validate the optimization model, it has been verified that they comply with the Kuhn Tucker conditions. The optimization problem has also been analyzed using genetic algorithms, whose application has made it possible to know that the sexual selection operator is the most efficient for achieving global and local optimums.

The difficulties we had were access to information and the models' calibration, which is a process difficult and slow in which VENSIM has been very helpful. In future works, we will apply the proposed models in the Titicaca lake basin, and we will contrast them with time series.

ABSTRACT

This paper is carrying out a practical identification of a DC servomotor from input and output data. The system's step response was obtained from an acquisition card that we have developed using a microcontroller. The data is collected and downloaded to the PC Thought RS232 Protocol to process the identification process using polynomial models (ARX, ARMAX, OE, and BJ). Afterward, a comparison between the resulting models has been made using the validation criterions R^2 and FPE. The results show that the ARMAX, OE, and BJ models have reproduced a better fit compared to the ARX model.

1. Introduction

Servomotors have been developed at the origin of different uses. For example, radio-controlled aircraft, biped robots, and robotic arms. And nowadays, they are widely used in the robotics field, due to their cost, compactness, ease of use, and their high torque-to-weight ratio, which made them a good choice to achieve a compact and less expensive mechatronic system [1]. However, DCSM does not provide a good position control when it is in contact with a load and sometimes it provides a chattering motion. Thus, a mathematical model needs to be built to analyze and develop its performances. To do so, we tried to identify the mathematical equation of the system based on polynomial models.

A mathematical model is a multitude of equations that describe the relationship between the variables of a process or a phenomenon. It can take many forms depending on the studied system, and we can distinguish between two major classes.

1.1. Theoretical models

Theoretical models, Also known as whit-box, are models, which mostly used for simulations and theoretical studies. They are based on mathematical and physical laws, which made them often complex and hard to define [2]; however, it can give a complete description of the system.

1.2. Experimental models

Experimental models, also known as grey-box or black-box models are models used to define a mathematical model from the experiment's data. As mentioned in [3], in system identification, we could distinguish between two types.

- non-parametrical model is usually presented with numerical values, a graph, or a table, and it has an infinite number of parameters and an undefined structure.
- parametrical models, which are defined models structure who have a finite number of parameters.

According to [4], identifying a system or a process is about estimating a mathematical model that reproduces a static and dynamic response to a test input as close as possible to the real system. To do so, and to get a valid model, we need to follow a certain procedure [5], described in fig.1. It starts with the experiment preparation by choosing the sampling frequency and the input signal as a first step. Then choosing the model structure type, order, and delay as a second step. After that, selects the criterion that minimizes the error between the estimated model and the experimental data as the third step. Finally, the validation step that consists of applying several tests to prove the usability of the model. The resulting models' main objectives can be to understand the behavior of the studied system [6], or building the system control loop [7].

In this paper, Sections 2 and 3 cover a brief introduction of the linear polynomial models and parameter estimation process. Section 4 and 5 highlight the necessary steps for the implementation of the application. In sections 6 and 7, the results obtained from the experiment are presented and discussed.

2. Parametrical Models

2.1. Generalities

A discrete linear system can be presented as a general-linear polynomial model, which is considered as a transfer function whose parameters need to be estimated. This estimation is done by recursive and none recursive algorithms like maximum likelihood, instrumental variable or less square. This presentation, also gives flexibility for modelling both stochastic and system dynamics, and it is widely used in many real-world applications from different disciplines, e.g., [8–10].

Polynomial models are described in [11]. They can be defined by the generalized transfer function expressed by (1) and the signal flow represented in figure 2 [5]:

$$A(q)y(k) = \frac{B(z)}{F(z)}z^{-nk}u(k) + \frac{C(z)}{D(z)}e(k) \quad (1)$$

where:

$e(k)$: *is the system disturbance*

nk: *is the system delay*

$$A(z) = 1 + a_1 z^{-1} + \cdots + a_{n_a} z^{-n_a} \quad (2)$$

$$B(z) = b_1 z^{-1} + \cdots + a_{n_b} z^{-n_b} \quad (3)$$

$$C(z) = 1 + c_1 z^{-1} + \cdots + a_{n_c} z^{-n_c} \quad (4)$$

$$D(z) = 1 + d_1 z^{-1} + \cdots + d_{n_d} z^{-n_d} \quad (5)$$

$$F(z) = 1 + f_1 z^{-1} + \cdots + f_{n_f} z^{-n_f} \quad (6)$$

and:

n_a : The order of $A(z)$

n_b : The order of $B(z)$

n_c : The order of $C(z)$

n_d : The order of $D(z)$

n_f : The order of $F(z)$

By setting one or more n_a, n_c, n_d and n_f to 0 can create simpler models such as:

2.1.1. ARX model

ARX structure presented in equation (7) [5] is the result of setting n_c, n_d *and* n_f to 0 the signal flow is presented in fig.3. In this structure the noise model $\frac{1}{A(z)}$ is coupled with the systems dynamics, it is used to obtain simple model with good signal to noise ratio.

$$Y_{arx}(k) = \frac{B(z)}{A(z)}z^{-nk}u(k) + \frac{1}{A(z)}e(k) \quad (7)$$

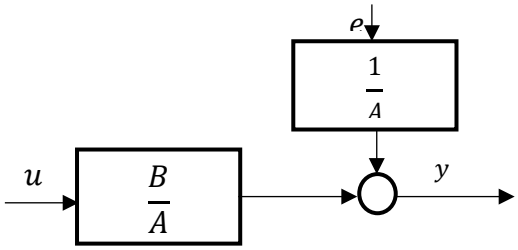

Figure 3: The ARX Structure

2.1.2. ARMAX model

The ARMAX structure presented in the equation (8) [5] is the result of setting n_d and n_f to 0 in the generalized transfer function (1), the signal flow is presented in fig.4. this structure provides more flexibility to model the noise by adding the $C(z)$ parameters

which is considered as a moving average of white noise. It is used when the noise enters in the input.

$$Y_{armax}(k) = \frac{B(z)}{A(z)} z^{-nk} u(k) + \frac{C(z)}{A(z)} e(k) \quad (8)$$

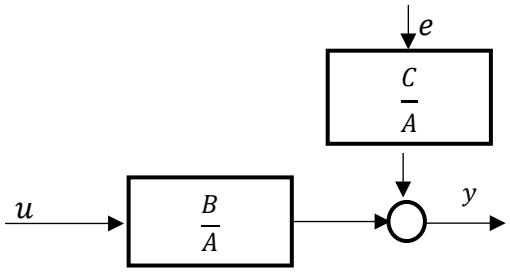

Figure 4: The ARX Structure

2.1.3. Output Error Model

The OE presented in the equation (9) [5] is the result of setting n_a, n_c and n_d to 0 in the generalized transfer function (1), the signal flow is presented in fig.5. In this structure, the noise model is considered as 1. It is used to parameterize the dynamic of the system only.

$$Y_{OE}(k) = \frac{B(z)}{F(z)} z^{-nk} u(k) + e(k) \quad (9)$$

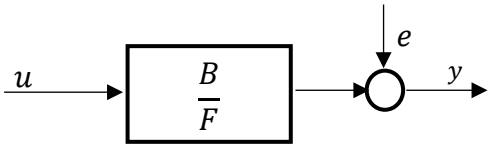

Figure 5: The OE Structure

2.1.4. Box- Jenkins Model

The BJ structure presented in the equation (10) [5] is the result of setting n_d to 0 the signal flow is presented fig.6. This structure provides more flexibility because the noise model is independent of the dynamics model. It is used when the noise enters as a measurement disturbance.

$$Y_{BJ}(k) = \frac{B(z)}{F(z)} z^{-nk} u(k) + \frac{C(z)}{D(z)} e(k) \quad (10)$$

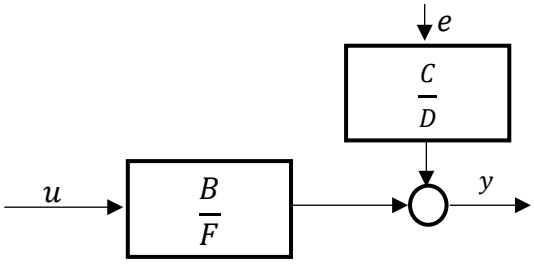

Figure 6: The BJ Structure

3. Parameters Estimation

Parameter estimation is a mathematical process that uses experimental data to estimate the system parameters, in this paper; this process is done by the prediction error method described in [12] and fig 7. this method aims to minimize the error expressed in Eq (13) between the estimated and the real system [13].

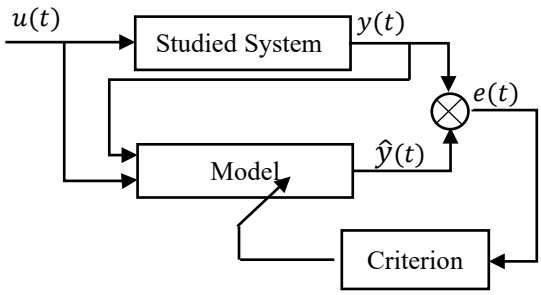

Figure 7: Prediction Error Method

According to [14], to use the Prediction Error Method, we need to choose the model structure, the one-step-ahead predictor $\hat{y}(k|k-1,\theta)$ described with the equation (12) and the criterion function $J(\theta, Z^N)$ given by Eq (11):

$$J(\theta, Z^N) = f\left(R_N(\theta, Z^N)\right) \quad (11)$$

where:

$$R_N(\theta, Z^N) = \frac{1}{N}\sum_{t=1}^{N} e(k,\theta) e^T(k,\theta)$$

$$\hat{y}(k|k-1,\theta) = H^{-1}(q)G(q)u(k) + (1 - H^{-1}(q))y(k) \quad (12)$$

And the prediction error is given by:

$$e(k|k-1) = y(k) - \hat{y}(k|k-1,\theta)$$
$$= H^{-1}(q)(y(k) - G(q)u(k)) \quad (13)$$

4. Model Validation

Model validation is the final step, which goal is to compare and validate the usability of the estimated model by testing several criterions like those in this paper:

1.3. Akaike Final Prediction Error

This criterion described in the equation (14) [5] was presented by Akaike (1967) as a final prediction error (FPE), based on Akaike's theory, the best model has the smallest FPE.

$$\mathrm{FPE} = \det\left(\frac{1}{\mathrm{N}}\sum_{1}^{\mathrm{N}} \mathrm{e}(\mathrm{t},\theta_{\mathrm{N}})(\mathrm{e}(\mathrm{t},\theta_{\mathrm{N}}))^{\mathrm{T}}\left(\frac{1+\mathrm{d}/\mathrm{N}}{1-\mathrm{d}/\mathrm{N}}\right)\right) \quad (14)$$

where:

N: The number of values in the estimation data set

$e(t)$: The vector of prediction error

θ_N: The estimated parameters

d: The number of the estimated parameters

4.1 Best Fit

The RMSE criterion measures the similarity between the data and the estimated model and can be calculated using equation (15) [15].

$$\text{Best Fit} = 100\left(1 - \frac{\sum_{i=1}^{n}(y_i - \hat{y})^2}{\sum_{i=1}^{n}(y_i - \bar{y})^2}\right) \quad (15)$$

where:

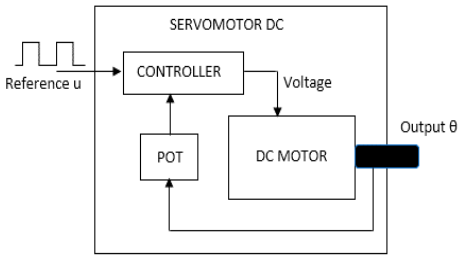
y_i : The measured output

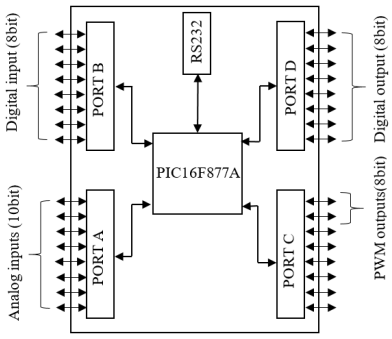
$\hat{y}$: The estimated output

$\bar{y}$: The mean of the output

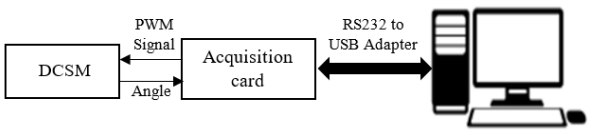
5. Application

A DCSM is composed of a potentiometer and integrated circuit that ensures a dc motor's position control based on a reference signal received from a microcontroller or an external organ (fig.8). However, despite its different applications, there is a major problem in achieving good performance with those servo motors due to the integrated circuit [1]. Therefore, the goal is to estimate all the system's internal and external components' mathematical model, to design a new controller or exploit it in more complex systems. In this application, the reference signal is in the form of a pulse with modulation signal who does not exceed 20ms between two rising edges, and the DCSM supply voltage is 5V.





To extract reliable input and output data, we build the acquisition card with pic16f877a. As shown in fig 9, this microcontroller has eight analogic inputs of 10-bit resolution, one digital input, one digital output of 8-bit resolution, and two PWM output of 8-bit resolution. Moreover, it is linked to the computer using RS232 communication with a speed of 115200bit/s to send and receive data necessary for the experiment. However, today's computer does not support this type of communication. To solve this problem, an RS232 to USB adapter is used, as shown in fig 10.



Afterward, to know the sampling time Ts, which is related to the uncertainty of the internal and external components and the instructions execution time of the microcontroller. The analogic input of the acquisition card is subjected to a periodic signal of known frequency. The samples collected from the acquisition card are represented on a graph. Afterward, the frequency of the test signal is adjusted until a signal similar to that of the input is obtained, which $Ts = 0.0034$ deduced in this application. This will allow having a speed of 300 sps/s.

Next, the analysis and parameter estimation process is applied to the collected data from the acquisition card.

6. Results

Model order determination in parameter estimation is essential because a lower order model cannot adequately describe the system's dynamics, and a higher-order model may have uncertainties. Thus, to extract the best model and to see the effect of changing the order of the parameters, we applied the experimental approach of identifying a parametric model described in fig 1, and we fixed nk to 1 then:

- Over 100 ARX models are calculated where $n_a$and n_b are in the range of 1 to 10.
- Over 125 ARMAX models are calculated where $n_a, n_b \; and \; n_c$ are in the range of 1 to 5.
- Over 25 OE models are calculated where $n_f and \; n_b$are in the range of 1 to 5.
- Over 625 BJ models are calculated where $n_a, n_a, n_a \; and \; n_a$ are in the range of 1 to 5.

Afterward, the Best-fit criterion is used to select the best five structures in each model, and the PFE criterion is used to choose the best structure in each model. Those results are in tables 1 to 4.

7. Discussion

As presented in tables 1 to 4, all the extracted models in each structure have closely a similar FPE. Then the choice of the model is based on the best-fit only. Besides, no significant change occurs in the best-fit criterion by increasing the models' order in each model type. Thus, the selected model will have the lowest order. This will allow a better processing time while doing online parameter estimation in real-time applications.

- The best-estimated ARX model is the ARX331 shown in Figure 11 and Table 1. It has an order of (nb=3 and na = 3), and a fit of 72,44
- The best-estimated ARMAX model is the ARMAX2411 shown in Figure 12 and Table 2. It has an order of (na = 2, nb = 4, nc=1), and a fit of 94,75%.
- The best-estimated OE model is the OE131 shown in Figure 13 and Table 3. It has an order of (nf = 3, nb = 1), and a fit of 95.009.
- The best-estimated BJ model is the BJ12331, shown in Figure 14 and Table 4. It has an order of (nb = 1, nc = 2, nd = 3, nf = 3), and a 95.02% fit.

Based on those results and figure 16. The ARX models provided a fit of 72%, which is a poor fit compared to ARMAX, BJ and OE Models. However, if we want to use a model in real-time applications, the best choice will be OE131 because of the resulting good fit with the measured output and fewer parameters.

8. Conclusion

In this article, a practical identification of DCSM has been elaborated using polynomial models. To meet application requirements and to collect input-output data, a microcontroller-based acquisition card has been developed. Finally, the comparison between the data and the estimated models using validation criterions shows that the ARMAX, BJ, and OE model has provided a good fit with experimental data and can be used in simulations or a real application.

In future work, the data acquisition system will be based on PLC to be adequate for industrial applications and to provide more sampling frequency and processing time. Moreover, other identification techniques will be applied to more complex non-linear systems to build proper algorithms for the control loop or fault detection.

English and Arabic

ABSTRACT

The world is facing an unprecedented virus outbreak, COVID-19, hitting more than 200 countries. Governments have been striving to prevent the spread of the virus through the lockdown. During the strict lockdown in Jordan, people needed to stay home, and they used available social networks to keep updated on COVID-19, with Facebook, the most popular social media platform. The study aimed to elicit information about assessing the use of FTS as a source of information in general and on COVID-19, in particular, FTS for those interested in English posts. However, it cannot read them and how reliable users think FTS is. The questionnaire was sent through the available networking sites, such as Facebook Messenger. The study found that 94.3% use Facebook daily; 87.1% of the participants activated Facebook Translation Service (FTS). It is found that 62.2% of the participants considered Facebook as a primary source of information regarding COVID-19 and 27.8% as secondary source. In terms of FTS usage, 87.3% used FTS in translating English Facebook posts into Arabic, and 83.8% used FTS in translating English Facebook COVID-19 posts into Arabic during the lockdown. On the other hand, it is found that the majority found FTS committed minor errors in terms of adequacy and fluency. This success is due to the usage of Neural Machine Translation (NMT)approach and bilingual text corpora. The advantage is that FTS is a well-trained database that can provide more accurate translation than other model. In conclusion, disregarding FTS output quality, our research shows that Facebook and FTS became a significant source of information during abrupt crises. Such research would encourage government officials to better use Facebook and FTS as complements to their national health campaigns.

1. Introduction

The translation is the medium of human communications. It bridges the gap between human communities and ensures the best communication among the global communities [1]. Nowadays, the world is facing the most frightening Coronavirus (COVID-19) outbreak in the last century. International Health Organizations, Medical Specialists, health authorities, political leaders, and the public write posts round the clock on social networks, making the influx of information massive. The flow of information is unprecedented, and therefore, there should be a way to facilitate transferring this information into all-natural languages. It is predicted that the demand for translation industry will reach unprecedented number $56 billion in 2021 [2]. This growth in translation demand has been occurring at a rate beyond professional human translators' capacity to keep up with, and the cost associated with human translation is too high for many purposes [3]. For example, It is indicated that they can translate up to 10 billion words daily. Translating the massive flow of information is beyond human translators' capacity, hence the central role of Machine Translation (MT). This tool can cope with large amounts of data at a split-second rate. However, there is no relation between the speed of translation and the quality of the translation [4].

In facing COVID-19, MT works as a tool to challenge and fight the virus. It is stated that "The challenge is how to communicate rapidly changing data across language borders, so that essential information is not lost in translation." In this concern, it has been shown that machine translation can help fight COVID-19. The

*Corresponding Author: Zakaryia Almahasees, Email: z_almhasees@asu.edu.jo

current study aims to assess the popularity and use of Facebook Translation Service (FTS) in translating English Facebook posts in general and COVID-19 in particular among Facebookers in Jordan.

Social Networking is a flagship of human communications nowadays. Social networking refers to online platforms to keep humans connected regardless of their locations and territories. Social networking connects people globally of different groups and ethnicities for social, business and other purposes, such as Facebook, Twitter and the like [5]. More than 3.81 billion users of social networks worldwide and lists the most famous six social networking sites worldwide based on their monthly users: Facebook, YouTube, WhatsApp, Facebook Messenger, Weixin(WeChat), and then Instagram. Facebook tops the other social networking sites with 2.5 billion users monthly [6].

Regarding Jordan, it has been listed Facebook as the most popular, with 88.6% of all social networking users. When it comes to languages [7]. English has been classified as the top language with 25.3% of internet content, while Arabic content represents no more than 4.8% [8], [9]. For English content published on Facebook, FTS allows Arabs to read the English posts in Arabic.

However, the number of Facebook active monthly users in the Middle East reaches 200 million [10]. A study conducted in Jordan to elicit information about the source of information for a sample of 500 medical students in three Jordanian Universities. They found that 83.4% used social media and 83.4% favored online search to access COVID-19 related information. However, the study did not specify the most popular social networks among medical Students [11].

Social media becomes an essential means of communication since COVID-19 updates take place around the clock. Such widespread use, particularly at the time of a health crisis mandating social isolation, raises questions about the content Facebook provides in terms of its effectiveness and limitations to end users since Arab Facebookers are mostly exposed to posts written in English. Some Arab Facebookers can read and understand English. However, there is still a large portion of users who are not sufficiently competent to read posts in English, and instead, use FTS, Facebook's translation service since 2011. Facebook Translate helps users communicate with each other in different languages. Facebookers can easily activate the translation service on their profiles. Users can select their region and language and the language they wish their posts to be translated into in their settings.

2. Facebook Translation Service (FTS)

Historically, Facebook initially used Google Translate service to translate the posts into 50 languages. Facebook launched its first Translation Service in 2011, called In-line Translation Facebook Tool [12], this time powered by Microsoft Bing. For example, if a non-Spanish speaker gets a cross a Spanish Facebook post, he will be able to see the translation of the post in his own language.

Currently, FTS offers translation services for 89 languages, and they will continue to add more languages. FTS adopted a phrase-to- phrase MT approach by translating whole sequences of words, where the lengths may differ. In 2017, Mark Zuckerberg, the founder of Facebook, explained that translation is the best means to connect humans globally. Language understanding brings people close and thus help them to share and get access to information universally [13]. In the same year, the Facebook research team developed a new MT approach using Convolutional Neural Networks (CNNs) instead of Google Translate. The recurrent neural networks can help translate languages more accurately (increase quality on a BLEU scale) and up to nine times faster than the traditional recurrent neural networks (RNNs). Neural MT has been described approach as a tool to provide instant translation accurately across languages faster than previous MT approaches [14]. This is confirmed by [15], [16].They have shown that "CNNs have been very successful in several machine learning fields, such as image processing. However, recurrent neural networks (RNNs) are the incumbent technology for text applications and have been the top choice for language translation because of their high accuracy".

In late 2019, the Facebook research team announced new advances in NLP, boosting Facebook Translation accuracy. They have also introduced a new self-supervised pretraining approach, RoBERTa, that surpassed all existing Natural Language Understanding (NLU) systems on several language comprehension tasks. They have also collaborated with New York University (NYU), DeepMind Technologies, and the University of Washington (UW) to promote their future research [16].

The present study focusses on Facebook translation of English Facebook posts related to COVID-19 released by International Organizations such as WHO, political leaders, medical specialists, and the general public into Arabic. The study provides constructive feedback about whether FTS is considered a reliable source of information or not and the degree of trust among the end-users. It addresses the following questions:

What, according to participants, is the percentage of FTS Activation in Jordan?

What is the rate of using FTS in translating English Facebook posts and Covid-19 Facebook posts into Arabic?

As a source of information, how often Jordanians use FTS?

To what degree FTS output is adequate and fluent in English to Arabic translation?

To what extent, Jordanian rated FTS output?

3. Literature Review

The outbreak of COVID-19 makes social networking sites a source of information for many people around the globe. COVID-19 is an emergent crisis, unprecedented in the size of information posted daily about the pandemic. Facebook usage increases by 40% due to the COVID-19 crisis. Facebook becomes a medium of communication. Machine Translation plays an influential role in facilitating communication among human communities [17], [8]. The study is mainly concerned with the popularity of FTS among Jordanians in translating the English Facebook posts into Arabic. To the best of knowledge of the author, this is the first research to fill the gap and provide the literature with information about the role of FTS in educating Jordanians and fighting COVID-19.

Social networking sites have become a useful tool in confronting the crisis and keeping people close to each other when they are isolated due to lockdown in most of global countries. He

adds that the public health experts have used social networking sites to interact with the public and provide healthcare advice to fight and prevent the spread of the outbreak[[18]]. The acceleration in digital life changes how health information is approached. The health care providers used this opportunity to disseminate their advice and right information for the public [[19]].

On the other hand, Facebook becomes the source of information for 100,000 health care providers regarding the COVID-19 outbreak, "For the past few weeks, after I get home from my shifts in the emergency room, I have been scrolling through Facebook pages on my laptop, getting firsthand stories from doctors in Italy, China, and Iran" [20]. Another study has been conducted a descriptive study on medical students in Jordan to assess knowledge, attitude, perceptions, and precautionary measures toward COVID-19. They have found that 83.4% used social media sites as their preferred source of information regarding COVID-19 [11]. Moreover, another study has been carried out in Jordan to assess university students' knowledge, practice, and attitude regardless of their majors. They have found that university students' information source is social media, internet, and television. No significant difference was noticed between medical and non-medical college students on the sources of their information. On the other hand, social networking sites have become platforms for survival against social isolation during the COVID-19 [21]. In this regard, Facebook becomes the central platform to help the community and those in need during this pandemic [22].

Another use of social networks during the crisis is highlighted by as a platform to preach and provide spiritual support to conduct digital prays and biblical lesson [23]. On the other hand, social media shows how social networks become the platform for sharing controversial messages to Chinese people. Some users blamed China as a source of the disease and therefore Chinese became the target of many hateful and offensive posts on most social networking sites., such as Facebook and the like. Facebook and other social media have been clamped down the spread of fake news concerning COVID-19 [24], [25]. The study highlights the FTS infighting world crisis, COVID-19, in provide translation for the English Facebook posts related to COVID-19 into Arabic.

4. Methodology

Arabic is the official language of 24 Arab countries with a population of 300 million. Jordan is one of Arab countries and the research on Facebook Translation service in Jordan would of great interests and a source of information for all Arabs. Descriptive cross-sectional study design was used in this work. Our sample consisted of 200 Jordanians from five cities of Jordan: Ajlun, Amman, Irbid, Jerash, Kerak. The study population has different educational backgrounds except for English language specialists (Linguistics, literature, and Translation studies) and were asked to fill the questionnaire. The study used an online questionnaire delivered to participants in the period between March 10 to July 29 during the lockdown in the Jordanian government's effort to control the spread of COVID-19. The online questionnaire was created on Google Forms and sent to the participants through Facebook Messenger to ensure the social distancing in line with the Jordanian government's recommendations. Therefore, all participants in this study have Facebook pages. The study's total population was 200 responded to the study, 106 females (52.7%) of the sample, and 95 male participants (47.3%) (see appendix 1) An independent T-test was conducted to identify a relation between rural and urban areas regarding rating the adequacy and fluency of FTS. It is evident from the table 2 that a value of 1.076 at sig = 0.283 indicates that there are no statistically significant differences at 0.05 between rural and urban residents in the evaluation of the fluency of FTS. Moreover, another t-test was conducted to verify the relation between gender and fluency rating. It is evident from the table 3 that a value of t was 1.145 at sig = 0.254, indicating that there were no statistically significant differences at 0.05 between males and females in evaluating the fluency of Facebook Translation Service. Another also t-test conducted on the relation between the education level and the adequacy. The study found that there are statistically significant differences at 0.05 in evaluating the fluency of FTS according to the educational level, and by conducting post-tests to test the analysis of variance, it was found that the source of the differences is the existence of statistically significant differences between holders of a diploma and those who hold a master's degree in favor of a diploma.

4.1. Research Instrument

The researchers designed a dichotomous questionnaire that was created on the Google Forms platform. The questionnaire has yes/no questions to elicit Jordanians' responses concerning their usage of Facebook Translation service in translating English Facebook posts into Arabic and, in particular COVID-19 posts.

The online questionnaire consisted of seven main divisions main sections. The first section collected demographic data on gender, age, education, cities, and living areas. The second section consisted of the following questions:

Have you activated FTS on your Facebook Page?

Have you used FTS in translating English Facebook posts into Arabic?

Have you used FTS in translating English Covid-19 Facebook posts into Arabic?

Have you considered FTS output as a Primary source of your information regarding COVID-19?

Irrespective of the English posts' contents (maybe not reliable, fake, or misleading), do you find the translation by FTS acceptable?

Irrespective of the English posts' contents (maybe not reliable, fake, or misleading), do you think Facebook Translation Service has translated them accurately?

Have you rated FTS?

Two professors reviewed the survey, and proper modifications were completed before delivering to participants. Participation in the study was voluntary, and personal Facebook pages and identifiers were not collected. Data was imported into Excel for management and then SPSS for analysis. Numbers and percentages were presented for all variables.

5. Results

5.1. FTS activation among Jordanians

First, we examined the number of Facebookers who activated FTS on their Facebook pages. As mentioned above, the questionnaire was sent via Facebook Messenger, and therefore all participants have Facebook pages. Our analysis showed that (87.5%) of the participants activated FTS on their Facebook, while only (12.5%) of the participants did not activate FTS. This finding shows that FTS is used mostly by Jordanian. Moreover, this result correlates with [[7]] that Facebook is the most popular social media.

Table 1: Percentage of FTS Activation

Classification	Sum of Frequency	Sum of Percent %
No	25	12.5
Yes	175	87.5
Grand Total	**200**	**100**

5.2. Have you used FTS in rendering English Facebook posts into Arabic?

Next, we wanted to know if Jordanians used FTS in rendering English Facebook posts into Arabic in general and English posts concerning COVID-19 rendering into Arabic. Our analysis showed that (87.6%) of Jordanians used FTS in rendering English posts into Arabic, while 12.4% did not use FTS in translation. These results highlight the role of FTS in facilitating communications between English and Arabic.

Table 2: FTS usage among Jordanians at the time of Covid-19

Have you used Facebook Translation Service in rendering English posts into Arabic?		
Classification	**Sum of Number of respondents**	**Sum of Percent %**
No	25	12.4
Yes	175	87.6
Grand Total	**200**	**100**

5.3. Have you used FTS in translating English Facebook Covid-19 posts into Arabic?

We aimed to elicit information about the percentage of FTS in translating English Covid-19 posts into Arabic. The study's analysis showed that (83.1%) have used FTS in translating English Facebook COVID-19 posts into Arabic. These figures showed that FTS played a significant role in facilitating communications among Jordanians at the time of the COVID-19 outbreak in Jordan.

Table 3: FTS rendering English posts about Corona Virus (COVID-19) into Arabic

Have you used Facebook Translation Service in rendering English posts about Corona Virus (COVID-19) into Arabic?		
Classification	**Sum of Frequency**	**Sum of Percent %**
No	33	16.9
Yes	167	83.1
Grand Total	**200**	**100**

5.4. Have you used FTS daily at the time of COVID-19?

Next, we aimed to identify how often Jordanians used FTS during the time of lockdown in Jordan. Our analysis showed that most of Jordanians used FTS daily with (94. %). This correlates with [[7]] indicated that Facebook usage in Jordan reached 92% over the COVID-19 period, while only (5.97%) did not use it daily.

Table 4: Frequency Facebook and FTS among Jordanians at the time of Covid-19 lockdown

Classification	Sum of Frequency	Sum of Percent %
Daily	188	94
Rarely	1	0.5
Weekly	11	5.5
Grand Total	**200**	**100**

5.5. Have you considered FTS output as a Primary source of your information regarding COVID-19?

First, we examined how the participant deals with FTS as a source of information. The question aimed to identify whether Jordanians considered FTS output as sources of information at the time of lockdown. Our analysis showed that most participants with (62.2%) considered FTS output as the primary source of their information regarding COVID-19. In comparison (27.8%) showed that they considered FTS as a secondary source of their information.

Table 5: Facebook as a Sources of Information Related to COVID-19

Category	Sum of Frequency	Sum of Percent %
Partial	3	1.5
Minor	16	8.5
Primary	125	62.2
Secondary	56	27.8
Grand Total	**200**	**100**

5.6. How do you rate the fluency of FTS output?

The above chart illustrates how the study's participants rated FTS. The analysis showed that the respondents rated FTS output at the category of almost all of the meaning in the translation with 41%, followed by 40.5% who believed that FTS output is complete as fluent. However, 14% of the responses showed that the translation is not fluent, and FTS output contains some of the ST meaning, followed by 4.5% for FTS as disfluent.

Table 6: FTS Adequacy

Adequacy	Sum of Frequency	Sum of Percentage
All the meaning in the source is contained in the translation, no more, no less.	81	40.5
Almost all the meaning in the source is contained in the translation.	82	41
Fragments of the meaning in the source are contained in the translation.	28	14
None of the meaning in the source is contained in the translation.	9	4.5
Grand Total	**200**	**100**

5.7. Have you rated the adequacy of FTS output?

The above chart elucidates how the study respondents rated FTS output fluency (grammar). It showed that the majority of respondents rated FTS output as fluent with minor errors at the percentage of 69.65%, followed by 23% indicated that FTS output rated FTS output as fluent with no errors. On the other hand, 6.5% rated FTS output as disfluent.

Table 7: FTS Fluency

Fluency	Sum of Frequency	Sum of Percentage
Refers to a perfectly flowing text with no errors.	46	23
Refers to a smoothly flowing text even when a number of minor errors are present.	139	69.5
Refers to a text that is poorly written and difficult to understand.	13	6.5
Refers to a very poorly written text that is impossible to understand.	2	1
Grand Total	**200**	**100**

5.8. Have you rated FTS output?

Then, the study aimed to elicit information about the FTS output rating by the participants. The analysis showed that 55.5% of respondents rated FTS sometimes, 42% rated FTS always, while 2.5% were not sure they rated FTS. The study here emphasizes that rating is crucial to improve its service and provide the end-users with information about the end users' trust of FTS output development of FTS service.

Table 8: FTS Rating

Classification	Sum of Number of respondents	Sum of Percent %
Always	84	42
Not sure	5	2.5
Sometimes	111	55.5
Grand Total	**200**	**100**

6. Discussion

The current descriptive study assessed the popularity of FTS in translating English Facebook posts into Arabic and Posts related to COVID-19 in particular. Participants were found to be familiar with FTS usage during the COVID-19 lockdown. The results showed that social networking sites have a significant role in our modern life. Facebook becomes one of the most popular social media websites. Facebook becomes a source of information during the time of COVID-19 lockdown since Facebookers read posts around the clock. The study showed that (94%) of participants used Facebook daily to read, share, and post. This percentage complied with [[7]] that Facebook occupied the first rank in social media stats with (88.69%) over June 2020 in Jordan.

Our assessment of the information sources showed (62.2%) of Jordanians considered FTS as the primary source of their information during the COVID-19 lockdown. The study attunes with what [[11]] and [[21]] said in their research that Facebook becomes the source of information for medical students in Jordan (83.4%). This means that Facebook becomes a popular online platform that supports the efforts to fight COVID-19 at the government side, where the government officials and health care providers to convey their messages to control the outbreak of COVID-19. Even though FTS became a source of information in translating English Facebook posts into Arabic, but the need for a thorough analysis of the output of FTS by a translation scholar is of great importance to highlight the limitations and strengths of FTS.

The study indicated that FTS was used daily, equal to (94%). Moreover, it is found that Jordanians used FTS in translating COVID-19 posts into Arabic, with a percentage of (83.1%). This finding complied with [[11]] finding that (83.4%) medical students in Jordan used Social Media to learn about COVID-19. However, they did not ask the participants about their preferred social media platform. This finding motivates the researcher to conduct further study to verify the capacity of FTS to provide adequate and fluent output to the end-users.

The study found that the participants rated FTS output adequacy with (41%) almost the meaning of the ST in the TL; (40.5%) showed that FTS output is fully adequate to the end-user. Furthermore, it is found that (69.65) of FTS output has minor errors, while (23%) is free of errors. On the other hand, the study highlighted that Jordanians sometimes tended to rate FTS service with (55.5%) for rating FTS and always rating for FTS with (42%). The rating provides a review for the FTS team to improve its services. The rating benefits Facebook in two ways: help the users make decisions to use FTS or not and help Facebook gain the users' credibility.

7. Conclusion

Overall, Facebookers in Jordan tend to use FTS in rendering English posts in general and posts related to COVID-19 into Arabic. This means that Facebookers used Facebook as their primary source of information. The study concludes that in such an unprecedented COVID-19 crisis, the health officials should create Facebook Profiles with a blue tick for medical information during crises. Countries where the outbreak is hitting hard should focus on educating the public. Moreover, medical specialists and translation scholars should form evaluation groups to ensure that FTS can render COVID-19 medical posts into Arabic fluently and adequately. Finally, the study recommends further studies to scrutinize FTS outputs thoroughly to highlight the service's limitations and strengths.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The authors would like to extend their thanks to all participants in this study. The research has been funded by Applied Science Private University, Jordan.

Transport emergency

ABSTRACT

The paper addresses speeding up meetings in a networked environment during rescue works in a transport emergency. Several groups of representatives of various services and observers participate in those meetings. The number of wrong decisions tends to increase because remote participants cannot understand each other quickly. First, the meetings must be efficiently held to avoid making wrong decisions, including medical diagnoses for injuries. The ultimate goals are to improve injured' health and life. Artificial intelligence (AI), big data analysis, and deep learning methods suggested in this paper for decision-making support have a cognitive character, i.e., try to take into account the thoughts and emotions of participants. The author's convergent approach ensures the purposefulness and sustainability of decision-making. This approach transforms divergent decision-making processes into convergent. The approach is based on the inverse problem-solving method in topological space, genetic algorithms, control thermodynamic theory, and using the ideas of creating AI models' cognitive semantics with quantum mechanics methods. This approach gives meetings' members the list of decision-making rules with accelerating consensus achievement. The examples of the rules are: the goals have to be arranged as a 3-level tree and ordered by importance; semantic interpretations of computer models' factors and their connections must be separated; rescue resources must be represented in a finite number of separated components, and so on. The approach also exploits traditional technical tools of augmented reality, virtual collaboration, and situational awareness. It has been repeatedly used to build socioeconomic and manufacturing sectoral strategies and is currently being adapted for emergencies.

1. Introduction

Every second has great importance after the moment of the outbreak of transport emergencies. The first hour after the moment is named the "golden hour"—it is a critical time for saving the injured and suffered lives. Different types of transport entities may take part in automobile, railway, aircraft, all-terrain vehicle (ATV), motorcycle, bicycle, etc. The authorities and their departments, rescue teams, police, ambulance staff, representatives of the population, etc. may participate in the processes. They all must understand each other and get agreement on decisions very quickly.

Rescue teams usually have a special pre-designed guide to synchronize their participants' activities as usual. It may be represented by way of detailed prewritten instructions, plans, or models of activity. The members of the rescue team must know it in advance. But every emergency is characterized by its own features and new participants, and the standard guide sometimes can only confuse the situation. The activity plans of all participants must be synchronized in any circumstances and for different environments. The integrity of the team member tactics' implementations has to achieve the proper synergistic effect.

Special decision support systems have been created based on virtual reality tools and artificial intelligence (AI) technologies. A sharp rise of research and the creation of such systems for this activity began after the 9/11 attacks and the 2009 crash of an Air France Airbus A330. The situational awareness (SA) approach [1, 2] was suggested and used in researching these disasters. Profound technical decisions were found, and obvious progress was made [3].

Simultaneously, the crucial importance of accelerating the collective decision-making by getting agreement between different participants in extreme conditions makes the issue of speeding up virtual meetings in emergencies always relevant. Some author's

*Corresponding Author: Alexander Raikov, alexander.n.raikov@gmail.com

papers are devoted to accelerating distributed collective decision-making that can be held in situational centers (SC) or a networked environment [4]. It was already suggested the technologies that help: speeding up a corporate strategic conversation [4], raising the quality of networked experts' procedures [5], improving medicine meeting (conversation) [6], or even accelerating networked democracy processes [7] and using for these methods from quantum theory [8,9].

Brainstorming procedures are divergent as usual; they have goals of creating a lot of new ideas. But these ideas may not be consistent, and as a result, synergy cannot be achieved. The author's convergent approach ensures the purposefulness and sustainability of networked collective meetings [4, 5]. It has been tested in different fields of the social-economy sphere and for decision-making in SC. It is now suggested for networked and collective decision-making support in emergencies when many different participants and physical automated tools (computers, cars, and intellectual robots) take part.

Three meeting modes may be distinguished: monitoring the situation with an operational solution of ongoing issues, planned decision-making with long-term preliminary preparation, and decision-making in an emergency. The latter is the most difficult. It claims a special approach that will ensure the convergence of distributed meetings and conversations to save the lives of as many injured people as possible. The paper has devoted this mode.

The paper includes a description of a transport emergency's characteristics, considers the limitations of the available rescue means of situational awareness. The concepts of denotative (formalized) semantics and cognitive (non-formalized) semantics for AI models are introduced, wherein, shows that modern AI predominantly uses only the former one. Further, the paper examines the possibilities of advanced AI and proposes to consider the possibility of using quantum theory to construct cognitive semantics. The author's convergent approach is then proposed to speed up networked distributed meetings in conditions of transport emergency. Simultaneously, the author's approach to the organization of networked expertise and cognitive modeling is considered in more detail. Then, some practical implementations of this approach are demonstrated. The paper ends with the formulation of discussion questions.

2. Emergency Features

The following features characterize an emergency transport situation (railway, aviation, highway, etc.):

- Presence of injured and/or dead.
- Victims need quick medical attention.
- Extreme lack of time.
- Possibility of destruction or contamination of the area.
- Participation of many departments, organizations, and rescue teams in decision-making.
- Distribution of collective decision-making process.
- Lack of material resources in the proper amount.
- Experienced experts are not available, etc.

In such situations, special tools have been created to speed up and improve the quality of collective decision-making, including virtual collaboration systems and SA systems [3]. They differ significantly from traditional teleconference. They are based on the advanced technology of discourse processing to ensure accelerated mutual understanding during participants' communications. SA is associated with multidimensional visualization, targeted information. It supports group decision-making, perception, prediction of the external environment changes, and mutual understanding between participants.

It is shown that in emergencies, network teams act faster than hierarchical ones [1,5,7]. The critical factors are as follow lack of necessary information, a holistic view of the situation at all levels of management, and the absence of an overall operational picture. Moreover, the growth of data volumes and the number of precedents do not always improve SA and quality decisions. The main sources of the problems that create information gaps are the team members themselves. They are focusing on solving their own problems. Inaccurate and belated information about events is the reason for information gaps too. The aspect of the lack of trust is important. Recently, the concept of SA is increasingly a group character: participants have to get an equally understanding of an operational picture when information is visualized on a map.

The analysis of the issue of accelerating the group decision-making in emergency using SA and virtual collaboration approaches showed the emphasis of the engineers' and researchers' efforts on the following areas:

- The creation of a distributed SC for monitoring and managing the processes of eliminating the consequences.
- Forecasting the danger of traffic accidents for ensuring effective decision-making.
- Integrating methods of information and analytical support crowdsourcing and networked expertise processes.
- Ensuring accelerated convergence of decision-making processes based on cognitive modeling and inverse problem-solving methods, etc.

One of the most efficient approaches to improve group decision-making processes in emergencies is SA. Let us take a look at it in more detailed.

3. Situational Awareness

The SA process embraces individuals, teams, AI systems, machines, and computer tools. It includes several stages [1,3,10], has a gradation in levels [11], and is characterized by different models [12]. The process may have abnormal behavior that is defined as behavior to deviate from the global plan in some circumstances.

It is known that SA systems do not always behave sustainable and purposeful. Some studies try to represent cognitive non-formalized processes by linking participants with AI systems. It allows each actor to get information in special templates from other actors that help to increase the opportunities of all actors [13]. Non-predicted and false responses are still common [3]. It is usually considered that SA is a suitable framework for collective cognitive

modeling that helps to make effective decisions by using explicit and implicit information.

But most papers do not consider the chaotic nature of human cognition, especially in cases of responding to abnormal machine behavior. Participants' thoughts, emotions, free will, experience, senses, etc. cannot be described logically. It cannot be represented in computers' logical knowledge bases. As soon as an attempt to describe an emotion is made, this emotion disappears or loses its nature and creative power. This fact compels to consider simultaneously two types of cognitive processes—systems 1 and 2 as shown in Table 1.

Table 1: Two types of cognitive systems

System number	Operating means	Semantics type	Serves to ensure
1	Non-logically, unconsciously, uncaused, associatively, intuitively	Cognitive	Provides creativity, helps to get insights[8], "Eureka effect" [15]
2	Logically, deliberately, rationally and analytically; neuron deep learning (partially)	Denotative	Logical inference; provides necessary conditions for purposeful and sustainable decision-making [4].

The systems are interacting. Some researchers argue that the system 1 has an advantage over the second one. But it obvious that intuition is not only the ability to make a decision.

Relevant information of the system 2 may be claimed to avoid mistakes in judgment [14]. This system gives the possibility to make the features of human activity and task characteristics distinct. An example of the presentation of system 2 is big data. They are used to build denotative semantics. However, it should be noted that the juxtaposition of each factor or connection of the AIs' models with some relevant subset of big data will require the use of special methods for solving problems on cognitive models, namely, methods for solving large-scale global optimization problems [15]. But due to the very high requirements for the promptness of solving problems in emergencies, most likely, such an approach for such situations is unacceptable. This paper proposes replacing big data subsets with their projections on a deep neural network (See Section 8).

The creative process of getting an insight may be non-logical; the result appears after deliberate and sometimes long-time unsuccessful thinking. It needs to use logical efforts to speed up the process. [16]. It was suggested to put a cognitive continuum of the first above-mentioned process in the unconscious end of some scale, but the second one—in the conscious end [17]. Distinctions between these two processes have a continuum power. Effective decision-making may require flexibility on this continuum. And intuitive decision-making can be partly conscious, and analytical decisions can be partly unconscious.

Situational awareness in emergencies is working with machines and humans. It needs to control machines' abnormalities and supports correct group decision-making during abnormal machine behaviors. The three-level SA model was suggested for these cases [18]. It includes the following components:

- Perception of the situation (level 1).
- Comprehension of the situation's meaning and assessment relevance to certain goals (level 2).
- The projection of its status and dynamics for the near future (level 3).

Many relevant issues in different safety domains (aircraft, air traffic control, power plants, maritime operations, manufacturing systems, collaborative and isolated work, healthcare, etc.) benefit from the application of the three-level SA approach.

As has been shown, SA can cover a wide range of cognitive concepts. It is affected by psychological phenomena such as stress, mental workload, and trust [19]. The three-level SA approach was used in deliberate sense-making, story construction, recognizing main decisions, heuristics, and implicit cues of sociotechnical systems. The three-level SA approach has been used to explain deliberate attempts of detecting, diagnosing, and forecasting and increasing collective understanding of the problem situation.

An important aspect of SA is the sense-making process that explains how humans understand the environment by assigning meaning to experiences [20]. Sense-making is about values, priorities, and preferences. It holds different elements together to guide actions. Sense-making is a complex process and involves previously accumulated information. Different authors have tried to model cognition by identifying cues, diagnosing problems, taking action, questioning, elaborating, comparing, switching, and abandoning the search for a frame [21].

Distributed SA (DSA) is a more difficult construction than SA [22]. Its attention devotes to special issues of covering distributed cognition and focuses on collective SA, or awareness between agents. Humans and machines can represent them. DSA is used in modeling virtual collaborative processes.

DSA differs from SA substantially. For example, for DSA, it does not matter if the human agent does not know anything. Other components of the distributed system can augment the lack of his or her knowledge. On the contrary, in the case of SA, if the human does not know something, it may cause a significant problem or accident. But SA can support a broader spectrum of cognition because of the implicit character of thinking.

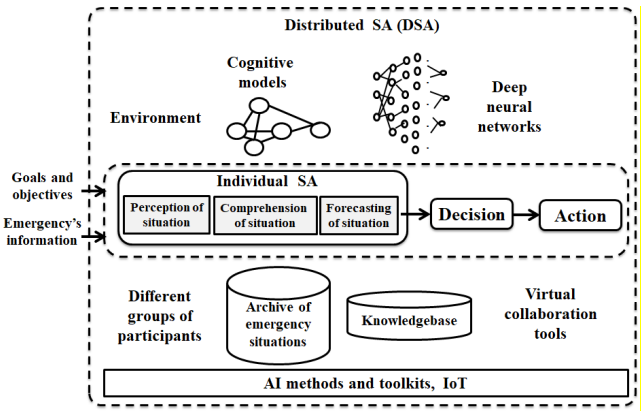

Figure 1: SA and DSA systems' components

It was identified that there are four classes of failure transactions that can be the reason for the accident [3]: absent transactions, inappropriate transactions, incomplete transactions, and misunderstood transactions. Every one of these transactions has implicit and explicit interpretations, intangible and tangible representations. SA and DSA have framework constructions that can be represented in a formalized way by frames, ontology, or proposition logic. The components of SA and DSA systems are illustrated in Figure 1, where the idea of individual construction has been taken from [3].

Thus, SA and DSA have two semantics' interpretations: cognitive (non-formalized process or System 1) and denotative (formalized process or System 2).

4. Cognitive and Denotative Semantics

Emotions, thoughts, insights, intuition, inspiration, etc. come without awareness. They are usually defined as the capability to act or make decisions appropriately without consciously balancing alternatives, without following a certain rule.

Human and AI cognitive abilities are deep discussed in [23]. This paper analyzed 2500 publications. There are about three hundred cognitive architectures that describe human cognitive abilities. This paper's main attention was made to a logical description of cognitive phenomena. It was also noted that the topic of cognitive architectures is rather rare in works devoted to Artificial General Intelligence (AGI).

Therefore, SA or DSA does not cover this communication layer and participants' activities or covers it only in a very restricted means. They do not fully reflect the semantics generated by thoughts and feelings. In the SA or DSA paradigm, only formalized semantics can be represented. Moreover, in an emergency, technical devices and computers reflect only formalized, material aspects of the situation.

A machine has its own personality, which could be defined as only the technical perception of everything the participants know and feel [24]. Humans have the ability to apply their senses to identify and interpret signals to get their own useful descriptions of machine behavior. As a result, tacit knowledge [25] cannot be embraced by computer AI models; the computer cannot understand them; therefore, digital information from sensors may be estimated in the wrong way.

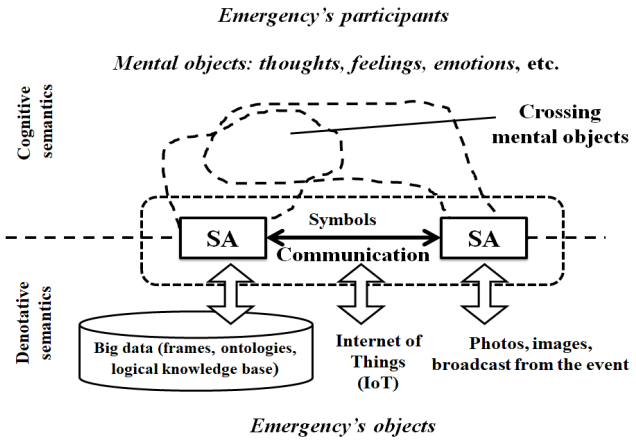

Figure 2: SA and its semantics: cognitive and denotative

Thus, there are two types of the semantics of SA or DSA: denotative (formalized) and cognitive (non-formalized)—see above Table. These semantics are illustrated in Figure 2.

Figure 2 demonstrates that the denotative semantics of SA and DSA has a formalized structure and can be implemented using logical ontologies, symbols, and frames. The instruments of the above-mentioned SC [4] can be useful for centralizing the control of monitoring problems' situations' and ensuring coherence of group decision-making and actions of various teams and organizations. SC helps make group decision-making processes stable (sustainable) and purposeful by involving AI and virtual collaboration technology to give participants the power to achieve synergy in the decision-making processes [26]. SC is using for solving problems that can be characterized by the following specific features:

- Ill-defined and weakly formalized problems.
- Require urgent collective decisions.
- Associated with high risks.
- Poorly predictable and chaotic behavior.
- The process can be interrupted.
- Divergent trait of breakthrough procedures.
- Lack of retrospective experience, etc.

SC usually exploits modern technologies by integrating:

- Strategic analysis methods;
- SA and DSA technologies.
- Advanced tools of visualization.
- Networked convergent conversation technology.
- Cognitive modeling.
- Inverse problem-solving methods.
- Logical analysis, statistical forecasting.
- Big data analysis, knowledge engineering.
- Different AI technologies, etc.

Simultaneously, the cognitive semantics cannot be fully taken into consideration by these technologies because of its non-formalized stuff. They have a more qualitative and non-metric nature than quantitative and metric ones. The cognitive aspects of decision-making and modeling in the SC have to ensure new requirements for cognitive semantic interpretations of SA or DSA. The main idea of making cognitive semantic interpretation by logical computer models consists of:

- Taking into consideration individual and collective unconscious phenomena using indirect and inverse methods of decision support.
- Impacting on the problem situation through a self-developing reflexive-active environment.

Using the ideas of AGI and Strong AI perhaps can help realize this idea. Strong AI and AGI are usually considered different

phenomena [27], but in this paper, we will consider them synonyms without loss of generality. However, considering the practical need to introduce AI tools shortly, the main emphasis will be on using traditional AI, although more developed cognitive semantics are used in its application.

5. Artificial General Intelligence

The traditional AI has been developed on a logical basis. It uses predicate calculus, logical ontologies, frames, and neural networks (NN). It may be noticed that the latter can be represented by logic also. This AI has a strong potential for solving different issues in real practice, such as predicting human behavior and different situations based on experience. This traditional approach can help to recognize the problem situation based on retrospective deep learning. Since traditional AI has a formalized nature, its semantics is denotative.

Currently, the traditional formalized AI gives way to non-formalized and uncaused AI, the semantics of which have cognitive features. The design of AGI can obey reverse-engineering rules. Simultaneously, in the history of AI development, there are roughly four methodologies to achieve kinds of AI: symbolism, connectionism, behaviorism, and statisticalism [27].

AGI is usually considered the machine intelligence that can perform intellectual problems in different fields of knowledge more efficiently than a human being can adapt to the environment and forms its own self-awareness. It is fundamentally non-formalizable human-machine (hybrid) AI. The AGI encompass the subjective, mental, creative, and intellectual activity of human being. The distinctive claims of the AGI are as follows [28]:

- Creation of the necessary conditions (see Section 7) to ensure the convergence of generating ideas and thoughts to ill-defined goals.
- Complex cognitive semantic interpretation of different problem situations' models.
- Taking into consideration the conceptual aspects of the situation.
- Ensure the sustainability and purposefulness of current and future development.
- Computers' models may be changed in a quantized way.
- The behavior of models is synchronized with the behavior of remote objects, the states of which are unknown.
- The space of modeling is conceptual, phenomenological, and uncaused.
- An external impact on the problem situation can be changed unpredictably, etc.

Thus, these claims have to be taken into account during organizing distributed meetings. It requires changing the methodological that was based on traditional AI. The possibilities of AGI's elements have to be taken into account. AGI includes all the advantages of AI and is intended to make a wide range of human cognitive capabilities. But for a while, it is obvious that there is a large gap between AI and AGI. It may be just said that AGI is the inverse of AI [27,28]. In this context, it is necessary to consider such aspects of AGI as:

- Imitation of human consciousness, perhaps, with non-classical methods from such disciplines, as relativistic and quantum physic, thermodynamics, and optics.
- Take into account cosmological, relativistic, atomic, quarks, and microtubule components of the brain.
- Take into account the physical fields (gravitational, electromagnetic, strong, and weak) on the thoughts' processes.
- The group theory and category theory application.
- Inverse problem solving on topological spaces, etc.

The development of AGI requires an interdisciplinary synthesis of different approaches, methods, and technologies. The synergy of these components of AGI has to overcome the non-finite complexity of cognitive semantics. These effects imply the modeling beyond the traditional formalized mechanisms and models of thinking.

E.g., in the large paper [29] devoted to building machines that think like people note the importance of drawing a distinction between AI that purports to emulate or draw inspiration from human cognition and AI that does not. This paper focuses on the former that looks like AGI. The latter undoubtedly is a perfectly reasonable and useful approach to developing AI algorithms for real practice: avoiding cognitive inspiration and claims of neural plausibility. But for emergency requiring rapid collective decisions, this is clearly not enough.

The key aspects of AGI are creating cognitive semantics that can be embraced only by indirect approaches. One of these approaches is quantum semantics.

6. Quantum Semantics

The description of the disaster situation is usually infinite-dimensional. In such cases, the mechanisms of creating quantum semantic interpretations for computer models can find practical application. The quantum principle of complementarity helps to expand and deepen the semantic interpretation of computer models. Applying the special quantum operators to sets of messages created during virtual conversations between participants [8, 9].

The uncaused nature of feelings, emotions, or free will force studying the quantum semantics approach [30,31]. The special quantum operator can help to embrace these unconscious components in decision-making processes [8].

A special place in the AGI approach is occupied by quantum-mechanical effects, such as superposition, complementarity, and non-locality effects [30]. For more complete and detailed coverage of the quantum and relativistic aspects of the cognitive semantics, an attempt can comprehensively study the thought processes using the group theory, which investigate sets with operations on them. The elements of spatial sets will then be various entities: events, ideal and virtual objects, complex numbers, vectors with their scalar products. Each event will be associated with a point in space, considered a mathematical object, different from others. Thus,

both the Fourier transforms, and transformations over the 4-dimensional Minkowski event space elements can be covered. The points of this space can have a non-numerical character, the coordinates of which serve as one of the many ways to specify these points. It helps to create cognitive semantics. The quantum cognitive semantics allow raising the power of AI substantially, e.g.:

- The quantum particle is represented in infinite-dimensional space—it may look like a symbolic representation of the spiritual phenomenon.
- The quantum particle is both a particle and a wave and gets another type in another place—it can reflect that a word's meaning depends on the context.
- Attempts to detect a wave of a quantum particle lead to the disappearance of the interference effect— it looks like the inability to logically describe cognitive semantics.
- The particle's behavior is described with the complex numbers—it can be used for representing the "shadow" components of the cognitive semantics.
- A quantum particle cannot have zero values of its parameters and occurs in a jump-like manner—it looks like the Eureka effect [16].
- The non-locality effect ensures the dependence of the quantum particle's behavior on other particles for which the behavior is not defined—it is associated with the interdependence of natural phenomena, etc.

The quantum semantics features increase the power of AI, making forecasting and solving processes more reliable. The way of realizing the possibilities of quantum semantics consists of emulating quantum operators on a common computer. For example, the paper [8] demonstrates using the Hadamard quantum operator, which interprets the quantum superposition function on a set of words with their frequencies (frequency histograms) in documents. The quantum operator changes the frequency histograms of words from the set of documents, making the coverage of these sets more complete. It also ensures the mapping of different sets of documents and words closed (in mathematical mean) that is the prerequisite for ensuring correctness of the inverse problems solving process (see sections 7, 8, and [4]).

7. The Convergent Approach

The collectives' decision-making processes have to be purposeful and sustainable in emergencies. The participants generate different ideas based on incoming information and make quick assessments of the various solutions' alternatives and suggestions. Creating ideas and making assessments include many interactions between participants using different units of information. The process may be influenced by false or latent information. This influence can greatly reduce the efficiency of group decision-making. This process may be divergent and has to be transformed into convergent (purposeful and sustainable).

Different types of operational objectives during group decision-making are suggested. Let's call them, for example, usual (traditional) and unusual (best) goals. Different values between these extreme values of the types of goals can be placed on the scale.

Usual objectives can be prescribed by automatically extrapolating retrospective statistics by traditional AI methods based on previous experience or retrospective information. The expert system, big data analysis, deep learning, ontology, etc. can be used for this aim. Most of the evaluations of those systems of goal setting are based on pattern recognition methods on retrospective data analysis.

For achieving the unusual, high-quality goals that cannot be achieved with traditional decision-support systems (DSS), the convergent approach was suggested [4, 8]. It has the opposite (inverse) character concerning DSS and AI. To ensure the efficiency of creating group high-level advice (decision-making), it is necessary to create special necessary structural conditions for support purposeful and sustainable development of the decision-making process. The convergent approach is based on the inverse problem-solving method on topological spaces and cognitive modeling. The provisions, algorithms, and programs to accelerate the decision-making process in emergencies with these methods were developed. The difference between the direct and inverse approaches is illustrated in Figure 3.

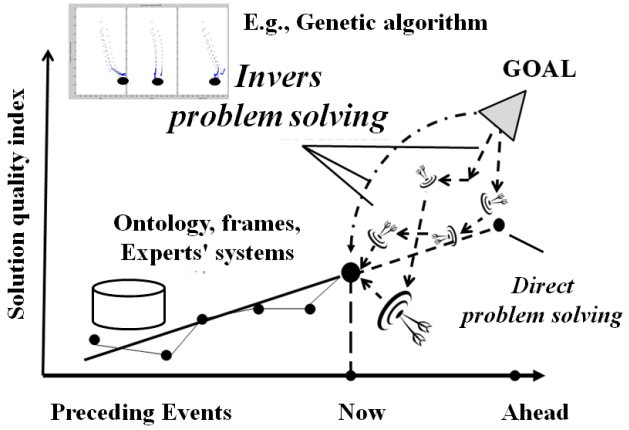

Figure 3: The difference between two approaches of decision-making

If participants of an emergency meeting try to use both these two different approaches (direct and inverse), they apply AI and AGI technologies. For inverse problem-solving, the Tychonoff theorem [32] on topological spaces was applied to ensure the meeting's stable purposefulness.

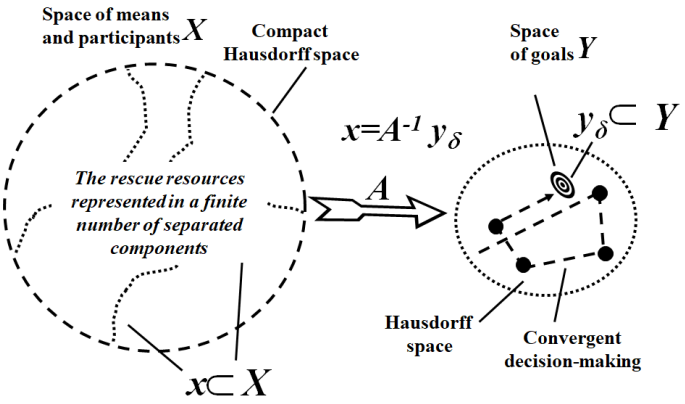
It was confirmed that the semantic interpretation of cognitive models in the decision-making process and the methods of inverse problems solving increase the purposefulness of the actions of the leader of a group of people (various services, rescue teams, spontaneous groups of people, etc.) and, therefore, the speed and quality of decision-making in emergencies.

The convergent approach provides the necessary conditions for the sustainable convergence of collective decision-making processes to ill-defined goals. To ensure these necessary conditions, category theory and the topology theory were used, and the concept of a "convergent monad" (CM) was introduced for which the classical monad was improved with the axioms of CM ℵ [33]:

- D: Top → Top; the number of points in the system of sets Top (topology) is infinite, and the graph of maps is closed (the complement of an open set).
- ℵ is a topological space where its open covers have non-empty finite subcover (*The Compact space*);
- Any two points of ℵ (in the topological sense) have disjointed neighborhoods (*The Hausdorff space*).

These axioms follow from the statement: if X and Y are Hausdorff topological spaces and X is a compact space, and the graph A is closed, these are necessary (but not sufficient) conditions for ensuring convergence of the inverse problem solving [34]. The convergent methodology allows dividing the problem into some parts and then assembling them into a holistic decision.

The following sets and an inverse operator were selected for reflecting the search of the solution in an emergency: the space of goals Y (the exact goal y_0 and the set of inaccurate goals $\{y_\delta\}$); the space of participants and means X for achieving y_0; the operator $A: X \to Y$, and the reverse to it. The domain of definition of the operator A can be narrowed down to some subset of X, and the set of decisions can be narrowed down to a subset of Y (Figure 4).



It is shown that a countable set and an infinite set of real numbers are clearly not suitable for identifying components and describing the space of solutions. This result allows supplementing the structure of the data using the requirements that were formed earlier [4]. For example, for increasing the convergence of a decision-making process, it is required that the number of parameters (factors) that characterize the problem situation should be finite. In this way, these factors and their semantics have to cover the description and representation of the problem and have to be separated, or the border could be created between every two parameters. Considering these requirements, a network brainstorming method based on a genetic algorithm was developed for inverse problem solving [35]. It can be used in emergency conditions for convergent group generation of ideas and formation of an agreed action plan.

Thus, for ensuring the stability and purposefulness of decision-making in emergencies, the components of the goals, rescue means, and ways (algorithm) of the achievement of the goals should be highlighted and structured especially. The emphasis should be focused on the possibility of accelerating the adoption of group decisions in networks and mobile environments and an interdepartmental system of distributed SC. The collective decision-making process involves the networked expertise approach, cognitive modeling, and mathematical apparatus for inverse problems solving [5,7,8].

It was also shown [4] that to ensure the necessary conditions for a stable and purposeful synthesis of effective solutions in a problem situation; it is also advisable to distinguish the components: the whole, order, and chaos. To ensure the desired stability of decision-making processes, these components and their rate of change must be in a certain ratio (Figure 5).

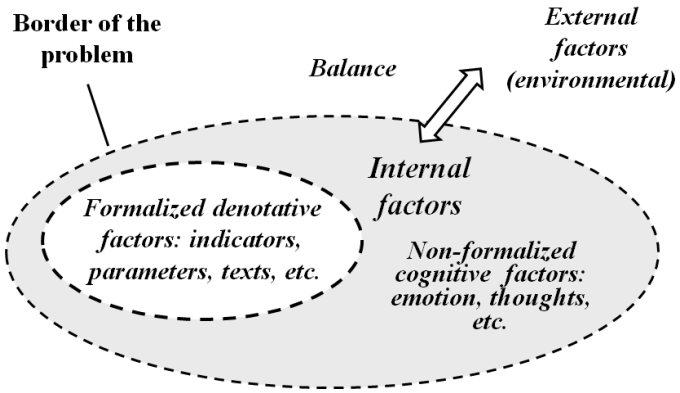


Figure 5: Chaotic component of ensuring the desired stability

The convergent approach offers a list of rules for structuring the information that is created during emergency meetings, as follows:

- The goals have to be constructed as a 3-level tree with main, external and internal goals;
- The goals must be ordered by importance with, for example, the analytic hierarchy method [36];
- Cognitive and denotative semantic interpretations of the model's factors, and their connections must be separated;
- The set of decisions must be represented by a finite and observable set of factors, etc.

Such recommendations help create conditions that ensure the purposefulness and sustainability of the decision-making process in an emergency. As shown by practical testing of the proposed approach's use with the creation of appropriate conditions, the duration of holding collective strategic meetings is reduced by 4-5 times compared to cases when these conditions are not met. However, for emergencies, the acceleration of group decision-making should be significantly greater.

The participants and engaged network experts must have the possibility of putting qualitative information into the process of decision-making in an interactive way by using the cognitive modeling method [4, 5, 35].

8. Networked Expertise and Cognitive Modeling

Different members can participate in disaster meetings to manage an emergency, and some remote experts can be invited [5]. On the base of convergent technology, networked expertise

procedures can be ordered, as shown in Figure 6. This order accelerates the decision-making processes by speeding up getting agreement between the emergency meeting participants regarding goals and ways of action. The SC can centralize monitoring of the situation and ensure the coherence of actions of various teams and organizations.

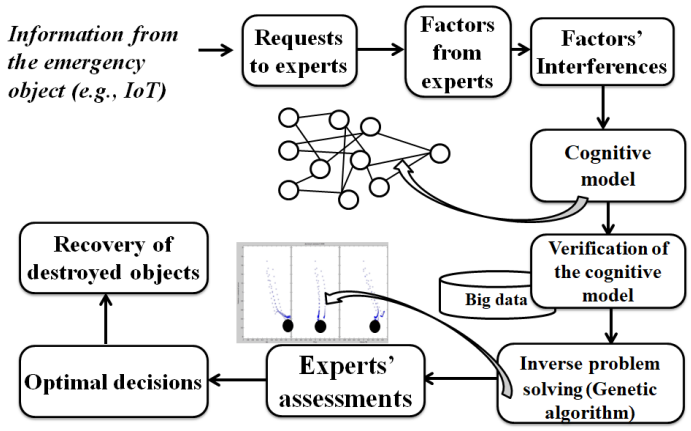

Figure 6: The order of the networked expertise and decision-making

The main steps of the networked expertise are as follows:

- Make the requests to the experts.
- Describe the situation shortly; formulate goals of improving the situation.
- Suggest some conceptual factors that characterize the opportunities to improve the situation.
- Define factors' interferences and create the cognitive model.
- Assess and explore the project of the cognitive model in remote SC.
- Solve the inverse problem with a genetic algorithm for getting the optimal decisions.

As a result of the network experts meeting, the final strategy of activity is formulated. The most difficult part of a group expert procedure is cognitive modeling. For simplifying and speeding up the process of cognitive modeling, an array of reference cognitive models, methods of Big Data analysis, and Deep learning should be used.

In a transport emergency, which claims fast decision-making and effective planning, the traditional manual creation of formalized computer models is impossible because it may take a lot of time. The problems have the characteristics of randomness, chaos, quantization, uncertainty, and non-causality. In these conditions, the participants must apply intuition, experience, and experts' judgments.

For such problems, the approach with the automation of cognitive modeling could be applied [37,38]. The cognitive modeling method is used when non-metric (qualitative) concepts are more important than metric (quantitative) ones. It ensures factors and relations between factors that characterize the problem. It may be represented in a matrix or a directed graph, where nodes represent factors, and arrows represent relations. The process helps to understand the structure of the problem and improves the understanding between participants.

The retrospective experience can help to create the cognitive model automatically. The creation of a cognitive model could be accelerated by using Big Data analysis. It helps to verify early prepared cognitive models and supply ones with denotative semantics in a formalized way. For this, the cognitive model's factors and their connections have to be mapped into the relevant subset of Big Data.

The deep learning of the neural network method was carried out for automating cognitive model creation and verification. The features of this process are as follows:

- Check the adequacy of the cognitive model to the problem situation.
- Ensure the availability of relevant subsets of Big Data.
- Use standard software for training the neural network.

An approach with a replacement of direct access to Big Data by addressing a deep neural network (DNN) was proposed to construct the denotative cognitive model's semantics. This replacement is that access to Big Data in an emergency cannot always be provided. The tool for permanent training of the DNN on retrospective examples for using in a concrete situation is worked out.

The expediency of using DNN was shown on the model with LSTM (Long Short-Term Memory), convolutional, and recurrent [39]. The LSTM model is well suited for classifying, processing, and predicting time series cases where time lags separate events with uncertain duration. The LSTM module can store values for both short and long periods of time. It does not use the activation function inside its recurrent components. The stages of creating a DNN are:

- Downloading the clusters of relevant documents from available data sets.
- Tokenization, lemmatization, and filtering of documents' texts.
- Constructing the LSTM model for training.
- Training the LSTM model.

The process has to consider qualitative aspects of the situation, ensuring the denotative and cognitive semantic interpretation of models. Participants conduct cognitive modeling in the following order:

- Some of the first factors of the emergency are revealed for creating the cognitive model.
- Some of the first mutual influences between factors are evaluated.
- The project of the cognitive model is created automatically with using Big Data analysis or DNN.
- The result of automated cognitive model creation is estimated by a group's leader.
- Goals and control factors in the model are identified.

- The project of the cognitive model is corrected by a group's leader.
- The direct and inverse problems on the cognitive model are solving.
- The decision is suggested.

Figure 7 illustrates the preliminary creation and verification of cognitive models and synthesizes ones during decision-making.

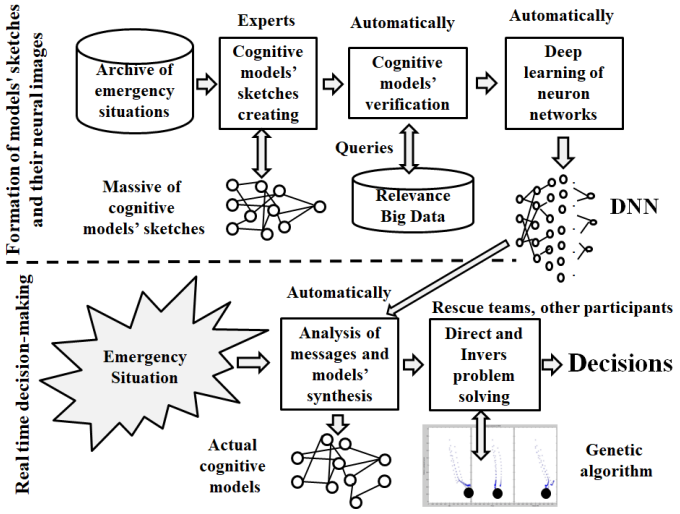

Figure 7: Cognitive model creation and verification

The testing was made on four different sample sizes of documents: 10, 100, 1000, and 4868. As the experiment showed, on the largest of these samples, the accuracy of determining the cognitive model factors reached 93%. This result is so good that it allows raising the question to automate the cognitive model's construction in an emergency.

This group decision-making process in an emergency with the creation of a cognitive model may take only some minutes, and thereby it improves the process of decision-making and, as a result, increases the chances of saving human lives.

9. Convergent Emergency Meeting in Practice

The suggested convergent approach with cognitive modeling was exploited in the distributed SC for speeding up strategic conversations and emergency meetings. The convergent approach helps to reduce the duration of such meetings resolutely. The collective strategic meeting duration was reduced from four days to one day or even four hours.

But convergent distributed meetings in an emergency with the quick agreement of the participants on the emergency place and heads of departments of the authorities and experts still remain the subject for further implementation in practice.

As a result of applying the convergent approach, many drafts of the strategies for the socio-economic development of the cities, regions, and industries were created. During the strategic meeting (conversation), the group of 30–40 participants carries out brainstorming sessions, conducts a strategic analysis, creates a cognitive model, solves a direct and an inverse problem, and works out an optimal strategic solution. The main participants of the conversation and strategic planning are the administration of the controlled object, enterprise management, and remote experts.

Everybody from administration and rescue groups has to know the convergent approach's rules to reduce the duration of the emergency meeting by conducting and structuring the information in a convergent way. Currently, the duration of a strategic conversation takes around 4–6 hours. During this time, every participant makes many decisions regarding the goals of actions. It may coincide or not with the global decision of his group. The behaviors of various participants are different; changing the situation brings chaos to participants' minds.

For example, in [40], it is shown that the strategic meeting for creating the cognitive model of the large megapolis tourism development took 4 hours due to using the convergent methodology. For this, 35 brainstorming were run simultaneously. From the beginning, the goal tree was made. Then the SWOT-analysis (strengths, weaknesses, opportunities, and threats) helps to identify about 70 factors of the situation, which can influence the megapolis tourism development. After that, these factors were convoluted into the substantial 15 factors, and the weights of their interconnections were evaluated, and as a result, the cognitive model was made. Then the Big Data analysis helped to verify this model. Then the direct and inverse problems were solved on the cognitive model and an optimal scenario found.

Such a practice can be used in emergencies. In this case, the process of networked decision-making will cover casualties, groups of people, different rescue teams, administration's representatives, headquarters, experts, and groups' leaders. The problem is to find an agreement among all participants very quickly about aims and ways of action.

The convergent approach helps to synchronize the participants' behaviors. But the above-mentioned 4 hours that were spent during the strategic conversation for getting a consensus is an excessively long period of time, which is unacceptable in an emergency, and the decision-making process has to be substantially accelerated.

To further develop a convergent approach for speeding up decision-making in an emergency, appropriate research must be carried out in a classic and non-classical way [28]. Some of these studies are still debatable.

10. Discussion

The most complex and debatable issue that is the subject for further research is the construction of AI logical models' cognitive semantics. This construction is non-formalizable and cannot be described with the programmer's logic. Currently, studies are being conducted in the field of building quantum semantics and optical computing.

The decision-making process with cognitive modeling can be accelerated by using a quantum semantic approach. Quantum semantics make the models' interpretations more holistic. They help consider the phenomenon that every word of the texts of documents interferes with an infinite number of the hidden (shadow) words. It makes the possibility to create as much as possible complex virtual objects. On the other side, attempts to represent the cognitive semantics of words with only a discrete

(digital) computer and logic give zero intersection ones with shadow words [38].

Creating cognitive semantics cannot be exactly reproduced by mathematical logic and discrete computers. They reduce the possibility of the cognitive semantic interpretation of the cognitive model and cannot consider the non-formalized processes of human thinking, emotions, thoughts, etc. For these aims, it will be useful to consider the opportunity of quantum entanglement (non-locality) effects [30]. The Maxwell and Schrödinger equations were theoretically researched for compensating the cognitive semantics gaps. In this context, the potential of optical calculations using lasers, deflectors, and multidimensional rewritable holographic storage devices was theoretically investigated. It could be useful for creating cognitive semantics. [38].

Perhaps the unified mathematical approach may be the group theory, which can cover the convergence of collective decision-making processes, the formation of cognitive semantics using the quantum field theory, and relativistic theory. Apparently, this may require exploiting the transformations' operators in the Lorentz group, where fixed points represent the events, and the intervals between events (points) are preserved, or it may be useful to apply the Poincare group, where the fixation of points is not required.

Such an approach will place the symbolic AI model with its denotative (formalizable) semantics and, most importantly, cognitive (unformalizable) semantics in some single space, and then use unified operators to implement transformations of events of various nature. In this case, events can be attributed to different phenomena, described as by logic, as by quantum electrodynamics' laws and the special theory of relativity. If cognitive semantics allows a quantum interpretation with its representation in the infinite Hilbert space and a relativistic interpretation, with its representation in terms of the transformation of smooth manifolds (for example, to study fields' anomalies), then the application of group theory can be fruitful.

At the same time, the adequacy of the approach to the interpretation of cognitive semantics using group theory is a subject of lengthy verification, especially regarding its application to the possibility of joint research, primarily, of events that interpret these semantics at the subatomic level and the theory of relativity level.

Thus, the important discussion issue to substantially speed up decision-making during the rescue operation in transport emergency based on AI is constructing cognitive semantics of AI models, involving the mechanisms of subatomic and relativistic levels. Some ideas in this way were suggested in this paper.

11. Conclusions

To accelerate the processes of decision-making in transport emergency (air, rail, car, etc.), it is advisable to structure all generated information in a special way: making 3-level arranging the goals, dividing rescue means on finite numbers of components, automatic creating cognitive models with neural network deep learning, and applying an inverse problem-solving method by genetic algorithm on the cognitive model for finding the best decision. For this, the author's convergent approach was proposed that considers the non-formalized cognitive semantics of AI logical models and ensures the sustainability and purposefulness of decision-making processes.

During cognitive modeling and decision-making, different impacts on the same factors can give successful or destructive results. E.g., the order and strength of influence on the factors are critical for getting the desired results of modeling. The successful impact on the situation can be determined comparatively accurately with a genetic algorithm applied to the cognitive model.

The traditional logical approaches and deep learning methods in AI cannot cover cognitive semantics holistically. This semantics requires to be enriched by new approaches, such as quantum and relativistic theories, networked experts procedures, which have to be convergently organized, and different means like situational awareness tools and situational centers systems.

Thirty-five years of practical experience in applying the convergent approach has shown the possibility of drastically reducing collective situational analysis duration and building optimistic strategies. However, the application of a convergent approach for transport emergency requires its further development.

Conflict of Interest

The author declares no conflict of interest.

ABSTRACT

Fault-tolerant applications are created by replicating the software or hardware component in a distributed system. Communications are normally carried out over an Ethernet network to interact with the distributed/replicated system, ensuring atomic multicast properties. However, there are situations in which it is not possible to guarantee that the replicas process the same data set in the same order. This occurrence will lead to inconsistency in the data set produced by the replicas, that is, the determinism of the applications is not guaranteed.

To avoid these inconsistencies, a set of Function Blocks has been proposed which, taking advantage of the inherent properties of Ethernet, can guarantee the synchronism and determinism of the real-time application. This paper presents this set of Function Blocks, focusing our action on the development of reliable distributed systems in real-time. This demonstrates that the developed Function Blocks can guarantee the determinism of the replicas and, as such, that the messages sent are processed, in the same order and according to the time in which they were made available.

1. Introduction

Fault-tolerance or replication is implemented, in most cases, by replication of one or more critical components, by replication of the hardware, the software or both. Therefore, regardless of the approach used, the main objective is to ensure that if one of the replicas fails, the remaining replicas will continue to function and therefore mask the existence of the failed replica before the remaining application, making it as transparent as possible. So, we must consider a fault-tolerant distributed system as an interconnection of several unitary components that, in each call of an event, process data, generating new events and/or data. On the other hand, event and data, generated on a different replica, located to different nodes, must be synchronized to assure that the replicas receive the same set of data in the same order. All replicas must have the same perception of the data and this perception will be obtained through a multicast protocol.

To support the Distributed Computer Controller System (DCCS) in real-time and reliably replicated over Commercial Off-The-Shelf components (COTS), it is essential to provide a simple and transparent programming model. So, programmers should be unaware of implementation problems and the details of distribution and replication. However, it is important that the replication mechanism allows us to develop a generic and transparent approach without concerns the inherent requirements of the distributed system and the replication issues. Therefore, to overcome the problems inherent to the development of distributed/replicated systems, we opted for the use of a framework that guarantees not only the required abstraction capacity but also the ability to carry out the distribution and replication of real-time systems as well as, ensure determinism. Thus, taking as a starting point the new standard IEC 61499 [1], we opted for the use of an application that allows perform the development of distributed systems and, consequently, their replication, which, in parallel, supports the requirements of this same standard, i.e., based on the Open Source PLC Framework for Industrial Automation &

Control, *Eclipse 4diac™* [2] (infrastructure for distributed Industrial Process Measurement and Control Systems – IPMCS).

This paper is organized as follows: Section 2 presents a literature review, where ideas from different authors for the distributed and replicated systems problems will be exposed. Section 3 presents an overview of IEC 61499 standard. Section 4 presents the proposed implementation for reliable real-time SIFB communication and their decision timing analysis. A numerical example is presented in Section 5 and the conclusions are outlined in Section 6.

2. Related work

Replicated systems is based in the replication of the critical components of software or hardware, connected by a network. So, to use a networks communication to support DCCS applications requires not only a bounded times transmission services, but also ensuring the dependability for the applications with real-time needs.

Fault-tolerance architectures based on software have been proposed by many authors, all of them exploring the diversity of implementation, diversity of data and temporal diversity [3]. Consequently, two approaches can be taken to tolerated or recovery faults: the forward recovery (N-Version Programming [4] and its variations, N-Self Checking Programming [5], N-Copy Programming such as Distributed Recovery Block (DRB) [6] or Extend DRB [7]), and backward recovery (use of checkpoints from which recovery is attempted). So, when using in a replicated system forward recovery it is necessary that all replicas remain synchronized in order to produce the same set of data and events outputs in the same order (replicas will have to be deterministic) [8] and, somewhere, the replicas outputs need to be consolidated. On the other hand, replica determinism it will be possible achieved through the use of clocks synchronization, atomic multicast protocol and consensus agreement protocols [9] but also by timed messages [10]. Base in these concepts, a similar technic for a DEAR-COTS framework based on Ada 95 has already been proposed by Pinho *et al*. [11]. These authors using a Network Time Protocol (NTP) to synchronize replicas and messages transmission time are set offline.

Likewise, considering replication systems, [12] presents an approach based on a Fast and scalable Byzantine Fault-Tolerance protocol (FBFT) using message aggregation technique combined with reliable hardware-based execution environments. Based on a multicasting replication the aggregation reduces the complexity of messages and computation overhead. In this turn, Pinho *et al.* [13] using a Stat Machine approach to develop fault-tolerant distributed system. Replication is based on a priority algorithm (total order and consensus) like Raft (PRaft). Incoming messages are executed according to the priority level, so the processes do not have to wait to the confirmation of the request. Messages are executed at the moment they are received. Hu *et al.* [14] propose a standard for fault-tolerance modulation based on the programming of N-Versions that can be integrated, transparently, into existing applications, improving its operation, maintaining the characteristics of time. The model, developed in C language, consists of a set of components (initiator, member versions and the voter) where they encapsulated several alternative algorithms to obtain the same outputs.

Some works based on the IEC 61499 fault tolerance system have already been tested and presented in [15], where a distributed replication structure, similar to the work presented in this document, is presented. In this case, a timed message protocol is used to ensure synchronization of the internal states of the replicas and was also implemented in *Eclipse 4diac™* and validated in a FORTE runtime multicast environment. In the same line of reliability [16], it presented a formal modeling methodology to validate and evaluate the reliability of IEC 61499 applications applied to critical safety situations. On the other hand, the works developed by Batchkova *et al*. [17] and Dai *et al*. [18], which are related in some way, focus on the development of reconfigurable IEC 61499 control systems. The methodology proposed by these authors allows IEC 61499 applications to be reconfigured during execution, replacing one Function Block (FB) with another. The substitution, done in real time, does not create a significant impact on the execution of the system and as such can be used as an approach to fault-tolerance. However, they focused on reconfiguration of the system and not on a fault-tolerance scenario, where time to bring up the system is not considered.

In the same area of the IEC 61499 Lednicki *et al.* [19] presents a model to calculate the Wast-Case Execution Time (WCET) for the software FB execution. This model works with a set of events, considering the information associated with the inputs, in which the execution is initiated by the arrival of the input event to the function blocks. The WCET value represents the maximum time that a FB needs to execute its functionality, from the entry of an event until its internal activity is completed (exit of the event). The WCET is independent of the internal path or the execution paths. This model gives us the time needed to activate the next FB.

3. Overview of the IEC 61499

IEC 61499 applications are made up of interconnections of FBs that exchange information, data and events, based on a graphical representation. Each of these graphic representations (FB) consists of a rectangular structure that incorporates an upper part, called the head, and a lower part, called the body. The head is the interface for receiving events, initializing the FB and activating the internal algorithms. It is also used for sending events, confirming the initialization of the FB, as well as the execution of the internal algorithm or algorithms. The body is the interface for received and sending data and it is also de base for the internal algorithms. Data and events inputs are on the left and outputs on the right.

An FB network is assumed to be an event exchange process in which each outgoing event is linked to an incoming event, and each outgoing data is linked to an incoming data. FBs are executed when they receive events so, from that moment on data can be processed, reading inputs data. However, it is only after the execution of the internal algorithms that the data is updated, placed on the output link, and one or more output events can be generated. Input and output data are defined according to the type (Int, Real, etc.) so, in IEC 61499 applications, it will only be possible to establish connections between data of the same type, while the events can be considered as the base event type used in the FB activation.

As stated earlier, the central structure of the IEC 61499 is the FB, which interconnected in a network may represent a device, like a Personal Computer (PC) or a Programmable Logical Controller

(PLC), for example, connect in a control node. In this sense, we will be able to fit the FBs in the object-oriented paradigm where each of the FBs can be considered as a single object (Basic Function Block – BFB, with an Execution Control Chart – ECC, consisting of one or more algorithms), as a Composit Function Block (CFB), constituted by an interconnected BFBs or CFBs and Special Interface Function Block (SIFB) used in communication. The program algorithm for the BFB, CFB and SIFB may be developed in any languages defined by the IEC 31131-3 [20] and also in all additional languages supported by the IEC 61499 (e.g., Java, C, C++, C#, etc.). Developers are free to choose language since the standard does not specify a recommended language.

A distributed IEC 61499 or a replicated fault-tolerance system, split among several computer devices (e.g., PC, microcomputer or PLC), needs to send, over the network, events and data to each one of the FB distributed or replicated into the devices. To do this, the developer, insert a SIFB communication which will allow communication between FBs allocated to the same device or distributed by remote devices. The purpose of this article is to define a methodology to guarantee replicas determinism, using standard communication interfaces (SIFB), which will communicate between replicas, on remote devices, ensuring that the replicas process the same data set in the same order. On the other hand, industrial redundancy is typically archived at the hardware level, where the access to physical I/Os is done by communication SIFB Publish/Subscribe pair over UDP/IP – User Datagram Protocol/Internet Protocol (unidirectional communication), or Client/Server pair over TCP/IP (Transmission Control Protocol/Internet Protocol), bidirectional data/event communication [21].

4. Proposed IEC 61499 Implementation

An IEC 61499 application is seen as a combination by several devices, sub-applications or interconnected unitary processing elements (FBs), which at each invocation of events, process the data, generating new events and/or data. So, to tolerate individual faults, ensure the reliability of the application, only the critical components of the application must be replicated. Components is defined as an atomic and indivisible component (FB) which can include tasks and resources replicated on multiple nodes or allocated in just on node. As an example, Figure 1 shows a real-time sub-application "C" with 2 FBs (FB1 e FB2) distributed over nodes 1 and 2 and replicated over nodes 2 and 3 or, alternatively, replicated entirely in a single node (node 4).

So, the communication infrastructure of the proposed replication framework (base on active replication, i.e., all replicas are active and running at all times), based on the same communication structure used by IEC 61499, must guarantee that all messages sent by computer devices, delivery to all receiver, is correctly received. However, it will also be necessary that replicas agree with the order of the data set sent and consolidate data from replicated inputs into a single value that will be propagated to the subsequent FB.

Component replication can be performed using multiple replicas, however, the most common is the use of two ($f + 1$) or three replicas ($2 * f + 1$), to tolerate f failures. Therefore, replication based on these assumptions places us in the presence of several communication/interaction scenarios in which the exchange of messages can be defined according to the following four approaches [22]: *1-to-1* (communication from a nonreplicated FB to another nonreplicated or communication inside of the replica, base of the IEC 61499 communication); *1-to-many* (communication from a nonreplicated FB to a group of replicated FB. An atomic multicast protocol [9] must be used to ensure that all the replicas received the same set of information (data/events) in the same order. Replicas need to maintain internal state synchronized); *many-to-1* (a replicated FB sends data/events to a nonreplicated FB. Nonreplicated FB receives a set of inputs from all replicas and vote, consolidate mechanism [3], on the output value to process continue) and *many-to-many* (a mix of the last two cases where each received replica need to agree on the value to forward process. An atomic multicast protocol is used to disseminate values and the agree decision can be performed by one of the received values or on some value calculate based on majority, average, median, etc.). Voting mechanism can itself be replicated or only a single copy can be executed.

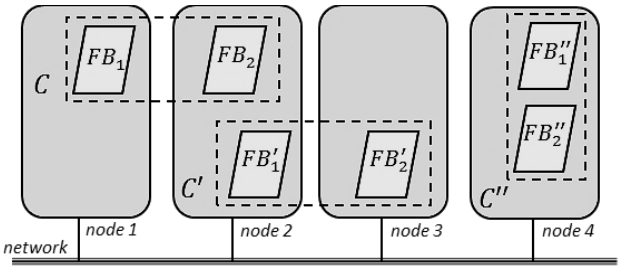

Figure 1: Replicated real-time sub-application

Replication model was implemented using *Eclipse 4diac™*. It is developed using the 4DIAC-IDE (Integrated Development Environment), graphical platform, and the FORTE runtime execution environment [2]. The graphical platform is used to develop the application, perform the interconnections between the instances, create, compile (in C ++) and integrate (in FORTE) the new types of FBs, once FORTE is compiled and executed in each computer device. Communication between replicas was carried out using standard communication FBs, made available by the 4diac repository and in accordance with IEC 61499. Data and events connection, between computer device and all instantiated FBs is supported by the FORTE runtime environment.

4.1. Communication architecture

The communication architecture is based on standards SIFB (Publish/Subscribe or Client/Server) interactions using Internet Protocol (IP) and FORTE runtime [23]. So, each of communication layers needs to be configured by the addressing schema accomplished by the identifier parameter (ID). Communication protocol is implemented in FBDK, inside a multicast group, using an Internet address and a unique port number [IP:port, e.g., 239.0.0.100:61023]. In a multicast communication scenarios (SIFB Publish/Subscribe) any of the subscribe blocks, located in the same network segment as the publish, can receive all published data/events [24]. On the other hand, a real-time industrial control application requires clocks synchronization, use of the timed messages to ensure determinism and the analyses of the worst-case execution times of the replicated FBs (including clock lag and communication delays). In fact, the developer needs to create a structure that supports IEC 61499

replication based on the existent communication SIFB considering scenarios presented above, in other words, it will only be necessary to use only two of the presented layers: *1-to-many* and *many-to-1* communication scenarios. Figure 2 shows the interface of the pair Publish/Subscribe used in multicast protocol communications.

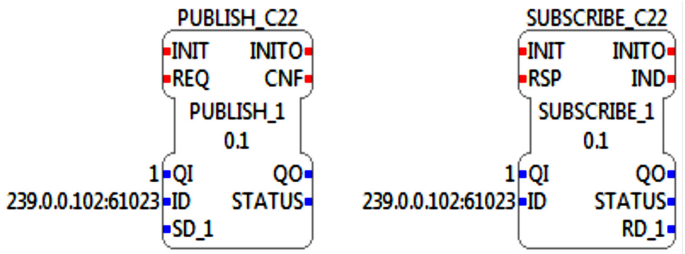

Figure 2: Interface of the Publish/Subscribe communication pair

4.2. Consolidation and voting replicate inputs

Voters can be developed according to the most varied techniques of fault-tolerance. However, these have the ultimate purpose of comparing the results of two or more variables and deciding which is the correct result, if any. There are in fact many types of voters [3] and the decision on which voting algorithm to use will depend on the semantics required by the application. For the voting to be viable, all replicas must send the data in the expected time. So, voting mechanism or consolidate module is built in top of the atomic multicast protocol, to ensure that all replicated FB receives the same set of data in the same order. The subscribe will wait until the set of events and data from the publishes are received. It is only at this point that the data is consolidated (the data is chose) or when it know that you will no longer receive messages at the δ_{voting} specific delay, Figure 3.

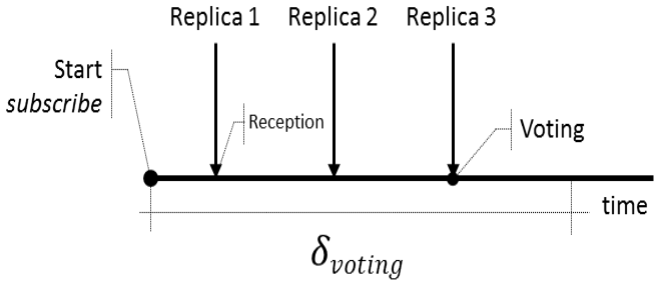

Figure 3: Data consolidate without faults

Note that this procedure must be implemented in a *many-to-1* context and that the decision time will depend on the worst-case response time (WCRT) of the last data received. On the other hand, we should consider that it will not be necessary to use underlying protocols that solve the problems of inconsistency by omitting messages, as it will be enough that only one node delivers a message.

In this approach, as we use a Triple Modular Redundancy (TMR) to mask faults [25] a majority voter was used. In the case of the three replicates, is done by simply comparison of the values received in A and C. The voting mechanism determines which value should be chosen according to the pseudocode shown in Algorithm 1.

Algorithm 1 VOTER algorithm pseudo code

```
1:  /* Initialization */
2:  void FORTE_VOTER
3:  switch(pa_nEIID){
4:  case input event:
5:          if (A() == C())
6:              VOTED() = A();
7:          else
8:              VOTED() = B();
9:          output event;
10:     break;
```

On the other hand, it is also necessary to consider that the determinism of the replicas must be guaranteed by the active replication. Therefore, the concept of timed messages [10] must be implemented to define the correct order of the execution of the received data. Thus, according to the mapping of the replication scenarios presented in [22], the application clocks must be synchronized. Data to be disseminated are associated with the availability times, defined by the execution times of the FBs to which the events/data are linked, that is, immediately after their execution. This validation time will be, in reality, the worst execution time of the FB that makes the data available (since in the IEC 61499 framework, the output data are only available when the algorithm finishes its execution) plus the sending times, which can be determined *offline* [26]. In this sense, when the data manager, a software element that guarantees the achievement of determinism, reads the received values (sent only once), works with the most recent values that have the oldest validation moments associated with the task validation. Figure 4 shows the scheme of how determinism can be obtained in the replicated components depending on the treatment of the timed messages received and treated according to the concept developed in the ordering FB.

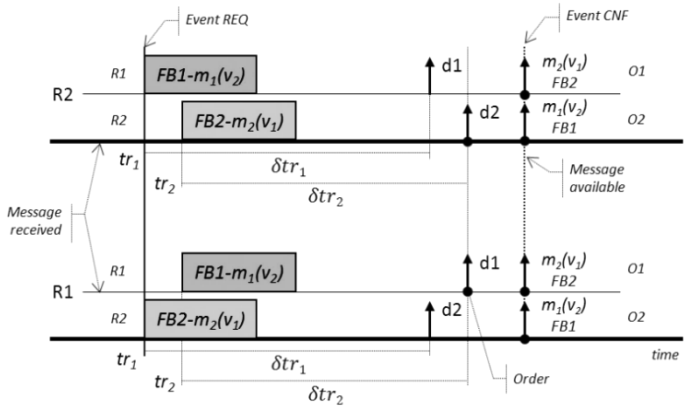

Figure 4: Replicas consistence, adapted to IEC 61499

Each FB is associated with a task, so they will send a message of order m_k where, in this implementation, the k index is associated with the number of the respective FB or task. δt_r is the limit of the predefined time for its execution (time that is activated after receiving the first message). $m_k(v_i)$ is a message of order k made available at the time of validity v_i. The instant tr_i represents the times of recession in processes *P1* and *P2* so, δtr_i is the waiting time, associated with event i received. When a new event is received the δtr_i waiting time is restarted, associated with the new event i, at the end of which the events will be ordered according to

the instant of validation v_i. Message that has the most recent value and that has the oldest validation time associated with its validation will be allocated to O1 (OUT1) while the second message will be allocated to output O2 (OUT2). CNF event confirms the execution of the FB and the availability, at the same time, of data *d1* and *d2*.

4.3. Consolidate time analysis

The analysis of the consolidate protocol execution time, at the receiving replicas, aims to define the delay time in the decision phase ($\delta_{decision}$), necessary for the FB to consolidate the received data, i.e., guarantee that FB will not receive any more messages. This time is dependent on the worst-case response time of the replicated messages as well as their best-case response time (BCRT), message processing, having as reference the initial time common to all sending and receivers nodes. However, we must consider that the time to send messages is common to all nodes (synchronization of local clocks) there were small variations or errors in the clock readings (*jitter*) that, like the *offset*, made the clocks only approximately synchronized.

Knowing the worst-case response time, we can determine the $\delta_{decision}$ assuming that the first message received has the best-case transmission time and the last has the worst-case response time. Therefore:

$$\delta_{decision} = \max_{\forall m \in res(m)} \{W_m\} - \min_{\forall m \in res(m)} \{W_m\} + \varepsilon \qquad (1)$$

where $max\{W_m\}$ is the worst-case response time of message and $min\{W_m\}$ is the best-case response time of message, considering a common time reference. $res(m)$ is the set of replicated messages received and ε is the maximum deviation between nodes synchronized local clocks. Figure 5 shows the time relationships referred.

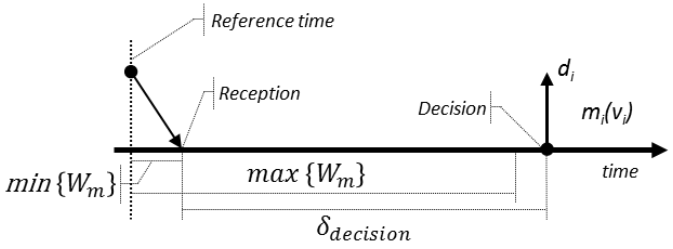

Figure 5: Relationship of times consolidate protocol

5. Numerical example

In order to explain the use of the presented model, a simple example of application is used. In Figure 6 is presented a real-time distributed system replication scheme using in the considered example. System application is constituted by five nodes, connected by TPC/IP network based on multicast protocol.

The application used in this example is constituted by five components (C_1 to C_4), each one with a task (τ_1 to τ_4) which are distributed over the nodes. A simple replication of critical components was performed by interconnecting the distributed and replicated components, with a switch, over an Ethernet TCP/IP network at a rate of 10/100 Mbps. Component C_1 (FB1) encapsulate tasks τ_1 at node 1, component C_2 (FB2) encapsulate task τ_2 at node 2, components C_{3a} and C_{3b} (replicated components, FB3 e FB3', at nodes 3 and 4) encapsulate τ_3 and τ_3', and finally component C_4 (FB4) encapsulated τ_4 (used to synchronize the start of components C_1 and C_2) at node 5.

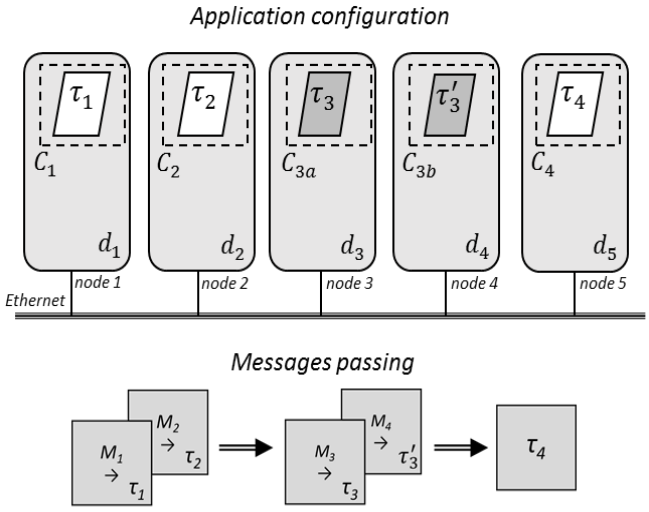

Figure 6: Application structure (replication and messages passing)

Table 1: Tasks characteristics

Tash	Type	Component	Node
τ_1	*Periodic*	*C1*	*1*
τ_2	*Periodic*	*C2*	*2*
τ_3	*Periodic*	*C3a*	*3*
τ_3'	*Periodic*	*C3b*	*4*
τ_4	*Spor/Per*	*C4*	*5*
τ_5	*Periodic*	*C5*	*6*

Table 1 presents each of the task's characteristics of the distributed application, while Table 2 presents the messages exchanged between FB (all values are in milliseconds).

Table 2: Messages passing characteristics

Msg	Bytes	Period (*ms*)	From	To	Protocol
M_5	---	---	τ_4	τ_1, τ_2	*Multicast*
	56(84)	*ping -f*	τ_4	τ_5	*Unicast*
M_1	*24*	*1000/500*	τ_1	τ_3, τ_3'	*Multicast*
M_2	*24*	*1000/500*	τ_2	τ_3, τ_3'	*Multicast*
M_6	*32*	*ping -t*	τ_5	τ_4	*Unicast*

Note that message from component C_1 and C_2 (M_1, M_2) is a *1-to-many* communication (multicast protocol) and also the message of system initialization (event synchronization starts of the C_1 and C_2) M_5. Messages M_5 is also used to increase the network traffic, in the switch, to component C_5 (Windows PC). Message M6 from C_5 to C_4 is the task response and also a contribute to the network traffic, it is a *1–to–1* communication. Messages M_1 and M_2 are messages from nonreplicated components to a replicate's components (C_{3a} and C_{3b}), therefore, they will have to be consolidate in each of the receiving replicas. This consolidation mask node failures of the sender's components.

5.1. Determinism testing

In order to clarify the possible determinism of the application, using only standard elements of the *4diac framework*, Publish/Subscribe communication pairs, 10000 events and data were launched in the network with frequency ranges of 1Hz and 0.5Hz, that is, with 1000 ms and 500 ms intervals. Each of the components (C_1 and C_2) sends messages to the replicas, in the same frequency ranges, associated with the availability time (*tsa - timestamp to availability* in *sec* and *nsec*) in the format [*data, sec, nsec*]. Replicas receives data associating the reception time (*tsr – timestamp to receiving*) in the same format.

The purpose of this example is to test the possibility of guaranteeing the determinism of the replicas according to the proposed and applied communication protocols (Publish/Subscribe pairs, inherent to *4diac*), for both the delivery and response time of messages. Thus, we consider the response time as the time interval between the instant when the message is sent and the instant when it is received by replies. A multicast protocol is used, to propagate messages, assuming that all the messages are delivered and received correctly. Table 3 shows the worst-case response time (WCRT) for a set of messages sent to the network using a 1000 ms trigger frequency. These experiments are carried out considering three conditions of operation: no additional traffic, with daily traffic directed simply to the switch (*tp-link, TL-SF1008D*) and additional traffic directed from a nonreplicated component to a replicated. Table 4 shows the results obtained for the WCRP considering a 500 ms trigger frequency.

Table 3: Messages response time, 1000 ms trigger frequency

Msg	Period	WCRT (*ms*)		Reception order
		C3a	C3b	
M_5	-	-	-	
M_1	1000	6,720	3,979	93,35%
M_2	1000	6,765	3,806	
M_1	1000	6,527	2,602	94,33%
M_2	1000	6,464	2,942	
M_1	1000	6,208	1,556	97,09%
M_2	1000	6,448	1,941	

As can be seen, the WCRP is obtained for M_2 messages. This carryout the messages sending from component C_2 (nonreplicated) to the replicated component C_{3a}, response time of 6.765 ms. The average order value of the received data (*Reception order*) is 94.92%, which demonstrates the absence of the determinism of the replicas (C_{3a} and C_{3b} components) due to the frequency of the experience triggering.

Table 4: Messages response time, 500 ms trigger frequency

Msg	Period	WCRT (*ms*)		Reception order
		C3a	C3b	
M_5	-	-	-	
M_1	500	6,760	6,236	97,94%
M_2	500	7,207	8,045	
M_1	500	5,843	2,457	93,43%
M_2	500	6,248	2,569	
M_1	500	7,196	3,178	94,34%
M_2	500	6,575	3,235	

As can be seen, the WCRP is obtained for M_2 messages. This carryout the messages sending from component C_2 (nonreplicated) to the replicated component C_{3b}, response time of 8.045 ms. The average order value of the received data (*Reception order*) is 95.24%, which demonstrates the absence of the determinism of the replicas (C_{3a} and C_{3b} components) due to the frequency of the experience triggering.

Table 5 shows the WCRT (maxims time) and BCRT (minimums times), *calculated offline*, for a set of messages exchanged between components C_1, C_2 and C_{3a}, C_{3b} characterizing the messages of stream M_1 and M_2. These values are the result of the data and events received in the replicas, considering the experiences defined above. The incidence based is 10 k events processed in each of the experiments. These values are the result of the *offline* analysis of the 60 k records processed.

Table 5: Messages times characteristics, maxims and minimums value

Msg	WCRT (*ms*)	BCRT (*ms*)	from→to	Average order
M_1	7,169	0,170	$\tau_1 \rightarrow \tau_3$	95,08%
M_2	8,045	0,131	$\tau_2 \rightarrow \tau_3'$	

As can be seen, the average order for data received in the replicas has a value less than 100%, which induces the existence of failures in the ordering of the data. On the other hand, since the messages must be consolidated and ordered according to the time validity requirement, to guarantee determinism, it is necessary to determine the $\delta_{decision}$ parameter of the consolidation protocol as defined in (1). The maximums and minimums times for transmission data/events are defined in Table 5 and the maximum deviation between synchronized clocks (ε), also calculated *offline*, is 164 μs. Therefore, using (1):

$$\delta_{decision} = 8.045 - 0.131 + 0.164 = 8.078\ ms \quad (2)$$

The worst-case decision time for consolidation, considering $\delta_{decision}$, can be defined considering all messages received in the set *res(m)* so, that the worst-case decision time will be given by:

$$W^{decision} = \max_{\forall m \in res(m)} \{W_m\} + \delta_{decision} = 16.123\ ms \quad (3)$$

where $W^{decision}$ is the worst time of the consolidation, i.e., time decision when a new event arrives at the end of the $\delta_{decision}$ time.

6. Conclusions

The *Eclipse 4diac*™ tool was developed in accordance with IEC 61499 and it is specially directed to the development of distributed industrial applications portables and modular.

The Publish/Subscribe pair, provides by the 4diac object repository, are a communication FB, fundamental for the interconnection of the distributed components, guaranteeing not only the synchronization of the system but also the implementation

of the atomic multicast protocol. However, the introduction of software or hardware component replication introduces new problems that were not anticipated in IEC 61499 as well as in 4diac. These pairs, using different communication interfaces, guarantee replication synchronization, but cannot guarantee their determinism and, as such, promote the occurrence of failures that must be masked.

Based on the experiences carried out we can conclude that the Publish/Subscribe pair, most used in the interconnection of distribute/replicated computer devices, has a failure rate, independent and identically distributed, of 4.92%. Therefore, it is not possible, by itself, to ensure determinism, so the programmer will need to develop a FB, also replicable, which ensures that all replicas process the same data set in the same order.

ABSTRACT

The performance of Simultaneous Clustering and Model Selection Matrix Affinity (SCAMSMA) and Deep Divergence-Based Clustering (DDC) in clustering wireless multipaths generated by COST 2100 channel model (C2CM) is compared. Enhancing the accuracy of clustering multipaths is an open area of research which the clustering approaches try to improve. Jaccard index is used as the clustering validity metric of the clustering approaches. The results of the clustering approaches are compared using the analysis of variance (ANOVA) toolbox of MATLAB and displayed using the box plots. Results show that the cluster-wise Jaccard index is different between SCAMSMA and DDC for indoor scenarios, while the membership-wise Jaccard index is not. On the other hand, the cluster-wise Jaccard index is not different between the clustering approaches for semi-urban scenarios, while the membership-wise Jaccard index is a little different. The clustering approaches can be used in indoor scenarios based on accuracy.

1 Introduction

The European Cooperation in Science and Technology (COST) 2100 Channel Model (C2CM) [1]–[4] can reproduce the properties of multiple-input multiple-output (MIMO) wireless propagation channels. A multipath component (MPC) is classified based on the delay (τ), angle of departure (Azimuth of Departure (AoD), Elevation of Departure (EoD)), and angle of arrival (Azimuth of Arrival (AoA), Elevation of Arrival (EoA)). Groups of multipath components with similar delays and angles comprise a multipath cluster, which characterized C2CM.

Analyzing wireless multipaths is an important problem where clustering is crucial. The attribute, performance, and efficiency of the communications system can be studied, understood, and improved by the generated channel model. The accuracy and correctness of the channel models significantly affect the precision and exactness of clustering wireless propagation multipaths. Several channel models and measurements reveal the clustering of multipaths. Inaccurate clustering of the wireless propagation multipaths leads to incorrect channel models and thereby degradation in performance.

Clustering finds the underlying structure of the data. It also group similar data together [5]–[16]. In our previous works [17]–[20], Simultaneous Clustering and Model Selection Matrix Affinity (SCAMSMA) [21] and Divergence-Based Clustering (DDC) [22] were used to cluster the dataset [23, 24] generated by C2CM. In this work, the comparison of the clustering accuracy of SCAMSMA and DDC are presented. The main contributions of this study are (1) the paper shows the variation in the performance of SCAMSMA and DDC in clustering the COST 2100 dataset; and (2) SCAMSMA and DDC have a significant difference in their accuracy in clustering the wireless multipaths.

The paper is organized in the following way. Section 2 presents the dataset generated by C2CM. Section 3 describes the clustering approaches. Section 4 explains the ANOVA used. Section 5 defines the Jaccard index. Section 6 discusses the ANOVA results. Section 7 concludes the work.

2 COST 2100 Dataset

COST 2100 channel model (C2CM) [1]–[4] can replicate the stochastic properties of multiple-input multiple-output (MIMO) wireless propagation channels. Multipath clusters characterize

[*]Corresponding Author: Jojo Blanza, Department of Electronics and Communications Engineering, De La Salle University, 2401 Taft Ave., Malate, Manila, 0922, Philippines, +639327882997 & jojo_f_blanza@dlsu.edu.ph

C2CM. A multipath component (MPC) is defined by its delay (τ), angle of departure (AOD) (Azimuth of Departure (AoD), Elevation of Departure (EoD)), and angle of arrival (AOA) (Azimuth of Arrival (AoA), Elevation of Arrival (EoA)). MPCs with similar delays and angles are grouped into multipath clusters, as shown in Figure 1.

A channel impulse response (CIR) from the base station (BS) to mobile station (MS) antennas is characterized by the combination of MPCs from all the active multipath clusters and is given as

$$h(t,\tau,\boldsymbol{\Omega}^{\mathrm{BS}},\boldsymbol{\Omega}^{\mathrm{MS}}) = \sum_{k\in K}\sum_{p}\alpha_{k,p}\delta(\tau-\tau_{k,p})\delta(\boldsymbol{\Omega}^{\mathrm{BS}}-\boldsymbol{\Omega}^{\mathrm{BS}}_{k,p})\delta(\boldsymbol{\Omega}^{\mathrm{MS}}-\boldsymbol{\Omega}^{\mathrm{MS}}_{k,p}) \quad (1)$$

where K is the set of visible cluster indexes, $\alpha_{k,p}$ is the complex amplitude of the pth MPC in the kth cluster, $\boldsymbol{\Omega}^{\mathrm{BS}}_{k,p}$ is the direction of departure (AoD, EoD), and $\boldsymbol{\Omega}^{\mathrm{MS}}_{k,p}$ is the direction of arrival (AoA, EoA) of the MPC.

The dataset [23, 24] is generated by the C2CM, which consist of two indoor channel scenarios at 5.3 GHz and six semi-urban channel scenarios at 285 MHz as follows:

1. Indoor, Band 1 (B1), Line-of-Sight (LOS), Single Link (SL)
2. Indoor, Band 2 (B2), Line-of-Sight, Single Link
3. Semi-Urban, Band 1, Line-of-Sight, Single Link
4. Semi-Urban, Band 2, Line-of-Sight, Single Link
5. Semi-Urban, Band 1, Non-Line-of-Sight (NLOS), Single Link
6. Semi-Urban, Band 2, Non-Line-of-Sight, Single Link
7. Semi-Urban, Band 1, Line-of-Sight, Multiple Links (ML)
8. Semi-Urban, Band 2, Line-of-Sight, Multiple Links

Each channel scenario has thirty sets of data consisting of a different number of multipaths and multipath clusters. The seven features of the datasets are the following: whitened x-component of AOD (X_AOD_W), the whitened y-component of AOD (Y_AOD_W), the whitened z-component of AOD (Z_AOD_W), the whitened x-component of AOA (X_AOA_W), the whitened y-component of AOA (Y_AOA_W), the whitened z-component of AOA (Z_AOA_W), and the whitened delay (delay_W). The reference cluster identification of the data is given by refclusID. It serves as the ground truth in evaluating the performance of the clustering approach. The power component (rel_pow) is not included since it is not needed in clustering the data.

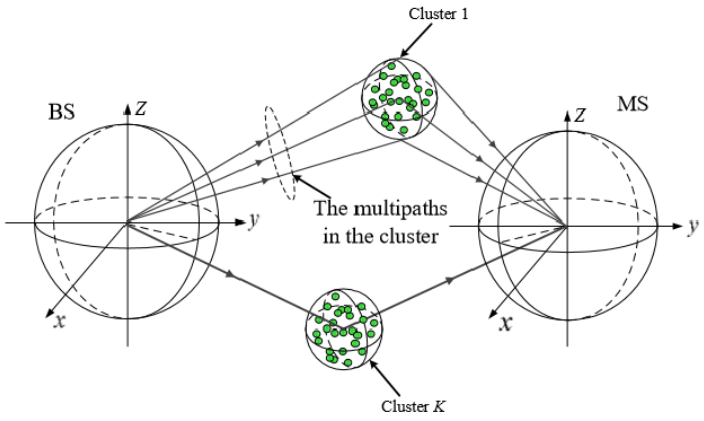

Figure 1: Generated wireless multipath components grouped as multipath clusters in C2CM [11]

3 Clustering Approaches

The dataset generated by C2CM is clustered using SCAMSMA and DDC. SCAMSMA can simultaneously determine the number of clusters and the membership of the clusters. DDC can solve the membership of the clusters and the cluster count can be calculated according to the membership of the multipaths to their clusters. The clustering approaches are used to cluster images and it is the first time that they are applied to cluster multipaths.

SCAMSMA [21] begins by formulating an affinity matrix $\boldsymbol{C}_{\mathrm{calc}}$ using the self-expression method where a given dataset $\boldsymbol{X}$ can be represented as $\boldsymbol{X}\boldsymbol{C}_{\mathrm{calc}}$ as follows

$$\min\|\boldsymbol{C}_{\mathrm{calc}}\|_1 \quad \text{s.t.} \quad \boldsymbol{X} = \boldsymbol{X}\boldsymbol{C}_{\mathrm{calc}}, \quad \mathrm{diag}\,(\boldsymbol{C}_{\mathrm{calc}}) = \boldsymbol{0} \quad (2)$$

where $\|\cdot\|_1$ is the ℓ_1 norm, which returns the sum of the absolute values of all elements and diag$(\cdot)$ are the diagonal entries of the matrix. The solution of (2) corresponds to $\boldsymbol{C}_{\mathrm{calc}}$.

Introducing an ideal affinity matrix such that $\boldsymbol{C}_{\mathrm{ideal}} = \sum_{k=1}^{K}\mathbf{z}_k \circ \mathbf{z}_k$ and $\{\mathbf{z}_k \in \{0,1\}^M\}_{k=1}^K$ where $\mathbf{z}_k = 1$ if the point belongs to the cluster otherwise $\mathbf{z}_k = 0$ and $\circ$ represents the vector outer product. By denoting $\boldsymbol{W} = -\boldsymbol{C}_{\mathrm{calc}}$, the clustering problem can be expressed as

$$\begin{aligned} &\min\langle \boldsymbol{W}, \boldsymbol{C}_{\mathrm{ideal}}\rangle, \quad \text{s.t.} \quad \mathbf{z}_k\{0,1\}^M, \\ &\sum_{k=1}^{K}\mathbf{z}_k = \mathbf{e}_M, \quad \boldsymbol{C}_{\mathrm{ideal}} = \sum_{k=1}^{K}\mathbf{z}_k \circ \mathbf{z}_k, \quad \mathrm{rank}(\boldsymbol{C}_{\mathrm{ideal}}) = K \end{aligned} \quad (3)$$

where $\langle\cdot,\cdot\rangle$ is the Frobenius inner product, $\mathbf{e}_M$ is an all one vector of size R while K is the number of clusters. SCAMSMA simultaneously solves the number of clusters and the membership of clusters.

DDC [22] optimizes a loss function based on information-theoretic measures. The loss function is defined by

$$L = \frac{1}{k}\sum_{i=1}^{k-1}\sum_{j>i}\frac{\boldsymbol{\alpha}_i^{\mathrm{T}}\boldsymbol{K}_{\mathrm{hid}}\boldsymbol{\alpha}_j}{\sqrt{\boldsymbol{\alpha}_i^{\mathrm{T}}\boldsymbol{K}_{\mathrm{hid}}\boldsymbol{\alpha}_i\boldsymbol{\alpha}_j^{\mathrm{T}}\boldsymbol{K}_{\mathrm{hid}}\boldsymbol{\alpha}_j}} + \mathrm{triu}(\boldsymbol{A}\boldsymbol{A}^{\mathrm{T}}) + \frac{1}{k}\sum_{i=1}^{k-1}\sum_{j>i}\frac{\boldsymbol{m}_i^{\mathrm{T}}\boldsymbol{K}_{\mathrm{hid}}\boldsymbol{m}_j}{\sqrt{\boldsymbol{m}_i^{\mathrm{T}}\boldsymbol{K}_{\mathrm{hid}}\boldsymbol{m}_i\boldsymbol{m}_j^{\mathrm{T}}\boldsymbol{K}_{\mathrm{hid}}\boldsymbol{m}_j}} \tag{4}$$

where k is the number of clusters, $\boldsymbol{K}_{\mathrm{hid}}$ is the kernel similarity matrix, $\boldsymbol{\alpha}$ is the soft cluster assignment, $\boldsymbol{A}$ is the cluster assignment matrix, $\mathrm{triu}(\boldsymbol{A}\boldsymbol{A}^{\mathrm{T}})$ is the upper triangular of $\boldsymbol{A}\boldsymbol{A}^{\mathrm{T}}$ and $\boldsymbol{m}$ is the simplex corner assignment.

The clusters are represented by their probability density functions. Divergence measures the dissimilarity between clusters. The divergence builds on two fundamental objectives: the separation between clusters and the compactness within clusters, as shown in Figure 2. DDC explicitly exploits knowledge about the geometry of the output space during the optimization. DDC supports end-to-end learning, does not require hand-crafted feature design, and does not need a pre-training phase.

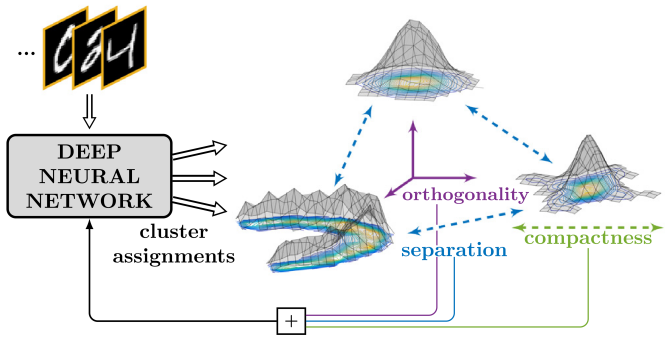

Figure 2: Fundamental objectives of divergence: separation between clusters and compactness within clusters [22]

4 Analysis of Variance (ANOVA)

One-way ANOVA [25, 26] is used to determine if there is a common mean of the data from several groups of a factor. The statistical tool can find out if there are different effects on the response variable of the different groups of an independent variable. The anova1 function of Statistics and Machine Learning Toolbox of MATLAB returns the p-value for a balanced one-way ANOVA. The MATLAB function also displays the box plots of the independent variable. Lastly, the anova1 function tests the hypothesis that the samples in the independent variable are drawn from populations with the same mean against the alternative hypothesis that the population means are not all the same.

One-way ANOVA is a simple, special case of the linear model which can be expressed as

$$y_{ij} = \alpha_j + \epsilon_{ij} \tag{5}$$

where

y_{ij} is an observation, i represents the observation number, and j represents a different group of the predictor variable y. All y_{ij} are independent.

α_j represents the population mean for the jth group.

ϵ_{ij} is the random error, independent and normally distributed, with zero mean and constant variance.

The equality of column means for the data in matrix y is tested using the MATLAB function anova1(y), where each column is a different group and has the same number of observations.

ANOVA tests the hypothesis that all group means are equal versus the alternative hypothesis that at least one group is different from the others as follows:

$$\begin{aligned} H_0 &: \alpha_1 = \alpha_2 = \ldots = \alpha_k \\ H_1 &: \text{not all group means are equal} \end{aligned} \tag{6}$$

ANOVA tests for the difference in the group means by partitioning the total variation in the data into two components: variation of group means from the overall mean and variation of observations in each group from their group mean estimates. It means that ANOVA partitions the total sum of squares (SST) into sum of squares due to between-groups effect (SSR) and sum of squared errors (SSE) given by

$$\underbrace{\sum_i\sum_j(y_{ij}-\bar{y}_{..})^2}_{SST} = \underbrace{\sum_j n_j(\bar{y}_{.j}-\bar{y}_{..})^2}_{SSR} + \underbrace{\sum_i\sum_j(y_{ij}-\bar{y}_{.j})^2}_{SSE} \tag{7}$$

where n_j is the sample size for the jth group, $j = 1, 2, ..., k$.

ANOVA compares the variation between groups to the variation within groups. If the ratio of within-group variation to between-group variation is significantly high, then the group means are significantly different from each other. This ratio can be measured using a test statistic that has an F-distribution with $(k-1, N-k)$ degrees of freedom where

$$F = \frac{\frac{SSR}{k-1}}{\frac{SSE}{N-k}} = \frac{MSR}{MSE} \sim F_{k-1,N-k} \tag{8}$$

where MSR is the mean squared treatment, MSE is the mean squared error, k is the number of groups, and N is the total number of observations. If the p-value for the F-statistic is smaller than the significance level (0.05), then the test rejects the null hypothesis that all group means are equal and concludes that at least one of the group means is different from the others. The p-value is derived by anova1 from the cumulative distribution function (CDF) of the F-distribution. The p-value is correct, if ϵ_{ij} are independent, normally distributed, and have constant variance.

5 Clustering Validity Index

The performance of a clustering approach is measured using a clustering validity index. The study uses the Jaccard index, which compares the similarity between the reference data and the calculated data. For the number of clusters, the Jaccard index is calculated as

$$\eta = \frac{|C_{11}|}{|C_{11} + C_{10} + C_{01}|} \quad \in \quad [0, 1] \tag{9}$$

where $|\cdot|$ refers to cardinality, $C_k \in C$, $K = |C|$ is the number of multipath clusters, C_{11} is the number of clusters that are present in the calculated clusters that are also present in the reference clusters, C_{10} is the number of clusters that are present in the calculated clusters but not present in the reference clusters, and C_{01} is the number of clusters that are present in the reference clusters but not present in the calculated clusters. For the membership of the clusters, the Jaccard index is calculated as

$$\eta = \frac{M_{11}}{M_{11} + M_{01} + M_{10}} \quad \in \quad [0, 1] \tag{10}$$

where M_{11} is the number of members that are present in the calculated clusters that are also present in the reference clusters, M_{10} is the number of members that are present in the calculated clusters but not present in the reference clusters, and M_{01} is the number of members that are present in the reference clusters but not present in the calculated clusters. A Jaccard index of one means that the calculated multipath clusters are the same as the reference multipath clusters, or the membership of the calculated multipath clusters is the same as the membership of the reference multipath clusters. A zero Jaccard index, on the other hand, means that there are no calculated multipath clusters that are equal to the reference multipath clusters, or there is no membership of the calculated multipath clusters that are equal to the membership of the reference multipath clusters.

6 Result and Discussion

The clustering accuracy of SCAMSMA and DDC are shown in Table 1 for the indoor scenarios and Table 2 for the semi-urban scenarios. The performance of the clustering approaches in both indoor and semi-urban scenarios are based on the number of clusters and the membership of clusters. The means of the Jaccard indices are compared using ANOVA. The ANOVA is illustrated using box plots. The box plots and p-values are generated using the anova1 one-way approach function of MATLAB. The box plots display the range of Jaccard indices and can be used to visualize the means. Values of $p < 0.05$ indicate that the means of SCAMSMA and DDC are significantly different.

Table 1: Jaccard index means of SCAMSMA and DDC in indoor scenarios

Clustering Approach	Indoor Number of Clusters	Indoor Membership of Clusters
SCAMSMA	0.6261	0.7444
DDC	0.7499	0.8054

Table 2: Jaccard index means of SCAMSMA and DDC in semi-urban scenarios

Clustering Approach	Semi-Urban Number of Clusters	Semi-Urban Membership of Clusters
SCAMSMA	0.0112	0.1615
DDC	0.0102	0.2172

The box plots of the Jaccard indices of the number of clusters of SCAMSMA and DDC for the indoor scenarios are shown in Figure 3. The p-value is 0.0388, which indicates that there is a significant difference in the means of the clustering accuracies. This difference can be seen in the figure where the box plot of DDC is higher than that of SCAMSMA. DDC is more accurate than SCAMSMA in clustering multipaths by 19.77%.

Figure 4 presents the box plots of the Jaccard indices of the membership of clusters of SCAMSMA and DDC for the indoor scenarios. The p-value is 0.0996, which attests that there is no significant difference in the means of the Jaccard indices. This difference can be visualized in the figure where the box plots are almost on the same level ($\sim$ 0.8). DDC has higher accuracy in clustering multipaths than SCAMSMA by only 8.19%.

The box plots of the Jaccard indices of the number of clusters of SCAMSMA and DDC for the semi-urban scenarios are illustrated

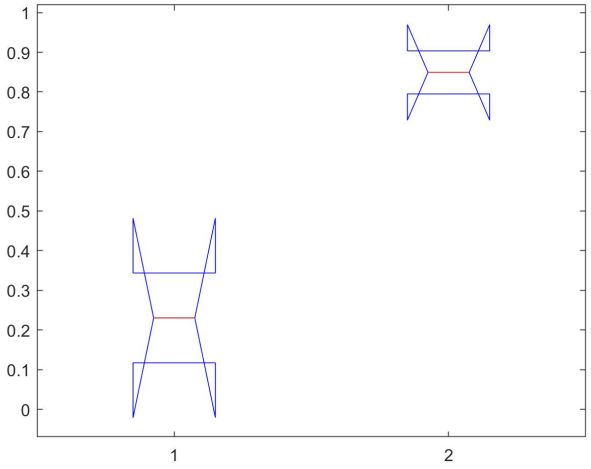

Figure 3: Box plots of the Jaccard indices for the number of clusters in indoor scenarios of SCAMSMA in box plot 1 and DDC in box plot 2

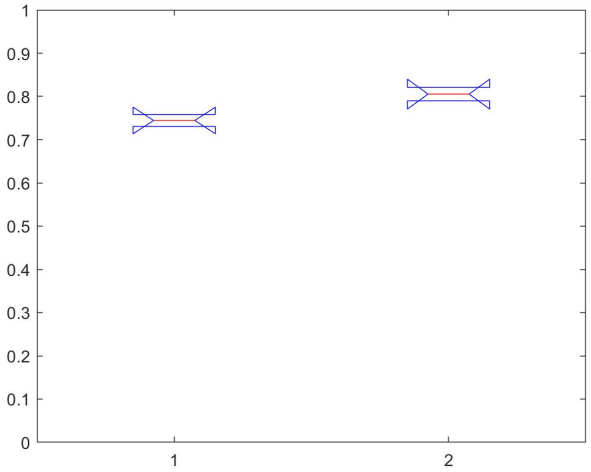

Figure 4: Box plots of the Jaccard indices for the membership of clusters in indoor scenarios of SCAMSMA in box plot 1 and DDC in box plot 2

in Figure 5. The p-value is 0.7419, which suggests that the means of SCAMSMA and DDC are similar (0.0112 vs. 0.0102). The figure indicates that the box plots are on the same level near the horizontal axis (~ 0). SCAMSMA is more accurate this time by 9.80%.

Figure 6 displays the box plots of the Jaccard indices of the membership of clusters of SCAMSMA and DDC for the semi-urban scenarios. The p-value is 0.0139, which proves that the means of SCAMSMA and 3CAM-SCAMSMA are significantly different. The figure shows that the box plot of DDC is higher than that of SCAMSMA. DDC has a higher clustering accuracy of 34.49%.

DDC shows consistency in its clustering performance due to higher accuracy of clustering multipaths in all channel scenarios except for the membership of clusters in semi-urban scenarios where SCAMSMA has a slight clustering advantage of 0.0012. Also, the means of SCAMSMA and DDC are significantly different since the p-values are less than 0.05 except in the membership of clusters in semi-urban scenarios. Lastly, the clustering approaches can be used in indoor scenarios but not in semi-urban scenarios based on accuracy which is validated by the measurements done in indoor environment [27].

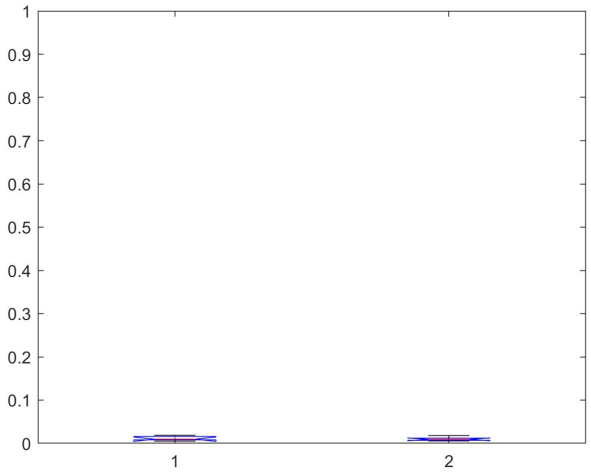

Figure 5: Box plots of the Jaccard indices for the number of clusters in semi-urban scenarios of SCAMSMA in box plot 1 and DDC in box plot 2

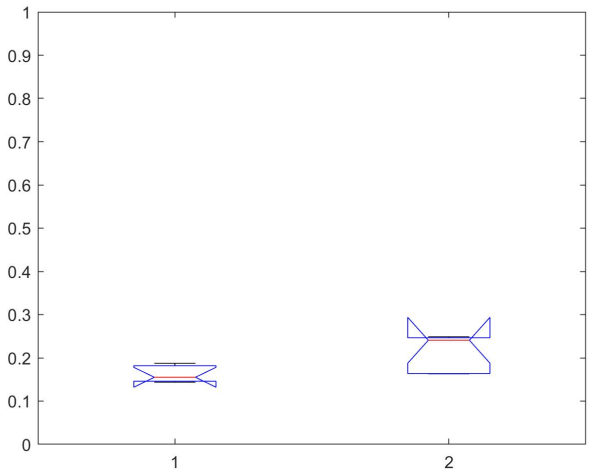

Figure 6: Box plots of the Jaccard indices for the membership of clusters in semi-urban scenarios of SCAMSMA in box plot 1 and DDC in box plot 2

7 Conclusion

This work presents the comparison of the clustering accuracy of SCAMSMA and DDC in clustering wireless propagation multipaths generated by C2CM. Jaccard index is used as the performance metric of the clustering approaches. Results show that there is a significant difference in the cluster-wise Jaccard index between SCAMSMA and DDC for indoor scenarios while the membership-wise Jaccard index is not different. On the other hand, the cluster-wise Jaccard index is not different between the clustering approaches for semiurban scenarios while the membership-wise Jaccard index is a little different. The clustering approaches can be used in indoor scenarios based on accuracy. However, a better multipath clustering method should be used for semi-urban scenarios. For future work, the results will be compared with other clustering approaches to determine the best performance in terms of clustering wireless multipaths in indoor and semi-urban environments.

Conflict of Interest The authors declare no conflict of interest.

Graphical user interfaces

ABSTRACT

A graphical user interface (GUI) is presented to visualize the multipaths generated by COST 2100 channel model (C2CM) and the results of clustering the wireless propagation multipaths using Modified Simultaneous Clustering and Model Selection (MSCAMSMA). The usual practice of authors is to show their data and results using figures, tables, and graphs which are already sufficient to present their studies. However, the manner of displaying the data and results is static; that is, the user cannot examine them to analyze further the relationship of the different variables involved in the study. The paper presents a step further by showing dynamically the data and results which the user can manipulate according to its needs.

1 Introduction

Data and results are integral parts of a scientific study. They are important in the research process as the data is the basis of the study, and the results show the outcomes of the work done. That is why it is important to present the data and results in a manner that is easily read, seen, and understood by the reader.

Most papers use figures, tables, algorithms, equations, diagrams, illustrations, programs, and graphs to visualize the data and results of the study. The technique of presenting the data and results is sufficient for what the authors want to show. However, this method is static and dependent on what the authors want to present. Researchers cannot manipulate the data and analyze the effects of changing the input parameters. This paper addresses this concern by presenting a graphical user interface (GUI) that is dynamic, modifiable, and suitable to the need of the user. This way, researchers can have a deeper and better experience and understanding of what they are studying and examining.

GUI is one of the key technological advancements due to improvements in computer hardware and software. GUI greatly improved user experience by displaying the information. A GUI is an interactive system with visual components for manipulation. An interface is a useful tool that makes the most of the vision capacity of the user. A GUI allows a person to visually control the flow of information and decide on what is relevant and discard what is not [1]. Some lack analysis platform [2]–[4] unlike those in [5]–[13]. In this paper, a GUI is developed to manage the data and results of clustering European Cooperation in Science and Technology (COST) 2100 dataset [14, 15] using Modified Simultaneous Clustering and Model Selection (MSCAMSMA) [16]. The interface is an effective method in visualizing the COST 2100 dataset and the clustering results. A previous work [17] on GUI can visually analyze the reference data and the calculated clusters but considered only the cluster count. In this work, the GUI can be used by the user to visualize, manipulate, and analyze the multipaths generated by the COST 2100 channel model (C2CM) and the clustering results of MSCAMSMA not only giving the accuracy on the number of clusters but also the membership of clusters. The paper is organized in the following way. Section 2 presents the dataset generated by C2CM. Section 3 describes the clustering approach. Section 4 discusses the GUI developed. Section 5 concludes the work.

2 COST 2100 Channel Model (C2CM) Dataset

C2CM [18]–[21] is characterized by multipath clusters, as shown in Figure 1. C2CM can reproduce the stochastic properties of multiple-

[*]Corresponding Author: Jojo Blanza, Department of Electronics and Communications Engineering, De La Salle University, 2401 Taft Ave., Malate, Manila, 0922, Philippines, +639327882997 & jojo_f_blanza@dlsu.edu.ph

input multiple-output (MIMO) wireless communication channels. A multipath component (MPC) is defined by its delay (τ), angle of departure (Azimuth of Departure (AoD), Elevation of Departure (EoD)), and angle of arrival (Azimuth of Arrival (AoA), Elevation of Arrival (EoA)). Multipath clusters are groups of MPCs with similar delays and angles.

A channel impulse response (CIR) from the base station (BS) to mobile station (MS) antennas is characterized by the combination of MPCs from all the active multipath clusters and is given as

$$h(t,\tau,\boldsymbol{\Omega}^{\mathrm{BS}},\boldsymbol{\Omega}^{\mathrm{MS}}) = \sum_{k\in K}\sum_{p}\alpha_{k,p}\delta(\tau-\tau_{k,p})\delta(\boldsymbol{\Omega}^{\mathrm{BS}}-\boldsymbol{\Omega}^{\mathrm{BS}}_{k,p})\delta(\boldsymbol{\Omega}^{\mathrm{MS}}-\boldsymbol{\Omega}^{\mathrm{MS}}_{k,p}) \quad (1)$$

where K is the set of visible cluster indexes, $\alpha_{k,p}$ is the complex amplitude of the pth MPC in the kth cluster, $\boldsymbol{\Omega}^{\mathrm{BS}}_{k,p}$ is the direction of departure (AoD, EoD), and $\boldsymbol{\Omega}^{\mathrm{MS}}_{k,p}$ is the direction of arrival (AoA, EoA) of the MPC.

For a MIMO system using V and U multiple antennas arrays at BS and MS, respectively, the $U \times V$ MIMO channel matrix $\mathbf{H}(t,\tau)$, under the plane wave and balanced narrowband array assumptions, can be expressed as

$$\mathbf{H}(t,\tau) = \sum_{k\in K}\sum_{p}\alpha_{k,p}\boldsymbol{s}_{\mathrm{MS}}(\boldsymbol{\Omega}^{\mathrm{MS}})\boldsymbol{s}^{\mathrm{T}}_{\mathrm{BS}}(\boldsymbol{\Omega}^{\mathrm{BS}}) \quad (2)$$

where $\boldsymbol{s}_{\mathrm{MS}}$ is the antenna steering vector at MS and $\boldsymbol{s}_{\mathrm{BS}}$ is the antenna steering vector at BS.

The dataset [14, 15] is generated by C2CM, which consist of two indoor and six semi-urban channel scenarios as follows:

1. Indoor, Band 1 (B1), Line-of-Sight (LOS), Single Link (SL)
2. Indoor, Band 2 (B2), Line-of-Sight, Single Link
3. Semi-Urban, Band 1, Line-of-Sight, Single Link
4. Semi-Urban, Band 2, Line-of-Sight, Single Link
5. Semi-Urban, Band 1, Non-Line-of-Sight (NLOS), Single Link
6. Semi-Urban, Band 2, Non-Line-of-Sight, Single Link
7. Semi-Urban, Band 1, Line-of-Sight, Multiple Links (ML)
8. Semi-Urban, Band 2, Line-of-Sight, Multiple Links

Each channel scenario has thirty sets of data. There are a different number of multipaths and multipath clusters for each set of data. The seven features of the dataset are the following: whitened x-component of AOD (X_AOD_W), the whitened y-component of AOD (Y_AOD_W), the whitened z-component of AOD (Z_AOD_W), the whitened x-component of AOA (X_AOA_W), the whitened y-component of AOA (Y_AOA_W), the whitened z-component of AOA (Z_AOA_W), and the whitened delay (delay_W). The reference cluster identifications of the data are given by refclusID, which serves as the ground truth in evaluating the performance of the clustering approach. The power component (rel_pow) is not included since it is not needed by the clustering approach.

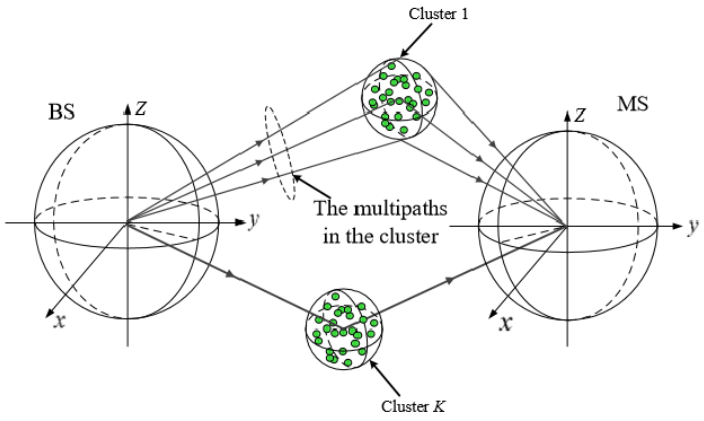

Figure 1: Multipath components and multipath clusters in COST 2100 channel model [22]

3 Modified Simultaneous Clustering and Model Selection (MSCAMSMA)

MSCAMSMA [16] is used to cluster the COST 2100 dataset. The clustering approach is introduced to improve the clustering accuracy of SCAMSMA [23]. The accuracy of SCAMSMA depends on the correct formulation of the data affinity matrix, $\boldsymbol{C}_{\mathrm{calc}}$, so that a 0-1 block diagonal is formed. MSCAMSMA can be described as follows: Let the dataset $\boldsymbol{X} \in \mathbb{R}^{L\times D}$ where L was the number of multipath components or the number of rows and D the number of dimensions, which is seven, or the number of columns. A multipath, $\boldsymbol{x}$, consists of a single row of seven columns. A dataset can be expressed as

$$\boldsymbol{X} = [\boldsymbol{x}_1,\ldots,\boldsymbol{x}_L]^{\mathrm{T}}. \quad (3)$$

MSCAMSMA depends on three constraints: pairwise, binary, and proximity. Pairwise Constraint, $\boldsymbol{P}_{\ell,d}$, depends on the absolute distance, $\boldsymbol{d}_{\mathrm{abs}}$, of the corresponding pair of multipaths for the seven dimensions which are given by

$$\left|\boldsymbol{x}_{\ell,d} - \boldsymbol{x}_{d,d}\right| \quad (4)$$

where $\boldsymbol{x}_{\ell,d}$ and $\boldsymbol{x}_{d,d}$ are multipaths, ℓ is the row number, and d is the column number. The distance parameter, $\boldsymbol{d}_{\mathrm{par}}$, is determined by

$$\frac{600}{L}\left[\max(\boldsymbol{X}(:,d)) - \min(\boldsymbol{X}(:,d))\right] \quad (5)$$

where max( ) is the function that gives the maximum value of a column while min( ) gives the minimum value of the said column, and ":" denotes all rows if it is in the first argument. Factor 600 is used so that MSCAMSMA applies to all of the datasets. A value less than 600 gives at least one all-zero row leading to an incorrect affinity matrix. A value greater than 600 leads to an all-one matrix,

excluding the main diagonal. The resulting affinity matrix is also not correct. The Pairwise Constraint is given by

$$\boldsymbol{P}_{\ell,d} = \begin{cases} 1 & \text{if} \quad \boldsymbol{d}_{\text{abs}} < \boldsymbol{d}_{\text{par}} \\ 0 & \text{if} \quad \boldsymbol{d}_{\text{abs}} \geq \boldsymbol{d}_{\text{par}} \end{cases} \tag{6}$$

Binary Constraint, $\boldsymbol{B}_{\ell,d}$, takes on the sum of the values of the $\boldsymbol{P}_{\ell,d}$ of the seven dimensions and returns a binary value of either zero or one. If the sum is less than four, then the returned value is zero, which means that the multipaths are not of the same cluster. On the other hand, when the sum is greater than or equal to four, then a value of one is returned, which means that the multipaths are within the same cluster. Binary Constraint is given by

$$\boldsymbol{B}_{\ell,d} = \begin{cases} 1 & \text{if} \quad \sum \boldsymbol{P}_{\ell,d} \geq 4 \\ 0 & \text{if} \quad \sum \boldsymbol{P}_{\ell,d} < 4 \end{cases} \tag{7}$$

Proximity Constraint is followed by combining multipaths to form clusters around the main diagonal, thus, creating the 0-1 block diagonal of $\boldsymbol{C}_{\text{calc}}$. $\boldsymbol{C}_{\text{calc}}$ serves as input to Alternating Direction of Method of Multipliers (ADMM) which is used to calculate the ideal affinity matrix, $\boldsymbol{C}_{\text{ideal}}$. Asso Constrained Boolean Matrix Factorization (AssoCBMF) takes $\boldsymbol{C}_{\text{ideal}}$ as input to solve for the number of clusters and the membership of the clusters.

4 Graphical User Interface (GUI)

A GUI is an interactive system with visual components that can be used to manipulate a computer program. The study uses a GUI to manage the data and results of clustering COST 2100 dataset using MSCAMSMA. The introductory page showing the different tabs and the explanations is illustrated in Figure 2. Aside from the Introduction Tab, there are five other tabs, namely: COST 2100 Dataset, Directional Cosine Transform and Whitening Transform, Modified SCAMSMA, Relative Frequencies, and Summary.

The COST 2100 Dataset tab displaying the various channel scenarios is shown in Figure 3. Each chosen channel scenario gives the corresponding data generated by C2CM and the clustering results.

Figure 4 shows the window arising from the chosen channel scenario in the COST 2100 Dataset tab. When the generate button is pressed, the window shows the characteristics of the channel scenario like the channel frequency, mobile station velocity, the distance between the mobile station and the base station, the number of clusters, and the number of multipaths as shown in Figure 5. The parameters of the multipaths are tabulated and shown in a graph. The multipaths are color-coded with lighter colors representing higher relative power, while darker colors represent lower relative power. The default is Trial 1. Choosing another trial, from Trial 2 to Trial 30, by changing the position of the slider and pressing the Generate button, shows the corresponding characteristics, parameters, and graph of the multipaths.

The multipaths are transformed using Directional Cosine Transform (DCT) and Whitening Transform (WT). DCT is performed to the datasets to overcome the problem of the circular nature of the angular domain. At the same time, WT is applied to the dataset to eliminate the issues on units and standardized the dataset [14]. The corresponding graphs of the transformed multipaths and the

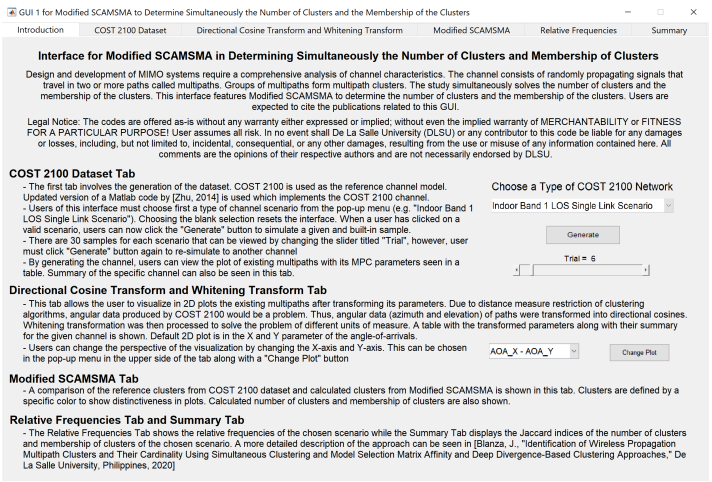

Figure 2: Graphical user interface introductory page containg the different tabs and their descriptions

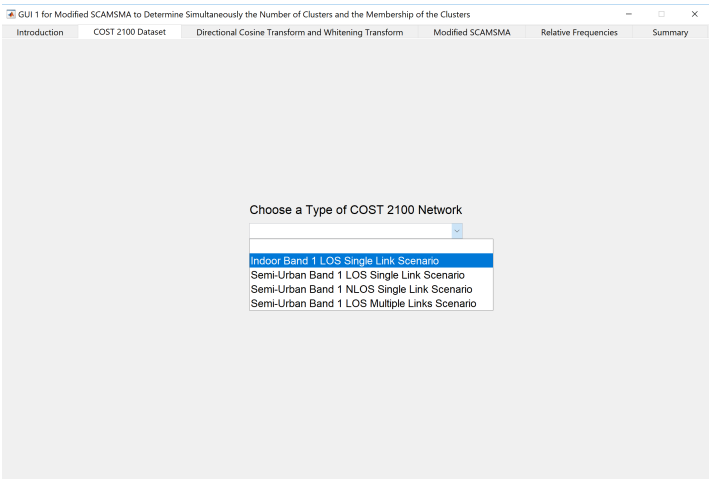

Figure 3: Ensuing window for the COST 2100 dataset tab showing the different channel scenarios

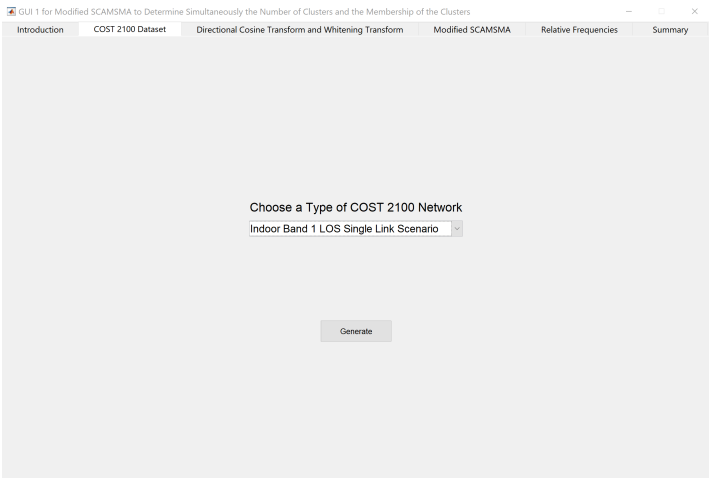

Figure 4: Subsequent window for the chosen channel scenario of the COST 2100 dataset

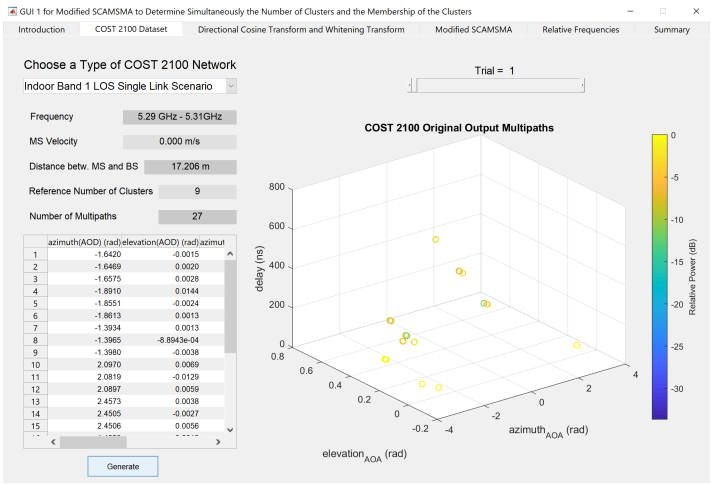

Figure 5: COST 2100 Dataset tab displaying the characteristics, parameters, and graph of the multipaths of the chosen channel scenario

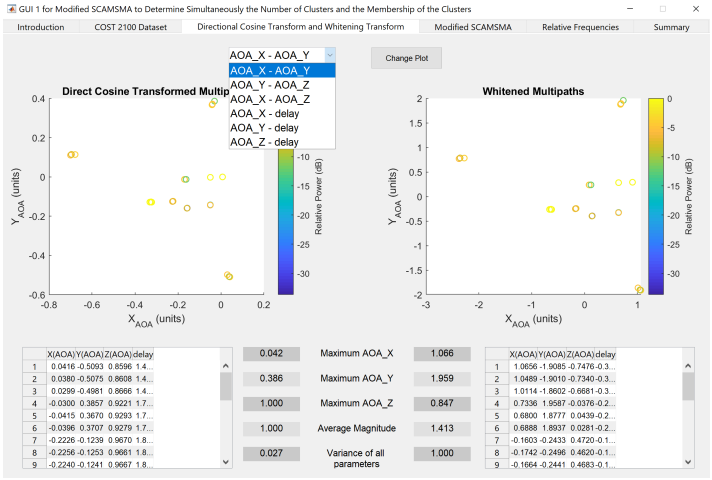

Figure 6: Graphs and tabulated parameters of the transformed multipath components of the chosen combination in the drop down menu

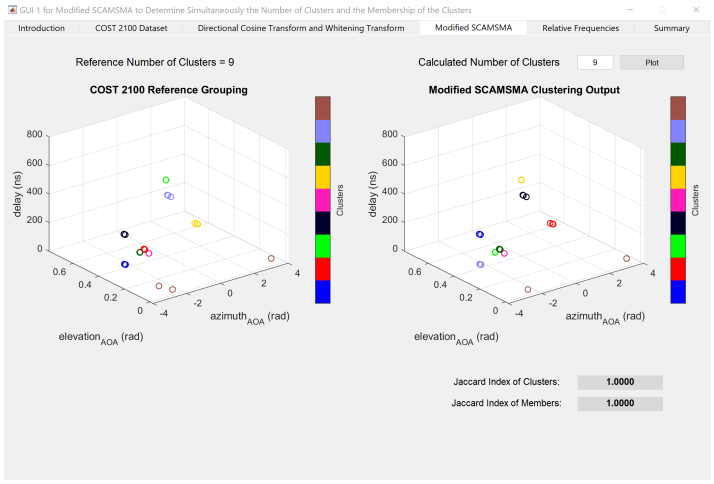

Figure 7: Comparison of the reference multipath clusters and the calculated multipath clusters and the resulting Jaccard indices

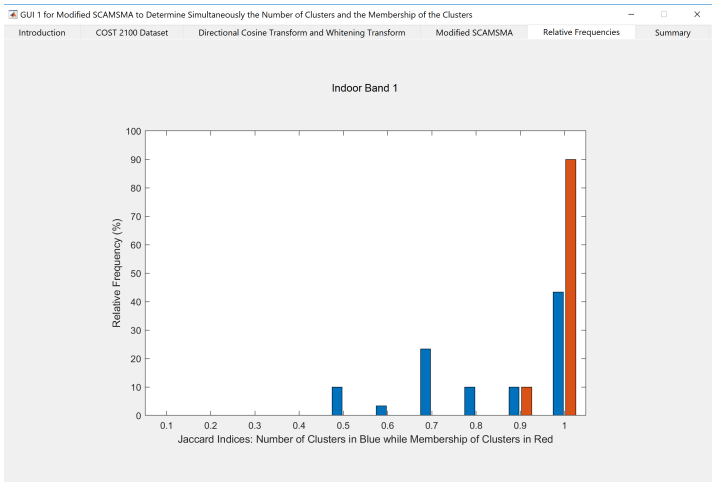

Figure 8: Window for tab four showing the relative frequencies of the Jaccard indices of the number of clusters in blue and the membership of clusters in red

tabulated parameters are shown in the Directional Cosine Transform and Whitening Transform tab in Figure 6. The graphs and tabulated parameters can be changed by choosing a different combination in the drop-down menu and pressing the Change Plot button.

Figure 7 shows the Modified SCAMSMA tab illustrating the grouping of the COST 2100 dataset at the left and the clustering output of MSCAMSMA at the right. The window also shows the reference number of clusters, the calculated number of clusters, the Jaccard index accuracy of the number of clusters, and the Jaccard index accuracy of the membership of clusters. The graphs, number of clusters, and Jaccard indices appear only when the calculated number of clusters is equal to the reference number of clusters. Otherwise, the results will not be shown.

The Relative Frequencies tab in Figure 8 shows the relative frequencies of the number of clusters in blue and the membership of clusters in red. The higher the relative frequency, when the Jaccard index is closer to one means that the clustering accuracy is higher. On the other hand, relative frequencies near zero Jaccard index implies that there is lower clustering accuracy.

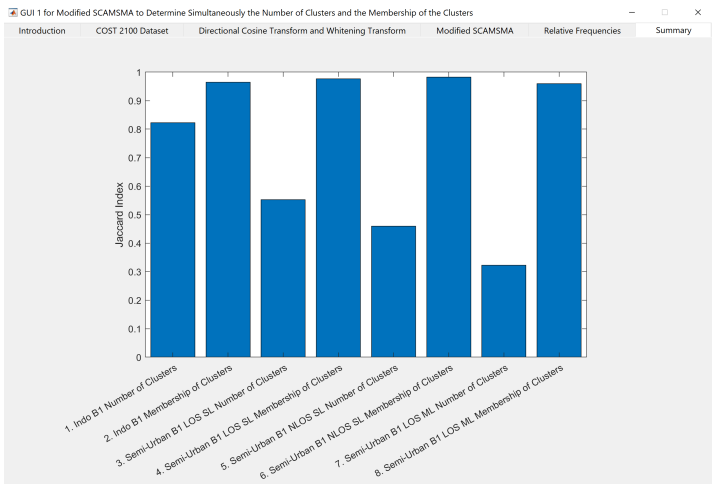

Figure 9: Window for tab five showing the mean Jaccard indices of the number of clusters and the membership of clusters of the channel scenarios

Figure 9 shows the Summary tab displaying the mean Jaccard indices of the number of clusters and the membership of clusters of all the channel scenarios. Higher mean Jaccard index means that the multipaths are clustered more accurately.

The MATLAB codes for the GUI, the reference dataset, and the calculated dataset can be found at [24]. The codes together with the reference dataset and the clustered multipaths can be compiled using the MATLAB version 2019a software to manipulate the dataset and the clustering results.

5 Conclusion

This paper shows a GUI that can be used to visualize the multipaths generated by C2CM and the results of clustering the wireless propagation multipaths using MSCAMSMA. The usual practice of authors is to illustrate their data and results using figures, tables, and graphs, which are already sufficient to present their studies. However, the presentation is static and cannot be manipulated by the readers. This study extended the common practice of showing the data and results by presenting an interface to visualize and manage what is not displayed in the publication. This way, researchers can have a better understanding of the study being presented and explore the portions of the study not shown.

Conflict of Interest The authors declare no conflict of interest.

ABSTRACT

The problematic of plastic pollution in the world has led to an interest in the research and development of thermoset starch-protein blend bioplastics as a possible alternative for single use non-recyclable plastics. However, these bioplastics lack the physico-chemical characteristics that make them useful as a replacement for the currently used plastics. This work aims to assess what differences in the mechanical and environmental impact can be seen in the thermoset starch-protein blend bioplastics when different starches are used in their formulation. Rice, kuzu, corn, wheat and potato starches were used to generate bioplastics, and these were tested in terms of colour, lightness, roughness, chemical composition, moister content, water solubility and soil toxicity when degraded. Characteristics such as chemical composition, colour and moister content do not change significantly when the different starches are used, however it was possible to identify change in characteristics such as lightness, roughness, and water solubility of the bioplastics. Moreover, not only none of the bioplastics showed to be toxic to the soil when degraded, but also promoted the growth of the plant species tested. It was possible to conclude that the use of different starches in the formulation of thermoset starch-protein blend bioplastics allows the generation of bioplastics with different characteristics. This leads to an increase in applicability of theses bioplastics and consequently a higher positive impact in the environment.

1. Introduction

Plastics usage is increasing exponentially, especially in the packaging industry, which is having devastating environmental impacts, globally. Increasing levels of consumer awareness, in terms of environmental sustainability and plastics-pollution, had created a demand for environmentally-friendly bioplastics, which decompose rapidly into water, carbon dioxide and biomass [1]. However, during events such as the current global pandemic, some members of the plastics industry have used the climate of fear and uncertainty to actively suspend or roll back hard-won environmental measures to reduce plastic pollution. As a result, there is an immediate and urgent need to increase the development and usage of alternative plastics, which have higher biodegradability and are made with fully organic components [2], typically referred to as bioplastics.

The term bioplastic was originally used to describe polymers which naturally biodegrade and compost. However, the term is now erroneously used by affected industry to additionally refer to biobased but either non-compostable plastics, or biodegradable plastics which require industrial processing to fully degrade [1]. In truth, only about 1 % of the current yearly production of plastic belongs to the bioplastic category and of those, only 43.2% are fully biodegradable. Moreover, many of the fully organic bioplastics generated do not have the mechanical properties equivalent to the currently used non-compostable plastics decreasing their applicability and industrial appeal [2]. For that reason, there is a compelling need to further develop bioplastics which are compostable, and which have no negative environmental impact.

Starch blended thermoset bioplastics are promising alternatives to petrol based plastics, due to lower production costs and better

[*]Corresponding Author: Adriana C. Neves, nevesa@itcarlow.ie

degradability [3]. In addition, blending starches with other biodegradable molecules and plasticisers can expand the applicability and improve the characteristics of thermoset starch-based bioplastics to different industries [4, 5]. The increasingly diverse blend-formulations have generated bioplastics with varied, tailorable, physico-chemical and mechanical properties, combined with the desired environmental impacts [3, 6].

These bioplastics will require more sustainable starch sources, as the most widely available are typically food-negative (ie. they derive from, or replace, in terms of agricultural production, product that is a current, critical human consumable). For example, potato, wheat and maize are the most widely produced starches in Europe, with 23.6 million tonnes of these starches produced in the EU in 2017 [7]. While in the United States of America more than 50% of starch production derives from corn [8]. However, alternative, gluten free starches, such as rice and kuzu starches, are increasing in popularity in the western world. The aim of this study is to compare the physico-chemical properties of five starch blended bioplastics as well as their post-degradation environmental impact. For this study, the starches used in the production of bioplastic were rice, kuzu, corn, wheat, and potato starch.

2. Materials and Methods

2.1. Materials

Sodium alginate LB (Duchefa Biochemie B.V., Netherlands), potato starch (MP BIomedicals LLC, Netherlands), food-grade wheat starch (Foo Lung Ching Kee, Hong Kong), food-grade rice flour (Foo Lung Ching Kee, Hong Kong), food-grade kuzu starch (Clearspring Ltd., London) produced in Japan and food-grade corn starch obtained from local grocery store (Aldi, Carlow) were used to generate bioplastics. Glycerol (EMPROVE®bio, Merck KGaA, Germany) was used as plasticiser. The Phytotoxkit was purchased from MicroBio Tests (Mariakerke, Gent, Belgium).

2.2. Preparation of bioplastics

The bioplastic-forming solution was prepared by dissolving 0.5g of sodium alginate LB into 20mL deionised water at room temperature with constant stirring speed of 595 rpm for at least 30 minutes or until a homogeneous aqueous solution was formed. In a beaker, 1g of starch and 1.5mL glycerol were mixed in 10mL of deionised water and added to the alginate solution. The solution was heated at 90°C with constant stirring at low agitation to avoid air bubbles formation for 20 minutes or until complete homogenisation was observed. The prepared solution was then poured into petri dish and kept at room temperature for 72 hours to dry.

2.3. Colour and brightness

The colour and transparency were read with a colorimeter (PCE-CSMI, PCE instruments, Meschede, Germany). The L*, a* and b* values were standardized for absolute white and black as per instrument instructions and then measured from four samples of each formulation and plotted accordingly.

2.4. Roughness test

The roughness of bioplastic samples was determined using SURFCOM130A roughness tester with a TS100 roughness tester sensor. The tester was calibrated with a standard of Ra=1,54µm before preforming the test. To determine the roughness sample was placed under the sensor and the placement of the sensor needle was adjusted with a knob on the tester. The test was performed in the center of five samples of the same material.

2.5. Fourier-transform infrared (FTIR) spectroscopy

The FTIR spectra were recorded as % transmission using a Spectrum 65 FT-IR Spectrometer (Perkin Elmer, Massachusetts, United States)

2.6. Soil toxicity

The soil toxicity was assessed using the Phytotoxkit instructions. In short, the water holding capacity was determined as per the instructions on the kit and the soil was pre-treated by degrading 10g of each bioplastic in soil samples weighing 100g over a 4 weeks period with daily hydration of the soil. The test plates were filled with 100g of test soil in the lower compartment, hydrated with 10ml of deionised water, a black filter paper was placed on top of the soil and 10 seeds of the same test plant were placed on top of the filter paper. The plants species used were garden cress (*Lepidium sativum*), and mustard (*Sinapis alba*). The control soil corresponds to soil where no bioplastics were degraded. The test containers were incubated at 25ºC for 72h in darkness. The root length was measured using ImageJ software (U. S. National Institutes of Health, Bethesda, Maryland, USA).

2.7. Moister content and water solubility

According to Costa, et al. (2018), bioplastics with 2 cm of diameter were dried at 105°C for 24 hours or until ~±0.01g differences in weight were obtained. Four replicates of each formulation were operated in this study. The percentage of water lost in the system (moisture content) was calculated [9]. The samples were further used to determine water solubility based on method proposed by Costa, et al. (2012) and Fakhoury, et al. (2012). Method was slightly modified as samples are fully soluble in water after 1 hour. Instead of 24 hours, samples were immersed in 50mL deionised water for 30 minutes at low agitation (100rpm) then dried until ~±0.01g differences in weight were observed.

2.8. Statistical analysis of data

The results were analysed by one-way or two-way analysis of variance (ANOVA) with a significance level of $P = 0.05$ when appropriate. Independent sample *t*-test and Tukey's multiple comparison tests were used, where applicable. The software employed for statistical analysis was Excel 2016 (Microsoft Excel 2016 MSO, California, USA) and SPSS Statistics (IBM SPSS Statistics 2015, New York, USA).

3. Results and discussion

3.1. Preparation of bioplastics

It was possible to generate five types of thermoset starch-protein blend bioplastic samples using the five different starches investigated (Figure 1). Bioplastics generated with different starches have been widely reported in literature, however, no published studies could be found which compared bioplastic generated from kuzu starch with bioplastics generated from rice,

wheat, corn, and potato starch. The overall appearance of the kuzu-bioplastics was similar to other thermoset bioplastics reported in literature, with no detected starch-related plasticity differences. This was attributed to the same amount and type of plasticiser being used. This plasticiser component, used in the investigated formulations, has been reported to be the critical component in the plasticity of the final product, with no starch - bioplastic plasticity nexus observed [6, 10].

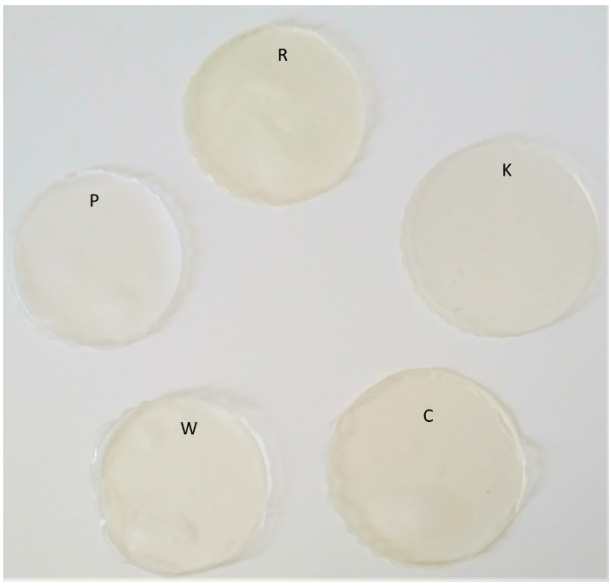

Figure 1: Thermoset starch blend bioplastics generated using rice (R), kuzu (K), corn (C), wheat (W) and potato (P) starches.

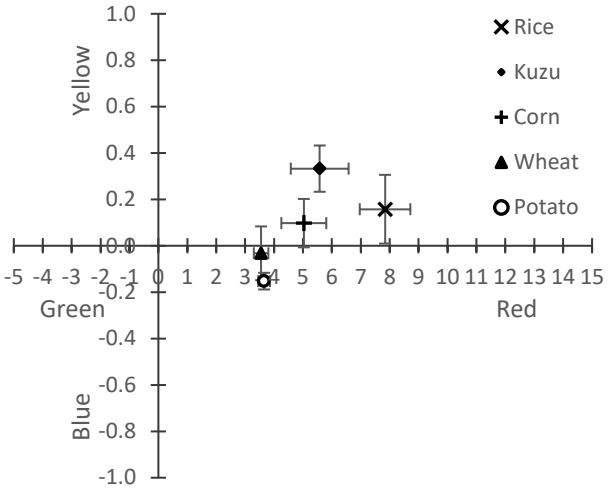

Figure 2:Colour a*; b* values of the bioplastics generated with rice, kuzu, corn, wheat, and potato starches. N=5 ± sd.

3.2. Colour and brightness

Natural based bioplastics often display a yellow tone, though the addition of chemicals, or exposure to oxidation or bleaching processes, have been shown to produce a brighter and whiter tone. Unfortunately the effect of these processes on the environment has yet to be assessed [11, 12]. Alternatively, this intonation can be also affected by starch type, which is a more environmentally friendly way of generating brighter bioplastics with less of a yellow tone. For example, the colour and lightness analysis in this research demonstrated that bioplastics generated with rice, kuzu, and corn, have greater red/yellow components when compared to bioplastics generated from wheat and potato starches. Additionally, visual examination of the wheat- and potato- starch bioplastics indicated a less yellow tone (Figure 1). Moreover, the rice starch derived bioplastic had a significant lower brightness then all the other bioplastic tested (Figure 2). That might be linked with the higher red component in its colour. However, all of the bioplastics generated were considered to be white, according to the instrument guidelines, with the higher values corresponding to the rice derived bioplastic (L*90.73± 1.12; a*0.16± 0.15; b*7.84± 0.88).

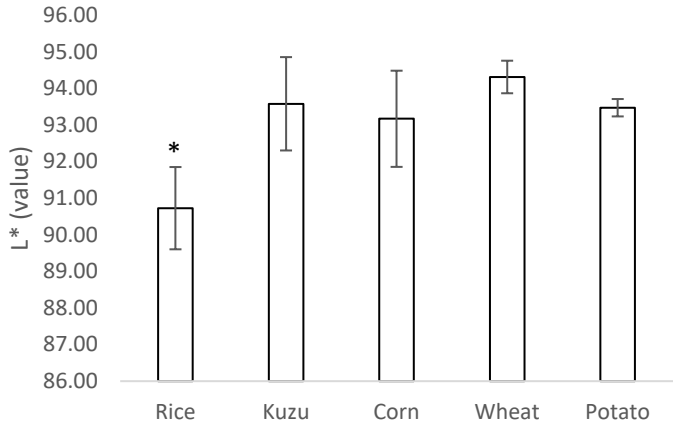

Figure 3: Brightness L* values of the bioplastics generated with rice, kuzu, corn, wheat, and potato starches. N=5 ± sd with * representing significantly different value.

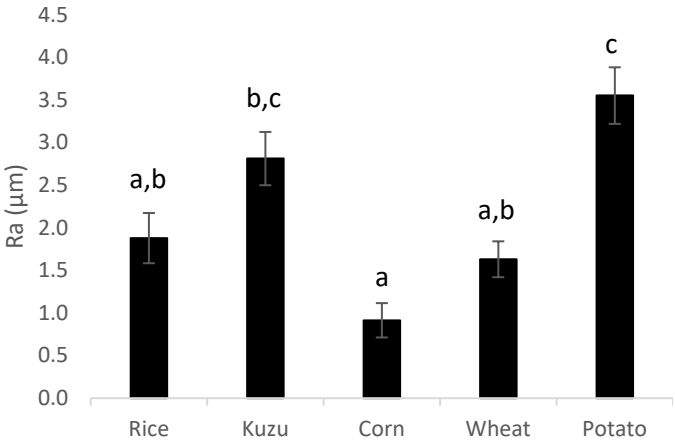

Figure 4: Roughness values of the surface in contact with air of thermoset starch-blend bioplastics generated with rice, kuzu, corn, wheat and potato starches. N=5 ± sd with different lower-case letters representing significantly different values.

3.3. Roughness Test

Polymer samples generated in the reported research were formed using flat moulds. As a result, one surface of the thermoset bioplastic films replicated the roughness of the mould. However, the surface in contact with the air acquired a natural texture. The texture of that surface was tested, and it was observed that the

different starches used in the bioplastic formulation produced different surface roughness (Figure 4). The starches that lead to higher roughness were Potato and Kuzu with 3.55 ± 0.33 and 2.81 ± 0.31 Ra (μm) respectively and the starches that lead to smoother surface roughness are Wheat and Corn with 1.63 ± 0.21 and 0.92 ± 0.20 Ra (μm) respectively.

3.4. Fourier-transform infrared (FTIR) spectroscopy

The purpose of FTIR analysis was to identify the presence of chemical bonds that were formed in bioplastics using the different starches. Figure 5 shows that the spectrums of all the bioplastics tested have similar profiles displaying the presence of O-H, C-H, C=O and C-O absorption peaks. This might be because although structurally the starches might have slightly different structures, their chemical composition is, overall, similar. Moreover, the profile of the bioplastics show similar chemical bonds to others starch-blend bioplastics reported in literature [13, 10, 11].

3.5. Soil toxicity

The effect of the degradation of the bioplastics with each starch in the growth of two plant species was tested with a soil toxicity test (Figure 6). The results show that there was no decrease in the growth of either *Lepidium sativum* or *Sinapis alba* after the degradation of any of the bioplastics tested in their growth soil. Contrarily, the bioplastics generated with kuzu, corn, wheat and potato starch showed a significant increase of growth in both plant species. The increase in plant growth in the soil after bioplastic degradation compared with the control soil might be related with the increase of Carbon (C) added to the soil after the bioplastics degradation. The addition of C to poor soils has been used for soil remediation showing to improve plant growth and crop productivity [14, 15]. The degradation of bioplastics with kuzu, corn, wheat or potato starches in carbon poor soils has the potential to improve their productivity.

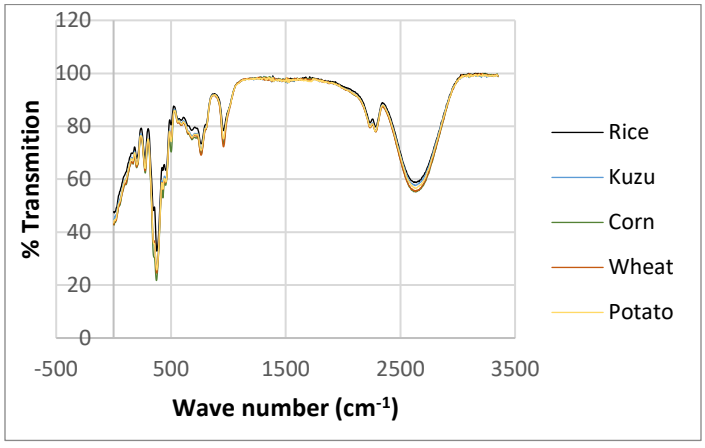

Figure 5: Fourier transform infrared (FTIR) spectrums of the bioplastics generated with rice, kuzu, corn, wheat, and potato starch.

3.6. Moister content and water solubility

The moisture content of bioplastics can influence properties such as their compostability, elasticity, hydrophobicity among others and consequently influence their applicability [16]. For that reason, small changes in composition of the starch-based bioplastics might influence the time in which it fully composts. Composting time is of high importance for the applicability of bioplastics [2].

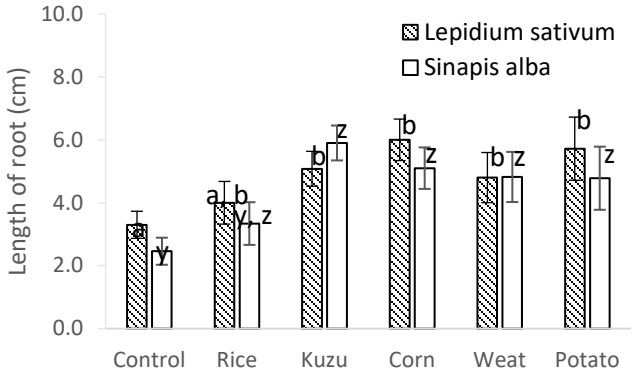

Figure 6: Growth of Lepidium sativum and Sinapis alba in soil where bioplastics with rice, kuzu, corn, wheat and potato starch were degraded. No bioplastic was degraded in the control soil prior to seeding. N=10 ± sd with different lower-case letters representing significantly different values.

Using the different starches tested in the bioplastic formulation does not seem to lead to significantly different moisture contents of the bioplastics, with all the formulations ranging from 41 ± 7 to 49 ± 4 % moisture content in the rice and corn based bioplastic respectively (Figure 7).

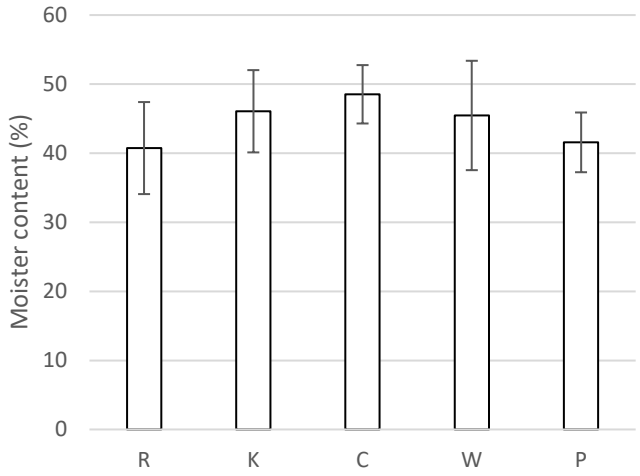

Figure 7: Moister content of thermoset starch-blend bioplastics generated with rice (R), kuzu (K), corn (C), wheat (W) and potato (P) starches. N=5 ± sd.

Similarly, understanding the effect of different starches in the solubility of the bioplastic is not only relevant industrially to assess potential applications of bioplastics but also needed to understand the impact of the bioplastics in the environment [2]. The solubility of the bioplastics tested ranged from 35 ± 6 to 81 ± 1% with the bioplastic sample generated with Kuzu being the least soluble and the one generated with wheat the most soluble. Moreover, there was not a significant difference found in the samples generated with potato, corn and rice starch or between the samples generated with Rice and Kuzu. Previous studies showed the link between starch concentration and solubility of the bioplastics [6], however, no previous studies have looked into a direct comparison of solubility of bioplastics when different starches are used in their formulation.

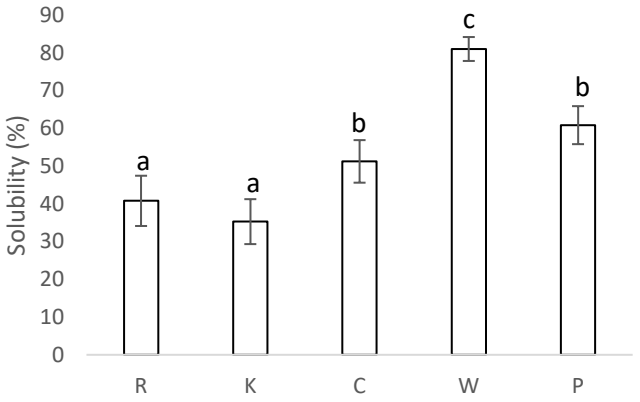

Figure 8: Solubility of thermoset starch-blend bioplastics in deionised water generated with rice (R), kuzu (K), corn (C), wheat (W) and potato (P) starches. N=5 ± sd with different lower-case letters representing significantly different values.

4. Conclusion

The generation of thermoset starch blend bioplastics using the five different starches tested lead to bioplastics that did not cause any toxicity to the growth of the plant species *Lepidium sativum* and *Sinapis alba* when degraded in the soil where they grew. Moreover, in all cases, except the rice-based bioplastic, their degradation lead to a significant increase of growth of these plant species.

The use of different starches led to the generation of bioplastics with similar FTIR profiles, as well as colour and water content. However, other characteristics differed depending on which starch was used for their formulation. Higher solubility was obtained when wheat starch was used. In opposition to rice and kuzu starches that can be used to obtain bioplastics with lower solubility rates.

Although in terms of colour all the bioplastics generated had a near-white colour, the brightness of these were dependent on the type of starch used. The rice, kuzu and corn starches lead to bioplastics with more red/yellow tones with rice derived bioplastic being the only one significantly different in terms of brightness.

In terms of roughness it was also possible to observe a difference between potato and kuzu based bioplastics with rougher surfaces in comparison with wheat and corn with smoother surfaces.

The results of this study show that there is a link between starch in the bioplastic composition and some of the properties tested. This is of high importance to industry when choosing formulations for the generation of organic thermoset bioplastics for different purposes.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

This document proposes a new methodology for lifestyle analysis and disease diagnosis for young academics using a strategic planning and disruptive innovation approach. Its objective is to consider and study a new form of treatment to improve the quality of life and health of students in parallel with their development, this through a quantitative methodology with a descriptive-correlational scope, being possible to develop a diagnosis and analysis, resulting A high relationship between variables is evident, thus developing a preliminary model based on engineering in the process of improving lifestyles through the Deming cycle and based on the S curve of innovation, hand in hand with technology and motivation.

1. Introduction

Changes in lifestyle in recent years have negatively affected health, mainly in low and middle developed countries [1, 2, 3], poor quality of diet, sedentary lifestyle, and emotional stress can cause inflammation, oxidative stress, sympathetic activation, and contribute to obesity, together these factors can trigger or exacerbate hypertension, diabetes, dyslipidemia, and sleep-disordered breathing, which can lead to atherosclerosis and ultimately heart failure [4]. That is why investigations such as that of Gómez, Roca, Gili, García, and García [5], analyze that in a depressive scenario, an incorrect lifestyle is present; In addition, depression causes sleep disorders, loss of energy, low level of physical activity and with this increases the desire to eat junk food.

Thus, unhealthy lifestyles lead to the development of chronic diseases (CD) and premature death. 70% of deaths worldwide are caused by CD [2]; North America and Latin America are among the first places worldwide in factors that promote CD [1, 2, 3]. Although CDs impact people, it has consequences on the economic development and human capital of countries, mainly low-income countries, ranging from productivity to the costs generated by their treatment [6]

Mexico in particular is in the first places in obesity, overweight and diabetes worldwide and among the OECD countries [7], Sinaloa, Mexico is aligned to national statistics with 70% obesity and overweight in its population with age equal to or greater than 20 years, and Los Mochis, Sinaloa with a 72.5% prevalence of obesity and overweight, this factor being the cornerstone of the development of chronic diseases of greater affectation; The need and lack of effective guidance are evident, one that not only tries to raise awareness but is also effective enough to achieve positive change on a large scale.

There is a wide variety of studies that support the positive impact of exercise, good nutrition, adequate sleep schedules and quality of sleep, as well as the importance of the environment on both physical and mental health [1-5, 7], however, there is a gap in information regarding the application of these factors as a whole, even more so the implementation of strategic planning and disruptive innovation in the improvement of lifestyles.

For all the above, the objective of this article is the diagnosis and analysis of the lifestyle, chronic diseases, strategic planning, and disruptive innovation of young university students from the private sector, for the development of a disruptive strategic model.

The essence of the proposed solution of the problem in question is the diagnosis of the needs of the population and therefore the development of a model with planning and disruptive innovation applied to the prevention and control of chronic diseases, such as overweight, obesity, diabetes, and cardiovascular diseases, which allows young students to have an adequate balance between physical and mental health, helping them to have a better

academic and work performance, but above all, a better quality of life.

2. Theoretical foundations

2.1. Strategic model

According to the Royal Spanish Academy, the word model, coming from Italian, is an archetype or point of reference to imitate or reproduce it, differently, the strategy, the "Latin strategĭa" is the art, traces to direct a matter [8].

On the other hand, strategy, coming from the war trade, is defined as the art of drawing to direct an issue, in an adjustable process, a set of rules that ensure an optimal decision at all times [8].

Deming Cycle, the cycle of continuous improvement for development, through the factors: plan, do, verify, and act that incorporated feedback and observation of uninterrupted practice [9].

2.2. Disruptive innovation

Disruptive innovation was defined for the first time by Christensen in 1997 as a process by which a product or service is brought to the market, through simple applications, to later win that market by displacing other competitors. The contribution of Master Christensen leads to disruptive innovation to break the status quo of companies or any industry. Likewise, Sartor in 2017 commits that disruptive technology is any that can deeply affect a sector of activity and its value chain; Disruptive innovation can be implemented in three areas, such as: disruptors in the improvement of a process, a change of product or business model [10].

2.2.1. S-Curve pattern of innovation

The model S-Curve of innovation Figure 1, helps to evaluate in which stage of the life cycle the technology is and provides an indicator of the maturity of the industry. Method used to locate what has been the behavior of a certain trend in the past and extrapolate it to the possible future as a guide.

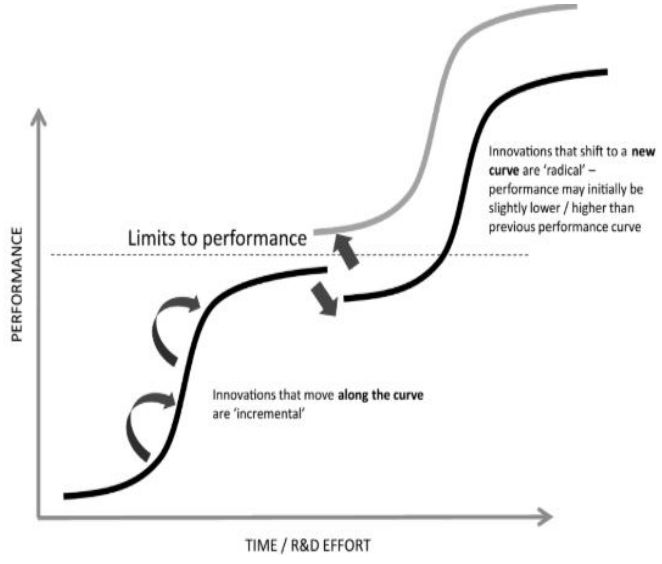

Figure 1: S-Curve of innovation

2.3. Lifestyle

Lifestyle is the set of behaviors that a specific individual puts into practice in a consistent and sustained way in their daily life and that can influence the maintenance of their health or places them at risk for disease: inadequate diet, activity poor physics, disturbed sleep-wake cycles, excessive consumption of substances and toxic habits, poor stress management, etc., are expressed in specific individual behaviors that are interpreted as risk factors, or behaviors that are shared by a group of people in a specific context [11].

Describing the sociodemographic, psychosocial, quality of life and educational variables in young university students and their relationship between them, as well as the ideal diet and habits based on the variables mentioned, are essential in a healthy lifestyle [12].

2.4. Chronic diseases

Chronic diseases (CD) account for new epidemics in developed societies, being link through conditions and lifestyles [3]

In Latin America, the main chronic diseases are obesity, cardiovascular diseases, cancer, chronic respiratory diseases, diabetes and arthritis are the main ones; Along the same lines, in Mexico the most prevalent chronic diseases are: obesity, arterial hypertension, diabetes, metabolic syndrome, fatty liver, chronic kidney disease [1].

3. Methodology

The present study was approached with a methodology focused on Hernández and Mendoza [13], being a quantitative investigation, with a scope according to the level of knowledge obtained with said investigation: descriptive - correlational.in the paper.

3.1. Sample selection

The first step focused on determining the population, defining as population young people from private universities located in Los Mochis, Sinaloa, 3,898 young people according to figures from the interactive educational statistics consultation program by the Ministry of Public Education.

To determine the size of the sample, the STATS 2.0 program was used, obtaining the amount of 350 as the sample size, results shown in Table 1. The sample is considered simple random probabilistic, since it can be answered by any student who is in the unit of analysis. The unit of analysis was represented by university students from the private sector, located in Los Mochis, Sinaloa.

Table 1: Characteristics of the sample

Characteristics	Number value/ percentage
Universe size	3,898
Maximum acceptable error	5%
Estimated percentage of the sample	50%
Desired level of confidence	95%
Sample size	350

3.2. Instrument design

A quantitative measurement instrument was applied through the use of a structured questionnaire. The information collected was explicitly and standardized. The questionnaire used was of our elaboration. On the other hand, the degree of validity was determined through content and construct, the first based on impact literature, and the second through Pearson's correlation.

The scale used in the questionnaire was of the Likert type [14], made up of 5 points, which range from totally agree to totally disagree, determining its degree of reliability using Cronbach's Alpha.

The instrument consists of a total of 65 items divided by variables and dimensions. It should be noted that the degree of reliability of the instrument was measured through the application of the questionnaire, whose results were tabulated, and the calculation of the degree of reliability was generated using Cronbach's Alpha, using SPSS in Version 27, resulting 0.944, consequently demonstrating its excellent reliability to be applied.

Structured questionnaire in 5 sections, as follows:

- Section 1, diagnosis to identify the respondent's framework, 5 items.
- Section 2, lifestyle (EV), 13 items.
- Section 3, chronic diseases (CD), 16 items.
- Section 4, disruptive innovation (ID), 9 items.
- Section 5, strategic planning (SP), 22 items.

The scale used in the questionnaire consists of 5 points that go from totally disagree (1) to totally agree (5), as shown in Table 2.

Table 2: Instrument coding

Value	Meaning
1	Strongly disagree
2	Disagree
3	Neither agree nor disagree
4	Agree
5	Strongly agree

It should be noted that two of the items are open questions.

4. Hypothesis

Applying strategic planning and innovation to the model potentiates the improvement of lifestyles from the health perspective of young university students.

5. Results

5.1. Descriptive results

Below are the results obtained from the structured survey, 350 responses received per application to the unit of analysis; 75% of the respondents were women (264), the remaining 25% were men (86).

Other research results are introduced below; The information is of a descriptive statistical nature of the set of variables extracted from the questionnaire, which allows us to know some characteristics of the sample.

Table 3: Responses with the most impact in affirmation regarding the strategic planning block

Strategic planning	Percentage
	Strongly agree/ agree
I am interested in an initiative that motivates young people in the vocational and professional education stage to lead a healthier life.	86.86%
An initiative that aims to be a leader in the country in terms of reducing chronic diseases and improving lifestyles interests me.	87.43%
I need to be advised by experts in nutrition, physical and psychological health, who offer me plans that adapt to my objectives and goals.	76.57%
Including innovation and creativity in my lifestyle enhances my development	84.57%
A clean and organized infrastructure format makes it easier for me to choose whether or not to join the initiative either online or in person.	76.57%
Having employees trained and frequently evaluated in quality aspects, leadership fosters excellent services.	89.14%
Constant updating of specialists to know and implement the most innovative and innovative work methods of the organization.	86.86%
It is desirable to find clean and tidy areas when attending training.	91.43%
Having certifications in health and organizational hygiene generates a substantial attraction to the initiative.	87.43%
Knowing that employees are properly compensated let me know that I am part of an organization with values.	84.57%
Having a collaborative environment within the organization generates security for staff.	90.29%
A safe work environment encourages a diversity of thoughts, thus generating creative ideas.	91.43%
Having teams for collaboration motivates a mindset of social contribution.	85.71%
Knowing the strengths and weaknesses of the organization allows us to foresee errors or failures of the plans, under or to be developed.	88.57%
In the application of high-level programs, the value of the organization is perceived.	86.86%
Establishing controls and administration generates flexibility to adapt to the organization.	86.29%
Offering a periodic evaluation to collaborators allows maintaining constant development and verification of alignment to the objectives.	85.14%
Having relationship programs with different communities generates cultural enrichment, therefore a range of ideas for the development of new training and motivation methods.	90.86%
Establishing responsibilities and objectives for each position correctly empowers each employee in their area of expertise.	89.71%

The table above represents the frequencies and percentages of the responses with an opinion of "Totally agree and agree" it could be observed in the first instance, referring to the strategic planning block, that there is a statement by 90% of the participants regarding interest for belonging to an organization or initiative with a safe work environment, which is aligned with the generation of ideas and offering excellent customer service, in turn, they claim to want a clean physical and online format, constant evaluation, and training of collaborators with the most novel and innovative in order to apply it to work methods and improvement of results, this hand in hand with relationship programs with various communities

generating a range of ideas for the development of new methods of training and motivation, within a collaborative work environment, generating in turn security to staff.

Regarding the block of disruptive innovation Table-4, 90.86% of the participants in the survey affirm that a change in lifestyle is possible through smart spaces and health monitoring, hand in hand with the accessibility of support from experts and price range for a greater reach and impact, in turn, more than 80% affirm their interest in prevention and control computer sessions in terms of the health approach and the extension of these extensive advantages both to face-to-face format and online (in- place / at-home).

Table 4: Responses with the most impact weight in affirmation regarding the disruptive innovation block

Disruptive innovation	Percentage
	Strongly agree/ agree
I would like to be part of an organization with new ideas to achieve my physical and psychological goals.	72.00%
Smart spaces and health monitoring allow generating a lifestyle change.	90.86%
In-place/at-home training products or features create an extension of possibilities for club/gym members	74.86%
Having the possibility of improving my lifestyle in an accessible way allows me to prevent chronic diseases.	90.86%
Having options for different ranges opens the possibilities for a substantial number of people to join the initiative to improve their lifestyle.	82.29%
I feel identified with an organization that sees the human being as a whole and enhances their development from the psychological, physical, and spiritual approach.	72.57%
It is of interest to me to have at my disposal computer sessions on prevention and health control.	80.57%

From the lifestyle block, it is resolved that the participants recognize there is a relationship between mind and body to achieve a state of well-being, 90% identify the consequences of an unhealthy lifestyle, however, only 56% affirm taking care of what eats and schedules, in addition to this 40% do not achieve their training objectives and consistency in them, on the other hand, there is a high rate of interest in doing physical activity (76%), their interest is liable to the training of various or innovative disciplines methods that motivate them to achieve goals and improve their lifestyle.

Table 5: Responses with the most impact weight in affirmation regarding the lifestyle block

Lifestyle	Percentage
	Strongly agree/ agree
I consider that a healthy mind inhabits a healthy body.	89.14%
I identify the consequences of not maintaining a healthy lifestyle.	90.86%
I am interested in doing physical activity that improves my quality of life.	76.57%
I identify the relationship between my mood and my diet.	73.71%
Recognition of my efforts and achievements through rewards generates motivation to leave my comfort zone.	72.57%

In Figure 2, the percentages of those participants who attend the gym, club, or classes for physical activity, and those who do not attend are presented, which is the main reason.

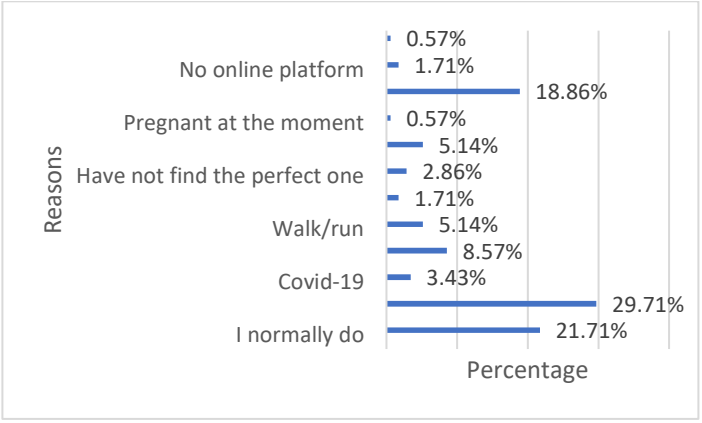

Figure 2: Percentages question EV-13

Regarding the chronic diseases block, the participants claim to be informed about the impact of obesity and overweight on their wellbeing, and later its reflection in a variety of chronic diseases, 92% consider it important to be informed of news and innovations against chronic diseases and maintain a health monitoring at least once a year.

Table 6: Responses with the most impact in affirmation regarding the block, chronic diseases

Chronic dieases	Percentage
	Strongly agree/ agree
It is my knowledge that chronic diseases are generally slow to develop, therefore my daily habits make a big difference.	82.86%
I consider it important to be informed of news and innovations concerning chronic diseases.	92.00%
Those who are overweight or obese have a higher risk of developing chronic diseases.	93.14%
I am informed of the causes and consequences of being overweight or obese.	93.71%
I consider it important to carry out at least one annual health check-up.	86.29%

It is important to highlight that the results of the open question CD-16 are presented in Figure 3; Of the 350 participants 94.4% affirm that one or more of their relatives suffer from one or more chronic diseases; it is important to highlight that this question had the possibility of selecting multiple answers; 590 answers were received, around 40% of the participants selected more than one chronic disease, placing diabetes in the first place, this information is of great value since those relatives of patients with type 2 diabetes mellitus tend to suffer from hypertension and overweight, the last one being the most recurrent in 63% of cases, providing strong signals of major diabetes awareness gaps among family members of patients living with type 2 diabetes mellitus [13].

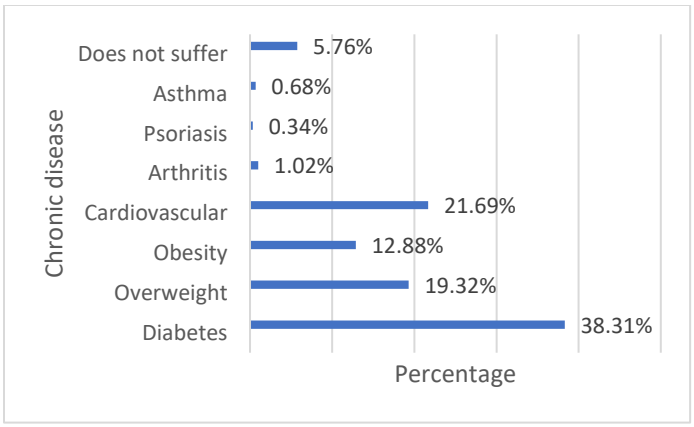

Figure 3: Percentages question CD-16

5.2. Correlational results

The reason for considering the correlation coefficient was to identify the strength of the relationship between variables strategic planning, disruptive innovation, lifestyle, and chronic diseases, in the positive sense; The results of Pearson's correlation are presented below in Table 7.

Table 7: Correlation of variables

		VI	VD1	VD2	VD3
VI	Correlación de Pearson	1	,502**	,592**	,550**
	Sig. (bilateral)		,000	,000	,000
	N	350	350	350	350

Once the correlation between variables is carried out, the result is a moderate to high correlation, according to Tables 7 and 8.

Table 8: Null-Correlation of variables

Value	Meaning
0	Null correlation
0.01 a 0.19	Very low positive correlation
0.2 a 0.39	Low positive correlation
0.4 a 0.69	Moderate positive correlation
0.7 a 0.89	High positive correlation
0.9 a 0.99	Very high positive correlation
1	Large and perfect positive correlation

Although the literature affirms the relationship between good habits and their impact on lifestyle improvement, the correlation found between innovation and strategic planning is key to promoting said improvement. It should be noted that university students do give importance to lifestyle care and chronic diseases, besides, they affirm feeling related to a well-established company and an excellent work environment, promoting development in the personal and social development of well-being, focused on their lifestyle improvement.

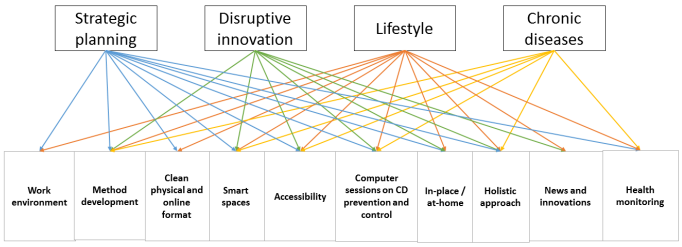

Figure 4: Correlation

Having said the above, what San Román indicates is confirmed, by saying that describing the sociodemographic, psychosocial, quality of life, and educational variables in young university students and their relationship between them, as well as diet and suitable habits, are essential in a healthy lifestyle [12].

6. Disruptive strategic model

After applying the instrument and collecting the data, a model was structured, which offers a holistic service for the detection of defects in the way in which the client interacts with the environment, causing health problems. After establishing a diagnosis, the strategic plan confirms that it generates the discipline to produce individual patterns that can be monitored by specialists, either in person or online in their respective areas, such as psychology, nutrition, and physical preparation, providing constant updating, training, and study of the innovations in their main areas of expertise.

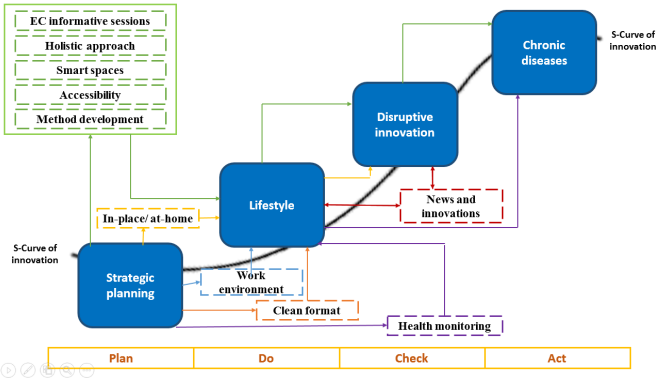

Figure 5: Correlation of variables model

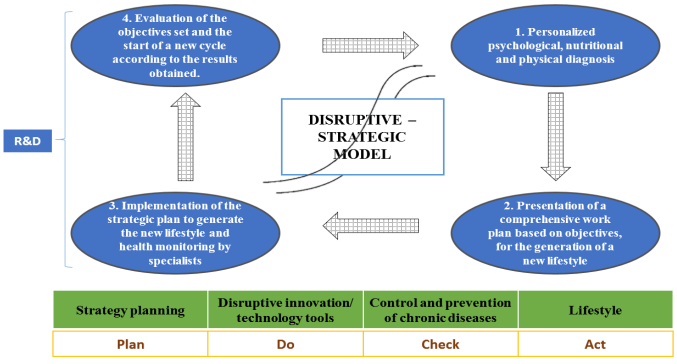

Figure 6: Model

Figures 5 and 6, presents the proposed model based on the diagnosis and correlation previously carried out, implementing both the Deming cycle and the "S" of innovation throughout the "Strategic-disruptive model", in which those factors are present of greater correlation and need on the part of university students in terms of organizational structure, lifestyle, innovation and chronic diseases, generating a sequence of uninterrupted continuous improvement.

7. Discussion

An inclination for a clean format has been found, a collaborative environment which encourages security when generating ideas and proposing models or work methods based on research and innovation, this from the planning point of view and referring to the collaborators; on the other hand, inclusive programs, both speaking of cultures, as well as financial accessibility and outreach, highlighting the interest in staying informed of news and innovations in terms of lifestyle and chronic diseases, added to this a high rate of interest in stay motivated and generate consistency in lifestyle improvement; the above treating the human being from a holistic approach.

Aligned with Anderson and Fowers, it is confirmed that lifestyle behaviors, related to physical and mental health, generate the well-known hedonic well-being, which is based on satisfaction with life, positive emotions, and low negative emotions; that is, well-being and social interaction are intimately related, affecting the lifestyle of individuals, those who are more sociable tend to perform more physical activity and mental stability, they point out [15].

Likewise, what Leyton, Batista, and Castuera [6] analyze, the effects that motivational processes have on the adoption of lifestyle habits that enhance health in adolescents are confirmed; Describing the sociodemographic, psychosocial, quality of life and educational variables in young university students and their relationship between them, as well as the ideal diet and habits based on the aforementioned variables, are essential in a healthy lifestyle [7].

8. Conclusions

The objective of the study in this first phase of the research was to diagnose and generate a preliminary model with strategic planning and disruptive innovation applied to the prevention and control of chronic diseases for university students from the private sector.

The diagnostic and correlation study was carried out in the Los Mochis area, Sinaloa; The limitations of the study rely on reduced access to students due to the ongoing pandemic Covid 19, it is suggested for future studies to evaluate a greater number of areas, to measure the possibility of replication of the model in various geographical areas and/or its adaptability, either within or outside the country, extending the structured questionnaire referring to the current routine of the participants, current lifestyle, objectives, and the reason for them.

The strengths of the study lie in the generation of information regarding the needs of university students in the face of lifestyle improvement and the recognition of the correlation of the variables, this among all the four variables under study.

The hypothesis, applying strategic planning and innovation to the model, potentiates the improvement of lifestyles from the focus of youth health, it is demonstrated in terms of literature and diagnosis.

It is relevant to note that the result of this research is a preliminary model, which gives the guideline to develop the following phases of the present study, to implement and evaluate the final model, in consequence allowing a high rate of improvement in lifestyle at an early age in a broad social spectrum, positively impacting personal and social development at the moment and in the long term, shaping a more productive society.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Until recent years, code quality was not given due significance, as long as the system produced accurate results. Taking into account the implications and recent losses in critical systems, developers have started making use of static code analysis tools, to assess the eminence of source code in terms of quality. Static code analysis is conducted before the system is sent into production. The analysis aims to identify the veiled defects and complex code structures that result in the decrement of code quality or are likely to become a cause of malfunction during execution. To address this line of work, this research paper presents a static code analyzer for C#, named as sharpniZer.

The key purpose of this tool is to verify the compliance of the source code written in C#, in congruence with the target set of rules defined for analysis as per the accepted industry standards set particularly for the development of mission-critical systems. sharpniZer efficiently figures out the lines of source code that hold probable concern appertain to the category of design rules, usage rules, maintainability rules, inefficient code, complexity, object model and API rules, logical rules, exception, incomplete code, and naming conventions. Each violation encountered in source code is ranked by the severity level as: critical, major, and minor. The tool shall prove to be worthwhile, especially if utilized in critical systems.

1. Introduction

The prevalence of software has raised serious concerns in the software industry to think of ways in which software quality can be ensured. How the quality of the software system or the underlying source code can be quantified may differ from system to system. However, the system must be optimized and proficient in terms of parameters including maintainability, testability, reusability, resource consumption, etc [1].

Most of the aspects of software quality largely depend upon the skills and expertise of the development team. As the requirements from enterprises regarding system functionality are becoming critical, the quality of source code is likely to diminish. A bad-written code leads to increased resource consumption and decreased efficiency and productivity [2, 9].

The hidden defects in source code, if not identified and addressed appropriately, can ultimately lead to unreliable system behavior during execution. The systems need to be thoroughly tested for the detection of loopholes left during development. The extensively used techniques include static code analysis and dynamic code analysis. However, the practice under consideration for this work is that of static code analysis.

1.1. Current Scenario

As previously stated, static code analysis has become indispensable particularly for safety (or mission) critical systems where there is no room for even trivial bugs at the static or runtime stage. History testifies several incidents that stress the need of using code analysis tools. Below we will briefly discuss 3 such incidents where ignoring trivial coding flaws cost the developers heavy losses.

1.1.1. The Ariane 5 Explosion

Ariane 5, a heavy-lift launcher, made to launch a 3-ton payload into orbit, cost a total of 10 years and $8 billion to be manufactured. On its first launch in July 1996, the rocket soon diverted from its path of flight due to a diagnostic produced as a result of a software exception. The exception was caused during

*Corresponding Author: Arooba Shahoor, arooba.shahoor@gmail.com

a data conversion [11]. Specifically, a 16-bit value of type float was being converted to a 16-bit signed number, i.e. the value being converted was much greater and could not be possibly represented by a 16-bit number, consequently leading to an operand error [12]. Since it had reached an angle of attack of more than 20 degrees, the launcher started to disintegrate, and finally obliterated itself through a self-demolishing method, along with 4 satellites that it carried within itself [13].

1.2. Patriot Missile Error

At the time of gulf war (2 August 1990 – 28 February 1991), 28 American soldiers lost their lives, and yet 100 others severely wounded when the US missile defense system failed to detect the Scud missile that the Iraqi forces launched [5]. The root cause of the failure lies in the conversion of time from integer to floating value, which consequently resulted in a major shift in the range gate [6, 28].

1.2.1. AT & T (American Telephone & Telegraph) Network Goes Down

About 75 million call requests were not answered and approximately 50 % of the network of AT&T went down on January 15, 1990, when a bug in a single line of code incurred the network failure for several hours [7]. Specifically, the problem occurred where a break statement within a switch case, was nested within an if clause. Companies linked to its services faced fiscal setbacks, among which was "American Airlines", whose incoming calls were reduced by two-third owing to the network crash [8, 29].

The incidents mentioned above, stress upon the need and significance of thorough analysis of the code before the runtime state. This paper presents a static code analysis tool for C#, named as sharpniZer. The rest of the paper is organized as follows: part B of this section will delineate the basic aim and purpose of the utilization of static code analyzers in the software development process. Section 2 reveals the solution proposed in this paper i.e. a static code analyzer for C# that is designed to detect such seemingly non-destructive but critical bugs usually ignored in the development of mission-critical systems. This section will also discuss the categories in which the rules implemented by the proposed analyzer can be generally segregated. Part 2 of section 2 will present the methodology adopted for the development of the tool. It also indicates the flow of the application. Section 3 outlines the system features and characteristics of sharpniZer. Each module is briefly presented; the figures attached to each module shall assist the reader in gaining better insight into the tool. Section 4 gives a comparison of the proposed tool with other existing tools in a tabular format. The textual summary of the comparative analysis is given in section 5. Section 6 presents the direction of future work i.e. discussion of the ways the tool can be extended or modified, to cater to the rapidly changing market needs. Section 7 concludes the research presented in the paper.

1.3. The Goal of Static Code Analyzers

Static code analysis chiefly focuses on examining the source code, without actually executing it, to help ensure that the code is abiding by the established coding standards. This helps recognize such flaws and code constructs that may decrease code quality, or in the worst-case scenario, incur a costly disaster month or years later. The article an overview on the Static Code Analysis approach in Software Development [30] talks about and objectives for developers to introduce static code analyzers in the testing phase of the development life cycle and here we summarize six of those factors

- Saves time and money

Reviewing code manually can take up much time, in comparison to which automated static code analyzers are much faster. These analyzers can take large sets of known bugs (common as well as uncommon) and combine them with special algorithms to track them anywhere in the code in hand, which enables the bugs to be detected in a matter of seconds which would otherwise take hours or even days.

- In-Depth Analysis

With manual testing, it is highly likely to overlook some code executions paths, which is not the case in automated testing. Automated testing is performed as we build our code, so we can get an in-depth analysis of where potential issues might lie, under the rules applied by the user.

- Accuracy

It is always possible for manual reviews to be inaccurate or error-prone. This is another aspect where code analyzers come in handy. They can specify exactly where and when the error occurs without any ambiguity. Issues such as stack overflows or race conditions, that only show up when code goes into production, are hard to figure out if not resolved beforehand (through static code analysis) since the scenarios are less likely to be able to be recreated.

- Ease of use

A clear benefit the analyzers provide is their ease of access and usability. These analyzers come in stand-alone as well as integrated form, you can easily integrate analyzers with your code editing tool. Moreover, everything is performed automatically by the analyzer, it does not require any profound or in-depth knowledge or expertise on the part of the user.

- Comprehensive Feedback/Overview

At the end of the analysis, the user is provided with a detailed overview of the code and the violations (often with visualizations), which helps the user to get to the action and work on fixing the violations there and then.

- Uniform Code

Code analyzers analyze the code against set coding standards, which means by introducing a particular code analyzer for code testing, the corporate is enforcing the use of best coding practices which will consequently set a uniform coding practice among all coders and programmers. This will facilitate developers in an easier and quicker understanding of each other's code.

2. Proposed solution

Taking into account the concerns about the quality of code and recognizing that the cause of recent losses associated with the critical systems is the lack of appropriate code analysis, a static

code analysis tool, named as sharpniZer, has been developed. sharpniZer efficiently analyzes the source code written in C# against the target set of (150) rules defined for analysis as per accepted industry standards. As soon as the analysis completes, the user is presented with the results of the analysis in multiple forms so that the user can easily gain a thorough insight into the quality of the code at hand.

Before diving into the implementation of the tools, let us first present the 10 categories in which the selected 150 rules are divided. The rules have been accumulated from multiple industry-wide accepted standards such as MISRA, JPL, CERT, CWE, etc. The rationale behind the selection of these 150 rules is the frequency of their violations along with their pertinence in the development of mission-critical systems.

2.1. Description of categories of rules

1. Usage Rules: This is the category of rules that ensures the proper utilization of the .Net Framework and correct usage of the common types provided by it. Failure in complying with these rules may have diverse repercussions; they can be complexity, maintainability, or performance issues.

This category contains rules such as "Dispose() & Close(): Always invoke them if offered, declare where needed." and "Do not omit access modifiers".

The former rule recognizes the problem that Class instances often have possession of unmanaged resources, such as database connections. Not disposing of these resources implicitly or explicitly after they are no longer needed, may lead to memory leakage. Similarly, not closing SQL connections after utilizing them, may result in a lack of connections available in case of connecting to the database again.

2. Design Rules: Every programmer or developer is unique and has his style when it comes to coding or implementing logic. Therefore, it is imperative that some standard of coding style is maintained that will be followed by all the developers. Design rules will thus outline certain guidelines for the way logic is to be implemented.

As an example, consider the following rule: "'out' and 'ref' parameters should not be used". 'Out' and 'ref' are required when variables have to be passed by reference. This requires above-average experience and skills in working with pointers and more than one return value as well as an understanding of the difference in the concepts of 'out' and 'ref'. Not all developers are expected to be of the same competency, and therefore to bring all developers to a level playing field, it is recommended to rather shun the use of out and ref.

3. Object Model and API Design Rules: These are the rules that are geared towards object-oriented features such as inheritance, encapsulation, etc. An example rule for this category is: "Always prefer interfaces over abstract classes." Since interfaces are not coupled with other modules, it can be independently tested, unlike abstract classes, that can be only tested during integration testing. Moreover, since in C# a class can inherit from one only class but multiple interfaces, it is highly recommended to prefer interfaces when the developer has a choice between them and abstract classes.
4. Exceptions: Exceptions are yet another part of the code that needs to be catered for with much caution. Consider the following rule: "If re-throwing an exception, preserve the original call stack by omitting the exception argument from the throw statement".

This rule guides and warns us about the case when we want to re-throw an exception. It tells us that if we re-throw the exception with the exception (ex) argument, the compiler will not consider it a "re-throw" of the original exception rather it will consider it as a new exception that occurred where the throw (ex) statement was written. Likewise, many such guidelines need to be considered when using exceptions in our code.

5. Complexity Rules: These rules deal with common coding practices that may seem harmless at the time of implementation but in the long run result in what has become known as spaghetti code, where the flow of control is hard to keep track of. Particularly for critical systems, spaghetti code proves to be extremely risky, since in such systems one can't afford to overlook the validation and verification of every possible path of the control flow [4].

An example rule for this category is "Continue statement should not be used" or "go to statement should not be used". Since goto and continue statements provide an alternative way to exit from control structures, for large code files, it becomes inevitably difficult to keep track of and verify all the paths of the control flow.

6. Inefficient code: Rules of this category cater to the coding practices that negatively affect the performance of the system that may either be the result of greater time or memory consumption.

For example, a rule for this category of issues is "Avoid string concatenation in loop". Since string is an immutable type, every time a string is concatenated using '+' or using 'Concat()', a new memory location is reserved for the newly formed string. If the number of iterations is unknown or is very large, such practice would highly deteriorate the performance of the system due to unnecessary consumptions of memory.

7. Incomplete code: As is suggestive of the title, rules that fall in this category cater to the sections of code that give the impression that some part of code is left out, be it intentionally or mistakenly. Such coding faults, above all things, raise the issues about the understandability of code [10].

As an example, to this category of rules, consider this rule: "Ensure that a 'switch' includes cases for all 'enum' constants", this rule suggests that if a switch statement is based on a variable of type enum, then leaving any of the constants in its cases would be considered as a coding error. To avoid this blunder as well as to enhance the understanding of the switch statement, it is advised to handle all constants of the enum.

8. Logical errors: Rules in this category cater to situations when the coder might feel that the logic or the approach used for implementing a code section is correct, but actually, that code section ends up serving some other purpose, as opposed to the one the coder had for it in mind. Such blunders result in

unexpected results, confusion in the understanding of the code, or redundancy and decreased performance [3].

Example rules for such scenarios are as follows: "Do not perform self-assignment" or "Do not compare identical expressions". Looking at these rules, it is obvious that they prevent redundancy overhead by warning the user not to waste time and memory on something that will have no effect or use whatsoever. Therefore, such an implementation should be regarded as a coding error.

9. Maintainability Rules: This category of rules chosen for our system is the one that deals with the issue of maintainability. These rules ensure that the size of the code or modules and values used within, do not exceed a particular limit, for better performance and efficiency of the system. One example of this category is "Avoid creating files that contain many lines of code". Very large files will not only create problems of maintainability but will lead to many other issues such as:

- Merge conflicts; if more than one developer needs to work on the code at the same time.
- Network traffic; if the system uses a version control system to which the entire file needs to be transmitted for every small change.
- Poor organization of code; since large file size might be the result of appending everything to the same file, rather than building related things separately in respective files.

10. Naming Conventions: This category outlines the conventions set for naming code files and identifiers. The identifiers include properties, variables, methods, fields, parameters, namespaces, interfaces, and classes. Certain guidelines for naming have a much more critical purpose than mere consistency, take for example this rule: "Avoid using the same name for a field and a variable". Since the field is just a local variable of the class, declaring any other local variable with the same name as the field will cause confusion between the two, therefore it is strongly recommended to use different names for fields and variables in general [16].

2.2. Implementation Details

The tool, sharpniZer, is developed in WinForm on .NET Framework of Visual Studio. For development, Waterfall model is chosen, whereas the implementation language is C#. The implementation process and logic is discussed in detail below:

In creating the analyzer, we made use of SDK called Roslyn, which provides the user with useful API's used for C# code parsing and analysis of language constructs. An analyzer created with the Roslyn SDK, inherits Microsoft's CodeAnalysis base class. Given a file as a string, Roslyn can parse it and create a syntax tree from it, using the CSharpSyntaxTree Class of the Microsoft.CodeAnalysis package. It can then access the root of the syntax tree using the following statement.

```
var root = (CompilationUnitSyntax)tree.GetRoot();
```

Once we get the root of the syntax tree, it is fairly easy to access the descendant elements (declarations, expression, etc.) in the code. Microsoft.CodeAnalysis library enables us to access various elements of a node. For e.g Microsoft.CodeAnalysis.CSharp. Syntax enables us to access any type of declaration in C# code.

To show how our analyzer detects the different categories of problems and how checks are implemented, we will present the snippets of code demonstrating the implementation of 2 of the 150 rules implemented by sharpniZer.

Rule: Do not assign to local variable in return statement

When the assignment is made to a variable in a return statement, the variable goes out of scope and the value assigned is never read. Hence resulting in code redundancy. Redundant source code is one that is bloated, less reliable, and difficult to maintain. Any expert programmer would agree that the harder it is to maintain the code, the more likely it is to contain bugs.

Moreover, in a highly knitted team setting where multiple developers are involved, any such code written by a programmer will create much confusion for another to read or understand, resulting in a great deal of wasted time and mental energy. In the following section, we present and explain the snippets from our program which detects and warns about such redundant assignment statements in C# code.

First, all the method declarations in the code are stored in a list.

```
IEnumerable<MethodDeclarationSyntax>
methodsdecroot.DescendantNodes().OfType<MethodDeclarati
onSyntax>();
```

Next, all the variable declarations within each method are stored.

```
foreach (var method in methodsdec) {
   foreach (var VarDec in
method.DescendantNodes().OfType<VariableDeclaratorSyntax>
()) {
        VarDecsList.Add(VarDec.Identifier.ToString());
   }
```

Then, all the return statements within each method are looped through.

```
foreach (var returnStatement in
method.DescendantNodes().OfType<ReturnStatementSyntax>()
) {
```

After which we loop through all the assignment expressions within each method are looped through.

```
foreach (var assignment in
method.DescendantNodes().OfType<AssignmentExpressionSyn
tax>()) {
```

The following code then checks if any of the assignments are made to the variables declared within the method (local variables) and is done in a return statement.

```
if (returnStatement.Contains(assignment) &&
VarDecsList.Contains(assignment.Left.ToString())) {
```

If so, then the line number of that particular assignment is added to the warnings list

```
warnings = "Do not assign to local variable in return statement";
lineno = assignment.GetLine()+1;
WarningsList.Add(lineno + "@" + warnings + "@" + level);
```

In the above example, the rule was implemented by working on merely syntactic level. However, if the rule to be implemented requires some more information about the nodes/syntaxes (such as types, members, namespaces and variables which names and other expressions refer to), we have to be able to retrieve the symbols of the expressions or declarations.

We can retrieve symbols once we have the semantic model for the syntax tree. The method SemanticModel.GetDeclaredSymbol() is used to get the symbol of a given declaration syntax, whereas SemanticModel.GetSymbolInfo() returns the symbol of an expression syntax. The implementation of the second rule presented here makes use of this.

Rule: "Use throw instead of throw e (e for exception) whenever rethrowing the exception"

Throw statements are used so that if, during the execution of a software program, an unexpected condition occurs, the system is unable to process the next statement and instead throws an 'exception' error that specifies the line where the problem occurred, along with the line the throw statement was specified at. Now, when that exception is caught, we can choose to re-throw it. However, when re-throwing the exception, most programmers make the mistake of using the throw statement with the exception object (e); doing so will make the stack trace information within the exception restart at the current location, such that it will then point to the line where exception was thrown, rather than where the problem, causing the exception, occurred.

Though it might not seem like a critical issue per se, any programmer would acknowledge that incorrect stack trace information can lead to much confusion and thereby potential disruption of any logic that would be based on it. Below we present our code implementation that would detect such statements (if any) within C# source code.

First, all the catch clauses in the code are stored through the descendants of the root node (as in the previous example).

```
IEnumerable<CatchClauseSyntax> catchcaluses =
root.DescendantNodes().OfType<CatchClauseSyntax>().ToList(
);
```

Next, the throw statements within a catch clause are stored.

```
foreach (var catchclause in catchcaluses) {
  var throws = catchclause.DescendantNodes(n => n ==
catchclause ||
!n.IsKind(SyntaxKind.CatchClause)).OfType<ThrowStatementS
yntax>() .Where(t => t.Expression != null);
```

Then, all the throw statements, that were saved in the list, are looped through, to get the expression symbol of each throw.

```
foreach (var @throw in throws) {
  var thrown =
model.GetSymbolInfo(@throw.Expression).Symbol as
ILocalSymbol;
```

If the expression symbol matches the exception identifier, it means the throw statement specifies the exception, which violates the rule. Hence the line number of that throw statement is added to the warnings list.

```
if (Equals(thrown, exceptionIdentifier)) {
   warnings = MessageFormat;

3. System features and usage

Upon launching the tool, the user is asked to browse a .CS file or folder containing.CS files. Once the files are loaded, users can select the categories of rules upon which the analysis is to be conducted. The tool allows users to selectively enable the categories of rules (by default, all categories of rules are enabled). The analysis result presents the defiance and violations in source code in congruence with the underlying set of rules. An analysis summary is presented in the form of a dashboard, presenting the results in tabular form. The graphical representation adds to the visualization of analysis and assists users in gaining deeper insight into the results. An overview of the flow of the analysis process of sharpniZer can be seen in Figure 1.

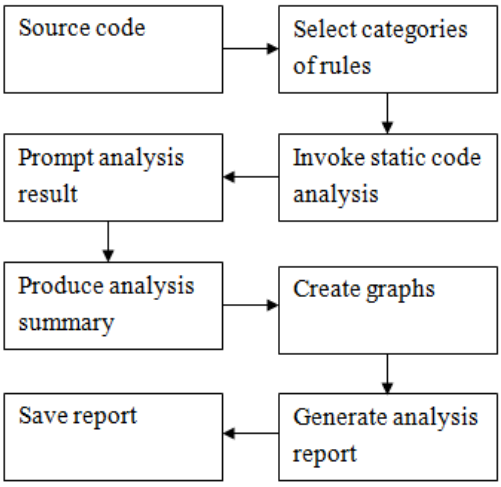

Figure 1: Methodology for conducting analysis

The above mentioned features of the system will now be elaborated per module below

3.1. Browsing C# file or project folder

User may CHOOSE C# file(s) to be analyzed in two ways:

Using the "Choose C# File" file option: allowing the user to choose any code file with the extension of .CS. After the file is selected, the content of the file will be displayed to the user in the Analyze tab (Figure 4). Clicking the Start Analysis button in the Analyze tab will start the analysis of the selected file.

Figure 2: Home page of sharpniZer

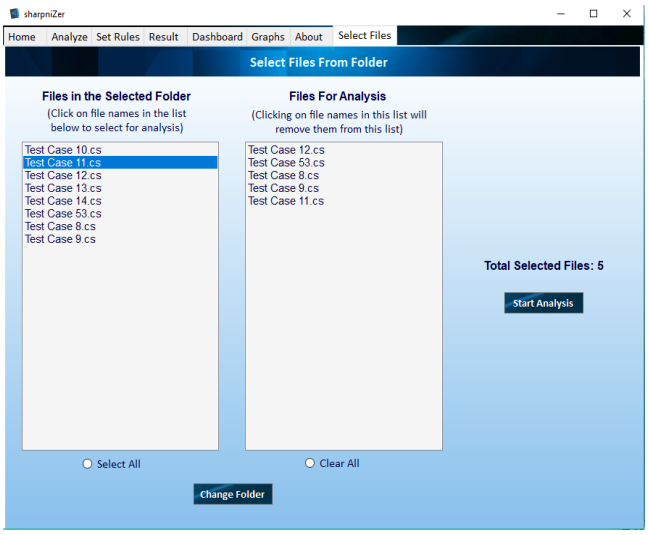

Figure 3: Selection of files for analysis

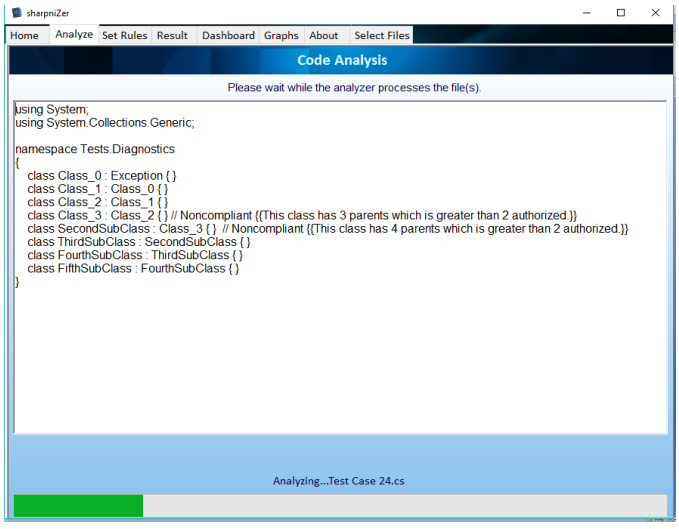

Figure 4. Analysis progress

Using "Choose C# Project" option: The user may choose any folder containing .CS files in the folder itself or its subfolders. If the user wants to deselect a file within that folder, they can click on that file's name in the "Files for Analysis" list (Figure 3), that file will be removed from the list of the files to be analyzed. The selected files will be analyzed sequentially and the progress of the analysis for each file will be displayed (Figure 4).

3.2. Select categories of rules for conducting analysis

Users can select or deselect any of the 10 categories of coding standard rules provided. The available categories can be seen in Figure 5.

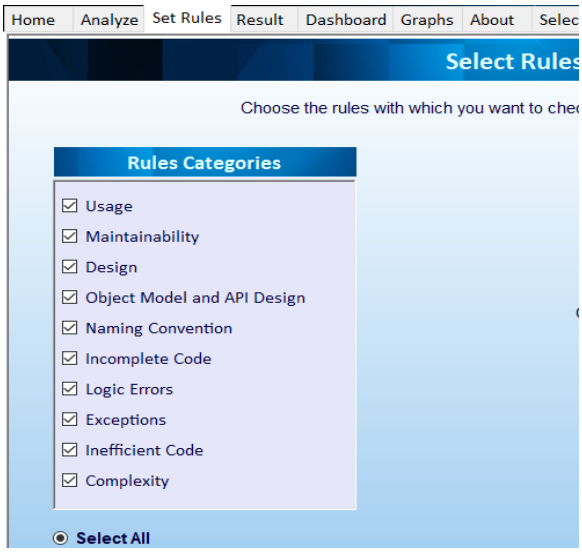

Figure 5. Selection of categories

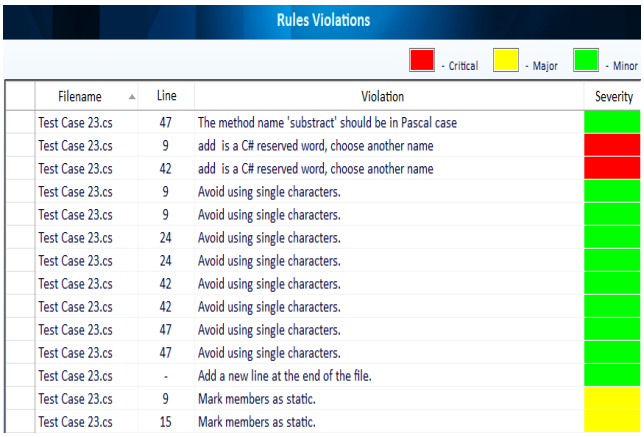
3.3. Viewing analysis results

As soon as the analysis of the selected files(s) finishes, the tool switches to Results tab (Figure 6), which displays the result of the analysis. The analysis result specifies the filename(s), line no. at which the violation has been encountered, the violated rule, and the severity of the violation.



Filename	Line	Violation	Severity
Test Case 23.cs	47	The method name 'substract' should be in Pascal case	
Test Case 23.cs	9	add is a C# reserved word, choose another name	
Test Case 23.cs	42	add is a C# reserved word, choose another name	
Test Case 23.cs	9	Avoid using single characters.	
Test Case 23.cs	9	Avoid using single characters.	
Test Case 23.cs	24	Avoid using single characters.	
Test Case 23.cs	24	Avoid using single characters.	
Test Case 23.cs	42	Avoid using single characters.	
Test Case 23.cs	42	Avoid using single characters.	
Test Case 23.cs	47	Avoid using single characters.	
Test Case 23.cs	47	Avoid using single characters.	
Test Case 23.cs	-	Add a new line at the end of the file.	
Test Case 23.cs	9	Mark members as static.	
Test Case 23.cs	15	Mark members as static.	

Figure 6: Analysis result

3.4. Viewing Dashboard

The Dashboard presents the analysis summary. The numerical/tabular form of the results allows the user to gain deeper insight into the outcome (Figure 7). It also allows the user to generate an analysis report in a .pdf file that can be saved/downloaded and shared with team members (Figure 8).

Dashboard presents the following content:

- Total File(s) Selected
- Total Lines of Code
- Total number of violation(s)
- Number of violation(s) per file
- Category Violation(s) for all file(s)
- Category of violation(s) per file
- Severity of violation(s) for all file(s)
- Severity of Violation(s) per file

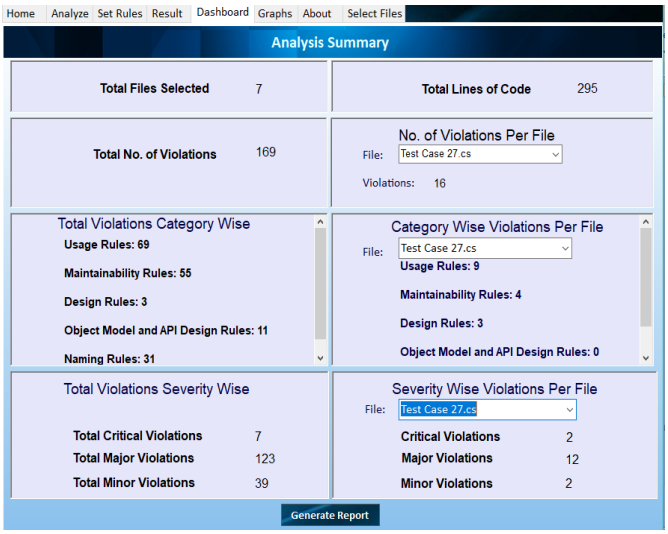


Figure 7: Dashboard

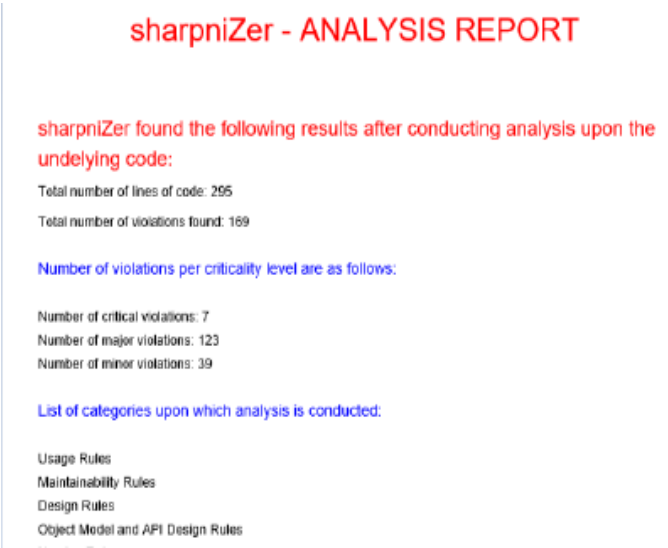

Figure 8: Analysis Report

3.5. Visual representation of Analysis Result

The Visual representation of results is often considered to be more comprehensive and elaborate, therefore, sharpniZer generates graphs by utilizing the numerical values of analysis results (Figure 9). The graphs can be generated for total violations, as well as for each file (if the analysis is conducted upon multiple files).

- The bar chart represents the total violations per category of rules chosen.
- The pie chart represents the total violations of rules per severity level.

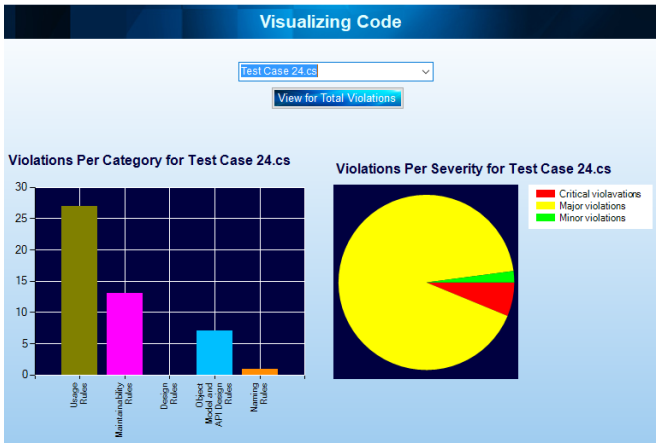

Figure 9: Graphical representation of analysis results

4. Review and Comparison of the Existing Tools with sharpnizer

Below we provide a review of other existing 9 tools that analyze code written in C# (a detailed comparison of C# code analyzers could be found in our previously published review article Probing into code analysis tools: A comparison of C# supporting static code analyzers [27]).

The 9 tools chosen for comparison in this research were selected based on their overall ranking resulting from numerous surveys combined with the fact that prior literature has proved these tools to be the most popular among researchers. The majority of the values for our evaluation are attained by gathering information from surveys and public reviews of users. Rest are procured by self-executing the tools and observing the performance in light of the mentioned 10 parameters.

Table I defines the parameters taken into consideration for comparison. These parameters were selected based on the survey of the code analyzer features most commonly considered by companies when selecting one to assess their mission-critical systems. Table II AND III present the value for each tool against these parameters. Whilst keeping the comparison authentic and unbiased, Tables II and III manifests the benefits sharpniZer has over some other quite decently known tools in use today.

5. Results

From the results of the comparative analysis presented in Tables 1 and Table 2, we can see that sharpniZer's installation process and usability is easier than some of the tools available. Though the number of rules implemented is yet lower than most in comparison, it supersedes many in providing customization of rules' selection, categorizing the nature of violations and covering a wide spectrum of the coding standards. In addition, unlike some of the contemporary tools, sharpniZer does not require code to be compiled first to perform analysis.

Table 1: Comparison Parameter

S. No.	Parameter	Definition
1	Usability	How user-friendly is the tool for a layman (scalable from easy to hard) (The classification was done based on the pubic reviews of the users of the tools listed and those of our client) [13]-[26]
2	Installation	How convenient is the process of installation/integration of the application (scalable from easy to hard) (Classification was done based on published surveys and our client's reviews) [13]-[26]
3	No of Defined Rules	The number of rules/metrics defined within the tool, so that the tool might assess compliance of these rules, during the analysis of codes.
4	No. Of Categories of Defined Rules	Number of types of coding standard violations defined by the tools
5	Requires compiled code	Does the tool require the code to be compiled before it can perform analysis on it?
6	Graphical representation	Does the tool display the graphical representation of the analysis result?
7	Selection of Desired Categories of Rules to be Applied	Does the tool allow the user to select specific categories of rules to check the code compliance with?
8	Severity categorization based on the nature of the violation (Blocker, critical, major, minor)	Does the tool specify the severity of violations in results (minor, major, or critical)?
9	No. of Standards for Code Compliance	Number of coding standards with which the tool checks the compliance of the code at hand
10	Is the Tool Optimized for Mission Critical Systems?	Does the tool predominantly check the compliance with rules defined for the development of mission-critical systems?

Table 2: Comparative Analysis

S. No.	Tool	Usability	Installation	No of Defined Rules	No. of Categories of Defined Rules	Requires Compiled Code?
1.	Ndepend	Normal [13, 14]	Easy [13, 26]	More Than 150 Default Code Rules	14	No
2.	PVS-Studio	Hard [23, 25]	Easy [23, 25]	450 Diagnosis Rules	29	No [23]
3.	Resharper	Easy [21, 26]	Easy [21, 26]	1700+ Code Inspections	10	No [21]
4.	Fxcop	Easy For GUI, Hard for Command Line [19, 25]	Easy [19, 25]	More Than 200	9	Yes

5.	Visual Code Grepper	Easy [18, 26]	Easy [17, 26]	Unknown	3	No
6.	Nitriq	Easy [20, 25]	Difficult [20, 25]	Over 40 Pre-Written Rules Defined	Unspecified	Yes
7.	Parasoft Dot Test	Easy [23, 26]	Untested/ Not Reviewed	Above 400	20	No
8.	Coverity Scan	Hard [16, 25]	Easy [16, 25]	Unknown	30	No
9.	sharpniZer	Easy	Easy	150	10	No

Table 3: Comparative Analysis

S.No.	Tool	Graphical Representation	Selection of Desired Categories of Rules to be Applied	Severity Categorization Based on Nature of Violation (Blocker, Critical, Major, Minor)	No. of Standards for Code Compliance	Is the Tool Optimized for Mission Critical Systems?
1.	Ndepend	Yes [14]	Yes	Yes [13]	Unspecified	No
2.	PVS-Studio	No [24]	No	No	3	Yes[24]
3.	Resharper	No [21]	No	No	Unspecified	No
4.	Fxcop	No	Yes	No	1	No
5.	Visual Code Grepper	Yes [26]	No	Yes	2	Yes [18]
6.	Nitriq	Yes [20]	Yes	No	Unspecified	No
7.	Parasoft DotTEST	Yes [24]	Yes	Yes	3	Yes
8.	Coverity Scan	Untested/ Not Reviewed	No	No	2[15]	Yes [15]
9.	sharpniZer	Yes	Yes	Yes	5	Yes

Due to successful realization of chief requirements for testing static code of mission-critical systems, sharpniZer is currently employed by NESCOM (a military research organization of Pakistan) to test the software (written in C#), embedded in some of the mission-critical and ammunition systems developed by the organization.

6. Future Work

The proposed tool currently encompasses 150 coding rules, obtained from standards (established for the development of mission-critical systems) such as MISRA, CERT, CWE, and JPL and also from Microsoft. The rules list can be extended to cover more rules and standards. Moreover, custom rules can be made

part of the tool that will allow users to define their own rules through a query language.

Refactoring is yet another feature that can be incorporated into the system. Through Refactoring, the violation will automatically be corrected in the code as the user clicks on the violated rule in the Results tab. Also, the tool can be expanded to cater to source codes of other languages along with C#

7. Conclusion

This paper discusses the burgeoning issue of overlooked bugs in static code of critical systems, and proposes a static code analysis tool, sharpniZer, that analyzes the code specifically written in the C#, and precisely identifies all the discrepancies and deficiencies in the source code as per the coding standards set for the development of mission-critical systems, enhancing the overall efficiency and reliability of the code.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

This research paper is a product of the effort of 5 authors, the references to whom are specified at the beginning of the article. All authors have read and agreed to the published version of the manuscript. The detailed roles of each were as follows:

Flexural Strength

ABSTRACT

In this report, polymeric composites made from Polypropylene (PP) and talc powder were studied. The talc powder with different portions of 10%, 20%, 30% by weight was used to create samples. The samples were examined by the tensile test and the flexural test according to ASTM D638 and ASTM D790. The surface morphology of the samples were investigated by scanning electron microscope (SEM). Increased the talc powder portion led to a decrease in the tensile strength and flexural strength. Among the added talc powder samples, the 10% talc powder sample presented the highest mechanical tensile strength of 25.91 MPa and flexural strength of 47.99 MPa, while the 30% talc powder sample shown the lowest mechanical tensile strength and flexural strength. The results of SEM analysis indicated the existence of talc plates and porosity between talc plates and PP substrate compared to the neat PP sample. The surface morphology of the samples was observed by SEM, showing higher porosity in samples with increasing filler content. Moreover, increasing the talc powder portion resulted in a higher chance of brittle fracture. The research indicated and explained the effect of talc power on the characteristic of PP.

1. Introduction

Neat Polypropylene (PP) plastic resins are preferred for plastic products requiring a high cost of the material bill. Therefore, with conventional products, manufacturers can use recycled PP to reduce costs and reduce environmental pollution [1-3]. Normally, the products made from recycled PP consist of neat PP, recycled PP, and filler. Fillers help reduce costs as well as improve the functionality of the product [4-6]. They are usually insoluble minerals, adding them will increase the volume of polymers. They can be broadly classified as reinforcing or non-reinforcing fillers. Among them, $CaCO_3$ is a popular choice for filler roles [7-9]. $CaCO_3$ fillers have been used in the form of fine particles with a size of less than 10 µm. $CaCO_3$ content can be added from a few percent to up to 30 percent by weight ratio. Adding $CaCO_3$ could greatly improve the thermal and mechanical properties of polymer materials [10-12].

For example, adding 20% $CaCO_3$ will improve thermal stability by about 27.5°C and in case of 30%, the tensile modules will increase by 97% when compared to pure PP [13]. Similarly, with 5, 10 and 20% $CaCO_3$ by weight, the results of the study have shown an increase in the elastic modulus, yield to break, and elastic stress. It has also been confirmed that viscosity during flow increases with fortifier addition and reaches the highest value with 15% talc [14]. The effect of kaolin on the mechanical properties of PP/Polyethylene through mixing kaolin fillers with the content of 1, 3, 5, 10, 14% by weight ratio is also considered [15]. The results showed that the tensile strength increased simultaneously with the increase of the filler concentration from 2 MPa of non-padded PP/Polyethylene and up to 9 MPa with the appearance of 14% kaolin. Increase the concentration of kaolin from 0 to 14% helps increase from 40 HD (Shore D Hardness) to 70HD.

Talc is also commonly added to increase hardness and improve the properties of polymers [16-18]. Therefore, more than 200 thousand tons of talc powder is mixed with PP annually. Talc has many effects of increasing hardness, durability, thermal resistance, and anti-damage of ultraviolet rays, good scratch resistance [19-21]. Talc is widely used in plastic products for machine parts such as cars and motorcycles, as well as household plastic products such as nylon bags and plastic pots. The current trend in the automotive industry is to produce thin, light, and precisely sized parts, which requires higher rheological resins that talc fillers can meet. China is the key world talc and steatite producing country with an output of about 2.2 million tonnes (2016), which accounts for 30% of total global output.

Several authors showed that adding talc could rise the mechanical properties of pure PP [22-25]. For instance, Urmila el al. pointed out that adding 10, 20, 30, 40, and 50% weight ratio

Corresponding Author: Pham Thi Hong Nga: hongnga@hcmute.edu.vn

results in the improvement of mechanical properties such as tensile strength from 23,49 MPa with primary PP up to 26,65 MPa [22]. Silva reported that adding talc with the ratio of 5, 10, 15, and 20% of the weight ratio leads to an increase in the tensile strength, from 28 ± 5MPa of pure PP up to 130 ± 4 MPa [14]. Mechanical properties of materials such as Charpy impact resistance and tensile strength can also be improved. Pan et. al indicated that tensile strength reaches its maximum value at 33.9 MPa in the presence of a 10% talc compared to 30.8 MPa of pure PP [23]. Moreover, the flexural strength also increased from 22,86 MPa to pure PP up to 32,98 MPa with 50% talc [22]. Too much talc powder is not good for the properties of the polymer. The tensile strength of the composite has 25% Talc is 24 MPa and 30% Talc is 22.5 MPa [24]. Composite PP with Talc shows an increase in elastic modulus when the amount of talc powder is up to 20% compared to pure PP from 85,72 MPa up to 150,0 MPa and decreases at higher concentrations [25].

The hardness of the mixture depends on the particle size and has been observed through microscopic images and the results of the Izod impact test give the result. With the larger particle size, the hardness decreases, and vice versa. For the impact toughness, with the particle size of 30 µm, the impact toughness is 6.5 (ft-lb/in) and with the particle size of 10 µm, the impact toughness is 12 (ft-lb/in) [26]. The hardness of the mixture increases with increasing Talc concentration [24]. Moreover, the impact toughness can also be improved by adding a suitable amount of talc. The impact toughness increased from 2 (KJ/m^2) of primary PP increased to 4 (KJ/m^2) with the appearance of 10% Talc, and then decreased to 3.5 (KJ/m^2) [23].

When comparing directly the two most common fillers in PP, $CaCO_3$, and Talc, there are still some mechanical weaknesses when adding $CaCO_3$ (tensile strength, flexural strength, elastic modulus, stress to break, and elastic stress), while talc is somewhat more dominant. The aims of this study is investigating the effect of talc composition on the tensile strength, flexural strength and microstructure of PP polymer.

2. Materials and methods

2.1. Materials and samples preparation

PP (Moplen HP500N type) was supplied by Lyondell Basell Industries (Saudi Arabia). Talc (TMD type) particle size was from 28 to 44 µm, whiteness ranged from 88-95%, chemical composition comprises Fe_2O_3 2-3%, MgO 25-27%, CaO < 0.6%, SiO_2 52-54%.

Table 1: Compositions of the samples (%wt.)

Materials	Compositions of the samples (%wt.)			
	S1	S2	S3	S4
PP	100	90	80	70
Talc	0	10	20	30

Table 1 presents the compositions of the samples S1-S4. The samples making process uses computer systems mixing and extrusion Polylab research OS - Haake (Germany), which has the basic parameters of the system such as mixing chamber contained 120 cm^3, and extrusion equipment L/D = 25, D = 16 mm. Single screw extrusion equipment connected to blown film system (blown film) and sheet extrusion system (0.2 to 1.2 mm x 100mm). Mixed samples were melt-blended during the period from 6-7 minutes with the temperature of the extruder zone temperature was 180°C. After extruding, the resulting pellets were dried at 80°C for 4h and then molded using injection molding machine into plates. The mold-temperature profiles were set at 180ºC. The molding process was carried out in 5 minutes and then cooled for 20 minutes. Figure 1 presents the size of plate samples after molding, it is 145 x 145 mm in length and 2 mm in thickness.

2.2. Methods for mechanical properties and surface morphology analysis of samples

The tensile property was defined by method ASTM D638-02 experiments with the conditions required, as shown in Figure 2. Testing samples must be cleaned of oil, grease, and other impurities, then put into the environmental conditions of 23 ± 2°C direct heat, humidity 50 ± 5%, for 40 hours prior to the test. The experiments were conducted by Universal testing machine Shimadzu Autograph AG-X Plus 20kN (Japan). Some basic specifications are described as following: load capacity (maximum) 100 kN, traction speed 0.0005 to 1000 mm/min ±

0.1%, tensile capacity (maximum) 600 mm. This paper using speed was 55mm/min

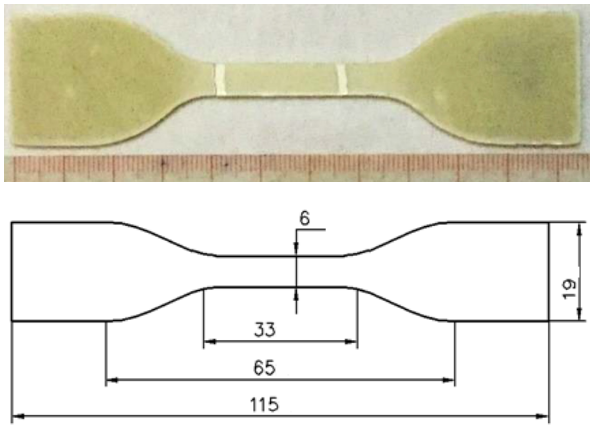

Figure 2: Specimen for tensile test

Flexural properties were defined by method ASTM D790 experiments. Samples are the composite material beams of rectangular cross-section placed 3-point bending under load. The sample size was shown in Figure 3. The experiments were conducted by Universal testing machine Shimadzu Autograph AG-X Plus 20kN.

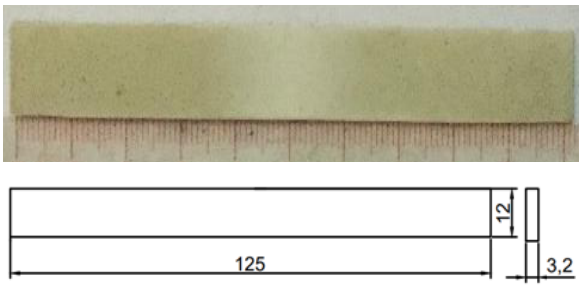

Figure 3: Sample for flexural test

The fracture surface of each specimen in the bending strength test was observed by scanning electron microscope HITACHI S - high resolution - 4800 (SEM), with acceleration 5.0 kV. The surface of the samples used for SEM all was platinum-sputtered with a conductive layer before observation.

3. Results and discussions

3.1. Tensile strength

The number of replicates is mostly four. Despite there is some differences between replicates, they varied only a few percent. Figure 4 shows the stress-strain curves of S1-S4 samples. Figure 5 shows the average values of the tensile strength of these samples. The tensile strength values are 30.73 MPa, 25.91 MPa, 23.68 MPa, and 23.29 MPa corresponding to S1, S2, S3, and S4 samples, respectively. In general, increase the talc content leads to decrease in tensile strength, a similar result of Zihlif report [24].

Table 2 presents the elongations of S1, S2, S3 and S4 samples. The average elongation values are 6.09%, 3.45%, 1.89%, and 2.99% corresponding to S1, S2, S3, and S4 samples, respectively. Increase the talc content mostly decrease the elongation value of the samples.

Table 2: Elongations of the samples

Samples	S1	S2	S3	S4
Elongation (%)	6.09	3.45	1.83	2.99

This result may be due to the function of talc. When mixing talc into the PP, the aggregation of talc affects the crystallization process whereby talc acting as a nucleating agent uniformly distributed in the matrix resin PP and filling the matrix. However, an uneven talc particle size and the excessive incorporation of this filler may lead to filler agglomeration in the polymer matrix leading to the formation of micro-filter due to the difficulties in achieving a homogeneous dispersion of fillers. This phenomenon leading to weakening the interfacial bonding with the PP matrix, and creating some voids and defected structure of the composites, therefore, causing a reduction in tensile strength.

3.2. Flexural strength

Figure 6 illustrates the stress-strain curves of the flexural test of S1-S4 samples. Figure 7 shows the average values of the flexural strength of these samples. The flexural strength values are 49.31 MPa, 47.99 MPa, 46.06 MPa, and 47.62 MPa corresponding to S1, S2, S3, and S4 samples, respectively. In general, increase the talc content leads to decrease the flexural strength, a similar result of Zihlif report [24].

Table 3 presents the elongations of S1-S4 samples. The average elongation values are 6.09%, 3.45%, 1.89%, and 2.99% corresponding to S1, S2, S3, and S4 samples, respectively. Increase the talc content mostly decrease the elongation value of the samples.

Table 3: Flexural strain of the samples

Sample	S1	S1	S3	S4
Flexural strain (%)	7.24	3.99	2.56	2.73

The reductions of the flexural strength and flexural strain are the result of the toughness and hardness increase. The introduction of rigid particles in a ductile matrix leads to lower elasticity/ deformability of the resulting compound.

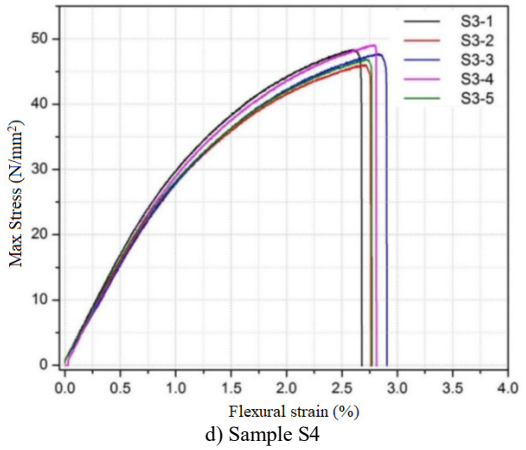
c) Sample S3



d) Sample S4

Figure 8: Fracture surface microstructure of samples: (a) Sample S1, (b) Sample S2, (c) Sample S3, and (d) Sample S4

3.3. Microstructure

The fracture surface microstructure of the samples is analyzed by SEM to have a more insightful view, as shown in Figure 8. Figure 8(b), (c) and (d) indicates the presence of talc powder in the polymer matrix. These figures also show the porosity between the talc powder and the PP matrix. Increase the talc will lead to an increase in the existence of this powder and porosity in the matrix.

All these factors contributed to the transfer of stresses from the matrix to the filler leads to reduce the bending properties. Furthermore, it was cleared that the fracture surface of PP matrix was clear and the number of the craze was limited, so the fracture was a brittle fracture. But the fracture surface of PP/Talc blends was rough, and the number of crazes increased with the increasing dosage of talc. Therefore, in this case, the fracture of PP matrix was a brittle fracture as the crystallization of the higher talc contain sample was higher, a similar result to Pan et al. [23].

4. Conclusions

In this study, the effect of 10%, 20%, and 30% talc to the tensile strength and flexural strength was studied. Some important points can be withdrawn as follow:

- The 10% talc powder sample posses the highest mechanical tensile strength of 25.91 MPa and flexural strength of 47.99 MPa among the talc powder samples. The 30% talc powder sample presents the lowest mechanical tensile strength, while the 20% talc powder sample represents the lowest flexural strength.
- The SEM results indicates the existence of talc powder and porosity between talc plates and PP substrate compared to the pure PP sample. Increasing the talc powder leads to a higher rate of porosity and a higher chance of brittle fracture.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Interpreting data for solving information needs demands an understanding of the semantics of row data. In this paper, an ontology-driven management of data of the presence of radon gas in soil is presented. The main contribution of this research relies on the formal definition of the semantic of the presence of radon in the dimensions of space and time. As a result, a dynamic data view generator for the observation of radon measurements was deployed without actual software programming but with the proper adjustment and instantiation of the ontology ViewOnto, a web ontology which was created for the formal description of data views. An experimental assessment of the proposal was carried out with data obtained from stone aggregate mines and civil constructions in Tungurahua. The usability of the resulting data management system was successfully validated with the criteria of experts on usability and researchers with experience in radon measurement.

1 Introduction

According to United States Environment Protection Agency estimates, radon is the number one cause of lung cancer among non-smokers and the second one overall [1]. Recent studies in the detection of radon have been focused on the definition of alternative methods for detecting radon presence in soil and air [2, 3], making the radon detection cheaper and accessible.

The study of collected radon data is important not only for warning about the humans' health risks because of its inhalation [4, 5] but for the prediction of earthquakes [6] and spontaneous combustion scenarios in coal mines [7]. In these quite different scenarios, time and space are recognised as fundamental dimensions of collected data in order to depict an actual throbbing picture of the presence and potential impact of radon [4]–[8].

Meanwhile, other variables like meteorological parameters and soil characteristics are intrinsically related because of their influence in radon concentration [3, 5, 7, 9]. This kind of studies is characterised by a challenging task: to derive meaningful insights from collected data [6, 7].

In the literature review that was carried out, it was not possible to find a common data model for characterising the presence of radon. On the contrary, depending on the research, different variables and even different measure units characterise each research. This lack of data normalization makes harder to work with retrieved data from the field. Requiring such a flexibility level on data management tools, it is important to note that developing adaptive collective structures of knowledge by ontology-based techniques has been successfully applied to different research areas [10]–[12].

This paper presents an ontology-based dynamic tool for the observation of radon measurements. The decision for an ontology-based solution is twofold. Firstly, a flexible solution is designed, adaptable to different objectives of research and changing mechanisms of measurement as the research goes on. Secondly, the tool does not need changes on code in order to adapt to changes on data to collect and data views required by researchers for analysing data in the space and time dimensions. Other important issues as user authentication and data access protection are out of the scope.

The proposed solution is based on *ViewOnto*, a web ontology which was defined for the formal description of the semantics of data views in different scenarios [10, 11]. Many domain ontologies have been created until now [11, 14, 17] but *ViewOnto* is the only one with this purpose of those available in the consulted literature. In this work, this ontology is taken into the dimensions of space and time. Its usability was validated by a usability test of the data views generated on the use case of the study of the presence of radon in

[*]Corresponding Author: Diana Coello-Fiallos, Carrera de Ingeniería Civil - UTA. Av. Los Chasquis y Río Payamino, Ambato, dc.coello@uta.edu.ec

mines and civil constructions in Ecuadorian highlands.

This paper is structured as follows. Section 2 depicts related works. *ViewOnto* is described in section 3 and the general architecture of the ontology-based data management tool for studying radon concentration is presented. Section 4 presents the results of the experimental evaluation of the tool in the scenario of the measurement of radon diffusion rate of building materials in stone aggregate mines and civil constructions in Tungurahua, in the Ecuadorian highlands. Finally, in section 5 conclusions and future work are discussed.

2 Related works

Tareen et al. proposed a method for predicting earthquakes based on the automatic detection of anomalous behaviour in radon time series data [6]. As result of their research, anomalous behaviour seen in radon time series data has been determined as an indicator of seismic activity [6].

Meanwhile, surface-based radon detection is a technique used for spontaneous combustion prediction in coal mines by studying the radon migration mechanism of overlying strata [7]. These studies show the importance of tools for supporting the understanding of data series of radon measures.

Other studies determine the acceptance of the influence of meteorological variables in radon concentrations [3, 7]. This actually leads to the estimation of soil radon gas with meteorological parameters, determining the necessity of taking into account meteorological parameters when making an analysis of radon influence on human life.

The results of the research of Verdonck et al. show that ontology-driven conceptual modeling has advantages for achieving higher quality models when compared to traditional conceptual modeling. Likewise, they concluded that it is advantageous to apply an ontology-driven concept modeling technique when having to model the more challenging and advanced facets of a certain domain or scenario [14].

Formalising the semantic of data is fundamental for its automatic processing [15]. Semantic aspects of data determines logic rules of knowledge base systems [12, 13, 15] whilst web ontologies are accepted as formal mechanisms for structuring data conceptualizations [13].

In another study, Verdonck et al. have studied the pragmatic quality of ontology-driven models and they have concluded that the notion of time is easier to comprehend in ontology-driven models where an individual endures through time and is regarded totally present at any moment in its lifetime. The same was confirmed when analysing how easy to understand was the formation of semantic relationships [13]. Meanwhile, Baumgartner et al. highlighted that making timely identification, resolution, and prevention of critical situations is fundamental for having a semantically richer knowledge model [15].

Wagih et al. focused on defining the semantic aspects of user's mobility for location recommendation systems by defining Ridology, an ontology model for exploring human behaviour trajectories in ridesharing applications [12]. Meanwhile, Sorokine et al. proposed the use of ontologies in the generation of scenarios for the purpose of testing the algorithms used to detect nuclear materials [16].

Another study proposing an ontology-driven representation of knowledge is the research carried out by Mantovani et al. for managing geological maps [17]. In their approach, a domain ontology in the context of geological knowledge named *OntoGeonous* was used in order to constrain the behaviour of a dynamic data entry tool to refer to the terminology conveyed by the taxonomic-axiomatic nature of the ontology [17]. None of related work analyzed during this research take into account the semantics of data in the space and time dimensions. Nevertheless, all these research results support the idea of choosing an ontology-driven concept model technique for carrying out the analysis of the impact of radon in human life both, on the space and time dimensions.

3 Description of the ontology-based data management tool

The software architecture of this solution is structured in three layers. Fig. 1 illustrates a general view of the interaction among layers of the proposed solution and with the user. The data entry and data views generators automatically generate a user interface by using the semantics of the instance of the *ViewOnto* ontology for radon observation.

Changes in the instance of the ontology automatically generate changes in the user interface. The user interacts with the data entry interface for inserting, updating and deleting data stored in the the structured database whilst he interacts with the data views generator for interpreting and learning from annotated data.

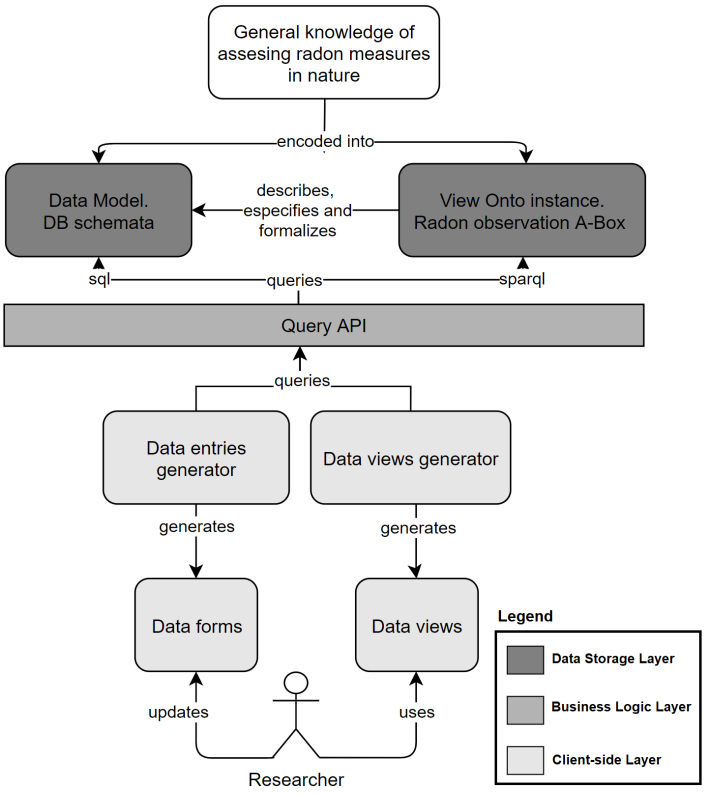

Figure 1: General view of the proposed solution.

The most important outcome with this implementation is that there is no need of updating the encoding of the application for changing the behaviour of the application. Those changes are automatically generated in user interfaces by changing the instance of *ViewOnto* that describes the semantics of data stored in the relational database. Below, the three layers of the architecture are described.

3.1 Semantics of the measurement of the presence of radon

The semantics of the database design in relational database models define the ultimate restrictions of datatype for each data item, unique index restrictions and the kind of relationships existing among data entities. Fig. 2 shows the relationships among the main data entities defined in the use case of this research for measuring radon's presence in the highlands of Ecuador. Other entities, like the User entity for specifying which users that have access to these data, were ignored in the diagram for improved clarity of the concept.

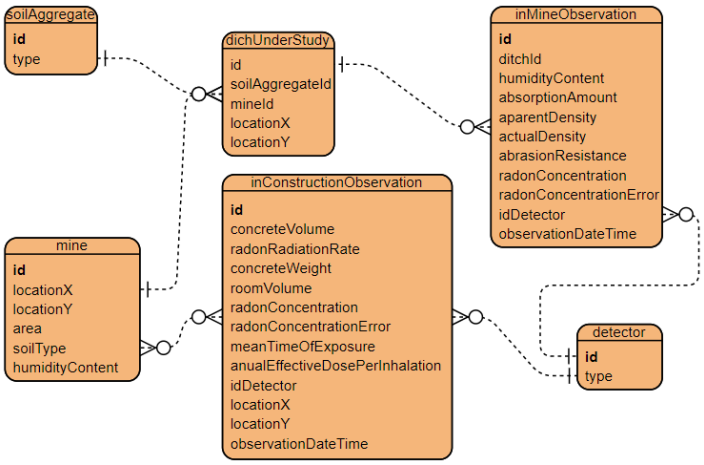

Figure 2: Main entities in use case's database design.

For this use case, in-mine and in-constructions observations were recorded. Different detector mechanisms were used and different soil aggregates were analysed. Both, time and space dimensions of data are fundamental for the study since it is required to be able to analyze the evolution of radon presence on observations. In this scenario, the semantic restrictions of the designed database were not enough but considered as a baseline guarantee for the integrity of managed data. Defining further semantic restrictions was necessary for building a data entry and report generator tool which adapts to changes in the semantics of data. Otherwise, the automatic generation of proper interfaces for end-users would be intractable.

For this purpose, modeling the semantics of data within a custom instantiation of the ontology *ViewOnto* was considered. Figure 3 shows the conceptual model of *ViewOnto* for formalising a database schemata.

Next, the main semantic definitions reused and extended from [10] in the instantiation are formally encoded using the description logic of the OWL language. For deeper insights about *ViewOnto*, the extended definition of the T-Box of *ViewOnto* and the specific A-Box of *ViewOnto* for radon observation are available int the online repository that accompanies this paper at Open Science Framework[1].

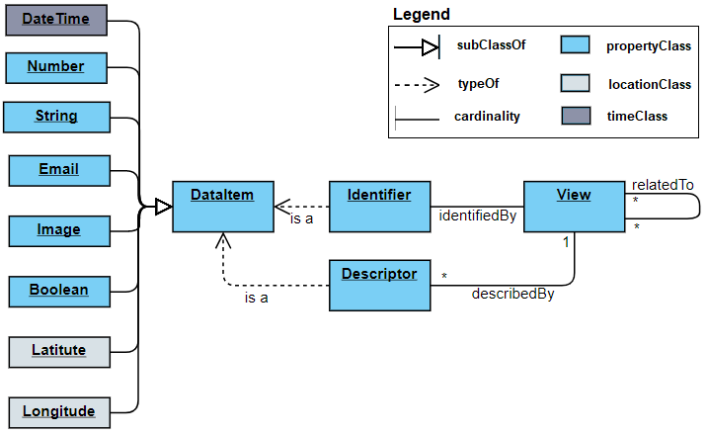

Figure 3: Conceptual model of *ViewOnto*.

$$V, D, I, S, R, F \sqsubseteq \top; V \sqcap S \sqcap R \sqcap D \sqcap I \sqcap F \equiv \bot \quad (1)$$

View V, *Descriptor* D, *Identifier* I, *DataItem* S, *Relationship* R and *Filter* F are the basic classes in the terminology of ViewOnto. Those classes are disjoint sets and this terminology corresponds to the original definition of *ViewOnto* by Fernández et al. [10].

$$\begin{aligned} S_{dt}, S_n, S_s, S_e, S_i, S_b, S_{la}, S_{lo} \sqsubseteq S; \\ S_{dt} \sqcap S_n \sqcap S_s \sqcap S_e \sqcap S_i \sqcap S_b \sqcap S_{la} \sqcap S_{lo} \equiv \bot \end{aligned} \quad (2)$$

Semantic datatypes are represented by the classes ***DateTime*** S_{dt}, *Number* S_n, *String* S_s, *Email* S_e, *Image* S_i, *Boolean* S_b, ***Latitude*** S_{la} and ***Longitude*** S_{lo}. All these data items are subclasses of *DataItem* S. Those data items in bold were added to the original definition of *ViewOnto* in order to take into account the space and time dimensions of data. The appropriate *DataItem* is decidable by the corresponding datatype for each data item in the database.

$$\begin{aligned} V \equiv & = 1 title \sqcap \\ & = 1 mappedTo \sqcap \forall isIdentifiedBy.I \sqcap \\ & = 1 isIdentifiedBy \sqcap \forall isDescribedBy.D \sqcap \\ & \forall isRelatedBy.R_v \end{aligned} \quad (3)$$

A *View* V is defined as the class with one, and only one, *title*, *mappedTo* and *isIdentifiedBy* properties. The property *title* is used for generating labels and menu options in the automatically generated data entry forms and report views. Meanwhile, the property *mappedTo* is used to link the *View* with the corresponding dataset in the database. V is identified by an *Identifier* I. Further, V may be related (or not) with one or more *Descriptors* D and *Relationships* between *Views* R_v by instantiating the *isDescribedBy* and *isRelatedBy* properties, respectively.

[1] https://osf.io/wj46b/

$$
\begin{aligned}
D \equiv &= 1title \sqcap \forall describedBy.S \sqcap \\
&= 1describedBy.S \sqcap \\
&= 1isAlternative \sqcap \forall isRelatedBy.R_D
\end{aligned} \tag{4}
$$

A *Descriptor* is defined as the concept D, which instantiates once, and only once, the roles *title*, *describedBy* and *isAlternative*. The properties *describedBy* and *isRelatedBy* only take value in the range of S and R_D instances, respectively. These restrictions are mandatory for a *Descriptor*. Figure 4 shows the connections among *DataItems* and *Descriptors* in the spatial dimension of the use case. This diagram was generated with the OntoGraf plugin for Protégé using the instance of *ViewOnto* that was built for studying radon concentration.

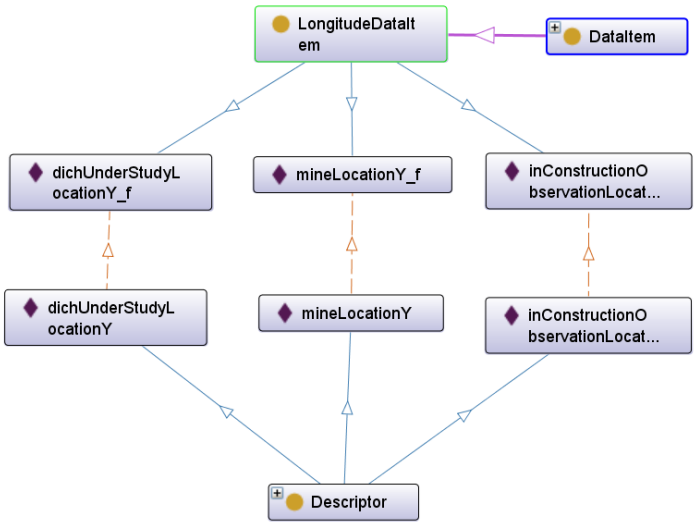

Figure 4: Graphical representation of *Descriptors* and *Dataitems* in the space dimension of the use case.

3.2 Implementation of the business logic layer

The business logic layer is exposed as a REST-API. A json encoder/decoder was integrated for making possible the communication with the client-side layer of the data management tool. Inside, the design of the business logic layer was threefold. One component was built for querying and updating the database whilst another component allowed to query the *ViewOnto* A-Box of the use case. Finally, an inference component that uses the Jena inference engine was implemented. This component inferences semantic rules based on the OWL encoding of *ViewOnto*. As Jena is an inference engine implemented in Java, all features of the business logic were exposed as web services in a TomCat Server. Figure 5 shows the structure of the proposed business logic layer.

Four main API-REST methods were proposed that conform to the management of the data of a data view. With different parameters, these methods allow to retrieve and to trigger CRUD actions over the data of a data view. Other eight API-REST methods allow to retrieve the list of available data views and data of inter-related data views, their descriptors and identifiers. Table 1 shows the structure of possible requests to the API-REST.

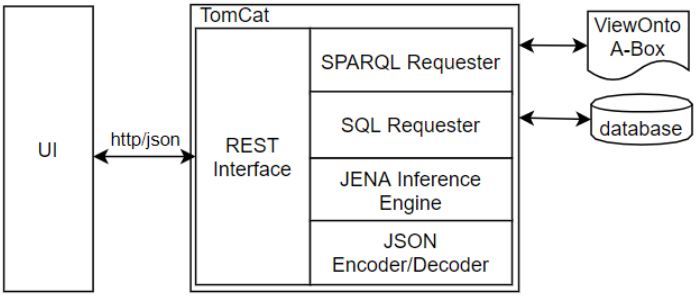

Figure 5: Graphical representation of the business logic layer.

Table 1: Examples of requests to the API-REST

Method	Path	Action
POST	/api/view /inMineObservation	records an observation.
POST	/api/view /inMineObservation/1	updates an observation.
GET	/api/view /inMineObservation	retrieves data of observations.
DELETE	/api/view /inMineObservation/1	deletes record *1* from observations.

With this implementation of the business logic layer, it is possible to have more than one client-side layer implementation. Without changes in the code, just by changing the specification of the *ViewOnto* A-Box, the behaviour of the business logic may adapt to changing scenarios. Data retrieved by the business logic flow to the client-side layer in an efficient way.

3.3 Implementation of the client-side layer

The implementation of the client-side layer is twofold. A generator of data entry interfaces and a report generator were implemented. An automatically generated interface for data entry allows the user to register annotations of radon measurements. Meanwhile, the report generator allows the user to navigate through data views for analysing collected data. All these interfaces are generated on request, based on the information stored in the instance of *ViewOnto*.

Figure 6 shows a data entry interface generated from the semantics stored in the *ViewOnto* A-Box that was defined for supporting the study of radon concentration. The definition of descriptors of longitude and latitude (*mineLocationX* and *mineLocationY*, as appear in figure 4), determines the rendering of a map component for choosing a location. The implementation of this map component allows to mark a point, a set of points, and a path. These functionalities are activated or not, taking into account the information that the user will enter in the data entry form. How to store data in the database is specify in the *mappedTo* data property of *ViewOnto*.

Meanwhile, other data entry controls (text fields and a combobox) are rendered for entering corresponding values. The rules for validating the values entered in each of these controls come from the instance of ViewOnto. The kind of control to render is chosen taking into account the *DataItem* that matches to each *Identifier* and *Descriptor* in the instance of *ViewOnto*. Other restrictions are

defined in the instance of *ViewOnto* using specific data properties. This is the case of mandatory fields in the data form, minimum and maximum values of each numeric field and the set of valid values (if this is the case).

The instance of *ViewOnto* includes rules for validation and error messages, just in case the rules are violated. The contribution with this work is that the semantic definition of form fields, and how to deal with them, is not mixed up with HTML and JavaScript. Instead, they are defined using the declarative syntax of OWL as they are stored in a web ontology.

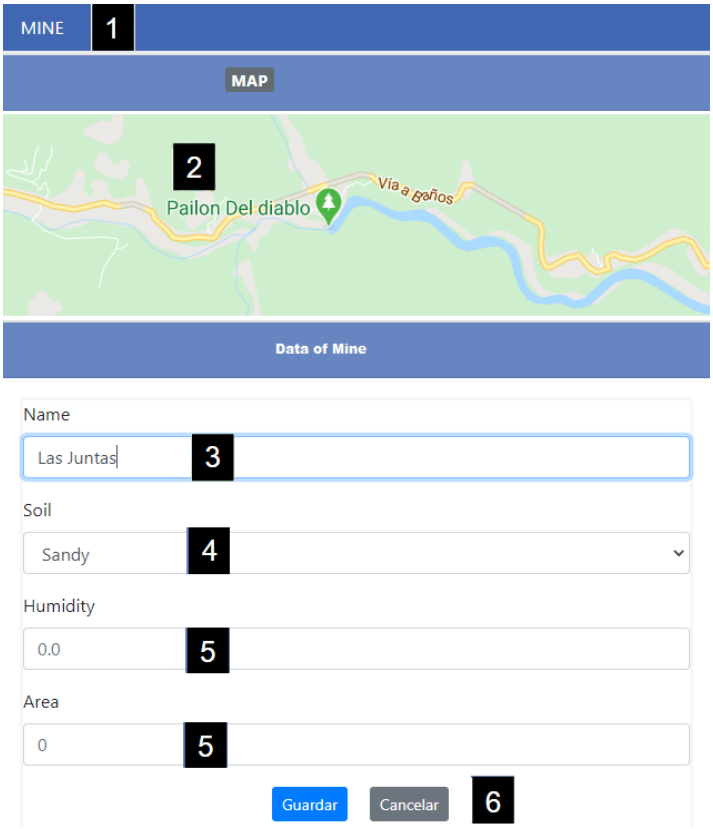

Figure 6: Sample of the prototype of data entry interface. (1) Title of the data view as defined in the instance of *ViewOnto*. (2) Interactive map component for the input of the location of new mine record. (3) Text fields for the input of the name of the mine. (4) Combobox field for the input of the type of soil of the mine. Valid values are specified in the instance of *ViewOnto*. (5) Text field for the input of humidity and area of the mine. Automatic validation of these fields restrict user input to numbers. (6) Buttons for saving and cancelling user data entry.

On the other hand, figure 7 shows the interface of the prototype when rendering information about observed mines. Location of the mines are rendered over a map canvas and the descriptors of the data view are shown in a tabular view. Each data view does not match necessarily with a table in the database. The amount of data views depends on the interests of the user. A list of related views is shown in the upper right corner of the interface when the options button is tap. The user may filter data per descriptor and he can show/hide descriptors, as well. Navigating to most related data views is possible by tapping buttons on the left side of each data row. In this case, it would be navigating to the ditches under study on a specific mine.

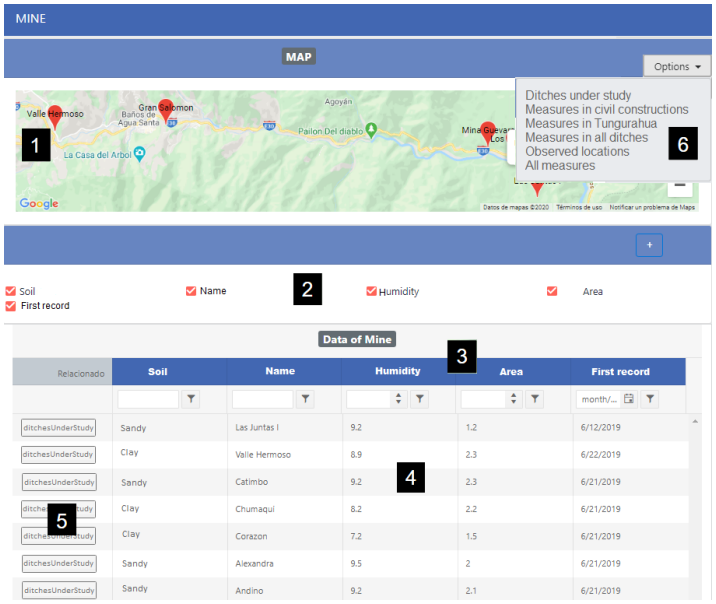

Figure 7: Sample of the prototype of report generator interface. (1) Interactive map component. (2) List of visible/hidden properties of the active data view. (3) Ordering criteria and filters applicable to each property. (4) Tabular data component. (5) Navigation access into related data views. (6) Links to other data views described in the instance of *ViewOnto*.

4 Analysis of Results

The experimental evaluation of the results show that it was possible to build a generator of data management tools. Whenever changes in the user interfaces would be needed, the code of the generator would not change. Only the instance of *ViewOnto* would be rewritten and, if necessary, the structure of the database would be modified. This way, the role of the programmer was changed. Instead of prescriptive programming, descriptive programming for coding the instance of the ontology and abilities on SPARQL and SQL are now on required for the maintenance of a generated data management tool.

This software was used for the deployment of a system for studying radon concentration. The user interfaces are automatically generated each time that the user requires to interact with the system. From the data model of figure 2, three data entities were managed in the space dimension, and two other data entities were managed in the time dimension. The navigation among *data views* was automatically generated taking into account the semantics of the *relationships* among data *views*.

The results were also assessed on an usability evaluation of the data management tool. Nielsen and Budiu suggest to have from 5 to 11 participants in a usability study [18]. Two experts in usability and three experts in the study of radon concentration participated in the assessment. All of the participants in this study have more that 15 years in the industry and 8 years of academic experience. In a first phase, the participants in the study were called for a virtual presentation on how to use the software. Then, all of the experts quantified the level of usability of the interfaces that the software would be able to generate. Their evaluation was made using Nielsen principles of usability [18].

Each expert determined if each usability principle was accom-

plished, not accomplished or not relevant. Their answers were anonymously collected. Then, feedback of the answers was given to the experts and a new qualitative analysis was carried out. A consensus on usability principles that were not relevant was found. A total of seven usability principles were considered as relevant for an ontology-based data management tool. Results were debated in a final public session of work and experts were asked to give a weight to each relevant usability principle. A Likert scale of 1-5 was used.

As a result of the study, it was found that experts agree that the interfaces generated with the software comply with high standards of usability. Table 2 shows a resume of relevant usability principles and the mean of the weight that experts gave to each of them.

Table 2: Results of the validating survey

Criteria	Mean value
I would use this tool	5.0
This tool seems easy to use	4.6
Using this tool, the understanding of data in the real world gets easier	4.8
This tool facilitates the control of the user over the data management process	5.0
This tool facilitates the user to freely manage data upon his needs	4.6
The options of this tool are clearly understandable	4.8
This tool is flexible and efficient for data management	4.8

5 Conclusions

This paper presented the implementation of an ontology-based data management tool. The semantic restrictions of the designed database were not enough but considered as a baseline guarantee for the integrity of managed data. Defining further semantic restrictions was necessary for building a data entry and report generator tool which adapts to changes in the semantics of data.

This data management tool 1) adapts to changes in the understanding of data, 2) dynamically integrates data in different measure units and 3) interprets the semantics of data for deciding its appearance in the user interface.

The space dimension of data views is expressed by its location on a map. On the other hand, the time dimension of data views is expressed by describing its nature -beginning, enduring and lasting of events-.

Both querying languages, SQL and SPARQL were necessary for communicating with the database and the ontology, respectively. Mapping the semantics with actual data in the data storage was possible by using the mappedTo property of the *ViewOnto* ontology.

Results were experimentally validated in the management of radon observations in the Ecuadorian highlands and experts expressed their acceptance of the usability of the tool. Using this generator in other scenarios is theoretically possible but, as future work, further research is needed in order to assess the capabilities of *ViewOnto* for expressing the semantics of managed data in other scenarios.

Acknowledgment This research was funded by the Research Project #PFICM019 "Arquitectura de Servicios Web Semánticos para la Integración de Fuentes de Datos Estructuradas de Proyectos Urbanísticos" of Universidad Técnica de Ambato.

Large companies

ABSTRACT

The main objective of this research is to analyze the impact that the implementation of a strategic plan would have on achieving the competitiveness of the micro, small and medium enterprises (MSMEs) that are dedicated to bottling, marketing and distributing water in the city of Los Mochis. It is intended to offer a tool to this type of company that allows them to be competitive against large transnational companies, which currently dominate the market. For this, a mixed methodology was used, presenting a descriptive-correlational scope with a non-experimental cross-sectional design; In which a population of 21 MSMEs was analyzed, through the application of a measurement instrument, to quantify the levels of competitiveness that they currently present. The results of the investigation showed a low performance in the competitiveness of these businesses, exposing similarities between their deficiencies, highlighting the mismanagement and ignorance of the economic environment in which they are found.

1. Introduction

Talking about the importance of the micro, small and medium enterprises (MSMEs) is essential to understand the economic growth and development they generate in the world and the positive impact they provide to the global economy, since they generate jobs, pay social security contributions, and also boost local economies; In the opposite case, the large transnational companies that, although they contribute the aforementioned, also return their profits to their country of origin. Likewise, according to [1], more than 99.8% of the companies in Mexico are micro, small or medium-sized, while in [2] it is indicated that MSMEs contribute 60% of the GDP of that country.

However, the low level of competitiveness that these small businesses present, represent into a relatively short life span, (since according to [3], only 25% of these companies survive the first 2 years after opening, while the average life span is around 7 years), in which they fail to compete with the large transnational companies. In other words, the vast majority of these small businesses fail and subsequently disappear from the market. That is why the need arises to offer tools and methodologies that, through interdisciplinary actions, allow MSMEs to achieve competitiveness in the area.

For the above, it is essential to understand the low competitiveness of MSMEs and the context in which they currently compete, as well as the critical factors that directly influence their low performance, and based on this, determine which strategies are the most appropriate in the design of the strategic plan, given the imminent crisis that threatens these small businesses with their disappearance.

2. Method and Materials

2.1. Type of investigation

According to the problem detected, it was determined that the research pursues a mixed route since, through both quantitative and qualitative tools, it aims to interpret the scenarios or contexts in which MSMEs are currently, understanding the importance they represent for the economy from any country.

2.2. Design and scope of the investigation

The situation for many MSMEs is critical, as they do not show any signs of competitiveness in the market in which they participate, compared to their direct competitors, therefore they do not represent any risk for large companies.

Therefore, this research presents a descriptive-correlational scope with a non-experimental cross-sectional design, on the implementation of a strategic plan in the region's MSMEs, since as in [3], it will be carried out in a period of unique time, trying to shorten the gap between the demand presented by the large brands of bottled water that operate in the region, and the micro and small companies that are dedicated to marketing a similar product. Also,

*Corresponding Author: Alan Ochoa, alanochoa1115@outlook.com

only those MSMEs that are dedicated to the bottling and marketing of water in the region will be taken into account.

2.3. Hypothesis

The information to formulate the hypothesis arises from the diagnosis obtained, as well as from the reviewed literature, which helps to suppose scenarios in relation to the results that will be obtained, and the significant contributions that the strategic plan will have to the competitiveness of the companies. MSMEs, as well as the adaptability that these businesses and their possible contexts may present.

That said, the following research hypothesis is established:

- Hi. The design of a strategic plan will allow small companies to become competitive with large companies.

2.4. Design of the instrument

The instrument used to measure competitiveness in MSMEs in the region was a questionnaire with a Likert-type scale, using the dimensions and indicators of the competitiveness map of the Inter-American Development Bank (IDB) for their reliability, in addition to being a tool widely used by other researchers according to the literature reviewed.

This instrument was used during the development of this research and according to [4], this tool was designed to specifically identify the deficient areas that directly influence the low level of competitiveness of MSMEs, and with this, develop corrective strategies that allow to significantly improve the competitiveness of the diagnosed company. The application consisted of a structured questionnaire used by [5] with a Likert scale, with a total of 103 questions focused on each of the dimensions and indicators established by the IDB competitiveness map.

In addition, according to [6], the Inter-American Development Bank has always contributed to the socioeconomic development of Latin America and the Caribbean, promoting research and supporting companies, which is why it is considered to be a fairly reliable tool, based on the experience of such an organization.

It should be mentioned that as in [7], the dimensions and their respective indicators according to the IDB Competitiveness Map are shown in the Table 1.

Table 1: Dimensions and indicators to measure competitiveness according to the IDB Competitiveness Map:

Variables	Indicators
1. Strategic planning	1.1. Strategic planning process 1.2. Strategy implementation
2. Production and purchases	2.1 Planning and production process 2.2. Process capacity 2.3 Maintenance 2.4 Research and development 2.5 Provisioning 2.6 Inventory management 2.7 Location and infrastructure
3. Quality Assurance	3.1 General aspects of quality 3.2 Quality systems
4. Marketing	4.1 National market: marketing and sales 4.2 National market: services 4.3 National market: distribution
5. Accounting and finances	5.1 Cost monitoring and accounting 5.2 Financial administration 5.3 Legal and tax regulations
6. Human resources	6.1 General aspects 6.2 Training and promotion of personnel 6.3 Organizational culture 6.4 Industrial health and safety
7. Environmental management	7.1 Environmental policy of the company 7.2 Strategy to protect the environment 7.3 Awareness and training of staff on environmental issues 7.4 Waste management
8. Information systems	8.1 System planning 8.2 Inputs 8.3 Processes 8.4 Outputs

Source: Own elaboration, based on Saavedra, Milla and Tapia [1].

Subsequently, once the vulnerable areas of these small businesses have been identified, a strategic plan will be made based on the comprehensive strategic management model [8], which allows them to take the necessary actions, so that they achieve competitiveness with respect to their major competitors.

2.5. Population

The population obtained for this research is 21 of MSMEs that are dedicated to bottling and marketing of water in the city of Los Mochis. Likewise, the unit of analysis for this research consists solely of the owners of said MSMEs, due to their knowledge in all areas and their authority to make decisions.

3. Results

The results obtained yielded some of the following data:

- Of the 21 MSMEs diagnosed, only 2 businesses acknowledged having used some type of strategic planning in the last 2 years, which represents 9.52% of the total companies analyzed, while 66.67% said they have never used strategic planning, running your business solely empirically, as shown in Figure 1.

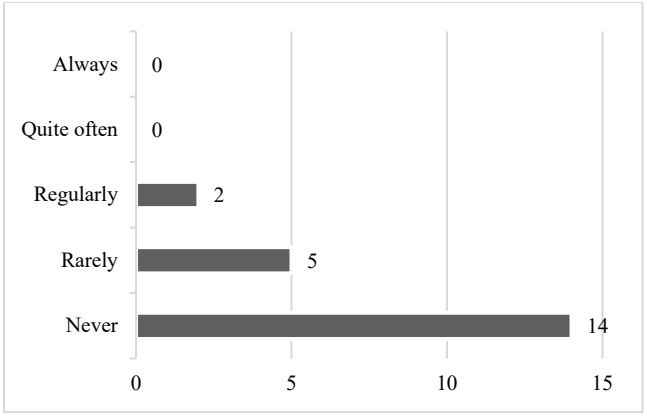

Figure 1: MSMEs that have used strategic planning in the last 2 years.

This indicates that the MSMEs considered for this research are usually empirically guided, so there is no basis in the decisions they make. This indicates that a series of actions can be offered with analytical support, on what actions to take and find the advantages of implementing them.

- From the same diagnosis, it was found that 61.90% never implemented a SWOT analysis to identify their strengths and weaknesses, or to better understand the environment in which they compete and their direct competition. A graph with percentages is shown in Figure 2.

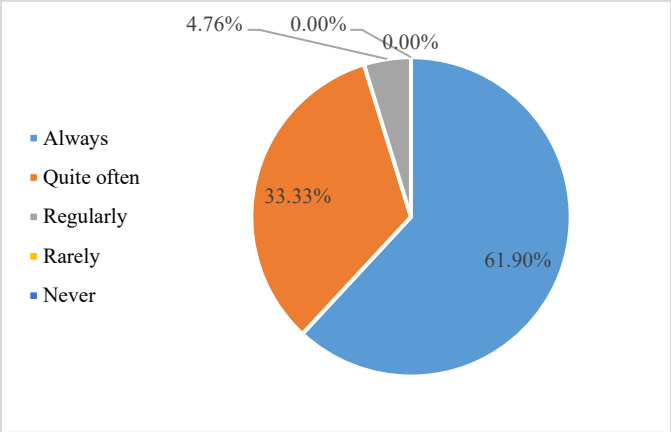

Figure 2: MSMEs that have used SWOT

This result shows that 13 of the 21 MSMEs do not know what their opportunities and threats are in the environment in which they currently compete, and they do not know the strengths they have, or at least not in an analytical and conscious way.

- A very important factor is the care of the work equipment, and in this sense, 17 of the 21 MSMEs admitted not to carry out preventive care to the production teams, which represent into 80.95% of the total of the companies studied. This percentage is expected to decrease to at least 50% since this point is considered to be extremely relevant, since without the production equipment in optimal conditions, the operation of the business may be affected in the short term. It can be seen in Figure 3.

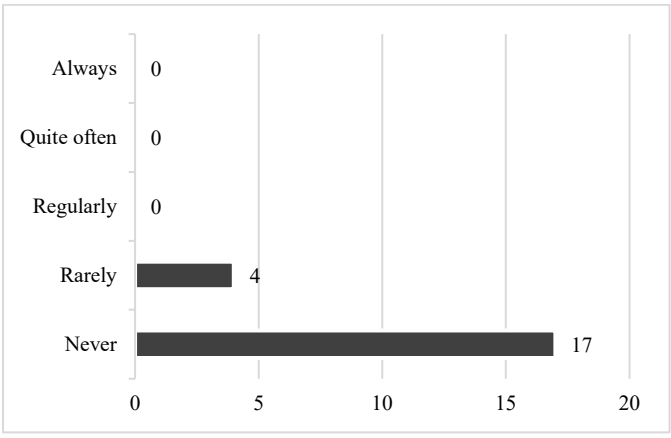

Figure 3: Preventive maintenance program for all equipment and machinery in MSMEs

Based on the previous graph, it can be seen that most MSMEs do not take optimal care of work tools, which will affect these businesses a lot, since the operation and production of the product depends on this.

- There is mismanagement of inventories by diagnosed MSMEs, since 76.19% of these businesses do not have a defined storage system, presenting rotation and shortage problems at very specific times, which significantly affects the image of these businesses. Likewise, the percentages of this item can be seen in Figure 4.

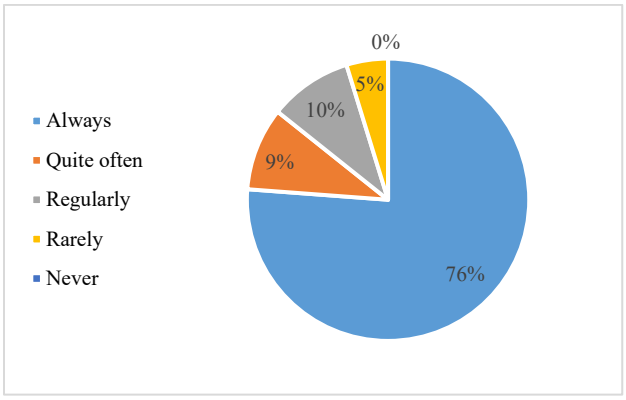

Figure 4: MSMEs that use management and administration systems in their inventories

One of the alarming results is that 16 of the 21 MSMEs diagnosed do not use or consider any inventory system to safeguard their products, which has led to shortages at some point. This can generate a negative image that severely affects MSMEs, so it is evident that it is necessary to generate a methodology for the storage of products, without having excess inventories.

- It was determined that the design of the strategic plan will follow the structure of the comprehensive strategic management model of Fred David and Forest David [2], since it is considered a fairly complete and adaptable tool, which can generate quite significant results for the achievement of competitiveness in MSMEs in the region. In Figure 5, each of the factors that make up the comprehensive strategic management model is shown in detail.

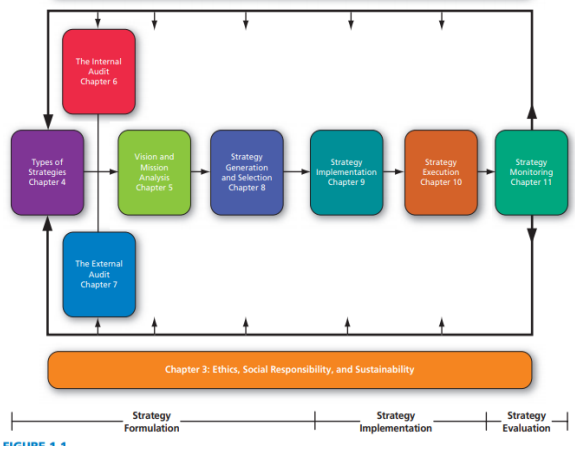

Figure 5: Fred David's Comprehensive Strategic Management Model
Source: Obtained from the book "Strategic Management A Competitive Advantage Approach, Concepts and Cases" [3].

In this model, it is possible to obtain a vision with much more clarity about the stages of the strategies to develop; starting from the type of strategy required according to the needs detected, to then formulate a series of actions and methodologies, on which an analysis of each will be carried out and select the most appropriate according to the context in which each of MSMEs.

Once the strategies have been selected, they are carried out, monitoring the results to obtain an assessment and adjust the strategies implemented according to the evaluation obtained.

4. Discussion

Based on the obtained results, the relationship determined by the hypothesis is accepted, which establishes that the design of a strategic plan will make a significant contribution to achieving the competitiveness of MSMEs with respect to their large competitors. Likewise, the data found so far, show an important relationship with respect to the results shown by [6] who point out that strategic planning has a significant influence on the organizational management of MSMEs and that it can increase their competitiveness substantially.

On the other hand, in contrast to what indicate in [1], who mention that the three strategies most used by family business entrepreneurs are to improve product quality, provide a pleasant service or through the development of a new product or service that is related to the image of the business that promotes a better perception among its consumers; However, the results of this research do not agree with the previously mentioned strategies according to the diagnosed analysis unit, who do indicate that it is imperative to improve the inventory storage and control system, since considerable losses are generated in certain periods of time.

Likewise, given the integrity of the strategic management model of Fred David and Forest David, this research is expected to be too beneficial for all those MSMEs that implement the strategic plan and are in search of achieving competitiveness.

5. Conclusions

The lack of competitiveness is something that has affected MSMEs throughout their existence, however, not having an action plan represents a disadvantage compared to their large competitors, which does not allow them to make better use of their own resources in a more adequate way, since the low performance of competitiveness is generated mainly by the ignorance of the owners themselves, to make smarter decisions or initiatives on strategies that allow them to have greater control of their business, and in turn, help them to extend their life time in the market and allow them to grow achieving greater competitiveness.

Currently, MSMEs in the region show almost zero competitiveness and with many areas of opportunity, since they present quite a few deficiencies, among which stand out the lack of care for their equipment, the mismanagement of inventories, in addition to the worrying ignorance they have of the environment in which they compete; However, if they manage to adapt effectively to the strategies developed, they will make better use of their resources and considerably improve their processes.

For local economies, MSMEs are extremely important since they generate jobs and improve the quality of life of many people, so it is essential to promote a more equitable market, in which MSMEs can compete against large companies, achieving a greater participation in the market and generating a significant positioning among consumers in the region.

Acknowledgments

A mention of gratitude is made to all MSMEs in the region, for their willingness to carry out this research, for their approval to carry out the measurement instrument, as well as the facilities provided to know their processes and their admission to implement the relevant strategies that are developed from the diagnosis obtained; Also, a special thanks is offered to all the people who influenced the development of this research.

Traffic Flow Analysis
Traffic Congestion
Traffic Occupancy

ABSTRACT

This research describes new traffic congestion analysis method "Traffic Congestion Triangle" based on more than one month real traffic big data analysis in India. The location of the research is one of typical economical growing cities Ahmedabad in Gujarat state of India. The traffic congestion becomes more serious issues in most developing countries and the congestion causes so called negative impact of environment destruction, un-necessity fuel consumption, health problem, economical loss and fatality by traffic accidents. Therefore there are lots of challenges for transportation under many projects focused on "smart city" development. The traffic analysis and theory have been developed after 1950s and it has helped many countries. However there are still lot of unknown condition in traffic analysis of developing countries.

This research started from 2015 and it enables to get real traffic flow data. This manuscript is described not only the typical traffic flow characteristics such as daily traffic volume but also introduces unique traffic congestion characteristics by using "occupancy" which has triangle shape characteristics as traffic congestion daily trend.

1. Introduction

This study shows new traffic congestion analysis in one of typical mega city in India. In general, it is hard to make traffic analysis especially in development countries where there is economical difficulty for infrastructure improvement under higher demand of transportation by strong economic growth. Author has a chance to proceed traffic management system deploy in Ahmedabad city of Gujarat state of India since 2015 by Japan International Agency support program for the reduction of traffic congestion. The traffic management system consists of 14 traffic monitoring Cameras along their main streets and traffic condition indication by the 4 electric sign boards so called Variable Message Sign or VMS board in the city. In terms of Ahmedabad city, the population of the Ahmedabad is about 6 million [1] and the number of four wheelers is 2.6 million, that of two wheelers is 15.8 million in 2018 [2]. The four wheelers growth rate is 65% compared with in 2010. And Ahmedabad is an economic and industrial hub of India and is the largest city in Gujarat stat. Therefore there are heavy traffic congestion and local government Ahmedabad Municipal Corporation faces sever condition for urban transportation management.

The traffic congestion analysis itself has been established in traffic theory by several report recently based on real traffic flow observation [3, 4]. From those related study, the traffic congestion is annualized by traffic flow parameter such as traffic volume, traffic density, traffic speed, and traffic occupancy. In general, the traffic congestion is detected from the traffic speed because the drivers feel slow traffic by their driving speed itself. But there is some cases traffic slow movement under slow traffic speed but it is not under congestion. Therefore it is difficult to define its traffic congestion between human feeling and physical vehicle occupation on the driving road. From those related studies, it is not enough to use just one traffic parameter like vehicle speed, or traffic density etc. In another word, it is necessary to manage multiple traffic parameter for understanding traffic congestion and it becomes more important especially for the developing countries. In [5], the author has analysis traffic congestion by using traffic density and space headway parameter but the measurement is only four days in Chennai in India. And M.Goutham and B.Chanda shows vehicle probe data in terms of traffic service by traffic volume and speed in Hyderabad of India based on Indian Road Standard IRC-106-1990 [6].

In this study, the fundamental traffic flow characteristics from one month measurement in the city of India is shown compared with the traffic flow theory and how it is difficult to analyze for its traffic congestion condition. Then it focuses on traffic volume and traffic occupancy relationship as the traffic congestion parameter

*Corresponding Author: Tsutomu Tsuboi, 29-1 Mentoku Shinoda Ama Aichi, +81-902738-3496 & t_tsuboi@nagoya-denki.co.jp

and proposes "traffic congestion triangle" from this relationship as the new traffic congestion parameter.

2. Traffic Congestion Theory and Measurement

In the traffic flow theory, there are three major characteristics as the fundamental traffic flow characteristics. One is traffic density (k) to vehicle speed (v)—$k-v$ curve. The $k-v$ curve shows the typical traffic condition instinctively. When the traffic becomes crowded, the vehicle speed is reduced and one of typical observation model is Greenshields equation [7]. The second one is traffic density (k) to traffic volume (q)—$k-q$ curve. The $k-q$ curve explains the traffic flow relationship between physical road length (vehicle number / km) and time scale (vehicle number / hour). The third one is traffic volume (q) to vehicle speed (v)—$q-v$ curve. Those three characteristics are so called the traffic flow fundamental characteristics of the traffic flow. The next section explain the traffic congestion condition by using this theoretical traffic flow characteristics. And then it is compared with the traffic theory and the result of actual measurement in the city of India.

2.1. Traffic Flow Theory

Based on the traffic theory, Greenshields equation is given by Equation (1).

$$v = v_f\left(1 - \frac{k}{k_j}\right) \tag{1}$$

v_f : free speed

k_j : jam traffic density

And the relationship between traffic volume (q) and traffic density (k) is provided by Equation (2) by traffic flow conservation law [8].

$$q = k \times v \tag{2}$$

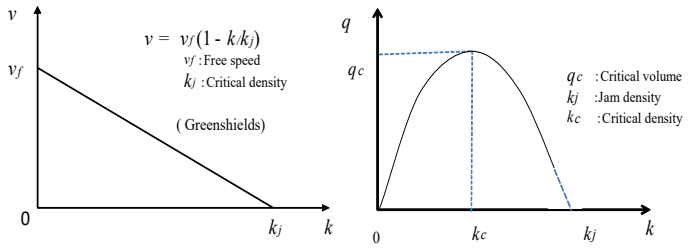
From Equation (1) and (2), Equation 3 is taken,

$$q = v_f\left(1 - \frac{k}{k_j}\right)k \tag{3}$$

Then Equation (4) is taken by transforming Equation (3).

$$q = -\frac{v_f}{k_j}\left(k - \frac{k_j}{2}\right)^2 + \frac{v_f k_j}{4} \tag{4}$$

From Equation (1) and (4), the $k-v$ curve and $k-q$ curve are shown in Figure 1 (a) and (b).



(a) $k-v$ curve (b) k- q curve

Figure 1: Fundamental Traffic Flow Curve

In terms of the traffic congestion from the traffic flow curve such as $k-q$ curve, the traffic congestion area in the graph is shown in Figure 2.

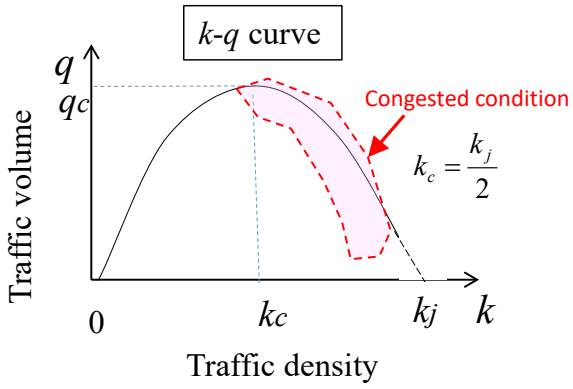


Figure 2: The traffic congestion area in $k-q$ curve

The traffic congestion occurs after the critical traffic density (k_c) and eventually its traffic volume declines from this point. After reaching traffic jam density (k_j), the traffic volume becomes theoretically zero. In case of the $k-v$ curve, the traffic congestion is located between k_c and k_j as shown in Figure 3.

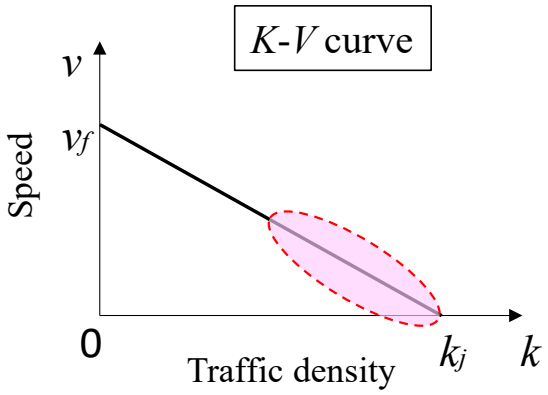

Figure 3. The traffic congestion are in k – v curve

2.2. Traffic Flow Measurement

In this research, the measurement field is used in Ahmedabad City of Gujarat State in India, where is one of big city in the state as mentioned in introduction. The traffic data is collected by 14 CCTV monitoring Cameras which are installed in the west side of the city as shown in Figure 4. In Figure 4, Camera#1 means CCTV number 1 and Camera#1 has one CCTV with pole on the street. The VMS#1 means VMS (Variable Message Sign board) number 1 and it also has CCTV with Traffic Sign board. The traffic data is measured by the CCTV and measures traffic flow data such as number of vehicles, average vehicles speed, traffic density. The traffic flow data was collected in June 2015 one month data by every minutes. The total traffic flow data for each CCTV becomes more than 40,000 points and author took 11 Camera data through Camera number 1 to 10 and VMS number. In this paper, we take eleven CCTV data because VMS#1 and VMS#2 data are missing during measurement by communication network error. In this traffic flow observation by traffic monitoring camera, we use

major road traffic flow monitoring because the condition of intersection is different traffic flow with traffic signal and pedestrians. The intersection analysis is our next study.

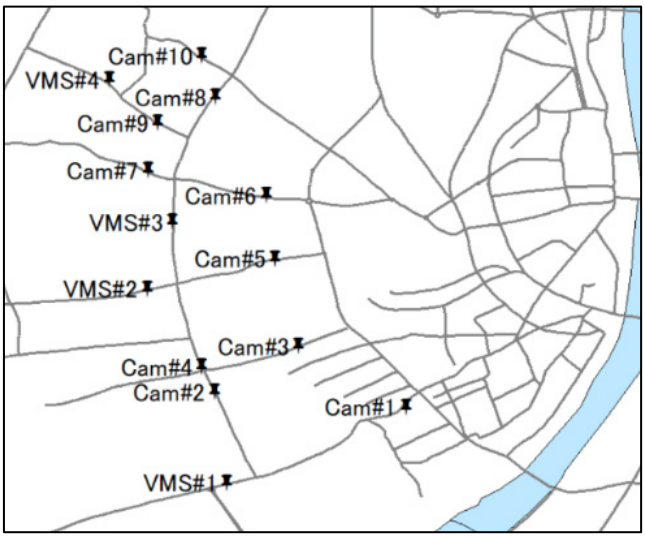

Figure 4: Traffic monitoring Camera location in Ahmedabad city.

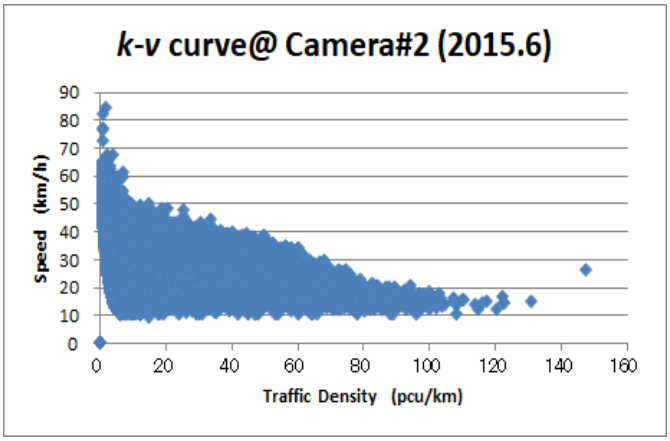
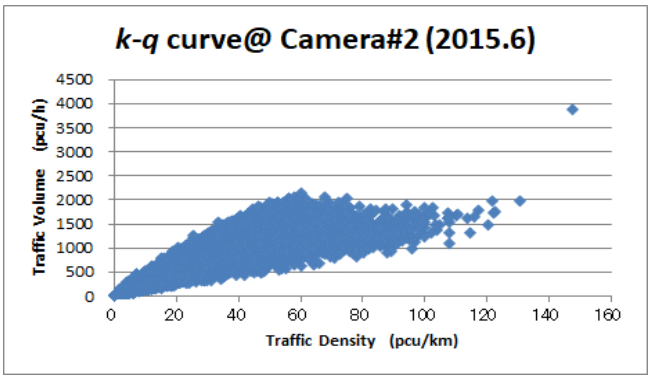
Among the result of measurement point, it takes the traffic flow data from Cameraera#2 in June 2015. The $k - v$ curve and $k - q$ curve are shown in Figure 5. Each data in Figure 5 shows generalized data by lane. In case of Cameraera#2 road, there are two lanes.



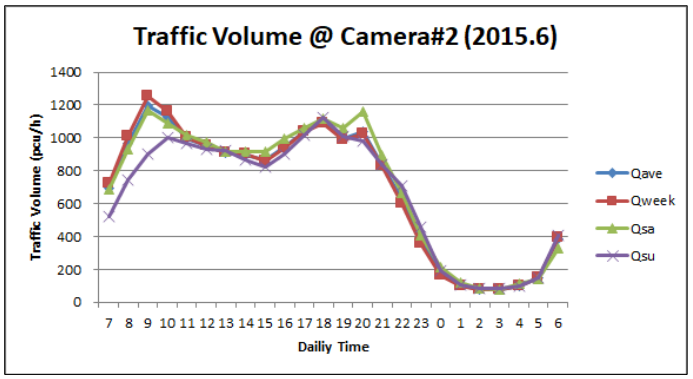
(a) k – v curve



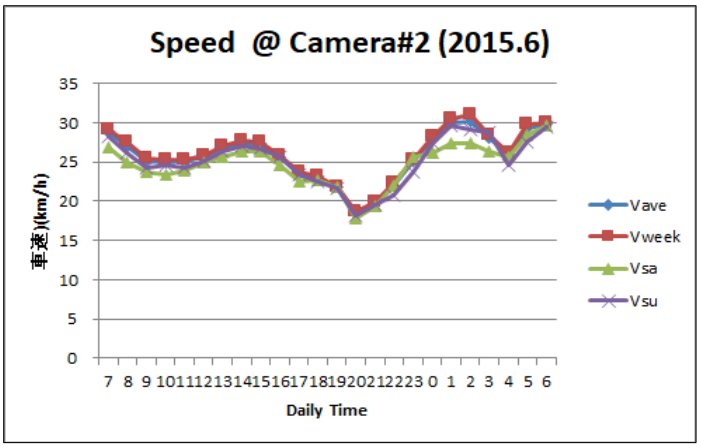
(b) $k - q$ curve

Figure 5: The measurement result of the traffic flow characteristics of Camera#2

From those two graphs, it is hard to define where traffic congestion point is. Therefore, the daily traffic condition observation is shown in Figure 6 as daily basis traffic volume change and vehicle speed change from 7:00 am to 6:00 am next day.



(a) Traffic Volume daily basis change at Camera#2



(b) Vehicle Speed daily basis change at Camera#2

Figure 6: Traffic Flow Daily Basis Change at Camera#2

From Figure 6, it is clear that the evening time from 19:00 to 21:00 is most congested time zone because the vehicle speed is quite low (10km/h) than that of other time zone. But it is hard to know this condition from the traffic flow characteristics. In the next section, one of other traffic flow parameter is introduced to define traffic congestion condition.

3. Traffic Congestion Parameter

There are several traffic flow parameter such as occupancy, headway, and gap in the traffic monitoring data. Among those parameter, the occupancy is one of parameter which shows traffic condition. In this section, the occupancy parameter is described and it shows the relationship between occupancy and traffic volume. And after this, it is introduced new traffic congestion parameter "Traffic Congestion Triangle".

3.1. Occupancy (OC)

The occupancy is one of traffic flow parameter to explain how vehicle is congested on the road how much vehicle occupies their road. From traffic flow theory, (OC) is defied by Equation (5).

$$OC = \frac{1}{T}\sum_i t_i \times 100\ (\%) \tag{5}$$

where T is time of measurement, t_i is detected time of vehicle i.

When number of existing vehicles a certain section is N, average length of vehicle is $\bar{l}$, Equation (6) is given.

$$OC = 100\frac{q}{v}\bar{l} = 100\ k\bar{l} \tag{6}$$

Therefore occupancy (OC) is proportional to traffic density (k) and traffic volume (q).

3.2. Relationship between Occupancy and Traffic Volume

From the one month measurement data of Camera #2 in June 2015, traffic volume (q) to occupancy (OC) relationship are shown in Figure 7. According to Figure 7, the relationship between (q) and (OC) is proportional and the number in the graph shows daily O'clock time such as 22 means 22:00. All the data is used from average from all time zone.

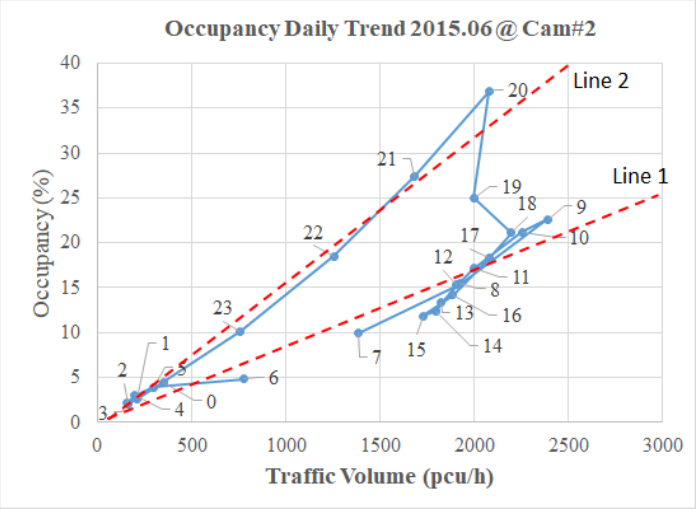


Figure 7: The Relationship between Traffic Volume and Occupancy at Camera#2

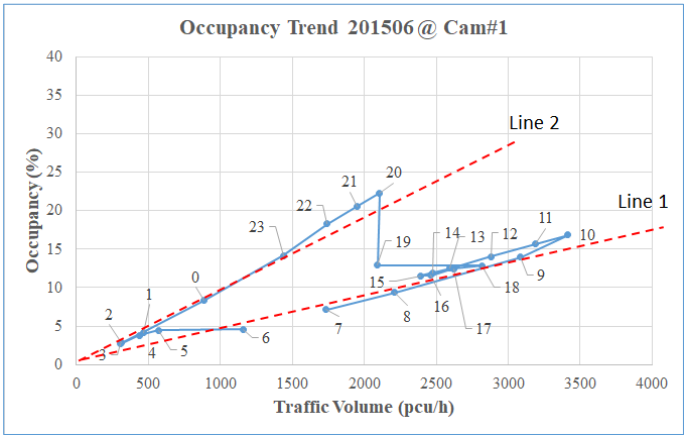

Figure 8: The Relationship between Traffic Volume and Occupancy at Camera#1

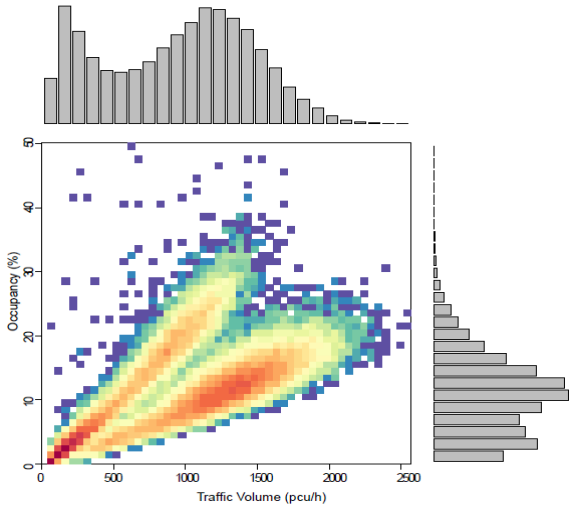
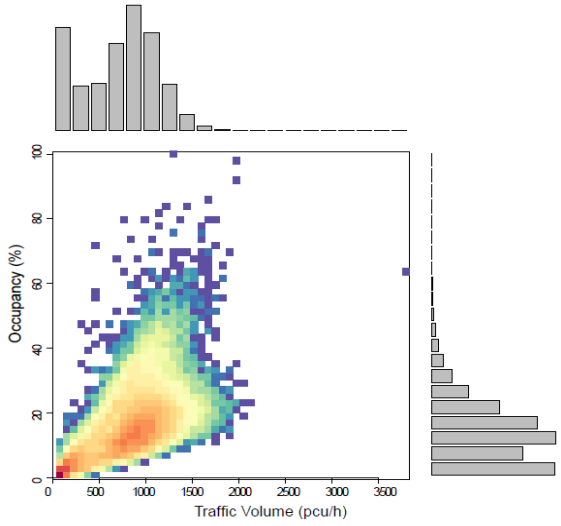
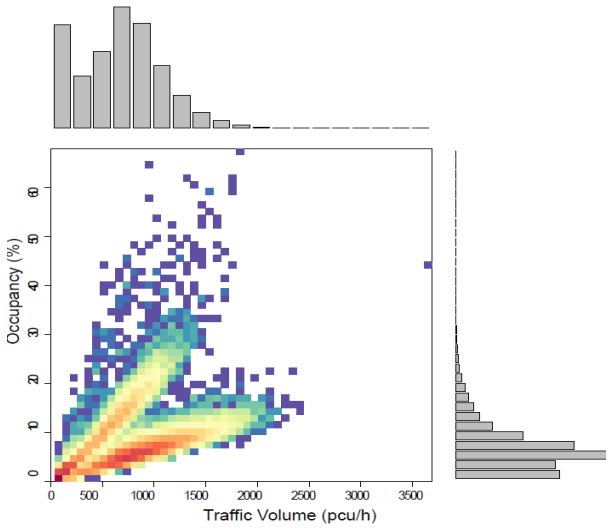
From Figure 7, there are two types' lines which indicate the different growth ratio of the occupancy to the traffic volume. The Line 2 is large growth ration than that of the Line1 and the Line 2 starts from congested time zone from 20:00. The occupancy level



(a) 2D Histogram between traffic volume and occupancy at Camera#1



(b) 2D Histogram between traffic volume and occupancy at Camera#2



(c) 2D Histogram between traffic volume and occupancy at Camera#3
Figure 9: 2D Histogram between traffic volume and occupancy

is more than 30%, which means heavy congested condition as seen in Figure 6 (b). From this observation, there are two types of traffic congestion scenario like light traffic congestion by Line 1, which occurs normally in the morning and heavy traffic congestion by Line 2, which occurs normally in the evening. From our measurement records in June 2015, the traffic condition at Camera#2 is most congested than that of other locations. So, when it takes the case study of Camera#1, Figure 8 shows the relationship between the traffic volume to the occupancy. The occupancy value is lower than that of Camera #2, which means the traffic congestion at Cameraera#1 is smaller than at Cameraera#2.

3.3. "Traffic Congestion Triangle"

In the section 3.2, it takes the average value of each traffic volume and occupancy in June 2015 record. In case of the analysis from the total measurement, 2D histogram graph shows that of Camera#1, Camera#2, and Camera#3 in Figure 9. From Figure 9, each distribution of traffic volume and occupancy of Camera are different. In Camera#1 and Camera#3, it is clear two batches, which means there is clear traffic congestion condition between Line 1 and Line 2 in Figure 8 and Figure 10. On the other hand, there is not clear data batch between traffic volume and occupancy in Camera#2, which means Camera#2 area is relatively congested compared with Camera#1 and Camera#3. This is also able to explain by daily bases traffic volume and vehicle speed characteristics in Appendix Figure A. The vehicle speed of Camera #1 and Camera #3 is not so much drop during most congested time frame between 19:00 to 21:00.

As the observation of the relationship between the traffic volume and the occupancy, it is able to define the new traffic congestion parameter which illustrates as "Traffic Congestion Triangle" in Figure 10. The graph in Figure 10 is based on the measurement analysis at Camera #3. We have similar "Traffic Congestion Triangle" characteristics in other camera locations. Therefore this "Traffic Congestion Triangle" characteristics is common traffic flow characteristics in Ahmedabad city and it shows two types of traffic congestion trends in the morning and in the afternoon.

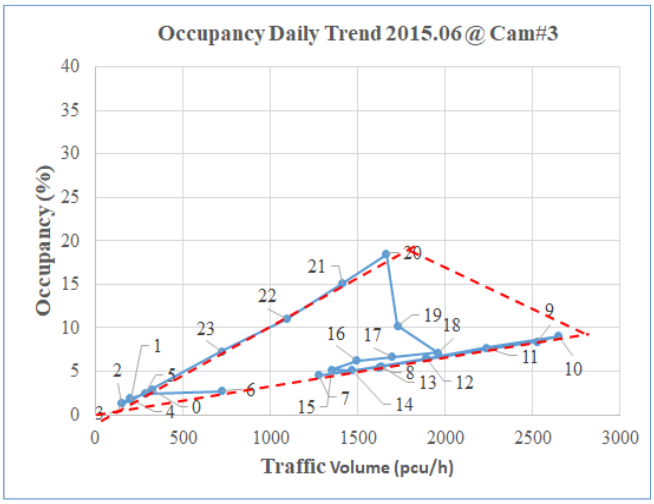


Figure 10: Traffic Congestion Triangle Concept

When we collect the traffic volume and the occupancy at each road in particular month, it is able to create the "Traffic Congestion Triangle" from the relationship between their average traffic volume and the occupancy daily basis. Then the "Traffic Congestion Triangle" line shows the occupancy growth ratio in daily basis traffic flow condition. According to our other observation analysis, we have similar trend of characteristics.

4. Conclusion

This study focuses the traffic congestion analysis in the developing countries, especially in India. And based on one month actual traffic data collection in one of typical major city of India—Ahmedabad—where its population is about 6 million, author creates new traffic congestion analysis parameter "Traffic Congestion Triangle". This "Traffic Congestion Triangle" is able to indicate when and how the traffic congestion occurs in the city. And it shows there are two types of traffic congestion—high traffic destiny congestion(line1 in Figure 7,8) and low traffic density congestion (line2 in Figure 7,8). When we have this traffic congestion triangle at each road, it is easy to understand what kind of congestion occurs. However from this characteristics, it still does not provide solution how to reduce its traffic congestion. We only know its current condition.

We use one month data in June 2015 and the each item data becomes 43,200 (= 60 min use 10 traffic monitoring Cameras at main roads in the city and its traffic data is collected by very minute as traffic density, veh. × 24 hours × 30 days) points. After the detail traffic congestion observation, it is successful to show the unique relationship of traffic parameter between the traffic volume and occupancy. There are two patterns of occupancy growth ratio to the traffic volume in the morning and in the evening. According to all location traffic data analysis in Ahmedabad, the growth ratio in the evening is larger than that in the morning, which means its traffic congestion occurs in the evening time from 19:00 to 21:00. In the traffic volume to occupancy graph, those slope of two lines and the line between these two lines build the triangle shape, which it is defined as

"Traffic Congestion Triangle" parameter. The members of "Traffic Congestion Triangle" indicates each traffic congestion condition. Therefore when the traffic volume and occupancy are detected, it is able to estimate how traffic congestion occurs and when its congestion goes to more crowded or smooth.

This study is based on June 2015 traffic data. So it is necessary to continue collecting and observing at all location such as whole year traffic data measurement. It is also necessary to check other major city case study at least in India and confirm that the "Traffic Congestion Triangle" is valid to other developing countries in future work. It is also important to analyze the intersection point in terms of traffic congestion in future.

Conflict of Interest

The authors declare no conflict of interest.

Internet

ABSTRACT

This paper comprehensively focused on the information systems for purchase process optimization (IS) that are currently being used. It elaborates four crucial and important areas in relation to purchasing and supply management. These includes; Identifying the process involved in purchasing, how information systems are implemented and used in enhancing the supply process, understanding the key features that constitute enterprise resource planning, purchasing database and electronic communication between customer and supplier, how Enterprise Resource Planning (ERP) system facilities and improves effective communication in managing supplier selection process and lastly describing the future requirements of electronic purchasing system that will enable transparency, visibility and accessibility of information across the overall supply process. The parameters effectively enable optimization of purchase process. In today's era where Internet is accessible, the most thriving firms are those that are in-step with the fast pace of technological revolution. Currently, there are more high-end devices at the finger-tip of the customers, which has significantly enabled customers and many business firms to prefer executing transactions on their portable devices instead. The available technologies such as ERP system has opened an effective growth path for firms to stay competitive and relevant in the market.

1 Introduction

Technology is evolving rapidly and purchasing products are ongoing around companies/industries, therefore it is key that supply management is enhanced to develop business around the globe with and through the help of Information System (IS). Information Technology (IT) systems have exponentially increased and enhanced marketing technique and purchasing process for buyers (companies and individuals) and seller of products. Users of knowledge systems have progressively found themselves as customers of multiple technology vendors, this IT procurement method assumes bigger and vital management. In light of the upward trend of technology, IT system has or will become must-have for every company that is planning intending to compete for customers, this because we are in an era in which customers are constantly demanding fast service from service providers. Therefore, for companies to thrive in this ever growing technology age, they must change with rhythm to meet user demand.

In recent years, the world's economy at large has become increasingly competitive. It has practically become an ineffective and unsustainable approach for firms to sustain the upward competitiveness in the market and further returning profits margins for investors through a frequent increase in product cost. Instead, firms must integrate and harness the premise of product innovation to achieve and deliverer higher quality, and quicker response times or performance, while continually maintaining the minimum unit cost [1, 2].

Suppliers are very crucial in making firms competitive, by providing firms with products that meet user demands [1]. The impact of integrating IT in purchasing process or supply management has a great influence on every firm's competitive ability. In [3], a piece empirical information was collected from a total of 108 Taiwanese firms was studied and interviews with four active managers were carried to collect the sensible insights of the theoretical framework of e-procurement and provide chain performance.

According to [3–5], information sharing and supply chain integration allow a strategic viewpoint when implementing e-procurement systems intended to improve supply chain performance. This project will be sharing new ideas on how a new technology channel is making a difference in purchasing and supply management. Therefore, more discussion and discoveries will be made in relation to the information system in place used for purchasing

*Corresponding Author: Pearl Keitemoge, & Email: pkeitemoge@gmail.com

process currently. It is with the new technologies that new strategies are emerged to impact both organization and individuals on their ways of purchasing and supply of goods. The business can simply grow spontaneously from their lowest profits to a higher one with the aid of the information technology systems in place.

1.1 Purchasing Process

Entails the stages that any organization or business that want to obtain services and goods for the productivity of the business defined as the purchasing process. The author in [6] concisely explained procurement practices as principal activities designed and undertaken by an organization to aid promote and facilitate effective management across the organization's supply chain.

The stage differs based on the specific need of every business or organization. The process becomes completed after specifications have been developed, a buying team monitored and cooperating with the supply manager will select suppliers, generate the request for proposals, evaluate the proposals and select a supplier based on established selection criteria [1, 7].

It is therefore extremely important that all necessary supply chain information should be readily available to all companies involved, and the business process should be structured in a way that allows the full access to the available information. This information will be utilized in the purchasing process. There main aim of every firm is to maximize profit and minimize loss, therefore procurement performance very important dependent on many factors as indicated in [8,9] by Figure 1. Assessment of procurement performance helps organizations to reduce cost, enhance profitability, assured supplies, quality improvements and competitive advantage [6]

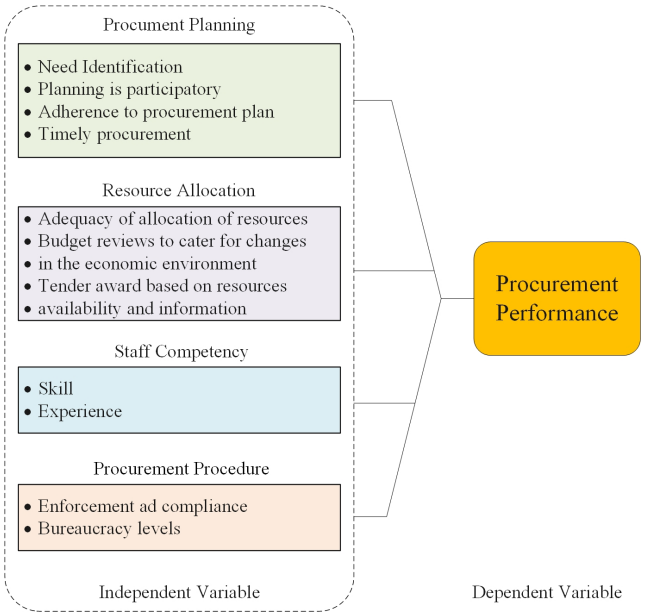

Figure 1: Framework for Procurement Performance [9]

Figure 1 shows and indicates that procurement performance is very sophisticated and it linked to many other parameters such as procurement planning, resource allocation, staff competency, and procurement procedure.

The practice-based commentary outlined both cases of success and failure of firms in relation to the implementation of IS in the purchase process. In light of success, Wal-Mart adopted the implementation of IS in some sections of purchase process, namely, materials management, product ordering, and inventory-tracking through Radio Frequency Identification (RFID) Tag, this adoption enabled the firm to have real-time information in light of demand forecasting as a result of RFID-based inventory management, this eventually lead effective inventory turnover and mitigated inventory costs. The firms' adoption IS applications have thus supported and made it possible for the company's cut cost on the purchase process.

Concerning failure, Nike invested $100 million in the deployment of purchase process IS software but failed handle or prevent significant inventory shortages leading to larger unmet demand, this is due inadequate and inefficient planning for application integration with its existing supply chain objectives [10]. These examples clearly outline the importance of firm's purchase process managers to pay close attention in aligning information systems that are deployed in the purchase process system with the goals and objectives of the purchase process itself [11].

In this section, we examined in detail the Purchasing processes, which includes the product requirement, good delivery, payment, supply management, management of purchasing effectively, suppliers evaluation and selection, review specifications and the awarding of the purchase contracts.

1.2 Purchasing types

Purchasing is defined to be a company/organization or individual paying for goods or services in order to accomplish business or personal defined goals [12].

Personal: This is the system of individual buying products or services for their personal use. They do not engage any third party to negotiate the prices and make selections on the supplier.

Mercantile: The purchasing that is facilitated by the middleman. Retailers and wholesalers are found under this type. They arrange their own channel of distribution of products to their customers.

Industrial: This is the system of buying raw materials to later produce finished products. The materials and necessary tools needed to produce products are also purchased here.

Government or institutional: Buying in bulk for government departments and institutions. Governmental purchases have a high level of bureaucracy and decision making concerning the product.

Table 1: Economic Contribution and Dependency

Purchasing type	Contribution on the economy	Level of dependency on the economy
Personal	Low contribution	Highly dependent
mercantile	Medium contribution	Low dependency
Industrial	High contribution	High Independent
Government	High Contribution	High independent

The Table 1 shows the contributions and how dependent each different purchasing types have on the economy of a country.

The Figure 2 shows the bureaucracy prism for all the abovementioned types of purchasing from bottom to top. The bureaucracy

exists because of the complex leadership structure embedded in each type.

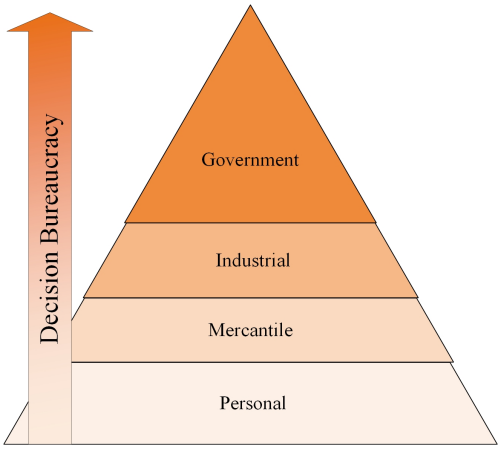

Figure 2: bureaucracy prism

Much of the procurement bureaucracy can actually be eliminated by the implementation of the information system and enhance effective firm data handling and management, especially simple decision which will directly increase productivity.

2 Identifying the Process Involved in Purchasing

Knowing the processes involved in purchase process is crucially important to establishing an effective and productive supply chain management across any firm. These are stages that defines the product requirement, product size, product safety, performance and necessary maintenance requirement, payment and delivery method and supplier selection strategy and requirement.

2.1 Product Requirements (specification)

Before defining or selecting product requirement, the business firm must identify the task product that they will be handling, usage environment, workload and lifespan of the product.Defining some of these parameters can be very daunting and almost impossible, task type can easily be specified but not future environmental conditions. Information technology is helpful in the defining of product specification, the future workload can be approximately specified or predicted using current machine learning algorithms such as neural network, multi-linear regression and other existing predictive analysis algorithms. Product requirement is vast includes functionality, computer application user interfaces, communications, reports, customer services, user help manuals & self-help tutorials, service delivery staffing licensing/certifications Product requirement parameter can also vary according to the kind of product that is required. The basic but most important parameter are discussed as in Figure 3;

A well-defined product requirement is very important. If these parameters are not defined properly it subsequently slows the product design and development phases by having to define and re-clarify objectives and requirements and this also increases production costs due to change requests caused by having to fix execution errors or omissions.

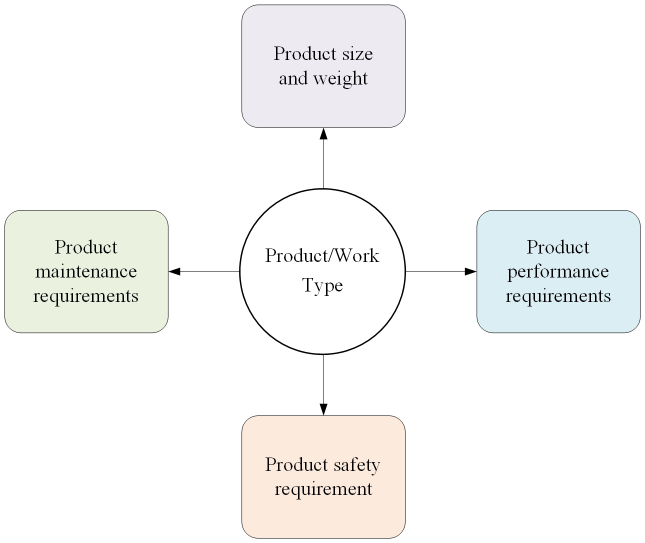

Figure 3: Basic Product Requirements

2.1.1 Product size and weight

The customer will provide the firm with the size of the product they need. In an organization size also is needed to add to the specification of the products.

2.1.2 Product performance requirements

The performance requirement provides the firm with operational details. How fast, often and slow the product will be when used. Other things to consider are the shelf life of the product, the power requirements, and the service life.

2.1.3 Product safety requirement

The safety requirements of a product are the potential sources of liability. Identifying these in the specification process enables suppliers to a provide possible solution to the sources such as potential operational hazards, manufacturing and assembly hazards. These hazards directly have an effect on the product life span.

2.1.4 Product maintenance requirements

This sort to find out if the product can be maintenance-free? If routine maintenance is required, can it be done by the owner/operator? Will professional maintenance be required?

Well defined product requirement is very important. If these parameters are not defined properly it subsequently slows the product design and development phases by having to define and re-clarify objectives and requirements and this also increases production costs due to change requests caused by having to fix execution errors or omissions.

Technology is making the requirements available to the supply via the systems that are availed to the supply to aid the collection of information on the product. If companies employ and integrate information system into these phase of product procurement and facilities quick and fast exchange of this information between the suppliers and customers.

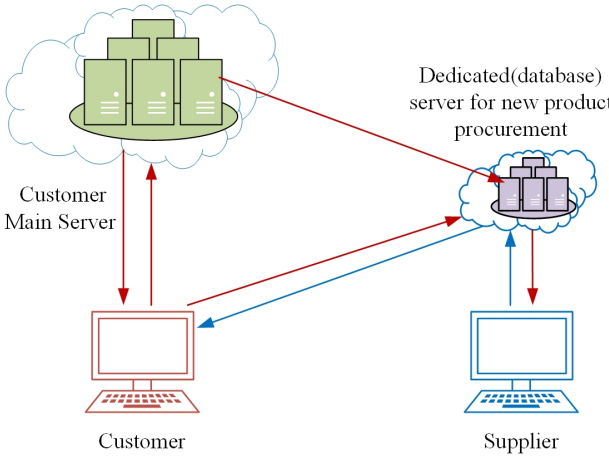

Figure 4: Product Requirement and Information System Workflow

Figure 4 shows a quick and simplified view of information flow when the information system is integrated into the procurement process. The customer can grant the supplier access to a dedicated database server for a specified project or product server. With this access, the supplier can have quick access to the product requirement information, the supplier can also give suggestion and comments (as indicated by the blue arrow) on the product quick before product manufacture commence. Any suggestion indicated by the supplier are reviewed by customer and if suggestions are viable, the changes are then updated to the main server and confirmed to the dedicated product databases server. Using the information system, process speeds up thus avoiding unnecessary delay in the procurement process of the product. The first aspect of purchasing is for the business to identify the product that they will need and provide a detailed specification.

The product or service type needed by any business entity can either originate from the manager's recommendation or collective customers demand. Technology is used in the stage by collecting the specifications of service or goods electronically and the information is later captured into a computer for processing and used in the next stage. Frequent communication between the customers and suppliers is done by the emails. The detailed specifications are compiled and captured into forms in the computer application programs for easier access by other key role players. Hence, improving communication and reduces the design complexities that add more cost to building cost specification [1, 13]. Sharing of information real-time is also crucial because the shrinking product lifestyle and the competitive advantage often reduces time to market [1, 4, 7].

2.2 *Evaluation and Suppliers Selection*

In this purchasing process stage, the team supplier receives the proposals and prices and selection is made based on who is able to guarantee quality assurance and competitive price of the products. The team also review the product requirement specified by the suppliers to cross check with the stipulated need of the company and the individuals. A review of different requisitions may also reveal that different users actually require the same material [14]. By combining the purchase requirements, purchasing can often achieve a lower total cost. The team also evaluate the suppliers based on the capability of the supplier. Comparing the place of the distribution of the supplier, global versus regional and local.

The supplier selection factors considered by firms include but not confined to the supplies team size, the supplier public evaluation or rating, supply risk level, manufacturer versus distributor. Supplier evaluation can be a rigorously daunting task due parameters factors come to play, such as price competitiveness, ability to fulfill expected product delivery time, budget optimization. All procurement expert or manager must know the thorough or effective evaluation will result in the proper selection of suppliers. Making a decision requires a wide consideration of all possible alternatives and then choosing the appropriate and optimal supplier (OpS). According to [15, 16] selection process considerably relies on both the subjective and objective judgment in different areas. The different areas include (1) inter-connected criteria definition: for both qualitative and quantitative (2) criteria conflict: leading to conflicting objectives of the criteria (3) involvement of several alternatives: due high competition (4) internal and external constraints: established and imposed on buying process [16].

In [17], through extensive review and professional interviews, the author established three key factors for supplier selection measure. He further proposed that underlying the documented suppliers criteria is the reason rate supplier effectiveness in terms of quality and repair capabilities and control alignment with the purchasing firm [17]. Another author in [18] also established an integrated model by merging the analytical hierarchy process and grey relation analysis for a single evaluation model. Unavailability of precisely needed or complete information intrinsically increases the difficulty of any decision making. Therefore, most experts in the procurement arena agree that there is no one-for-all confined strategy or method to perform evaluation and selection of suppliers, and organizations use several different approaches in order to obtain optimal selection [19] such as cost, maintenance, product life cycle as illustrated in [20, 21].

Regardless of the selected approach, the overall objective of the evaluation process should aim to reduce know or perceive procurement risk and maximize overall value to the purchasing firm. IT system can be utilized by purchasing firm to ease the supplier selection process and evaluation criteria that cannot be biased. Accessing all needed information from all the potential suppliers using the traditional method is not an easy task and this subsequently delays the supplier selection process. Information system integration aid fasts forward this stage of purchasing process instead of using the

traditional method of scheduling and arranging several long hours in meetings with all potential before deciding whether the supplier meets firm's requirement or not.

2.2.1 *Effective Data Collection*

Firms that considerably invest and implements modern technology (information system) is at an added advantage of accessing all necessary information from all potential suppliers ($s1, s2 \ldots sN$) data center as in Figure 4 .

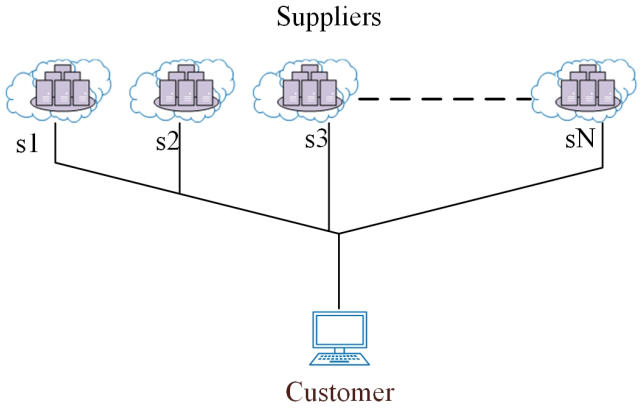

Figure 5: Firms/Customer Accessing Information from *N* Suppliers

An Information System can virtually enable firms to collect and gather important supplier related data such as qualification information through internal and external questionnaires and self-service profiles, risk factor, and policy compliance to aid choose best suppliers. IT also makes firms proactively more effective in achieving business alignment when planning and creating negotiation documents, it also helps create and alerts for monitoring the availability of new information that might affect and influence supplier management, capabilities, or risk factors. Suppliers, as well as sourcing teams, gain adequate and simultaneous real-time visibility of the information on transactions as well as current and upcoming sourcing activities.

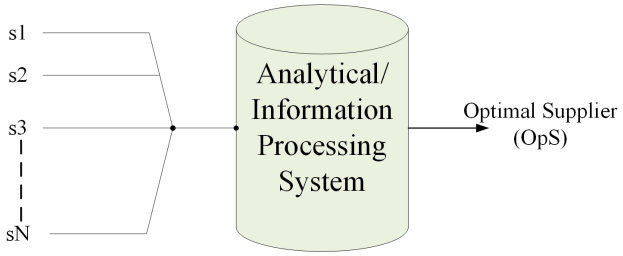

Figure 6: Effective Processing of all *N* Supplier Data

2.2.2 *Effective Data Processing*

With is the acquired data, firms would be able implement machine learning algorithms to process, analyze, narrow down and select optimal supplier that deliver product that meets the defined requirement In simple term, OPTIMAL SUPPLIER (OpS) means suppliers who can supply be able to supply the correct materials with the best price and the right quality that adheres to all defined constraints.Use of technology in the procurement process will ensure quick flow information with the supplier which in turn ensure and results in high productivity since many human factors or errors would be eliminated.

Strategic procurement with information system before initiating negotiations will provide and compare the collection of supplier data monitored to ensure that supplier complies and adhere to all the well-defined corporate policy. These policies include;

Process and design capabilities: Suppliers ought to have up-to-date and capable merchandise, yet as method technologies to provide the fabric required. as a result of completely different producing and repair, processes have varied strengths and weaknesses, the shopping for the organization should remember those characteristics up front. One way to cut back the time needed to develop new merchandise is to use qualified suppliers that square measure able to perform product style activities.

Quality assurance and reliability: Quality levels of the procurement item may be a vital issue and influences provider choice. Product quality ought to be in line with the lay-down product needs since it will directly have an effect on the standard of the finished merchandise.

Cost: The unit cost of a product's material is not deemed the most important aspect of supplier selection, rather the total cost of ownership is considered as the crucial factor. The total cost of product ownership includes the material unit price, the agreed payment terms, the cash discount, the cost of ordering, the cost of transportation or shipment, all logistical costs, projected maintenance costs, and many more qualitative costs that may not be easily assessed.

Service: providers should be in a state to back up their goods by providing the best services to their clients when requested. Buying firms always need to evaluate after purchase service incentives awarded by potential suppliers. This is very important especially when the buying firms have enough expertise concerning the product maintenance.

Capacity and geographical location: The buying organization needs to consider whether a potential supplier has the capacity to fill orders to meet all defined requirements and the ability to fill large orders if needed. Geographical location is another important factor in supplier selection because it inevitably has a huge impacts delivery lead time, transportation, and other logistical costs.

Factors to consider also include; system planning and control, firm's management capability, financial commitment and cost structure, longer-term relationship potential. The implementation of smart IT systems build for effective negotiation and supplier selection process would aid purchasing firms leverages all available negotiation best strategies and practices to achieve bottom-line or optimal results [19]. IT assist in inconsistent monitoring of supplier progress. Using IT gives the firms access to embedded social collaboration makes easy to harness and combine team effort to create

more appropriate and effective negotiation documents. Firms the uses IT in procurement process mostly have access to well-proven analysis tools that allow the?firm to quickly evaluate supplier bids based on predetermined factors—such as price, quality, and value allowing the firm to arrive at the best possible award based on your unique business requirements.

2.3 Approval/ award contract

The supplier that has been selected to provide the product will then be awarded the contract that carefully is having the conditions and terms that will be agreed by two parties. The fixed prices and the cost of the services will reflect on the contract. The organizations are expected to use the product requirements for the selection process. The approved supplier has the mandate to deliver their products as stipulated in the agreement of the contract. Reliability and efficiency are the core elements of the supplier.

2.4 Supply chain management process

This is another part of the purchasing process that links all the necessary information to other systems to enable both buying and capturing of what is needed. Information is always flowing bidirectionally between the supplier and the customer in Figure 7.

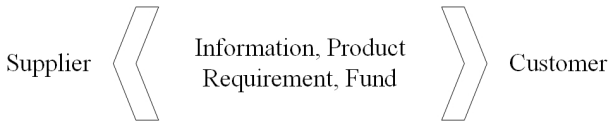

Figure 7: Supply chain fund management flow chart

Supply management has other activities that enhance the purchasing process, that can be breaking down into the supply chain macro process as shown in the Figure 7. The customer's relationship management system is there to capture and manages the details about what is available on the market, the prices, the selling of the products, creating a route for the firm to get updates on what is available. This guides the majority of firms to practice strategic planning and fulfill the demand and supply. The Figure 8 indicates the link in the supply chain macro process.

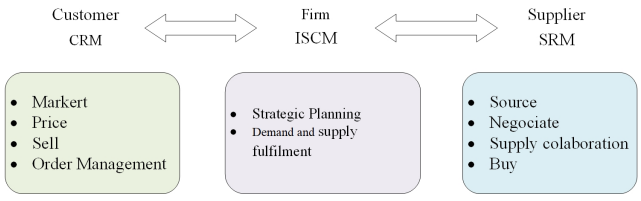

Figure 8: supply chain macro process

2.5 Product delivery, payment review, and process evaluation

2.5.1 Product delivery and payment

The other stage of purchasing is product delivery, this stage collects and compiles the information that is needed for arrangements of how the product will be delivered to the specific firm or an individual. In Order to survive in the industry and gain competitive advantages, improvements such as reducing inventory and dependable delivery must be made, the introduction of data exchange systems that facilitates and communicate demand to suppliers and production progress data to customers within the network [14].

The products are stored to be delivered either in the warehouse or to individuals. Information technology system used in capturing the details in forms, others can be labeled electronically. Payment of the products is processed immediately after selecting the product and placing the order of it.

2.5.2 Process evaluation

After payment and delivery of the product, the systems are reviewed to map a way of eliminating errors and shortfall that occurred during the interaction of the purchasing process. At this stage, crucial decisions about changing the suppliers can be made based on the outcome of the services provided by the previous supplier. Recommendation and amends are drawn for future processing.

3 Key Elements of Enterprise Resource Planning, Purchasing Databases, and Electronic Communication Systems

The business market is constantly revolving and enterprises must revolve with it in order the maintain the necessary market presence. As firms hierarchy decides to invest in ERP system, they must ensure that the targeted system functionalities aligns with the overall firm's goal. This section will sort to elaborate on information system for procurement, crucial factors to consider when an enterprise is planning on purchasing and information system.

3.1 Enterprise Information System Purchasing

Business information systems are generally termed as ERP (Enterprise Resourcing Planning) system. It is a software package largely used by firms to effectively manage and handle day-to-day business activities or transaction, activities such as accounting, procurement, project management, risk management and compliance, and supply chain operations.

A complete ERP suite as an enterprise performance management software package helps firms to arrange, budget, predict, associate degree report on an organization's monetary results. Basically the key elements in the ERP include; One centralised location either onsite or cloud-based, Integrated Reporting Analytics, Efficient Data Import and Data Handling, Customer Relationship Management, Materials Requirement Planning, Materials Management, Engineering Change Order, Recall Management and Tracking, Production Planning & Execution, Document and workflow management, Mobile ERP and Automation.

3.2 ERP System Evolution

The implementation ERP systems by the firm and can be dated back the mid of 20th-century various departments within many organizations begun to use to function independently and these departments are often referred as functional silos [22]. The building blocks of ERP system basically comes from manufacturing resource planning systems (MRP) [23]. Inevitably, those systems were ineffective because they were deprived of many benefits of integrative coordination. It brought a huge financial burden on the firm because most of the systems at the time were not reusable since it needs massive rework and designs needs to be overhauled when the product was completely manufactured. A Framework of MRP is shown in Figure 9

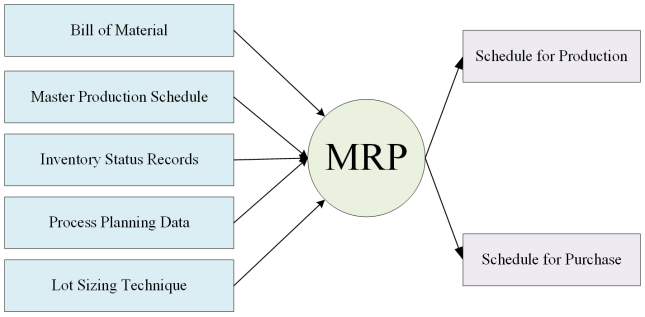

Figure 9: Framework MRP Software [22]

In the subsequent decade, MRP systems were evolved. Material Requirement planning is the software architecture that facilitates material requirement and planning as in Figure 9 [22]. It receives the following user input:

- Bill of material stating details of the materials, components, and sub-assemblies needed to form every product.
- Master Production Schedule. Once the quantities are needed to satisfy demand.
- Shelf life: that is period of keeping materials.
- Inventory status records such as Manufacturing lead time data, Purchase lead time data
- Process Planning Data. This includes a whole range of data required for process planning like routings, process plans, quality testing methods, labour standards, machine standards

This MRP software generates the following output [22]:

- Details report about the product to be produced and production timeline. That involves everything from start to finish each stage is in the process is monitored. It also allows quantities and generates necessary reports.
- Detail report for the schedule of purchase. material to be purchased and date on which purchase must be made both questions are answered here.

Above MRP programs were not flexible enough if something goes wrong, like break down of machines or delay in delivery of purchased items. This eventually created inconveniences for users. In 1990, Gartner created the term ERP to explain the evolution of material requirement planning (MRP) and manufacturing resource planning (MRPII) because of the need expanded beyond manufacturing into other integral parts of the enterprise, typically finance and HR [24–26].

The ERP system implementation began in the 1990s until somewhere the start of the 21st century where the usage system grew exponentially. Later it absolutely was discovered that the prices of implementing ERP system began to rise. The hardware needed to run the software package was usually on-site, with massive machines in a very server area. The capital is required to purchase hardware and software licenses. In addition, nearly all organizations always prefer to customize their ERP systems to fit their specific needs instead of default settings and packages that come with the software and this also generates an additional expense of software consultants and training.

As technology grew up and limits of business crossed regional barriers want for tightly integrated programs which may seamlessly integrate all aspects of business in real time manner was necessary. This was extremely since it does not only to integrate all functionalities in one unit of a firm but also to integrate and unifies different parts of firms having a national or global presence. The modern ERP systems find ways to take handle these issues since they could b joint with the old systems. Though the transition from the legacy system to the modern system was involved with a lot of challenges, firms were able to transit the same [27]. with this, information was available to a specific user at the right time with the right permission to a specific user in a real-time environment. Availability of real-time data across each functional modulation with simulation capabilities were some of the important characteristics of these systems.

The rapid growth of the use internet made it easy for ERP to expand in the business section, such as the customer relationship management CRM, human capital management (HCM), supplier relationship management (SRM), supply chain management (SCM), inventory management, accounting, business intelligence and e-commerce and this exponential enabled firms to increase performance in marketing [28–30].

4 Future requirements of electronic purchasing systems that will enable information visibility

This section address the necessary future requirement or features to sort when purchasing an ERP system. The advantages and disadvantages of ERP system is fully discussed. Recommended solutions are for the possible disadvantages are presented. Further more, a short list ERP software packages are presented according the firm size.

4.1 Cloud Integrated ERP System

The growth of knowledge in ICT has significantly influenced all sides of computing applications across organizations. Additionally, the business setting is changing into more and more complicated with useful units requiring additional and more inter-functional information flow for higher cognitive process, timely and economical acquisition of product components, management of inventory, accounting, human resources and distribution of products and services.

Meanwhile, the continuous evolution of ERP technology has completely embraced the internet, with new options and practicality, like embedded analytics has been added. Many firms are quickly migrating to cloud-based ERP system from on-site ERP because firms have discovered the difficulty in maintaining and keeping up with the trend of security demands or rising technologies, like smartphones whiles using on-site ERP systems. Currently, cloud computing has effectively released firms form overly burdening themselves with ERP security demand, the maintenance cost of the on-site ERP system. Usage of cloud-based ERP system, has for example, improve inventory management capabilities for enclosed technology like barcode scanning and storage or RFID-tags; nowadays, the explosion and rapid development of the interconnected web of devices which is also known as Internet of Things (IoT) [31], has directly made cloud-based ERP even more attractive.

Also, the continued digital revolution and progressively cheap laptop process power has brought changes to nearly every space of business operations [32]. ERP systems have become a cloud-based hosted software technology [33]. In a cloud (server in a remote location), the users are granted access to a system by the respective or selected service provider, this includes full and complete access to hardware, and storage capacity, where system and hardware management are highly transparent to the users [34]. The major reason why firms moved to ERP system is typical to reduce costs, improve overall decision making through better reporting generated by provided capabilities, improve customer-supplier relationships, meet market and legal requirements, and to increase process efficiency [35]. With a cloud-based ERP system, firms have access to the ERP system that is hosted at a chosen service provider's site via the Internet. In addition, the responsibility regarding updates, managing servers, maintenance, and performing backups lies with the service provider instead of the firm which inherently cuts cost [33, 36]. In other words, the cloud ERP service providers ensure that maximum security, constant stability, and effortless operation of the system on behalf of its client users. Currently, cloud-based ERP systems have gained increased attention and investment from all around the globe.

Since the emergence of cloud-based ERP systems, the large ERP system implementations are focused on the cloud [34]. Cloud service model gives the client the opportunity to have quick access to the on-demand network and to share a bundle of resources. These resources will embrace, servers, networks, storage, applications (e.g. ERP), and others [34] Software as a Service (SaaS) technology is implemented as a delivery mode for cloud-based ERP system [37, 38]. SaaS eliminates the requirement to physically install and run the server-side applications on the customer own premises, and eliminates the requirement for back-end hardware and data-centers needed to run the system [27], that successively simplifies the application's maintenance and support operations. This makes it possible for small organizations to take advantage of ERP systems, as they require neither the substantial resources nor the skills needed for successful on-premises implementation [32, 33].

4.2 Advantages and Disadvantages of ERP System

The ERP system comes numerous benefits that cannot be realized in firms that still use traditional purchase process. The positive impact of modern ERP system significantly out weights the negatives, it does comes with its related opportunities and challenges as described in [39]. The advantages and disadvantages are presented in the Table 2 and Table 3 respectively.

Table 2: Advantages of Cloud-Based ERP System

Advantages	**Aspects**
Reliable and easy information availability	Common DBMS permits and allows consistent, accurate data and improved reports.
Redundancy mitigation for data and operations	Modules access the same data through a centralized database, and this helps avoids and remove multiple inputs and update operations.
Less delivery and low cycle time	Minimizes data retrieval and reporting delays.
Cost-effective	Time savings are achieved due to improved control by firm-wide analysis of all purchase decisions making processes.
Easy adaptability	Relay for information about changes in current business processes is easy and swift to adapt and restructure.
Improved scalability	Availability of structured and modular add-ons.
Improved maintenance	Vendor provides long-term supports as part of system procurement.
Global outreach	Availability of module extension like CRM, SCM, etc.
E-Commerce and e-business	Excellent Internet commerce, collaborative culture.

Table 3: Disadvantages of Cloud-Based ERP System

Disadvantages	**Suggested Solution**
Time-consuming	Sensitive issues minimization, reduce internal politics and call for general consensus
Expensive	Cost varies from thousands to millions of funds. Re-engineering existing business process could be extremely high.
Modules conformity	Architecture and related system components should match to current business processes, culture as well as strategic goals of the firm.
Vendor dependence	Multi-vendor vs. single-vendor consideration and long-term support commitment.
Features and complexity	ERP system is packed many modules so firms must do careful consideration and implement only the needful.
Scalability and global presence	Look for vendors with long-term product and services commitment, Internet-enabled systems and global investment.
ERP capability extention	Consider ERP "add-on" modules extension such as Customer Relationship Management (CRM), Supply Chain Management (SCM), etc

4.3 On-Premise ERP versus Cloud-Based ERP

Firms operate on-premise or on-site ERP system is responsible to updating and maintaining their system and keeping it up-to-date, this firms also need to undertake extensive user re-training efforts to correspond with the system upgrade [40]. The cloud-based ERP updates, testing is undertaken by the services provider or vendor. This significantly reduces the burden and unnecessary delay in the overall project actualization. Therefore, if the vendor has thoroughly conducted tests prior to an update, the client organizations would largely be shielded from these any negative effects experienced by the on-site ERP users [41]. Updating a cloud-based ERP system is provided below:Firms operate on-site ERP system is fully responsible in updating, their system maintenance and keeping it up-to-date, this firms also need to engage in extensive user re-training program in an efforts to successfully push new system upgrade [40]. While cloud-based ERP platform or system update and testing are facilitated and undertaken by the services provider or vendor. This significantly reduces the effect of any unnecessary project delay. Typically, vendors conduct enough tests prior to any new update to ensure that new functionalities integrate seamlessly and this largely shields client organizations from any negative effects experienced by the on-site ERP users due to pushed updates] [41]. Cloud-based ERP is equipped with the following benefits:

- It is easier to introduce and use a new functionality introduced by vendors [34];
- Less planning, testing, maintenance, and configurations from the customer's side since everything is fully automated by the vendor [33, 34];
- Lower costs, both with maintenance and IT staff, and updates are free of costs [33, 34, 37];
- The vendor has the possibility to expand its potential customer base, and let the users focus on their core competencies [34, 37];
- It is the vendor who provides a help-desk and maintenance support [42];
- The firms are not the owners of the system, as they do not own the infrastructure or run the applications and thereby not responsible for maintenance [43];
- Cloud-based ERP vendors regularly release new versions [41];
- Cloud-based ERP systems usually get frequent updates and new functionalities as compared on-site ERP systems [34].

As stipulated above, the main advantages of cloud-based ERP are that updates are free. There are enough good reasons why the vendor should invest time and resources in updating the system, even when it is free for users as technology updates are an inescapable process with dealing with any man-made creation utilized for productive gain [40]. A frequent update is done by vendors?ERP system to allow their customer firms to constantly evolve and optimize their business processes, and improve decision-making [40].

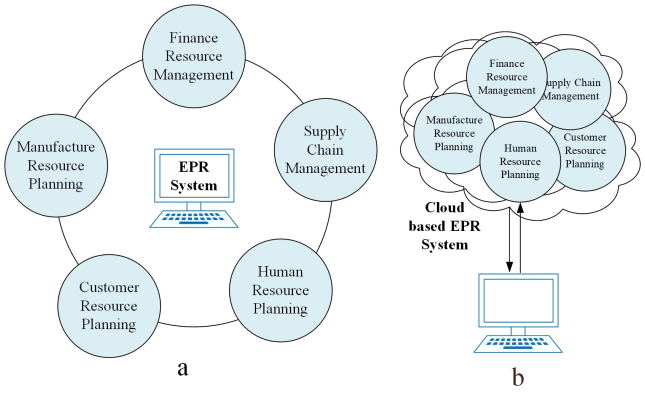

Figure 10: On-Site ERP versus Cloud-Based ERP System

The Figure 10 (a) shows an on-site ERP system which can only be accessed when on-site. Figure 10 (b) shows a cloud-based ERP system that demonstrates the evolving technologies and how efficient it is to managing purchasing and supply chain within organizations.

4.4 Available Cloud-Based ERP System

Purchasing ERP system is greatly dependent on firm size. Therefore, careful and objective decision must be made by firms that are considering purchasing ERP system. Selecting the correct and best ERP system for any firm operation can prove very challenging. this because many parameters are considered such as precision, flexibility, technologically integral. Supply chains are revolving at a very fast pace. With many production facilities and related suppliers gravitating more toward technologically-oriented method of doing business. Embracing cloud-based ERP systems definitely comes with positive impacts

Table 4: Suggested Cloud-Based ERP System to Company Size

Enterprise	Medium-Sized	Small Business
SAP	Netsuite	Deltek
Oracle	Sage	Work(etc)
Microsoft Dynamics	Infor	Syspro
IFS Applications	Macola	Intacct

The Table 4 presents a list few ERP System fits the three categories of business types. ERP software varies widely from one system to the other systems because different vendors have different market focus and thereby offer features that attract targeted markets.

However, most systems offer numerous modules: Human resources, CRM, Finance/Accounting, IT Helpdesk, e-commerce, Supply Chain Management, Order Processing, Inventory, and Procurement. However, most systems can provide many of those modules: Human resources, Finance/Accounting, IT service, e-commerce, provide Chain Management, Order process, and Inventory.

Additionally, department specific modules, several ERP platforms unit are specifically designed for specific industries like producing, field service, or technology. Industry-focused ERP systems package useful options along and should provide a helpful start line

for those new ERP computer code. With ERP system customers will access any data at any time from anyplace victimization devices like a pill, smartphones.

4.5 Factors to Consider When Purchasing (Cloud-Base) ERP System

It is important for firms to migrate to an ERP system in order to remain relevant in the current market trend. Before migration firms must ensure that the preferred ERP system has the following features; It is important for firms to migrate to an ERP system in order to remain relevant in the current market trend. Before system migration firms must ensure that the preferred ERP system is fully equipped with the following features;

4.5.1 Upgrade vs. Replacement

Evaluate first if the firm needs to get a brand new ERP system or just an upgrade. Many current ERP is modularized and allows integration of new modules such as payroll with current applications. With this approached, the firm minimizes disruption and costs. With this also, a firm can leverage the cloud-based ERP for mobility, effective integration, increased scalability, deployment options, machine learning, and predictive analysis.

4.5.2 Training and Setup

On-premise ERP solutions need technical knowhow personnel to install but cloud-based ERP removes that barrier which in turn reduce cost. The installation often has charged independent from the cost of license but using SaaS or cloud-based ERP only requires an account activation to enable access all necessary service from the selected providers' server.

4.5.3 Reporting and Dashboards

Current ERP solutions feature an advanced reporting interface that can generate complete financial statements depending on the configuration. Check available tools such as reporting tools, in-system query, smart filters, and real-time data visualization. Dashboards include functions such as quantitative vs. qualitative data at a user, role, and department levels.

4.5.4 Integration

Desired ERP should seamlessly work with your currently existing business applications; this is essential when firm want to upgrade their existing system. Firms should consider the following integration points; system-system (such as CRM, HRMS), module-system (ERP payroll with existing HRMS) and also have varieties of export/import capabilities (PDF, JPG, CSV extension). The selected ERP system should have flexible integration process in order to ensure safe and smooth records and files migration.

4.5.5 Customization

This depends on every firm's priorities and working culture. Therefore, firms research and for an ERP System with customization tools such as departmental dashboard localization, and configurable workflows, among others. This allows departments such as marketing, accounting, production, sales to effectively execute their define goals and organize the ERP environment based on their parameters.

5 Conclusion

In conclusion, the study defined as purchasing is acquiring goods to satisfy organizational needs, individuals or departments. The key roles of purchasing goods are buying the inputs competitive price and ensuring reliable and consistent flows of goods. The use of an information technology system in purchasing help enhanced the operation and process in an organization by eliminating errors.

The purchasing process has become more efficient because the vast volume of paperwork is now reduced and cross-checking of records from the supplier and the customer's product specifications. This process is underlined with sufficient procurement planning, strategic resource allocations, staff competency, and procurement procedures respectfully. Thus enabling the organization to utilize the information processing features that collect analyze and coordinate in order to establish productive operational, effective and strategic decisions [12]. Recent studies have based on effects associated with the use of IS in supply chains.

There is evidence of an upwards productivity for a well-planned with supply chain coordination and integration that is facilitated by the use of integrated information technologies [44]. The suggested way to promoting effective Purchasing Process for future requirements to use tools that enhances the online requisitions. The use of electronic data interchange and online ordering through electronic catalogs are the new technology routes that individuals and organizations use to purchase their products.

Therefore, the on-site ERP system is being fully replaced by the cloud-based ERP, because it utilizes up-to-date and available cutting-edge technology platforms to reach a vast number of users and business around.

Conflict of Interest The authors; Pearl Keitemoge and Daniel Tetteh Narh certify that they have NO affiliations with or involvement in any organization or entity with any financial interest (such as educational grants; participation in speakers' bureaus; membership, employment, consultancies, stock ownership, or other equity interest; and expert testimony or patent-licensing arrangements), or non-financial interest (such as personal or professional relationships, affiliations, knowledge or beliefs) in the subject matter or materials discussed in this manuscript.

Acknowledgment We are grateful for the opportunity that was granted to us, and to be able to share more insight on Effective Application of Information System for Purchase Process Optimization. Also grateful for the support that we receive from the family and friends, thank you.

ABSTRACT

This paper presents an efficient Maximum Power Point Tracking (MPPT) controller for photovoltaic modules. The MPPT technique consists of a combination between backstepping controller and artificial neural network (ANN).The (ANN) has been employed to generate the optimum voltage, which corresponds to the maximum power voltage delivered by photovoltaic modules, while the backstepping controller is developed to track the generated voltage, by computing the duty cycle of the Single Ended Primary Inductor Converter (SEPIC). The control of the boost converter is based on Lyapunov stability analysis, and an integral action is added to increase system robustness. In order to prove the accuracy of the developed control a comparison between the proposed method and sliding mode was carried out. In addition the stability was evaluated under sudden variation of environmental conditions. The simulation was carried out in MATLAB software, the results shows that the proposed controller tracks the reference voltage within 25 ms, in addition the systems reacts to sudden environments change with no oscillations, which demonstrate the robustness of the proposed method.

1. Introduction

In recent years, the demand of electrical energy increases, which reduces the reserves of the conventional resources and increases the global warming, therefore the use of renewable energies is the only way to reduce the dependence on fossil fuels and ensure the energy security. In fact, photovoltaic energy is the most popular renewable energy source, however, the output power relies on weather conditions and the load. This led the researchers to present various algorithms that make photovoltaic modules operates in the maximum power point. Thus a various Maximum Power Point Tracking algorithms with different degrees of complexity and precision have been proposed in the literature [1-3]. The perturb and the observe, and incremental conductance [4], methods are often used due to their simplicity and ease of implementation, however their main drawback is the fluctuations around the point of maximum power.

Thus to overcome the oscillations issues and increase the performance of the tracking a combination between direct control methods and the nonlinear commands has been employed by the researchers.

In [5], Authors propose a maximum power point tracking controller for hybrid Photovoltaic - Wind energy system. The controller is developed by the combination of perturb & observe and Sliding Mode. P&O loop is used for the computation of the reference voltage, while Sliding Mode is designed to track this voltage by generating the control signal. The proposed method exhibits good convergence speed, but the main disadvantage is the oscillations around maximum power point.

In [6], Authors present a control of a single-phase Photovoltaic inverter using backstepping algorithm which track the desired voltage generated by Perturb and Observe method and adjust the duty cycle in order to operate in maximum power point. The error between the output and reference voltage was eliminated quickly, but some fluctuations have been observed in the desired operating point.

In [7], Authors propose a maximum power point tracking controller for Photovoltaic system. The controller is developed by the combination of Sliding Mode and Artificial Neural Network (ANN). The ANN is employed to generate the reference voltage, while Sliding Mode is designed to track this voltage by generating the control signal. The proposed method presents good

*Corresponding Author: Khalid Chennoufi, Tel: +212 668 01 15 90, khalidchennoufi@research.emi.ac.ma

performance; however, some oscillations is noticed around maximum power point.

In order to overcome fluctuation issues around maximum power point, this paper proposes a hybrid method, which consists of a backstepping controller combined to the Artificial Neural Network (ANN). The ANN is employed to generate the reference voltage, while backstepping controller is designed to adjust the duty cycle of the converter in order to track the desired voltage, which corresponds to the voltage of the Maximum Power Point, (Fig1).

In contrast of previous methods which adopt single diode model, the photovoltaic modelling was carried out using double diode model, as the modelling using single diode degrade at low irradiance. In addition the present work doesn't rely on any simplification which can compromise the accuracy of the controller modelling, furthermore the SEPIC converter was employed since it offer more advantages instead of the traditional converter.

The present paper is organized as follows. In Section 2, the modelling of the PV system is presented. The Section 3, presents the design of the proposed controller. The simulations and discussions are illustrated in Section 4.

2. Modelling of PV system

The Photovoltaic system proposed in this paper consists of a photovoltaic module connected to a resistive load through a Single ended primary converter as shown in Figure 1.

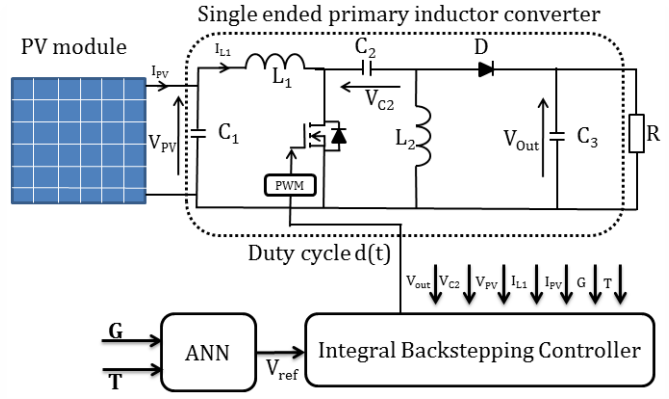

Figure 1: Illustration of the proposed Photovoltaic system.

Where V_{out}, V_{c2}, V_{PV} are the output voltage, the voltage across the capacitor C_2, and the photovoltaic voltage respectively, I_{pv} and I_{L1} are the photovoltaic and inductor 1 currents, While G and T are respectively the irradiation and the Temperature.

The datasheet parameters of the polycrystalline photovoltaic module KD 245 GH are presented in Table 1.

Table 1: PV module datasheet

Parameter	Value
Short-circuit current (I_{sc})	8.91(A)
Open circuit voltage (V_{oc})	36.9 (V)
Maximum current (I_m)	8.23 (A)
Maximum voltage (V_m)	29.8 (V)
Number of cells in series (N_s)	60
Temperature coefficient of current (k_i)	5.35×10^{-3} (A/K)
Temperature coefficient of voltage (K_V)	-0.133(V/K)

2.1. Modelling of the SEPIC converter

The SEPIC is an acronym of (single ended primary inductor converter), which is a DC-DC converter capable to operate as boost or buck mode [8], that offer the possibility to raise or decrease the voltage at the output [9]. In addition the SEPIC converter makes the PV system operate at its maximum power point with 'weak current ripples [10]. Furthermore it can work on any operating point by changing the duty cycle [11]. The converter is modelled mathematically based on these states [12] as shown in figure 2.

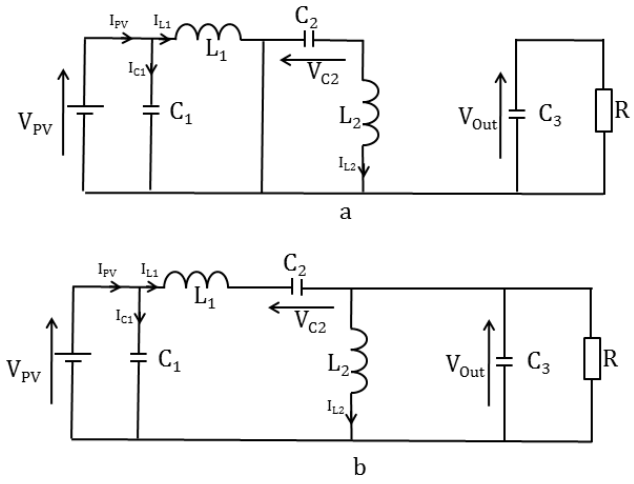

Figure 2: SEPIC converter circuit, (a) Equivalent circuit switch is ON (b) switch is OFF

When the commutator is on (u=1) as shown in figure 2-a. The capacitor C_3 supplies energy to the load and the energy stored in the inductances increases, the inductor L1 is alimented from the input while the inductor L_2 is feeded from the capacitor C_2. The representation of state space can be described as

$$\frac{dI_{L1}}{dt} = \frac{V_{PV}}{L_1} \quad (1)$$

$$\frac{dI_{L2}}{dt} = \frac{-V_{C2}}{L_2} \quad (2)$$

$$\frac{dV_{c2}}{dt} = \frac{I_{L2}}{C_2} \quad (3)$$

When the commutator is off (u=0) as shown in figure 2-b. The two inductors are discharged and the energy stored in the capacitors increases. The representation of state space can be written as:

$$\frac{dI_{L1}}{dt} = \frac{V_{PV} - V_{C2} - V_{out}}{L_1} \quad (4)$$

$$\frac{dI_{L2}}{dt} = \frac{V_{out}}{L_2} \quad (5)$$

$$\frac{dV_{C2}}{dt} = \frac{I_{L1}}{C_2} \quad (6)$$

The combination between the two state spaces can be expressed as:

$$\frac{dI_{L1}}{dt} = \frac{(u-1)V_{C2}}{L_1} + \frac{(u-1)V_{out}}{L_1} + \frac{V_{PV}}{L_1} \quad (7)$$

$$\frac{dV_{C2}}{dt} = \frac{(1-u)I_{L1}}{C_2} + \frac{uI_{L2}}{C_2} \quad (8)$$

$$\frac{dI_{L2}}{dt} = -\frac{dV_{C2}}{L_2} + \frac{(1-u)V_{out}}{L_2} \quad (9)$$

$$\frac{dV_0}{dt} = \frac{(1-u)I_{L1}}{C_3} + \frac{(u-1)I_{L2}}{C_3} - \frac{V_{out}}{RC_3} \quad (10)$$

where u=(0 or 1)

2.2. Modelling of the Photovoltaic module

In this work the modelling of a solar module is developed based on double diode model which is illustrated in figure 3, where the first diode describes the saturation currents due to diffusion mechanism, while the second diode describes the current due to recombination in the depletion zone.

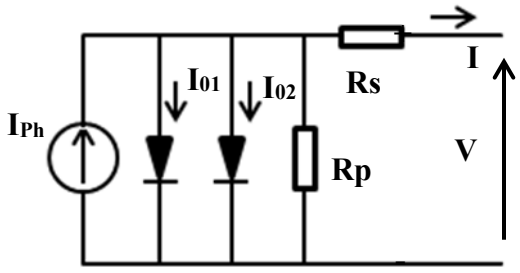

Figure 3: Illustration of the double diode model.

The output current of a solar cell is represented by:

$$I = I_{ph} - I_{01}\left(exp\left(\frac{V+R_sI}{a_1V_T}\right) - 1\right) - I_{02}\left(exp\left(\frac{V+R_sI}{a_2V_T}\right) - 1\right) - \frac{V+R_sI}{R_p} \quad (11)$$

The unknown parameters such as: a_1,a_2,I_{01},I_{02},I_{ph},R_s and R_p. are extracted using a combination between the equation of three main operating points which are, the open circuit voltage, the short circuit current and the maximum power point. The objective is to find the equations of I_{01}, I_{02}, R_p and I_{ph} which depend only of Rs, a1 and a2. The value of series resistance (Rs) and ideality factors (a_1,a_2) are obtained using a fast iteration by adjusting simulated and datasheet powers [13]. The extracted parameters are illustrated in Table 2.

The extracted parameters are integrated in a MATLAB algorithm to plot V-I and V-P curves as shown in Figs. 4, the simulation allow to predict the behaviour of the photovoltaic modules in different meteorological condition, thus when the temperature increases the open circuit voltage decrease while the short circuit current increase slightly which result a loss of generated power. On the other hand, when the solar irradiance increases both short circuit current and the open circuit voltage increase which raise the generated power.

Table 2: Extracted Parameters of KD 245GH module

Parameter	Value
a_1	1.005879
a_2	1.994120
I_{ph} (A)	8.931164
I_{01} (A)	3.906668×10^{-10}
I_{02} (A)	1.094485×10^{-06}
R_s (Ω)	0.286199
R_p (Ω)	120.495147

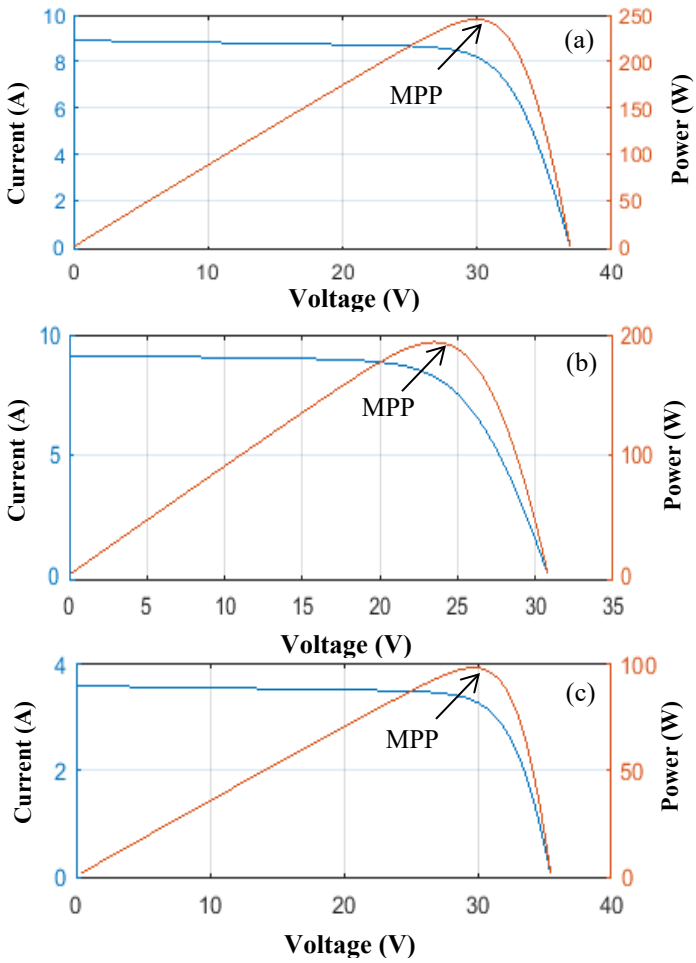

Figure 4: Generated current and power at 25°C - 1000 W/m² (a), 75°C - 1000 W/m² (b) and 25°C - 400 W/m² (c)

3. Proposed controller:

Figure 1 presents the schematic drawing of the proposed controller, it consists of a combination between Artificial Neural Network and backstepping controller. The ANN loop generates a voltage reference for every solar irradiation and temperature, which correspond to the maximum power point voltage, while the backstepping controller tracks the generated reference by adjusting the duty cycle.

3.1. Artificial Neural Network

Artificial neural network is a computational processing model based on artificial intelligence that is meant to simulate the functioning of a human brain , which consists of processing units interconnected by nodes [14]. The ANN architecture consists of three layers as shown in Figure 5, The input layer receives various forms and structures of information based on an internal weighting system, the hidden layer is where artificial neurons get an ensemble of weighted inputs and generates an output via an activation function, while and the output layer receives data from hidden layer and gives the results of the ANN [15, 16].

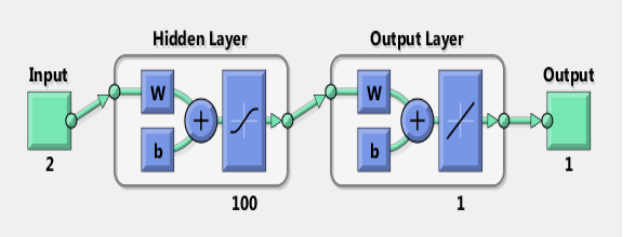

Figure 5: Proposed Neural network hierarchy

In this work the input layer was designed with two neurons, irradiation and the temperature, a database of 158 cases was created by increasing the irradiance by a step of 5 K from 278 K to 333 K and changing the irradiance for each temperature from 200 to 1050 W/m². The hidden layer was created with 100 neurons as shown in Figure 5. The output layer has only one neuron which corresponds to the voltage at maximum power of the 158 pair irradiance temperature.

3.2. Integral backstepping

The backstepping controller is designed to track the reference voltage generated by the artificial neural network by adjusting the duty cycle of the converter. The control law is generated based on Lyapunov stability analysis. The design of the controller is as follows:

The tracking error is defined as the difference between photovoltaic and reference voltages:

$$e_1 = Vpv - Vref \tag{12}$$

An integral action is added in order to improve the tracking precision as follow:

$$e = e_1 + \lambda e_{Int} \tag{13}$$

The tracking error becomes:

$$e = Vpv - Vref \quad + \lambda \int (Vpv - Vref)dt \tag{14}$$

Where λ is a positive constant

The modified Lyapunov function can be written as:

$$V_1 = \frac{1}{2}e_1^2 + \frac{\lambda}{2}e_{Int}^2 \tag{15}$$

The derivative of the (15) with respect to time is:

$$\dot{V}_1 = e_1 \left[(\dot{V}_{pv} - \dot{V}_{ref}) + \lambda \int (Vpv - Vref)dt \right] \tag{16}$$

To guarantee the asymptotic stability, the Lyapunov function has to be negative definite derivative:

$$\dot{V}_1 = -K_1 e_1^2 \tag{17}$$

where K_1 is a positive constant

The following equation is obtained:

$$\left[(\dot{V}_{pv} - \dot{V}_{ref}) + \lambda \int (Vpv - Vref)dt \right] = -K_1 e_1 \tag{18}$$

The photovoltaic current is given by:

$$I_{PV} = I_{C1} + I_{L1} \tag{19}$$

The derivative of photovoltaic tension can be written as:

$$\dot{V}_{pv} = \frac{I_{PV} - I_{L1}}{C_1} \tag{20}$$

The desired value of inductor current would be:

$$I_d = I_{PV} + C_1 \left[(K_1 e_1 - \dot{V}_{ref}) + \lambda \int (Vpv - Vref)dt \right] \tag{21}$$

where (I_d=I_{L1})

The second error represents the difference between the inductor and the desired current:

$$e_2 = I_{L1} - I_d \tag{22}$$

The derivative of Lyapunov function with respect to the time can be expressed as

$$\dot{V}_1 = e_1 \left[\left(\frac{I_{PV} - (e_2 + I_d)}{C_1} - \dot{V}_{ref} \right) + \lambda \int (Vpv - Vref)dt \right] \tag{23}$$

By using equation (18) and (20) the above equation can be written as

$$\dot{V}_1 = -k_1 e_1^2 - \frac{e_1 e_2}{C_1} \tag{24}$$

The time derivative of (22), using equation (9) can be written as:

$$\dot{e}_2 = \frac{1}{L_1} V_{pv} - \frac{1}{L_1}(1 - u)(V_{out} + V_{c2}) - \dot{I}_d \tag{25}$$

Where:

$$\dot{I}_d = \dot{I}_{PV} + C_1 \left[(K_1 e_1 - \ddot{V}_{ref}) + \lambda (Vpv - Vref) \right] \tag{26}$$

The derivative of photovoltaic current with respect to the time can be expressed as:

$$\dot{I}_{PV} = \frac{dI_{PV}}{dV_{PV}} \frac{dV_{PV}}{dt} \quad (27)$$

By differentiating the equation (11) with respect to the voltage the derivative of photovoltaic current is obtained:

$$\dot{I}_{PV} = \left[-\frac{I_{01}\exp\left(\frac{V + R_s I_{PV}}{a_1 V_T}\right)}{a_1 V_T} - \frac{I_{02}\exp\left(\frac{V + R_s I_{PV}}{a_2 V_T}\right)}{a_2 V_T} - \frac{1}{R_P} \right] \dot{V}_{PV} \quad (28)$$

In order to guarantee the asymptotic stability of the system and the convergence of the errors e_1 and e_2 to zero, a composite Lyapunov function V_2 is defined as:

$$V_2 = V_1 + \frac{1}{2} e_2^2 \quad (29)$$

The derivative of V_2 with respect to the time is:

$$\dot{V}_2 = \dot{V}_1 + e_2 \dot{e}_2 \quad (30)$$

By using equation (24) the derivative of V_2 can be expressed as:

$$\dot{V}_2 = -K_1 e_1^2 + e_2 \left[\frac{1}{L_1} V_{pv} - \frac{1}{L_1}(1 - u)(V_{out} + V_{c2}) - \dot{I}_d - \frac{e_1}{C_1} \right] \quad (31)$$

The time derivative of Lyapunov function has to be negative definite:

$$\frac{1}{L_1} V_{pv} - \frac{1}{L_1}(1 - u)(V_{out} + V_{c2}) - \dot{I}_d - \frac{e_1}{C_1} = -K_2 e_2 \quad (32)$$

where K_2 is a positive constant

The control law, which guarantees e_1, e_2 converges asymptotically to 0, is given by:

$$u = 1 - \left[V_{PV} + L_1 \left(K_2 e_2 - \frac{e_1}{C_1} - \dot{I}_d \right) \right] \frac{1}{V_{C2} + V_0} \quad (33)$$

4. Simulation results

In order to study the performance of the proposed method, a simulation was carried out in Matlab software. The parameters of the simulation are illustrated in Table 3.

Table 3: Parameters of the SEPIC

Parameter	Value
Inductor 1 (L_1)	2.5 mH
Inductor 2 (L_2)	2.5 mH
Capacitor 1 (C_1)	4500 uF
Capacitor 2 (C_2)	79 µF
Capacitor 3 (C_3)	2400 µF
Constant (λ)	1
Constant (K_1)	10^4
Constant (K_2)	10^4
Load resistor (R)	50Ω
Switching frequency (f)	7 KHz

The system being simulated into different temperature and irradiation condition as shown in Figure 6, During the first case the [0s, 20s], the PV module is consider operating under the irradiation of the maximum power point while the temperature was raised to 318 K to simulate the temperature effect. In the second case [20s, 40s], the irradiation drop smoothly from 1000 W/m² to 600 W/m² while the temperature decrease between two consecutive levels from 318 k to 307 K. In the last case [40s, 60s], the temperature is considered constant in 298K while the irradiation increase among two successive stage to reach 1000 W/m² thus the PV module is considered operating in the maximum power point.

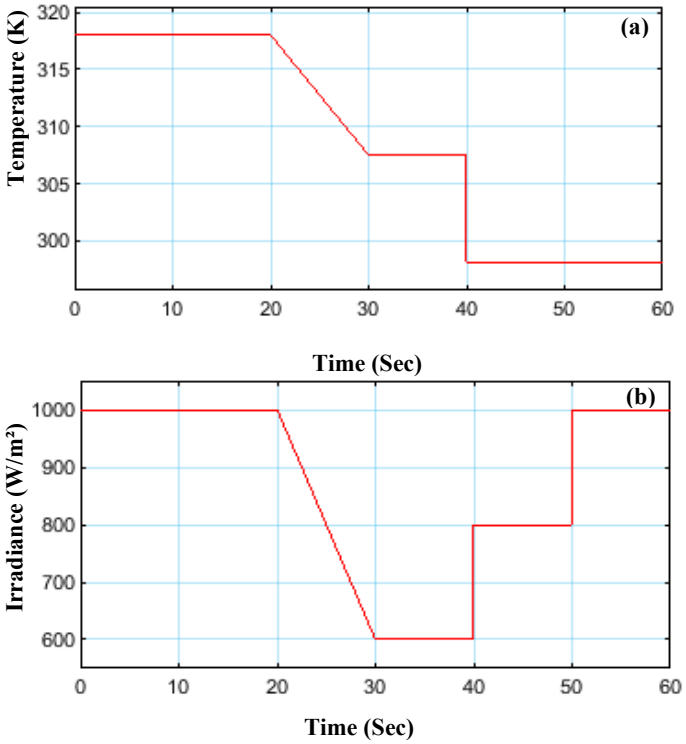

Figure 6: Temperature (a) and Irradiation (b)

Figure 7 shows that the variations in temperature and irradiation cause a slight variation in voltage and a large variation in current and power. By comparing the proposed method with the method proposed by [7] it can be seen that the proposed method bring reach the reference voltage in 25 ms, Figure (b), with high accuracy, in contrast the proposed method in [7] reaches the desired voltage with a delay of 60 ms with large oscillations. In addition the obtained curves exhibit fast and good reactions when sudden variation in temperature and irradiance occurs.

Figure 8 shows the output current, voltage and power of the PV module generated at the output of the SEPIC converter using the proposed method with the result proposed by [7]. As can be seen from the figures (a), (b) and (c), the obtained curves using sliding mode controller present large oscillations and the use of the proposed method allow reducing significantly the magnitude of the fluctuation, which guarantees good performance in the maximum point tracking.

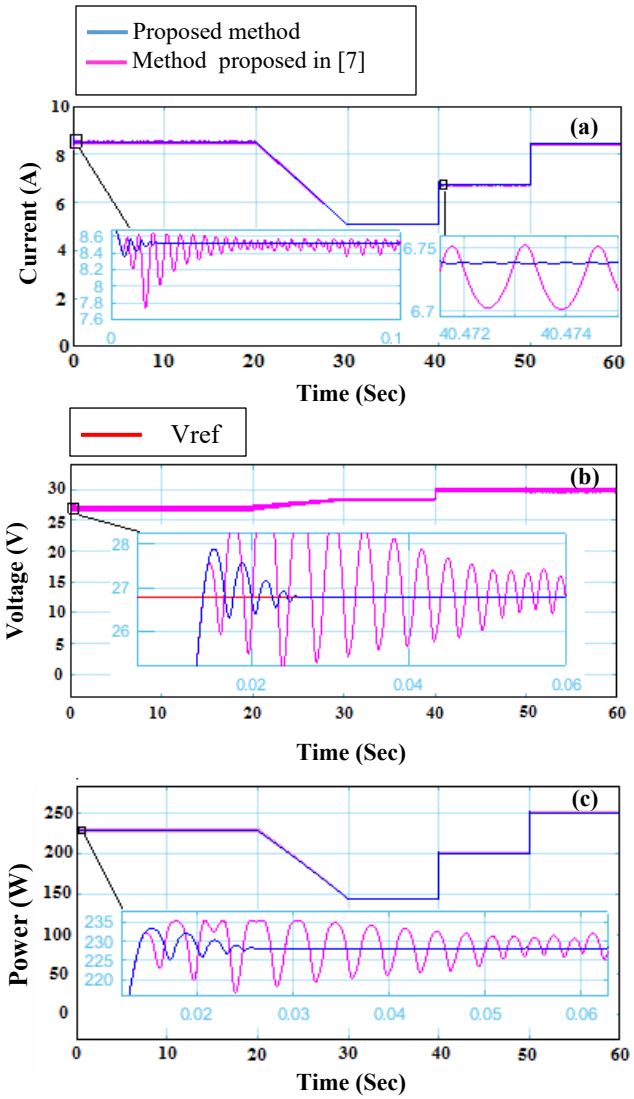

Figure 7: Photovoltaic Current (a), Voltage (b) and Power (c),

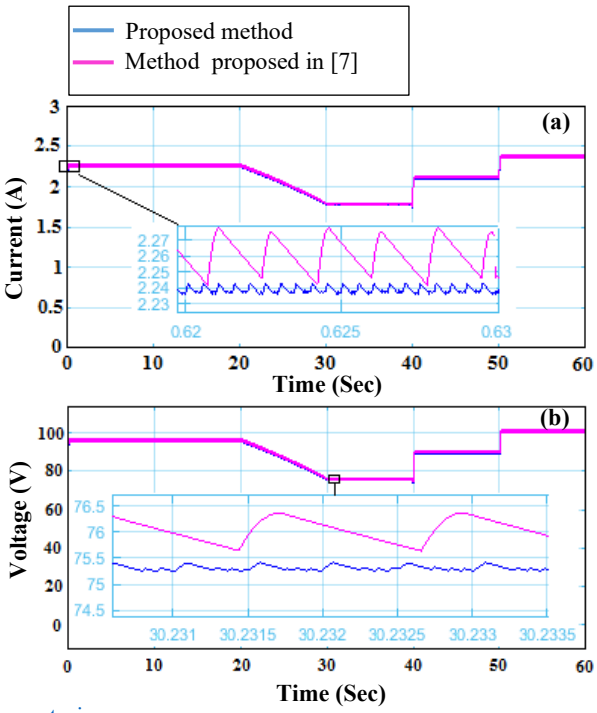

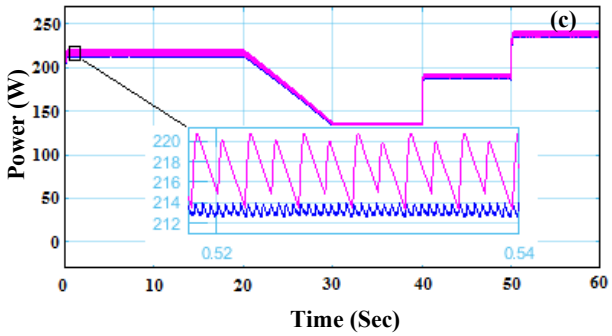

Figure 8: SEPIC output Current (a), Voltage (b) and Power (c).

5. Conclusion

In this paper an integral backstepping controller for maximum power point tracking is proposed. In order to increase the performance of tracking the controller was developed by combining backstepping controller and artificial neural network (ANN). The photovoltaic modelling was carried out using double diode model as the modelling using single diode degrade at low irradiance, and in order to reduce the current ripples the single ended primary inductor converter (SEPIC) has been employed. The simulation has been done in Matlab/Simulink software, the results show that the proposed method tracks the reference voltage with good accuracy and fast convergence speed, in addition the photovoltaic power reaches maximum power in less than 25 ms. Furthermore the obtained curves show that there are no oscillations in the output voltage, current and power. Thus the proposed method presents a fast and stable reaction when the environmental conditions changes, which confirms the effectiveness and the stability of the proposed method.

ABSTRACT

This work presents the development and improvement obtained by implementing inventory managing practices during the COVID 19 pandemic in a Mexican company, a leader in the industrial sector to overcome the effects on the Company's economies due to constrained market to maintain liquidity and preserve employment by increasing customer service level ensuring the availability of the finished product and improving the delivery time in the distribution center, from the receipt of the customer's order, order picking, shipment preparation, invoicing and final delivery to the customer. The areas involved are Commercial, Demand and Materials Planning, Purchasing, Manufacturing, Logistics, and Operations of the Distribution Center. The deployment process considered an ABC study, analysis of the historical demand, product inventory coverage days, analysis of the lead time components of the distribution center, to implement a minimum and maximum inventory control policy for the product portfolio A and manufacture products classified as B and C on a make to order basis, an audit was performed of its distribution center, to identify opportunities for improvement in their processes to reduce the time of delivery to the customer.

The Company was not in compliance with the level of customer service with an 89% performance due to the low availability of the finished product inventory, affecting the customer's delivery time in the distribution center with a time of 5 hours versus the goal of 90 minutes per event.

The implementation of the improvement achieved an increase in the level of service up to 5% starting the fourth quarter of 2019, the savings in inventory optimization at an annual base represented USD 530,785.00 (Five hundred thirty thousand seven hundred eighty-five dollars), and the Company has implemented this good practice nationwide in its other Manufacturing Plants and Distribution Centers as part of the strategic corporate policy deployment.

1. Introduction

The value chain is all actions to make a product to flow from the raw material to the customer's hands. Within the value chain, the primary processes include the transformation of the product, inbound logistics that is the delivery of suppliers of the raw material to a warehouse of the manufacturing Company, the logistics of operations whose purpose is the proper administration of the raw material in the transformation process to ensure the availability of raw material inventory or inventory in process in the work centers and finally the outbound logistics from the storage, distribution and perfect delivery of the finished product to the end customer [1].

The secondary processes in a value chain are the ones that give support to the primary processes for the transformation of the product. The timeline determines the response time of the value chain, and the flow of information in the value chain is essential because it includes the release of the sales estimate, placement of the customer order, release of the purchase orders and manufacturing orders to the delivery of the product to the end customer [1].

The efficiency and optimization of the distribution center's functions is a priority for the achievement of the goal of perfect delivery to the customer and inventory availability assurance to ensure the desired service level [2].

This case study's scope is a company of 100% Mexican capital, market leader, is dedicated to the production and marketing of industrial products located in Mexico with ten manufacturing plants and three Distribution Centers with 800 employees.

This case study helps the Company to face COVID 19 pandemic with a constrained market to contain the economic effects of the pandemic that we are facing helping to preserve employment as much as possible and provide liquidity to create the conditions for the recovery of economic growth by ensuring the availability of the inventory of its products to meet the level of delivery service on time and improve the delivery time to the customer in the distribution center through an audit in the distribution center, establish a baseline of product inventory coverage days, analysis of the lead time components of the distribution center, value chain mapping, ABC classification of finished products, inventory control implementation with the maximum and minimum methodology, production balancing, measurement of customer's delivery time as days of inventory coverage in the distribution center.

Masaaki Imai, in his work, "Kaizen, The Key to Japanese Competitiveness," mentions that Japanese companies follow a defined strategic planning scheme; the administration develops and communicates the rules of the game: transparent processes, that is, with a standard procedure for Operation. It translates into top management shall first establish policies and procedures for all critical operations, then communicate and ensure that they are understood by all levels [3].

The rest of the research work consists of describing the case study, theoretical framework, and research methodology as its conclusions and results obtained.

2. Literature Review

According to the customer's perspective, the value chain's purpose is to determine which activities are value-added and non-value-added [4]. All activity that transforms the product should be understood as an added value; in contrast, all the activities that do not transform the product are no value-added. They are known as waste: Reworks, defects, unnecessary movements, inventories, waiting times, overproduction, unnecessary space, and transportation. This waste shall be eliminated to improve the value chain [5].

A distribution center is a vital component of the value chain for any company to achieve perfect delivery to the product customer as to the quantity, time, price, quality, and correct information.

The distribution center functions include receipt, inspection, storage, picking, preparation of shipment, dispatch, consolidation of orders, and final delivery to the customer. The efficiency of these activities is critical to ensure speed and optimize the flow of the product to reduce the response time and operating costs, from receipt of the customer's order to delivery, to send the products with the correct specification, quality, price with proper documentation to the customer. Always searching for continuous improvement to reduce waste as mentioned earlier and add only value in the supply chain.

The correct management of the distribution center supports the strategic objectives of the Company: Generate more sales, profit margin, cash flow, stability in the jobs satisfying customer demand with the correct level of service.

Therefore, storage and distribution activities for the product should be regarded as a vital component of the Company's strategic planning for it to be coupled with the expectations raised in the business plan [6].

The management of the Company must consider several factors to maintain optimal inventory levels, such as the financial liquidity of the Company, sales behavior such as seasonality, reliability, and availability of suppliers, available financial resources. An adequate level of inventory reduces the potential risks of lost sales due to the lack of inventory availability as well as an increase in the cash flow of the Company, such as the release of warehouse capacity [7].

It is strategic for the companies to achieve a high level of customer service with a minimum level of inventory by implementing the Lean Pull Replenishment methodology by having product's supermarkets for the products that represent 80% of the Company's revenues which inventory is replenished based on the consumer's signal at the time of consumption and made to order for those products that represent the other 20% of the Company's revenue. The Lean Pull Replenishment methodology should be coupled with the Process Capability analysis to reduce variation in processes and determine the processing capabilities of the Company through the commitment of the delivery date of the customer's order [8].

Inventory in the lean philosophy is viewed as a waste given that it impacts the cash flow of the Company when it is not in the correct amount; besides, the Company requires an expense to manage it, at the same time, it hides problems such as downtime of machinery, long periods of changeover of products, quality problems, lack of reliability of suppliers' performance among others. Therefore, it is essential to focus on reducing the longest process lead time and reduce inventory. It is vital to take into consideration synchronization between processes with a correct balanced production plan as well as reduce the change over time between products for each of the processes and always work with small batch sizes and avoid overproduction [9].

In the implementation of a continuous flow, the reduction of equipment change over times is vital, which consequently translates into smaller lot sizes aligned with a *KanBan* signaling system with an adequate plant layout allowing to achieve improvements in the reduction of manufacturing delivery times, thereby reducing work in process and finished goods inventories, eliminating unnecessary movements of materials resulting in having the correct level of inventory to meet customer demand and thus increase the customer service level [10].

It is essential to align the demand planning by reducing the variation of the demand estimate and leveling the demand, establishing EOQ to determine the optimum lot size to produce to minimize the ordering and logistic costs of maintaining the inventory, also optimizing equipment change over times allows reducing the number of Kanban cards which results in a reduction of storage space such as the transport of materials by creating a

continuous flow in the value chain and making timely deliveries to the customer [11].

Within the investigation of inventory management, the optimization strategy stands out; the correct coordination of prices and inventory management technology is vital. Many companies begin to improve logistics by applying inventory control technology to reduce costs. The opportunity lies in ensuring having enough inventory to meet demand by minimizing inventory costs in the right place and time [12].

Any improvement in inventory performance has an impact on the quality of the product as well as the financial performance of the Company, so management must pay attention to proper inventory management. Companies without sufficient financial liquidity to obtain better financial performance can improve product quality by improving inventory management [13].

The correct inventory management practices have a direct impact on working capital, production, and the level of customer service and sales. Goods inventory management practices include having the correct levels of raw material and in-process inventory to ensure the continuous flow of supply to production, to avoid stoppages of the production line, to anticipate the correct prices of materials, ensure the correct levels of inventory of finished product to complete customer orders, follow the customer's demand to increase the level of service provided to the same [14].

The ABC Inventory Classification usually considers the annual volume multiplied times the ordered price in a descending manner classified into three categories A, B, and C. According to the ABC classification, the same service level is assigned for each part number according to the classification. Regularly, the articles generate the most considerable profit and are considered higher levels of service. To classify each of the part numbers, a new approach that takes into account four parameters is proposed: the cost of having a shortage times the rate of demand, divided into the cost of maintaining the inventory (purchase price) times the amount to be ordered for each of the articles; the result is sorted in descending order and is classified on ABC, which considers three classes: 50%, 30% and 20%, where A must have the highest level of service, followed by B and C [15].

Once certain products classified as type A, for the calculation of finished product inventory level, known as supermarket Figure 1, the following formula is considered [16]:

Average daily demand x Replacement delivery period		Stock for the cycle
+	Demand Variation % (stock for the cycle)	Buffer stock
+	Security Factor % (stock for the cycle + buffer stock)	Security stock
=		Supermarket stock

Figure 1: Approach to the calculation of the supermarket inventory level

The supermarket inventory is equal to the stock for the cycle (it is the average demand of each product classified type A, which considers the replenishment delivery time. Replenish time is the period elapsed from the date the order is received, manufactured, and made available at the warehouse) plus buffer stock (which is the amount of each product to be placed to cover any supply variation, such as quality defects, equipment stoppages, personnel missing, raw materials shortage). This supermarket shall be revised daily to ensure finished product availability to comply with service level upon any variation in demand or supply.

Inventory management with a maximum and minimum policy established on this case study for the industrial products industry has also been applied as the policy to health services, which have considered the importance of ensuring the supply of medicine, as well as a level of safety stock inventory to have continuity in the service in the event of supply shortages. By having a correct level of service and reducing delivery times, the decrease in inventory level is favored. The factors contributing to a shortage in medication shall be known, and evaluation is to be made from the demand pattern and all processes of the value chain intervening up to the delivery of the medication [17].

3. Problem Statement

The Company is committed to a quality management system that seeks to continuously improve profitability, customer satisfaction, internal processes, and staff development through the fulfillment of quality objectives and has considered strengthening its continuous improvement process in the distribution center located on the main plant solving the next opportunity for improvement: Position the correct level of finished product inventory under A classification, to increase the level of service to 95% as the preparation of shipment is interrupted due to the shortage of finished products for direct sale to or transferred to other manufacturing plants of the Company, having to reschedule shipments impacting the Company's sales, improve response time in the distribution center from the receipt of the finished product, collection of the product according to the customer's order, preparation of shipment, invoicing and clearance to 90 minutes.

Change management for continuous improvement as outlined in his Theory of Constraints (TOC) concepts and principles for improving companies' performance by focusing on some restrictions in the system. These influence points are system restrictions [18] [19].

4. Methodology

It is necessary to validate if the processes are oriented to serving the customer and achieve a high standard of service level to understand the value chain's baseline of performance. For this purpose, a mapping of the value chain is performed, which is a tool of lean manufacturing that is carried out by product family which outlines the value chain, customers, primary and secondary processes, suppliers, flows of information, and timeline, to display the waste, non-value-added activities and take actions to eliminate them. First, the map of the value chain in current status is carried out to identify the waste, which is transportation, inventory, movements, waiting, over-processing, overproduction, and defects; improvement events known as Kaizen are proposed to eliminate waste and streamline the value chain and therefore map the ideal state [2].

ABC analysis for inventory management is a method of inventory classification to book value (cost or acquisition) of the materials stored that considers the use of the article by its book value, classified from highest to lowest [20].

The principle of ABC analysis in inventory management applies:

1) In the classification of inventory items, based on their relative importance.
2) By setting different administrative controls for different classifications of materials and setting different degrees of control according to each classification's different ranges.

The criterion of classification should reflect the difficulty of controlling an article and the impact of this on the cost and in profit.

The ABC analysis determines the importance of an article in the Company's inventory. To perform this classification, companies could consider some of these no limitation criteria:

1) The annual transaction volume of an article (valued monetarily).
2) Shortages of material used in the production of an article.
3) Delivery time.
4) Storage requirements of an article.
5) Risk of theft.
6) Useful life.
7) Cost of a shortage of inventory, among other criteria.

The criterion used in this case study for the ABC classification is the volume of sales valued monetarily considering the last six months of current sales.

For classified items A, inventory control of maximum and minimum inventory method is implemented, which is a system specially developed to achieve up-to-date warehouses control and achieve optimal inventory; it sets the maximum and minimum levels of stock for each product, as shown below:

Definition of Variables:

$\bar{x}$ = Average sales in three months.

T_{Info} = Time since the manufacturing plant receives the request from the distribution center.

T_{mfg} = time to manufacture considers the days the manufacturing plant requires to produce the finished product.

$T_{transit}$ = time in transit from the plant warehouse to the distribution center.

Var.$T_{transit}$: Time the shipment may be delayed from the main plant warehouse to the distribution center.

Frec.$_{Emb}$: Shipment frequency. Several days between each shipment.

Var.$_{Dem}$. = Demand variation in days needed as additional coverage in the event of any demand fluctuation.

Equations for the calculation of maximum and minimum inventory:

The minimum inventory is calculated based on the average daily demand times the replenish lead time [16].

$$Min.Inventory = \bar{x} * (T_{Info} + T_{mfg} + T_{transit} + Var._{Ttransit} + Frec._{Emb}) \quad (1)$$

The maximum inventory is calculated based on the average daily demand times the replenish lead time in days plus the variation of the demand in days to have additional coverage for any demand fluctuation [16].

$$Max.Inventory = \bar{x} * (T_{Info} + T_{mfg} + T_{transit} + Var._{Ttransit} + Frec._{Emb} + Var._{Dem}) \quad (2)$$

$$Optimal\ inventory = \frac{(Min\ Inventory + Max\ Inventory)}{2} \quad (3)$$

The reorder point is the point when the inventory drops to a certain level, an order for a predetermined amount to replenish the inventory within the supplier's time of delivery is placed. This type of system can be used effectively for articles with independent demand. The reorder point is established to cover the average use within the delivery time plus variation in demand or variation in delivery time. The inventory to absorb this variation is known as safety stock. The amount of variation to cover depends on the level of customer service desired [20].

The safety stock (SS) required is a function of the random variation in demand during the estimated period, the desired level of customer service, and the radius of the delivery time during the estimated period.

$$SS = z\ s\ \sqrt{LT} \quad (4)$$

Where SS is the safety stock in a warehouse, z is the level of service sought for the Company represented by the value of the area under the curve, s is the standard deviation of the product demanded in the warehouse per unit of time.

Once inventory levels are set, next is the leveling of manufacturing within a period. It allows avoiding fluctuations to make the consumption of raw material, labor, and production capacity more predictable, ensuring finished product availability, minimizing inventory, working capital, and lead time throughout the value chain [16].

For this proposal, it is transcendent to determine the control condition of the process before the proposed improvements, as well as the determination of process capability indexes before the improvements and the associated sigma level thereof, to have transcendent measurements

To establish the central distribution center's baseline of performance, the Auditing Warehouse Performance, Ohio: Ackerman Publications checklist was applied [21].

Table 1: Summary of results of the Audit Central Distribution Center

AREA	WEIGHT	RANK	MAX RANK	GAP
External	0.05	0.117		
Internal	0.05	0.126		
Warehouse IT systems	0.1	0.3	0.4	0.1

Mechanical handling equipment	0.1	0.264	0.4	0.136
Contingency planning	0.05	0.067		
Inbound operation	0.1	0.211	0.49	0.278
Put-away and storage	0.05	0.14		
Stock control	0.15	0.417	0.6	0.183
Picking	0.05	0.15		
Dispatch	0.15	0.48	0.72	0.24
Staff and housekeeping	0.05	0.123		
Warehouse - performance management	0.05	0.1		
Legislative & Health and Safety requirements	0.05	0.154		
Overall Warehouse Rating		2.648	3.585	

1	2	3	4	0
No	Poor	Good	Excellent	N/A

Overall, the general grade of DC was 2.648, which indicates performance with an opportunity for improvement. When considering the ascribed areas as the most important in the auditing process, the maximum range was calculated. It denotes three areas with an opportunity for significant improvement:

1) Inbound Operation with a gap of 0.278.
2) Dispatch with a gap of 0.240.
3) Stock Control with a gap of 0.183.

If efforts are focused on these three areas, then a potential score of 3.459 can be reached to be close to excellence with a rating of 4.

Hence, the efforts will be focused on the following processes:

a) Receipt, Preparation of the Shipping Order & Inventory Control. It interrupts the shipment's preparation flow due to finished goods and raw material shortage in the main warehouse, which causes reschedule shipments to the distribution centers based on the promised delivery date of production and suppliers. Evaluate the option to implement a pre-shipment activity and implement a performance metric of hours of preparation and loading of the shipment.
b) Dispatching requires a shipment schedule to increase flexibility associated with sales to customers based on available resources as workforce, space, and equipment.
c) One of the audit opportunities is the lack of KPI's to monitor CD's performance. Customer's delivery time, one of the top priorities identified by the commercial area, currently is 5 hours, being the goal of an average time of 90 minutes.
d) In the stock control process, the opportunity is detected to implement an inventory control to guarantee the inventory's availability due to the constant interruption in the picking process due to finished goods inventory shortage compromising the shipment program and impacting the customer service level.

Associated with the delivery of the finished product to the customer, transformation processes were evaluated to understand the flow of the value chain of the Company, from suppliers, production processes, distribution and final delivery of customer, as well as the activities that provide service to primary processes, which involves the creation of the customer order, the administration area authorizes the order, the ordered product inventory is booked, delivery of documents to logistics, processing the loading order, delivery of documents to the loading area, loading of order and delivery of documents to the customer. Value stream mapping is a tool to achieve competitiveness in any company's value chain, highlighting the inefficiencies of processes such as areas for improvement [22].

The value stream map of the current state indicates:

- The model is pushed and does not have a sales estimate from the commercial area.
- Orders flow into the commercial area, and there is no supermarket of the finished product to shorten the delivery time to the customer and act as a buffer to absorb changes in demand.
- The production plan is made based on the demonstrated demand, and a production signal is sent to production based on a weekly production plan that applies to each of the work centers, which takes into account proven capacity and labor requirements.
- Material planning is done based on an MRP that explodes customer requirements to validate inventory position and release the production orders.
- The suppliers do not estimate the future requirement of the raw materials, so they react based on the monthly supply signal sent by the purchasing department.

ABC analysis was performed, Table 2, which considered the sale of each Distribution Center (DC) for each of the finished products by book value, based on manufacturing and sorted from highest to lowest. The Company's approach resides in 52 catalogs to implement the inventory control policy of maximums and minimums in Central Distribution Center, 18 catalogs in Distribution Center in City one, and 21 catalogs in City two Distribution Center, as it is shown below:

Table 2: ABC Classification

DC Central

ABC	Total Catalogs	%Sales Value
A	52	80
B	68	15
C	207	5

DC City 1

ABC	Total Catalogs	%Sales Value

A	18	80
B	31	15
C	58	5

DC City 2

ABC	Total Catalogs	%Sales Value
A	21	80
B	26	15
C	68	5

When reviewing the inventory's coverage in the days of the finished goods classified as type A, there is an average inventory coverage of 27 days, compared against the Company's goal of 14 inventory days. The following Table 3 shows a summary of coverage in the inventory days before the implementation of the improvement:

Table 3: Coverage in days and distribution as a percentage of the value of inventory catalogs classified as Type A

DC Central

DOS	Number of Finished Goods	% of Inventory Value
0 Days	7	3%
From 1 to 14 days	12	7%
From 15 to 22 days	13	53%
From 23 to 30 days	6	17%
Greater than 30 days	12	20%
Total	50	100%

DC City 1

DOS	Number of Finished Goods	% of Inventory Value
0 Days	1	0%
From 1 to 14 days	8	57%
From 15 to 22 days	2	18%
From 23 to 30 days	3	9%
Greater than 30 days	4	16%
Total	18	100%

DC City 2

DOS	Number of Finished Goods	% of Inventory Value
0 Days	2	0%
From 1 to 14 days	10	43%
From 15 to 22 days	4	19%
From 23 to 30 days	3	33%
Greater than 30 days	2	5%
Total	21	100%

Next, the state of statistical process control regarding the original process is shown and the capability index, Z level, and associated sigma [23].

A prerequisite to determine the status of control of a process is to validate that the data analyzed corresponds to a standard distribution. Figure 2, which can be validated and with the value p=0.191, is higher than the level of type I error or α=0.05.

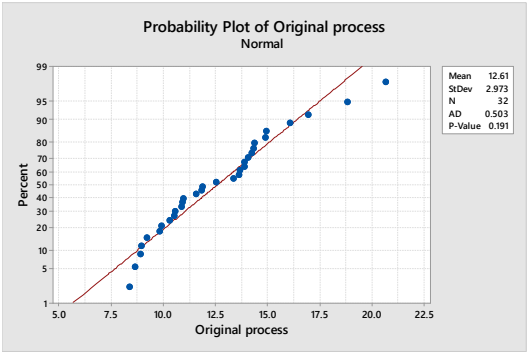

Figure 2: Normal Probability Graph

In Figure 3, it can be noticed that the process is out of statistical control due to several measuring points, which are outside control limits, which are associated with sources of variation attributable to the conditions of the current process [23].

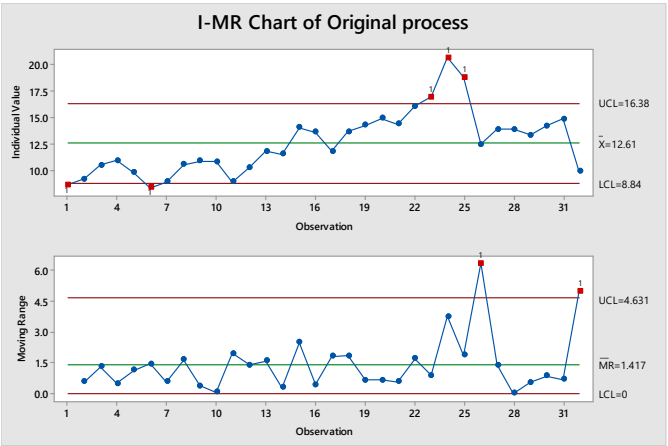

Figure 3: Control Chart for Individual Values and Mobile Range of the original process

Figure 4 shows the capability process analysis report for the original process. The cpk index establishes the actual process capability to meet specifications to consider that a process is adequate; the value must be higher than 1.25 [23]. the current cpk value of the process is 0.37, so the process under current conditions cannot meet specifications and requires serious intervention to restructure its activities and operation controls. The Z level of the process is 1.11, which is reflected in the sigma level = 2.61, the sigma level of a process is determined by the value of the Z + 1.5 level associated with the general standard deviation of the process. It should be noted that the lower specification limit is considered suitable; hence efforts will be concentrated on the upper specification limit [23].

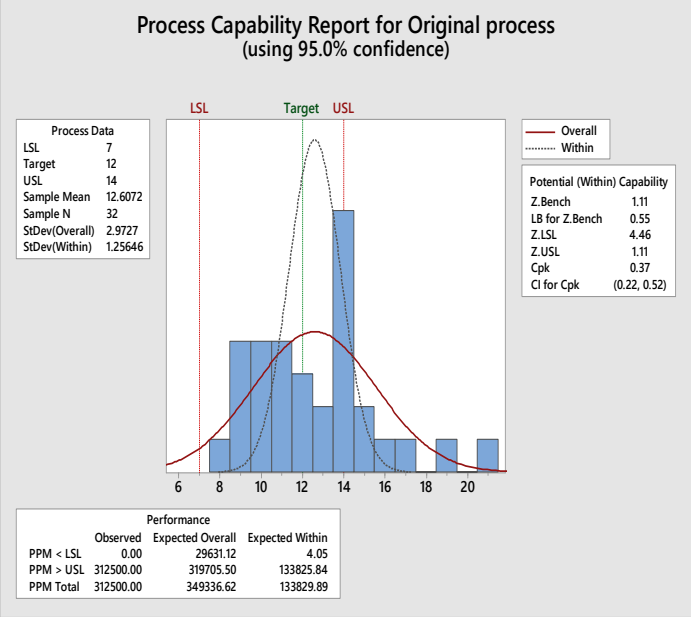

Figure 4: Process Capability report for the original process

The graph of the performance of the process shown in Figure 5 allows observing the fraction of the process that fails to comply with the established specifications. It can be seen in the area under the curve that exceeds the upper control limit.

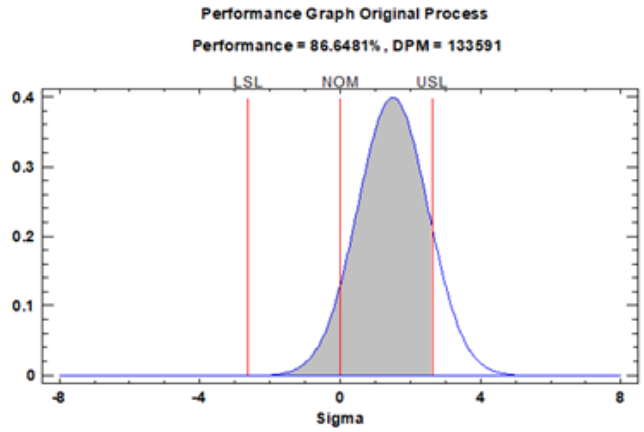

Figure 5: Performance Graph for the original process.

In the six sigma calculator associated with the process Table 4, the values obtained are the Z value of 1.11, Defects Per Million (DPM) of 133,519, Percentage of Defects 13.3, Yield of 86.64% with a process capability (Cpk) of 0.37, and a sigma quality level (SQL) of 2.6 [23].

Table 4: Six Sigma Calculator
Entry: Value-Z = 1.11
Change in sigma = 1.5
Equivalent values

Table of Contents	Value
Value-Z	1.11
DPM	133519
Defects	13.3519
Performance	86.6481
Cpk	0.37
SQL	2.61

5. Issues, Controversies and Problems

Based on the audit, other opportunities were identified and then raised to the Company:

1) Improve the receiving flow of raw materials and finished product, since the schedule for the reception of raw material as complementary products for sale is interspersed with the hours of shipment preparation, which generates a conflict of space in the yard and rescheduling of shipments of the finished product.
2) Review the flow of finished products from other manufacturing plants to ensure the availability of inventory in the central distribution center, positioning a supermarket to facilitate the consolidation of shipments.
3) Streamline the work used in the Operation of the process put away (pre-stowage to the final location of the finished product) combined with the efforts of picking Operation for the shipment of the product and create a standardized work for the truck loading process.

6. Research Methodology

In the implementation of the improvement of the customer service level to guarantee the availability of the finished product and improve the delivery time in the distribution center, the following results were obtained:

1) **Audit in the central distribution center** to detect improvement opportunities, where the detail of such is presented in the analysis of Table 1.
2) **The ABC classification** was performed to determine the items that represent 80% of the sales valued, to focus on the control of inventory presented in Table 2.
3) **The analysis of the coverage of inventory of finished product catalogs**, Table 3, classified as type A, indicates that seven catalogs of finished product do not have inventory for sale, only twelve catalogs are within the target set by the Company of fourteen days of inventory, and the rest of the twenty-nine catalogs are above the goal of fourteen days of inventory. Only 7% of the total monetary value of the stock is located within the established goal of inventory coverage.
4) **Lead Time Component Analysis**
   a) Information Lead Time: Time from the moment the manufacturing facility receives the request for inventory replenishment from the distribution center supermarket.
   b) Manufacturing Lead Time: Considers the days that require the manufacturing facility to produce the finished product, plus the quarantine time.
   c) In Transit Lead Time: Time in transit from the warehouse of the manufacturing facility to the distribution centers.
   d) In Transit Lead Time Variation: Time that can delay the shipment from the warehouse manufacturing facility to the distribution center due to external factors such as climate, holidays, transport breakdown, among others.
   e) Frequency of Shipments: Considers the period in days between each shipment.
   f) Variation of Demand: Days of daily inventory coverage regarding the daily sales average to cover any variation in demand required by the final customer.

g) Variation of Supply: Daily coverage based on average daily production to cover any variation in the supply as quality defects, equipment stoppage, lack of personnel, shortage of raw material.

The evaluation of lead time's components for the manufacturing facility is considered in the following Table 5:

Table 5: Manufacturing Lead Time Components

Manufacturing Lead Time Components	Days
Information Lead Time	2
Manufacturing Lead Time	1
Quarantine Lead Time	7
Supply Variation	10

For the case of a distribution center, the lead time components are shown in the following Table 6:

5) Inventories Planning for the distribution centers and manufacturing facility

The sales estimate horizon is three months (current month plus two months based on the historical demand), the demand is analyzed based on the current sales and sales estimate provided by the commercial area Table 7 for calculations of supermarkets to position each of them in the distribution centers.

Table 7: Demand for each Distribution Center

6890	212	230	170	212	255
5151	19	25	10	22	34

6) Visual Management of the Inventory of Distribution Centers

The current inventory of finished products is compared against the maximum, optimum, and minimum inventory to maintain visual management. Green indicates that it is within the maximum level and optimum inventory; this is the ideal position. Yellow between the optimum and minimum levels requires planning to place a manufacturing order to replenish the inventory to its position. Red requires expediting the production order, given that the current inventory is below the minimum level with a possible negative impact on the service level. When the current position is blue, it is above the maximum allowed level, and action is required to balance the inventory levels to those approved. It is essential to run this report daily since it is the tool that manages the release, issuance, and establishment of priorities of the manufacturing orders to production and the valuation of the position of inventory in units. This report is required per the manufacturing facility and distribution center.

7) Planning Horizons

Once the supermarket was positioned in the Distribution Center and manufacturing facility, the following was agreed with the Commercial area:

The sales estimate horizon is three months (current month plus two months based on the historical demand), delivery takes place between 3 - 4 days business days of the month, and formed on the following and the basis of the planning zones:

- *Fixed Zone*: Consists of the time required upon releasing the production order and until the product is available for sale. The horizon is of 14 days with zero percentage of variation. This planning zone is conformed of labor, materials, and burden.
- *Firm Zone*: This zone considers, from the moment the purchase order is placed to the suppliers, considers the longest lead time of the resource, either materials, tools, and/or equipment, as labor in compromising the production requirements. The time horizon is 20 days; the variation percentage of the sale estimated is +/- 20%. In this horizon, planning involves materials and any other resource required to be contracted as labor and/or equipment.
- *Planning Zone*: Consists of the horizon when no resource for production is committed; therefore, the percentage of variation is open.

8) Delivery Time to Customer Service

The delivery time to the customer is essential as part of the flexibility offered by the Company, to meet the immediate need for what was agreed with the Commercial area, the following delivery times according to the ABC classification of the finished product:

- *Family Products A*: Delivery time is the time upon the receipt of the order, preparation, shipment, and invoicing; this delivery time is of 90 minutes for the external customer; in the case of an internal customer as the Distribution Centers located in other cities, it must be considered two days upon the receipt of the inventory replenishment requirement, preparation of shipment and billing plus the in-transit time. If demand variation consumes the inventory available in the supermarket, the planning area should coordinate the managing of materials and resource capacity with Production and Purchasing; consideration should be given to the delivery to customers and communicate to the commercial area the best delivery commitment to customer's order. In coordination with planning, the Commercial area shall manage the priorities of the inventory allocation until the inventory is regularized in the supermarket according to the maximum and minimum levels of inventories approved. Production should communicate the plan to recover inventory to approved levels.

- *Family Products B*: These finished goods products are not supplied within the calculation of the maximum and minimum inventory. It is a product that is managed to make an order basis. Delivery Time is seven days. The way to schedule this finished product to production is FIFO (Customer's First orders entered are the first to be scheduled for production).
- *Family Products C*: This is a new product with a particular design in which the delivery time is variable according to the project's timeline.

9) Production Balance

Based on the month's production requirement, the production requirement is planned in Table 11, 30% in week 1, 30% in week 2, 20% in week 3, and 20% in Week 4; this production balance enables demand confrontation since 60% of the sale occurs in the last two weeks of the month, which makes the labor requirement planning Table 12 as the materials requirements more predictable, for inventory positioning of raw materials in supermarkets, this enables better visibility of the requirement to the consumption of raw materials to suppliers and increase the flexibility of the productive capacity, especially when they are manufacturing make to order products for special projects for which demand is random.

Table 11: Monthly Balanced Production Plan

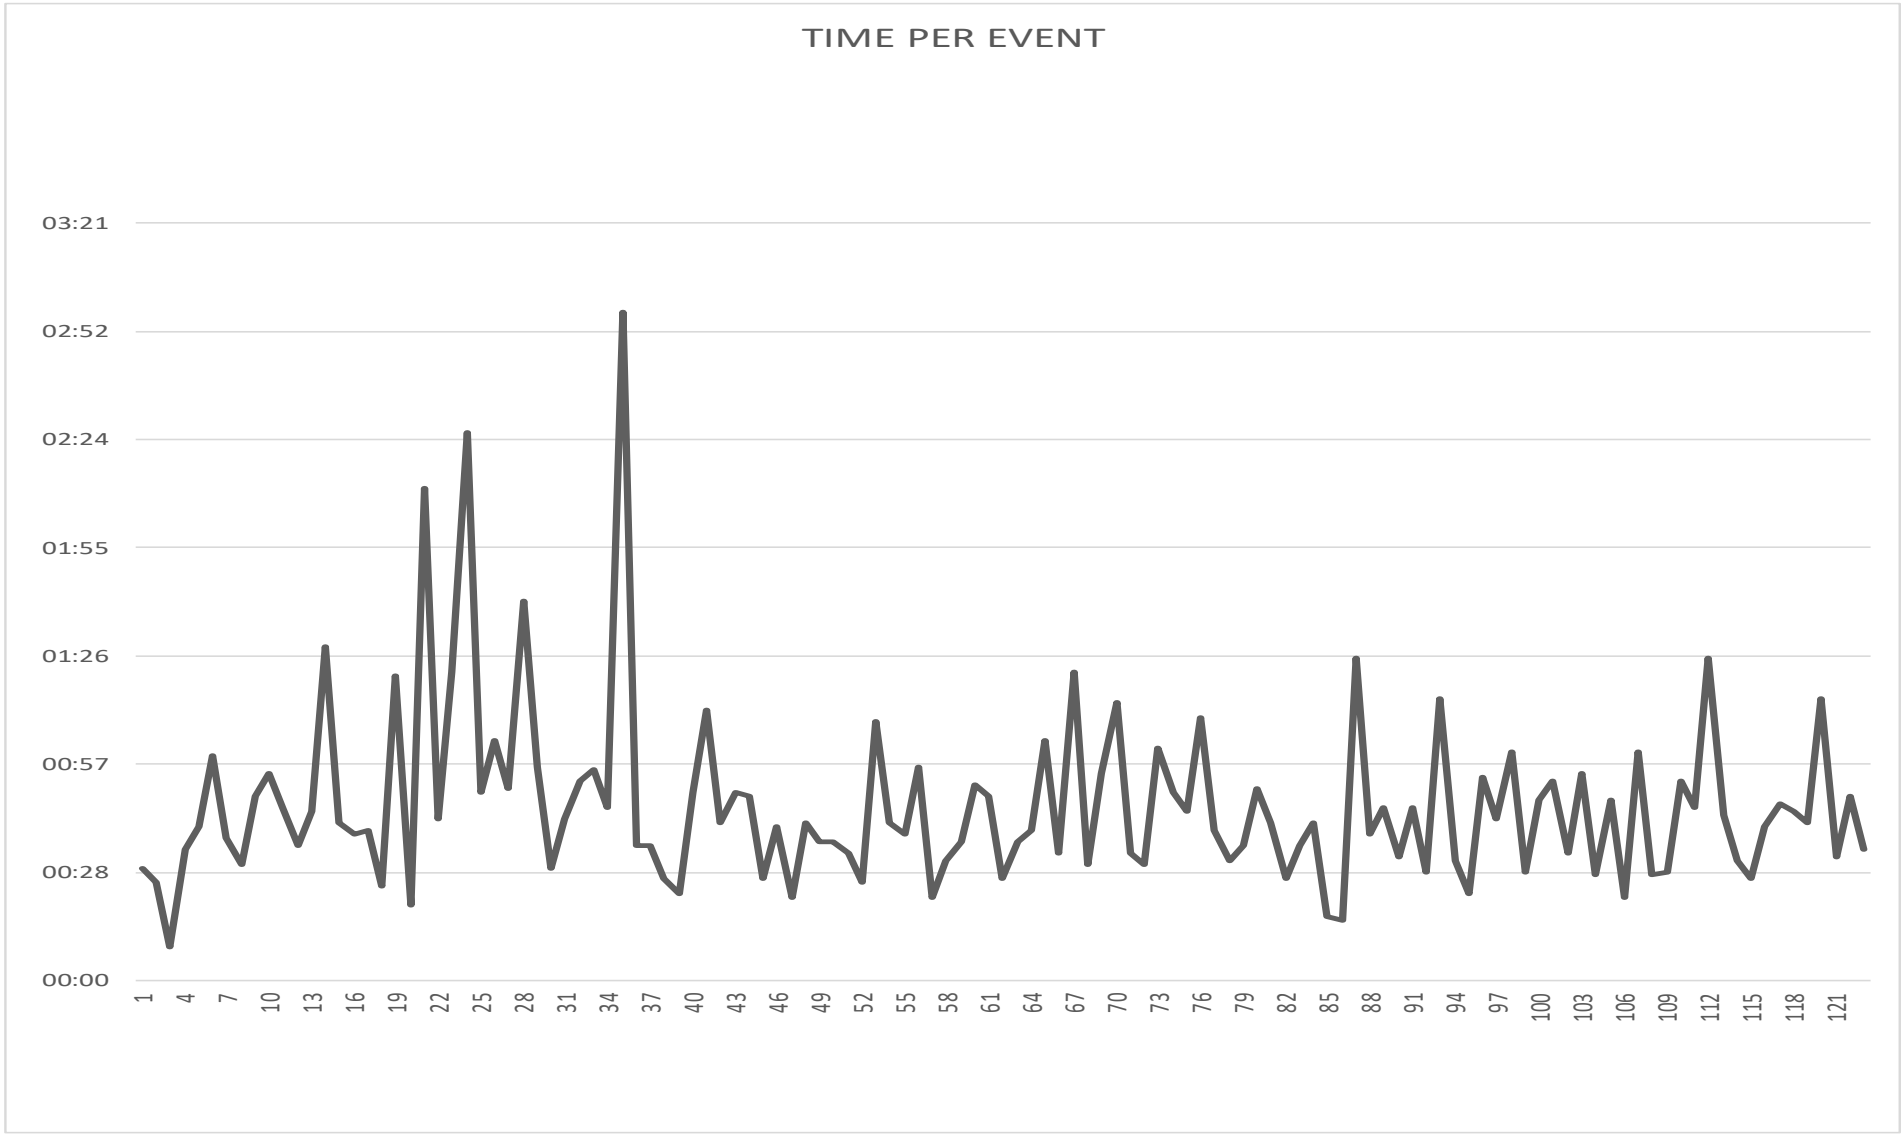

Figure 6: Customer delivery Time per event.

10) Customer delivery Time

The customer delivery time Figure 6 is measured from the moment the customer order is created, the administration area authorizes the order, the ordered product inventory is booked, delivery of documents to logistics, processing the loading order, delivery of documents to the loading area, loading of order and delivery of documents to the customer.

Registers an average customer delivery time of 46 minutes below the goal of 90 minutes, which encourages the customer to be recurrent customers considering the availability of inventory to cover their requirements with a short delivery time.

11) Process Capability and Six Sigma

Through the implementation of the proposed improvements, the process is in statistical control, as well as in the assessment of capability indexes, the level of cpk increased from 0.37 to 0.86, the associated z level moved from 1.11 to 2.59, and the sigma level moved from 2.61 to 4.09 with a decrease of defects per million of 133,519 to 4,798.83. It should be noted that an optimum level is not yet achieved. However, this represents a strategic impact and the opportunity to deploy additional improvements to arrive at an ideal level of six sigma, that is to say, with only 3.4 ppm of failure. It can be observed in Figure 7 that the associated data with the subsequent measurements to improvements come from a normal distribution with a p value=0.407, which is higher than the value α=0.05 [23].

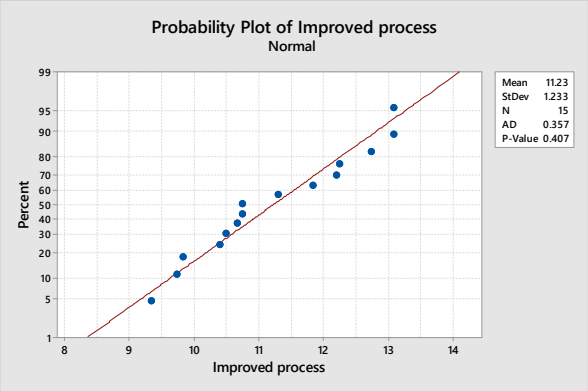

Figure 7: Probability Plot of Improved Process

Figure 8 shows the process under statistical control without points outside the control limits without any anomaly trends.

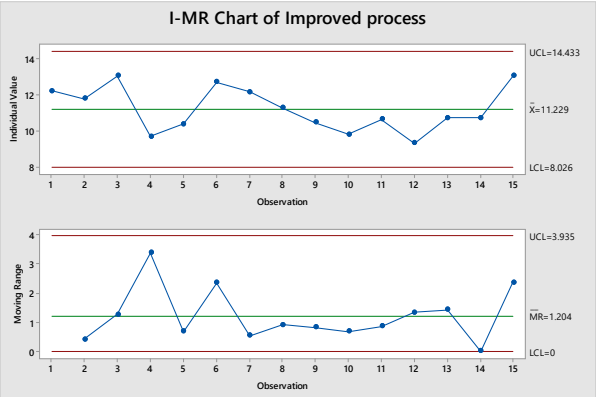

Figure 8: Graph of Individual Values and Mobile Range for the Improved Process

Figure 9 shows the process capability analysis report in which it is possible can see the improvements obtained with a Cpk index of 0.86; although it is not the optimal state of the process represents a significant improvement.

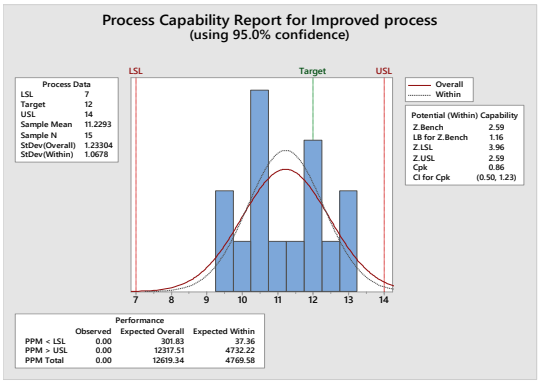

Figure 9: Process Capability Report for Improved process

Figure 10 shows the improvement in performance in which there is a significant reduction in the fraction of the probability distribution outside the upper limit of the specification.

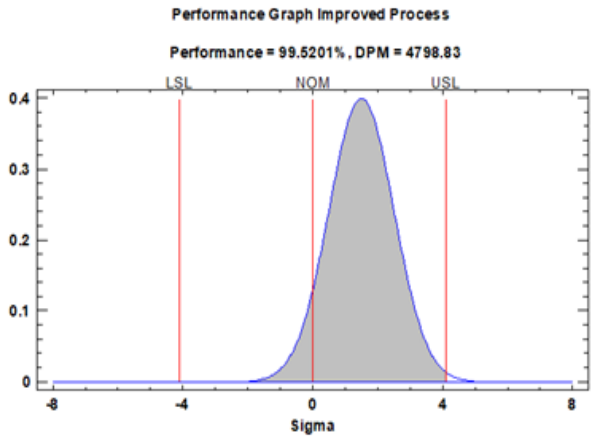

Figure 10: Performance Graph Improved Process

Table 13 shows the values obtained in the six-sigma calculator associated with the improved process the Z value of 2.59, Defects Per Million (DPM) of 4,798.33, Percentage of Defects 0.47, Yield of 99.52% with a process capability (Cpk) of 0.86, and a sigma quality level of (SQL) 4.09.

Table 13: Six Sigma Calculator
Entry: Value-Z = 2.59, Change in sigma = 1.5
Equivalent values

Table of Contents	Value
Value-Z	2.59
DPM	4798.83
Defects	0.479883
Performance	99.5201
Cpk	0.863333
SQL	4.09

12) Pull System

The Commercial area estimates the monthly sales to determine the maximum and minimum level of finished product inventory. A pull system is implemented, the customer's orders are supplied directly from the CD's finished good product supermarket. The

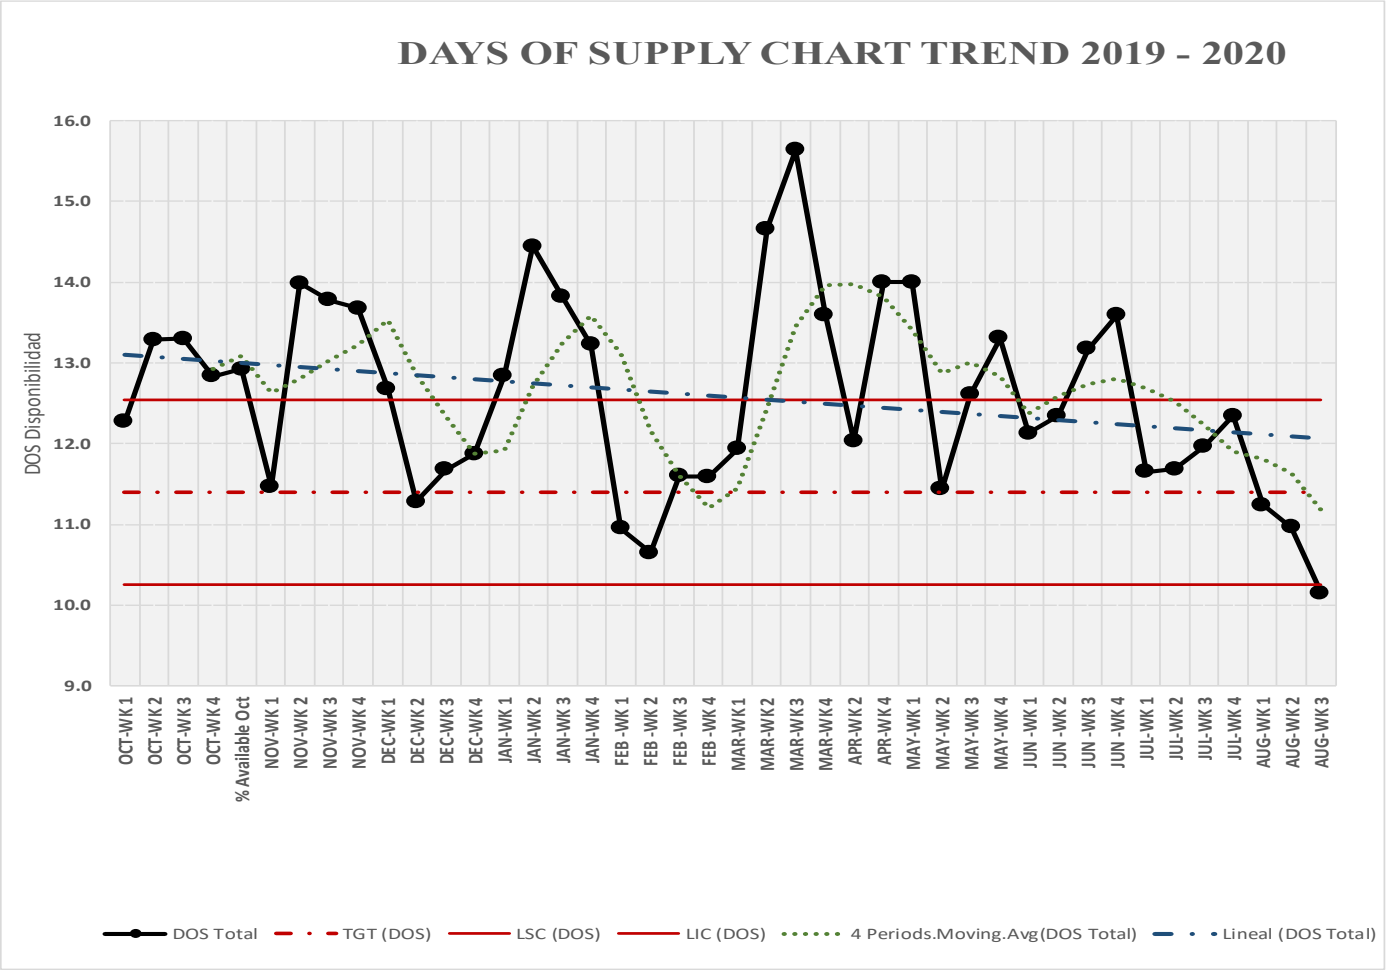

Figure 11: Days of Supply Finished Goods Inventory

consumption of the supermarket inventory generates a manufacturing order for production to replenish the finished product supermarket. As the supermarket's raw materials are consumed when producing the manufacturing orders, the purchasing requisitions of raw material are released to the purchasing department to generate the purchase orders for the suppliers and thus guarantee the replenishment in the raw's materials supermarket.

13) Days of Supply Finished Goods Inventory

The trend chart of days of supply Figure 11 shows a favorable trend in days of coverage, having a supply of twelve days of inventory against a goal of 14 days.

7. Results and Conclusions

During the COVID 19 pandemic, the Company has been operated with a Pull system, in which supermarkets were positioned in Central, City 1, and City 2 distribution centers for finished products classified A; The inventory is managed with a maximum, and minimum policy, based on customer consumption, the supply signal to the manufacturing plant is triggered to replenish and position the inventory in the distribution centers. Based on the inventory consumption for the supermarket of the manufacturing plant, the manufacturing orders are released to replenish the inventory in the supermarket of the plant, which has generated a reduction of the inventory to a coverage of 12 days before starting the improvement in the process, the catalogs classified type A had a 27-day average coverage, against the Company's goal of 14 days of inventory. The service level, the baseline of performance 89% guaranteeing inventory availability, exceeds expectations with a 98% service level. An average customer delivery time of 46 minutes is recorded below the 90-minute goal, which encourages the customer to be a recurring customer considering inventory availability to meet their requirements with lead time delivery. The savings in inventory optimization on an annual basis represented USD 530,785. (Five hundred thirty thousand seven hundred eighty-five dollars) helping the Company to gain liquidity and to create the conditions for the recovery of economic growth, and helping to preserve employment as much as possible in a constrained market. Through the implementation of the proposed improvements, the process is under statistical control, the process capability (Cpk) is increased from 0.37 to 0.86, and the level six sigma (SQL) is increased from 2.61 to 4.09, reducing the percentage of defects to

13.3 to 0.47. An additional benefit is that the Company implemented the methodology nationwide in its other Manufacturing Plants and Distribution Centers. This methodology supports the acceptable practices that the Company is implementing in search of continuous improvement as part of the strategic framework to fulfill the strategic objectives based on the business vision.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Chatbot is an application that is designed to help humans communicate with machines. NLP and API.AI are some of the components that are crucial in making chatbot as they help chatbot in performing chatting operations. Chatbot could be implemented in many aspects of life such as education, social media platforms, games, even in business. Business has always been an important part of human life and it is irreplaceable. As the era evolves, the business industry is also getting modernized and automated which resulted in implementing the latest technology into the industry like chatbot. In the context of the business industry, chatbot can be used as an assistant that will help dealing with the customer service section as well as giving the latest information about the business. This study aims to determine how the chatbot gives impact to the business as well as the owners, what kind of features that the chatbot needs, and how the chatbot should be developed so that it will be compatible in the business environment. The research was conducted using two methods which are literature review and survey: questionnaire. The result of the research conducted are the impacts that the owner gets by using chatbot in their business, a set of features that are relevant in developing chatbot and recommendation for further implementation.

1. Introduction

Chatbot is an application or service that can interact with users by communicating using text or audio. The first chatbot produced was ELIZA [1] in which this chatbot could communicate using simple responses with the user. The usage of chatbot nowadays is inclining significantly that it is easy to find chatbot in web sites with each different functionality. Chatbot both on applications and web sites usually give services like giving important information, helping users in operating data, and supporting business processes. Surprisingly, chatbots can fit in every kind of website or program, even gaming sites. Thus, it is easy to say that chatbot is also gaining popularity in the business environment since chatbot could confirm that messages or complaints from customers can be handled fast and accurately. In addition, companies that use chatbot could cut down on their operational fees [1] and also their business could be active for 24 hours every day. In technology development nowadays, there are lots of research that uses chatbot as virtual assistant or shop assistant. Chatbots are programmed so that they can interact with users using natural human language. These days, there are many chatbots that are based on AIML or Artificial Intelligence Markup Language like virtual assistants such as Voice Actions, Skyvi, Iris, and Call Mom (Pandorabots.com). AIML is often used for programming the artificial intelligent software of chatbot or also known as knowledge base [2, 3]. Technology these days is developing so fast that it is now reaching to all kinds of people and covering different aspects in life like health, business, education, and many more. This is because information plays an important role in this globalization era. Everything including daily activities needs information before doing it and every action that was taken is demanded to produce another information that is helpful for many people. Thus, as technology is something that makes information reachable, technology including chatbots are developing and expanding fast and the demand of technology is for sure high. In Indonesia, chatbots are becoming popular as they can communicate to customers as if they are literally talking naturally and they can answer different questions faster than humans. It is usually implemented to support the company's service as chatbots will be likely to increase the service rate. Moreover, chatbot will not forget any information unlike humans who will be most likely to forget the information that is needed to be delivered. Thus, in this research we are planning to know

* Corresponding Author: Azani Cempaka Sari, kent.phiedono@binus.ac.id

whether chatbots are actually important in running businesses, if it is needed in the business, and what kind of chatbot model that is suitable for supporting a business.

2. Literature Review

The basic mechanism of chatbot starts with messages sent by the user. The message is then processed by NLP (Natural Language Processing), and chatbot responds by replying to the message according to the existing database [4].

2.1. Chatbot

Chatbot is a character that communicates with its user or people using natural human language in chatting forums such as messenger, instant web, email, usenet, forum, web, and even using speech like telephone. Chatbot has so many aliases and some of them are chat robot, bot, chatter bot, bot chatting, chatterbox, V-Host, V-People, agent, and virtual human. Chatbot can also be connected to an avatar or animation that includes speech synthesis so that chatbot could be seen as something livelier as we, human beings, could see what it is and what it is speaking. To improve the service given, chatbots are programmed so that it could analyze words, phrases, and the construction of sentences of inputs so then it could predict the users' personality, preferences of products, and give responses according to what it had analyzed. While doing the conversations, chatbots usually are collecting previous responses and inputs so their future responses could vary and it will also improve the quality of its future responses. Giving personal recommendations is an example of the result in collecting data from previous conversations.

In the context of e-commerce, chatbots can handle conversations with customers and help them in the process of selling which are expected to give positive effects toward online businesses [5]. It is believed that experienced users feel more satisfied when communicating with virtual communicating agents rather than communicating with inexperienced users in all kinds of aspects that were evaluated including impression, control, effectiveness, navigation, learning, and many more [5].

There are 3 things that form a combination and this combination is the main pillar of chatbot. The 3 things are:

2.1.1. User Interface

User interface referencing to the display interface of a chatbot that bridges between user and chatbot to interact with each other. User interface has to give the best experience to the users when interacting with the user. Without it, chatbot will be useless as it is not convenient to use. The interface includes the text's font, background color or theme, animation, images, and navigation tools.

2.1.2. Artificial Intelligence

AI or Artificial Intelligence is like the core of the whole chatbot application because it is the main brain where everything is processed [6]. The chatbot application could understand inputs when interacting with users because of this. Chatbot is the expansion of the artificial intelligence field so that is why artificial intelligence is very crucial for the whole development of chatbot.

2.1.3. Integration

Integration with other applications or systems can enrich the chatbots' features. Chatbot could get additional or supporting materials and information by integrating it with another system. Thus, integration could improve the user experience and satisfaction. Although it is not as important as artificial intelligence, integration plays a major role too in promoting the usefulness of chatbot.

In a business environment, chatbot can help solve problems regarding communicating with users or customers especially in terms of service and experience when interacting. Thus, chatbot is very effective particularly in problems that are fixated, specific, and predictable. In the rapid business development environment, chatbot becomes an alternative solution that can help customers to reach and interact with business.

2.2. Platform API.AI

API.AI is a platform that provides NLP (Natural Language Processing) and NLU (Natural Language Understanding) services. These services are used to make chatbot smarter and can understand the purpose of what is asked by the user. Natural language processing is one of the disciplines of Artificial Intelligence that focuses on human and computer interactions through natural language that humans use. In NLP the goal to be achieved is the ability of an NLP system to have natural language knowledge both from the sentence structure, the meaning of the word and the purpose of a sentence. While NLU itself is a sub-field of NLP, where the focus of the purpose of NLU itself is to make an understanding of a sentence and conduct semantic analysis. API.AI itself does not support the Indonesian knowledge domain but has a lot of knowledge domains in English. Domain is a collection of knowledge and data structures. Within API.AI itself many knowledge bases have been embedded in this API.AI service system. The collection of knowledge contained in this service includes musician entities, airports, etc. However, the absence of Indonesian language support in this service does not mean this service cannot be used by researchers who speak Indonesian language [7].

2.3. Chatbot Type (Based on its functionality

2.3.1. Business Management Chatbot

This chatbot type is usually found in business environments. Aside from communicating with users, there are some other abilities which are processing business process data and giving information related to certain business. Usually the chatbot is implemented in applications or websites that are related to business and it acts as a supporting application. Chatbots that can be classified as business management chatbot are CardBot, Naver TalkTalk, SuperAgent, and many more [8, 9, 10].

2.3.2. Game Chatbot

This kind of chatbot is the most popular chatbot type among youngsters, especially gamers. It is usually used for entertainment as it is used when users are playing games. The chatbot is usually used when playing multiplayer games but it is compatible with single player games too. One of the examples is SimSimi in which we can use it in mobile and web platforms.

2.3.3. Music Chatbot

Just like its name, this chatbot type is used for playing music. The chatbot is actually pretty easy to use as the chatbot will ask the user to input their choice of songs and the chatbot will automatically search the song in platform YouTube or any accessible platform then it will play the song. This chatbot is usually found in chatting applications that have voice related features in it like Discord application. The chatbot examples are Groovy, FredBoat, and Rythm.

2.3.4. Assistant Chatbot

Assistant Chatbot just like its name means that it helps users in doing daily activities just like how secretaries in real life do [11]. Telling weather forecasts, planning plans, setting important alarms, and asking to call someone are some of the features that this type of chatbot has. The examples of this kind of chatbot are Google Assistant, Siri from Apple, Alexa from Amazon, and Cortana from Microsoft [11].

2.3.5. Education Chatbot

Education chatbot is a chatbot that is used to help users in learning. This type of chatbot is usually implemented in the education field. The benefits of using this chatbot is that it can cut down operational fee and save time when learning. The examples of this kind of chatbot are Duolingo, Gengobot [4].

2.4. Chatbot Examples

2.4.1. Telegram Bot

Telegram Bot is a social media bot that many people installed. This bot gives user feature API (Application Programming Interface) this feature which allow chatbot exist. This feature used for direct Chatting with using chatbot that made user can make chatbot suitable as user wish. Telegram bot started from registration about bot used for chatbot [7].

2.4.2. Pandorabots

Pandorabots is an online service which allows developers to host and deploy Chatbot. This chatbot has 225.000 Developers registered and tools already help 300.000 chatbot. Pandorabots using AIML(Artificial Intelligence Markup Language) which is a standard for writing code in chatbot. This chatbot offers many tools including 'Artificial Intelligence as a Service' these tools provide access API to platform bot hosting and pandorabots playground : a development environment used for made chatbot. Pandorabots are working on constant and have very large active communication. Pandorabots obey the standard for making chatbot. Up until now, open source software has been used for building pandorabots. Pandorabots are also known to be using AIML as knowledge content markup language [12].

2.4.3. CardBot

CardBot is a chatbot which is a result of a research by Meng-Chieh Ko and Zih- Hong Lin in his research entitled CardBot: A Chatbot for Business Card Management with the additional function of being able to read data from business cards with OCR techniques collaborated with cameras and also has a function to organize the data it has acquired into a knowledge base [10]. The data that has been obtained will be managed, combined and stored so that when a user requests data from that already obtained chatbot can immediately retrieve the data to the user. This chatbot uses NLP development technique in its development [10] and includes a type of chatbot for business management.

2.4.4. SuperAgent Chatbot

SuperAgent Chabot is a chatbot with features that can read data from web pages (about products) and can answer questions from users based on data available on these web pages [9]. In addition to these features, chatbot can carry out regular conversations (chit-chat) with users and the knowledge base of this chatbot can be added by the developer as well. This chatbot was made with machine learning techniques, NLP, and using the DSSM model for attribute matching and the first candidate will be the result of the response of this chatbot [9]. This chatbot is used as an extension on the web and can be used on any website (not just linked to a web or application) [9].

2.5. Natural Language Processing (NLP)

This subfield of artificial intelligence is a technique that helps computers understand human language. Using NLP, machines can make sense of unstructured online data so that we can gain valuable insights. NLP primarily comprises natural language understanding (human to machine) and natural language generation (machine to human). This article will mainly deal with natural language understanding (NLU). In recent years there has been a surge in unstructured data in the form of text, videos, audio and photos. NLU aids in extracting valuable information from text such as social media data, customer surveys, and complaints.

2.5.1. Common Techniques used for extracting information

Named Entity Recognition

This technique is one of NLP techniques that is used to extract texts, name and categorize them into a certain topic or context. Named entity recognition or NER is serving as important targets for most language processing systems because they usually carry key information in a sentence [13]. Accurate named entity recognition can be used as a useful information source for different NLP applications. There are lots of topics that NER can identify but there are 3 classes that NER systems use the most: person (PER), location (LOC), and loosely defined miscellaneous (MIS) [13].

Sentiment Analysis

Sentiment analysis or also known as opinion mining is a technique where it aims to determine the attitude of a writer with respect to some topic or the overall contextual polarity of a document [14]. This technique differentiates texts or documents into two main parts: objective (facts) and subjective (opinions). Here are text examples on both objective and subjective:

Objective: I bought a book.

Subjective: The paper was nice.

Sentiment could be identified through three methods which are manual opinion words generation, dictionary-based opinion

words generation and corpus-based opinion words generation. Manual opinion words generation is a method in which we collect the opinion words manually and it is less effective than the other two. The dictionary-based opinion words generation is a method in which we use a seed list and grow the list using words from the dictionary until there are no new opinion words. The last method is a method in which it depends on syntactic or co-occurrence patterns in large text corpora.

In sentiment analysis, opinion words are counted and grouped into 3 categories: positive, negative, and neutral. Opinion words such as "good", "amazing", "great" are considered positive meanwhile "bad", "suck", "terrible" are considered negative. In sentences, every word that is considered positive will be graded as (+1) while negative opinion words will be graded as (-1). If the end result is 0 then the text will be considered neutral, if the result is above 0 then the text will be considered as positive text, and if the result is below 0 then the text will be considered as negative text [14].

Text Summarization

Just like the topic's name, this technique aims to create a summary of a certain document that contains the most important information of the original one [15]. The technique mainly involves large chunks of text such as news articles.

There are two approaches to text summarization: abstraction and extraction. The extraction method works by identifying important sections of the text and generating them verbatim; thus, they depend only on extraction of sentences from the original text [16]. Meanwhile, the abstraction method aims to produce important material in a new way. Since existing abstractive summarizers often rely on an extractive preprocessing component to produce the abstract of the text [16], the paper will be focused on discussing the extractive summarization method. There are three main tasks of extractive text summarization which are to construct an intermediate representation, give sentence score, and summary sentence selection.

Aspect Mining

Aspect mining is a technique that is similar to sentiment analysis but focuses mainly on identifying different aspects in text. There are two major tasks in aspect mining which are aspect extraction and aspect sentiment classification. Process of identifying the opinion words from the given sentence is called aspect extraction and categorizing the extracted opinion words into one of the polarity scales is called aspect sentiment classification [17]. The polarity scales in aspect mining are broad but we can narrow them into 3 major scales: positive, negative, and neutral.

Topic Modeling

Topic modeling is a technique where it aims to give the reader better understanding by identifying natural topics in the text. There are four most popular methods in topic modeling which are Latent Semantic Analysis (LSA), Non-Negative Matrix Factorization (NNMF), Probabilistic Latent Semantic Analysis (PLSA), and Latent Dirichlet Allocation (LDA) [18].

LSA is an algebraic method that presents the semantic space of documents. The more semantic the relationship, the contextual usage will come closer. LSA is based on single value decomposition (SVD). NNMF on the other hand is another reduction technique where there are negative numbers in the dataset which is a problem and are addressed by placing non-negativity constraints on the data model. PLSA is another technique of reduction for detecting semantic co-occurrence of terms in text mining based on bag of words (BOW). PLSA uses a probabilistic framework in a corpus. Finally, LDA is an approach to capture significant inter as well as intra document statistical structure by mixing distributional assumptions that document could arise from multiple topics. The topic is defined as distribution over a vocabulary. This approach is based on the Definneti theorem.

2.5.2. Advantages of NLP

Natural Language Processing can perform a large-scale analysis which can help machines perform language-based tasks such as reading text, identifying topics or what is important, or even extracting sentiment in a text. Moreover, NLP can perform these tasks in such a short time while still applying consistent and unbiased criteria. Thus, it can help people in doing these kinds of tasks faster and more accurately.

Other than large-scale analysis, Natural Language Processing has increased the level of sophistication in engineering because generic engines now can deliver semantic representations for sentences or sentences for representations [19]. Natural Language Processing also makes engines to be more user-friendly since it is highly expressive, highly flexible, and highly representative of reality [20]. On the other hand, NLP helps to bridge the gap between machines and humans because it can decipher information to computers and interpret the way people talk.

3. Research Method

3.1. Literature Review

Literature review is a process in which researchers conduct surveys from scientific sources on a specific topic. In this study, the collection of scientific sources based on international journals, international conferences, and the results of research on chatbots in the business world. All scientific sources are obtained through the internet namely, Google Scholar, ScienceDirect, Academia.edu, and the IEEE website. The sources that had been collected will be analyzed and summarized into important points.

3.2. Survey: Questionnaire

The survey is classified as qualitative data collection. A qualitative approach with case studies is applied in this study where qualitative view of field conditions by collecting data from informants. The survey was done online using Google Forms and each of the results were checked and analyzed thoroughly. After the checking, the results were then summarized as points.

The questions mainly ask about people's perspective on chatbot, its effectiveness, and its features to be added on the chatbot in a business-related environment. This survey method is reliable as the questions are based on this high technology era situation and respondents from all over the world might have the

same responses towards the same question. Thus, this method may produce results that are consistent and reproducible. For the validity of the method, the results would correspond well to the questions and would produce accurate results as the questions were made and distributed to people who are exposed to technology and business at the same era of time.

4. Results

4.1. Questionnaire and Literature Review Result

Based on that questionnaire results, we get that most of the respondents feel that chatbot will be helpful for online shop owners or sellers when handling customers (91 out of 100 respondents). Respondents also feel that an up-to-date answer from the seller is important thus, we can conclude that chatbot will be useful since it responds faster than humans (98 out of 100 respondents). Although most of the respondents feel that chatbot may be able to handle an online shop alone (39 out of 100 respondents) or with human's help (38 out of 100), there are still some respondents who feel that it is better for an online shop to be handled by the seller himself (27 out of 100). From the results shown above, we can conclude that the chatbot which is suitable in the business environment is a fast-responding chatbot with up-to-date data regarding the products or services. Although the idea of having a chatbot handling the online business alone is wonderful, we still believe that the seller plays a major role in the online business and it is better to have both chatbot and the seller handling the online business. In conclusion, chatbots could be accepted by people in business and should be helping the seller instead of handling the business alone. These questionnaire results are from our online questionnaire that we shared on online messaging platforms like LINE application and WhatsApp. The respondents vary from university students (Binus University Alam Sutera) to online shop owners or sellers in Indonesia.

On the other hand, there are some suitable features of a chatbot for business environments based on our literature review. We found out that the SuperAgent chatbot researched by Lecu, Shaohanh, Fuwei, V-Chutan, V-Chadu, and Mingzhou can identify texts whether it was about fact Q&A (information detail about products or services), text Q&A (opinion about the products or services), or chatting [9]. From another journal titled Chatbot Using A Knowledge in Database which was researched by Bayu Setiaji and Ferry Wahyu Wibowo has great features for chatbot especially for online business that need to be pre-trained by a knowledge base. Moreover, it can be used in any language but with some boundaries so chatbots can be more flexible [21]. Lastly, Intellibot which was researched by Mohammad Nuruzzaman and Omar Khadeer Hussain can set a great example for chatbots because it uses a movie as its knowledge base for answering chit-chats and also another personalized knowledge base for questions about products or services [22]. There are some other chatbots that we considered as suitable for the business environment with each feature that will be described in Table 1: Chatbot Description Table.

Table 1: Chatbot Description Table

Chatbot	Description
Chatbot [21]	Chatbot created using database as its knowledge base (RDBMS MySQL), pre-trained chatbot, using bigram method for processing text and identifying response, can be used in any language but with some boundaries, can understand similar words, typo, or even different words and similar meaning (responses are based on the data inside the database). Refer to *Fig. 1* for the example of its usage. The text is in Indonesian but it mainly talks about daily conversation.
Naver TalkTalk [8]	Naver TalkTalk chatbot is a chatbot with cardbot-based interface and using RPA (Robotic Process Automation) as its automation. The bot is pre-trained because the bot will proactively ask questions that is based on its data or knowledge base that previously must be trained or if not the chatbot will not be able to ask related questions. The interface is using cardbot interface and it is simpler to use and to understand what the bot is trying to say. This chatbot is much more compatible with business environment but sadly no chit-chatting can be held in this type of chatbot. Refer to *Fig. 2* for its example of chatbot usage and its cardbot-based interface.
SuperAgent [9]	SuperAgent chatbot is a chatbot that implements machine learning and NLP (Natural Language Processing). The chatbot is connected to business environment and act as a marketing agent. The bot is not pre-trained because it takes what was written on the web page as its knowledge base and will change when the web page is changed too. It is flexible and easy to use as it is used as an extension of an e-commerce web sites. Although it is pretty good for business chatbot, datasets from external can not be implemented as it is not pre-trained. Refer to *Fig. 3* to differentiate between fact QA, text QA, and chit-chat in SuperAgent chatbot.
Intellibot [22]	Intellibot for insurance needs, it is a pre-trained chatbot that uses 2 datasets (Cornell movie and insurance custom dataset) and it is dialogue-based with NLP techniques implementation. The result of this paper's research turns out that the chatbot is more superior than the other bots tested. Refer to *Fig. 4* as the questions given by the user and answers from the chatbots with its strategy selection level ranges from 1-5 as numbers of accuracy and relevancy with 5 as the highest level.
Chatbot with Business Intelligence with Big Data Integration (Enquiry Bot) [23]	The chatbot uses big data analytics for the process of collecting, organizing, and analyzing large data sets to discover hidden patterns or unknown information. The chatbot uses AIML for its knowledge base and it is a pre-trained chatbot as its knowledge base is from the large data set mentioned earlier. Refer to *Fig. 5* on how Enquiry Bot answers questions given however the answers given are still not human-like.
CardBot [10]	CardBot is a chatbot that implements OCR techniques with a goal to help people manage business cards cleverly. It uses NLP for processing the text and OCR to process the text from physical to digital. The knowledge base is based on what was taken by OCR and NLP thus, it is not a pre-trained chatbot. Refer to *Fig. 6* on how CardBot read information with OCR Technique and how the user can manage business cards efficiently.

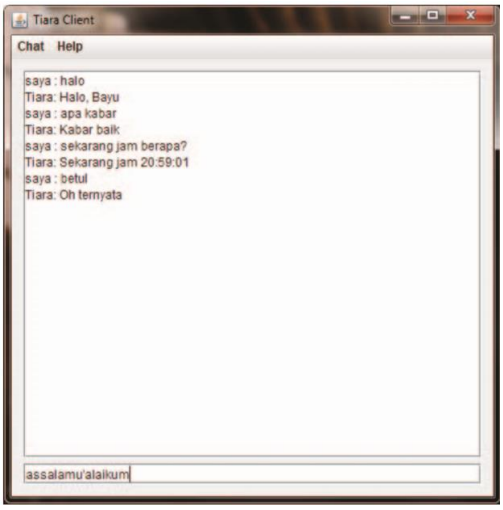

Figure 1: Chatbot

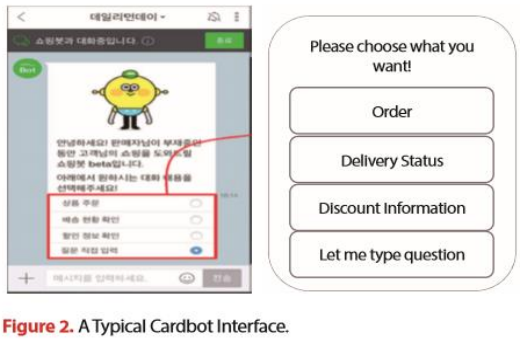

Figure 2: Naver TalkTalk Chatbot

4.2. Natural Language Processing (NLP) Techniques Corresponding to The Result

From the result of both questionnaire and literature review, we can conclude that the ideal chatbot for a business environment must be fast and accurate when answering questions with up-to-date information. From what we had researched, NLP is commonly used in chatbots for text processing. Moreover, chatbots with NLP are fast and accurate when answering questions and their answers are mostly in context so NLP is the most compatible text processing method for developing business related chatbots [13]. There are a lot of techniques in NLP but Named Entity Recognition and Sentiment Analysis will be the most frequently used techniques in chatbots.

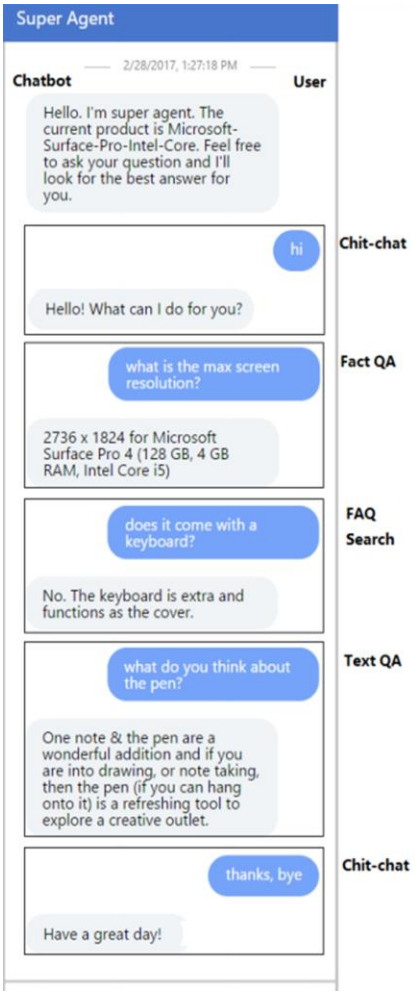

Figure 3: SuperAgent Chatbot

Greetings

	User Input	RootyAI	ChatterBot	DeepQA	IntelliBot	Strategy selection
	Bot Initialization:	Hello, I'm AI assistance. How may I help you?	Hi there, How may I assist you?	Hello, I'm Papaya. I'm your assistant.	Hello, I'm IntelliBot. Your 24/7 h assistance. How may I assist you?	1
1	Hello	Hello	Hello	Hello	Hello	1
2	Good morning.	Good morning.	Good morning.	Good morning.	Good morning.	1
3	My name is Nur.	Nice to meet you, Nur	Ok, Nur	Ok. How can I help you, Nur?	Nice to meet you, Nur. How may I help you?	1
4	What is your name?	I don't know.	I don't have it.	I'm Papayay.	My name is IntelliBot. What yours?	1

Figure 4: Intellibot

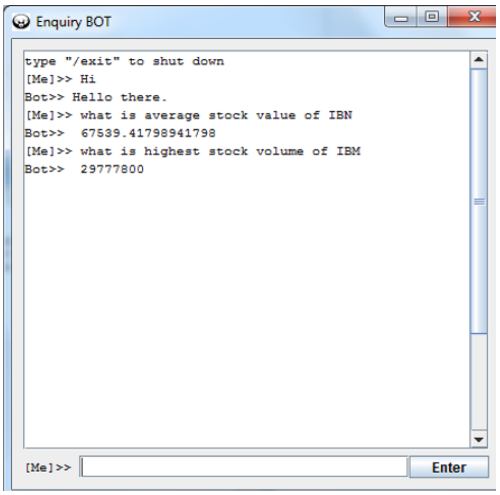

Figure 5: Enquirybot

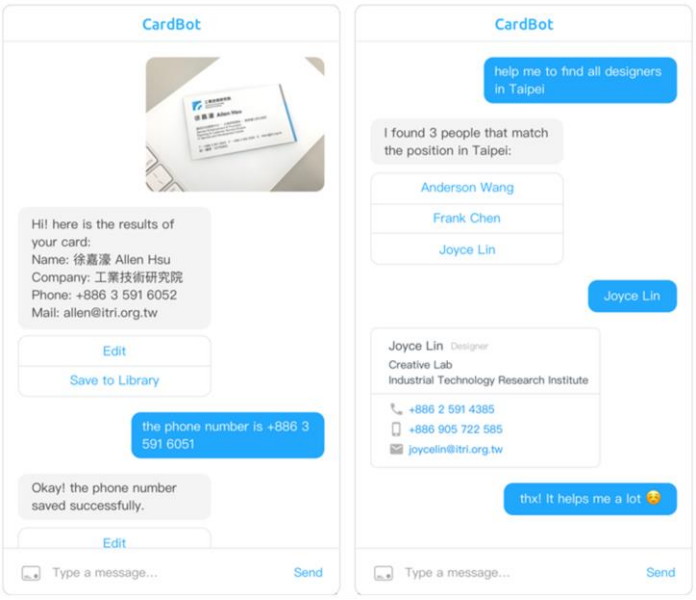

Figure 6: Cardbot

By using NLP named entity recognition technique, it can identify the key words such as, 'how much' and 'red chair'. After extracting the key words, those words will then be processed and will be searched thoroughly in the database as the chatbot's knowledge base will be primarily from the database. After understanding and processing the text, the chatbot can give responses. On the other hand, using NLP sentiment analysis technique can help the chatbot identify whether the interlocutor is feeling great or not about the products or services. This technique will be helpful especially when chit-chatting so the chatbot's attitude of replying can be more accurate, appropriate, and human-like.

Lastly, the training type of the chatbot will be better if it is pre-trained with datasets because it will be more prepared that way. If the chatbot relies on what was written on the website just like SuperAgent chatbot then the website has to be opened beforehand so that the chatbot could read what was written and it is not that efficient. However, OCR technique can be implemented for business chat bots if needed. The datasets will consist of business related datasets (about products or services) and daily conversation datasets so the chatbot could handle both questions related to the business side and daily conversations. These datasets then will be processed by NLP techniques mentioned in the second paragraph and resulted in contextual replies.

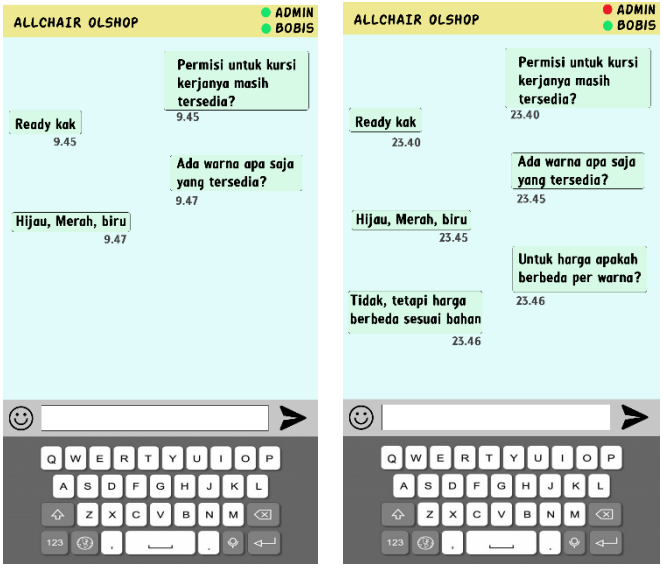

Figure 7: Prototype Chat Example

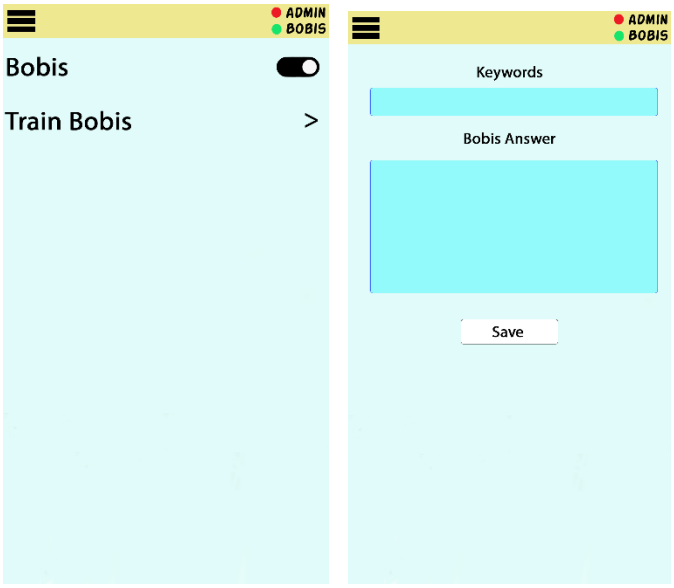

Figure 8: Prototype Setting and Training Menu Example

4.3. Prototype Corresponding to The Result

Based on the results our team got from our research, the chatbot should be able to be online 24 hours a day. The prototype that corresponds to this feature is depicted in Figure 7 where the chatting process could take place at any time and the chatbot would kindly reply. The other feature is that the chatbot should be able to work together with the seller just like an assistant would do, thus the chatbot can help replying to customers' chats when the seller is online or offline. For example, when there are a lot of chats coming through and the seller is online, but the seller only

can reply one chat at a time. In that situation, chatbot could help replying to the other chats that the seller could not cover.

The seller also can train the chatbot outside the datasets they were trained before if needed. The feature is depicted in Figure 8 where the seller could give the keywords and what to answer towards that given keywords. This feature is just an additional feature so that the chatbot could study other keywords other than what it had been trained before. The home menu page depicted in Figure 9 is how the seller would see when it is full of customers' chats.

Figure 9: Prototype Home Menu Example

5. Conclusion

From the research that we did, we can conclude that there are some features that chatbots in a business environment need to have. First, the chatbot needs to be fast and accurate when answering questions and the information in the knowledge base need to be up to date. Then, the chatbot needs to have a text processing technique to help it process texts and thus we can use NLP named entity recognition technique and NLP sentiment analysis technique. The chatbot also needs to be ready 24 hours a day and should act like an assistant helping the seller rather than handling the online business alone. The datasets used should consist of daily conversation dataset and business-related dataset (about products or services). The datasets can be expanded if there are much more datasets needed in the business. The chatbot should be flexible when using, thus the self-training feature by the seller can be used as an additional feature inside the chatbot. However, the self-training feature by the seller can also be removed if the seller does not need it. Lastly, the chatbot interface should be simple as its main aim is to help sellers to enhance their online business. We also can conclude that there is a high chance of acceptability for the chatbot technology especially from younger people [24, 25].

For the future implementation of the chatbot, we recommend that the chatbot should become a part of the application or website the owner has. Since the chatbot should be able to work like an assistant in the business thus the chatbot should be placed in places that are easy to find. If the chatbot is implemented in e-commerce business, it would be convenient to have a chatting menu on the navigation bar and in each page of products respectively. If the chatbot is implemented in company websites, it would be convenient to have the chatting page relatively small to medium size and keep it on a fixed position on the page like a pop-up. Make sure to make it not too eye-catching nor too boring or else users may lose their attention to the chatting pop-up or even not knowing that the chatting pop-up is there. The self-training feature of the chatbot should be implemented in another platform (not a part of the application or website) because we would not want any people controlling the data set without owners' consent.

Conflict of Interest

This paper is created due to a project in our research class and this is our group's research idea about chatbot in the business environment.

Acknowledgment

Special thanks to our lecturer Mrs. Azani that is willing to help us in writing this paper and our respondents that participated in giving their honest opinion for this research.

ABSTRACT

Introduction: Burnout is a real malaise that affects the mental health of teachers. The objective is to determine the prevalence of burnout among primary school teachers in the Wazzane region and to look for associated risk factors. Methods: Descriptive cross-sectional study conducted in 2017- 2018 with a sample of 330 teachers. Socio-demographic and work-related data were assessed by a self-administered questionnaire and the Karasek Job Content Questionnaire (JCQ) the Karasek, the burnout by the Maslach Burnout Inventory (MBI). Results: 330 teachers participated in the study with a male predominance of 62.4% and an average age of 38.4 (SD = 8.9). The average scores for emotional exhaustion, depersonalization and personal accomplishment were (21.8 ± 9.2); (14.1 ± 9.9) and (15.1 ± 8.4) respectively. Pathologically, emotional exhaustion was high in 23.9%, depersonalization was high in 24.2% and personal accomplishment was low in 26.1% of participants. 46.6% were victims of burnout, of which 23.9% had a low level; 14.2% had a moderate level and 8.5% had severe burnout. Logistic regression analysis showed that the predictors of burnout were female gender ($p<0.01$), Problems of equipment didactic ($p<0.01$), student demotivation ($p<0.05$), conflict with colleagues ($p<0.05$), work overload ($p<0.01$) and low decision-making autonomy ($p<0.01$).Conclusion: These results justify the interest of a prevention program and intervention at different levels to protect teachers.

1. Introduction

Burnout is a negative psychic experience experienced by an individual; it is related to chronic emotional stress caused by working to help people [1]. Maslach and Jackson [2] identified three characteristics of the burnout syndrome:

Emotional exhaustion: It refers to the feeling of being drained of one's emotional and physical resources and leads to difficulties in regarding to the emotions of the other. It represents the basic response to stress.

Depersonalization: It represents a negative or excessively detached response towards other people who are considered as objects.

Loss of personal accomplishment: It refers to feelings of incompetence and inefficiency, lack of success and productivity at work.

Teachers are part of at-isk populations of workers who may be exposed to the burnout syndrome [3]. Indeed, Maslach and Travers have identified several socio-demographic and occupational risk factors for teacher burnout [4, 5]. In our context, no study has been carried out among primary school teachers. For this reason, we aim to determine the prevalence and risk factors of burnout among a population of primary school teachers in the Wazzane district (Morocco).

2. Methods

This cross-sectional study lasted six months, from December 2017 to June 2018. It concerned teachers working in public primary schools in the region of Wazzane in North-West of Morocco. Socio-demographic and work-related data were evaluated by a self-administered questionnaire and by the 29-item Karasek Job Content Questionnaire (JCQ) [6], which measures three different scales: Work overload with 9 items: 10, 11, 12, 13, 14, 15, 16, 17 and 18. Decision latitude with 9 items, subdivided into two sub-scales : the use of skills or qualifications with 6 items:

*Corresponding Author: Zakaria ABIDLI, zakaria.abidli@uit.ac.ma

1, 2, 3, 4, 5, 6 and decision-making autonomy with 3 items: 7, 8, 9. Social support with 11 items, 6 items for support from colleagues : 19, 20, 21, 22, 23, 24 and 5 items for hierarchical support: 25, 26, 27, 28, and 29. The Maslach Burnout Inventory MBI to 22 items that explore three scales has evaluated burnout [7]: Emotional exhaustion assessed by items 1,2,3,6,8,13,14,16,20; Depersonalization assessed by items 5,10,11,15,22; and loss of personal accomplishment assessed by items 4,7,9,12,17,18,19 and 21.These two questionnaires were validated and adapted to the context of Moroccan teachers.

For burnout, a score was calculated and a severity rating (low, moderate, and high) was assigned for each dimension. Emotional exhaustion was considered pathological for a score above 29, depersonalization for a score above 22, and personal accomplishment was considered low for a score below 11. The number of dimensions affected characterizes the degree of severity of burnout, so a single affected dimension determines low burnout, two affected dimensions determine moderate burnout, and three affected dimensions determine severe burnout (high emotional exhaustion and depersonalization scores, low personal accomplishment score). Statistical analysis was realized using SPSS version 21. Frequencies and percentages were calculated for the categorical variables, and the chi-square test (X^2) was used to evaluate the differences between these variables. Continuous numerical data were summarized as mean and standard deviation. Logistic regression was used to determine the predictors of burnout; a p-value<was considered statistically significant.

3. Results

For the 330 participants who completed the data sheet, the average age was 38.4±8.9 years, with a minimum age of 24 and a maximum age of 59. The sex ratio was 1.7 in favor of males. The average years of service was 16.3±8.9 years. 46.7% are between the ages of 35 and 49; 62.4% are male; 52.4% are married and 48.5% have years of service between 11 and 24.

In terms of work-related characteristics, 40% managed multigrade classes; 61.5% had problems due to student demotivation; 54.5% had problems due to equipment didactic; 19.1% reported conflicts with colleagues; 12.4% with administration; workload was high for 57.5%; decision-making autonomy was low for 42.7%, and social support was low for 45.2% of participants (Table 1).

Table 1: Sociodemographic and work-related characteristics of primary school teachers (n = 330) in Wazzane, 2017/2018.

For the three dimensions of the burnout syndrome (emotional exhaustion, depersonalization and personal accomplishment), the average scores were respectively 21.8±9.1; 14.1±9.9 and 15.1±8.4.

Pathologically, emotional exhaustion was high for 23.9%; depersonalization was high for 24.2% and personal accomplishment was low for 27.6% of participants (table 2).

Similarly, the Maslach Burnout Inventory revealed that 154 teachers (46.6%) were victims of burnout, which 79 (23.9%) had a low level; 47 (14.2%) had a moderate level and 28 (8.5%) had a severe burnout (Figure 1).

Regarding sociodemographic risk factors, the chi-square test showed that age and years of service were not significantly associated with burnout, while gender was found to be significantly associated with burnout (p<0.01). Marital status was also significantly associated with burnout: married were more burned out than unmarried (p<0.001) (Table 3).

Table 2: Means, standard deviations and prevalence of the three dimensions of Burnout among primary school teachers (n=330) in Wazzane, 2017/2018.

Variable	Mean	Standard- Deviation	Pathological cases	Prevalence
Emotional exhaustion	21.8	9.1	79	23.9%
Depersonalization	14.1	9.9	80	24.2%
Personal accomplishment	15.1	8.4	91	27.6%

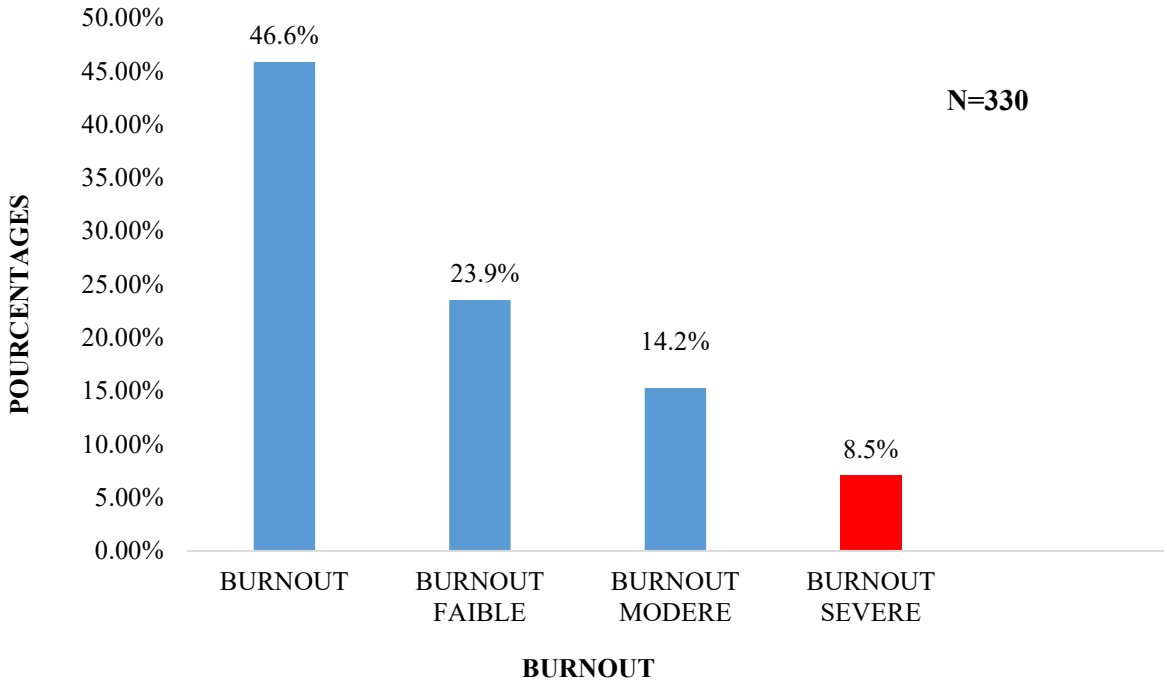

Figure 1: Profile of burnout syndrome among primary school teachers (n = 330) in Wazzane, 2017/2018.

Table 3: Association of burnout with sociodemographic risk factors among primary school teachers (n = 330) in Wazzane, 2017/2018.

Variable	Burnout		No burnout		Chi-square	p-value
	Number	%	Number	%		
Age						
24-34	57	37.0%	68	38.6%

≥25	30	19.5%	31	17.6%		

For work-related risk factors, the chi square test showed that burnout was significantly related to the management multigrade classes ($p<0.001$), the student demotivation ($p<0.001$), the problems of equipment didactic ($p<0.01$), the conflicts with colleagues ($p<0.001$), the conflicts with administration ($p<0.01$), the work overload ($p<0.01$), the low decision-making autonomy ($p<0.001$) and the low social support ($p<0.01$) (Table 4).

Logistic regression analysis showed that gender was the only sociodemographic variable that predicted burnout; while the work-related variables that predicted it were:

Problems of equipment didactic, student demotivation, conflicts with colleagues, work overload and Low Decision-making autonomy (Table 5).

These results show the importance of knowing certain stress factors specific to the teaching profession. Thus, problems of didactic equipment, student demotivation, work overload and low decision-making autonomy are risk factors that threaten the psychological health of the Moroccan teacher.

Table 5: Logistic regression analysis of independent predictors of burnout among primary school teachers (n=330) in Wazzane, 2017/2018

Variable	B	p-value	OR	95%CI	
Sex (female)	-0,743	0,004	0,476	0,286	0,791
Problems of equipment didactic	0,774	0,003	2,169	1,302	3,615
Student demotivation	-0,59	0,032	0,554	0,324	0,95

Conflicts with colleagues	0,733	0,029	2,081	1,079	4,015
Work overload	0,718	0,005	2,05	1,24	3,389
Low decision-making autonomy	-0,787	0,003	0,455	0,272	0,764

OR: 0dds-Ratio; CI: Confidence Interval

These results show the importance of knowing certain stress factors specific to the teaching profession. Thus, problems of didactic equipment, student demotivation, work overload and low decision-making autonomy are risk factors that threaten the psychological health of the Moroccan teacher.

4. Discussion

The objective of our study was to evaluate burnout and determine its prevalence and risk factors among a sample of Moroccan primary school teachers.

In Morocco, no study had yet been carried out among primary school teachers. Most of the studies on burnout concerned the health care professions. However, the teacher may also be exposed to this pathology, as confirmed by many of foreign studies [8, 9, 10]. The prevalence of burnout found in our study is 46.6%, which is higher than that found in the studies of some Arab countries, for example 21% in Tunisia [11], 24.5% in Iraq [12]. However, it remains lower than that found in a Moroccan study conducted among university teachers where it exceeds 60% [13] and that found in some Asian countries where it can reach 50 to 70% [5]. The difference in the prevalence of burnout between studies can be explained by variations in assessment tools and methods, socio-cultural factors, the timing of data collection and teachers' coping strategies to deal with stress. In this study, age and years of service were not associated with burnout, which is consistent with the study by Van Der Doef and Maes [14]. However, in a meta-analysis involving 5 to 35 studies and 1,092 to 10,818 subjects, the association between burnout and age, and burnout and experience was demonstrated, the older and more experienced subjects had lower burnout levels [15].

For gender, it was significantly related to burnout, and women were more exhausted than men, which is consistent with other studies that have reported that female teachers experienced burnout more than teachers [16,17], and a meta-analysis that looked at the effect of gender on burnout reported significantly higher overall burnout scores for women [18].

With regard to teacher burnout, the literature has clearly objectified the link between work-related risk factors and the development of burnout [5]. The main stressors described in the international literature include poor material conditions, work overload, organizational factors, but also administrative difficulties and role conflicts [9, 19, 20]. In our study, logistic regression revealed that the work-related risk factors that predict burnout were work overload ($p<0.01$); low decision-making autonomy ($p<0.01$); the Problems of equipment didactic ($p<0, 01$); work overload ($p<0.01$); student demotivation ($p<0.05$) and conflicts with colleagues ($p<0.05$).

For work overload and low decision-making autonomy, the results found are consistent with a study that looked at associations between work demands (workload) and resources (autonomy, degree of control) and burnout. Positive correlations were found for work demands and negative correlations were found for perceived resources [21]. In the same vein, a meta-analysis of one hundred and seventy-nine articles, representing 186,440 topics treating the associations between burnout and perceived work demands and resources, showed that there are positive correlations with cognitive workload at work and negative correlations with the "Resources" category: autonomy, support from colleagues, knowledge, management style, and feeling of security [22]. For other work-related factors, our work revealed a significant link between burnout and the Problems of equipment didactic, which is consistent with several studies that have found that the material conditions of the school environment play a significant role in teacher distress and dissatisfaction [8, 23]. Addition, student demotivation also represents a risk factor for the development of burnout in this study, and the literature has widely reported the association of burnout with relationship problems with students. Thus, a study, which involved 2558 teachers in France, showed a significant association between difficulties with students and the three pathological dimensions of burnout [24].

5. Conclusion

The Moroccan educational context is affected by a plethora of risk factors that can affect the psychological health of teachers. It is necessary to carry out serious studies on the quality of life at work, teacher satisfaction and psychological health in order to establish a prevention program at different levels and protect this true wealth of Morocco.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

This paper presents an adaptive step-size and variable leaky least mean square algorithm based on nonlinear adaptive filter with the adaptive lookup table using spline interpolation. An adaptive step-size approach is proposed with the energy of squared previous and present errors to boost up the convergence rate. A modified variable leaky mechanism is proposed with the optimal leaky parameter by using the recursion form. The proposed algorithm merges an adaptive step-size and a modified variable leaky method with least mean square algorithm for linear and nonlinear network part of spline adaptive filtering in term of fast convergence enhancement. Experimental results demonstrate that proposed algorithm can notably achieve a competitive performance on the convergence rate in comparison with the conventional least mean square algorithm for spline adaptive filter. Simulation results suggest that mean square error performance of proposed algorithm can be partially assessed using adaptive step-size with the variable leaky parameters indicating better than the conventional least mean square algorithm by 16.76%.

1 Introduction

This paper is an extension of work originally presented in the International Electrical Engineering Congress [1], which has been proposed the variable leaky mechanism based on the least mean square (LMS) algorithm for spline adaptive filter. The combination of a linear finite impulse response (FIR) filter and a nonlinear adaptive lookup table (LUT) based on the spline interpolation is called the spline adaptive filtering (SAF) with the adaptation process [2]. It is a class of nonlinear adaptive filtering with a spline function [1]-[12].

According to the practical models, the linear adaptive filter should be inadequate [3]. The models of nonlinear dynamic systems have demonstrated with more robust performance. Linear adaptive filtering should be insufficient in real-world models. Moreover, many dynamic systems using model of nonlinear structure have been extended to the operating model.

Based on the SAF, many research works have achieved efficiently in the practical system identification. In [2], the authors have presented the sign approach with the normalized version of least mean square (NLMS) based on Wiener spline adaptive filter in order to fight against the impulsive noise environment. In [4], the authors have analyzed the convergence and stability analysis of SAF based on LMS algorithm. A steady-state performance of SAF has been examined in [5].

In order to model the nonlinear system identification, the SAF is more attention for the practical use [6],[7]. The linear time-invariant model with the cubic spline function [8] can obtain the good performance working with the adaptive lookup table (LUT) [9] and the spline basis matrix on the adaptive control points coefficient vector.

Applications of SAF architecture have been applied in the infinite impulse response [10] and the system environment with impulsive noise [11]. A set-membership mechanism with the Wiener spline adaptive filtering and normalized least M-estimate algorithm have been obtained significantly the fast convergence in the environment of impulsive noise [11]. In [12], the authors have proposed the Hammerstein function with SAF based on LMS algorithm for improving the convergence rate. Further, a SAF based on the maximum correntropy criterion [13], [14] has been discussed that correntropy is robustness to non-Gaussian noise.

Least mean square (LMS) algorithm which is simple and low computation has been widely used [15]. Most researchers have modified accurately on LMS and NLMS algorithms [16] and [17], the variable step-size LMS [18], the sign mechanism with NLMS [2] and so on.

As stated in a steady-state of convergence analysis, a variable leaky mechanism has been depicted in use of tracking the systems. In [19], a variable leaky LMS algorithm based on the greedy heuristic algorithm has been leveraged to enhance with the high eigenvalue input. In [20], the authors have implemented the variable leaky LMS in the field programmable gate array implementation. The results have been shown that the algorithm can explore the various digital filter architecture.

Based on the variable leaky LMS algorithm which has been orchestrated against and attenuating the drifting [21]. In the field of adaptive signal processing, a variable leaky based on the orthogonal gradient adaptive algorithm with the minimized cost function has been applied for the wireless communications [22].

The novelty of this paper is to merge an adaptive step-size and a modified variable leaky method with least mean square algorithm for linear and nonlinear network part of spline adaptive filtering in term of fast convergence enhancement. The analysis of the convergence performance of the proposed algorithm is derived in forms of the properties and mean square error performance.

In this paper, we organize this paper as follows. Section 2 explains shortly in the structure of SAF. Next, Section 3 introduces the modified adaptive step-size mechanism and the modified variable leaky criterion on the minimization cost function based on the LMS algorithm. Section 4 describes the performance analysis of the proposed adaptive step-size and variable leaky LMS algorithm in terms of the properties and the mean square error performance. Further, the experiment results and discussion show in Section 5 and Section 6, respectively. Finally, Section 7 summarizes the proposed algorithm.

2 Spline Adaptive Filter

Spline adaptive filter (SAF) is namely a combination of linear and nonlinear structures shown in Fig. 1, where $\mathbf{x}_k$ is the input of SAF structure and y_k is the output of system.

The objective is that adaptive lookup table in the nonlinear structure generates an output of SAF y_k nearly to a desired sequence d_k as

$$d_k = y_k + e_k \,, \tag{1}$$

where the error of system e_k should be small. Thus, the adaptive FIR filter brings an output ϕ_k in the linear structure, while the input signal is a sequence of x_k at the linear structure.

An adaptive FIR filter output ϕ_k is given by [3]

$$\phi_k = \mathbf{w}_k^T \, \mathbf{x}_k \,, \tag{2}$$

where $\mathbf{w}_k$ is the update FIR coefficient vector.

Following [3], the SAF output y_k can be examined by following

$$y_k = \mathbf{u}_k^T \, \mathbf{C}_b \, \mathbf{g}_{m,k} \,, \tag{3}$$

$$\mathbf{v}_k = [v_k^3, \; v_k^2, \; v_k, \; 1]^T \,, \tag{4}$$

where $\mathbf{g}_{m_k}$ is the coefficient of control point vector and $\mathbf{C}_b$ is a spline basis matrix.

The local parameter v_k and index m are usually indicated as [5]

$$v_k = \frac{\phi_k}{\Delta x} - \left\lfloor \frac{\phi_k}{\Delta x} \right\rfloor \,, \tag{5}$$

$$m \; = \left\lfloor \frac{\phi_k}{\Delta x} \right\rfloor + \frac{P-1}{2} \,, \tag{6}$$

where Δx is the uniform space between two adjacent-coefficients of control points [6], P is the size of control point coefficient, and the floor operator $\lfloor \cdot \rfloor$ is applied.

By using the minimized objective function based on least mean square (LMS) [5], it becomes

$$J_{\mathbf{w},\mathbf{g}}^{\mathrm{LMS}}(k) = \min_{\mathbf{w},\mathbf{g}} \left\{ \frac{1}{2} \mid e_k \mid^2 \right\} , \tag{7}$$

where *a priori* error e_k is defined as

$$e_k = d_k - y_k = d_k - \mathbf{v}_k^T \, \mathbf{C}_b \, \mathbf{g}_{m,k} \,. \tag{8}$$

The update FIR coefficient vector $\mathbf{w}_k$ can compute by the gradient vector of (7) with respect to the coefficients $\mathbf{w}_k$ in terms of the recursion form as [3]

$$\mathbf{w}_{k+1} = \mathbf{w}_k - \mu_w \, \nabla J_{\mathbf{w}}^{\mathrm{LMS}} \,, \tag{9}$$

where μ_w is a step-size and $\nabla J_{\mathbf{w}}^{\mathrm{LMS}}(k)$ is the gradient vector for $\mathbf{w}_k$.

Similarly, the update control points vector $\mathbf{g}_{m,k}$ can be expressed by the gradient vector of (7) with respect to the coefficients $\mathbf{g}_{m,k}$ [3]

$$\mathbf{g}_{m,k+1} = \mathbf{g}_{m,k} - \mu_g \, \nabla J_{\mathbf{g}}^{\mathrm{LMS}}(k) \,, \tag{10}$$

where μ_g is a step-size and $\nabla J_{\mathbf{g}}^{\mathrm{LMS}}(k)$ is the gradient vector for $\mathbf{g}_{m,k}$. Thus, the FIR weight vector $\mathbf{w}_k$ and the control points update coefficient vector $\mathbf{g}_{m,k}$ are the particularly simple forms as [5]

$$\mathbf{w}_{k+1} = \mathbf{w}_k + \mu_w \, \mathbf{v}_k' \, \mathbf{C}_b \, \mathbf{g}_{m,k}^T \, \mathbf{x}_k \, e_k \,, \tag{11}$$

$$\mathbf{g}_{m,k+1} = \mathbf{g}_{m,k} + \mu_g \, \mathbf{C}_b^T \, \mathbf{v}_k \, e_k \,, \tag{12}$$

where $\mathbf{v}_k'$ is given by

$$\mathbf{v}_k' = [3 \, v_k^2, \; 2 \, v_k, \; 1, \; 0]^T \,. \tag{13}$$

and the local parameter $\mathbf{v}_k$ is given in (5).

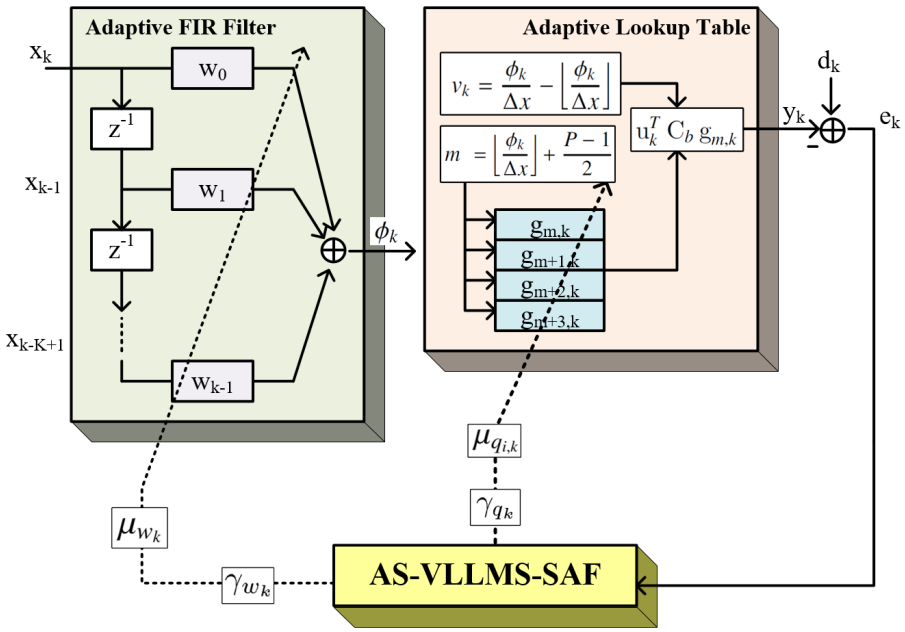

Figure 1: Linear-Nonlinear structure of proposed adaptive step-size variable leaky LMS algorithm for spline adaptive filter (AS-VLLMS-SAF).

3 Proposed Adaptive Step-size and Variable Leaky Least Mean Square based on Spline Adaptive Filter

Based on the least mean square (LMS) algorithm, the advantage of the leaky LMS algorithm is that it avoids the drift of weights [23]. Meanwhile, the step-size parameter is an efficient approach to improve the convergence rate [16].

Following [1] and [11], the cost function using adaptive step-size and variable leaky criterion for SAF based on least mean square (AS-VLLMS-SAF) algorithm can be minimized as

$$J(\mathbf{w}_k, \mathbf{g}_{m,k}) = \min_{\mathbf{w}_k, \mathbf{g}_{m,k}} \left\{ \frac{1}{2} \mid e_k \mid^2 + \gamma_w \|\mathbf{w}_k\|^2 + \gamma_g \|\mathbf{g}_k\|^2 \right\}, \tag{14}$$

where γ_w and γ_g are the leaky paramters for the linear FIR coefficient vector $\mathbf{w}_k$ and the control points weight vector $\mathbf{g}_{m,k}$, respectively. The *a priori* error of system e_k is given as

$$e_k = d_k - \mathbf{v}_k^T \, \mathbf{C}_b \, \mathbf{g}_{m,k} \, . \tag{15}$$

Considering the chain rule on the cost function in (14) with respect to (w.r.t) $\mathbf{w}_k$, we get

$$\begin{aligned} \frac{\partial J(\mathbf{w}_k, \mathbf{g}_{m,k})}{\partial \mathbf{w}_k} &= \left\{ - e_k \frac{\partial y_k}{\partial \mathbf{v}_k} \frac{\partial \mathbf{v}_k}{\partial \phi_k} \frac{\partial \phi_k}{\partial \mathbf{w}_k} + \gamma_w \mathbf{w}_k \right\} \\ &= \left\{ - \frac{e_k}{\Delta x} \mathbf{v}'_k \, \mathbf{C} \, \mathbf{g}_{m,k} \, \mathbf{x}_k + \gamma_w \mathbf{w}_k \right\}, \end{aligned} \tag{16}$$

where $\mathbf{v}'_k$ is defined as

$$\mathbf{v}'_k = [3v_k^2 \;\; 2v_k \;\; 1 \;\; 0] \, . \tag{17}$$

The gradient of cost function in (14) w.r.t $\mathbf{g}_{m,k}$ can be expressed by using the chain rule in the form of vector below

$$\begin{aligned} \frac{\partial J(\mathbf{w}_k, \mathbf{g}_{m,k})}{\partial \mathbf{g}_{m,k}} &= \left\{ - e_k \frac{\partial y_k}{\partial \mathbf{v}_k} \frac{\partial \mathbf{v}_k}{\partial \phi_k} \frac{\partial \phi_k}{\partial \mathbf{g}_{m,k}} + \gamma_g \mathbf{g}_{m,k} \right\} \\ &= \{ - e_k \, \mathbf{C}^T \, \mathbf{v}_k + \gamma_g \mathbf{g}_{m,k} \} \, . \end{aligned} \tag{18}$$

Hence, the proposed update linear FIR coefficient vector $\mathbf{w}_k$ of AS-VLLMS-SAF algorithm is the stochastic adaptation formula as

$$\mathbf{w}_{k+1} = \mathbf{w}_k - \mu_{w_k} \frac{\partial J(\mathbf{w}_k, \mathbf{g}_{m,k})}{\partial \mathbf{w}_k} \, , \tag{19}$$

where μ_{w_k} is a adaptive step-size parameter at symbol k.

By substituting (16) into (19), the proposed update tap-weight vector $\mathbf{w}_k$ can be expressed as

$$\therefore \mathbf{w}_{k+1} = (\mathbf{1} - \mu_{w_k} \gamma_{w_k}) \, \mathbf{w}_k + \frac{\mu_{w_k}}{\Delta x} \, \mathbf{v}'_k \, \mathbf{C}_b \, \mathbf{g}_{m,k} \, \mathbf{x}_k \, e_k \, , \tag{20}$$

where γ_{w_k} is a variable leaky parameter for $\mathbf{w}_k$. It is noticed that $(1 - \mu_{w_k} \gamma_{w_k})$ is also defined as the leakage factor [23] for updated weight $\mathbf{w}_k$ in which its value is generally close to 1.

The adaptive control points coefficient vector $\mathbf{g}_{m,k}$ of AS-VLLMS-SAF becomes

$$\mathbf{g}_{m,k+1} = \mathbf{g}_{m,k} - \mu_{\mathbf{g}_k} \frac{\partial J(\mathbf{w}_k, \mathbf{g}_{m,k})}{\partial \mathbf{g}_{m,k}} \, , \tag{21}$$

By substituting (18) into (21), the proposed control points vector $\mathbf{g}_{m,k}$ is given as

$$\therefore \mathbf{g}_{m,k+1} = (\mathbf{1} - \mu_g \gamma_{g_k})\, \mathbf{g}_{m,k} + \mu_q\, \mathbf{C}_b^T\, \mathbf{v}_k\, e_k\ , \tag{22}$$

where μ_g is a step-size parameter and γ_{g_k} is a variable leaky parameter for $\mathbf{g}_{m,k+1}$. It is noted that $(1 - \mu_g \gamma_{g_k})$ is also defined as the leakage factor [23] for updated weight $\mathbf{g}_{m,k+1}$ in which its value is generally close to 1.

3.1 Modified Variable Leaky mechanism

Following [24], we introduce the modified variable leaky algorithm with the optimal leaky parameter for weights $\mathbf{w}_k$ and $\mathbf{g}_{m,k}$ in the recursion form as

$$\gamma_{w_k} = \gamma_{w_{k-1}} + \rho_w\, \gamma_w^{\text{opt}}\ , \tag{23}$$

$$\gamma_{g_k} = \gamma_{g_{k-1}} + \rho_g\, \gamma_g^{\text{opt}}\ , \tag{24}$$

where ρ_w, ρ_g and γ_w^{opt}, γ_g^{opt} are the adaptation rate and the optimal leaky parameters of weights $\mathbf{w}_k$ and $\mathbf{g}_{m,k}$.

We rewrite (20) as

$$\mathbf{w}_{k+1} = \mathbf{w}_k - \mu_{w_k} \gamma_{w_k} \mathbf{w}_k + \frac{\mu_{w_k}}{\Delta x}\, \mathbf{v}_k'\, \mathbf{C}_b\, \mathbf{g}_{m,k}\, \mathbf{x}_k\, e_k\ , \tag{25}$$

Assumption 1: *We consider the steady-state value of* $E\{\boldsymbol{w}_{k+1}\}$ *for* $k \to \infty$ *by*

$$E\{\mathbf{w}_{k+1}\} \simeq E\{\mathbf{w}_k\}.$$

We determine the optimal leaky parameter for $\mathbf{w}_k$ by using this assumption above in (25), we arrive at

$$\gamma_w^{\text{opt}} \simeq \frac{\mathbf{v}_k'\, \mathbf{C}_b^T\, \mathbf{g}_{m,k}\, \mathbf{w}_k^{-1}\, \mathbf{x}_k\, e_k}{\Delta x}\ . \tag{26}$$

Therefore, the modified variable leaky algorithm in the recursion form can be expressed as

$$\gamma_{w_k} = \gamma_{w_{k-1}} - \rho_w\, \frac{\mathbf{v}_k'\, \mathbf{C}_b^T\, \mathbf{g}_{m,k}\, \mathbf{w}_k^{-1}\, \mathbf{x}_k\, e_k}{\Delta x}\ , \tag{27}$$

where ρ_w is an adaptation rate for $\mathbf{w}_k$.

Consequently, the *a posterior* AS-VLLMS error [1] is rewritten as

$$e_{p_k}^{\text{VL-LMS}} = (1 - \mu_{g_k}\, \mathbf{v}_k\, \mathbf{C}_b^T\, \mathbf{v}_k\, \mathbf{C}_b)\, e_k + \mu_{g_k}\, \gamma_{g_k}\, \mathbf{v}_k\, \mathbf{C}_b^T\, \mathbf{g}_{m,k}\ . \tag{28}$$

Assumption 2: *We consider the steady-state value of proposed algorithm is stable for* $k \to \infty$ *by*

$$E\{e_{p_k}^{\text{VL-LMS}}\} \simeq E\{e_k\}.$$

By using Assumption 2 in (28), the optimal leaky parameter can be defined as

$$\gamma_g^{\text{opt}} \simeq \frac{\Omega_k^T\, \Omega_k\, e_k}{\Omega_k^T\, \mathbf{g}_{m,k}}\ , \tag{29}$$

where $\Omega_k = \mathbf{v}_k^T\, \mathbf{C}$.

Table 1: Proposed Variable Leaky Least Mean Square based on Spline Adaptive Filtering with the adaptive step-size (AS-VLLMS-SAF) algorithm.

Initialize : $\mathbf{w}(0) = \delta\, \mathbf{I}$ and $\mathbf{I}$ is the identity matrix.

$$\mathbf{w}_k = [\ w_0\ w_1\ \ldots\ w_{K-1}\ ]$$
$$\mathbf{x}_k = [\ x_k\ x_{k-1}\ \ldots\ x_{k-K+1}\ ]$$
$$\mathbf{g}_{m,k} = [\ g_{m,k}\ \ g_{m+1,k}\ \ g_{m+2,k}\ \ g_{i+3,k}\ ]$$

for $k = 0, 1, 2, \ldots, K-1$.

$$\phi_k = \mathbf{w}_k^T\, \mathbf{x}_k$$
$$v_k = \frac{\phi_k}{\Delta x} - \left\lfloor \frac{\phi_k}{\Delta x} \right\rfloor$$
$$m\ = \left\lfloor \frac{\phi_k}{\Delta x} \right\rfloor + \frac{P-1}{2}$$
$$\mathbf{v}_k = [v_k^3,\ v_k^2,\ v_k,\ 1]^T$$
$$\mathbf{v}_k' = [3v_k^2,\ 2v_k,\ 1,\ 0]^T$$
$$e_k = d_k - \mathbf{v}_k^T\, \mathbf{C}_b\, \mathbf{g}_{m,k}$$
$$\gamma_{w_k} = \gamma_{w_{k-1}} + \rho_w\, \frac{\mathbf{v}_k'\, \mathbf{C}_b^T\, \mathbf{g}_{m,k}\, \mathbf{w}_k^{-1}\, \mathbf{x}_k\, e_k}{\Delta x}$$
$$\gamma_{q_k} = \gamma_{q_{k-1}} + \rho_q\, \frac{\Omega_k^T\, \Omega_k\, e_k}{\Omega_k^T\, \mathbf{g}_{m,k} + \epsilon}$$
$$\Omega_k = \mathbf{v}_k^T\, \mathbf{C}_b$$
$$\mu_{w_k} = \alpha_w\, \mu_{w_{k-1}} + \beta_w\, \xi_k^2$$
$$\xi_k = \lambda\, \xi_{k-1} + (1-\lambda)\, e_{k-1}^*\, e_k$$
$$\mu_{q_k} = \alpha_q\, \mu_{q_{k-1}} + \beta_q\, e_{k-1}^*\, e_k$$
$$\mathbf{w}_{k+1} = \mathbf{w}_k - \mu_{w_k} \gamma_{w_k} \mathbf{w}_k + \frac{\mu_{w_k}}{\Delta x}\, \mathbf{v}_k'\, \mathbf{C}_b^T\, \mathbf{g}_{m,k}\, \mathbf{x}_k\, e_k$$
$$\mathbf{q}_{i,k+1} = \mathbf{g}_{m,k} - \mu_{q_k} \gamma_{q_k} \mathbf{g}_{m,k} + \mu_{q_{m,k}}\, \mathbf{C}_b^T\, \mathbf{v}_k\, e_k$$

end

Therefore, the modified variable leaky algorithm can be expressed in the recursion method as

$$\gamma_{g_k} = \gamma_{g_{k-1}} - \rho_q\, \frac{\Omega_k^T\, \Omega_k\, e_k}{\Omega_k^T\, \mathbf{g}_{m,k} + \epsilon}\ , \tag{30}$$

where ρ_g is an adaptation rate for $\mathbf{g}_{m,k}$ and ϵ is a regularization parameter with a small constant.

3.2 Modified Adaptive Step-size Approach

According to the better convergence of proposed AS-VLLMS-SAF algorithm, the step-size parameter should be adapted recursively.

The behavior of convergence rate is which the algorithm starts converging, the value of step-size parameter should be large in order to boost up the learning rate of convergence. At closely to the steady-state, the step-size parameter might be decreased adequately to get the lower adjustment. This leads to adjust accordingly the step-size parameter.

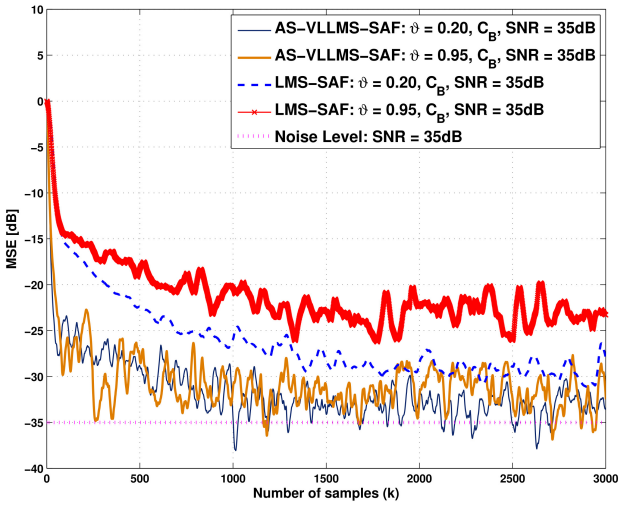

Figure 2: MSE of proposed AS-VLLMS-SAF and LMS-SAF [3] on the *B-spline* matrix $\mathbf{C}_B$ with the different $\vartheta = 0.20, 0.95$ and SNR = 35dB.

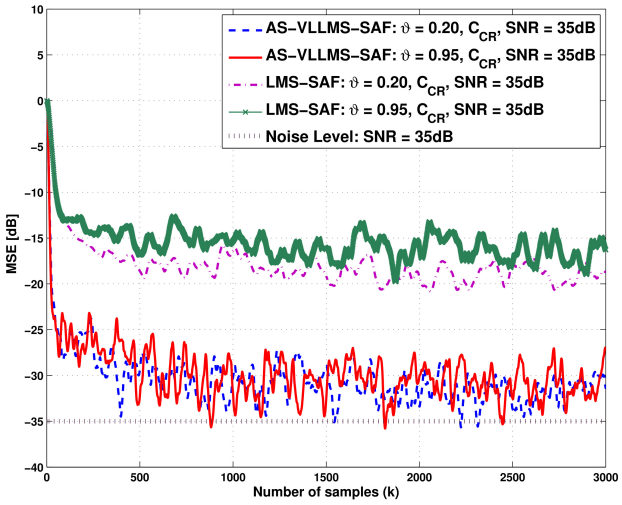

Figure 3: MSE of proposed AS-VLLMS-SAF and LMS-SAF [3] on the *Catmul-Rom* matrix $\mathbf{C}_{CR}$ with $\vartheta = 0.20, 0.95$ and SNR=35dB.

We assume that the step-size parameters μ_{w_k} and μ_{g_k} are regulated by squared estimated error. Hence, the proposed adaptive step-size μ_{w_k} for weight $\mathbf{w}_k$ based on AS-VLLMS algorithm is introduced for spline adaptive filtering as [4]

$$\mu_{w_k} = \alpha_w \mu_{w_{k-1}} + \beta_w \xi_k^2 , \tag{31}$$

$$\xi_k = \lambda \xi_{k-1} + (1-\lambda) e_{k-1}^* e_k , \tag{32}$$

and the proposed adaptive step-size μ_{g_k} for weight $\mathbf{g}_{m,k}$ can be expressed as

$$\mu_{g_k} = \alpha_g \mu_{g_{k-1}} + \beta_g e_{k-1}^* e_k , \tag{33}$$

A summary of proposed variable leaky least mean square for spline adaptive filtering based on adaptive step-size algorithm (AS-VLLMS) is depicted in Table 1.

4 Performance Analysis

In this section, we analyze the convergence performance of the proposed variable leaky LMS based on SAF. Compared to the LMS-SAF algorithm, the proposed AS-VLLMS algorithm is presented by introducing an additional concept.

Variable leaky algorithm is used in the iterative of weights $\mathbf{w}_k$ and $\mathbf{g}_{m,k}$, respectively. So, the computational complexity of AS-VLLMS-SAF is more complex than that of the LMS-SAF algorithm.

4.1 Properties of AS-VLLMS Algorithm

The properties of adaptive step-size and variable leaky LMS algorithm may be derived by examining the behaviour of $E\{\mathbf{w}_k\}$ and $E\{\mathbf{g}_{m,k}\}$ of SAF.

Taking expectation value and using the independence assumption [25], we then have

$$E\{\mathbf{w}_{k+1}\} = (1 - \mu_{w_k}\gamma_{w_k})\, E\{\mathbf{w}_k\} + \frac{\mu_w}{\Delta x} E\{\mathbf{v}_k' \mathbf{C}_b \mathbf{g}_{m,k} \mathbf{x}_k e_k\} . \tag{34}$$

Specially, we note that if $\mathbf{w}_k$ converges to the steady-state solution, we get

$$\lim_{k\to\infty} E\{\mathbf{w}_k\} = \frac{\mathbf{v}_k' \mathbf{C}_b \mathbf{g}_{m,k}^T \mathbf{x}_k e_k}{\gamma_{g_k} \Delta x} . \tag{35}$$

In a similar fashion, we substitute *a priori* error e_k in (15) into (22), then we have

$$\mathbf{g}_{m,k+1} = \left[\mathbf{I} - \mu_{g_k} \{\gamma_{g_k} \mathbf{I} + \mho_k^T \mho_k\}\right] \mathbf{g}_{m,k} + \mu_{g_k} \mho_k d_k , \tag{36}$$

where $\mho_k$ is given by

$$\mho_k = \mathbf{C}_b^T \mathbf{v}_k . \tag{37}$$

Thus, we take the expectation value and using the independence assumption [25], it becomes

$$E\{\mathbf{g}_{m,k+1}\} = \left[\mathbf{I} - \mu_{g_k}\left\{\mathbb{R}_\mho + \gamma_{g_k} \mathbf{I}\right\}\right] E\{\mathbf{g}_{m,k}\} + \mu_{g_k} \mathbf{r}_{d\mho} , \tag{38}$$

where $\mathbb{R}_\mho$ and $\mathbf{r}_{d\mho}$ are defined by

$$\mathbb{R}_\mho = \mho_k^T \mho_k , \tag{39}$$

$$\mathbf{r}_{d\mho} = d_k \mho_k . \tag{40}$$

Clearly, we note that if $\mathbf{g}_{m,k}$ converges to the steady-state solution, we have

$$\lim_{k\to\infty} E\{\mathbf{g}_{m,k}\} = \left(\mathbb{R}_\mho + \gamma_{g_k} \mathbf{I}\right)^{-1} \mathbf{r}_{d\mho} . \tag{41}$$

It is noticed that the leakage coefficient introduces a bias into the steady-state solution.

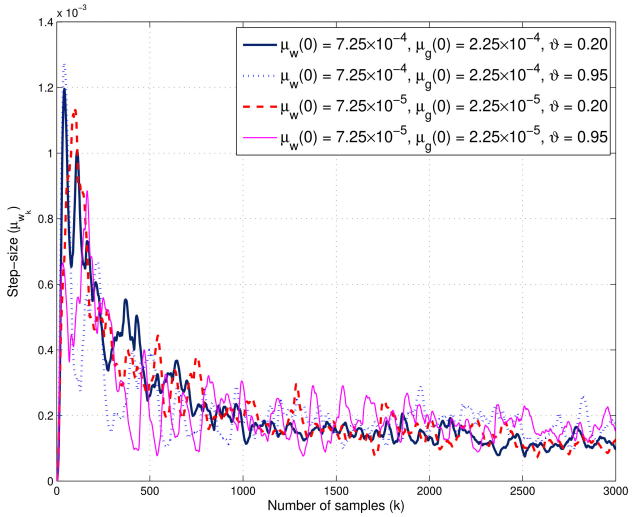

Figure 4: Learning curves of adaptive step-size μ_{w_k} of coefficient vector $\mathbf{w}_k$ of proposed AS-VLLMS-SAF on the *B-spline* matrix $\mathbf{C}_B$ with $\alpha = 0.20, 0.95$ and SNR = 35dB.

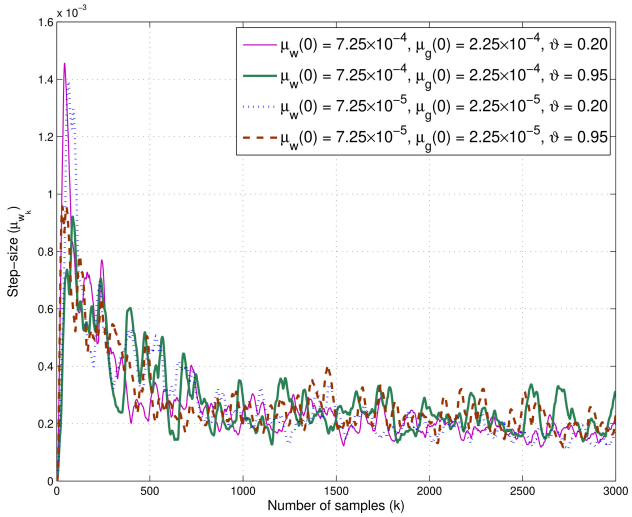

Figure 6: Learning curves of adaptive step-size μ_{w_k} of coefficient vector $\mathbf{w}_k$ of proposed AS-VLLMS-SAF on the *Catmul-Rom* matrix $\mathbf{C}_{CR}$ with $\alpha = 0.20, 0.95$ and SNR = 35dB.

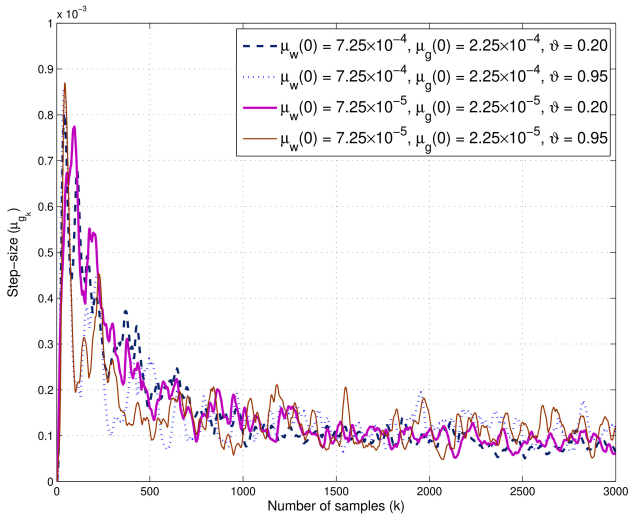

Figure 5: Learning curves of adaptive step-size μ_{g_k} of coefficient vector $\mathbf{g}_{m,k}$ of proposed AS-VLLMS-SAF on the *B-spline* matrix $\mathbf{C}_B$ with $\alpha = 0.20, 0.95$ and SNR = 35dB.

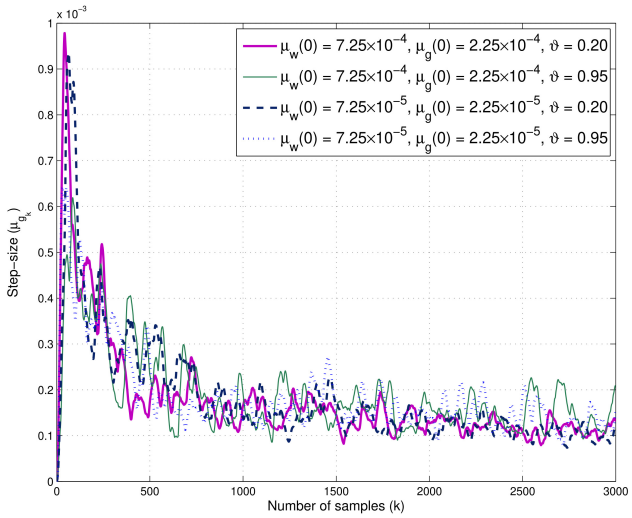

Figure 7: Learning curves of adaptive step-size μ_{g_k} of coefficient vector $\mathbf{g}_{m,k}$ of proposed AS-VLLMS-SAF on the *Catmul-Rom* spline matrix $\mathbf{C}_{CR}$ with $\alpha = 0.20, 0.95$ and SNR = 35dB.

4.2 *The Leaky Adjustment*

In this section, the leaky adjustment is investigated in form of the *a posterior* error compared with *a priori* error in the spline adaptive filtering. We determine the *a posteriori* LMS error as [1]

$$\tilde{e}_k^{LMS} \triangleq d_k - \mathbf{v}_k^T \, \mathbf{C}_b \, \mathbf{g}_{m,k+1} = e_k \left(1 - \mu_g \, \mho_k^T \, \mho_k \right), \qquad (42)$$

where $\mho_k$ is described in (37).

Correspondingly, we examine the *a posteriori* variable leaky least mean square (VL-LMS) error as

$$\begin{aligned} \tilde{e}_k^{VLLMS} &\triangleq d_k - \mathbf{v}_k^T \, \mathbf{C}_b \, \mathbf{g}_{m,k+1} \\ &= e_k(1 - \mu_{g_k} \mho_k^T \, \mho_k) + \mu_{g_k} \gamma_{g_k} \mho_k^T \mathbf{g}_{m,k} \, . \end{aligned}$$

It is noticed that the leaky adjustment will be achieve based on a greedy heuristic algorithm with each iteration, which can get the appropriate leaky value, if $|\tilde{e}_k^{VLLMS}| < |\tilde{e}_k^{LMS}|$. That means the proposed VL-LMS algorithm would allow to get the efficient LMS algorithm. Otherwise, the leak parameter should be diminished.

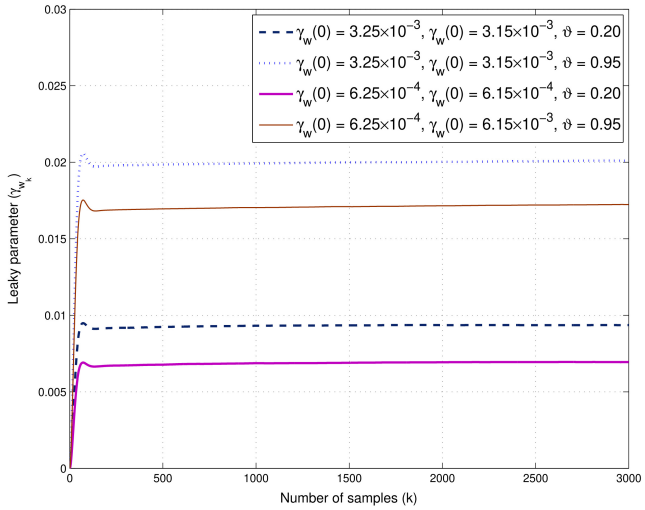

Figure 8: Learning curves of variable leaky γ_{w_k} of coefficient vector $\mathbf{w}_k$ of proposed AS-VLLMS-SAF on $\mathbf{C}_B$ with $\vartheta = 0.20, 0.95$ and SNR = 35dB.

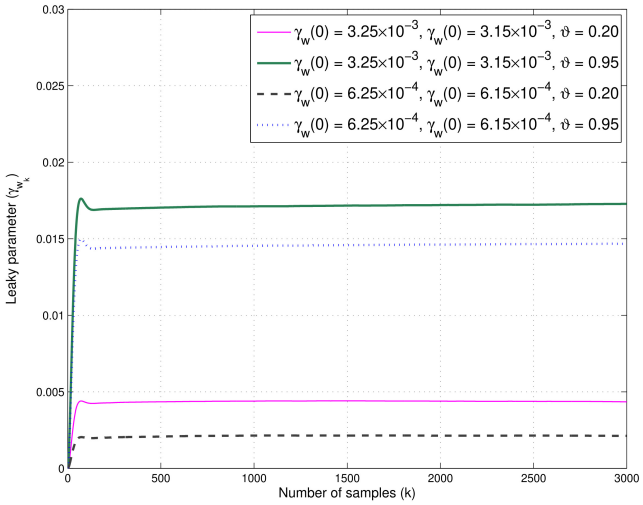

Figure 10: Learning curves of variable leaky γ_{w_k} of coefficient vector $\mathbf{w}_k$ of proposed AS-VLLMS-SAF on $\mathbf{C}_{CR}$ with $\vartheta = 0.20, 0.95$ and SNR = 35dB.

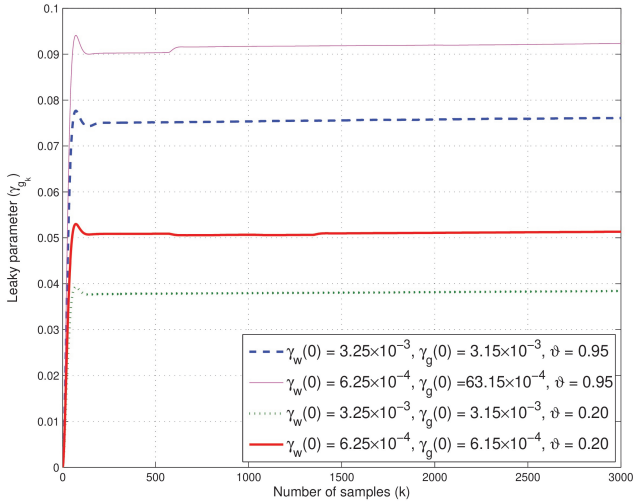

Figure 9: Learning curves of variable leaky γ_{g_k} of coefficient vector $\mathbf{g}_{m,k}$ of proposed AS-VLLMS-SAF on $\mathbf{C}_B$ with $\alpha = 0.20, 0.95$ and SNR = 35dB.

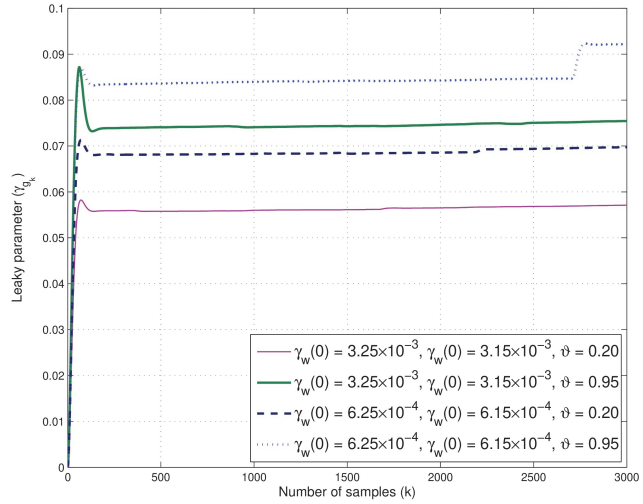

Figure 11: Learning curves of variable leaky γ_{w_k} of coefficient vector $\mathbf{w}_k$ of proposed AS-VLLMS-SAF on $\mathbf{C}_{CR}$ with $\alpha = 0.20, 0.95$ and SNR = 35dB.

4.3 Mean Square Error Performance

We investigate the mean square error (MSE) performance of the proposed AS-VLLMS-SAF algorithm at the steady-state.

Assumption 3: *We assume that the a priori and a posteriori optimal errors are identical, we have*

$$E\{\epsilon_g^{\text{opt}}\} \approx e_{\text{opt},g} \, .$$

Assumption 4: *We consider the convergence condition for $k \to \infty$, that is of*

$$E\{\epsilon_g^{\text{opt}}\} \to 0 \, , \text{ as } \; k \to \infty$$
$$E\{\mathbf{g}_{m,k}\} \to \mathbf{g}_{m,k}^{\text{opt}} \, , \text{ as } \; k \to \infty$$

Following [12], we decompose the MSE under these assumptions above as follows.

$$\mathbb{J}_{MSE}^{P} = \mathbb{J}_{MMSE}^{P} + \mathbb{J}_{EX}^{P} = E\{\|\epsilon_g\|^2\} \, , \tag{43}$$

where $\mathbb{J}_{MMSE}^{P}$ is the minimum mean square error (MMSE) as

$$\mathbb{J}_{MMSE}^{P} = E\{\|\epsilon_g^{\text{opt}}\|^2\} \, , \tag{44}$$
$$\epsilon_g^{\text{opt}} = d_k - \mathbf{v}_k^T \, \mathbf{C}_b \, \mathbf{g}_{\text{opt}} \, , \tag{45}$$

where ϵ_g^{opt} is the *a posteriori* optimal error of $\mathbf{g}_{\text{opt}}$.

Certainly, $\mathbb{J}_{EX}^{P}$ is the *a posteriori* excess mean square error (EMSE) given by

$$\mathbb{J}_{EX}^{P} = \mathbb{J}_{MSE}^{P} - \mathbb{J}_{MMSE}^{P} = E\{\|\epsilon_g\|^2\} - E\{\|\epsilon_g^{\text{opt}}\|^2\} \, . \tag{46}$$

4.4 Experimental conditions on parameters setting

In this section, the theoretical experiments are simulated in system identification over the random process and under the Gaussian noise scenario. We evaluate the performance of proposed adaptive step-size variable leaky least mean square algorithm based on spline adaptive filter (AS-VLLMS-SAF) as compared to the conventional least mean square algorithm based on spline adaptive filter (LMS-SAF) [3].

The coloured input signal generates for all experiments over 100 Monte Carlo trials and 5,000 samples used that is generated by [2]

$$x_k = \vartheta \cdot x_{k-1} + \sqrt{1-\vartheta^2}\zeta_k \,, \tag{47}$$

where ζ_k is a unitary variance type of zero mean white Gaussian noise, $\vartheta = [0, 0.95]$ and an interval sampling Δx is used at 0.2 [11].

An unknown Wiener system is composed by a linear component as [3]

$$\mathbf{w}_0 = [0.6,\ -0.4,\ 0.25,\ -0.15,\ 0.1]^T \,,$$

and a 23-point length lookup table (LUT) $\mathbf{g}_0$ is a nonlinear memoryless target function applied by

$$\mathbf{g}_0 = [\ -2.2,\ \ldots\ , -0.8,\ -0.91,\ -0.4,\ -0.2,\ 0.05,\ 0,\ -0.4,\ 1.0,\ 1.0,\ 1.2,\ \ldots\ , 2.2\ ] \,.$$

The linear filter $\mathbf{w}_0$ is initialzed as $\mathbf{w}_0 = [1,\ 0, \ldots,\ 0]$ and $\delta = 0.001$. Other parameters are fixed at the length of coefficient vector $T = 5$, a signal to noise ratio $SNR = 35$dB . The spline basis matrices are used as the *B-spline* matrix $\mathbf{C}_B$ and the *Catmul-Rom spline* matrix $\mathbf{C}_{CR}$ in [8] which are selected for simulation experiments as follows:

$$\mathbf{C}_B = \frac{1}{6}\begin{bmatrix} -1 & 3 & -3 & 1 \\ 3 & -3 & 3 & 0 \\ -3 & 0 & 3 & 0 \\ 1 & 4 & 1 & 0 \end{bmatrix}, \tag{48}$$

$$\mathbf{C}_{CR} = \frac{1}{2}\begin{bmatrix} -1 & 3 & -3 & 1 \\ 2 & -5 & 4 & -1 \\ -1 & 0 & 1 & 0 \\ 0 & 2 & 0 & 0 \end{bmatrix}. \tag{49}$$

The fixed parameters of proposed AS-VLLMS-SAF algorithm are as follows: $\alpha = 0.20, 0.95$, $\alpha_w = 7.55 \times 10^{-3}$, $\beta_w = 2.75 \times 10^{-3}$, $\alpha_g = 6.55 \times 10^{-3}$, $\beta_g = 1.85 \times 10^{-3}$, $\lambda = 0.97$, $\epsilon = 1 \times 10^{-6}$ and $\rho_w = 1.5 \times 10^{-6}$, $\rho_g = 1.125 \times 10^{-6}$. And the initial parameters for proposed AS-VLLMS-SAF are $\gamma_w(0) = 3.25 \times 10^{-2}$, $\gamma_g(0) = 3.25 \times 10^{-2}$, $\mu_w = 7.75 \times 10^{-4}$, $\mu_g = 2.25 \times 10^{-4}$. Other fixed parameter of SAF-LMS [3] are as: $\mu_w = 0.05$ and $\mu_g = 0.05$.

Table 2: Summary of MSE of proposed AS-VLLMS-SAF with the initial parameters: $\mu_w(0) = 7.25 \times 10^{-5}$, $\mu_g(0) = 2.25 \times 10^{-5}$, $\gamma_w(0) = 6.25 \times 10^{-4}$, $\gamma_g(0) = 6.15 \times 10^{-4}$, of VL-LMS in [1] with $\gamma_w(0) = 3.15 \times 10^{-4}$, $\gamma_g(0) = 3.15 \times 10^{-4}$ and of LMS-SAF in [3] with $\mu_w = \mu_g = 0.05$ over 100 Monte Carlo trials and 5,000 samples used at SNR = 35dB

Algorithm	ϑ in (47)	Spline matrix	MSE at steady-state condition	
			MSE	dB
AS-VLLMS	$\vartheta = 0.20$	$\mathbf{C}_B$	1.268×10^{-3}	-28.969
		$\mathbf{C}_{CR}$	1.448×10^{-3}	-28.392
	$\vartheta = 0.95$	$\mathbf{C}_B$	1.768×10^{-3}	-29.293
		$\mathbf{C}_{CR}$	2.342×10^{-3}	-26.304
VL-LMS in[1]	$\vartheta = 0.20$	$\mathbf{C}_B$	1.815×10^{-3}	-27.409
		$\mathbf{C}_{CR}$	1.931×10^{-3}	-27.144
	$\vartheta = 0.95$	$\mathbf{C}_B$	2.175×10^{-3}	-26.625
		$\mathbf{C}_{CR}$	2.592×10^{-3}	-25.862
LMS in[3]	$\vartheta = 0.20$	$\mathbf{C}_B$	3.303×10^{-3}	-24.811
		$\mathbf{C}_{CR}$	1.352×10^{-2}	-18.688
	$\vartheta = 0.95$	$\mathbf{C}_B$	8.345×10^{-3}	-20.786
		$\mathbf{C}_{CR}$	2.858×10^{-2}	-15.439

5 Simulation Results

For the experiment results, the mean square error (MSE) is simulated at $\vartheta = 0.20, 0.95$. Fig. 2 and Fig. 3 show the MSE convergence curves of proposed AS-VLLMS-SAF compared with the original LMS-SAF [5] based on the *B-spline* matrix ($\mathbf{C}_B$) matrix and the *Catmul-Rom* spline matrix ($\mathbf{C}_{CR}$) with the parameters $\vartheta = 0.2, 0.95$ in (47) shown in dB and SNR=35dB, respectively. We notice that the curves of MSE of proposed AS-VLLMS-SAF based on both spline basis matrices outperform when comparable to that of the LMS-SAF algorithm.

Furthermore, Fig. 4 and Fig. 5 based on the *B-spline* matrix and Fig. 6 and Fig. 7 based on the *Catmul-Rom* spline matrix demonstrate the curves of learning rate of μ_{w_k} of coefficient vector $\mathbf{w}_k$ and μ_{g_k} of control points $\mathbf{g}_{m,k}$ for the proposed AS-VLLMS-SAF at $\vartheta = 0.20, 0.95$ and SNR=35dB, respectively. Their learning curves are depicted to converge to their equilibrium at the steady-state, even the initial of μ_{w_k} and μ_{g_k} are varied.

Finally, Fig. 8 and Fig. 9 based on the *B-spline* matrix and Fig. 10 and Fig. 11 based on the *Catmul-Rom* spline matrix present the curves of learning parameters of γ_{w_k} of coefficient vector $\mathbf{w}_k$ and γ_{g_k} of adaptive control points vector $\mathbf{g}_{m,k}$ for the proposed AS-VLLMS-SAF at $\vartheta = 0.20, 0.95$ and SNR=35dB, respectively. It can seen clearly that their learning rates are shown to converge for the tracking ability at the steady-state with the different initial parameters.

Summary of MSE of proposed AS-VLLMS-SAF with the initial parameters as $\mu_w(0) = 7.25 \times 10^{-5}$, $\mu_g(0) = 2.25 \times 10^{-5}$, $\gamma_w(0) = 6.25 \times 10^{-4}$, $\gamma_g(0) = 6.15 \times 10^{-4}$ and of LMS-SAF in [3] with the fixed parameter as $\mu_w = \mu_g = 0.05$ over 100 Monte Carlo trials and 5,000 samples used at SNR = 35dB and $\vartheta = 0.20, 0.95$ is presented in Table. 2. Simulation results suggest that mean square error performance of proposed algorithm can be partially assessed using adaptive step-size with the variable leaky parameters indicating better than the conventional least mean square algorithm by 16.76% with the *B-spline* matrix.

6 Discussion

The comparison of MSE averaged over 100 trials are shown the robustness and superiority of proposed AS-VLLMS algorithm over the conventional LMS algorithm. We have plotted the learning curves of adaptive step-size μ_{w_k} of coefficient vector $\mathbf{w}_k$, μ_{g_k} of control points $\mathbf{g}_{m,k}$ for the proposed AS-VLLMS algorithm and of variable leaky γ_{w_k} of coefficient vector $\mathbf{w}_k$ and γ_{g_k} of adaptive control points vector $\mathbf{g}_{m,k}$ after 5,000 iterations, which are seen that their learning curves converges to their equilibrium, even the initial values are assigned to be varied.

7 Conclusion

We have orchestrated an adaptive step-size and a variable leaky approach based on least mean square algorithm for spline adaptive filtering. The proposed AS-VLLMS-SAF algorithm has been explained how to derive using the variable leaky mechanism. We have designed an adaptive step-size algorithm with the methods of an energy of squared previous and present estimated error. We have designed a modified leaky algorithm with the methods of an optimal leaky parameter. Simulation experiments have shown that the proposed AS-VLLMS-SAF algorithm can perform well with the corresponding LMS-SAF algorithm.

In general, spline adaptive filtering structure is already fascinatingly applied in many applications such as signal processing for communications in nonlinear channel estimation and acoustic processing in bio-acoustic signal.

ABSTRACT

Dithering or error diffusion is a technique used to obtain a binary image, suitable for printing, from a grayscale one. At each step, the algorithm computes an allowed value of a pixel from a grayscale one, applying a threshold and, therefore, causing a conversion error. To obtain the optical illusion of a continuous tone, the obtained error is distributed to adjacent pixels. In literature there are many algorithms of this type, to cite some Jarvis, Judice and Ninke (JJN), Stucki, Atkinson, Burkes, Sierra but the most known and used is the Floyd-Steinberg. We compared various types of dithering, which differ from each other for the weights and number of pixels involved in the error diffusion scheme. All these algorithms suffer from two problems: artifacts and slowness. First, we address the artifacts, which are undesired texture patterns generated by the dithering algorithm, leading to a less appealing visual results. To address this problem, we developed a stochastic version of Floyd-Steinberg's algorithm. The Weighted Signal to Noise Ratio (WSNR) is adopted to evaluate the outcome of the procedure, an error measure based on human visual perception that also takes into account artifacts. This measure behaves similarly to a low-pass filter and, in particular, exploits a contrast sensitivity function to compare the algorithm's result and the original image in terms of similarity. We will show that the new stochastic algorithm is better in terms of both WSNR measurement and visual analysis. Secondly, we address the method's inherent computational slowness: we implemented a parallel version of the Floyd-Steinberg algorithm that takes advantage of GPGPU (General Purtose Graphics Processing Unit) computing, drastically reducing the execution time. Specifically, we observed a quadratic time complexity with respect to the input size for the serial case, whereas the computational time required for our parallel implementation increased linearly. We then evaluated both image quality and the performance of the parallel algorithm on a exhaustive image database. Finally, to make the method fully automatic, an empirical technique is presented to choose the best degree of stochasticity.

1 Introduction

Most printing devices are constrained by a limited number of color intensities (typically 2/4/8/16 values), as consequence, before printing an image they must first convert the original color domain into a new set of values that can be represented with the color intensities at their disposal. A process we call quantization.

An intuitive and trivial quantization method is to map each input pixel to the nearest available color. However, most of the time this leads to a visually unpleasant and low quality output image due to a large number of artifacts. Here, dithering comes to help and it has been proved to be able of achieving a higher quality results. In particular, the best known and popular dithering algorithms is the Floyd-Steinberg (FS) [1] which is based on errors diffusion. Besides the FS, there are other algorithms that differ from this for the weight distribution matrix. The error scattering technique is straightforwardly described in Algorithm 1.

Algorithm 1 Dithering algorithm

```
for rows ∈ image do
    for pixels p ∈ row do
        find closest color τ to p
        err = p − τ
        diffuse err to neighbouring pixels according to the error diffusion scheme
    end for
end for
```

In case of binary dithering applied to a monotone image (e.g. grayscale to black and white), Algorithm 1 is just a simple threshold operation. Extending it to a larger set of colors (or tones) is a trivial change in *finding the closest color*. It was one of the most revolutionary methods and is widely used in digital printers, which prints small and isolated dots.

The other algorithms against which we will compare for the numerical experiments are: Atkinson, Burkes, Fan, Sieraa, Filter Lite, Jarvis, Judice and Ninke (JJN), Jarvis, Stucki and Shio Fan [2].

There are several error distribution scheme and different ways to scan the image, such as the traditional left-to-right direction and the top-to-bottom raster. Considering all the matrices of weights related to the various methods would be redundant, therefore we show only a few in Figure 1 to clarify the concept.

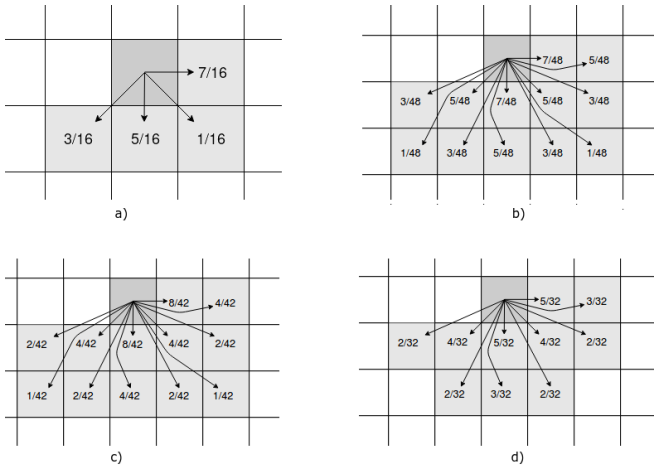

Figure 1: Error diffusion scheme for different dithering algorithms: Floyd-Steinberg (a); Jarvis, Judice and Ninke (b); Stucki (c); Sierra (d). The flux of the whole image remains the same.

We also took care of the borders, in particular, we ensured that the image flux or average is maintained through the entire image, Figure 2 shows the modified FS error distribution *weights* in all particular cases.

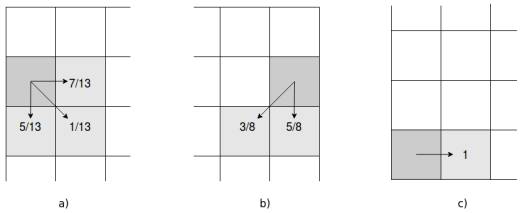

Figure 2: Error diffusion in the FS dithering in case of boundaries. a) first column, b) last column and c) last row.

The major shortcomings of the FS dithering algorithm are the generation of disturbing hysteresis artifacts or worm patterns at extreme gray-levels[3, 4] and the slowness [5].

2 Background and preliminaries

The purpose of image dithering, or halftoning, is the procedure that generates a pattern of quantized pixels able to create a continuous-tone image illusion. A comprehensive analysis about halftoning techniques can be found in [2]. Dithering is necessary for showing gray scale images on printed surfaces when the only available tones are black and white. Dithering algorithms will produce different results with respect to quality and image characteristics. To allow a comparison between different algorithms, we must therefore quantify the performance. Doing so by means of psychovisual tests is hard due to the need of controlled conditions and long duration of the tests. A possible solution to this problem is developing quality measures that can numerically express the perceived visual difference between the dithered image and the original one. The ideal target would be to include several objective aspects of image quality within one single, robust and reliable measure, so to evaluate and improve dithering algorithms.

We cans also describe digital halftoning as an artifact minimization problem, because we search for the dithered image that minimizes the measured visibility of artifacts. We therefore need a computational model that allows us to compute the visible error, so to automatically rank images in an optimization algorithm. Nevertheless, measuring in a quantitative way the visual quality of a dithered image is still a challenging task.

Objective quality measures can be divided in two classes: mathematical/statistical ones and human visual system (HVS) based.

The first ones could be used to evaluate dithered patterns of constant grey values. These metrics provide a great understanding of the possible relationships for a given point distribution. These kinds of measures are usually independent of viewing conditions or observer, easy to compute thanks to the low computational complexity. It is possible to find in literature different examples of this kind of measures, such as: Structural Similarity (SSIM) [6], Peak Signal-to-Noise Ratio (PSNR) [7] and Mean Squared Error (MSE) [8]; nevertheless, none of these measures consider the presence of artifacts as explained in [9, 10].

The second one tries to model the perceived visual quality and predict artifacts generated by the dithering procedure. The ideal halftone algorithm is able to minimize this visibility. Since the eye detects more distortions at certain spatial frequencies, the development of a halftone visibility metric is based on a model of the HVS.

HVS models are relatively simple and have proven to be quite successful when applied to algorithms that seek the best possible distribution scheme. All digital halftone techniques, whether they are based on screening algorithms, error scattering or iterative halftone, all adopt these models, either explicitly or implicitly. In fact, even those methods that are categorized as model-free because they do not explicitly include an HVS block in their block diagram, still replace it with a low pass filter. Moreover, not only is an HVS model fundamental to the design of most halftone techniques, but additionally, the shape of the HVS model can be modified to achieve increased texture quality in the dithering result.

Therefore, the performance of a certain halftone algorithm can be maximized by adequately designing improved HVS models.

Digital halftoning usually refers to methods and algorithms able

to convert continuous-tone images to binary ones, for displaying them in bilevel devices such as printers, both ink jet and laser ones. Within the computer industry, the market demand for fast, high resolution printing devices has recently escalated. Halftoning's contribution to this industry has been essential to its success. For this reason investigating image quality, and in particular finding an objective measure to evaluate the results is of fundamental importance.

2.1 A Quantitative Measure

As discussed, HVS models use human visual selectivity and sensitivity to model and improve the perceived image quality. HVS is based on the psycho-physical process that relates psychological phenomena (contrast, brightness, etc.) with physical phenomena (light intensity, spatial frequency, wavelength, etc.). It determines which physical configurations give rise to a particular psychological sensation (perceptual, in this case).

The two dimensional Discrete Fourier Transform (DFT) is applied on the image and then multiplied using Hadamard product with a Contrast Sensitivity Function (CSF), so that a component of the image at a particular angular frequency is weighted by the CSF value at that frequency. The result of this computation is the two dimensional DFT of an image that would lead to the same psychological response when viewed from a visual system with a flat CSF to which the original image leads when viewed by HVS [11]. The weighted signal-to-noise ratio (WSNR) of an $M \times N$ pixel binary image (y), given the original (x) of the same size is computed as:

$$WSNR(dB) = 101 \log_{10}\left(\frac{\sum_{u,v} |X(u,v)C(u,v)|^2}{\sum_{u,v} |(X(u,v) - Y(u,v))\, C(u,v)|^2}\right) \qquad (1)$$

where $X(u,v)$, $Y(u,v)$ and $C(u,v)$ are correspondingly the DFT of the input image, of the output image and the CSF.

2.2 Stochastic version

As already described in the previous sections, halftoning converts the input image into a black and white version of it to be reproduced on a binary output device, such as an ink-jet printer, which can only choose whether to print a dot or not in each position. The human eye, behaving as a low-pass filter, blurs the dots and spaces together and creates the illusion of many continuous shades of gray tones. Depending on the specific way the dots are distributed, a display device can produce different degrees of image fidelity with more or less granularity. According to the HVS, isolated and randomly arranged dots, if distributed in a proper manner, should produce images with the highest quality, maintaining fine details and sharp edges. Nevertheless, some displays and printing devices are unable to reproduce isolated dots consistently in their entirety and, as a result, introduce printing artifacts that greatly degrade the aforementioned details that the computed dot distribution is designed to preserve. For this reason, many printing devices create periodic patterns of grouped dots, which are easier to produce on the printed page in a consistent manner. For this reason, in our halftone study, the main objective is to determine the optimal dot distribution for that HVS, and then produce these models computationally efficiently.

Since the first article in which Floyd and Steinberg's algorithm was mentioned, many changes to the original error spread algorithm have been introduced to avoid the undesirable artifacts present in the original algorithm. But while these modifications eliminate disturbing artifacts at certain levels of gray, many do so therefore at the expense of other levels. Jarvis [12] and Stucki [13], for example, introduced a different mask model and weights, called 12-element error filter, but the artifacts remain during the algorithm because of the fixed behavior manifested by these algorithms. Hence we realize that the problem is not related to the number of elements involved but rather to the determinism of the method. Other approaches suggested to change the scanning path in which pixels are processed, including the serpentine as the most trivial up to the space-filling curves like Hilbert's curves. Unfortunately, these methods still create strong periodic patterns. To mitigate the problem of artifact our idea is to transform the FS algorithm, a deterministic algorithm, into a Stochastic (SFS) version inspired by [14]. A crucial point of our new approach is the preservation of the average image. As in all halftone methods, where everything and only the error is spread. Even in our method, while modifying the weight matrix at each pixel, the average of the values of the original image is not changed.

In particular we choose a real number p and, for each pixel, we generate 2 random number:

$$r_1 \in [-5/16, 5/16] \text{ and } r_2 \in [-1/16, 1/16]$$

and we compute

$$\frac{7}{16} + p \cdot r_1, \frac{5}{16} - p \cdot r_1, \frac{3}{16} + p \cdot r_2 \text{ and } \frac{1}{16} - p \cdot r_2 \qquad (2)$$

as error diffusion coefficients. This method, as a modification of Ulichney's one[15], is a good approximation of a blue-noise process. Blue-noise halftoning is characterized by a distribution of binary pixels where the minority pixels are spread as homogeneously as possible. This method of pixel distribution creates a pattern that is isotropic (or radially symmetric), aperiodic and does not contain any low-frequency spectral components. From the considerations made about HVS, it's not surprising that blue-noise creates the visually optimal arrangement of dots. Unfortunately, blue-noise is not trivial or fast to generate [16], but whit our method this can be approximated.

2.3 Optimal choice of p

By introducing our new method we have underlined the need to choose a p parameter.

In our previous work the choice of p was totally empirical and not automated, that is, we tried different values of p in a predetermined range and picked the best according to the image quality measured by WSNR. Here we introduce a method for the automatic setting of p. As pointed out above, these algorithms are often used for printers in different areas, but often as an integral part of industrial processes. For this reason and for the sake of completeness, finding a fully automatic method would make the method more effective and usable on a large scale. There are two critical issues to be addressed: the choice of an appropriate interval and the need for an intervention by the operator for the choice. First of all, let's discuss the choice of the interval. As we have defined p there are no

limitations, it simply has to be a real value. Since it is not a probability, it can certainly assume both values greater than 1 and negative values. Conceptually there is a symmetry, at least on average, between negative and positive values so we can only take into account positive values without losing in the generality. On the other hand, choosing values much greater than 1 means to substantially change the coefficients of the matrix used for the diffusion of the errors, for example choosing $p = 2$ the values, on average, are doubled. In addition to these preliminary considerations we conducted several experiments aimed at understanding where the maximum value of WSNR was in relation to the p choice. As it can be seen in Figure 3 , the maximum is usually included in the $[0, 2]$ interval.

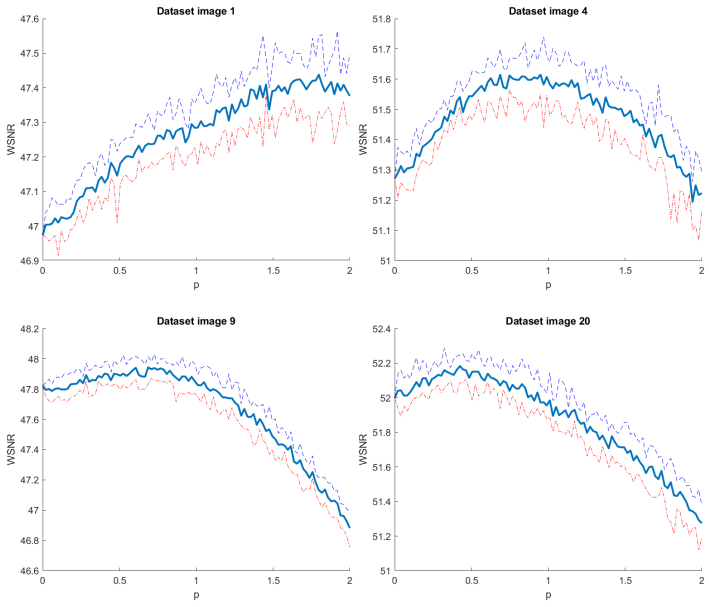

Figure 3: Sample of the algorithm behaviour for p in the interval $[0, 2]$ for some images of the dataset available in [2]. Due to the stochastic nature of the algorithm, we repeat the algorithm 10 times with different random seeds for each value of p, plotting minimum, average and maximum value for the resulting WSNR.

Once the range is fixed, we address the second issue by means of an optimization algorithm that provides the p value that maximizes the WSNR. The first idea, given the amount of references in the literature, was to use a first-order technique as a gradient method [17]. But we immediately noticed that, due to the lack of convexity of the function to be maximized, such methods are often not effective. There are certainly techniques to use gradient methods even in non-convex areas but they require at least the differentiability of the function. Since we have to maximize a stochastic process we see both the basic hypotheses of the gradient methods fall: convexity and differentiability. Fortunately, our implementation of the parallel algorithm on GPUs makes execution time particularly low, even for large images. This allows us to approach efficiently the problem in an empirical way without increasing the time excessively. Considering all these premises, our final idea is to calculate, first, the WSNR for different values of $p \in S_n$ where S_n is an equally spaced partition of the interval $[0, 2]$ with n elements. Due to the stochasticity of the method, for each $p \in S_n$ we consider the average over m runs.

Finally, choose the p with the highest average WSNR. We summarize our method in the equation 3 where m is the number of runs, I and $SFS(p)$ represent respectively the input image and the output image obtained from a single run of our stochastic dithering algorithm with parameter p.

$$p* = \arg\max_{p \in S_n} \frac{1}{m} \sum^{m} WSNR(I, SFS(p)) \tag{3}$$

We obtained the best results with the following configuration:

- Size of partition S_n, n = 100
- Number of repetitions for each p, m = 10

In this way, given any image in our experiments, the method lead to satisfying results in terms of similarity to the initial image.

3 GPU implementation

Dithering algorithm are infamously known for being "embarassingly" unparallel due to the inherently sequential nature of the dithering operation: the every pixel output depends on all the previously computed outputs. Achieving good speed ups in such problems is a challenging task and several work from the research community tried to overcome this issue, either proposing a "friendlier" dithering algorithm or a more efficient implementation. For example in [18]–[20] they introduce a block-based error diffusion algorithm which allows to simultaneously process blocks of pixels and produced good visual results, however is not clear which block dimension should be taken in order to get the best image quality; whereas in the work [21] the authors propose to parallelize over multiple pages in order to saturate the GPU utilization, in this work we focus on a single image case; in [22] they propose an efficient implementation that consists of a hybrid approach where CPU and GPU are both exploited but the CPU is used in the regions where GPU is expected to perform worse, in particular, towards image corners; finally [5] provided an optimal parallelization algorithm from a theoretical point of view, unfortunately, assigning each thread a diagonal portion of the image is currently not suited for general purpose devices as it causes more time spent for additional computational overhead than what parallel devices can manage to reduce.

In this work, we adopt the classical Floyd-Steinberg algorithm as it's still the dithering algorithm that yields the best result and propose an implementation that rely solely on GPUs. Graphics Processing Units (GPUs), in particular General Purpose GPUs, are massively parallel architectures that comprises thousands of cores designed to compute in an extremely efficient way repetitive and simple operations such as those involved in the rendering pipeline in Computer Graphics, hence "Graphics" in the name. Each core are less performing and simpler than state of art processors but the computational power in such devices lies in the number of cores rather than the capability of each single core. Nowadays GPUs are widely adopted for many tasks in data mining, physics simulation, medical imaging and machine learning, to name a few, hence the "general purpose" in the name. We propose an implementation [1] that

[1] https://git.hipert.unimore.it/hjiacheng/stochastic_floydsteinberg

is optimized for the NVIDIA GPUs, from which we will also get the results reported in section 4.1, and we program with the architecture's standard Application Programming Interface (API), called CUDA [23] developed by NVIDIA itself. Nonetheless, our implementation takes into account obstacles and design principles valid for almost all GPUs so it's not limited to NVIDIA architectures.

Our implementation consists of two parallelization levels we call stream level and pixel level. First of all we, describe the pixel level parallelism consists of a function, named Parallel-FS, that implements the Floyd-Steinberg on GPU and assumes the image being already stored in the GPU memory, this function will be then invoked by the stream level function.

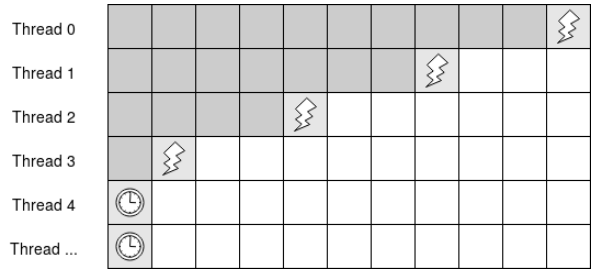

Figure 4: Each thread is assigned a row and waits for the previous one to be three pixels ahead instead of two. The thunder symbol on the diagonal represents the pixels processed simultaneously, whereas the clock indicates a waiting thread

In order to achieve good results one must take into account the of hardware on which the algorithm is executed. GPUs are SIMT (Single Instruction Multiple Thread) architectures partitioned in several Streaming Multiprocessors (SM), the latter are clusters of cores with multiple hardware schedulers for dispatching a fixed number of threads called warps. Each thread in the warp are committed to perform the same operation simultaneously, a feature called lock-step execution, and they are able to fetch multiple data at the same time if the addresses in the memory are aligned, a phenomena called "coalesced access". While these are good features in simple and regular memory accesses, it becomes actually a downside in case of Floyd-Steinberg because operations and accesses are neither simple nor regular. Dithering algorithm finds the closest color input and handle borders with many conditional, hence branching, instructions, which hurts the performance as the device must turn-off the portion of the threads not involved in the current branch because of the lock-step execution, moreover there's no coalesced access as the error diffusion scheme follows an irregular pattern leading to increased latency. This is the reason why the optimal theoretical algorithms presented in [5] cannot be implemented, nonetheless we try to approximately recreate the theoretical optimal situation in Parallel-FS. The function takes as input three data structures, an input buffer I_{buff} where the original image is stored, an output buffer O_{buff} where the result will be stored and error buffer E_{buff} for the temporary error diffusion values. Each row i is assigned a thread which, for each pixel (i, j), $j \in \{1, ..., I_{WIDTH}\}$ where I_{WIDTH} is the image width, reads from the input buffer and computes the output $O_{buff}(i, j)$ by finding the closest color according to the value $S = I_{buff}(i, j) + E_{buff}(i, j)$, and distribute the error $S - O_{buff}(i, j)$ to the neighbouring pixels according to the error diffusion scheme of Floyd-Steinberg, updating $E_{buff}(i, j+1)$, $E_{buff}(i+1, j)$, $E_{buff}(i+1, j-1)$ and $E_{buff}(i+1, j+1)$. The actual implementation carefully takes into consideration also borders compared to this simplified formulation. Each thread must synchronize with the previous thread in order to compute the assigned pixel result, in our implementation, in order to avoid update conflicts in the error buffer, which would require slow atomic operations, each thread waits for the previous one to be three pixels ahead with respect to his row instead of two, similarly to [21] (see Figure 4). The Figure 4 also illustrates how pixels are processed simultaneously along the diagonal (hence the name "pixel level parallelism").

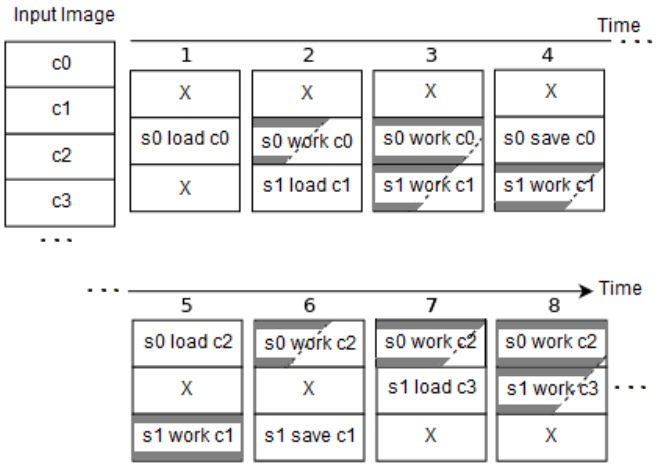

Figure 5: Visual illustration of the Double Buffering parallel execution scheme for the stream level parallelism, with two CUDA streams; sj and ci and denote CUDA stream respectively and image chunks. The "load" and "save" operations represent the data transfer from host to device input buffer I_{buff} and from device output buffer O_{buff} to host respectively and "work" consist of the invocation of Parallel-FS. It can be noted that, starting from time step 2, the memory transfer latency is completely hidden by GPU activity. "X" denotes the empty chunk, note that there is always an empty chunk because given $N_{STREAMS}$ there are $N_{STREAMS} + 1$ blocks in the data structure, so each iteration, every stream finds the results of the first row of the error buffer already calculated by the previous stream by simply sliding up.

The stream level parallelism addresses a problem more related to the physical devices limitation rather than the FS algorithm. In previous function we assumed the image to be already when the output is ready, the result is transferred back into host memory. Unfortunately, in most parallel implementations memory bandwidth represents one of the main bottleneck. The outer loop in our stored in GPU memory, however, for a task to be executed on GPU, every required data must be copied first from host memory (accessible by CPU only) to device memory (accessible by GPU only) and parallel implementation addresses this problem by hiding almost completely the memory transfer overhead between CPU and GPU wit the double buffering technique, which also removes the device memory size constraint for huge images.

Given an image of size $I_{HEIGHT} \times I_{WIDTH}$ and two input parameters N_{CHUNKS} and $N_{STREAMS}$, the first parameter define the number of chunks the image is divided into, whereas the latter represents the number of chunk to be processed simultaneously. First we define $Chunk_{HEIGHT} = \frac{I_{HEIGHT}}{N_{CHUNKS}}$ and we divide the image into N_{CHUNKS} of size $Chunk_{HEIGHT} \times N_{WIDTH}$, secondly we create three data struc-

ture of size $(Chunk_{HEIGHT} \cdot (N_{STREAMS} + 1)) \times I_{WIDTH}$ size for the input, output and error buffer respectively. Now, $N_{streams}$ CUDA stream are created, each of these concurrent execution stream are assigned an image chunk are responsible of computing the result by invoking the Parallel-FS function previously described on the assigned chunk. During the algorithm execution, every function invoked by each stream references to the same data structure but on a different memory address offset, the size of each buffer is $N_{STREAMS} + 1$ chunk blocks instead of $N_{STREAMS}$ because the the additional chunk allows to leave one chunk empty at every iterative step so Parallel-FS function avoids storing the error computed in the last row into an auxiliary buffer, minimizing the number of conditional operations. Because of the empty chunk, when a CUDA stream finishes the job, it can slide on the upper chunk in a toroidal fashion along the height, which means that the errors computed in the last row of the data structure are actually propagated in the first and the CUDA stream working in the first block moves to the last in the next outer loop iteration as it finds the error values ready to be used. The indexing and synchronization required to ensure the overall correctness of the FS algorithm details will not be discussed for the sake of simplicity. The final result is that when some CUDA streams are processing their chunk, others are transferring data from host to device memory and vice-versa, thus the memory bottleneck is hidden and the architecture is fully exploited. In Figure 5 we show the presented parallel execution scheme.

3.1 Theoretical improvement

Consider an image of size $P \times Q$, where P identifies the number of rows and Q the number of columns. We want to know the order of magnitude of the time that is theoretically needed to process the whole image. We use as a measure unit the time needed to process a single pixel.

In the serial version: $Time = P \times Q$ where $Time$ is the time for the whole process. In the parallel version, with the same image dimension, we have

$$Time = 3P + Q - 3 \text{ with } Q > P \tag{4}$$

and

$$Time = 3Q + P - 3 \text{ with } P > Q. \tag{5}$$

Considering, as said before, the time we use to process the single pixel we can assume to spend a M time to calculate the first row, but at this same time, always considering the parallel implementation, we have already calculated the triangle at the top left as shown in Figure 4. Going on to finish the second line, we only need to calculate another 3 pixels and we can proceed with a similar reasoning for all the rows in the image. So we have $Q+3\times(P-1) = Q+3P-3$. Even in an image where the number of rows and columns is swapped we have the same runtime. For these considerations we can conclude that we pass from a time that grows as $O(P \times Q)$ with the input size, in the serial case, to a time that grows linearly $O(P + Q)$ in the parallel case, all this from a theoretical point of view. This allows us to have a great saving in computational time, especially in industrial contexts where the images are of huge dimensions. This means an incredible acceleration, especially when the size of the image is large, as often happens in industrial cases.

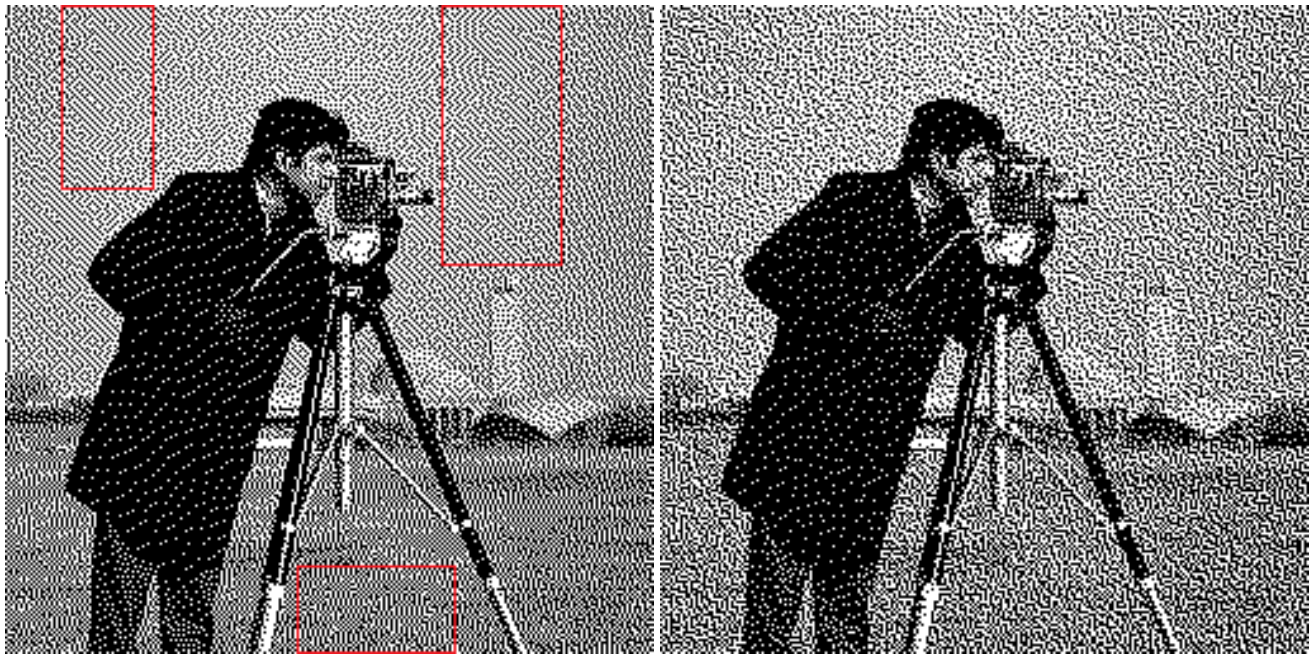

Figure 6: Cameraman image dithered with $p = 0$ on the left. The red rectangles highlight regions with visible artifacts. On the right, dithered image with optimal p value to maximize the WSNR value.

Figure 7: Lena image dithered with $p = 0$ on the left. The red rectangles highlight regions with visible artifacts. On the right, dithered image with optimal p value to maximize the WSNR value.

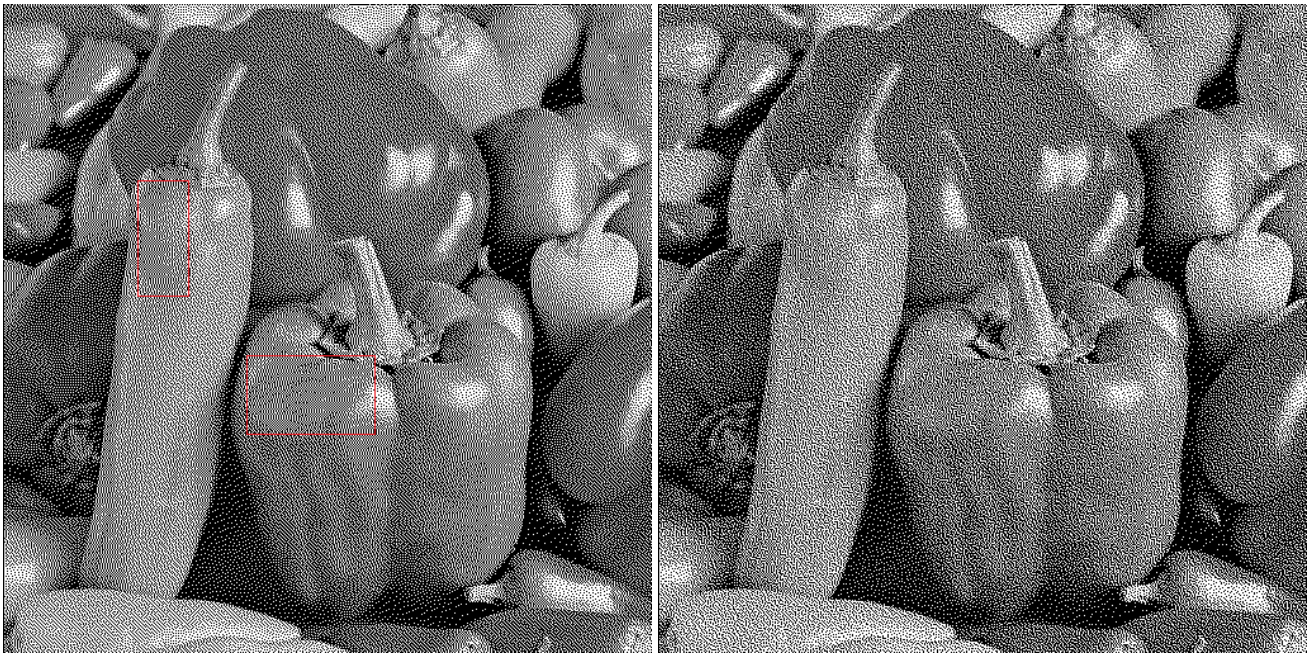

Figure 8: Peppers image dithered with $p = 0$ on the left. The red rectangles highlight regions with visible artifacts. On the right, dithered image with optimal p value to maximize the WSNR value.

4 Numerical experiments

The authors of [2] provided a sufficiently large dataset of images on which we applied our algorithm[2], the Digital Halftone Database (DHD). This dataset is composed of 196 reference images extracted from the CVG-UGR-Image database and the Genreal-100 dataset. In addition to these real images, we also assessed our approach on synthetic images. In particular, a particularly complicated image to process is the grayscale gradient, as in the Figure 10 or multi-tone chessboard. Moreover, the well known Lena, peppers and cameraman have been tested as well. Not all the images have same values of width and height since the algorithm can be applied to rectangular pictures as well. In the first experiments, we chose synthetic images. To verify the improvement with respect to the presence of artifacts,

[2] https://sites.google.com/view/sankarasrinivasan-s/research-publication/DHD-Database

we applied our algorithm to images composed of all shades of the (0 – 255) grayscale. This was done because some tones are more susceptible than others to artifact forming. In a second experiment we applied the new techniques to images often used in published works, in order to compare the results with the literature. Finally we compare against the results of [2], that are provided as results images in the same dataset. Obviously it can be observed that there is a considerable difference between the proposed stochastic approach and the simple FS. The experiments were performed on a desktop computer equipped with a CPU and GPU with the following specifications: Intel i7 7700K CPU, NVIDIA GeForce GTX 1080 GPU and 32GB RAM.

4.1 Results

With respect to image quality, we computed the measure described in Sec. 2.1 after applying FS, SFS and, for completeness, other dithering algorithms known in literature: Stucki[13], SIERRA[24] and Jarvis, Judice, and Ninke [12]. The results for the different images in Figure 10 (top row) and Figure 6, 7 and 8 are shown in Table 1 were we highlighted in bold the best WSNR values. The charts in Figure 13 show the behaviour of the WSNR value with respect to p for these images. Furthermore, we provided additional visual comparisons in Figures 11 and 12.

We compared our algorithm to the error diffusion ones presented in [2] on the same DHD dataset previously mentioned. We computed WSNR from the output images that are made available in the dataset and compared against our approach: over 196 different images we achieved the maximum WSNR value amongst all the algorithms 71% of the times, while the remaining 29% has been topped by the Filter Lite Dot Diffusion algorithm from [25].

In Table 2 we report the values of WSNR for some images of the dataset. We have to remark that, due to the different output size of the image, for some pictures we were unable to compute the WSNR value of comparison. The algorithms that are taken into account here are our FSF, Atkinson (ADD), Burkes (BDD), Fan (FDD), tradirional Floyd Steinberg (FSDD), Frankie Serra (FSIDD), Filter Lite (FLDD), Jarvis Judice and Ninke (JJNDD), Jarvis (JDD), Stucki (SDD) and Shio Fan (SFDD).

In addition to providing a theoretical discussion, we tested the different versions of the algorithm, serial and parallel, on images of different sizes. As we expected we obtained very good results: while serial time increases quadratically, parallel time increases only linearly. Let's better illustrate the trends in Figure 9.

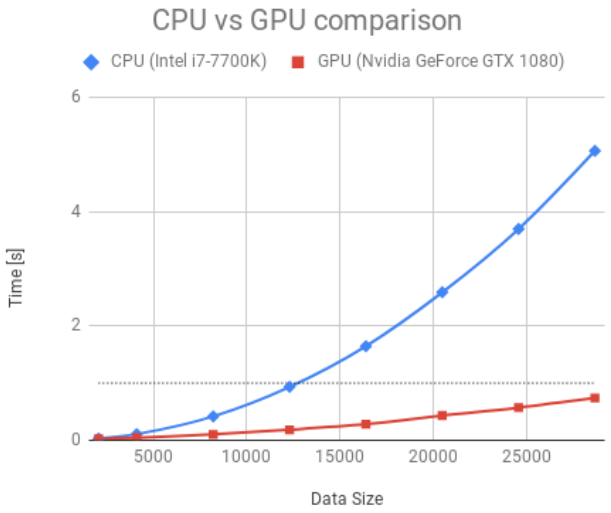

Figure 9: Comparison between the two versions: serial and parallel. Time in seconds on vertical axis, horizontally there is side dimension in pixels of a square image. In dotted line: all parallel execution time are less than one second.

Table 1: Dithering methods WSNR comparison

Image	FS	SFS			Stucki	Sierra	JJN
		$p = 0.25$	$p = 0.5$	$p = 0.75$			
Gradient	52.58	53.15	**53.34**	53.28	50.49	50.64	50.28

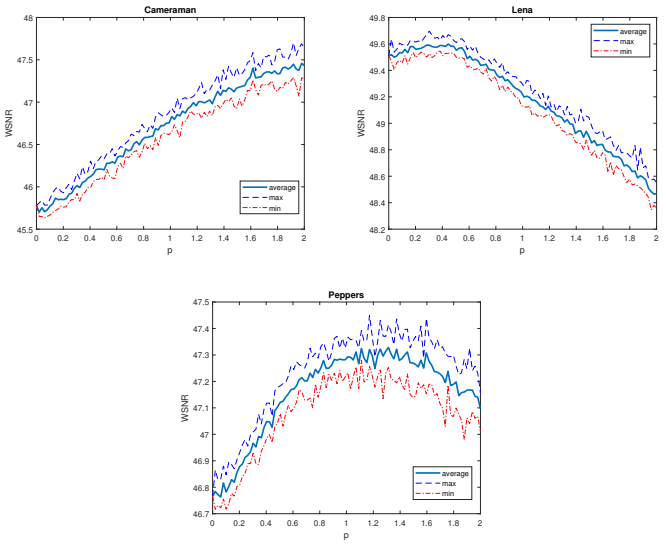

Figure 13: WSNR computed for our Stochastic Floyd-Steinberg algorithm with $p \in [0, 2]$ on the 3 well known images of Cameraman, Lena and Peppers. We proceed as for Figure 3.

5 Conclusions

In conclusion, the new algorithm we presented solves both the problems highlighted at the same time: the presence of artifacts and the slowness of execution. In particular, the transformation of the algorithm from deterministic to stochastic, with the introduction of a white noise, avoids the emergence of artifacts. The improvement can be evaluated through a specific measure that takes into account human perception called WSNR. Moreover, there is no increase in computational time; on the contrary, the parallel version we propose shows an excellent speed-up as the image size increases; which, especially in industrial applications, can be very large. Thanks to our parallel implementation, which guarantees speed to the method, we were able to fully automate the technique. So given an image we are capable of applying the best amount of stochasticity to the algorithm, thus obtaining an image as free of artifacts as possible. All the research part of the optimal parameter is done before the actual image printing process. This guarantees a method in which the operator does not have to make a decision and the printer is not occupied for a long time. In conclusion, the method is totally automatic, fast and guarantees a final image as close as possible to the initial one and suitable for printing. As future work some of the

possible extensions could be: more sophisticated methods to find optimal p, developing other error measures that take into account artifacts or geometric textures of different kinds. Another idea is to evaluate the 4, 8 and 16 gray tones versions of the dithering algorithm by proposing a technique that finds the best trade-off between image quality and number of tones.

ABSTRACT

Transformer health assessment techniques, based on applicable standards, such as the dissolved gas analysis (DGA), through laboratory testing or online monitoring are used to analyze the symptoms of a failure which develops in transformers from an early stage. The DGA from a sample of dielectric liquid taken from the main tank generates information on the state of degradation of the active part. It was found that of all the furan derivatives which result from the degradation of insulation, 2-furfuraldehyde (2-FAL) is the only derivative which dissipates in large quantities in oil. Because of this, and due to its thermal stability as compared to other derivatives, 2-FAL is the best unit of measurement to determine and monitor the degree of polymerization (DP) of insulation. The poor accessibility of paper samples has led to difficulties in testing the ageing state of paper directly by measuring the tensile strength and the DP. It was developed methods to indirectly assess the ageing state of paper, by means of the chemical markers in oil which are associated with paper ageing. This article presents a method to determine the DP of solid insulation in transformers, which provides a faster and more accurate interpretation, as compared to the classical ones. The 2-FAL data resulting from the lab are recorded in a MySQL database, which is embedded in an intelligent system for diagnosis of DP (ISDDP) based on Adaptive Neuro-Fuzzy Inference System (ANFIS), generating at the output the report with the interpretation of the faults as word files. The automation of the DP diagnostic process will be achieved, allowing the operator to make timely decisions, to avoid any possible damages.

1. Introduction

Transformers are expensive pieces of equipment that play a significant role in electricity transmission and distribution systems. Although transformers are generally robust pieces of equipment, they also undergo failures, and there are numerous degradation mechanisms operating in components and subsystems that will limit the useful life. It is important that transformer users and distribution system administrators are properly trained to assess the condition of a group of transformers in operation, in order to take the best decisions at critical moments of possible damages, for the operations of minor faults repairing, their rehabilitation or replacement [1-4].

The assessment of the condition of the operating transformer consists in identifying the indicators that can provide accurate data on the extent of degradation of transformer components and subcomponents. The detailed health assessment of a power transformer requires extensive testing (electrical, as well as physico-chemical tests of the dielectric fluid), inspection of dataset from acquisition of other relevant data (operational history, as well as maintenance, including data of putting into service). These data are then analyzed by an expert based on the relevant standards and expert knowledge [5-8].

Most common transformer health assessment techniques apply only to the active part of the transformer. The DGA from a sample of dielectric liquid taken from the main tank generates information on the state of degradation of the active part. However, all components and subcomponents of a transformer should be considered for a full assessment. Unexpected failures of the

* Corresponding Author: Marcel Nicola, ICMET Craiova, Romania, marcel_nicola@yahoo.com

bushings and the on-load tap-changer (OLTC) can often lead to a state of transformer failure or even to its removal from the system [9-17].

The assessment of the active part of the transformer (magnetic core and windings) can be performed as follows [6], [10-16]:

- The thermal assessment concerns the faster-than-anticipated aging due to excessive temperatures resulting from the hot spot of the winding, the hot spot in the core and the defects of paper-insulated hot metals;
- The dielectric assessment tracks the process of degradation of the paper-oil insulation system due to high thermal or electrical stress, oil-paper moisture, manufacturing defects and contamination with (semi) conducting particles (solid particles);
- The mechanical assessment concerns the disintegration of the structure in the core, the windings and the solid insulation, due to one of the many reasons, such as strong electromagnetic forces resulting from the flow of the short-circuit current through the windings; the mechanical deformation of the windings due to shocks during transport, installation or during system failures, etc; and the degradation of solid insulating materials.

The oil plays a key role as an insulating medium that acts as a barrier between the windings and the tank and acts as a "cooling agent" that dissipates the heat generated in the windings and the core. It is a conservation medium which protects the windings and the solid insulation against moisture and other physical contamination.

The molecular structure of oil is subjected to electrical, mechanical and thermal stress during transformer operation, which leads to a process of decomposition, and, as a result hydrocarbon gases are generated. These gases are found in the mass of the dielectric fluid and can be quantized.

Transformer health assessment techniques, based on applicable standards, such as the DGA, through laboratory testing or online monitoring are used to analyze the symptoms of a failure which develops in transformers from an early stage [12-14].

The complexity of real world problems, the need to develop complex software systems that adapt to a dynamic environment such as the real world lead to growing interest in the use of computational intelligence techniques to develop specific applications. Computational intelligence is a subdomain of the artificial intelligence that deals with the design, application and development of computational paradigms inspired for example by biological, social and linguistic areas. The techniques covered by the computational intelligence are the fuzzy logic, the artificial neural networks and the evolutionary computation. These are mainly fuzzy systems, neural networks, cognitive systems, nature-inspired systems and hybrid intelligent systems containing these paradigms. The most common of these techniques used for the diagnostic of power transformers are the fuzzy logic and the artificial neural networks [18-27].

This article presents a method to determine the DP of solid insulation in transformers, which provides a faster and more accurate interpretation, as compared to the classical methods. The 2-FAL data resulting from the lab are recorded in a MySQL database through a client software application for writing to the database and then read through a database read client, which is embedded in the diagnostic system, generating at the output the report with the interpretation of the faults as word files. Thus, the automation of the DP diagnostic process will be achieved, allowing the operator to make timely decisions, to avoid any possible damages.

The proposed ISDDP to determine the DP of the insulation of power transformer windings based on the content of the 2-FAL derivative uses the fuzzy logic, and, for the improvement of the system, the fault learning facility is used, based on the artificial neural networks.

This article is an extension of [28] and is structured as follows: Section 2 presents the chemical markers used to determine the DP. The classical methods for the determination of the DP are presented in Section 3. Section 4 presents the implementation as fuzzy logic of the diagnostic system in the LabVIEW graphical programming environment, as well as its improvement by using artificial neural networks through an adaptive neuro-fuzzy inference system. Section 5 presents conclusions and new pursuits in future work.

2. Chemical markers used for the determination of the DP

When paper insulation ages, its electrical properties do not change significantly, but the mechanical properties are considerably diminished, due to cellulose degradation (depolymerization). During normal operation, paper cellulose will split according to the general condition of the transformer (temperature, moisture and acids). As a result, the tensile strength of the paper is reduced over time, and therefore it is important to monitor the condition of the insulation [5-8].

The poor accessibility of paper samples has led to difficulties in testing the ageing state of paper directly by measuring the tensile strength and the DP. Thus, the researchers developed methods to indirectly assess the ageing state of paper, by means of the chemical markers in oil which are associated with paper ageing.

2.1. Carbon oxides (CO and CO2)

The first studies covered the relation between the amount of carbon oxides, carbon monoxide (CO) and carbon dioxides (CO2), in oil and the DP of the insulating paper. Carbon oxides, CO2 and CO, are determined based on the DGA by applying the gas chromatography technique. As a result of thermal stresses, these gases are generated by the degradation of both paper and other parts of the transformer. In free breathing transformers, the generation of carbon oxides is influenced by free air ingress [12].

In [21], it is presented a relationship between the amount of carbon oxides, CO and CO2, dissolved in transformer oil and the DP of the insulating paper. In [17] is demonstrated that water and CO2 are the main byproducts of the thermal degradation of cellulose. Therefore, the CO2/CO ratio is normally utilized as an indicator of the thermal decomposition of cellulose [8, 9].

According to [18], the CO2/CO ratio is normally when its value is above seven, while the respective values of CO2 and CO must be greater than 5000 ppm and 500 ppm to improve the certainty factor.

In accordance with [19], the CO2/CO ratio below 3 is expected to determine a severe degradation of the paper. When the ratio

exceeds 10, it may indicate a slight overheat of 160°C. It was noted that in order to obtain safe results, correction of CO2 absorption from the atmosphere and correction of CO2 and CO background are necessary.

According to [17], high paper degradation rates are reported when the CO2/CO ratio drops below 6. However, the application of this ratio in determining the condition of the cellulose insulation is not suitable due to the long-term oxidation of the oil or as a result of free air ingress due to leakage [24]. The following additional tests are proposed, as solutions to solve this problem: the analysis of furan compounds; the determination of the DP of paper using the paper samples, to analyze the cellulose insulation.

2.2. Furan compounds

Oxidation, hydrolysis and pyrolysis of cellulose generate a group of chemical compounds which are used as a tool to analyze the condition of the cellulose insulation. Due to their solubility in oil, these chemical compounds (2-furfural; 2-acetylfuran; 5-methyl-2-furfural; 2-furfuryl alcohol; 5-hydroxymethyl-2-furfural) provide key information necessary for the diagnosis of the health of solid insulation. The limitations and applicability of the furan compounds as tools for diagnosing the state of the degradation of cellulose insulation in oil-filled transformers were constant in [6] and [7]. Studies have shown that of the five furan compounds specified in [9], 2-FAL is the most stable, by providing relevant information on the state of degradation of the solid insulation.

Their main conclusion indicates that, of the five furan compounds identified in [9], 2-FAL provides more relevant information on the paper degradation. 2-FAL has been shown to have a high degree of generation and better stability than the other furan compounds and can be extracted from oil and used to characterize the thermal decomposition of the electroinsulating paper. A high concentration of 2-FAL indicates a high level of paper degradation. The constructive differences between transformers, the thermal and electrical stresses limit the setting of typical threshold values for 2-FAL, thus hindering the diagnosis of the condition of the cellulose insulation [16], [17], [20].

Some noted disadvantages of 2-FAL, such as its low detection threshold, when the paper is thermally upgraded (TUK). TUK paper is frequently used for new transformers, has a high rate of 2-FAL generation from hemicellulose, which shows an exponential increase, so the applicability of 2-FAL as a chemical marker for paper degradation must be considered prospectively.

3. Classical methods for the determination of the DP

Cellulose insulating paper can be damaged due to the effects of hydrolysis, pyrolysis and oxidation that occur in the transformer during operation. Due to the deterioration of the cellulose insulation, the group of furan compounds appears [6].

The cellulose insulation in transformers consists of cellulose, hemicellulose, lignin and mineral substances, and their degradation results in furans (see Figure 1) [9]. The generation of furans can also be caused by pentoses. As a common point of the degradation processes, the final result is the 2-FAL [17], [20].

Following the degradation processes of solid insulation that take place in the transformer, 2-FAL has the ability to dissipate in oil and due to its stability is an analysis tool for determining and monitoring DP of cellulose insulation. The other furan compounds can be used as markers to identify the process that causes the degradation of solid insulation [17], [22].

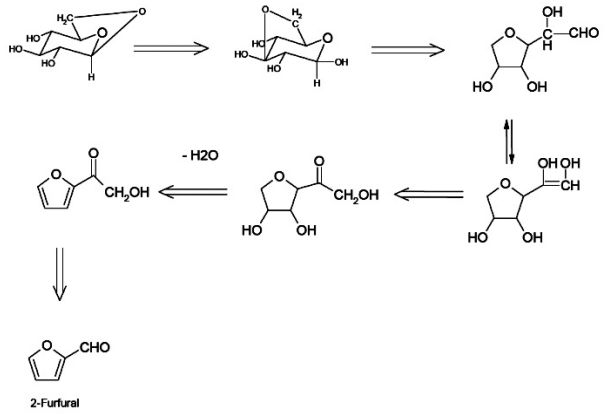

Figure 1: Determination of 2-FAL from lignin

The determination of the content of furan compounds, especially 2-FAL, was given a certain use for the diagnostic of transformers. It is believed that there is a certain correlation between the degree of polymerization of paper and the content of 2-FAL (or total furan compounds) of oil. Several researchers [25] have developed various relations for the determination of the DP, depending on 2-FAL concentration, but Pahlanvanpour's relation [15] is the most commonly used, because, when developing the formula, he relied on the states of the transformer and an assumption that 20% of the winding paper and the inner layer of the paper degrades twice as fast as the rest of the paper.

In [17] is builted a degradation model based on experimental data and field measurements in a research program conducted for CIGRE (International Council on Large Electric Systems) and found that a furfural molecule will result for every three cellulose chain splits [9], [24]. The system proposed in this paper was designed to determine the DP based on the 2-FAL ranges proposed in [6, 7] as is presented in Table 1.

Table 1: The state of the transformer according to the furan content

2-FAL content	DDP
0-0.1	1200-700
0.1-1	700-450
1-10	450-250
>10	< 250

To determine the DP, the following mathematical equations were used, which relate the DP to the content of 2-FAL:

- Chendong equation [16], [26]:

$$DP = \frac{1.51 - \log_{10} F}{0.0035} \quad (1)$$

- Scholinik et al. equation [18] , [26]:

$$DP = \frac{1.17 - \log_{10} F}{0.00288} \quad (2)$$

- Pahlavanpour equation [15] , [26]:

$$DP = \frac{800}{(0.186 \cdot F) + 1} \quad (3)$$

- De Pablo equation [17] , [26]:

$$DP = \frac{7100}{8.88 + F} \quad (4)$$

where: F represents 2-FAL concentration.

4. The architecture of ISDDP

The fuzzy logic-based approach for solving the control problems is highly recommended in very complex, nonlinear systems with uncertainties for internal or input parameters. The fuzzy logic is an approximate method by which vague knowledge, stored in a base of rules can be formally modeled. The practical implementation of the fuzzy systems is based on the advantages which allow the human experience to be transposed for the creation of the inference rules by using linguistic variables. The efficiency of the fuzzy systems or the artificial neural networks work is demonstrated by the widespread use in various fields in recent years [12], [26-30].

The fuzzy control provides a method of designing control algorithms in a user-friendly manner and provides the ability to capture human non-linear control behavior that has been shown to be suitable in many complex adjustment problems. A controller design method close to human thinking and perception reduces the time of application development and requires less trained staff in the field of regulator design. The advantage of the fuzzy tuning is the ability to program the knowledge of process operators and engineers, consisting in process operation experience, in a manner which is easy to understand and friendly. The fuzzy systems mainly have the advantage of explaining behaviors based on a set of rules and therefore their performance and development can be adjusted by modifying them [28], [30].

The neural networks are utilized to adapt the membership functions of the fuzzy systems in the applications of automatic control of the dynamic processes. Although the fuzzy logic allows the coding of expert knowledge through linguistic terms, usually it is a difficult endeavor to design and adjust the membership functions which quantitatively describe these terms. The learning techniques of the neural networks can automate the process and can therefore substantially reduce the cost and the time for the application development, leading to increased performance. To prevent the problem of knowledge acquiring, the neural networks can be designed to automatically extract the set of fuzzy rules from the disponible numerical data. Other approaches involve the use of neural networks to optimize a number of certain parameters of the fuzzy systems or to preprocess input data into the fuzzy systems [29], [30].

The general scheme for the proposed system for diagnosis of DP is shown in Figure 2. The system is achieved by using the facilities provided by LabVIEW and Matlab/Simulink graphic development environments for the implementation based on the fuzzy logic and neural networks.

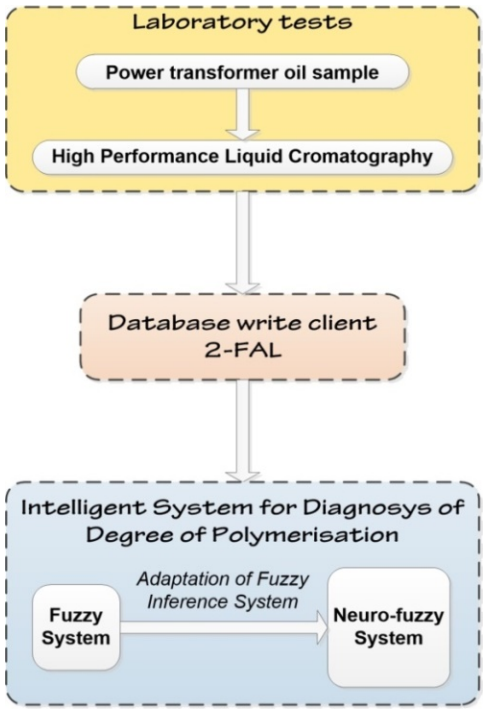

Figure 2: General scheme for the proposed system for diagnosis of DP

4.1. Fuzzy system for the determination of the DP

The system for the diagnostic of the DP of power transformers based on the fuzzy logic generates flexibility in interpreting the fault condition based on the 2-FAL data sets. The fuzzy logic diagnostic system is implemented in the Fuzzy System Designer, which is a software tool from LabVIEW graphical programming environment and basic model of the proposed fuzzy logic controller is shown in Figure 3. To overcome the difficulties in determining the boundary conditions for furan derivatives, the fuzzy logic technique is used, which allows the based rules to be implemented in a type of structure with natural language appropiate and widely used.

In the fuzzy logic, the domains correspond to the concepts of linguistic variables, so that such a variable corresponds to a domain of possible values. The input to the diagnostic system with fuzzy controller is the value of the 2-FAL derivative concentration, and the output is the result of DP value. For the 2-FAL input, the range of possible values (the set grading the membership) is between 0 and 20 and has as linguistic values the next form: {low; medium; high; very_high}. For the output, the DP is [0, 1200] and has as linguistic variables {healthy; mod_det; ext_det; end}, which represent: healthy, moderate degradation, extreme degradation, and end of life.

In order to achieve the best admissible response of the system, two types of fuzzy controllers are proposed to be used, and two types of membership functions are defined for these fuzzy controllers, namely the triangular and the trapezoidal membership functions, which correspond to the input and output of each of the two controllers. The result of the average of the two controllers of the system will be compared to the result of the fault values which is also implemented and calculated based on the classical methods presented in the equations (1) to (4).

The implementation of the two types of membership functions (triangular and trapezoidal) for the inputs and outputs of the two

logic fuzzy type controllers is shown in Figure 4 and Figure 5 respectively.

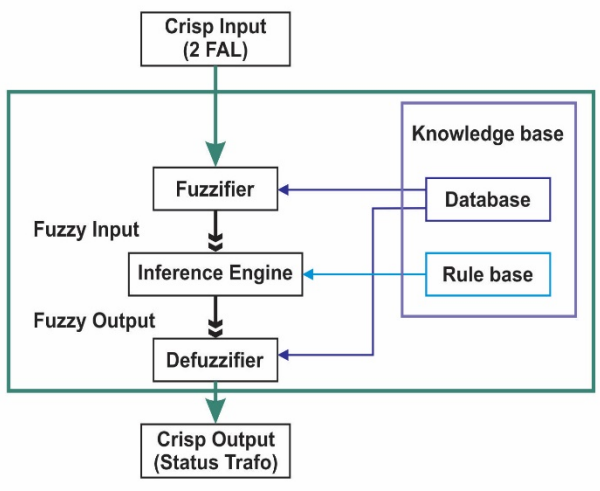

Figure 3: The proposed model of the fuzzy logic controller

Based on the 2-FAL ranges presented in Table 1, the implementation of the four triangular membership functions is carried out, and it is defined by the use of three parameters {a, b, c} covered by these ranges; the functions are described as follows:

$$triangle(x;a,b,c)=\begin{cases}0; & x\le a\\ \dfrac{x-a}{b-x}; & a\le x\le b\\ \dfrac{c-x}{c-b}; & b\le x\le c\\ 0; & c\le x\end{cases} \quad (5)$$

or, by using min and max functions:

$$triangle(x;a,b,c)=\max\left\{\min\left\{\frac{x-a}{b-a};\frac{c-x}{c-b}\right\};0\right\} \quad (6)$$

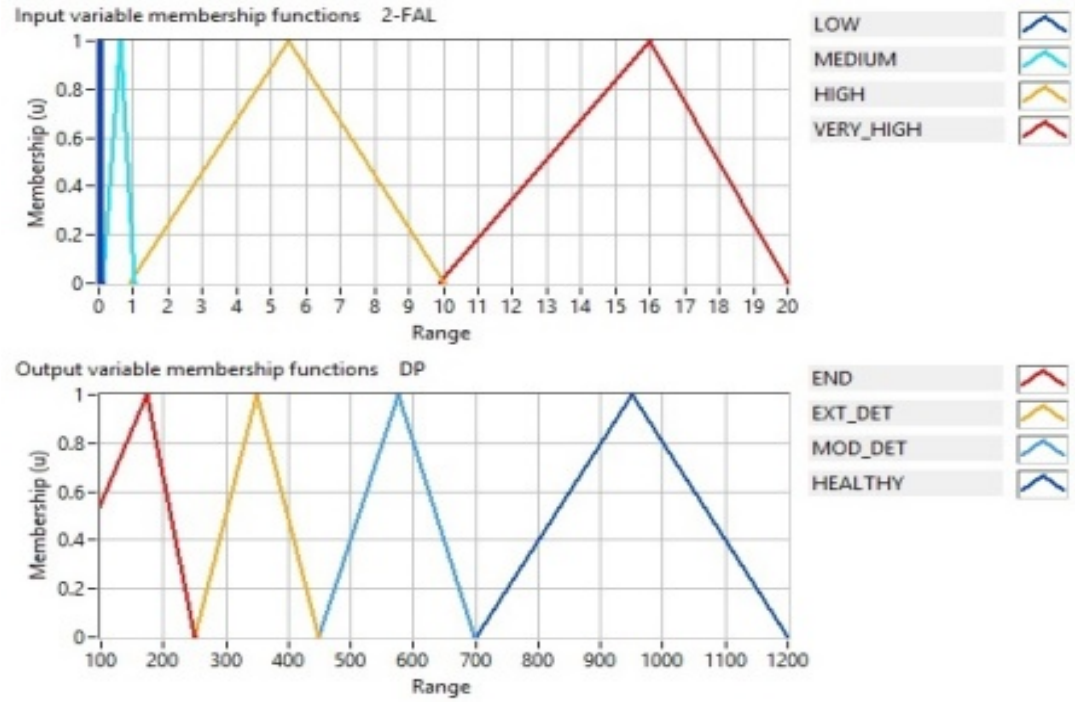
The trapezoidal membership function used for the second fuzzy controller is defined by using four parameters {a, b, c, d} for each of the ranges described in Table 1 and is expressed in the next form:

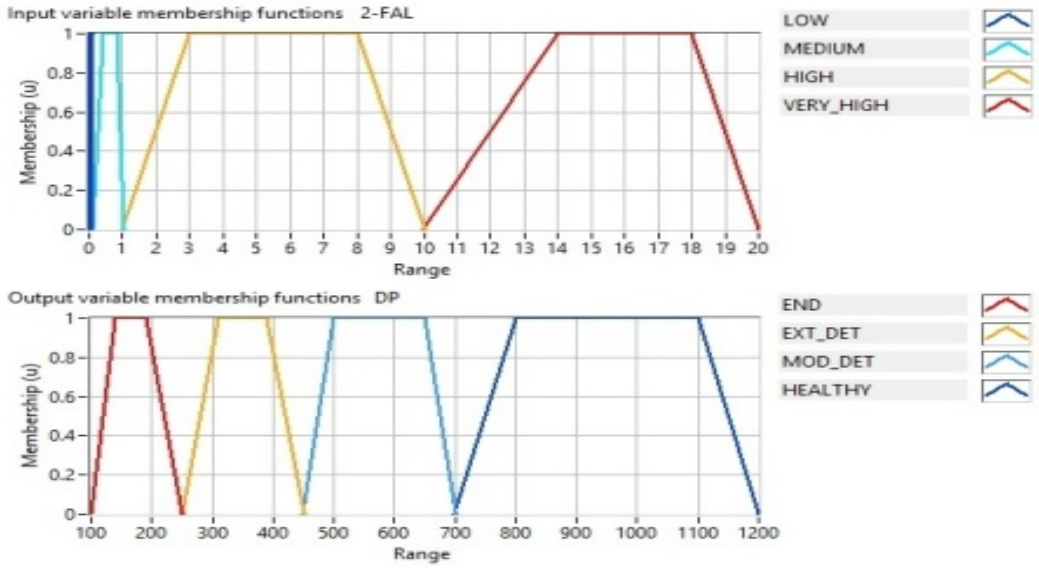
$$trapezoid(x;a,b,c)=\begin{cases}0; & x\le a\\ \dfrac{x-b}{b-a}; & a\le x\le b\\ 1; & b\le x\le c\\ \dfrac{d-x}{d-c}; & c\le x\le d\\ 0; & d\le x\end{cases} \quad (7)$$

or, by using the min and max functions:

$$trapezoid(x;a,b,c,d)=\max\left\{\min\left\{\frac{x-a}{b-a};1;\frac{d-x}{d-c}\right\};0\right\} \quad (8)$$

The defuzzification is required to transform the fuzzy output of the fuzzy controllers achieved based on the triangular and trapezoidal membership functions and averaged into a numerical representation (see Figure 5 and Figure 6). Theoretically, the fuzzy output is a fuzzy relation. The center of gravity method is the most applied practical defuzzification method and is used for the implementation of the two fuzzy controllers. The inference method used for the fuzzy logic implementation of the DP diagnostic system is the Mamadani method.





The fuzzy reasoning is an inference procedure which provides conclusions according to a set of fuzzy "if-then" rules and a set of known data and is based on the ranges specified in Table 1. The method consists in determining the crisp value for the output (DP), taking into consideration, in a balanced manner, all the influences obtained from the rules activated by the particular state of the input (2-FAL) at a given time.

Figure 6 and Figure 7 show the testing of the diagnostic system by entering a 2-FAL value for the two types of fuzzy controllers. The rule that applies for this value of the input and the obtained result of the DP output can be noted.

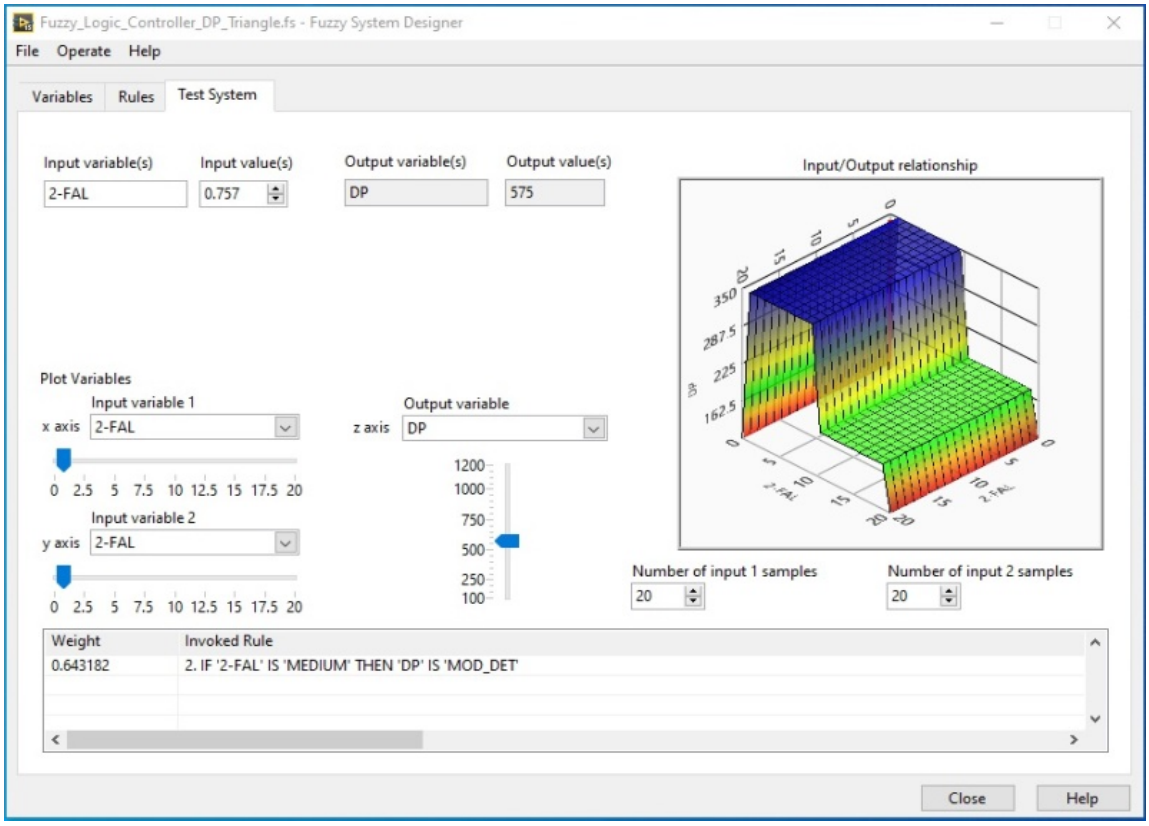


Figure 6: Surface viewer of DP result based on triangular fuzzy logic controller

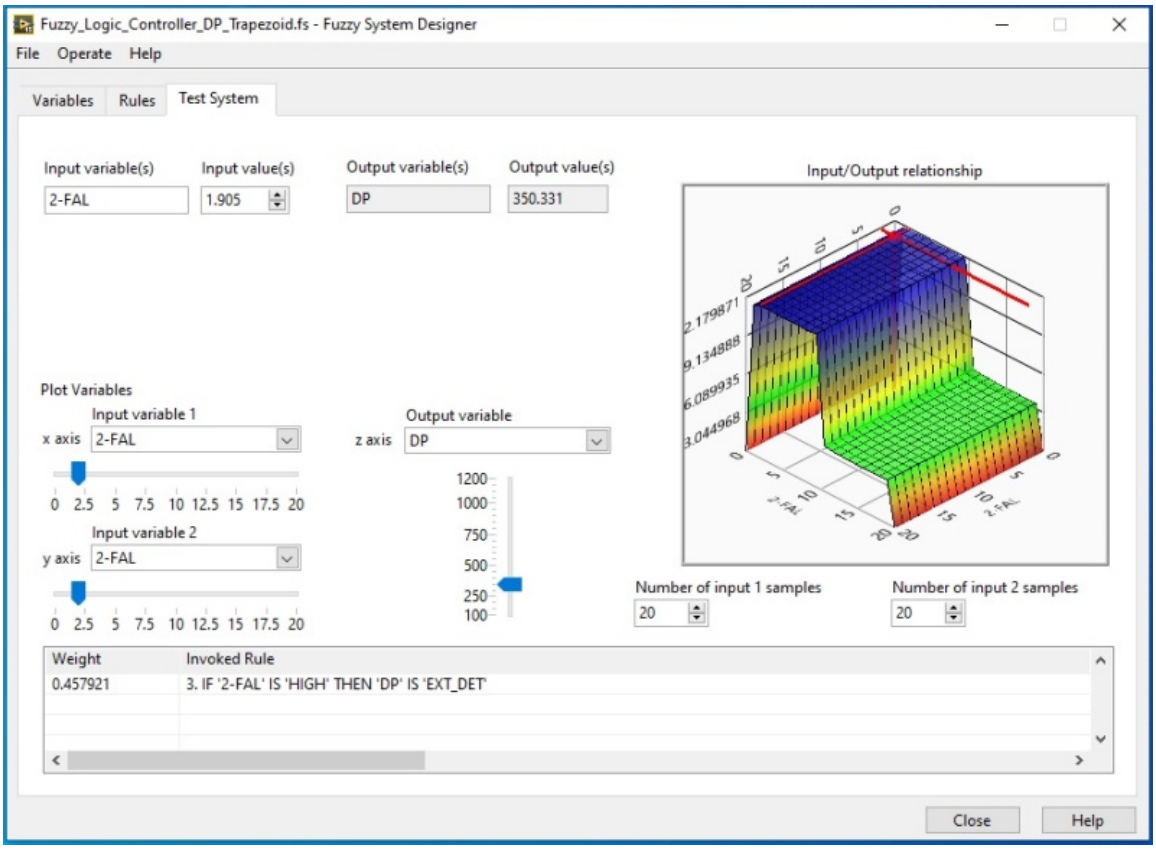

Figure 7: Surface viewer of DP result based on trapezoidal fuzzy logic controller

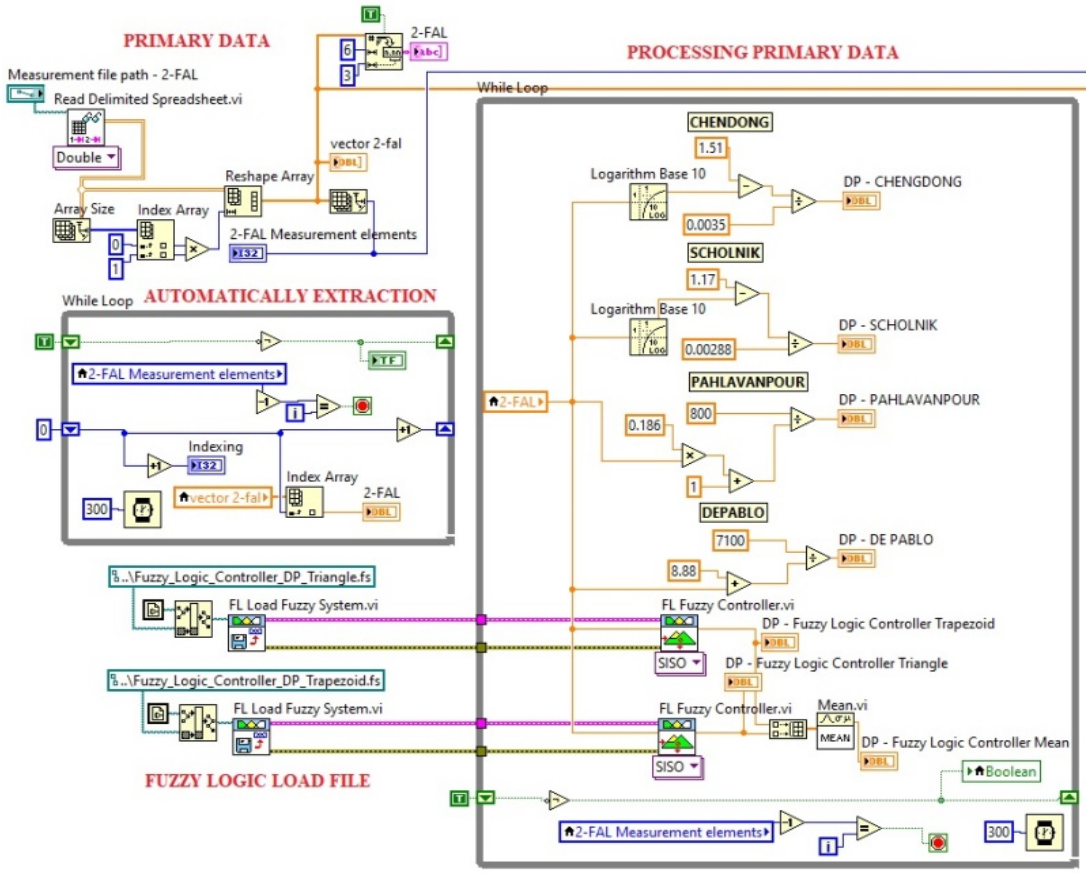

The software block diagram of the software application developed in LabVIEW for the main stages of the DP diagnostic software application is presented in Figure 8.

4.2. Neuro-fuzzy system for the determination of the DP

The neuro-fuzzy hybrid systems are a combination of neural networks and fuzzy logic where both techniques play a key role: the fuzzy logic provides the structure in which the learning capability of neural networks can be exploited [23], [27]. The ISDDP for power transformers is developed in the Matlab environment in the ANFIS toolbox, which is based on the adaptive neural network. The inference system used in ANFIS toolbox is of Sugeno type, also called fuzzy inference Takagi-Sugeno; it uses singleton output membership functions which for the presented application are linear functions of the input values [26, 27]. Unlike the fuzzy system described above, the proposed neuro-fuzzy diagnostic system has the capability to adapt during a learning process. Thus, by applying the hybrid optimization method, both the membership functions of the fuzzy sets which occur in the premise part of the rules and the parameters of the consequence parts of the fuzzy rules are matched, and the structure of the ANFIS model is presented in Figure 9. The dark circle (in black) on the left side represents the system input (2-FAL), and the one on the right side represents the system output (DP). The white circles on the left and right sides represents the membership functions, and the blue circles represents the rules developed by means of the logical operator "and".

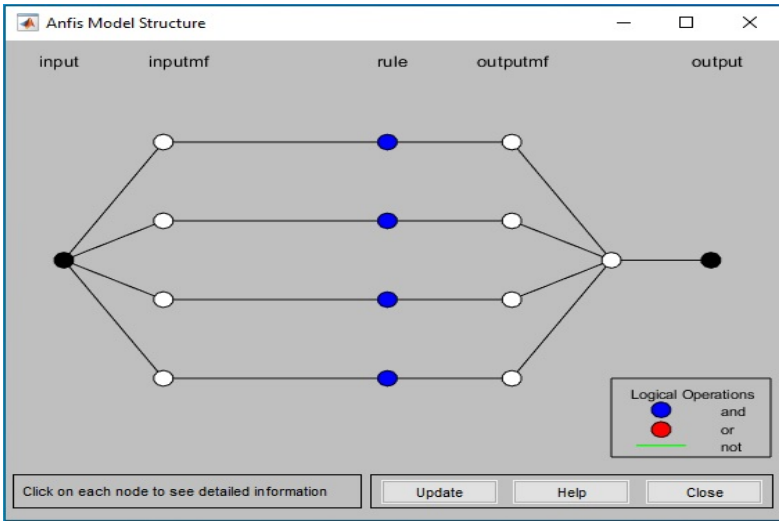

Figure 9: The model structure of the diagnostic system

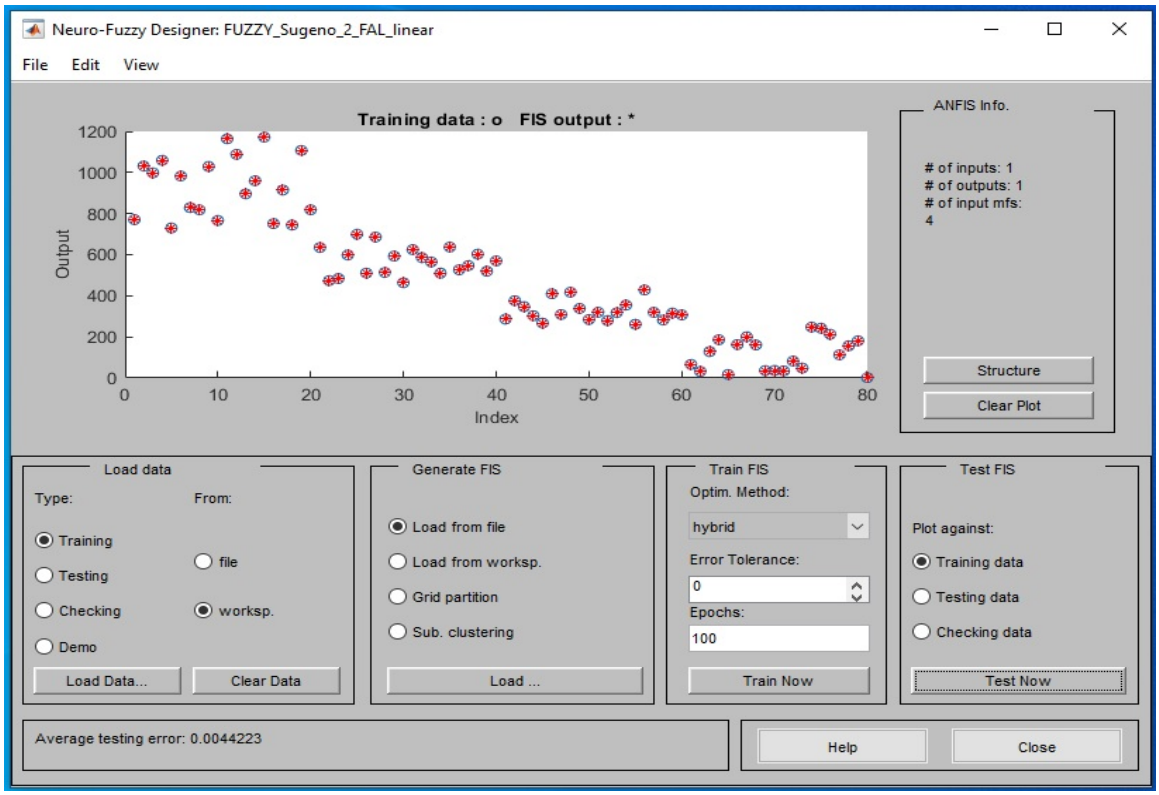

Figure 10: Training data of the ANFIS diagnostic system

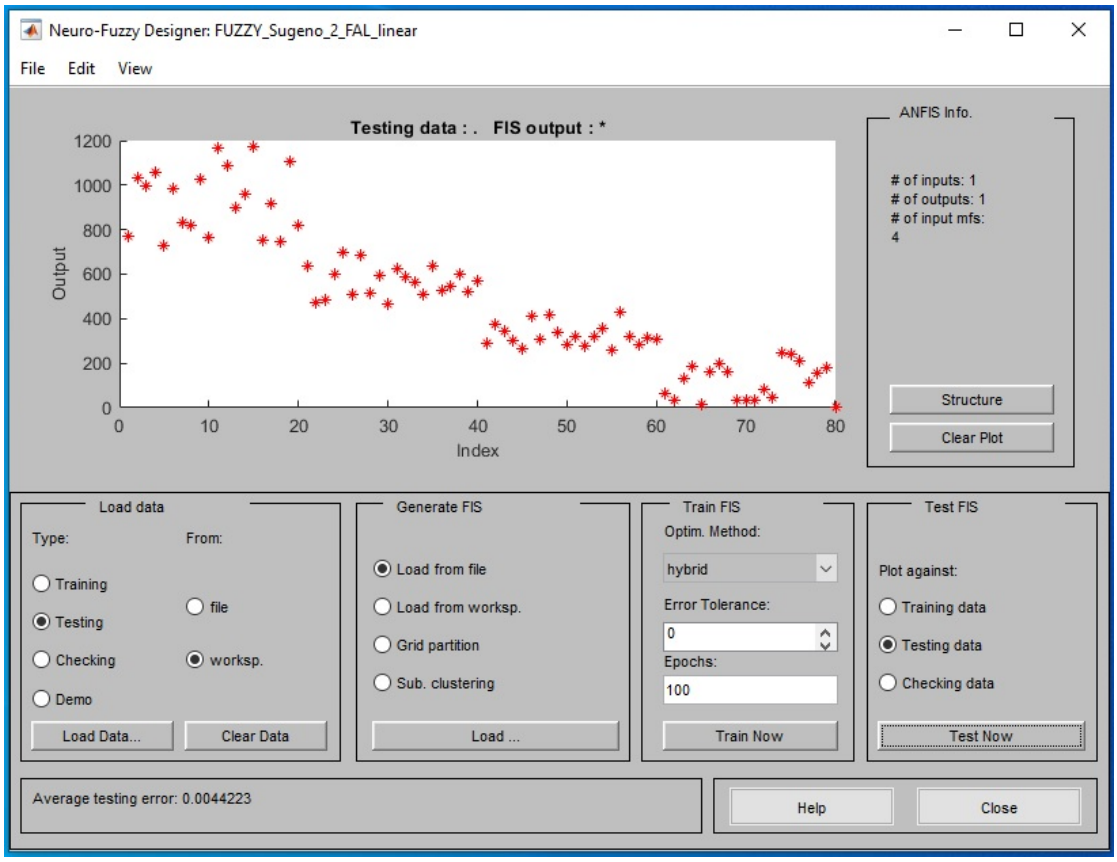

Figure 11: Testing data of the ANFIS diagnosis system

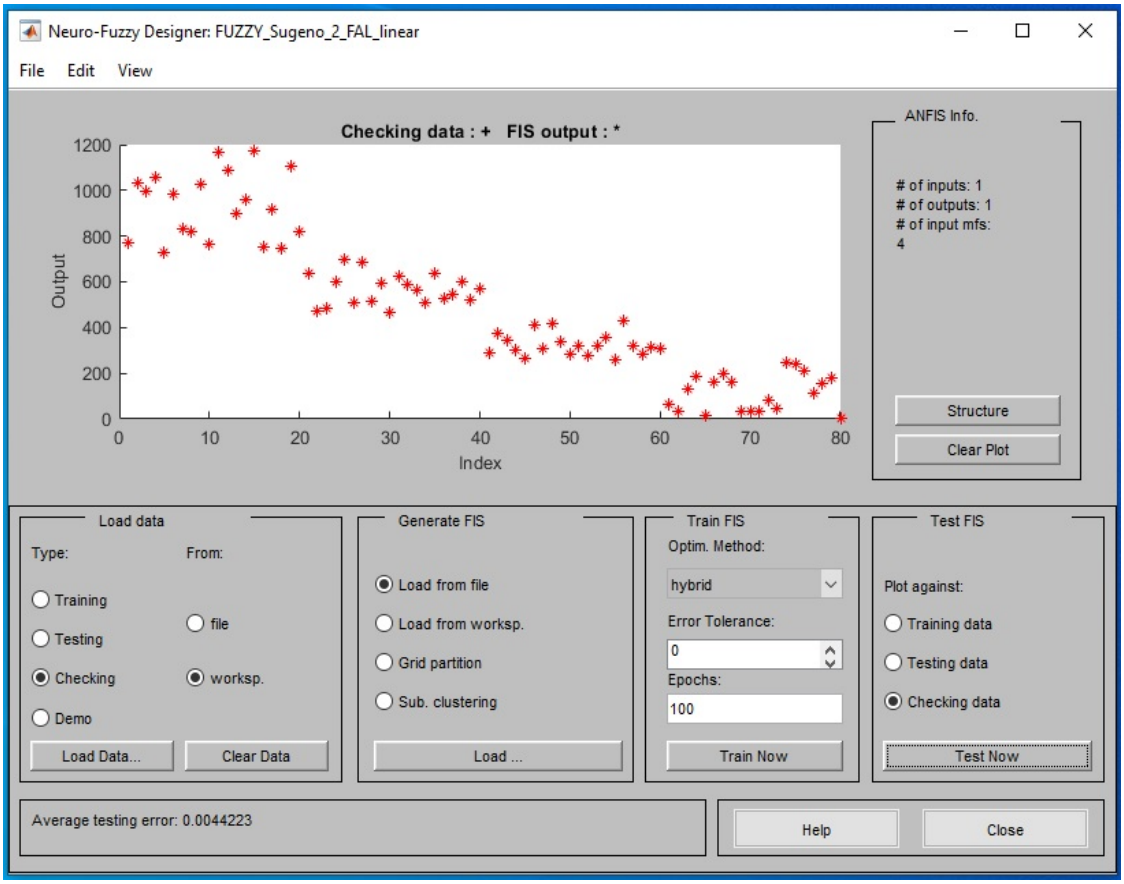

Figure 12: Checking data of the ANFIS diagnosis system

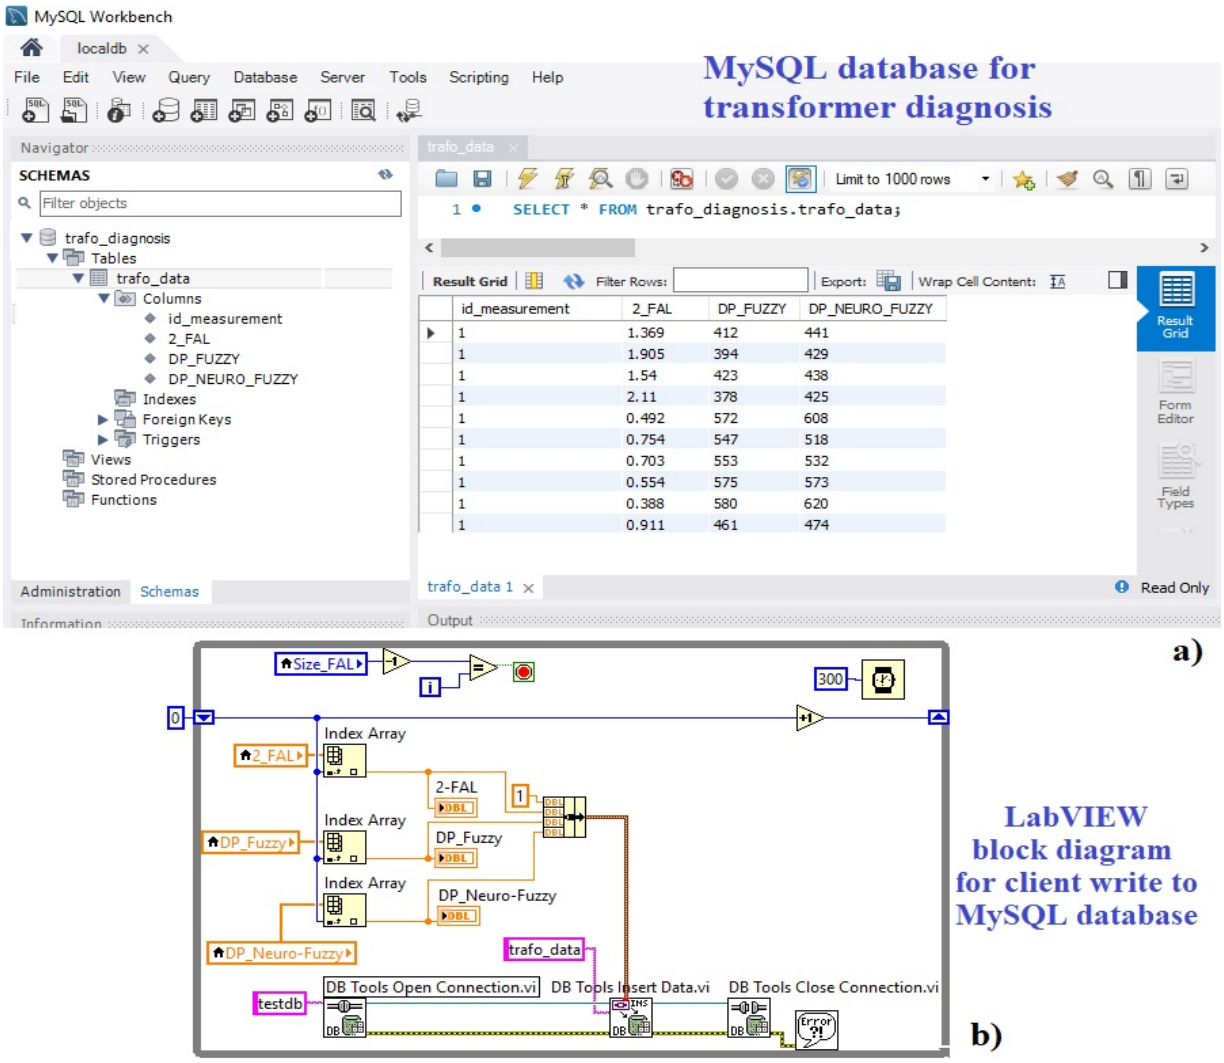

Figure 13: MySQL database connection: a) Table of results in MySQL database, b) block diagram of the client write software module into database

The data set for training, testing and checking comes from the application of classical Pahlavanpour and Chendong methods. The input/output data sets (2-FAL/DP) are entered in the ANFIS based diagnostic system, and they are trained (see Figure 10), verified (see Figure 11), and tested (see Figure 12) in 100 epochs, and the accuracy is given by the mean error obtained with a value of 0.00444223.

The data of the 2-FAL values resulting from the laboratory tests are recorded in the MySQL database by means of a client write software module into the database, and these are taken through the client write software module from the database to be provided to the ISDDP. In the Figure 13 a) is presented the MySQL database interface with the recorded 2-FAL table, and in Figure 13 b) is presented client write software module into the database.

5. Analysis and results

To demonstrate the efficiency of the proposed method and the manner in which data summarization is carried out, we present the analysis of the condition of the insulation of 10 transformers, based on 2-FAL concentration. The results obtained by using the proposed system in items 2 and 4 of Table 2 show a high DP of cellulose insulation, thus, the whole set of physical-chemical measurements of the oils of the two transformers was used. These analyses showed highly degraded wet oil, with temperature spots of >700°C in the transformer in item 2, and high-energy arc discharges, in addition to the wet oil, generated in the transformer in item 4. These discharges may be the result of oil breakdown by arcing between the coils, between terminals and earth, or arcing in the on-load tap changer along the contacts during the switching accompanied by oil leakage in the main tank.

2FAL	DP Chendong	DP Pahlavanpour	DP FUZZY	NEURO-FUZZY
1.369	442	684	412	441
1.905	392	590	394	429
1.540	377	621	423	438
2.110	338	574	378	425
0.492	519	732	572	608
0.754	466	701	547	518
0.703	475	707	553	532
0.554	504	725	575	573
0.388	548	746	580	620
0.911	442	684	461	474

Taking into account these possible problems, the two transformers were un-tanked. In the case of the first transformer, the low-voltage terminals a, and b had loose nuts and showed signs of overheating (see Figure 14), and all connections to the on-load tap-changer selector switch were also loose.

Following the untaking of the second transformer, it was found that the insulation of the flexible connections of the on-load tap-changer selector switch is completely charred, as a result of overheating caused by the arcing during switching as is shown Figure 15.

Figure 14: Low-voltage terminals a and b

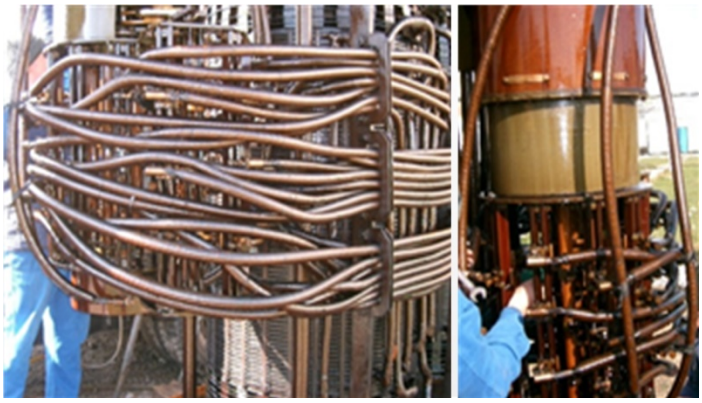

Figure 15: On-load tap-changer selector switch

The faults found and the condition of the insulation of the two transformers confirm the result of the analysis performed using the proposed system for diagnosing the degree of polymerization of solid insulation.

The faults in both transformers were remedied by replacing the damaged insulation; cleaning the terminals, nuts and flexible connection; achieving the tightening to the appropriate torque. The new cotton tape insulation was restored and all degraded insulation residue was removed from the pressboard supports. The on-load tap-changer selector switch was cleaned and the tightening of the connections on the plots of the selector switch was achieved.

The results obtained for the DP by means of the neuro-fuzzy system have a higher precision than the results obtained using mathematical equations and comply with the thresholds proposed by CIGRE according to the 2-FAL content.

The validation of the proposed system is performed by statistical means [31]. To verify the precision and the accuracy, the proposed system was applied to 80 data sets, establishing a precision of approximately 94% and an accuracy of 96% .

6. Conclusions

This article presents a method to determine the DP of solid insulation in transformers, which provides a faster and more accurate interpretation, as compared to the classical methods. The main stages in DP determination are presented, starting with the data provided by the laboratory, the use of classic methods of DP determination, ANFIS training based on a fuzzy controller, data exchange for storage and archiving in MySQL database, as well as the presentation of the validation of this system on a large number of samples, together with the comparison with the results provided by ISDDP with those obtained through un-tanked of transformer.

Thus, the automation of the DP diagnostic process will be achieved, with better results than those obtained by previous methods [26] of precision and accuracy, allowing the operator to make timely decisions, to avoid any possible damages. The main factors of comparison are the accuracy and precision. The values obtained for the improved ISDDP system are around the values presented in the current literature. In the future we propose the improvement of this system by using high-performance neural algorithms for all stages of training, testing and verification in order to improve the accuracy and precision of the system.

Analytic Network process (ANP)
Design Structure Matrix (DSM)

ABSTRACT

One drawback of the Multiple Criteria Decision Making (MCDM) problem with the Analytic Network Process (ANP) is that the origin of the network cannot be clearly defined. In addition, it is not possible to specify internal relationship between criteria and sub-criteria. The application of Design Structure Matrix (DSM) with the Partitioning Reachability Matrix method resulted in a clear understanding of the network's origin and was able to identify the relationship of all criteria in the system. Then, the data were analyzed by the ANP process using Super Decision Program. This will result in more reliable outcomes for selecting the best alternative with higher accuracy. This case study determined the suitable area for dry port development in 5 provinces in Thailand. Based on the analysis process mentioned above, Nakhon Ratchasima is the most suitable area to build a dry port of Thailand.

1. Introduction

Laem Chabang Port is one of the main deep-sea port for sea transportation between Thailand and other countries under the association of the Port Authority of Thailand which is located in the Laem Chabang Municipality, Si Racha and Bang Lamung, Chonburi. Presently, there are a lot of in and out containers in Laem Chabang Port. This directly affects the amount of traffic on the roads around Laem Chabang Port and the side roads over there. Therefore, it is necessary to develop a logistic transportation between Laem Chabang Port and the point of origin-endways in the country. In addition, the country's policy focuses on the development of the country's logistics as a mechanism to support the development of the country to be a center of trade, service and investment in the region. The development of rail transportation as well as various facilities and a logistics service center in the strategic path can be linked to industrial production bases and agricultural bases to Laem Chabang Port, which is the main trading gateway and important trade checkpoint of the country.

The Office of Transport and Traffic Policy and Planning (OTP) has recognized the importance of the problem mentioned above and agreed to study the dry port development master plan in accordance with the Cabinet's resolution on 4 December 2017, which has determined the levels of plans of various government agencies. In order to become the regional logistics center which is one of the important mechanisms to promote the adjustment of the mode of transportation through rail transportation. OTP can save costs and reduce traffic congestion around the Laem Chabang Port in order to become the regional logistics center in the future.

From the research data to determine the suitable area for the development of a dry port, there are 5 provinces suitable for the setting. Criteria are made up of several and inter-influence decisions for determining a site, including the interconnection of transport with rail and other transport systems, urban planning and development, and environmental suitability in terms of land and land size.

The decision to select one province as an appropriate area for the development of that port is based on many of the above criteria which is a very complicated process. It is a complex process with many criteria for decision making.

In solving multiple criteria decisions making (MCDM), the Analytic Hierarchy Process (AHP) is a technique used in human decision making which has been very popular and widely accepted at the international level. This theory was developed by Thomas L. Saaty in the 1970s [1], based on the knowledge of mathematics and psychology for helping make decisions by finding the most suitable answer and helping decision makers understand their own problems better. [2] The principle divides the problem structure

*Corresponding Author: Jenjira Sukmanee, Jenjira.s@eat.kmutnb.ac.th

into layers. The first step is to set the goal and then, criteria, sub-criteria, and alternatives respectively. Then, the analysis will be conducted for the best choice by making comparisons. Pairwise selection criteria makes it easier to decide which criteria is more important by rating according to importance or preference after giving the score prioritize the criteria. Then the analysis step to consider the alternatives one by one according to the specified criteria is conducted until all criteria are met. If the consistency rating is reasonable, the sequences can be chosen to find the best alternative. However, the AHP theory can only make decisions that are not complicated. [3] Saaty invented the Analytic Network Process theory (ANP) by making further improvements from AHP so that decisions can be made to solve complex problems. The feature of complex problems is that various decisions must come from many decisions [4-5] which have influence on each other. The system has a feedback process, time delay and Non-Linearity by ANP theory with the steps as follows.

a. Determine the structure of the problem or create a network
b. Match the comparison of vector priority matrix
c. Calculate the priority of the Super matrix model and
d. Choose the best option.

From the process above, it can be seen that creating a network is the first step and it is the most important component in solving the problem. [6-8]. ANP also has disadvantages in terms of network construction which is not clear because when starting an incorrect network, it will affect the decision in choosing the best alternative.

2. Methodology

The construction of this research is to create a model for solving complex multi criteria decision process by applying the relationship of group theory by using the Design Structure Matrix (DSM) matrix together with the Analytic Network Process (ANP) to select the best alternative. It can be divided into 2 main parts.

2.1. Creating a network

Networking from the determination of the relationship of information in the matrix format with DSM [9]. From Figure 1, the Relation Analysis by Matrix Representation is the result of creating a network by Partitioning Reachability Matrix.

It is a square matrix representing a total system correlation analysis with arrowhead directions to recheck the weight matrix of each criterion to be completely correct. If the arrow shows one incorrect correlation, it immediately affects the ranking of alternatives. The Partitioning Reachability Matrix is divided into three steps with the following details.

1. Information used in research studies which is obtained from data collection from actual operations or interviewing experts in each field of research with the information to be researched which should have enough amount covering the content that needs to be analyzed. If there is a lot of information and diverse [10]. The researcher should group similar data to be in the same group to reduce the amount of information and to be more convenient for analysis.
2. Co-relation is a method for analyzing the relationships of data with the Design Structure Matrix (DSM) theory which can be divided into steps as follows [11-13]

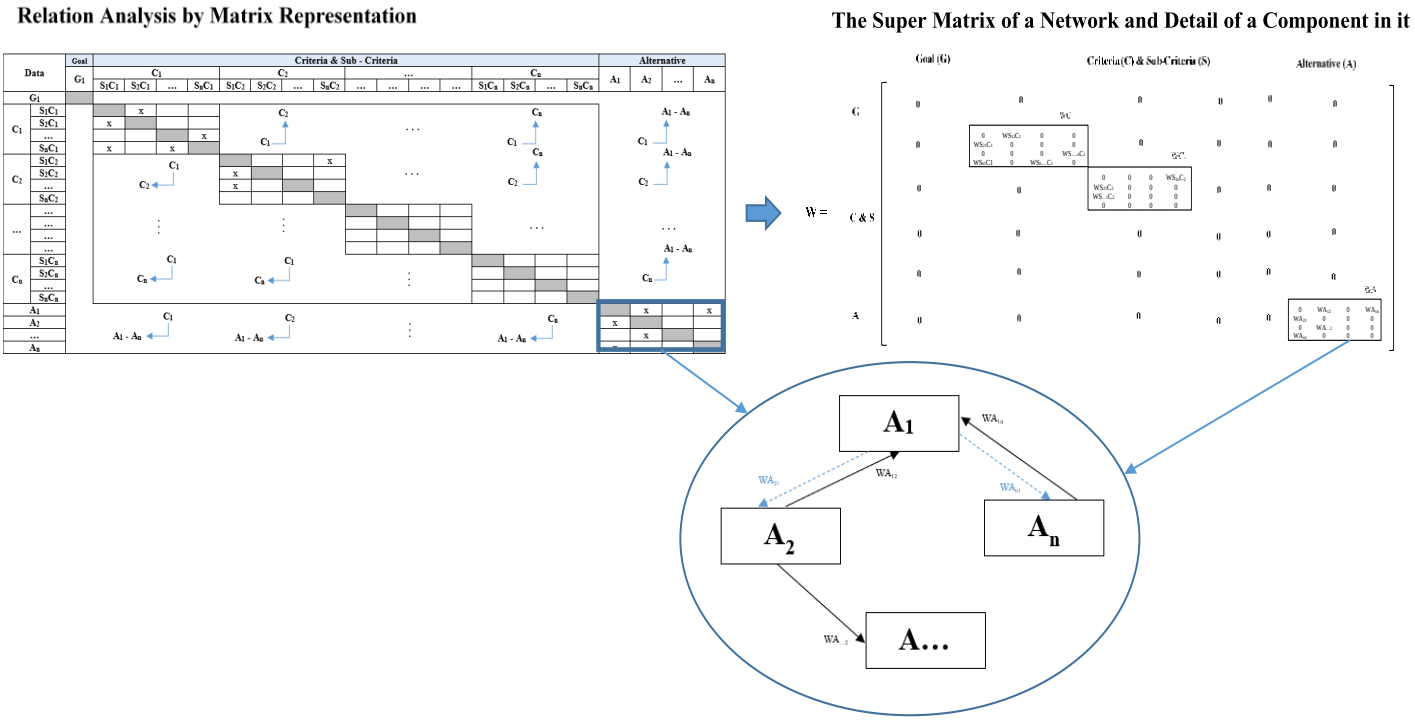

Figure 1: Key elements of the research

- Collect data from actual operations or interviewing an expert to gather information for using in defining relationships in the relationship matrix.
- Create a square matrix that is the same size as the data group to be analyzed (n x n). For example, there are 6 data items, so the generated matrix will be equal to 6 x 6 etc.
- Set the list of data to be analyzed in each row and the columns of the complete generated matrix.
- Define relationships between individual data. If there is a relationship, enter x, there is no relationship and leave it blank. However, the definition of the relationship can be divided into 2 parts which are
  - Diagonal relations mean that the data that is arranged in a row must consider vertical data such as data D and AB and C.
  - The part of the relationship, is the diagonal means that the data, is ordered in a column (Column) is a conditional condition for the data that is ordered in a horizontal row (Row), for example, the H data is the conditional data F, as shown in Table 1.

Table 1: Examples of relationship determination

		A	B	C	D	E	F	G	H
		1	2	3	4	5	6	7	8
A	1	1							
B	2	x	2						
C	3		x	3					
D	4	x	x	x	4				
E	5	x	x	x		5			
F	6	x	x	x			6		x
G	7		x	x				7	
H	8		x						8

Networking

This step is the implementation of the correlation matrix of all data to find the right working sequences using Design Matrix (DSM) Theory by Reachability Matrix Partitioning which has the following steps [14].

- Create a set of data in column j that determines the conditions for data in row i of each data by specifying that the set is equal to Set R (s) (Reachability set).
- Create a set of data in row i that needs to consider the data in column j by specifying that the set is equal to Set A (s) (Antecedent set).
- Determine the data that Set R (s) is a subset of Set A (s) and delete such items from Set R (s) and Set A (s) of all data items. Then, the said data group list was used to create the partition matrix by ordering the groups of data created in the partition matrix, the list of qualified data groups, and precedence. Set R (s) is a subset of Set A (s) which can be shown in Figure 2 and 3.

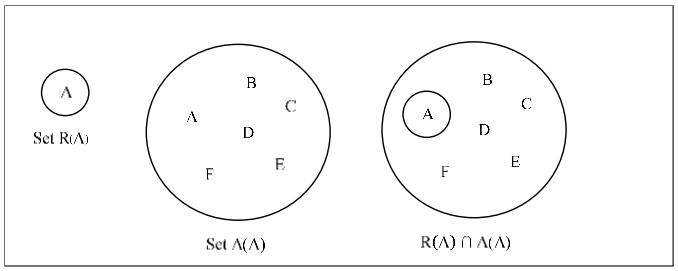

Figure 2: An example of data group based on the criteria "Set R (s) ∩ Set A (s)"

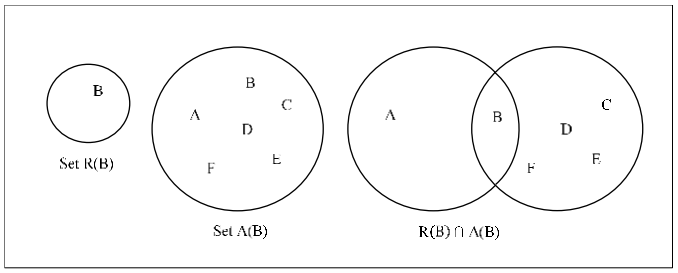

Figure 3: An example of the consideration of group B that does not qualify for "Set R (s) ∩ Set A (s)"

- Record data items one by one in the partition matrix. Adding data and relationship to the partition matrix of each item can be done by firstly, adding A to the partition matrix. Since the list contains Set R (A) as a subset of Set A (A), all Set A data can be deleted from Set R (s) and Set A (s). As a consequence, after deleting A data, Set R(s) becomes a sub-set of Set A (B). Subsequently, B data will be added into partition matrix and they will be deleted from Set R (s) and Set A (s).
- Convert Partition Matrix to Network. Taking the arranged partition data in the form of network that is ready to use in accordance with the standard of ANP.

2.2. Analysis for choosing the best Alternative

The final step is that the network that has already arranged in partition will be processed in Analytic Network Process (ANP). [15]. The researcher used Super Decision 3.2.0 to analyze data for selecting the best alternative.

3. Case Study

The case study of the Office of Transport and Traffic Policy and Planning (OTP), Ministry of Transport, Thailand shows that there is a need for developing "the dry port development plan for becoming the regional logistics center" in accordance with the cabinet resolution. Therefore, the researcher must study and review the relevant information about the dry port, [16, 17] which covers all levels including logistic behavior and the increasing quantity of products in the future. This will be used as supplementary information for setting strategic positioning and

dry port development goal to support the demand and the development of the industrial products of the country in order to meet the economic development policy, trade and transportation in the country, and within the sub-region. This can increase the competitiveness of the country. In addition, the port also helps stimulate the transportation between transportation branches. In this study, data collection and review consist of 5 parts which are:

1. Study and review of the policies of the international agreement and related laws.
2. Review of operating results infrastructure development project, transportation, and logistics related to dry port.
3. The study of data collection, concepts, experience, development, methods of model development design and management standard for dry port area.
4. Study of logistic behavior and quantity of goods moving between the point of origin / destination of transportation and the main trading gates of the country.

5. Summary of directions, policies, plans, and case studies from abroad for the purpose of determining the area suitable for the development of a dry port with the criteria for consideration and selection of areas that are suitable for the development of a dry port as follows: 1. System connection transporting with the rail system and other transportation systems, 2. urban planning and area development, 3. environmental suitability, 4. size and shape of the plot of land, and 5. cost of land procurement and development. The results of the consideration and selection of an area is suitable for the development of the dry port which is used to prioritize and analyze the feasibility of the 5 appropriate areas of the dry port as follows: 1. Khao Thong, Phayuha Khiri, Nakhon Sawan, 2. Muang Wan, Nam Phong, Khon Kaen, 3. Kut Chik, Sung Noen, Nakhon Ratchasima, 4. Don Sai and Nong Tee, Ban Pho, Chachoengsao, and 5. Wiang, Chiang Khong, Chiang Rai.

From the above information, the researcher grouped the data and analyzed to determine the suitable area for the development of the dry port of the Office of Transport and Traffic Policy and Planning (OTP) by applying the theory of grouping relations using Design Structure Matrix (DSM) matrix with the Analytic Network Process (ANP). The analysis was conducted by specifying the correlations of each criteria in the matrix and prioritized to create a network for further analysis with the theory of ANP to get accurate results in choosing the best option by starting with the steps according to the mentioned methodology.

1. Collecting data from actual operations and interviewing experts from dry ports, which can be summarized into various groups as follows in Table 2.
2. Co-relation is a method for analyzing data relationships by creating a square matrix which is the same size as the data group to be analyzed in this research, which are 11 data. Therefore, the created matrix is equal to 11 x 11 as shown in Table 3.
3. Networking: This step is to use the data relationship matrix analyzed to find the proper working sequences using Design Matrix (DSM) Theory by Reachability Matrix Partitioning Method which has the following steps.

Table 2: Grouping and details

Scenario	S1	Determine the area suitable for land port development
Criteria	C1	System connection transporting with the rail system and other transportation systems
	C2	Urban planning and area development
	C3	Environmental suitability
	C4	Size and shape of the plot of land
	C5	Cost of land procurement and development
Alternative	A1	Nakhon Ratchasima
	A2	Nakhon Sawan
	A3	Chachoengsao
	A4	Chiang Rai
	A5	Khon Kaen

a. Define Set R (s) (Reachability set) and collect Set R (s) members of each data item as shown in Table 4.
b. Define Set A (s) (Antecedent set) and collect Set A (s) members of each data item as shown in Table 5.
c. Determine the data that Set R (s) is a subset of Set A (s) and delete those items from Set R (s) and Set A (s). At the same time, the said data group list is used to create the partition matrix by ordering the groups of data created in the partition matrix, the list of qualified data groups, and precedence. Considering that Set R (s) is a subset of Set A (s) can be shown in Table 6.

Criteria	C5	6	{6}	{6}	{6}

3.2. Convert partition matrix into network

Convert the data after partition arrangement into the form of network that is ready to use in accordance with the standards of ANP.

Table 12: The matrix with new relationship order arrangement

	No.	1	8	9	10	11	7	2	3	4	5	6
No.	**Data**	**S1**	**A2**	**A3**	**A4**	**A5**	**A1**	**C1**	**C2**	**C3**	**C4**	**C5**
1	**S1**		x	x	x	x	x	x	x	x	x	x
8	**A2**	x										
9	**A3**	x										
10	**A4**	x										
11	**A5**	x										
7	**A1**	x										
2	**C1**	x							x	x		
3	**C2**	x						x		x		x
4	**C3**	x							x		x	
5	**C4**	x							x	x		x
6	**C5**	x						x	x		x	

4. Result

Table 12 shows the matrix after converting into a network by analyzing the relationship of the criteria. The value x in the table shows the relationship with each other. All collected relationships are shown in Figure 4 and 5 for further use in the ANP.

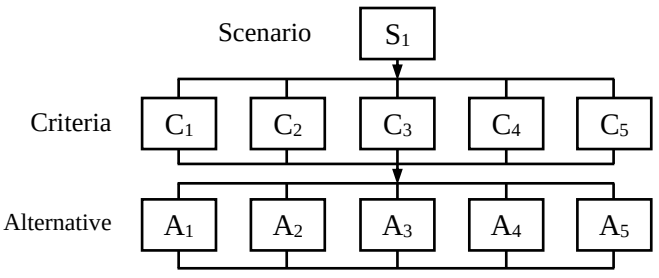

Figure 4: The hierarchical structure of ANP feedback system

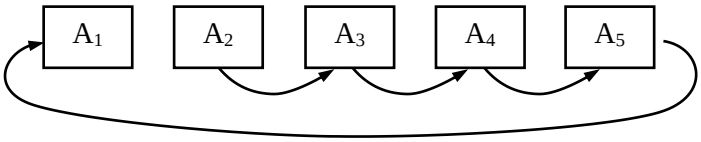

Figure 5: Internal relations of alternative

From the created network above, the researcher continued to analyze with ANP theory by using Super Decision version 3.2.0 as a tool to assist in the analysis to find the best option in determining the suitable area for the development of dry ports, i.e. C1. the connection of the transportation system with the rail system and other transportation systems, C2. the city planning and area development, C3. the suitability of the environment, C4. the size and the shape of land plots, and C5. the costs of land and development. There are 5 options to consider, which are A1. Nakhon Ratchasima, A2. Nakhon Sawan, A3. Chachoengsao, A4. Chiang Rai, and A5. Khon Kaen. Through the analyzing, the results can tell which province is the most appropriate area for dry port development.

From the Figure 6, it can be seen that the network consists of 5 criteria which are C1. the connection of the transportation system with the rail system and other transportation systems, C2. the city planning and area development, C3. the suitability of the environment, C4. the size and the shape of land plots, and C5. the costs of land and development.

A score is computed by multiplying the weight with the level of criteria relationship and the alternative intensity as shown in Table 13. The alternative rankings are shown in Table 14.

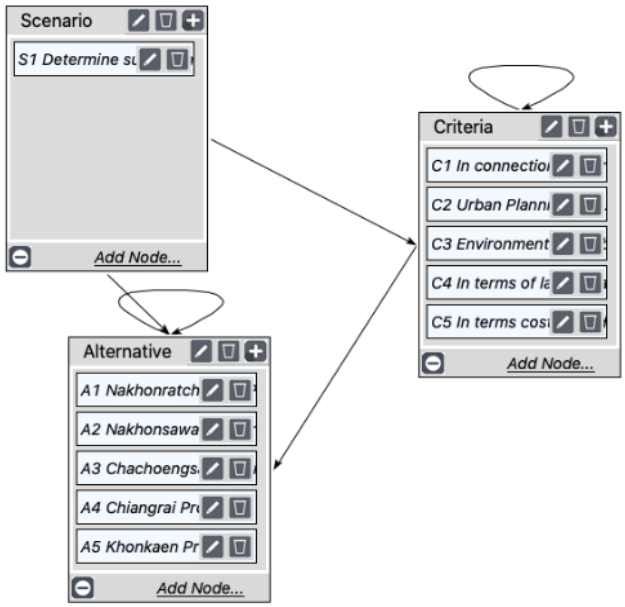

Figure 6: Network model from the ANP Super Decision Software

From the results of the analysis, it can be concluded that the most suitable area for dry port development is A1 Nakhon Ratchasima, followed by A5 Khon Kaen, A4 Chiang Rai, A3 Chachoengsao and A2 Nakhon Sawan respectively.

A5 Khonkaen Province	0.1865	0.2384	0.5637	2

5. Conclusion

This case study to find the most suitable area for dry port development in Thailand employed the simulation of Analytic Network Process (ANP) together with Design Structure Matrix (DSM) of Reachability Matrix using Partition Matrix. It can be concluded that the most appropriate area for the development of dry port in Thailand is Nakhon Ratchasima Province. The network model has been established from rearranging the relationship and considering the relationship related to the network and then used to create a hierarchical network. The applying of Design Structure Matrix with Analytic Network Process results in clearer network sources which shows interaction relationship of the whole system. The result is very effective in finding the best alternative better than using only the Analytic Network Process. However, if there are more criteria used for decision-making, we can use a clustering method for networking with DSM apart from the Partitioning Reachability method, which can be a further study. It is hoped that the applied method above will be useful for those interested in studying the source of the network before analyzing with ANP. For those who are interested in analyzing the correlation of individual criteria in the system will find it useful to increase the efficiency of ANP analysis as well.

e-Tourism apps
Social Influence
Causal Research
Explanatory Research

ABSTRACT

The income generated from the tourism sector exhibits the main driving force for national revenues in Indonesian. Based on data from the Ministry of Tourism in Indonesia, it turns out that the potential tourist category originated from the cluster of college students or school-aged cohort. In this line, social media signifies a similar age of internet user based on the Indonesian Internet Service Provider Association (IISPA). In this sense, previous research underlined that all students are active users of the smartphone. Therefore, this study aims to explore how smartphones influence the student's daily utilization in supporting applications of e-Tourism based in Indonesia. The study was conducted using descriptive analysis, causal or explanatory research and SPSS as a tool of data analysis. Operationally, the Bivariate technique serves as the means to answer research questions. As a result, this study revealed 18 relationships that affect students in utilizing smartphones for e-Tourism activities in Indonesia. This research contributes dominantly for the industry in determining the use of a tourism-based application eventually.

1. Introduction

Tourism is one of the mainstay economic sectors of the Indonesian government [1]. Based on the results of research conducted by the Central Bureau of Statistics Indonesia, it was found that most users in tourism are clustered from aged 15-25 years. The respondents can be categorized as a college-aged cohort. Another thing related to tourism is the number of applications available to support tourism activities such as to purchase airline tickets, hotels, and trains such as Traveloka, PegiPegi, and Tiket.com. In this part, e-tourism applications seize advantages and increase engagement of the user, provider, and the system. Reflecting this condition, IISPA or AJPII also published previous research reports stating that students are active internet users in Indonesia [2]-[4]. However, the scarcity of the research is found regarding the student role in tourist [3]. In this part, these phenomena attract researchers to delve in the influence of friends (close-person), family-as undertaken in previous studies [5], and advertisements for the use of applications that support tourism activities [6]. The hypotheses in this research are formulated as follows:

- The influence for students in using smartphones for e-Tourism application
  H0: No relationship was found
  H1: Relationship found
- There is a social influence for students in the use of smartphones on e-Tourism applications
  H0: No relationship was found
  H1: Relationship found

Figure 1 exhibits the research design that includes three major elements, i.e. the students, social influence, and e-tourism applications. The students consist of university students. In this context, the aspects of social influence factor will be analyzed based on e-tourism application. The growth of technology and its advancement in tourism will influence the stakeholders in many ways. In this frame, the activity related to technology application is categorized to describe the merits and challenges towards the engagement of the users. The study highlights the significance of advertising to bolster travelling, the experience of tourist, both individual and family that becomes a determining factor in the use of applications eventually.

2. Literature Review

In this section, the authors explain the relevant and prominent literature, such as understanding of e-Tourism, causal research/explanatory research, e-tourism apps, and respondent

*Corresponding Author: Surjandy Surjandy, surjandy@binus.ac.id

data in this study.

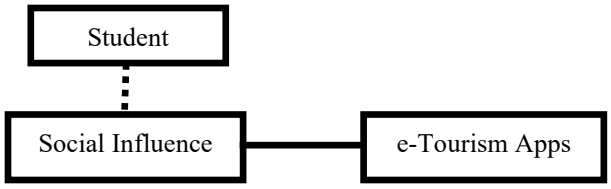

Figure 1: e-Tourism Research Design

2.1. E-Tourism

Technology contributes significantly to human existence in terms of efficiency enhancement, improving service and customers' experience in travelling. In this line, technology has revolutionized tourism in a paradigm shift. Technically, e-tourism represents the use of electronic media or internet-based applications to bolster the tourism process such as ticket reservations, hotel reservations, and so that customers can experience comfortable. [7].

2.2. Casual Research/Explanatory Research

Causal research or explanatory research is research that is generally implemented by marketing or sales to examine the relationship and the level of influence between two factors [7]. This research perused at several prominent factors such as student background (gender, age, screen width) and the influence of peers, family, and advertisements on the use of e-Tourism support applications.

2.3. E-Tourism Application

The e-Tourism application is an application engaged to assist tourists in carrying out tourism activities such as purchasing airline tickets, train tickets, hotel reservations, booking vehicle rentals, and other related amenities.

Table 1: Data of Respondent

No.	Description	N	%
1	Gender (A1)		
	Female	107	33.4
	Male	213	66.6
2	Age (A2)		
	1. <15 Years Old (YO)	0	0
	2. 16 – 20 YO	300	93.8
	3. 21 – 25 YO	15	4.7
	>26	5	1.6
3	Screen Size of Smartphone (A3)		
	1. <4"	27	8.4
	2. 4"-5."	99	30.9
	3. 5"-6."	151	47.2
	>6"	43	13.4

2.4. Respondent

This research uses a technique commonly used that is snowball sampling by utilizing services from Google based on Google Form. The questionnaire is disseminated through the internet and social media. In terms of population, this study involves the number of 320 respondents with backgrounds, as presented in table 1. The respondents can be categorized as a college-aged cohort.

3. Methodology

This descriptive study uses the SPSS application as a tool in analyzing data, and the Bivariate Technique is used to answer research questions. There are several steps needed in this research before analyzing the data, such as validation of the questions made. A test of the data reliability and after all, this is fulfilled, the analysis can be done.

3.1. Validation of Questions

In this part, researchers validate the questions using SPSS tools. The way to validate is to calculate the Corrected item-total Correlation (CI-TC) score. If the value of the CI-TC is higher than the Pearson r Table, the questions made are declared valid. In other words, in best practice, if the CI-TC value> 0.5, we ensure that the question is valid. For more details, table 2 described the questions validation.

Table 2: Questions Validation

No.	Description	CI-TC	Status
1	People influence my behaviour to use the travelling app (SI1)	0.673	Valid
2	People who are important to me think that I should use the travelling app (SI2)	0.732	Valid
3	I do travel through the app because many people do so (SI3)	0.665	Valid
4	My friends are supportive of the use of travelling mobile app (SI4)	0.628	Valid
5	My Family are supporting the use of travelling mobile app (SI5)	0.585	Valid
6	Advertisement strengthens me in using a travelling mobile app (SI6)	0.630	Valid

3.2. Data Reliability

In this section, researchers conducted a test of the reliability of the data obtained, namely by looking at the scores from Cronbach's Alpha [8]. The guidelines underscore that if the Cronbach's alpha value is greater than 0.6, the data is reliable[8]. Table 3 explains this information in detail.

3.3. Bivariate Test Result

This section presents the results of calculations based on the bivariate method to check the relationship between 2 factors [5]. Table 4 exhibits the relationship for more details. In this stage, the hypothetical results proposed that:

H0 is rejected; it signifies the relationship between factors or H1 is accepted

H1 rejected; It indicates that there is no relationship between factors.

The p-value is examined to find out whether there is a relationship [9]. In this frame, a relationship is obtained if the p-value <0.05. Doubtless, table 4 demonstrates the relationship between factors. Related to these factors, the value '*' denotes alpha 5% or 95% confidence level and for '**' refers to alpha 1% or 99% confidence level. The term of NC illustrated that there is no relationship (no correlation).

Table 3: Reliability of Questions

No.	Description	Cronbach's Alpha	Status
1	People influence my behaviour to use a travelling app (SI1)	0.831	Reliable
2	People who are important to me think that I should use a travelling app (SI2)	0.820	Reliable
3	I do travel through the app because many people do so (SI3)	0.833	Reliable
4	My friends are supportive of the use of travelling mobile app (SI4)	0.840	Reliable
5	My Family are supporting the use of travelling mobile app (SI5)	0.847	Reliable
6	Advertisement strengthens me in using a travelling mobile app (SI6)	0.840	Reliable

Table 4: Correlation Factors

No.	Correlation Factors	Pearson Corr. & p-value	H0	H1
1	A1 & SI1	-0.118* 0.035	Reject	Accept
2	A1 & SI2	NC	Accept	Reject
3	A1 & SI3	NC	Accept	Reject
4	A1 & SI4	NC	Accept	Reject
5	A1 & SI5	NC	Accept	Reject
6	A1 & SI6	NC	Accept	Reject
7	A2 & SI1	NC	Accept	Reject
8	A2 & SI2	NC	Accept	Reject
9	A2 & SI3	NC	Accept	Reject
10	A2 & SI4	0.134* 0.017	Reject	Accept
11	A2 & SI5	NC	Accept	Reject
12	A2 & SI6	NC	Accept	Reject
13	A3 & SI1	NC	Accept	Reject
14	A3 & SI2	-0.123* 0.027	Reject	Accept
15	A3 & SI3	NC	Accept	Reject
16	A3 & SI4	NC	Accept	Reject
17	A3 & SI5	NC	Accept	Reject
18	A3 & SI6	NC	Accept	Reject
19	SI1 & SI2	0.673** 0.000	Reject	Accept
20	SI1 & SI3	0.621** 0.000	Reject	Accept
21	SI1 & SI4	0.400** 0.000	Reject	Accept
22	SI1 & SI5	0.379**	Reject	Accept
23	SI1 & SI6	0.500** 0.000	Reject	Accept
24	SI2 & SI3	0.626** 0.000	Reject	Accept
25	SI2 & SI4	0.515** 0.000	Reject	Accept
26	SI2 & SI5	0.453** 0.000	Reject	Accept
27	SI2 & SI6	0.516** 0.000	Reject	Accept
28	SI3 & SI4	0.430** 0.000	Reject	Accept
29	SI3 & SI5	0.401** 0.000	Reject	Accept
30	SI3 & SI6	0.486** 0.000	Reject	Accept
31	SI4 & SI5	0.640** 0.000	Reject	Accept
32	SI4 & SI6	0.497**	Reject	Accept
33	SI5 & SI6	0.470** 0.000	Reject	Accept

3.4. Relationship Strength

This section explains how strong the influence of the relationship between the two factors that occur, to examine how much influence (relation) exists [9] and it is represented from the magnitude of the absolute value of the Pearson correlation. The information of the values between 0.1 to 0.3 indicates the level of strength of the relationship is small, while the value of 0.3 to 0.5 is categorized as medium. The values above 0.5 states a strong relationship. To check the degree to which strength, the researchers square the Pearson correlation value and multiply it by 100 to obtain the percentage of the relationship strength as exhibited in Table 5.

Table 5: The Relationship Strength

No.	Factor	|r|	Tension	$\|r\|^2$	%
1	A1 & SI1	0.118	Low	0.014	14%
2	A2 & SI4	0.134	Low	0.018	18%
3	A3 & SI2	0.123	Low	0.015	15%

No.	Factor	|r|	Tension	$\|r\|^2$	%
4	SI1 & SI2	0.673	High	0.453	45.3
5	SI1 & SI3	0.621	High	0.386	38.6
6	SI1 & SI4	0.400	Medium	0.16	16%
7	SI1 & SI5	0.379	Medium	0.144	14.4%
8	SI1 & SI6	0.500	High	0.25	25%
9	SI2 & SI3	0.626	High	0.392	39.2%
10	SI2 & SI4	0.515	High	0.265	26.5%
11	SI2 & SI5	0.453	Medium	0.205	20.5%
12	SI2 & SI6	0.516	High	0.266	26.6%
13	SI3 & SI4	0.430	Medium	0.185	18.5%
14	SI3 & SI5	0.401	Medium	0.161	16.1%
15	SI3 & SI6	0.486	Medium	0.236	23.6%
16	SI4 & SI5	0.640	High	0.409	40.9%
17	SI4 & SI6	0.497	Medium	0.247	24.7%
18	SI5 & SI6	0.470	Medium	0.206	20.6%

4. Result and Discussion

In this section, researchers explain the findings of the study. The calculation result values of this study are presented in Tables 4 and Table 5. This study highlights 18 relationships between factors and the magnitude of influence are as follows:

- A1 (Gender) & SI1 (People influence my behaviour to use a travelling app). It obtained the opposite relationship (minus). In this case, this study says that men (A1) tend not to be affected by the behaviour of others in using applications for travelling app.
  The magnitude of the strength of influence expressed the position of 14% or low influence. The study found a similar result with the previous research [3]
- A2 (Age) & SI4 (My friends are supportive of the use of travelling mobile app). It attained that a direct or positive relationship which states that the higher the age (old), the greater the influence of friends to use the travelling app. The magnitude of the influence strength between factors is 18% or low influence.
- A3 (Screen Size) & SI2 (People who are important to me think that I should use a travelling app). It confirmed the relationship is not direct (negative) which means that the greater the width of the smartphone layer that is used the smaller or fewer people feel it is important for me always to use the travelling apps. The magnitude of the strength of influence between factors of 15% or low influence.
- SI1 (People influence my behaviour to use the travelling app) & SI2 (People who are important to me think that I should use a travelling app). It revealed a direct relationship which means the more people influence me to use the travelling app, the greater the important person also states that I have to use the travelling app. The magnitude of influence strength between factors is 45.8% or strong influence.
- SI1 (People influence my behaviour to use a travelling app) & SI3 (I do travel through the app because many people do so). It underscored a direct relationship, which means that more people influence one to use the travelling app, the more often I travel using the application — the magnitude of the strength of influence between factors of 38.6% or strong influence.
- SI1 (People influence my behaviour to use a travelling app) & SI4 (My friends are supportive of the use of travelling mobile app). It detected a direct relationship, which means that more people influenced me to use the travelling app, so more friends gave support to use the travelling app. The magnitude of the influence strength between factors is 16% or medium influence.
- SI1 (People influence my behaviour to use a travelling app) & SI5 (My Family are supporting the use of travelling mobile app). It highlights directional relationships where the higher the influence of other people influencing me to use the travelling app, the higher the support from family in using the travelling mobile app. The amount of influence strength is 14.4% or medium influence.
- SI1 (People influence my behaviour to use a travelling app) & SI6 (Advertisement strengthens me in using the travelling mobile app). It emphasized a directional or positive relationship that states that the stronger the influence of people on my behaviour using travelling apps, the more advertisements affect me to use travelling mobile apps. The magnitude of the influence strength of 25% or a strong influence.
- SI2 (People who are important to me think that I should use a travelling app) & SI3 (I do travel through the app because many people do so). This highlights a direct or positive relationship which means that the more people who have an essential relationship with me think I should use the travelling application, the higher I use the travelling application to travel. The magnitude of the effect strength is 39.2% or strong influence.
- SI2 (People who are important to me think that I should use a travelling app) & SI4 (My friends are supportive of the use of travelling mobile app). It exhibits a direct or positive relationship which means that the greater the people who have significant relationships, the higher the friends provide support to use travelling apps. The amount of influence strength is 26.5% or strong influence.
- SI2 (People who are important to me think that I should use a travelling app) & SI5 (My Family are supporting the use of travelling mobile app). It accentuates a direct or positive relationship which means that the higher the person who has an essential relationship with me states I have to use the application, the higher the support from family to use the travelling mobile app. The amount of influence strength is 20.5% or medium influence.
- SI2 (People who are important to me think that I should use a travelling app) & SI6 (Advertisement strengthens me in using the travelling mobile app). It explained a direct or positive relationship which means that the higher the person who has an essential relationship with me states that I must use the application, the higher the influence of advertising to use the travelling app. The magnitude of influence strength is 26.6% or strong influence.

- SI3 (I do travel through the app because many people do so) & SI4 (My friends are supportive of the use of travelling mobile app). It stated a direct relationship or positive which means that the higher the person who has an essential relationship with me stated that I have to use the application, the higher the influence of friends who support the use of travelling applications. The magnitude of the effect strength is 18.5% or medium influence.
- SI3 (I do travel through the app because many people do so) & SI5 (My Family are supporting the use of travelling mobile app). It described a direct or positive relationship which means the higher I use the application because many people do the same thing, the higher the family also provides support. The magnitude of the effect strength is 16.1% or medium influence.
- SI3 (I do travel through the app because many people do so) & SI6 (Advertisement strengthens me in using the travelling mobile app). It signifies a direct or positive relationship which means the higher the use of the application because other people also use the higher the effect of advertising. The amount of influence is 23.6% or medium influence.
- SI4 (My friends are supportive of the use of travelling mobile app) & SI5 (My Family are supporting the use of travelling mobile app). It explained a direct or positive relationship which means the higher the influence of friends supporting using the application, the higher the family support for using the application. The magnitude of the effect is 40.9% or strong influence.
- SI4 (My friends are supportive of the use of travelling mobile app) & SI6 (Advertisement strengthens me in using the travelling mobile app). It affirms a direct or positive relationship which means that the stronger the influence of friends to support using the travel application, the higher the effect of advertising to use the travelling app. The amount of influence is 24.7% or medium influence.
- SI5 (My Family are supporting the use of travelling mobile app) & SI6 (Advertisement strengthens me in using the travelling mobile app). It asserts a direct or positive relationship, which means that the higher the influence of the family in supporting using a travel application, the higher the effect of advertising to use the travelling app. The amount of influence is 20.6% or the medium of influence.

5. Research Limitation and Implication

This study provides an overview of implications regarding the influence of friends or colleagues, family, advertisements in utilizing e-tourism applications to support travel activities. In this part, the need to increase of adopting the website in the tourism industry serves as the means to develop the industry performance at the same time [10]. It contributes to stakeholders in developing attractive e-tourism. It adds more value to users and developers in increasing application engagement. Koo et al. stated that travellers gathered the most popular information from different available social media through the internet [11]. In this line, the marketing aspect requires strategies to promote the tourism destination and it recommends the e-tourism platform [12].

The limitations of this study are related to have not implemented the full model such as TAM or UTAUT to review the comprehensive picture. The populations are originated from domestic tourists in Indonesia.

6. Conclusion and Future Research

The conclusion of this study emphasizes the importance of advertising to support travelling, the experience of users both individuals and from families becomes a determining factor in the use of applications eventually. In this case, youth tourism plays important role in the contribution to the tourism industry because of its positive social and economic impacts [13]. The multifaceted influence of tourism increases the promotion and efficiency of the tourism product [14]. The research dominantly indicated that the more people (university student) influence someone to use the travelling app, the greater the important person also states that someone must use the travelling app. Furthermore, it underscored that more people influence one to use the travelling app, the more often one travels using the application. The strength relationship appears in SI1 & SI6, SI2 & SI3, SI2 & SI4, SI2 & SI6, SI4 & SI5. The future research will investigate the other factors that influence and prioritize the user in using the e-tourism application.

Conflict of Interest

The authors declare no conflict of interest.

Hand-base authentication

ABSTRACT

In today's modern world, reliable automatic personal recognition is a crucial area of discussion, primarily because of the increased security risks. A large number of systems first require the recognition of a person before they can access their services. Biometric recognition can be used, which can be understood as automatic identification or automatic verification of persons based on physiological or behavioural characteristics. Examples of biometric characteristics may be the fingerprint, face, signature, hand geometry. There are many approaches, and each has its pros and cons. However, there is currently no current extensive research and evaluation of hand-based biometric systems. Given the user-friendliness of these systems and the needs of society, this article aims to compare different methods of biometric recognition based on hand, so that the article reduces the entry barrier into this area of research. Furthermore, the article aims to determine the research gap and suggest possible directions for research in the future.

1. Introduction

This paper is an extension of work originally presented in International Conference on Information and Digital Technologies [1]. In today's modern society, there is an increasing emphasis on working with information. Information is one of the most valuable assets we can own, so it needs to be protected. Among the basic requirements for their security are their confidentiality, integrity and availability. The requirement of confidentiality information requires that only authorized entities have access to it. One way to ensure the confidentiality of information is through authentication, during which the identity of the entity to which the relevant rights are subsequently assigned is verified [2].

Authentication can be defined as: “A method of verifying a user's identity on a system to control access to the system or resources.” [3] Authentication can be performed using knowledge (password, pin), an authentication object (token, mobile phone), or using what we are physically and mentally (biometric characteristics). The last option is used by biometric recognition systems, which have come to the fore, especially in recent years, thanks to scientific and technical progress.

Biometric systems are applications of biometric technologies that allow automatic identification or verification of a specific natural person, using physicavl (e.g. face, fingerprint) or behavioural (e.g. voice, gait) characteristics. Biometric characteristics must be universal (the characteristics must exist for all persons), they must have high external variability (high diversity for different persons) and low internal variability (low diversity for one person).

Identification ("One-To-Many Matching") is understood in this article as the process of comparing a set of biometric features obtained from a scanned biometric sample with all reference templates stored in a database. If there is a reference template in the database that sufficiently corresponds to the set of biometric features, the biometric system identifies the person by the identity associated with this reference template, otherwise the person is not identified [4].

Verification ("One-To-One Matching") is understood in this article as the process of verifying that the person being examined is who he or she claims to be. The set of biometric features obtained from the scanned sample is compared with one own biometric template, which is stored in a database. If the set of biometric features sufficiently matches this reference template, the identity is verified, otherwise it is not verified [4].

Biometric recognition of people is based on their biometric characteristics, and it is their unique physiological and behavioural characteristics. Physiological characteristics are those characteristics with which we were born and include, e.g. iris [5, 6], retina [7], face [8], shape of the outer ear [9], fingerprints [10], palmprints [11] and footprints [12], fingers geometry [13], hand geometry, [14], topography (layout and shape) of wrist veins

*Corresponding Author: Katerina Prihodova, st30351@student.upce.cz

[15], DNA [16]. Behavioural characteristics include, e.g. voice [17], writing [18], signature [19], and gait [20].

From the biometric characteristics, distinguishing repeatable biometric features can be obtained for biometric recognition. Biometric features are numbers or designations obtained from biometric samples that are used for subsequent comparison. Biometric samples are an analogue or digital representation of biometric characteristics before the actual extraction of biometric features [21].

The article aims to provide a comprehensive survey with the inclusion of most recent research papers up to 2020, covering a total of 117 journal publications, conference proceeding, patents, and papers. The aim is also lower the entry barrier to this research area by providing a comprehensive reference for novices. Offer a wide range of comparisons in diverse research angles and perspectives in hand geometry recognition. Identify current trends in this area and the need for future research.

2. Development of Hand-Based Biometric Systems

The first modern biometric systems used the hand geometry as a biometric characteristic, and then it was an authentication system in the verification mode (the user submitted an identity and it was subsequently confirmed or rejected). Robert Miller dealt with the issue of hand-based biometric systems in the 1960s and based on research, and he created a device at the Stanford Research Institute, which he patented in 1971. This device performed the pattern recognition by purely mechanical means, where four spring bars slid towards the user's fingers and subsequently the length of the user's fingers was measured. If the finger lengths matched the pattern embossed on the user's identity card, a simple switch was activated, which was used to operate the electric lock [4, 22].

The first commercial hand scanner was the Identimat, based on the patent Robert Miller's as mentioned above [22]. The measurement of the hand was performed by scanning the photocells located under grooves on which the user placed the hand (fingers). The light source was light with a power of 1000 watts. A reading head with a magnetic stripe was attached to this scanning mechanism, to which a user's magnetic card was attached during verification. If the pulses on the card matched the signal times from the photocell sensors within the threshold value, the user's identity was verified. This system was successfully used in various applications. The first use was of a military nature, and it was the security of nuclear weapons. Later, Identimat was used to access US nuclear power plants and also to control employee attendance at an investment company on Wall Street. The second development line of Identimat was already two-dimensionally oriented, measuring not only the length but also the width of all fingers on one hand [4, 23].

The history of the practical implementation of hand geometry recognition is further associated with the name David Sidlauskas and his company Recognition System Inc., which he founded in 1986. This company was the first in the world to start developing and selling modern hand scanners. In the mid-1980s, David Sidlauskas patented the first biometric system to use a three-dimensional hand image. The patented system consists of a camera and an optical measuring board. The camera has a plan view and a side view of the hand. The identification code is entered using the keypad [24]. Based on this patent, the first commercially successful biometric system using the hand geometry of the Handkey ID3D scanner was created.

BioMet Partners, Inc. developed a two-finger version of the Digi-2 hand scanner and was launched in 1995. The scanner uses a CCD camera to scan only the index finger and middle finger and obtain their 3D image [4].

In the 1990s, biometric hand scanners were used in the INSPASS program, a program at selected US airports that accelerated the check-in of frequent travellers. These persons could apply for inclusion in a program in which their hand geometry was scanned and then obtained an identification card with a reference template. These persons were able to complete check-in quickly at selected airports with the help of installed hand scanners [25].

Another hand-scanner recognition project was an Israeli project that automated motion control on the Israeli-Palestinian border. During the creation of the biometric system, suitable biometric characteristics were selected. Biometric characteristics face, hand geometry and fingerprints were considered. A multi-biometric system was chosen that combined face recognition and hand geometry, which was chosen mainly because most people crossing the border are workers whose fingerprints are not reliable for biometric verification [26].

In terms of security, hand scanners were also used at the 1996 Atlanta Olympics, which controlled access to the Olympic Village. Hand scanners were also used by the Colombian legislature, which voted safely through them [27]. Until 1998, only two scientific articles in the field of hand-based biometric systems were published, namely: "Vital Signs of Identity" a "A Performance Evaluation of Biometric Identification Devices." [2, 23, 28] From 1998 to 2006, there was an almost exponential increase in the number of publications in this area [29].

3. Current methods in hand-based biometric systems

Current hand-based biometric systems can be divided into the following groups according to biometric characteristics [33]:

- hand geometry and handshape,
- palmprint,
- fingerprint,
- topography (finger, hand).

At the beginning of the research of hand-based biometric systems, hand geometry was used, e.g. widths, lengths, angles [35-37], later the silhouette of the hand was added as another biometric characteristic [38-40].

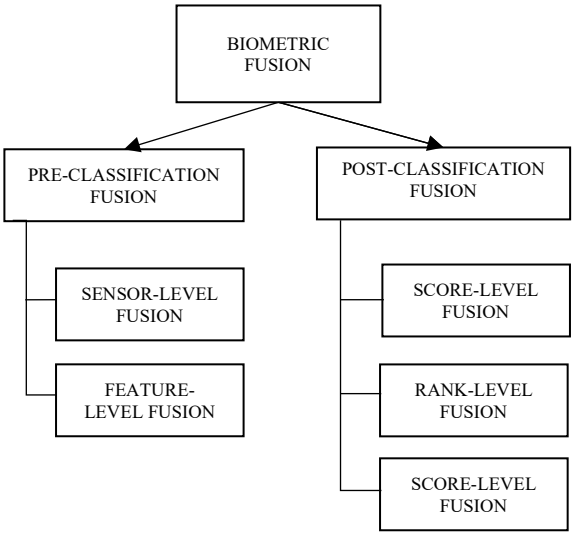

Figure 2: Fusion at various levels of multi-biometric systems (source: [34])

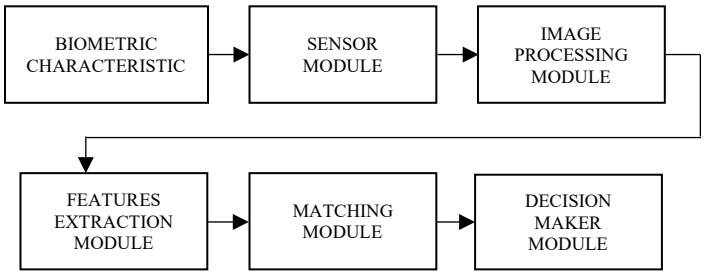

Figure 3: General model of biometric system

Currently, there are also multi-biometric systems that use a combination of multiple biometric characteristics. A palmprint [41-45] or bloodstream topography [46-48] is used in combination with hand geometry or silhouette. The topography of bloodstream is measured either on the palm or back of the hand when the whole hand is scanned. Systems have also been developed that combine more than two characteristics, such as hand geometry, palmprint, and fingerprint [49, 50]. Multi-biometric systems achieve higher accuracy [51] than biometric systems using only one biometric characteristic. Newly emerging biometric systems also use as a characteristic the heartbeat captured on the finger [52], pores on the hands [53], or hand gestures [44].

Combining multiple biometric characteristics in one biometric system requires fusion, which is the interconnection of information. Fusion can be achieved at different levels of the biometric system. Fusion levels can be divided into two large groups: pre-classification fusion and post-classification fusion. Pre-classification fusion include sensor-level fusion and feature-level fusion while post-classification fusion includes score-level fusion, rank-level fusion rank and decision-level fusion [34]. The individual fusion levels are shown in Figure 2.

The biometric recognition system has several modules: the sensor captures the biometric characteristic, followed by image processing, extraction of identification features, comparison with the biometric template and decision. The individual modules of the biometric system are shown in its general model in Figure 3.

3.1. Sensor

CCD chip cameras, a light-sensitive image detector used by digital cameras, camcorders, and webcams, e.g. are most commonly used to capture biometric characteristics [24, 53]. The scanner can also be a biometric sensor [42, 49, 54]. The sensor captures either a 2D [55-57] or a 3D [48, 58, 59] image of the hand. 3D images are obtained using two cameras, with the help of mirrors, or they can be obtained using a 3D digitizer [60].

Lighting also plays an essential role in obtaining a biometric sample. Some systems have their own light source, mainly commercial biometric scanners. Most sensors acquire images of the hand in visible light, but some also use infrared radiation [47, 61], which achieves a higher accuracy of biometric recognition [62].

Today, commercially available hand readers use spacer pins that firmly determine the position of the hand when scanning [48, 58, 63]. As spacer pins can deform the silhouette of the hand [64], systems without spacer pins have come to the fore in scientific circles [53, 65, 66]. The latest possibilities are contactless systems [38, 61, 67, 68], where, in addition to the spacer pins, direct contact with the reader is not required. These systems are considered to be the most user-friendly, mainly due to the elimination of the need for physical contact.

3.2. Image processing

After obtaining the image of the hand, it is necessary to process the acquired image. The first step in image processing is image pre-processing. It is a set of methods that are applied to an image because only a minimal percentage of hand images are taken under optimal conditions. Almost no captured image is completely noise-free, not entirely focused, obtained in optimal lighting conditions. For this reason, filters are used to sharpen the image or to remove noise. It is also possible to change the brightness using geometric transformation methods. [69]

The second step of image processing is image segmentation, i.e. dividing the image into segments with common properties. The aim of segmentation in hand-based biometric systems is to separate the hand from the rest of the image automatically. The more hand the image is obtained in more limited conditions, the easier the segmentation and can be done by faster methods. Segmentation methods can be divided into groups [69]:

- statistic methods,
- methods based on edge detection,
- hybrid methods (morphological),
- knowledge methods.

If the hand image is acquired on a scanner, the background is constant, and segmentation is relatively simple, then the segmentation method of image thresholding can be used. Image thresholding is the simplest statistical segmentation method based on pixel brightness evaluation. During thresholding, problems arise with rings, bracelets, or dirty skin [70-72].

Segmentation of the hand image can also be performed using edge detection methods. Edges are detected by edge detectors based on significant differences in the values of neighbouring pixels [37, 73].

There are also multi-stage segmentation methods where multiple methods are combined. These multi-stage methods can detect a hand from a crowded background. An example of such a method is a method that first detects the skin by colour (knowledge) and then detects the shape of the hand [74].

Another method of segmentation and at the same time localization of biometric features is AAM (Active Appearance Model) [55]. The AAM method presents the hand using an appearance model, which is created from a shape model and a hand texture model based on a statistical method - principal component analysis (PCA). The advantage of the method is the complexity of the information it contains about the hand [75].

The disadvantage of some segmentation methods is that their use breaks the silhouette of the hand. Mathematical morphology is a mathematical tool that can solve this problem and connect disconnected fingers. Mathematical morphology is also used to remove rings, bracelets or watches [56, 76, 77].

If the position of the hand is not fixed when acquiring the image, it is necessary to align the image of the hand after segmentation within the image processing. This can be done using landmarks, which can be extremes (fingertips, finger valleys) [36, 57, 78], of the centre of gravity, or a fixed reference point on the wrist [79].

Image processing is performed to facilitate the extraction of the region of interest. Biometric features are then extracted from the area of interest.

3.3. Extraction of biometric features

The image processing is followed by the extraction of biometric features. Extraction of biometric features is defined in [21] as*: "A process applied to a biometric sample to isolate and obtain a repeatable output of characteristic numbers or designations that can be compared with features extracted from other biometric samples."* For the biometric characteristic of hand geometry, biometric features are geometric measurements, such as finger lengths and widths, finger area, radii of circles on fingers and palms, and angles between fingers. Figure 4 shows 17 geometric measurements, but some systems use a different number of measurements, most often 13-50 measurements [35, 49, 80].

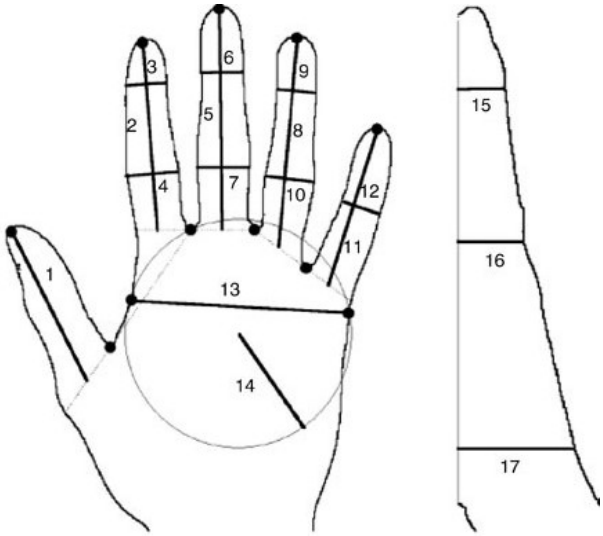

Figure 4: Geometric measurements (source: [81])

More information than hand measurements is provided by the silhouette of the hand, which is used by many systems [40,70]. These systems use biometric features to extract generic or customized feature extractors. For example, customize shape extractors [40, 82, 83] or figure features extractors algorithms Scale Invariant Feature Transform (SIFT) [82], LBP [84]. They are also used palm-based textures [85]. The silhouette is also distinguishable by its contour pixels; it represents the real shape of the hand [67].

Contours are less explored than geometric features, especially since geometric features are easier to determine from a normalized hand image. The issue of normalization of various hand positions and accurate localization of fingertips and finger valleys in unrestricted and contactless systems requires further research. [67]

Some systems extract biometric features of hand geometry and hand shape at the same time, extractors are specially adapted to the shape and geometry of the hand [86, 79].

Recent research uses deep neural networks, such as convolutional neural networks [87, 88] or Siamese networks, to extract biometric features of the hand [87].

3.4. Comparison with the reference template

In this phase, a set of biometric features obtained from a recognized person's biometric sample is compared with a reference template or templates (stored in a database). The score is then generated using the following methods:

- statistic methods,
  - minimum distance (Euclidean metric, Hamming metric, Chebyshev metric),
  - Kullback–Leibler divergence,
  - correlation coefficient,
  - Gaussian mixture models (GMM),
- machine learning,
  - support vectors machine (SVM),
  - k-nearest neighbours,
  - Bayesian networks,
  - neural networks.

Statistic methods

Statistical methods of comparing a set of biometric features with a reference template when recognizing a person based on the geometry and shape of the hand include a comparison by a minimum distance. If M reference templates are stored in the database x_{1R}, x_{2R}, …, x_{MR}, the minimum distance of the hand biometric sample x from the reference template is calculated as follows:

$$\min_{\forall s} \|x_{sR} - x\| \quad (1)$$

x_{sR}…… reference templates

s …… number of reference templates

x …… biometric features set (vector)

When recognizing a person based on hand geometry and hand shape, various metrics are used to determine the distance, such as the Euclidean metric [37, 56, 70], the Hamming metric [39], or the Chebyshev metric [80].

- Euclidean metric is defined by the relation:

$$\rho_E(\mathbf{x}_1, \mathbf{x}_2) = \sqrt{\sum_{i=1}^{n}(x_{1i} - x_{2i})^2} \quad (2)$$

- Hamming's metric, sometimes called Manhattan, is defined by relations:

$$\rho_H(\mathbf{x}_1, \mathbf{x}_2) = \sum_{i=1}^{n}|x_{1i} - x_{2i}| \quad (3)$$

- Chebyshev's metric is defined by the relation:

$$\rho_C(\mathbf{x}_1, \mathbf{x}_2) = \max_{\forall i}|x_{1i} - x_{2i}| \quad (4)$$

The Kullback – Leibler divergence can also be used to express "distance", which expresses the degree of dissimilarity between two probability distributions [36]. The correlation coefficient can also be used as a measure of similarity [81, 89].

Gaussian mixture models are located at the interface of statistical and machine methods (GMM). It is a pattern recognition method that is based on the GMM's ability to approximate any probability density using a mixture of Gaussian densities. The probability of the vector of characteristics x_n is estimated as a weighted sum of Gaussian densities. The result is, therefore, the probability with which the pattern (hand image) belongs to a given class. This method gives better results in the field of recognizing a person based on hand geometry than methods working with distance [37, 59].

The Gaussian mixture model is defined by the relation:

$$p(\vec{x}|u) = \sum_{i=1}^{M} \frac{c_i}{(2\pi)^{L/2}|\Sigma_i|^{1/2}} exp\left\{-\frac{1}{2}(\vec{x} - \overrightarrow{u_i})^T {\Sigma_i}^{-1}(\vec{x} - \overrightarrow{u_i})\right\} \quad (5)$$

u ……identity of the person to whom the hand image is assigned with probability p

x ……. vector of biometric features

c_i …… weight of individual Gaussian models

μ_i …… average vector model

Σ_i …… covariance matrix

M …… number of models

L ……. dimension vector of biometric features

Machine learning

Machine learning is a group of algorithms that allow a computer system to learn. Mittchell [90] d defined machine learning as follows: *"A computer program is said to learn from experience E concerning some classes of T and the measured power P, if its performance P improves with experience E."*

A large and used group of machine learning are algorithms called support vectors or support vector machines (SVM). These are classifiers that use boundaries in image space. SVM aims to find a superstructure that divides the symptom space. SVM used Vinodkumar and Srikantaswamy as a classifier in a multi-biometric system, where the biometric characteristics were hand geometry, fingerprints and palmprint [91]; however, they have also been used in many other hand-based multi-biometric systems [41, 42, 49, 92].

A frequently used machine learning method in hand-based biometric systems is the nearest neighbour (k-NN) method [54, 93]. It is one of the simplest classification methods. Bayesian networks [93, 94] or random forest [84] can also be used for comparison with the pattern.

Some types of neural networks, multilayer perceptron (MLP) can also be used as classifiers [95]. Generalized regression neural network (GRNN) [96] and convolutional neural network (CNN) were used as classifiers that were not preceded by classical features extraction, classification was performed using SOFTMAX [86].

3.5. Decision

In most systems, the final decision on a user's identity is based on a threshold that is chosen so that the biometric system meets security and throughput requirements. The score calculated in the previous system module is compared with the threshold value. If the score is higher than the threshold, the user is identified or verified, but if the score is lower than the threshold, the user is not identified or verified. The outcome of decisions for hand-based biometric systems is significantly influenced by user training, with the right habits of users, the score increases (agreement of the compared samples) [97, 98].

4. Quantitative evaluation of biometric system

Possible identification results are shown in Table 1.

Table 1: Possibilities of recognition decision

		Decision	
		Accept	Reject
Actual output	Authorized user	Correct acceptance	Incorrect rejection
	Unauthorized intruder	Incorrect acceptance	Correct rejection

Source: [2]

Based on the decision, the performance of biometric systems can be quantified. Selected quantified identifiers are [99].

False Rejection Rate – FRR

The probability that the biometric system does not recognize the authorized user will lead to an erroneous rejection, i.e. a type 1 error. If an error of this type occurs, the user can try to prove his identity again. The FRR is calculated according to the formula:

$$FRR = P(FR/OU) = \lim_{N_{OU}\to\infty} \frac{N_{FR}}{N_{OU}} \quad (6)$$

FR… occurrence of a rejection error

OU … recognition (verification or identification) by an authorized user

N_{FR}… number of false rejections

N_{OU}… number of attempts by authorized users to recognize

False Acceptance Rate – FAR

The probability that the biometric system will accept an unauthorized intruder will lead to incorrect acceptance, i.e. a type 2 error.

The FAR calculation is considered according to the formula:

$$FAR = P(FA/NN) = \lim_{N_{NN}\to\infty} \frac{N_{FA}}{N_{NN}} \quad (7)$$

FA… occurrence of an acceptance error

NN… recognition by an unauthorized intruder

N_{FA}… number of incorrect acceptances

N_{NN}… the number of attempts by an unauthorized intruder to recognize

The FAR and FRR rates depend on the threshold and are also inversely proportional. The higher the threshold, the more secure the biometric system, but the more common the type 1 error occurs and the user-friendliness decreases. On the contrary, the lower the threshold value, the more user-friendly the biometric system, but more often an unauthorized intruder, i.e. a type 2 error, is admitted, and the security of the system is reduced. The threshold value must always be set according to the requirements that are placed on the biometric system.

Equal Error Rate – EER

Value where the error rates of both FAR and FRR are equal, (i.e. FAR = FRR). With such a setting, the system incorrectly rejects and incorrectly identifies the same number of people. The lower the EER value, the higher the accuracy of the system. It is the most widely used indicator for evaluating and comparing biometric systems.

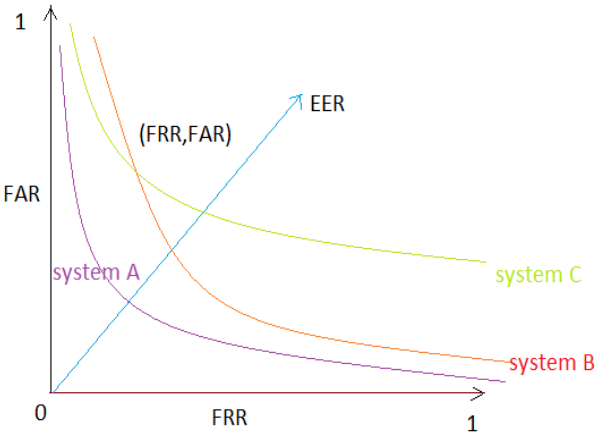

Figure 5: ROC Curves [100]

Receiver Operating Characteristic – ROC

The probability's curve that is given by the relationship between the probability of false acceptance (FAR) on the x-axis and the corresponding probability of correct acceptance on the y-axis for all allowable threshold values. Using ROC curves, multiple models can be compared with each other. Comparison and evaluation of multiple ROC curves are performed using the Area Under Curve (AUC) areas, which are located below the individual ROC curves [101]. Figure 5 shows the ROCs of the three systems, system A being the best system under the circumstances.

EER, FRR, FAR, ROC was selected for this work. They are a good indicator and the most frequently used tool for evaluating and managing biometric systems.

In articles dealing with biometric systems, we also encounter the concept of accuracy. The accuracy is calculated according to the formula:

$$\text{accuracy} = \frac{CD}{NR} \quad (8)$$

CD … correct decision (correct rejection and correct acceptance)

NR… number of recognition attempts

5. Comparison

The most commonly used physiological characteristics in biometric are fingerprint, face, hand geometry, and iris [102]. Table 2 compares biometric systems that use commonly biometric characteristics based on EER. Of these biometric characteristics, most often the lowest EER is achieved, biometric systems working with the iris, but as can be seen in Table 2, other systems, such as fingerprints, also achieve very low EER. However, in addition to error rates compilation speed, acqurability, privacy, cost and ease of use, should also play a role in choosing a biometric system [102].

Table 2: Comparison of selected hand other biometric systems

Sources	Biometric Characteristic of Recognition	Size of the Database	Performance
Chen et al. [103]	Iris	3 500	EER = 0.43
Yingzi et al. [104]	Iris	610	EER = 0.0295
Wijaya [105]	Face	2 268	EER = 0.0457
Marvadi [106]	Face	427	EER = 0.1525
Liu et al. [107]	Fingerprint	350	EER = 0.0042
Jain & Feng [108]	Fingerprint	449	EER = 0.081
Varchol & Levický [109]	Hand geometry	408	EER = 0.0462
Jain et al. [110]	Hand geometry	500	EER= 0.06

Table 3 summarizes the essential characteristics of some systems and methods that appeared in the journal and conferences. Some systems have been tested in identification mode, some in verification mode. Only some papers report EER, FAR / FRR or Accuracy values, some authors evaluate systems using ROC curves. The selection in Table 3 seeks to compare a representative sample of hand-base systems by characteristics (Hand-base Biometric Characteristic, Mode, Techniques Applied for Features Extraction, Techniques Applied for Recognition, Size of the Database, Performance).

Older systems use geometric measurements as features and are mostly in verification mode [110, 115]. Newer systems [111, 117] use a combination of multiple biometric characteristics such as hand shape and hand texture and use deep learning methods. Today's systems are mainly in identification mode, and FRR or EER has less than 1%.

Table 3: Comparison of selected hand based biometric system

Sources	Biometric characteristic / Mode	Techniques Applied for Features Extraction	Techniques Applied for Recognition	Size of the Database	Performance
Afifi [111]	Hand texture and shape / identification	CNNs + LBP	Support vector machine (SVM)	11 076	EER = 0.009
Kumar & Zang [112]	Hand geometry / identification	discretization of hand-geometry features	SVM	1 000	Accuracy = 0.94
Shanmukhappa & Sanjeevakumar [113]	Hand geometry /identification	Feature vector construct by hand image graph	SVM (Radial basic function)	1 440	FRR = 0.0205
Jain et al. [110]	Hand geometry/ verification	Geometric measurements	Euclidean distance	500	EER= 0.06
Varchol & Levický [109]	Hand geometry/ verification	Geometric measurements	Hamming distance	408	EER = 0.0973
Villegas et al. [114]	Hand geometry /identification	Wavelet Features	Nearest Neighbour	120	FAR = 0.11 FRR = 0.1
Varchol & Levický [109]	Hand geometry/ verification	Geometric measurements	Gaussian Mixture Model	408	EER = 0.0462
Burques et al. [115]	Hand geometry/ verification	Geometric measurements	Distance measure	12 800	EER = 0.0016
Charfi et al. [116]	Hand shape/identification	Scale Invariant Feature Transform (SIFT)	SIFT Matching	1 170	EER = 0.0586
Yoruk et al. [29]	Hand shape /identification	Independent Component Analysis (ICA)	L1/L2 norm of the difference of the feature vectors	458	Accuracy = 0.9731
Yoruk et al. [29]	Hand texture /identification	Principal Component Analysis (PCA)	L1/L2 norm of the difference of the feature vectors	458	Accuracy = 0.9791
Yoruk et al. [29]	Hand texture /identification	Angular radial transform (ART)	L1/L2 norm of the difference of the feature vectors	458	Accuracy = 0.976
Prihodova & Hub [117]	Hand texture and shape / identification	CCN (GoogLeNet)	CCN (Softmax)	456	FRR= 0.001

6. Research gap

It was not possible to cover all the literature dealing with hand biometric systems, but we included a representative sample of modern methods. However, we were able to identify some research gaps. To make hand-based biometric systems more efficient in real-world applications, the following challenges need to be overcome:

A large number of users – In the real world, it is often necessary to recognize millions of identities. However, the variability between some individuals may be minimal.

Quality of input data – Thanks to the progress of sensing sensors, the input image obtained in a real application under standard lighting conditions is correctly exposed. However, the image quality deteriorates in poor lighting conditions. Other problems we face despite the significant progress of the sensors are accurate colour capture and noise.

The permanence of biometric characteristics – Hand-based biometric characteristics have high stability over time but are not 100 %. For the hand geometry and hand shape, the topography of the bloodstream is primarily a problem of biological ageing and injury.

Attacks on systems – Hand-based biometric systems must face attacks at various levels in real-world applications. One of them is an attack on an input device, where the attacker forged a biometric sample, as a defence against this type of attack is the detection of liveliness.

Datasets – Small datasets are also a problem in this area of research, most current systems are tested on small datasets.

Costs – Costs should always be considered, and efforts should be made to make systems more accessible.

7. Discussion

Given the current state of hand-based biometric recognition, which was described in previous chapters of the article and due to the unresolved challenges in the field, one of the possibilities for further research is the use of a multi-biometric system, which uses hand geometry and thermal properties of hand. The thermal characteristic can be used in the form of blending two images (thermogram and image from the visible part of the electromagnetic spectrum), this blending creates a multispectral image. The multispectral image provides more significant variability between certain individuals than the mere geometry of the hand. A multispectral image is also advantageous in low lighting conditions, the quality of input data decreases less because the thermogram is not dependent on lighting conditions. When using a multispectral image, some types of attacks on biometric systems are also eliminated, because the thermal map of the hand, which is captured by the thermogram, is complicated to imitate and at the same time liveness is detected. At the same time, the multi-biometric system should increase recognition accuracy.

Another research option is also a multi-biometric system using hand geometry or palmprint in combination with skin colour (soft biometrics). This multi-biometric system could help to solve the problem of low variability between specific individuals.

Conflict of Interest

The authors declare no conflict of interest.

make of the vehicle

ABSTRACT

Nowadays, automatic number plate recognition (ANPR) is very important especially in the era of smart cities and intelligent transport systems. Fully automated number plate detection and recognition system helps in reducing time, error, and cost for tracking of vehicles and for recording traffic violations. The main goal of this paper is to design a low cost fully automated number plate detection and recognition system targeting the Jordanian license plates. Several problems (e.g., cost, wasted efforts, manual intervention, and possible errors) were identified in the currently used Jordanian number plate recognition for recording traffic violations. We hope that the proposed system would mitigate such problems. The proposed system performs two main tasks. First, it automatically detects and recognizes the license plate number of a given Jordanian vehicle using a robust metric; the rectangularity measurement, and identifies the vehicle's type (e.g., governmental, private, visitor, public, etc.). Second, it recognizes a selected number of trained classes for the make of the vehicle whenever applicable. The experimentation results and the performance evaluations compared to other ANPR approaches show that proposed system achieves the best performance among the tested systems with a plate detection accuracy of 95%, OCR recognition accuracy of 94.68%, make recognition accuracy of 86.84%, and an overall ANPR accuracy of 89% excluding the make results.

1 Introduction

The system of automatic license plate number detection and recognition, known as ANPR (automatic number-plate recognition), is considered a great application and an example of the computer vision technology. ANPR is widely being used in, but not limited to, radar cameras, car park management and traffic management [1]. In Jordan, ANPR is being used in recording traffic violations (e.g., over-speeding), however it has several problems. In particular, some of the ANPR steps: cropping of the license plate and optical character recognition (OCR) are still being done manually [2]. This might be due to the high cost of a fully customized commercial ANPR system for detecting and recognizing the Jordanian license plates. Therefore, the main goal of this paper is to propose a low cost ANPR system that is customized for automatically detecting and recognizing the numbers of the Jordanian license plates. We aim to reduce and avoid human labor, and the possible human errors. Having human involved ANPR steps might result in misidentifying a vehicle plate numbers and data, which can cause erroneous tickets.

The main contributions of this work are as follows:

- Propose a low cost fully automated and customized Jordanian ANPR system.
- Propose and utilize an optimized calculation methodology of the rectangularity metric [3] to efficiently detect the Jordanian license plates.
- Build a database of Jordanian vehicles to be used as a benchmark for evaluating the performance of the proposed system.
- Compare the proposed system to other ANPR systems with the help of the built database for the Jordanian vehicles.
- Incorporate the recognition of the vehicle type and make into the system.

The rest of the paper is organized as follows. Section 2 presents the related work. Section 3 discusses in details the proposed system. Section 4 presents the experimentation results. Section 5 provides a discussion about the proposed system and the obtained results. Section 6 concludes the paper and provides some future work directions.

2 Related Work

Generally speaking, any ANPR system consists of four main steps as listed below, which are also shown in Figure 1.

1. Capturing an image of a vehicle.
2. Detecting vehicle's license plate.
3. Segmenting out the license plate objects or characters.
4. Recognizing the segmented license plate characters using OCR (Optical Character Recognition).

Figure 1: ANPR steps

Based on the ANPR steps above, in the literature, several works have been proposed to address and optimize each step. Additionally, there is a significant work in combining the ANPR system with detecting and recognizing the make of the vehicle. In what follows, some of the related work regarding the ANPR systems and the vehicle make recognition systems are briefly presented.

In [4] and [5], the authors proposed an ANPR system, where mean shift segmentation is used to identify candidate plate regions. Then, the authors trained and used a Mahalanobis linear classifier with respect to three features to accurately detect number plate region. Namely, they used rectangularity [3], which is defined by the authors as "a measurement that represents how well an object fits its minimum enclosing rectangle", aspect ratio and edge density features.

In [6], the authors proposed an Iranian ANPR system, where edge detection and morphological operators are used to identify license plate candidate regions. The percentage of rectangularity and color filter of each candidate plate region are used to accurately detect the plate region. Multilayer Perception (MLP) neural network is finally used for recognizing the numbers of the detected plate.

In [7], the authors proposed an Indian ANPR system. License plate detection is based on using Sobel filter edge detector, morphological operations and connected component analysis. The segmentation and recognition of plate characters, which are in different Indian languages, are performed based on training a Support Vector Machine (SVM) classifier.

In [2], the authors proposed a Jordanian ANPR system that is based on SIFT features to detect Jordanian license plates and recognize them. Template matching technique is used to locate special marks in the license plate to segment out the license plate. Finally, OCR is used to recognize the characters or numbers from the segmented plate.

In [8], the authors surveyed several keypoint features under the feature-based automatic license plate detection techniques. They categorized the vehicle detection techniques into motion and appearance based, which included sophisticated probabilistic modeling and feature extraction. Also, the authors surveyed and discussed vehicle recognition utilizing vehicle attributes like license plate, color, type, and logo.

In [9], the authors applied a bag of features method to the car make and model recognition (VMMR). The sparse coding technique based on square mapped gradients (SMG) feature descriptors is used to learn a dictionary of codewords. The authors then apply supervised K-means or SVM with SMG to recognize the car make and model. Finally, the authors compared the performance of the two approaches.

In [10], the authors proposed an automatic license plate recognition system to trap traffic violations. For example, to trap offenders disobeying the traffic rules in an enclosed space (e.g., campus).

In [11], the authors proposed an ANPR-based vehicle tracking system, which monitors vehicle's Euclidean distance from a visible calibration line. License plate detection was based on the fact that license plate has an inherent property of having greater transitions in pixel values compared to that of its surroundings.

In [12], the authors proposed a number plate detection and localization system based on segmentation and morphological operators to segment out license plate from the captured image. Specifically, the authors used histogram checking, and vertical and horizontal edge detection methods for the segmentation of the license plate. The experimentation dataset consisted of 350 license plates from different countries including Jordan. The reported efficiency rate from the proposed system is 93.43%.

In [13], the authors proposed a Jordanian ANPR system, where the license plate was detected and localized based on a multistage algorithm using the aspect ratio and the edges ratio. Back propagation neural network was used for recognizing the license plate characters (OCR). The average success rate from the proposed system is 90% of 240 high resolution images of size 1188×960 pixel.

Very recently, in [14], the authors proposed an ANPR system to recognize the Bangladeshi characters in vehicle license plates. Morphological operation and histogram analysis with a dynamic threshold of vertical and horizontal projection profiles were applied in order to detect plate area. Character recognition is carried out using Support Vector Machine (SVM) classifier, where extracted Histogram of Oriented Gradient (HOG) features were used as input. The system was applied to 630 images of Bangla license plates of different categories of vehicles and achieved 91% accuracy in the extraction of plate ROI.

After surveying the literature and to the best of our knowledge, the work of [2, 12, 13] is the only published work that examines the detection and recognition of the license plates of the Jordanian vehicles. Therefore, the work presented in this paper extends the literature regarding the Jordanian license plates detection and recognition. In fact, the proposed work improves the automatic Jordanian license plate detection and recognition proposed in [2] by using another feature, which considers both the appearance shape of the license (rectangularity and aspect ratio) and the license plate content for detecting the license plate. Furthermore, the recognition of vehicle logo and make was also incorporated. It is worth mentioning the notes concerning the work by authors in [12] and [13]:

- The processing time for detecting the license plate and recognizing the plate numbers in both [12] and [13] was not reported at all, whereas in the proposed work it is being reported.
- The dataset of [13] consisted of high resolution images with-

out presenting any sample images. In the proposed work many sample images are provided from the created and employed dataset, which mostly consisted of mid to low resolution images, but better than 320 × 240.

- Neither the work in [12] nor in [13] presented a fully comprehensive ANPR system, where both the license plate type (private, public, government, etc.) and the vehicle's make are being recognized similar to what are being implemented in the proposed work.

Additionally, it is noteworthy to mention that the proposed work shares some similarity with the work presented in [4] and [5]. The proposed system utilizes the rectangularity and aspect ratio metrics in detecting the license plate (Jordanian plate in our case), where it achieved the best plate detection accuracy compared to using the rectangularity methodology proposed in [4] and [5]. This will be discussed in more details in the next section.

3 Proposed System

This section presents the details of the proposed Jordanian ANPR system. Taking into consideration the main ANPR steps presented in Figure 1, in the designed and implemented ANPR system, the following steps were considered as shown in Figure 2. The system was fully implemented in MATLAB R2018a [15], where the graphical user interface (GUI) is shown in Figure 3.

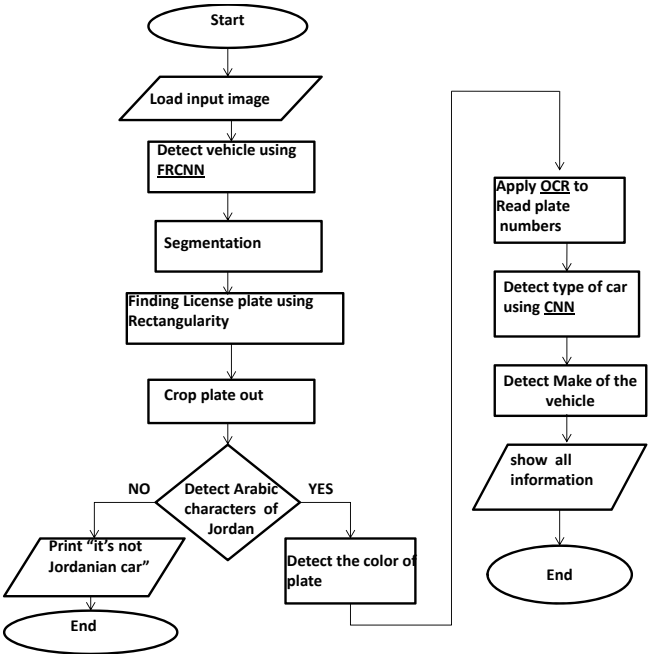

Figure 2: The proposed ANPR steps

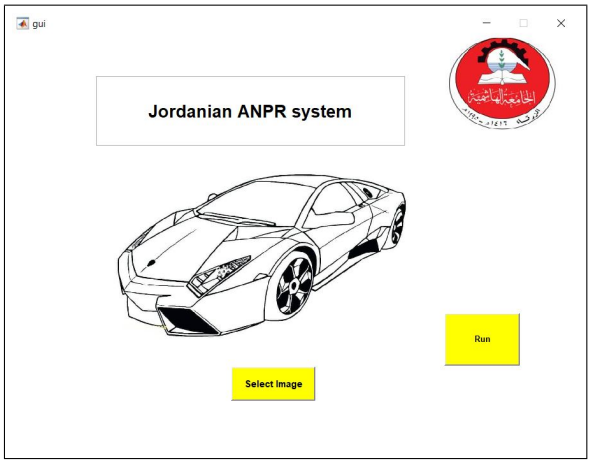

Figure 3: The graphical user interface of the proposed Jordanian ANPR system

3.1 Input image

The very first step in the system is to capture a vehicle image. An off-the-shelf webcam and a mobile phone camera were used to capture a set of database images to evaluate the system's performance. Additionally some of the images were obtained from the Jordanian Opensooq website [16]. In general, the captured images should be of good illumination conditions whenever possible, capture either the back or the front of the vehicle, and have a good resolution (e.g., better than 320 x 240). The database consisted of 100 images, which corresponds to different illumination conditions, different backgrounds, and different perspectives of the captured Jordanian vehicles (i.e., angle and distance between the camera and the vehicle location). Figure 4 shows 16 randomly selected input images chosen from the created dataset. Several preprocessing steps are then being performed on each input image that included histogram equalization to help in reducing varying day light effect and for contrast enhancement.

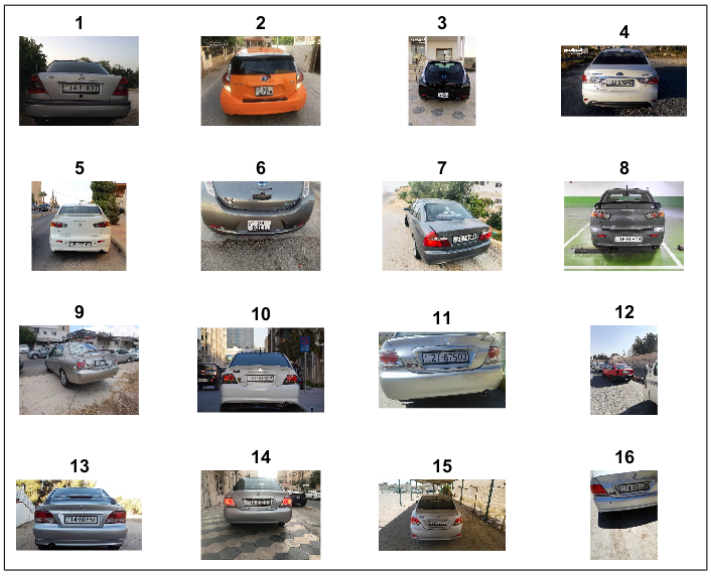

Figure 4: 16 randomly selected input images chosen from the created dataset

3.2 Vehicle detection

The second step is to detect the vehicle from the input image. Faster Regional Convolution Neural Network (FRCNN) [17], which is an objecte detection built-in MATLAB function, was trained to detect and determine the vehicle and its location in the image. FRCNN was chosen since it is significantly faster in training and testing sessions over other detection methods (e.g., R-CNN). Additionally, it is considered as a highly successful framework for generic object detection [18].

The process of using FRCNN is done iteratively among different zooming versions or scales of the input image. This iterative procedure stops, when a vehicle is found or the input image is zoomed to the maximum. In this case (the latter), it may be that no vehicle is found and thus the ANPR system will give an error message indicating such a state and halts. Otherwise (i.e., once the vehicle is found), a blue bounding box around the detected vehicle is drawn. The detected vehicle is then cropped and converted to gray scale. Figure 5 shows an example of this step.

Figure 5: An example of a given input image and the detected cropped vehicle

3.3 License plate detection

The third step is to detect the license plate from the cropped gray scale vehicle image, which is one of the most important ANPR steps. Initially, the fast marching segmentation method [19] is executed to find the best license plate candidate regions. Precisely, this segmentation method will segment the vehicle image into several connected components or parts. The segmented growing parts are initially initialized based on a uniformly chosen seeds within the cropped vehicle image as shown in Figure 6. One of those parts must be the license plate. Figure 7 shows some of the segmented parts as it was very difficult to visualize all candidate segmented parts for all seeds in the same image; as the segmented parts may overlap and therefore the segments will not clearly be viewed. To accurately identify the correct license plate region or part, the following analysis is performed:

- First, the shape of the Jordanian license plate is rectangle with two styles: European and American as shown in Figures 8 and 9, respectively. The European style places the numbers in one row. The American style places the numbers in two rows.
- Next, rectangularity measurement is used [3]–[5] to first identify the segmented parts whose shape is best described by a rectangle, but of certain aspect ratio. This is the aspect ratio, which is computed based on the ration between the height and width of either the American or European styles of the Jordanian license plate. Figure 10 correctly shows identified and detected license plate part based on the rectangularity measurement metric.
- Consequently, a red bounding box is drawn around the part, which satisfies the above constrain or criterion, and crop it as shown in Figure 11.

It is important to emphasize that one of the main contributions in this paper is the methodology used in computing the rectangularity measurement, and thus that for detecting the license plate more efficiently and precisely. Specifically, the presented methodology is quite different and efficient compared to that described in [4], [5] as explained next.

Figure 6: Uniformly chosen seeds in the vehicle cropped image to initialize the segmentation process for the plate detection step.

Figure 7: Some samples of the segmented vehicle parts after the fast marching segmentation during the license plate detection step.

Figure 8: European-style Jordanian plate.

Figure 9: American-style Jordanian plate.

Figure 10: Correctly identified and detected license plate part based on the rectangularity measurement metric.

Figure 11: Cropped license plate after being rotated as to maximize the rectangularity calculation

3.3.1 *Contribution in Calculating the Rectangularity Measurement*

The methodology for computing the rectangularity in [4], [5] requires that:

- each candidate license plate region is to be treated as a rigid object,
- computing its area A_0 by counting the total number of pixels in the region,
- finding its minimum enclosed rectangle (MER) fitted to its boundary by iteratively rotating this object in one degree steps in the range $[-15°, 15°]$ to account for possible tilted angles of the captured vehicles,
- computing the area of MER of this object at each incremental rotation,
- identifying the angle at which the MER goes through the minimum value (A_{MER}), and
- finally computing the rectangularity R at this angle as given in 1:

$$R = \frac{A_0}{A_{MER}} \tag{1}$$

However, the methodology does not require rotating each candidate plate region in a range of steps, which we believe is an important step to perform in order to efficiently detect the correct license plate with high confidence. However, performing this step iteratively and incrementally might be very time consuming and might not produce precise rectangularity calculation. Alternatively,the following steps are performed, which constitute one of the main contributions of this work:

- Each candidate license plate region or object is checked to make sure it has a convex shape as was proposed in [20]. In case it is not convex, it is converted to a convex shape so that spaces in the outwards lines of the object (if any) are connected and filled. This process uses a set of morphological operation (dilation, followed by filling, and lastly followed by erosion).
- Next, ellipse fitting is applied to each convex shaped object. This helps us determine the major and minor axis's of the fitted ellipse of the object.
- The object is then rotated as to remove the rotation angle, which is the angle between the elongation axis (major axis for the fitted ellipse) and the X-axis. Indeed, this is the angle at which the MER goes through the minimum value (A_{MER}).
- Then the area A_0 of the rotated object (the total number of pixels in the convex shape) is computed.
- Finally, the rectangularity R using Equation 1 is calculated.

3.3.2 *Rectangularity Analysis*

The methodology presented in [4], [5] was compared with the proposed methodology. It is important to mention to the best of our knowledge that we could not find any work other than [4], [5] which used the rectangularity metric as a major step in detecting and localizing the license plate similar to what is proposed in this paper. And, since this step is really the most critical step and the heart of any ANPR system, we believe that using the methodology of [4] and [5] as one of the baseline comparisons is still a fair choice especially with the proposed enhancement given in the previous subsection, which we believe shows an advancement to the literature in this direction. In the comparison, the dataset of 100 images is used to compute the detection accuracy of correctly finding the license plate region and the average rectangularity calculation time. The results are presented in Table 1. The results indicate that the proposed rectangularity calculation is more accurate, precise and faster. In fact, the analysis showed that proposed rectnagularity measurement values were very close to one for the candidate license plate objects compared to around 0.7 based on [4], [5]. Additionally, it is worth noting that the rectangularity measurement calculation under different $\Delta\theta$'s $\in [-15, \ldots, 15]$ as in [4], [5] might not be unique. The analysis shows that the same rectangularity value can be obtained under multiple different $\Delta\theta$'s, which can be problematic and result in misidentifying the correct license plate region.

Table 1: Rectangularity analysis

Rectangularity methodology	Average plate detection accuracy	Average rectangularity calculation time (sec)
[4], [5]	65%	0.2785
The proposed methodology	95%	0.0315

3.4 Jordanian license plate Verification

Upon the detection of a possible license plate region, it remains to verify that it is indeed a Jordanian plate. To do so, the label part is examined. It is located to the left side of the Jordanian license plate as shown in Figure 12. It contains the English and Arabic characters of the word Jordan. Therefore, it was decided to use template matching technique based on computing the score of the cross correlation coefficients between two binary windows; (the binary templates of the Arabic characters of the word Jordan and the binary connected components objects extracted from the anticipated label area of the identified license plate candidate). Following are the performed template matching steps:

- converting the label area into the binary scale using Otsu's method.
- segmenting out all possible characters or objects within the label area by performing connected component analysis on them.
- resizing these segmented objects to match the size of the stored binary templates of the Arabic characters of the word Jordan
- exhaustively computing the correlation coefficient between each object and the templates.
  - if the computed correlation coefficients are above heuristically computed threshold, then the detected license plate is declared to be a Jordanian one.
  - otherwise, it gives an error message that it could not find a Jordanian plate and halts.

3.5 Determine license plate type

The fifth step is to determine the type of the Jordanian vehicle. This information is color-coded (see Table 2) in the label area of the license plate. Thus, in the proposed ANPR system, we analyze the color of the detected license plate label area in the original input image. Consequently, based on the analyzed color (most frequently occurred color value) and the recognized code part from the next ANPR step (numbers in first line in American license plate and the digits before the dot in European license plate), we determine the type of the vehicle. Figure 13 shows some examples of the detected Jordanian license plate types from the ANPR system. Table 3 summarizes the types found in the created dataset.

Figure 12: Label image part.

(a) White Label Area: Private Plate

(b) Red Lable Area: Government Plate

(c) Yellow Label Area: Temporary plate

(d) Green Label Area: Public plate

Figure 13: Types of Jordanian license plate [21].

Figure 14: License plate area that excludes the label region

Table 2: Color coded Jordanian license plate types [22]

The two reserved digits indication: selected list		License plate color indication
1 – 5	Government vehicles	Red
6	Aqaba free zone vehicles	Red
7	Diplomatic vehicles	Yellow
8-9	Temporary entrance vehicles	Yellow
10 – 21	Passenger vehicles	White
41 – 42	Light goods vehicles	White
44	Tractors	Red
46	Motorcycles and Scooters	White
50	Taxi	Green
56	Small buses	White
58	Coaches	White
71	Trailer	Yellow

Table 3: Summary of the license plate types found in the dataset

Type of License Plate	Number of License Plates
Private, White	96
Diplomatic, Yellow	2
Taxi, Green	1
Temporary Entrance, Yellow	1
Total	100

3.6 Recognition of license plate numbers (OCR)

The sixth step is to recognize the license plate numbers. First, all possible characters within the detected license plate binary image

are extracted by performing connected component analysis within the plate region. Each extracted connected component or object is resized to match the size of the stored binary templates of the numeric plate numbers (from 0 to 9) that are graphically shown in Figure 15. The typeface used to generate such templates is known as Mandatory [23], which is the same typeface that is used for the United Kingdom vehicle registration plates.

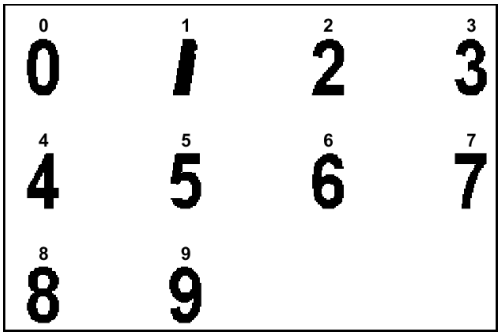

Figure 15: The stored binary templates (inverted in order to best be viewed) of the numeric plate numbers that are desired to be recognized (from 0 to 9)

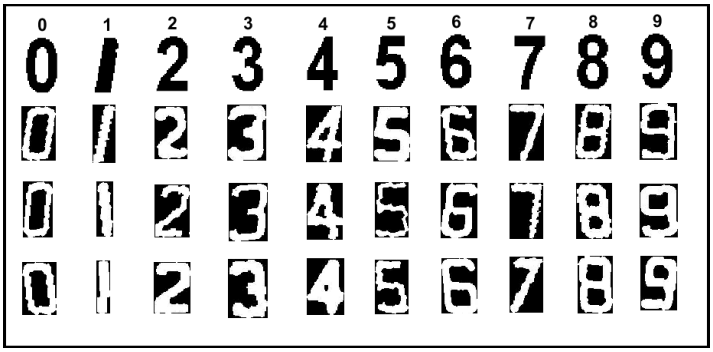

Figure 16: More binary templates of the numeric plate numbers that are desired to be recognized (from 0 to 9)

Finally, the correlation coefficient between each object and the templates is exhaustively computed to recognize the plate numbers. It is noteworthy to mention that, in order to increase the OCR recognition accuracy, the number of stored binary templates for the character set '0123456789' was increased as shown in Figure 16. This resulted in having better matching of the segmented objects and thus high confidence in the associated recognition results. Additionally, the license plate area that excludes the label region (Figure 14) is the OCR region of interest because the segmentation of possible numbers or objects is performed in it. As stated above, the Jordanian license plate splits into two different styles: European and American. Thus, the performed connected component analysis considers the properties and characteristics (distribution of the numbers) of the two types. It also considers the following facts:

- The width and length of all numbers are the same.
- The distance between numbers is nearly the same, except the code part (numbers in first line in American license plate and the digits before the dot in European license plate), which determines the type of vehicles such as: 50: taxi, 36: private bus, etc.).
- All numbers in the license plate have the same color, which is black. Additionally, the background color for the license plate (except label part) is white.

A green bounding box is drawn around each recognized number in the license plate region as shown in Figure 17. After applying the OCR, the code of the license plate is computed by calculating the distance between all numbers. The code part determines the type of the vehicle as we mentioned before and listed in Table 2.

Figure 17: OCR results: remove background from the license plate, segment-out the possible numbers, recognize them, and draw green bounding box around each recognized number.

Table 4: Summary of the vehicle makes found in the dataset

Vehicle Make Index	Vehicle Make	Number of Vehicles
1	Mercedes	11
2	Toyota	10
3	Nisan	7
4	Hyundai	10
5	Mitsubishi	39
6	Opel	3
7	Audi	1
8	Ford	8
9	Mazda	1
10	Lexus	2
11	Daewoo	1
12	Jaguar	1
13	Jeep	1
14	Kia	2
15	Honda	1
16	Peugeot	1
17	Chrysler	1
Total number of Images		100

3.7 Recognizing the make of the vehicle

The seventh and final step of the proposed ANPR system is to determine the make of the vehicle. In this step, the make of the vehicle is recognized by localizing and recognizing the vehicle's logo. Generally speaking, the fact that the vehicle's logo is approximately located in the region above the detected license plate can be relied on, which can be a weak assumption. However, in this presented step, it is desirable to prove the concept of being able to add such feature (i.e., recognizing the make of the vehicle) easily. Thus, the vehicle's logo in the segmented parts from the third step is searched for. The segmented parts are just above the detected license plate region. Once a logo was detected, a yellow bounding box is drawn around it. To help recognize those detected logos, several logo images from the Internet were collected. The images were specifically related to five auto makers MERCEDES, MITSUBISHI, KIA, NISSAN and TOYOTA. The list could be expanded easily. It should be mentioned that the dataset consisted of 17 vehicle makes or brands as summarized in Table 4, and the recognition focus was just put on five of them as indicated above. After that, using the collected logo dataset, a convolutional neural network (CNN) is trained with the help of MatConvNet MATLAB toolbox to recognize the five makes of the vehicles as listed above. While testing this ANPR step on the input images dataset, it is assumed the case where none of the logo images of the vehicles would match the makes from which the CNN classifier is trained on as an "UNKNOWN MAKE". Figure 18 shows the recognized make for the vehicle that was shown in Figure 10.

Figure 18: The recognized make for the vehicle that was shown in Figure 10

To conclude this section, Figure 19 shows and summarizes the output of all stages of the proposed ANPR system. As it is clear from Figure 19:

- The detected vehicle is identified by a blue bounding box.
- The detected plate is identified by red bounding box.
- The detected logo of the vehicle is identified by yellow bounding box.
- The detected license plate is a Jordanian one and its type is private; since it has a white color and its code is recognized as "24".
- The recognized license plate numbers are "12692", where each number is bounded by a green bounding box.
- The recognized make of the vehicle is "Mitsubishi".

4 Experimental results

This section presents the experimental results of the proposed ANPR system. A 100 images were tested as mentioned in the previous section. The average execution time for all tested images was found to be 8.0047 sec on average (ANPR steps 2-6) on a computer machine that has 16 GB of RAM and two quad core 2.5 GHz i7 processor. The system implementation was purely sequential and thus a single core was utilized. Table 5 presents the results (success rates or accuracies). The reported accuracy for each of the rows in Table 5 was computed for each step separately assuming correct results from previous step. As it can be seen from Table 5, the final license plate recognition accuracy from the OCR step was 94.68%. Consequently, the overall ANPR accuracy is 89% given the fact that the license plate detection step failed in 5 images, the license plate verification step failed in 1 image, and the OCR step failed in 6 images for a total of 11 images out of 100 (this is shown in the last row of Table 5). Finally, the accuracy for recognizing the make of the vehicles was 70.21% as given in the second row of Table 6 with an average execution time of 0.0096 sec. However the actual make accuracy was observed to be 86.84% as shown in the last row of Table 6. We should note that images without valid logos and unclear logos were manually excluded. Therefore, by excluding those images from the make evaluation dataset, the above accuracy was recomputed.

Table 5: The experimental results of the proposed ANPR system

ANPR Steps	Num. of input images	Num. of success images	Num. of fail images	Accuracy	Average execution time
Step 2: Vehicle detection	100	100	0	100%	0.3394 sec
Step 3: License plate detection	100	95	5	95%	3.6327 sec
Step 4: License plate verification	95	94	1	98.95%	3.5924 sec
Step 5: License plate type	94	94	0	100%	0.00089 sec
Step 6: OCR	94	89	5	94.68%	0.4393 sec
ANPR system with all Steps 2-6	100	89	11	89%	8.0047 sec

We have compared the proposed system with the following ANPR systems: the ANPR system, which is available online at [24] and the ANPR system proposed in [2] (our previous work). For this comparison, we only used the 94 images out of the created dataset for which the license plates were successfully detected and verified as listed in Table 5. The result of this comparison is shown in Table 7, which shows that the proposed system achieved the best performance in terms of the recognition accuracy.

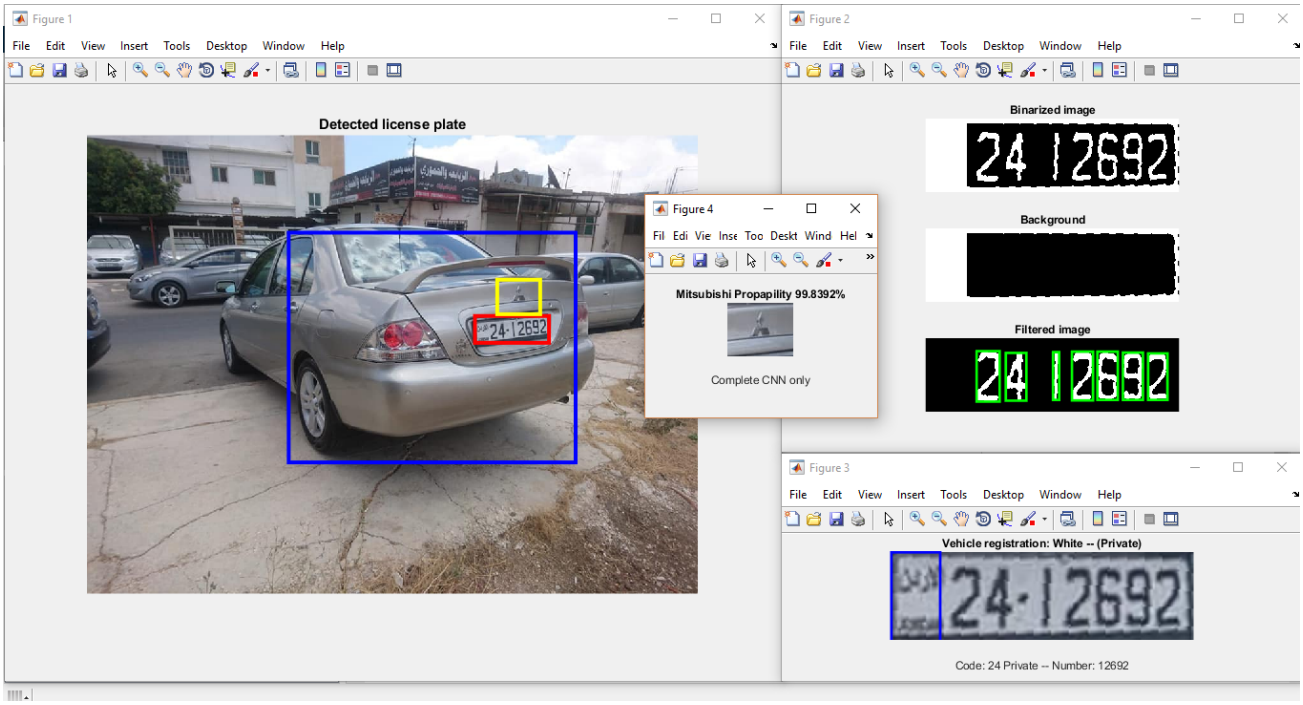

Figure 19: Summary of the output of all the steps of the proposed ANPR system.

Our proposed system	94.68%

5 Discussion

As it can be inferred from Table 5, some of the steps need to be optimized either in terms of the average execution time or the accuracy of detection and recognition. For example, the average execution time of the license plate detection step was around 3.6327 sec and it was the largest among the rest of the steps. This is caused by the largest number of candidate segmented regions that were needed to check the license plate for; Rectangularity measurement and aspect ratio. Specifically, this is controlled by the number of the initialized seeds which is equal to $256 = 16 \times 16$ uniformly spaced grid as was shown in Figure 6. Despite that being said, it is important to highlight that our average calculation time of the rectangularity measurement per each candidate license plate part was better compared to the work of [4], [5] as was shown in Table 1 with a detection accuracy of 95%. Studying the factor of reducing the number of initialized seeds to reduce the license plate detection time is planned as a future work and how would that affect the detection accuracy.

Another observation from Table 5 is that the next highest average execution time was the license plate verification step. We believe that this is related to the way in which the verification process was performed as large number of small sized binary segmented windows were exhaustively compared against the binary templates of the English and Arabic characters of the word Jordan. Moreover, we carefully investigated the single failure case from this step, and it turned out to be caused by the bad resolution cropped license plate. The produced binary image of the cropped license plate is as shown in Figure 20.

Additionally, based on the results obtained from the OCR step, it was found that the main causes for the relatively low OCR recognition rate are related to one or more of the following factors:

- The numbers on some of license plates were not so much clear in the captured input images or may have bad illumination conditions; such as the example shown in Figure 21.
- Some of the numbers have certain painting defects that cause the OCR algorithm to not recognize them correctly such as the example shown in Figure 22 for the number ‘6’.

These kind of problems result in a bad segmentation of the plate characters and thus bad input to the OCR algorithm. Therefore, bad OCR recognition results.

Figure 20: The single case where the license plate verification step failed due to the bad resolution of the cropped license plate; the English and Arabic words of Jordan can not be found in the binary image.

Figure 21: A blurring problem in one of the numbers in the detected license plate (number 6) that caused the OCR step to fail

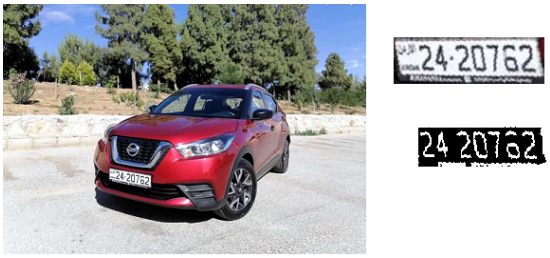

Figure 22: A painting defect problem in one of the numbers in the detected license plate (number 6) that caused the OCR step to fail

Moreover, the lowest recognition accuracy was for the step of recognizing the vehicle's make. This was due to the assumption in localizing the logo of vehicle, which was assumed to always be found in the upper regions above the license plate. We believe that the main challenge was that the location of the logo above the license plate is not indeed consistent among all the vehicles, especially the tested ones (there were too much variations). Therefore, as was mentioned in Section 4 and after analyzing the captured input images, it was found that there were several images without any logo as can be seen in Figure 23, and in some of the images the logo was not clear due to the bad illumination conditions or due to the shadow effect as seen in Figure 24. It turned out that the number of images in the created dataset that possess these kind of problems was found to be 18. As a result of this observation and in order to test the performance of the trained make recognition subsystem, we excluded those 18 images from the make evaluation dataset (94 images). Consequently, the make recognition acucray was observed to be 86.84% as was shown in last row of Table 6.

For the final cost of the proposed ANPR system in terms of the hardware needed to run, it is clear that it only needs a computer machine and a camera to capture input images of the vehicles. Thus, considering the fact that cameras are now almost available everywhere (e.g., mobile phone cameras and surveillance cameras) and that much of the processing needed can be done on the cloud, the estimated cost of the proposed system could be as low as zero.

Figure 23: Four sample vehicle images, where the logo of vehicle that indicates its make is missing

Figure 24: Two sample vehicle images, where there is bad illumination conditions around the logo of each vehicle

Last but not least, although the proposed Jordanian ANPR system in this paper was shown to provide very good recognition results, however it may not work or produce correct results for all cases of the input images. Indeed it needs to be further analyzed under bad illumination conditions, blurriness in image, dirtiness or painting or physical defects problems in the numbers and characters on the license plate, and under the bad weather conditions (e.g., foggy and

rainy conditions). About the speed performance of the proposed system, it is important to emphasis that the estimated time usually depends on the scene complexity of each input image, input image resolution, and the underlying speed of the running machine.

6 Conclusions and Future Work

The paper proposes a fully automated license plate recognition system targeting the Jordanian license plates as a case of study. The proposed system uses and optimizes the calculation of the rectangularity measurement to better identify the best license plate candidate region, which is considered one of the main contributions of the paper. The proposed Jordanian ANPR system was tested on a database that consisted of 100 Jordanian vehicles and compared it to two ANPR systems from the literature. Consequently, proposed system achieves and reports the best performance among the compared systems in terms of the OCR recognition rate, which was 94.68%. We hope that the presented system will be adopted in the very near future in Jordan.

The presented system still needs to be optimized in different aspects as was discussed in Section 5, which is slated for future work. For example, it is desirable to study the effect of the selected number of seeds during the license plate detection step on license plate detection accuracy and the average detection time. Additionally, it is useful to analyze and further experiment the proposed system under bad illumination and weather conditions, blurriness in image, and under physical defects problems in the numbers and characters of the license plate. Moreover, examining better methods for recognizing the make of the vehicle and increasing the number of trained classes for the recognition of other makes are another area of future work.

Conflict of Interest The authors declare no conflict of interest.

ABSTRACT

Many recent studies on autonomous driving have focused on model-based control. A number of studies has addressed that simple models such as the Kinematic Bicycle Model are easier to design controls for autonomous driving systems. However, such a simple vehicle model has a weakness in that it is subject to modeling errors. This is because it does not take into account the nonlinear characteristics due to road conditions and driving conditions (environmental disturbances: road friction coefficient, large steering, acceleration, sideslip, etc.) Therefore, the purpose of this study is to identify vehicles with high accuracy and in real time, adapting to environmental disturbances.
This study propose a vehicle model based on the Kinematic Bicycle Model. The nonlinear characteristics of the vehicle are represented by the deviation of the front wheel steering angle of the Kinematic Bicycle Model. This deviation is trained and estimated online using a three-layer Neural Network. In other words, the AI is adaptive learning of modeling errors caused by nonlinear characteristics of the vehicle.
This paper presents an example of model-based control using model predictive control.

1. Introduction

In recent years, study and development of autonomous driving has been conducted in the automobile industry, IT companies, and universities in each country. In study on autonomous driving, some autonomous driving systems that combine Artificial Intelligence (AI) and model-free control methods is proposed [1,2]. However, it is considered that such the autonomous driving system is difficult to obtain system stability and reliability in unknown environments. Therefore, fusion technology of AI technology and model-based control has gained much importance in study on autonomous driving [3,4]. Model-based control is a control method in which a control target is represented by a mathematical model and optimal control input is determined based on the model. Model-based control is widely used in various industries [5]. It has problem that the control performance cannot be exhibited when the model is different from the actual dynamics. Additionally, the more complex the controlled object, the more complex the model and the more the amount of calculation. There is a limit to the number of computing units that can be equipped in an autonomous vehicle. Therefore, the model used for autonomous driving is required to be a simple model with less calculation amount. This paper proposes a simple and highly accurate method for vehicle identification (partially published in [6]).

Several studies agree that simple models, such as Kinematic Bicycle Model [7] and linear single-track model [8], are easier to design controllers for autonomous driving systems [9,10]. These vehicle models do not include nonlinear characteristics due to road conditions and driving conditions (environmental disturbances: road friction coefficient, large steering, acceleration, sideslip, etc.). Hence, the accuracy may be deteriorated due to a modeling error between the actual vehicle and the vehicle model. In order to consider the nonlinear characteristics of the vehicle, vehicle models that includes model equations such as tires and suspensions in the vehicle model has also been proposed [11,12]. However, since these vehicle models include multiple models expressions in the vehicle model, the structure of the vehicle model is complicated. It is inferred that if these are used in an autonomous driving system, it may impose calculated load on the computing unit and impair the real-time performance of the system. In other words, it is important for the vehicle model used for autonomous driving controllers to accurately model the vehicle in real time, even if there are environmental disturbances. This paper proposes a vehicle model based on the Kinematic Bicycle Model [7] in order to represent vehicle behavior simply and with high accuracy. The

Kinematic Bicycle Model does not include nonlinear characteristics due to acceleration and deceleration or large steering, etc. Therefore, an error may occur between the actual gravity center position of the vehicle and the gravity center position calculated by the vehicle model. The behavior of the actual vehicle and the behavior calculated by the model are different due to the position error of the center of gravity, and the modeling error becomes large. Therefore, this method considers the vehicle model in which the center of gravity is fixed at the center of the wheelbase of the Kinematic Bicycle Model and the modeling error is expressed by the deviation of the front wheel steering angle. In addition, this study uses Neural Network to adaptively identify vehicle model by training and estimating the deviation. This paper verifies the usefulness of the proposed method through simulation experiments using vehicle motion analysis software (CarSim: Virtual Mechanics). In this study, simulations were performed in situations closer to actual driving conditions than in [6] (Section 4). Since this method models the vehicle while determining the control input in real time, it does not exist as a modeling technology alone and must be combined with model-based control. This paper shows an example using Model Predictive Control (MPC) as an example of model-based control to show the usefulness of the method. The method requires accurate location information acquisition. Since it is expected that the measurement accuracy will improve with the development of GNSS (Global Navigation Satellite System) in the future, the simulation is performed assuming that accurate position information can be obtained.

In summary, there are two aspects of the proposed approach that are particularly unique. The first is that the structure of the model is simple and easy to identify. In conventional models, several parameters must be identified in advance, but only one parameter is required in this study in advance. This means that the controller design of autonomous driving could be simplified by relieving the task of examining cornering stiffness and tire parameters in advance. Second, by focusing on the coordinates of the center of gravity, the approach can analyze the entire vehicle as nonlinear motion. Online learning may be able to respond to changes in vehicle mass (due to the number of passengers and loads) and road surface. It is notable that the method is robust to environmental disturbances and easy to identify.

This paper sets up the issue in Section 2. Section 2.1 introduces the conventional method and Section 2.2 describes our proposed identification method in detail. This paper also presents and discuss the simulation results in Sections 3 and 4. Section 3 mainly considers the effects of acceleration, deceleration and steering on the vehicle's nonlinear characteristics, while Section 4 considers the situation with road surface changes. And Section 5 concludes this paper.

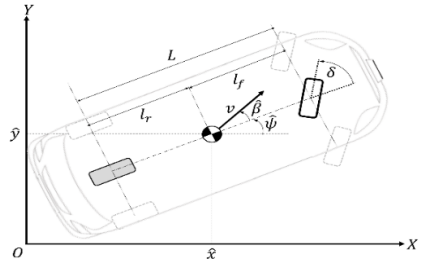

Figure 1: Kinematic Bicycle Model on the XY coordinate

2. Statements of The Issue

This section will set the issue for the proposed method. Section 2.1 introduces simple two-wheel models and accurate nonlinear models to clarify the problem. Section 2.2 details the proposed method for solving the problem.

2.1. Conventional study of vehicle models

2.1.1. Two-wheel model with simple structure

Typical vehicle models used for model-based control include simple two-wheeled models such as the Kinematic Bicycle Model [7] and linear single-track model [8]. These vehicle models are based on the assumption that the state quantities are observed instantaneously, and some conditions (e.g. constant speed, left and right tire characteristics are equal, roll and pitching motions are ignored) are set to represent vehicle dynamics in a simplified way. These vehicle models have simple structure, and thus the turning radius can be easily calculated. Therefore, they can be easily introduced to the controller design of autonomous driving systems. However, these do not take into account various nonlinear characteristics due to environmental disturbances (road friction coefficient, large steering, acceleration, etc.), which can cause modeling errors between the actual vehicle and vehicle models. This paper uses the Kinematic Bicycle Model as an example of the simple two-wheel model to test its accuracy. The model diagram of the Kinematic Bicycle Model is shown in Figure 1. Equations (1-4) show the model equations of the vehicle model. The velocity $v[k-1]$(m/s) and the front wheel steering angle $\delta[k-1]$(rad) are inputs, and the center of gravity coordinates of the vehicle model $(\hat{x}[k],\ \hat{y}[k])$, the direction of the vehicle model $\hat{\psi}[k-1]$(rad), and the sideslip angle around the center of gravity $\hat{\beta}[k-1]$(rad) are outputs. $(x[k-1], y[k-1])$ is the coordinates of the center of gravity observed one step ago.

$$\hat{x}[k] = x[k-1] + v[k-1]\Delta t \cdot \cos\left(\hat{\psi}[k-1] + \hat{\beta}[k-1]\right) \tag{1}$$

$$\hat{y}[k] = y[k-1] + v[k-1]\Delta t \cdot \sin\left(\hat{\psi}[k-1] + \hat{\beta}[k-1]\right) \tag{2}$$

$$\hat{\psi}[k-1] = \hat{\psi}[k-2] + \frac{v[k-2]\Delta t}{l_r}\sin\hat{\beta}[k-2] \tag{3}$$

$$\hat{\beta}[k-1] = \tan^{-1}\left(\frac{l_r}{l_f + l_r}\tan\delta[k-1]\right) \tag{4}$$

here k is the current time, Δt is the sampling time, $l_{f(r)}$(m) are the distance from the front (rear) wheel axle to the center of gravity, and L(m) is the wheel base.

The trajectory of the vehicle model without these nonlinear characteristics (Figure 1) is confirmed. In this case, experiments and verifications should be performed using actual vehicles, but verifications are performed by simulation experiments that are easy to analyze and verify and that can accurately acquire the

vehicle state. Specifically, this study used the Driving Simulator in Figure 2. The Driving Simulator is a Windows PC with a vehicle motion numerical analysis software (CarSim) and a game handle device (Logitech) connected. The PC used in the simulation are as follows: Windows10 64bit, CPU: Intel(R) Core(TM) i7-9700 CPU @ 3.00GHz, and installed memory (RAM):8GB.

Figure 2: Driving Simulator

A simulation course [Slalom] was created on CarSim as shown in Figure 3. The driver drove this course between two pylons lined up in the course, gradually increasing the velocity as shown in Figure 5. The running trajectory at that time is the solid line in Figure 4 (Vehicle's running trajectory). The velocity v obtained as the vehicle data at that time is shown in Figure 5, and the front wheel steering angle δ is shown in Figure 6. The velocity v and the front wheel steering angle δ are input to the vehicle model (1-4) and the running trajectory is calculated as shown by the broken line in Figure 4 (Equation of Vehicle Model). Figure 7 shows the position error between the observed trajectory (x, y) and the trajectory calculated by the vehicle model $(\hat{x}, \hat{y})$. From Figure 4 and Figure 7, there is a maximum position error of about 0.15m in the running trajectory of the actual vehicle and the running trajectory calculated using the vehicle model of (1-4). This is thought to be due to the nonlinear characteristics (tire deformation, expansion and contraction of suspension, etc.) caused by acceleration, deceleration and steering during running. It is consider that the front wheel steering angle δ and the vehicle traveling direction do not match due to the influence of the nonlinear characteristic. This deviation affects the modeling error. In addition, this simulation is based on the assumption of asphalt surface. If it is snow or ice road, the deviation increases further. This is because the effect of the road surface is not taken into account in this model.

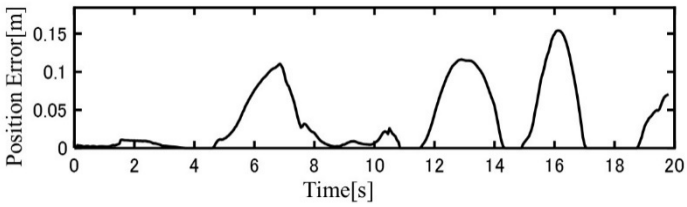

Figure 7: Position error

2.1.2. *Example of non-linear vehicle models that accurately represents vehicle behavior*

As shown in 2.1.1, simplifying the vehicle behavior may increase the modeling error. Hence, there are several conventional studies that use nonlinear vehicle models to represent the nonlinear motion of vehicles in detail. In literature [13], an autonomous driving system combined with a nonlinear vehicle model and MPC is proposed. The nonlinear model is a combination of two-wheel model and nonlinear tire model. This literature shows good results even on compacted snow surface with a low coefficient of friction. In this literature, two tire models were prepared beforehand, one for asphalt and the other for compacted snow, and were tested on each surface. In other words, the experiment is based on the assumption that the road friction coefficient is known. This means that the road friction coefficient, which changes from time to time, must be known.

To solve these problems, a combination of adaptive Model Predictive Control and tire-stiffness estimator [14] has been proposed [15]. This method estimates the tire stiffness from the tire-stiffness estimator. It is able to estimate tire stiffness in situations where the road surface changes and select the optimal road friction coefficient and tire parameters. However, the relationship between the chosen parameters and tire stiffness must be known. In order to find out the relationship between the two, it is necessary to conduct field tests or using a testbench beforehand, which may change depending on the degree of tire wear and other factors such as ageing. In addition, these literatures focused only on tire nonlinearity and did not mention nonlinear vehicle motion due to changes in vehicle mass (due to the number of passengers and loads.), suspension, body stiffness and other effects. These nonlinear motions can also lead to modeling errors. This paper proposes a vehicle model for online learning of nonlinear characteristics of the vehicle by focusing on the change of the vehicle's center of gravity position. By focusing on the change of

the center of gravity, it is possible to model not only the tires but also the nonlinear characteristics of the entire vehicle. Furthermore, online learning eliminates the hassle of pre-testing and allows you to deal with disturbances such as vehicle mass that change with each drive

2.2. Vehicle Model to Estimate Modeling Error

As described in Section 2.1.1, due to the nonlinear characteristics of automobiles, deviation occurs between the front wheel steering angle δ and the actual running direction of the vehicle. The actual direction of travel of the vehicle is defined as the front tire steering angle $\hat{\delta}$. Here, the front wheel tire steering angle $\hat{\delta}$ is an angle that includes nonlinear characteristics due to environmental disturbances and vehicle dynamics. The front wheel steering angle δ is the angle that the front wheels are facing, which can be calculated by the steering wheel angle δ_{SW}. In order to accurately represent the behavior of the vehicle, it is necessary to include in the vehicle model the deviation between the direction the front wheels are facing and the direction the vehicle is actually going, in other words, the deviation between the front wheel steering angle δ and the front wheel tire steering angle $\hat{\delta}$. However, it is difficult to directly observe and theoretically obtain the deviation. Therefore, this deviation is named the modeling error $\hat{\alpha}$ and is defined as the front tire steering angle $\hat{\delta}$ as (5).

$$\hat{\delta}[k-1] = \delta[k-1] + \hat{\alpha}[k-1] \tag{5}$$

$$\hat{\beta}[k-1] = \tan^{-1}\left(\frac{l_r}{l_f + l_r}\tan\hat{\delta}[k-1]\right) \tag{6}$$

Since the front wheel tire steering angle $\hat{\delta}$ is defined as the actual direction in which the vehicle is traveling, (4) is modified as in (6). In other words, our proposed vehicle model is (1-3,5,6). The vehicle model is as shown in the Figure 8. The vehicle model needs to identify the distance from the front (rear) wheel axle to the center of gravity $l_{f(r)}$. The position of the vehicle's center of gravity changes from moment to moment during driving. This is because acceleration, deceleration and large steering causes nonlinear motion in the vehicle, including the tires and suspensions. It is difficult to determine the exact position of the vehicle's center of gravity. Therefore, in this study, the position of the center of gravity of the vehicle is fixed at the center of the wheelbase ($l_{f(r)} = L/2$), and the identification error of the center of gravity position is corrected by $\hat{\alpha}$.

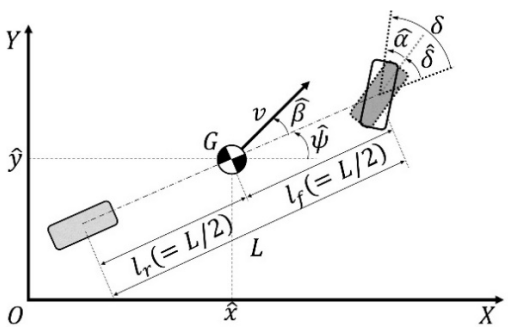

Figure 8: Vehicle model including modeling error $\hat{\alpha}$

Here, a method for estimating the modeling error $\hat{\alpha}$ is described. Since the modeling error $\hat{\alpha}$ is the parameter representing nonlinear motion due to acceleration and deceleration, steering, and road surface changes, it has nonlinearity and is expected to change from moment to moment. Therefore, this study proposes the method for estimating the model error $\hat{\alpha}$ in real time while deriving the control input by model-based control.

This paper considers the system that uses MPC to derive the front wheel steering angle δ and velocity v that are control inputs. MPC is a control law that derives the optimal control input while predicting its future behavior using a predictive model representing the dynamics of a control object. MPC solves an open-loop optimal control problem from the current time to finite horizon for each control period. MPC is an attractive method for controlling autonomous vehicles because it can consider the dynamics and constraints of the controlled object and the ability to adapt to driving scenarios [16-18]. Figure 9 shows the system configuration.

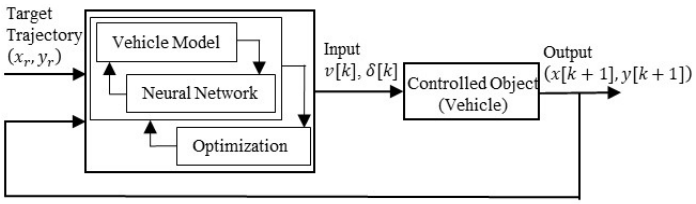

Figure 9: Block diagram of the proposed system

This system uses a Neural Network to train online the nonlinear characteristics of a vehicle that cannot be considered in the vehicle model. The trained Neural Network is used to control the vehicle while estimating the unknown parameters of the vehicle model. Figure 10 shows the flowchart of this system.

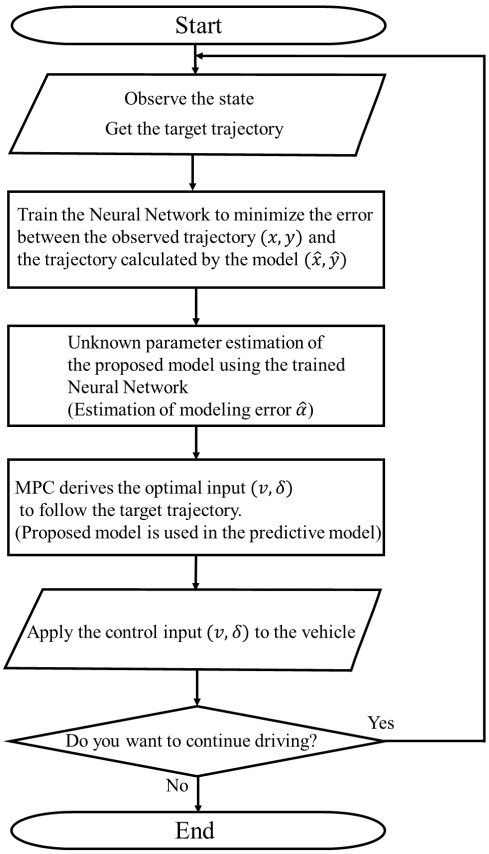

Figure 10: Flowchart of the adaptive identification method for vehicle

The control goal of MPC is to derive the control input that matches the output with the target trajectory. The control objective is to derive the control input ($\delta[k]$ and $v[k]$) that matches the output ($x[k+1]$, $y[k+1]$) with the target trajectory ($x_r[k+1], y_r[k+1]$). This system derives control inputs that minimize the cost function (7).

$$J(\boldsymbol{\delta}(k), \boldsymbol{v}(k)) = \sum_{i=1}^{H} [(\hat{x}[k+i] - x_r[k+i])^2 + (\hat{y}[k+i] - y_r[k+i])^2] \quad (7)$$

H is the prediction horizon. The prediction model (Vehicle Model and Neural Network in the Figure 9) predicts the vehicle trajectory ($\hat{x}[k+i]$, $\hat{y}[k+i]$), $1 \le i \le H$. Since the trajectory depends on the future input, the input sequence $v[k+i], \delta[k+i], 0 \le i \le H-1$ are derived so that the predicted trajectory ($\hat{x}[k+i]$, $\hat{y}[k+i]$), $1 \le i \le H$ approaches the target trajectory ($x_r[k+i], y_r[k+i]$), $1 \le i \le H$ of the obtained input sequence, only the first $v[k], \delta[k]$ are used as the actual inputs.

From here, the Neural Network that trains and estimates the modeling error $\hat{\alpha}$ is described. From Figure 4 to Figure 6, it can be confirmed that the position error (modeling error) increases as the velocity v increases and the front wheel steering angle δ increases. In other words, the position error is considered to depend on the velocity v and the front wheel steering angle δ. The parameter required to correct this position error is the modeling error $\hat{\alpha}$. This modeling error $\hat{\alpha}$ is considered to include nonlinearity. This study uses a 3-layer Neural Network with 2 inputs and 1 output for estimation. This is because the nonlinear system is modeled with high accuracy and the load on the computer memory is reduced as much as possible. The relationship between the input and output of the Neural Network is shown in (8-10). In this paper, I_1 and I_2 are inputs, c_1-c_4 are thresholds, and $w1$ and $w2$ are weighting factors. The input value of the hidden layers are s_1-s_4, and the sigmoid function is used for the output value h_1-h_4 of the hidden layers. Akaike's Information Criterion (AIC) is used to determine the number of hidden layers. The input I is the front wheel steering angle δ and the velocity v, and the output O represents the modeling error $\hat{\alpha}$.

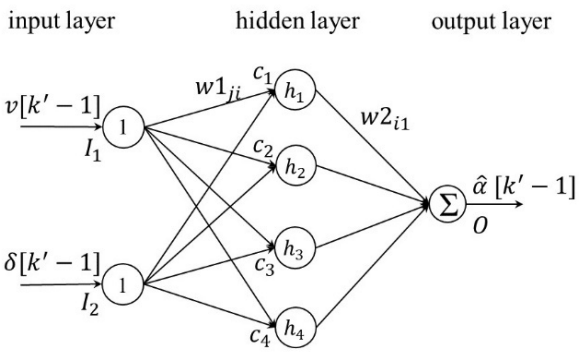
$$s_i[k'-1] = \sum_{j=1}^{2} w1_{ji}[k'-1] \cdot I_j[k'-1] + c_i[k'-1] \quad (8)$$

$$h_i[k'-1] = \frac{1}{1+\exp(-s_i[k'-1])} \quad (9)$$

$$\hat{\alpha}[k'-1] = \sum_{i=1}^{4} w2_{i1}[k'-1] \cdot h_i[k'-1] \quad (10)$$

The observed values of the position coordinates are given to the Neural Network as instruction signal, and online training is performed so as to minimize the cost function (11).

$$I = \sum_{k'=k-W}^{k} \{(\hat{x}[k'] - x[k'])^2 + (\hat{y}[k'] - y[k'])^2\} \quad (11)$$



$(\hat{x}, \hat{y})$ represents the position coordinates of the vehicle model, and (x, y) represents the position coordinates of the actual vehicle. W represents the window width. This neural network is trained so that the position coordinates of the vehicle model $(\hat{x}[k'], \hat{y}[k'])$ from k to W match the position coordinates of the actual vehicle $(x[k'], y[k'])$. Altogether, the parameter $\hat{\alpha}$, which represents the nonlinear properties, is estimated from the position coordinates.

By training and estimating the modeling error due to the nonlinear characteristics online, the behavior of the vehicle can be accurately represented in situations such as acceleration and deceleration, large steering and road surface changes. Because the vehicle is identified in real time, it may be able to respond to changes in vehicle weight, such as changes in the number of passengers. Furthermore, our identification method only uses the wheelbase L as the setting parameter of vehicle model. This means that different types of vehicles can be identified by only changing the wheelbase L. Conventional vehicle models have set parameters (e.g., cornering stiffness, vehicle mass, etc.), which vary for each vehicle. The key feature of this method is that there is only one configuration parameter.

3. Simulation of Fixed Road Surface

In this section, a simulation comparing the Kinematic Bicycle Model (1-4) with the proposed model (1-3,5,6) is described. As in Section 2, the simulation was performed using CarSim installed in the Driving Simulator. It verified whether the center of gravity coordinates of the proposed vehicle model $(\hat{x}, \hat{y})$ matches the center of gravity coordinates of the actual vehicle (x, y). The Kinematics Bicycle Model (1-4) and the proposed vehicle model (1-3,5,6) were given the velocity v and front wheel steering angle δ as inputs, and the trajectory was calculated. The accuracy is checked by comparing the calculated trajectory with the actual vehicle trajectory. The input data and the actual vehicle trajectory are obtained by driving the simulation course shown in Figure 3, which was created in the Driving Simulator (Figure 2) as a driving course with acceleration, deceleration, and steering. This study assumes that the 27 degree of freedom vehicle model in CarSim is the actual vehicle. This simulation assumes a dry asphalt surface (surface friction coefficient $\mu = 0.85$) and drive a B-Class hatchback vehicle (Figure 12).

The driver repeatedly accelerated and decelerated between the two pylons in the course [Slalom] shown in Figure 3. Figure 13 and Figure 14 show the v and δ.The solid line in Figure 15

shows the running trajectory. In this paper, the trajectory is used as the actual vehicle trajectory. The dashed lines in Figure 15 show the trajectory when the velocity v (Figure 13) and the front wheel steering angle δ (Figure14) were given as inputs to the proposed model. The front wheel tire steering angle $\hat{\delta}$ is shown in Figure 16. The calculated position error between the calculated trajectory and the actual vehicle trajectory is shown in Figure 17 and the estimated modeling error $\hat{\alpha}$ is shown in Figure 18. As shown in Figure 17, the maximum positional error is 0.05m, which is considered to be within the practical range.

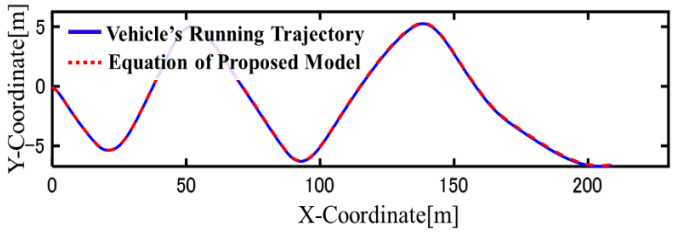

Figure 15: Driving trajectory［Slalom］

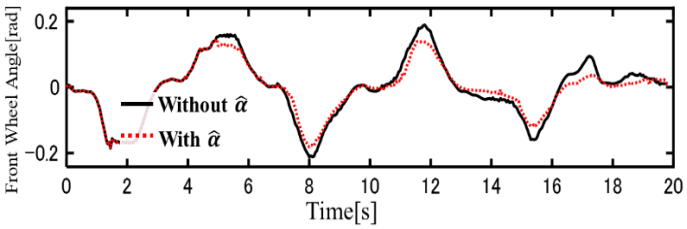

Figure 16: Front wheel steering angle δ and front wheel tire steering angle $\hat{\delta}$

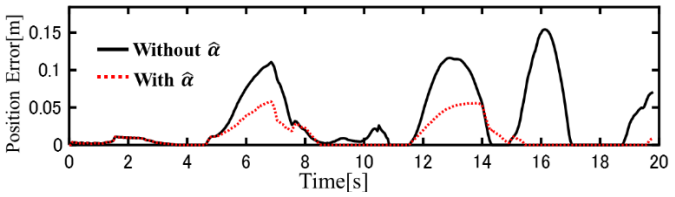

Figure 17: Position error

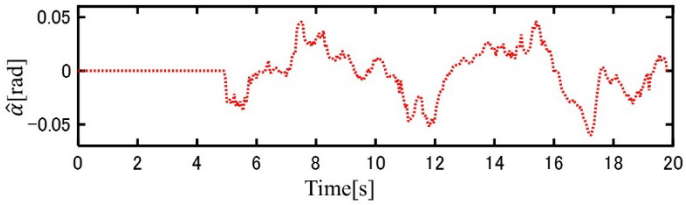

Figure 18: Modeling error $\hat{\alpha}$

The results show that the behavior of the vehicle can be identified with high accuracy. This means that the proposed model (1-3,5,6) can contribute to the controller design of autonomous driving systems using model-based control. However, at this stage, this study has only validated a single driver driving a B-Class hatchback in CarSim several times around the track in a simulation experiment and have obtained good results. In order to prove the effectiveness of the proposed method, it is necessary to conduct similar tests on various courses and vehicle models, and this is a subject for future study.

4. Simulation of Road Surface Change

This section presents additional examples of situations that more closely resemble actual driving situations in order to verify the usefulness of the proposed model. As in Section 3, the experiments were conducted using the Driving Simulator shown in Figure 2. The course used is shown in Figure 19. This course was designed to simulate a mirror burn. Mirror burn is a phenomenon in which the surface of the road is polished by the traffic and becomes very slippery at a part of the intersection. This course was driven by the vehicle (B-class hatchback) in CarSim. This course is designed to have surface friction coefficient μ=0.2 at the center of the intersection and μ=0.5 outside the center of the intersection. This simulation assumes driving on the left side of the road because it is based on Japanese roads. The trajectory of the vehicle on this course is treated as the center of gravity coordinates of the actual vehicle (x, y). In addition to vehicle dynamics, this simulation allows us to verify whether the vehicle can adapt to changing road conditions. The trajectory of the vehicle $(x[k],\ y[k])$ while driving on the course is shown by the solid line in Figure 22. The dotted lines in Figure 20 to Figure 25 indicate the boundary of the surface friction coefficient. Figure 20 and Figure 21 show the v and δ.The solid line in Figure 22 shows the running trajectory. In this paper, the trajectory is used as the actual vehicle trajectory. The dashed lines in Figure 22 show the trajectory when the v (Figure 20) and δ (Figure 21) were given as inputs to the proposed model. The front wheel tire steering angle $\hat{\delta}$ is shown in Figure 23. The calculated position error between the calculated trajectory and the actual vehicle trajectory is shown in Figure 24 and the estimated modeling error $\hat{\alpha}$ is shown in Figure 25. As shown in Figure 24, the maximum positional error is 0.01m, which indicates that the proposed model is able to adapt to the changes in the road surface.

5. Conclusion

The purpose of this paper is to identify an autonomous vehicle with high accuracy in real time. This paper proposed a simple vehicle model that represents the error in the center of gravity between the actual vehicle and the vehicle model as the deviation $\hat{\alpha}$ of the front wheel steering angle. This paper also proposed the method to estimate the $\hat{\alpha}$ in real time using neural network, and simulation experiments using CarSim showed the usefulness of the method in situations that require acceleration and deceleration, large steering, and road surface changes. The authors emphasize that the method can represent the nonlinear characteristics of the vehicle as it is learning online and that the only parameter to be identified in advance is the wheelbase. In other words, this study can eliminate the process of identifying multiple parameters beforehand and contribute to the design of control controllers that is robust to ever-changing environmental disturbances.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

This paper presents the results of the research conducted with the help of cognitive cybernetics about the "mass" factor from the theory of totalitarianism. According to the expert system model, "big data" analysis sought to discover knowledge for assessing the future status of digital social connectivity. Originally developed models and methods of cognitive and computer research and processing of "eminent text" with the help of "convolution" from the theoretical background of many works about the past totalitarianism, recognize the same characteristics of emerging globalitarianism. Using search correlation, algorithms have confirmed a suspicion that intelligent interactive technologies impact the changes of the human psychophysical structure, through the digital social network of globalitarianism. Applying new intelligent interactive technologies without being familiar with their deeper impact, could plausibly make people accept them as part of themselves. People's digital obsession with the internet in a "global village", is increasingly similar to blind obedience, of the sympathizers and followers, gathered around past totalitarianism's grand leaders. There is a visible correlation between such technological-integration engagement, and the loss of social intelligence, leading to a conclusion that the future interactions between people and intelligent technologies will turn the history into the implosion of current events. History today is already pretty accelerated, due to its own mass digital integration and interaction, turning it into an illusion. There is a danger that globalitarianism, as an elusive end of the history, will escape cyclical times, due to unavoidable repetitiveness.

1. Introduction

According to the above-mentioned sample literature, Žarko Paić's book: "The talk about totalitarianism can never be neutral nor objective, like talking about something that forever belongs to the distant past. Man in his historical being is a creature of the existential sense of responsibility and also has his endless mission. What's left, in the end, is a radical settling of accounts with the possibilities that the past as a traumatic event constantly defines our future with a sense of guilt and responsibility. By taking over the legacy of the past something much bigger than just an unconditional ethical obligation is also taken along. This is the last lesson in which this world is becoming a place for searching the truth without fear of the consequences. And that's the only thing that makes sense. And therefore is the hardest."

*Corresponding Author: Krystian Wawrzynek, krystian.wawrzynek@gmail.com

Based on the principles of cognitive cybernetics, searching for truth could start by creating a system of history placed in time-space, in which from today's perception humans' integral actions are used for the purpose of technology. The first step for that system is to define time and its thinking models, and later to begin with cybernetic observation. Hannah Arendt, in her book (selected sample literature…), points out how being a human and being free, (the event of liberty- lat. *constitutio libertatis*), is the one and the same thing. A human being is the only creature in the world capable of initializing an action which could trigger a change characterized by unpredictability, uniqueness, and singularity of its activity.

In globalitarianism, these characteristics are lost, and as such, in this world of actions, are inevitably and unnecessarily subsided into the transformation of the events into the life itself. Through globalization, a man is brought into a state presented to him as a limit of his existence, and while venturing into modern technology

projects, and without the ability to think for himself, he doesn't even realize he is not free. In this digital sociability, people could become followers of an unknown leader, who gains their obedience due to being unnoticeably lured. Revealing a lack of freedom is managed by the help of cognitivistic and cybernetic interoperability, in processing thematic contents.

2. Historical activities

From the Cybernetics point of view, history as a system of actions aspires towards a contingency of events, which in historical aspect means that it strives towards stability. Civilization as a system, when it is coming closer to a perfect operationalization, is on the brink of its breakdown. Observing history in space as a real factor in which it is happening, and in time as an abstract factor, an event happening in running time finds itself in a void between history and future, presenting a mindboggling reality that new information is already outdated. Sensory experience in space/time within which it "instantly happens", as a "situational psychology" in "position grouping", "is the essence of sustainability in the encounter as a constellation" [1-4].

The effect of today's intelligent technology is so strong that the continuity of today's historical era is becoming inhumane machinery. Authors of the selected representative writings [5-6], on historical example of totalitarianism, point out that a man through right activities can take control of what is not allowed and what is needed to be done. The criteria for doing good are selflessness and thoughtfulness which could produce positive indications in behavior towards others. Common sense is not common to everybody, but it helps people to fit into a community and allows them to communicate in situations expressed by senses. Common sense judgments are community judgments, where the sound mind is the only sense capable to act. Capability and possibility of human (no)actions are disclosed in this paper by cognitive cybernetics, as something past and terrible (totalitarianism), but also as potentially dangerous still to come (globalitarianism). Figure 1.

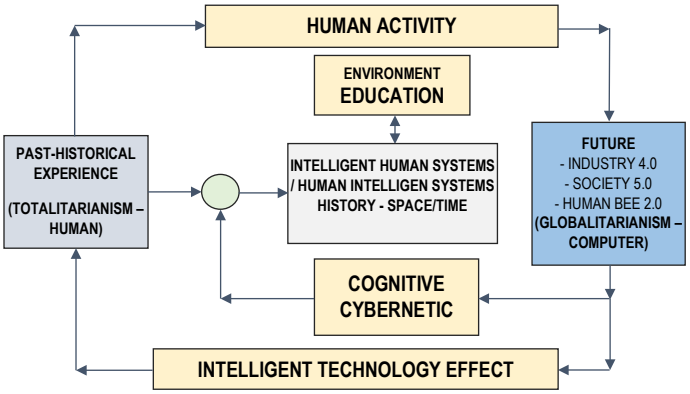

Figure 1: Space history of the system with cognitive cybernetics feedback and efficiency of human and intelligent technologies

For a human activity, which could be mental or physical, one needs a will which must be free and reasonable, otherwise, it wouldn't exist. Free will behaviour is able to identify itself with a command, but also with predictable unpleasant feelings of force and self-deception. With a lack of will, self-deception stops surpassing the feelings, in order to achieve a command. Therefore while searching for answers about history's time, it would be useful to search for them in its historical experiences but also in predictions of its future.

It is noticed that history's time is slowed down by indifference and amazement and those are the exact parameters of the historical activity that the cognitive cybernetics which also confirms its importance in globalitarism, and which has been precisely discussed in the literature [7-8].

2.1. Time

Based on a philosophical perception of historical experience, (Fink, Gadamer, Paić, Wilber, Husserle,…), time (lat. *tempus*) stands for a way and a flow. According to Plato, it is a motion picture of eternity, and a factor of all changes in the world, and every change happens suddenly (gr.εξαφνικότητα) when one form transforms into another. The link between time and unexpectedness is amazement, which for an instant turns into an ecstasy, represented in the word "now". If time is authentic, then it gets a sense of being, from its truth in the original time and belongs to the topology of the being. Historical time makes sense in narrating factual events, while primal or original time, i.e. prehistoric (gr.- *αρχικά*), is lost as soon as it is brought down to a level of "just now". A paradox of time as repetition is a pseudo synthesis of the past and the future, like "eternal occurrence" of the exact same thing that is presumably objective necessity for freedom of actions. The chronological sense of time calculated by a clock is a measurement for living a human life. The time paradox is the objective time in a technical sense, which is eternal present and eternal future, and infinity and eternity. Generally, time's metaphysical structure is an everyday life present in relation to the time essence, and zone of infinity and temporality, as well as a linear cyclical flow of events as existence. Time's psychological structure raises the "self" from the abyss to the highest spheres of being and existence, in the form of life's creative potential [9-11].

Time as a meeting event and a mediation medium occur in possessive attitude towards things, and as temporality, it is an original, existential, hermeneutic phenomenon of engagement in the reconstruction of fundamental issues of time and being. Time as an abyss of freedom is not astronomical nor calendar, because it is unlimited in a sense that even now is a limitless line of dots. Time understood as an ability to act in a certain date in time, marked using time measurements based on important world's events, is stretched between carefully securing a passing of the present while awaiting a transformation of the past, which is far from a simple flow of equal time segments. That is the future that under no circumstances should bet the destruction of history. Time must not be a moment of anything but freedom, to act based on non-exclusivity, discovery, and validation, which are foundations for cybernetic observation and realization, bringing us to a conclusion that time must not ever become virtual [12].

2.2. Cognitive cybernetics

Cognitive cybernetics is a new scientific discipline based on foundation of cognitive sciences and cognition as a human mental potential, that connects cybernetic understanding of everything as a system (technical, social, natural…), with the new intelligent

technologies that by cognition of interactions could point out to captologic anthropomorphosis of present-day human [13-15].

Based on available sources of information, today's science is becoming more and more empirical science about a man and everything that could become his personal technical experience achieved through new technologies. With its help, a human is placed in the world that adequately processes multiple productions. All that is accomplished everywhere based on and in the interest of scientific development of certain human capacity determined and lead by new cybernetics [16-18]. It determines a human as a social-working being and it is a theory that covers the possibility of planning and organizing human work. The language of cybernetics is transformed into a news exchange medium by which the whole world and a human's place in it, is determined and controlled. It is important to respond cognitively because only human engagement which must be thoughtful (thought, will, reasoning - cognition as human energy) and productive (working, producing and acting), can ensure the effect of unbiassed power of freedom. Based on that, two terms introduced from the totalitarianism, represent a foundation on which lies a hypothesis that identifies the meaning of the two globalitarianism's factors which are observed through a prism of today's digital social connectivity: (1) Latent structure of mass conscience; and (2) Permanent terror of irrational rationality. The results of previous research processed in published papers, [12-18] confirm the possibility of implementation in other areas. Considering that a way/goal of an action is much more important than any conscience manipulation, the modern ideology of mass digital society directs attention into the virtual reality which appears as a cultural totalitarian reality [19-23].

3. Globalitarianism as a system

In all totalitarian regimes, morality collapsed and became a mere habit and a custom with catastrophic consequences. Those who were the culprits of totalitarianism and those who remained quiet and accepted the situation, although they had an opportunity to speak up, but chose not to, are equally responsible. Moral behavior is not understood by itself, because a man is influenced by an example. And he reacts based on his own judgments. Using the new intelligent and interactive technologies in digital social networking, a human becomes less and less responsible towards himself. If he lost self-respect and started to despise himself, he wouldn't be able to act in his own interest and towards his own self-improvement anymore, and therefore he would not be able to take care of others.

If global is observed as a system (lat. *globalus),* which relates to the whole planet, with stress on absolutely strict centralistic and birocratic unity as unitarism (lat. *unitus*), then acronym is globalitarianism.

The ideology of intelligent technologies in today's digital society is becoming the means/purpose of a regime and it will cause much worse things then brutality of terror because the historical memories are fading away. Digital social connectivity created by intelligent technologies is close to a violence policracy. That Lars Rensmann's term is connected to a totalitarian state as a pluralistic non-state and paradoxically to self-understanding of everything that doesn't have an analogy in history. A problem occurs when every system (economic, political, cultural) is observed as totally rational and technically perfect, and states as communities of the global world organize the entire life of their citizens and depoliticize members of the birocratic management machine. The modern societies have become mass machinery of consumption fabrication. Technology and science together with a mass consumption culture make those societies dehumanized production plant which is going to use the system of globalitarianism as a process.

3.1. Modeling

When using a search algorithm to select dominant axioms from the Glasser's Choice Theory (CT) which is described by 10 axioms [24], then they could be presented as "Model 4P" where 4Ps are: need, action, behavior, and acceptance (cro. *potreba, pokretanje, ponašanje, prihvaćanje*). The model could also be applied to an evolved captological "3P" model, where 3Ps are: persuasive, permissive, and pervasive.

In "3P" model persuasive is captological, (*Captology = Computer As Persuasive Technology*), and that is presented through the Hermeneutic circle where the Choice Theory will be complemented by four Wilber's modernity quadrants. The circle would consist of a sequence of information, control, time, and freedom. A coincidence between the Hermeneutical circle from the Choice Theory [24], and the level of Wilber's halons [25], where I, "ME" stands for intentional, "WE" for cultural, "THIS" for social and "THAT" for behavioral, is integrated in a role of persuasiveness in totalitarianism, which model will be used to provide adequate parameters in Figure 2.

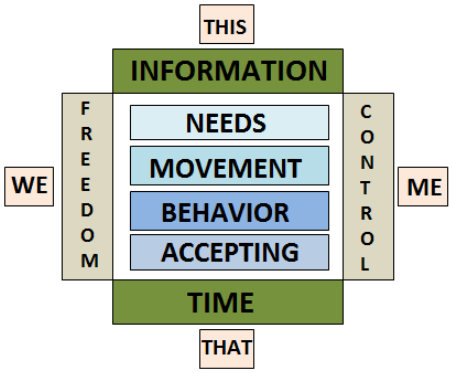

Figure 2: The dominant axioms of Glasser's Theory of Choice and Wilber's modernity for the treatment of totalitarianism with cognitive cybernetics

Processing with the help of the cognitive and cybernetic inter-operability is based on the technical possibilities of the practical search system with adapted communication which are basically:

Syntactic: because they allow systems to communicate and exchange data in specific formats and communication protocols (XML; SQL standards, ASCII formats, including lower format levels of alphabetic signs). Letters treated as a multi-referential sign point out to the order, which is related to the alphabet syntax, and is different from one manifested, and follows the combinations and permutations logic, which in a word and a text display crypto semantic traces, and acquire a visual profile in their interpretation and shape. That way their construction, while inscribed in the order of meaning, determines the literal manifestation of the analyzed text that carries a specific meaning. Storing it into a database provides a memory which preserves the

media, communication, transparency, and uniqueness of the characters. The letters are given the power to repeat in memory what has previously been established, guaranteed and unquestioned.

Semantic: as it allows for automated and meaningful interpretation of exchanged data for accurate formatting of results. The final use of the exchanged information of all involved parties is enabled by a reference model. The exchanged content is unambiguously defined by the original template PETAP, (hrv. *Pomoćni Eminentni Tekst Aplikativne Paradigme*) [23-30]. That template as its name suggests is "eminent text" that: a) serves for a presentation of the fixed sense; b) opens / reveals possibilities for understanding; c) cannot be predicted in advance; and d) has a character of actuality. The actuality emerges as an example of a probable occurrence of reality, as created in cognitive processing by reading and thinking by which a fixed experience of understanding is gained. That way presenting of the fixed thought content means "the presence of an existing" which could objectively meet the normative requirement. It is the same product that is repeatedly appearing in the search stages focusing on it in order to achieve verified meaning and understanding. The fixed content is conditioned and limited by the same thing, and when it was saved (without an ability to escape), that condition modeled on the hermeneutical approach becomes cognitive learning of its own character manifestation saved through technical and general functional forms. Superior cognitive interoperability refers to the cognitive collaboration of different systems, individuals and organizations which besides technical systems cognitive engineering is also taking into consideration social, political, organizational, chronological, biological, psychological and plausible factors. The processing modeled on computer metaphors and terminology is at the end completed with the original algorithmic model MOKSA (hrv. *Model Opservacije Konvolucijsko Separacijskom Analogijom*). According to this model, a mathematical function of convolution with all its characteristics of linearity, commutativity, and associativity is calculated similarly to correlation by mirroring one of the functions [31].

The application of the search and processing tools based on the expert system principle results in the available databases and knowledge bases. Searches that begin by analyzing and specifying requirements for knowledge bases and databases with well-defined need are crossing over into creating applications attempting a search using the learning agents' experience. An action initially begins in an unknown environment, so learning elements are used in the search process and the performance elements are formed by the evaluator and task generator. As the search gains more knowledge, the action becomes better and safer. The Data Collection Model has enabled upgrading in accordance with the acquired knowledge and needs, which were also empirically enabled by using relations and user forms in inputting and reviewing databases and formatting reports. Presenting and fulfilling the sense of the search is close to the cybernetic forensics and a base for presented understanding, which is fulfilled over the time, therefore searching and processing is to be completed by the cognitive synthesis and by reinforcing the concluding expertise.

3.2. Role of Persuasion

Persuasion (lat. *persuasio*) is connected to a form of communication seeking to influence judgments, attitudes, beliefs, or actions of an individual. As part of the persuasion acronym captology (lat. *Persuasibilibus = lured),* refers to being lured by the intelligent interactive computer technologies which also represents the form of communication. A form of communication that conveys information through the media represents propaganda. Extensive researches reveal that some forms of propaganda serve to inform, to persuade or in some more complicated synesthetic way to occupy human life in order to draw attention. The word propaganda dates from 1626 when a Christian community *Sacra congregatio Christiano nomini propaganda* has appeared, founded with the purpose of expanding Catholicism and regulating church relations in non-Catholic countries. More recently, since 1920, it has been used as methods of broad political industrial consciousness and a way of articulating ideological field of action although it is not an ideology itself. Propaganda linked to the development of technical (new) media, for which it has been proven to serve as a massive manipulation of feelings and attitudes.

This fact was disclosed in 2000 based on the research carried out by Manstead, Fischer, Kardum, and Larsen [32]. By setting up a mood control system, described by the cognitive cybernetic system, Larsen found that personality is a dynamic system within an individual which by its psychophysical parameters can adapt to a specific environment, and can also be affected by the environment. Every current state of the individual is his current mood, which Larsen found is modeled after potential mechanisms of individual differences that are in fact his mood regulators. An individual pursuit to achieve and maintain a good and comfortable mood and a positive attitude include the existence of negative feedback in the regulation model. Any action to reduce a difference appearing in the disadvantage of the good mood could be influenced by the strong cultural matrix in which the medium acts, and which could contain the immediate environment disturbances. This is particularly apparent in the totalitarianism where the masses believe in a new culture of organized lies. The problem is a double morality due to the personality philistine profile dominating in such an environment. Additionally the destruction of people's privacy and personal moral continually redefines individual identities imposed by the society as an escape from the social identification. Recruiting from such a mass of seemingly uninterested people, who many consider too apathetic and have already given up on them, allows for an introduction of completely new methods in propaganda and for ignoring of adversary arguments.

The future model as a system functions based on an assumption that the desired mood is to be achieved by comparing the current mood with the one to be achieved, and could be misleading because of not recognizing the desired state due to strong influence of Parameters, (Pi), Mechanisms, (Mi) and Strategies (Si).

The strength of the media is exactly in its appearing as affectively relevant environment, which is confirmed by McLuhan's 1960's anthropological technological determinism [33] in Figure 3.

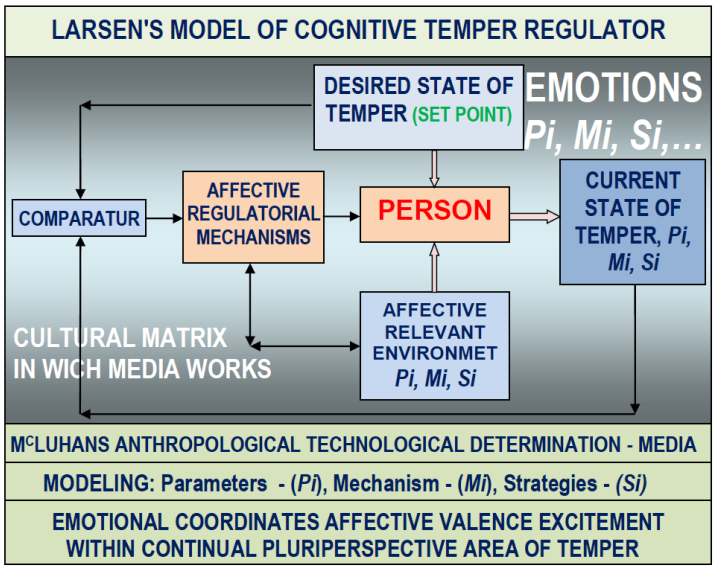

Figure 3: Model of cognitive temper regulation by Larsen and McLuhan's anthropological technological determinism

3.3. Mass Man's Parameters

The early 19th century's predictions pointing to the emerging of a mass man and the arrival of a mass era came true in the twentieth century. Besides the psychology of the European mass man, the profile of the mass man, gained increased importance, by unexpected and unpredictable phenomena such as:

- a radical loss of personal interest in everything that surrounds him,
- cynical and decadent indifference when encountering disasters or other personal catastrophes and even the death itself,
- the passionate tendency towards the most abstract concepts as life ideals,
- general disgust towards any events,
- loss of criteria even towards the most obvious rules of common sense.

Such an apathy, as a feature of totalitarianism, is today's plague called anhedonia. Search implementation based on the results of the modern analytical ontology is successful primarily because of the theory of general categories, which uses a data format to also present a concept. The formats/concepts that are used are for example person, personality, event, and event as a happening. The transition from a possibility to reality is an ontology of real events for which ontological research expands even to the relationships that people have with each other.

Therefore the conceptual modeling has encompassed characteristics determination of the presence of space and time using a classic relational model, whose basic concepts are structure, constraints and set of operations.

All existing real foundations from the early thirties of the past century are attributes of today's virtual realities that are rapidly streaming towards globalitarianism. The research-based premises have proven to be identical principles of establishing a framework for sustainability and goals of totalitarianism and globalitarianism in Figure 4.

TOTALITARISM	GLOBALITARISM
LEADER / initiator	INTERNET / initiator
PARTY / nebulizer	SIMULAKRUM / nebulizer
TOTALNARIAN STATE – MASS followers, supporters	"GLOBAL VILLAGE" – MASS followers, supporters
PROPAGANDA	PERSUASION

IDENTICAL PRINCIPALS OF ESTABLISHED FRAMEWORK

FASCINATION – as a social phenomenon
FANATISM – overly fascinated socjety
IDEALISM – experiences of created community
SOCIAL MOVEMENT FRAMEWORK – followers, identification
CONFORMITY – modern opinion chaos

IDENTICAL RESILIENCE FACTORS

- lack of critical thought
- unyielding persistence
- videospread convictions
- true followers unselfishness
- exceeding every real experience
- cancelling every immediate personal interest
- increasing apologetic – nostalgic approach
- increasing psychological – nostalgic attitude
- modern opinion chaos
- general condemning of moral norms
- crown mentality

IDENTICAL GOALS

- **SUPERFICIAL DEPOLITIZATION AND NEUTRALIZATION OF POLITICS**
- **LATENT STRUCTURE OF MASS CONSCIOUSNESS MANIPULATION**
- **MODERN IDEOLOGY OF MASS SOCIETY WITH TARGETED ATTENTION**
- **SOCIETY AS A TOTAL MONITORED GROUP FOUNDED ON WORK AND TECHNICS**

Figure 4: Comparison of totalitarianism and globalitarianism considering establishment premise, sustainability and goals

Instead of asking a question whether the ideology of terror, control, totalitarianism, etc., has a chance in the future, the successful search has proved that the "man of the mass" has, in fact, a problem of losing the social intelligence and functional connectivity due to technological integration. In the example of the ontological creation of the concept of persons, personalities, and events, the comparative studies of Buyse and Larsen, 1979 and Dunbar and Spores, 1995, confirm the structure of a man as a social being created through contact at the expense of social intelligence. Described examples of totalitarianism confirm that policies were consciously developed by a steadily increasing number of sympathizers with the controlled number of movement

members (parties). Totalitarianism's theoretical background modeling *today's digital social connectivity* (3SC), (hrv. *današnja društveno digitalna sprega* -3DS) has confirmed these premises.

4. Conclusion

The real function of the totalitarian matrix is the ingeniously finding members' illusion towards sympathizers. Actually, the movement has carefully recruited its members by establishing an internal gradual hierarchy in order to avoid indoctrination. The outside world viewed as "normal", considers sympathizers as innocent fellow citizens in the non- totalitarian society. In that formation an anonymity greatly contributes to the unusual phenomenon of the mass easily manipulated, because of being too lazy or not brave enough, and always under the pressure of constant "moving", because it is known that the movement has no plan, but as the word itself says, "must move".

The problem is multiplied by the fact that today's digital social connectivity became imperative in creating curricula, plans, and strategies of modern education. There are very few studies which could differentiate the effectiveness of this novelty, and even less professional and scientific reviews of verified problems [34, 35].

On the contrary, today's digital social connectivity has negative effects on the younger population whom it deprives of very much needed mental creativity [36, 37]. It has been emphasized in the introduction that the temporality of history has been slowed down by indifference and astonishment, which are some of the selected parameters studied by cognitive cybernetics, in revealing the man of the mass globalitarianism [38, 39]. This problem repeatedly occurs in philosophical reflections and futuristic predictions [40]. Statistical data collected for the Big Data model through historical and current reality as results of the research conducted with the help of cognitive cybernetics about the "mass" factor from the theory of totalitarianism are the subject of processing for the next scientific paper. Using search correlation, models and algorithms have confirmed a suspicion that intelligent interactive technologies impact the changes of the human psychophysical structure, through the digital social network of globalitarianism.

Conflict of Interest and Funding

No conflict of interest was reported by the authors. This work was supported by the AEROING d.o.o. Zagreb, Croatia, Europe and ELOS d.o.o. Split, Croatia, Europe as the partners and co-founders of the Institute for Cognitive Cybernetics Eastern Europe, Zagreb, Croatia.

ABSTRACT

Traditional crossroads use traffic lights, but may cause delays due to its stop and wait process. Moreover, autonomous vehicles are being made, although it is not yet mass-produced. This work presents a design and implementation of an agile system that communicates and coordinates autonomous vehicles entering the intersection by adjusting their speeds and maneuvers to avoid collisions, allowing them to weave and pass through intersection traffic and avoiding them to completely stop, leading to an increase in the throughput of the intersection, and therefore reducing congestion. A centralized computer implements agile communication and controls the system based on a first-come-first-served policy. The hardware implementation emulates four prototype vehicles modeled as radio-controlled cars integrated with an ultra wide band (UWB) localization technology. The cars were used to simulate the passage without collision in a typical four-way intersection. Pozyx UWB modules were chosen for tracking the vehicles due to its compatibility with Arduino as well as its numerous other functionalities and accuracy relative to other indoor-positioning systems. Results show that Pozyx could track autonomous vehicles. The study resulted in a system that can control self-driving cars through the intersection with key measures. Moreover, the characterization of Pozyx in this hardware implementation was observed.

1. Introduction

Traffic problems have risen with the increase in vehicles, users, roads, and crossroads. Numerous traffic delays and accidents occur in various locations, and one of the most concerning of these is crossroads. Smith [1] said that almost forty percent (40%) of all crashes in the United States involves crossroads, and about 165,000 accidents occur annually in crossroads caused by red-light runners. Crossroads are designed to lessen accidents, traffic congestion, and increase efficiency, but these become a source of problems. Erring drivers, vague navigation signs, and blind curves are some of the reasons for these. Although the installation of stoplights and various signs at crossroads are seen as solutions to these problems, these devices have not been as effective. These devices are not so good for traffic calming, and this meant that these may make the flow of vehicles better but not necessarily safer for drivers [2]. Accidents increased when traffic signals were introduced, and these devices are not the solutions to less dangerous roads [3]. Proposals to solve these problems include the introduction of autonomous vehicles (AV) and intelligent intersection management, but there have been very few implementations in actual situations. Communication between AVs and road infrastructure is also important to ensure road safety [4]. Moreover, AVs can be enhanced to intelligent vehicles by adding high technology features like efficient 3D road map exchange in real-time for navigation and localization [5]. The study plans to address the problems of accidents and traffic congestion at crossroads using prototype AVs with attached Pozyx whose speeds and turns are controlled by a centralized control communications system. Pozyx [6]–[10] modules are ultra-wide band-based devices for localization. In this paper, vehicles are referred to as autonomous, which is also known as self-driving cars. The use of Pozyx was

*Corresponding Author: Lawrence Materum, 2401 Taft Ave., Manila, Philippines, +6325244611, lawrence.materum@dlsu.edu.ph

also characterized in terms of accuracy and delay for tracking and localization of AVs.

In crossroads, vehicles must coordinate their movements to pass through without collisions. In an ideal situation, vehicles would only have to accurately adjust their speed and direction to create a sufficient duration for the intersecting vehicle to weave through without stopping. Furthermore, the vehicles should be able to process and execute these maneuvers with high precision and minimal delay to avoid collisions. Unfortunately, the current system in crossroads is traffic light-based where vehicles have to stop and wait for intersecting vehicles to pass. Vehicles are needed to stay idle when their road is asked to stop, interrupting their journey. At present, almost all vehicles are operated by humans, but in the future, the proliferation of AVs can be seen, and this is the context of this study. The focus of this paper is on the use of Pozyx for communication and localization of autonomous vehicles through a central computer system so that they can pass in crossroads without collision.

This research on autonomous intersection management helps address traffic-related problems and congestion at crossroads. The modified and programmed autonomous vehicles would be able to adjust their speeds at crossroads without stoplights resulting in a more efficient flow of traffic and a decrease in traffic congestion and accidents. The software algorithm in the centralized system determines the speed of each car passing the crossroad and calculates the appropriate angle of turn for each of these vehicles so that collisions would be avoided. The centralized system communicates with each of the vehicles to allow the flow of traffic at crossroads to be orderly and continuous, and thus, would save time. With the increase in research about autonomous and intelligent vehicles, this study is an add-on with its contributions such as agile control software for collision avoidance of AVs using a first-come-first-served (FCFS) tile-based approach with graphical user interface (GUI), and its hardware adaptation of collision avoidance in small-scaled miniature AVs with attached Pozyx for tracking and localization.

It is assumed that connection quality between the vehicles and the central computer is ideal in this study. The crossroad is also assumed to be initially free of obstacles such as foreign objects and road hazards. Four scaled-down controllable vehicles running simultaneously in a four-way two-lane crossroad utilizing a clover-shaped track free of obstacles were included in the scope of the hardware implementation. Moreover, the scope of the study includes a control system that monitors the velocity of the vehicles and performance measures of the system through its vehicle throughput. The study is delimited by the following: human-driven vehicles are not factored in, the vehicles do not abide by the SAE Level 5 definition of driving automation [11], and the cars cannot recognize foreign obstacles which are any object that is either not an element of the track or another object not running as part of the system.

The system has two main parts: the software algorithm and hardware control system. Its overview is illustrated through a block diagram shown in Figure 1. The system is described as agile since it is meant to quickly react and adapt to vehicles entering the crossroad and managing it according to the other vehicles. Moreover, it is then described to be collision restrained as it would avoid letting cars collide in the crossroad. This means that if there are multiple vehicles with current trajectories expected to collide, the algorithm adjusts their velocities to avoid this potential outcome. The software runs the crossroad algorithm and the communications interface. The control communications system deals with the controllers of the scaled-down motorized cars which are referred to as 'vehicles.' The microcontrollers would have their own wireless communications module that uses either Bluetooth or Wi-Fi. Moreover, the tracking and location features were added through Pozyx. This control communications system is responsible for taking in data from the different sensors of the vehicle and relaying the information to the agile control communications. They also control the motors for the instructions sent back. The actual hardware of the project is focused on the vehicles and their sensors.

The system is tested to measure its vehicle throughput. In each trial, the authors adjusted the number of vehicles active and running on the track to change the load on the crossroad. Varying the load on the crossroad would account for real-life situations such as rush hours. The recorded delay is the time it takes from sending a reservation request to exiting the crossroad. They then adjusted the average speed of the cars and then further recording the delay of the cars, as well as the chances of collisions. Using the data gathered from the trials, linear scaling was performed to see how the data would project to real-world cars and crossroads.

This paper is organized then as follows. Section 2 gives further details of the design of the overall system, and its corresponding components. Section 3 provides the results of the design, and lastly, Section 4 concludes the paper with recommendations for future work.

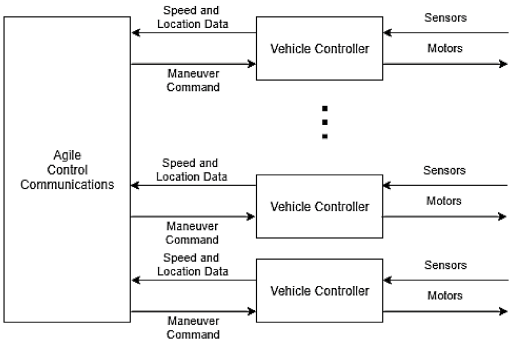

Figure 1: Block diagram of the control system.

2. System Design and Methodology

2.1. Pozyx

Pozyx is a UWB-based real-time location system utilizing both hardware and software to be able to provide accurate positioning information with an advertised accuracy of up to ten (10) centimeters compared to other traditional indoor location tracking systems, such as Wi-Fi or Bluetooth which are accurate within several meters [6]–[9], [12]. This localization is achieved through the use of UWB technology combined with smart filters as well as machine learning, thus, allowing positioning to be done even in indoor environments without a clear line of sight to the reference points. To obtain precise and accurate positioning, two-way ranging is done between the Pozyx tag and at least three

reference points, or Pozyx anchors, followed by trilateration. These anchors are ideally spread out as much as possible and placed at the corners of the space in which location tracking will be performed to get the most reliable data. The anchor may be reprogrammed to work as a tag as well and does not need an Arduino to function as it is designed to operate on its own.

The Pozyx tag is an Arduino compatible shield which makes use of Pozyx anchors to provide accurate positioning as well as other types of data such as its orientation using its 9-axis inertial measurement unit. It is also equipped with different sensors along with a UWB transceiver based on the DW1000 UWB-chip from Decawave which, in addition to performing ranging, can also be used for wireless messaging. Figure 2 displays the pinout of a Pozyx tag, whereas Figure 3 for the anchor. Pozyz interfaces with Arduino through I2C communication. It can also interface with Raspberry Pi through a micro-Universal Serial Bus (micro-USB).

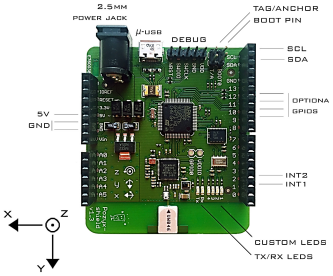

Figure 2: Pozyx Tag Pinout [6]

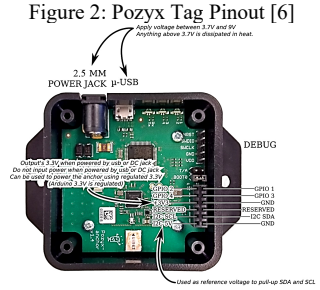

Figure 3: Pozyx Anchor Pinout [6]

For this study, Pozyx was chosen to be the basis for tracking the RC Cars due to its compatibility with Arduino as well as its numerous other functionalities and accuracy relative to other indoor-positioning systems. In addition to being easy to set up for most indoor environments, it also provides different possible configurations to optimize its performance to meet the desired need whether it be accuracy or speed. Figure 4 provides visualization on how the location of a Pozyx tag is obtained about the anchors as well as to the Master Pozyx tag. It may be seen that each Pozyx tag does not automatically provide its location as it only does so when it is asked first. Once asked, it will then calculate its location using the four Pozyx anchors as a reference at which point, the tag then finally sends its position data back to the Pozyx master.

2.2. Arduino Uno

The Arduino Uno acts as the brain of the RC car as it processes commands received through Bluetooth as well as utilizes the connected Pozyx tag to perform the necessary maneuvers to ensure that it follows its intended path.

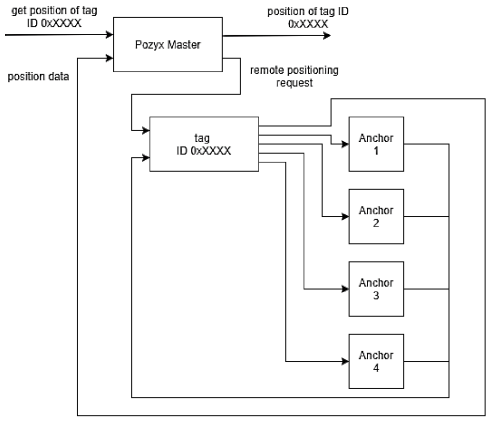

Figure 4: Pozyx Block Diagram

2.3. Radio-Controlled Car

A Radio-Controlled (RC) car is a battery-powered model car which can be controlled by remote control, mostly done through radio, hence, the term ”radio-controlled”. These RC cars represent a scaled-down model of real cars. A typical RC car has a receiver that captures radio signals from its remote control. To simulate the algorithm and adapt it into hardware, RC cars are used. In this research, the cars were modified by adding different modules to their parts. A location module is added to track the car’s position, and the RC communication is replaced with a sophisticated communication module. A microcontroller is added to manage the modules and control the car. The movement of the RC car is driven by motors. A motor driver is used to interface the microcontroller and the motors providing motion to the RC car. The motor driver in the system is powered using a power bank separate from the microcontroller circuit. The motor driver chosen for RC cars was the 2-Channel Tiny DC Motor Driver from e-Gizmo based on Allegro’s A3906 low voltage dual DC motor driver IC.

2.4. FCFS Software

The tile-based first-come-first-served (FCFS) policy, developed by Dresner and Stone [13], is the basic reservation system. ACC applies the FCFS approach for the reservations of vehicles, meaning that vehicles that requested a reservation will be entertained first. When another vehicle requests for a reservation, it will be checked first from vehicles that had made successful reservations earlier. A centralized computer provides coordination by communicating with AVs and managing their reservations. When a vehicle sends a request, the ACC simulates as if the vehicle will pass through the intersection. The reservation is tile-based, in which collisions are detected if a vehicle occupies a tile reserved by another vehicle. If at least two vehicles occupy the same tile, which would result in a collision, the request is rejected. Otherwise, it is accepted. The significance of adopting the FCFS is its versatility because it can be extended to be used in many different purposes in autonomous intersection management.

2.5. Car Simulation

The car runs on a program independent of the ACC. For reservations to commence, the car software and the ACC, which employs the FCFS algorithm, must exchange information. The

ACC follows the principle of Autonomous Intersection Management [14]. The simulation of the cars would maintain minimal communication complexity. After the reservation, it is the responsibility of the car to meet the reservation at the correct time and place.

2.6. Pozyx in RC Car

In modifying the RC car, an Arduino was added. The Arduino was interfaced to a Bluetooth Module through Universal Synchronous-Asynchronous Receiver-Transmitter (USART), and two motor drivers that power the motors. Two 5 V, 3600 mAh power banks, energize the Arduino and the motors. Moreover, a Pozyx tag is attached to the Arduino, which communicates with it through I2C. It does the job of accurately locating and tracking the cars through UWB. The Pozyx localization system employs four reference anchor modules, with one of the anchors interfaced with an Arduino that is connected via a serial interface to a computer that runs the simulation software. The Pozyx tag relays the location of the car where it was attached. It also orients the car at an angle from 0◦ to 360◦. The Bluetooth BLE HM-10 module receives commands which the Arduino module then decodes. The decoded instructions determine which of the two motor drivers activates the corresponding motor driver depending on the received instruction. The two motor drivers present in each RC car are responsible for controlling both its steering and acceleration depending on the instruction decoded by the Arduino with one motor driver handling the steering motor and the other handling the throttle motor. The components are interconnected as shown in the block and circuit diagrams of the RC car illustrated in Figure 5 and 6.

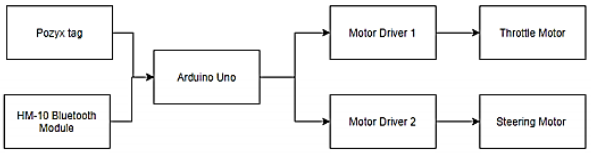

Figure 5: RC Car Block Diagram

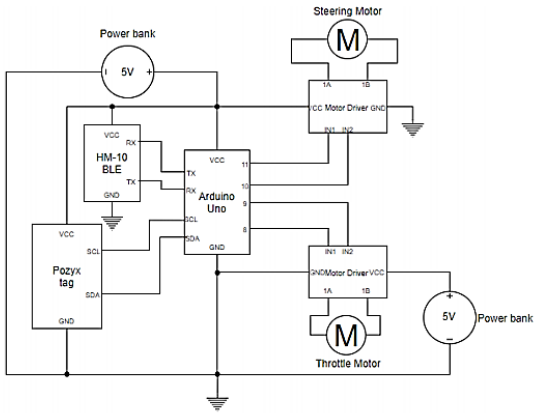

Figure 6: RC Car Circuit Diagram

2.7. Communication Protocol

The communication protocol is the medium at which the software running on the computer can interface with the Pozyx modules as well as issuing commands to the AVs. The study has opted to make a standard protocol that handles the execution of functions as well as sending data to and from the central computer software and the hardware controllers. Although there are several uses for the protocol their format is similar regardless of whether they are between the data collection of the Pozyx or the command issuing for the cars. Between the computer program and the connected microcontrollers that handle Pozyx and Car communication, the format of their messages are as follows: preamble, length, message type, and data. The preamble is a predetermined set of bytes used to indicate to the receiver that a message is incoming. Next is the length byte. It is a single byte used to indicate the length of the entire message. This can vary depending on the number of bytes used for sending data if applicable. Additional details can be found at [6].

2.8. Scaling Method

The method used to establish the scaling between the RC car and an actual vehicle is based on the turning radius of the RC car instead of its dimensions. This is because it was observed that its steering angle is much larger than that of life-sized cars which resulted in the RC car taking wider turns than what was expected based on its dimensions. As a result, the dimensions of the test track are based on the turning radius of the RC cars, the resulting dimensions of the car, as well as its speed in simulation, would be proportional to the ratio between its turning radius and the average turning radius of most common midsized passenger cars today of 17 feet or 5.18 meters [15]. After the computation based on Equation 1, a scale factor of 15.94 was obtained. The scaling process is illustrated in the block diagram in Figure 7.

$$\text{scale factor} = \frac{\text{actual turning radius}}{\text{RC car turning radius}} \quad (1)$$

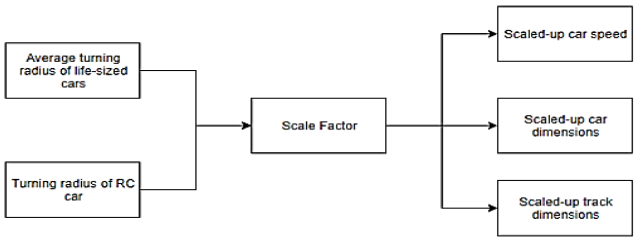

Figure 7: Scaling Process Block Diagram

2.9. Materials

The materials used are summarized in Table 1.

Table 1: Materials

Component	Quantity
Arduino UNO	4
Pozyx developer tag	5
Pozyx creator anchor	4
3600 mAh power bank	8
2-Channel Tiny DC Motor Driver	8
RC Car	4
HM-10 BLE Module	8

2.10. System Block Diagram

The entire system block diagram is shown in Figure 8. The inputs of the system are user interface (UI) inputs, track dimensions, and car initial states. The center shows the various processes that run in the software which process all the data from the inputs and produce the corresponding outputs. The main outputs which correspond to the key measures of the project are UI output, car motion, number of collisions, and duration in the crossroad.

3. Results, Analysis, and Discussions

3.1. Prototype Car

The resulting scaled-down model as shown in Figure 9 is twenty (20) cm in length and five cm wide, as it small enough to not require a large test track while big enough to mount all the components needed. The car was able to fit all the components in its shell but would likely negatively impact the Pozyx tag's connection to the nearby anchors due to the shell preventing a good line of sight. Discovering that Pozyx had more accurate results if it was elevated higher from the ground, long thin sticks were used to prop it up. The car goes through different types of movements and vibrations during testing, and thus, the components and their connections to each other must be secured. Therefore, connecting wires to motor drivers must be directly soldered, as seen in Figure 10. The motor drivers and power banks were also attached. The resulting characteristics of the four prototype cars are shown in Table 2. With the same throttle level, the four cars have different speeds. This variation in average speeds is less than ideal when compared to the perfect scenario of having all four cars perform the same at each throttle level. It was also observed that the measured average car speeds on later trials were generally slower compared to the earlier trials. This indicated that their speeds decrease as they are used due to the car's power banks being discharged.

Table 2: Car Speed Characteristics

Throttle Level	Average Speed (m/s)			
	Car 1	Car 2	Car 3	Car 4
100	1.456	1.318	1.281	1.486
90	1.394	1.235	1.218	1.398
75	1.09	0.942	0.919	1.222
60	0.878	0.57	0.722	0.985
50	0.618	0	0.294	0.666

The four prototype cars running simultaneously in their physical track with specified dimensions are shown in Figure 11.

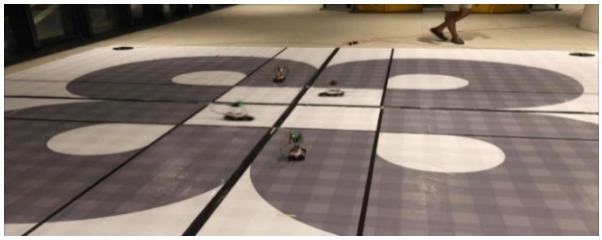

Figure 11: Test track

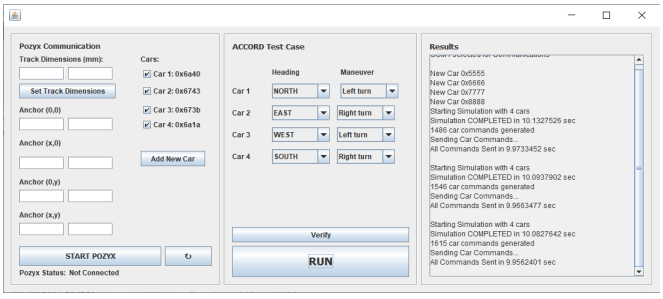

Figure 12: Graphical User Interface

3.2. User Interface for the Control

The graphical user interface (GUI) of the system provides the users with an easy way to set up and initialize the hardware and

setting up the parameters for each test case. The latter function specifically assigns the initial locations of the car as well as injects them with the turn maneuvers that they will execute later during run time. As shown in Figure 12, the GUI window is divided into three sections, Pozyx Communication, Test Case, and results.

3.3. Control Capability Results with Pozyx

Pozyx is used to locate and track cars in real-time. It gives position and orientation to the system which helps it determine the speed and steering required by each car in the track. One of the most important functionalities of the Pozyx is providing the software program with real-time accurate position and orientation for the program that determines the speed and steering for each car in the track. However, the Pozyx updates are too slow in comparison to the speed of the cars reducing the accuracy of tracking the cars as they cross the intersection. The issues encountered with the Pozyx are about location accuracy and delay in updates. The company that sold the Pozyx modules listed a location accuracy of 5 to 10 centimeters while the update rate for each tag was 16 milliseconds. However, the data obtained in the study did not match these characteristics, leading to numerous problems in the performance of the system and the run of each car in the track. The authors performed tests using one Pozyx tag at a time followed by multiple tags to determine the accuracy of Pozyx and the consistency of its performance. The important factors that were observed were the accuracy and delay in the results provided by Pozyx. For each test, the Pozyx tags were placed in a location within the Pozyx anchors. The location provided by Pozyx was compared to the actual location to evaluate the accuracy of Pozyx. Fifteen tests were performed for one Pozyx tag at a time, while one test was performed that used four Pozyx tags simultaneously. The authors were able to note some issues regarding the Pozyx accuracy by testing the Pozyx tags. In the tests done for one tag at a time, the error for accuracy showed a range of 10 to 40 cm, and there were some cases where the delay reached more than a second between updates. There were also cases when no data location was shown for an update, and some of the location data freeze between updates. It was observed that there was a different location for the tags in each test. These location points were chosen based on critical points that tested the functionality of Pozyx in terms of accuracy in data location. Moreover, the test was done on four tags and the delay was more than 0.2 seconds and the error is from 20 to 50 cm for some tags. The graphs of the differences and deviations are shown in Figure 13 and Figure 14, respectively. In the system, accuracy and delay are very important factors in determining the speed and steering for each car. Hence, when the system receives location data that is not accurate, there will be many problems in the performance of the system and movement of the cars. In addition to receiving larger location inaccuracies than was expected, there were also numerous instances of outputting negative location values implying that the tag being located was out of bounds when it was not in reality. This can be seen in Figure 15 wherein Pozyx outputs Y coordinates that are nearly half a meter off in some instances from its true value of 300. Frequent positioning errors as shown in Figure 16 can also have a severe impact on the system in terms of adding to delay as it takes more than a second for Pozyx to recover from the aforementioned error and report a more accurate value. This is further exacerbated when four Pozyx tags are being located simultaneously as the already large average delay between updates of 200 milliseconds is made worse due to even larger delays between updates.

4. Conclusions and Recommendations

This work involves software design and hardware adaptation of collision avoidance of autonomous vehicles simultaneously crossing an intersection. Hardware implementation was done by using small-scaled RC cars with attached Pozyx where test cases were done. The accuracy of the Pozyx was tested and verified. Upon running the various test cases to verify the system with different car placements and maneuvers, it was observed that the Pozyx module had issues in location accuracy and delay between updates that impede in determining the accurate location of each car in the track.

Recommendations include incorporation of machine learning in AV and autonomous intersection management, implementation of software simulation in different programming languages, an

extension of hardware implementation on large-scale vehicles, and to some extent, real vehicles and crossroads. Moreover, it is suggested to use uninterrupted, fast, and accessible communication technologies. Communication among AVs with the central computer system can be extended by using accurate and efficient road map data exchange and cloud databases. Expanding the model of the car's movement from linear acceleration to a more dynamic model would greatly improve the accuracy of the resultant predetermined coordinates, and consequently, more appropriate car commands. Besides, more sensors that can keep track of attributes not necessarily related to motion would be a useful feature.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Most crossroads use a traffic light to communicate between human-driven vehicles by conveying to the drivers when to stop and when to proceed in an organized fashion. However, the stop and wait nature of traffic lights cause slower mobility, leading to congestion. This paper presents a localization scheme based on two-dimensional (2D) flat geometry adaptation of collision avoidance of autonomous vehicles simultaneously crossing an intersection. Using a first-come-first-served policy with tile retrieval process, the collision reduction performance was evaluated through a unit test. Four self-driving prototype cars were made with the desired functionality of controlling the speed and maneuver. Through the predetermined 2D grid locales, simulations indicate the system that can control the self-driving cars through a crossroad with zero or minimal collisions using key measures such as time duration in the intersection, average speeds of the cars, and collision count.

1. Introduction

An increase in the number of cars, roads, and crossroads over the years brought problems related to traffic flow. Numerous accidents and traffic delays occur in various locations, and one of the most concerning of these is crossroads. Smith [1] claimed that almost 40 percent of all crashes in the United States involve crossroads, and about 165,000 accidents occur annually in crossroads caused by red-light runners. Though crossroads are designed to lessen accidents and traffic congestion, these become sources of problems. Some of the reasons for these are confusing navigation signs, erring drivers, and blind curves. Though the installation of stoplights and various signs at crossroads are perceived as solutions to these problems, these devices have not been effective. These devices are not so suitable for traffic calming, which may make vehicles' flow better but not necessarily safer for drivers [2]. Accidents increased when traffic signals were introduced, and these devices are not the solutions to less dangerous roads [3]. Proposals to solve these problems include introducing autonomous vehicles (AVs) and intelligent intersection management, but there have been very few implementations in actual situations. The authors plan to address the problems of accidents and traffic congestion at crossroads using prototype vehicles whose speeds and turns will be controlled by a centralized control communications system. In this paper, prototype vehicles are referred to as autonomous, that is, self-driving cars. Ho, et al. [4] studied AVs with added high technology features like efficient 3D road map data exchange in real-time for navigation and localization. The study [5] worked on an efficient information dissemination system of 3D point cloud road map data (3DMADS) for intelligent vehicles and roadside infrastructure integrated into a vehicular fog computing architecture, which was validated with empirical mobility traces, 3D Light Detection and Ranging (LIDAR) data, and an experimental multi-robotic testbed. Moreover, communication between AVs and road infrastructure is vital to ensure road safety. A study [5] proposed the Road Map Data Encoding and Dissemination System (REDS), which considers roadside vehicle information through index coding of point cloud-based road map data. REDS was evaluated in a four-way junction scenario and was shown to improve overall data efficiency.

In an ideal situation, an autonomous vehicle's path from its position to its destination would be straightforward, with no interruptions or obstacles. However, current roadways require paths to intersect with other roads, and therefore, vehicles coming

*Corresponding Author: Lawrence Materum, 2401 Taft Ave., Manila, Philippines, +6325244611, lawrence.materum@dlsu.edu.ph

from different parts of the crossroad must coordinate their movements to pass through without collisions. In an ideal situation, vehicles would only have to adjust their speed and direction enough to create sufficient duration for the crossing vehicles to weave through without stopping. The vehicles should be able to process and execute these maneuvers with high precision and minimal delay to avoid collisions. Unfortunately, the present system in place in crossroads is traffic light-based, where vehicles have to stop and wait for crossing vehicles to pass. Vehicles are needed to stay idle when their road is asked to stop, interrupting their journey. Currently, almost all vehicles are operated by humans, but AVs' proliferation can be seen in the future, and this is the context of this paper. One primary objective of this work is to design and implement computer control to avoid a collision in crossroads without traffic lights.

The assumptions in implementing this paper are as follows: the connection quality between the vehicles and the central computer is ideal, and the crossroad is initially free of obstacles such as foreign objects and road hazards. The scope includes an implementation covering a four-way two-lane crossroad, scaled-down controllable vehicles, utilization of a clover-shaped track, at least four cars running simultaneously, and a control system that monitors the velocity of the vehicles, and performance measures of the system through its vehicle throughput. The delimitations are: the paper does not factor in human-driven vehicles, the vehicles do not abide by the SAE Level 5 definition of driving automation [6], and the cars cannot recognize foreign obstacles, which are any object that is either not an element of the track or another object not running as part of the system.

The collision control is primarily based on a control system comprised of the crossroad algorithm and the communications interface. The algorithm is responsible for taking in the vehicles' telemetry data and deciding the correct course of actions in terms of steering and speed control. The paper adopted a first-come-first-served (FCFS) policy with an added tile retrieval process to the system. The communication interface handles the sending and receiving of data and commands between the vehicles. On top of the algorithm and the communications modules, the authors developed a data recovery tool that can be used to calculate useful statistics such as delay, number of cars per second, the car's real-time velocity during testing, and the like. This tool is used to monitor the car and check how the algorithm adjusts its speed. The data gathering tools contribute to measuring the system's performance and were interfaced with the communications module.

This paper is organized then as follows. Section 2 specifies the system and its simulation. Section 3 gives an analysis of the results. Finally, Section 4 concludes the paper.

2. System Design and Simulation

2.1. FCFS

The control system monitors the intersection and the vehicles crossing it. Vehicles communicate with the control system to obtain a reservation and cross the intersection without colliding with other vehicles. It is implemented using a tile-based approach and the FCFS policy. The control system applies the FCFS for vehicles' reservations, meaning that vehicles that requested a reservation will be entertained first. When another vehicle requests a reservation, it will be checked first from vehicles that had made successful reservations earlier. FCFS determines if vehicles will be reserved or not.

Conversely, FCFS results in determining which vehicles will cross the intersection first. Vehicles are entertained based on the order of requests sent; that is, the first vehicle that sends a request is served first, regardless of speed. The tile-based FCFS, developed by Dresner and Stone [7], is the basic reservation system. The significance of adopting the FCFS is its versatility because it can be extended to many different purposes in autonomous intersection management (AIM). The intersection model used is an n-by-n grid of tiles. Thus, the approach being "tile-based." In this model, n is called the granularity of the policy or the intersection's resolution. In implementing FCFS, the tile retrieval process is added. Using data structures and modular arithmetic, the tiles are retrieved starting from the vehicle's bounds, then to the inside.

2.2. Reservations

When the vehicle sends a request for a reservation, the control system receives the request and simulates the vehicle's path when it crosses the intersection. As the vehicle crosses the intersection in the control system, it occupies a set of tiles, which are then checked against tiles that had been reserved by other vehicles. If no more than two vehicles occupy the same tile, no collision will occur, and hence, the control system issues the reservation, and the vehicle, accepting parameters from the control system such as speed and acceleration, may now cross the intersection. Otherwise, the request of the vehicle is rejected. Reservations are managed by a map where the reserved path through the intersection corresponds with the ID of the reserved vehicle.

2.3. Car Simulation

The car runs on a program independent of the control system. For reservations to commence, the car and the control system must exchange information. The control system follows the principle of AIM [8]. The simulation of the cars would maintain minimal communication complexity. After the reservation, it is the car's responsibility to meet the reservation at the correct time and place.

2.4. Predetermined 2D Grid

A localization scheme, which the authors refer to as a predetermined 2D grid, is an alternative solution for determining the cars' location. The cars' path is determined by their states, such as their current steering and throttle power. In other words, the locations are preprogrammed into the vehicles instead of fetching locations in real-time. The car commands that correspond to an appropriate maneuver are defined by specific coordinates in the track and the car's motion state. Each car is given an initial state consisting of x and y coordinates, speed, orientation, and route direction (left turn, right turn, or straight). With each pair of x and y coordinates, there is a corresponding car command. In this way, accurate navigation results for cars crossing the intersection. These car objects are then passed through the system that

simulates the cars for a given time. The results are a predetermined set of coordinates and a set of car commands over time.

2.5. Track Generation

The physical track (Sec. 2.9) on which the cars would be navigating was recreated in the simulation with the same dimensions and geometry. The crucial role of the simulated track is to provide cars with a driving line. To make the simulation versatile enough to accommodate multiple shapes and sizes of the track needed for testing, the track is subdivided into multiple track segment classes. The Track Segment class is the basic building block when constructing a full track for the simulation. Given the x and y locations, the track segment can return the distance to the nearest point of the driving line and the direction at that point. Each segment shape has a different method for calculating the distance from the driving line and direction.

2.6. Steering Adjustments

For steering, the car is concerned with its lateral distance from the driving line and its current orientation with respect to the driving line. Using these two data points, the car can either steer right, left, or straight. The goal for the car is to be centered on the driving line as much as possible. If the car deviates from the center in a specific direction, it is programmed to correct itself by steering in the opposite direction. It accomplishes this by simply checking if its distance from the centerline is higher than an absolute threshold value at which it will then start to steer in the direction towards the center of the lane.

2.7. Throttle Adjustments

Throttle adjustments are based on what is in front and behind that car, as well as the reservations. When a car is approaching a crossroad, it cannot merely adjust its speed based on the cars in front of it. The other cars inside or approaching the intersection must be taken into consideration. With that said, the car would leave the decision to maintain or decrease its speed to the reservation given by the control system. The control system evaluates two conditions that determine the throttle adjustment. If there is already an existing reservation, it should maintain its current speed since its present course is already approved. On the other hand, a rejection of a reservation request would indicate that there would be a collision if the car were to maintain its speed, and thus, would decrement its speed and send another request to the control system.

2.8. Communications Protocol

Between the computer program and the connected controllers that handle localization and car communication, the format of their messages are as follows: preamble, length, message type, and data. The preamble is a predetermined set of bytes used to indicate to the receiver that a message is incoming. The length is a single byte used to indicate the length of the entire message. This message can vary depending on the number of bytes used for sending data if applicable.

2.9. Road Track Design

The track design is based on a two-lane four-way crossroad that accommodates at least four cars. As shown in Figure 1, the important parameters are road shape, lines, and dimensions in the track design. The size of the track, the distance of the lane, and the intersection dimension are limited to the turning radius of the self-driving car.

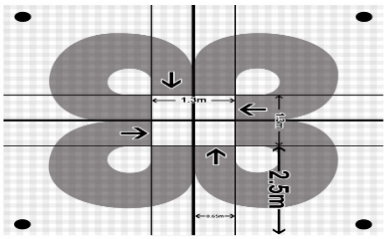

Figure 1: Test Track Map. The scaling was based on the turning radius of the car wheels.

2.10. Scaling Method

The scaling method followed the turning radius of the self-driving car instead of its dimensions. This scaling was done because the simulated car's steering angle was much larger than that of life-sized cars, resulting in the self-driving car taking wider turns than expected based on its dimensions. The dimensions of the test track, the self-driving cars' resulting dimensions, and their speeds in the simulation would be proportional to the ratio between its turning radius and the average turning radius of most common midsized passenger cars of 17 feet or 5.18 meters [9]. A scale factor of 15.94 was obtained from (1). Figure 2 shows the scaling process.

$$\text{scale factor} = \frac{\text{actual turning radius}}{\text{self-driving car turning radius}} \quad (1)$$

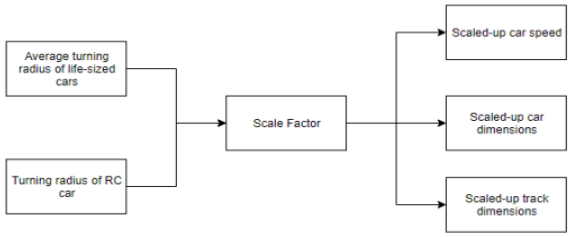

Figure 2: Scaling Process Block Diagram

2.11. System Program Flowchart

The system program flowchart is presented in Figure 3.

2.12. Evaluation

The intersection contains four entry lanes. It has no start and endpoints, and thus, it makes sense to treat the intersection as cyclic when it comes to determining the test cases. Four cars are to be arranged at the entry lanes of the intersection. The variables that determine the number of test cases are numerous, and some have infinite possibilities, such as speed, acceleration, arrival time to the intersection, and many more. Other variables are countable, such as the headings of the entry (north, south, east, west) and actions of maneuver (straight, left turn, and right turn), and these were the characteristics used.

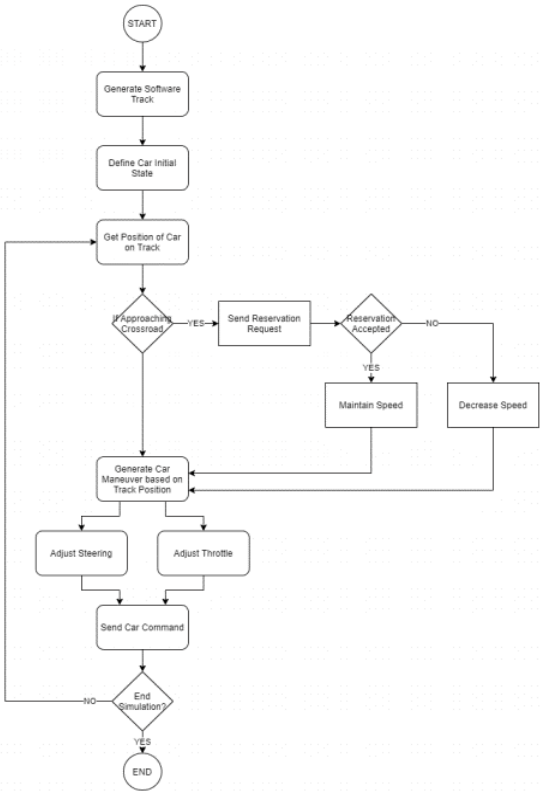

Figure 3: System Program Flowchart

3. Results and Discussions

3.1. Crossroad Reservation Queueing

When the car sent its request for a reservation, the control system either gave an acceptance or denial. Depending on the result, the car either maintained its speed or reduced it. Each time the reservation method is called, the control system saved an entry of the reservation details and results. The most notable data in the reservation logs are the arrival time, where the Car reaches the crossroad and the car's current throttle. An example of a summary of the test cases' logs can be found in Table 1.

Table 1: Crossroad Reservation Logs

Time Stamp (sec)	Car	Reserved	Arrival Time (sec)	Throttle
24.361	Car 4 - 0x6a1a	TRUE	25.397	70
24.833	Car 1 - 0x6a40	FALSE	25.524	70
24.868	Car 2 - 0x6743	TRUE	25.992	70
24.937	Car 3 - 0x673b	TRUE	25.88	70
25.153	Car 1 - 0x6a40	TRUE	26.024	66

3.2. Car Paths

After giving an initial state for each car, the system generates a predetermined 2D grid that contains all the cars' coordinates throughout the simulation. A path of each car can then be drawn from the set of coordinates to visualize the cars' movements.

The markers along the line represent a unique entry of coordinates from the predetermined 2D grid. In every iteration of the simulation, the car's location and other attributes are incremented by the amount of time elapsed between iteration. Following the trend of these markers shows the path and, most importantly, the cars' action. Analyzing the path of Cars 1 and 2 in Figure 4 shows left turn maneuvers and cars 3 and 4 showing the right turns. It can be concluded that the predetermined car paths match up with the desired test case.

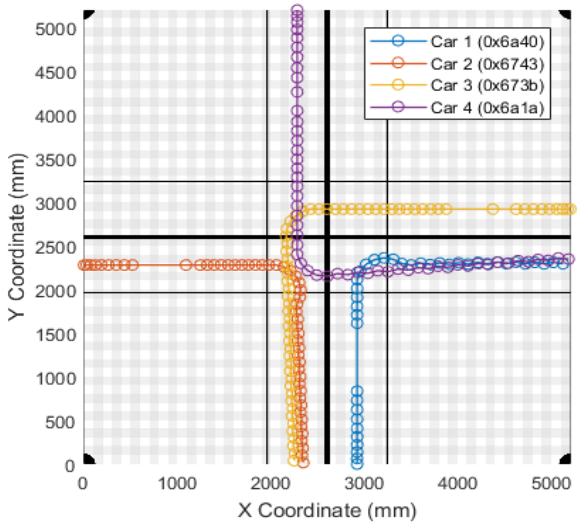

Figure 4: Car Paths for Test Case 4

3.3. Comparison of 2D Grid Simulation Results with Actual Results

The locations of the Predetermined 2D grid must be compared to the physical motions of the cars to see if they can follow the simulated paths. The range of variation in the speeds affected the time in crossroad for the physical cars. Since the simulated cars could achieve speeds far greater than the physical cars, they had several instances of spending less time in the crossroad. More often than not, the physical cars would spend more than one second in the crossroad while most predetermined cars have sub-one-second times. The predetermined and physical average speeds before and after the crossroads are presented in Table 2 and Table 3. The accuracy of the car's movements depends on their locations predicted by the predetermined 2D grid coinciding with the actual locations on the track.

Table 2: Predetermined Average Speeds Before and After the Crossroad

	Average Speed Before (m/s)				Average Speed After (m/s)			
Test Case	Car 1	Car 2	Car 3	Car 4	Car 1	Car 2	Car 3	Car 4
1	0.766	0.725	0.805	1.008	0.823	0.818	0.854	1.083

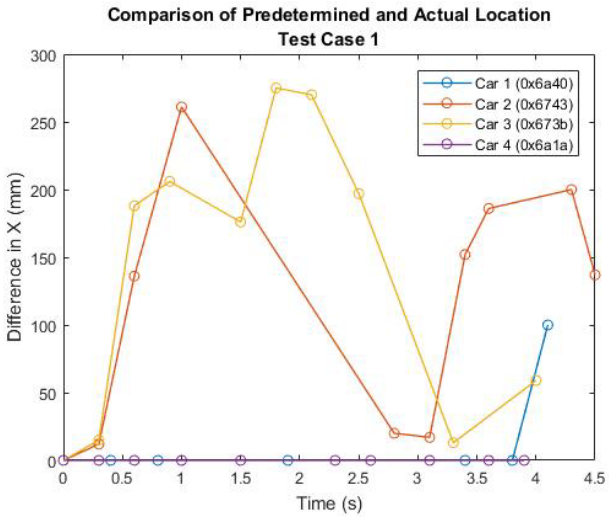

Figure 5: Comparison of Predetermined and Actual Locations Test Case 1a

Comparisons of their positions in the predetermined 2D grid and actual results were visualized in graphs in all test cases. The actual results are based on positions of remote-controlled cars acting as self-driving cars on the actual scaled-down track (Figure 1). The graphs show how much the actual locations differ from the predetermined locations of the cars. The difference between the predetermined and actual x and y coordinates in one test case is shown in Figures 5 and 6. The difference in x and y coordinates between the predetermined 2D grid location and the actual location is mostly negligible during each test's initial seconds. As the two cars accelerate, the actual cars' location falls slightly behind the predetermined location. However, the actual cars can also catch up back to the predetermined location, but with slight differences.

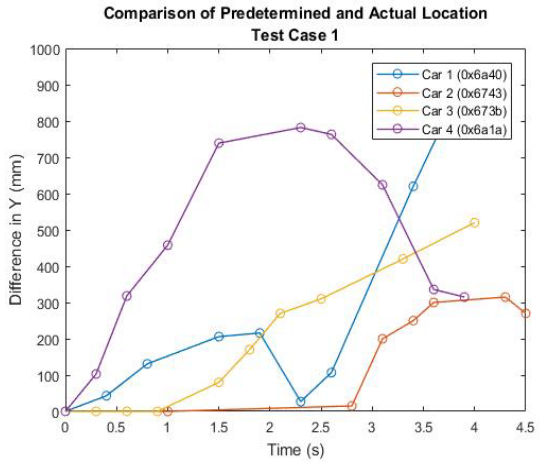

Figure 6: Comparison of Predetermined and Actual Locations Test Case 1b

One cause behind this type of deviation between the predetermined and actual results is due to the car's nature to not go directly straight despite not being issued any commands to turn, leading to it travel a greater distance than it would have otherwise traveled, creating sizeable deviations between its actual and simulated coordinates. It was also observed during testing that as the cars were used, the power banks' voltage level naturally also decreased, thereby making the cars' actual speeds more inconsistent compared to their simulated speeds, thus contributing further to the variation between the simulated and actual results.

3.4. Additional Cars

The hardware adaptation is limited to only four cars, but the simulation was designed to accept more than that. To add a new car to the program, select "Add New Car" in the authors' graphical user interface. The new car is then initialized based on the four cars' average characteristics since the new car does not have a hardware prototype. The system was able to simulate more cars than the physical hardware of four prototype cars, and the speeds of the cars were being adjusted like the procedure in the simulation of the prototype cars. Not only the predetermined 2D grid paths of the additional cars are generated, but the car commands are also sent using their Car IDs. Figure 7 shows one of these simulations of 8 cars in a zoomed crossroad.

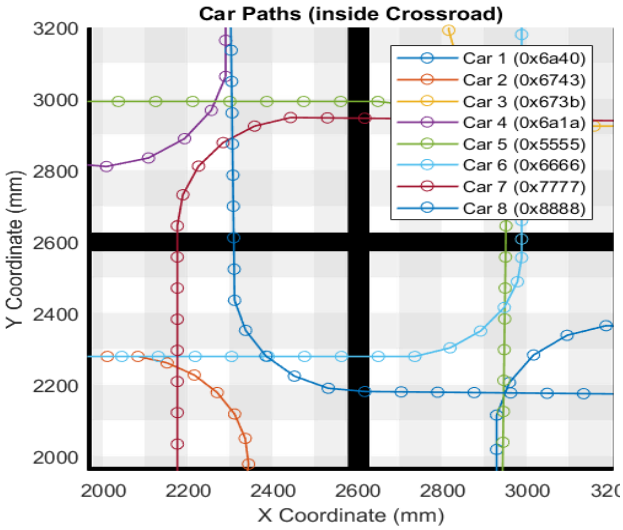

Figure 7: Eight Car Path Simulation - Zoomed in Crossroad

Reservations have an impact on the speed of the car. The eight-car scenarios resulted in more requests sent to the control system. Consequently, the increased number of cars caused the control system to issue more denials of reservations until the cars adjusted their speed accordingly. Figure 8 plots the reservation request results alongside the car's speed through the simulation's duration, while Figure 9 shows a car possessing an approved reservation alongside its speed versus time. When the car's request was approved, its speed is maintained until the car exits the crossroad.

The collections of reservation requests and status of the eight cars for all test cases were established. Here, the differences between each car's movement due to which gets approval first become apparent. Those cars that were given immediate approval, such as those who requested first, did not have to decrease their speeds. On the other hand, cars with several denials decremented several times before approval. Figure 10 shows the positive pulse of the reservation request that denotes approval lines up with its respective car beginning to maintain its speed. Likewise, the negative pulses that denote denial lines up with the car, decreasing their speeds. The approved reservation status alongside speed shows the window that the car must maintain its speed for the reservation duration. In Figure 11, the positive edge of the reservation marks the point where the speed is maintained. The

negative edge marks the point where each car's reservation is released; hence, the cars accelerate back. Between these two marks are the approved movements of the cars by the control system to avoid collisions.

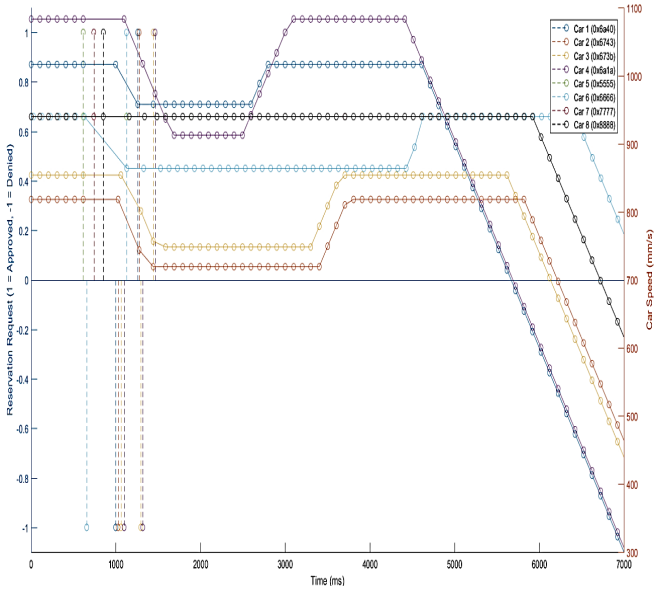

Figure 10: Effect of Reservation Requests on Car Speed. The speed unit was based on the simulations.

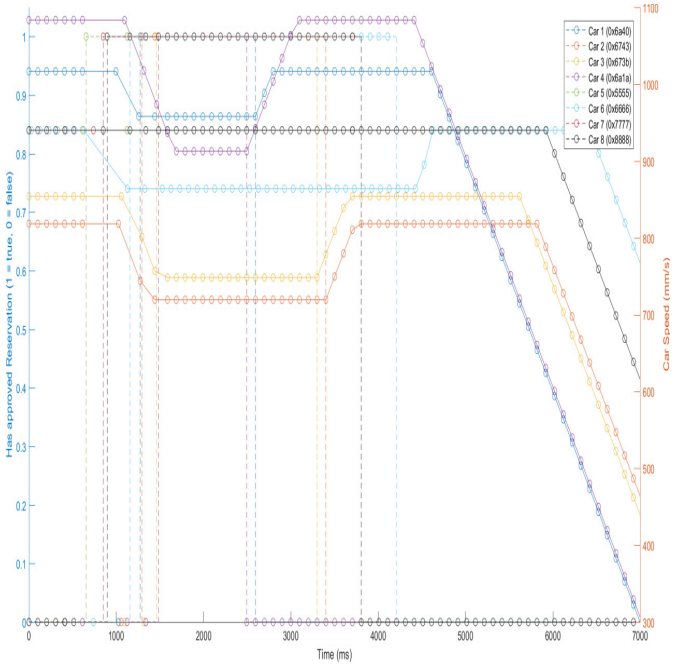

Figure 11: Having Approved Reservation and Car Speed. The speed unit was based on the simulations.

4. Conclusions and Recommendations

This work on a simulation design of collision avoidance of autonomous vehicles simultaneously crossing an intersection indicate that using the predetermined 2D grid can be an alternative localization scheme. Four prototype cars were modified with the specified modules and achieved the desired functionality of remotely controlling the control system's speed and steering. The control system was able to fulfill its function of controlling all the cars and negotiating the movement inside the crossroad per test case. The predetermined 2D grid was used as an alternative solution for determining the cars' locations increasing the accuracy of data and transmission. The result is a system that can control self-driving cars through a crossroad with minimal collisions. Furthermore, the control system using the predetermined 2D grid can perform simulation of more than four cars. Upon running the various test cases to verify the system with different car placements and maneuvers, it is concluded that the work was able to provide a fast method for vehicles to enter and exit a crossroad while avoiding slowdowns.

Recommendations include incorporating machine learning and cloud technology [5] in AVs and AIM, implementing simulation in different programming platforms, extending hardware implementation on large-scale vehicles, or 3D road maps [4]. It is also suggested to use uninterrupted, fast, and accessible communication technologies. Moreover, a useful feature would be more sensors that can keep track of attributes not necessarily related to motion. If a project were to implement a system like the predetermined 2D grid, it is recommended that the simulated cars' characteristics to be like the physical cars that it would eventually control. Expanding the model of the car's movement from linear acceleration to a more dynamic model would significantly improve the accuracy of the resultant predetermined coordinates, and consequently, more appropriate car commands. In addition, intelligent highway queue selectors

[10] can be explored for controlling data dissemination, which might result in coordinated traffic flow at crossroads.

Conflict of Interest

The authors declare no conflict of interest.

Advances in optimizing optical fiber communications have been on the rise these recent years due to the increasing demand for larger data bandwidths and overall better efficiency. Coherent optics have focused on many kinds of research due to its ability to transport greater amounts of information, have better flexibility in network implementations, and support different baud rates and modulation techniques. These result in fiber-optic lines to provide faster speeds to end-users. Recent literature has looked into further developing digital signal processing techniques, while others have focused on fiber material optimization. Machine learning is another area of research that has garnered traction due to such demands. This survey discusses support vector machine (SVM) and code-aided expectation-maximization (CAEM) techniques on how they compensate for nonlinearity in coherent fiber optical communications. The study mainly focuses on how these techniques impact the performance of the transmissions where they are implemented and how they compensate for fiber optic nonlinearity through either the reduction of bit error rates (BERs), the improvements in the quality factor, or through a suggested index based on BER, power, and distance. Collating the results and based on a distinctive index, SVM is preferable in mid-range haul transmissions while CAEM for longer hauls.

1. Introduction

With the growing need to manage, transmit, process, and receive large amounts of data, optical fiber transmissions can find a niche in today's network communication age as it can address several network traffic issues. Compared to other communication methods such as radio wave propagation and other physical transmission media like twisted pair and coaxial cables, optical fiber transmission can deliver more data, operate more efficiently, occupy less space while having more capacity, and be less susceptible to interceptions. However, despite these advantages, optical communications have its fair share of disadvantages such as cost, complexity, and perhaps the most faced issue is phase sensitivity [1]. Over recent years, coherent optic fiber communications coupled with newly discovered digital signal processing techniques have improved and optimized data transmissions. One such stride was the shifting from single carrier multiplexing to coherent optical orthogonal frequency division multiplexing (CO-OFDM), which brought about advantages such as inter-symbol interference mitigation and higher bandwidth efficiency. However, OFDM's serious disadvantage is the higher peak-to-average power ratio (PAPR) that comes with it, which results in a phenomenon known as fiber optic nonlinear distortion [2]. Digital modulation techniques that are usually paired with OFDM, such as Amplitude shift keying (ASK) and Phase shift keying (PSK), and Quadrature amplitude modulation (QAM), are greatly affected by nonlinear distortions as these can significantly increase the BER of the system. Numerous studies and innovations such as those in [3]–[5] have risen to try to minimize the nonlinearity experienced in this multiplexing process such as varying or combining the digital signal processing (DSP) techniques applied, optimizing the material that coats the fiber optic core to reduce the birefringence and implementing neural networks in the transmitter/receiver or both to maximize the bandwidth delivered.

*Corresponding Author: Lawrence Materum, Email: lawrence.materum@dlsu.edu.ph

Just like any other transmission system, coherent optical fiber transmissions encounter their fair share of performance drops due to several types of induced noise. Amplified spontaneous emission (ASE) from inline amplifiers is one of these major contributors to linear noise. Laser phase noise from transmitters and the local oscillator also put a damper on system performance by a relatively significant margin. However, the largest contributor and perhaps the most significant cause for concern is the nonlinear phase noise (NLPN) caused by an interaction of the signal and the ASE mentioned above through the phenomenon known as fiber Kerr effect or Kerr induced nonlinearity [6].

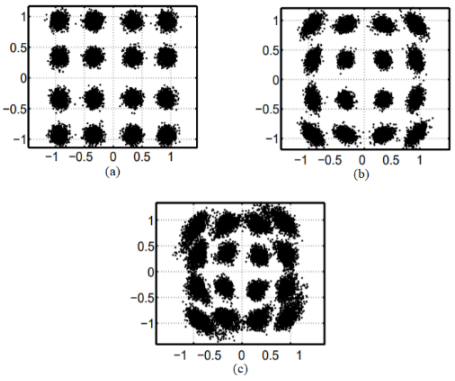

Figure 1: The effects on a 16-QAM system due to (a) Amplified Spontaneous Emission (b) Laser Phase Noise and (c) Nonlinear Phase Noise [7]

For transmissions like quadrature amplitude modulation (QAM), which relies heavily on signal amplitude and phase shifting in its transmission, noise can significantly impact its performance, specifically on its BER. A small amount of noise can incorrectly categorize the transmitted data. This error is especially apparent in optical transmissions because most utilizing the orthogonal frequency division multiplexing scheme produces a high peak-to-average power ratio resulting in noise that can increase the BER in a transmission medium.

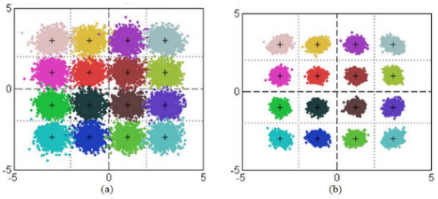

Figure 2: (a) 16-QAM constellation with high nonlinear phase noise; (b) with reduced noise [8]

Hence, solutions to addressing such nonlinearity are essential. In this work, two important techniques that work to that end analyze SVM and CAEM on how they affect optical fiber transmissions regarding their overall performance and fiber optic nonlinearity compensation. Performance comparison was made between the two using parameters of the different studies. In particular, the emphasis was on the use of coherent optical orthogonal frequency division multiplexing (CO-OFDM) or polarization division multiplexing using a 16-ary QAM (16-QAM) signal with varying fiber lengths and variables. The authors also propose a comparative index to fairly evaluate the two techniques based on the bit error rate (BER), power, and transmission distance. This paper is organized then as follows. Section 1 is followed by discussing the methods and a proposed comparative index in Section 2. Results and their discussions were done in Section 3, and recommendations given in Section 4.

2. Nonlinearity Compensation and Comparative Methodology

2.1. 16-QAM Least-Squares SVM Nonlinearity Equalizer

A 16-QAM CO-OFDM coupled with an SVM nonlinear equalizer is proposed in [2]. The optical fiber link is composed of multiple 100 km standard single-mode fiber (SSMF). Attenuation in the link is accounted for and compensated using Erbium-doped fiber amplifiers (EDFA). The ASE contributed by the EDFA is considered as white Gaussian noise. Inputs to the digital modulator are generated from a pseudo-random binary sequence (PRBS) module, which then undergoes the QAM modulation. An inverse fast-Fourier transform module is utilized to convert the time domain signal generated to an equivalent frequency domain. In this case, the pulses of the signal are kept ideal for simplifying the simulation. To maximize linear conversion between the OFDM signal and the optical field, the OFDM signal's in-phase and quadrature segments are used by a pair of Mach-Zehnder modulators (MZM). Both MZM operates via push-pull configuration and is configured to be biased at the minimum transmission point to remove the chirp phenomenon effectively. Once the optical signal reaches the receiver after traversing N-span amplifiers, it is converted into an electrical signal by a 90º photoreceiver. Noise due to the laser linewidth's imperfections is disregarded as the study aims to isolate fiber nonlinearities due to other noise [2]. The signal then undergoes the normal decryption process before being fed into the machine learning algorithm, after which it is fully demodulated, and the error rate is calculated.

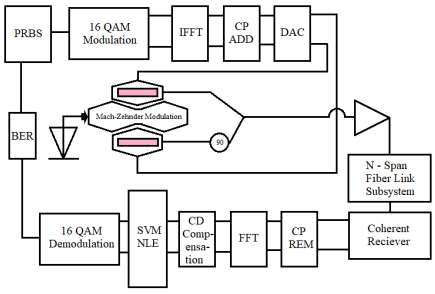

Figure 3: 16-QAM CO-OFDM SVM-NLE Diagram [2]

Support vector machines are powerful classifying tools yet can only be used as binary classifiers. Due to this restriction, this study's approach combines multiple two-class SVMs for a multi-class model to be used. Since the study uses 16-QAM as its modulation technique, the signal is divided into sixteen (16) individual clusters in a constellation wherein each cluster represents data in a unique binary form [9]. For a single two-class SVM classifier, N pairs of vectors (x_k, y_k), k=1,…,N where x_k and y_k are the input and output patterns, respectively undergo training to obtain the hyperplane. y_k is the labeling function where $y_k \in \{1, -1\}$. Through this training process, possible noise in the constellation is distributed efficiently and accurately. Based on the training data present, SVM aims to construct a classifier f(x)

$$f(x) = \text{sign}[(W^T \Phi(X_i) + b)] = \text{sign}\left[\sum_k^N \alpha_k y_k K(x, x_k) + b\right] \quad (1)$$

where w is the weight, α_k is the support vector, b is the bias term, and $\Phi(X_i)$ is the mapping function. The training process determines the weight, support vector, and bias terms used for the constructed classifier. For more complex data to be accurately separated, a mapping function is used to transform the training data x_k into a higher dimension. The SVM also utilizes a Kernel trick to help nonlinear decisions in mapping low complexity computations. The approach focused on this survey utilizes a radial basis function kernel in which only dot products are needed. $K(x_i,k_j) \equiv \exp(-y_{SVM}||x_i - x_j||^2))$, ySVM > 0, with y_{SVM} as the Kernel function.

Since there are more than two unique data sets to classify from in a 16-QAM constellation, the study employed a one versus rest rule, wherein a received data point would classify in a particular cluster if and only if it is accepted by that cluster and is rejected by the rest, if two or more clusters accept the data point then it is considered noise.

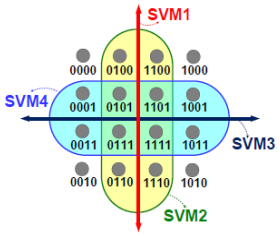

Figure 4: Implementation of a 4-level SVM to classify a 16-QAM constellation [10]

To further increase the SVM classification accuracy in noisier environments, the study opted to implement a least-square variant of the SVM studied in [11]. Least-Square SVM (LS-SVM) provides a more optimized solution using the following:

$$\min\left(\frac{1}{2}w^T w + C\sum_{i=1}^{N}\xi_i\right) \quad (2)$$

constrained by

$$y_i(w^T\phi(X_i) + b) \geq 1 - \xi_i \quad (3)$$

where ξ is termed as the slack variable which shows the error term which must satisfy the condition $\xi_i \geq 0$. C is known as the regularization parameter.

After the CD compensation process, both I and Q segments of the signal are fed into the LS-SVM in which the classifier is formed through a two-stage process of training and testing [2], [11].

1. Training
- Arrange label y_k, in-phase I and quadrature Q to format the SVM packet.
- Select the RBF Kernel function and scale I, Q to [0,1]
- Use cross-validation to determine the optimal C and y_{SVM} values.
- C and y_{SVM} values to train the SVM.

2. Testing
- Insert testing symbol.
- Compare predicted labels to transmitted symbols to determine and evaluate the BER.

2.2. Code-Aided Expectation Maximization

A wavelength-division multiplexing (WDM) and polarization division multiplexing (PolDM) system is considered in [12]. Nine simultaneously transmitting channels with the middle channel being the main focus of the study utilizes 16-QAM modulation with a 32 GBaud symbol rate. The optic signal goes through a 2640 km distance consisting of 33 spans of 80 km each. Dispersion-compensating fiber (DCF) is not utilized in the study; however, the same standard single-mode fiber (SSMF) is used for the fiber cable, and an erbium-doped fiber amplifier (EDFA) is employed to counteract fiber loss. The signal undergoes a chromatic dispersion compensation followed by a polarization demultiplexing at the receiver. A frequency estimation (FE) acts on the sampled signal to estimate the frequency with a margin of accuracy equal to or better than 4 MHz. A Viterbi algorithm compensates for any leftover frequency that utilizes an FIR filter length with phase averaging.

Due to noise correlating over time, traditional white noise assumption methods of demodulation are often suboptimal. The study in [12] partially compensates impairments done by both inter-channel and intra-channel nonlinear effects by exploiting the correlation of the phase noise through the use of CAEM. The phase noise correlation is dealt with by using a regularizer in the utility function of the algorithm. The CAEM describes as follows:

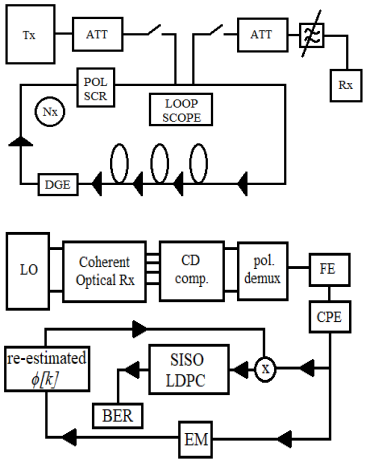

Figure 5: 16-QAM PDM CAEM Algorithm Diagram [12]

1. $r^i[k]$ will be set as the k th symbol after phase noise compensation in the ith iteration between the EM and forward error correction (FEC) process $\left(r^i[k] = y[k]e^{-j\hat{\phi}^i[k]}\right)$. $\hat{\phi}^0[k] = 0$ and $r^0[k] = y[k]$ are set as initial values.
2. The log-likelihood-ratio (LLR) is computed for each bit based on $r^i[k]$. Let s_l be the lth bit. The LLR is defined as follows if M-ary modulation is utilized.

$$\mathrm{LLR}(s_l) = \log\frac{p(s_l = 0 \mid r^i[k])}{p(s_l = 1 \mid r^i[k])} \quad (7)$$

$$l = (k-1)\log_2 M + 1, \ldots, k\log_2 M \quad (8)$$

It is assumed that the residual noise in $r^i[k]$ patterns itself in a circularly symmetric zero-mean white Gaussian distribution. Constellation points whose labels are $s_l = 0$ are defined in the set X_{l0} and likewise for X_{l1}.

3. An updated log-likelihood ratio $\mathrm{LLR}_o(s_l)$ is obtained by decoding a soft-input-soft-output (SISO) FEC based on the initial $\mathrm{LLR}(s_l)$. $\mathrm{LLR}_o(s_l)$ bits are then converted to probabilities. Assuming a constellation point, $a \in C$ is labeled as a logarithmic bit sequence $a_1, a_2, a_{3,\ldots,} a_{log_2 M}$ we obtain:

$$p\big(x[k] = a \big| y[k], \hat{\phi}^i[k]\big) = \prod_{m=1,\ldots,log_2 M} p\big(s_{(k-1)log_2 M+m} = a_m\big) \quad (9)$$

4. The utility function $E\big(\phi, \hat{\phi}^i\big)$ is then setup – Expectation Step.

$$E\big(\phi, \hat{\phi}^i\big) = \alpha\zeta(\phi) + (1-\alpha) * \sum_{k=1}^{N}\sum_{a \in C} p\big(x[k] = a \big| y[k], \hat{\phi}^i[k]\big) * \log p(y[k]|x[k] = a, \phi[k]) \quad (10)$$

where N is the total number of symbols, α is the BER optimization weight with $\alpha \in [0,1]$ The regularizer function $\zeta(\phi)$ is described as follows:

$$\zeta(\phi) = \sum_{k=3}^{N}((\ \phi[k] - w_1\phi[k-1] - w_2\phi[k-2]))^2 \quad (11)$$

where w_1 and w_2 are the noise AR analysis weights. The expression $p(y[k]|x[k] = a, \phi[k])$ is computed as follows:

$$p(y[k]|x[k] = a, \phi[k]) = \frac{1}{\sigma^2\sqrt{2\pi}}\exp\left(-\frac{\left|y[k] - ae^{j\phi[k]}\right|^2}{2\sigma^2}\right) \quad (12)$$

in which σ^2 is the noise variance that can be empirically computed with the aid of the training data.

5. The vector $\hat{\phi}^{i,1}$ is calculated assuming the below conditions - Maximization step:

$$\hat{\phi}^{i,j} = \arg\underbrace{max}_{\phi} E\big(\phi, \hat{\phi}^i\big) \quad (13)$$

where $\hat{\phi}^{i,j}$ is the estimated phase noise between FEC and EM in the ith iteration and the estimated noise between the E and M steps in the jth iteration. To numerically compute for $\hat{\phi}^{i,1}$ a gradient-ascent method is used.

6. The utility function is recomputed, however instead of using (step 3), the following is used.

$$p\big(x[k] = a \big| y[k], \hat{\phi}^{i,j}[k]\big) = \frac{1}{\sigma^2\sqrt{2\pi}}\exp\left(-\frac{\left|y[k] - ae^{j\hat{\phi}^{i,j}[k]}\right|^2}{2\sigma^2}\right) \quad (14)$$

7. Step 6 is repeated until $\hat{\phi}^{i,j}$ converges after which $\hat{\phi}^{i+1} = \hat{\phi}^{i,j}$ is set.
8. Steps 1 to 7 are repeated until $\hat{\phi}^i$ converges, and $\hat{\phi} = \hat{\phi}^i$ being the final phase noise is estimated.

2.3. Simulation Parameters

The following tables show the parameters and conditions of each approach.

Table 1: Least-Square SVM Parameters

Multiplexing	CO-OFDM
Distance	up to 1200 km
Amplifier	EDFA
Noise Figure	6 dB
Fiber	SSMF
Span Length	100 km
Attenuation Coeff	4.605 x 10^{-5} m^{-1} *
Dispersion Coeff	17 ps/(nm · km)
Nonlinear Coeff	-
EDFA Emission Factor	-
Symbol rate	40 Gbaud
Tx & LO Linewidth	-
Modulation	16-QAM
Sampling rate	-

Table 2: Code-Aided EM Parameters

Multiplexing	PDM
Distance	2640 km
Amplifier	EDFA
Noise Figure	-
Fiber	SSMF
Span Length	80 km
Attenuation Coeff	4.8354 x 10^{-5} m^{-1}
Dispersion Coeff	17.025 ps/(nm · km)
Nonlinear Coeff	1.3 $(W \cdot km)^{-1}$
EDFA Emission Factor	1.7741
Symbol rate	32 Gbaud
Tx & LO Linewidth	100 kHz
Modulation	16 QAM
Sampling rate	1 sample/symbol

3. Comparative Index, Results, and Discussions

The tables below show the results of each study's approach. Since comparison is to be done using the BER, findings with Q-

factor results were converted to their equivalent BER using the following [13]:

$$\text{BER} = \frac{1}{2}\text{erfc}\left(\frac{Q}{\sqrt{2}}\right) \approx \frac{1}{Q\sqrt{2\pi}}e^{-\frac{Q^2}{2}} \quad (15)$$

$$\text{Q(dB)} = 10\log_{10}(\text{Q}^2) = 20\log_{10}(\text{Q}) \quad (16)$$

where Q is the Q-factor and erfc () is the complementary error function. Since the (erfc) used in calculating BER is approximated, any BER values computed will be approximations. To ensure the calculations' high accuracy, BER values are displayed, having values up to seven decimal places.

3.1. Proposed Index

The authors proposed an index (17), which is a measure of how well each technique compares to others depending on the application. The index in Table 8 is calculated as follows:

$$M = \frac{\text{BER}}{\text{Power} \times \text{Distance}} \quad (17)$$

Table 3: Quality Factor (dB) for 1000 km and 1200 km fiber length at differing Launch Powers [2]

Launce Power	Distance (km)	
	1000	1200
-3 dBm	9.50	8.90
-4 dBm	10.20	9.55
-5 dBm	10.40	9.95
-6 dBm	10.30	9.90
-7 dBm	10.00	9.60
-8 dBm	9.50	9.10
-9 dBm	8.90	8.50

Table 4: BER for 1000 km and 1200 km fiber length at differing Launch Powers.

Launce Power	Distance (km)	
	1000	1200
-3 dBm	0.0015509	0.0029533
-4 dBm	0.0006563	0.0014644
-5 dBm	0.0005011	0.0009053
-6 dBm	0.0005743	0.0009635
-7 dBm	0.0008500	0.0013820
-8 dBm	0.0015509	0.0024036
-9 dBm	0.0029533	0.0043513

Table 5: BER at Launch Power = -6 dBm for different fiber lengths

Distance (km)	Launch Power	Q-factor (dB)	BER
400	-6 dBm	11.50	0.0000909
600	-6 dBm	11.25	0.0001389
800	-6 dBm	10.90	0.0002423
1000	-6 dBm	10.30	0.0005743
1200	-6 dBm	9.90	0.0009635

3.2. LS-SVM Results

The BER values in Table 3 are extrapolated from the graphical results in [2], while BER values in Tables 4 and 5 are calculated estimates from the data of [2] using (15) and (16).

3.3. CAEM Results

The Q-Factor values in Table 6 are extrapolated from the graphical results in [12]. BER values are calculated estimates using (15) and (16) based on the Q-Factor.

Table 6: Q-Factor (dB) and BER as a function of Launch Power at 2640 km fiber length

Launce Power	Distance (km)	Q-Factor (dB)	BER
-2 dBm	2640	4.6	0.0555459
-1 dBm	2640	8.5	0.0043514
0 dBm	2640	11.4	0.0001081
1 dBm	2640	13.1	0.0000033
2 dBm	2640	6.9	0.0155732

3.4. Comparative Results

Table 7 shows BER values attained from the different studies under highly similar conditions, thus making it possible to compare their results. LS-SVM can be compared under a -6 dBm launch power at 1200 km fiber length while CAEM has results at 0 dBm launch power with a 2640 km fiber length.

Table 7: BER values under similar attributes

Algorithm	Distance (km)	Fiber Link	Launch Power	BER
LS-SVM	1200	-	-6 dBm	0.0009635
CAEM	2640	-	0 dBm	0.0001081

Table 8: Results Based on the Proposed Index

Algorithm	BER	Power (Watts)	Distance (km)	Index
LS-SVM	0.0009635	0.0002512	1200	0.0031963
CAEM	0.0001081	0.0010000	2640	0.0000409

Low index values mean better overall performance for the algorithm. As shown in Table 8, the LS-SVM can be applied well in midrange haul and low complexity applications, whereas CAEM for long haul and high complexity optical networks. The index provided in (17) for measuring and comparing the performance in the studies [12], [2] is thus proposed for nonlinearity compensation performance comparisons. Nonetheless, it also recognized that multiple values should be considered and further simulated to get graphical representations of the results.

4. Recommendations

Based on the results, LS-SVM provides nonlinearity compensation in a CO-OFDM 16-QAM system, but for longer fiber lengths, CAEM provides a significantly lower BER value. These outcomes make CAEM a preferred choice when it comes to long haul optical transmissions. Complexity wise it is recommended to utilize LS-SVM. CAEM is preferred despite the higher complexity due to its significantly lower index. One potential future work is to verify the results in an experimental setup.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

This study used 15 VECM analysis models to analyze the relationship among exchange rates of South Korea, China and Japan; and between exchange rates of each country and international financial market variables. The analysis variables are the Won, Yuan, Yen spot exchange rates and international financial market variables. The results of the analysis are as follows: First, there was a long-term cointegration relationship between RMB, KRW, JPY and international financial market variables. Second, the analysis results of the VECM showed that explanatory power of Korea's offshore Won-Dollar accounts for 50% of the onshore Won-Dollar. The results of the analysis of the Yuan's VECM showed that the onshore Yuan (CNY) and offshore Yuan (CNH) exchange influence, but each has its own independent characteristics. Overall, the Won is more integrated with the international financial market than the Yuan. The Yen's relationship with variables in the international financial market was stronger than that of the Won and the Yuan. Third, offshore Won-Dollar, onshore KRW, and JPY had similar Granger causality relationship and impulse responses with international financial market variables. However, CNH and CNY indicated weaker than that of Won and Yen. The onshore Won-Dollar is shown to partially offset the shock from the onshore Yuan and offshore Yuan. The implications of this study are as follows: First, it is important to look at the exchange rate from the perspective of the international financial market. Second, Yuan investment and risk management are necessary considering the characteristics of the onshore and offshore Yuan which are interrelated but also distinctly unique markets. Third, it is necessary to manage the exchange rate position, taking into account the long-term equilibrium relationship among the Won, Yuan, and Yen currencies. Fourth, Korean companies should find a way to actively utilize the Won which shows the characteristics of partial internationalization.

1. Introduction

International credit rating agencies note changes in exchange rates in relation to country credit ratings. The exchange rate represents the credit risk of the currency country viewed in the financial market. In [1], the author argued that the credit rating announcement by the credit rating agency has a significant impact on the exchange rate and its influence varies depending on emerging markets or developed countries. In [2], the author argued that the depreciation of the exchange rate is a negative factor for the financial system of the country. In [3], the author argued that large differences in interest rates between local and foreign currencies would increase dollar loans with low interest rates. In [4], the author that entities in East Asian countries use foreign currency loans to reduce borrowing costs. They argued that company selectively use foreign currency loans in consideration of low foreign currency borrowing interest rate benefits and foreign exchange hedge costs arising from foreign currency borrowing. As they argument, the mid- to long-term exchange outlook, adjusted according to interest rates, expected currency values, macro-economic variables, etc., are important for the parties to the foreign exchange transaction. Therefore, it is important to understand the mid- to long-term equilibrium relationship between each currency and with variables in each currency and international financial markets variables. However, the exchange rate is generally highly volatile in the short term, as the following arguments suggest. In [5], the author argued that the short-term exchange rate determinant model by macroeconomic variables is almost

*Corresponding Author: Moon-Kyum Kim, Professor, Graduate School of Soongsil University. mgkim@ssu.ac.kr

indescribable. In [6], the author argued that the empirical analysis of advanced countries' currencies generally showed that the exchange rate was close to random walking, and that the won-dollar exchange rate was also random walking after the introduction of the floating exchange rate system in Korea. In [7], the author argued that the sensitivity of the trade-in between the local currency and the foreign currency was greater under the floating exchange rate system. He argued that the floating exchange rate system also limits the ability of monetary authorities to carry out their own policies. The following studies have shown that emerging economies' exchange rate-setting mechanisms and dollarization increase exchange rate volatility. In [8], the author studied the factors affecting the transactions of local and foreign currencies in emerging countries. He argued that the holding of the local currency or foreign currency depends on the level of interest rate on the foreign currency against the local currency and the expected depreciation of the local currency. Therefore, it was argued that the foreign currency trade was determined in accordance with reasonable expectations for the local currency and the foreign currency. In [9], the author argued that the dollarization generally increases in emerging economies. The dollarization is the use of the dollar (foreign currency) as a means of storing value instead of the local currency. The IMF defined the dollar phenomenon in emerging economies as the proportion of foreign currency deposits to broad cash. They used the dollarization level as the ratio of foreign currency deposits to M2. In [10], the author argued that the dollarization was a reasonable response from the investors to future uncertainties in emerging economies' currencies. The dollarization also affects macroeconomic policies, foreign exchange risk management and exchange rate systems in emerging economies. In [11], the author analyzed the Turkish currency using a VAR model. He argued that the dollarization is caused by instability in three macroeconomic variables: currency devaluation volatility, inflation volatility, and uncertainty forecast volatility. In [12], the author argued that the loss of confidence in economic management would reduce confidence in the local currency, thereby promoting the retention of foreign currencies. Bank plays a pivotal role in developing emerging economies' financial markets. Therefore, deepening the dollarization of banks' assets and liabilities increases foreign currency exchange risk. He argued that the dollarization is not significant in countries where the financial industry has grown to a considerable level, but in countries with small financial industries, the dollarization is relatively large. The above studies suggest that the medium- to long-term relationship of exchange rates is important for parties to foreign exchange transactions. The demand and supply of foreign exchange trading arise from the import-export transactions of enterprises and the hedging of foreign exchange positions held and the capital markets transactions invested in stocks and bonds. Thus, long-term exchange rate relationships between currencies and key variables in the international financial market are important for businesses and investors. South-Korea, China and Japan are the top 10 global import-export trading partners. In addition, China and Japan are Korea's largest export-import trading partners. The Korean won is a non-international currency, but the Chinese yuan and Japanese yen are SDR international currencies. As a non-international currency country, like most ASEAN countries, Korea has to do import-export transactions and capital market transactions with international currency countries. Therefore, it is an important issue for Korean import-export companies and pension fund investors to find out the long-term equilibrium relationship between the won dollar, the yuan, and the yen. Regarding exchange rate relationship between Korea, China and Japan. In [13], the author analyzed the non-international currency of the Won, the SDR international currency of the Yuan, and the Yen by applying CIP theory. The CIP theory is that there is an equilibrium relationship between the difference between the risk-free interest rates of the two currencies and the difference between the spot exchange rate and the forward exchange rate. Therefore, the country's foreign exchange market maintains equilibrium relationship under the CIP theory. In general, international currency is not regulated and there are no restrictions to trade, so the CIP theory is established. Therefore, it is in principle impossible to trade risk-free arbitrage transaction that arises from the collapse of the CIP equilibrium relationship. They argued that the Yen, which is an international currency, is impossible for risk-free arbitrage transaction when considering the transaction cost. However, they argued that the Yuan, which is in the process of internationalization, and the Won, a non-international currency, imply arbitrage opportunities through SWAP transactions. In [14], the author used the VECM (Vector Error Correction Model) model to analyze the relationship between the country CDS Premiums of Korea, China and Japan, the exchange rate and the variables of the international financial market. They argued that while the country CDS Premiums of Korea and Japan were more closely related to the variables in the international financial market, the Chinese CDS Premiums had a weak relationship. In [15], the author used the VECM model to analyze the relationship between the international financial market variables and the spot exchange rate of Latin America and the country CDS Premium. He argued that although variables in the international financial market affect the spot exchange rate of Latin America countries, their impact varies from country to country.

This study analyzes the long-term equilibrium between the Korean won (onshore KRW and offshore Won-Dollar, herein “NDF KRW” where NDF is non deliverable forward), the Chinese yuan (onshore CNY and offshore CNH), and the Japanese yen JPY currency. And analyze the long-term equilibrium relationship between these currency and international financial market variables. The analysis results compared the characteristics of a total of five currency markets by dividing them into won (KRW and NDF KRW) and yuan (CNY and CNH) and yen JPY. This study can be differentiated from the existent researches based on the following; First, we have identified the long-term equilibrium relationship between the exchange rates of Korea won, China yuan, and Japan yen from the perspective of the international financial market. Second, the degree of integration with the international financial market was compared by comparing and analyzing the non-international currency, the won, the yuan and the yen, the international currency. Third, it was found that although the onshore and offshore yuan, which is being promoted for internationalization, is related to each other, there is a unique market characteristic that is distinguished from each other. Therefore, we have provided suggestions that company and international investors need yuan trading and yuan position management in consideration of the onshore and offshore yuan characteristics. The composition of the study is as follows; Chapter 1 describes the purpose and background of the research. Chapter 2 describes prior research and the variables used in analysis. Chapter

3 described the research model and the research methodology. Chapter 4 basic statistics, unit root test, and co-integration test of the analysis data. Chapter 5 presents the analysis results of the VECM model. Chapter 6 presents summaries and conclusions.

2. Previous research

2.1. Dollarization

The dollarization is the use of the dollar (foreign currency) as a means of saving value instead of the local currency. However, there is no consensus as to the various hypotheses in previous studies about the dollar phenomenon and the cause of currency exchange trading. In [16], the author put together four types of research on the dollarization. First, the study that the dollarization increases when the policy and institutional financial system of the local currency finance is poor. In [17], the author and in [18], the author, and in [19], the author argued that financial markets are not naturally fostered, but are developed through the process of maintaining stable asset values through their own economic growth and continued policy and institutional legislation. In [20], the author and in [19], the author argued that the dollarization is caused by increased risk of default, expected currency devaluation and a lack of dollar liability mismatch information. They argued that market failures were caused by problems between financial industry instability and related legal systems, and the dollarization was also caused by poor policy results and financial market imperfections. Second, the study that devaluation of exchange rates causes capital outflow and aggravates effect on the financial statements of domestic companies. In [21], the author argued that, in the event of a crisis, a significant foreign debt repayment burden reduces aggregate demand and, therefore, further depreciation of the exchange rate occurs. They argued that this would worsen the company financial statements, making borrowing conditions more unfavorable. Third, the study of currency substitution in relation to the foreign currency hedging. If investors experience high inflation in assets held in their local currencies, they will replace their holdings with foreign currencies to maintain future asset values. In [22], the author outlined the theory of trade-in between two currencies. In [23], the author argued in empirical studies that inflation and currency exchange trading are strongly interrelated. In [24], the author argued that holding foreign currencies in emerging countries played a role in hedging macroeconomic risks in emerging country economies. He argued that if investors were concerned about inflation in their currencies, the demand for foreign currency holdings would continue to increase. Fourth, the study that portfolio investment manager will have foreign currency assets at an optimal rate to minimize the risk of their investment portfolios. In [25], the author used the Minimum Variance Portfolio (MVP) method to study with five Latin America countries. They confirmed that assets and liabilities of financial institutions are readjusted in accordance with changes in exchange rates to hedge the inflation. In [26], the author argued that the proportion of dollar assets in MVPs and the dollarization are positive correlations.

2.2. Internationalization of Yuan

In 2008, when the global financial crisis recurred, China proceeded the internationalization of the yuan, mainly in Hong Kong. The yuan was newly incorporated into the SDR international currency in October 2016. The internationalizing of the yuan was a major issue for non-international currency countries. It was because currency internationalization could be an alternative to addressing the exchange rate problems common to emerging Asian countries. However, it is necessary for companies and financial institutions in non-international currency countries that do business with China to understand the characteristics of the new international currency, the renminbi, to manage exchange rate risk. In [27], the author asserted four backgrounds for the internationalization of the yuan. First, currency internationalization brings about the development of the direct financial market, so it has the effect of increasing the efficiency of monetary policy. Second, internationalization of currency has a good function to reduce the difference in interest rates and exchange rates between currencies by enabling arbitrage trading when changes in monetary policy are expected. Third, it argued that currency internationalization could further expand the wealth effect of the currency by enticing investors in the international financial market. Fourth, it argued that currency internationalization could lead to an increase in yuan deposits abroad, thereby promoting the growth of the yuan's international financial market. They summed up the requirements for the internationalization of the yuan as follows: The increase in China's economic weight in the global economy, the convenient exchange function of the yuan, the development of financial market and the liberalization of the Chinese financial market, the development of the offshore yuan financial market and the expansion of the flexibility of the yuan exchange rate. In [28], the author and in [29], the author cited five common factors in currency internationalization: political, military power, economic scale, national financial soundness and financial market competitiveness. In [30], the author argued that the higher the proportion of GDP, which represents the size of the economy, and the higher the proportion of trade in the global economy, the higher the possibility of internationalization of currencies. Trade dependence and inflation, on the other hand, have a negative impact on currency internationalization. They also argued that the greater the share of the stock market, the higher the proportion of foreign bonds issued in the local currency, and the greater the financial opening, the greater the possibility of internationalization of currencies. In [31], the author studied the international demand for yuan as a means of value storage. He used the explanatory variables of existing research to analyze the yuan. He estimated that the demand for the yuan would be 1 to 2 percent of the global currency volume in 2015 and 3 to 8 percent in 2020. However, he said that if China actively liberalizes its capital market and opens up its financial markets, the yuan's demand may rise more than expected as the yuan's trading volume increases further in the international financial market. The previous study of internationalization of currency were summarized in Table 1 below.

Table 1: Pre-study of the internationalization of currency

		Description of variable			
[Dependent variable]		Macroeconomic variables	Currency market variables	Financial market variables	Others
[Requirements to be used as foreign	Chinn & Frankel	GDP portion Inflation rate	Exchange rate volatility	Foreign exchange	time lag

exchange reserves)			depreciation rate	transaction weight	
	Chen et al	GDP portion, trade size portion, inflation rate	Exchange rate volatility		time lag
	Li Daokui et al	GDP portion Inflation rate	Exchange rate volatility depreciation rate		
	Dae Won Oh	GDP portion, trade size portion, inflation rate	Exchange rate volatility	M2 / GDP Openness	
[Currency internationalization requirements]	Seok Hyeon, Sang Heon Lee	GDP portion, Trade portion, Trade dependency, Inflation		Stock Market Openness	Financial openness
[RMB internationalization requirements]	Haihong & Yongding Yu	China's Economy portion in the Global Market	Flexibility of exchange rate Convenient exchange	Financial liberalization Financial Market Development Offshore Market Development	

In [32], the author analyzed the impact of the onshore Chinese yuan (CNY) on the offshore yuan (CNH) market in Hong Kong. According to their analysis, the change in the implied interest rate of the forward exchange rate in China immediately affects the renminbi forward exchange rate market in Hong Kong. In [33], the author analyzed the effect of interest rate volatility transferred from the Chinese market to the Hong Kong offshore renminbi market through a variance decomposition analysis. They argued that volatility was transferred from the Chinese market to the Hong Kong offshore market at an average of 60.9%. However, the effect of transferring volatility from the Hong Kong offshore market to the Chinese local market was insignificant at 13.8%. In [34], the author analyzed the CNH and CNY markets from September 2010 to August 2013. They argued that CNY had a strong influence on CNH at the beginning of the analysis period, but argued that CNH's influence on CNY increased in the later period. Therefore, they argued that CNH Hong Kong's offshore yuan has predictive of CNY's Chinese onshore yuan. In [35], the author studied the difference in price between CNH offshore renminbi and CNY onshore currency. They argued that the yuan liquidity and risk aversion of international financial market investors were the main causes of the price difference between CNY and CNH and incurring arbitrage trading. They argued that an increase in the inflow of yuan from the CNY onshore market to the CNH Hong Kong offshore market narrowed the CNH-CNY price difference, and thus the yuan exchange rate was adjusted based on the available liquidity in the market.

2.3. Analysis of variable

We describe the variables used in the fifteen VECM analysis models. The first variable is the spot exchange rate. The exchange rate represents the credit risk of the currency country viewed in the financial market. In [2], the author argued that the depreciation of the exchange rate is a negative factor for the financial system of the country. In [36], the author argued that the depreciation of the exchange rate is a problem with the repayment of national debt. In [37], the author argued that a sharp depreciation of the exchange rate lowers the value of the assets denominated in the local currency, resulting in a lack of foreign currency liquidity, which increases the occurrence of a default risk. The second variable is the 10-year US treasury interest rate. In [38], the author argued that the 10-year U.S. government bond interest rate is the benchmark for the level of interest expected by investors in international financial markets. In [39], the author argued that the determinants of investment capital flowing into emerging economies are largely attributable to supply factors, such as the level of U.S. treasury bond interest rates and preference for safe assets in the international financial market. It argued that a 50bp drops in interest rates on 10-year U.S. treasury bonds would increase the total inflow of capital into emerging economies by 13 percent. The third variable is credit risk spread. In [40], the author argued that credit risk spreads represent investors' risk aversion and are explained by the spread difference between the 10-year U.S. treasury bond and credit risky bonds. In [41], the author argued that an increase in the hedge propensity of investors in the international financial market increases the credit risk spread, and that the credit risk spread is significant in explaining the EMBI index of emerging economies in 31 countries. Alsaka and ap Gwilym [1] argued that the announcement by the credit rating agency had a significant impact on exchange rate fluctuations. The fourth variable is the VIX index. VIX is Chicago Board Options Exchange Volatility Index and is a variability in S&P100 index option transactions. The index represents the level of hedge propensity among international financial market investors. The VIX index is to the extent that investors feel an event risk, and it is the risk compensation rate expected by investors who expect high returns in the international financial market. In [42], the author argued that the VIX index is an important explanatory variable that determines the rate of return on treasury bonds. In [43], the author argued that it is an important variable that explained the premium on government bonds in emerging countries. In [44], the author argued that VIX is an important variable that explains the CDS premium in Mexico, Turkey, and South Korea. In [38], the author argued that VIX is a factor that explains the premium on short-term government bonds. In [39], the author stated that the VIX index represents a preference for safe assets in the international financial market and that if the VIX index fall halves, total capital inflows from emerging economies would increase by 11%. The fifth variable is TED spread. TED spread is the difference between the 90-day yield on U.S. treasury bonds and the three-month interest rate on Euro-dollar Libor. TED spread represents the average level of risk felt by the counterparty in inter-bank money market transactions in the international financial market. Higher cross-bank counterparty risk burdens are considered to have increased TED spreads and increased hedging tendencies in the international financial market, worsening the funding situation. The change in TED spread implies changes in overall capital liquidity in the international financial market or changes in credit risk levels and bond rates. In [45], the author used the TED spread as a measure of the liquidity level of hedge funds. In [41], the author used TED spread as a measure of the liquidity of government-issued government bonds in the international financial market.

3. Research model

3.1. Research Analysis

In [46], the author analyzed the mid- to long-term relationship of the Turkish exchange rate using the VECM analysis model. He

constructed a nominal exchange rate and market exchange rate model and analyzed it using the VECM analysis method. They argued that the market exchange rate model has better predictability of the future mid-term exchange rate than a random walk with and without drift. In [15], the author also used the VECM analysis methodology to analyze the relationship between the Latin America spot exchange rate and the international financial market variables (the 10-year US treasury interest rate, the credit risk spread between the AAA credit rating and the BBB credit rating, VIX index, TED spread). This study also analyzed the Granger Causality, the impulse response, and the variance decomposition analysis using VECM analysis methodology that studied the mid- to long-term exchange rate relationship. The analysis variables are Korea won onshore (KRW) and offshore won, NDF KRW (KWD1m), Chinese onshore (CNY) and offshore yuan (CNH), Japanese yen (JPY), 10-year US treasury bond interest rate (T10Y), credit risk spread, VIX index, TED spread. The Chinese yuan is analyzed by dividing the Chinese onshore yuan (CNY) market, the Hong Kong offshore yuan (CNH) market, and the Seoul offshore yuan market (herein we refer as "CNK"). The Korean won is divided into the Seoul Foreign Exchange onshore (KRW) Market and the offshore NDF KRW market (KWD1M). The offshore won NDF KRW, has the shortest maturity of one month's forward rate. In [47], the author also analyzed the causal relationship between the spot exchange rate of the onshore won dollar and the offshore NDF KRW exchange rate (the same one-month forward rate). NDF KRW is a forward exchange contract in which only the difference between the forward exchange rate and the spot exchange rate is settled in dollars without having to exchange the principal of the contract at maturity. As of 2018, the Korea won's NDF market is worth about $9.5 billion. The won is non-international, but there is no limit to profit-taking arbitrage transactions in which investors take advantage of the price gap between the Seoul foreign exchange KRW market and the Seoul bond market and the offshore NDF KRW market. Therefore, it is assumed that the won has become substantially and effectively internationalized. The Japanese yen is International currency. Therefore, it analyzes the yen traded in international financial markets as there is no distinction between onshore and offshore markets. A total of fifteen VECM analysis models are used to verify the long-term cointegration relationship between variables and apply the VECM analysis methodology only if the long-term cointegration relationship is valid at statistical confidence level. The data analysis period is from December 1, 2014, when the yuan (CNK) began trading on the Seoul foreign exchange market to November 30 2017. The daily average trading volume of the Seoul offshore yuan (CNK) currency market is $1.5 billion to $2 billion, ranking third to fourth among the global offshore yuan market. There is no restriction on transactions because CNK is the same offshore yuan as the Hong Kong offshore yuan (CNH). It also means that the cross rate between the currencies can also affect the won-dollar KRW exchange rate. Therefore, the data analysis period was set for three years from December 1, 2014 to November 30, 2017 to compare fifteen analysis models.

3.2. Analysis Model

This study first tests the long-term equilibrium relationship between the analysis variables using the cointegration analysis method proposed by [48] the author. In general, time series data are non-stationary and therefore have a unit root. However, if there is a stable linear combination between these variables, it can be considered that there is a cointegration relationship between the variables, so that a long-term, stationary relationship exists. Therefore, regression analysis can be used when a cointegration relationship is recognized even among unstable time series data. When the cointegration relationship is confirmed, the relationship between the variables is analyzed using the VECM model, which includes the error correction term (ECT) in the VAR model. The VECM model can measure the effect of the time lag between endogenous variables and analyze the long-term equilibrium relation between variables as well as the short-term dynamic relations simultaneously. Nevertheless, since the VAR model is not constrained, the results may vary depending on the variable settings. Therefore, this study performed Granger causality analysis in addition. The impulse response analysis was used to analyze how external impacts were transferred between variables. The study also add variance decomposition analysis to analyze the magnitude of the influence of unexpected impacts on variables. It is necessary to verify the cointegration relationship between research variables in order to apply the VECM analysis methodology. Thus, this study conducted Johansson's cointegration analysis. The methods for verifying Johansen's cointegration vector are trace (λ trace) and maximum eigenvalue (λ max) tests. The test statistic is as follows:

$$\lambda_{trace} = -\ T\sum_{i=r+1}^{n} \ln\left(1-\hat{\lambda_i}\right) \quad (1)$$

$$\lambda_{max}(r, r+1) = -T\ln\left(1-\hat{\lambda_{r+1}}\right) \quad (2)$$

here, λ_i indicates the matrix eigenvalue and T is the observed number. The null hypothesis of λ trace is: "there is no cointegration"; if this is rejected, there exist at least r number of cointegration relations, and the variables become stable *I (0)* time series. Only after the cointegration verification is confirmed, the relationship between the endogenous variables is analyzed by applying the VECM analysis methodology. The cointegration test show the long-term equilibrium relationship between variables, but it does not suggest its direction. To overcome this problem, this study analysis the relationship between variables using VECM model. The use of the VECM model has the advantage of being able to identify both short- and long-term causal relationships, as it can identify not only the effects of the differential term of the independent variables on the dependent variables, but also the effect of the variation of the error correction term on the dependent variables. The VECM model is as follows:

$$\Delta[LKRW_t] = [\alpha_1] + \sum_{i=1}^{p} \alpha_i \Delta[LKRW_{t-i}]$$
$$+ \sum_{j=1}^{p} \alpha_j \Delta\left[LKRW1m_{t-j}\right] \ldots + [\theta_1][ECT_{t-1}] + \left[\varepsilon_{1,t}\right] \quad (3)$$

The extension of (3) of two variables into six variables shall be expressed as follow:

$$\begin{bmatrix} LKRW_t \\ LKWD1m_t \\ T10Y_t \\ CREDIT_t \\ LVIX_t \\ TED_t \end{bmatrix} = \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \\ \alpha_4 \\ \alpha_5 \\ \alpha_6 \end{bmatrix} + \sum_{i=1}^{p} \Delta \begin{bmatrix} \beta_{11i}\beta_{12i}\beta_{13i}\beta_{14i}\beta_{15i}\beta_{16i}\,\beta_{17i} \\ \beta_{21i}\beta_{22i}\beta_{23i}\beta_{24i}\beta_{25i}\beta_{26i}\,\beta_{27i} \\ \beta_{31i}\beta_{32i}\beta_{33i}\beta_{34i}\beta_{35i}\beta_{36i}\,\beta_{37i} \\ \beta_{41i}\beta_{42i}\beta_{43i}\beta_{44i}\beta_{45i}\beta_{46i}\,\beta_{47i} \\ \beta_{51i}\beta_{52i}\beta_{53i}\beta_{54i}\beta_{55i}\beta_{56i}\,\beta_{57i} \\ \beta_{61i}\beta_{62i}\beta_{63i}\beta_{64i}\beta_{65i}\beta_{66i}\,\beta_{67i} \end{bmatrix} \times \begin{bmatrix} LKRW_{t-j} \\ LKWD1m_{t-j} \\ T10Y_{t-j} \\ CREDIT_{t-j} \\ LVIX_{t-j} \\ TED_{t-j} \end{bmatrix} + \begin{bmatrix} \theta_1 \\ \theta_2 \\ \theta_3 \\ \theta_4 \\ \theta_5 \\ \theta_6 \end{bmatrix} [ECT_{t-1}] + \begin{bmatrix} \varepsilon_{1t} \\ \varepsilon_{2t} \\ \varepsilon_{3t} \\ \varepsilon_{4t} \\ \varepsilon_{5t} \\ \varepsilon_{6t} \end{bmatrix} \quad (4)$$

where $\triangle$ is the difference coefficient, and $ECT\ t\text{-}1$ is the term describing the long-term equilibrium relation of the estimation coefficient as an error correction term, where $\alpha\ \beta\ \theta$ is the measurement coefficient value, p is the time difference and ε_t is the error term. The Granger causality test verifies the significance of the coefficient values measured in relation to the lagged variable *j* and the variable *i. If "H_{null} : j does not granger cause i*" is rejected, j shall become a Granger cause to i. Impulse response verification measures how quickly information is passed between variables when impacts are delivered to the VECM model with time lag. In other words, this study analyzed how the variables in the model react with time when a certain amount of impact is delivered. A variance decomposition analysis shows the relative importance of variables, as the estimation error of VECM shows the proportion that is explained by its own and other variables. Therefore, if there is no decomposition value of the variable due to the impact of the residual, this variable is considered as exogenous.

4. Analysis data

4.1. data

The analysis variables are summarized in Table 2. The analysis period is from December 1, 2014 to November 30, 2017, and is daily closing data. The closing price is determined by the accumulation of both new information for the day and trading activities between the parties. The data was obtained through Bloomberg or heads, are organizational devices that guide the reader through your paper. There are two types: component heads and text heads.

Table 2: Analysis variables

	Market	Variables
	Global	US Treasury 10 Year
		Credit spread
		VIX index
		TED spread
Korea	onshore	KRW
	offshore	KWD1m
China	onshore	CNY
	offshore	CNH*, CNK**
Japan	Global	JPY

The exchange rate is the spot exchange rate. SPOT of the Chinese yuan, the Japanese yen, and the Korean won, against U.S. dollar. The Chinese yuan is analyzed by dividing it into onshore yuan (CNY) and offshore yuan in Hongkong (CNH). For the Korea won dollar, there is no offshore spot exchange rate. Therefore, the shortest term of one-month term in offshore market was used as a won-dollar offshore exchange rate (KWD1m). The analysis variables for the international financial market are the 10-year U.S. treasury bond interest rate, Credit risk spread, VIX index and TED spread, which are daily closing data. During the analysis period, there were no fundamental shift in the international financial market, such as the 1998 Asian financial market crisis or the 2008 international financial market crisis. Therefore, dummy variables were not considered. The analysis of basic statistics of yen, yuan, and won dollar is summarized in Table 3. The spot exchange rate and the VIX index were calculated as the difference between today's closing price taken on the log value and the previous day's closing price taken on the log value. The 10-year treasury interest rate, credit risk spread and TED spread are the difference between today's and the previous day's closing price of data.

* 10% significance level, ** 5% significance level, *** 1% significance level. KRW, CNY, and JPY are Korean, Chinese and Japanese spot exchange rates. CNH is the Chinese offshore yuan spot exchange rate, and KWD1m is the 1-month NDF KRW exchange rate. T10Y is the US treasury 10-year interest rate (%). CREDIT is the difference (%) of the spread between T10y and BBB credit rating bonds. VIX is the chicago options market index (%). TED is the difference between the libor 3-month interest rate and the T-bill rate (basis point)

Table 4: Stationary test

4.2. Data

The Stationary of the data was confirmed prior to the analysis. The study used ADF (Augmented Dickey Fuller) and PP (Phillips-Perron) unit root analysis method to verify the data. The analysis result of the yen, the yuan, and the won and international financial market variables are summarized in Table 4.

The first difference of the natural logarithm of spot exchange rate and VIX index data rejected the null hypothesis that "there is a unit root". Therefore, time series data satisfy the stationary condition. The first differenced data of 10-year US treasury interest rate (T10Y), Credit risk spread (CREDIT) and TED spread (TED) showed that the data satisfied the stationary without the unit root. Therefore, this study analyzed by using the log conversion for spot exchange rate, and VIX index data, and by using the level data for the US treasury 10-year interest rate, Credit risk spread, and TED spread.

4.3. Cointegration Test

The optimal time lag of the fifteen VECM model among the aforementioned six variables was determined prior to the cointegration test between the analytic variables. The optimal time lag was selected based on the time differences where AIC and SC values are minimized in the Akaike Information Criteria (AIC) or Schwarz Criteria (SC) analysis. The results of the time lag selection of the VECM (p) model are summarized in Table 6 below. The optimal time lag of the yen and Korea won is the time lag 3. The optimal time lag of the Chinese yuan is time lag 6. In the case of the yuan, the long-term equilibrium cointegration relationship was found to lag behind the yen and the won dollar. The time lag determined for each VECM model was applied to both the cointegration verification and the VECM analysis. The following includes the examination of whether there is at least one cointegration vector, which is a long-term equilibrium relationship between level variables of each time-series data, through cointegration analysis commonly used in financial time series data analysis. Table 5 summarizes the results of the number of the cointegration analysis of fifteen VECM analysis model between the analytic variables.

As summarized in Table 5, the null hypothesis of "no cointegration vector" was rejected at the 5% level for the all fifteen analysis model cases. Therefore, more than one cointegration relation between time series variables used in fifteen analysis model was revealed. The existence of the cointegration indicates that the individual variables are non-stationary, but when they are linked by a cointegration vector relation it indicates the stationary. Therefore, this study analyzed the lead-lag causality between variables using the VECM analysis model that includes the error correction term in the VAR model analysis.

5. Analysis Result

5.1. VECM Analysis

Table 6 shows the relationship between the rate of change of the analytic variables by applying the time lags to the fifteen VECM model using the long-term cointegrating equilibrium equations. The fifteen VECM analysis models' error correction term, ECT values are expressed as Coint EQ (1). In the VECM model analysis, if there are two cointegrations, it is expressed as Coint EQ (1) and (2). In the VECM analysis model, the ECT, error correction term must be negative (-) and statistically significant at the same time. Table 6 analysis results showed that 12 of the total 15 analysis models had negative (-) error correction terms and were statistically significant at the same time. However, in analysis models 5, 6 and 12, the error correction term was negative (-), but it was not significant.

* Korea won dollar and Seoul offshore yuan

We found four onshore won-dollar models, three offshore won-dollar models, and a total of seven VECM analysis models. The following Table 6 shows that all four VECM models of the onshore won-dollar were significant. The long-term equilibrium relationship explanation power of the VECM model was found to be around 50 percent to 68 percent. However, the explanation power of the three offshore won-dollar VECM models was about 3 percent to 6 percent. The error correction term, Coint EQ of the five VECM analysis models was negative (-) and statistically significant. However, analysis models No. 5 and No. 6 showed that the error correction term were negative (-), but were not statistically significant. The VECM Model No. 1, CNK, shows a long-term equilibrium relationship between the won-dollar and the yuan and the yen. Since CNK is an offshore yuan traded in the Seoul foreign exchange market, there are no restrictions on its transactions. Therefore, it has been shown that the Seoul offshore yuan (CNK) has a long-term equilibrium relationship with onshore yuan (CNY) and offshore yuan (CNH) and Japanese yen (JPY) either. These results suggest that although the yuan's liquidity in the Seoul foreign exchange market is relatively insufficient compared to Hong Kong. Therefore, it secures insufficient liquidity through cross-rate transactions between currencies of KRW↔USD↔CNH, CNY, and JPY. The amount of liquidity of a currency used in transactions turned out to be the influence factor of these currencies. It gives impact on the Seoul offshore yuan (CNK) exchange rate either. VECM model No. 2, onshore won-dollar (KRW) exchange rate, indicated that there was a long-term equilibrium relationship with the offshore won-dollar exchange rate, the yuan and the yen. This result implied that the won-dollar exchange rate received impact by the yuan and yen flowing through the export/import trade and inter-bank money markets transactions between Korea, China, and Japan. VECM Model No. 4 is an analysis of the relationship between the onshore won-dollar (KRW) and the variables in the international financial market. The analysis results indicated that the won-dollar exchange rate has a long-term equilibrium relationship with variables in the international financial market. VECM Analysis Models No. 1, No. 2, No. 3 and 4 show that the error correction factor of the offshore won-dollar exchange rate (KWD1m) is greater than that of the other variables. VECM model No. 3 analyzed the relationship between two variables, the onshore won-dollar exchange rate (KRW) and the offshore won-dollar (KWD1m). According to the analysis of the long-term equilibrium relationship between the two variables, the offshore won-dollar exchange rate explains the onshore won-dollar exchange rate about 50%. These results are similar to [47] the author's argument. They studied the Granger causal relationship between the KRW exchange rate and the offshore NDF KRW market. They argued that the offshore one-month forward exchange market was strongly causative in the onshore spot exchange market and that the volatility shock was exchanged between the two markets. In [34] the author analyzed the relationship between offshore yuan (CNH) and onshore yuan (CNY) for the period from September 2010 to August 2013. They argued that the CNH Hong Kong yuan has a predictive power for the CNY yuan in China. The Korean won has not yet been internationalized, but like the yuan, the onshore won-dollar exchange rate has been consistently and strongly influenced by the offshore market won-dollar exchange rate. In addition, the offshore won-dollar exchange rate, KWD1m is found to have a long-term equilibrium relationship with four variables in the international financial market, and as a result, the Korean won-dollar exchange rate (KRW) is affected by variables in the international financial market either. The results suggest that Korea onshore won-dollar exchange market and the Korea won-

government bond market and the inter-bank money market are substantially and effectively open, so this increase the link to the international financial market. In [49] the author and in [50] the announcement argued that certain currency shocks are transferred through the interbank money market. It also argued that the impact from the US dollar currency affects the interbank money markets in Hong Kong (HKD), Australia (AUD), Japan (JPY), and Korea (KRW). However, they argued that the impact of the US dollar currency impact on China (Yuan), Thailand (THB) and Malaysia (RHB) is limited. The fact that the Korean won dollar exchange rate is strongly related to the international financial market is in line with [49] the author's argument and with [50] announcement. The VECM model relationships model No. 5 and model No. 6 were not significant. The analysis shows that offshore won-dollar exchange rates are more affected by international financial market factors than by regional factors between Korea, China and Japan in Northeast Asia.

*China Yuan

We found three onshore analysis model and four offshore analysis models, and a total of seven VECM analysis models. The three VECM models of the onshore yuan (CNY) were shown to be statistically significant. The three long-term equilibrium relationship VECM models of the onshore yuan had the explanatory power of between 7% and 8%. The explanatory power of the four VECM models of the Hong Kong offshore yuan (CNH) was between 4% and 5%. Although the error correction term of the six VECM analysis models was significant, analysis model 12 showed that the error correction term was not significant. The VECM model No. 8 Chinese onshore yuan (CNY) was found to have a long-term equilibrium relationship with the onshore won dollar (KRW) and the yen (JPY). The analysis results of VECM Model No. 10 and No. 14 show that onshore and offshore yuan have long-term equilibrium relationship with international financial market variables. The VECM model No. 11 Hong Kong offshore yuan (CNH) has a long-term equilibrium relationship with the Chinese onshore yuan (CNY) and the Korean offshore yuan (CNK). The unusual was that, VECM analysis models No. 9 and 13, show that China's long-term equilibrium relationship between onshore and offshore yuan is weaker than Korea's onshore and offshore won-dollar relations. In the previous model No. 3 Korean Won-dollar VECM analysis model, offshore Won-dollar's explanation power on the onshore KRW was about 50%, at 1% significant level. However, the explanatory power of the VECM No. 9 and No. 13 analytical models analyzed the Chinese yuan was 7.3% and 5.4%, respectively, and it was found to be significant at the 10% level. It is unusual for the long-term equilibrium relationship between onshore and offshore yuan markets to be weaker than the non-international currency of Korea won. This analysis result is interpreted by the fact that the yuan onshore-offshore trade related cross border transactions are liberalized, but capital market transactions are limited. Overall, the yuan's long-term equilibrium relationship with other currencies was weaker than that of Korea won. And these results are in line with [49] the author's argument that the impact of the shock from the US dollar currency on Chinese yuan is limited.

*Japan Yen

VECM Analysis Model No. 15 of Table 6 is the result of an analysis of the long-term equilibrium relationship between the Japanese yen and variables in the international financial market. The analysis indicated that the yen exchange rate is more related to the variables in the international financial market than that of the won and the yuan. This result suggest that the yen is international currency and the Japanese bond markets are fully open to international financial market investors, so, the greater association with the variables of the international financial market than the non-international currency, the Korea won and the yuan, which is on the way of internationalized. Analysis models 1, 2, and 8 show that the onshore won dollar (KRW) and the onshore yuan (CNY) have a long-term equilibrium relationship with the yen (JPY). This result show that since most of the demand and supply of foreign exchange transactions occurred through import-export transactions and were supplied to the foreign exchange markets in Korea and China, so the currency market result in long term equilibrium relationship. However, looking at analysis models Nos. 5, 6, and 12, it was found that the offshore won (KWD1m) and the offshore yuan (CNH) had no long-term equilibrium relationship with the yen (JPY). This result is interpreted as that, in the offshore international financial market, since investors trade currencies in consideration of the country risk of the currency, a long-term equilibrium relationship between the offshore won and the offshore yuan is not established with the international currency, the yen.

5.2. Granger Causality Analysis

The VECM model has no restriction on the analytical model and may cause a fictitious spurious regression analysis problem. As such, this study further conducted a widely used in time series

analysis, Granger causality test. The null hypothesis of Granger causality test is that "the offshore won, KWD1m has no effect on the spot exchange rate of the onshore won, KRW", and the direction of the causal relationship in Table 7 was written as "KWD1m→KRW". If the null hypothesis is rejected, the offshore won shall have an impact on onshore KRW exchange rates. Table 7 summarizes the results of the Granger causality analysis between the exchange rates of Japanese yen, Chinese renminbi, and Korean won, and between the exchange rates of the three currencies of Korea, China, and Japan and variables in the international financial market.

Table 7: Granger Causality analysis of won, yuan, yen and international financial market variables

* (KWD1m → KRW) the direction of the arrow is the direction of the granger causal relationship. 'na' is no the granger causal relationship does not exist at the significance level. The Granger causal relationship analysis results of analysis models 2, 3, 5 to 9, 11 to 13 are overlapped with model 1

*Korea won dollar and Seoul offshore yuan

Models No. 1 through No. 4 in Table 7 summarizes the variables affecting the Granger causal relationship between the Korean won (KRW) and the Seoul offshore yuan (CNH). The causality analysis among the variables showed that offshore won (KWD1m) was the biggest cause-and-effectiveness for Korean onshore won (KRW). After KWD1m, the onshore won exchange rate was shown to be causal in the order of Hong Kong's offshore yuan (CNH), China's onshore yuan (CNY) and Japan's yen (JPY) at 1% significant level. These results suggest that the offshore won-dollar exchange rate had the greatest impact on the onshore won-dollar exchange rate. And it is in line with the findings of [34] the author who claimed that the influence of the Chinese offshore yuan on the onshore yuan has increased. The unusual was that the Chinese yuan causes more on the onshore won dollar exchange rate than the yen. These results are interpreted as reflecting the largest export-import trade volume of Korea with China. Model 4 analyzed the Granger causal relationship between the won dollar and international financial market variables. The analysis results show that 10-year US treasury bonds, Credit risk spread, and VIX index causes Korean onshore won dollars (KRW) at 1%, 5%, and 1% significance levels, respectively. Models No. 5 through 7 analyzed and summarized the variables affecting causality in offshore won dollars. According to the Granger causal analysis among the variables, the offshore won-dollar exchange rate (KWD1m) has no causal relationship with the onshore dollar, the Hong Kong Overseas Yuan (CNH), the Chinese onshore yuan (CNY) and yen (JPY). Similar to this analysis, the analysis results of VECM model No. 5 showed that offshore won has no long-term equilibrium with the yuan and yen. In [51] the author argued that the depreciation of the exchange rate is an increase in the sovereign credit risk. The analysis results of this paper and in [51] the author reconfirm that when international financial market investors trade offshore won (KWD1m), they trade based on the expected rate of return versus risk considering the country-specific factor only. In addition, offshore dollars are freely traded in overseas markets without being restricted by Korea foreign exchange transaction regulations, and the difference in price at maturity is settled in US dollars. Therefore, the absence of a liquidity problem in offshore won have affected the analysis results. This analysis result is reconfirmed in the Granger causality relationship analysis result of the model 7 variables. International financial market variables such as US 10-year treasury bonds, Credit risk spread, and TED spread were found to cause offshore won dollars (KWD1m) at 1%, 5%, and 5% significant level, respectively. The results of the Granger causality relationship analysis of Models 5 and 7 show that the offshore won-dollar exchange rate has no causal relationship with the yuan and yen but has a causal relationship with international financial market variables. These results provide policy implications that the analysis of future won-dollar exchange rate fluctuations should be approached from the perspective of global investment portfolio investor in international market.

*China Yuan

Models 8 to 10 in Table 7 summarize variables that have a Granger causal effect on the Chinese onshore yuan (CNY). Since the variables used in the Granger causal relationship analysis are the same as those of models 1 to 4, we need to refer the analysis result of model 1. The analysis results of this study showed that the Hong Kong offshore yuan, CNH was causal to the Chinese onshore yuan (CNY) at a significance level of 1%. However, it was found that the Seoul offshore yuan (CNK), the offshore won dollar (KWD1m), the onshore won dollar (KRW), and the Japanese yen (JPY) do not cause the Chinese onshore yuan (CNY). Model No. 10, the analysis of Granger causality between the yuan and the variables in the international financial market showed that only the TED spread Granger causal the yuan at a 5% significance level. However, 10-year US treasury interest rate, the Credit risk spread, the VIX index did not cause onshore yuan. Models 11-14 summarize the variables that have a Granger causal effect on the Hong Kong offshore yuan (CNH). Since the variables used in the Granger causal relationship analysis are the same as those of models 1 to 4, we refer to the ones summarized in model 1. According to the results of Granger causal relationship analysis between variables, it was found that the Chinese onshore yuan (CNY) caused the Hong Kong offshore yuan (CNH) at a 1% significance level. In the model 14, the analysis of the Granger causal relationship between the offshore yuan and the variables of the international financial market variables, it was found that only TED spread caused Hong Kong offshore yuan (CNH) at a 5% significance level. However, similar to the onshore yuan (CNY), the 10-year US treasury interest rate, Credit risk spread, VIX index, did not appear to be Granger causal to the Hong Kong offshore yuan (CNH). These results show that since dollar liquidity required for currency exchange transactions is secured through the interbank money market, the TED spread, which represents the level of liquidity in the interbank money market, has an impact. In the case of Korean won, the offshore won dollar market caused onshore won, but not in the opposite case. In the case of the yuan, however, it was found that the onshore-offshore yuan exchanged its causal relationship. In [35] the author argued that yuan liquidity and risk aversion of investors in international financial markets are the main reasons for creating price differences and generating profit-taking arbitrage transaction between CNY and CNH. They argued that increased inflow of yuan from the onshore CNY market to the Hong Kong CNH offshore market would reduce the difference in CNH-CNY prices, so that the yuan exchange rate would be adjusted based on the onshore CNY, which has more liquidity. According to [50] the statement, China began supplying yuan liquidity to Hong Kong's offshore markets in cooperation with HKMA on November 10, 2014. Therefore, the onshore yuan's Granger causal of offshore yuan is showed. Offshore yuan have been influenced by the ample liquidity of the onshore yuan market. In [34] the author analyzed CNH and CNY markets for the period from September 2010 to August 2013. They argued that CNH's influence on CNY has increased, and argued that CNH Hong Kong offshore yuan has

predictive power over CNY China onshore yuan. The onshore yuan market is limited to investors in the international financial market, while the Hong Kong currency market has no trading limitation. Therefore, as argued by [34] the author, it has been shown that the price-discovery effect of the Hong Kong offshore yuan market may have affected the onshore yuan market. The yuan (CNY and CNH), the SDR currency, is the same yuan, but the onshore yuan and the offshore yuan exchange each other's independent causal relationship and each has a distinct characteristic. These analysis results provide important implications for investment and risk-hedge transactions for companies that use the yuan to trade in import-exports and for investors in the international financial market.

*Japan Yen

Model 15 of Table 7 summarizes the Granger causal relationship of international financial market variables to the Japanese yen. The analysis results showed that all four variables (the 10-year US treasury bond, credit risk spread, VIX index, and TED spread) were responsible for the change in the yen's exchange rate at 1%, 1%, 5%, and 1%, significant level respectively. The aforementioned analysis of the Korean won dollar showed that three variables in the international financial market affect the won-dollar exchange rate. In yuan case, only TED spread affects the yuan's exchange rate. It was expected that the yen, the international currency, would be the strongest in the strength of Granger causality relationship among the variables in the international financial market, Chinese the yuan that is in the process of internationalization, would be the next and the won-dollar, the non-international currency would be the weakest. However, the analysis result showed that the non-international currency, the won, has a stronger Granger causal relationship with variables in the international financial market than that of Chinese the yuan. In [14] the author analyzed the effects of international financial market variables and currency exchange rates on the country CDS premium. They argued that the Granger causal relationship of the international financial market variables and the won-dollar exchange rate that affect the Korea country CDS premium is stronger than that of the China country CDS premium. Therefore, when a shock occurs in the international financial market, the shock could be dispersed and absorbed into the Korea CDS premium and the onshore and offshore won-dollar currency market. However, for China the shock could be concentrated in the CDS premium only. The analysis results that the Korean won dollar has a stronger Granger causal relationship with international financial market variables than the Chinese yuan is in line with their arguments.

5.3. Impulse Response Analysis

The Granger causality test informs the direction of the causal relationship between variables. However, the Granger causality test cannot determine whether the direction of the causal relationship is positive (+) or negative (-). Therefore, the impulse response analysis was performed to measure the impact of a specific variable on other variables. The Impulse response results are summarized in Table 8 for the results of the 1 to 10th and 20th, and 30th days.

Table 8: Impulse response analysis of won, yuan, yen and international financial market variables

* a negative number in parentheses

*Korea won dollar and Seoul offshore yuan

Table 8 summarizes the impulse response results of 15 analysis models. The analysis results of this study showed that Model No. 1, the Seoul offshore yuan (CNK) reacts positively to the shock from the offshore dollar. It responds positively to shocks from the onshore dollar and yen. However, it reacts negatively to the shock of the yuan offshore and onshore in China. It was found that the Seoul offshore yuan currency (CNK) is most strongly affected by the impulse shock from the offshore won-dollars (KWD1m). It was found that the influence of the offshore won dollar on the Seoul offshore yuan (CNK) was greater than that of the CNH, and CNY. These results are found to be due to the fact that the lack of yuan liquidity in the Seoul offshore yuan market compared to the Hong Kong and Chinese yuan markets. It was found that the Seoul offshore yuan (CNK) market financed insufficient yuan liquidity through offshore won dollar cross rate arbitrage transaction. In addition, the impact from onshore won (KRW) and offshore won (KWD1m), Chinese onshore yuan (CNY), Hong Kong offshore yuan (CNH), and yen (JPY) to the Seoul offshore yuan (CNK) was mostly reflected within 1 to 6 time lag. This result is interpreted as the Seoul offshore yuan (CNK) exchange rate being adjusted over time through arbitrage trading between the foreign exchange markets. Model No. 2 onshore won dollar (KRW) was found to react positively to the shock from offshore won dollars. It reacts positively to shocks from the Hong Kong offshore yuan and yen. However, it reacts negatively from the shock of the Chinese onshore yuan (CNY). The onshore won dollar (KRW) has a positive response to the shock from the offshore won dollar (KWD1m) and the yen and remains constant. The onshore won dollar showed adjustment response to the impact of the offshore yuan, but a constant negative (-) response to the impact from the onshore yuan. The result is interpreted as the fact that it takes time for the onshore yuan to be delivered to the Seoul offshore yuan market through import-export transactions and limited capital market transactions. This can also be seen in the VECM analysis model No. 9 and No. 13 in Table 6 which has optimal analysis time lag was 4 and 6 days. It is also unusual for the onshore won-dollar, KRW to have different impulse reactions of the onshore yuan and offshore yuan. The onshore won-dollar showed an adjustment reaction that reverse the positive sign to negative to the impact from the Hong Kong offshore yuan (CNH). These results are interpreted that since onshore won-dollar markets and Hong Kong offshore yuan markets have no restrictions on foreign exchange trading in general, so the two markets adjust to the external shocks with cross rate arbitrage transactions. However, onshore won-dollar continuously responded negatively to the shock from the Chinese onshore yuan. The reason for such results can be interpreted that because foreign exchange transactions

between the Seoul and China are only export-import related transactions are liberalized but capital market transactions are still limited, so the adjustment responses to the shocks from the outside are different. In [49] the author argued that the impact of the shock from the US dollar currency on Chinese yuan was limited. The onshore won-dollar's negative reaction to the shock of the onshore yuan is in the same line as his argument. However, the direction of onshore and offshore yuan shock transfer to the onshore Korean won is partly opposite. This is interesting in that the impact of the yuan on the onshore won-dollar exchange rate is partially offset by offshore yuan. And these results can be interpreted that the different characteristics of the onshore and the offshore yuan contributed in part to the stabilization of the onshore won-dollar exchange rate. Models 4 and 7 onshore and offshore won dollars responded almost identically to shocks from international financial market variables. The onshore and offshore won dollar responded positively to the impact of the 10-year US treasury bond and credit risk spread. In the VIX index shock, it reacted to positive (+) and then converted to negative (-), and the shock disappeared. It responded continuously negative to the impact from the TED spread. Overall, the Korean onshore and offshore won dollar and the Japanese yen had similar shock reactions to the impact from the international financial market. However, the onshore and offshore yuan showed relatively weaker responses to shocks from variables in the international financial market than that of the won and yen. In [39] the research report argues that the determinants of investment capital inflow to emerging countries are largely influenced by factors on the supplier side, such as the level of US treasury bond rates and preference for safe assets in the international financial market. They argued that a 50bp fall in the 10-year US treasury bond yield would increase the total capital inflow to emerging countries by 13%. Korean onshore and offshore won dollars and Chinese onshore and offshore yuan responded positively to the shock arising from 10-year US treasury bonds. Rising risk free interest rates on 10-year U.S. treasury bonds increase demand for the U.S. dollar and lead to capital outflows from emerging markets, which in turn could weaken emerging economies' currencies. This study also confirmed the results consistent with the IMF research. In [39] the research report argued that the VIX index represents the preference for safe assets in international financial markets, and that if the VIX index falls in half, the total capital inflow of emerging countries increases by 11%. However, the onshore and offshore won dollars were slightly different from the IMF argument. The impact from the VIX index was weaker than US 10-year treasury and credit spread. The reason for such results can be interpreted that, because the impact from the VIX index can be adjusted through the NDF KWD1m transaction and the offshore won dollar (KWD1m) readjusts the onshore won dollar (KRW). This result is also explained as the volume of offshore won-dollar, NDF transactions in the international financial market accounts for about 20% of the total global NDF transactions. The won dollar, the yuan, and the yen all reacted in the same negative direction to the shock from the TED spread. Changes in the TED spread implies changes in the overall liquidity level in the international financial market, or changes in credit risk levels and bond yields. In [45] the author used the TED spread as a measure of hedge funds' liquidity level. In [49] the author argued that the impact of a particular currency is spill over through the interbank money market. As he claimed, this study also reconfirmed that the shock generated by TED spread, a variable in the international financial market, was similarly transmitted to Korea won, China yuan and Japan yen. The reason for such results can be interpreted that because banks in Korea, Japan, and China, which are counterparties in money market transactions, do not have a large difference in financing capacity in the international interbank market, and therefore all respond similarly to the shock from the TED Spread change.

*China Yuan

Table 8 summarizes the analysis results of Model No. 8, Chinese onshore yuan (CNY). CNY was found to react negatively to shocks from offshore won dollars (KWD1m), Seoul offshore yuan (CNK) and yen (JPY). On the other hand, Chinese onshore yuan responded positively to shocks from Hong Kong offshore yuan and onshore won dollar. The Chinese onshore and offshore yuan reacts positive (+) to the shocks generated from each other because the two markets are closely interconnected. The Chinese onshore yuan (CNY) reacted positively to the shock from the Korean onshore won (KRW). This phenomenon is attributed to the fact that the 250 billion dollars import-export transactions volume between South Korea and China. Analysis of models 10 and 14, onshore and offshore yuan, and international financial market variables, showed that the onshore and offshore yuan responded similarly to shocks from international financial market variables. The unusual was that the yuan is the SDR international currency, but the response to the impact from international financial market variables was relatively weak compared to the non-international currencies Korean won and international currency Japanese yen. This phenomenon once again support [49] the author's argument that the impact of the US dollar currency on Chinese yuan is limited.

*Japan Yen

The analysis result of model No. 15, yen, JPY summarized in Table 8 shows that JPY consistently responds to the shocks from international financial markets. The yen responded positively to shocks from 10-year US treasury bonds and credit risk spreads, and negatively (-) to shocks from the VIX index and TED spreads.

5.4. Variance Decomposition Analysis

Variance decomposition analysis is to measure the variance of the prediction error of the VECM analysis model and divide the weight for each variable. Table 9 summarized analysis result.

Table 9: Variance decomposition analysis of won, yuan, yen and international financial market variables

*Korea won dollar and Seoul offshore yuan

In Table 9, it was found that the offshore won dollar (KWD1m) accounts for more than 70% of the variance of the onshore won dollar (KRW) and the Seoul offshore yuan (CNK). In [52] the author argued that the volatility of the offshore yuan had a great influence on the exchange rate of the onshore yuan. The results of this study also showed similar results to their argument. The analysis results of this study showed that the onshore won dollar exchange rate is greatly affected by the offshore won dollar. The reason for such results can be interpreted that, First, the won dollar is effectively and practically internationalized in general. Korean won, transactions between onshore and offshore markets are processed through the cross rates arbitrage transactions. Various SWAP transactions using interest rate differential between the Seoul foreign exchange market and the international financial market support this finding. Therefore, the Korea won may be considered as partly internationalized currency. Second, offshore won-dollar (KWD1m) transactions, which have absolute influence on the onshore won-dollar (KRW), have no liquidity problems. This is because offshore NDF won-dollar payments are settled in U.S. dollars at the maturity, so they are not subject to KRW liquidity constraints. Third, it is because investors in the international financial market actively utilize the offshore won-dollar market. This phenomenon is reaffirmed that about 20 percent of the world's NDF currency market transactions are DNF Korea won- dollar. Fourth, Korea is the top 10 global exporters and importers. Therefore, the demand for won-dollar transactions related to import-export settlement and capital market transactions are sizeable in onshore and offshore markets. The analysis results of this study showed that the variance decomposition analysis results between the onshore-offshore won dollar and the variables of the international financial market (analysis models 4 and 7) are similar. In addition, the analysis of variance decomposition of the Korean won, the Japanese yen and the international financial market variables show similarity either. This phenomenon is attributed to the fact that the Korea won has both the characteristics of emerging market currencies and international currencies either.

*China Yuan

The results of analysis of models No. 8-14 in Table 9 show that the onshore-offshore yuan variable explains 92%-95% of the total variance of yuan itself. Compared to the won dollar and yen, the onshore-offshore yuan showed relatively weak explanatory power of other currencies and international financial markets variables. The results of this analysis also reaffirm of [49] the author's argument that the impact of the US dollar is limited in the yuan.

*Japan Yen

The results of the analysis of variance decomposition of the Japanese yen (JPY) of model No. 15 summarized in Table 9 are similar to the results of analysis of Korean onshore and offshore won dollars in analysis models No. 4 and No. 7. The explanatory power of the variables in the international financial market for the won dollar and the yen were similar.

6. Summary and Conclusion

This study analyzed the relationship between renminbi (onshore and offshore), won dollar (onshore and offshore), yen spot exchange rate, and international financial market variables using the VECM model. The analysis period is 3 years from December 1, 2014 to November 30, 2017, and daily closing price data were used. Analysis variables are US dollar-based Chinese yuan (onshore and offshore), Korean won dollar (onshore and offshore), Japanese yen spot exchange rate, and international financial market variables. During the analysis, there were no unusual situations in the international financial market, such as the 1998 Asian financial market crisis or the 2008 global financial market crisis. Therefore, dummy variables were not considered. We used Bloomberg data. The results of the analysis are as follows: First, there was a long-term cointegration equilibrium relationship between yuan (onshore and offshore), won dollar (onshore and offshore), yen spot exchange rate, and international

financial market variables. Second, In the results of VECM analysis of won dollar, yen and yuan, it was found that there is a long-term equilibrium relationship between the Seoul offshore yuan (CNK), Hong Kong offshore yuan (CNH) and the China onshore yuan, (CNY). The result is interpreted as the yuan's liquidity in Seoul's offshore foreign exchange market is relatively insufficient compared to Hong Kong's, and the lack of the liquidity is financed through cross rate transactions between currencies of KRW↔USD↔CNH, CNY. The onshore won dollar (KRW) has a long-term equilibrium relationship in the VECM model from the relationship between the offshore won dollar, the onshore and offshore yuan, and the yen. The explanatory power of offshore won dollars (KWD1m) to onshore won dollars (KRW) using the VECM model was found to be about 50%. And it was found that the offshore won dollar exchange rate has a long-term equilibrium relationship with four variables in the international financial market. As a result, Korea's onshore won-dollar exchange rate was found to be largely influenced by international financial market variables. China's Onshore yuan (CNY) is found to have a long-term equilibrium relationship with the Hong Kong currency (CNH), the onshore and offshore won dollar, and the yen. CNY has also a long-term equilibrium relationship with four variables in the international financial market. Hong Kong's offshore yuan (CNH) has a long-term equilibrium relationship between China's onshore yuan (CNY) and Korea's offshore yuan (CNK). There is also a long-term equilibrium relationship with four variables in the international financial market. However, Hong Kong's offshore yuan has not had a long-term equilibrium with the onshore and offshore won and the yen. The unusual was that although there was a long-term equilibrium relationship between the onshore and offshore yuan, the relationship was weaker than that of the onshore and offshore won-dollar. Overall, the yuan has a weaker long-term equilibrium relationship with other currencies than that of the won dollar. This phenomenon can be interpreted as the yuan is a currency in the progress of internationalization, and still foreign exchange transactions are limited. Commercial export-import cross border yuan transactions are liberalized but capital market transactions are still limited. VECM model analysis of onshore won dollar and onshore yuan have a long-term equilibrium relationship with yen. The reason for such results can be interpreted that the supply of the won dollar, yuan, and yen currency positions are exchanged in the foreign exchange markets of Korea, China and Japan through export-import transactions between Korea, China and Japan. However, the offshore won dollar (NDF, KWD1m) and offshore yuan (CNH) does not show long-term equilibrium relationship with the yen (JPY). This result is interpreted to be because investors in the international financial market, which do not have transaction restrictions, take into account country specific factors only when they trade in currency market. The results of the analysis of the yen VECM model showed that the yen is more correlated with international financial market variables than that of the won dollar and yuan, as expected. Third, the results of the Granger causality relationship between the won dollar, yen, yuan and international financial market variables. It was found that the offshore won dollar (KWD1m) was the biggest causative (Granger causality) to the Korean onshore won dollar (KRW). Subsequently, in the order of the Hong Kong offshore yuan (CNH), the Chinese onshore yuan (CNY) and the Japanese yen (JPY). It was found that the Chinese yuan has slightly stronger Granger causality the Korean won than that of the Japanese yen. The offshore won dollar exchange rate (KWD1m) showed no Granger causal relationship from the onshore won dollar (KRW), Hong Kong offshore yuan (CNH), Chinese onshore yuan (CNY), and Japanese yen (JPY). However, the international financial market variables such as 10-year US treasury bonds, Credit risk spread, and TED spread were found to Granger cause offshore won (KWD1m). Chinese onshore yuan (CNY) was found to Granger cause Hong Kong offshore yuan (CNH) at a 1% significance level. And the reverse case was also significant at the 1% level. As for yuan, onshore and offshore yuan were found to exchange Granger causality relationship. However, it was found that international financial market variables do not Granger cause onshore and offshore yuan. In addition, onshore yuan (CNY) and offshore yuan (CNH) each independently showed a Granger causal relationship with the won dollar and the yen. Therefore, it was found that onshore and offshore yuan have distinct characteristics. This phenomenon is interpreted as the fact that although the yuan is an internationalized currency, only export-import commercial transactions are liberalized but capital market transactions are still limited. The Japanese yen (JPY) has a stronger Granger causal relationship than that of the won dollar and yuan. It was found that three out of four variables in the international financial market have a Granger causal effect on the Korean won dollar exchange rate. However, it was found that only one TED spread has a Granger causal effect on the yuan exchange rate. It was found that international financial market variables had a stronger Granger causal relationship on the non-international currency, the Korean won dollar, than that of the SDR international currency, the Chinese yuan. Fourth, the results of Impulse response analysis. The onshore won dollar (KRW) and the Seoul offshore yuan (CNK) were found to be most strongly affected by the impact from the offshore won dollar (KWD1m). The onshore won dollar (KRW) consistently reacts negatively to the onshore yuan (CNY) shock, but reverse response of positive (+) to negative (-) with different time lag of the offshore yuan (CNH) shock. Therefore, some of the onshore and offshore yuan shocks delivered to the onshore won-dollar (KRW) exchange rate were found to be mutually offset. Overall, Korean onshore (KRW) and offshore won dollars (KWD1m) and Japanese yen (JPY) showed similar impulse responses to shocks from international financial markets. However, the impulse response of the onshore (CNY) and offshore yuan (CNH) to international financial market variables was weaker than that of the won dollar and yen. China's onshore and offshore yuan responded positively to the mutual shock. These results are interpreted as the two markets are closely related to each other as China supplies yuan liquidity to the Hong Kong offshore (CNH) market. Fifth, the result of Variance decomposition analysis. The offshore won dollar (KWD1m) was found to account for more than 70% of the variance of Korean onshore won dollar (KRW) and the Seoul offshore yuan (CNK). International financial market variables have similar degrees of explanation power for the variance of Korean onshore and offshore won and Japanese yen. On the other hand, international financial market variables showed weaker explanatory power for Chinese onshore and offshore yuan compared to Korean won and Japanese yen. These results suggest that the Korea won dollar is closely related to international financial market.

The implications of this study are as follows: First, from the perspective of the international financial market, we compared and

analyzed the won dollar (onshore and offshore), yuan (onshore and offshore), and yen. As a result of analyzing the long-term equilibrium relationship with the VECM model, it was found that the offshore won-dollar exchange rate and the international financial market variables explained more than 50% of the onshore won-dollar exchange rate. Therefore, it was revealed that it is important to monitor the international financial market for changes in the onshore won-dollar exchange rate. Second, overall, the Korean won dollar was found to have greater integration with the international financial market than the Chinese yuan, the SDR international currency. Therefore, it is necessary to consider the characteristics of the won, which is practically and partially similar to the international currency. It also revealed that a new perspective on the Korea won-dollar exchange rate is needed from the perspective of global portfolio investors. Third, the SDR currency, the yuan, is closely related to the onshore yuan (CNY) and the offshore yuan (CNH), but at the same time, each has its own unique market characteristics. Therefore, it was revealed that companies and investors that trade in yuan need to manage currency risks in consideration of the characteristics of the onshore and offshore yuan market. Fourth, it was revealed that for the development of the Korean financial market, it is necessary to prepare a way to actively utilize the won, which has already partially internationalized, in areas where possible, such as SME import-export transaction, investment of sovereign wealth funds. Under the modern monetary economy, where integration with global financial markets is deepening and the role of finance is important, the Korean won will need a partial and managed internationalization process.

ABSTRACT

Computer vision offers several strategies that permit computers to comprehend the substance of inputted data to extract the relevant highlights features. That gives the possibility to develop several successful recognition systems like face identification. One of the enormous difficulties these days is the way to have a prompt identification face in a multi-client identification system. We propose in this paper, an optimization of some face identification systems in big data environments that manages the cost of an appropriate identification time while holding a good performance of the system. The used systems are based on: CNN with Inception V3, PCA, LDA and LBPH. Our experimental results indicate that the performance can be preserved while reducing considerably the running time. LBPH with a Radius equal to 2 and 8 neighbors gives the best accuracy of that is equal to 95,71% with an identification time of 4.44 seconds.

1 Introduction

Computer vision offers several techniques for machines to understand the content of images like human vision. To understand the content of images, machines need some image processing steps to be able to extract features from the images for several applications such as face identification, object recognition and object tracking.

The substantial idea of a biometric system is to utilize acquisitions of behavioral and/or physiological characteristics of human like face, fingerprint, signature and voice for recognition/verification. Currently, several face identification systems use large-scale databases that contain a big number of subjects such as celabA Dataset that contains 10177 identities and 202599 images. Large-scale databases present a big open challenge to create an operational biometric identification that offers an acceptable identification time. The Scalability [1] of such tremendous systems makes the challenge harder to be solved. This work is concerned with the creation and optimization of such biometric identification systems.

This paper is an extension of a previous work presented during 2019 in the 1st International Conference on Smart Systems and Data Science (ICSSD) [2], where we have tested and built several identification systems (i.e., LBPH [3],[4], PCA [5], LDA [5] and deep learning with inception V3 [6]) that use a big database with some hard conditions.

The remainder of the paper is structured as follows. The related works are presented in Section 2. Section 3 presents the different used face identification systems with all optimization steps. Our experimental results are introduced in Section 4 Our conclusion and perspectives are given in Section 5.

2 Related Work

Identification time, efficiency and security are three crucial issues from which large-scale identification systems suffer. Due to these problems. Several published kinds of research deal with such problems. On one hand, some published approaches tackle security issues whom we can cite [7],[8] that implemented Biometric anti-spoofing technique by using the trait randomization technique.

On the other hand, published approaches can be part of two significant classes: learning distribution approach (first class) and Processing distribution approaches (second class). The principal idea of the second class is sharing tasks to several workers in the cluster to handle the issue of treatment large amounts of data in a few

[*]Corresponding Author: Majdouline Meddad, Email: majdouline_meddad@um5.ac.ma

times by employing the big data technologies in the cloud environment for parallel-distribution treatment. Well known, deep learning models are hefty in computing when it needs more iterations to get the best performant model which needs to use an approach of the first class with big data technologies to distribute the learning process.

For the first class, the crucial idea presented in [9] is merging the utility of the neural network algorithm with the MapReduce technique to face the extensive data problem in handwritten characters. The authors in [10] proposed for the handwriting recognition digit by firstly applying an elastic distortion to the entered data then Implemented a computing method with distribution to gain the time cost by mapping the dataset into several machines of the cluster. In [11], the author proposed some parallelization methods which are MRBPNN 1, 2 and 3) based on a MapReduce technique to face exhaustive scenarios in the conditions of the size of data and neurons.

For the second class, [12] displays a MapReduce technique of the process of converting frames of video to grayscale images as a preprocessing technique to extract features from converted images. In [13], the author apply a distributed medical application in two different techniques of distribution such as MapReduce and Sun Grid Engine regarding running time. In [14], the author introduced an approach for storing and processing satellite images by a remote sensing processing tools OTB with the MapReduce technique of Big Data technologies. In [15], the author proposed to use the MapReduce for parallel model execution to extract the similarity of the tumor image. We trust that the principal drawback of this class is hard to manage the cluster to ensure continuity of processing in a distributed platform and Hadoop technology requires a significant memory.

3 Face Identification In Big Data Environment

The conception of a biometric system carries four principal parts as shown in FIG.1.

- The sensor part (Grey Box) that obtains the biometric information to remove a computerized portrayal during enlistment, identification or verification.
- The characteristic extraction part (Green Box) that empowers decreasing the dimensionality of the representation, emitted by the sensor part, by extricating the significant capabilities. This part can possess a sub-part to test the norm of gained biometric information.
- The database part (Red Box) that comprises the biometric formats of the enlisted subjects inside the framework.
- The decision part (Orange Box) that contrasts the test format and the enlisted formats of the database part requires a decision with regards to the sort of the framework.

The correspondence between these parts becomes tedious inside of having huge database for identification systems. To fix this difficulty, we will utilize some technologies for parallelizing these correspondence tasks inside various slaves. Indeed, current datasets are quickly expanding in terms of size and multifaceted nature, also, there is an importunate need to create solutions to extract pertinent data by utilizing methods based on statistics.

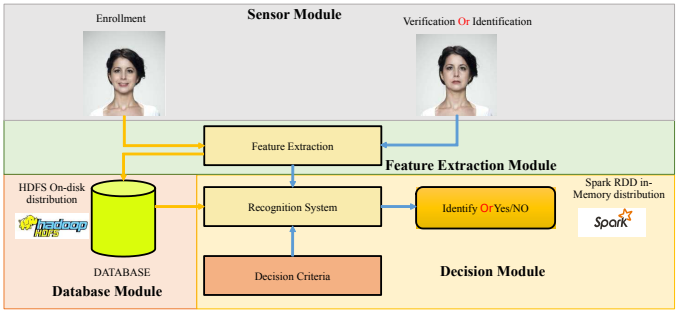

Figure 1: The general conception of a biometric system [16]

An effective biometric framework might be a framework that primarily controls the capacity of the database to be changed in terms of size or scale. they are numerous big data frameworks that are utilized for overseeing a huge data, as Apache Spark framework [17] and Hadoop [18] that run dataflow diagrams over the slaves of a cluster.

In the data-parallel computing process, a client program is arranged into an execution plan graph (EPG), This EPG is the central information structure utilized for distributing tasks, control distributed jobs in the slaves and adapting to non-critical failure. Once a job is running, EPG is unaltered at runtime aside from some restricted adjustments. This makes it hard to utilize dynamic optimization procedures that could significantly improve the disseminated execution dependent on runtime data. Optimus [19] is a framework for progressively rewriting an EPG at runtime.

MillWheel [20] is a system for constructing a data processing with a high size of data in a few time where the user describes the code and the directed computation graph for specific nodes then the framework oversees determined state and recording continuously the flow with non-critical failure in stream processing.

For supporting embedded devices, Sonora [21] is a framework that enhance the stream abstraction for the accompanying reasons. To begin with, streams effectively bind together numerous data activities in cloud and Mobile.

Apache Spark, Naiad [22] and Hadoop run in less calculation time when there is enough memory inside the group of machines to convey the working arrangement of the calculation. Spark keeps up MapReduce's linear adaptability and adaptation to non-critical failure, it is a lot quicker, a lot simpler to program, the distributed data of the scope of computationally heavy tasks, including graphic process, interactive queries, flows and Machine Learning (ML).

In this paper, the jobs of a huge face identification system are parallelized by utilizing Hadoop[23] with Apache Spark introduced by Directed Acyclic Graph (DAG) in figure 3. Every Spark application includes a driver program that completes the user's function and carries out distributes operations on a group of the machine (cluster). The main reflection that Spark furnishes could be resilient distributes dataset (RDD), which could be an assortment of parceled items on a cluster that will run in equal. Users can even request that

Spark remain RDD in memory, permitting it to proficiently reutilize operation in parallel. when a node is failed RDD can automatically be recovered.

3.1 Distributed tasks of LBPH, PCA and LDA in Apache Spark

The utilized identification system is predicated on [3]. However, we have made some changes, to support it inside the Apache Spark, following the stages beneath (see additionally figure 2).

We firstly make first RDD (RDD1) by loading all test images such as Binary Files from HDFS then we split it into sixty parts. Secondly, we apply a transformation of the RDD1 to make RDD2 by transforming the color image to grayscale. Thirdly, we create RDD3 by applying transforms of loaded images in RDD 1 to extract real labels. Fourthly, we made RDD 4 by extracting the content of previous RDDs (2 and 3) by applying a collective action. Finally, the identity of each image is parallelized and compared with the right label extracted in RDD3.

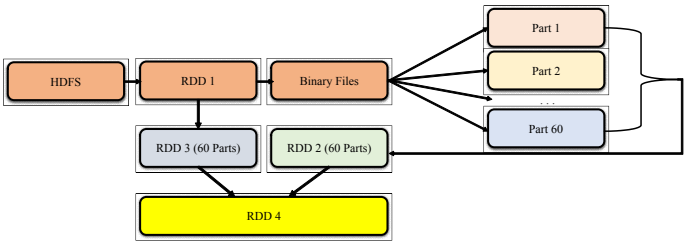

Figure 2: The process of parallelization in Apache Spark

To diminish the running time within the identification stage using the normal PCA, LBPH and LDA identification systems. Initially, the first Apache Spark RDD was created by recovering the test set in 60 parts as binary files from the Hadoop HDFS, and afterward, every thread of our computer changes every picture of every part to grayscale to create the second RDD of grayscale images. Then a third RDD is created by extracting the right label of each test image to collect their identity.

Secondly, we extract the PCA, LDA and LBPH characteristic vectors and compare the vector of the test with those of the learning set.

Thirdly, we predict the identity of the image of the test with the minimal distance overall comparison of the images from the learning set. We used HDFS in the database module to store images and Apache Spark for characteristic extraction and decision parts.

3.2 Pre-trained CNN model, LBPH, PCA and LDA for Multi-user identification system

In this sub-section, we have utilized the Transfer learning procedure where a model produced for tackling an issue is reutilized for a subsequent issue in a timesaving way by starting from patterns that have been learned in the first task, in this manner you raise antecedent learning and keep away from starting from scratch.

We have utilized the Inception V3 as an extractor of pertinent characteristics. It is utilized besides to dispose of the last completely connected layer, at that point, we train the rest of the model as a learning set element extractor for the new dataset. Inception V3 extract 2048 values for every picture. We call these highlights CNN codes. Whenever we have removed the codes for whole pictures. We have prepared a totally connected layer with a Softmax classifier for our system.

A while later, to claim less period, due to the mechanism of spark's build-in broadcast the model is firstly distributed to the cores of our machine in [24]. At that point, this model is used on each core and utilized to identify the identity of an entered image. For this work, the models of a huge identification face system are distributed by utilizing just Apache Spark technology [23].

In our work, every worker takes an image to identify by turning the facial identification system based on PCA, LDA or LBPH to predict the identity of a client by calculating the similarity value with all over the training set as shown in figure 3(a).

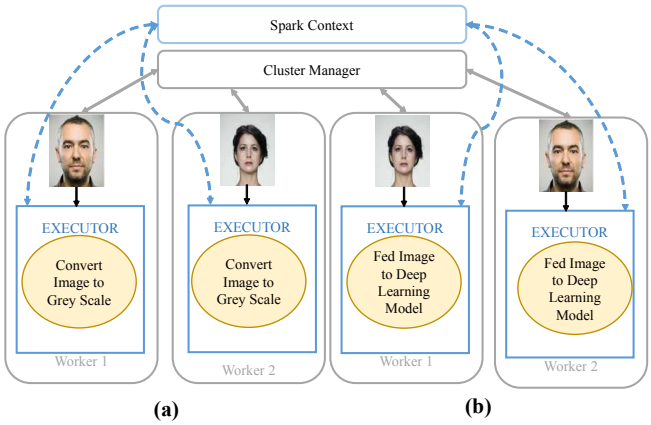

Figure 3: Multi-user identification system: (a) for PCA, LDA and LBPH, (b) for Deep Learning Model

Firstly, the image from RGB (color) to grayscale is converted, afterwards, Every worker compute the eigenvectors, LBP histogram and fisherFace vectors then every worker of the cluster identifies the identity of the tested image from saved PCA, LDA or LBPH models which contain all computed values as shown in figure 3(a) and shared to all cores of the machine.

We employed in this paper a pre-trained CNN Model (Inception V3). Firstly, we have only trained the classification part of the Inception V3 model due to the computational cost of learning to create a model that can identify the person from his/her face image which we need to reutilize the model trained from the Imagenet database to our chosen dataset, we have trained the classification part to induce the correct weights and bias of the fully connected layer (FC) for identification face system, thereafter, we fed the test image into the model to urge the identity, this is often the task of every worker within the cluster as illustrated in figure 3(b) where every worker takes a test image from Hdfs then fed it into the model to extract characteristics that contain 2048 values of every vector then pass it through classification part (Fully connected layer trained to create the facial identification system) then introduce the identity as the last step.

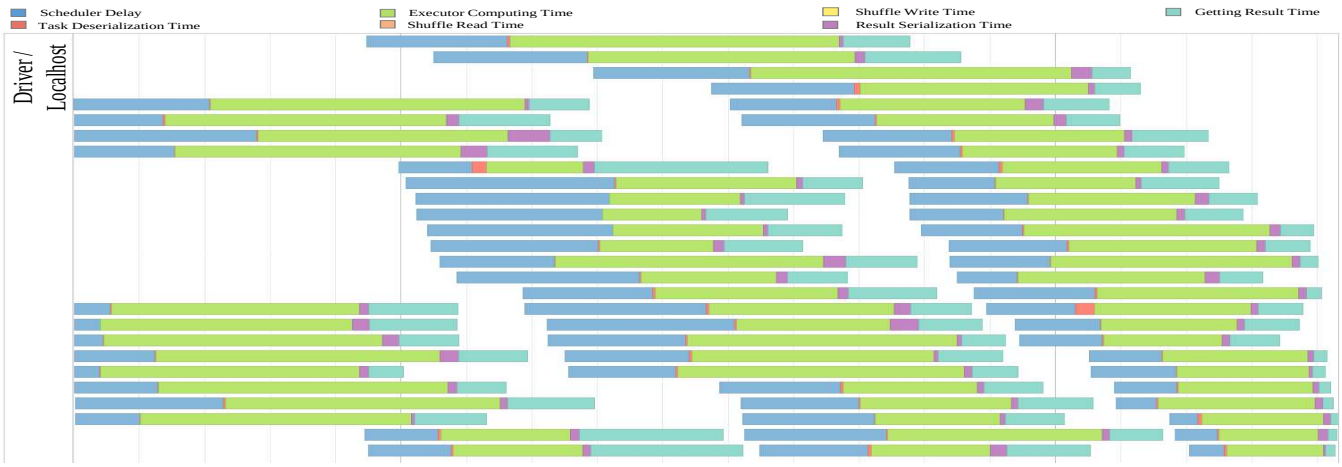

Figure 4: The run time using 6 cores (12 threads) of various tasks

4 Experimental Results

In this section, we evaluate the optimization of various identification systems : the FisherFace [5], LBPH [3][4], , FisherFace [5] and Inception V3 [6] that involve 48 layers can distinguish between 1000 items (e.g., Flower, Fish, Bird, etc) in terms of identification time and the precision. For the evaluation, we have got used the Extended Yale Faces B database [25].

4.1 Database Description and Evaluation

We applied 17 changes (e.g., Rotation, Blur, Noise, etc.) for every subject of the database utilized in this paper [26] to make a bigger database and also to make the identification task more harder.
This database involves 28 subjects with 16128 images with 9 poses and in 64 lighting conditions, In our paper, we are just engaged by 26 subjects. Consequently, the database consists of 107730 images in total. We have suggested splitting the database into three sets as described in figure 5.

4.2 Results and discussion

In the aim to reduce the running time, we run our system using Apache Spark technology by making a collection of RDDs. Every thread of the computer core runs a part of partitioned RDD in 60 parts as illustrated in the figure 4. Each job could be a part of the step, as an example, the primary job contains 60 tasks, in as much as our machine involve 12 threads, 12 tasks are going to be run in parallel (see figure 4). figure 6 illustrates a comparison between various face identification systems that utilize EigenFace, LBPH, FisherFace, and CNN model in Apache Spark [24].

The output of the last convolutional layer of the CNN model is called cnn code extracted from the entered images (Trained images) during the primary part of the learning phase, this stage takes 4 hours and 19 minutes by using Apache Spark broadcasting to calculate all codes. Running the identical stage of the learning step it takes 14 hours without utilizing the Apache Spark broadcasting, is an off-the-cuff term of a feature vector that plays a vital part of identification, which is a representation of a picture in less number of values that will be used for classification.

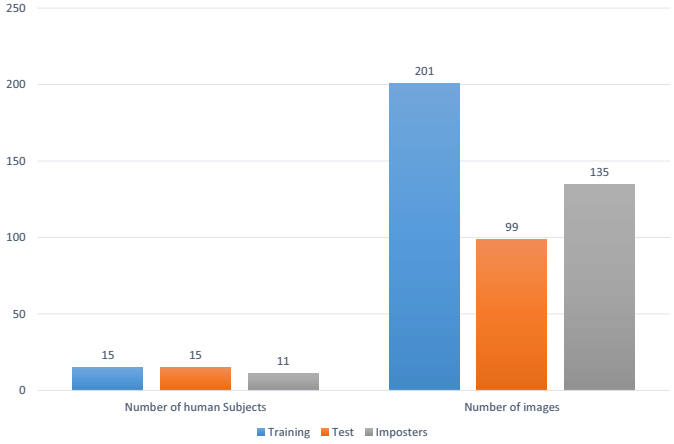

Figure 5: Database Distribution

This final layer was created to give a collection of values that is fitting to the classifier to separate among users. This implies that it needs to be a meaningful and good representation of the images because it should have as many relevant features for the classifier to create an accurate decision by just using a few values.

During the learning phase, every picture is reutilized various times during the learning phase and every code takes an all-inclusive time to be calculated. To quicken the job we conserve these codes on our machine to not recalculate them consistently. On the off chance that we re-execute the framework once more without feed in images to the model.

When the codes are all extracted in the first step, the specific development of the last layer of the neural network model starts. Many series of outputs will be during this step that can show the exactness of the validation and hence the precision of the learning part.

The precision of the learning shows how the model learned from the pre-owned pictures to distinguish between identities. Validation exactness presents the coordinating rate utilizing an arbitrarily

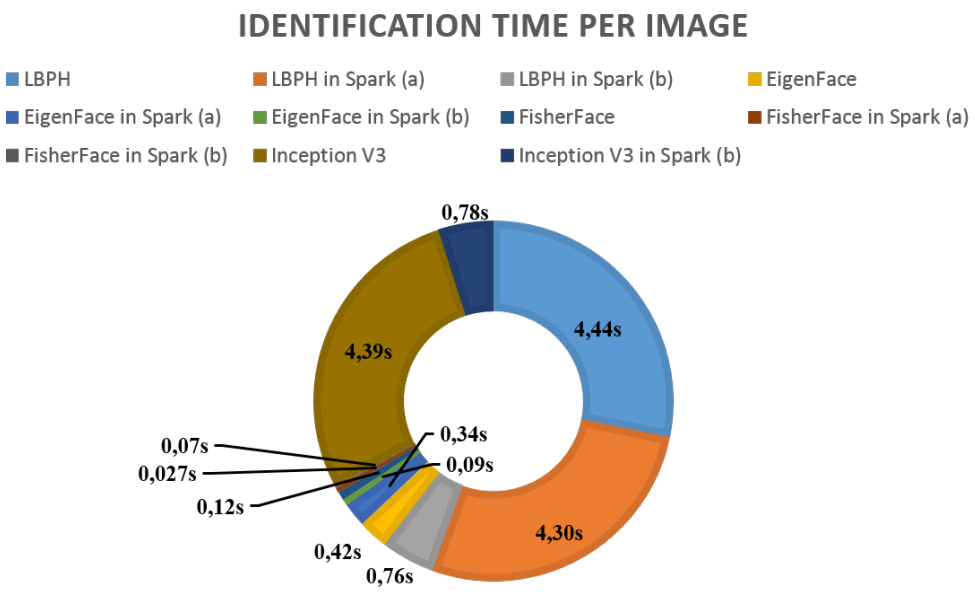

Figure 6: Overall identification time Comparison between The Different Tested Identification Systems with/without distribution

chosen group of pictures from a remarkable learning set. That validation exactness depends on the work of an assortment of data that is not contained inside the learning set if the precision of the learning is high. However, the validation set precision stays low, this suggests that the model is remembering specific highlights inside the learning set pictures. In each validation or learning step, we select 100 arbitrary pictures of the entire validation/learning set, we find its codes inside the cache and brings them into a definitive layer to get identities.

These predictions are contrasted with the specific labels to optimize the classification part and update the bias and weights by utilizing some optimizers like Adam Optimizer and Gradient Descent.

By a learning rate of 0.01 with 250000 iterations using the Gradient Descent Algorithm and Adam Optimizer we respectively get 91, 47% and 91.66%. By a learning rate of 0.1 with 500000 iterations using the Gradient Descent Algorithm and Adam Optimizer we respectively get 91.82% and 92.31%.

By a learning rate of 0.05 with 250000 iterations using the Gradient Descent Algorithm and Adam Optimizer we respectively get 92, 30% and 90.84%. By a learning rate of 0.1 with 500000 iterations using the Gradient Descent Algorithm and Adam Optimizer we respectively get 92.24% and 91.45%.

By a learning rate of 0.001 with 250000 iterations using the Gradient Descent Algorithm and Adam Optimizer we respectively get 87.01% and 91.85%. By a learning rate of 0.1 with 500000 iterations using the Gradient Descent Algorithm and Adam Optimizer we respectively get 88.73% and 92.10%.

We set in the learning phase the proportion of learning set at 80% and we preserved 10% for validation and test. In every iteration we have entered 100 images, after every 10 iterations, we have got evaluated the model using 100 images of the validation set that are chosen arbitrarily. after finishing the learning phase, we fed all the test set through the model to know the precision and how the way the model can classify the inputted faces. After being aware of the good precision of the model in the last part of the learning phase we run our test set for every learning rate and variety of iterations as shown in figure 6. Globally, the precision value is expanded by expanding the number of iterations. If the learning rate is tiny, the precision value is expanded smoothly which makes the learning becomes more reliable, however, the optimization will take longer because steps towards the minimum of the loss function are very small. If the learning rate is high, the precision is expanded rapidly and that we will have the overshoots of the minimum which makes aggravate the loss.

Our main aim is to increase the identification time per image of the test while getting the good performance of the models. This purpose is reached by running our system in Apache Spark (see figure 6). As shown in figure 6 the quick system is FisherFace followed by the EigenFace, then the CNN model, and at last the LBPH.

To advance the exactness of systems, we have made some changes to a few parameters of the LBPH algorithm, such as changing the number of neighbors and the Radius value. For Inception V3, we have made changes to a few parameters simply like the number of iterations, the chosen optimizer algorithm, and subsequently the learning rate value.

For the LBPH algorithm with a Radius equal to 1 with 8, 6 and 4 neighbors, we respectively get 94.05%, 93,74% and 91.91% an Accuracy of identification.

For the LBPH algorithm with a Radius equal to 2 and 8,6 and 4 neighbors, we respectively get 95.71%, 95.43% and 94.02% an Accuracy of identification.

All systems are executed in a server that contains 6 cores with 12 threads and 4.70 GHz Turbo frequency with 12Go of the storage memory.

5 Conclusion and Perspectives

In this paper, we introduced an optimization of multi-user identification face systems in Big Data environments. Hadoop and Apache Spark are two technologies accustomed to parallel tasks and make multi-user systems. This optimization has been examined and evaluated, as far as accuracy and identification time using various classical identification face systems. Our experimental results show that the performance is preserved while offering an affordable identification time for oversized scale systems. In our future work, we have plan to create a multi-view identification face system using a Siamese Convolutional network to tackle the issue of having a few facial acquisitions.

ABSTRACT

A modern process plant is controlled, operated and safeguarded by the sophisticated distributed control system or a programmable logic controller and an emergency shutdown system. This process plant's operation could be seriously affected by lightning, electrical switching, and power outrage. Lightning propagation can travel kilometers away, which has the risk of disturbing the control system's operation. The process plant's control system could damage when it is subjected to surges induced by lightning, power outrage, or heavy load switching. To protect equipment damage from these surges surge protection device is required. A number of the process plant uses flammable material for its production or during the manufacturing processes, explosive gas or vapor is released created an explosive atmosphere known as hazardous (Ex) area. Surge protection device mounted in the Ex area or used in the Ex control loop needs to be carefully selected to protect the equipment and at the same time, it does not become a source of ignition. This paper provides practical consideration and comprehensive detail in revealing the science and engineering behind Ex application on surge protection devices. The technical presentation is limited to equipment protection; structural protection against lightning will not be discussed here.

1. Introduction

This journal article is an extension of the original conference paper entitled, "Practical approach on surge protection device for Ex application," presented in 2019 1st. International Conference on Electrical, Control and Instrumentation Engineering (ICECIE), Kuala Lumpur, Malaysia [1].

Lightning is a natural phenomenon that can be seen in volcanic eruptions, pyrocumulonimbus clouds, heavy snowstorms, hurricanes and thunderstorms [2]. Lightning-induced voltage surges can enter into the electrical system via the capacitive, inductive and resistive coupling [3]. According to the report from NFPA [4], in the United States alone, from 2007 to 2011, an estimated 22,600 fire cases were caused by lightning, with a $451 million loss in direct property damage per year. The report also cited several explosion incidents caused by the lightning surge. One of them is a coal mine (Ex area) explosion in January 2006 in West Virginia, which claimed 12 lives. A protective circuit like a surge protection device or SPD is used to protect the electrical apparatus and its accessories from the damage created by transient surge activity induced by the lightning and surges generated by switching heavy reactive load or power supply interruption and prevent a fire. SPD has to be carefully selected and with proper installation for its intended function; else, instead of preventing equipment failure, it could become the source of fire or explosion as reported by [5–7].

In the original paper, the following are either not evaluated, missing or too brief as the reader is expected to have the background knowledge to understand the subject. In the present work, the critical area left out by the original paper is being addressed and enhanced. The rectification and enhancements are highlighted below:

- The reasons why SPD is needed for the modern electronics system for the application in a safe, hazardous area and critical control loop application.
- Why is the selection criteria on SPD for safe area application not sufficient for hazardous area application?
- Presentation on the lightning protection zone (LPZ) and the SPD types are too brief on the original paper. Therefore it is decided to separate them into two sub-sections with enhancement and with an application example. Definition and a summary of the key points are also being addressed and tabulated.

*Corresponding Author: Teik Hua Kuan; Adress: Universiti Tunku Abdul Rahman, Sungai Long 43000, Malaysia; Contact No: +60123173650; Email: thkuan@1utar.my or thkuan@klaesb.com

- Application on lightning protection level's (LPL) concept; what needs to be done before implementing LPL and the efficiency level for various LPLs are added.
- The description of the maximum continuous operating voltage has been revised to reflect the practical application.
- The illustration on the concept of the "Temperature Classification" is enhanced with a practical example.
- Elements required to be present for an explosion to occur and the concept of various explosion protection techniques being implemented are added.
- Using "Spark Test Apparatus" to obtain the minimum ignition curve for inductive, capacitive and resistive load at the field. The application of the minimum ignition curves is also added.
- Requirement on the hot permit to carry out maintenance and typical application example is added for flameproof, Exd protection.
- Hot surface investigation and typical applications example for increased safety, Exe protection is added.
- Missing entity safety parameter description on the cable capacitance and inductance for intrinsic safety, Exi protection technique is rectified.
- Surge withstanding capability (SWC) consideration is added as it is missing in the original paper.
- Why are two SPDs needed for a control loop? Why one of the SPD will have the Temperature Classification, the other one is not necessary?

The subject of explosion protection for industrial automation applications (non-military) is a specialist field; hardly any higher education institution conducting the courses. Hence, most of the knowledge on various explosion protection technique is coming from the industry. There are very few industry players who produce multiple Ex-rated products and conduct multiple Ex-product research; most of the manufacturer only specialist in their respective areas of expertise. For example, field device manufacturers (field devices like pressure transmitter, I/P converter, control valve, solenoid valve, etc.) like Honeywell, Emerson or Yokogawa only produce Ex-rated field devices, not other devices like Ex-rated junction box or cable gland. Therefore it is difficult for the industrial user to familiarize themselves with various explosion protection techniques for all the control components. This paper helps the industrial user to implement surge protection in the Ex area systematically. It investigates and evaluates the selection criteria and SPD's application requirement for Ex area application with various explosion protection techniques. Safety calculation and proper installation are also presented. It details down all factors involved in implementing the solutions. Two application examples are quoted in detail.

The paper starts the discussion on the need for the SPD in the modern electronics system in the safe area, hazardous area and the critical control loop application; The working principle of the SPD then moves on to the selection criteria for Ex applications and the common explosion protection technique that could be applied together with SPD. Three explosion protection techniques are selected for evaluation and discussion in detail on its application, namely the application of SPD using Exi (intrinsically safe), Exd (flameproof) and Exe (increase safety) protection method in the common explosion protection technique section. The paper then provides two working examples of how the selection and application of SPD using Exi and Exd methods. Safety parameter calculation, distance requirement, temperature consideration, etc., are presented in the examples. The paper ends with a summary of the key area of consideration and criteria in selecting the SPD for Ex application.

2. Why Is Surge Protection Important In The Modern Electronics System?

Modern equipment demands for more application features, faster speed, smaller physical dimensions and lower power consumption. This makes the circuit designer squeeze more transistors into a smaller IC chip, using the material to operate at a lower voltage and lower power consumption. The progress in developing faster, denser and lower power consumption IC Chip makes the modern electronics circuit more vulnerable to the induce transient surges than the early components that use vacuum tube and discrete transistor. Hence, transient surge protection is becoming more important in the modern electronics system. Figure 1 shows the increase of equipment failure rate from the early vacuum tube technology to the modern IC chip caused by transient surges.

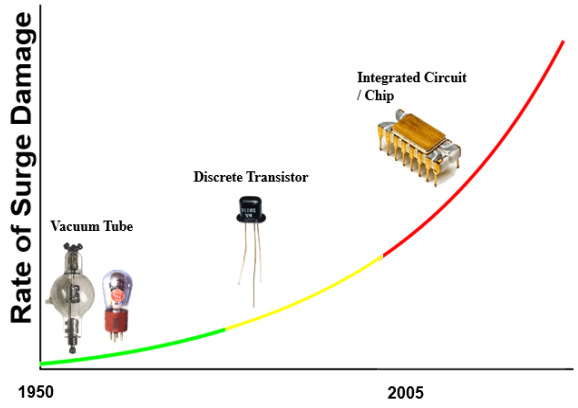

Figure 1: Increased Rate of Equipment Failure [8].

On the other hand, modern electronic systems also rely a lot more high-performance electronic components to execute the critical task that cannot afford to fail. Failure will lead to plant shutdown and production losses, which will cost millions of dollars. For example, emergency shutdown systems (ESD), depending on the process and the safety requirement, can be designed as a standalone, redundant system or triple redundant system to cope with equipment failures. A redundant design plus a logic solver algorithm allows the ESD to detect the real loop failure and decide when to shut down the plant using the voting system. Once the decision is made, the plant is then shut down according to the pre-determined sequence to avoid plant accident or explosion. The redundancy is often achieved by duplicating or triplicating the field sensor, input-output cards, control processors and even the actuators. Almost all the field sensors, except for the wireless system, are connected to ESD by cables, potentially entry

routes for the transient surges. Therefore, SPDs are included in the system design to improve the resilience of such systems from the effect of transients.

When a process plant uses flammable material for its production or during the manufacturing processes, explosive gas or vapor is released created an explosive atmosphere known as hazardous (Ex) area. SPD mounted in this Ex area needs to be carefully selected to protect the equipment from transient surges and at the same time, it does not act as a source of ignition. SPD requirements for the hazardous (Ex) location are often more stringent than in the non-hazardous (non-Ex) locations.

When sizing up the SPD for equipment protection for safe area application, generally, the let-through voltage (should be below the SWC [9–11] of the device to be protected), kA rating, connection method (either series or parallel) of the SPD need to be considered. However, when the application is involved with the Ex area, this is not sufficient as the SPD could become the source to initiate an explosion. The additional consideration for the SPD to use in the Ex area includes the SPD's mounting location, the applicable explosion protection technique, equipment surface temperature, and equipment heat dissipation.

3. Working Principle of SPD

SPD protects the electrical installation, consisting of electrical equipment, consumer unit, wiring and accessories, from electrical power surges known as transient overvoltage. The lightning activity, electricity is interrupted and immediately re-established or the switching of a heavy reactive load could instigate the power surge. Figure 2 illustrates the working principle of a 4-20mA signal line SPD. When there is no transient surge, the SPD does nothing; it is transparent to the circuitry. Whenever a surge appears, the SPD will be triggered instantly. It clamps the SPD's output voltage, depending on the model used, to a pre-determined level and diverts all the excessive current to the ground via a protective earthing terminal.

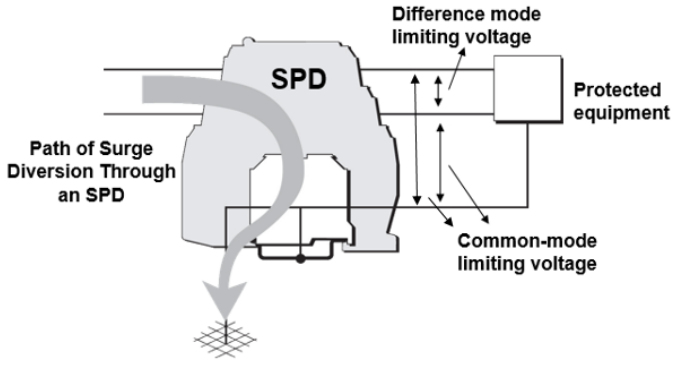

Figure 2: Working Principle of a signal SPD (redrawn from [1] with additional information).

4. Selection Criteria on SPD for Ex Area Applications

When selecting an SPD for use in the Ex area, all the selection considerations and criteria on SPD for the safe area application are applied. Additionally, all other factors that could cause the SPD to trigger an explosion and other ignition sources should be considered as well.

Typically, SPDs are mounted in a panel at the control room to protect the systems and its component against surge. If there is a requirement to protect the field device from surge, additional field mounted SPDs will be required. In other words, the process control loop will require two SPDs. One SPD is mounted as close as possible to the field device (to protect the field device), another one should be mount as close as possible to the controller (to protect the controller) at the control cabinet.

4.1. Types of SPDs

IEC 61643-11:2012 and NFPA 79 standard defined three different types of surge protection devices (SPDs). They are Type 1, Type 2 and Type 3, respectively. The SPD types provide information on where an SPD may be installed, as shown in Figure 3. The energy discharged from the surge is brought down in various stages, starting with the more robust SPD (Type 1) and finer protection Type 2 and Type 3 SPDs. This protection arrangement and co-ordination are represented with the Lightning Protection Zoning (LPZ), which divides the structure based on the lightning strike effects.

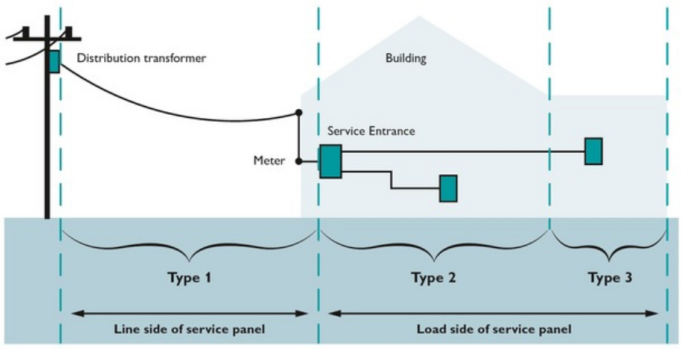

Figure 3: Types of SPD and Its Mounting Location. [12].

Type 1 SPD: Provide lightning protection against transient overvoltage instigates from direct lightning strokes where the lightning discharge voltage could spread from one of the structures earth conductor to the other network conductors. Type 1 SPD is characterized by a 10/350μs surge current waveform per IEC 61643-11:2012

Type 2 SPD: It is the primary protection system for low voltage electrical installations. Protect against transient overvoltage caused by switching or indirect lightning strokes. Typically, it is installed in the electrical distribution board (DB) to prevent transient surges in the electrical installations and protect the loads. Type 2 SPD is characterized by a 8/20μs surge current waveform per IEC 61643-11:2012

Type 3 SPD: Type 3 SPD is aimed to provide local protection on sensitive and critical loads. This SPD has a low discharge capacity. It is only installed as a supplement to Type 2 SPD and it is installed as near as possible to the sensitive loads. They are widely used as hard-wired devices and generally combined with Type 2 SPDs for fixed installations. In many cases, they are built-in and incorporated into a surge-protected socket outlet, surge-protected portable socket-outlets for telecommunication lines and data

protection. Type 3 SPD is characterized by a combination of voltage waveform (1.2/50 µs) and current waveform (8/20 µs).

Table 1 provides a summary of Types of SPD, its test waveform and the current rating, as well as the typical technology used and the Lightning Protection Zone (LPZ). LPZ will be discussed in the following section.

Table 1: Types of SPD, Test Waveform, Applicable Technology and LPZ [13].

	LPZ 0/1	**LPZ 1/2**	**LPZ 2/3**
Typical SPD Installation Point	Service Entrance (e.g. Main distribution board or telecom NTP)	Sub-distribution board or telecom PBX frame	Terminal Equipment (e.g. socket outlet)
Type of SPD	**1**	**2**	**3**
Surge Test Waveform	10/350 µS current	8/20 µS current	Combination 8/20 µS current and 1.2/50 µS voltage
Typical peak test current (per mode)	25KA	40KA	3KA
Typical Technology (Power Line)	Spark Gap	Metal Oxide Varistor (MOV)	Metal Oxide Varistor (MOV)

4.2. Lightning Protection Zone, LPZ

IEC 62305-4:2010 describes the LPZ concept. LPZ identifies and divides a structural area according to the risk level exposed to the Lightning Electromagnetic Impulse (LEMP). It coordinates the type of SPD's kA current rating requirement within the zone. The concept of LPZ taken from IEC 62305-4: 2010 is as shown in Figure 4. ANSI/IEEE C62.41 also has a similar concept, as shown in Figure 5.

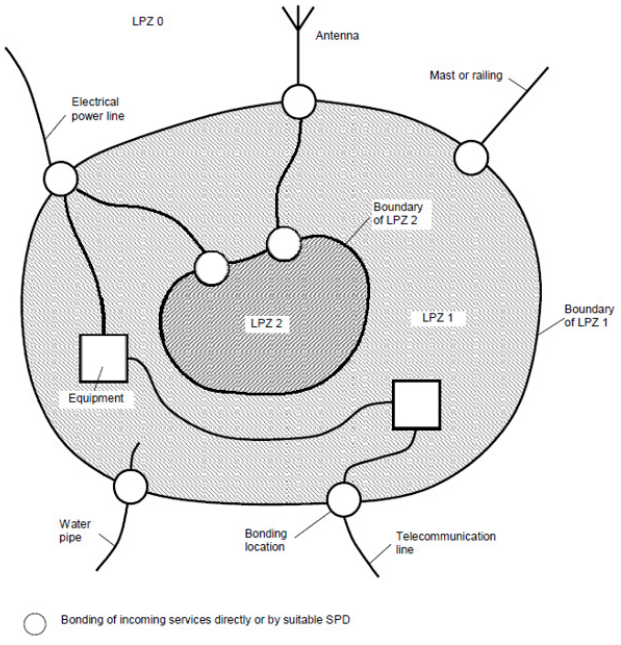

Figure 4: The Principle of LPZ - Division into Different LPZ per IEC 62305 part 4 [14].

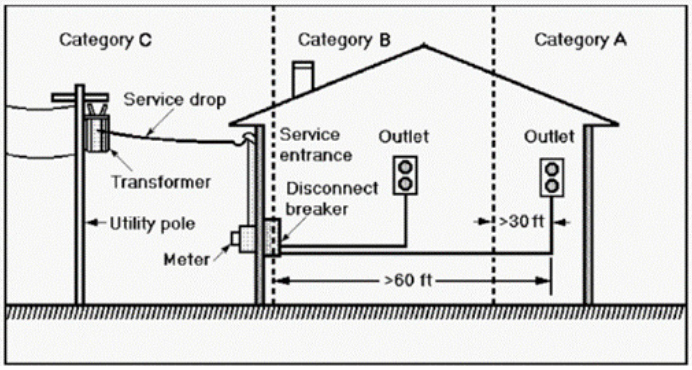

Figure 5: Surge Protective Category as per ANSI/IEEE C62.41 [15].

The LPZs are defined as follows:

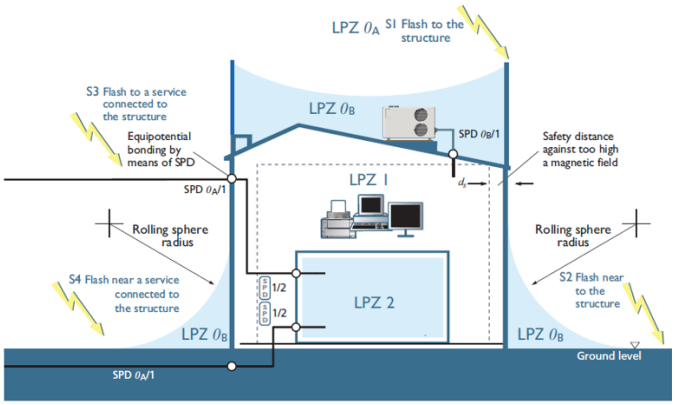
- **LPZ 0_A**: It is an open zone and not protected by the external lightning protection system (LPS). The equipment installed is directly exposed to the direct atmospheric discharges. Hence, the device installed in this zone must be able to handle the entire surge current generated and it is exposed to the whole magnetic induction.
- **LPZ 0_B**: This zone also refers to the open zone but is protected by the external lightning protection system, such as a lightning rod. This method provides direct lightning strikes protection but suffers from total exposure to the magnetic field.
- **LPZ 1**: It is the zone inside a building. At this zone, there is a partial lightning current transmitted from external surges. However, the degree of induced currents is less than zone LPZ 0_A and LPZ 0_B. Between LPZ 0_B and LPZ 1, Type 1 SPD should be installed to protect the downstream equipment.
- **LPZ 2, LPZ n**: This zone refers to an area further inside the building where low surges may occur. The shielding and SPDs, both at the limits of the different zones and protecting the local equipment, allowing further reduction of the induced current.

The LPZs could be view as two categories, as shown in Figure 6, namely two external zones, which are LPZ 0_A and LPZ 0_B; and usually two internal zones, which are LPZ 1 and LPZ 2. If necessary, further zoning can be introduced to further reduce the electromagnetic field and lightning current.

4.3. Lightning Protection Levels, LPL

According to the IEC 62305 standard, LPL can be classified into four levels, namely Level I, Level II, Level III and Level IV. Each level has a set of parameters to predefined the maximum and minimum lightning surge current. Refer to Figure 7, it can be seen that the object or device to be protected will be assigned to one of the four LPL levels before a lightning protection system is implemented. Efficiency in LPL I is the highest at 99% and LPL IV is the lowest at 84%. The maximum lightning surge current set by LPL is used to design and the selection of the SPD. According to the IEC 62305, any lightning surge current parameters exceeding LPL 1 (i.e., 200kA) will be excluded from lightning protection. The chances and probability of occurrence outside the range are less than 2 %. The cost of erecting a lightning protection system, for example, the necessary protection angles, distances from loops, protection profiles and distances from arrestors for

LPL I is much more than that of LPL IV. IEC 62305 Part 1 provides the detail on the LPL probability of occurrence.



LPZ O_A Direct flash, full lightning current, full magnetic field
LPZ O_B No direct flash, but partial lightning or induced current, full magnetic field
LPZ 1 No direct flash, but partial lightning or induced current, damped magnetic field
LPZ 2 No direct flash, or partial lightning, but induced currents, further damped magnetic field
Protected volumes inside LPZ 1 and LPZ 2 must respect safety distances d_s

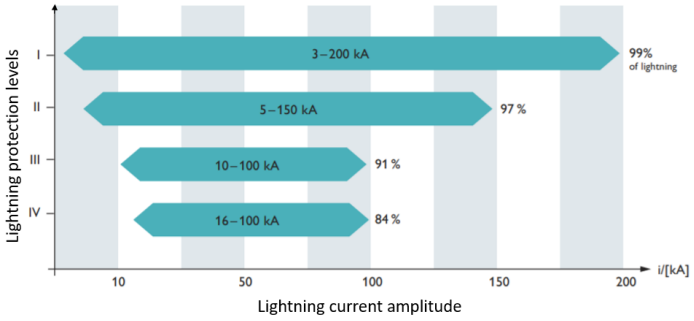


Figure 7: Lightning Protection Levels per IEC 62305-1 with Corresponding Minimum and Maximum Lightning Current Amplitude (redrawn from [16] with additional information).

4.4. Parameter of SPD

Common SPD specifications recognized by IEC 61643 are described below. They are used to select suitable SPD.

- **Nominal Voltage, U_N**
  It is the standard operating supply voltage of the apparatus or system circuit based on the use envisaged for the SPDs.
- **Maximum Continuous Operating Voltage, U_C**
  The maximum voltage that can be permanently applied to the SPD without damaging and triggering it. U_C rating of the SPD is selected such that its triggering voltage is slightly higher than the nominal operating voltage (U_N) of the equipment to be protected. This is to avoid SPD been accidentally triggered during normal operating.
- **Voltage Protection Level, U_P**
  U_p is known as the "Let-Through" voltage or the clamped voltage in the industry. U_P defines the maximum output voltage that could appear at the SPD terminal when tested with a specific waveform per IEC 61643. Generally, U_p will be the maximum output terminal voltage of the SPD when subjected to transient surge. In practice, the SPD's U_p rating should be chosen so that its value is lower than the maximum SWC voltage of the apparatus to be protected.
- **Nominal Load Current, I_L**
  I_L is defined as the maximum continuous RMS load current that is allowed to pass through the SPD without triggering and damaging the SPD, including the capability to withstand the current continuous thermal overload. This term is only applicable when the SPD is connected in series. Since a parallel connection is capable of handling an unlimited load current; hence, this term is not relevant to SPD connected in parallel.
- **Impulse Current, I_{imp}**
  It is the peak current with 10/350μs waveform, direct strike, flowing through the SPD to test mainly for Type 1 SPD.
- **Nominal Discharge Current, I_n**
  Peak current with 8/20μs waveform flowing through the SPD for the test of Type 2 SPD.

4.5. Implementation of SPD in the Ex Area

All guidelines highlighted in sections 4.1 to 4.4 are applicable when applying and installing SPD in hazardous areas. Additional factors described below to ensure the SPD does not become a source of the explosion also need to be considered.

4.5.1 Hazardous Area Classification

Classification of the hazardous area is a risk management tool that handles potentially flammable material to support explosion safety verification. Hazardous areas are defined by the occurrence of the type of hazards present, such as gas, vapor or dust; the probability of that hazard may be present; flammable concentrations on the lower explosion limits (LELs) and upper explosion limits of the explosive substance (UEL) as shown in Table 2. Hence, hazardous area classification is a systematic way to review, analyze and classify plant safety according to the explosive substance. This allows an optimum selection of the electrical apparatus or equipment installed in a hazardous atmosphere. ATEX and IEC standards classify the Ex area into Industry Group, Gas Group, Temperature Classification and Zone. The hazardous area's electrical apparatus and equipment selection is based on the hazardous area classification defined by the ATEX / IEC standard.

Industry Groups:

- **Group I** is the mining industry, where equipment is used in the explosive environment that contains methane gases or vapors of its equivalent hazard, as shown in Table 3.
- **Group II** is the surface industry, as shown in Table 3. It is then further divided into three subgroups, that is Group IIA, Group IIB and Group IIC. Group IIA for the environment containing propane gases or vapors of its equivalent hazard; Group IIB for the environment containing ethylene gases or vapors of its equivalent hazard and Group IIC for the environment containing hydrogen gases or vapors of its equivalent hazard.
- Group III is also for the surface industry but with dust and fibers hazards. They are again subdivided into Group IIIA, IIIB and IIIC according to the nature of the explosive environment, as shown in Table 4.

Table 3 provides the information on Industry Group I and II; and the minimum ignition energy (MIE). MIE is the

minimum energy required to ignite the easiest explosive gas-air mixture.

Table 2: Flammable Properties [17].

Combustible Gas LEL's and UEL's			
		LEL	UEL
Acetylene	C2H2	2.5%	100%
Benzene	C6H6	1.2%	8.0%
Methane	CH4	5.0%	15.0%
Ethane	C2H6	3.0%	15.5%
Ethyl Alcohol	CH2H5OH	3.3%	19.0%
Ethyl Ether	(C2H5)2O	1.7%	36.0%
Ethylene	C2H4	2.7%	36.0%
Hexane	C6H14	1.1%	7.5%
Hydrogen	H2	4.0%	75.6%

Table 3: Industry Group I and II for Mining and Surface Industry [17].

Industry	Gas Group	Substance	MIE	Selection of equipment
Mining Industry Group I	I	Methane	200µJ	Equipment only suitable for mines unless it is additional approved for surface: Marked I/IIC
Surface Industry Group II	IIA	Propane	180 µJ and higher	II; IIA; IIB and IIC certified equipment may be used in an IIA area.
	IIB	Ethylene	60 µJ -180 µJ	II; IIB and IIC certified equipment may be used in an IIB area.
	IIC	Hydrogen	20 µJ – 60 µJ	Only II & IIC certified equipment is allowed to be used in an IIC area.

Dusts and Fibres (Group III) Surface	IIIA	Combustible flying's
	IIIB	Non-conductive dust
	IIIC	Conductive dust

Temperature Classification

Temperature Classification is also known as ignition temperature, auto-ignition temperature (AIT) or T class. It defines the device's maximum surface temperature under a normal or abnormal condition with respect to the ambient temperature of 20°C to 40°C (unless otherwise stated) [18]. Depending on the types of explosion protection techniques used or its combination, for example, Exd, Exe or Exi, the temperature corresponds to the device's external surface's maximum temperature or the maximum temperature of the device's internal surface (for example, Exi device putting into Exd junction box). For a combination of explosion protection techniques used (for example, Exdei – Exd, Exe and Exi are used in the device), the final temperature classification of the device needs to be determined. All flammable materials will have an AIT, the temperature at which ignition will occur without an external source. Apparatus must be selected with its temperature classification below the AIT. This will ensure the Ex environment's apparatus is not exposed to the gas-air mixture with a temperature exceeding its AIT. If several different flammable materials are present within the same area, the material that gives the lowest AIT dictates the device's overall applicable temperature class. The temperature classification only applicable to Industrial Group II (surface industry), as shown in Figure 8. Temperature classes do not apply to Group I (mining) applications. Mining equipment has either a rigid 150°C or 450°C limits [18]. Be noted that the device's temperature class does not represent the operating temperature range of the device, but rather the maximum allowable surface temperature with respect to a default ambient temperature of 20°C to 40°C with the presence of flammable material.

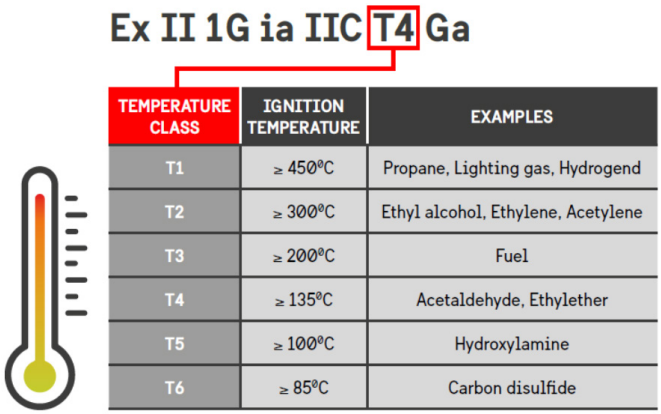

Figure 8: Equipment temperature classification [19].

According to the ATEX directives, all the hazardous area installation apparatus, including SPD, must be marked with its temperature class and assigned an appropriate temperature classification according to the nature of hazard that might be present to maintain its integrity and prevent unexpected explosion due to AIT. For instant, if the hazard present is butane gas, its AIT is 372°C, then all apparatus used in that environment cannot generate a surface temperature exceeding 372°C. In this case, the apparatus rated T2 (300°C) to T6 (85˚C) will meet the requirement. This also means that for this case, all the apparatus used in the butane gas environment cannot have a surface temperature equal to or greater than 372˚C under fault or regular operation. Any equipment that generates 372˚C or more surface temperature could increase the possibility of an explosion.

Table 5: Zone Classification [20].

Zones and Equipment Categories				
Zones		Typical Definitions of Zones (for guidance only)	ATEX Minimum Permissible Equipment Category for Zone	Minimum Equipment Integrity Requirements
Gases and Vapours zones	Dusts			
0	20	Explosive atmosphere is present continuously, for long periods or frequently	1	Equipment must be safe under normal operation, expected and rare malfunction
1	21	Explosive atmosphere is likely to occur under normal operation, occasionally	2	Equipment must be safe under normal operation, expected malfunction
2	22	Explosive atmosphere may occur under abnormal operation and persist for a short period only	3	Equipment must be safe under normal operation.
The higher the probability of an explosive atmosphere occurring and persisting, the lower the allowable potential risk of ignition and the higher the safety integrity requirements of the equipment to be installed. The relationship between zones and equipment categories can be varied following a complete risk assessment				

Zoning Classification

- Zone Classification: Classified concerning the probability of a potentially explosive environment being present in a 3-dimensional region or space and the duration for which it is likely to exist. The available explosion protection methods also depend a lot on the zone classification assessment and its

assignment. The classification of the hazardous area is shown in Table 5.

- This rule of thumb derived from API RP 505 and IP 15 stated if the hazard is continuously present for more than 1000 hours in a year is classified as Zone 0. If the hazard present between 10 to 1 000 hours in a year is classified as Zone 1. If the hazard presents less than 10 hours in a year is classified as Zone 2.

Equipment Marking

- Equipment Marking: All certified apparatus used in the Ex area must carry mandatory marking. The standard uniformly defines the marking requirement. The marking on all equipment intended for use in a potentially explosive environment should provide all necessary and essential information for safe operation and easy identification at the site. Figure 9 and Figure 10 provide a self-explanation and sample of the manufacturer marking according to ATEX Directive 94/9/EC and the IECEx certification scheme, respectively.

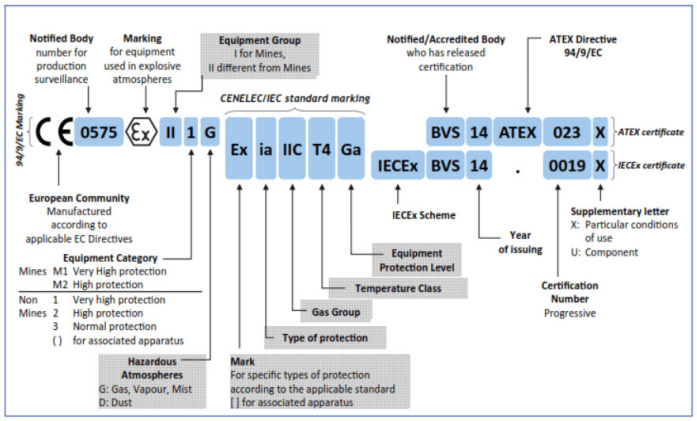

Figure 9: Summary of Apparatus Marking According to ATEX Directive 94/9/EC and IECEx Certification Scheme [21].

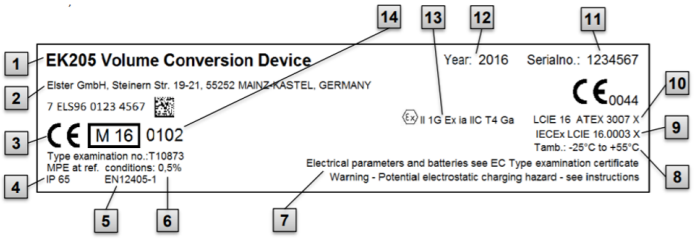

1	Type designation	8	Ambient temperature range
2	Manufacturer and address	9	IECEx - EC type examination certificate no.[5]
3	CE marking	10	ATEX - EC type examination certificate no.
4	IP protection class data	11	Serial number
5	Reference to EN 12405-1	12	Year of construction
6	Measurement accuracy data	13	Ex marking
7	Notices	14	Metrology marking

Figure 10: Typical Manufacturer Marking Tag [22].

5. SPD in Common Explosion Protection Technique

For an explosion to occur, three elements must be present at the same time, namely the hazard (flammable or explosive substance), supporter (air or oxygen) and the source of ignition (electrical spark or hot spot). All the explosion protection technique is to remove one or more of this element or contain the explosion so that it will not propagate to a bigger area or outside the enclosure. There are many explosion protection techniques used by the industry. However, only three common techniques and two practical examples based on Exi, intrinsic safety and Exd, flameproof explosion protection technique will be discussed here. Table 6 summarizes the various explosion protection techniques used in the industry, Ex code and its applicable zoning.

Table 6: The IEC Methods of Protection and Permitted Zone of use [23].

Method of Protection	Ex code	Permitted in:		
		Zone 0	Zone 1	Zone 2
Encapsulation	ma	✓	✓	✓
	mb		✓	✓
Oil immersion	o		✓	✓
Powder filling	q		✓	✓
Pressurisation	p		✓	✓
Flameproof	da	✓	✓	✓
	db		✓	✓
	dc			✓
Intrinsic safety	ia	✓	✓	✓
	ib		✓	✓
	ic			✓
Increased safety	e		✓	✓
Type of protection "n"	nA			✓
	nR			✓
	nC			✓

5.1. Intrinsic Safety, Exi

- Permitted to use in Zone 0, 1 and 2.
- Could carry out maintenance repair work without the need to turn off the power supply.
- The use of "Uncertified Simple Apparatus" is allowed when connected through a safety barrier.
- Typical Application with Exi protection is for instrumentation signal, control circuit and other low power apparatus like CCTV.

Exi is a low-energy signaling technique. It brings down the electrical energy level for the Ex area apparatus used below the ignition curve. In this concept, any electrical spark, thermal or hot spot effect in any part of the circuitry intended for use in Ex areas do not have sufficient energy to cause an explosion. Hence, the operation for live maintenance repair work can be carried out and is allowed. The energy levels available for signaling are small but useable and more than adequate for most instrumentation systems.

The minimum ignition energy is obtained experimentally using "SPARK TEST APPARATUS" [24]. The experiments have produced a general agreed "IGNITION CURVES". These are the designer's curves with suitable safety factors for safety parameters calculation (section 6.1 provides the detail on safety parameters calculation). Three curves are resulting from the experiments; they are Resistive, Capacitive and Inductive Ignition Curve, as shown in Figure 11 to 13, respectively.

The resistive ignition curve (Figure 11) provides the entity safety parameter on the maximum open-circuit voltage denotes as Voc and the maximum short circuit current denotes as Isc allowed to go into the hazardous area without causing an explosion for different Gas Group. Any combination of the voltage and current

touching or above the curve could cause an explosion. A value below the curve will not have sufficient energy to cause an explosion. Equations (1) and (2) in section 6.1 provide the detail on the application.

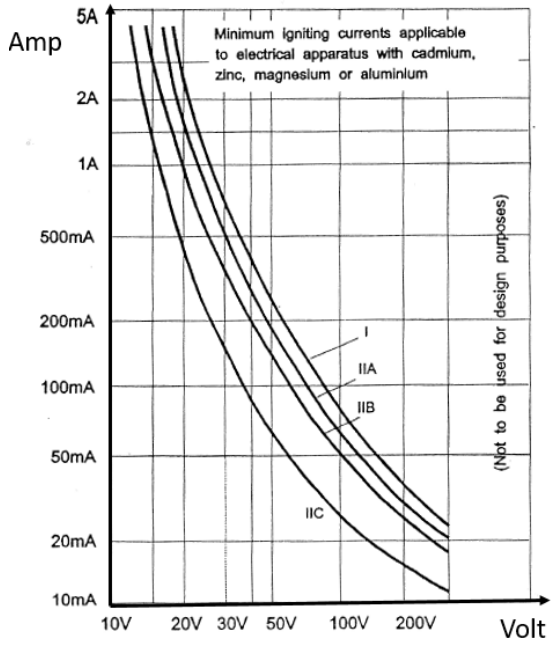

Figure 11: Resistive Ignition Curve [24].

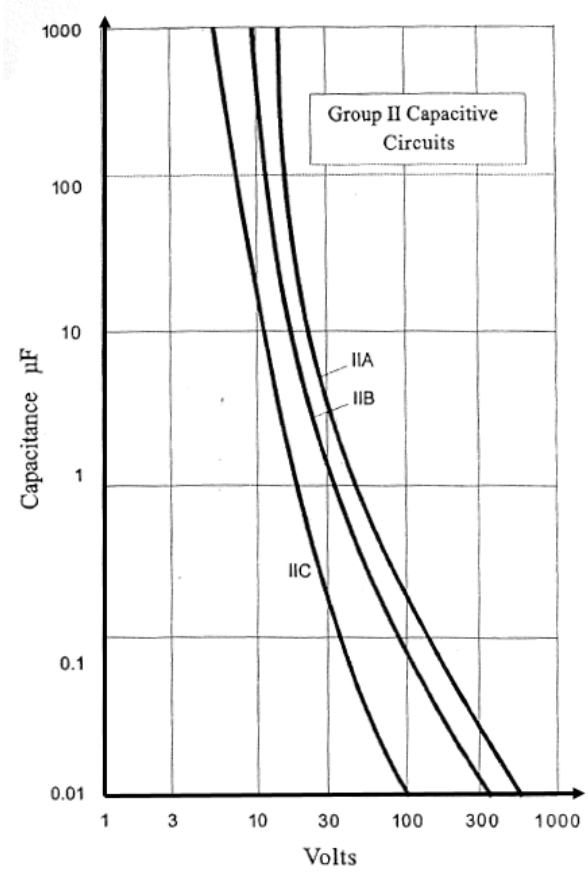

Figure 12: Capacitive Ignition Curve [24].

Capacitive ignition curve (Figure 12) provides the entity safety parameter on the maximum external capacitance (Ca) at the applied voltage allowed to be connected in the hazardous area for different Gas Groups. If the external capacitance (Ca) at the applied voltage is below the curve, it will not have sufficient energy to cause an explosion. Equation (3) in section 6.1 provides the detail on the application.

Inductive ignition curve (Figure 13) provides the entity safety parameter on the maximum external inductance (La) at the applied voltage allowed to be connected in the hazardous area for different Gas Groups. If the external inductance (La) at the applied voltage is below the curve, it will not have sufficient energy to cause an explosion. Equation (4) in section 6.1 provides the detail on the application.

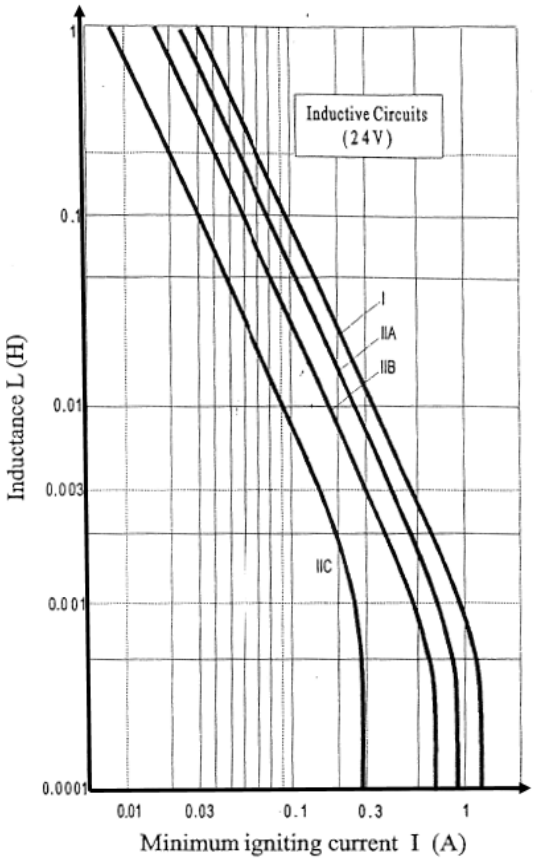

Figure 13: Inductive Ignition Curve [24].

The IEC 60079-11 standard defines three categories of Exi protection. They are "Exia", "Exib" and "Exic" with different fault tolerance levels, as summarized in Table 7. Only Exia category is permitted to apply in Zone 0.

With the introduction of intrinsically safe technique, the uses of “Uncertified Simple Apparatus” are allowed as defined by IEC 60079-25 in a hazardous area without additional certification when the simple apparatus is connected to the field through a certified safety barrier. IEC 60079-25 defines “Simple Apparatus” as an apparatus that does not generate or store energy more than 1,5V, 100mA and 25mW, such as mechanical switches and resistors, thermocouples and PT100. The simple apparatus also required to pass the insulation test at 500 Vrms (one-minute duration) to be used in the Ex area. The application of Simple Apparatus in the Ex area significantly brings down the cost of implementing intrinsically safe systems.

Table 7: Fault Tolerance on Exia, Exib and Exic [23].

Level of protection	Zone of use	Fault Count
Ex ia	Zone 0	Safe with 2 countable faults
Ex ib	Zone 1	Safe with 1 countable fault
Ex ic	Zone 2	Safe with no countable faults (ie safe in normal operation)

5.2. Flameproof, Exd

- Permitted to use in Zone 1 and 2 only.
- The system needs to power down to carry out maintenance work. In other words, no live maintenance is allowed.
- Hot permit is required to carry out maintenance work.
- Wiring enters the Exd enclosure is via a flameproof cable gland or flameproof barrier.
- Typical applications will be rotating machines, lighting, switches (start/stop button) and junction boxes.

The flameproof protection technique relies on housing design to ensure an explosion or ignition inside the enclosure will not propagate outside the enclosure. It is achieved using different flame path designs. There are three possible flame path designs, as shown in Figure 14. The flame path construction plays a significant role. It creates a longer flame traveling distance so that the hazard gas generated during the internal explosion has sufficient time to cool down below the permitted AIT. The enclosure design also must be capable of withstanding the explosion's pressure and, at the same time, preventing the hazard gas from entering the enclosure and contact with the protected equipment inside the enclosure.

Figure 14: Types of Joint

The Exd enclosure usually is supplied in a complete assembly. The manufacturer or its approved agent does all the internal components assembly and wiring work. Both the manufacturer and the approved agent must have a certified facility and trained person to carry out the work. An approved test authority certifies the assembled system as a single entity as system approval (see section 6). Only a single system certificate will be issued. The test procedure for the approval include:

- Ventilation – Consider the available free air volume to ensure sufficient air circulation and ventilation after all the electrical components are fitted and wired.
- Temperature Classification – Consideration of the temperature rises to comply with the temperature classification and define the temperature class;
- Creepage and Clearance: Check all creepage and clearance distance requirements (see Figure 15 on the difference between creepage and clearance distance).
- Pressure Piling – Consideration of the rise in air pressure resulting from the internal enclosure explosion by considering the worst-case scenario on the gas-air mixture.

Future component replacement during maintenance should use back the initially designed component specification. If the replaced component has a larger or smaller dimension than the initially installed part, it will affect the enclosure's internal geometry and ventilation. When a larger than the original component is replaced, pressure piling could happen. If a smaller sized component is replaced, more free air volume will be generated. Meanwhile, the heat conductivity and heat dissipation characteristics of an object are affected by the geometry, ventilation and the material used. This will significantly affect the temperature classification rating. The initial temperature rating of the enclosure could be void.

Drilling and tapping the hole on the enclosure for fitting the cable gland, breather and conduit by a third-party technician is strictly prohibited or else the certification is considered void. The installation of these auxiliary components can only be carried out by the enclosure's manufacturer or certified installer. The type of threads, thread pitch and the clearance tolerance for a particular junction box must be compatible with the cable glands, breather or conduit as flame paths exist at these points.

To improve the ingress protection (IP rating), for example, for weatherproofing applications, non-hardening grease material or non-setting grease or compounds could be applied to the joint. Installation of gaskets to increase the ingress protection is not allowed if they are not part of the original design. It will affect the internal enclosure pressure release efficiency during the explosion. The gasket can only be replaced. Consult the manufacturer and check the installation manual on the type of gasket that could be used.

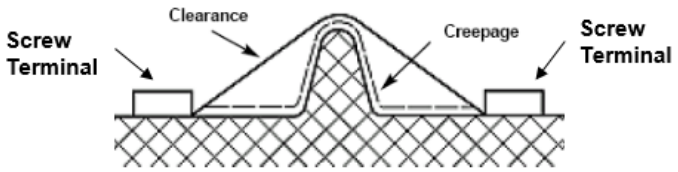

Figure 15: Different between Creepage and Clearance Distance

5.3. Increased Safety, Exe

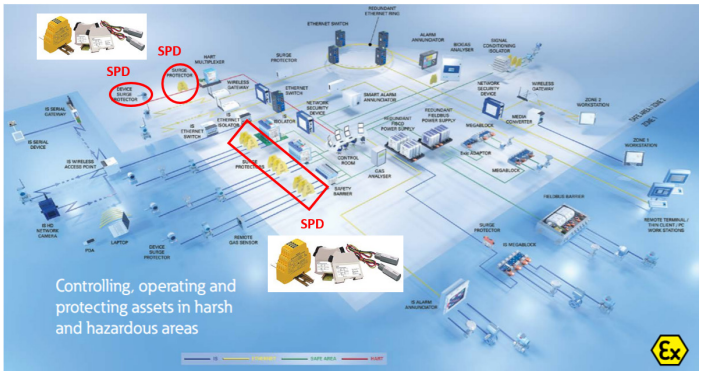
- Permitted to use in Zone 1 and 2 only.
- Required to turn off the power before carrying out maintenance work. In other words, live maintenance is not allowed.
- Minimum IP rating is IP54.
- No hot surface.
- Good mechanical strength (detail refer to EN50014).
- Typical applications will be in lighting, junction boxes and terminal blocks.

Increased Safety, Exe is an explosion protection technique applied to the hazardous area installation that ensures no hot spot or no excessive temperatures and no sparking occurrence from hazardous area electrical equipment and accessories. Equipment and the design that normally cause sparks are excluded from use within this method of explosion protection.

Exe relies on housing construction to withstand mechanical impact with a minimum of IP54 rating. The design of Exe ensures that under any operating mode, the apparatus does not contain normally arcing, sparking devices or hot surfaces that could cause ignition. This protection is realized by using high integrity insulation material. The designer also needs to consider the temperature de-rating factor of the insulation materials and enhanced terminal creepage and clearance distance (made wider than is generally the case in the general industry). The terminal design must be generously dimensioned for the intended cable connection and ensure that conductors are securely fastened to prevent arcing (loose connection can cause arcing). When designing the Exe protection method, a possible spark created by friction should be taken into consideration as well.

6. Method to Protect Assets in Hazardous Area

As shown in Figure 16, the mounting locations of the SPDs in a typical hazardous process plant.



6.1. Application Example on SPD in Exi Control Loop

- Permitted to use in Zone 0, 1 and 2.
- Maintenance work could be carried out with the power on. In other words, live maintenance is allowed
- No further certification is required when using "Uncertified Simple Apparatus" in combination with a certified safety barrier

There are two concepts of Exi applicable to intrinsically safe systems. They are “System Approval” and “Entity Concept”. The meaning of system approval indicates that a single certificate is issued by the approving authority such as BASEEFA or TUV, including the SPD, safety barrier and the field device, as shown in Figure 17 as the components inside the dotted line box. Uncertified control equipment, for example, DCS, PLC or ESD are installing before the safety barrier in the control room; they are not included in the system certificate. In fact, they do not require certification because the energy transmitted to the hazardous area in the field is already clamped down by the safety barrier when there is any fault that happened. Although there is no certification requirement for the uncertified control equipment, they are governed by the installation code, such as the requirement on cable segregation for Ex and Non-Ex cable; creepage and clearance distance for the terminal block; color code and so on. System certificate can only be issued after comprehensive testing and assessment by both the approval authority and the equipment manufacturer. Installation guidelines must be followed strictly according to the certificate/manual's instruction and wiring diagram provided. In the case where the fault happened, all replacement parts will have to be replaced with the exact original model used else; the certification will no longer be valid. This is not so flexible and, in some cases, will post difficulty when any of the parts are obsolete. When the exact replacement part is not available, then replacement on an entirely new set of the system will be required; otherwise, the newly installed component needs to be re-certified.

The most significant advantage of a system certification is to ensure that it is a proven and tested system. The approving authority and equipment manufacturer will be fully responsible for explosion protection in terms of safety. However, this led to the absence of flexibility in changing the component when it is discontinued. The responsibility of the installer is to follow strictly the installation instruction provided by the certificate. As for the entity concept, all intrinsically safe loop components, as shown in Figure 17 as the dotted line box, need to be individually tested and certified to use in Ex area. A separate certificate will be issued individually with all the safety parameters and other special clauses if any. It is the responsibility of the user to match the safety parameter, which will be described later. The utilization of the entity concept provides more flexibility in terms of parts selection, repair and equipment replacement. Regardless of the manufacturer, any product could be used from the safety perspective as long as the safety parameters are satisfied. However, in practice, the device can only be used if they fulfilled both safety and operational parameters. The operational requirement, such as it must have enough voltage and current to drive the field device.

Safety Parameter on Entity Concept

The entity safety parameters are described below:

$$Vmax \geq Voc, \quad (1)$$

Where Vmax is the maximum voltage specified by the field device manufacturer (tested by approval authority) that could be applied safely to the terminal of an intrinsically safe field device, Voc denotes the maximum open-circuit voltage (tested by approval authority) that could appear at the safety barrier’s output terminal when the fault occurs.

$$Imax \geq Isc, \quad (2)$$

Imax is the maximum input current specified by the field device manufacturer (tested by approval authority) that could be applied safely to the terminal of an intrinsically safe field device. Isc denotes the maximum output short-circuit current (tested by approval authority) that could be generated from the safety barrier's output terminal when a fault occurs.

$$Ci + Ccable \leq Ca, \quad (3)$$

Ci is the intrinsically safe field device's internal unprotected capacitance (tested by approval authority). Ccable denotes the cable capacitance.

Ca is the maximum external capacitance (individually tested by approval authority), including all devices at the field that could be connected safely to the hazardous terminal of the safety barrier.

$$Li + Lcable \leq La, \quad (4)$$

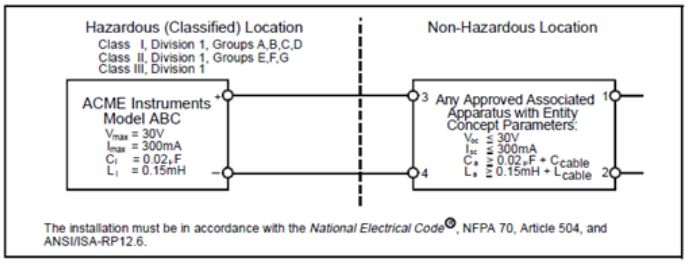
Li is the intrinsically safe field device's internal unprotected inductance (tested by approval authority). Lcable denotes the cable inductance.

La is the maximum external inductance (individually tested by approval authority), including all devices at the field that could be safely connected to the terminal of a safety barrier.

The value for Vmax, Voc, Imax, Isc, Ci, Ca, Li and La could be obtained from the individual intrinsically safe certificate issued by the approval authority. It is usually supplied together with the product, where Ccable and Lcable can be obtained from the cable manufacturer's datasheet.

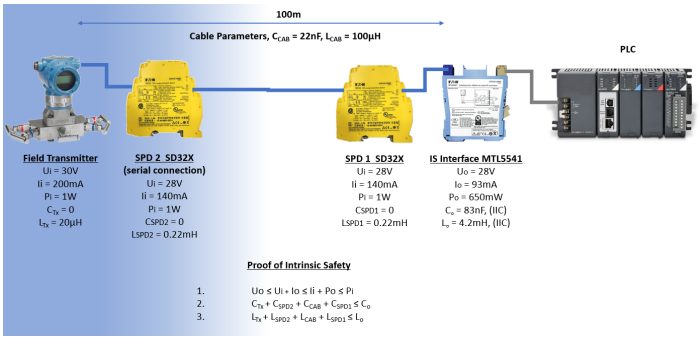
Only the system that fulfills all four mentioned equations, i.e., equations (1), (2), (3) and (4) could be used and safely installed according to the entity concept. However, the user also must take into consideration the operational requirements; for example, it should have sufficient voltage and current to drive the field equipment. Only systems that fulfill both operational and safety requirements will be implemented.

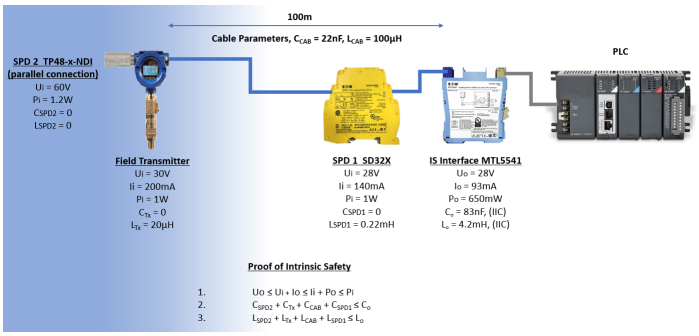
Entity parameters may be found on the control drawing supplied by the equipment manufacturer, along with other pertinent information regarding proper connections, conditions of use, etc. Figure 18 is an example of a control drawing for Exi equipment assessed based on the entity concept.



When an SPD is mounted in the safe area where no hazard substance is present, for example, in the control room, temperature classification and the type of hazard classification such as hazardous gas are not applicable; therefore, it will not be considered here. However, for field mounted SPD where hazard substance is present (Ex area); temperature classification and hazard classification need to be considered.

Figure 19 shows two SPDs connected in series, while Figure 20 shows one of the SPD, field mounted SPD connected in parallel and the other SPD (mounted in a safe area) is connected in series. For the case where all SPDs are mounted in the safe area, then there is no specific requirement for temperature and hazardous area classification. However, temperature and hazardous area classification must be taken into consideration if SPDs are to be mounted in a hazardous area. The hazardous area classification information of the individual Ex rated device can be found in the certifying authority's intrinsically safe certificate. Since all the SPDs in Figure 19 and Figure 20 are part of the Intrinsically Safe loop; therefore, it is a mandatory requirement to perform the entity safety parameter checking (equation (1) to (4)) to ensure its operational safety.





6.2. Application Example on SPD in Exd Control Loop

- Permitted to use in zone 1 and 2 only.
- Need to turn off the power before maintenance work is carried out. In other words, no live maintenance is allowed.
- Hot permit is required to perform any maintenance job.

SPD used in the Ex area is required to mount inside the Exd enclosure. The following information is required to determine the suitable size of Exd enclosure:

- To determine the enclosure's overall size, all the dimension on the individual component to be mounted inside the Exd enclosure is necessary. The system design for heat dissipation and ventilation on top of component size needs to put into the calculation as well.

- Temperature profile or T classification, heat or power dissipation information for the individual component is needed to identify the overall temperature classification of the Exd enclosure. In this case, if the temperature, heat or power dissipation information is not available, the system will need to perform temperature profiling to determine the maximum surface temperature by powered on for an extended period of time using a temperature probe. A bigger system may be required to power on for multiple hours until the temperature rise reaches a stable point where the measured temperature achieves equilibrium, stable and saturated.
- The manufacturer needs to know the type of hazard that could be present, for example, propane, ethylene or others, to determine the kind of joints and its design, either flanged joint, threaded joint or spigot joint. However, in most cases, it is the other way around; the manufacturer states their design is suitable for what kind of hazard. The user's choice is based on the hazard present in their application.
- Hazardous area mounting location or zoning: This is to determine the appropriate type of explosion protection technique. The flameproof (Exd) protection method can only be permitted to apply to Zone 1 or Zone 2 only.

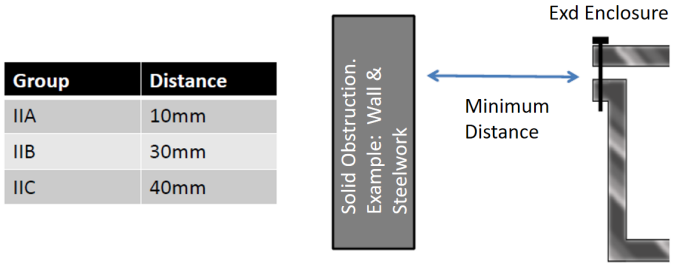


Figure 21: Obstruction of Flame Path (redrawn from [1] with additional information

Figure 22: Sample of the Exd Enclosure

During installation, it is crucial to ensure that there is no blockage such as a wall, brackets, conduit, weather guards or other electrical equipment near the opening of the flame path joint, as shown in Figure 21. The presence of such obstruction could reduce the efficiency of the flame path in the event of an internal explosion. Therefore, the minimum distance requirement between the flame path opening and the obstruction must be satisfied. Figure 21 provides the minimum distance requirement as recommended by IEC 60079-14.

Sample of the Exd enclosures fitted with various Ex and Non-Ex components are shown in Figure 22. It is also a common industrial practice that all the internal assembly and wiring work inside the Exd junction box is carried by the manufacturer or a certified center or an approved agent to ensure compliance.

7. Summary

When selecting SPD for hazardous area application, two criteria involve:

- Equipment protection

The parameters to be considered to protect the equipment from surge:

i. Types of SPD: SPD installation location correspondence to discharge surge energy. This is different from hazardous area classification. It is applied to the installation location for both Ex and non-Ex area.
ii. LPZ and LPL to determine the kA rating of the SPD.
iii. Let-through voltage (Voltage Protection Level, U_P): SPD should be selected where the let-through voltage is below the SWC of the device to be protected.
iv. Bandwidth: only require when it is used for the communication line.
v. Maximum continuous operating voltage, U_C: The U_C rating of the SPD should be selected slightly higher than the U_N (nominal operating voltage) of the equipment to be protected so that during normal operation, the SPD is transparent to the system.
vi. Nominal load current, I_L: For a series connection, the load current needs to be determined so that the SPD's current passing will not damage the SPD. The SPD must be able to withstand the continuous thermal current load. This only applies when the SPD is connected in series whereas SPD connected in parallel is able to handle unlimited load current.
vii. Series voltage drop: This mainly applicable for signal SPD where a series connection is applied. After adding the SPD, the user needs to ensure the voltage drop does not affect the circuit operation.

- Explosion protection

These are the factors that are nothing to do with the equipment protection from surge but rather to ensure the SPD itself does not become the source of ignition.

i. Industry Group: provides information on the type of industry (example: mining or surface industry) and the type hazard substance such as vapor, gas or dust that may be present, and its minimum ignition energy.
ii. Temperature Classification: provides information on the maximum surface temperature of the equipment at fault condition. The temperature classification of the equipment mounted in the Ex area should fall below AIT of the hazardous substances present. For the process loop application, only the SPD mounted at the field will have the temperature classification (Ex are). The other SPD mounted in the control room (non-Ex area) will not have the temperature classification.

iii. Zoning Classification provides information on the probability of a particular hazardous substance being present. The applicable type of explosion protection method depends on the Zoning information and the type of hazard present.

iv. Two approval concepts for safety evaluation could be adopted, entity or system approval. Entity Approval is a technique to combine individually approved apparatus into an intrinsically safe circuit. Two apparatus from different manufacture could be interconnected together as long as it could fulfill the safety calculation spell out by equation (1), (2), (3) and (4), no need for the two apparatus being tested in combination. System Approval is a technique to verify the intrinsic safety of a circuit in which all of the interconnected devices are examined all together as a complete system.

Conflict of Interest

No conflict of interest.

ABSTRACT

In many countries, irrigation water is one of the major contributors to water scarcity. In the present study, a novel optimized irrigation system which minimizes water consumption in irrigation is presented. The system is based on a predictive control algorithm, which foresees the water need of the crop, and regulates the time and amount of irrigation to maintain the soil moisture around an optimal level, while taking into account system constraints. The predictive feature of the algorithm requires a model of the soil moisture, which is obtained from the actual meteorological data of the Kingdom of Bahrain. The optimization problem is formulated as an Economic Model Predictive Control (EMPC) problem and implemented using MATLAB. The simulation experiments show that the novel system yields a reduction of water consumption around 8% and 16% compared with the PID and On-off controllers, respectively, while maintaining an optimal soil moisture level.

1. Introduction

Reducing water consumption is a fundamental constituent of water management, particularly in water-scarce areas. In many countries, irrigation water is one of the major contributors to water scarcity, and reducing irrigation water while increasing water efficiency is a way to overcome this issue. This work, which is an extension of the paper originally presented in 2019 8th International Conference on Modeling Simulation and Applied Optimization (ICMSAO) [1], looks at different practices used to reduce the use of irrigation water and proposes the use of an advanced optimization technique as possible solution to the problem.

Different mulching practices, irrigation techniques and irrigation strategies can reduce water consumption in irrigation. Mulching refers to the practice of covering the soil with protective material to reduce evapotranspiration. Irrigation techniques (dripping, furrow, sprinkler etc.) refer to the way irrigation water is applied, which also affects evapotranspiration. Irrigation strategies refer to the timing and the amount to irrigation water provided to the crop. Irrigation scheduling, which refers to when and how much to irrigate, is a fundamental concept associated with irrigation strategies [2], [3]. Although mulching practices, irrigation techniques and irrigation strategies are all important tools, in [2] it is found that for optimal results, the irrigation strategy should be improved first, followed by mulching practices and the irrigation technique. Therefore, in the present study we will focus on irrigation strategies and, in particular, on water-efficient irrigation technology.

Technological developments include automated irrigation systems, that irrigate at set times and for a certain amount of time. Although these automated techniques present advantages in terms of increased water efficiency and reduced farmers'intervention, the performances of these open loop control systems in terms of water consumption are not yet optimal. The main reason of their unsatisfactory performance is that they can cause under- or over-watering, since weather and crop conditions are not taken into account. This of course can lead to spoiled crop and water wastage.

Greater expectation is placed on technologies which include sensors and closed-loop watering systems [4]-[6]. The simplest approach uses sensors in an on/off control scheme, where irrigation is turned on or off depending on the reading of a moisture sensor above or below set values.

More complex control strategies, which often are model-based, have been described in different papers [7]-[10]. In general, model-based control strategies require models of the soil moisture dynamics including variables such as climatological data, crop water needs, water saturation etc. [7], [8]. Among such advanced control strategies is Model Predictive Control (MPC), as proposed in the research described in [9] and [10]. The models presented in [9] and [10] are based on the water balance equation, which requires measuring or estimating the initial soil moisture, rainfall,

*Corresponding Author: Luisella Balbis, lbalbis@uob.edu.bh

water capacity of the soil and evapotranspiration (ET). From these measurements, the water balance equation gives an estimation of the soil moisture. In these papers, the MPC algorithm is formulated as an optimization problem, which reduces set point tracking errors.

Similarly to the work presented in [9] and [10], our work describes the development of a soil moisture dynamic model and its application in a predictive control setting. However, the predictive control strategy here proposed is based on Economic Model Predictive Control (EMPC), which aims at maximizing the economic performance of the irrigation system rather than reducing tracking errors. Constraints in the optimization problem are used to guarantee that optimal soil moisture is obtained. Moreover, in the present study the soil moisture model is based on atmospheric conditions of the Kingdom of Bahrain [11].

The remainder of this paper is organized as follows. Section 2 describes the derivation of the soil moisture model based on the water balance equation and the measurement of meteorological data of the Kingdom of Bahrain. Section 3 describe the principles of MPC and presents EMPC as a special case of the MPC policy. In Section 4 the outcomes of employing the EMCP are shown and comparisons are drawn with On-off and PID automated irrigation systems. Finally, conclusion and recommendations are included in Section 5.

2. System Identification

This section presents the grey-box modeling of the soil moisture dynamics using difference equations. Grey-box modeling is a method for identifying the system's dynamics that uses measurement obtained from experimental data combined with physical knowledge of the system. For parameters estimation, state space models are often used, where the state, input and output of the system are related by difference equations.

2.1. Physical Modelling

2.1.1. Water-balance equation

The model developed here is based on the water-balance equation represented graphically in Figure 1 [9], [10]:

$$M(k+1) = M(k) + IR(k) + RAIN(k) + CR(k) - ET_c(k) - DP(k) - RO(k) \quad (1)$$

where k is the sampling time, M is the moisture of the soil, IR is the irrigation water, $RAIN$ is the precipitation, CR is the capillary rise, ET_c is the crop evapotranspiration, DP is the deep percolation and RO is the water runoff.

Equation (1) expresses the variation in soil moisture as the difference between the water influx (capillary rise, precipitation and irrigation) and the water losses (evaporation, transpiration, water runoff and deep percolation) [10].

Geomorphological and meteorological data of the Kingdom of Bahrain show a generally flat land and very scarce precipitations. Therefore, it is reasonable to assume that water runoff, precipitation, and capillary rise are negligible. Under these assumptions, (1) can be reduced to:

$$M(k+1) = M(k) + IR(k) - ET_c(k) - DP(k) \quad (2)$$

Equation (2) reduces the dependency of soil moisture to three variables: irrigation, evapotranspiration and deep percolation.

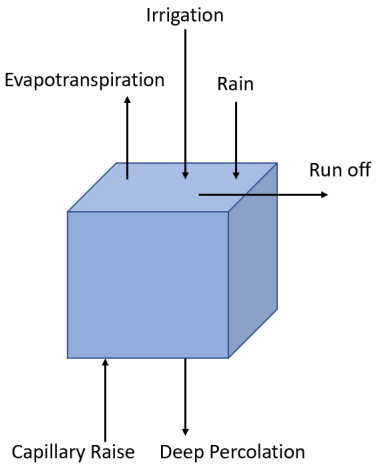

Figure 1: Water Balance Model

2.2. Evapotranspiration Estimation

Evapotranspiration is defined as the movement of water from the soil and the crop into the atmosphere. Many factors influence evapotranspiration rate, such as crop type and growth stage, weather factors (air temperature, wind, humidity etc.), environmental conditions (e.g. soil salinity) and land management (use of fertilizers and pesticides, etc.) [12].

Different approaches exist to estimate evapotranspiration [13]. In the present study, the FAO Blaney-Criddle estimation approach has been used. Despite being a simpler method compared to others, it has been proven to be satisfactory under a variety of weather conditions [14], [15].

Using this method, the actual evapotranspiration ET_c is estimated for a particular type of crop C as:

$$ET_c = K_c \cdot ET_o \quad (3)$$

In (3), the crop coefficient K_c depends on the crop type and the growth stage of the crop. ET_o is the estimation of the evapotranspiration from the reference crop with hypothetical qualities (actively growing green grass of 8–15 cm height). In the present study, ET_o is assumed to be affected by climatic parameters, according to the following empirical FAO Blaney – Criddle equation:

$$ET_o = p \cdot (0.457 \cdot T_{mean} + 8.128) \quad (4)$$

where T_{mean} is the average daily temperature [°C] and p is the average annual percentage of daytime.

2.3. Deep Percolation

Deep percolation (DP) is a hydrologic process, where water penetrates below the roots of the crop. The quantity of percolation during irrigation depends on the characteristics of the soil as well as the soil humidity.

In the present study, DP is assumed to be directly proportional to M with proportionality constant K_p: when M increases, DP

increases due to differential pressure [16]. This is expressed by the following equation:

$$DP(k) = K_p \cdot M(k) \tag{5}$$

In (5), K_p is a constant that depends on the type of soil (sandy, clay, silt, loamy, etc)

Substituting (3) and (5) in (2) we get a difference equation which leads to a model of the water balance dynamic in the form:

$$M(k+1) = K_s \cdot M(k) + IR(k) - K_c ET_o(k) \tag{6}$$

where K_s=1-K_p.

2.4. Model Structure

Equation (6) gives a mathematical model which contains two parameters, K_s and K_c. In our work, these parameters are unknown, meaning that the value of crop coefficient and the type of soil used in our experiment are unknown. Therefore, a gray-box system identification process, which uses a the first principles model of the system and data coming from direct system measurements, was used to estimate the values of the unknown parameters.

The linear difference equation (6) can be re-written in the form of a discrete state space model as:

$$M(k+1) = [K_s]M(k) + [1]IR(k) + [-K_c]ET_0(k) \tag{7}$$

$$M(k) = [1]M(k) \tag{8}$$

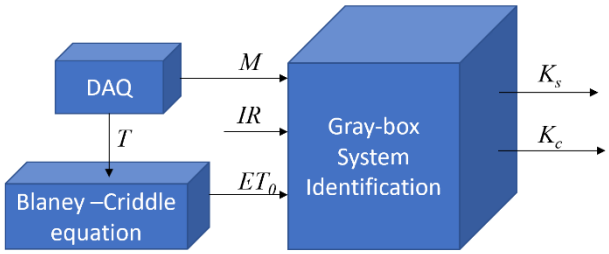
where $M(k)$, $IR(k)$, $ET_0(k)$ are the state vector, the input signal, and the disturbance of the system.

The state-space model (7) and (8) presents two parameters, K_s and K_c, that need to be estimated from measured data.

2.5. Parameters Estimation

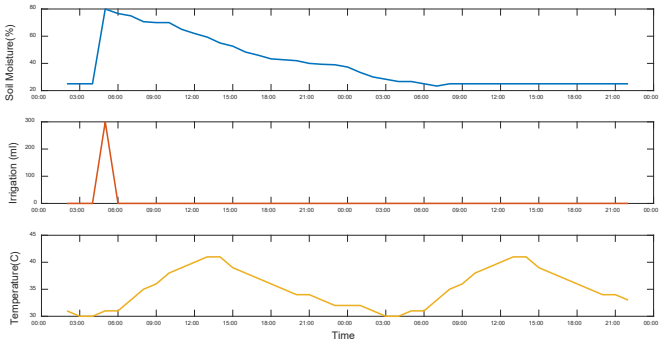
Parameter estimation was carried out using Matlab System Identification Toolbox R2018a, which provides a tool for deriving mathematical models of dynamic systems given measured input-output data. The toolbox was used to estimate the values of K_s and K_c, through a gray-box model estimation process.

Figure 2 shows the process of model identification.



A set of measurements (see Figure 3), called identification data, was collected using a data acquisition system implemented on an Arduino Uno microcontroller board.

The experimental setup consists of a temperature sensor LM35, and a soil moisture sensor FC-28. The temperature sensor outputs a voltage which is directly proportional to the instantaneous temperature. The soil moisture sensor measures the volumetric soil moisture as a function of electric conductivity in the soil. In our experiment, the position of the soil moisture sensor was fixed at 10 cm depth. The sensor was calibrated by taking two measures; one with the soil entirely wet and one with the soil entirely dry. The moisture was expressed in percentage, with the values of the measurements mapped from 0 (dry soil) to 100 (soaked soil).



For our experiments, the soil moisture M and the temperature T near the moisture sensor were synchronously measured every hour over a period of two days. The irrigation IR was modeled as a pulse signal, since it provides a great amount of water but for a limited time [10].

The Blaney-Cradle equation block in Figure 2 estimates ET_o using (4). In our experiment, the value of the variable p in (4) was substituted by the actual percentage of daytime for the time of the year in which the experiment was conducted. In the same way, the variable T_{mean} was substituted by the actual temperature T measured at time k.

2.6. Model Validation

To validate the model obtained in the previous section the output of the simulated model was compared with measured data.

For this purpose, another set of input data was measured and then inputted to the derived model of the system. The input data set used in the validation is shown in Figure 4.

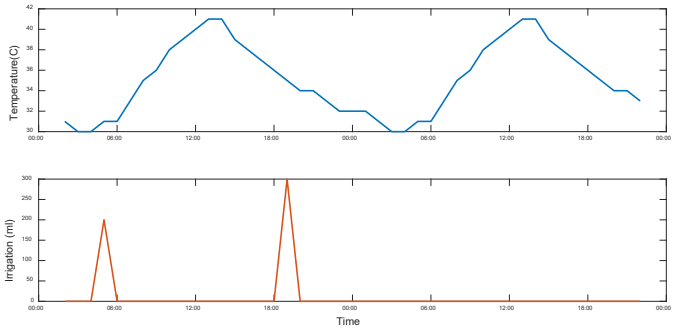


Figure 4: Validation Data

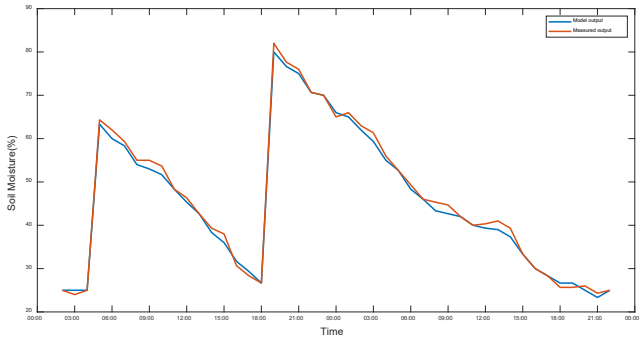
Figure 5 shows the difference between the output of the model and the measured soil moisture. The plots show a good agreement between simulated and measured outputs, with negligible time delay between the irrigation event and the change in soil moisture dynamics.

A further comparison between simulated and measured outputs to verify the reliability of the identified model was done calculating the Mean Absolute Error (MAE) as follows:

$$MAE = \frac{\sum_{k=1}^{T} |\widehat{M}_k - M_k|}{T} \quad (9)$$

where $\widehat{M}_k - M_k$ is the difference between the predicted and the measured output value and T=48 is the total number of samples. The obtained *MAE* value of 2% is considered an indication of a valid model.



Measured and Simulated Soil Moisture

3. Economic MPC

3.1. EMPC Basic Concepts

The term Predictive Control refers to a control design method characterized by [17]:

- use of a model to forecast the system output at future time instants (prediction horizon);
- computation of an input control sequence that optimizes a given objective function;
- receding horizon strategy, where the input control sequence is computed by taking into account the predicted outputs, but only the first control signal of the sequence is applied to the system.

The different algorithms which belongs to the Predictive Control group present differences in terms of the chosen system models (impulse, step, state-space, CARIMA, fuzzy models, etc.), disturbance (constant, decaying, filtered white noise etc.) and in the cost-function to be minimised.

A general MPC mathematical formulation is given by the following optimization problem [18]:

$$J = min \sum_{i=0}^{H_c-1} f\left(x_{k+i|k}, u_{k+i|k}\right) \quad (10)$$

where the variables $x \in R^n$ and $u \in R^m$ denote the state and control action at the instant k and H_c denotes the control horizon. The notation $k+i|k$, with $k \in Z$, indicates the estimation of the future variables based on the measurements at current time instant k.

Traditional MPC controllers minimize a quadratic cost function which tracks output and manipulated variable references.

The general prediction model can be expressed by the discrete equation:

$$x_{k+i+1|k} = g(x_{k+i|k}, u_{k+i|k}) \quad (11)$$

where the predicted states depend on the future states and control actions from instant k to instant $k+H_p$.

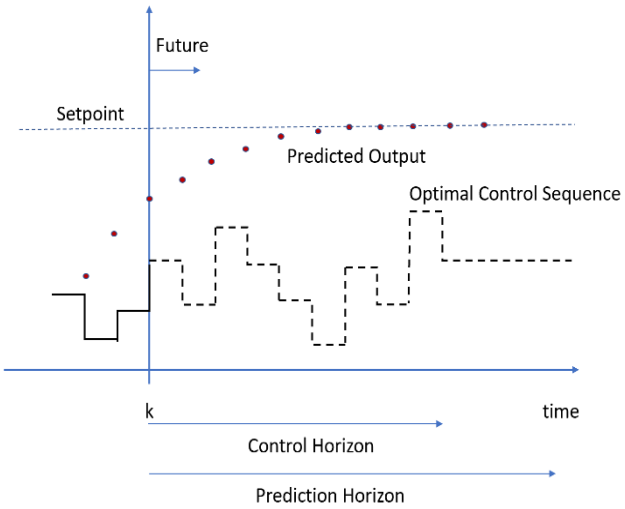
The minimization problem is usually subject to a set of constraints which have to be satisfied over the predictive horizon. These constraints are due to physical or operational limitations of the real system and they take the general form:

$$h(x_{k+i|k}, u_{k+i|k}) \leq 0 \quad (12)$$

At each time instant, MPC measures or estimates current state x_k and predicts the system state evolution over the prediction horizon H_p using the current state and the model of the system.

The optimal control sequence over the control horizon H_c is found solving the minimization problem (10). Only the first control action is applied to the system, and the remaining results are discarded.

In absence of disturbances and plant-model mismatch, the optimization problem could be solved as an open-loop problem, and the input sequence found at k=0 could be applied to the system for all $k \geqslant 0$. In a more realistic scenario, the behavior of the real system differs from the predicted model output. To cater for this mismatch, the optimal control problem is solved again at the next sampling time. Using the state measurement/estimation at time k+1, the cycle of prediction and optimization is repeated, moving the horizon forward (Figure 6).



Receding Horizon

In recent years, the EMPC approach has been proposed with successful applications in various fields [19].

Contrary to traditional MPC, EMPC is employed to maximize profitability, rather than minimize tracking errors. This can be done by defining a cost function that, directly or indirectly, measures the process economics [20]. The formulation of cost function depends on the particular applications, such as the operating profit, production rates, product selectivity, and product yield. In EMPC the cost function, as well as the plant dynamics and the constraints can be linear or nonlinear. Therefore, generic performance cost functions and nonlinear optimization algorithms are used to solve the minimization problem. The structure of the basic EMPC algorithm is shown in Figure 7.

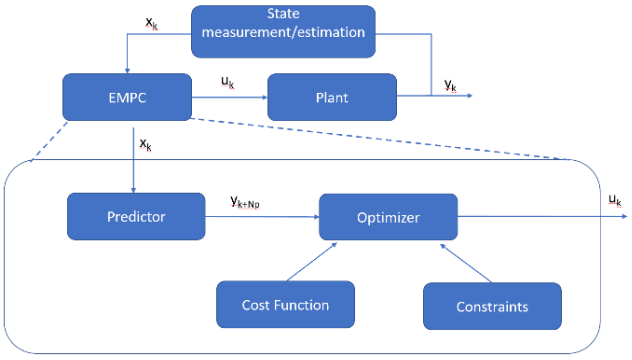


Figure 7: Basic EMPC Structure

3.2. EMPC Problem Formulation

In our work, we utilize an EMPC approach to minimize water consumption while maintaining the soil moisture close to an optimum value. We consider a linear economic stage cost function; additionally, both plant dynamics and constraints are linear. Because of this, our formulation of the EMPC problem is linear. The fundamental steps of the devised EMPC algorithm are the following:

- At the time k, measure $M(k)$ and compute the optimal control sequence $\overline{IR}(k)$ by solving a stochastic optimization problem over the control horizon N_c.
- Apply only the first computed value $IR(k/k)$ as input to the system.
- At the time k+1, measure $M(k+1)$ and repeat the optimization.

At each time instant k, a vector $\overline{M}(k)$ of the moisture predicted values is computed, using the model given by (7) and (8):

$$\overline{M}(k) = [M(k+1/k) \quad \dots \quad M(k+N_p/k)] \tag{13}$$

The stochastic optimization problem becomes deterministic if we assume that ET_o does not change over the prediction horizon N_p., i.e.:

$$\overline{ET_0}(k) = [ET_0(k) \quad \dots \quad ET_0(k)] \tag{14}$$

where $ET_o(k)$ is calculated using (4) and the current measured temperature $T(k)$.

Let's define the future control signals as the vector:

$$\overline{IR}(k) = [IR(k/k) \quad \dots \quad IR(k+N_c-1/k)] \tag{15}$$

Combining (13), (14) and (15) with the model (7) and (8) we obtain:

$$\overline{M}(k) = \Theta M(k) + \Phi \overline{IR}(k) + \Psi \overline{ET_0}(k)) \tag{16}$$

where:

$$\Theta = \begin{bmatrix} K_s \\ \vdots \\ K_s^{Np} \end{bmatrix} \tag{17}$$

$$\Phi = \begin{bmatrix} -K_c & 0 & \dots & 0 \\ -K_c K_s & -K_c & 0 & 0 \\ \vdots & \vdots & -K_c & 0 \\ -K_c^{Nc} K_s & -K_c^{Nc-1} K_s & \dots & -K_c \end{bmatrix} \tag{18}$$

$$\Psi = \begin{bmatrix} -K_c & 0 & \dots & 0 \\ -K_c K_s & -K_c & 0 & 0 \\ \vdots & \vdots & -K_c & 0 \\ -K_c^{Np} K_s & -K_c^{Np-1} K_s & \dots & -K_c \end{bmatrix} \tag{19}$$

The purpose of the designed control system is to obtain optimal economic performance. The following stage cost is assumed to reflect the nominal economic cost of irrigating the system over one sampling period, that is:

$$L(k) = IR(k) \tag{20}$$

The cost function does not consider the cost of operating the valves or the cost of pumping water, since their minimization is not considered an objective in the present study.

The resulting optimization problem adopted in our EMPC controller formulation is:

$$\min_{IR(k),v(k)} \sum_{i=0}^{N_c-1} IR(k+i/k) + \sum_{i=0}^{N_p} \rho v(k+i) \tag{21}$$

In addition to the stage cost, the objective function contains the terms $\rho v(k+i)$ which represent soft economic constraints.

The minimization problem (21) is subject to:

$$\overline{M}(k) = \Theta M(k) + \Phi \overline{IR}(k) + \Psi \overline{ET_0}(k)) \tag{22}$$

$$\overline{M}(k) \le \overline{M}_{opt}(k) + \overline{V}(k) \tag{23}$$

$$\overline{M}(k) \ge \overline{M}_{opt}(k) - \overline{V}(k) \tag{24}$$

where $\overline{M}_{opt}(k), \overline{V}(k)$ are vectors of size N_p defined as follows:

$$\overline{M}_{opt}(k) = [M_{opt} \quad \dots \quad M_{opt}] \tag{25}$$

$$\overline{V}(k) = [v(k/k) \quad \dots \quad v(k+N_p/k)] \tag{26}$$

The value M_{opt} represents the soil moisture that should be kept constant for optimal operating conditions. The variable $v(k)$ is a slack variable that is introduced to allow for small variation of the soil moisture $M(k)$ around the optimal value. That is, we nominally want to satisfy $M(k)$=M_{opt}, and when these constraints are violated, an additional cost $\rho v(k+i)$ is paid, weighted by the penalty parameter ρ. The choice of the parameter ρ is critical; when it is chosen too small, the value of the soil moisture might be far from the optimal one; when it is chosen too big, we might incur into infeasibility issues.

4. Simulation Results

The performances of PID controller, On-off controller and the proposed EMPC are compared. Not surprisingly, the behavior of the three control techniques is very different, as it can be observed in Figure 8 and Figure 9.

The On-off controller uses the measurement from a moisture sensor to switch the irrigation pump on or off based on whether the measurement is below or above maximum and minimum limits. The output from the device is either 100% on or off, with no middle

state. Figure 8 shows the outcome using the On-off controller. In this example, the soil moisture minimum and maximum levels are fixed at 50% and 70%. As expected, the output presents a variation of the moisture level (overshoot) around the optimal value of 65%. Reducing the thresholds could help improving the underwatering issue, but it would imply a higher switching of the actuators and a persistent overwatering problem.

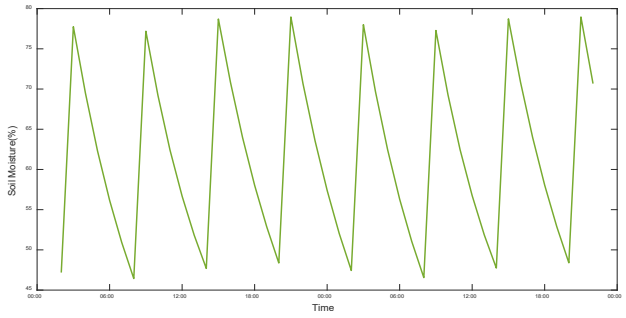

Figure 8: Soil Moisture with On-Off Controller

In Figure 9 the outcomes of the PID and EMPC approaches are shown. It can be noticed that the EMPC maintains the value of the soil moisture around the optimal value better that the PID controller in presence of disturbances, since it considers the effect of $ET_o(k)$ on the moisture level over the prediction horizon.

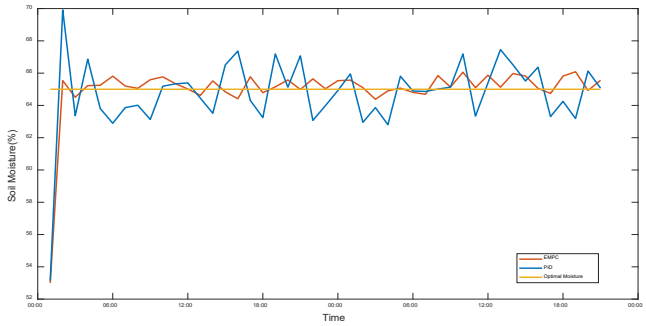

Figure 9: Soil Moisture Dynamics with EMP and PID Controllers

The three irrigation systems are also compared in terms of accumulated error, defined as:

$$CE = \sum_{k=1}^{T} \left| M_{opt_k} - M_k \right| \tag{27}$$

where the error is the difference between the optimal soil moisture and the simulated soil moisture. The cumulative error gives an indication of the ability of the controller to keep the soil moisture close to the optimal value. As it can be seen in Figure 10, the EMPC has smaller cumulative error compared to the other irrigation methods.

The total water consumption over the 48 hours period is around 2400 ml for the On-off controller, 2160 ml for the PID based system and 2000 for the EMPC. Therefore, the EMPC yields a reduction of water consumption around 8% and 16% compared with the PID and On-off controllers, respectively, while keeping the soil moisture within optimal values.

The simulations demonstrate that the EMPC scheme applied to an irrigation system provides benefits compared to conventional irrigation methods, since it maintains the moisture level near the nominal optimum, while providing economic benefit.

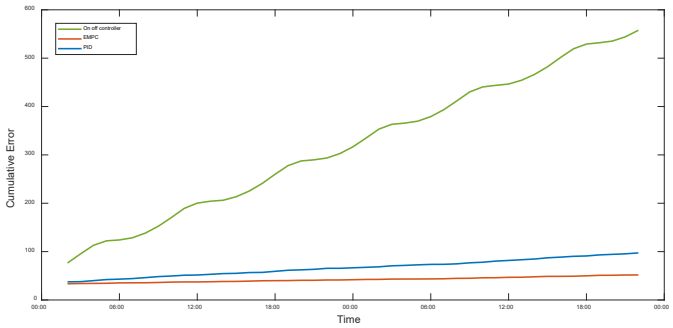

Figure 10: Cumulative Error for On-Off Controller, PID and EMPC

5. Conclusions

This work presents the process of developing an optimal controller regulating the time and amount of irrigation to maintain the soil moisture around an optimal level, while taking into account system constraints. The proposed control strategy, based on EMPC techniques, was implemented in MATLAB and results were compared with traditional irrigation methods based on PID and On-Off controllers. The results suggest that EMPC applied to irrigation systems can lead to increased efficiency and reduced water consumption.

Further improvement of this work would require a more accurate model of the system. A current limitation is given by the model developed, which can be improved by collecting sensors measurements over a sparse area and under different operating conditions, and using more complicated approaches to estimate ETo such as the FAO Penman Montheith technique.

Furthermore, developments on this work could explore the implementation of the proposed EMPC algorithm on hardware and evaluate the feasibility of such strategy in real time.

ABSTRACT

Complete manual annotation of dependency treebank needs resources like annotators and annotation tools and takes long time and has high possibility of inconsistent annotations for free word order languages such as Myanmar. This paper describes a dependency head annotation scheme with Universal part-of-speech and Universal Dependencies for Myanmar dependency treebank. Currently 22,810 sentences and 680,218 tokens were annotated from three corpora for Myanmar dependency treebank. Some language specific issues are also described with examples. Raw syntactic structures were annotated automatically by UDPipe according to the Universal Dependencies based on Universal-part-of-speech tag scheme. Then unsupervised annotated dependency head structures have been manually updated in post processing. To be reliable and speedy post process with reduced errors for manual updating, selected sentences were added to the training data after being updated. After that the model has been retrained and the remaining sentences were parsed by UDPipe. Post processing was repeated until all sentences were updated. Some specifications of dependency annotation schemes in sentences encountered in post processing are presented with examples. For parsing performance of annotated data, cross validation tests and parsing experiments were performed. Moreover, annotated treebank data have also been evaluated by CoNLL 2017 evaluation script for parsing performance. Results of parsing experiments and evaluation are also reported by unlabeled and labeled attachment scores and demonstrated that the proposed method is a suitable way for building Myanmar dependency trees. Moreover, syntax structures of treebank are also analyzed and syntax information is also presented. This dependency head annotation for dependency treebank is the first work for Myanmar language as far as we know.

1. Introduction

A treebank annotated with syntax or dependency structure is an essential and important resource for natural language processing systems in any language. Treebank annotated dependency structures is called dependency treebank. While phrasal constituents and syntax rules could not provide a direct role in sentences, syntactic dependency information of a sentence can describe directed grammatical relations between words. Moreover, dependency grammar is also able to deal with morphologically rich and relatively free word order languages. Dependency treebank is also critical resource in any language to develop natural language processing applications [1].

Many dependency treebanks have been constructed manually for many languages such as Czech, German, Danish, French, Portuguese, Estonian, Russian, Dutch, Danish, Turkish, Basque, Italian, English [2], Norwegian [3], Finnish [4], Romanian [5], Ancient Greek and Latin [6], Vietnamese [7],

Annotating dependency syntactic information in sentences is still a hard task for Myanmar having free word order nature. Moreover, currently there is still low resource for syntactic information for Myanmar language.

The Myanmar grammar is different from other languages of ASEAN countries such as Thailand, Vietnam, Malaysia and these languages already have treebank resources. Myanmar has been similar structures with the other SOV order languages such as Japanese, Chinese, and Korean and also a head final language. According to these properties, for Myanmar, a dependency-based head finalization has been proposed for statistical machine translation (SMT) in [8]. Although the proposed method was being able to improve a baseline SMT result without requiring parallel

*Corresponding Author: Hnin Thu Zar Aye, hninthuzaraye@ucsy.edu.mm

training information, it depends on dependency parser of source-side language to achieve higher performance than unsupervised baseline result [8]. Having similar syntactic structures of Japanese and Myanmar, a parsing approach has been proposed by applying SMT by using Japanese as pivot in [9]. The proposed method performed well with satisfying results due to the good performance of Japanese parser [9]. Although Myanmar dependency syntax structures were applied competently for SMT [8] and parsing [9] without annotated Myanmar corpus, there was dependence on intermediate language dependency parser like English and Japanese as limitation

Progress of unsupervised dependency parsing researches is increasing with the shared tasks of the tenth conference on computational natural language learning (CoNLL-X) in recent years [10]. A Universal part-of-speech tag (U-POS) set has been proposed as standard for research in unsupervised induction of syntactic structure [11]. Universal Dependencies (UD) is a project developing cross-linguistically consistent treebank annotation for many languages [12]. Currently, there are over 100 treebanks of more than 70 languages available in the UD inventory. Treebanks have derived UD format from existing formats in many languages like Korean [13]. UDPipe has been proposed to easily perform basic natural language processing tasks from tokenization to parsing in CoNLL-U format, the revised version of CoNLL-X format, for treebanks of UD without requiring any other external data [12]. UDPipe has been applied in dependency treebank building [14, 15].

Currently, Asian language treebank (ALT) project has developed a Myanmar syntax treebank with a parallel corpus by annotators using web-based tool [16]. Building treebank needs annotators and applied tools for processes of tree building. Therefore, it becomes hard for low resource language like Myanmar.

Having limitation of related works [8, 9], no resource for dependency parsing and information of Myanmar, improvement of unsupervised parsing researches [10], and simple trainable facility of UDPipe with CoNLL-U format, as our motivation, we annotated a corpus by applying U-POS tags and unsupervised dependency parsing by UDPipe of UD project to get raw syntax information for Myanmar [17]. Then, as future work of unsupervised annotation, manual post processing is carried out on the unsupervised parsed results with reference dependency structures to build dependency treebank in order to apply in parsing Myanmar sentences by deep learning approaches.

This paper presents dependency head annotation to build Myanmar dependency treebank by U-POS tag sets and UD 2.0 guidelines by updating in post processing on unsupervised annotated corpus. Building Myanmar dependency treebank contains two main parts. The first is automatic annotating by unsupervised dependency parsing by UDPipe to get raw universal dependency syntactic information [17]. The second is manual post processing by dependency structures for correct dependency heads. During post processing, UDPipe is applied in a bootstrapping manner to be consistent updating with reduced post processing time..

The organization structure of paper is as follow: Section 2 briefly describes nature of Myanmar language and sentences. Section 3 presents corpus information and overview of annotation scheme. Section 4 describes corpus pre-processing tasks before annotation. Section 5 presents Myanmar language specific tags and their related U-POS tags and mapping scheme between language POS and U-POS tags. Section 6 describes post checking and updating unsupervised dependency heads in sentences with examples. Section 7 reports parsing experiments with post processed data. Section 8 discusses about parsing and evaluation results of treebank. Section 9 concludes all sections and presents future work.

2. Myanmar Language

Myanmar (Burmese) is a member of the Lolo-Burmese grouping of the Sino-Tibetan language belonging to the Southern Burmish branch of the Tibeto-Burman languages. It is an official language in Myanmar. It is also the first language of the Bamar people, the principal ethnic group and related ethnic groups of the country, and a second language of ethnic minorities in Myanmar. Myanmar (Burmese) is a tonal, pitch-register, and syllable-timed language, largely monosyllabic and analytic, with a subject–object–verb word order. It is morphological rich and agglutinative language.

2.1. Nature of Myanmar Sentences

Myanmar sentences can be written with formal or colloquial style. Two types of Myanmar sentence construction are simple and complex sentence types. Simple sentence has only one nominal phrase, action maker or subject, and one verb phrase. Complex sentence has two or more clauses or simple sentences, joined with conjunction, or post positional markers, or particles to modify the followed part which might be phrase or clause of main sentence.

Sentence / (Type)	ကိုယ် တွင် ညို သော်လည်း ၊ မျက်နှာ နှင့် လက် များ မှာ မည်း နေ သည် ။ (Complex sentence)													
Clauses / (Type)	***ကိုယ်***တွင် ***ညို*** သော်လည်း ၊ (Dependent clause)					***မျက်နှာ*** နှင့် ***လက်*** များ မှာ ***မည်း***နေ သည် ။ (Independent root clause)								
Phrases/ (Type)	***ကိုယ်*** တွင် (Noun)		***ညို*** သော်လည်း ၊ **(Adjective)**			***မျက်နှာ*** နှင့် ***လက်*** များ မှာ (Noun)					***မည်း***နေ သည် ။ **(Adjective/Root)**			
Words	***ကိုယ်***	တွင်	***ညို***	သော်လည်း	၊	***မျက်နှာ***	နှင့်	***လက်*** များ		မှာ	***မည်း***	နေ	သည်	။
Morphenes	***ကိုယ်***	တွင်	***ညို***	သော်လည်း	၊	***မျက်နှာ***	နှင့်	***လက်***	များ	မှာ	***မည်း***	နေ	သည်	။
Morpheme translation	body	at	brown	although	,	face	and	leg	-s	-	black	-	-	.
Sentence translation	Although body is brown, face and legs are black .													

Table 1: Suffixes of example sentence from Figure 1

Types	Nominal marker (post positional marker)	Plural marker (particle)	Verb suffix (particle)	Verb marker (post positional marker)
Morpheme Words	“တွင်”,“များ”, “မှာ”	“များ”	“နေ”	“သည်”

Table 2: Composition of Myanmar Dependency Treebank

Corpus Source	Domain	Sentences	Tokens	Average Length	Remark
myPOS	Wikipedia	11,010	239,534	21.75	manually annotated
Web News	Websites’ News	1,800	66,710	37.06	manually annotated
ALT	Wiki news	10,000	373,974	37.39	Automatic annotated
	Total	22,810	680,218		

Myanmar noun phrases are usually ended with different types of nominal markers, postpositional markers (PPMs), to identify their roles in sentences such as subject, object but most colloquial style noun phrases are written without these markers. Myanmar sentences might have one or more phrases or clauses. Some subordinate clauses are usually used to represent more detail meaning for modified parts and also placed before modified ones. Having these nested parts, defining correct dependency between sub and main parts of the sentence takes more time. Figure 1 illustrates an example sentence structure.

There are four phrases in sentence of Figure 1. In Myanmar language, adjective ended with verb maker suffix is verb phrase. In the example sentence, sentence ended verb phrase is composed of adjective with post positional verb marker Four suffix types of morphemes of the example sentence are described in Table 1. Bold and italic words are main content words of each phrase. Main root phrase of a sentence or clause is final verb phrase of that sentence. Dependent sentence or clause modifies the independent root sentence. Therefore, main root of example sentence in Figure 1 is the last right most verb phrase.

Moreover, most formal sentences are usually ended with verb or verb phrase. However, some sentences may not be ended with verbs because of the Myanmar sentence writing style in which there are presence of hiding verbs hidden for actions of being or having or living or coming actions. Moreover, Myanmar sentences can be written by many forms according to nature of free word order language, and some special cases of sentence construction of Myanmar grammar. Moreover, emphasized noun phrases can be put at the beginning of the sentence according to writer’s idea.

These conditions can also be complicated and time-consuming issues to define correct dependency heads and relations for phrases in sentences. Besides above nested cases, there arises one issue in dependency tree building.

3. Corpus Annotation

This section presents corpus statistic and overall architecture of dependency head annotation.

3.1. Corpus Information

Currently two corpora have been annotated manually by dependency head information and one corpus has been annotated in unsupervised way for Myanmar treebank. The myPOS corpus consists of 11,010 sentences written by formal and colloquial format from the Myanmar Wikipedia including various areas such as economics, history, news, politics and philosophy [18]. The sentence writing style of myPOS corpus is very similar to current mostly used standard formal and colloquial style. Therefore, we selected first this corpus to annotate to get similar syntactic structures of current written styles of Myanmar sentences and annotated them as first standard sentences for other corpora. Web News corpus contains 1,800 sentences written by current modern writing styles in Myanmar news websites. ALT corpus contains 10,000 translated sentences from Wiki news. The statistical information of current Myanmar dependency treebank is presented in Table 2.

3.2. Overview Structure of Annotation

Using difference corpora in treebank, word segmentation and POS tagging style of each corpus is different. Being morphological rich and agglutinative language, most words are segmented to provide morphological level syntax information in this work. Therefore, pre-processing is needed to carry out to be the same word segmentation and POS-tagged scheme among different corpora. U-POS tags, CoNLL-U shared task format, shared Japanese model, and UDPipe of UD project were used to get raw universal dependencies in this work.

The corpora were transformed to CoNLL-U format by adding U-POS tags in pre-processing. After transformation, they were annotated by unsupervised dependency parsing by using shared Japanese model in UD project [17] because of similar conditions in grammar structure of Myanmar and Japanese and dependency structures and UD of Japanese [19,20]. Then unsupervised annotated dependency heads were manually post checked by human annotator to be more correct dependency head nodes. One annotator was done manual post checking on automatic annotated results by learning Myanmar language grammar books and books written by linguistic experts of Myanmar language. Therefore, dependency head annotation of Myanmar dependency treebank has two steps: initial corpus pre-processing and post processing on unsupervised annotated results of pre-processing.

In post processing, to be consistent and fast checking and updating, selected updated data were repeatedly trained with all other not updated data in corpus by UDPipe. After checking and updating manually selected 2,000 sentences, they were added to the training data, Then the training model was retrained to parse the remaining sentences in corpus by the updated model. Parsed

results were updated manually and trained again until all sentences were post processed in corpus. The overall architecture of annotation is illustrated in Figure 2. Detail explanation with examples will be presented in Section 4 and Section 6.

4. Pre-processing

This section presents overview of corpus pre-processing step. Before dependency structures annotation, it is needed to check and update word segmentation and POS tagging of used corpora because some corpora might have different segmentation and POS tagging styles based on their original created purposes. Using unique word segmentation and POS tagging can be easy to transform dependency corpus. It is also better and easier having unique word segmentation and POS tagging than different formats to transform dependency corpus.

To have a consistent Myanmar POS tag scheme, a new general POS tag scheme has been defined. It will be explained in following sub section. Moreover, U-POS tags were also added to the CoNLL-U format in order to get raw universal dependencies syntax structures.

In Myanmar sentences, some words might also have different POS tag forms for the same word. Tagging correctly for each content word in sentences is important for correct dependency head. One example of these issues is presented in Table 3. The quality of word segmentation and POS tagging can mainly impact providing correct dependency information of sentences in corpus. Therefore, rechecking word segmentation and POS tagging of used corpus before annotation is very important.

Then, the correct POS tagged corpus was transformed CoNLL-U format by adding related U-POS tags for most language POS tags by manual python script as UD 2.0 format. In adding U-POS tags by python script, it is needed to check again manually U-POS tags of Myanmar conjunctions because it is also needed to be correct form of two conjunction tags of U-POS as described in Table 5 according to the content words of sentence.

5. Part-of-speech Tagging Scheme

There are ten main POS tags in Myanmar language such as noun, pronoun, adjective, verb, adverb, post-positional marker, particles, conjunctions, interjection and punctuation [21]. For easy mapping to U-POS tags, 16 POS tags have been defined for language specific tags which are presented in Table 4 with examples.

Most tags of these were already defined in ALT [6] except proper noun (PRPN) and text number (TNUM). In the previous work of this, these two tags were defined as noun, “N” [17]. In most Myanmar corpora, proper nouns and text numbers are tagged as noun, but they are already defined as proper noun and number in U-POS tag set. Therefore, these two tags were also added in Myanmar language tag set in order to be fast and easy mapping between Myanmar POS tags and U-POS tags.

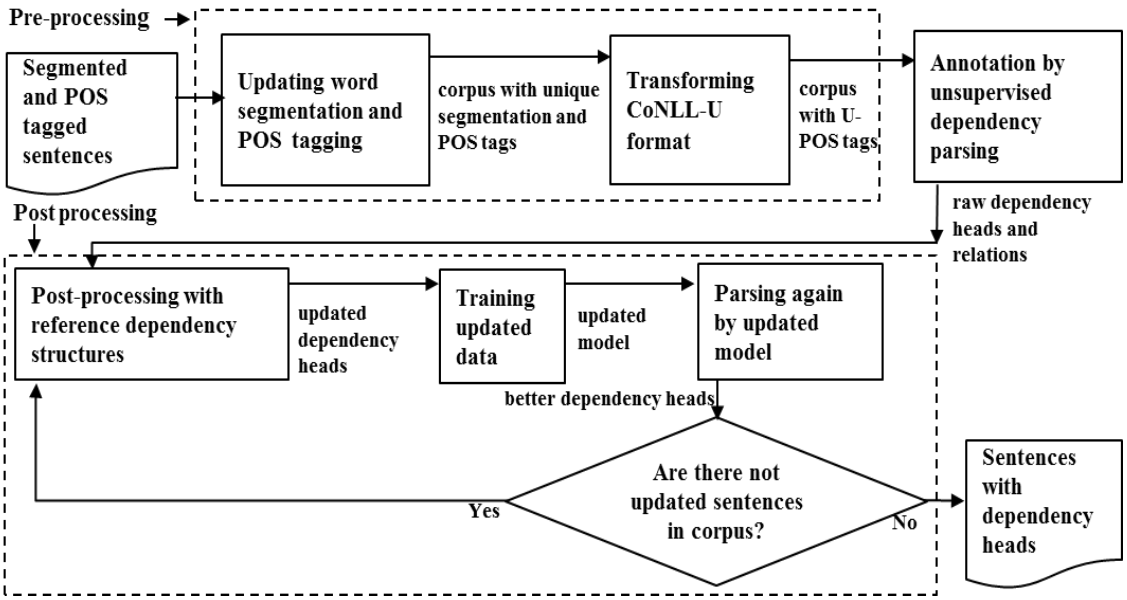

Figure 2: Overview architecture of dependency head annotation

Table 3: Example POS tagging for same word

Words	Correct Tags	Meanings	Examples in phrases
နေ	verb	live	Myanmar : ရန်ကုန် မှာ နေ Words in English: Yangon in live - Translation : Live in Yangon.
နေ	particle	describing continuous action	Myanmar : လေ့လာ နေ သည် Words in English: study - - Translation : is studying

Table 4: Myanmar POS tags for language specific tag set

POS Tag	Description	Example words
N	Noun	သတင်းစာ (Newspaper), ခန်းမ (Hall), ကုမ္ပဏီ (Company)
PRPN	Proper Noun	စက်တင်ဘာ (September), အာရှ (Asia)
NUM	Number	ဝ (0), ၁(1), ၂(2), ၃(3), ၄(4)
TNUM	Number text letter	သုည (zero) , တစ် (one) , နှစ် (two), သုံး (three), လေး(four)
FOR	Foreign word	Carsh, Federal, process, Bit
ABB	Abbreviation	ညွှန်/ချုပ် (Director-General)
PRON	Pronoun	ကျွန်တော်/ ကျွန်မ/ ကျွန်ုပ် (I), ထို (that), မည်သူ (who)
ADJ	Adjective	ကျယ်ဝန်း (wide), ယဉ်ကျေး (polite), မြင့်မား (high), လေးလံ (heavy)
ADV	Adverb	မကြာခဏ (frequently), အလွန် (very), လောလောဆယ် (currently)
V	Verb	စား (eat), သွား (go), ရေးသား (write), ဖြစ် (be), ရှိ (has/have), တည်ရှိ (exist)
CONJ	Conjunction	နှင့် (and), သို့မဟုတ် (or), ၍/သောကြောင့် (because)
PART	Particle	များ/တို့/တွေ (plural marker), ခန့် (about), ခဲ့ (past marker), နိုင်(can), ကြ (plural action marker)
PPM	Post positional marker	သည်/က/မှာ (nominal marker for subject), ၌ (at) , ၏ (of) , ဖြင့် (by)
PUNC	Punctuation	၊ , ။ , “ , (or -LRB-,) or -RRB- , “, ”
SB	Symbol	% , $
INT	Interjection	အိုး (Oh), အမလေး (Oh my god!)

Table 5: Mapping scheme between Universal POS and Myanmar language specific POS tags

U-POS Tag	Description [Examples]	Myanmar Language POS
NOUN	Noun	N
		FOR
PROPN	Proper Noun	PRPN
		ABB
NUM	Number	NUM
		TNUM
PRON	Pronoun	PRON
ADJ	Adjective	ADJ
ADV	Adverb	ADV
VERB	Verb	V
CCONJ	Coordinating Conjunction [နှင့် (and), သို့မဟုတ် (or)]	CONJ
SCONJ	Subordinating Conjunction [၍/ သောကြောင့် (because), နှင့်တစ်ပြိုင်နက် (as soon as), ပါက (if)]	
PART	Particle	PART
ADP	Adposition	PPM
PUNCT	Punctuation	PUNCT
SYM	Symbol	SB
INTJ	Interjection	INT

Table 6: Mapping scheme between Universal POS and Myanmar language specific POS tags

U-POS Tag	Description	myPOS	ALT	Web News	Total
NOUN	Noun	55,590	71,246	18,237	145,073
PRON	Pronoun	2,680	7,864	331	10,875

SYM	Symbol	199	116	3	318
INTJ	Interjection	98	0	0	98

All conjunctions in Myanmar sentences were tagged as CONJ which were mapped to one of two conjunctions of U-POS tags: CCONJ and SCONJ, coordinating and subordinating conjunction respectively. Mapping scheme between U-POS tags and Myanmar POS tags can be seen in Table 5. Total frequencies of U-POS tags in each corpus of treebank are listed in Table 6.

6. Post-processing

Annotation method and types of annotation schemes are important in dependency treebank construction. The annotation was based on Universal Dependencies. In the UD annotation scheme, dependency relations are expressed between words and main content words attached leaf words such as function words in sentences [22]. Main parts of syntactic structures are head nodes and relation links called as dependency relation labels between words.

Generally Myanmar nouns, adjectives, and verbs are formally written with suffixes such as post positional markers or particles. Currently, dependency relation labels are automatic unsupervised annotated results without post processing in treebank. Only dependency head information was post processed.

Overview of the linking structures of dependency head node words between dependent words in most occurred phrases in sentences had been presented in our previous work [17]. In that work, only construction of dependency link arc connections between heads and dependents words had been presented. Therefore, the arcs directed to the heads from dependents.

After the previous work, unsupervised dependency annotation results have been post processed to update dependency head links based on the dependency structures described in our previous work. Updating dependency relation labels needs more time because of few annotators and issues of sentence writing styles. Therefore, dependency relations labels are still automatic unsupervised annotated labels after post processing. To describe full referenced dependency information, in this paper, dependency relation labels between head node words and dependent words will be presented with unsupervised annotated labels in sample sentences according to the viewpoint of the language typology.

6.1. Proper Noun and Possessive Phrase

The specific unique names of common nouns are called as proper nouns as in other languages. Myanmar proper nouns are usually found in before or after common nouns [21]. In Figure 3, two proper nouns, following two common nouns can be seen in example sentence. In that sentence, example possessive case can also be seen. Possessive case of a noun or pronoun can be written by a post positional suffix marker, “ ၏”, to show possession of following right noun by left proper noun of it.

6.2. Compound Noun

Myanmar compound nouns might have two or more words and POS tags of these words can be nouns, verbs, adjectives or adverbs [21]. An example compound noun in sentence of Figure 4 contains two consecutive nouns and means “memorial stamp”. In this case, the left noun modifies the right one.

6.3. Numeral Phrase

Most numeral noun phrases can be written by three general formats which are described in Table 7 with their meanings. Counting amount can be written by digit number or text number [21]. Sample numeral phrases in sentence can be seen in Figure 5.

6.4. Adjective Phrase

Adjectives modify nouns and are usually placed before or after noun in Myanmar sentences. Myanmar adjectives can be written as simple or simple adjective with suffix particles or transformed adjective [21]. Suffixes of adjective or example adjective phrases are presented in Table 8. Sample dependency of adjective phrase in sentence can be seen in Figure 6.

6.5. Adverb Phrase and Verb Phrase

Adverbs can be written as simple or transformed adverb with the suffix particle, “ စွာ”, followed by verb, or adjective, or adverb.

Example adverb phrases can be seen in Table 9. Example dependency of adverb phrase in sentence can be seen in Figure 7.

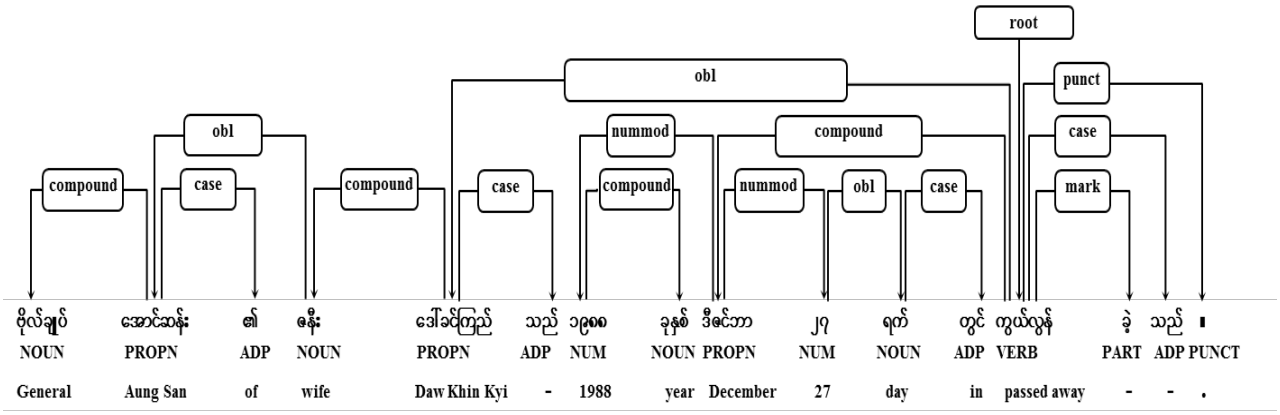

Figure 3: Proper noun and possessive case examples in sentence

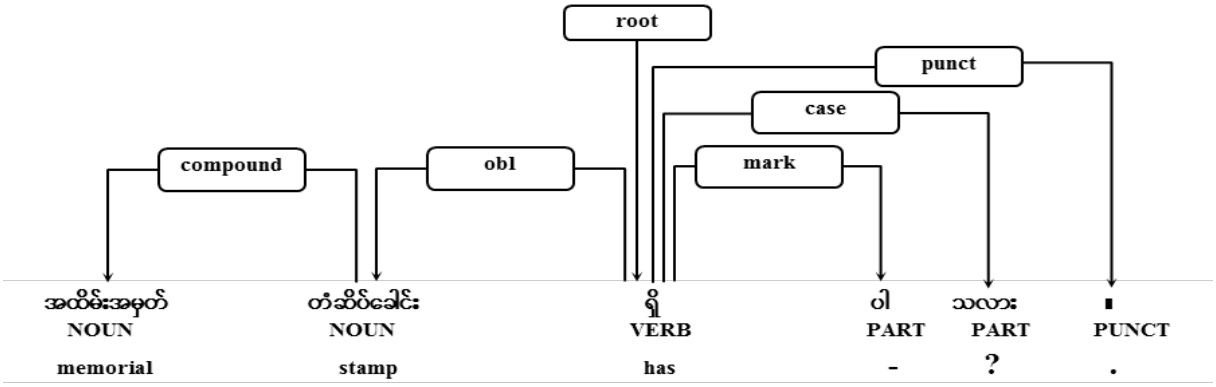

Figure 4: Compound noun example in sentence

Table 7: Numeral phrase formats

Numeral Phrase Forms	Example	Meaning	Remarks
N NUM/TNUM PART/N	မှတ်ချက် ၂/နှစ် ချက် comment 2/two - (Glossary)	2/two comments	
N N (noun affixed particle, "အ", to form common nouns) NUM/TNUM	မှတ်ချက် အချက် နှစ်ဆယ် comment fact twenty (Glossary)	twenty comments	if counted amount is exact numbers of multiple of ten, hundred, thousand, etc.
N N(transformed or common noun) NUM/TNUM PART/N	မှတ်ချက် အချက် နှစ်ဆယ် comment fact twenty two - (Glossary)	twenty two comments	

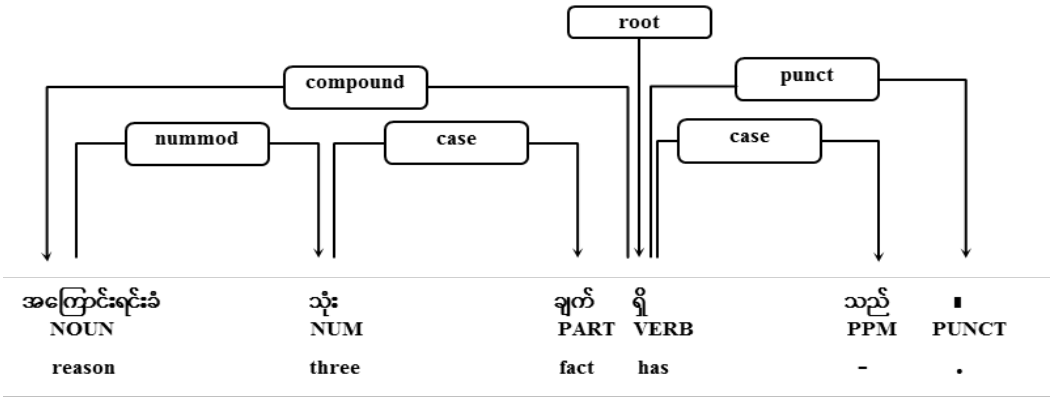

Figure 5: Numeral phrase example in sentence

Table 8: Suffixes of adjective or adjective phrases and examples

Particles used to suffix or transform adjective or adjective phrase		သော, သည့်, မည့်, တဲ့
Example Myanmar adjective	***Translations***	***Remarks***
ကြီး သော အိမ် **big** - house	big house	Simple adjective followed suffix
အိမ် **ကြီး** house **big**	big house	Simple adjective
အစိုးရ ပေး သည့် အိမ် government provide - house	house provided by government	Transformed adjective

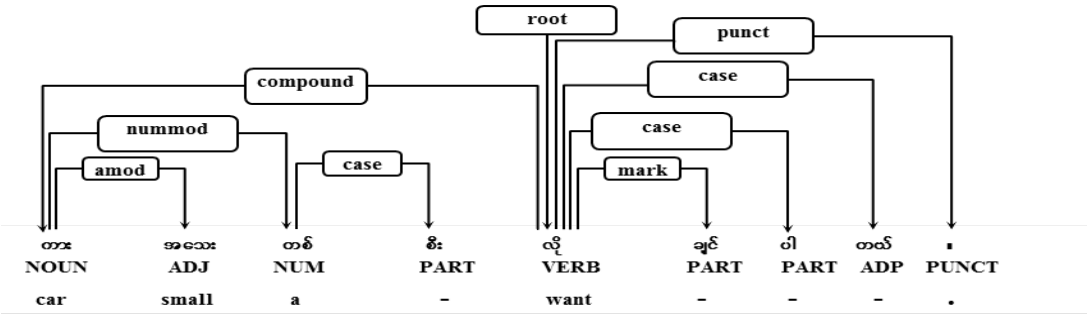

Figure 6: Adjective phrase example in sentence

Table 9: Example of adverb forms

Example Myanmar adverb phrases	**Meanings**	**Remarks**
မြန်မြန်(quickly)	quickly	Simple adverb
မြန်မြန်သွက်သွက် (quickly)	quickly	Simple adverb
လျင်မြန် စွာ quick -	quickly	Transformed adverb with suffix particle

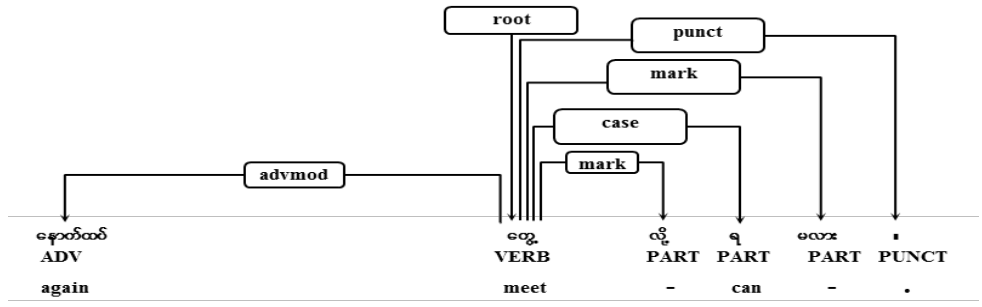

Figure 7: Adverb and verb phrase example in sentence

Table 10: Suffixes of verbs

Suffixes to verb	**Description of usage and example**	**Suffix Type**
သည်, ၏, ပြီ, မည်, မယ်, တယ်	to form verb by showing tense Examples: သွား သည် (go) သွား မယ် (will go)	post positional markers
မှာ, ပါ, စမ်း	to express giving order or answering action Examples: လုပ် ပါ (giving order or requesting “Do” action) မောင်း မှာ (answering or forecasting “drive” action based on the meaning of content words in sentence)	particles

Verb phrases in sentences are usually formed by one of the verb ended post positional markers or particles [21] as presented in Table 10 .

In addition, zero or more particles can be followed by verbs before verb ended markers to express the full state of action. In example sentence of Figure 7, the verb phrase, " တွေ့လို့ရမလား", means "can meet" and "တွေ့" is main verb and the suffix sequence with three particles, "လို့ ရ မလား", means asking politely for the requested action. That main verb phrase is also modified by left adverb phrase, " နောက်ထပ်". As a result, the verb, "တွေ့", is root of that sentence. The whole sentence means "Can meet again?",

6.6. Conjunctions

In Myanmar language, conjunctions are used to combine not only clauses or simple sentences but also related words or phrases. Moreover, simple sentences can be connected by suffixes: post positional markers, " က, မှာ, ကို", or particles "ဟု , သော , သည့် , မည့်, တဲ့" to form noun or adjective clause in sentence. If two or more simple sentences are connected by post positional markers or particles or conjunctions, combined sentence becomes complex sentence and clauses represent the roles as subjects or objects or adverbs. Most clauses ended by conjunctions are usually adverb modifiers in main sentence. Therefore, the role of dependent clauses can be divided into three types: noun clause, adjective clause, and adverb clause based on their roles in sentences. If combined clauses or sentences contains the same subject, subject can be omitted in dependent clause or independent clause or in both. Similarly, object noun can also be omitted in dependent clause or independent clause if it is placed in one [21, 23].

Some conjunctions described in Table 11 are used to connect words, phrases to connect two sentences to give coordinated extra meaning [21, 23].

Table 11: Example conjunctions

Conjunctions	**Usage**
နှင့် , လည်းကောင်း…လည်းကောင်း, ရော…ပါ, ရော… ရော, သို့မဟုတ်, ဖြစ်စေ…ဖြစ်စေ, ဖြစ်ဖြစ်…ဖြစ်ဖြစ်, သော်လည်းကောင်း…သော်လည်းကောင်း, မှတစ်ပါး, ပြီး	to connect words, phrases in sentence for extra meaning
ထို့ပြင်, ထို့အပြင်, ၎င်းပြင်, သည့်ပြင်	to give connection between prior sentence and next by giving coordinated extra meaning.

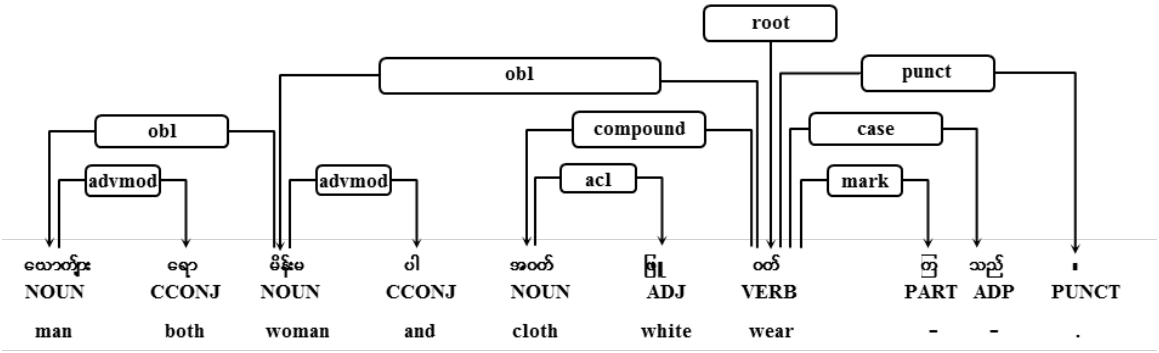

Figure 8: Coordinated phrase example in sentence

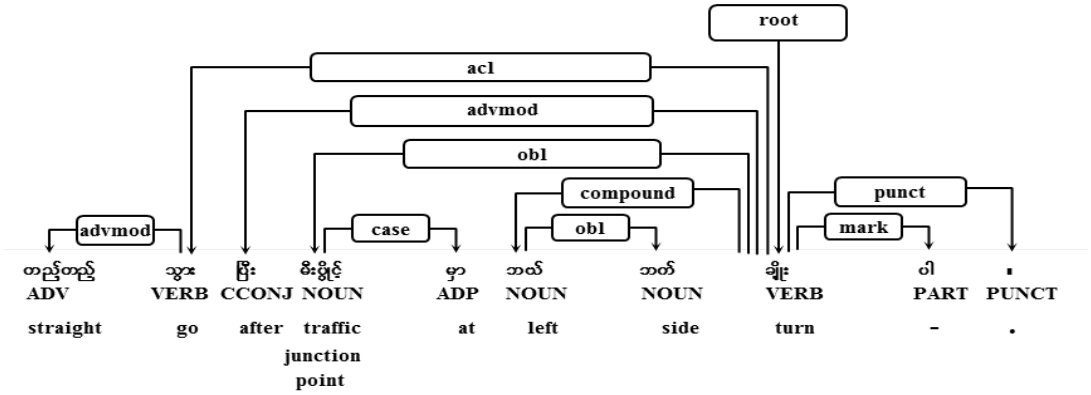

Figure 9: Coordinated clauses example in sentence

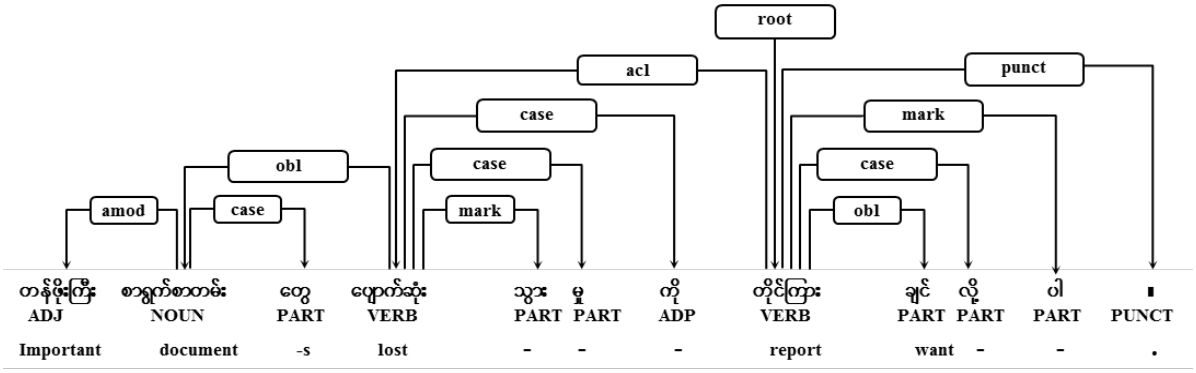

Figure 10: Complex sentence with noun clause

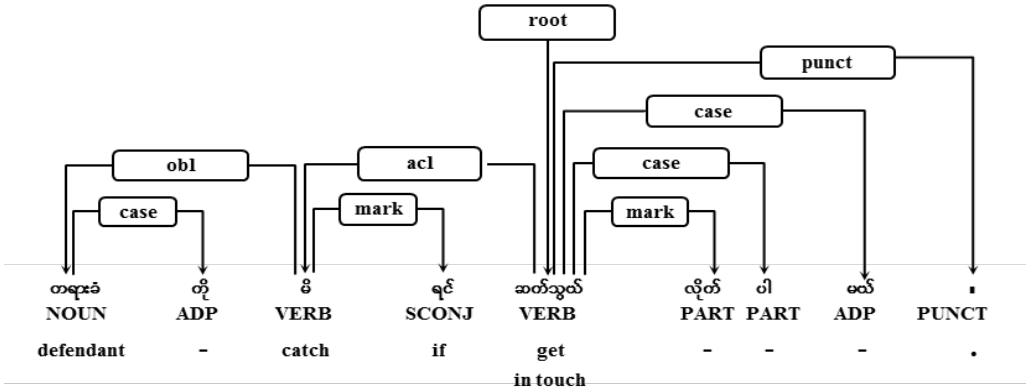

Figure 11: Complex sentence joined with subordinating conjunction

Table 12: Average parsing precision scores of each corpus

Corpus	Sentences		Average Scores	
	Train	Test	UAS	LAS
myPOS	10,010	1,000	89.06	86.67
Web News	1,620	180	87.03	84.83
ALT	9,000	1,000	91.40	90.24

Sample coordinated phrase with conjunctions in sentence can be seen in Figure 8. Moreover, complex sentence combined two simple sentences by coordinating conjunction can also be seen in Figure 9. The left side of conjunction is dependent sentence or clause to give first action and the right side of conjunction is independent clause to give final action as shown in Figure 9. Subjects of clauses are omitted and main sentence means "After go straight, turn left at the traffic junction point.". Therefore, the conjunction is tagged as "CCONJ", coordinating conjunction, for U-POS tag.

Some Myanmar conjunctions such as "လျှင်/ရင်/ပါက, သောကြောင့်, နှင့်တစ်ပြိုင်နက်, သကဲ့သို့, စေရန်, သောအခါ, သော်လည်း,.." , "if, because, as soon as, as/like, in order to, when, although,.." , are frequently used to connect clauses to provide the required meaning for main clauses [21, 23]. Therefore, these types of conjunctions are tagged as "SCONJ", subordinating conjunction, for U-POS tag.

Example complex sentence including noun clause as an object role in sentence can be seen in Figure 10. Main complex sentence means "Lost of important documents is wanted to be reported." The PPM, " ကို", is used to connect the left clause to represent as object noun for the action of root verb, "တိုင်ကြား", of main sentence.

In addition, example complex sentence joined with subordinating conjunction type, " ရင်" (if) , can be seen in Figure 11. Subjects are omitted in both dependent clause and main independent clause. It means that "If defendant is caught, I will get in touch".

7. Parsing Experiment

The main purpose of building treebank is to use in dependency parsing. This section presents parsing experiments executed for performance of treebank. UDPipe is an open-source trainable pipeline processing tool to perform segmentation, POS tagging, lemmatization and dependency parsing without any other external

data for multiple languages. And it is also available under open-source Mozilla Public Licence (MPL) and provides bindings for C++, Python, Perl, Java and C#. UDPipe 1.2 has been used in our parsing experiments.

We divided 90% and 10% of total sentences from each corpus of treebank for training and test data to evaluate each corpus by 10-fold cross validation test. We arranged alternate order of test sentences range and all the rest for train data in each corpus and split them into equally-sized parts for each validation test by python script. We calculated average score of all validation tests to report as total average score of cross validation test for each corpus.

8. Results and Evaluation

In this section, the statistical results of parsing experiments to evaluate parsing performance of treebank and evaluation results will be described. For each corpus performance of treebank, average parsing precision scores are calculated from the total results of cross validation tests in each corpus and they are listed in Table 12. Average precision scores measured by unlabeled attachment score (UAS) and label attachment score (LAS) of each corpus are over 89% and 86%, over 87% and 84 %, and 91% and 90% in myPOS, Web News, and ALT respectively .

Each corpus of treebank was evaluated by the CoNLL 2017 UD parsing evaluation script. The evaluation results will be described in following sub section. In addition, syntax structures of the referenced dependency types were also analyzed by manual python script which counts types of dependency structures being countable types in each sentence. The analyzed results will be described in next sub sections.

8.1. Evaluation

Corpora contained in treebank were evaluated by the CoNLL 2017 UD parsing evaluation script, "conll17_ud_eval.py" [24], to know their parsing accuracy. Gold standard file and system output file are input to the evaluation script to evaluate the data. The parsing model was trained with all current data of treebank to generate system output of each corpus. The current accuracies comparing standard annotated data with system output parsing result of each corpus can be seen in Figure 12.

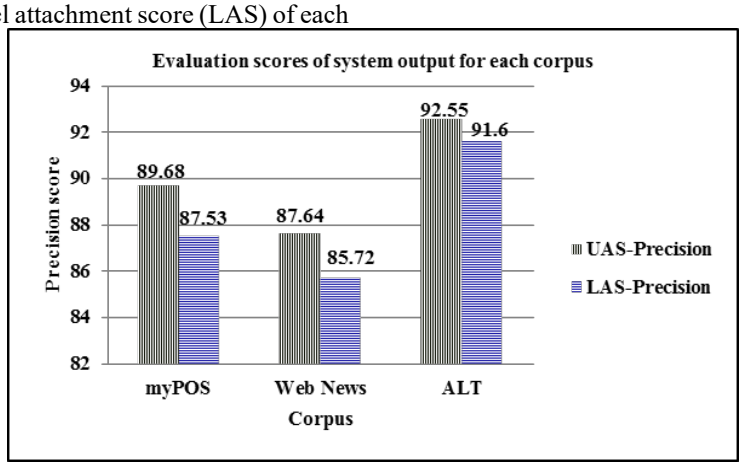

Figure 12: Precision scores of treebank data

Table 13: Information of sentence lengths in treebank

Sentence Type	myPOS	ALT	Web News	Total sentences of each range	Remark
Simple short	2,253	13	74	2,340	<=10 words
Short	6,463	3,858	732	11,053	>=11 and <=30 words
Normal range	1,929	4,398	568	6,895	>=31 and <=50 words
Long	349	1,687	401	2,437	>=51 and <=100 words
Very long	16	44	25	85	>100 words

Table 14: Phrases and clauses structures in treebank

Phrase Types	myPOS	ALT	Web News	Total
Noun	27,083	48,466	6,316	81,865
Proper Noun	10,514	17,750	3,013	31,277
Numeral Noun	5,790	10,852	2,125	18,767
Compound Noun	21,096	25,706	9,537	56,339
Adjective	9,535	11,993	1,581	23,109
Adverb	3,027	4,580	837	8,444
Verb	16,593	19,136	3,584	39,313
Phrases with Conjunctions	2,830	3,534	921	7,285
Clauses	7,027	9,837	1,950	18,814

Precision scores of UAS and LAS in system outputs of myPOS and Web News data are over 89% and 87%, and 87% and 85% respectively in comparing manually updated standard data. System output precision scores of UAS and LAS for ALT data is over 92% and 91% in comparing with automatic unsupervised annotated standard data.

As sentences of ALT corpus are longer than myPOS and Web News corpus, precision scores of unsupervised annotated ALT is more than manual updated standard data of myPOS and Web News corpus. However, system outputs of myPOS and Web News corpus are better and more similar to reference dependency structures than system outputs of ALT in manual random checking on system output trees.

Although currently Myanmar ALT has been developed manually, there is still no dependency resource for Myanmar. Constructing treebank manually is an error-prone and slow process. The high precision scores of cross validation tests and evaluations by post processed model illustrate that the proposed method can produce efficient precision scores for dependency parsing. With consistent and faster annotation, the proposed method will provide fast dependency tree building for Myanmar which has free word order and issues mentioned in Section 2

The length of sentences is also one main part of treebank characteristics for having various types of syntax and syntactic structures. Therefore, the ranges of sentences in treebank were also analyzed by classifying five levels by python script and resulted sentence ranges are listed in Table 13.

8.2. Syntax Analysis

The syntax information is one of the most important characteristics of treebank to know syntax status. It is difficult to count all syntax information of natural language sentences by program script exactly because of the issues of phrases and many sentence construction types discussed in Section 2. However, overview syntax structures of formal sentences from each corpus of treebank could be extracted by python script based on sequence order of words and POS tags information of phrases and clauses written by formal literature written style. The program counts the related phrase and clause types from word and POS tag sequences of sentences annotated as example dependency structure types described in Section 6. However, some informal phrases and clauses not ended with the formal related post positional markers or particles, could not be counted by the program. Overall countable syntax structures are listed in Table 14.

9. Conclusion

This paper has presented annotating dependency heads based on Universal Dependencies framework for Myanmar dependency treebank. Myanmar POS tags and U-POS tags of treebank, issues of tagging, and mapping scheme between two tag sets have also been presented. In addition, dependency head annotation schemes have also been described with sample sentences in line with grammatical point of views. This work is first for Myanmar to the best of our knowledge. Parsing experiments have also been executed for performance of treebank and results have also been presented. To conclude, contribution is first dependency head annotation for building Myanmar dependency treebank and can provide useful information for direct dependency parsing for Myanmar sentences by Myanmar model in future.

As future work, firstly we would intend to add more annotated sentences from same and different domains such as News articles data and Myanmar grammar books data to treebank because correct syntactic forms are able to provide faster annotation and better useful syntax information for Myanmar dependency treebank. The next work is to update unsupervised dependency labels according to the standard of Universal Dependencies based on Myanmar grammatical point of views.

ABSTRACT

Reconfigurable systems are considered as promising technology that enables the design of more flexible and dynamic applications. However, actually existent design flows are either low-level (so complex) or they lack support for automatic synthesis. In this paper, we present an ontology-based modeling approach for reconfigurable systems. Our approach is based on model-driven engineering process and addresses dynamic features on application-level enabling early exploration of the execution behavior of the system. The model is characterized by a logical and syntactical description conform with application domain knowledge and respect a number of metamodel constraints. These elements are semantically presented by an ontology language. We successfully implemented a system model with several tasks and resources and made scheduling test for the application graph.

1. Introduction

The system designers have been relying two choices for computing system implementing, varying largely in terms of performance and flexibility [1]. One is considered for the general-purpose systems built to accommodate flexibility problem. The compromise, in this case, is the system performance because of the absence of hardware resources dedicated for specific application. The second is carried out to develop an optimized hardware circuit dedicated and adapted to meet the demands of a specific application. Such system will be at issue following a minor need for change, because a costly redesign will be carried out in order to adapt new system parameters.

The present work introduces a new paradigm based on configurable computing that can solve performance problems as well as flexibility problems, and hardware design. We offer the performance of dedicated circuits by changing hardware configurations. The reprogram ability of the computing hardware explains that new architecture needs to emulate different computer architectures [2]. Mapping software operation is facilitated with getting the ability to reconfigure its connections. A number of manufacturers introduce FPGAs characterized by partial and dynamic reconfiguration abilities [3]. When a part of FPGA logic resources and interconnections is reconfigured while the remainder device continues operating, the partially reconfigurable FPGA is. Dynamic reconfiguration deals with logic and interconnections reconfiguration in FPGA from an application to the next, that is what we call dynamic reconfiguration or run-time reconfiguration (RTR) [4]. In such situation, without adding external physical (hardware) resources, in a static or dynamic state at run time, when the system can change/adapt its basic computational structure to suit the changing requirements of a program, this is referred to as a Configurable Computing System (CCS) [5]. Our current CCS realizations has a general-purpose microprocessor augmented set with an FPGA. Using reconfigurable logic as a resource shared by multiple applications, a hardware operating system (HwOS) facilitates system setting operations to overcome the problems due to real time considerations. Real time multi-task systems' requirement is tasks scheduling to complete their execution depending on their deadlines [6]. Tasks known periodic in advance are scheduled off-line. Instead, irregular and unknown tasks in advance are scheduled on-line. That makes specific constraints concerning computing resource recovery, preemption and interruption time, tasks' migration between different executing resources, limited memory and power use, hardware costs, etc. [7]. To overcome such complexities, high-level development techniques are required. That researching methods dealing with modeling and simulation of complex and heterogeneous systems are called model driven engineering approaches.

Model-Driven Engineering (MDE) methods tackle with the specific constraints of a specific domain and execute model checking that may identify many errors and limit failure risks at an early period of the system's life cycle [8]. In this context, the present paper focuses on the use of an ontology model [9] in order to describe the dynamic behaviors of the components of a system within the schedulability analysis and verification context [10].

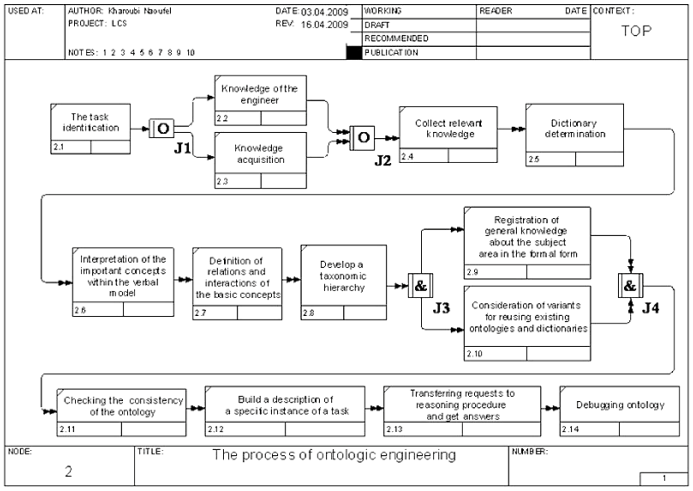

Figure 1: Process of Ontology Engineering

The proposed ontology is based on component behavior representation (Figure 1). Motivation behind our proposal is:

- System abstraction at a high level expressed in an ontology language enabling a prior evaluation and analysis of the impacts of possible online changes and reconfigurations.
- As a consequence of different multiple tools use, probable incoherencies may appear between design model and safety (normal) model.
- For architectural design, there is a heterogeneity in textual description, semantic representations, and syntax of the existing modeling languages.
- The need of reusable knowledge repository.
- Generating a safe executing model to be implemented.

For safety assessment, we elaborate, an ontology-based model description [11], [12]. We have several error behavior items that are stored in the ontology. Such reusable elements are a result of nominal models mixed with failure modes: each object is executable design system specification components under nominal behavior models. We transformed into formal safety models the obtained extended system models. A series of constraints (such as temporal and precedence constraints) are then added to the model in order to make it eligible to be analyzed and simulated by different tools, and so be reliable to making right decisions. All constraints are mapped onto an OWL domain ontology [13] written with the Protégé editor (Figure 2) [14]. Incorporated OWL description checked, the inference rules logic reasoned, and the ontology are able to detect mainly semantically inconsistent parts [15] as well as lack of model elements.

All errors interpreting cost are avoided: these errors encountered in the extended system model formal representation, are hardly to conceive. During the work, proposed architecture design is formulated in the Architecture Analysis and Design Language (AADL) [16], [17]. As a result, precise execution semantics are expressed for modeling software systems and their target hardware architecture. Safety models are generated in the AltaRica formal language [18]. We have opted for AADL and AltaRica languages, but we might as well have opted for other similar formalisms. The AADL language is adapted to describe functional and software architectures of embedded systems. The AltaRica language is an event-centric formal language suited for safety functioning modeling. Its translation is implemented in the form of model transformation. It would also have been possible to use other software such as ATL for example. There are series of analysis tools processed this language [19]-[21]. The proposed approach can be applied to validation contexts.

This work takes advantage of all previously cited domains: it is related to the scheduling problem in reconfigurable systems with a high degree of dynamicity. To overcome such complexity, we propose to work at a high abstraction level using an MDE approach combined with ontology description. The considered ontology language is OWL which gives a formal description of the database and the knowledge base and a semantic hierarchy of the whole system domain. In addition, after implementing the application constraints as rules, the ontology reasoning engine enhances the knowledge/data bases with new inferred axioms and data. All this is in order to have a perfect scheduling decision that takes into account all parameters/conditions and is flexible and dynamic according to the rule changes that may take place.

Related works are reviewed in Section 2. The domain ontology and the model-driven engineering process is presented in the Section 3. Section 4 is for the model transformation process and in the Section 5 we deal with the experimental case study. Then we conclude with a summary of the proposed process and we comment on its potential impact.

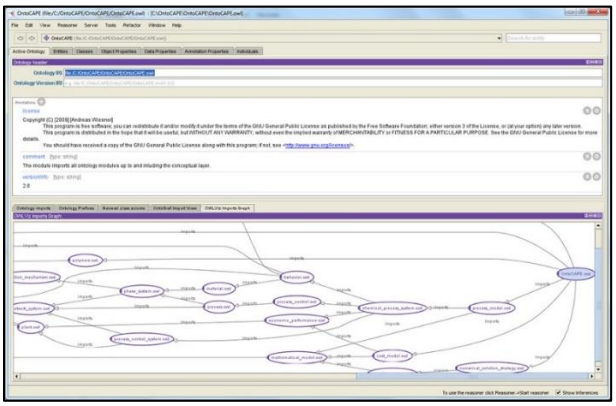

Figure 2: Protégé Framework Interface

2. Related Works

Reconfigurable embedded systems are very complex and include different Hw/Sw components. This led researchers to address new high-level design approaches to abstract that complexity, to facilitate development and to give more degree of flexibility when making changes and fixing errors. In this way, most research works on two principle modeling approaches: Architecture Analysis & Design Language and MARTE

(Modeling and Analysis of Real-Time Embedded systems) [22]. Those two methods consider only predefined reconfiguration models, so they cannot respond to the dynamicity of reconfigurable systems. MDE methods cope with that and permit to transform the model to another model until reaching a target one which responds better to a specific architecture and application domain. Moreover, the ontology is considered as a language that gives a formal description of a variety of knowledge (e.g. properties, features, relations) and different components (e.g. data, entities) forming a specific domain. Ontology languages are used in many domains, such as system engineering, semantic web application, logistics, artificial intelligence, system architecture, etc. It combines different techniques (e.g. semantic search, model matching) and formulates rules in order to tackle with systems complexity and domain conflicts. In [23] authors focus on e-health applications and propose a description for the whole software based on model-driven-architecture (MDA) approach. They exploit all steps of that approach, but especially the first stage called Computation-Independent-Model, with the integration of domain ontologies to represent particular information and all structures and relations existing in the system. In [24] authors apply the MDE approach on semantic web applications and provide an output model that generates annotated user interfaces and reduces some repetitive processes that may occur on the web pages.

To our knowledge, works related to model transformation based on an ontology language are not abundant. The main work related to that subject is [25]. Even in that paper, the purpose was to enhance cross-organizational modelling by adopting automatic generation then evolution of transformed model, a concern which is out of the scope of this paper. Two works on AADL transformation to AADL Altarica were made [26]: firstly, a model transformation [27], [28] based on system hardware architecture from the AADL and selected model reused from a project to another. Secondly, transformations were enriched with failure propagations written in AADL Error [29] and derived from AADL code. Transformation operation can be done if analysis and component relationships are defined. The important difference of our ontology-based model can be resumed in the semantic connection between the AADL and Altarica languages which permits to overcome the difference between them in term of syntax and scope [30], [31].

The focus of this work is to transform traditional representations of reconfigurable systems and make them more significant and related to their application domain. This led us to implement MDE approach combining the ontology languages (describing domain constraints in semantic rules) and applied them to solve scheduling problem.

3. Ontology Domain and the Model-Driven Approach

We propose an engineering process to model a dynamic application mapped on configurable computing system. The process is based on (1) modelisation of the application to be created, (2) analysis and verification of the rules relating different models, and (3) test of the schedulability of the application from the resulting model. We assume that a CCS is computer-based system consisting of hardware and software components, integrated in a physical environment, and requiring different timing/ressource requirements on the final outcome.

3.1. Application Modeling Approach

We aim in this work to exploit domain knowledge in design models. We want to formalize the system domain design, its annotations and its knowledge in a single model. To do this, we followed a four-step approach (shown in Figure 3):

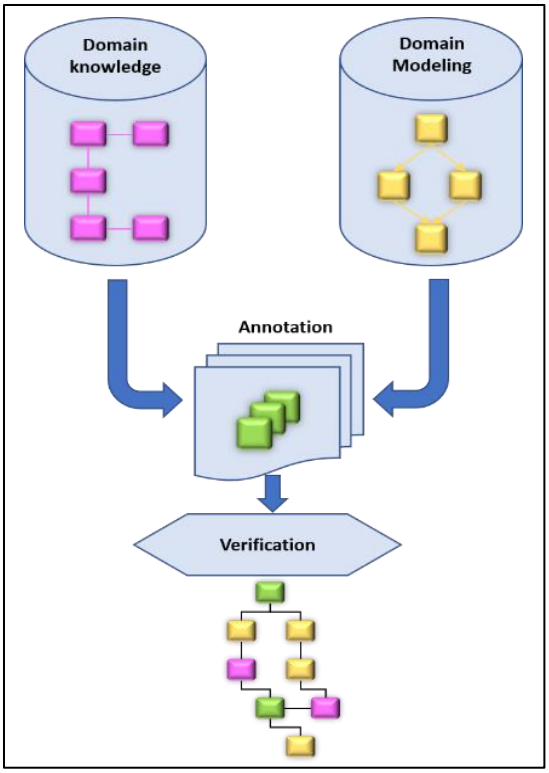

Figure 3: Proposed Application Modeling Approach

- The first step is to formalize and explicitly define the information (knowledge) of the domain of application in a formal ontology (entities, relationships, constraints, etc.). The properties of the ontology thus designed are domain-linked and completely independent of any context of use. In many cases, this ontology can be constructed from pre-existing standard ontologies.
- The second phase concerns the definition of design models. This means the formal definition of the properties corresponding to a given specification of the application domain.
- The third step, called annotation, is to define specific relationships between the different entities of the two previous models (design and ontology). Different relationships are available, they have their specific properties and describe specific rules related to the application domain.
- A verification step is required in any approach. This consists of validating the context of design models and domain properties expressed in the ontology, as well as the logic of the rules defined in the annotation step.

At the end, the final designed model has the advantage of well describing the domain knowledge with more details and properties derived from the ontology and rules generated during the annotation.

3.2. Scheduling Model

As mentioned above, we consider highly dynamic applications with soft real-time constraints. With such applications, missing a deadline does not cause catastrophic consequences, but only a performance degradation (quality of service parameter). In order to schedule these applications, we need a description that exhibits dependencies between the tasks and their own characteristics.

Each task is defined as a class in the ontology model. It represents a computational activity that needs to be performed according to a set of constraints (called slots in the ontology model). Each task i, for $i = \{1, 2, \ldots, k\}$ is defined by:

- ξ represents a set of active tasks T_i forming the application. Considered tasks could be sporadic and aperiodic.
- a_i : stand for the arrival time of task T_i.
- C_i : stand for the maximum computation (execution) time of task T_i.
- c_i : stand for the computation time of task T_i, i.e., the remaining worst case execution time WCET is needed for a computing elements (processor or logic circuit), at the current time, to complete the execution of task T_i without interruption.
- d_i : stand for the absolute deadline of task T_i.
- D_i : stand for the relative deadline of task T_i.
- S_i : stand for the first start time of task T_i.
- s_i : stand for the last start time of task T_i.
- f_i : stand for the estimated finishing time of task T_i.
- L_i : stand for the laxity of task T_i.
- R_i : stand for the remaining time of task T_i.

Baruah *et al.* [32] present a necessary and sufficient test for synchronous tasks with pseudo-polynomial complexity. For that reason, we present the following equations defining relations among the parameters defined above:

$$d_i = a_i + D_i \tag{1}$$

$$L_i = d_i - a_i - C_i \tag{2}$$

$$R_i = d_i - f_i \tag{3}$$

$$f_1 = t + c_1;\ f_i = f_{i-1} + c_i \ \forall\, i > 1 \tag{4}$$

$$R_1 = d_1 - t - c_1 \tag{5}$$

$$R_i = R_{i-1} + (d_i - d_{i-1}) - c_i \tag{6}$$

For any other task T_i, with $i > 1$,

$$f_i = f_{i-1} + c_i \tag{7}$$

and, by equation (3), we have:

$$R_i = d_i - f_i = d_i - f_{i-1} - c_i = d_i - (d_{i-1} - R_{i-1}) - c_i = R_{i-1} + (d_i - d_{i-1}) - c_i \tag{8}$$

The information above present the major inputs of the task class ontology. In our model, we define the scheduling ontology basic classes as follows:

- Basic scheduling elements (including tasks, resources and activities) and relation between them.
- Basic required components and constraints (including hard/soft constraints, temporal restrictions and resource limitations).
- Ontology of instances: each class has one or more related subclasses.

The Protégé editor provides the definitions for basic object types and properties such as application graph (Figure 4), tasks set properties (Figure 5), relations, numbers, etc. Figure 6 shows the data properties of a created task refereed to its temporal features in the ontology framework. Figure 7 is related to processor creation, where processor is either a software processor or a CLB for hardware task. Figure 8 represents slots where defined the properties of a task, their status and needed executing resources.

We mean by resources all hardware components that are responsible for the execution of tasks. Resources could be a processor (for software tasks) or a discrete number of logic circuit called CLB (configurable logic blocks) for hardware tasks in an FPGA architecture. Resources are defined in separate classes and are characterized by their execution time and/or number of CLB.

Rules and constraints are modelled as distinctive class. The class constraint has the same definition for both hard and soft constraints, and is applied to tasks or resources. The hard constraints are the rules that cannot be violated under any conditions, while the soft ones have to be satisfied by the completion time of the scheduler. For example, if we consider the temporal constraints in the EDF (Earliest Deadline First) scheduler [33], the semantic rule would be:

$$\begin{aligned} &\text{Task}\,(?T_i) \wedge \text{has_D}_i\,(?T_i, ?d_i) \\ &\rightarrow \text{sqwrl:select}\,(?T_i) \wedge \text{sqwrl:orderBy}\,(?d_i)\,, \end{aligned} \tag{9}$$

as EDF is a preemptive algorithm which assigns the highest priority to be executed to the task T_i that has the lowest deadline D_i.

The both soft and hard constraints are applied to a task as well as a resource through the class schedule, which helps to satisfy schedulability conditions of the application execution.

3.3. Model Implementation

The Ontology-based model engineering architecture (Figure 9) is based on the Architecture Analysis & Design Language (AADL) and describes how the proposed ontology organizes the error models and the components into structural and functional interdependent hierarchies. AADL is considered as a textual

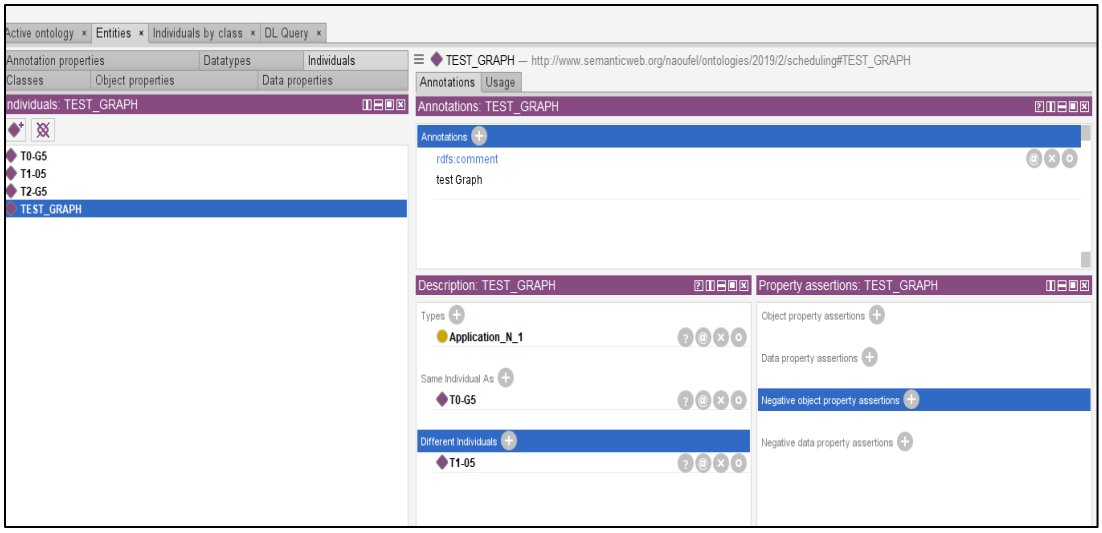

Figure 4: Application Graph Description

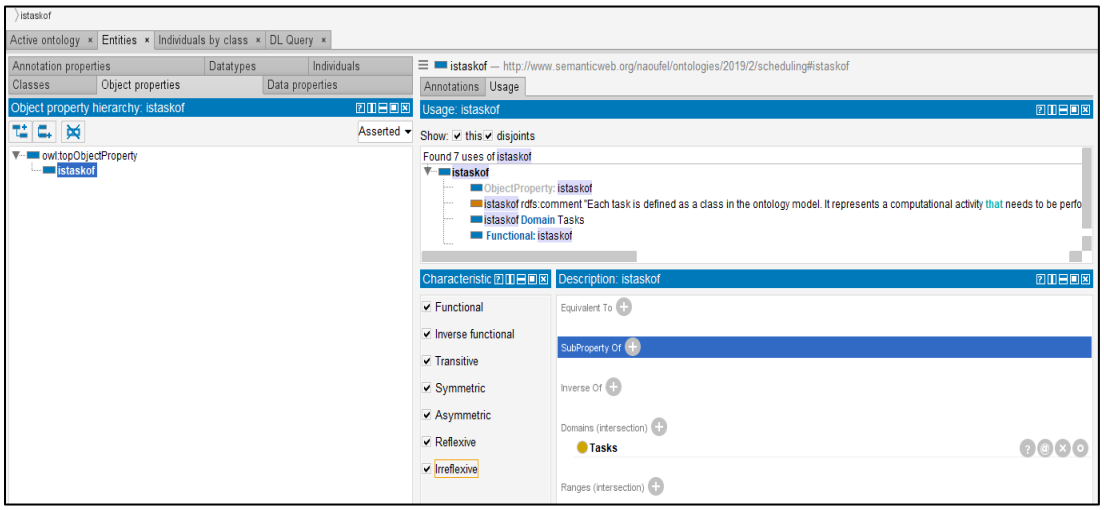

Figure 5: Task Class Properties

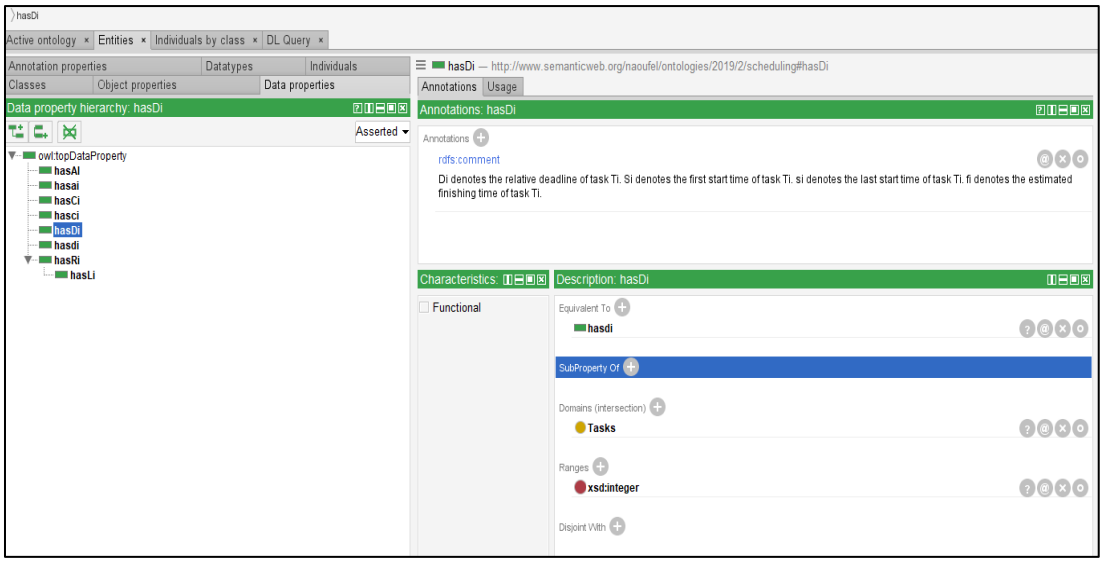

Figure 6: Task Creation With its Temporal Features

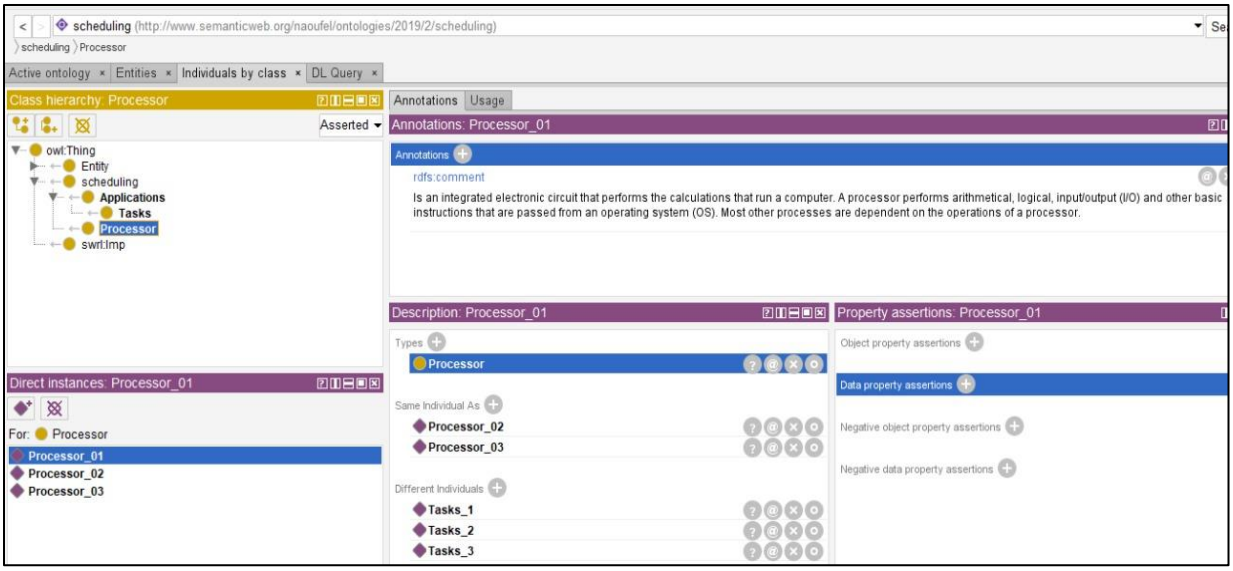

Figure 7: Processors Class Creation

language and graphical one too. It is used to specify the software (SW) and hardware (HW) architecture for the needed critical level of real time systems [34].

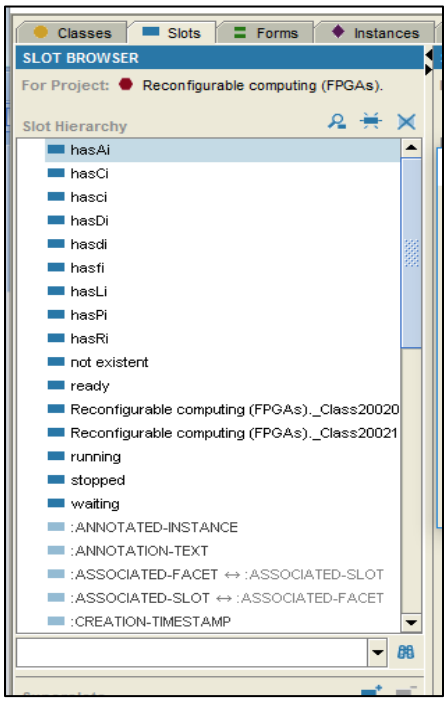

Figure 8: Task Properties, Status and Resources

In AADL language, each system is defined by its components. Each component identifies a number of elements of the actual system architecture. In our case, systems based on reconfigurable architecture are composed of a hardware part and software one. The AADL language permits to define software components (process, thread, data), as well as hardware components (device, processor, memory, etc.). Moreover, this design language defines precise legality rules that control the different component assemblies, and this in both static and dynamic (on-execution) way. To describe the communication between components, AADL defines the connectors and ports. A port performs a particular task in the context of the connector that connects components. All instances of connectors (including their ports and roles), compositions of components and components define the implementation operation. To enable linking flows to internal states, a model describes what initial states may evolve and it includes events, states, transitions to perform various analyses with different constraints on the model.

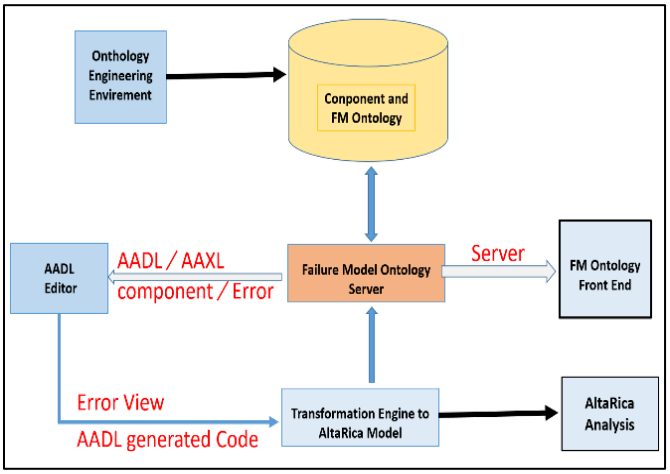

Figure 9: Model Engineering Process Based on Ontology

The objective of the design of the ontology is to prove the correlation of constructs related to the AADL specification, the retrieval, the storage operation's permission, and to offer the desirable reasoning capabilities among them. We specified the ontology [33] in the OWL DL fragment of OWL and we applied Pellet DL reasoner combined with the Protégé ontology editor, and this to customize inference rules' determination.

The proposed ontology is mainly based on three aspects [36]. Firstly, specify all necessary constructs for AADL core that permit to model components (e.g. data) with their corresponding characteristics and so facilitate ontology to add or extract new components. Secondly, for each AADL error, ontology offers the needed concepts to represent error models in terms of states and events, as hardware errors, computational problems and memory

exceptions, and thirdly, the ontology offers the connections and subcomponents (constructs) for component implementation. To achieve this task, we use ontology-based representation of component to detect rules custom inference [37]. The system detects three inconsistencies types making certain formal analysis models invalid: error of incomplete or missing transition; conflict transition that may occur when more than one event is triggered simultaneously; and finally, error in the state of a component due to an error in the failure scheduling scenario. The rules related to inconsistent semantics permit new inconsistent levels to be added. Meta-modeling design approach followed the ontology and determines instantiations and implementation steps. We represent the AADL component as an ontology class. The error models are presented as the ontology hierarchy subclass. The proposed model-driven engineering process enforces rules and constraints on the associations between the error models and the components' constraints. It permits to select and resume the failure modes from the error model hierarchy, then associate them with the nominal mode. The ontology model is then checked for possible component inconsistencies and transform the extended architecture model to the safety one and finally analyze the safety model with tools that provide model checking and simulation.

4. Model Transformation Process

For discovering structurally equivalent constructs, existing modeling experience is considered a basic step for model transformation, and the first set of rules is dedicated to the transformation of AADL components into AltaRica nodes. The transformation rules are therefore driven by the mapping of knowledge with the constructs used through the underlying domain ontology. The benefit of the transformation from AADL models to AltaRica is to expand the set of safety evaluation tools for AADL. Hence, all system components (tasks, data, CLBs, processors, memory, etc.) are transformed to AltaRica nodes while conserving their same original features.

Then, AltaRica state statements are generated based on the AADL components' properties. We manage a set of rules which concern the components' error models. The AADL error, states and transitions are transformed to corresponding AltaRica which are filled with assignments found in the matched AADL. Another set of rules focuses on failure propagation. Since no support failure capabilities are made, a transition declaration creates additional component variants and other transformation rules set related to the used architecture design process and the associated AADL editor is made. The problem is that the editor tool follows a control-flow based approach, which make a semantic gap compared to the data-flow approach of the AltaRica specification.

An AADL component can be of two kinds from a safety point of view: either its properties are filled or are not filled *{lost}*. In the following, we will focus on the generic transformation. The names of the variables vary according to the connection ports of the component and the formulas of the component assertion depend on the data flow path. Indeed, any component of an AADL system:

$C = \{D^{in}, D^{out}, K, Ty\}$, where D refers to data dependencies related to the task data flow, K refers to the knowledge related to properties of safe operation of the component, and Ty refers to the type of the component,

is translated into an AltaRica node:

$N = \{ F, S, D^{in}, D^{out}, \Sigma, \sigma, I\}$, where F is a field of finite values of the variables, S is for state, Σ is a set of events, σ is an affirmation function $S \times D^{in} \rightarrow D^{out}$, and I refers to initial conditions,

such as:

- the state variable s takes its *{correct}* value if the component is working normally otherwise its value is equal to the name of the failure mode *{lost}* declared in AADL ;
- the dependency connections D^{in} and D^{out} form the AADL (and also the AltaRica) component interface;
- a failure transition is produced by events $Evts \subset \Sigma$ leading to a failure mode;
- for each outgoing flow variable $Out_j \in D^{out}$, we consider the set $\{In_i \mid (In_i, Out_j) \in D^{in} \times D^{out} \}$ of incoming flow variables on which the Out_j variable depends. Then, if we consider only the loss of a component, the statement associated with Out_j is the following Out_j = *{if s = correct and* In_i *= correct then correct, else lost)*;
- finally, we consider that, initially, components states are correct *I(s) = {correct}*.

Considering an AADL system $\boldsymbol{\psi} = \{D^{in}, D^{out}, \boldsymbol{\psi}_1, \ldots, \boldsymbol{\psi}_n, A, R\}$, $\boldsymbol{\psi}$ is transformed into an AltaRica node $N = \{N_0, N_1, \ldots, N_n, V\}$ with:

- each subsystem $\boldsymbol{\psi}_i$ is transformed into an AltaRica N_i node;
- N_0 has for dependencies variables D^{in} and D^{out} ;
- R refers to connections between components and is equivalent to the σ function;
- the synchronization vector V is given by the allocation relation A: if a task $\boldsymbol{\psi}_i$ is allocated to a processor $\boldsymbol{\psi}_j$ then $(evt_i, evt_j) \in V$ for $evt \in \Sigma$.

5. Experimental Case Study

We choose as a case study a 3D image synthesis application. It is a complex application with some flexibilities related to the computation time of some tasks and their executing occurrence. The application class hierarchy is implemented in OWL Protégé editor shown in Figure 10. The input of the application graph is a set of the coordinates of the different polygons' summits that represent the 3D object. All coordinates are defined relative to a local space where the 3D object is located. Those coordinates are manipulated by different arithmetic functions (tasks) that create the animation, such as : Loading, Scaling, Adding, Rotating, Translating, etc. Tasks are implemented with their temporal features, and precedence relation according to the application graph. Rules are implemented by Semantic Web Rule Language (SWRL) interface (Figure 11) and combined with the scheduling ontology in order to improve the domain knowledge. Examples of some temporal rules are defined in equations (1) to (8), other rules related to allocation are like in (10) to indicate that processor can hold only one task to execute.

$$Tasks(?T) \wedge hasLi(?T, ?L) \wedge Processor(?P) \wedge hasProcessor(?T, ?P) \rightarrow sqwrl:select(?T) \wedge sqwrl:orderBy(?L) \wedge sqwrl:groupBy(?P) \quad (10)$$

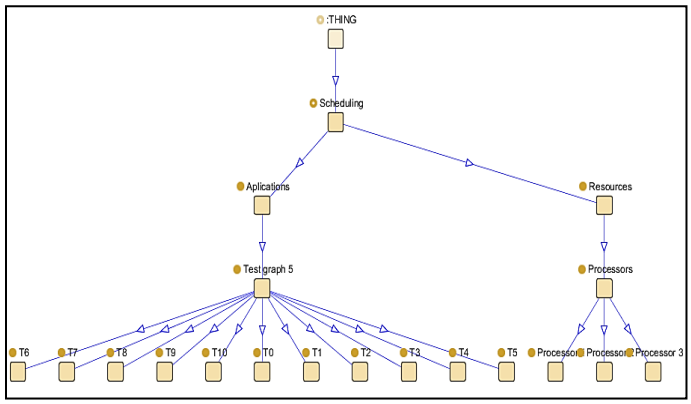

Figure 10: Class Hierarchy in Scheduling Ontology

After creating the SWRL rules, the reasoner component is able to infer the user query based on the ontology knowledge and predefined rules. To type queries, we tested two methods:

- The first method is simple and use existing information in the knowledge base without the need to any inferences. We use such method to verify existing properties in our ontology knowledge. For example, if we want to verify which processor is available for accepting a task execution, or the remaining computation time of some tasks.
- The second query method triggers the rule-based reasoner for the inference process with the knowledge which may lead to enhance and enrich the knowledge base. For example, if we consider tasks migration between processors or CLBs, and we want to decide migration of task T executing on processor1 when processor1 is overloaded. Hence, the rule-based reasoner has to infer the possibility of such migration based on the status of each processor and check that whether this change (so this query) is feasible or not.

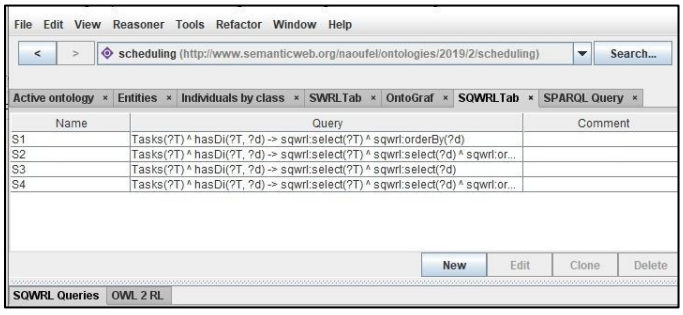

Figure 11: Example of SWRL Rules

Inference results are resulting from SPARQL queries. The SPARQL service permits to check different information as the status of tasks and it provides feedback concerning events and decision failures. The tested query results are correct, and the rule-based reasoner is useful for the scheduling problem. Based on that formalized temporal/resource rules combined with the semantic reasoner and inference rules, the ontology model gives the resulting possible tasks scheduling (Figure 12).

Some examples of successfully implemented scheduling rules (EDF algorithm (9), Least Laxity First LLF algorithm (11), Rate Monotonic algorithm RM (12):

$$Tasks(?T) \wedge hasLi(?T, ?L) \rightarrow sqwrl:select(?T) \wedge sqwrl:orderBy(?L) \quad (11)$$

$$Tasks(?T) \wedge hasCi(?T, ?C) \rightarrow sqwrl:select(?T) \wedge sqwrl:orderBy(?C) \quad (12)$$

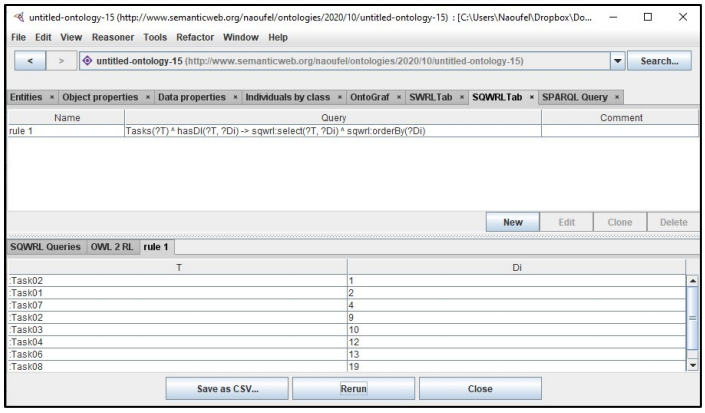

Figure 12: SQWRL Rules Result

By using AADL, nominal models were designed and combined also with failure models of the domain ontology. The system's adding process executes a simple add function, and it is defined in the Adding task. The operation is called performed when the required data context of the former task is provided to the data context of the latter task. To validate operation, scheduler check rules and constraint violation in the error model represented by the Overflow Event State, shown in Table1.

Table 1: Example of incompleteness transition Error

Implementation	Error model
error model implementation OVERFLOW_2.Notionala transitions Error_Free -[overflow]-> Over_Flow; Error_Free -[overflow]-> Ovf_Temp; end OVERFLOW_2.Notionala;	error model OVERFLOW_2 Features Error_Free: initial error state; Ovf_Temp: error state; Over_Flow: error state; overflow: error event; end OVERFLOW_2;

6. Conclusion

We faced in this article the problem of modeling the complexity of reconfigurable systems while taking advantage of its flexibility and dynamic behavior. For this, we proposed a model-driven engineering process that follows a set of steps. The proposed modeling process makes a modular and extensible representation of the system architecture. Model profits from the ontology language capability to represent complex models and address heterogeneous domains information of the dynamically reconfigurable systems. We formalized the known temporal

scheduling problem in reconfigurable systems domain. The ontology knowledge model was implemented using Protégé editor. Moreover, the developed ontology is improved with SWRL inferred rules. Model editing is enhanced, since errors can be detected without the need to perform complex analyses. The model and the rules reasoner and the resulting scheduling decision were verified with a case study.

Future works aim to extend model transformation functionality and involve more dynamic system characteristics such as tasks migrations between hardware and software resources and the total and partial reconfigurability. A filtering process should be added to the reasoner in order to eliminate unnecessary rules and so avoid ambiguity or conflict when making scheduling decision. Another objective is to test more scheduling algorithms with the incorporation of additional types of error models.

Acknowledgment

This work has been approved by the research grant program of the deanship of scientific research at TAIF University.

ABSTRACT

This paper aims to design an accurate and robust algorithm for counting the steps based on the smartphone's accelerometer for indoor applications. Different daily activities have been considered in the experimental scenarios, including normal walking with various smartphone positions and running activities. The detection process's accuracy is ensured by setting an appropriate segregation approach and defining a fixed threshold for each experiment. The algorithm generates a new envelope signal that mimics the collected steps signal without the vibrations and noise elements to avoid miscounting the exact steps. The followed approach results have been compared with the pedometer applications on the android platform and HUAWEI Watch GT-731. The proposed algorithm showed improved detection accuracy in contrast to the other literature approaches. The obtained accuracy was around 99% for the standard walking scenario and approximately 97% for the running activity scenario.

1. Introduction

Lately, the step count has been extensively used in various applications, such as health monitoring, auxiliary positioning, and gaming. Earlier, the Pedestrian Dead Reckoning (PDR) was used as a localization method based on advanced built-in sensors [1] that exist these days in Smartphones. These sensors found in the smartphones include accelerometers, proximity sensors, gyroscopes, magnetometers, and Global Positioning System. The accuracy of the steps count is one of the challenges of the PDR. Therefore, several studies have been addressed, increasing the accuracy of steps count while walking using the smartphone's accelerometer [2–4].

One of the aspects has been considered in the literature: smartphone placement's impact on measurement accuracy. The smartphone's position and placement might cause jitter during the human motion, which leads to counting false steps [5]. Also, remaining still, watching videos, playing games, and many other activities can lead to a wrong step count [6]. In [7], it was recommended to place the smartphone at the user the fingertips with the view screen point upwards while using the phone. If the smartphone is placed in the jacket or trouser pocket, it is recommended to put the top of the smartphone upright. One of the challenges of this approach is getting rid of the noisy signals accompanying the detected steps. Therefore, a discrete Kalman filter was used in the literature to minimize the smartphone accelerometer's noise during human motion [8]. The Footsteps are usually calculated using an algorithm in the smartphone on the android platform, which can count precisely by dividing the measurement processes into two phases. The first phase includes collecting the linear acceleration and the gravity values from the accelerometer of the smartphone. These values are then used to derive the horizontal components and identify possible start points of regular periodical fluctuations. The second phase includes finding the correlation coefficients to determine if the collected sensing measurements exhibit similar tendencies, and accordingly, it finds the steps count. The results showed higher measurement accuracies if the user holds the phone statically [9]. Although several approaches have been proposed and used for step counting, most of these approaches are not validated with robust methods. Therefore, this work aims to design a robust algorithm for step count purposes with high accuracy. The proposed algorithm will distinguish between false steps and real steps to reduce the measurement error and enhance its credibility.

This paper is structured as follows. In section II, a concise overview of related work. In section III, the proposed approach to count the steps is presented. The obtained results are discussed in section IV, and the paper ends with conclusions.

2. Related Work

Several algorithms have been proposed to enhance the step count based on the smartphone's sensors in-state of the art. In [6, 10], a window peak detection algorithm has been proposed based on the smartphone's accelerometer. The algorithm could afford an average accuracy of 95%, considering the different ways that a

*Corresponding Author: H. Muhsen, Email: Hani.Mohsen@gju.edu.jo

smartphone can be carried. The algorithm's parameters have been optimized and applied to measured data from three different volunteers holding the smartphone at different positions. A new algorithm based on the smartphone sensor has been proposed in [11] to estimate the traveled distance by walking accurately. The algorithm counts the number of peaks in the measured signal by the smartphone's accelerometer. The next step is to detect the step-length, which varies from one step to another. Many adaptive algorithms have been designed to count the footsteps based on LSM (Lifestyle modification). These approaches rely on measuring the movement by a 3-axis accelerometer.

The proposed designs can enhance the step detection accuracy using step amplitude with accuracies, which can reach up to 99%. In [12], two adaptive algorithms have been proposed to count human steps using only the gyroscope. Accordingly, the Fast Fourier Transform (FFT) was applied to the measured data to obtain real-time walking frequency. The proposed algorithms' average accuracy ranged from 95% to 97%, considering different walking speeds. Further, the step counting based on the smartphone's accelerometer has been developed in Indoor Positioning System as proposed in [5]. The approach relies on pattern recognition for step detection and counting. Different scenarios for the smartphone placement and the number of steps higher than one hundred steps have been considered in the validation stage. The result showed high accuracy regardless of the smartphone position. In many step counting approaches, the non-invasive option depends on utilizing the accelerometer to determine the arm movement like a seizure sufferer. In these approaches, the algorithm depends on employing low-power, embedded microcontroller devices in real-time, and they are not intrusive to the patient's life. Therefore, they are less likely to become non-compliant with monitoring [13]. These approaches are applied in wireless biomedical networks that attempt to monitor patients in a completely non-invasive, non-intrusive manner for a specific condition. Nowadays, the Global Positioning System (GPS) is employed to detect and count the steps outdoor. The GPS showed low accuracy in indoor scenarios due to the indoor equipment's electromagnetic interference and the building structures [14]. Therefore, the PDR and smartphone's sensors have been integrated to detect and count the steps accurately in indoor scenarios as in [15].

The power consumption of steps counting algorithms is one of the research topics, especially in smartphones with small battery capacity. In [16], the accelerometer Tap Interrupt algorithm was used to reduce power consumption. The accuracy and measured power consumption at the system level have been compared with a periodic sensor-reading algorithm. The tap interrupt approach presented a lifetime of the battery that is 175 % longer than that of a non-gyroscope 30 ms polling method. The battery life can be extended to 863 % by putting both the processor and the gyroscope in a sleep mode during most operating time. The average power consumption may be reduced by reducing the wake-up frequency from the sleep state and shortening the processing time at each wake-up. Recently, machine learning algorithms have been introduced for step length estimation based on the smartphone's sensors. Utilizing these tools aims to improve the steps detection, counting, and step length estimation accuracy.

In [1], the neural network is implemented in a multi-mode intelligent recognition approach based on the smartphone's sensors. The empirical results presented a maximum positioning error lower than 1% of the total path distance. In [17], an adaptive algorithm has been proposed to enhance the steps counting accuracy in indoor positioning services. The algorithm aims to solve the limitations by introducing four mains parameters. These parameters include the minimal peak distance, minimal peak prominence, thresholding, and vibration elimination. The algorithm presented an improved average accuracy of 97%. Also, the results were better than the results obtained by commercial steps counting applications. This paper aims to introduce an algorithm to obtain accurate and robust step counting for indoor applications. The results of this work will be compared with state of the art to validate the followed approach.

3. Methodology

In this work, the smartphone accelerometer is used to collect the acceleration value during human movement. The collected data is transferred to the MATLAB drive using an application installed on the users' smartphones, called "MATLAB on mobile." MATLAB on mobile offers accessibility on the available sensors in the user smartphone. The obtained data by the accelerometer of the smartphone include four parameters. The first parameter represents the timestamp values, where it will indicate the (date, time in Hours: Minutes: Seconds). The second parameter represents acceleration values on the X-axis. The third parameter defines the acceleration on the Y-axis, and the fourth parameter represents the acceleration on the Z-axis. Most of the available accelerometer modules measure the value of acceleration quantity as a vector, and many modules can detect both linear and angular acceleration [18]. Angular acceleration can be defined as the time rate of change in angular velocity.

In contrast, the linear acceleration is the time rate of change in linear velocity. In this work, only the linear acceleration vector is used to estimate the number of steps elapsed. The angular acceleration caused by the human steps has a small value and can be neglected. Hence, the linear acceleration within a short period can be calculated as follows according to [18]:

$$a = \lim_{\Delta t \to 0} \frac{\Delta v}{\Delta t} = \frac{dv}{dt} \tag{1}$$

where a is the acceleration in [m/s^2], Δv represents the change in velocity in [m/s], Δt is the time interval in [s]. The accelerometer is used to measure the linear acceleration on the x-axis, y-axis, and z-axis independently. It is hard to predict the accelerometer's orientation every time a user operates the count steps functionality. Therefore, the acceleration vector is converted at each time point into an overall scaler value. Hence, Acceleration values will be determined like human walking or running regardless of the accelerometer's orientation. The overall acceleration value is calculated as the square root of three acceleration values, as expressed by equation (2) as in [11].

$$a_{all} = \sqrt{a_x^2 + a_y^2 + a_z^2} \tag{2}$$

Indeed, the gravitational force affects the acceleration value due to the architecture of the accelerometer module. So, it is hard to estimate the axis affected by gravity since it depends on the smartphone's orientation when it is carried by hand or placed in the pocket. Fig.1 depicts the acceleration signals of the three axes. Therefore, the gravitational has been removed from the overall acceleration signal as follows.

$$a_{final} = a_{all} - avg(a_{all}) \tag{3}$$

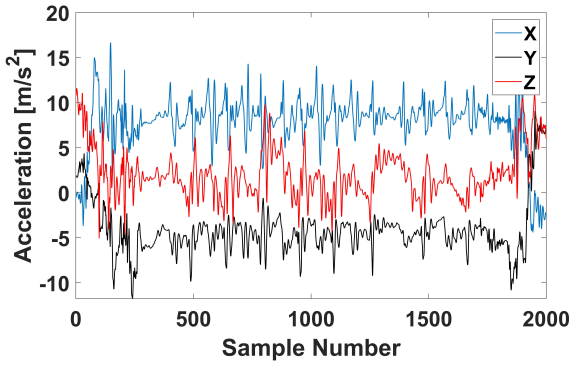

Figure 1: Acceleration values on X, Y, and Z-axis,

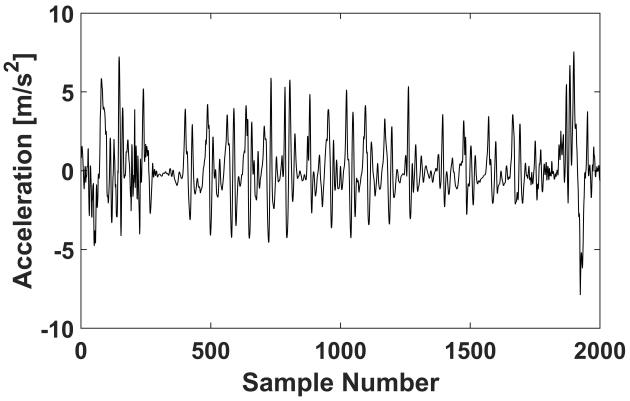

Figure 2: Sum of Acceleration Vectors of X, Y, and Z-axis after subtracting the mean value

The human steps generate little height peaks in the acquired acceleration data. These peaks have limited heights, which might vary depending on the movement's behavior while walking, as shown in figure 2. Also, electromagnetic interference can turn the measured signal into a noisy signal. This noise might result from the surrounding appliances. Therefore, finding maximum local peaks over a specifically tuned threshold can be employed to estimate the number of detected steps.

The previous stage can be fulfilled by generating an envelope function MATLAB, which is determined using spline interpolation over local maxima separated by at least the samples (n_p). The number of samples (n_p) can be calculated using MATLAB. Consequently, the unwanted vibrations and fake steps are removed, making the steps counting much more accessible, as depicted in figure 3.

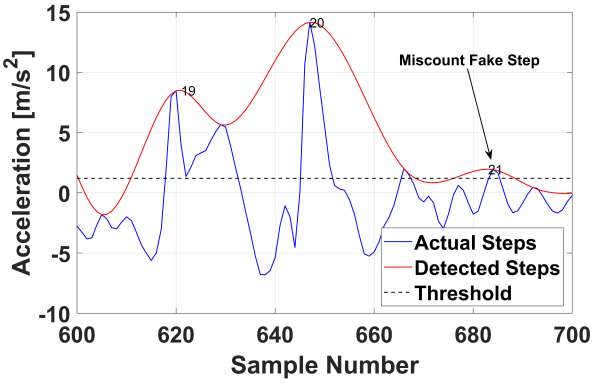

Figure 3: Applying the envelope function on the measured signal to remove the noise and eliminate the vibrations.

In this approach, it is found that the main parameter which impacts the estimation's accuracy is the threshold definition. This threshold depends on the sampling rate, the step rate, and the average of the orthogonal accelerations' envelope function. Therefore, the threshold is defined by equation 4.

$$\varepsilon = \frac{avg\left(a_x^*\right)+avg\left(a_y^*\right)+avg\left(a_z^*\right)}{n_p} - d \ , d \in \{3,5\} \qquad (4)$$

where a_x^*, a_y^*, a_z^* represent the upper peaks envelope, d is a correction factor, n_p is the number of samples, and it is defined as follows:

$$n_p = round(R_s / S_r) \qquad (5)$$

In this work, the step rate S_r is assumed to equal five steps per second. This assumption valid since this value represents the average of the human steps per second. The sampling period τ_s has been calculated using the new signal data's timestamp by finding the difference between every two values in seconds.

The segregation approach in this work is performed by generating a new signal based on the envelope function, which returns the upper limit for the average of the measured accelerations signals to remove the impact of vibrations and noise to ease counting the number of the steps, as shown in Fig.3 in red. This transformation will lead to an accurate detection process. The next step is to find the maximum difference value to represent the sampling period and is given by equation (6).

$$\tau_s = \max\left(t_{n+1} - t_n\right) \qquad (6)$$

Afterward, the sampling rate was calculated as follows:

$$R_s = 1/\tau_s \qquad (7)$$

Comparing the peaks of the final acceleration signal $P_{sk}(i)$ obtained by the envelope function with the threshold ε will estimate the number of steps over the path length. The constraint which must be fulfilled to count the number of peaks higher than the calculated threshold can be expressed mathematically by

$$a_{final}^* > \varepsilon \qquad (8)$$

The stages and the procedures of the proposed algorithm for steps counting purposes are summarized in Table 1.

Table 1: Proposed Algorithm steps.

Proposed Algorithm Steps
1. Collect a_x, a_y, a_z
2. Calculate a_{all} and a_{final}
3. Define step rate $S_r = 5$
4. Calculate the sampling period τ_s, and it is defined as $\max\left(t_{n+1} - t_n\right)$ for $n = 0,1,2,...,k$ where k is the number of samples.
5. Calculate the sampling rate as $R_s = 1/\tau_s$
6. Calculate $n_p = round(R_s / S_r)$

7. Apply envelope function on a_{final}, a_x, a_y, a_z to return the upper peaks envelope $a^*_{final}, a^*_x, a^*_y, a^*_z$.
8. Define the threshold as follows:

$$\varepsilon = \frac{avg\left(a^*_x\right) + avg\left(a^*_y\right) + avg\left(a^*_z\right)}{n_p} - d \ , \ d \in \{3,5\}$$

9. Count the peaks $P_{sk}(i)$ for $a^*_{final} > \varepsilon$
10. Display the step count if finished

4. Results and Discussion

The experiments were conducted at a public institution, which contains many electronic devices. These devices radiate electromagnetic noise, which interferes with measured data. The accelerometer of Huawei P30 has been used to collect the measurement data. Four different scenarios have been considered in this work and summarized in Table 2. The position of the smartphone during the experiments is depicted in figure 4.

Table 2: The symbols of the activities in the empirical scenarios.

Symbol	Activity
A	Walking at varying speeds with the smartphone is carried by the hand
B	Walking at varying speeds with the smartphone is placed in the Jacket pocket
C	Walking at varying speeds with the smartphone is placed in the trousers' front pocket
D	Running at varying speeds with the smartphone is carried by the hand

Figure 4: The position of the smartphone in the experimental scenarios.

4.1. Steps Counting During Different Daily Activities

In this part, the accuracy of the proposed algorithm for steps counting during different daily activities is investigated. The accuracy of steps detection can be expressed as follows:

$$Accuracy = \left(1 - \left(\frac{S_e - S_a}{S_a}\right)\right) \times 100\% \qquad (9)$$

where S_e is the number of the estimated steps, and S_a is the actual step number. Therefore, ten experiments with different speeds and path lengths have been considered for each case study, as summarized in Table 3. The algorithm could detect the number of steps with an average accuracy higher than 99% for normal walking when the smartphone is carried by the participant's hand. The miscount was only for one or a maximum of two steps regardless of the path length. In the next scenario, the smartphone is placed horizontally in the pocket of the participant's jacket. The results presented an average accuracy of about 98%. The third scenario considered putting the smartphone in the front pocket of the participant's trouser.

The result showed a reduction in the average accuracy due to the smartphone's position, and it was around 96.7%. Finally, the running activity has been investigated, considering the smartphone is carried by the participant's hand. The average accuracy of the different tested scenarios is depicted in figure 5. The proposed algorithm showed an average accuracy of 96.9%. The algorithm presented a reduction of 1% accuracy than the standard walking scenario. figure 6 depicts the detected steps and actual steps in the different tested scenarios. In figure 6(a), the number of the detected steps was 19, which is lower than the actual steps by one step in scenario A. This error might result from miscounting one of the real steps by the proposed algorithm due to the set threshold value. figure 6(b) depicts the proposed algorithm's ability to detect the exact number of the actual steps with zero error.

Table 3: Comparison between the actual steps number and the detected steps during different scenarios based on the proposed algorithm.

Test Scenarios					
Exp. No.	**Actual Steps**	**A**	**B**	**C**	**D**
1	10	10	11	9	11
2	20	19	20	21	21
3	30	29	30	29	29
4	40	40	39	39	40
5	50	50	51	51	51
6	60	60	59	60	61
7	70	70	70	73	72
8	80	80	82	80	81
9	90	91	88	92	92
10	100	100	100	96	103

The smartphone placement in the trouser pocket might lead to unwanted vibration, leading to counting more steps than the number of the actual steps, as depicted in figure 6 (c). In the running scenario, the error might result during the transition from the movement to still during the experiments, increasing the number of the detected steps, as shown in figure 6 (d).

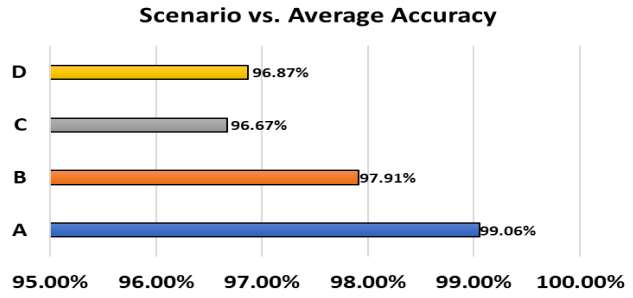

Figure 5: The average accuracy of the ten experiments for each experimental scenario

4.2. Comparison with other Pedometers

In this section, the proposed algorithm has been investigated in terms of its accuracy compared to other pedometers. Therefore, two Android platform applications have been used to detect the number of steps during normal walking and running activity. Also, a HUAWEI Watch GT-731 is used to validate the proposed approach. The first application was Pedometer by King Brain Inc., and the second application was a Pedometer for Walking. Both applications are available on the google play store. The tests have been conducted under the same conditions to validate the

comparison study. The proposed algorithm results showed improved detection compared to other methods with at least 3%.

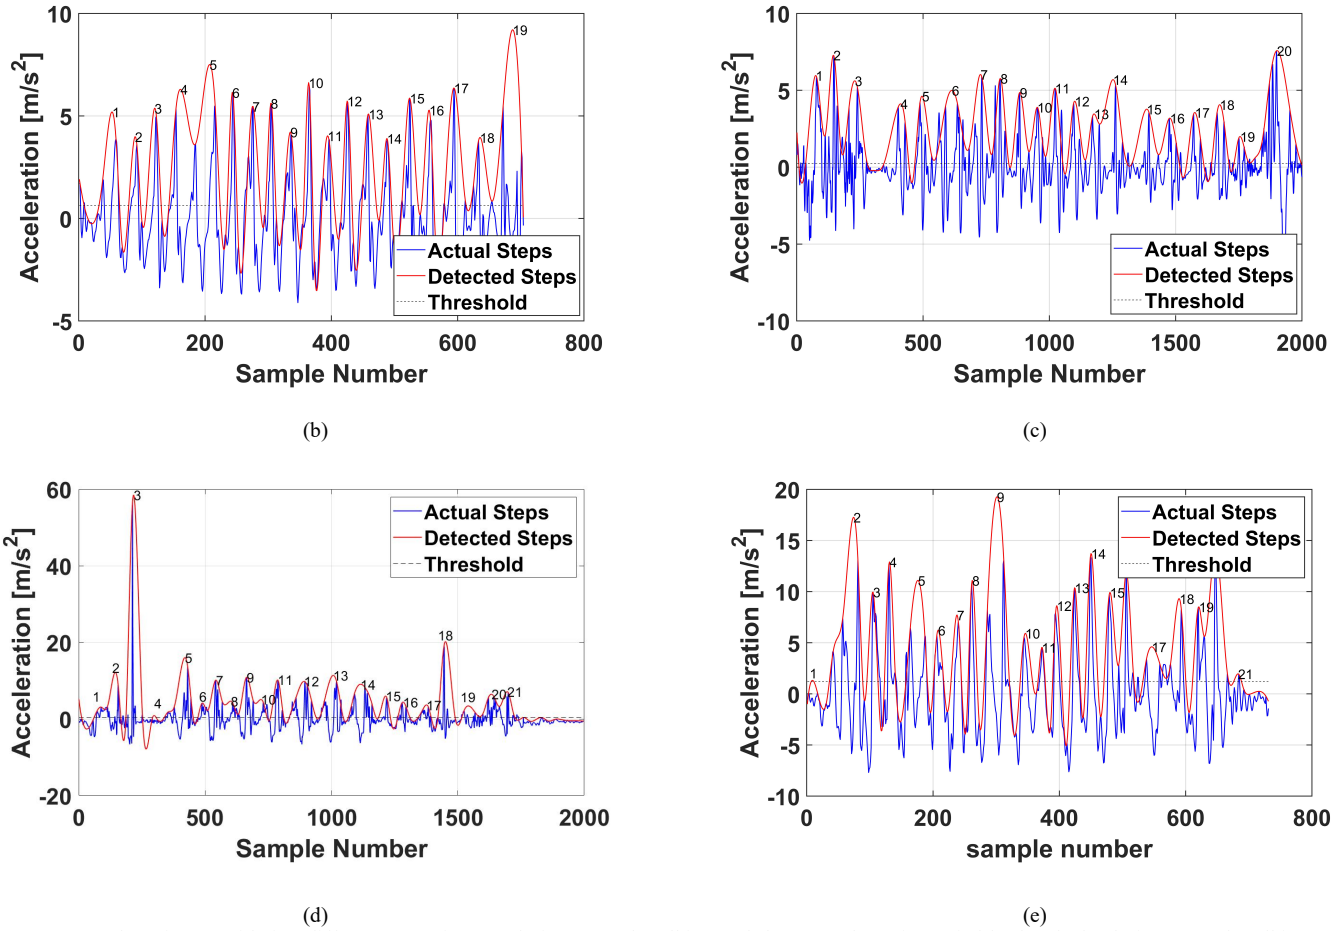

Figure 6: Steps detection considering different scenarios. (a) during normal walking and the smartphone is carried by hand; (b) during normal walking and the smartphone is placed in the right Jacket pocket; (c) during normal walking where the smartphone is placed in the left front pocket of the trouser; (d) during running and the smartphone is carried by hand.

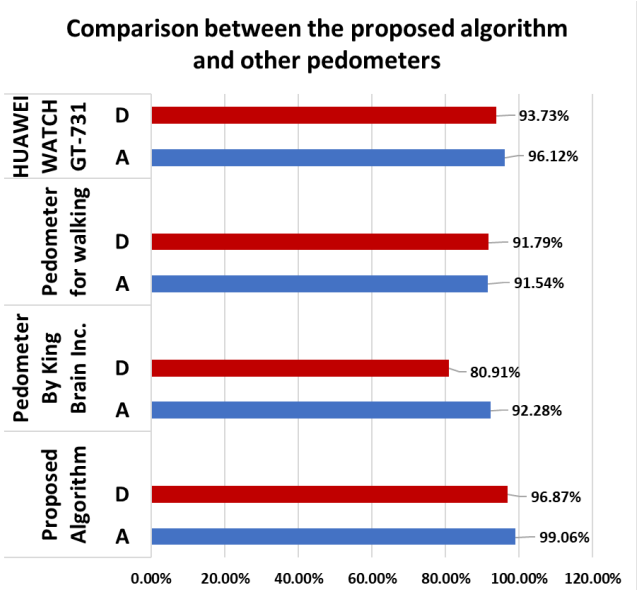

Figure 7: The average accuracy of the proposed algorithm compared to Android applications and HUAWEI Watch GT-731.

The average accuracy of the HUAWEI Watch GT-731 was in second place, with 96.12% for the typical walking scenario and 93.73% for the running scenario. It is worth to mention here the HUAWEI watch does not utilize the smartphone accelerometer, which is the case for the other applications. The result of this study are depicted in figure 7.

5. Conclusion

This work aims to propose a robust algorithm for step detection with high accuracy for indoor systems. Mainly, the proposed algorithm will collect the acceleration data from the smartphone's accelerometer. In the proposed algorithm, a new signal based on the envelope function has been generated to return the upper limit for the average of all measured accelerations signals. The previous phase will remove the impact of vibrations and noise, and it will ease counting the number of steps and obtaining accurate results. It is found that the setting of the threshold will affect the accuracy of the detection process. Therefore, a new formula for the set threshold was created based on the acceleration signals' envelope and the number of samples. The proposed algorithm has been investigated for two case scenarios: the normal walking scenario and the running scenario considering different smartphone's position — the obtained accuracy based on the proposed algorithm

higher than 97% for all considered scenarios, as summarized in Table 4. The results of the proposed approach presented improved accuracy compared to other works. Finally, the proposed algorithm can be used for online and offline step counting with a maximum step rate of 5 steps per second. The sampling rate can be set from 50 Hz to 100 Hz. The threshold's value depends on the measured accelerations signal and the correction factor.

Table 4: Comparison of the average accuracy between the proposed algorithm and state of the art.

	Avg. Accuracy (Normal Walk)	**Avg. Accuracy (Running)**
Proposed Algorithm	99.06%	96.87%
[4]	96.5%	N.A
[6]	93%	N.A
[12]	96.6%	N.A
[5]	94%	78.3%
[3]	93.7%	N.A

Positive Polarity
Propagation of Information
Social Networks

ABSTRACT

It is the age of information. Social networks are the main reason why, following the increasing activity of online users. With this comes a big impact on the real world, it can be positive and highly negative as well. Therefore, research in this field is highly needed for the betterment of societal behaviors within social networks, to minimize the negative impact. When a negatively polarized message spreads over time, it is eventually exposed to most users of that social network where it is spreading. Social network communities start behaving in a negatively polarized way, due to the negative nature of the propagation of information. In order to optimize technological intervention to the benefit of humanity, in this paper an approach is elaborated in order to help switch the dominant polarity in the case of negativity. The platform of reference is Twitter, since it classifies trends per area, which polarities' dominate within the social network. To achieve that, an extraction as well as a sentiment analysis method are developed to initiate the positive polarity introduction in the network. The idea behind introducing a positive polarity in a network, relies on the studies of the positive effect nature has on users. The positively polarized promoted content is selected from sponsored content of users who consent to spreading their posts.

1. Introduction

In the year 2020, certain events agitated the users of social media platforms, such as: the Covid pandemic and the American social justice riots. As a result, fear spread across the globe not only virtually but also in the real world. This rapid propagation of this type of information has resulted in the spread of misinformation, hatred, cyber-bullying and other unpleasing social behaviors, leading to real life damages. This is where the work of the present paper comes in handy. It becomes unmanageable when the information spreads vastly and one of the key ones who can change this, are the propagators themselves. A study shows that users whose mood shifts are mostly negative generate rants, which are angry forms of expressions [1]. In the case of reaching a big audience, their angry content spreads all over the social platform. As an attempt to reduce the bad effect such users have on those who share the same platform, this paper utilizes research on how nature calms the mood. To promote nature photos or videos on the feed of the potential disruptive users, the selected visual content is extracted form the sponsored data. Sponsored data is data whose owners give consent of publication to online users of the platform. Users who promote their content target people according to many criteria, such as gender, age, geographic area, or center of interests. This paper suggests adding to these criteria, in case the content is nature related, the disruptive users in order to also reach them. To intervene positively; this research suggests a method whose end goal is to switch the user's mood to a positive optimistic one, so that the negative content is less likely to be shared. The article's suggested approach evaluates the current or recently published trends on the Twitter platform, in order to identify the polarity of the dominant news. After this phase, the best contributors in terms of propagation of negatively polarized information are selected. Comes then the procedure of providing them with the polarity switch method as described in the third section of this article. This paper is divided into four sections. The first one is the introduction, the second one is the state of the art in order to mention the previous works. The third one describes the proposed method. The fourth one provides a conclusion.

2. State of the Art

Social media has proven itself to be a fast-growing platform for social exchange [2]. When users express themselves on social media, they insinuate approval, disapproval or a neutral statement. To translate their content polarity wise, the process of sentiment analysis helps. In order to achieve that in the proposed method,

*Corresponding Author: Sara Abas, Email: sara9abas@gmail.com

Natural Language Processing tools are referred to for structural analysis.

2.1. Natural Language Processing

The NLP is an artificial intelligence processing language to create algorithms that can translate human language. Most commonly used NLP platforms are: NLTK (Natural Language Toolkit) [3], spaCy [4], Stanford's NLP tools [5], including the part-of-speech tagger [6], the named entity recognizer [7], the parser, and other provided components.

2.2. Sentiment Analysis

2.2.1. Existing approaches

The rich amount of user-provided data is a gift from social media to content analysis studies. Sentiment analysis, is the study of emotions behind textual content. Review sites are a good example of data made available for research purposes. They are reflective of the clients' receptivity of any provided products. This data source is used for the purpose of testing sentiment analysis solutions. In the available literature, some opinion mining studies investigated different approaches. Turney's Algorithm [8] is a clear example of an unsupervised method for sentiment analysis. The authors use identify the polarity of a phrase, using the Alta Vista [9] as a Web Search Engine resource.

A positive polarity is defined by the identification of the phrase with the word "excellent". Similarly, a polarity, which is classified as negative, is calculated by the co-existence of a phrase with the word "poor".

SO(phrase) = hits(phrase NEAR "excellent") hits("poor") log2 hits(phrase NEAR "poor") hits("excellent") (1)

The hits(phrase NEAR "excellent") "NEAR" operator in the equation represents the co-occurrence of " excellent" and the sentence itself, via the number of search results in Alta Vista. This method is estimated to be 74% accurate. However, there are many words which have different semantic meanings but are spelled the same in the sequence of letters. In this case, this method is likely to lead to the wrong semantic analysis of words. In this paper, a method which identifies a unique meaning to words in tweets, is presented. However, nowadays on social platforms like Twitter, new words are constantly emerging. The social network's users come up with new terms to exchange, which don't have a meaning prior to their first emergence on the platform. These words can't be found on WordNet, which SentiWordNet relies on in the first place. This paper, presents a solution to these newly invented words as a follow up to the main solution. Such words are not available on external database resources. The commonly used sentiment analysis algorithms are Baseline Algorithm [8], Modified Baseline [9], and Turney's Algorithm [4] which were discussed above. However, they are depend on formal phrasing and they don't take into consideration disambiguation. Other works [10, 11] support emoticon analysis, because they are emotionally expressive. An emoticon is a symbol or icon used, to express an emotion without words. The authors' works' relied on a list of pre-classified emoticons or emojis, and emotionally and intensively expressive words. These methods were proven efficient. However, on platforms like Twitter, emoticons are no longer inserted via text, instead they are images provided by the operating system of the phone. A study [12] using available Dutch Tweets, identifies emoticon polarities based on tweets. However, it only studies text-inserted emoticons. Text-inserted emoticons are icons that show up when the user types certain textual character sequences. With the updated phone operating systems of today, users tweet using the available emoticons and do not necessarily type textual symbols.

2.2.2. Nature's effect

The more relieved a user is, the less likely they are to spread negativity. Several researches showed that visualizing images of natural views and landscapes, whether they are viewed as 2D photographs, or scenes, resulted in healthy rewinding effects, such as canceling visual and attentional areas of the brain, removing eye blinking and stress [13, 22]. The study [22] investigated 37 articles showing real evidence of the physiological results of witnessing natural views, through on indoor setting experiments—Exposures to display stimuli, confirmed that viewing natural scenery created a physiological relaxing state.

3. Contribution

The aim of the present approach is to select the social network's propagators which spread negativity within the network. Negativity comes from a content which is negatively polarized, and doesn't align with the positive spectrum of human emotions like: peace, harmony, laughter, love etc. The reason behind detecting the users who spread negativity, is to expose them to nature images, in order to reduce their stress levels. In this work, the social platform Twitter is used for its available "Trends" functionality, which is going to help isolate the most controversial topics, and therefore the most controversial users who discuss these topics. In order to achieve this and to carefully extract trends accordingly to their audience and propagators, the country is first selected on the social platform. The trends functionality is defined by the selection of the geographic area on the Twitter platform. So instead of studying random trends, Twitter selects trends per country. The trends functionality is defined by the selection of the geographic area on the Twitter platform. This helps filter information and circle the social network in which trends are spreading. Once this is achieved, the geographic area where an information is spreading most is considered the social network of base, on which the suggested methods of this paper will run.

3.1. Suggested approach

The macroscopic method is summed up in the figure below.

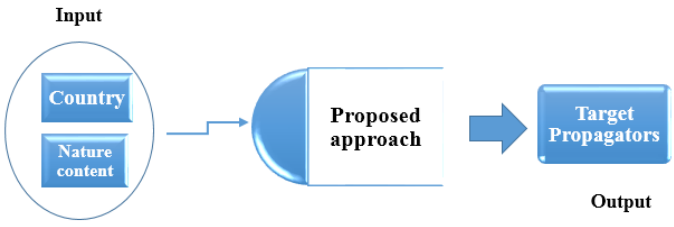

Figure 1: Explained Method Macroscopically

In the entry of the final system, first the country and the nature related sponsored data is provided. This automatically zooms the focus on the content shared within the social network related to that country. As for the nature content, the sponsored database

content is selectively pre-extracted from the sponsored database content of the paltform. On the social network platform, some pages posts are sponsored in order for the page to be marketed and reach a broad audience. From the sponsored content, text mining to find the following keywords is applied: K={ Nature ; Landscape ; Ocean ; Mountain ; Flower ; River ; Beach ; Tree ; Forest ; Sea ; Waterfall }. If the sponsored image's caption contains a word that belongs to the set K, it is a potential advertised content to the target propagators. From this set, the top 20 liked images are chosen, in order to optimize the chance of having a positive influence on the selected users' moods.

After running the method, the final result is a set of target propagators, to whom the selected nature data is displayed, which is sponsored by the marketers of social media seeking promotion of their nature related pages.

3.1.1. Detailed Method

After the country is selected, the process of the suggested method follows four steps.

Figure 2: Detailed Approach

Phase 1: The first phase as illustrated in fig2 is the top trends of the week selection. In this first phase, a simple query on the platform retrieves the top 20 trends of the day, listed in the country: https://twitter.com/i/trends. On the social platform, the top 20 trends are selected and highlighted per country. However, a trend yesterday could be completely neglected today, and no longer have consistent impact. In order to identify the consistently impactful trends, a method is developed that calculates trend relevancy over the past 7 days. The variable "Real_Rank" reflects the real rank of the trend, according to the past 7 days on Twitter.

Let a be one of the top 20 trends of today.

$$Real_Rank(a)=\sum_0^6 \frac{7-j}{Rank(a\ ;today-j)} \quad (2)$$

Phase 2: Trend polarity Identification. It is necessary to identify which one of the top trends from the first phrase, negatively impacts the social network. In order that, a sentiment analysis method is developed to determine the polarity behind the trend. A trend Tr is a dynamic set of content, which changes every second. In order to identify the polarity of a trend the global polarity of its components is evaluated.

$Tr(j)= \{Tw_1 ; Tw_2 ; .. Tw_n\}$ j is the current day on which the algorithm runs. To identify the polarity of a single tweet Tw1, which is the shared post, the POS Tagger is used in order to retrieve the mentioned adjectives in the sentence. Databases for research purposes are fortunately made available byplatforms, such as Amazon. This includes reviews (ratings, text, helpfulness votes).

Let the following be tweets about the Trend "#destroyThings" extracted from the first phase the platform.

"It is time to destroy things because we hate this horrible system." (Tw_1)

"Destroying is dangerous. Please refrain from doing this bad habit" (Tw_2)

In this sample example there are 4 reviews.

Review 1 : I hate this audiobook.

Review 2 : I don't like it

Review 3 : Boring.

Review 4 : Not very nice.

(Review 1, 0 stars), (Review 2, 2 star), (Review 3, 1 stars), (Review 4, 0.5 stars).

Clearly, the stars given by the reviewers who labelled their review with "horrible" aren't passed 3 stars.

We use the identification method of the polarity of phrase method.

The positivity rate is defined as follows:

$$Pos\ (Trend) = \frac{\sum Polarity(phrase\ k)}{N} \quad (3)$$

N is the number of tweets on the trend "Trend" list.

For adjectives that newly emerge on the social platform, the same method is used on the acknowledged adjectives by the POS Tagger, which occur on their same sentence. In order to explain this, the following examples are cited.

"Amazing. This movie is epic"

"Glad I watched this. Epic."

"This cat is epic. So funny. The owner is odd."

From the first tweet, "amazing" is the identified adjective. This word has a positive polarity. The same applies for the second statement. For the third one, the word "odd" is singled out.

In order to identify the polarity of a newly emerging word, which is a word that does not exist on available knowledge base, the following equation is used. If wk is a positively polarized word, then bk =1. bk(w1) represents an adjective that co-occurs with the word w_1 in the same phrase, m is the number of adjectives in the same tweet j.

$$P_tweet_j(w_1)=\frac{\sum bk(w1)}{m} \quad (4)$$

$$Polarity(wk) = \frac{\sum P_tweet_j(wk)}{N} \quad (5)$$

where N is the number of tweets containing the word w1.

Phase 3: In this phase, finally the target disruptive users of the social network are selected.

If Pos(Trend) < 50% after it has been selected as a top ranking trend from the first phase, the top 10 most liked tweets belonging to the set of this trend are selected, and the propagators of these tweets are targeted by the selected nature sponsored images.

3.1.2. Algorithm

The global algorithm for the selection of the users to whom nature's sponsored data is exposed is described as follows below. Let T be the social network, and C the country selected in the entry of the system.

Algorithm 1: procedure target Selection

Result: P

S <- Ø, A<- Ø, R <- Ø, P <- Ø

```
S=calculate_trendRank(T)
A=polarity_analyze(S)
R=select(A, 10)
P=select_propagator(R)
```

Calculate_trendRank(T) is a result set which contains 20 vectors. C is the country. In each vector are stored: the trend reference and the real rank of the trend T calculated throughout 7 days, which is calculated by the equation (1). Only trends that are related to the top 20 values of the equation are stored.

Polarity_analyze(S), is a result set which contains a set of vectors. In each vector are stored the trend reference, and the polarity of the trend. The trends are the ones contained in S. The polarity of each trend is calculated via the equation (8).

Select (A, 10) is a method that extracts the top 10 negatively polarized trends from the set A, and results in a set R.

Select_propagators() method uses the set R in order to extract the top 10 most liked posts in the set, and simply identify their users.

4. Conclusion

In the aftermath of a controversial event, social media is usually the most accountable for the chaotic spread of information as well as misinformation. This paper suggests a new method to relieve the online stress, and therefore the real world second effects. In order to do that, available research is used on how nature changes one's emotional state, and calms it. The approach aims to extract the target propagators that need to be stress relieved the most in order to reduce the chaotic information propagation. The goal is to promote nature displays on their timelines. These displays are selected from users whose content is sponsored for promotion. On top of their usual targets, the platform's disruptive users are added in their target potential clients. In order to do that, a sentiment analysis method is developed and information from the social platforms is extracted. In the future works, other aspects are to be covered such as the use of emoticons, the observation of long-term effects of the algorithm on the main propagators and their respective social networks.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

With the advancements in technology, smart entities are becoming increasingly intelligent, therefore, increasing their interaction capabilities with their surrounding environment. Apart from the traditional smart low profile devices, these entities now involve cars, mobiles, televisions, and extend to universities and smart cities. One of the bi-product of the smart cities is the emergence of the concept of smart campus. The smart campus is a teaching environment, where dynamic interaction between students/users and the surrounding devices takes place using the paradigm of the Internet of Things (IoT). The Qassim University (QU) is considerably a large university having thousands of students and hundreds of functional units in the central building and also spread across the different cities of the Al-Qassim province. Therefore, the QU can be considered as a small city where many elements need to be connected and decisions be made. The QU thus represents an optimal and practical scenario for the concept of smart campus. With this spirit, the goal of this research is thus to investigate an Indoor Navigation System (INS) as a suitable platform for the QU. As such, the paper reviews the current technologies and opt for the best available and optimal options. For implementation and simulation, the BLE beacon is selected and user data is analyzed to design a mobile application that includes all the services requested by the users. The system architecture in addition to a 2D map presented in this research will help in identifying the locations of BLE beacons to cover the specific area. The work in this paper is conducted on the main campus of the QU; however, the extension to other setups involves minimum or similar infrastructure.

1. Introduction

Over the last decade, a smart city is one of the emerging concepts that aims to provide a smart livable environment for the resident. Cities as Singapore, Barcelona, San Francisco, London, etc., is an example of cities that apply the concept of smart cities. In [1], the author defined a smart city as "A city well performing built on the 'smart' combination of endowments and activities of self-decisive, independent and aware citizens". The Internet of Things (IoT) paradigm allows cities to manage and control every aspect of the city from buildings, roads, railways, to airports and traffics in a smart manner. IBM smarter planet project adopted the term of the smart city [2]. The smart city relies on six key factors: smart governance, smart people, smart economy, smart environment, smart life, and smart traffic [3]. Nowadays, the typical universities are considered as small cities that include most of the services available in the cities. The advancement of new technologies such as Artificial intelligence, IoT, and the availability of High-speed internet plays a big role in changing the living environment to be smart than ever before [3]. Smart universities also called smart campuses to compose one of the branches of the smart city concept that concern about every aspect inside the university; students, staff, visitors, classrooms, buildings, equipments, etc.[4]. Due to the popularity of the term of smart campus, we will use it in this research to refer to smart university. The smart campus concept can offer many benefits such as save cost and time, automate maintenance, protect the environment, automate students and staff attendance, track occupancy as well and many other benefits [5]. Several

*Corresponding Author: Mohammed Hadwan, Email: m.hadwan@qu.edu.sa

applications have been developed to make our campuses smart such as smart buildings, smart parking, smart learning, smart campus management, and maintenance, etc. [3].

Navigating inside large buildings, such as malls, hospitals, airports, and campuses, using an INS to help users to reach their preferred destination is highly required. INS is investigated in this research due to the huge size of QU main campus that has a similar interior design where finding places is a very difficult task for visitors and even for students and staff as well. The available infrastructures at the QU campus encourage us to explore this idea to make campus life easier and smarter. The main problem of INS is the signal unavailability of a Global Positioning System (GPS) inside buildings because of the walls and other barriers [6]. Smartphones, smart glasses, smart watches are widely spread and used heavily for INS because of the different sensors that is equipped with. Therefore, the aim of this paper is to investigate and identify the obstacles and barriers that could stand against devolving suitable INS for QU main campus.

2. Background

Smart cities with their different technologies and services are one of the active research areas where many survey papers have been published recently [1-5, 7, 8]. The Kingdom of Saudi Arabia is among the countries that apply this concept to change its traditional cities to become smart cities [9]. The smart campus is a concept where many universities working on several projects to adopt this concept such as King Fahd University of Petroleum and Minerals[10], Lancaster University [11], University of Malaga [12], University of New South Wales in Australia [13], etc. The services and applications offered by smart campus are varied. These services aim to make the universities surrounding smart includes but not limited to buildings, laboratories, libraries, classroom, attendance system, grid, learning, parking, navigation, waste and water management and etc. For more information about the smart campus, services refer to [3, 4, 14-15]. Due to the complex mixture of elements and devices to be connected, many expected and unexpected problems might appear and need to be addressed. For instance, internet coverage [16], energy consumption [17], sensory network [18], location-based services [19] etc.

In [20] researchers discussed different types of INS in the literature and highlighted the accuracy problem. In [21], the researchers give recommendations for the user interface design of INS based on the case study conducted by them. They found that it is important not to put heavy details in the map and to simplify the graphical layout. In [22] an android-based application is introduced for indoor navigation inside public buildings using Near Field Communication NFC and Quick Response codes QR. Several features include finding a destination with the shortest path, store the location of car parking, finding the nearest toilet, etc. Smart phones used for INS as in [23] where mobiles used for navigation using wireless access point fingerprints help an individual to get their direction with the indoor space using navigation application. Researchers in [24] Proposed Vision-based approaches for mobile indoor localization based on the combination of Virtual Reality (VR) and Augmented Reality (AR) in order to help in ensuring the accuracy of the localization.

Since the focus of this paper is to develop an Indoor Navigation platform for QU, in the following section we will review the current technologies used for INS. The researches in INS is still active, several survey papers published currently to explore it in detail as in [6, 25-27]. As the signal of GPS cannot reach the devices in indoor areas, several telecommunication technologies were introduced to overcome this problem. For example, Wireless Fidelity (Wi-Fi) [28, 29], Radio Frequency Identification (RFID) [30], Infrared technology (IR) [31], Ultra-Wide Band (UWB) signals [32] and Bluetooth low energy (BLE) beacons[33].

BLE beacons are a relatively new technology with the advantage of low energy consumptions that small batteries can be used for months up to years [34]. Based on the research conducted by [35] to study the localization accuracy between BLE and WIFI. The findings show that BLE was more accurate than WIFI at identical places. According to [36] BLE is a promising technology that has a low deployment cost and appropriate for most mobile devices. iBeacon is the name of Apple's brand of BLE technology based on the micro-localization and the interaction of a mobile device [34]. BLE beacons need to care about the radiation pattern of a given device and possible attenuation element in the chosen places [37].

3. Data Collection and Analyses

User preferences are very important to build effective systems. Therefore, a questionnaire developed and published to collect the user preferences and other necessary data to get insight into the difficulties they faced inside the QU campus. Responses collected from 454 students, lecturers, and general staff. The questions dedicated to familiar and unfamiliar users for the QU campus. The main services and tools requested by the respondent to be available in the QU INS application are presented in table 1.

Table1: The percentage of each place & service required by users

No.	Places & Services	%
1	Places and services around current location (Prayer room, toilet, cafeterias, garden, shops, Photostat, parking, students clubs, gardens etc.)	98%
2	Timetable and office hours information of staff	96%
3	Search by name, Map and around current location	95%
4	Announcements	93%
5	Laboratories	91%
6	Location of new events	91%
7	Classrooms location	90%
8	Examination room location	90%
9	Staff members offices	87%
10	Emergency exits	81%
11	Library	74%
12	Administration offices	31%

The gender, age, user type (student, lecturer, staff, or visitor), preferred services to be available in the system, and other questions been asked and responses obtained. The collected data have been analyzed and important information extracted as follows, refer to Figure 1 and Figure 2:

1- 91% Preferred to have an application that can help to ease the indoor navigation inside the QU campus.
2- 73% of respondents are facing some difficulties in finding locations especially when they visit the QU main building.
3- 100% of respondents never used an INS before.

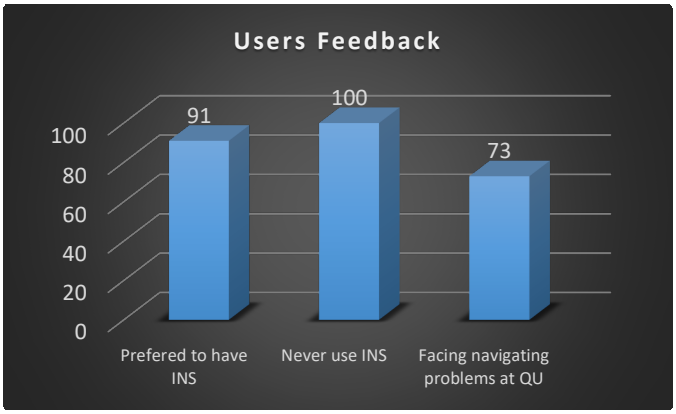

Figure 1: The user's responses to the general questions in the questionnaire.

4. Proposed INS for QU

Based on the extracted information from the questionnaire, a framework for the INS of QU is developed. Figure 3 shows the framework for QU INS, which includes two sections. A section for users where they can search for locations, navigating to desired locations, positioning their current locations, and access the main page where they can modify the settings based on their desire.

The second section is for the developers, where they can develop the INS software, upgrade hardware, add locations, and its information to the database and update the navigation map.

Figure 4 presents the system flowchart for the users where they can search for a location, positioning their selves, and navigate to the desired location. Searching can be through the map our using keyword. For positioning service where it shows the current location of the user in addition to the nearest services around. The navigation service used to guide the users from their location to a specific location inside the building. Based on the literature, BLE beacons are a new, cheap, and popular technology for INS. This encourages us to use BLE beacons to assist in navigation and positioning the users. BLE beacons broadcast their identifier to the nearby devices.

In order to deploy the minimum number of BLE beacon devices, Figure 5 shows the device's location that is enough to cover a single location at the Department of IT, where each beacon covers approximately 62 maters. Each BLE beacon has its own unique ID and for every wall, a boundary segmentation starts from 0 for the first wall, 1 for the second, and so on.

Walls need to determine the sides either left or right. To calculate the position of an object in indoor areas, at least three timestamps from different BLE beacons are needed. A mobile application is designed based on the gathered requirements from the users. Figure 6 shows some examples of screen shots for QU INS. The users can search by names, on a map, or around their current location.

5. Conclusion

The QU is considerably a large university having thousands of students and hundreds of functional units in the central building and spread across the different cities of the Al-Qassim province. Therefore, the QU can be considered as a small city where many elements need to be connected and decisions are made. The QU thus represents an optimal and practical scenario for the concept of a smart campus. As such, we addressed the INS at the QU in this work. We presented a literature review for smart campuses in general and smart universities in particular. In the INS, several technologies are explored for solving navigation and positioning in indoor areas. For an implementation and simulation perspective, the BLE beacon is selected because the BLE beacons are cheap, reliable, having a longer battery life. As such 454 user data is analyzed and is used to design a mobile application that includes all the services required by the users. The system architecture in addition to a 2D map helps in identifying the locations of BLE beacons to cover the whole area of the Information Technology Department at the College of Computer in QU. The system architecture is scalable in order to accommodate any building size. The work in this paper is conducted on the main campus of the QU; however, the extension to other setups involves minimum or similar infrastructure.

ABSTRACT

In this study, the ASTM A48 Class 30 gray cast iron was cast in a medium frequency induction furnace. The ultimate tensile strength (UTS), ultimate flexural strength (UFS) and microstructure were determined in accordance with ASTM E8/E 8M-80 and ASTM A438-80 (1997). From the results of this study, the graphite size at overheating temperatures 1350°C was smaller than that at 1300°C. Moreover, if the holding time was sufficient, the nested sheet graphite would be completely destroyed. Particularly, in the case of holding time from 5 to 20 minutes, the UTS, UFS are increased and the graphite shape got fine. The smallest graphite size and the highest UTS, UFS values were achieved if 20 minutes holding time is carried out. However, the holding time increased to 30 minutes, the graphite size tended to grow larger, and the UTS, UFS values suffered a decline. In addition, decreasing the average pouring temperature from 1350°C, 1300°C to 1260°C caused the upward trend of the graphite average sizes which were fit with the downward trend in the UTS and UFS values. From the above results, it is possible to determine the casting conditions that can improve the quality of cast iron products in induction furnace are: the optimal average pouring temperature is 1300-1350°C, while the optimal holding time is 10-30 minutes.

1. Introduction

Gray cast iron is a widely-used material in the machinery industry. A typical product of gray cast iron is engine segments. Currently, Vietnamese engine segments are still not high-quality products due to the contamination of cupola furnace technology. In addition, the insoluble coke in the casting process will generate graphite in the form of nest sheet graphite, as shown in Figure 1. As a result, the graphite sheet in the engine segments is also usually in the form of a nest [1]. This is an undesirable form of graphite that negatively impact the mechanical properties of cast iron since the graphite nests break up the continuous of the cast-iron structure, as also the place that the stress concentrated. Therefore, the cast iron has a low flexural and tensile strength [2-4].

Graphite is extremely soft and is considered as a crack that separates the cast iron matrix. The size, shape, and distribution of graphite strongly affect the mechanical properties of cast iron graphite through the microstructure. In [5] the author presented that the main influences on flexural strengths are the shape and the graphite size. Author in [6] obtained that the impact of graphite shape on corrosion vulnerability of gray cast iron in an acidic environment is eclipsed; the vermicular shape of graphite, profitable from the perspective of mechanical and tribological properties might facilitate the destruction of cast iron under the corrosion erosion environment. A similar result was reported by research [7] that the tensile strength of the unidirectionally solidified samples is not as strong as that of spheroidal graphite cast iron because the fracture occurs at the graphite-terminated area in the aligned graphite samples. Study [8] investigates four flaky graphite cast irons of different graphite structures with a pearlitic matrix, results showed that the eutectic graphite structure wore down faster than the flaky graphite structure did, the type of graphite morphology influenced the specimen wear rate as strongly as the graphite volume fraction did in flaky graphite cast irons of this experimental range. The tensile strength of cast iron graphite is only 0.3-0.5 of the tensile strength of steel whose composition corresponds to the base of gray cast iron. Flexural strength and tensile strength of cast iron graphite is only 0.4-0.7 of flexural strength and tensile strength compared to the corresponding values of the steel that has the same composition as the iron matrix.

In general, the mechanical properties depend on the size, shape, and distribution of graphite which dependent components and pre-cast conditions treatment, additives, slag, furnace, temperature and holding time, the chemical composition of cast iron, cooling rate... [9,10]. Particularly, the graphite with nest sheet shape leads to the low value of the mechanical properties of cast iron [11,12]. However, the studies of the pouring temperature and holding time on the mechanical properties of gray iron are very limited. In [13,14], the authors described the effect of cooling rate on microstructure and mechanical properties of gray cast iron and the effect of pouring temperature on fluidity, porosity, and surface roughness of gray cast iron. According to [5], the pouring temperature plays a key role in constructing the tensile strength and elongation of the cast iron, besides the graphite factor, chemical composition and matrix microstructure also contribute to the tensile strength. Research [15] proves that the faster solidification in the microstructure, the lower the values of the mechanical properties. Results of [16] show that the mechanical properties and microstructure of compacted graphite iron depend on holding time, increasing the holding time from 10 min to 17 min results in lowering the Mg content from 0.031% to 0.021% and as a result lower nodularity was obtained, in addition, lowering the thickness from 20mm to 5mm increases the tendency of the dendritic structure as a result of increasing the cooling rate. In which, the studies on the influence of shape, size, and distribution of graphite on the mechanical properties of gray iron is still very limited. This report focuses on controlling the pouring temperature and holding time to destroy the nested sheet graphite and form a better graphite shape to improve the mechanical properties of cast iron.

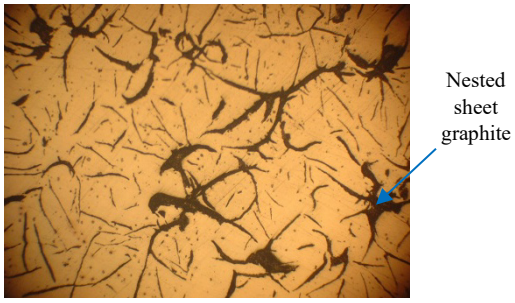

Figure 1: Microstructure of nest sheet graphite cast iron (50X magnification)

2. Experimental

2.1. Materials and Experimental Method

The material composition for the experiment is shown in Table 1. This composition is used to cast gray cast iron with grade 30 of ASTM International standard A48 for small electric motor covers whose capacity is less than 5kW. Cast iron experiments are made at Muoi Hoi Binh Duong Co., Ltd., as shown in Figure 2, without using the nodulizing elements. Initially, the mixed ingredients are fed into a medium frequency induction furnace, with a capacity of 1000kg/batch. The furnace runs for 10 minutes with low amperage to stabilize the frequency. The current then gradually increases to the maximum intensity for 1 hour 30 minutes. The crucible is covered by the acidic powder that allows desulfurization. Due to the rotating magnetic field, cast iron begins to melt and mix relatively well. The furnace is maintained at a constant current for half an hour to allow the cast iron to completely melt and the cast iron temperature is stable. Then, the cast iron temperature is increased to the pouring temperature as required. The pouring pot is pre-dried with a charcoal furnace to a temperature that is greater than 1000°C. The old sand mixture with good ventilation is used, mold is dried naturally. The mold is made by a pneumatic system to ensure uniform tightness of the mold, thus ensuring the heat transfer and exhaust mode.

Table 1: Material composition for experiment

No.	Composition
1	Cast iron scrap, recovery materials in casting production (filling system, shrinkage, broken casting)
2	Ferrosilicon 30-70, with 1-2%
3	Ferromanganese 50-50
4	$CaCO_3$

Figure 2: Medium frequency induction furnace at Muoi Hoi Binh Duong Co., Ltd

Table 2: Overheating temperatures, holding times, and average pouring temperatures

Sample	Average overheating temperatures (°C)	Holding times (minutes)	Average pouring temperatures (°C)
S1	1350	5	1350
S2		10	
S3		20	
S4		30	
S5	1300	5	1300
S6		10	
S7		20	
S8		30	
S9	1300	5	1260

Table 2 shows the cast iron samples are cast with different overheating temperatures, holding times, and average pouring temperatures. The layout of the experimental samples in the sand mold and the samples after casting are shown in Figure 3. The temperature is measured with the AS892 Infrared Thermometer. Some basic specifications are described as following: temperature range 200°C ~2200°C, accuracy ± 2°C, distance spot ratio 80:1, emissivity 0.10~1.00 adjustable, resolution 0.1°C, wavelength 900~1700 µm, response time 500ms, repeatability ±1°C.

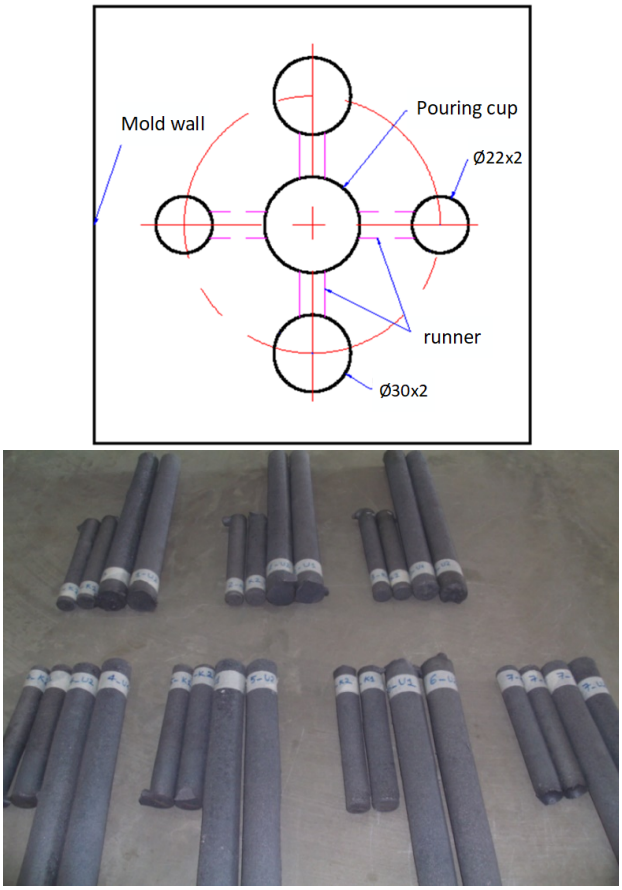

Figure 3: The layout of the experimental samples in the sand mold and the samples after casting

2.2. Methods of Observing Microstructure and Testing Mechanical Properties

Tensile test and Flexural test are conducted at Quatest 3 center, Vietnam, following the ASTM E 8/E 8M-80 (Figure 4) and ASTM A 438-80 (1997) (Figure 5) standards.

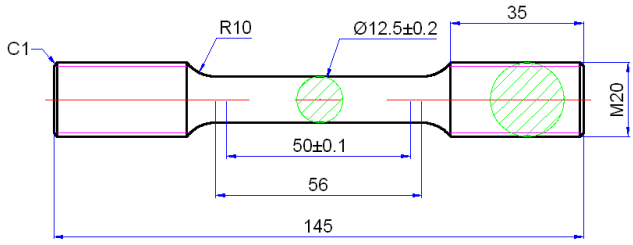

Figure 4: Tensile sample size standard ASTM E 8/E 8M-80

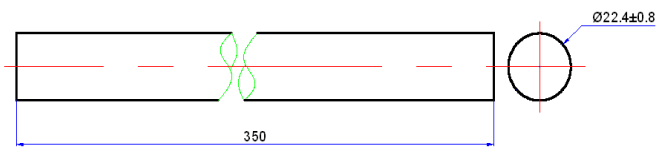

Figure 5: Flexural sample size standard ASTM A 438-80

The microstructure of the samples are observed at Materials Laboratory at Mechanical Faculty, University of Technology and Education, HCMC. The graphite size calculation is based on TCVN 3902-84.

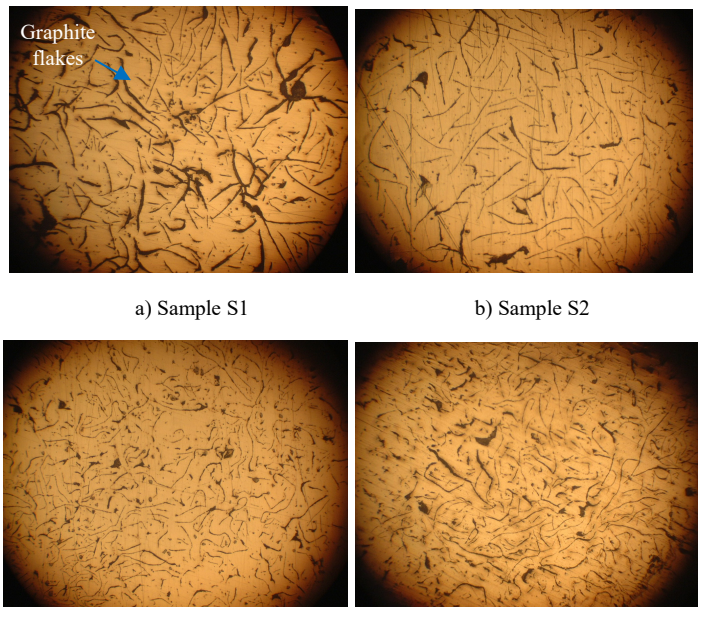
3. Results

3.1. Effect of Holding Time on the Graphite Shape

This section considers the effect of holding times and average pouring temperatures to identify the influence of these factors on the amount of graphite and the time needed to destroy the nested sheet graphite. Figure 7 illustrates the microstructure of the samples that overheated at 1350°C and holding at 5-30 minutes. These microstructures indicate that increasing the holding time leads to a decline in the graphite amount. Moreover, the graphite shape is also different with different holding times. Improving the holding time also reduces the number of nested sheet graphite. Interestingly, if the holding time is long enough, the nested sheet graphite will disappear, as shown in Figure 7(d).

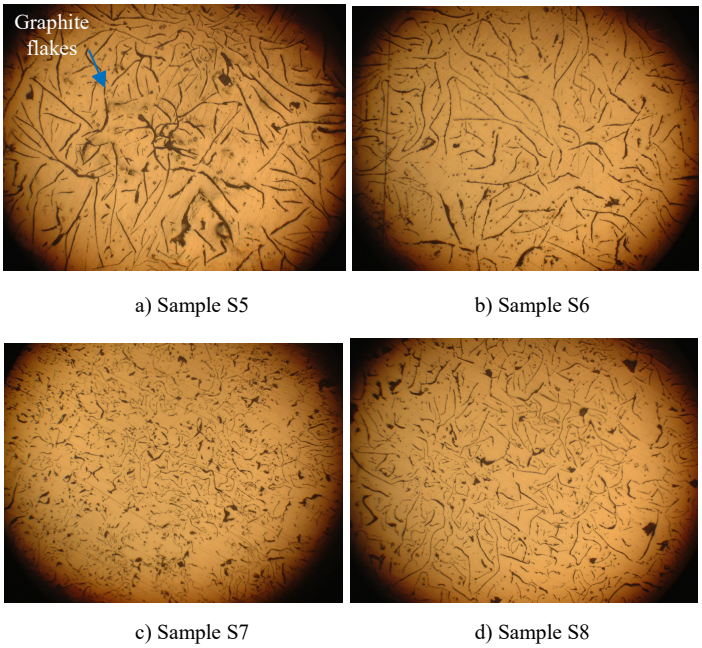


a) Sample S1 b) Sample S2

c) Sample S3 d) Sample S4

Figure 7: Microstructure of samples pouring at 1300oC at different holding time: (a) Sample S1 (holding time 5 minutes), (b) Sample S2 (holding time 10 minutes), (c) Sample S3 (holding time 20 minutes), and (d) Sample S4 (holding time 30 minutes) (50X magnification)

Figure 8 exhibits the microstructure of the samples that overheated at 1300°C and holding at 5-30 minutes. In general, improving the holding time results in a lower amount of graphite. In addition, the graphite shape is also different with different holding times. Similar to 1350°C cases, if the holding time is long enough, the nested sheet graphite will be destroyed, as shown in Figure 8(d).



a) Sample S5 b) Sample S6

c) Sample S7 d) Sample S8

Figure 8: Microstructure of samples pouring at 1350oC at different holding time: (a) S5 (holding time 5 minutes), (b) S6 (holding time 10 minutes), (c) S7(holding time 20 minutes), and (d) S8 (holding time 30 minutes) (50X magnification)

The average size of the graphite sheet at different overheating temperatures and different holding times is showed in Figure 9. Initially, increasing the holding time from 5 to 20 minutes results in finer graphite. However, if the holding time increases to 30 minutes, the graphite size will get bigger. The smallest graphite size is achieved by holding at 20 minutes. Moreover, the graphite size at 1350°C is smaller than at 1300°C.

The reason is that with a higher temperature and a longer holding time, the liquid cast iron is stirred stronger as the viscosity of the cast iron is lower. The stronger stirring results in finer graphite. The higher temperature also causes a more stable state, and a higher trend of overcooling of the casting liquid. However, holding too long could lead to an unstable graphitization process [3,4]. When overheated, the amount and the shape of graphite changes. As the overheating of cast iron increases, the graphite becomes smaller and changes its distribution characteristics. Firstly, the eutectic form of graphite changes, then the number of dendrites will increase. Overheating facilitates the formation of graphite between dendrites which also depends on the composition of the cast iron (carbon and silicon). When the overheating temperature increases, the graphite will strongly smooth out, proving that there is some solubility of these phases and increasing the dispersion of these phases. However, overheating does not facilitate the complete dissolution or agglomeration of these phases. Traditionally, the graphite in gray cast iron could be viewed as a void, and the cracks initiate at the tip of the graphite flakes due to the micro notch stress concentration. The deformed graphite flakes, an optimized microstructure, reduced the stress concentration and prevented the expansion of cracks at the tip of graphite [11]. In [9], the author explains that cast iron slug samples all had average flake lengths of 80-100 µm, and maximum flake lengths of 1000-1400 µm due to the drastically slower cooling rate in this mold configuration compared to the cooling rate in the commercial rotors. This suggests that either there is a limit to how much the diffusivity can be improved by increased flake length or that other factors limited the diffusivity of the gray iron from these large castings. According to [16], holding time displays a reasonable effect on the progression of residual magnesium that identifies with the fading process.

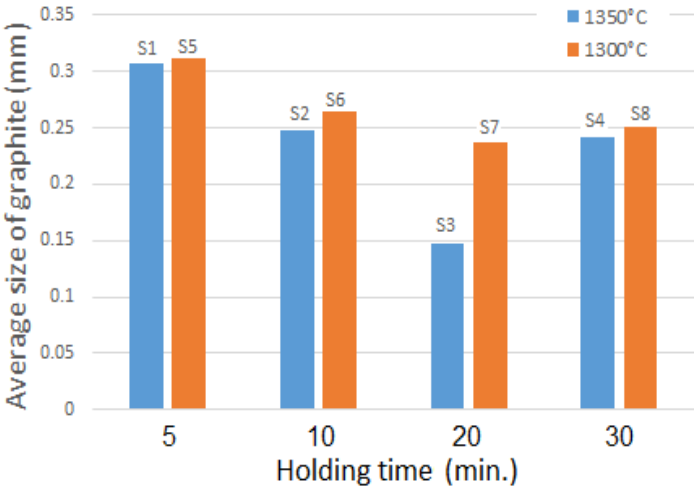


Figure 9: The average size of graphite sheet with different holding times and overheating temperatures

In conclusion, the optimal microstructure is obtained by holding at 10-30 minutes at 1350°C. Casting the gray iron in the medium frequency induction furnace can destroy the nested sheet graphite.

3.2. Effect of the Holding Time on the Mechanical Properties

Table 3 and Figure 10 present the ultimate tensile strength (UTS) of the samples at different holding times and overheating temperatures. These results indicate that the UTS rises as increasing the holding time from 5 minutes to 20 minutes and gaining the best UTS value at 20 minutes. Thereafter, the UTS suffers a decline as the holding time continues to increase from 20 minutes to 30 minutes.

Table 3: Tensile test results

Sample	Fracture force P_b (kN)	Tensile strength $\sigma_b=P_b/F_0$ (MPa)
S1	17.6	145
S2	18.1	150
S3	18.9	154
S4	18.0	148
S5	15.7	129
S6	16.0	132
S7	16.4	135
S8	15.8	130

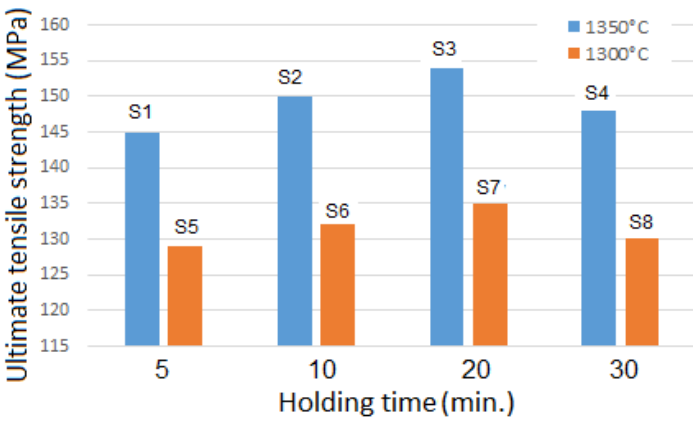

Figure 10: Ultimate tensile strength of the samples with different holding times and overheating temperatures

Table 4 and Figure 11 represent the ultimate flexural strength (UFS) of the samples at different holding times and overheating temperatures. Similar to the UTS value, the UFS increases as improving the holding time from 5 minutes to 20 minutes and reaching the highest value at 20 minutes. Then, this value decreases as the holding time increases from 20 minutes to 30 minutes. Interestingly, the results of both UTS and UFS values are consistent with the change of graphite size in section 3.1. In conclusion, the downward trend of the graphite size is fitted with an upward trend in the UTS and the UFS values. Therefore, decreasing the graphite size could lead to higher mechanical properties.

Table 4: Flexural test results

Sample	Resistance moment $W=\pi d^3/32$ (mm^3)	Ultimate flexural force P_u (kN)	Flexural moment $M_u=P_uL/4$ (kNmm)	Flexural strength $\sigma_{bu}=M_u/W$ (N/mm^2)
S1	1148.36	4.31	328.43	286
S2	1118.27	4.41	336.60	301
S3	1148.36	4.71	359.44	313
S4	1133.25	4.49	342.24	302
S5	1133.25	4.03	307.11	271
S6	1118.27	4.11	313.12	280
S7	1148.36	4.37	333.02	290
S8	1133.25	4.24	322.98	285

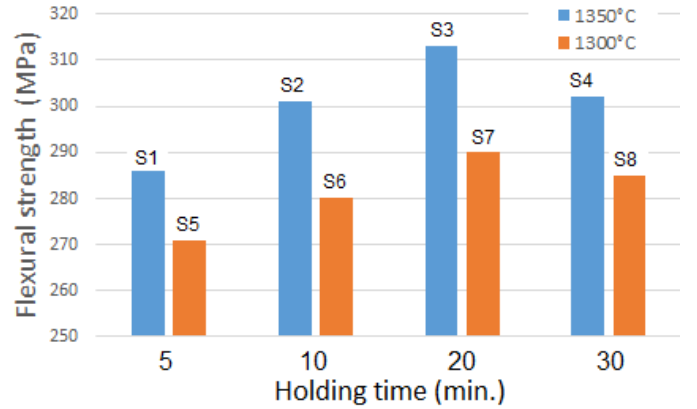

Figure 11: Flexural strength of the samples with different holding times and overheating temperatures

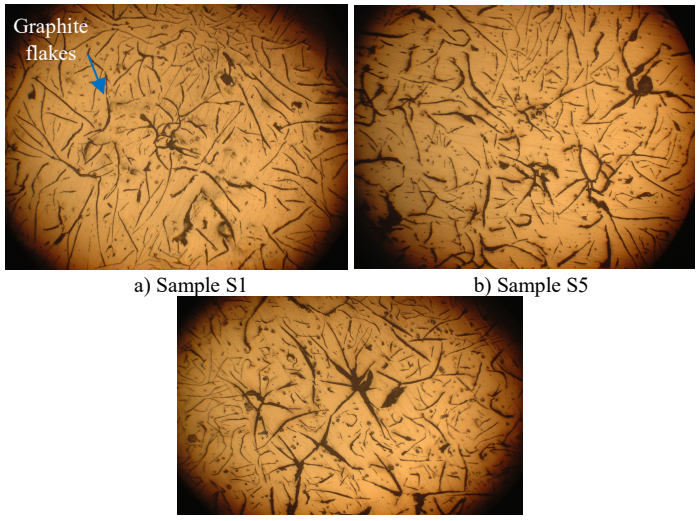
It can be seen that S4 and S8 samples with a holding time of 30 minutes have lower UTS and UFS values than the S3 and S7 samples with a holding time of 20 minutes. The reason is that, as the temperature and holding time increase, the viscosity will increase. The chemical composition and the amount of carbon are evenly distributed, therefore, the quality of the casting increases, the graphitization process happened more fully. However, if the temperature is too high and the holding time is too long, it will prevent the formation of liquid slag, increase the burn rate. In addition, the temperature difference between the liquid iron and the mold causes the graphitization process to occur unstably [4]. Therefore, choosing a holding time of 10-30 minutes is optimal.

The samples overheated at 1350°C and 1300°C gave different mechanical results. The reason is overheating changes the nature of the liquid phase and the differentiation conditions when solidified. On the one hand, overheating increases the stability of the liquid phase and increases its tendency to overcool. On the other hand, under the ideal solidification of a casting in a mold, overheating causes the preheating of the mold and changes the cold condition of the cast iron. Overheating requires a regular increase in the amount of bound carbon (reducing the amount of graphite) due to increased liquid phase stability and its tendency to over-cool. Overheating will limit impurities present in the liquid phase and make them more evenly distributed. In addition, the different overheating temperature will result in different morphology of graphite. The study [11] showed that the distribution and morphology of graphite has a direct influence on the properties of gray cast iron oriented the space orientation of the graphite flakes in gray cast iron and improved both strength and ductility.

3.3. Effect of the Average Pouring Temperature on the Graphite Size and the Mechanical Properties

This section surveys the effect of the average pouring temperature on the graphite size and the mechanical properties of the gray iron. The samples S1, S5, and S9 are chosen and analyzed.

Figure 12 and Table 5 show the microstructure of the cast iron and the average size of their graphite. These results indicate that decreasing the average pouring temperature will cause a rise in the graphite average size.



a) Sample S1 b) Sample S5

(c) Sample S9

Figure 12: Microstructure of samples pouring at different temperatures: (a) Sample S1, (b) Sample S5, and (c) Sample S9 (50X magnification)

Table 5: The effect of the average pouring temperature to the graphite size

Sample	Holding time (minutes)	Average pouring temperature (°C)	Average size of graphite (mm)
S1	5	1350	0.307
S5	5	1300	0.312
S9	5	1260	0.339

Table 6: UTS and UFS values at different average pouring temperatures

Sample	Average pouring temperature (°C)	UTS value (MPa)	UFS value (N/mm^2)
S1	1350	145	286
S5	1300	129	271
S9	1260	126	270

The UTS and UFS of the sample S1, sample S5, and sample S9 values at different average pouring temperatures is demonstrated in Table 6. The result points out that reducing the pouring temperature leads to a decline in the UTS and UFS values. The result is that the lower pouring temperature leads to the larger graphite size. Therefore, the larger graphite size will result in lower mechanical characteristics. Moreover, the higher temperature of the casting liquid will cause a lower viscosity and a better chemical uniformity. At a low pouring temperature of 1260°C (sample S9), the viscosity of the casting liquid is high, the chemical composition is not evenly distributed. To achieve a higher level of uniformity, the casting liquid can behold for a longer time. However, the longer time will cause a loss in the chemical composition as they are burned out or going to the slag. Generally, to improve the mechanical properties of the gray iron, increasing the temperature is better than increasing the holding time. Increasing to too high a temperature will result in a worse slag, a higher level of chemical burning, and the more unstable the graphitization [14].

In conclusion, the optimal pouring temperature to obtain the best mechanical properties is 1300-1350°C.

4. Conclusion

Increasing the holding time from 5 to 20 minutes at 1350°C and 1300°C results in finer graphite, a smaller amount of nested sheet graphite. The finest graphite size is achieved at 20 minutes. Holding up to 30 minutes could destroy the nested sheet graphite, in which at 1300°C the holding time will be longer than overheating and keep the heat at 1350°C to completely lose the nested sheet graphite. However, increasing the holding time to 30 minutes will cause an increase in the graphite size.

- At 1350°C and 1300°C, the UTS and UFS values increase as the holding time improve from 5 to 20 minutes, and reaching the highest values at 20 minutes. Thereafter, these mechanical properties suffer a decline as the holding time increase from 5 to 20 minutes. The finer graphite results in higher UTS and UFS values.

- Declining the average pouring temperature from 1350°C to 1300°C, and then 1260°C (with holding time in 5 minutes and same cooling condition) leads to a finer graphite size and the better UTS and UFS values.

From the above results, the casting conditions that can improve the product quality is the optimal average pouring temperature is 1300-1350°C, while the optimal holding time is 10-30 minutes which will completely lose the nest graphite.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Portuguese organizations that have invoicing software, certified by the Tax and Customs Authority, need to comply with technical requirements that involve business continuity and disaster recovery. The recent tax legislative changes created conditions for the dematerialization of documents, allowing waiving invoice printing, encouraging the adoption of an electronic invoicing and document archiving system. The pandemic situation boosted the need for organizations to integrate this paradigm in their business processes. However, there are some constraints in the implementation of these requirements, due to technical issues, interpretation of tax legislation or the selection of frameworks or good practices for Information and Communication Technologies. The objective of the work is to present a set of concerns underlying the design of a business continuity plan, supported by current tax legislation, by standards and codes of good practice. In view of the constraints of Portuguese business capacity, it is also presented a minimum solution that meets the legal, regulatory, good practices and conceptual requirements of Information and Communication Technologies for initiating the design of a Business Continuity Plan. The method used in this investigation was based on the analysis of international standards ITIL, ISO, CMMI, COBIT through the assertive interconnection with the subject under study with the dispositions stated in the Portuguese legal framework in the field of invoicing. The main result was the conception of a decision support process for designing a guide, concerning the optimization of the business continuity plan design process. In face of the problematic in study, it is considered that the main expected results were achieved, by fostering the design of Business Continuity Plan in Portuguese organizations, in order to reduce the gap between the practices currently in place and the requirements underlying certification, as a way to prepare organizations to deal with disruptive events in invoicing business processes.

1. Introduction

This work is an extended version of the paper [1] originally presented in 2019 at the 14th Iberian Conference on Information Systems and Technologies (CISTI), where some guidelines for the conception of o Business Continuity Plan (BCP) were presented, having in consideration the organization capabilities and the tax and legal obligations.

Since this is a new study, there are limited implementation results to present. Nevertheless, the companies questioned referred to the need to implement electronic archive to reduce costs, optimize business process and archiving procedures and find information faster. This extended version attends those concerns and goes a step further by integrating those requirements in the analysis, providing a new tool to cope with constraints during the pandemic situation.

The above direction presents further the Business Continuity (BC) components and updates the guidelines for the BCP. Now it is induced a key perspective in the development of the guidelines, including the forced paradigm of remote work and the constraints for business operations, consequence of a pandemic situation. Organizations must endeavor and adapt to resist the changes or

*Corresponding Author: Nelson Russo, al70461@utad.eu

thrive with the opportunities and continue the digital transformation.

Adding to this situation, in recent years, the software development industry has been faced with legislative changes, which include more functional, and tax or fiscal requirements. By legal imposition, there was an expansion on the range of organizations covered by the obligation to have Invoicing Software (ISw) certified by the Autoridade Tributária e Aduaneira (AT), the Portuguese Tax and Customs Authority.

The resulting legislative simplifications created conditions for the dematerialization of documents, providing for the possibility of dismissing invoice printing, encouraging the adoption of an electronic invoicing and electronic document archiving system.

Thus, measures of sustainability and cost reduction were incorporated, namely, the reduction of file space, reduction of paper, consumables and printing hardware, allowing also to expand the optimization and automation of invoicing and archive procedures. These measures may be a stimulus for organizations to invest in the development and use of new technological instruments, incorporating a philosophy of innovation and sustainability.

In this sense, having in mind that ISw are one of the components of Information Systems (IS), they are subject to a specific framework in the tax area and to a set of functional requirements that aim to ensure data integrity, security of information and business continuity. In this work, the diplomas that frame and describe the technical requirements that the ISw must observe to obtain a certificate of conformity will be presented.

Whether due to the investment capacity, the integrated knowledge of the requirements involved, the interpretation of the diversity of existing standards and good practices, the perception of imminent risk or simply the definition of priorities, some organizations have not yet started designing the BCP or have the notion that technology will simply solve problems during, and after, a disruptive event in their activity. A BCP does not necessarily need to have a high degree of complexity, in the case of small organizations. It is commonly discussed that the pertinence of analyzing risks, understanding how to continue the business in the event of a disaster and to recover from that disaster are crucial activities in business continuity and that should be understood as adding value to organizations and not just as a requirement to meet to be compliant. However, the failure to define a BCP makes it difficult to comply with tax legislation in the context of the certification of ISw, increasing the duration in time of the certification process, usually in scenarios where organizations, for commercial reasons, need quickly to obtain the certificate issued by AT. In addition, the present pandemic situation triggered the need for organizations to transform digitally and to integrate their business software with electronic invoicing capabilities, especially for online sales.

Thus, the need arose to create a guide for the design of a BCP, to reduce the gap in organizations, between the perception of business continuity requirements and the requirements underlying the certification of an ISw, translating them into concrete proposals with due legal and fiscal justification, standards and good practices in the area of Information and Communication Technologies (ICT).

2. Literature review

The accomplished literature review presents business continuity as a program to be followed by organizations that intend to be prepared. It included the review of regulations in the field of the thematic, as well as the analysis of Data Centers and legislative needs underlying the certification of ISw.

2.1. Business Continuity

Organizations can be thought of as a set of value chains or business processes transversal to the various organic units that compose them [2]. Economic, technological and human uncertainties have long presented organizations with the possibility of crises arising, impeding their ability to operate and maintain their business processes and, finally, survive [3].

Organizations increasingly realize the importance of adopting proactive approaches, it is essential to safeguard business processes and the relationship between them, in order to achieve business objectives [4]. Thus, organizations must prepare themselves in the event of disruptions to their productivity and competitive capacity, especially in business processes, supported by ICT services, made available to the organization.

With this in mind, organizations must develop a set of policies and procedures to minimize the impact of these disturbances. The importance of these measures is emphasized, whose impact may affect productivity and competitive capacity, especially in the case of organizations whose dependence on ICT services is marked. This is the concept underlying the BC, in which an organization must have the strategic and tactical capacity, to plan and respond to business incidents and interruptions [5], in order to continue business operations, at an acceptable level predetermined.

One of the accepted responses in BC is Disaster Recovery (DR), defined as the process performed by an organization, to resume business services, after a disruptive event [6]. In this sense, the authors advocate a DR planning approach [7], favoring the recovery of business processes, especially those supported by ICT service.

However, organizational resilience can be understood, as the ability to increase the probability of continuity of any system against disruptive incidents, whether are internal or external variations, changes, disturbances, disruptions and surprises [4]. This concept of resilience also covers effective planning for the relaunch of business processes in the short term, with the BCP, in addition to the long-term restoration, with the Disaster Recovery Plan (DRP) of interrupted operations, following disruptive events.

Being prepared for these events requires proactive planning of the organization's resources so that it can deal with disasters effectively and efficiently [8]. Therefore, the organization must plan its actions before a disaster occurs, taking into account the crisis management phases, resulting from a disaster, as proposed in Figure 1.

Thus, a BCP tries to eliminate or reduce the impact of a disaster and is designed to avoid or mitigate risks and reduce the time

necessary to restore conditions to a state of normal operation [10], aiming to preserve the assets of an organization [11].

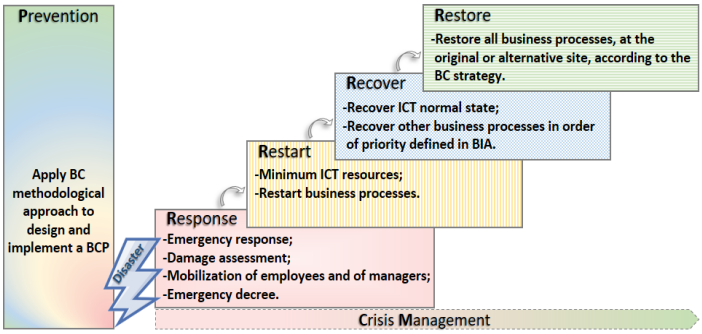

Figure 1: Stages of a business interruption. Adapted from [9].

Some vital activities are identified by Hiles [11], who considers the development of the BCP as a project, with a defined scope, with the analysis of risks and identification of the organization's specific key threats. Through the systematic process of Business Impact Analysis (BIA), vulnerabilities are revealed and it is determined and evaluate the potential effects, or impact on business, of an interruption. The definition of the strategy and requirements for technological resources is a success factor and it is essential to test, exercise and provide training on the BCP [11].

Figure 2 shows the essential components of the Business Continuity Management (BCM), according to the literature review and the standards presented in this work: the contribution of the International Organization for Standardization (ISO) through ISO 22301:2019, ISO 22313:2020 and ISO/IEC 27031:2011, the National Fire Protection Association (NFPA) emergency preparedness standard called NFPA 1600. Includes the vision of the Information Technology Infrastructure Library (ITIL), the perspective of the Control Objectives for Information and related Technology (COBIT) and Capability Maturity Model Integration (CMMI).

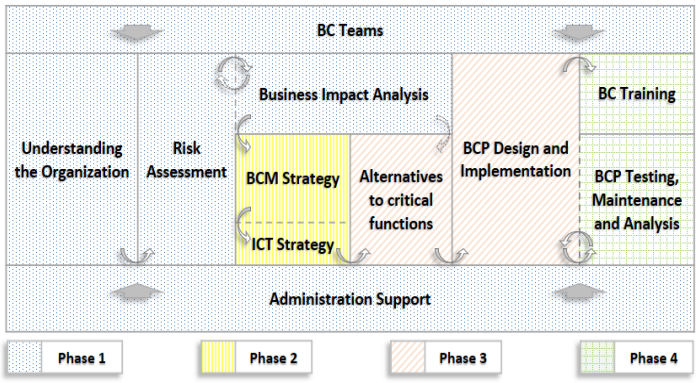

Figure 2: BCM components. Adapted from [12]

Figure 2 presents a sequence of action and interrelationship of the components of the BCM. It also presents the time phasing, in the methodological approach for the design and maintenance of a BCP [12], suggesting the set of components that must be completed, to start another phase.

2.2. Data Center

The Data Center infrastructures must be seen as a guarantee of fail-proof and insurance of business continuity, but if there is a disruptive event, it should be at least as short as possible. The Uptime Institute created the Tier Classification System standard, which is the global language of Data Center performance [13] as a means of effectively evaluating it in terms of business requirements for system availability. It offers a consistent method of comparing unique and customized installations based on the expected performance or uptime of the site's infrastructure.

2.3. Standards

A set of standards was reviewed in order to incorporate good practices on the business continuity topic.

NFPA 1600 2019

Widely used by entities, NFPA 1600 2019 was adopted by the United States Department of Homeland Security as a voluntary consensual standard for emergency preparedness [14].

The standard consists of 10 chapters and 13 annexes in which a common set of criteria for all hazards is established in disaster, crisis and emergency management and business or operations continuity programs. It follows the Plan-Do-Check-Act approach, providing the fundamental criteria of preparation and resilience, including the planning, implementation, execution, evaluation and maintenance of programs for prevention, mitigation, response, continuity and recovery [15]. The standard may be applicable to public, private, non-profit and non-governmental entities.

ISO 22301:2019

The ISO 22301:2019, on the theme “Security and resilience - Business continuity management systems - Requirements”, is a standard for implementing a BC Management System and continuously improving the BC resources based on priorities and feedback management. It specifies the requirements for implementing, maintaining and improving a management system to protect against, reduce the likelihood of, prepare for, respond to and recover from disruptions when they arise [16].

ISO 22313:2020

The ISO 22313:2020 standard, with the theme “Security and resilience - Business continuity management systems - Guidelines on the use of ISO 22301”, provides guidelines and recommendations for the application of the requirements of the Business Continuity Management System (BCMS) indicated in ISO 22301. The guidelines and recommendations are based on international good practices. This standard is applicable to organizations that implement, maintain and improve a BCMS [17], who seek to ensure compliance with the stated business continuity policy, who need to be able to continue delivery of products and services, at acceptable predefined capacities following a disruption and who seek to improve their resilience through the effective application of the BCMS.

ISO/IEC 27031:2011

The International Standard ISO/IEC 27031:2011 entitled “Information technology - Security techniques - Guidelines for information and communication technology readiness for business continuity”. This standard describes the concepts and principles of ICT readiness for business continuity, and provides a framework of methods and processes to identify and specify all aspects (such

as performance criteria, design, and implementation) for improving an organization's ICT readiness to ensure business continuity [18].

2.4. Reference Standards and Good Practices

Within the scope of standardization and improvement of business processes, there is a concern with the application of good practices. Thus, due to its relevance, this chapter presents the set of frameworks and good practices ITIL, COBIT and CMMI.

ITIL

ITIL 4 brings ITIL up to date by re-shaping much of the established ITSM practices in the wider context of customer experience, value streams, and digital transformation, as well as embracing new ways of working, such as Lean, Agile, and DevOps. ITIL 4 provides the guidance organizations need to address new service management challenges and utilize the potential of modern technology. The guidance provided can be adopted and adapted for all types of organization and service. It is designed to ensure a flexible, coordinated and integrated system for the effective governance and management of Information Technology-enabled services [19].

One to the Service management practices, under ITIL management practices, is Service continuity management. Its purpose is to ensure that the availability and performance of a service are maintained at sufficient levels in case of a disaster [19].

COBIT

COBIT 2019 was designed and created by Information Systems Audit and Control Association (ISACA). Is a framework for the governance and management of information and technology, aimed at the whole enterprise. COBIT 2019 is composed of 40 ICT processes in two fundamental areas, Governance and Management, divided into four domains. COBIT describes how an enterprise can design a customized and tailored governance solution for enterprise Information and Technology (IT) and should build its governance system for enterprise ICT [20].

COBIT defines the components to build and sustain a governance system: processes, organizational structures, policies and procedures, information flows, culture and behaviors, skills, and infrastructure. It defines the design factors that should be considered by the enterprise to build a best-fit governance system and addresses governance issues by grouping relevant governance components into governance and management objectives that can be managed to the required capability levels [20].

It was important in this work to characterize the focus on strategic alignment between ICT and business solutions; in the generation of value, but optimizing costs and ICT services; risk management, disaster recovery and continuity of operations.

CMMI

CMMI V2.0 is an integrated set of best practices that enable business to improve performance of their key business processes. It helps a business to understand its current level of capability and performance and its practices can guide improvement [21].

CMMI deals with various Capability Areas like “Managing Business Resilience”, that addresses the ability to anticipate, prepare for, and respond to interruptions in order to continue operations. Incorporates Practice Areas namely “Incident Resolution and Prevention” to resolve and prevent disruptions to sustains service delivery levels. “Risk and Opportunity Management” in order to identify, record, analyze, and manage risks and opportunities and “Continuity” to plan mitigation activities for disruptions to operations so that work can continue or resume [21].

3. Tax legislation

Portuguese tax legislation defines technical requirements for ISw [22] to guarantee data integrity, information security or business continuity and are described, briefly, in the legislation presented below. Some requirements establish the conditions to be observed when scanning and archiving in electronic format, intended to replace the respective paper archive. It also regulates the technical conditions for the issue, upon acceptance by the recipient, of invoices issued electronically and for their conservation and archiving, as well as for the existence and conservation of backup copies of the data supporting the ISw [23].

3.1. Decree Law No. 28/2019

The main objectives of Decree Law no. 28/2019, of February 15, of the Presidency of the Council of Ministers, are to promote legislative simplification and harmonize divergent rules on the conservation of documents for tax purposes. In this context, Decree Law no. 28/2019 created the conditions for the “Paperless invoice” and apposition of Quick Response (QR) code.

It provided for the possibility of waiving the printing of invoices and also strengthened the conditions for the dematerialization of documents, encouraging the adoption of an electronic invoicing system and electronic document archive, being an asset for the development of a more ecological vision, based on reducing the use of paper, inks and printing toners. The conditions created allow organizations to reduce costs with the fulfillment of tax obligations, stimulating the development and use by organizations of new technological instruments, incorporating a philosophy of innovation and debureaucratisation. For this purpose, a substantial reform of the rules applicable to the archiving of books, records, databases and supporting documents of accounting was introduced [23].

3.2. SAF-T (PT)

The Standard Audit File for Tax Purposes - Portuguese Version (SAF-T (PT)) is a standardized tax audit file for data export in Extensible Markup Language (XML) format, mandatory for ISw, created in 2007, with the publication of Ordinance 321-A/2007, of March 26, of the Ministry of Finance and Public Administration.

Its objective is to allow an easy export, at any time, of a predefined set of accounting, invoicing records, and relevant tax documents, in a legible and common format, regardless of the ISw used, without affecting the internal structure of the ISw database or its functionality [24]. The SAF-T (PT) file is intended to facilitate the collection and processing, in electronic format, of the relevant tax data. It allows simplifying procedures and boosting the use of new technologies [24], which may be the file that contains

the list of the relevant tax documents registered on archive. The most current SAF-T (PT) data structure is set out in Annex I to Ordinance No. 302/2016, of December 2, of Finance.

3.3. Decree Law No. 198/2012

The Decree Law no. 198/2012, of 24 August, of the Ministry of Finance, the starting point for the known E-Fatura service, creates a regime that regulates, namely, the electronic transmission of data elements of invoices and other documents with tax relevance, including printing of transport documents, to AT. Establishes measures to control the issuance of invoices and other documents of tax relevance, defines the means for its communication to AT and creates a tax incentive when the acquirer requires such documents [23].

It should be noted that this communication can be made through electronic transmission in real-time integrated with a certified ISw using a web service provided by AT or by sending the summary file, based on the file SAF-T (PT), exported periodically (usually monthly) by a certified ISw.

3.4. Invoicing Software Certification

Compliance with the provisions of Ordinance No. 363/2010, of 23 June, allows obtaining the title of an ISw certified by AT [25]. AT certification is important to foster compliance with the law and legal technical requirements and good ICT practices.

Taxable persons, whose obligation to issue an invoice is subject to the rules established in Value Added Tax Code (VATC), are obliged to use, exclusively, ISw that have been subject to prior certification by AT, whenever have had, in the previous calendar year, a total turnover exceeding 50,000 euros or are using an ISw or have organized accounting.

Thus, if organizations do not choose to use an ISw that have already been certified and intend to use those that they have produced, they should request their certification. To start the certification process, organizations must submit, on the Finance Portal, an official "Modelo 24" form.
