The traceability of operations as well as the recovery of traceability links between documents is an important phase in order to reduce the number of documents processed when the user launches a search query. All of the document techniques algorithms help automate the process to have better results and identify relevant documents with very good precision. The Spark environment takes into account the sheer mass of data and its exponential growth, as well as the analysis done, in order to meet needs and help make decisions.

For the implementation of our approach we have carried out tests on tools to show what the approach can guarantee for the improvement of document management. We used KNIME (KoNstanz Information MinEr) [49], a software developed in 2004 by the German University of the city of Constance (Konstanz). It is open source software written in java. KNIME is a tool that allows the design and execution of workflows using nodes that are already predefined as components of the platform. What is also huge is that this platform also allows the processing of large volumes of data depending on the resources of the user's machine (storage capacity, RAM, etc.); That is, there are no restrictions with regard to the volume of data or with regard to the platform itself. KNIME is an easy-to-use application, what you just have to respect is the order of operations as well as the logic of the process so you have to choose the node corresponding to the task seeking to be executed in order to make the execution of the workflow successful ; In KNIME, a node represents an entity that performs a well-defined task.

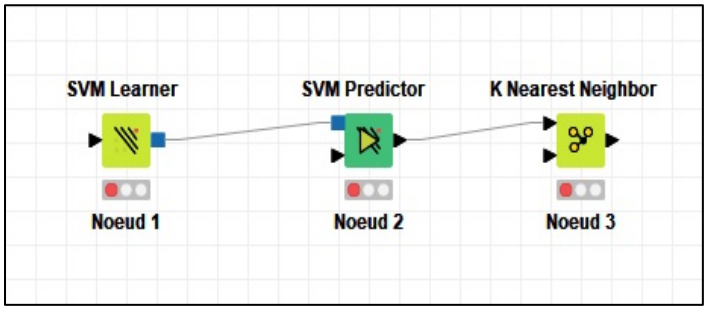

Figure 3: Example of node in KNIME

Figure 3 shows an example of nodes corresponding to the use of the VSM model with the KNN algorithm; The first node is used to train an SVM model against the input data. The second node uses the SVM model generated by the first SVM node to predict the output for given values. The third node classifies a dataset based on the KNN algorithm using the training data. A node consists of input, output and its state; if the state is in red it means that the node is not configured, if the state is in yellow it means that the node is well configured and if it is green, it means that the node is well executed, otherwise there is an error.

The visualization of the precision statistics shows in figure 4, the good precision taken with respect to the sets processed using the three types of VSM algorithm, Decision tree and KNN.

This approach is presented in the form of examples of tests in order to show the interest and the advantages brought to improve the management of documents by a system which allows to have a global vision on the history of the operations made on the documents. , as well as the relationship between them. On the other hand, it also makes it possible to facilitate the processing and application of information retrieval algorithms in order to extract adequate information according to specific needs. The use of the big data environment, especially Apache Spark, will allow to perform distributed calculations on a large volume of data and in a reasonable time. Our approach does not differ much from other approaches, but the proposed process has never been discussed in relation to electronic document management systems. On the one hand, we offer an important management of the traces made on the documents as well as the links between them, and on the other hand, by increasing the speed and the ease of treatment we offer the techniques of information retrieval as well as analyzes the distributed computing offered by Spark. While, the other works generally offer a classic system for managing documents manually. The works that offer tools for the electronic management of semi-automatic documents are rare, and those already existing are limited to private and commercial use.

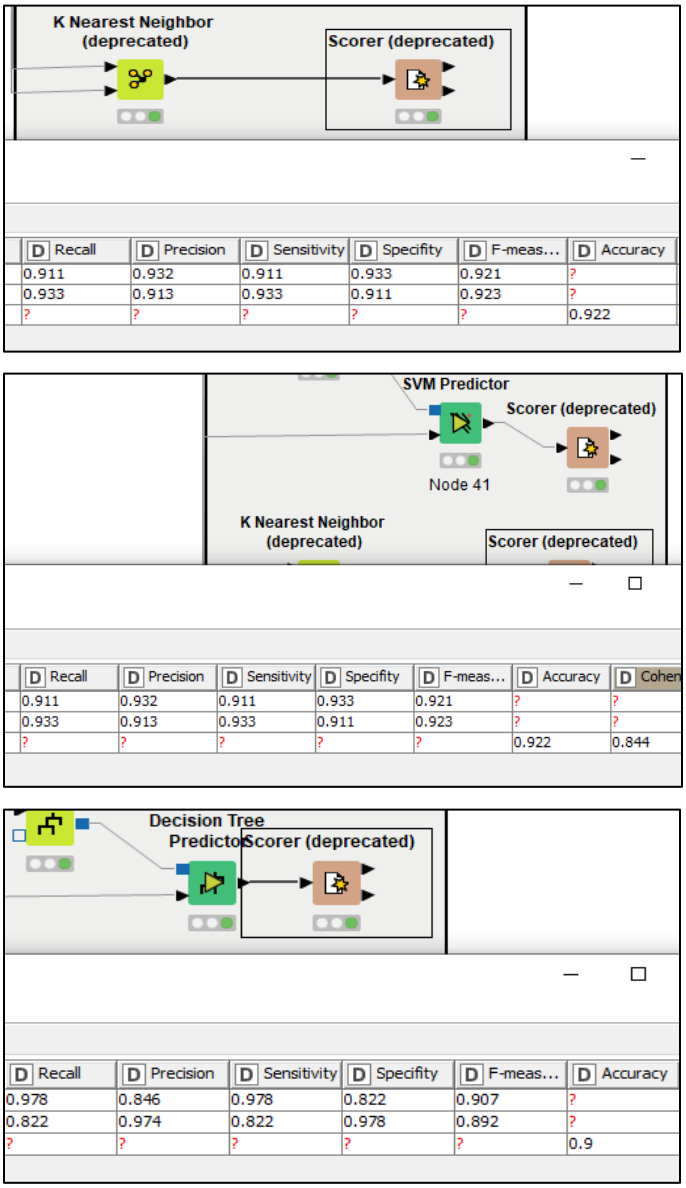

Figure 4: Precision statistics

4. Using Contents Recognition techniques in document management

4.1. Context

Several approaches to machine learning have been applied successfully to real world problems. Indeed, the choice of method in each case seems to be based largely on the experience and preference of the researchers involved. This success is also apparent in information retrieval applications, the different paradigms being used in similar proportions to those in other fields. Much of the information retrieval work can be automated. Processes such as document indexing and query refinement are usually done automatically, while document classification and term selection are more often done semi-automatically or manually. However, algorithms that classify documents by types to index information and model user interests to help them formulate queries, reduce workload, and ensure more consistent behavior. These algorithms are based on machine learning, a dynamic and growing field of computing.

The objective of this contribution is to propose an approach to improve document management based on information traceability retrieval but also on effective machine learning to extract data, create a model and provide a classification. Implementing such a solution could reduce administration costs, speed up the document delivery process and improve customer satisfaction in businesses. At the level of our proposal, we present a kind of multimedia management system; the use of machine learning also helps us in the automatic classification and extraction of data when a user adds any document (image, video, audio or text) to the corpus, using classification algorithms and content recognition algorithms. Until now, most companies simply scan these documents, index them with a date and number, and store them in a repository. There is currently a wide range of specialized algorithms for certain parts of document analysis. In large scale applications, these approaches must cope with the wide variety of documents. Machine learning algorithms are a possible treatment in this situation. From a set of documents, these algorithms are able to extract a lot of relevant data, and even they are able to weight this data in such a way that changing some information does not lead to a loss of performance. We aim in this work to propose an automatic classification of documents in predefined categories as well as by document type (image, video, audio or text). Supervised learning techniques are used for automatic classification, where predefined category labels are assigned to documents based on the probability suggested by a set of document training. Some of these techniques are described below. Several algorithms or combination of algorithms as hybrid approaches have been proposed for the automatic classification of documents. Among these algorithms there are VSM, decision trees and KNN (k-nearest neighbors) and their hybrid system with the combination of different other algorithms and techniques [50].

Computer systems that could learn to predict from a set of data and improve without having to be reprogrammed were a dream until recent years. But now, it has been made possible through machine learning. Today, machine learning is the most widely used branch of artificial intelligence which is adopted by major industries to benefit their businesses. Machine learning unveils a breakthrough science in how computers can learn and make predictions. It has applications in various industries and it is widely used. Machine learning has grown in popularity since its inception and it won't stop immediately. Data scanning is on the increase to help cut costs and save time, but simply converting documents using a scanner into an image or PDF file is not enough. A document in printed or handwritten form can be modified or edited at any time, which is not possible for a converted image. Thus, content recognition becomes a requirement to add search and edit functionality in a scanned document.

The most important documents and files today are stored in digital format. This is because digital storage is simple and does not involve physical storage space. In addition, the digital retrieval of documents is much easier than with filed paper documents. However, scanned documents are treated as image files and cannot be searched or edited because they are not machine readable. Optical Character Recognition (OCR) is a solution to convert these scanned documents into machine-readable text files. Files processed with OCR can be searched and edited as needed. Recognizing content in a document management system will therefore be a new approach that promises to transform the way businesses manage document processing. It will aim to recognize invoices, tax forms, survey forms and various other business and administrative documents which may be formal or loosely structured with proper storage and retrieval of these documents for business purposes.

4.2. Machine learning for document management

The essential goal of using machine learning in this work is to apply it to multimedia documents and also to have a classification, initially, by type of document (Image, video, audio or text), then and thanks to these content recognition algorithms we will try to extract the information that will be used on the information retrieval part. After this processing on the content of the documents, an automatic categorization is proposed. The automatic classification of documents is quite a complicated task. All the varied documents have different visual parameters: size, format, shade of paper, font size and type. The fact that some of the documents are handwritten complicates things and it was very difficult to distinguish the handwriting. Documents vary to a great extent and new documents are expected. This is why it is almost impossible to solve this task by software implementation of algorithmic solutions but by offering machine learning, this processing by learning algorithms seems reasonable.

Recognizing content in a document management system will therefore be a new approach that promises to transform the way businesses manage document processing. It will aim to recognize invoices, tax forms, survey forms and various other business and administrative documents which may be formal or loosely structured with proper storage and retrieval of these documents for business purposes.

4.3. Recommended documents

Spark MLlib is an Apache Spark module that provides machine learning primitives as APIs. Machine learning typically processes a large amount of data. Spark's basic IT framework is a huge plus. Additionally, MLlib provides most of the popular machine learning and statistics algorithms. This greatly simplifies the task of working on a large-scale machine learning project. MLlib offers recommendation techniques for unsupervised learning and

especially in the part of clustering that will be proposed in this work. Recommendation systems are software tools and techniques that provide suggestions of documents for a user to use. For our recommendation tool to be effective, it must have a comprehensive and properly cataloged resource repository. In addition, it must be precise to understand the user's needs and must essentially profile the user correctly. Ideally, you should take into account that a user's preferences are constantly changing. To address this need, we provide an interactive document recommendation tool that observes the different themes that arise in user work over time and continues to learn user preferences continuously based on feedback. of the user on the documents recommended to him. We then estimate the similarity between the query and each document using processed by the IR process presented in the first contribution. To take into account user preferences, we keep track of user documents to ensure traceability throughout the process.

Our recommendation phase depends on the user's profile. A profile can be made up of several types of information. In this proposition, we distinguish two types of information:

- A template of user settings, that is, a description of the types of documents that are of interest to the user. There are many other possible representations of this description, but a common representation is a function that, for any item, predicts the likelihood that the user will be interested in that document. For efficiency reasons, this function can be used to retrieve the n documents most likely to interest the user.
- A history of user operations with the document management system. This may include documents the user has viewed. The history also includes the recording of requests entered by the user.

5. The proposed system

5.1. Architecture

The architecture of the system proposed in this section covers most of the components involved in data processing

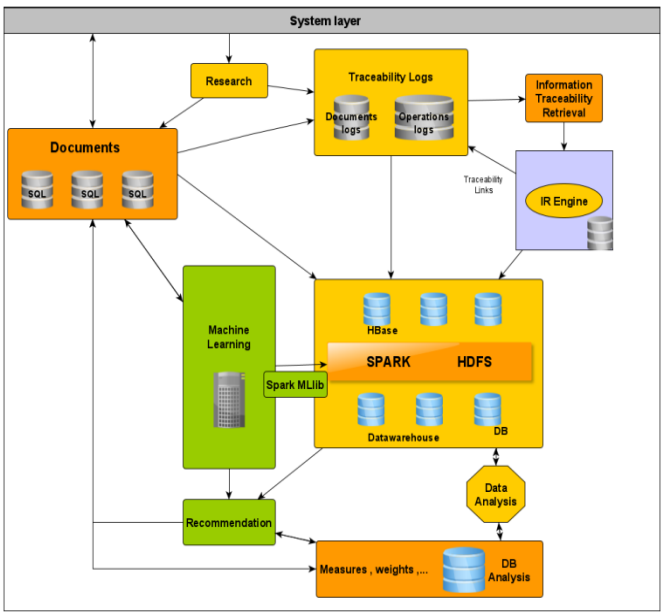

Figure 3: Architecture of the proposed system

Our system architecture consists of four main components:

- Corpus of documents: The documents coming from the corpus are heterogeneous. The user uses their interface to add new documents, even just with the action of "click and drag". Usually this is SQL data storage; (MySQL, Oracle, PostgreSQL, MongoDB, etc.). Log files will be used to manage traceability (user clicks (Action), user visits (Operation), activity, etc.).
- Data transformation: Data transformation involves the information retrieval part and converting documents into vectors, as well as data extraction so that the document can be indexed for easy searching. Indexing is a way to classify a document by adding terms to its metadata, such as tags, order numbers, or customer information. Mainly this phase is used to load the data to be processed. Logging and traceability management tools can also be considered part of data transformation, as they generate useful events from log files and present an important history to analyse.
- Data processing or integration: For data processing, this concerns the generation of usable data from a set of heterogeneous documents that can be consumed by machine learning and the big data environment; (Spark and its ecosystem (Spark / HDFS, Map-Reduce, HBase, MLlib, etc.). Spark offers in-memory scans, so this is an emergent task by reading directly from HDFS.
- Data visualization and recommendations: Visualization and recommendation represent forms of display of results and information to users or to other entities such as managers or decision-makers, in order to predict or estimate overall performance and also to generate recommendations, to using a set of algorithms, tasks defined by the user himself. (Reporting, personalized dashboards, interactive tables, statistics, research results, etc.).

5.2. Benefits and advantages

The improvement that is being made to document management systems today through this work is to offer new functionalities while keeping the classic functionalities of the system (Capture, Storage and distribution of documents):

- Traceability management: traceability management allows managers to control and track changes made to documents in the system. Traceability ensures that all actions and operations are tracked and recorded.
- Integration: Many document management systems integrate with programs such as messaging, a CRM (Customer Relationship Management) application or an ERP (Enterprise Resources Planning) database.
- Scalability: document management system should grow with the business so you don't have to change systems later.
- Security: The system must prioritize the security and protection of information and documents, as a data breach or storage problem could be disastrous for the entire organization.

- User-friendliness: The document management system should be easy to use. Users in the company should be able to easily access, manage and browse the necessary documents.
- Collaboration: The system must allow users to share and collaborate on documents.

The proposed improvement of the document management system supposed to make the work easier and more efficient, bringing many benefits: The system automates many aspects of document management. The system makes it possible to follow and see all the activities on a given document. It should apply built-in security and access controls to regularly control who can access which documents. The system ensures easy search of documents so as not to waste time and money. This makes it possible to find a document in seconds and also helps to retrieve some more relevant ones. It facilitates information sharing and collaboration, allowing documents to be accessed from multiple locations. The user can share documents, monitor workflows, grant or deny access to their documents and see what changes have been made. Also, the system offers users documents according to their profile and the history of their activities on the documents.

6. Conclusion

Using a document management system powered by machine learning, companies can modernize the way data is extracted. Such an advanced system can read information precisely to understand its intention. Based on specific models, the analysis of the document management system activated by machine learning and retrieves only the information useful to accomplish a particular job. Machine learning can also be a powerful tool for data mining and analysis in this kind of system, which will save a lot of time and effort. It is useful to examine the accuracy to 10 returned documents if one is interested in the system's ability to return relevant documents to the top of the list (which is a traditional concern of search engine users). The precision at 5, 10, 30,… returned documents nevertheless has limits: for example if a given request has only 8 relevant documents, and the processing does restore these 8 documents at the top of the list, the approach will have a precision of 10 returned documents equal to 0.8, which does not show that all the relevant documents available were found. In addition, in this example, a precision of 10 restored documents equal to 0.8 does not make it possible to determine where the two irrelevant documents are located among the ten returned. Document traceability management provides each user with proof that business processes have been respected, because if there is an error, it will easily be traced, as well as the associated time saving and improvement. Project management especially at the level of collaborative work. Several jobs are needed to improve the performance and accuracy of the document classification process. New methods and solutions are needed to obtain useful information from the growing volume of electronic documents:

- Use of semantics and ontology for document classification and information retrieval.
- For filtering and categorizing documents, the user may have folders and may want a classifier to classify each incoming document which automatically moves it to the correct folder. It is easier to find documents in sorted folders in a very large corpus.
- Reduce classifier processing and response time and improve classification accuracy, precision, and recall.
- An implementation of a meaning-based text classification procedure is required to retrieve meanings from words used in a specific context.

VSM stands out and occupies first place by its performance in all three cases. Thus, it confirms its good reputation in the literature as being one of the best classifiers. With the constant development and adaptation of machine learning, the proposed approach to document management systems will not only ensure better data analysis to meet customer needs, but also establish optimal research results. With the rapid pace at which technology and innovations invade industries with each passing day, it goes without saying that early adopters will also be the first to reap the myriad benefits that come with it.

In an electronic document management system, the majority of solutions on the market today are more concerned with the dynamic side of the system which concerns the workflow part of the document. In this work, the major objective that we tried to study is the static part by proposing for the improvement of this kind of system a multitude of techniques and approaches for this static part by attributing it a kind of fuel in order to automate it and make it as dynamic in relation to user expectations and its needs for the organization and readability of documents.

The first contribution in this direction, was the proposal of the use of traces throughout the system, thus the recovery of traces between documents in order to reduce the dimension of the treatment proposed also on documents using the techniques of information retrieval and the extraction of payload data. The voluminous mass of data has forced us to think about using a big data environment which will also help us in the analysis and distributed calculation of data.

The second contribution is also an important proposal, concerns the use of machine learning techniques in order to add to this system new types of documents (image, video, audio and text) which will be processed by proposing powerful algorithms. in this sense, and which are used to extract important data, and therefore offer users and businesses a new service in this type of system. An image or a document scanned in an electronic document management system, without it being processed manually by adding descriptions and fields to list it, it will be archived all the time. Hence the usefulness of our approach, in order to automate these methods and extract text content assembled from the metatdata of a document. This allows the IR engine and especially the indexing part which relies on the texts, the processing and the indexing of the images of the document. Because it is very easy to work on text than to work on an image. That is why we have proposed the use of content recognition algorithms which greatly assist in automatic document processing. An important point also, regarding the use of machine learning is that the preprocessing done on the images using OCR allows to extract high value textual data added during the training of an algorithm, and the The extraction of this data generates a serious increase in the volume of data, hence the aim of using a big data environment. This automated processing of multimedia documents prompted us to think of the user by offering an integrated module for recommending multimedia documents according to two criteria;

their profile settings and the history of their operations in interaction with the system.

The system proposed in this article is an improvement of the modern electronic management systems offered today. Thanks to this proposal, documents management tools also becomes easy to use, especially with an environment such as big data.

Conflict of Interest

ABSTRACT

Due to the advent of cloud computing and Internet of Things, smart meters have become a crucial part of smart cities. Smart meters generate vast amounts of fine-grained data that can immediately provide useful information to electricity consumers, such as automatic billing, load monitoring, and dynamic time pricing. This will make the electricity consumers more energy-efficient and self-organized in IoT and cloud computing technology. Smart meters also enable two-direction flow of energy and balance the measurement of inflows and outflows of energy between the meter and electric utility's central system through remote reporting. Besides, they help designers integrate renewable energy generation, such as solar rooftops to cover remaining energy needs. However, smart meters entail some severe security challenges. From a security point of view, these meter readings have a potential threat on personal privacy and the collected meter data. They may also reveal some details about consumer's lives. Thus, the data acquisition from those meter readings is expected to incorporate privacy requirements and application demands. In addition, the collected raw data from various meter readings needs to be collected from IoT smart metering sensors and stored in the cloud to be accessed and analyzed by electricity consumers. Subsequently, this considerable information Is prone to privacy threats and security vulnerabilities as the transmission of data to the cloud is most likely to cause a data breaching. In this paper the privacy and confidentiality of meter readings is protected through trusted platform module, which will allow the electricity provider to get the energy consumption at a periodic time granularity.

1. Introduction

The future smart meters are expected to provide details on individual appliance consumption and enable customers to access electricity safely and economically [1]. These technologies lead the trend to shift from conventional power grid to smart grid that uses sensors, smart meters, advanced communication systems and information technologies to create monitoring and visualizing real-time electricity information. But these technologies pose threats to individual's privacy as they can simply reveal one's daily activities [2]. Fine-grained electricity consumption aggregation scheme for smart meters can be used to reveal some information about consumers' lives and their activities. It can be also used to detect the presence or absence of occupants [3], [4]. In addition, transmitting the smart meter data to private or public cloud storage will allow the household consumers to monitor their usage, change their energy habits, adjust their electric power consumption, and give them better management to their energy costs. Real-time monitoring, then, can be accessed via the cloud using mobile browser, or any PC/Mac browser in the world. Subsequently, these meter readings and information are prone to privacy and security threats as the transmission of data to the cloud is most likely to cause a data breaching. In this paper, a storage outsourcing in the cloud is considered secure where the external storage is often untrusted or only semi-trusted. In addition, privacy-preserving analytics for IoT and cloud-based smart metering system is ensured by using a trusted hardware module which is used in conjunction with generated random number generator. The proposed framework guarantees an

[*]Corresponding Author: Hesham El Zouka, AAST, P.O. Box: 1029 Alexandria, Egypt, helzouka@aast.edu

improved secure data storage of IoT smart meter reading and provides real-time measures of electricity consumption and the estimations of the consumption during operations.

In this system, the consumer grants the service company a meter reading request service at a time of charging and the granted utility company is only allowed to get the power readings during that granted time. This system also provides practical security measures and protects the privacy of consumers who have smart meters at their homes. Also, a privacy model is provided here to achieve the privacy requirement and experience that the proposed system may have a significant effect on privacy-preserving systems if the system is built under the assumption that the utility provider is semi-honest.

In addition, strong access configuration and authentication management protocols should be constructed in IoT - cloud outsourcing process, and any unauthorized access should be utilized and reported. Moreover, due to the lack of privacy and security issues, sensitive personal data can be revealed to third parties such as utility companies and cloud service providers. Today, energy might be collected and stored for future use as per demand. Additionally, data analysis programs can be used to improve the efficiency of power consumption of a particular meter.

It is true, of course, that adding memory or a processor to the smart meter will enhance its security services capabilities, but contradictorily, the cost of implementing these smart meters will be increased dramatically. The proposed security system in this paper is designed to support multiple time segment granularities and let the meter readings to be stored securely on the cloud. It also comprises the design, construction, and operation of proposed two-way communication scheme, which ensures secure and reliable connections between the smart meters and getaways.

The rest of this paper is structured as follows. Section II discusses the architecture and characteristics of smart metering system with the cloud computing. The related work is given in Section III. The system design and modeling are presented in Section IV. Results in terms of system implementation, authentication, security and privacy are presented and discussed in Section. V. The performance analysis of the proposed system is discussed in Section VI. In the final section, the conclusion and future work are presented.

2. Cloud Metering Infrastructure

Smart technologies like the IoT, artificial intelligence (AI), and other digital technologies are providing new opportunities to smart grid network, and can be used to control, monitor, maintain production, transmission, and consumption of electricity in smart metering systems. Many benefits could be obtained through the deployment of the smart grid services in cloud computing, in order to achieve energy savings. Cloud computing is also used to speed up communication with telemetry devices [5]. Moreover, power grid technology can be combined with smart meters to reduce the energy consumption in the peak demand and, hence, improve cost savings.

However, fine-grained technical approaches can cause security and privacy concerns for smart meter users. Current smart/interval meters can record electricity consumption in 30-minute intervals; however, the new generation of smart meters use more advanced technology and could convert all time units to seconds. Mechanisms for large-scale distributed sensor networks and other complex issues are likely to be addressed in order to prevent personal privacy from being breached and prevent revealing detailed information of one's daily activities. It should be made clear that smart meters record the energy usage exactly in the same way as the standard meters, and send this data to the consumers and the utility provider, on a required time interval, which allows consumers to monitor their power consumption at very fine time granularities. As opposed to the conventional method of electricity billing [6], the proposed approach does not require a person from the electric companies to read the number of units of energy consumed in the meter. The proposed system can play an important role in minimizing overall energy consumption and, hence, making significant contribution to energy efficiency and power saving.

One of the most important aspects of the proposed privacy-preserving energy scheme is its capability of providing a fine-grained smart meter access, while preserving the privacy of consumers based on an encryption scheme.

Therefore, the proposed fine-grained anonymous metering system will encourage consumers to use limited electricity during peak hours, especially when energy demand is high and inform them with their consumption patterns, and challenge them to fully utilize potential while saving costs. Finally, a Load Monitoring Center (LMC) will be introduced in attempt to access the sum of meter readings from various smart meter-time resolutions (e.g. half-minute, one minute, five minute, etc.).

Some previous studies have focused on privacy, security, and accuracy issues of plug load monitoring system in smart grid environment [6]. Other related studies have focused on payment predication and automatic bill generation. Various privacy-preserving models were proposed to protect the individual's privacy and minimize the energy consumption [7]. However, most of the corrupted meters will disclose the activities of users by measuring their usage frequency. Furthermore, cyber security can be utilized to characterize the surrounding magnetic field of smart meter, which in turn will expose some vulnerabilities with the data being transmitted from smart meters. To solve such problems, many researchers have developed and investigated a wide variety of approaches over the years in order to prevent disclosing the consumer living activities and invade their privacy. In this paper, cloud computing offers an alternative storage model to the traditional in-house smart meter model. This is a quite effective way, so that the data stored in the cloud will be secured by using multiple levels of encryption and, hence, only authenticated consumers would be getting access to it. All meter readings will be read at specified time intervals and readings will be stored in a secure cloud-based server which will be accessible from anywhere through a web browser or any mobile device. The meter reading privacy will, then, be protected within the cloud environment, and,

as a result, only authorized household consumers will get permission to access the sensitive content in the cloud.

The Cloud metering system (CMS) proposed here consists of three main parts: trusted identity module, cloud storage unit, and the utility service provider. The trusted identity module is embedded on a smart meter for the purpose of securing the metering services. The external cloud storage allows consumers to do their reading remotely, with no need to buy expensive equipment or hire large IT staffs. The energy service provider pools consumers' services, and demand different time granularities [9]. The proposed model has a mechanism to manage and grant meter readings to the utility company at specific time and date.

The utility company, then, can get energy readings at specific time intervals by analyzing meter data stored in the cloud. Meter readings are securely sent over the mobile network to be stored in the cloud for monitoring and analysis purposes. The meter construction and two-way communications capability will enable the system to process remote connections and disconnections of power service [10], [11]. The smart meters have the ability to measure, store, and report both energy inflows and outflows [12], [13]. The utility provider then, aggregates the consumption data from the storage system on the granted date in order to balance between the privacy requirements and the functionality of the system. Also, a privacy model is considered, as the meter readings should not be exposed to unauthorized persons or processes during transmission, storage and retrieving [14], [15]. Figure 1 illustrates the construction of the proposed CMS model.

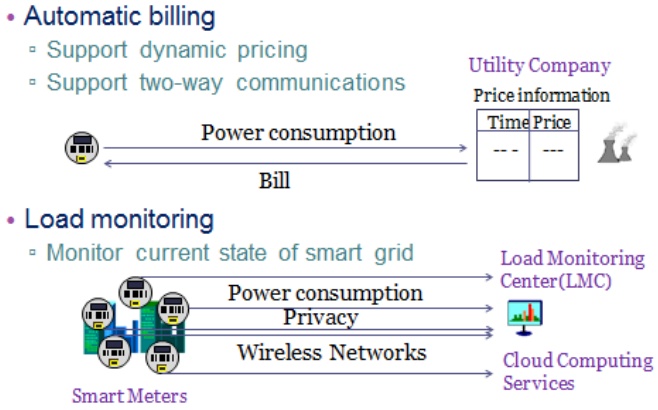

Figure 1: CMS Architecture

Clearly, the privacy is preserved by hiding smart meter's individual readings. Thus, sensitive data should be inaccessible to eavesdroppers. For example, data utilization, visualization, detection of emerging failures, centralized and decentralized operations and controls, all need to be considered when designing a secure network. There are complex security requirements to be deployed either on the cloud or on the smart meter with potentially limited resources like authentication and ID management. Thus, strong authentication protocols should be implemented in the cloud network to provide protection against privacy violations. Meanwhile, unauthorized users are rejected through the use of access control or privacy features. Without cloud, smart meters cannot preserve consumer privacy and confidentiality. On the other hand, sensitive data or meter readings should be encrypted before being outsourced to the cloud. [16], [17].

3. Related Work

Different secure architectures and data aggregations have been proposed to reduce the cost of digital signatures in smart meters. All these schemes aim to protect the transferred readings of energy data. There are different types of smart metering architectures, some are of a meter and others are of many meters. The former contribute to the billing applications and the later contribute to applications such as load monitoring.

Aggregation and the role of Trusted Third Parties (TTP} has been discussed in [18]. The role of a trusted third party is to validate and safeguard protected meter readings on the basis of privacy policies of third party services. Others have used cryptographic primitives. [19]-[21], for example, smart meters can greatly benefit from accessing cloud processing and storage services if security measures, like homomorphic encryption, are applied. This can be achieved by encrypting smart meter data before storage takes place in the cloud.

This model is quite unique when it comes to the aggregation of meters' readings using zero knowledge protocol and tamper proof signature.

As for [22] and [23], they replaced tamper proof signature by TPM. Mc Laughlinet al [24] propose an approach to privacy-preserving data aggregation being transmitted using a random noise. This random noise must be chosen in a manner that is transparent and does not affect the validity of aggregated data from smart meters. They also presented a privacy-preserving technique that is based on inserting the result of three aggregation functions for any given neighborhood in a short time period ψt. Based on these functions, the aggregation technique is implemented in such a way that the aggregator can produce an accurate aggregate number while maintaining the confidentiality of individual meter reading.

Moreover, [25] have proposed an approach that can utilize privacy settings on smart meters by using secret sharing scheme combined with symmetric encryption. The paper [26] has proposed a hybrid approach that uses random noise and pseudorandom sequences to preserve the privacy of readings collected from smart meters. Their proposed system supports load monitoring and billing applications as they claimed in their paper. However, most of the privacy preserving approaches in smart metering systems concentrate on the sensitivity of meter readings in attempt to protect time-series in general and not designed for very fine time granularities. Also, it is not clear which reading is considered sensitive and how it should be handled. While privacy-preserving solutions have been studied, users' privacy concerns have been not fully defined and the privacy of smart meter readings has not been formally addressed. Currently, many gaps exist between linking the meter readings to the status of specific applications. Appropriate regulatory protections vary from one application to other.

In this paper, the privacy of smart meter users is preserved by providing a flexible platform that supports multiple time granularities. In addition, the provided storage services of these smart metering systems are highly dependent on the cloud infrastructure. To ensure authenticity and integrity, a trusted platform module will be employed in this paper. The suggested module will be used to create signatures over the data to be signed.

4. System Design and Modeling

In this section, time scale notation, metering system and the proposed security model are described along with a brief introduction to the proposed privacy requirement.

4.1. Time Scale Notations

At the lowest level of time granularity S1, time is divided into several time units T1, T2, ….,Tn of 1 ms. Each time interval unit Ti is allocated to weight wi. At the startup routine, all the weights are equal, and the system entity structures extension to integrate weight hierarchies and time granularities into real time workflow. Automatically, a time granularity S is defined to support different applications. An example of three different time granularities, S1 , S2 and S3is shown in Figure2.

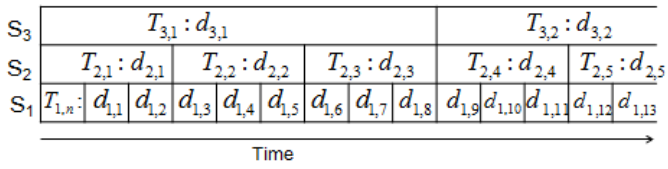

Figure 2: Time Granularities System

4.2. Smart Metering Process

The proposed metering system consists of a meter, an external cloud storage platform and the cloud service provider SPi which has a key pair: a public key (PK1) and a private key (SK1).

Figure3 shows an example of the proposed platform with a cloud computing architecture. Supposedly, a meter is fully trusted and the storage platform as well as the cloud service provider are honest, as they follow specific procedures in extracting individual meter readings from storage devices and communication links. If a consumer has a meter SM that records energy consumption d_1 at time unit T_1, H agrees time granularities Si with different service providers SP_i, and constructs SM by storing S_1.

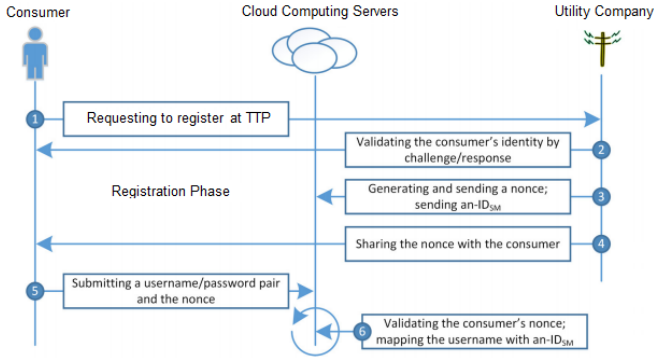
Meter M, then, encrypts the meter reading d1 as C_1 and stores C_1 into the cloud storage system. By getting the access right at a given time granularity S_i, an energy consumption di at time interval T_i is a sum of meter readings:

$$d_i = \sum_{S=(j-1)/i+1}^{j} d_1 \qquad (1)$$

The proposed model consists of 3 layers, hardware layer, application layer and Kernel layer. The hardware layer consists of all hardware modules including the precision measurement unit, the platform module and a communication and processing module. As for the kernel layer, it has a set of modules that interacts with hardware layer. Then comes the application layer that is constructed upon the kernel layer to offer facilities such as cloud network management service, transaction service and web edge for monitoring current meter readings which can be stored on the cloud. This allows easy access to such readings from anywhere through any web-based interface application.

5. Trust Assumptions and Security Requirements

The meter readings can be transferred directly to the cloud using a Trusted Third Party (TTP) encryption, which is responsible for the registration of consumers and servers. TTP can manage meter data using standard Internet connections and has the capability to provide data confidentiality, data integrity and fraud prevention. Due to these capabilities, the consumers can utilize the best authentication and registration features. Hence, home residents can easily monitor and control home electricity facilities through computer and smart phones over the TTP. The whole registration, authentication method is illustrated in Figure 3.



Consumer Authentication Process

The residential home has local renewable resources, energy storage and electrical appliances that are able to adjust power consumption behavior and predict demand-capacity. It then works with a set of service providers as each service provider primarily delivers access of meter readings at a time periodically. In addition, each network/service provider SP_i with a key pair (private and public) has a demanded time granularity Si, and the startup time at the initial time granularity $T_{i,j}$ can be approximated by the following equation :

$$T_{i,j} = \left(\sum_{v=(j-1)/si+1}^{j} T_i \right) modN \qquad (2)$$

Therefore, a network provider can compute the energy consumption di at time Ti by editing the encrypted meter readings as long as it knows a random value ri of sometime unit Ti . Then, the energy consumption di can be easily calculated by the following equation:

$$T_{i,j} = \left(\sum_{v=(j-1)/si+1}^{j} \mathrm{d}_i \right) modN \qquad (3)$$

The consumer appliances, local renewable energy generators, smart grid utility will all be connected by the cloud and controlled by smart home meter which has the skill of getting consumption information from cloud services.

This smart-home meter is also capable of static scheduling and runtime scheduling to reduce the total cost of electricity energy while sustaining power requirements [27].

From security point of view, the consumer appliances should give the corresponding random numbers rito SPi in order to permit the right access of meter reading at a specific time Si to a network provider SP_i. In order to reduce the communication cost of random number ri derives the next one $r_{i,j+1}$ by using a shared PRNG where a random number is generated so that the equation would be:

$$r_i = \left(\sum_{v=(j-1)/si+1}^{j} T_i \right) mod N \quad (4)$$

Where the time granularity Si is derived from r1 using the pseudorandom number generator g1. The consumer, then, will securely give ri, Si to the service provider SPi in order to grant the right access. SPi can consequently, derive other random numbers.

5.1. Trust Model

Let h be a crypto system and has h function where the encryption and decryption procedures used by the network provider SP_i to authenticate the communication parties and to create a secure connection. The consumer will, then, share random number generator g: with SP_i, correspondingly. Then, the consumer will configure a meter SM by setting initial state number of a specific time Si.

The TPM and SM will generate a master key K by the using a seed θ, the sequence number SN and the hash algorithm h. The session key k is securely saved in the TPM of SM which creates a seed key K_i by using the session key K and description D_i. M, then, computes r_i , and encrypts it by using public key PK_i as r_i and stores n_i to the external data storage system.

5.2. Usability Goal

Permanent data storage mechanisms are urgently needed for the development of smart-meter system which aims at reducing the electricity cost at a residential home by scheduling the power demands according to a rich set of power – related data that can describe the dynamic status of smart grid, local power generation, energy consumption of consumer appliances, sensor data, weather data and occupants' activity data.

All this data will be stored in the cloud by a data base that is implemented by MYSQL which will also support queries over data and metadata from the smart home systems.

$$c_i = \left(\sum_{v}^{j\pi i} c_1 \right) mod\ N \quad (5)$$

where $\eta_{i,[j/\pi i]} = enc^{i}_{pki}\ (d_{i,[j/\pi i]})$

Meaning that the service provider SPi gets the encrypted power assumption di of every time unit T_i , for $j \geq 1$ since $di < N$. In the next part, the privacy requirement that is proposed here is defined and it is proven that the proposed system meets it. Moreover, it is shown that managing meter data collections and billing are secure.

5.3. Privacy-Preserving Requirement

Privacy here requires that a network provider SP_i cannot get energy consumption di at specific time intervals S_v, where $j \geq 1$ and $v < I$. Paying into consideration that if SP_i cannot get energy consumption at specific time intervals S_{i-1}, it wouldn't get energy consumption at any time intervals S_v for $v < i - 1$. The privacy preserving requirement here is to keep the time granularity adapted to a prior time constraints when determining the maximum time boundary. For example, a demand phase continues first when A adoptively gets meter readings di at time intervals T_1, j as $j = 1$ and C returns back to A the encrypted meter readings C1. A, then, specifies to enter the experiment phase at $(j^* - 1) + 1$. A then chooses two challenge sets meter readings for a time $\in \{0, 1\}$. The intersection of the two sets is that the consequential di , j^* are the same as illustrated in the following equation:

$$\sum_{v=\pi_{i-1}(j^*-1)+1}^{\pi i-1 j^*} d_i^0 = \sum_{v=\pi_{i-1}(j^*-1)+1}^{\pi i-1 j^*} d_j^1 \quad (6)$$

After reading the encrypted meter data, A passes to the second phase. For a second time, A adaptively indicates a meter reading dj for subjective time interval Ti and C automatically returns the encrypted meter reading C1 back to A. Hence, a smart metering scheme satisfies the privacy preserving requirement against a network provider SPi for any probabilistic polynomial time function T bounded adversary A attacking the real process.

Table 1: Implementation analysis of the proposed system

Initialization phase	Computation cost (ms)	Storage cost
Registration phases	≤ 10 ms	1592 B
Generating a nonce number	1.2 ms	2 B
Encrypting a meter reading	< 12 ms	19
Session key exchange	4.3 ms	17 B
Data transmission phase	2.8 ms	68 B

5.4. Storage System Security

The meter readings are shown to be securely stored in the cloud storage devices, bearing in mind that each network provider has more information than the storage devices and that the proposed metering algorithm is securely integrated with privacy-preserving scheme.

The security requirement of cloud storage is the collective processes, technologies and controls that ensure that only authorized and legitimate users can store, access and use storage resources. The attacker A has the same role of the storage system, but without the knowledge of the stored pseudorandom number r. Hence, the metering systems satisfy the secure storage constraints by considering any probabilistic parameterized polynomial time algorithms which are employed by the users during the initialization and the security phases, assuming that all encryption algorithms used by network provider SPi are completely secure.

6. Performance Analysis and Results

The performance of the offered smart metering system is examined in terms of benefit-to-cost ratio and storage cost. Moreover, a specific scenario is considered where four time measures; years, months, hours, and seconds are used in the smart meter. The utilization of the system shows that the time of the generated key is the highest among the transmitted and authentication time.

In addition, the proposed system minimizes the overhead of the authentication process as compared to the other know authentication algorithms in smart metering networks because the key used in transfer time as well as the key used in the verification time produce a lower amount of overhead. As shown in Table 1, it is obvious that the encryption time is the highest among the authentication and transfer time.

It is also obvious, from the table, that the time complexity for key generation is in the order of O(log n) and it takes nearly less than 20 seconds on average to be accomplished. Despite the long generation time and relatively low encryption time, the total key transfer time range is 0.6 to 3 seconds, whereas the total key authentication time range is 0.8 to 5 seconds.

Noticing that the scheduling scheme produces a total of N sub-keys of the size of 32 bits and that the encryption system used by network providers is standard RSA encryption. The proposed system showed that the generated 2048-bit key of RSA algorithm takes significantly longer than the 1042-bit key. A commercial Information on Trusted Platform Module (TPM) chip is used to enhance the performance of cryptographic system in terms of space and speed, which is capable of supporting a 1024-bit signature in 50 ms and 2048-bit RSA signature in 250 ms.

The TPM can be initiated to cope with multiple security services, including the protection and secure storage of the keys. TMP can be used also to cope with RSA algorithm for key signing and encrypting data.

It is also assumed that calculating Si optimal additions is not slower than the estimated time complexity to factor 1024-bit RSA modulus, and the fastest known factorization algorithm requires around 265 times complexity to factor a 1024-bit signature. The task of generating a 1024-bit RSA signature, would take less than 100 ms to be generated.

Thus, the complexity of encrypting a meter reading takes less than 35 ms. Additionally, the storage cost of a meter is considered to be constant and the cost of storing data in the cloud system is analyzed as follows: for each reading, the cloud system stores an encrypted data reading of (log2 n) bits. In order to grant the access right to a network provider SPi, a cipher text is stored in the cloud storage system at the first time interval T1.

Consequently, for every Ti time unit at time granularity S1, an encryption of a nonce digits is stored. In the proposed model, the cloud storage efficiency of encrypted data reading of a month is around 325 MB, and as for the storage cost of encrypted data for a month is about 3.4 MB, which make the overall storage cost of the cloud storage system for a meter system per month is fewer than 126.3 MB.

Level of trust operations of cloud network providers includes encryption, modular arithmetic and the computation of nonce numbers are all within efficient range and work under all standard reference conditions required by secure service providers. The computation efficiency of meter system is analyzed as follows: large keys are converted into small keys by using MD5 hash algorithm and the data encryption takes place during the initialization process.

The calculation in the initialization process is subject to the computation of generated RSA keys. As the encrypting of a nonce takes 2 ms, the initialization itself takes 2 seconds. At T1, the meter reading is encrypted by using the nonce r1 that on average, takes between 10 – 15 ms to be completed.

On the other hand, the efficiency analysis and the security analysis show that the proposed protocol is secure and efficient ; the efficiency is verified by ns2 simulation results, which show a high authentication rate. The average time for the authentication phase is between 1 and 2 ms, and the average time of key exchange protocol is also utilized and was in the range of 1 to 7 ms.

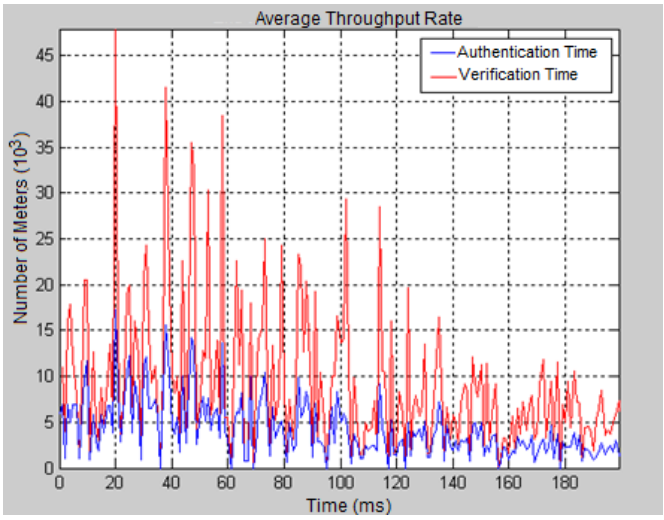


Figure 4: End-to-End Delay

The verification time has been calculated for various security measures in accordance with the key generation time and the key computation time to prevent intruders from decrypting the keys.

The simulation results showed that the elapsed time to complete the verification process including the key exchange protocol and the hash function is approximately equal to the total time required for exchanging of all smart meter readings within the communication channel.

The performance analysis of this system for varying number of meters is presented in Figure 4 and Figure 5, respectively. In the former figure, the measured end-to-end delay between the creation and aggregation of the meter readings at the cloud server and the readings response time at the utility company is illustrated by implementing the authentication protocols.

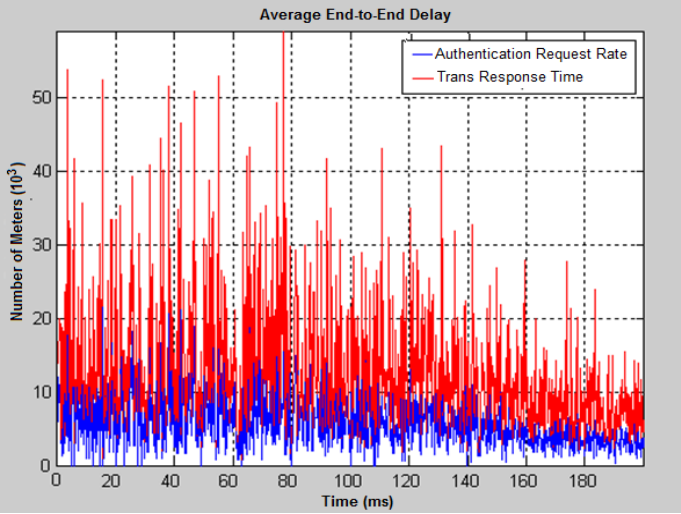

Figure 5: Throughput Rate

Cleary, the delay is affected by the time slot where the meter is assigned in the schedule of time granularity created by the users. Another reason for the increase in the message delay is the computational overheads taking place at the communication layers of the network. Furthermore, the suggested authentication scheme reduced the response time and the communication overhead in the proposed smart metering system because the verification time and the key transfer time produce minimum amount of data overhead. It is noted from Figure 5 that the generation time of the key pair is the lowest among the computation time and verification time. It is clear also from the figure that the generation time of the key-pair was performed in less than 9 ms. When considering the key exchange time over different network bandwidth, the key transfer time was quite high compared with key verification time. The average transfer time was less than one second and the verification time was the 6.2 ms on average. To avoid the risk of key-guessing attack and code replication attack, a strong crypto system together with a secure digital signature were used interchangeably to encode smart meter readings during transmission between the cloud server and the smart meters. As for the results, the proposed security and meter privacy preservation scheme in this paper have offered alternative ways for preserving the cloud storage and time granularity while still providing privacy in smart meters.

7. Conclusion and Future Work

In this paper a data processing and storage system that is applicable to smart meters with many modules that is connected as an internet of things via the public network and uses the full strength of cloud computing and secures users' privacy and the confidentiality of data exchanged on the grid by encrypting smart meter data before sending to the cloud for the sake of processing and storage with the help of a homomorphic asymmetric key cryptosystem. Each smart meter includes a set of public and private keys to which the grid operator can access and the household owner, on the other hand, can only access the decryption key corresponding to their own smart meter. With the help of the homomorphic feature of the cryptographic technique, several methods are created to enable most of the computing works to be done directly on the data encrypted by the cloud which is the main focus of this model. The smart reading system which is proposed in this paper considers an external storage cloud server and supports multiple time granularities in a privacy preserving manner against host-but-curious providers. The consumer gives different time granularities to different service providers. It is shown in this paper that a service provider gets power consumption of the consumer at only the granted time granularity. The security analysis in this paper confirms that the proposed security protocol preserves the overall privacy of the smart meter readings by allowing an efficient authentication and key management protocol for cloud-based smart metering systems. The performance of the proposed system is analyzed in terms of computation cost and storage cost of a meter. The results confirm also that the key generation time is the highest among the transfer and the verification time. Furthermore, the suggested scheme reduced the overhead of the authentication time as compared to the other existing authentication schemes in smart metering systems. The analysis also provides a solid step towards the practical construction of privacy in cloud-based smart grid technologies.

Trafic congestion

ABSTRACT

Traffic congestion is being experienced daily by many travellers both on the inner-city roads as well as on the highways. The toll plaza can become a real highway bottleneck, as vehicles must stop and manually pay the tolls at the toll booths. This stop-and-go process can seriously affect traffic fluidity, resulting in a lower quality of service at the plaza. One of the solutions used to improve the efficiency of toll plazas operation was the implementation of electronic toll collection (ETC), where vehicles can pass through the tolls without having to stop. In this research, a model that evaluates the benefits of the ETC system was developed using ARENA, a microscopic simulation tool. These benefits were visualized by conducting a comparative analysis of different scenarios. The Bouznika toll plaza, one of the major toll highways in Morocco, was selected for illustrating the improved operation realized from the use of ETC technology.

1 Introduction

One of the main causes of traffic jams on freeways is resulted from the conventional toll collection at toll gates, where each vehicle is required to stop to pay toll fees. The process of stopping to pay the toll reduces the traffic flow, increases the waiting time, queue length and thus reduces the efficiency of the toll plazas.

Therefore, in order to improve the level of service of toll plazas, a new technology has been introduced: The Electronic Toll Collection (ETC) Systems. These systems make it possible to pass through tolling location without being required to stop, and that it is thanks to a vehicle-mounted transponder that allows to uniquely identify each vehicle and to electronically collect the tolls.

With the development of ETC systems, various studies have been proposed to evaluate its performance and impacts.

Burris and Hildebrand had developed a discrete-event simulation model to examine the effect of ETC on traffic operations at the Halifax-Dartmouth Bridge in Nova Scotia, Canada. They simulated various scenarios of toll plaza configurations with and without ETC [1].

In [2], the authors used the INTEGRATION simulation model to study the impacts of ETC deployment on toll station at the Massachusetts Turnpike in Boston. Different scenarios were evaluated, and the simulation results showed an increase in the efficiency of traffic operations with the implementation of ETC. Throughput volumes, average queue length, and average waiting time spent in the system were used as measures of effectiveness.

Anthony A. Saka used a microscopic simulation model to evaluate the benefits resulting from the use of ETC technology by undertaking a comparative analysis of traffic operation condition before and after the ETC implementation [3] .

David Levinson and Elva Chang developed a model to maximize social welfare associated with toll stations. A payment choice model was used to estimate the share of traffic using ETC as a function of delay, price, and a fixed cost of acquiring the in-vehicle transponder [4].

Lu Jian made a qualitative analysis on the impacts of ETC and developed the performance index system of ETC benefits (2003) [5] . Jia Hong-fei estimated the monetary benefits of implementing ETC projects under different traffic volume conditions by using a cost-benefit analysis method [6].

Following this introductory section, a description of the proposed methodology is provided. Simulation results and performance evaluation are introduced in section 3. Finally, concluding remarks are stated in section 4.

2 Methodology

2.1 Study site selection

The selected study site is the Bouznika toll plaza. This plaza is one of the major toll highways in Morocco. It is located on the motorway axis that connects Casablanca, the nerve center of Mo-

*Corresponding Author: Alimam Mohammed Karim, Morocco, Tangier, karim.alimam@gmail.com

rocco's economic activity, to Rabat, the administrative capital of the country. This is the busiest section of the country's highways, with a throughput volume that could approach 50000 vehicles per day during peak periods.

The configuration of the toll facility consisted of nine manual lanes, two automated lanes and four ETC lanes.

2.2 Data collection and analysis

Data collection consisted of two major activities: (1) collection of service time (i.e., the time required to pay the toll and cross the barrier) data and (2) collection of traffic arrivals at the toll plaza [7]–[9].

The service time may be affected by a number of factors, such as the amount to be paid, the experience of the toll collector, the method of payment and the type of vehicle being serviced.

To determine service time distribution, we collect data over a given period of observation time. We record the time when the vehicle stops to pay the toll and the time after it crosses the toll barrier.

ARENA's Input Analyzer was used to find a probability distribution that best fits to the collected data. It is a tool designed to adjust theoretical distributions to observed data by estimating their parameters and measuring the quality of their adjustment.

With a sample size of 65 observations, we found that the service time distribution is 5.5 + Logn(16.7, 16.8) for the manned tollbooths and a triangular distribution with parameters 8, 10 and 12 for the automatic toll lanes (See figures 1 and 2). As for the ETC lanes, we assume an average toll transaction time of five seconds.

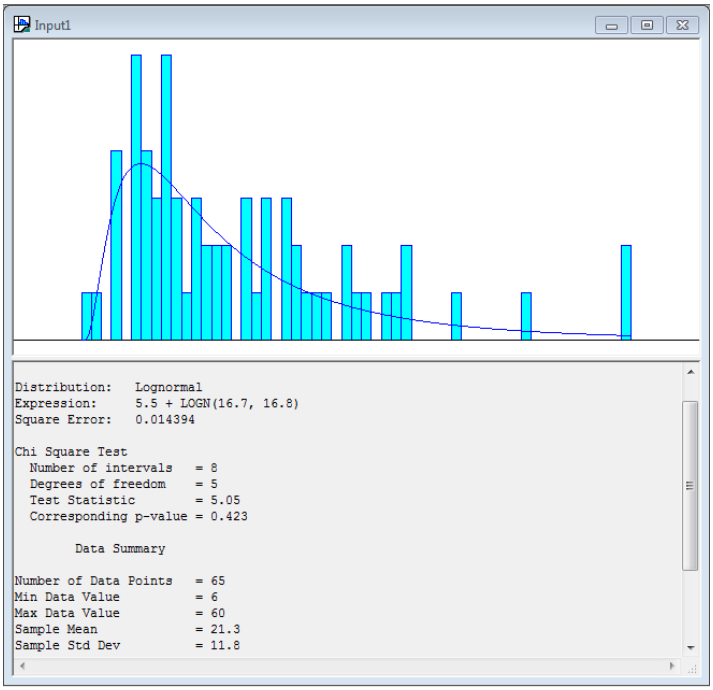

Figure 1: Results obtained for the service time distribution(Manual Tollbooth).

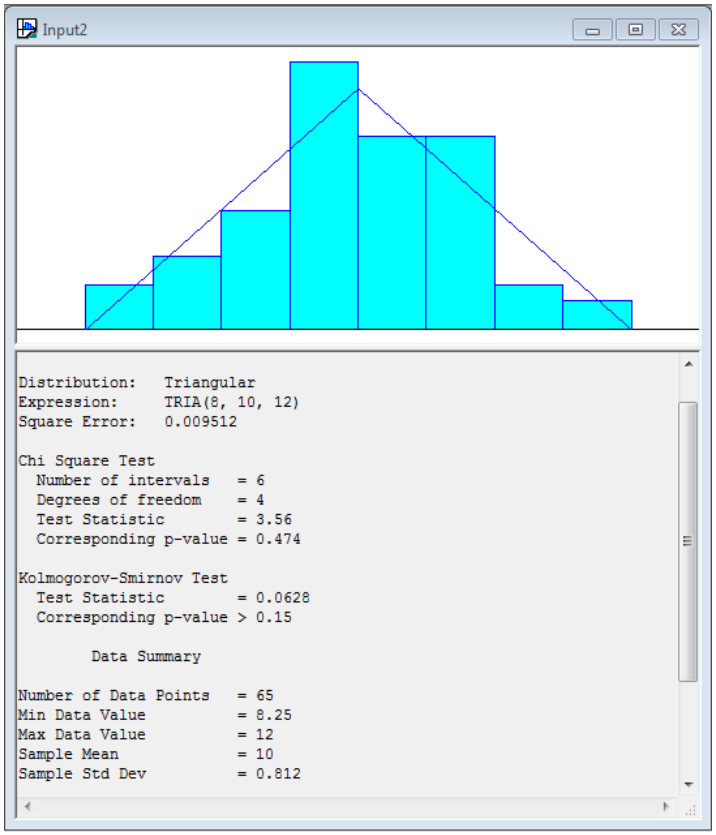

Figure 2: Results obtained for the service time distribution(Automatic Toll Lanes).

2.3 Model development

Simulation modelling provides a better understanding of the dynamic behaviour of systems, allows the user to compare different configurations and evaluate performance.

By using simulation, it is possible to analyse each of the system's component and to measure their relative impact on the overall performance of the system.

In our case, we use simulation in order to evaluate the impact of ETC on toll station. This evaluation was accomplished by utilizing collected field data and simulated scenarios using ARENA software. Arena is the most widely used discrete event simulation software in the world. It contains all the resources for modelling, process representation, statistical analysis and results analysis.

Furthermore, it combines the capabilities of simulation language in an integrated graphic environment, allowing for an easy user interface for model building.

Although the software was not specifically designed for toll plazas, its functionalities enable the user to model practically any type of process. It covers all discrete flows, all basic process functions: time, resources, information... at a very detailed level.

Arena provides a considerable number of statistics, automatically generated after each run, that estimate the performance measures of the system under study. These statistics are related to various components in the model, such as entities (Number in, number out, average total time in system...), resources (utilization, average number of busy resource units, number of times seized), queues (average queue delay, average queue size and minimal and

maximal observed values), and so on [10].

To construct this model, a great deal of empirical data were required, particularly traffic volumes, service time distribution, number of lanes and percentage of vehicles using each payment option.

Figure 3 shows the flow chart of the simulation model.

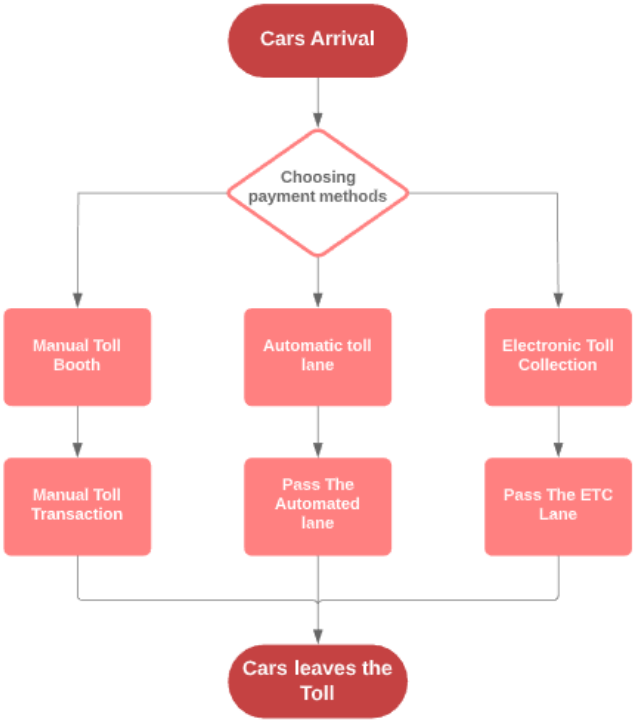

Figure 3: Simulation Flow Chart.

The simulation begins with the generation of entities (vehicles) according to a non-homogenous Poisson distribution.

The Poisson process is one of the most widely used counting processes. It is usually used in scenarios where we are counting the occurrences of certain events that appear to happen at a certain rate, but completely at random (without a certain structure).

A counting process is called a Poisson process if the following conditions hold:

- The number of entities that arrive in one interval is independent of the number of entities that arrive in any other non-overlapping interval.
- The number of occurrences in each interval can range from zero to infinity.
- The rate at which arrivals occur does not change over time.

If we look at our case study, only the two first conditions are true. In this case, we have a non-homogeneous Poisson process. Such a process has all the properties of a Poisson process, except for the fact that its rate is a function of time, which is the case for traffic arrival rate.

The traffic arrival rate varies over the course of the day, and is expressed in vehicles per hour. For the simulation, we used the hourly traffic volume obtained from the prediction results for the year 2030.

These traffic arrival rates are given in 1.

Table 1: Traffic arrival rates (vehicles per hour)

Hours	Traffic
1	1477
2	1160
3	930
4	730
5	802
6	797
7	1160
8	1576
9	1865
10	2300
11	2670
12	3184
13	3489
14	3419
15	3426
16	3419
17	4202
18	4487
19	5155
20	5238
21	6034
22	5116
23	4507
24	2860

Once generated, the vehicles were sent to either an ETC lane, automated lanes or manual lanes according to the rate of each payment option (The percentage of automated lanes users is fixed at 0.5%). Each vehicle would then join the queue that has the shortest length in its category and waited to be served. Once the toll lane become empty, the vehicle is serviced and sent to a model block where it exited simulation. Each vehicle was tracked from its creation in the model to its destruction, and statistics were recorded throughout the vehicle's evolution.

2.4 *Model calibration and validation*

The calibration and validation process consists of adjusting the input parameters for the simulation model in order to achieve reasonable correspondence between field data and simulation model output.

The input parameters for our simulation model are arrival rate (vehicles per hour) and service time. The arrival process follows a non-homogenous Poisson distribution and the service time follows a lognormal distribution.

The average waiting time at the toll plaza was selected as the measure of effectiveness of the model (index of comparison), which is part of the simulation output data.

The purpose of this study was to evaluate the performance of the toll plaza during heavy traffic conditions. Therefore, we started by configuring the model based on the data recorded on the busiest day for traffic of the year 2019.

Unfortunately, the waiting times at the toll plaza on this particular day are not available. We therefore decided to compare the model outputs with expert judgment, which indicate that the simulation results are relatively realistic.

3 Results and analysis

Scenarios with various ETC rates were simulated in order to evaluate the impact of electronic tolling system on toll plaza efficiency. Measures such as queue delay, queue length and capacity were observed when comparing the different scenarios.

Table 2 shows the experimental design of scenarios. Each scenario was simulated for 24 hours (a weekend : a sunday).

The figures 4, 5, 6 and 7 show the performance measures for the following four scenarios. They were summarized in terms of maximum, minimum, and average of queue length and waiting time.

The *Queues* section provide statistics for each of the fifteen toll-booth queues (nine cash receipt CR queues, two automated lanes AL queues and four electronic collection EC queues), such as average queue delay and average queue size.

As expected, in the case of manual service, the delay is longest compared to the ETC service. Increasing the ETC rate, without changing the configuration of the toll facility, has a direct effect in decreasing the queue length and the waiting time of the manned tollbooths, but on the other hand it increases the waiting time at the ETC lanes.

So we need to find a reasonable number of tollbooths for each payment method, considering different values of ETC rates, that minimizes the total time drivers spend waiting in the toll plaza [11]–[13].

The first scenario: We will consider a tolerable waiting time of 7 minutes and an ETC rate of 40%.

By adjusting the number of booths, the maximum value of total average waiting time obtained is 7 minutes, which happens when the number of active tollbooths is 22: 18 manual lanes, 3 ETC lanes

ETCQ_4	739.96	(Correlated)	0.00	3589.00

(b) Number waiting

Figure 7: Performance indicators: Scenario 4.

and one automated lane (See figure 8).

Table 2: The experimental design of scenarios

Case study	No of toll booth	ETC penetration rate
Case-1	9 manual lanes, 4 ETC lanes, 2 automated lanes	40%
Case-2	9 manual lanes, 4 ETC lanes, 2 automated lanes	60%
Case-3	9 manual lanes, 4 ETC lanes, 2 automated lanes	80%
Case-4	9 manual lanes, 4 ETC lanes, 2 automated lanes	95%

The second scenario: We will consider a tolerable waiting time of 7 minutes and an ETC rate of 60%.

By adjusting the number of booths, the maximum value of total average waiting time obtained is 7 minutes, which happens when the number of active tollbooths is 17: 12 manual lanes, 4 ETC lanes and one automated lane (See figure 9).

The third scenario: We will consider a tolerable waiting time of 7 minutes and an ETC rate of 80%.

By adjusting the number of booths, the maximum value of total average waiting time obtained is 5 minutes, which happens when the number of active tollbooths is 13: 6 manual lanes, 6 ETC lanes and one automated lane (See figure 10).

The fourth scenario: We will consider a tolerable waiting time of 7 minutes and an ETC rate of 95%.

By adjusting the number of booths, the maximum value of total average waiting time obtained is 1.4 minutes, which happens when the number of active tollbooths is 10: 2 manual lanes, 7 ETC lanes and one automated lane (See figure 11).

From 3 summarizes the main results obtained from the simulation.

4 Conclusion

The benefits resulting from the use of ETC technology was evaluated in this paper. The analysis was accomplished by utilizing collected field data and simulated scenarios using ARENA simulation software. A comparison of different case studies was performed.

Results showed that an optimal toll plaza depends largely on the number of different types of tollbooths and the ETC share. An increase in the rate of ETC have a considerable impact in reducing the total delay caused at the manual lanes, but on the other hand it reduces the efficiency of the ETC lanes as they become gradually saturated with the increasing of its users.

Therefore, under a given time-dependent traffic flow and a set of different ETC rates, several scenarios were considered in order to find the optimal number of tollbooths that provide the best possible service.

As the proportion of the ETC user increases, number of tollbooths, queue length and waiting time are all decreased, resulting in high operating efficiency.

Table 3: Simulation results

Scenario	ETC rate	Optimal number of tollbooths	Maximum Average Waiting Time Obtained (min)
Scenario-1	40%	18 manual lanes, 3 ETC lanes and one automated lane	7
Scenario-2	60%	12 manual lanes, 4 ETC lanes and one automated lane	7
Scenario-3	80%	6 manual lanes, 6 ETC lanes and one automated lane	5
Scenario-4	95%	2 manual lanes, 7 ETC lanes and one automated lane	1.4

Conflict of Interest The authors declare no conflict of interest.

ABSTRACT

We consider the estimation of empirical probability distributions, both discrete and continuous. We focus on deriving formulas to estimate number of categories for the discrete distribution, when the number of categories is hidden, and the means and methods to estimate the number of components in the Gaussian mixture model representing a probability density function given implicitly in terms of its realizations. To reach the stated goals, we solve certain combinatorial problems for discrete distribution and develop methods to compute the expected Kullback-Leibler divergence for Gaussians. The last mentioned result is needed to develop the theory of continuous distributions. Sample applications and an extensive numerical study are given.

1 Introduction

This paper is an extension of work originally presented in 2019 Signal Processing Symposium [1]. The extension includes:

- measure theoretic account,
- derivation of the results first presented in the paper [1],
- new section devoted entirely to estimation of the number of components in continuous distributions,
- a numerical study of algorithms dealing with estimation of the continuous distributions,
- a specialized algorithm for counting number of monomials in a trace of covariance matrix raised to a power.

Empirical probability distributions are a crucial element of many applications such as machine learning [2], source coding [3], data compression [4], speech recognition [5], speaker recognition [6], image recognition [7], noise reduction [8], bandwidth extension [9], and many others. It is also a scientific discipline in itself, which is studied independently [10], [11]. In this paper, we deal with the means and methods to estimate probability distributions, both discrete and continuous. That being said, we also focus on a particular problem encountered during probability distributions estimation, which is the problem of an unknown number of components. In case of discrete distribution, the number of components is the number of categories, and in case of continuous probability distributions, it is the number of Gaussian components in the Gaussian mixture model (GMM) [2]. We provide estimators and methods to determine the number of components. Toward this, in case of GMMs, we formulate an information-theoretic criterion that allows the selection of an optimal, in some sense, number of components.

To strengthen the ties between discrete and continuous probability distribution, we provide a short account of measure theory and probability spaces. In particular, we show that the difference lies in the type of the underlying measurable space, which is a *standard space* with finite countable alphabets in case of discrete distributions and a *Polish Borel space* (where the *Polish space*, i.e., the complete separable metric space, is the sample space) in the case of continuous distributions. The name *Polish space* originates from the pioneering work by Polish mathematicians on such spaces.

1.1 Measure Theoretic Account

This account is based on the presentation provided by Robert M. Gray in an excellent book [12].

*Corresponding Author: Marcin Kuropatwiński, marcin@talking2rabbit.com

1.1.1 Measurable Space

A measurable space is a pair, $(\Omega, \mathcal{B})$ consisting of a sample space Ω with a σ-field $\mathcal{B}$ of subsets of Ω (also called the event space). A σ-field or σ-algebra $\mathcal{B}$ is a collection of subsets of Ω with the following properties:

$$\Omega \in \mathcal{B} \tag{1}$$

$$\text{If } F \in \mathcal{B}, \text{ then } F^c = \{\omega : \omega \notin F\} \in \mathcal{B} \tag{2}$$

$$\text{If } F_i \in \mathcal{B};\ i = 1, 2, \ldots, \text{ then } \cup F_i \in \mathcal{B} \tag{3}$$

The type of the measurable space is what differentiates discrete from continuous distributions. More precisely, it is the topology of the sample space. The discrete topology gives rise to discrete probability distributions, and the euclidean topology gives rise to continuous probability distributions.

Let $\mathcal{F} = \{F_i, i = 0, 1, 2, \ldots, n-1\}$ be a finite field of sample space Ω, that is, $\mathcal{F}$ is a finite collection of sets in Ω that are closed under finite set theoretic operations. To make it more concrete, let us give an example of such a field, which is the power-set of a finite, countable set of atoms (also called categories in the sequel). A set F in $\mathcal{F}$ will be called an *atom* only if its subset is also a field member of itself and the empty set, that is, it cannot be broken up into smaller pieces that are also present in the field. Let $\mathcal{A}$ denote a collection of atoms of $\mathcal{F}$. Then, one can show that $\mathcal{A}$ consists of exactly all nonempty sets of the form

$$\bigcap_{i=0}^{n-1} F_i^* \tag{4}$$

where F_i^* is either F_i or F_i^c. Let us call such sets *intersection sets*; we observe that any two intersection sets must be disjoint since for at least one i, one intersection set must lie inside F_i and the other within F_i^c. In summary, given any finite field $\mathcal{F}$ of the sample space Ω, we can find a unique collection of atoms $\mathcal{A}$ of the field such that the sets in $\mathcal{A}$ are disjoint, nonempty, and have the space Ω as their union. Thus, $\mathcal{A}$ is a *partition* of Ω. Such a sample space has a *discrete topology* with the basis given by the set of all atoms $\mathcal{A}$.

Now, we turn our attention to continuous distributions. As already mentioned, the underlying space is the *Polish Borel space*. An example of such a space, which will be used in this paper, is the *Euclidean space* endowed with the Euclidean topology. The basis for the Euclidean topology is the set of all open balls in that space. The *Polish space* is a complete, separable, metric space. We will explain what the listed properties of the *Polish spaces* mean.

A space is called *metric* if it is a set A, with elements called *points*, such that for every pair of points in A, there is an associated non-negative number $d(a, b)$ with the following properties:

$$d(a, b) = 0 \text{ if and only if } a = b \tag{5}$$

$$d(a, b) = d(b, a) \quad \textit{symmetry} \tag{6}$$

$$d(a, b) \leq d(a, c) + d(c, b) \text{ all } c \in A \quad \textit{triangle inequality} \tag{7}$$

A set F is said to be *dense* in A if every point in A is a point in F or a limit point of F.

A metric space A is called *separable* if it has a countable dense subset, that is, if there is a discrete set, say B, such that all points in A can be well approximated by points in B. This means that all the points in A are points in B or limits of the points in B. For example, n-tuples of rational numbers are dense in $\mathbb{R}^n$.

A sequence $\{a_n; n = 0, 1, 2, \ldots\}$ in A is called a *Cauchy sequence* if for every $\epsilon > 0$, there is an integer N such that $d(a_n, a_m) < \epsilon$ if $n \geq N$ and $m \geq N$. A metric space is *complete* if every Cauchy sequence converges, that is, if a_n is a Cauchy sequence, then there is $a \in A$ for which $a = \lim_{n\to\infty} a_n$.

1.1.2 Probability Spaces

A *probability space* $(\Omega, \mathcal{B}, P)$ is a triple consisting of a sample space Ω, a σ-field $\mathcal{B}$ of subsets of Ω, and a probability measure P defined on the σ-field; $P(F)$ assigns a real number to every member F of $\mathcal{B}$ so that the following conditions are satisfied:

Nonnegativity:

$$P(F) \geq 0, \text{ all } F \in \mathcal{B}, \tag{8}$$

Normalization:

$$P(\Omega) = 1. \tag{9}$$

Countable Additivity:

$$\text{If } F_i \in \mathcal{B},\ i = 0, 1, 2, \ldots \text{ are disjoint, then}$$
$$P(\bigcup_{i=0}^{\infty} F_i) = \sum_{i=0}^{\infty} P(F_i). \tag{10}$$

1.1.3 Densities

The probability density function (PDF) is a measure theoretic term defined through the *Radon-Nikodym theorem*.

A measure m is said to be *absolutely continuous* with respect to another measure P on the same measurable space, formally $m \ll P$, if $P(F) = 0$ implies $m(F) = 0$.

Theorem (*Radon-Nikodym theorem*)

Given the two measures m and P on a measurable space $(\Omega, \mathcal{F})$ such that $m \ll P$, there exists a measurable function $h : \Omega \to \mathbb{R}$ with the property that $h \geq 0$ such that

$$m(F) = \int_F h dP, \text{ all } F \in \mathcal{B}. \tag{11}$$

The function h is called the Radon-Nikodym *derivative* or *density* of m w.r.t. P and is denoted by $\frac{dm}{dP}$. If $\int f dP = 1$, then f is called a *probability density function*.

2 Discrete Distributions

For the statement of all results, as well as notations conventions, we refer the reader to the paper [1]. The results in the article [1] include discussion of the sun rise problem by Pierre-Simon Laplace from the essay [13] and some applications of the theory. We reference the paper [1] in its entirety. Here, only extensions of the material from the paper [1] are included, which have not found place there due to the form of a conference paper. However, for the readers convenience we provide a short summary of the notations used in the derivations:

- K - number of categories, possibly a hidden variable
- M - number of random experiments

- S - the partition, set of all categories
- $\{p_i\}_{i\in S}$ - multinomial proportions
- $X = \{x_i\}_{(i\in[1,M],x_i\in S)}$ - observations from the random experiments
- $|A|$ - cardinality of the set A
- UNIQUE(X) - unique elements in the multiset X
- $Z = |\text{UNIQUE}(X)|$ - the diversity index
- $P_i = |\{x_j : x_j = i\}|$ - counts of the observations

2.0.1 Derivations of the results for the uniform distribution

Assumption of uniform distribution is restrictive. However, it gives initial insight into the problem and, thus, is briefly presented here. As already introduced by X, we denote the sequence of observations. We can show that conditional probability of this sequence given the hypothetical K is equal to:

$$p(X|K) = \binom{K}{Z}\binom{M}{P_1 P_2 \cdots P_3}\frac{1}{K^M}. \tag{12}$$

It can be seen that the maximum likelihood estimate for the hypothetical number of categories, does not depend on the middle term, which includes the multinomial coefficient. Thus, the estimate can be obtained by,

$$K_{\text{ML}} = \underset{K}{\text{argmax}}\left[\binom{K}{Z}K^{-M}\right]. \tag{13}$$

It is convenient to introduce another quantity, which plays an important role in our theory. This quantity is the *generalization coefficient* N, which equals by definition:

$$N \equiv \frac{M}{Z}. \tag{14}$$

The ML estimate of K can then be obtained by solving the following equation:

$$\frac{1}{v}\ln\left(\frac{1}{1-v}\right) = N, \tag{15}$$

where:

$$v = \frac{Z}{K_{\text{ML}}}, \tag{16}$$

is the fraction of the number of observed categories to the number of all categories. The condition for the likelihood to be monotonically decreasing is as follows:

$$M > \log_{\left(\frac{Z+1}{Z}\right)}(Z+1). \tag{17}$$

If this condition holds, the ML estimate for K is equal to Z. The derivations of the above conditions are in place next. First, we note a property that establishes the link with the known in the statistical literature problem of coupon collector [14]:

$$\lim_{K\to\infty}\left(\frac{K\times H(K)}{\log_{\left(\frac{K+1}{K}\right)}(K)}\right) = 1, \tag{18}$$

where one can easily recognize that $K \times H(K)$ is the expected number of trials before the coupon collector collects the whole collection. In the above expression, $H(K)$ is the harmonic number, equal by definition:

$$H(K) \equiv \sum_{i=1}^{K}\frac{1}{i}. \tag{19}$$

The main vehicle of the derivation is the following expression that is valid for the harmonic numbers [15]:

$$\sum_{i=1}^{K}\frac{1}{i} = C + \ln K + \frac{1}{2K} - \sum_{i=2}^{\infty}\frac{A_i}{K(K+1)\cdots(K+i-1)}, \tag{20}$$

where C is the Euler-Mascheroni constant. It can be seen that asymptotically, as K approaches infinity, the terms after the logarithmic term vanish to zero. This leads to the following property:

$$\lim_{K\to\infty}\left(\sum_{i=1}^{K}\frac{1}{i} - \ln K\right) = C. \tag{21}$$

The derivation for the condition (15) begins with taking the logarithm of the considered expression (13):

$$\ln[p(X|K)] = \sum_{i=1}^{K}\ln i - \sum_{i=1}^{Z}\ln i - \sum_{i=1}^{K-Z}\ln i - M\ln K. \tag{22}$$

Suppose, i is a continuous variable, which setting follows from allowing that variable to take on non-integer values. It can be seen that the middle sum does not depend on K; therefore, derivative w.r.t that variable reads:

$$\frac{d}{dK}\ln[p(X|K)] = \sum_{i=1}^{K}\frac{1}{i} - \sum_{i=1}^{K-Z}\frac{1}{i} - \frac{M}{K} = \ln K - \ln(K-Z) - \frac{M}{K}. \tag{23}$$

The last expression allows us to immediately state the (15) and (16). Equations (15) and (16) allow us to conclude that the sample length needed to learn a given percent of the categories S is a multiple of K. Setting $Z = M$, we see that, indeed, this ($Z = M$) is the sufficient and necessary condition for optimal K approaching infinity. This is due to the following identity:

$$\lim_{K\to\infty}\frac{K}{M}\ln\left(\frac{1}{1-\frac{M}{K}}\right) = 1. \tag{24}$$

It remains to prove the (17). In this case, the maximum of the likelihood should be attained at $K = Z$. Thus, we have the following inequality:

$$\ln[p(X|Z)] > \ln[p(X|Z+1)], \tag{25}$$

which implies:

$$\ln(Z+1) - M\ln(Z+1) < -M\ln Z, \tag{26}$$

and, after some algebra, we attain at the (17). From the above reasoning all the results pertaining to the discrete, uniform distribution from the paper [1] can be deduced. In Figure 1, we illustrate the dependence of the data amount M needed to learn a given percent of all categories.

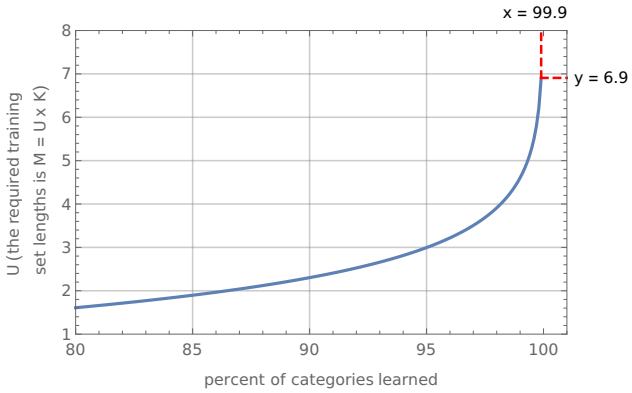

Figure 1: Data amounts requirement to learn a given percent of categories in case of uniform distribution

Next, we discuss the case of the non-uniform distribution, which is more relevant for real-world applications.

2.0.2 *Derivations of the results for the non-uniform distribution*

The next step will be the derivation of the conditions analogous to that introduced in the previous section, which are distribution-free (we relax the assumption of categories of equal probabilities). The desired effect will be achieved by using the earlier introduced multinomial proportions $\{p_i\}_{i\in S}$. Since we do not impose a constraint on the multinomial proportions, the considered probability function is now in the form,

$$p(X|K, p_1, \cdots, p_K) = \binom{M}{P_1 P_2 \cdots P_Z} \sum_{\{\mathbf{k}\,:\,\text{combinations of } Z \text{ objects out of } K \text{ objects}\}} \prod_{i=1}^{Z} p_{k_i}^{P_i}, \tag{27}$$

where $\mathbf{k} = [k_1, \cdots, k_Z]$. We integrate the above function over a unit simplex D:

$$D = \left\{ \mathbf{p} : \sum_{i=1}^{K} p_i = 1, p \in \mathbb{R}_+^K \right\}. \tag{28}$$

This corresponds to the assumption that all PMFs are equally likely, meaning we assume that we do not know the true PMF and attach to each possible $\mathbf{p} = [p_1, \cdots, p_K]$ an equal weight (we assume they are equally probable):

$$p(X|K) = \frac{1}{\text{vol}(D)} \int_D p(X|K, \mathbf{p}) d\mathbf{p} = \binom{K}{Z}\binom{M}{P_1 P_2 \cdots P_Z} \frac{1}{\text{vol}(D)} \int_D p_1^{P_1} \times \cdots \times p_Z^{P_Z} d\mathbf{p}, \tag{29}$$

where the expression (29) follows the fact, that the value of the integral does not depend on the choice and order of the probabilities in the monomial integrand. To proceed with the derivation, we compute the integral in (29) using Brion's formulae; please see [16]:

$$\frac{1}{\text{vol}(D)} \int_D p_1^{P_1} \times \cdots \times p_Z^{P_Z} d\mathbf{p} = (K-1)! \frac{\prod_{i=1}^{Z} P_i!}{(M+K-1)!}. \tag{30}$$

In light of the above expression, we get,

$$p(X|K, M) = \frac{K! M! \Gamma(K)}{Z!(K-Z)!\Gamma(K+M)}, \tag{31}$$

and next,

$$p(Z|K, M) = \frac{M\Gamma(K)\Gamma(K+1)\Gamma(M+Z)}{\Gamma(Z+1)^2\Gamma(K+M)\Gamma(K-Z+1)}. \tag{32}$$

To get the probability of the hypothetical number of categories, given M and Z, we apply the following derivation:

$$p(K|Z, M) = \frac{p(Z|K, M)p(K)}{p(Z|M)} = \frac{p(Z|K, M) \times C}{\sum_{K=Z}^{\infty} p(Z|K, M) \times C} = \frac{p(Z|K, M)}{\sum_{K=Z}^{\infty} p(Z|K, M)}, \tag{33}$$

where C is some constant (not to be confused with the Euler-Mascheroni constant used earlier in this document). Evaluation of (33) yields the following:

$$p(K|Z, M) = \frac{\Gamma(K)\Gamma(K+1)\Gamma(M-1)\Gamma(M)}{\Gamma(Z)\Gamma(Z+1)\Gamma(K+M)\Gamma(K-Z+1)\Gamma(M-Z-1)}. \tag{34}$$

From the reasoning presented above we can state the following:

$$s = \frac{u}{u+1}, \quad s = \frac{Z}{K}, \quad u = \frac{M}{K}. \tag{35}$$

Also, all results pertaining to non-uniform distribution, stated in the paper [1], are a consequence of the above reasoning. Based on (35) we can plot the dependence of the amount of data needed to learn given percent of all categories. This dependence is shown in Figure 2.

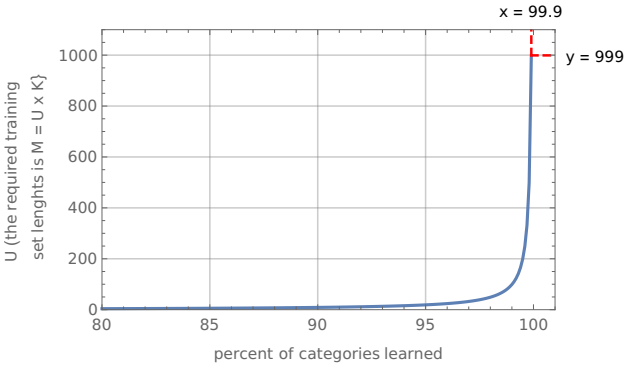

Figure 2: Data amounts requirement to learn a given percent of categories in case of non-uniform distribution

3 Continuous Distributions

The prominent method of density estimation for continuous distribution are Gaussian mixture models (GMM). The GMMs can approximate a PDF given by some training vectors drawn from that PDF. A wide-spread fitting procedure of the GMMs to the given training vectors is based on the Expectation-Maximization (EM) algorithm. Both, the mathematical definition of GMMs and the fitting procedure based on the EM is explained in detail in the book [2]. The neat property of the GMMs is that their expressive power allows modeling any PDF to any accuracy, given enough training

vectors are available. However, the traditional fitting procedure is susceptible to overtraining if too many components are chosen. Thus, in this paper, we study a fitting method that does not overfit, and, secondly, allows for the estimation of the number of components given the newly introduced information-theoretic criterion. To reach the goal of formulating the criterion, we first develop a mathematical approach to compute the expected Kullback-Leibler (KL) divergence for the single multivariate Gaussian, whereas the expectation is taken over given number M of samples used to estimate the multivariate Gaussian. In this section, we first develop the theory of expected KL divergence; next, we provide the modified training procedure and end the section with a numerical study.

3.1 Computation of expected Kullback-Leibler divergence

To the best of the authors' knowledge, the computation of the expected Kullback-Leibler divergence for multivariate Gaussian variables has been never previously explored in the literature. Thus, this paper deals with this problem, which can be formally expressed as,

$$\mathrm{E}_{\mathrm{KL}}(M) = \mathbb{E}_{x_i\sim p(x)}\left[D_{\mathrm{KL}}(p(x)\|\hat{q}(x,x_1,\cdots,x_M))\right], \tag{36}$$

where $p(x)$ and $q(x)$ are multivariate Gaussians.

The solution to the problem indicated above can be used in the context of the Minimum Description Length (MDL) cf. [17] or Minimum Discrimination Information (MDI), cf. [18]. MDI and MDL principles have been used often for solving computational learning problems (see [19]–[23]).

The well-known result from the statistics is the following formula for the KL divergence between two multivariate Gaussians:

$$D_{\mathrm{KL}}(p\|q) = \int p(x)\log\frac{p(x)}{q(x)}\mathrm{d}x, \tag{37}$$

for $p(x)$ and $q(x)$ given as:

$$p(x) = \mathcal{N}(x|\mu_1,\Sigma_1) \quad \text{and} \quad q(x) = \mathcal{N}(x|\mu_2,\Sigma_2), \tag{38}$$

where:

$$\mathcal{N}(x|\mu,\Sigma) = \det(2\pi\Sigma)^{-\frac{1}{2}}\exp\left(-\frac{1}{2}(x-\mu)^T\Sigma^{-1}(x-\mu)\right), \tag{39}$$

and finally (see [24]):

$$D_{\mathrm{KL}}(p\|q) = \frac{1}{2}\Big[\log\left(\frac{\det(\Sigma_2)}{\det(\Sigma_1)}\right) - d + \mathrm{tr}(\Sigma_2^{-1}\Sigma_1) + (\mu_2-\mu_1)^T\Sigma_2^{-1}(\mu_2-\mu_1)\Big], \tag{40}$$

where d is the dimension of PDFs p and q.

Next, let us assume that the positively defined and symmetric Σ_1 is given, μ_1 is a zero vector, and Σ_2 and μ_2 are estimated from samples x_i, where $x_i \sim \mathcal{N}(x|\mu_1,\Sigma_1)$:

$$\mu_2 = \frac{1}{M}\sum_{i=1}^{M} x_i \quad \Sigma_2 = \frac{1}{M}\sum_{i=1}^{M}(x_i-\mu_1)(x_i-\mu_1)^T = \frac{1}{M}\sum_{i=1}^{M} x_i x_i^T, \tag{41}$$

where M is the number of samples (length of the observation). We also assume that Σ_2 is positively definite and thus well-conditioned (otherwise KL divergence would go to infinity). This assumption leads to the requirement that M has to be greater than the dimension of Σ_1 when Σ_2 is non-diagonal.

As already indicated in (36), we are looking for the expectation of the Kullback-Leibler divergence over finite sample:

$$\mathbb{E}_{x_i\sim p(x)}\left[D_{\mathrm{KL}}(p(x)\|\hat{q}(x,x_1,\cdots,x_M))\right],$$

where $p(x)$ and $q(x)$ are given in (38).

We consider two cases: the first case is when the covariance matrix is diagonal, and the second case, which is a more complicated one, is when the covariance matrix is full.

3.1.1 Diagonal Case

At first, it is worth noticing that the expectation of the Kullback-Leibler divergence does not depend on a specific form of the covariance matrix Σ_1. Let us introduce the following substitution:

$$x_i = \Sigma_1^{\frac{1}{2}} y_i \quad \text{where} \quad y_i \sim \mathcal{N}(y|0,I), \tag{42}$$

which, in turn, under the assumption given by the (41), gives:

$$\mathbb{E}\left[\log\left(\frac{\det(\Sigma_2)}{\det(\Sigma_1)}\right)\right] = \mathbb{E}[\mathrm{tr}(\log\Sigma)], \tag{43}$$

where:

$$\Sigma = \frac{1}{M}\sum_{i=1}^{M}\mathrm{diag}(y_i\odot y_i), \tag{44}$$

where $\odot$ denotes the element-wise product, the Hadamard product. It is worth mentioning that we have used the following identity (see [25]):

$$\log(\det(\Sigma)) = \mathrm{tr}(\log\Sigma). \tag{45}$$

Since Σ is diagonal and y_i has a zero mean vector, we conclude,

$$\begin{aligned}\mathbb{E}[\mathrm{tr}(\log\Sigma)] = \\ \mathbb{E}\left[\sum_{k=1}^{d}\log\left(\frac{1}{M}\sum_{i=1}^{M} y_i(k)^2\right)\right] = \\ \mathbb{E}\left[\sum_{k=1}^{d}\log(\sigma_M(k)^2)\right] = \\ = d\cdot\mathbb{E}[\log(\sigma_M(1)^2)] = \\ d\left(\psi\left(\frac{M-1}{2}\right) + \log 2 - \log(M-1)\right),\end{aligned} \tag{46}$$

where $\psi(n)$ is the digamma function.

The next expression, which appears in (40), is:

$$\mathrm{tr}(\Sigma_2^{-1}\Sigma_1) = \mathrm{tr}(\Sigma^{-1}), \tag{47}$$

where Σ is defined as in (44). After a number of transformations, we get

$$\mathbb{E}[\mathrm{tr}\Sigma^{-1}] = \mathbb{E}\left[\sum_{k=1}^{d}\frac{1}{\sigma_M^2(k)}\right] = d\cdot\mathbb{E}\left[\frac{1}{\sigma_M^2(1)}\right] = d\frac{1}{M-2}. \tag{48}$$

The last expression, which needs to be calculated, is

$$\mathbb{E}[\mu_2^T \Sigma_2^{-1} \mu_2] = \mathbb{E}\left[\sum_{k=1}^{d} \frac{\bar{x}(k)^2}{\sigma_M(k)^2}\right] = d \cdot \mathbb{E}\left[\frac{\bar{x}(1)^2}{\sigma_M(1)^2}\right] = d\frac{M-1}{M\cdot(M-2)}. \quad (49)$$

And finally, our derived formula reads,

$$\mathrm{E_{KL}}(M) = \frac{d}{2}\left[\psi\left(\frac{M-1}{2}\right) + \log 2 - \log(M-1) - 1 + \frac{M}{M-2} + \frac{M-1}{M\cdot(M-2)}\right]. \quad (50)$$

3.1.2 Non-diagonal Case

In the non-diagonal covariance matrix case, we first introduce the same substitution as in the diagonal case, which is shown in (42):

$$x_i = \Sigma_1^{\frac{1}{2}} y_i \quad \text{where} \quad y_i \sim \mathcal{N}(y|0, I). \quad (51)$$

We start by calculating the logarithmic expression, which appears in (40). By using identity in (45), and transforming the expression using (41), as previously, we get,

$$\log\left(\frac{\det(\Sigma_2)}{\det(\Sigma_1)}\right) = \mathrm{tr}(\log \Sigma). \quad (52)$$

To calculate the expectation of this expression, we use the expansion of the matrix logarithm into the power series, see [26]:

$$\log A = \sum_{k=1}^{\infty} (-1)^{k+1} \frac{(A-I)^k}{k}, \quad (53)$$

and, after a number of transformations, we get,

$$\mathbb{E}[\mathrm{tr}(\log \Sigma)] = \mathbb{E}[\mathrm{tr}(\log m\Sigma - \log mI)] = \mathbb{E}\left[\mathrm{tr}\left(\sum_{k=1}^{\infty}(-1)^{k+1}\frac{1}{k}\sum_{j=0}^{k}\binom{k}{j}(-1)^j m^{k-j}\Sigma^{k-j} - \log mI\right)\right], \quad (54)$$

where m is chosen so as to $\|m\Sigma - I\| < 1$ is satisfied.

We further develop our approximation by introducing the following auxiliary function:

$$z(k, k_{max}) = \begin{cases} \sum_{i=1}^{k_{max}} (-1)^{k+1} \cdot \binom{i}{k} \cdot \frac{1}{i} & \text{when } k = 0 \\ \sum_{i=k}^{k_{max}} (-1)^{k+1} \cdot \binom{i}{k} \cdot \frac{1}{i} & \text{when } k > 0 \end{cases}, \quad (55)$$

and, consequently:

$$\mathbb{E}[\mathrm{tr}(\log \Sigma)] = \sum_{k=0}^{k_{max}} z(k, k_{max}) \cdot m^k \cdot \mathbb{E}\left[\mathrm{tr}\left(\Sigma^k\right)\right] - d \log m, \quad (56)$$

where d is a dimension of the covariance matrix. To proceed further, we calculate the expectation of $\mathrm{tr}(\Sigma^k)$. It is worth noticing that the integral

$$\int_{-\infty}^{+\infty} t^n \mathcal{N}(t|0,1)\mathrm{d}t = \frac{1}{\sqrt{2\pi}} 2^{\frac{n-1}{2}}((-1)^n + 1)\Gamma\left(\frac{n+1}{2}\right), \quad (57)$$

vanishes for odd n. At this point, we need to calculate the number of monomials with only even exponents that appear in $\mathrm{tr}(\Sigma^k)$.

Now we can describe the algorithm for calculating the number of such monomials. First, we introduce the following auxiliary matrix:

$$A = \frac{1}{\sqrt{M}}\left[y_1 \middle| \ldots \middle| y_M\right]. \quad (58)$$

One can easily notice that:

$$\Sigma = \frac{1}{M}\sum_{i=1}^{M} y_i y_i^T = A \cdot A^T, \qquad \Sigma^n = \underbrace{(AA^T)\ldots(AA^T)}_{n}, \quad (59)$$

which leads to formula for the specific element, ${\Sigma^n}_{ij}$, of the covariance matrix raised to the n-th power:

$${\Sigma^n}_{ij} = A_{i*} \cdot A^T \ldots A \cdot A^T_{*j} = \sum_{s_1=1}^{d}\sum_{k_1=1}^{M} a_{ik_1} \cdot a^{(T)}_{k_1 s_1} \ldots \sum_{s_{n-1}=1}^{d}\sum_{k_n=1}^{M} a_{s_{n-1}k_n} \cdot a^{(T)}_{k_n j} = \sum_{s_1,\ldots s_{n-1}} \sum_{k_1,\ldots,k_n} a_{ik_1} a_{s_1 k_1} a_{s_1 k_2} \ldots a_{s_{n-1}k_n} a_{jk_n}, \quad (60)$$

The number of the above configurations with only even exponents is equal to the number of even partitions of $2n$. For such a partition, we have to calculate the number of monomials separately. The detailed description of the algorithm for counting monomials is presented in section A. Implementation of the algorithm for counting monomials and computing expected KL divergence is available (see [27]). Below, we have shown examples of the formulas derived by the above-mentioned algorithm, for the power of $n = 3$, where d is a dimension of the covariance matrix and M is the number of samples used to estimate the matrix:

$$\begin{gathered} \text{Partition: 2 2 2} \\ dM(M-1)(M-2) + dM(d-1)(d-2) + 3dM(M-1)(d-1) \\ \\ \text{Partition: 4 2} \\ 3dM(M-1) + 3dM(d-1) \\ \\ \text{Partition: 6} \\ dM \end{gathered} \quad (61)$$

Once we have calculated the number of monomials for each power n, it is relatively easy to calculate the expectation in (56).

The second expression, which has to be calculated, is

$$\mathrm{tr}\left(\Sigma_2^{-1}\Sigma_1\right). \quad (62)$$

We start in the same way as in the diagonal case:

$$\mathrm{tr}\left(\Sigma_2^{-1}\Sigma_1\right) = \mathrm{tr}\Sigma^{-1}. \quad (63)$$

The next step is to expand inversion of the covariance matrix into the Neumann series (see [28]):

$$\Sigma^{-1} = m \sum_{k=0}^{\infty} (I - m\Sigma)^k, \tag{64}$$

where m is selected so that $\|I - m\Sigma\| < 1$ is satisfied. After several transformations, we get

$$\Sigma^{-1} \approx \sum_{k=0}^{k_{max}} (-1)^k m^{k+1} \binom{k_{max}+1}{k+1} \Sigma^k, \tag{65}$$

which finally gives,

$$\mathbb{E}[\mathrm{tr}\Sigma^{-1}] \approx \sum_{k=0}^{k_{max}} (-1)^k m^{k+1} \binom{k_{max}+1}{k+1} \mathbb{E}[\mathrm{tr}\Sigma^k]. \tag{66}$$

We note that the resulting expression has a similar form to (56), with the difference of the k-dependent expression. The last expression for which the expectation needs be calculated is

$$(\mu_2 - \mu_1)^T \Sigma_2^{-1} (\mu_2 - \mu_1). \tag{67}$$

By using substitution (41), and subsequently (42), we get

$$\mu_2^T \Sigma_2^{-1} \mu_2 = \left(\frac{1}{M} \sum_{i=1}^{M} \Sigma_1^{\frac{1}{2}} y_i \right)^T \Sigma_2^{-1} \left(\frac{1}{M} \sum_{i=1}^{M} \Sigma_1^{\frac{1}{2}} y_i \right) = \left(\frac{1}{M} \sum_{i=1}^{M} y_i \right)^T \Sigma^{-1} \left(\frac{1}{M} \sum_{i=1}^{M} y_i \right), \tag{68}$$

then, given (58), and by expanding the inverse of the covariance matrix as in (64) into the Neumann series, we get:

$$\mu_2^T \Sigma_2^{-1} \mu_2 = \sum_{i,j} \left[\frac{1}{M^2} A^T \Sigma^{-1} A \right]_{ij} \approx \frac{1}{M^2} \sum_{i,j} \sum_{k=0}^{k_{max}} (-1)^k m^{k+1} \binom{k_{max}+1}{k+1} A_{i*}^T \Sigma^k A_{*j}. \tag{69}$$

Now, we need to calculate the following expression:

$$A_{i*}^T \Sigma^n A_{*j}. \tag{70}$$

By multiplying out we get:

$$A_{i*}^T \Sigma^n A_{*j} = \sum_{s_0=1}^{d} \sum_{s_n=1}^{d} a_{is_0}^{(T)} \left[\Sigma^n\right]_{s_0 s_n} a_{s_n j} = \sum_{s_0} \sum_{s_n} a_{s_0 i} \sum_{s_1,\ldots,s_{n-1}} \sum_{k_1,\ldots,k_n} a_{s_0 k_1} a_{s_1 k_1} a_{s_1 k_2} \ldots a_{s_{n-1} k_n} a_{s_n k_n} a_{s_n j} = = \sum_{s_1,\ldots,s_{n+1}} \sum_{k_1,\ldots,k_n} a_{s_1 i} a_{s_1 k_1} \ldots a_{s_{n+1} k_n} a_{s_{n+1} j}. \tag{71}$$

An important observation is in place, namely, the monomials cannot have only even exponents if $i \neq j$. This allows us to bring down the calculation of the expectation of the above expression to the expectation of the trace of Σ^{n+1}. Thus, finally, we get

$$\mathbb{E}[\mu_2^T \Sigma_2^{-1} \mu_2] \approx \frac{1}{M} \sum_{k=0}^{k_{max}} (-1)^k m^{k+1} \binom{k_{max}+1}{k+1} \mathbb{E}[\mathrm{tr}\Sigma^{k+1}]. \tag{72}$$

Obviously, the algorithm for calculating the above expression is the same as in the case of the two previously examined terms.

3.2 Procedure

Here, we show how to estimate the GMM using the modified training procedure. The introduced procedure solves the problem of overtraining. First, we focus on training the GMM with fixed K - the number of components in the mixture. Based on this development, we formulate a method to select the optimal number of components for a given training set without resorting to the development sets. The classical Expectation-Maximization algorithm, cf. [2], produces in each iteration more and more accurate estimates of the mean vectors, covariance matrices, and weights. We denote the trajectory of these parameters in subsequent iterations as,

$$\theta = \left[\theta^{(1)}, \cdots, \theta^{(J)}\right], \tag{73}$$

where J is the maximum acceptable number of iterations (or the number of iterations until convergence), and

$$\theta^{(j)} = \left[\Sigma_1^{(j)}, \cdots, \Sigma_K^{(j)}, \mu_1^{(j)}, \cdots, \mu_K^{(j)}\right], \tag{74}$$

with j the iteration number, Σ_i denoting covariance matrix for the $i-$th component, μ_i denoting the mean vectors for the $i-$th component, and K the number of components in the Gaussian mixture. Moreover, we denote $\theta_k^{(j)} = [\Sigma_k^{(j)}, \mu_k^{(j)}]$. To proceed further, we introduce and define some mathematical entities:

- the *entropy* in nats of the categorical distribution $\{r_i\}_i$ is defined as $H(\{r_i\}) = -\sum_i r_i \log r_i$
- the *kernel width* is the effective number of samples used to estimate a given component. Given the samples $\{x_i\}_{i=1}^M$, we compute the *kernel width*, $w(\theta, \{x_i\})$, also abbreviated by $w(\theta)$, using the following set of formulas:

$$r_i = \frac{\mathcal{N}(x_i|\theta)}{\sum_l \mathcal{N}(x_l|\theta)}, \tag{75}$$

$$w(\theta) = \exp\left(H(\{r_i\})\right), \tag{76}$$

- Gaussian *component differential entropy* in nats, $H(\theta)$, will be defined as:

$$H(\theta) = \frac{1}{2} \log\left(\det(2\pi e \Sigma)\right), \tag{77}$$

- the *score* or *cross entropy* for the component is expressed by the following formula:

$$s(\theta) = H(\theta) + \mathrm{E}_{\mathrm{KL}}\left(w(\theta)\right). \tag{78}$$

We see that the expression for *cross entropy* depends only on the observed quantities.

Equipped with the above definitions, we can formulate the algorithm,

Algorithm 1: train GMM

Require: starting parameters values $\theta^{(0)}$, maximal number of iterations J, initial scores $s\left(\theta_k^{(0)}\right) = \infty$, set all weights to $\rho_k = \frac{1}{K}$.
Ensure: $\theta^{(J)}$ and weights $\{\rho_k\}$.
1: **for** $j \in [1, \ldots, J]$ **do**
2: compute $\theta^{(j)}$ update according to EM (keeping weights unchanged)
3: **for** $k \in [1, \ldots, K]$ **do**
4: **if** $s\left(\theta_k^{(j)}\right) > s\left(\theta_k^{(j-1)}\right)$ **then**
5: $\theta_k^{(j)} = \theta_k^{(j-1)}$ (backtracking)
6: **end if**
7: **end for**
8: **end for**
9: run few EM updates of weights alone
10: **return** $\theta^{(J)}$ and weights $\{\rho_k\}$

Algorithm 2: train GMM

Require: starting parameters values $\theta^{(0)}$, maximal number of iterations J, initial scores $s\left(\theta_k^{(0)}\right) = \infty$, set all weights to $\rho_k = \frac{1}{K}$.
Ensure: $\theta^{(J)}$ and weights $\{\rho_k\}$.
1: **for** $j \in [1, \ldots, J]$ **do**
2: compute $\theta^{(j)}$ update according to EM (keeping weights unchanged)
3: **for** $k \in [1, \ldots, K]$ **do**
4: **if** $s\left(\theta_k^{(j)}\right) > s\left(\theta_k^{(j-1)}\right)$ **then**
5: $\theta_k^{(j)} = \theta_k^{(j-1)}$ (backtracking)
6: **end if**
7: **end for**
8: **end for**
9: ~~run few EM updates of weights alone~~
10: **return** $\theta^{(J)}$ and weights $\{\rho_k\}$

The mechanism behind the algorithm 1 is as follows:

- if the number of components is large in comparison to the number of training vectors, the precision of each component goes up with each iteration until it eventually reaches infinity; this means at the same time, $H(\theta)$ goes toward $-\infty$ (in practice, it will stop at a low value due to the constraint we put on the minimal eigenvalue of the covariance matrix)
- the second term in the expression for *score*, see 78, to the contrary, grows toward $+\infty$ as *kernel width* approaches dimension of the training vectors d. Thus, even if *componenent differential entropy* goes toward $-\infty$, the *cross entropy* has a minimal extreme point and at the very last grows toward $+\infty$.
- thus, the statements from 3-7 in the algorithm 1 prevent the collapse of the components to something resembling a dirac delta
- in effect, the algorithm does not overtrain

We also examine the algorithm 2, which does not run a few EM updates of weights (statement 9 in algorithm 1).

3.2.1 Number of components selection criterion

The *cross entropy* in 78 is the expression on number of nats needed to code from the component. Based on the *cross entropy*, we can get the number of bits needed to code with given fidelity using the Shannon-Lower-Bound [29].

Given the component *weights* $\{\rho_k\}_{k=1}^K$, the average number of nats needed to code from the GMM modeled source PDF is equal to

$$C_1\left(K, \theta^{(J)}, \{\rho_k\}\right) = C_1(K) = \underbrace{H\left(\{\rho_k\}_{k=1}^K\right)}_{\text{components indices entropy}} + \underbrace{\sum_{k=1}^{K} \rho_k s\left(\theta_k^{(J)}\right)}_{\text{mean per component cross entropy}} . \quad (79)$$

We also consider a second criterion, which seems to give meaningful results:

$$C_2\left(K, \theta^{(J)}, \{\rho_k\}\right) = C_2(K) = \underbrace{\sum_{k=1}^{K} \rho_k s\left(\theta_k^{(J)}\right)}_{\text{mean per component cross entropy}} . \quad (80)$$

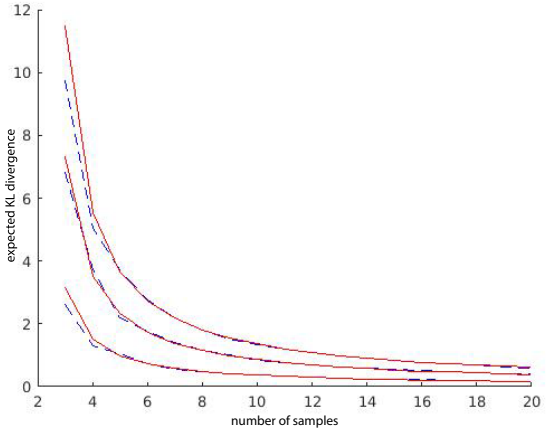

Figure 3: Comparison of the empirically and analytically obtained expectation of the KL divergence for Gaussians with the diagonal covariance matrices. Dashed lines represent the Monte Carlo result. Dimensions of covariance matrices from the beginning of the coordinate axes: 3, 7, and 11, respectively.

To find the optimal number of components K (which minimizes the average number of nats needed to code from the source), we proceed as follows:

- we swap the K from 1 to M
- for each K we run the algorithm 1 or 2.

- we smooth with smoothing splines, see [30], the resulting curve $C_*(K)$, obtaining a smoothed curve $\tilde{C}_*(K)$
- we select $\hat{K}$ for which $\tilde{C}_*(\hat{K})$ attains minimum and returns the optimal number of components.

Above, the asterisk means either 1 or 2.

3.3 Numerical experiments

3.3.1 Expected Kullback-Leibler Divergence

In this section, the comparison our analytical results with the Monte-Carlo obtained curves of expected Kullback-Leibler divergence will be presented. First, the results for the diagonal covariance matrix will be shown in Figure 3.

As can be seen, the analytical expectation shows high accuracy for the diagonal covariance matrices.

The results are a bit worse for the non-diagonal matrix. The following issues affected the accuracy of the result:

- the calculation of the higher degree series expansions was too hard as the computation of the number of even exponent monomials grew exponentially with n. We were able to compute the number of monomials for n as high as eight (the formulas for $n = 8$ when written on A4 page taking 44000 rows).
- The Monte-Carlo curves on the left are sensitive to the threshold for the detection of the semi-definiteness of the matrices. It sometimes happens that one of the eigenvalues of the covariance matrix is very small. Then value of term $\mathrm{tr}\Sigma^{-1}$ grows enormously. It is clear that the result depends on the choice of the threshold.

Figure 4 depicts the results for non-diagonal covariance matrices. To obtain the plot, we rejected matrices with the smallest eigenvalue less than 0.01 (which is around $\frac{1}{100}$ of the largest eigenvalue).

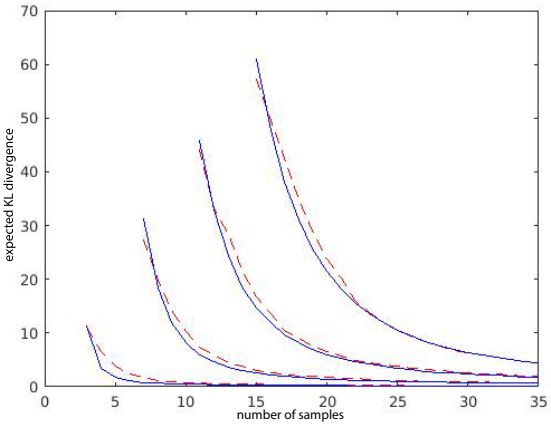

Figure 4: Comparison of empirically and analytically obtained expectation of the KL divergence for Gaussians with the non-diagonal covariance matrices. Dashed lines represent the Monte Carlo estimation. Dimensions of covariance matrices from the beginning of the coordinate axes: 3, 7, 11, and 15, respectively.

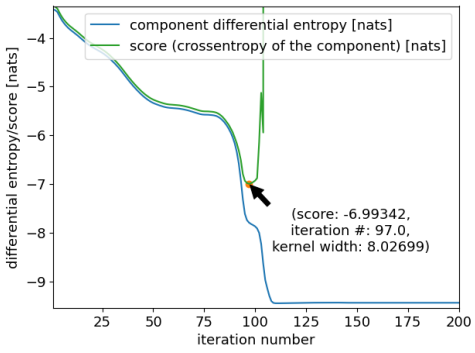

Figure 5: Illustration of the overtraining prevention mechanism. Plot shows that score prevents the overtraining, differential entropy of the Gausssian component goes down and the score starts increasing after kernel width exceeds 8 training points

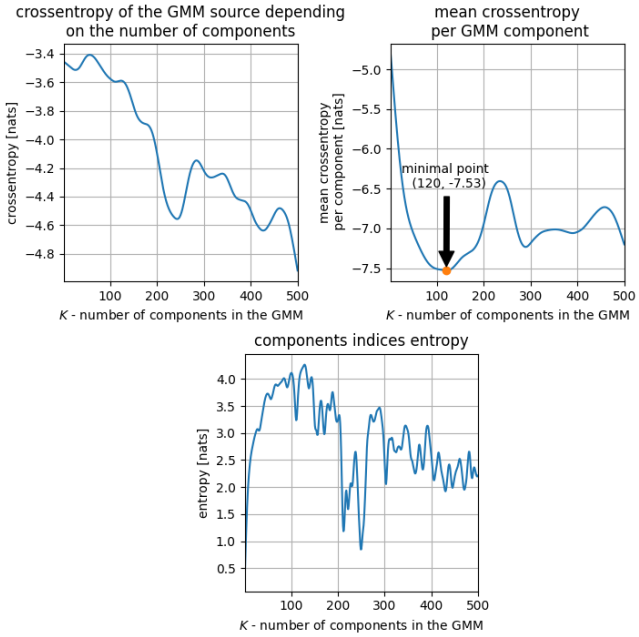

Figure 6: Results of the algorithm 1 for $d = 2$

3.3.2 Overtraining Prevention Mechanism

Here, we present a drawing (Figure 5) showing the trajectory of the *score* and *component differential entropy*. The plot has been obtained by by recording the parameters for subsequent iterations for one chosen component of the GMM. We see that the *score* attains minimum but *component differential entropy* goes to $-\infty$. This allows to use the backtracking procedure present in algorithms 1 and 2.

3.3.3 Numerical Analysis of the Number of Components Selection Criteria

All numerical experiments of this section has been carried out using the Line Spectral Frequencies (LSF) as the data to which the GMMs are fitted. The LSFs were computed from the LibriSpeech database. In all subsequent experiments the training set length M equals 1000.

First, the workings of the algorithm 1 will be presented. The Figure 6 shows the criteria C_1 and C_2 and the *components indices entropy* on pictures from left to right and from top to bottom, respectively. We see erratic behaviour of the *components indices entropy* that falls down, meaning it silences some components by driving some weights to zero. The criterion C_1 suggests that the optimal number of components is > 500, what is unlikely and probably caused by silencing of some components by zero weights. The C_2 criterion, instead, gives a sensible result. We see that for algorithm 2, selected by the C_2 criterion, number of components is similar.

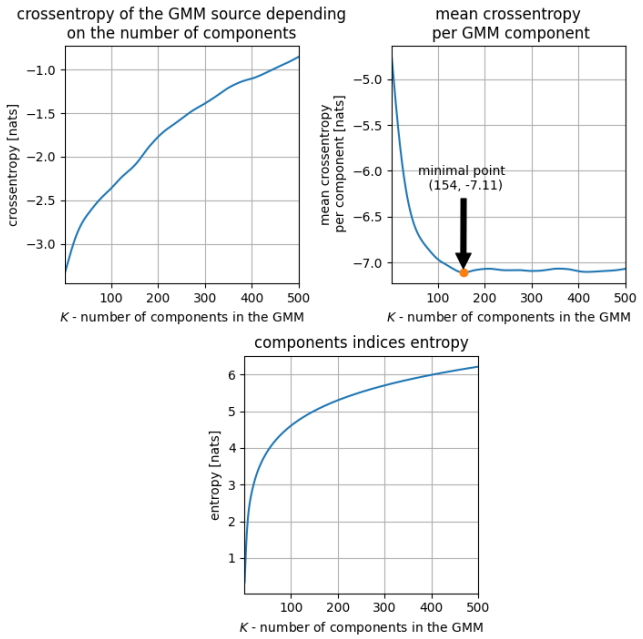

Figure 7: Results of the algorithm 2 for $d = 2$

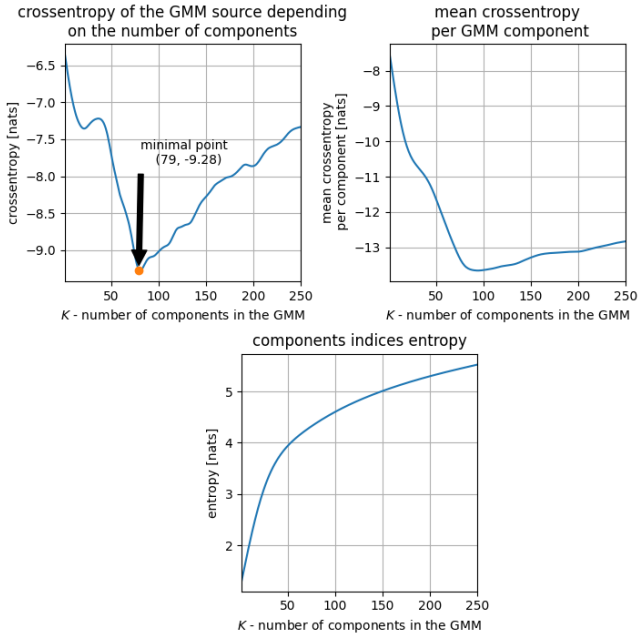

Figure 8: Results of the algorithm 2 for $d = 4$

As the second example, we show the workings of the algorithm 2. The plots in Figure 7 show the same curves as in the case of the Figure 6 (see previous paragraph). The C_1 criterion points as the optimal number of components exactly one component, that is, a single Gaussian. Above $K = 1$, the *components indices entropy* penalizes the *score* to the extent that the score curve is monotonically increasing. Another optimal number of components is suggested by C_2. We computed the GMMs for the number of components selected using the C_2 criterion, for which the contour plots are shown on Figure 10. We see that the GMM is tightly fitted to the data for the selection criterion C_2. However, the composite criterion C_1 suggests a single component, which seems to by trivial, but still optimal, as indicated by the methodology proposed.

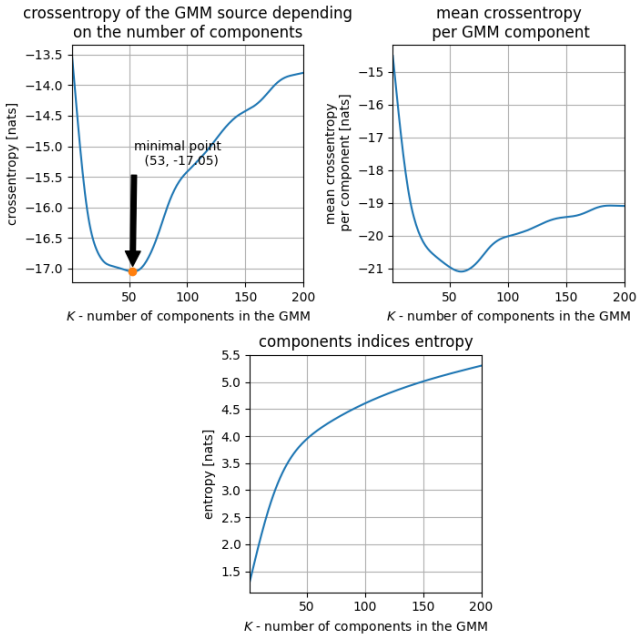

Figure 9: Results of the algorithm 2 for $d = 8$

As the third example, we show the working of the algorithm 2 for the problem dimension $d = 4$ (first four line spectral frequencies). In this case, the criterion C_1 returns trustworthy results, the minimum on the C_1 curve is clearly noticeable. The returned result is sensible and indicates that for $d = 4$, the training vectors distribution needs more components to be modeled accurately; the distribution is probably far from Gaussian. The curves are presented in Figure 8. This experiment is an indication that the proposed methodology is sound. To make the evidence even stronger we present more experiments for dimensions $d = 8$, Figure 9, and $d = 16$, Figure 12. As expected the optimal number of components decreases with the dimension of the problem. This is to maintain proper generalization.

The last result shows the behavior of the classical number of components selection criterion, that is the maximization of the likelihood on the development set. For this experiment, from 1000 samples of the training set, we excluded 100 samples as the development set. In Figure 13, we show the plot of the log-likelihood on the development set as a function of the number of components. It is evident that the plot is quite erratic of what decreases trust in this method of selection of the number of components. The results can

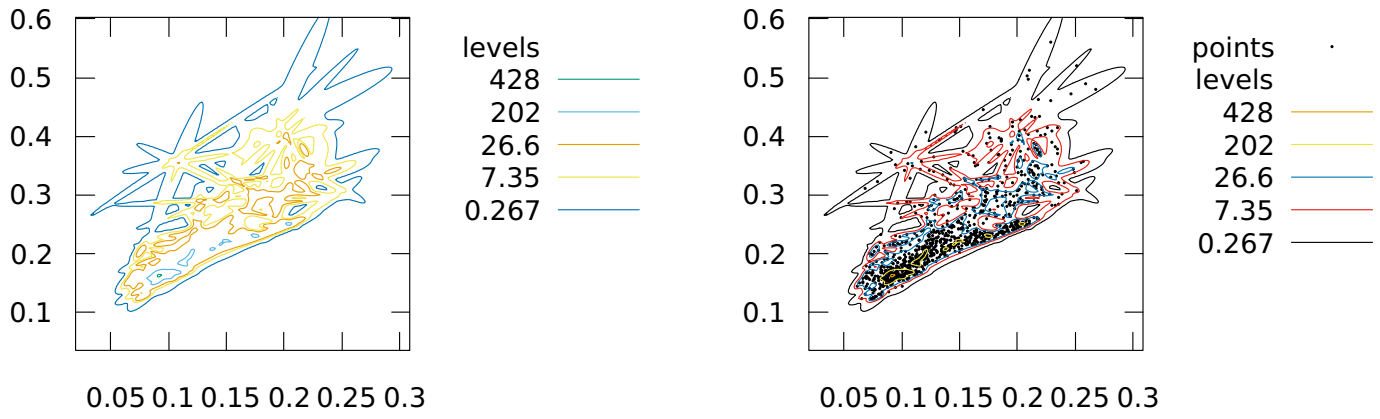

Figure 10: GMM fitted using algorithm 2 with number of components selected using the criterion C_2

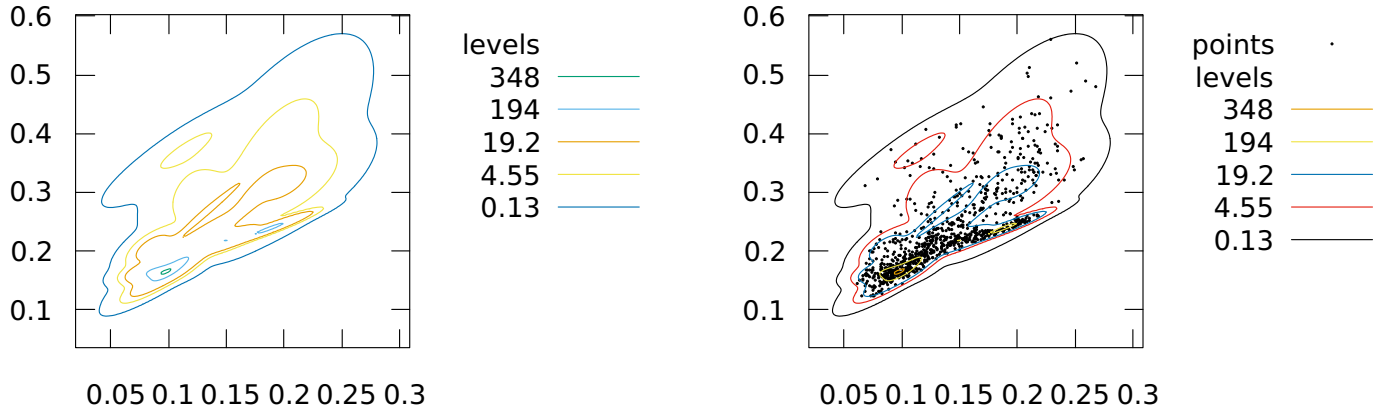

Figure 11: GMM fitted using traditional EM algorithm with number of components selected using tuning on the development set

be made more stable if we allow the development set to be larger. Such a measure will come at the cost of reducing the number of training points. Here, our proposed method shows the advantage of not using development sets. The contour plots for the GMM fitted using traditional method with the number of components tuned on the development set are shown in Figure 11.

4 Conclusions

In this paper, the theory of both discrete and continuous distribution with unknown number of components has been developed. The measure theoretic reason for the inherent similarity between PMFs and PDFs, with the difference in the structure of the underlying sample space, has been given. The difference causes the two distribution categories to be treated with much different mathematical tools. The main result of the paper are the means and methods of computing the number of components, that is, the number of categories in the PMF case and the number of Gaussian components in the GMM modeling in a PDF case, which is given implicitly in terms of its realizations.

Development of the theory required considering the expected Kullback-Leibler divergence - a difficult problem on its own rights. Especially, the algorithm for counting monomials with only even exponents in the expression for a trace of a matrix raised to a power has been developed. This algorithm allows to compute certain integrals analytically without resorting to the Monte-Carlo experiments. This algorithm can also be of interest on its own rights.

We believe that the theory presented in this paper will find many practical applications in diverse fields of science, technology, and engineering as a convenient tool of data analysis.

A The algorithm for counting monomials

The solution of the problem from section 3.1.2 is divided into six short algorithms

Algorithm 3: Counting monomials with only even exponents for given even partition of number n

Require: Even partition $\mathcal{P} = \{p_1, ..., p_k\}$ of the number n, problem dimension d,number of random samples m
Ensure: Number of monomials with only even exponents
1: $S := 0$
2: **for** every multipermutation of $\mathcal{P}$ **do**
3: Create $\mathcal{T} = \{\underbrace{1, ..., 1}_{p_1}, ..., \underbrace{k, ..., k}_{p_k}\}$
4: **for** every multipermutation of $\mathcal{T}$ **do**
5: Check if $\mathcal{T}$ is correct with Algorithm (7).
If Algorithm (7) returned false, go to the next multipermutation of $\mathcal{P}$.
6: Create matrices D and M for the table $\mathcal{T}$ with Algorithm (4).
7: If there are unfilled places in matrices D and M, create pairs of matrices D' and M' by filling unfilled places in D and M in every possible way.
8: From the set of every generated in previous step pairs of matrices, discard these which are incorrect. Correctness of the pair of matrices is checked with Algorithm (5).
9: For every pair of matrices calculate it's numerical value with Algorithm (6) and add it to S.
10: **end for**
11: **end for**
12: **return** S

Algorithm 4: Creating matrices D and M

Require: $\mathcal{T} = \{t_1, ..., t_n\}$, where $t_i \in \{1, ..., k\}$
Ensure: Filled matrices D and M
1: Create matrices D and M of a dimension k
2: **for** $i = 1$ to n **do**
3: **if** i is odd **then**
4: To $M_{t_i t_{i+1}}$ and $M_{t_{i+1} t_i}$ write "=".
5: To $D_{t_i t_{i+1}}$ and $D_{t_{i+1} t_i}$ write "$\neq$".
6: **end if**
7: **if** i is even **then**
8: To $D_{t_i t_{i+1}}$ and $D_{t_{i+1} t_i}$ write "=".
9: To $M_{t_i t_{i+1}}$ and $M_{t_{i+1} t_i}$ write "$\neq$".
10: **end if**
11: **end for**
12: **return** matrices D and M
Note: If there is an occurrence of writing "$\neq$" or "=" in previously filled place, stop the algorithm and return nothing.

Algorithm 5: Checking if given pair of matrices D and M is correct

Require: Matrices D and M
Ensure: *True*, if given pair is correct; *False* in other cases
1: **for** every pair of indexes i, j of the matrix **do**
2: **if** $D_{ij} = M_{ij} =$ "=" **then**
3: **return** *False*
4: **end if**
5: **if** the negation of any from implications listed below is true:
$[(X_{ij} =$ "=") $\wedge$ $(X_{ik} =$ "=")$] \Rightarrow X_{kj} =$ "=" or $[(X_{ij} =$ "=") $\wedge$ $(X_{ik} =$ "$\neq$")$] \Rightarrow X_{kj} =$ "$\neq$"
where X is a matrix D or M **then**
6: **return** *False*
7: **end if**
8: **end for**
9: **return** *True*

Algorithm 6: Calculating a component of sum from formula for number of monomials

Require: Pair of matrices D and M, problem dimension d, number of random samples m
Ensure: A component of sum from formula for number of monomials
1: $q = 1$
2: **for** $i = 1$ to dim D **do**
3: **if** $i = 1$ **then**
4: $q = q \cdot d \cdot m$
5: **else**
6: Calculate c_d oraz c_m with Algorithm (8) with input data: (D, i) and (M, i)
7: **if** there exists $i < j$, such that $D_{ij} =$ "$\neq$" **then**
8: $q = q \cdot (d - c_d)$
9: **end if**
10: **if** there exists $i < j$, such that $M_{ij} =$ "$\neq$" **then**
11: $q = q \cdot (m - c_m)$
12: **end if**
13: **end if**
14: **end for**
15: **return** q

Algorithm 7: Checking if table $\mathcal{T}$ is correct

Require: $\mathcal{T} = \{t_1, ..., t_n\}$, where $t_i \in \{1, ..., k\}$
Ensure: *True*, if $\mathcal{T}$ is correct; *False* in other cases
1: $A = \emptyset$
2: **for** $i = 1$ to n **do**
3: **if** there exists $s < i$, such that $t_s > t_i$ and $t_i \notin A$ **then**
4: **return** *False*
5: **end if**
6: insert t_i into A
7: **end for**
8: **return** *True*

Algorithm 8: Calculating auxiliary minuend

Require: Matrix X, number i
Ensure: Auxiliary minuend
1: **if** $i = 1$ **then**
2: **return** 0
3: **end if**
4: **for** each $j < i$ **do**
5: **if** If $X_{ij} =$ "$\neq$" **then**
6: Calculate c_j with Algorithm (6) with input data (X, j)
7: **end if**
8: **end for**
9: $c = \min_j c_j$
10: **return** $c + 1$

Non-Invasive Temperature Measurement

ABSTRACT

High Intensity Focused Ultrasound (HIFU) was widely used for treating tumors non-invasively. In this treatment, ultrasound is focused on the target volume inside the human body to ablate cancerous tissues and Magnetic Resonance Imaging (MRI) is mainly used to grasp the target position and to measure the temperature distributions around the target. However, MRI is very expensive, and a large space is required.

In this paper, we presented a method for measuring the temperature distribution using an ultrasound diagnostic device, which is inexpensive and commonly used in many clinics, and actually showed the results of heating experiments on a human shaped agar phantom. The proposed method for measuring the temperature distribution around the heated target was conducted by performing image processing on two ultrasound images before and after heating. Furthermore, it was confirmed that it was possible to grasp the three-dimensional temperature distribution from the images in multiple layers. The effectiveness of the temperature distribution measurement results by the proposed method was shown by comparing the temperature measurement results with the infrared thermal camera. The error between the results was approximately 1 ℃.

It was found that the non-invasive measurement method of the three-dimensional temperature distribution around the target volume using the ultrasound images was useful for effective HIFU treatments.

1. Introduction

This paper is an extension of a previous work originally presented at the 21st edition of the International Conference on Electromagnetics in Advanced Applications (ICEAA 2019) [1].

High Intensity Focused Ultrasound (HIFU) devices are used for treating uterine fibroids, liver tumors, brain tumors, etc. as a minimal invasive treatment method [2, 3]. As shown in Figure 1, this treatment method focuses on ultrasound waves emitted from the outside of the body to a target inside the body and causes ablation necrosis of the tumor by the thermal energy generated at the focal point. This method is considered to be a treatment method that has a much smaller burden on the patient than conventional open surgery. Focused ultrasound treatment is performed at a high temperature of approximately 70 °C or higher, and therefore there is a risk of cauterizing normal tissue around the tumor. When performing this treatment, a device with MRI's guidance (MR-guided focused ultrasound surgery: MRgFUS) is commonly used. However, a large amount of introduction funds and a large space are required. In addition, this method is not considered to be suitable for cases in which there is metal inside the human body or MRI contrast media cannot be used because the inside of the body is monitored using MR images [4-6].

[*]Corresponding Author: Ryosuke Sakakibara, 1-1-1, Higashi-mita, Tama-ku, Kawasaki, Kanagawa, 214-8571, +81-44-934-7907, rsakakibara9@gmail.com

Therefore, in order to perform Focused Ultrasound Surgery (FUS) treatment, non-invasive temperature measurement using an ultrasound diagnostic imaging device that is cheaper and more convenient to move than an MRI device has been previously attempted [7-12]. In this study, the ultimate goal is to establish a method for non-invasively measuring three-dimensional temperature distribution in a living body with high resolution in subpixel units [9]. In the temperature measurement method using ultrasound images, it is a prerequisite that the used ultrasound diagnostic imaging system was designed to draw images with constant ultrasound velocity. The velocity of ultrasound waves changes depending on the temperature of the propagating tissue. Therefore, if there is a temperature change inside the tissue, the ultrasound velocity in that part locally changes, and it appears as an extremely small image displacement on the ultrasound image. The temperature could be measured by detecting this slight displacement with image analysis technology [8, 9].

In the present paper, first, the algorithm of two-dimensional temperature distribution measurement using ultrasound images is described. Next, the agar phantom was heated in a temperature-controlled water tank, the relationship between the temperature increase of the agar and the displacement of the ultrasound image was described. Next, the temperature distribution was measured from the ultrasound image inside the agar phantom when it was heated using the focused ultrasound heating device. The temperature distribution inside the agar phantom during heating was measured using two types of transducers with different focal lengths. In the previous research, we investigated the basic heating characteristics by measuring the temperature distribution using a cylindrical agar phantom [10]. In this study, we measured a wider region of temperature distributions using a human shaped agar phantom in order to confirm that the proposed temperature measurement method is effective in situations closer to clinical treatment.

From the examination of the above experimental results, the usefulness of temperature distribution measurement using an ultrasound diagnostic imaging system was clarified quantitatively.

2. Materials and Methods

2.1. Principle of Temperature Measurement Using Ultrasound Images

As reported by Iseki et al., the temperature increases in living tissue can be obtained by solving (1) and (2) [8, 9].

$$\Delta T(x) = K_{tissue} \frac{\partial(\Delta d)}{\partial x} \quad (1)$$

$$K_{tissue} = \frac{1}{\alpha - \beta} \quad (2)$$

In these equations, ΔT is the temperature increase inside the tissue and K_{tissue} is the thermal constant that varies with the tissue. The subscript "tissue" is added to emphasize that it differs depending on the tissue. Δd is the displacement of the ultrasound image due to the temperature increase (the difference between the images before and after heating). The thermal constant K_{tissue} is expressed by (2). Here, α is the coefficient of thermal expansion of the tissue, and β is the coefficient of ultrasound velocity change due to the temperature increase inside the tissue. It is considered that the thermal expansion coefficient α and the ultrasound velocity change coefficient β change linearly in a relatively narrow temperature change region such as during focused ultrasound treatment [6].

2.2. Measurement System of Thermal Constant

Figure 2 shows the general-purpose ultrasound imaging system Nemio SSA-550A (Toshiba Medical Systems, Japan) with the attached ultrasound probe PLM-805AT (Toshiba Medical Systems, Japan) used in the experiment. The ultrasound probe used in the experiment is a linear probe as shown in Figure 2 (b). The number of elements is 128, the focus length is 20 mm, and the size of the contact part with the body is (12 mm × 67 mm). The size of the captured ultrasound image is (560 pixels × 450 pixels), which is a 256-gradation bitmap image. Here, 300 pixels were assigned to a distance of 70 mm on the captured ultrasound image.

Figure 3 shows an illustration of experimental setup for measuring thermal constant "*K*" to know the relationship between the temperature increase of the agar used as the heated object and the displacement of the ultrasound images before and after heating [8,9]. As shown in Figure 3, a cube agar phantom was fixed inside a water tank where the water temperature was constantly controlled using a thermostat and a stirring pump, and the ultrasound images inside the agar were taken from 20 ℃ to 30 ℃, because the experiment of temperature distribution measurement is in that temperature range.

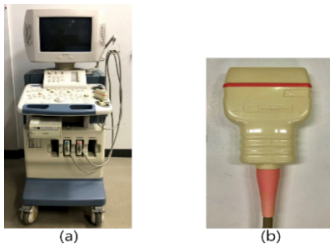

Figure 2: Ultrasound Diagnosis Device (a) Ultrasound Diagnosis Device, (b) Linear Probe.

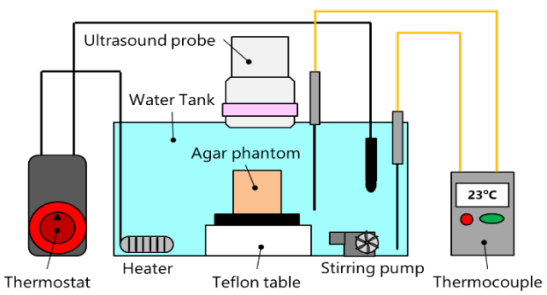

Figure 3: Illustration of Experimental Setup for Measuring Thermal Constant "*K*".

2.3. Image Analysis Algorithm

Figure 4 shows the image analysis algorithm proposed by authors for temperature distribution measurement [8, 9]. This algorithm is divided into 7 steps. First, the ultrasound images of the heated object before and after heating are input. Second, template matching is performed to measure the amount of displacement Δd between the ultrasound images before and after heating. Third, a median filter is applied to reduce the erroneous vector of displacement Δd on the ultrasound image. Fourth, since the displacement Δd distribution detected by template matching is expressed in pixel units, interpolation processing was performed to interpolate Δd distribution. Fifth, a moving average filter is applied to smooth the displacement amount of the distribution map subjected to this interpolation process. Sixth, the temperature increase ΔT during heating is calculated from the displacement Δd detected by applying the Sobel filter. Finally, a moving average filter is applied to the temperature increase distribution map to smooth the distribution. For the development of the image analysis program, general-purpose program Microsoft Visual Studio (Microsoft Japan) was used.

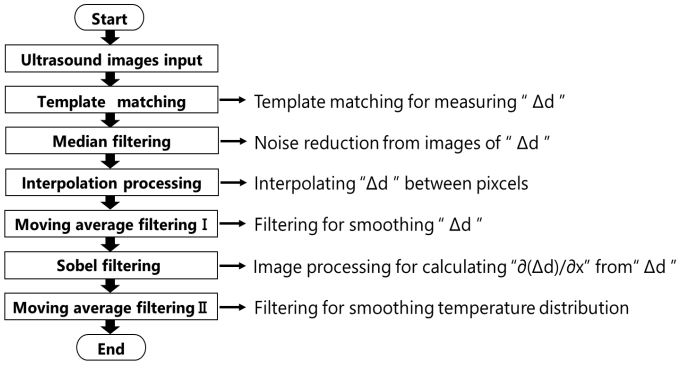

Figure 4: Flow Chart for Measuring Temperature Distributions.

2.4. Measurement System of Temperature Distributions

Figure 5 shows the device system for capturing ultrasound images before and after heating. This system mainly consists of two work sliders, an arm and a jig for fixing the ultrasound probe. As shown in Figure 5, the ultrasound probe was supported by the arm and fixed to the slider. Here, the ultrasound probe can be moved three-dimensionally by combining the two sliders. The range of motion of this slider is (0.0 to 66.0 mm), and the minimum movable interval is 0.05 mm.

Figure 6 shows an illustration of the focused ultrasound heating experiment. As shown in Figure 6, in order to measure the temperature distribution in the X-Z cross section using an infrared thermal camera, the human shaped agar phantom was previously cut at the center position. The transducer was placed underwater to focus on the position 65 mm from the bottom. Then, the ultrasound probe was moved up and down ± 15.0 mm from the center cross section every 5.0 mm along the Z direction, and ultrasound images were taken before and after heating in a total of 7 layers. These operations were performed for heating experiments with short focus and long focus transducers respectively. The heating time was 5 minutes and the heating power was 200 W. In addition, we compared the temperature distribution results by the present method using the ultrasound image and the thermal image taken by the infrared thermal camera in the central section of the human shaped agar phantom.

The focused ultrasound heating device used in the experiments was CZ901 (Mianyang Sonic Electronic, China). Two kinds of transducers were prepared for this device. Figure 7 shows the transducer used in the experiments. The short focus transducer as shown in Figure 7 (a) had an outer diameter of 170 mm, an inner diameter of 98 mm, an outer peripheral surface height of 75 mm, an inner peripheral surface height of 53 mm, and a focal length of 120 mm. The outer and inner diameters of the long focus transducer as shown in Figure 7 (b) were almost the same as those of the short focus transducer, however the inner peripheral surface height was 61 mm and focal length was 200 mm. The frequency of the focused ultrasound was 1 MHz. In the heating experiments, a frequency oscillator AWG1025F (Frequency Band: 1μHz – 25MHz, AS ONE, Japan) and a power amplifier L-400BM-HC (Frequency Band: 700kHz – 3.5MHz, JSE, Japan) were connected to the transducers to heat the human shaped agar phantom.

Figure 8 shows the human shaped agar phantom used in the experiments. The width of heating area was 160 mm and the height was 120 mm.

3. Results

3.1. Thermal Constant of Agar Phantom

Figure 9 shows the relationship between the temperature change (ΔT) of the agar phantom and the degree of ($\partial(\Delta d)/\partial x$) of the ultrasound image when heated as shown in Figure 3. The template size used in the image analysis as shown in Figure 4 was (13 pixels × 13 pixels). The total number of plots in Figure 9 is 45. As a result of finding the approximate straight line from these data by the method of least squares, the slope of the graph was 102.92 and the intercept was -0.5262. The thermal constant of the agar phantom used in this heating experiment was set to K_{agar} = 102.92. In addition, the coefficient of determination R^2, which is the degree of fitting of the approximate straight line, is 0.9941, which confirms that there is a high correlation.

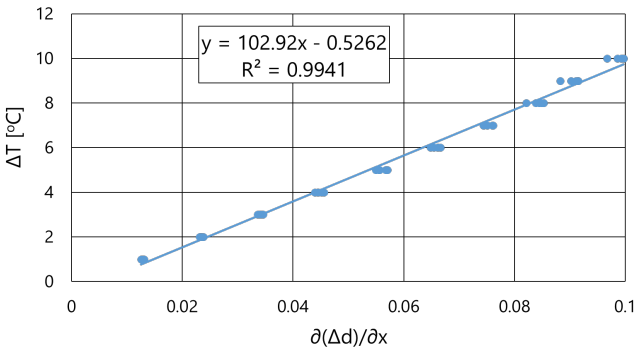

Figure 9: Relationship between ΔT and $\partial(\Delta d)/\partial x$.

3.2. 2-D Temperature Distributions

Figure 10 shows the comparison results of the temperature distribution in the central cross section of the human shaped agar phantom when heated with a short focus transducer. In the temperature distribution measurement result from the ultrasound image as shown in Figure 10 (a), the maximum temperature increase value ΔT_{max} was 10.1 °C. On the other hand, it was 10.8 °C from the infrared thermal camera as shown in Figure 10 (b). The measured temperature error by both methods was 0.7 °C, and the error rate was approximately 7 %. When comparing the absolute temperatures of both during and after heating, an error naturally occurs. However, it is useful to know the temperature distribution patterns.

Figure 11 shows the temperature in the center section of the agar phantom when the same heating was performed using the long focus transducer. In the temperature distribution measurement result from the ultrasound image as shown in Figure 11 (a), the maximum temperature increase ΔT_{max} was 7.2 °C. On the other hand, it was 5.9 °C from the image of the infrared thermal camera as shown in Figure. 11 (b). The measured temperature error was 1.3 °C, and the error rate was approximately 18 %.

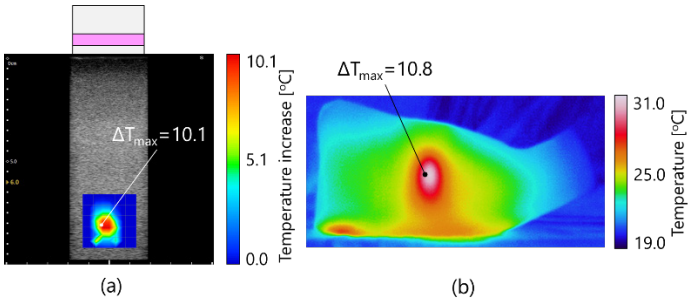

Figure 10: Comparison between Temperature Distributions inside Human Shaped Agar Phantom (Short Focal Length). (a) with Ultrasound Image, (b) with Thermal Camera

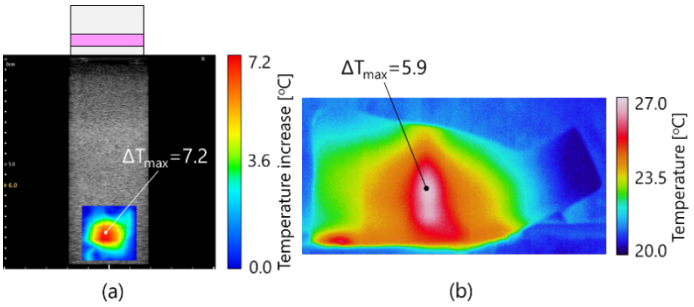

Figure 11: Comparison between Temperature Distributions inside Human Shaped Agar Phantom (Long Focal Length). (a) with Ultrasound Image, (b) with Thermal Camera.

3.3. 3-D Temperature Distributions

Figure 12 shows the two-dimensional temperature distribution results measured from the ultrasound images of the top and bottom (± 15.0 mm) taken at 5.0 mm intervals in the center section of the agar phantom. As shown in Figure 12, the two-dimensional temperature distribution results are three-dimensionally displayed by stacking them. Figure 12 (a) shows the case when using the short focus transducer. It can be confirmed that the temperature increase is the highest value in the central cross section and

decreases with increasing distance from the central cross section, and there is almost no temperature increase above ± 10.0 mm. On the other hand, Figure 12 (b) shows the case when using a long focus transducer. Also in this case, it can be seen that the temperature increase is the highest value in the central cross section. However, in the other image layers, unlike the case when the short focus transducer was used, it can be confirmed that the heating region is wide and the temperature increase value at ± 10.0 mm is similar to the value at the center cross section.

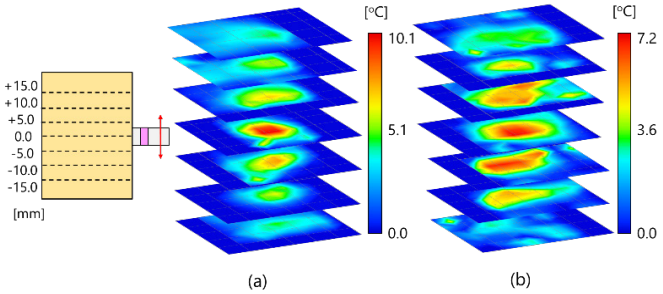

Figure 12: Temperature Distributions from Ultrasound Images. (a) Short Focal Length, (b) Long Focal Length.

4. Discussion

In order to improve the accuracy in the temperature distribution measurement method of applying ultrasound images, we have been working on, (i) taking the images before and after heating at the same position, and (ii) grasping the thermal constant K_{tissue} of the targeted object. Regarding item (i), as shown in Figure 5, the ultrasound probe could be moved three-dimensionally by using two sliders with a movement accuracy of ± 0.05 mm. Regarding item (ii), the value of the agar phantom was actually measured using the self-made device as shown in Figure 3. However, in the results shown in Figure 9, the variation of the measured 45 data was large. It is necessary to control the temperature of the object more accurately by using a higher quality thermostat.

In clinical HIFU treatments, the cauterization temperature of the tumor is mainly 70 °C - 80 °C. The human shaped agar phantom used in the HIFU experiments was prepared with the component ratio recommended by the Japan Hyperthermia Society. When the maximum temperature near the focal point, where ultrasound waves were focused, was 50 °C or higher, the agar phantom melted. Therefore, heating experiments of the agar phantom were conducted at 50 °C or lower. As shown in Figure 12 (a) and (b), heating results using transducers with different focal lengths had different maximum temperatures. Therefore, the normalized temperature (ΔT_N) shown in the following (3) was calculated, and the heating characteristics of both transducers were compared.

$$\Delta T_N = \frac{\Delta T - \Delta T_{min}}{\Delta T_{max} - \Delta T_{min}} \quad (3)$$

Here, ΔT_{max} is the maximum temperature increase value and ΔT_{min} is the minimum temperature increase value in each layer as shown in Figure 12.

Figure 13 shows the calculation results of the normalized temperature (ΔT_N). As shown in Figure 13, when a short focus transducer is used, the temperature increase at a position about ± 10 mm away from the focal point is 60 % or less of that focal point. That is, when the maximum temperature at the focal point is 80 °C, the temperature at the distance (± 10 mm) is approximately 50 °C. However, when a long focus transducer is used, the temperature at the same distance is approximately 60 °C, and the difference in temperature between them is 10 °C. From this result, careful attention is required at the boundary between the healthy tissue and the tumor tissue during HIFU treatments.

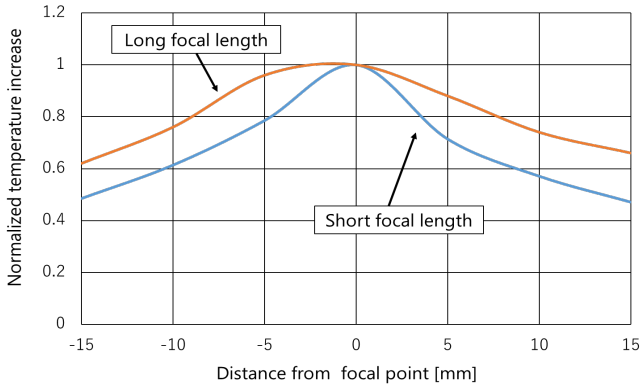

Figure 13: Normalized Temperature Profiles.

5. Conclusion

In this paper, we investigated the possibility of non-invasive measurement of the three-dimensional temperature distribution of the human shaped agar phantom during focused ultrasound heating from ultrasound images before and after heating. First, an algorithm of temperature distribution measurement using ultrasound images was presented. Second, the relationship between the temperature increase inside the heated object and the displacement of the ultrasound images before and after heating was described. Third, we measured the temperature distribution inside the agar phantom during HIFU heating using two types of transducers with different focal lengths. In the temperature measurement results, at the central cross section of the agar phantom, the error between the results of the proposed method using ultrasound images and the measurement results of the infrared thermal camera was approximately 1 °C. In addition, in order to discuss the heating characteristics of two types of transducers with different focal lengths, their three-dimensional temperature distributions were compared. Finally, we highlighted the problems in HIFU treatments using transducers with different focal lengths.

In the future, we have a plan to measure the three-dimensional temperature distribution inside heated animals and to discuss the problems of HIFU treatments.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Discrete component based ultra-wideband SPDT switch modelling, design and implementation challenges are reported in this article. The basic SPDT switch is planned to design using PIN diodes (bare die). Nonlinear parameters extraction steps of PIN diode from datasheets have been proposed in this article instead of using readymade nonlinear PIN diode models. Equalizers are designed as per requirement using discrete components and quarter wave transmission lines for different source and load impedances. Then all the designed components are integrated with a low noise amplifier (LNA). Extraction of PIN diodes' nonlinear parameters are carried out using diode equations along with datasheet parameters. Layout has been implemented using microstrip and CPWG techniques. Quickly responding driver is designed using transistors and logic gates. CPWG based layout achieves better isolation compared to microstrip line-based layout at highest frequencies. Measured and simulated responses are tallied and they are matching together respectively except few exceptions. Measured responses also validates the well agreement between the proposed nonlinear diode modelling and equalizer design with different input and output impedances.

1. Introduction

Modern miniaturized systems require compact, light-weight and low cost components with high yield rate [1]. Excellent ultra wideband electronic warfare (EW) receiver like RWR (Radar Warning Receiver) system requires compact, lightweight and faster SPDT (single pole double through) switch which will be used to switch between BITE and RF ports. This active SPDT switch is basically used to control the RF port isolations while examining the whole Radar in BITE (built in test) mode. As the operating bandwidth of this module is very wide, microwave devices always struggle with uncertain gain gradients and ripples. Thus, excellent class wideband receiver of an RWR system are placed far away from its distributed antenna arrangement systems and connected through a lengthy cable. Thereby, it experiences enormous gain flatness problems particularly at higher frequencies due to excessive transmission line losses. To maintain the best flatness response, it is important to compensate the gain by flattening the gain response over the operating frequency band. It is commonly carried out by using passive equalizers. This article describes various design and development concerns/ problems etc. of wideband discrete components like SPDT switch, passive equalizers and the active SPDT switch. This article also shows a detailed method of nonlinear PIN diode model parameter extraction. Then a suitable PIN diode model is made using those extracted nonlinear parameters and has been used to design the PIN diode based SPDT switch. A suitable wideband LNA (Low Noise Amplifier) has also been introduced at the output path to compensate the loss of the SPDT switch. Prior art survey is carried out over design and development procedures of SPDT switches [2-9]. Allanic et. al. proposed a new passive SPDT design using silicon substrate in [2]. It is band limited to 5GHz with unequal losses in Tx and Rx ports. Additional amplifier is required to make it active SPDT. A high-power passive SPDT design is reported in [3]. Here also an additional LNA is required to make it active switch. Yang et. al. proposed an active SPST switch in [4]. This proposed SPST is band limited to 4GHz using InGaP/GaAs HBT process. This proposed switch consists of seven transistors. This SPST (single pole single through) switch is active in nature but does not cover wide frequency band. A high isolation active absorptive SPST is reported in [5]. It is band limited to 10GHz. Values of various parameters like, minimum gain, gain flatness, isolations and VSWR are -0.4dB, ±1.5dB, 35dB and 3.6:1 max respectively. Single chip SiGe BiCMOS based active SPDT and SPST designs are reported in [6] respectively. This design is also

*Corresponding Author: Mahadev Sarkar, 8553551075, mahadevsarkar@bel.co.in

suffering from P1dB, gain, VSWR etc. Active wideband SPDT switch designs are proposed for V, D and Ku bands in [7–9] respectively. These proposed active SPDT switches are also suffering from gain, gain flatness, input output matching and isolations respectively. These reported designs are also lacking about P1dB and switching speed information except [9] (it provides only P1dB data). Present article uses a discrete LNA and integrates with PIN diode based SPDT switch. This article proposes nonlinear diode parameter extraction steps with an example using limited source of data (datasheet) and diode equations. Readymade nonlinear diode models have not been taken into consideration as vendor often do not extends support. Suitable diode models have been made using extracted nonlinear parameters and tuned up to 18GHz. Then those models have been used to design broadband switch. Equalizers are also designed separately with different input/output impedances to cope up with flatness issues. Only logic gates and discrete active components are used to design the driver where, NAND gate translates input logic to output logic control signals and transistor builds current over it. Active SPDT switch integrates separately designed SPDT, gain equalizers, LNA, attenuation pads, driver etc. Active SPDT switch was designed using microstrip lines initially, but isolation was not achieved 50dB. Then, co-planner waveguide (CPWG) approach is tried with one more extra shunt element for both the paths. This configuration achieves >50dB isolation at 18GHz. Switch isolation of microstrip line and CPWG based method is compared in the article. Switching speed of any switch is directly related to the signal throughput of the driver. Thus, how fast the driver acts switching speed will also be so faster. That is why it will be a combination of driver and switch's performance respectively [10, 11].

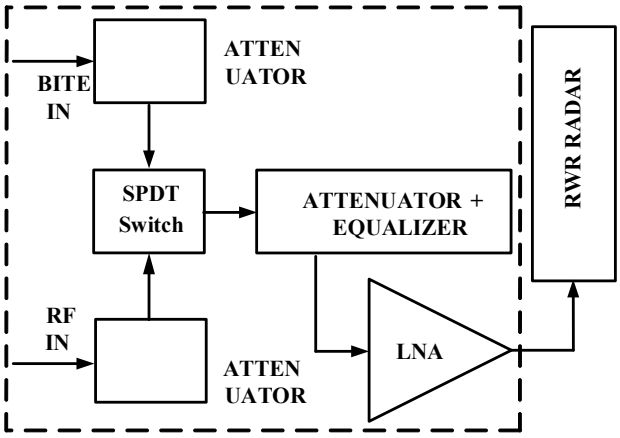

Figure 1: Block diagram of ultra-wideband high speed active SPDT Switch consists of basic SPDT, equalizers, attenuator pads and LNA

This present work advances P1dB performances, power dissipation, better input/output matching and superior packaging with reduced weight respectively from the previous work reported in [1]. Figure 1 shows the block diagram of active SPDT switch where, BITE and RF-in are the two ports of the SPDT switch. Attenuator pad/equalizer are kept at the input of the switch for better matching [1]. It increases noise figure very little as compared to the previous situation where, active switch was absent. An appropriate LNA is integrated just at the output port of the discrete SPDT switch. Equalizers are used before and after LNA to keep flatness within the specifications. Measured and simulated responses are compared in this article and analyzed the probable cause of discrepancy. An appropriate reason is explained for this discrepancy and conclude about limitations of the nonlinear diode modelling. This article has been organized as follows. In Section 2, PIN diode parameters extraction, diode modelling, SPDT switch, equalizer and driver design are discussed. In Section 3, design implementation and experimentation are shown along with simulated results. In Section 4, fabricated switch is shown and the conclusions are given in Section 5.

2. Individual Components Design

This section explains about design steps of three important components design likely, nonlinear parameter extraction of PIN diodes, modelling and comparison with measured response (plotted in the datasheets), equalizer design and driver design respectively. The major work is involved in nonlinear parameter extraction of PIN diodes from datasheet and then prepare a suitable model out of it. Here this extraction steps will be explained in details. PIN diode modelling is carried out both for the diodes used in series and shunt branches of SPDT switch. Discrete component based equalizer design explained in the next and at last NAND gate based driver design also shown in details.

2.1. *Nonlinear parameter extraction and PIN Diode Modelling*

SPDT block of the active switch shown in Figure 1, has been designed using PIN diode bare dies. Simple nonlinear model of PIN diode is costly and most often component vendors' do not support with exact nonlinear model parameter values in the datasheets. Thus it is necessary to make nonlinear model of PIN diode. It is possible to prepare nonlinear model of PIN diodes using data given in the datasheet [12]. Thus it has become designer's capability to build an acceptable model for diodes using existing data in the datasheet. Extraction of all nonlinear model parameters are extremely difficult using limited source. Approximate (mere accurate) model is possible to make using these extracted parameters by fine tuning other model parameters and that can tackle the issue [12].

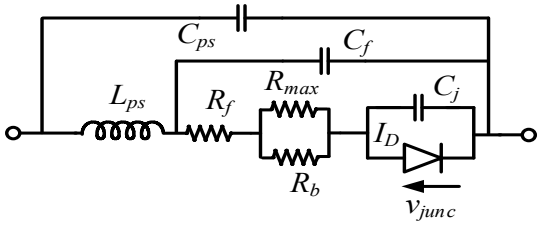

Figure 2: Classic diode model used to design circuit model of PIN diode

Adopting the above technique separate models have been prepared for shunt and series diodes respectively and compared with its measured responses. Figure 2 shows the basic diode model to be used to make equivalent PIN diode circuit model where, C_{ps}, C_f, C_j, L_{ps}, R_f, R_b, R_{max} I_D and V_{junc}, are package parasitic capacitance, beam lead parasitic capacitance, junction capacitance, package parasitic inductance, minimum resistance when diode is in forward bias, variable *i* region resistance on PIN diode, maximum resistance, diode current and voltage across the junction respectively. Equation mentioned below (in 1) describes

the current flowing through the diode where, I_s, q, n, k, T_j and I_{RBD} are, saturation current, electron charge, ideality factor, Boltzmann constant, temperature in kelvin and reverse breakdown current respectively [13].

$$I_D = I_s\left(e^{\frac{qV_{junc}}{nkT_j}} - 1\right) - I_{RBD} \quad (1)$$

and

$$I_{RBD} = I_{RBDS}e^{\frac{-q(V_{junc}+V_{RBD})}{kT_j}} \quad (2)$$

where, V_{RBD} and I_{RBDS} are reverse breakdown voltage and saturation current respectively. Datasheet does not provide and package parasitic like, C_{ps}, C_f and L_{ps} and to describe the bonding pad paracitics. Thus, it is very difficult to extract all the model parameters from manufacturers' data sheets, which only provide limited information. Fortunately, most of the critical parameters like, I_s, R_f, C_j, τ, α_c, δ etc. can be derived from the manufacturers' data sheets where, τ, α and ζ are transition time, arbitrary constant and built in potential respectively [14]. Datasheet provides the I-R and C-V characteristics of diodes. Thus, all the above parameters can be extracted using these characteristic curves.

$$\alpha_c = \frac{qV_{junc}}{nkT_j} \quad (3)$$

$$C_j = \begin{cases} C_{J0}\left(1 - \frac{V_{junc}}{\delta}\right)^{-\gamma(V_{junc})} + C_D & V_{junc} \le \mathrm{F}_c\mathrm{X}\delta \\ C_{J0}\mathrm{Xf}(V_{junc}) + C_D & V_{junc} > \mathrm{F}_c\mathrm{X}\delta \end{cases} \quad (4)$$

where C_D, C_{J0}, F_c and γ are capacitance due to the finite transit time (τ) through the *i*-region, depletion capacitance at $Vjunc = 0$, function of $Vjunc$, coefficient to divide the forward-bias, depletion capacitance into two regions and expressed by a 3rd order polynomial.

$$f(V_{junc}) = (1 - F_c)^{-(1+\gamma(V_{junc}))}\ \mathrm{X}\ \left\{1 - F_c\left(1 + \gamma(V_{junc})\right) + \gamma(V_{junc})\frac{V_{junc}}{\delta}\right\} \quad (5)$$

$$\gamma(V_{junc}) = \gamma_0 + \rho_1 V_{junc} + \rho_2 V_{junc}^2 + \rho_3 V_{junc}^3 \quad (6)$$

$$C_D = \tau\frac{\partial I_D}{\partial V_{junc}} \approx \frac{\tau I_D}{0.0256n} \text{ at } T_j = 300\mathrm{K} \quad (7)$$

The resistance in the i-region is a function of the forward current. At high forward current level, *Rb* becomes close to zero. Thereby the minimum resistance becomes *Rf*. At reverse bias condition, *Rb* is almost infinite, therefore the maximum resistance is *Rf* +*Rmax*. The resistance at low and moderate forward current level is written in (6) [14].

$$R_{Total} = \mathrm{R}_f + \frac{R_b X R_{max}}{R_b + R_{max}} \quad (8)$$

$$R_b = \begin{cases} \frac{\beta_1}{{I_D}^{\beta_2}} & I_D > 0 \\ \infty & I_D \le 0 \end{cases} \quad (9)$$

Variable resistance can be found by putting in (9) in (8) considering β_2=1, where R_m is the arbitrary RF resistance at current level I_m.

$$\beta_1 = I_m(R_m - R_f) \quad (10)$$

Table 1 shows the extracted parameters considering HPND4018 PIN diode datasheet using (1) to (10). Here few parameters are directly taken from datasheet, like forward resistance, breakdown voltage, junction capacitance, transition time etc. Few other parameters have been finalized using curve fitting technique to match the response with datasheet while simulation of model. PIN diode model simulation is performed in

Table 1: The extracted model parameters for HPND4018 Diode

Sl. No.	Parameters	Extracted Values
1	I_s	1.21X10^{-9} A

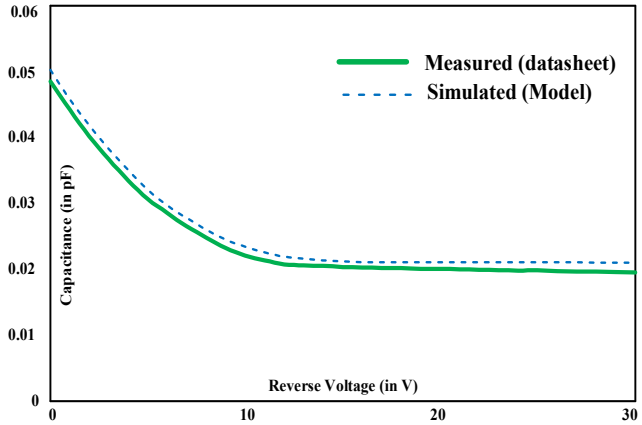

Figure 3: Comparison between modeled and measured DC C-V characteristic of HPND1084 PIN diode at 1MHz

2½D software taking parameters values from Table 1. Influence of bonding wires cannot be ignored while simulation. Thereby model is extracted including them. Tuning of the required model parameter values are carried out to match the model characteristics virtually similar as compared to the datasheet.

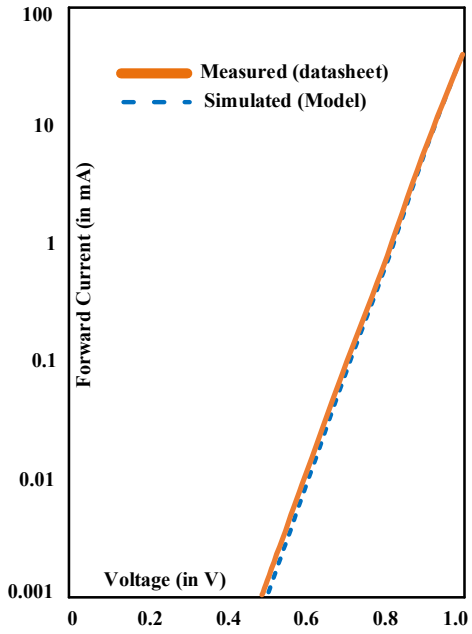

Figure 4: Comparison between modeled and measured DC I-V characteristic of HPND1084 PIN diode

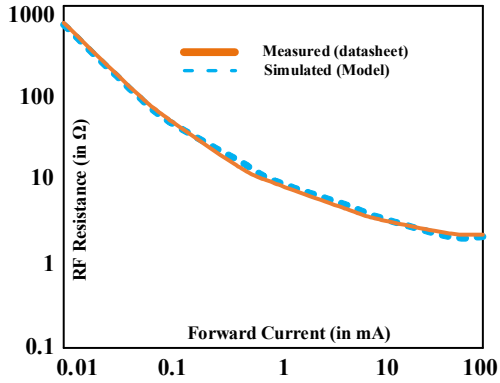

Figure 5: Comparison between modeled and measured RF resistance – Forward current at 100 MHz characteristic of HPND1084 PIN diode at 100 MHz

These models are purely made based on datasheet parameters and used for specific applications. Figure 3 shows the comparison between modeled and measured DC C-V characteristic of a HPND1084 PIN diode. Here modeled capacitance almost optimized as measured capacitance values. Figure 4 shows the comparison between modeled and measured DC I-V characteristic of the same PIN diode. Modeled current is showing a good agreement with measured current. Figure 5 shows the comparison between modeled and measured RF resistance characteristic. Here simulated resistance indicates that model parameters are optimized properly. Nonlinear model of MP6002 has also been carried out by following the above procedure. These two diode models are used for SPDT switch design, where, HPND1084 is used as series diode and MP6002 is used as shunt diode. Figure 6 shows the response of a modeled PIN diode (HPND1084) for 1– 20 GHz bandwidth. Maximum insertion loss is below 1dB at 18 GHz and it is well matched up to 18 GHz. Isolation is around 20dB at 18 GHz. The same loss characteristic is also calculated for shunt diode and kept ready for next level simulation. Here diode models are tuned several times to make it suitable and well matched with datasheet characteristics.

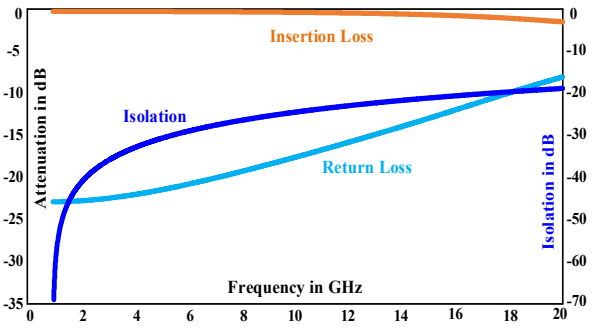

Figure 6: Simulated response of insertion loss, return loss and isolation characteristic of HPND1084 PIN diode

2.2. *SPDT Switch Design using PIN Diodes*

Simulated and verified nonlinear PIN diode models are used to design the SPDT switch where, HPND1084 is used in the series branch and MP6002 is used in the shunt branch. Schematic design

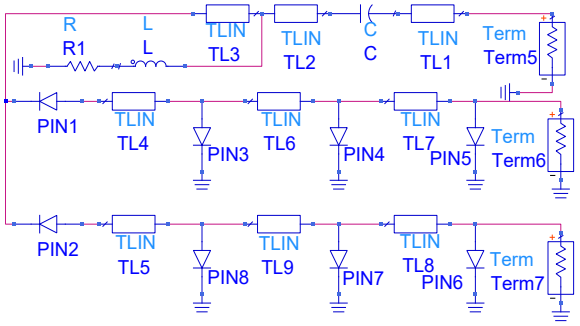

Figure 7: Schematics of basic SPDT switch using PIN diodes

of the switch is performed in 2½D software and shown in the Figure 7. Each branches of the switch having one series and three shunt diodes respectively. Here DC current return path is getting completed through inductor L and resistor R1 in the common path. Resistor R1 is used to limit the maximum current through the series diode. Bonding wires (2mil gold ribbon) have not been added in the schematics as it is already considered as parasitics in the diode modelling. The insertion loss (I_L) and isolation (I_{iso}) parameters of the SPDT switch are estimated using (11) and (12) respectively. Here, R_{fse}, R_{fsh}, Z_0, and X_C are forward resistance of series and shunt diode, characteristic impedance, and reactive impedance respectively. Tendency of the simulated isolation response is fluctuating around middle of the frequency band which will be recompensed in final layout simulation [14].

$$I_L = 10log\left[\left(1+\frac{R_{fse}}{2Z_0}\right)+\sum_{j=1}^{n}\left(\frac{Z_0+R_{fsh_j}}{2X_{C_j}}\right)\right] \quad (11)$$

where, $X_C = 1/2\pi f_L C_D$, $f_L = 1/2\pi\rho\varepsilon$, here ρ and Ɛ are the resistivity of the I region and dielectric constant of the silicon.

$$I_{iso} = 10log\left[\sum_{j=1}^{n}\left(1+\frac{Z_0}{2R_{fsh_j}}\right)^2 X\left(\frac{X_{C_j}}{2R_{fsh_j}}\right)^2 + \left(1+\frac{Z_0}{2R_{fse}}\right)^2\right] \quad (12)$$

Reverse breakdown voltage, power handling, switching speed, capacitance, forward resistance, carrier lifetime, thermal resistance etc. have been kept in mind while selecting diodes.

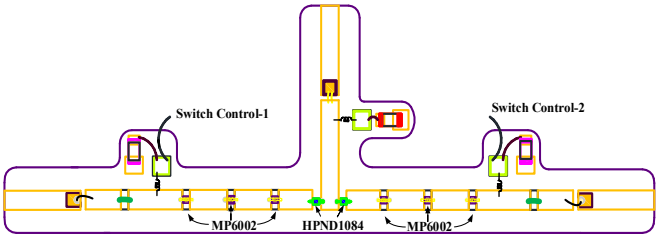

Figure 8: Proposed layout diagram of basic SPDT switch using PIN diodes

Final assembled layout of the proposed basic SPDT switch is shown in Figure 8. Here extra shunt diodes assembly option is kept in the layout so that fabrication iterations become less but, it has a disadvantage of higher insertion losses. This option will not affect at the overall performance as LNA is in the common path to compensate the extra losses. Initially, SPDT layout was carried

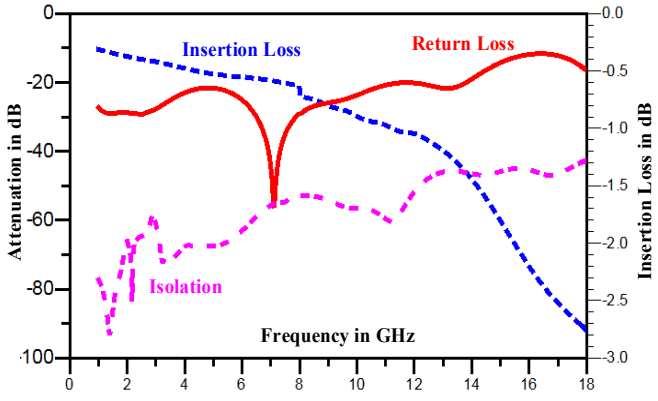

Figure 9: Simulated responses of proposed SPDT switch in 2½D software

out using microstrip lines and fabricated but, it was not meeting isolation specifications at higher frequencies (measured response is shown in the experimentation section). Thereby final layout of SPDT switch is made using CPWG lines in the first iteration. Figure 9 shows the simulated responses of the SPDT switch. Here insertion loss is about 2.8dB around 18GHz. Return loss is more than 20dB up to 14 GHz and it reduces to around 12 dB at 16–18GHz. Isolation is 50dB at 18 GHz. Now it is ready for next level integration with equalizer and LNA.

2.3. *Equalizer Design*

Equalizers are crucial parts for equalizing flatness of the module which, deteriorates with frequencies moving higher and higher. It is evident from Figure 9 that almost 2.5dB slope adjustment is must to flatten the switch response. Now there is an LNA in the common path that has its own gain slope (almost 2dB). Thus requirement specific equalizers are necessary in the various locations (common path as well as in the SPDT branches) to

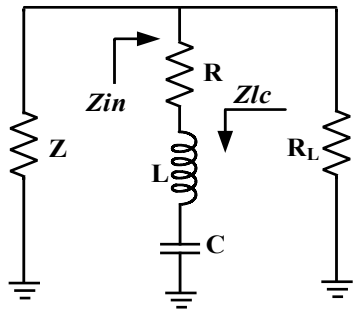

Figure 10: Schematic diagram of single section equalizer

compensate all the loss/gain slopes. Figure 10 shows elementary schematic diagram of a single resonator based equalizer [1]. This equalizer is comprising of discrete thin film resistor and a resonator of $\lambda_g/4$ length at the highest frequency. Slope of the equalizer has been finalized after analyzing the integrated switch response in the system level simulations. Thereby case to case final component twigging will be performed as per need basis. The ultimate discrete component values can be finalized at the final level of simulations to maintain tiniest gain flatness (within ±0.5dB). Driving point impedance of the R-L-C network can be calculated using (13) where, R, L and C are the shunt resistance, inductance and capacitance respectively [15-17].

$$|Z_{in}| = \sqrt{R^2 + \left|\frac{1-\omega^2 LC}{\omega C}\right|^2} \quad (13)$$

Final transfer characteristics of the equalizer containing n sections have been calculated by (14) where, Z_L, ω is the load impedance and angular frequency respectively where, $\omega = 2\pi f$ and f is the operating frequency.

$$H_{total}(\omega) = \sum_{i=1}^{i=n} \frac{2(j\omega C_i R_i - \omega^2 L_i C_i + 1)}{j\omega C_i Z_L + 2(j\omega C_i R_i - \omega^2 L_i C_i + 1)} \quad (14)$$

Although (14) has been calculated for n number of sections but the actual number of equalizer sections may be changed/decided according to flatness characteristics at the final

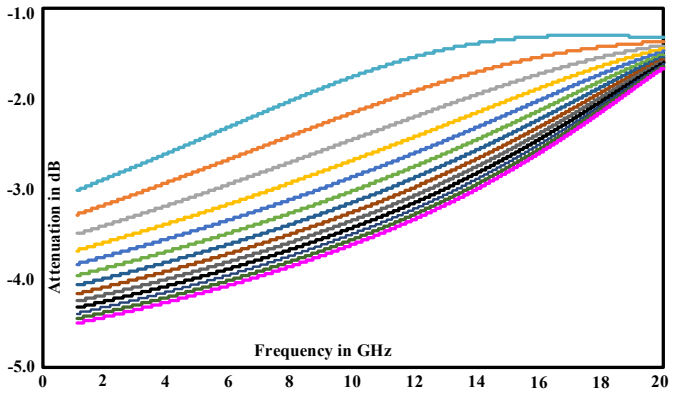

Figure 11: Insertion loss response of equalizer for different resistor values.

level of realization. Figure 11 shows insertion loss characteristics of passive equalizer varying numerous resistor (R) values where, upper and lower response curves are for lower and higher resistor values respectively. Now when it interacts with output impedance of SPDT switch as input impedance of it and input impedance of

LNA as arbitrary load then its input and output port matching also changes respectively. Figure 12 shows the input and output return loss characteristics of the equalizer for numerous R values. Here source impedance is almost 50Ω but load impedance is the input impedance of the next stage thus, input and output return loss response is not symmetric. In the system simulations various resistor values have been tuned to achieve different slopes.

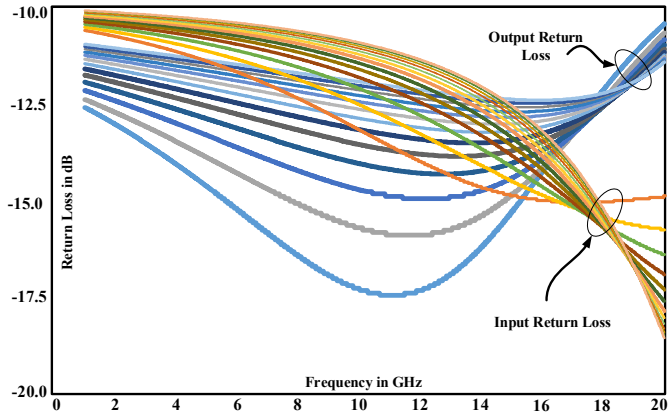

Figure 12: Input and output matching of equalizer for different resistor values

2.4. *Driver Design*

A suitable driver is designed to generate the required control signals to operate the switch and LNA (supply sequencing) from external control signals. As it is discussed that the switching speed is a combination of driver and switch's performance respectively [1]. Thereby design of appropriate driver is very crucial to achieve the best switching speed. Sequencing circuit is also required to feed supplies to the LNA. Here driver and sequencing circuit design is described in details. Logic gates, transistors, diodes etc. are used to design sequencing and driver circuit. External logic is passed through high throughput NAND gate and it passes through combination of transistors, zener diodes and resistor combinations to produce the output. Schematics level simulation of the driver is carried out using spice simulator tool. The design has also been verified by simulating the same circuit in 2½D simulator. The outcome of both the simulator tools are compared and they are very much satisfying**.** Figure 13 shows schematic diagram of a driver circuit comprises of logic gate (74LS00; dual-NAND gate) and zener diode (BGV90-C4V3) followed by transistors (current booster) and resistors in various combinations [1]. Simulated driver response is illustrated in the same Figure 13. In the Figure 13 the red color bit streams indicate the input control bits. The blue and violet color bit streams represent the output control–1 and control–2 bit streams respectively. These two output control bit streams are being used to alter the active switch RF and BITE paths respectively. It is also evident from the figure that, both the controls (control–1 and –2) are out of phase.

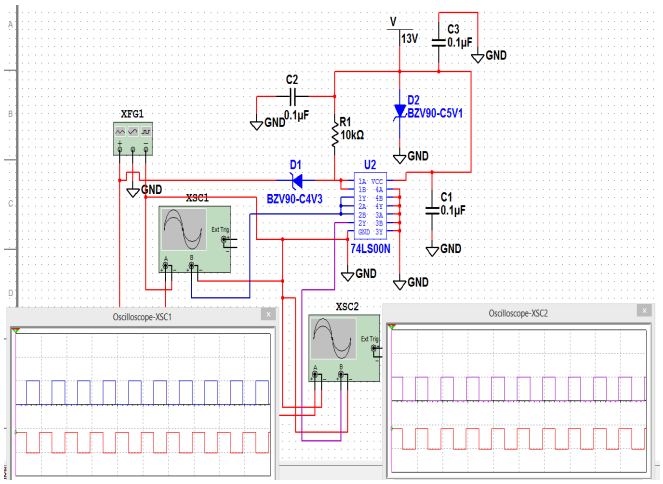

Figure 13: Schematic diagram and responses of switch driver circuit

3. Active SPDT Switch Design

Active SPDT switch design has finally been performed by employing scattering parameter (.sNp) files of all the individually designed modules. RF system analysis depends upon the precise design of all the discrete modules. Hence it will meet all the necessary specifications across all the environmental conditions over an extensive frequency spectrum. Layout is made using CPWG lines as basic SPDT switch. This technique has been adopted to rectify isolation and insertion loss characteristics of the channel respectively. The final schematic level simulation is performed using 2½ D simulator tool. Schematic diagram of the active SPDT switch for forward and reverse (isolation) channel respectively are shown in Figure 14 [1]. Tapers used to interconnect two different impedance lines are not CPWG lines also shown in this Figure 14. Figure 15 shows the simulated blue

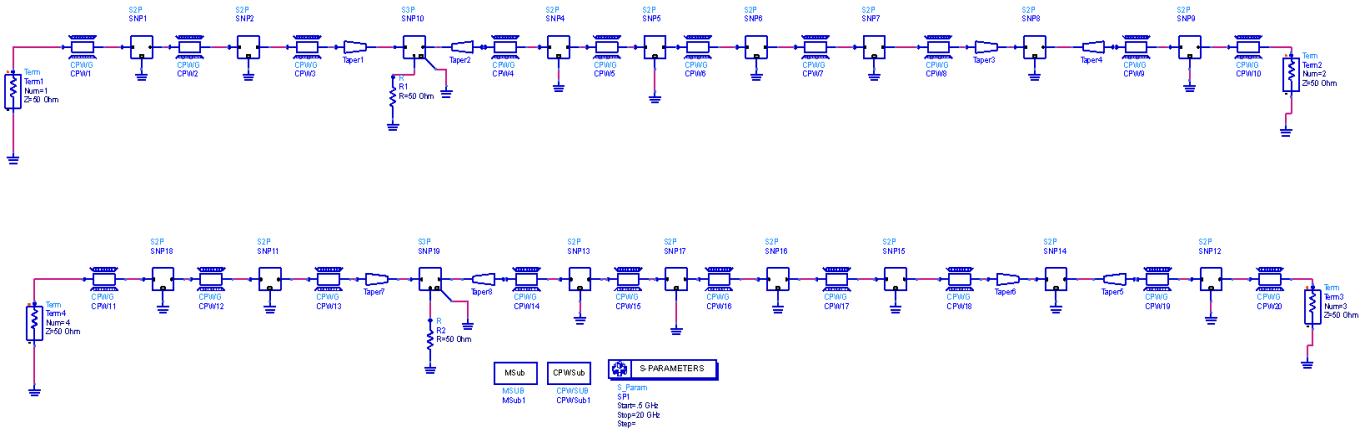

Figure 14: CPWG based schematic circuits staring from input port to output port of proposed SPDT switch for forward signal and Isolation path respectively

color insertion gain curve and saffron color isolation curves of the proposed active SPDT switch. Here the overall gain about 2 dB is achieved with flatness within ±0.5dB. More than 50 dB isolation has successfully been met at 18 GHz which is very crucial parameter. Almost 95dB isolations are also met at the lower frequencies. Appropriate LNA (die), discrete component attenuators and readily available (designed) equalizers are used in the output track of the active SPDT to match the gain flatness. Simulated VSWR response is shown in Figure 16. Budget analysis has also been performed at -7 dBm input power level and at mid-band frequency (10 GHz) using 2½D software. Parameters like isolation, dynamic range, SFDR (spurious free dynamic range) and cascaded P1 dB had been the prime concern and they have attained 54.4 dB, 64 dB, 53.24 dB and 20 .7 dBm respectively. 3D EM simulation is carried out for the layout and mechanical channels respectively. It ensures any cavity resonance is present up to 18GHz or not. Ultrathin soft substrates have been used for fabrications. Driver and control circuit is made over FR4 material. The SP2T switch and driver/control circuits are mounted on opposite sides of the same housing respectively. Switch control, sequencing and other supply connections are taken from driver circuit board to switch side through small holes, keeping in mind the EMI/EMC effects. Appropriate mechanical channeling for RF circuits are important for achieving expected responses. Microwave channel dimensions are kept narrow enough to avoid higher mode resonance (excitations), as it disturbs characteristics of the module at higher frequencies. Carrier plate are made to ensure robust ground effects at higher frequencies and very good mechanical support to the PCBs. 0.4 mm kover and copper-molly sheets having nicely nickel plated with minimum impurities have been used to make carrier plates [19].

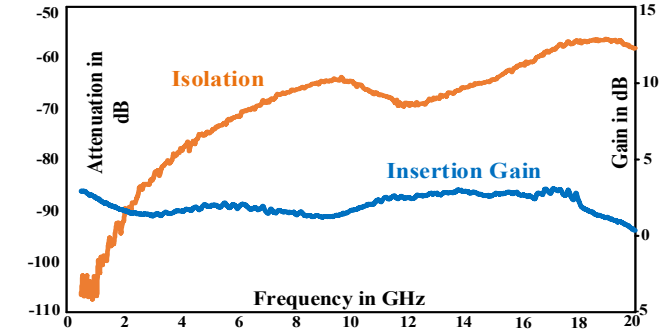

Figure 15: Gain and isolation simulation response of proposed SPDT switch in the transmission and isolation paths respectively

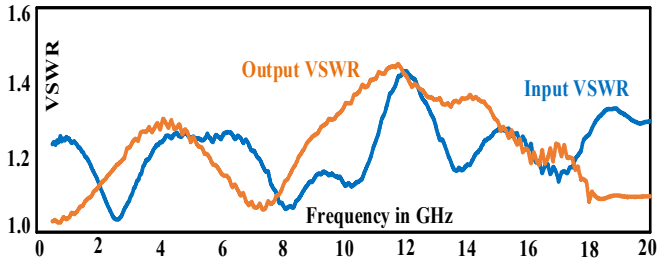

Figure 16: Input and output VSWR simulation response at input and one of the output ports of proposed SPDT switch

4. Experimentation

Active broadband SPDT switches have been developed using microstrip as well as CPWG lines respectively. Initially microstrip line based SP2T is developed and then CPWG line based switch due to noncompliance of isolation specification. The realized active SPDT switches are evaluated separately. Figure 17 shows the isolation responses of SPDT switch of microstrip line based approach. In this approach microwave channeling and air cavity sizes were not taken care precisely thereby output responses like isolation characteristics affected drastically. It is evident from the figure that isolation at 18 GHz is not meeting the requirement of 50dB. It is actually around 42dBc compared to gain plot. Gain plot of the microstrip line based SPDT is not shown as gain plot is identical to CPWG approach based SPDT. Comparison between measured and simulated responses of gain and isolation of CPWG approached based SPDT is shown in Figure 18 respectively. Here all measured and simulated responses are shown in firm and dotted lines respectively. Overall insertion gain met in this approached is 2.5dB except few frequencies. It is in good agreement with simulation responses. Each arm of this switch contains of sufficient gain equalizers to fit the gain flatness within ±0.4dB (maximum) over the entire spectrum at 27°C (Room Temperature; RT) as well as ±0.6 dB (maximum) across the wide temperature range -40°C to 71°C. Figure 18 also depicts the isolation response at RT which reached minimum 53dB (55dBc compared to gain response) in CPWG based approach.

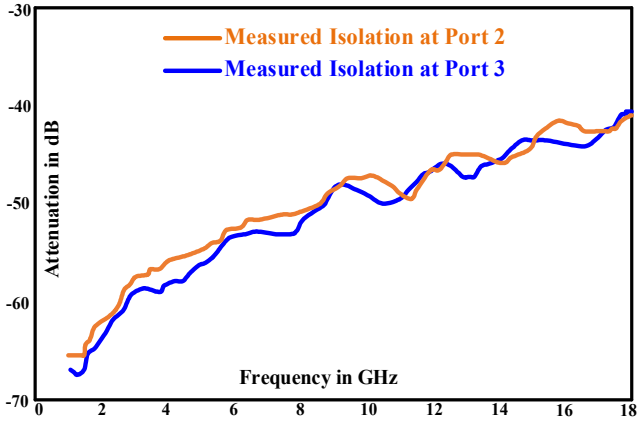

Figure 17: Measured isolation responses between common port and port-1 and port-2 of the developed SPDT switch following microstrip line approach

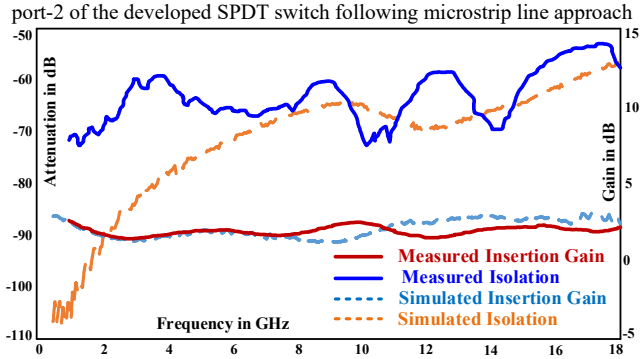

Figure 18: Comparison between measured and simulated responses of gain and isolation of common port – port-1 and common port – port-2 of the developed SPDT switch following CPWG line approach

Any input port out of two input ports of the active SPDT switch can be accessed at any instant of time according to the external logic signal. This process achieves ON/OFF input output port isolation of 55dBc at the highest frequency and more than 60dBc across 1–15.5 GHz frequency. Tested isolation response is

comparable with simulated response beyond 6GHz (6–18GHz). From 1–6GHz measured isolation is not matching to the simulation response due to more idealistic diode characteristics of the PIN diodes. Comparison between measured and simulated responses of VSWR of CPWG approached based SPDT is shown in Figure 19 respectively. The measured VSWR is 1.45:1 and 1.35:1 at the input and output ports respectively. Measured VSWR responses are in very good agreement of simulation responses. Better than 1.7:1 VSWR is measured across frequency band under ESS. About 50nS switching speed is measured with a very good rise and fall time characteristics.

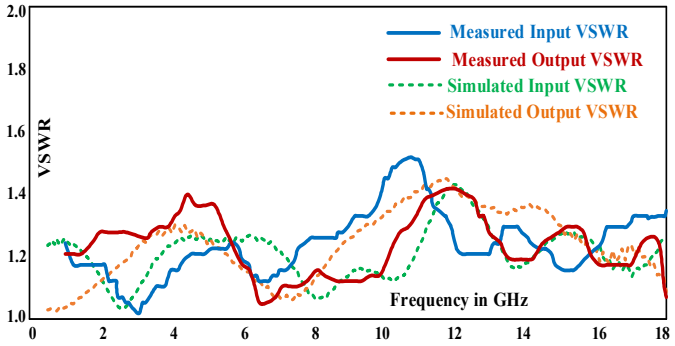

Figure 19: Comparison between measured and simulated responses of gain and isolation of common port – port-1 and common port – port-2 of the developed SPDT switch following CPWG line approach

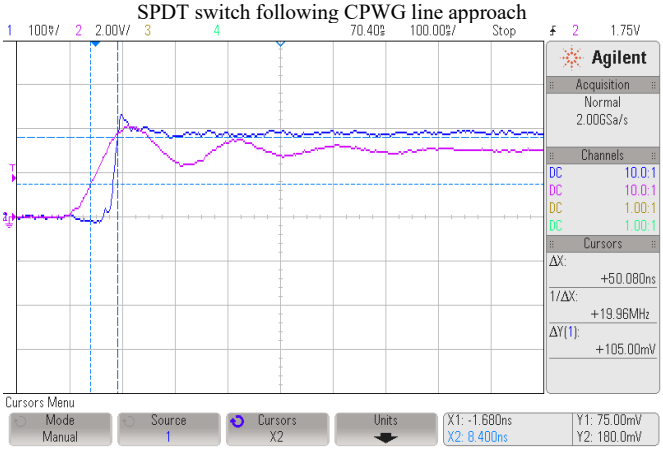

Figure 20: Response of measured switching speed at the rising edge of the developed CPWG approach based active SPDT switch

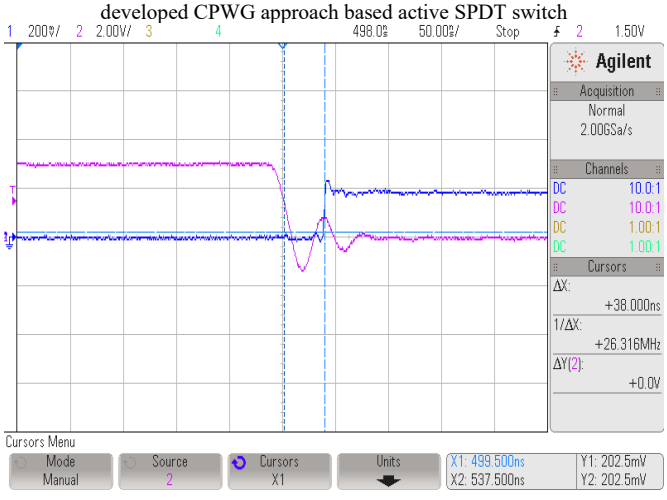

Figure 21: Response of measured switching speed at the trailing edge of the developed CPWG approach based active SPDT switch

Figure 20 and 21 describes the tested switching speed responses at rising and trailing edges against the input logic signal respectively. Here input switch control pulse is in 'volt' scale and detected output pulse in 'millivolt' scale although voltage scaling factor of input switch control and detected output pulses respectively is same (10:1). The detected output pulse will always be less than the input pulses as the input power level is fixed at -3dBm for switching speed measurement. This happens due to the absolute power level of the output pulses which is almost -1.5 – -1.0dBm (188–200mV) at 10GHz frequency and measured against a high value resistor (120Ω) is also shown in Figure 22 [18]. Thus final detected voltage after detector is very less compared to the external TTL signal. Achieved switch speed is 50nS including all RF and digital circuits. This module exhibits input P1 dB is >20 dB compared to prior work reported in [1]. This is achieved by replacing LNA with higher P1dB LNA, rectifying input/output port matching and twigging equalizer losses respectively. Developed active SPDT module also displays tremendous harmonics characteristics. Measured harmonics levels for 0dBm and 8dBm input signal for the active SPDT are 34dBc and 27dBc respectively. temperature cycling (TC) has been performed over -40° to +71° C and 3-axes random pre and post TC vibrations respectively.

Sl. no	Parameters	Specifications	Min	Max

*switching speed has been measured including driver and others are without driver.

developed SPDT module and a classic arrangement for switching speed assessment [1]. It is clear form Figure 20 and 21, that, the switching speed is being measured between 50% of the external input control pulse and 90% or 10% of the final output pulse of the detector for rising and trailing edge respectively. Final achieved switching speed is nothing but the combination of active switch as well as doctor diode delay respectively. Thus the switching speed mentioned in the table 2 is more than the actual switching speed of the active SPDT switch. Signal delay of the detector diode has been measured and it showed almost 5nS at highest frequency. Table 3 shows a comparative study of various parameters of recent works and the present work. Switching speed shown in the above table is different from other work as additional driver delay is added to the active SPDT switch of the present work. VSWR, gain flatness, isolation etc. are excellent compared to other work listed in the table. Another significant change has happened in the DC supply circuits. Earline simple line regulators were used to produce required supply from ±13V thus power consumptions were very high (almost 1.2W) in [1]. In the present work DC-DC converters are being used to generate required supplies for active components thereby power consumptions reduce drastically (almost 270mW). Thus, it can be established that the design goal has efficiently been reached as projected in the initial calculations.

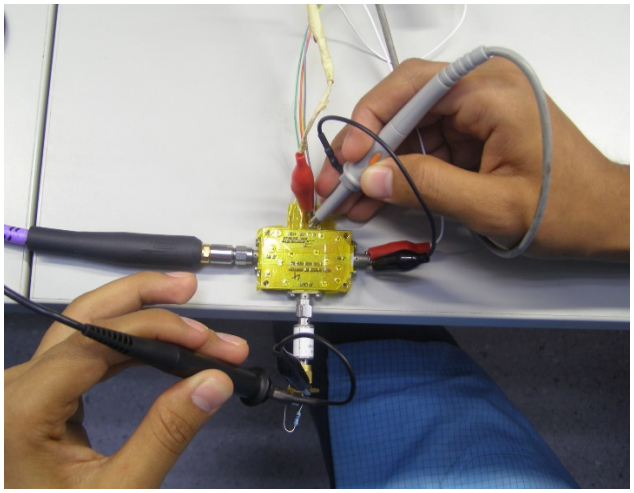

Figure 22: Measurement of switching speed by accessing input (TTL) signal to active SPDT switch and output detected pulse of the developed active SPDT switch module.

5. Conclusion

Ultra wideband active SPDT switch is designed using discrete modules like basic SPDT switch, equalizers, LNA, driver etc. Nonlinear PIN diode parameters extraction steps are shown in details using datasheet and diode equations. Nonlinear modelling is PIN diode is carried out and compared with measured responses (datasheet) for capacitance vs reverse voltage, forward current vs voltage and RF resistance vs forward current respectively. Extracted model parameters showed very good agreement with measured diode parameters. Separate modules are investigated, designed, assembled and evaluated separately. Passive equalizer with various component values are designed and finally most proper one has been selected for this active switch design. Final active switch parameters are plotted and tabulated against specification. Measured responses have been compared with simulated responses. Isolation characteristics of the developed module are not matching between simulation and measured responses from 1–5.7GHz. It happens due to limitations of PIN diode modelling. From the comparison of data, it is evident that the measured responses are in well in agreement with the simulated responses except few discrepancies. There are lots of future scopes regarding this work. LNA used in the present work has high gain which is not required as per present requirement. Thereby customized LNA can be designed to reduce power consumption further without affecting P1dB. This active SPDT switch can be compact by combining equalizers, PIN diodes, attenuators, driver and sequencing circuits as a multilayer (RF, DC and control circuit) single board solution as future work and further LNA can also be included within it using MMIC design solution as super compact light weight tiny chip.

ABSTRACT

Interpolation tools are used daily in hydrology and climatology. With the purpose to regionalize spot´s registration parameters, such as depth of precipitation, temperature, humidity, among others. The accuracy of these methods is not fully validated. This research presents a comparative study between the most used interpolation methods for the regionalization of hydrological and climatological parameters. Comparative analysis of spatial interpolation; it was carried out using the IDW, Kriging and Spline methods, for this the ARGIS software was used, because its widespread and widespread use. The depth of precipitation was considered as a parameter for the comparison. Accuracy was determined by cross validation. Also, for the coefficient of determination and the comparison for visual errors such as "bull's eyes". The research was spatially restricted to a politically delimited region; Boyacá, Colombia, South America. The best method for spatial interpolation in this case was shown to be Spline.

1. Introduction

Rainfall records are of great importance, because from this information can be obtained among other analyses of flows, design storms and changes in rainfall behavior. The records and their analysis usually come from a network of meteorological stations, each corresponding to a specific geographical point [1]. With this information it is possible to estimate and design structures for water control, economic evaluation of flood protection projects, planning and management of land use, water quality control, among others [2].

Because rainfall information represents the record of a single geographical point, it is common for information to be researched and developed for interpolation in the form of regionalization maps [3]. This information is more common than rainfall, due to its simplicity in the form of record, in both cases can be obtained from calculation treatments and analysis rainfall runoff models and obtain important information such as the curves intensity, duration and frequency [4]. In this sense, regionalization can be defined as the transfer of data or spatial information from one station to another [5]. The transfer can range from data characteristics to hydrological models, [6]. A factor which determines a better condition in regionalisation is homogeneity which essentially refers to the geographical proximity or contiguity and hydrological similarity of meteorological stations [7].

Geographical dispersion in measurement networks means that there are gaps in the spatiality of information, specifically in areas without station coverage [8]. It is evident that the same applies to rainy seasons, for this reason, it is usual that different investigations are presented that seek to find the best method of regionalization and interpolation of hydrological data in order to present a viable alternative for obtaining data in areas where there is no availability. This may influence better and more accurate hydrological models, especially in small and medium catchment areas [9].

This paper presents the evaluation of three interpolation methods; Interpolation with Weighted Inverse Distance (IDW), Interpolation by Gaussian Regression Processes (Kriging) and Segmental Interpolation (Spline), applied to the regionalization of rainfall data, looking for the best method for current and future research, determining the degree of reliability of each method. The interpolation and evaluation were carried out for the rainfall data of monthly and annual records, the application of the study was

[*]Corresponding Author: P. M. Acosta Castellanos, pedro.acosta@usantoto.edu.co

limited to the geographical area comprised by the entire department of Boyacá, Colombia. These three methods or interpolation techniques were evaluated because they are the most commonly used by consultancies and research [10].

2. Methodology

2.1. Interpolation

This research seeks to validate or give support to what is used daily, for this reason the ordinary kriging and the circular model were used because within the wide spectrum of the kriging method, these are the two most used, it is important to note that they can make and create the empirical models for semivariograms but the vast majority of references and even companies like ARGIS indicate that the ordinary kriging and the circular model are the most used [11–19].

Due to the fact that rainfall information is of a point type due to the need for a spatial range and not a point range, interpolation tools are often used, which can define regions with similar behavior [20]. The commonly used methods are Inverse Distance Weighting or IDW, Kriging and Spline, in this sense there are few comparative studies that seek to define the most suitable spatial interpolation method for climatic or environmental variables such as precipitation [21]. Spatial interpolation methods can be defined in four categories: regression method or model and trend surface, local methods, geostatistical methods and mixed methods [9], Only local methods (IDW, Spline) and a known geostadistic method Kriging were evaluated for this research. Likewise, only monthly and annual rainfall depth record values were interpolated for the region of Boyacá, Colombia, because it has a spatially acceptable coverage of rainfall stations, which has a direct bearing on the use of interpolation methods since it is necessary to have a regional coverage to carry out interpolation, since the techniques preside over the variable of interest in a specific place taking values from the surrounding region, resulting in homogeneity [22]. The project will be carried out in the department of Boyacá, Colombia, which has 123 municipalities and 116 rainfall stations of which 60 were useful, since they fulfilled a range of 20 years of historical records counting from 1998 to 2018.

2.2. IDW method

The IDW interpolation method is widely used because of its simplicity [23]. Which is based on the fact that the unknown or sought value of a point has the greatest influence of the nearby control points and the degree of influence or weight of them [24], this implies that it is directly proportional to the inverse of the distance between the points posed [25]. When defining a high power, greater emphasis will be on the nearest points and the result of the surface will be more detailed, but less smoothed. By specifying a lower power, greater importance will be given to the more distant points and therefore the resulting surface will be smoother. equation (1) represents the method

$$Z = \frac{\sum_{i=1}^{N} W_i Z_i}{\sum_{i=1}^{N} W_i} = \frac{\sum_{i=1}^{N}\left[\frac{Z_i}{D_i^P}\right]}{\sum_{i=1}^{N}\left[\frac{1}{D_i^P}\right]} \quad (1)$$

where Z is the interpolated value for a point with the unknown observed value, Wi is the weighting function that determines the importance and relationship of each control point Zi, while Zi is the observed value of the control point i (i=1,...,n), which is the closest zone to the interpolated point and n is the total number of points used in interpolation [26]. The surfaces obtained by this method tend to be symmetrical over the points and reflect the mean value of the dispersion points in the regions between the points. In this method it is possible to control the importance of known points over interpolated values based on distance.

2.3. Kriging method

The method of interpolation Kriging, has a large number of variants that have been developed in recent times, the common is the Kriging Ordinary (KO). We have in this method that the observed or not observed search points are calculated by the linear weighted average of the observed or existing points [23], as shown in equation (2).

$$\widehat{Z_0} = \sum_{i=1}^{n} \lambda_i Z_i \quad (2)$$

where $\widehat{Z_0}$ represents the point searched or not observed, Zi means the attribute of the value of an observed point i, λi is the weight or significance of Zi.

The KO method presents the best linear prediction for points not observed, this means that in theory the value sought or point not observed is equal or very similar to the true value and the variance in the error is minimal [27].

2.4. Spline method

This interpolation method determines the unobserved points using a mathematical function that minimizes the general curvature of the surface, which has the particularity of being a smoothed surface. Many tests performed with Spline show their accuracy which means that the interpolated regions pass through the observed points [28]. There are two types of Splines mostly diffused, the Regularized and Stress, the first refers to softened regions or surfaces and the second creates less smoothed surfaces that are closer to the observed values, both cases result from the general equation of the equation method (3).

$$Z_{(x,y)} = T_{(x,y)} + \sum_{i=1}^{n} \lambda_i Z_{ri} \quad (3)$$

where Z is the value sought or point not observed, n, the number of points, λi coefficient of the system of linear equations, Zi is the distance of the point (x,y) to the point I [29].. T and R, are defined according to whether it is regularized or tension.

2.5. Hydrological Information

The information used for the assessment of interpolation methods is of the monthly and annual rainfall type. We reviewed the records of 116 stations located at the site of the study (Boyacá, Colombia), of which 60 had continuous records between 15 and 20 years. It should be recalled that rainy seasons record only the precipitation depth measured in (mm). The place where the research was applied is located in Colombia, South America, in the department of Boyacá, with an area of 23189 km², which represents 2.03% of the Colombian territory [30]. It is a region with three main hydrographic basins on the rivers Magdalena, Arauca and Meta, in the central area of Colombia, the figure 1, shows the area of study.

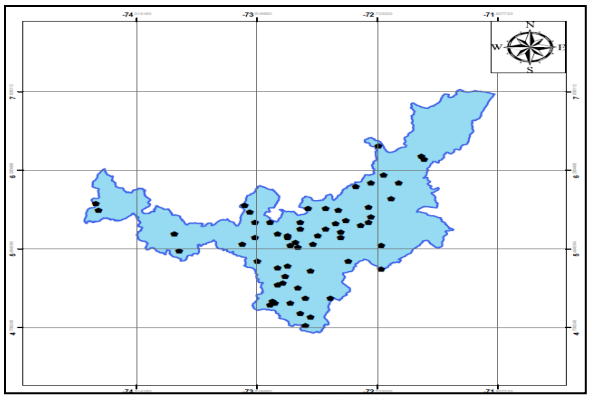

Figure 1: Location of rainfall seasons

3. Results and discussion

3.1. Validation of the methods evaluated.

The validation of the interpolated points using the three methods was performed by cross-validation, technique used to evaluate the results of a statistical analysis and to ensure that they are independent of the partitioning of the data obtained in this case from rainfall stations. The estimated value must be similar to the actual value, that is the measured value, so that the error committed by the model, that is, the difference between the two, is as low as possible [31].

The difference indicates how out-of-date the precipitation depth data calculated by the software are, when compared with the actual or measured information presented in the study area, that can be analyzed by the coefficient of determination or R2.

3.2. Cross-validation

Cross-validation is a way of predicting the fit of a model to a hypothetical test data set when the explicit test data set is not available. The cross-validation process gives a precise approximation of performance and error prediction [32]. Cross-validation in this study was performed by interpolating the totality of the rainfall stations and subtracting one weather station at a time, interpolating again, to verify by crossing the interpolated information against the actual or measured of each meteorological station. In other words, the interpolated data at the points where the measured data is held are verified and the actual or measured values and the interpolated values are compared.

3.3. Comparison of interpolation methods

Raster maps generated by a GIS were used in order to identify which interpolation method presents better results from different points of analysis; cross validation, coefficient of determination (R2) and the visual aspect, in the latter was sought to identify the error called "bull's eye". Based on the measured and calculated differences, statistical analyses were performed for the maximum annual and maximum monthly precipitation depth. The mean, median, minimum and standard deviation were compared, although it should be noted that greater importance was given to the statistical parameter of the mean, since it was considered to be the most relevant parameter in this case.

3.4. Interpolation of Annual precipitation depth.

It was observed that the Kriging technique has the least variation in the statistical parameter of the mean (54.70), of data standardization, but has the greatest dispersion of data with respect to the measured data (standard deviation), in addition it does not present an anisotropic behavior with spherical distribution behavior normalizing thus adjusting the plateau, data tolerance and bandwidth as shown in Figure 2.

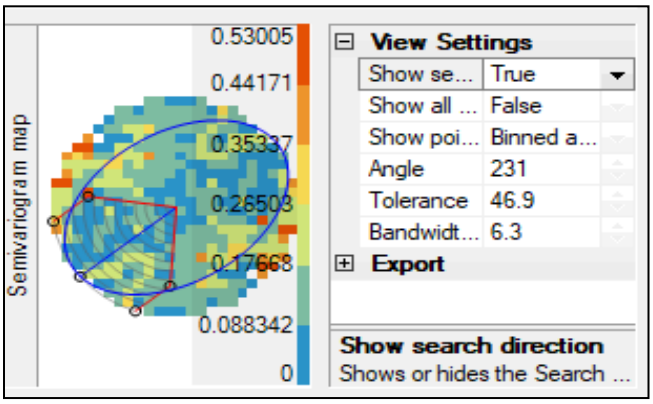

Figure 2: Data adjustment

In the standardization of data, a circular or spherical model was used in the semivariogram, adjusting the data to an exponential trend Figure 3, thus obtaining the highest reliability to perform the interpolation of IDW, ordinary kriging and spline as shown in Figure 4, 5, and 6 for 2008 year.

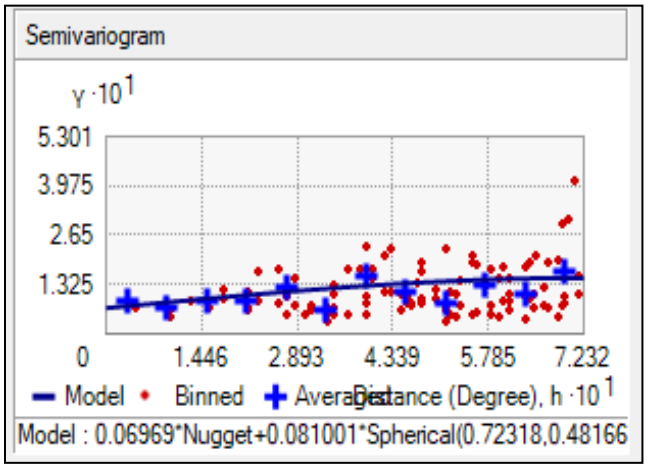

Figure 3: Semivariogram

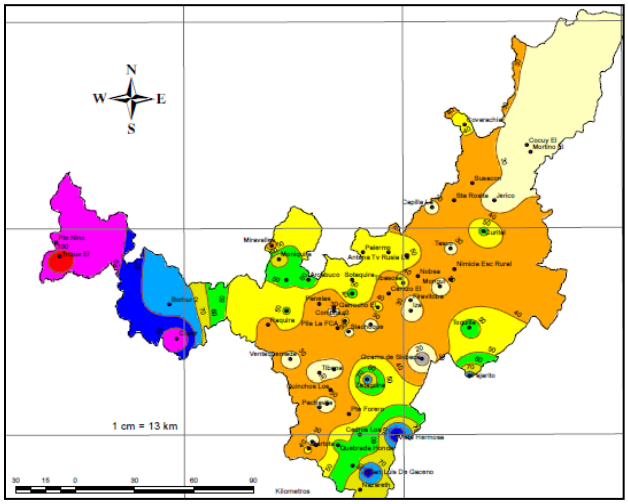

Figure 4: Interpolation by IDW, january 2008

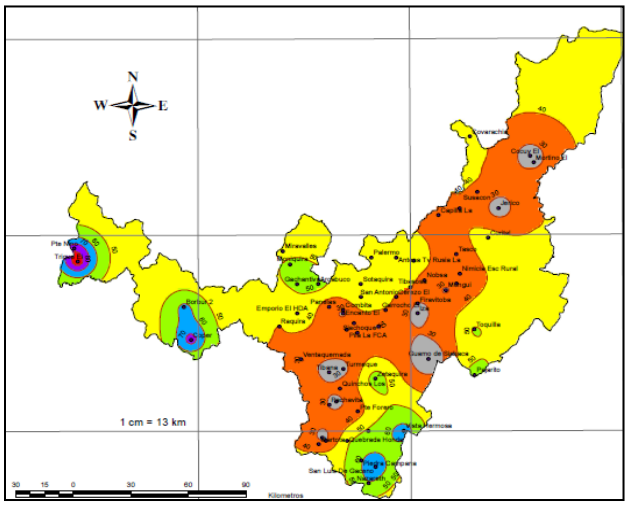

Figure 5: Interpolation by Kriging, january 2008

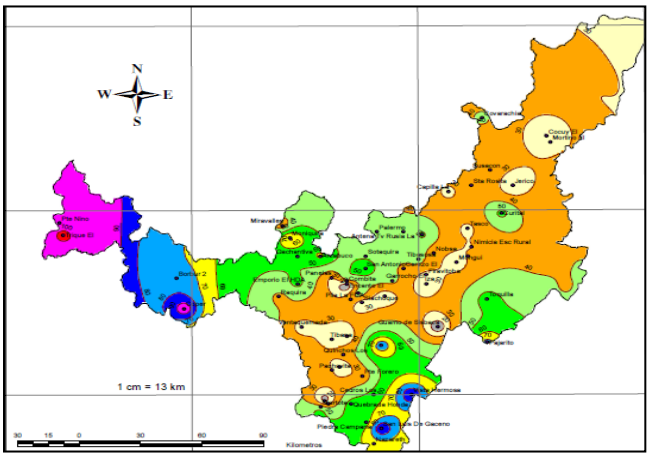

Figure 6: Interpolation by Spline, january 2008

On the other hand, the Spline technique also shows good performance in terms of average (54.66), but less than the Kriging value. The Spline method presented less dispersion than Kriging. Similarly, it was found that the IDW technique shows the greatest difference between the measured data and the interpolated data, in Table 1; the results of the analysis are evident.

Table 1: Statistical analysis of annual precipitation depth for 2008

Statistics	*Data measured*	*IDW*	*Spline*	*Kriging*
Mean	56.81	53.02	54.66	54.70
Median	47.1	49.04	48.40	51.04
Estándar deviation	30.51	20.12	20.99	16.26
Minimun	10.50	25.10	27.40	34.12

For the analysis of the interpolation of annual precipitation, it was determined that the kriging technique is the best fit in the statistical analysis of data, since the mean with the Kriging technique has a more appropriate behavior than the other two evaluated techniques.

3.5. Interpolation of monthly precipitation depth.

In the case of the interpolation of the monthly precipitation depth data, the Spline technique presented better results in terms of the statistical parameters of the mean and median, compared with the other techniques, although with great closeness between each method. In the second place, the Kriging technique is found in Table 2; the results of the analysis are evident.

Table 2: Statistical results of methods evaluated against mesuared monthy values, 2008

Statistics	Data measured	IDW	Spline	Kriging
Mean	66.31	62.22	63.95	63.86
Median	55.15	54.60	55.14	53.17
Estándar deviation	32.04	22.58	24.75	25.20
Minimun	28.80	35.13	31.70	34.44

3.6. Análisis de contornos.

Raster maps because they represent the space in a regular array of pixels, where the representation of the elements is made by pointing out the existence or not of data within each pixel [33], in the case of the regionalization of precipitation depth facilitates the visual behavior of the three interpolation techniques used in this investigation. Where we visually compared which of the three techniques has better contours and a more detailed surface in areas where there are no weather stations. One of the characteristics that is intended to show both in presence and absence is the typical error of "ox eyes" where interpolation techniques usually create concentration points or form islands around interpolated or measuring points [34], in this case the rainfall seasons. This anomaly is evident that with the IDW method where concentric circles are presented, as can be seen in Figure 1, this anomaly was presented as a visual trend a large percentage of the generated maps.

Ordinary kriging was the technique that presented the best results, since visually it presents different contours of precipitation depth, which is more accommodated to the recorded precipitation, consistent with the cross validation performed. In addition to performing the ordinary kriging, an additional raster is also interpolated to validate the interpolation of standard prediction errors, where the less data is those that may reliability and the larger data are those that should be resampled, as shown in figure 7.

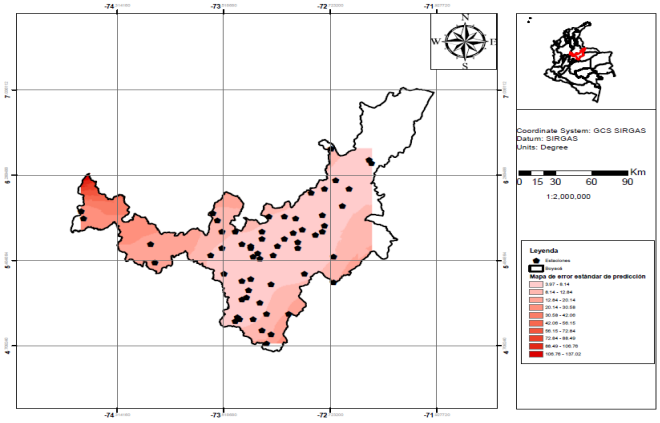

Figure 7: Standard Prediction Error Map.

3.7. Coefficient of determination R2

Raster maps because they represent the space in a regular array of pixels, where the representation of the elements is made

by pointing out the existence or not of data within each pixel [33], in the case of the regionalization of precipitation depth facilitates the visual behaviour of the three interpolation techniques used in this investigation.

3.8. Measurement of R2 in precipitation interpolation Annual

In this sense the method of interpolation of Kriging presents better correlation in the interpolation with depth of precipitation, the coefficient of determination is close to 1, with respect to the other models (Idw and Spline), thus yielding a high degree of reliability for choosing this model and carrying out the interpolation with which the regionalization of precipitation depth can be generated, due to the nature of this method it can be observed that it has a better behaviour with a higher data density, since analyzing interpolation with depth of monthly precipitation shows that the so-called spline model presents a greater correlation between its data, this allows choosing it to generate monthly regionalization.

Table 3: R2, para los métodos evaluados.

Interpolation Depth of Precipitation Max. Annual		Interpolation Precipitation Depth Max. Monthly	
Method	R2	Method	R2
Kriging	0,5762	Kriging	0,6717
Spline	0,5484	Spline	0,6861
IDW	0,5308	IDW	0,655

4. Conclusions

It was identified that visually the methods do not present an obvious difference, but in the case of the IDW technique generates the so-called portholes. For the regionalization of the maximum monthly precipitation depth it was possible to identify that the Spline method has a better behavior compared to the real data, since the R2, had a higher value (0.6861) compared to the other two methods evaluated.

In the case of the maximum monthly depth, the method that had a greater difference compared to the real data was the IDW, added to the visual errors (portholes) it is not advisable to use this method to regionalize hydrological data. Based on the analysis of both visual and cross-validation results, it can be stated that the kriging technique has a high degree of reliability when performing regionalizations with annual precipitation information.

In addition to the comparative results of the methods evaluated, the resulting information can be used as input for the determination of hydrological models in areas or locations that do not have their own information or measurement. In other words, they do not have a hydrological station. It could be shown that it is possible to use regionalized information with a high degree of confidence provided that it comes from data interpolated by the Spline method or the Kriging method

Twenty-four raster maps were generated, with maximum monthly and maximum annual rainfall depths, where twelve of these maps belong to the Spline technique which generates greater reliability with the maximum monthly values, and the remaining twelve were generated by the Kriging technique for maximum annual precipitation depth values. Maps generated by the IDW technique were discarded. It is evident that having a greater number of stations in optimum condition could make a more precise regionalization since interpolation would be more accurate, as well as having support stations would minimize the effect of "bull's eye".

ABSTRACT

Gender detection and age estimation become an active research area and a very important field today, wish has been widely used in various applications including them: biometrics, social network, Targeted advertising, access control, human-computer interaction, electronic customer, etc. The need to further improve the recognition or classification rate keeps increasing day after day. In this paper, we explore how deep learning techniques can help in the classification of gender from human face images and moreover raise the recognition rate. We propose in this contribution an approach called SH-CNN based on Discrete Shearlet Transform (DST) as a first step of feature extraction layer, and Deep Convolutional Neural Network (DCNN) as a second automatic feature extraction layer and also a classification step. The idea behind our contribution is to generate trough DST several features (in different decomposition and orientation) of an image. These features of each image will be the input of the DCNN, to enrich the training step, and so, improve the recognition rate. The obtained results have shown that the proposed approach import a significant enhancement.

1. Introduction

This paper is an extension of work originally presented in The Third International Conference on Intelligent Computing in Data Sciences ICDS2019 [1].

Automatic age and gender classification of humans through their image faces is a fundamental task in computer vision. It is an important research focus this last years, and plays a key role in a large variety of applications. In this last years, The Convolutional Neural Networks (CNNs) model has shown high level classification capacity, and mainly in cases of face images taken in real-world conditions. The performance of this model result in the ensured high level feature extraction and classification, through the used layers.

The Feature Extraction Function (FEF) is the key factor that determines the efficiency of a Face Recognition System and considered as one of the important parts. Several feature extraction function have been proposed in this domain of face feature extraction, such as, wavelets [2], SIFT [3] and other [4], [5]. Until today, the need for more efficient feature extraction function increases, seen the use of face gender recognition system in sensitive and important area. The Shearlet transform as feature extraction function allows generating more sensitive and significant features [6]-[8].

The field of learning has undergone a revolution with the appearance of CNN because the CNN can extract features of different complexities. Unlike the learning technique, convolutional neural networks learn the features of each image automatically, and that's where their strength lies. Today, the most successful models for image classification are those based on CNN. Since the model is based on learning, so we will enrich this phase with features extracting by DST. The Discrete Shearlet Transform (DST) is used in our paper as a first feature extraction layer for our proposed SH-CNN. The idea is to extract more significant features of the input face, to further enhance the gender recognition rate.

2. Related work

There is already a rich literature on the subject of classification by age and gender in an attempt to further improve the recognition rate. We briefly reviewed the age and gender classification studies that use neural network or Convolutional neural network. The authors in [9] present a structure including CNN and Extreme Learning Machine (ELM), where the CNN is used to extract the features from the input images and ELM, to classify the interposed results, and to combine the co-action of the two classifiers, to perform age and gender classification. In [10], the authors

*Corresponding Author: Chaymae Ziani, Email: chema.zin@gmail.com, chaymae.ziani@uit.ac.ma

implement a CNN of 3 convolutional layers and 3 fully connected layers for the tasks of estimating age and gender, it is trained exclusively on Audience. For the forecast, they do several crops around the face in different sizes. The final prediction is the average prediction value for all of these crops. They achieve an 86.8% rate of good classifications on the audience test images. A Deep gender classification is performed in [11], which is based on AdaBoost-fusion of isolated facial features and foggy faces. They applies an approach based on local features of the face by separating it into several parts (mouths, eyes, nose). They also include the discriminating features surrounding the face while blurring it. These images are then used to train several CNNs followed by an Adaboost classifier grouping the classification scores of the CNNs. This method yielded 91.75% on LFW and 83.06% on Adience using Gallagher as training data. In [12] the authors address the estimations problem with a classification based model which considered the age value as an independent etiquette and a separate class, and propose a deep convolutional neural network model learns the pertinent informative age and gender characterizations from the image pixel. A Male/female identification method from very low resolution face images by using neural network have proposed in [13]. In [14], the authors proposed a method named the full component CNN, which holds the full faces and the facial component networks, to obtain human age/gender classification through the facial image data. For age and gender classification, the authors in [15] propose a method applying deep learning based learning, the feature extractor HOG is applying on the input image on the network. The structure of the network used in this study is GoogLeNet. In [16], the authors present a review and a study of the advanced research technique for gender classification, which can be useful for researchers who work on gender classification. In [17], a convolutional neural network is used for the estimation of age and gender of a person from the facial image, and the PCA is applied to reduce the dimensions of the extracted features.

Among the research works countable on fingers that use CNN and shearlet transform, we find a contribution in [18], where the authors use an algorithm based on CNN and Shearlet transform, to classify the patient having Alzheimer's disease and early or late mild cognitive impairment using the florbetapir PET (positron emission tomography) amyloid imaging data. The authors had concatenated shearlet coefficients into the convolution layers on the CNN.

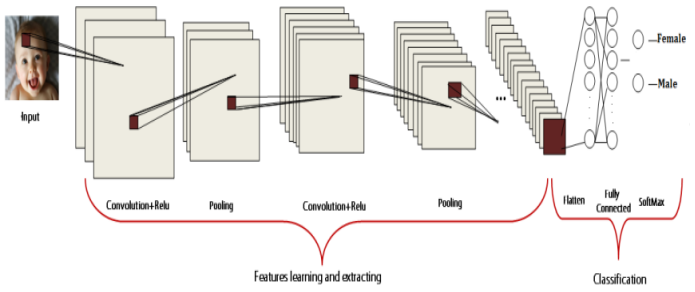

Figure 1: Example of a DCNN architecture for gender prediction

In our knowledge, this is the first time that Shearlets are used as first pretreatment, in order to enrich the training phase of the DCNN. The idea is to add as first treatment a DST, to exploit the calculated features extracted through decompositions and orientations. These operations allow us to generate from one input image, several feature views. Based on these generated features, we enrich the training phase, by injecting to DCNN the image and its feature views (the DST decompositions and orientations). The proposed approach will allow us to enhance the gender recognition, seen that the training phase is improved.

3. Deep Convolutional neural network and shearlet transform

3.1. DCNN

Convolutional Neural Networks [19] was proposed mainly to treat 2D shapes variability. They have been used widely in computer vision and they showed the best results and outperformed all other technique. Now, DCNN has become a major research orientation for researchers in the domain of computer vision, especially for image classification.

DCNN is powerful model, which is capable to capture effective information due to his architecture (Figure 1). DCNN architecture is divided into 2 steps, the first step is learning and extracting features and the second step is classification. There are four types of layers for a CNN: the convolutional, the pooling, the ReLU correction, and the fully-connected.. These components work together to learn a dense feature representation of an input.

- The convolution layer (Figure 2) is the important component of CNN, and always constitutes their first layer. Its goal is to identify features in the images received as input. To do this, convolution filtering is applied, by sliding window that represents feature, and by computing the convolution product of each image part and feature. Then, a feature is viewed as a filter. An activation map is obtained for each pair (image, filter) which indicates where the features are located in the image, when the value elevated, the more the corresponding place in the image looks like the feature. And then, these feature maps are normalized (with an activation function) [20].
- The ReLU correction layer used as an activation function, it is defined by ReLU (x) = max (0, x) [20], to replace all negative values with zeros

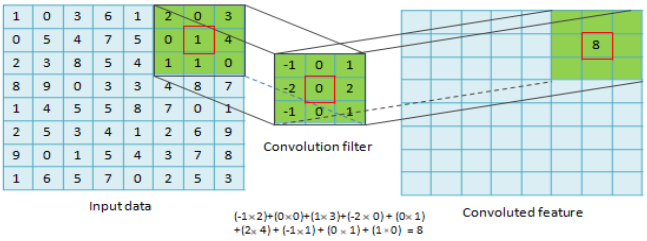

Figure 2: Convolution filter applied on input image

- The pooling layer (Figure 3): feature maps are injected as input to this layer. The principal of pooling is to reduce image size without losing the essential characteristics. In general, the pooling layer is nested in two convolution layers, and aims to enhance network-learing, by minimizing over-calculations [20].
- As last layer of the network. The fully-connected layer [20] has as input a vector, on which it applies linear combination

and activation function, and so, generated output vector. The returned vector by this layer to classify the input image represents the possible output classes of the classification system. Each value of the vector represents the corresponding probability of the input image to a class. The input matrix resulting from the previous layer contains an activation map, which represents the position of feature in the image. According to the position of feature in the image, the fully-connected layer can calculate the corresponding probability to each output classes. In general, for the DCNN classification systems, the softmax method is often used at the end of the network [21].

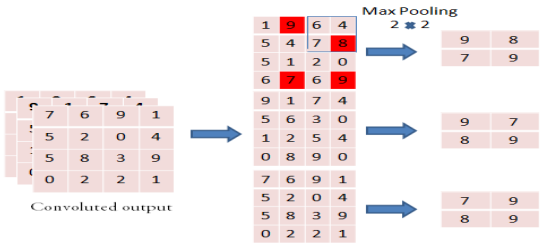

Figure 3: Example of a max pooling operation [22]

3.2. Shearlet transform

A multidimensional version of wavelet transform were invented in 2006 [23] named Shearlet, that encode anisotropic features in multivariate problem classes. The limitation of wavelets is the incapacity of capturing anisotropic features. Therefore, this transform provided optimal sparse representation for images with edges, surpassing the wavelet.

The successful use of shearlets in many image processing applications, especially face detection, feature extraction and denoising [24]-[26], is due to their properties: parabolic scaling, shearing, and translation. Expressly, the Continuous Shearlet Transform (CST) [27] is defined as:

$$f \longmapsto SH_\psi f(a,s,t) = \langle f, \psi_{a,s,t,} \rangle, \quad f \in L^2(\mathbb{R}^2)\ , (a,s,t) \in \mathbb{R}_{>0} \times \mathbb{R} \times \mathbb{R}^2 \tag{1}$$

where,

$$\psi_{a,s,t(x)} = \mid det M_{a,s} \mid^{-\frac{1}{2}} \psi\left(M_{a,s}^{-1}(x-1)\right) \tag{2}$$

The parameter of this system calls as wavelets with composite dilations.

And
$$M_{a,s} = \begin{pmatrix} a & s \\ 0 & \sqrt{a} \end{pmatrix}. \tag{3}$$

The matrix $M_{a,s}$ is factorized as B_sA_a, where $B_s = \begin{pmatrix} 1 & s \\ 0 & 1 \end{pmatrix}$ is a shearing matrix and $A_a = \begin{pmatrix} a & 0 \\ 0 & \sqrt{a} \end{pmatrix}$ is a parabolic scaling matrix (or anisotropic dilation matrix).

The Shearlets transform function is based on three variables (Figure 4): a is the scale parameter measuring the resolution level, s is the shear parameter measuring the directionality and t is the translation parameter measuring the position.

To get a frame (or Parseval Frame) for $L^2(R)$, a CST sampling is applied on a suitable discrete set of the three parameters: scale, shear, and translation. A discrete shearlets can be generated by sampling those three parameters:

$$a_j = 2^j (j \in \mathbb{z}), \qquad s_{j,k} = k a_j^{\frac{1}{2}} = k 2^{\frac{j}{2}} (k \in \mathbb{z})\ ,$$
$$\text{and} \qquad t_{j,k,m} = D_{a_j,s_{j,k}} (m \in \mathbb{z}^2) \tag{4}$$

For $\psi \in L^2(\mathbb{R}^2)$, the Discrete Shearlet Transform of $f \in L^2(\mathbb{R}^2)$ is the mapping defined by:

$$f \longmapsto SH_\psi f(j,k,m) = \langle f, \psi_{j,k,m} \rangle,$$
$$f \in L^2(\mathbb{R}^2)\ , (j,k,m) \in \mathbb{z} \times \mathbb{z} \times \mathbb{z}^2 \tag{5}$$

Where (6) is the discrete Shearlets function (DST)

$$\psi_{j,k,m,}(x) = 2^{\frac{3j}{2}} \psi(B_k A^j x - m), j \geq 0, -2^j \leq k \leq 2^j - 1, \quad m \in \mathbb{z}^2 \tag{6}$$

and $M_{a,s}$ is discretized as $M_{j,k} = B_k A^j$. Thus, SH_ψ maps the function f to the coefficients $SH_\psi f(j,k,m)$ correlated with the indexes of scale j, the orientation k, and the position m.

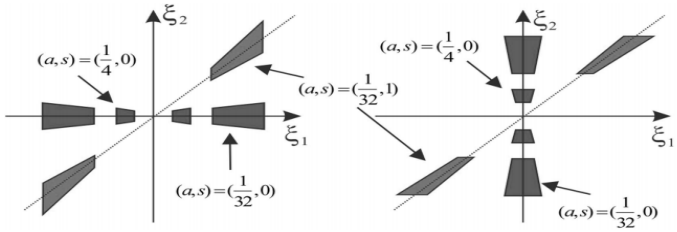

Figure 4: The horizontal and vertical shearlets Frequency support [28]

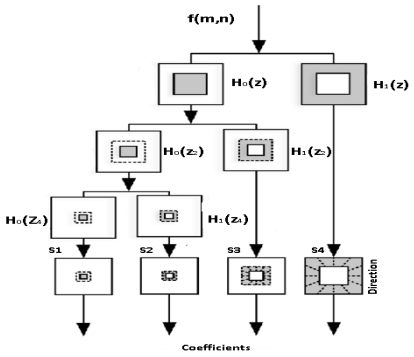

The shearlet transformation is a decomposition function based on scales and direction set. As shown in Figure 5, the decomposition is done by 4 scales levels denoted S1, S2, S3, and S4 with 6 directional filtered coefficients. At first, repetitively, a decomposition of the input image is done to a low-pass image and a high-pass image, based on a decomposition of two-channel non-subsampled [30], [31]. The used filters are: $H_0(z)$ for low pass filter function, and $H_1(z)$ for high pass filter function. The decomposition steps are: first, a frequency transformation domain applied on the high pass image, using two dimensional Fourier transform. Secondly, a cartesian coordinate system with six directions is used, to generate six directional subbands from the frequency domain. For the low pass image, a decomposition of two-channel non-subsampled is applied again, and the same

decomposition steps are repeated. The shearlet coefficients are generated as result of this transformation [29].

4. Proposed Approach

The idea which motivated us to propose this solution is the objective of enriching the learning phase to improve gender recognition. To enrich the DCNN learning input sample. We proposed to use as the first preprocessing of the CNN, a layer which uses the DST. The latter allows us to generate from a CNN learning input image, several views made up of the features generated from the decompositions and orientations of the DST. At this point, in the learning phase, the input will be represented not just by the images but also by their feature views. In this way, we will increase the input sample from the same number of starting images. Such a technique will be very useful in the case where the image sample in the training phase is small.

In our proposed approach, the training and the testing phase of the system performs essential operations. Each operation contributes to ensure a high recognition level. Figure 6 and Figure 7 showed these operations:

- Face detection
- Preprocessing
- Features extraction using DST
- Automatic features extraction and classification

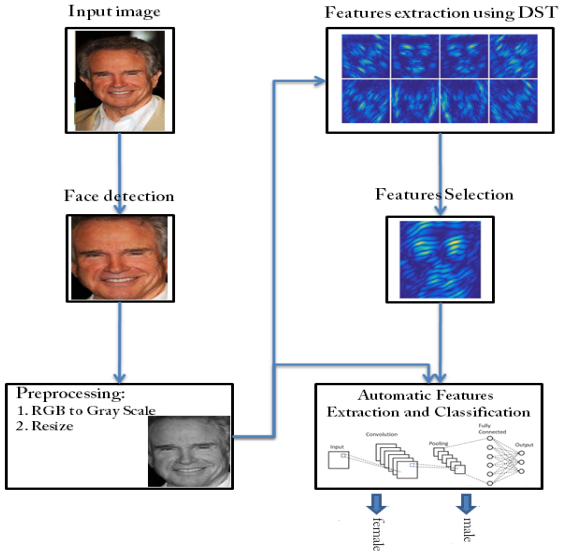

Figure 6: Proposed SH-CNN approach (training phase)

In our approach, haar-cascades [32] are used for face detection in order to eliminate any unusable information in the image. As a result, we will focus just on faces.

4.2. Preprocessing

At this level, two main treatments are applied on each face photo. The first treatment is to convert the photo from a RGB color level to a Gray level. The second treatment is to reduce the size of the faces photos. These steps reduce the calculation time in extracting features, and also in CNN layers.

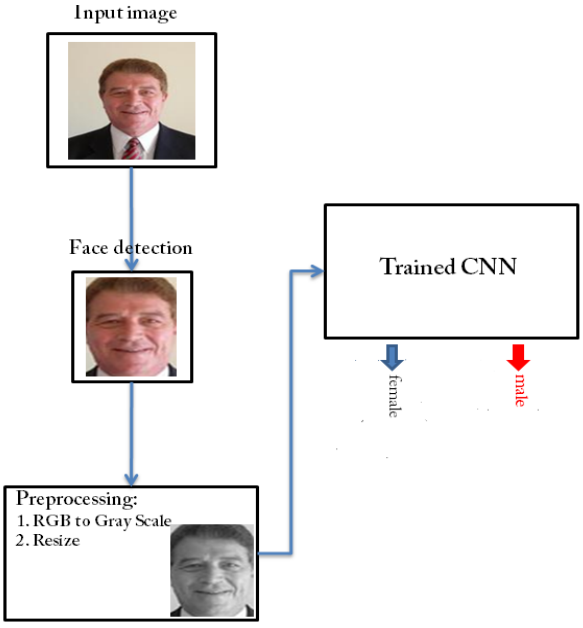

Figure 7: Proposed SH-CNN approach (testing phase)

The Feature Extraction Function (FEF) is a key factor that determines the efficiency of gender Recognition System. DST as a FEF is applied in each face image; the images will decompose along a number of directions and scales to extract important facial features. At the end, for each image we get a set of images in different orientations. That will enrich the CNN's learning step and facilitate the classification phase. And that is the goal for combining it with the CNN. This operation is used only in training phase, and so, we will not increase the processing time in the testing phase.

4.4. Automatic features extraction and classification (CNN)

The idea is very simple. The trainable system consists of a series of modules, each one representing a processing step. Each module is trainable, with adjustable parameters similar to the weights of linear classifiers. The system is trained from end to end: in each instance, all parameters of all modules are adjusted to bring the output produced by the system closer to the desired output.

To enrich the training phase, we inject as an input in our CNN the face and the corresponding coefficients calculated using DST. This operation allows the CNN to adapt more the weights and to increase the learning step.

5. Experiment results

This section presents the experimental results of our proposed approach. Our method is implemented using Python as a high-level programming language, with the Tensorflow [33] (an OSS framework for machine learning on decentralized data) and Keras(is a deep learning API) [34] libraries for CNN learning and classification.

5.1. UTKFace dataset

UTKFace dataset [35] is composed from over 20,000 face images (e.g. Figure 8), which are tagged by age and gender. The

images of this dataset present multiple facial expressions. Certain images are with high and low resolution, things that allow testing our system well. The UTKFace dataset is frequently used in gender/age classification and face detection, etc.

The images size is 200×200 pixels. We have resized all the face with the dimension of 100×100 pixels.

5.2. Operations of extracting features and classification

In the previous section, we presented our approach with successive operations. In this section, we present more details on the proposed SH-CNN approach for automatic gender recognition.

The DST ensures a good representation level of images with edges. At the features extraction step, the pre-treated images were decomposed into 4 levels (Table 1), by varying shear parameter from 2^0 to 2^3, and scale parameter from 0 to 3, and hence we obtained shearlet coefficients on many directions (Figure 9).As we said before these coefficients will be used later as input of a CNN. We repeat this procedure for all faces of the training database.

Table 1: Used DST parameters.

Decomposition levels	Directions	Shearing filters size
Level 1	4	32×32
Level 2	8	32×32
Level 3	16	16×16
Level 4	16	16×16

In our proposed approach, and during all experiments for gender classification, we used a CNN composed from three convolutional layers and one fully-connected layer. Gender classification on the face dataset requires distinguishing between two classes, that the reason why we choose a smaller network.

The input layer is a face image of size 100 × 100 pixels. The three convolutional layers are respectively of 96@7 × 7, 256@5 × 5, and 384@3 × 3 feature maps. After each one of these convolution layer, a ReLU function and a max pooling layer (the max value of 3×3) are applied. To generate the needed 512 neurons for the fully connected layer, a flatten layer is used. The next layer is a fully connected, that maps to the final gender classes. As a last step, a soft-max layer is applied to attribute a corresponding probability for each class. The class having the probability max value represents the closest prediction

The used criteria in this experiment results take into consideration our need in terms of features extraction part and CNN classification part. For the DST feature extraction part, we have used four level of decomposition with directions (4, 8, 16, and 16). In general in the existing works, and as the recommended values, the used decomposition number is approximatively 3, 4 or 5 levels, and for directions we found (4, 8, 16, and 32) [6]-[8], [26]. In our contribution we have used four level with directions (4, 8, 16, 16), which have clearly shown the added value of our contribution. For the CNN classification part, we have used three convolutional layers with a kernel size of 7x7, 5x5 and 3x3, in order to reduce the training time. And for the fully connected layer, we used 512 neurons, since using larger values in case of 100x100 input image size will not improve the results, contrary, it will increase the calculation time.

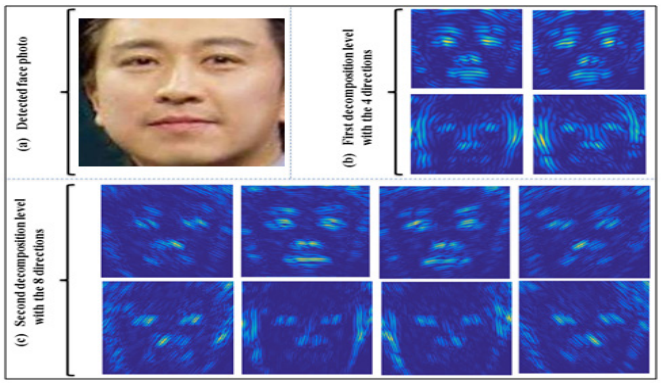

Figure 9: (a) Detected face photo (b) 1st decomposition level with 4 orientations applied on the detected face (c) 2nd decomposition level with 8 orientations applied on the detected face.

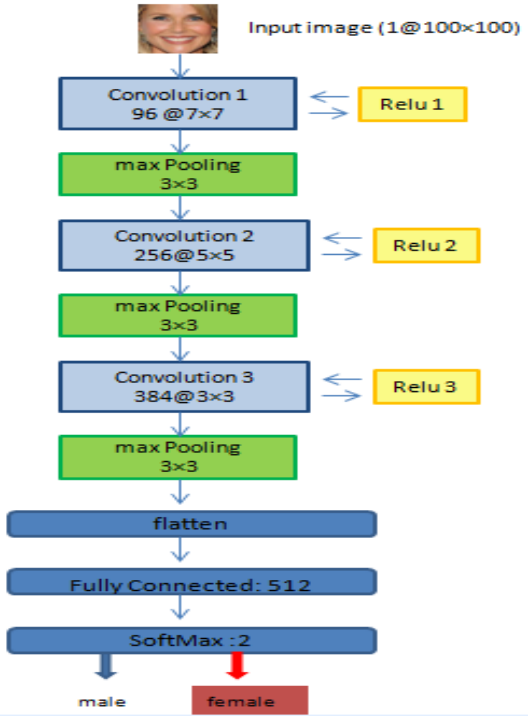

Figure 10: Proposed CNN architecture

5.3. Results and discussion

Regarding the comparison phase of the proposed approach (SH-CNN), we carried out a direct comparison study with the CNN, without seeing the other models that already exist, proposed as part of the improvement of the gender recognition, and based on CNNs. It is seen that our first objective was to test the added value of our SH-CNN compared to CNN. Add to this that the proposed preprocessing layer concatenated with the CNN can be concatenated with all the proposed models based on the CNN as

well. Because the add layer plays the role of an enrichment phase of the sample of the learning part of the CNN. From this explanation, we understand that the comparison must be made with CNN directly.

The obtained results in terms of accuracy rate and loss rate (see Figure 11 and 12), shown clearly the added value of our proposed approach. The generated coefficients for each face using DST, enrich the training phase as expected, and so, increase the recognition rate. In this simulation, we have used just one generated coefficient of DST as input with the associated face. If we use more coefficient as input to enrich the training phase, we may obtain more efficient recognition system, and this will be our coming research work. Also, in our simulation, we have used just 3 epochs, to show the capacity of our approach to increase more the accuracy rate within a few epochs.

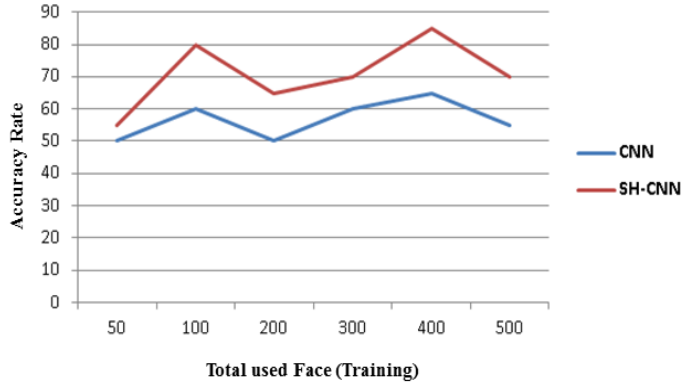

Figure 11: The obtained Accuracy Rate (CNN vs SH-CNN)

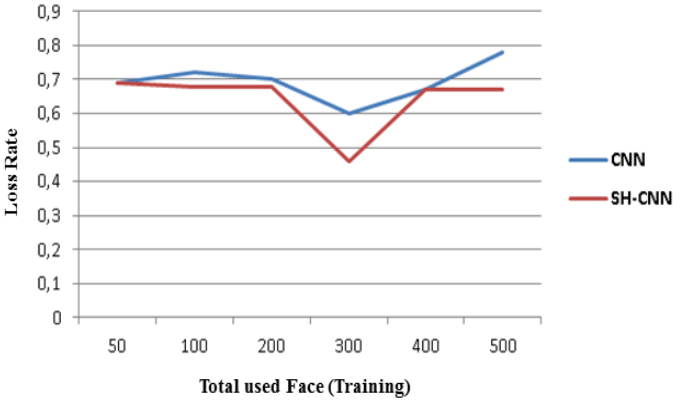

Figure 12: The obtained Loss Rate (CNN vs SH-CNN)

6. Conclusion

The need to increase the gender recognition rate has pushed us to search lower-cost solutions (processing time, dataset size, etc.). In this paper, we have proposed an approach based on CNN and especially on DST as a first layer. The idea behind this solution is to enrich more the training phase, by using the generated coefficients of each image using DST. The obtained results have shown the clear added value of this approach. The ensured accuracy rate of our system is also related to the capacity of DST to extract the significant features of each image.

In our future work, we will add also the age as output of our proposed system. We will also use high and low values of epoch, and explore the capacity of our proposal in others databases (FERET, etc.).

ABSTRACT

***Background**: The quality of care of the nursing professional in relation to the hospitalized patient refers to the set of knowledge and attitudes that the nursing professional must provide quality care, preventing risks and improving patient satisfaction, for which its objective is to determine the quality of nursing care in hospitalized patients at the LanFranco la Hoz Hospital.* ***Method:** it is a quantitative, non-experimental, descriptive, and cross-sectional study with a study population of 143 patients in total hospitalized at the Carlos LanFranco la Hoz Hospital.* ***Results:** The results obtained in the quality of nursing care in hospitalized patients, it can be seeing that 86 patients representing 60.1%, are moderately satisfied, followed by 36 patients that represent 25.2% are satisfied, 12 patients that represent 8.4% are dissatisfied, 7 patients that represent 4.9% are very satisfied and finally 2 patients that represent 1.4% are very dissatisfied. In the dimension, experience of the nurse in the care of hospitalized patients, it can be observed 69 patients that represents 48.3% are moderately satisfied with the experience of the nurse in the care and in the dimension satisfaction with nursing care in hospitalized patients, it can be see 93 patients that represents 65% are satisfied with the quality of care.* ***Conclusions:** It is concluded that the high demand for patients sustains a decrease in quality nursing care due to the scarcity of human resources in the hospital and it is recommended that the hospital have a permanent evaluation system of quality of care to meet the expectations of hospitalized patients.*

1. Introduction

The World Health Organization (WHO) notes that 421 million people are hospitalized annually, these patients suffer approximately 42.7 million adverse events according to the most accurate evaluations and damage to patients during their hospital care are the cause of global mortality [1].

One of the factors of the quality of care is the perception that the hospitalized patient has during its hospital stay under care of hospital health personnel [2], since they fix their gaze on health personnel, easily judge and criticize the care provided, therefore, the position of the hospitalized patient will be evident when it comes to refusing care and advising that they should not be treated in that health facility [3].

Likewise, the care provided by the nurse towards patients has been perceived as deficient, because technology has influenced the nurse, where patient care is managed in a less humanized way, therefore the nurse-patient relationship loses every time trust [4].

*Corresponding Author: Brian Meneses-Claudio, Mr., +51 1 950159924 & bmeneses@uch.edu.pe

Likewise, the relationship of the family members of the hospitalized patient and the nurse who cares is essential for comprehensive health care, the adverse effects generated by negative environments for not providing good information timely and understandable for the family are negative factors for hospitalized patients [5].

The length of stay of hospitalized patients in the hospital is an impact on the accessibility of new patients entering the hospitalization service for the first time, generating demand both in the emergency area and hospitalization in the health sector [6].

In [7], the authors presented a study carried out in Jordan, it indicates that in the health area a topic of quality and safety is needed, this contributes to all personnel being trained responsibly, providing quality care and safety. The presence and permanence in health services are considered as a fundamental factor to promote the safety of hospitalized patients.

In [8], the authors mentioned a study carried out in Colombia, it was possible to find a total quality of care reached in 62%. The

dimension with the highest quality was " monitoring and follow-up" (73.2%) and the lowest was "anticipates" (56.1%). 42% of the patients said they had not been attended and did not recognize the nurse of the service.

In [9], the author described a study carried out in Russia, it refers that the perception, both of the health professional and the users, have a link in the human resource, which is ethical, the evaluations of hospitalized patients showed that are linked to the changeable, the concern of the hospital, and the obligation of public employees to provide quality care.

In [10], the authors presented a study carried out in Mexico, indicates that the quality of nursing professionals care towards patients highlighted 31patients that represents 44.0% reported that the nursing staff managed their work tools (baumanometer, stethoscope, secretion aspirator, among others) as they expected; 22 patients that represents 31.0%, better than they expected, and 32 patients that represents 30.0%, as they did not expect.

The objective of the study is to determine the quality of nursing care in hospitalized patients of the Carlos Lanfranco la Hoz hospital, in which it will allow to observe the quality of care that nursing professionals have towards hospitalized patients. This study is important since it will give relevant and real data about how the nursing care is provided to patients hospitalized for a disease.

In the study, the Spanish-version quality of care data collection instrument (CUCACE) was applied by Alonso R. and the original version The Newcastle Satisfaction with Nursing Scales (NSNS) by Thomas in Scotland has been demonstrated its usefulness to assess the quality of nursing care.

The data collection was processed through the survey of hospitalized patients of the Carlos LanFranco la Hoz Hospital, the data to be entered was carried out in a data matrix that will be designed in the statistical program IBM SPSS Statistics Base 25.0, it was proceeded to its corresponding analysis, in which it will allow a better data processing to make statistical tables and graphs so that can be described and interpreted in results and discussions, respectively.

The following research work is structured as follows: In section II, the development of the hospitalized patient data collection process will be presented, as well as the guidelines to consider so that they are within the research work. In section III, the results will show the quality of care presented by nursing professionals according to the specified dimensions of the instrument in the measurement of the variable. In section IV, it will present the discussions of the research work, in section V, the conclusions and in section VI the recommendations as well as the future work that is intended to be reached with the research work.

2. Methodology

In this part, the type and design of the research will be developed, as well as the population and the sample that will be carried out in the research work, the inclusion and exclusion criteria in detail and finally the technique and the instrument for collecting data.

2.1. Research type and design

The present study, due to its characteristics, the way of collecting data and measurement of the variables involved is a quantitative approach. Regarding the methodological design, it is a non-experimental, descriptive, cross-sectional study [11].

2.2. Population

The study worked with a total population of 143 hospitalized patients from the Carlos LanFranco la Hoz Hospital, which are distributed in 4 areas (Medicine, Surgery, Gynecology and Emergencies).

2.3. Inclusion criteria

- Adult patients with more than 2 days of hospitalization.
- Patients not receiving sedatives as treatment.
- Patients who have signed the informed consent.

2.4. Exclusion criteria

- Adult patients with less than 2 days of hospitalization.
- Patients with an altered state of consciousness, a language disorder, or a risk complication.
- Patient who has not signed the informed consent.

2.5. Technique and instrument

The data collection technique used in the research work was the survey, which important data will be obtained optimally and effectively. The survey will determine the quality of care in hospitalized patients using the (CUCACE) questionnaire, the Spanish version was validated by Alonso R. and the original version is The Newcastle Satisfaction with Nursing Scales (NSNS), validated by Thomas in Scotland. The CUCACE questionnaire has three sections: The first is the experience with nursing care that it has 26 items, the second is the satisfaction with the nursing care that it has 19 items and the third is the sociodemographic variable such as: age, sex, educational level, days of stay in the service and some general questions [2].

Regarding statistical validity, this was obtained using the Kaiser-Meyer-Olkin sample adequacy tests and Bartlett's sphericity test. The results of the sphericity test are significant while the sample adequacy test obtained a value of 0,897 (KMO> 0.6) and the results of the sphericity test obtained a favorable value (X^2 3702,347; g.l. = 990; p = 0,000). Likewise, Cronbach's alpha index obtained a value of 0.939 ($\alpha > 0,6$). All the above tests confirm an acceptable index of validity and reliability of the instrument.

This research work will consider the safety aspects of human research participants regarding to quality in hospitalized patients. The ethical behavior of deontological and moral health personnel. The bioethical principles: autonomy, justice, beneficence and non-maleficence, which constitute the basis for reasoning and orientation to their actions [12].

Medical ethics deals with the foundations that govern professional conduct in the practice of medicine, both in the doctor-patient and interprofessional relationships [13]. For this reason, the ethical authorization was carried out correctly when

coordinating with the hospital authority and with the patient itself and its family to carry out the research work.

Bioethical principles are interpreted into fundamental values and rights of hospitalized patients [14]. In the present research work, the bioethical principles of beneficence, non-maleficence, justice, and autonomy were mainly taken.

2.6. Place and Application of the Instrument

The questionnaire to measure the quality of nursing care in hospitalized patients of the Carlos Lanfranco la Hoz hospital, Lima - Peru was carried out on a programming date with the hospital, the time used in each service was approximately 25 minutes, in each service a document was requested for the hospitalized patient to participate in the research work (according to the criteria of inclusion and exclusion), concluding with good satisfaction when collecting the questionnaires from hospitalized patients since they provided a lot of support to carry out the research work.

It is important to emphasize the presence of relatives of some hospitalized patients at the time of completing the questionnaire, since while the family member has the decision in turn that the hospitalized patient can participate in the research, in which they provided support to complete the questionnaires. At the same time, the presence of the nursing staff, since the questionnaire is based on patient care, which allows to observe if the nursing staff adequately performs the appropriate and/or necessary care for the patient.

3. Results

Below is a summary table of the surveys carried out following the guidelines corresponding to the research work:

Table 1: Sociodemographic Data of Quality of Nursing Care in Hospitalized Patients of the Carlos Lanfranco La Hoz Hospital, 2019 (N = 143)

Participant Information	**Total**	
	N	**%**
Total	143	100
Gender		
Female	99	69,2
Male	44	30,8
Marital Status		
Single	37	25,9
Married	21	14,7
Separated	5	3,5
Cohabiting	79	55,2
Widow	1	0,7
Type of Family		
Nuclear	100	50,2
Extended	26	6,6
Expanded	7	11,1
Single parent	6	17,0
Reconstituted	3	6,2
Single Person	1	0,7
Study Degree		
No study	4	2,8
Incomplete primary	12	8,4
Complete primary	22	15,4
Incomplete secondary	33	23,1
Complete secondary	46	32,2
Incomplete University Studies	7	4,9
Complete University Studies	19	13,3
Occupation Condition		
Stable	14	9,8
Eventual	41	28,7
Without occupation	75	52,4
Retired	2	1,4
Student	5	3,5
Does not apply	6	4,2
Days of hospitalization		
Three days	51	35,5
Four days	54	37,8
Five or more days	38	26,6

In Table 1, it has the sociodemographic data of the study participants in total, there were 143 hospitalized patients from the Carlos Lanfranco La Hoz Hospital. Regarding gender, the female sex predominated with 99 patients representing 69.2%, followed by the male with 44 patients representing 30.8%.

Regarding the study degree, complete secondary school stands out with 46 patients representing 32.2%, followed by incomplete secondary school with 33 patients representing 23.1%, followed by complete primary school with 22 patients representing 15.4%, followed by complete university studies with 19 patients representing 13.3%, followed by incomplete primary school with 12 patients representing 8.4%, followed by incomplete university studies with 7 patients representing 4.9% and finally no study with 4 patients representing 2.8%.

Regarding the days of hospitalization, four days predominate with 54 patients representing 37.8%, followed by 51 days with 51 patients representing 35.5% and finally five or more days with 38 patients representing 26.6%.

Below are figures that show the results about the total quality of nursing care in hospitalized patients and its dimensions according to the data based on the research instrument:

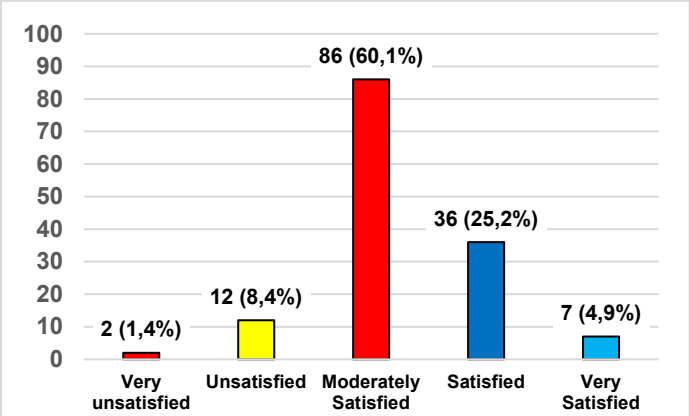

Figure 1: Quality of nursing care in hospitalized patients of the Carlos Lanfranco la Hoz Hospital, 2019 (N = 143)

In Figure 1, the quality of nursing care in hospitalized patients of the Carlos Lanfranco la Hoz Hospital, it can see that 86 patients representing 60.1% are moderately satisfied, followed by 36 patients representing 25.2% are satisfied, 12 patients representing 8.4% are unsatisfied, 7 patients representing 4.9% are very satisfied and finally 2 patients representing 1.4% are very unsatisfied.

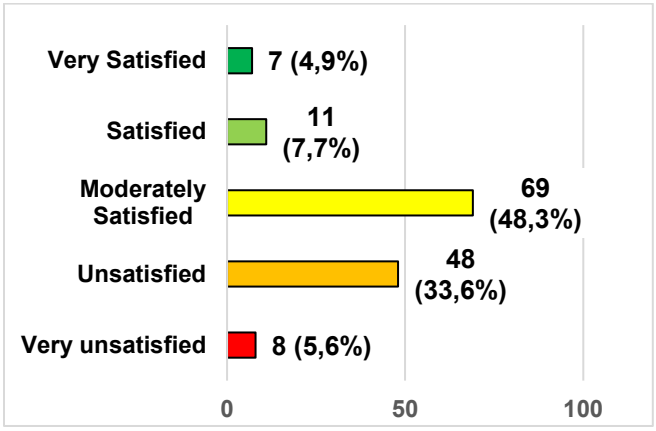

Figure 2: Quality of nursing care according to its dimension experience with nursing care, in inpatients in a public hospital in Lima Norte, 2019 (N = 143)

In Figure 2, the quality of nursing care according to its dimension experience with nursing care, in hospitalized patients of the Carlos Lanfranco La Hoz hospital, it can see that 69 patients representing 48.3% are moderately satisfied, followed by 48 patients representing 33.6% are unsatisfied, 11 patients representing 7.7% are satisfied, 8 patients representing 5.6% are very unsatisfied and finally 7 patients representing 4.9% are very satisfied.

In Figure 3, the quality of nursing care according to its dimension of satisfaction with nursing care in hospitalized patients of the Carlos Lanfranco La Hoz hospital, it can see that 93 patients representing 65% are satisfied, followed by 32 patients representing the 22.4% are moderately satisfied, 13 patients that represent 9.1% are very satisfied, 5 patients that represent 3.5% are unsatisfied and finally 0 patients that represent 0% are very unsatisfied.

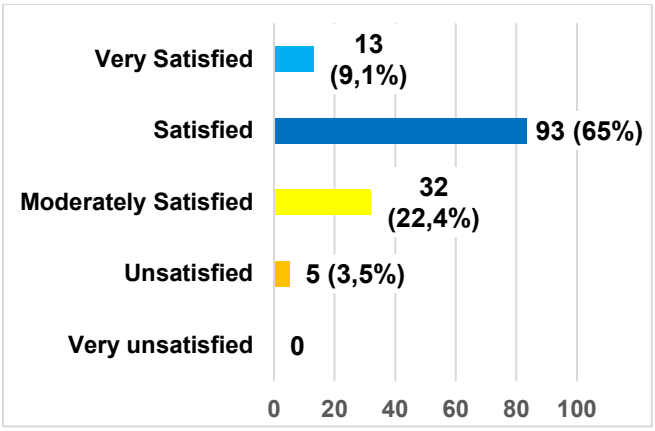

Figure 3. Quality of nursing care according to its dimension of satisfaction with nursing care, in hospitalized patients of the Carlos Lanfranco La Hoz hospital, 2019 (N = 143)

Knowledge of these results is important since it will allow to show if the nursing professional is adequately caring for hospitalized patients, in the same way, it will allow to show if the hospitalized patient in turn collaborates with the staff of nursing for its care during its hospital stay.

4. Discussion

The quality of nursing care constitutes a fundamental tool that values nursing care in hospitalized patients in all aspects and dimensions that are involved in the health of the person and the population.

We agree with what was indicated by Kol E. et al., who affirm that the fundamental objective of measuring the quality of health-related nursing care is to assess the care provided in health services [15].

Regarding the quality of nursing care in hospitalized patients of a public hospital, 60.1% predominantly are moderately satisfied, followed by 25.2% are satisfied, 8.4% are unsatisfied, 4.9% are very satisfied and finally 1.4% are very unsatisfied. These findings can be explained due to the perception that hospitalized patients have, during their stay in the hospital, to the care of health personnel since they fix their gaze and easily judge, criticize the care provided.

Our findings coincide with those of Weldetsadik A. et al., they determine that the satisfaction of hospitalized patients symbolizes the care provided, if it meets their expectations. This magnitude is not necessarily directly related to the degree of scientific-technical quality of the care provided [16].

The quality of nursing care is related to the dimension of experience with patient care mentioned by Amanda G. et al., they highlight the experience that hospitalized patients will have with the health professional, they are linked to the time that is provided during their hospital stay [17].

According to Becker R., he mentions that the wisdom of human resources is safe in medical practice, not only the care of patients is required and the attempt to provide quality care, the gift of expression is needed so that hospitalized patients can recover and reintegration into their family [18].

According to Allen A. et al., they point out the importance of technology as management support, but that it is not essential if there are trained or capable human resources. In many cases, a technological defect or the improper use of the equipment can lead to a failure in clinical analyzes that can lead to severe consequences for the life of hospitalized patients [19].

5. Conclusions

It is concluded that the use of a questionnaire CUCACE is important to evaluate the care received from hospitalized patients by the nursing professional, to evaluate the dimensions of experience and satisfaction with nursing care.

It is concluded that the high demand for patients sustains a decrease in quality nursing care due to the scarcity of human resources in the hospital.

It is concluded that the experience and work capacity of the nursing professional improves the quality and care of hospitalized patients.

It is concluded that it is essential to continue executing studies of this category, to analyze the outcome found and compare with current research, as well as facilitate its validity and reliability of CUCACE to measure the quality of nursing care in hospitalized patients.

6. Recommendations

It is recommended to carry out activities that promote communication with patients, since this interaction improves the nurse-patient relationship.

It is recommended that the hospital have a permanent quality of care evaluation system to meet the expectations of hospitalized patients.

Conflicts of Interest

The authors declare no conflict of interest.

ABSTRACT

This research shows the study carried out on the Health Related to Quality of Life (HRQL) focuses on aspects related to the perception of health experienced and declared by the person, in different dimensions such as physical, mental, social, general perception of health and satisfaction achieved measured at different levels; the objective of the study is to determine the quality of life in patients with type 2 diabetes at the Central Hospital of the Peruvian Air Force, 2019. To determine the validity of the instruments, the Kaiser-Meyer-Olkin (KMO) sample adequacy index was used and the Bartlett sphericity test, which result in a significance value of 0.005, being an acceptable validity of both instruments. Among the most relevant results is that the following dimensions: Energy and Mobility, 147 patients representing 73.5% have low level. Likewise, regarding to Social Burden, 156 patients representing 78.0%, have a low level. Lastly, regarding the Sexual Functioning dimension, 178 patients representing 89.0%, have a low level; patients significantly affect quality of life. "Non-adherence to drug treatment" represents 159 patients, of which 115 who represent 72.3% have a low level with respect to their quality of life, of 44 patients who represent 27.7% have a high level regarding their quality of life; "Adherence to pharmacological treatment" 41 patients representing 92.7% have a low level regarding their quality of life and 3 patients who represent 7.3% have a high level regarding their quality of life.

1. Introduction

According to the International Diabetes Federation, 382 million adults worldwide had diabetes and 5.1 million died from the disease. About half (48%) of those who died were under the 60 years old. Three of four people living with diabetes (352 million) are in an active age (that is, between 20 and 64 years old) this number is projected to increase to 417 million by 2030 and 486 million by 2045 [1].

They also estimate that by 2035, if current trends continue, the global prevalence of diabetes will rise to 592 million, and the World Health Organization predicts that by 2030 it will become the seventh leading cause of death in the world [2].

This disease is considered as one of the main reasons for deaths worldwide, due to the poor quality of life without measuring the complications that it will bring them in the long term [3].

This non-communicable pathology is a worldwide concern, since due to the multiple organic complications it causes deaths, mostly related and complex with the organs of the cardiovascular system [4].

Diabetes is a chronic disease that is released when the pancreas does not produce insulin necessary for the body (a hormone that regulates the level of sugar, or glucose in the blood) or when the body cannot vigorously use the insulin it produces; they have a substantially increased risk of cardiovascular disease. It has also been related to hypertension and hyperlipidemia, it has vascular complications and is considered one of the four non-communicable diseases [5], [6].

Its own symptoms such as thirst, polyuria, blurred vision, weight loss, and sometimes polyphagia is recurrent. Perennially, the symptoms are not severe or may be distant; consequently,

*Corresponding Author: Brian Meneses-Claudio, Mr., +51 1 950159924 & Email: bmeneses@uch.edu.pe

hyperglycemia can provoke functional and pathological changes for a long time before diagnosis [7].

Diabetes is a chronic disease, and the associated stress of long-term symptoms, medical appointments, research, and daily treatments can affect sexual function through a person's mood, anxiety levels, fatigue, and well-being. In general, people with diabetes may have comorbidity of hypertension, hyperlipidemia, cardiovascular disease, or other endocrine dysfunction, and their associated treatments, may affect sexual function [8].

In [9], these problems cannot be addressed without a solid medical and scientific base that allows local solutions to be identified and proposed; unfortunately, the scientific production on diabetes in Peru is limited with only 81 scientific articles published in Web of Science and Scopus between 1996 and 2015.

In [10], diabetes was positioned as the fifth cause of death with 10 528 (7.11%) of the cases, in addition, the numbers of patients with this disease who died from causes of kidney complications were from 2 266 cases (1,191 men and 1,075 women) in 2011 to 3,190 cases (1,638 men and 1,552 women) in 2016.

In [11], this study shows that the mean time of evolution of the disease was 11.37 years old. Quality of life was self-perceived as deficient in 67.57% of older adults at the expense of satisfaction with their health (75.68%).

In [12], it is believed that, in Peru, more than 2 million people suffer from diabetes. The national average is 8% and in Lima, up to 10%. However, it is good to clarify that, in many regions, up to at least 50% of the population does not know if they have diabetes.

According to the [13], 4.0% of the population residing on the Coast reported having diabetes mellitus, being the urban area with the highest incidence of this disease (4.1%) and in the rural area only 2.7%; followed by the jungle regions with 1.9%, the urban area registers 2.7% and rural 1.1%; while the highlands area register 1.6 %, urban area 2.5% and rural with 1.0%.

The objective in this study is to determine the quality of life of patients with diabetes mellitus who come to the consultation of the Central Hospital of the Peruvian Air Force, using the Diabetes questionnaire 39.

2. Methodology

2.1. Research Design Approach

The present study has a quantitative, descriptive, and cross-sectional approach. A survey was carried out as a data collection technique, by applying a questionnaire as a documentary instrument. The study population was made up of patients with diabetes mellitus from the Central Hospital of the Peruvian Air Force [14].

2.2. Inclusion Criteria

All continuous patients over 18 years old with type 2 diabetes mellitus, regardless of the sex treated at the Central Hospital of the Peruvian Air Force.

2.3. Exclusion Criteria

- Patients with type 1 diabetes mellitus or gestational diabetes.
- Patients seen for the first time.
- Resigned with intellectual inability to recognize the question, and those who refuse to report the study.

2.4. Measurement Techniques and Instruments

Data collection technique: The technique used for this study was the survey, it is not the same as the questionnaire, however, the questionnaires are usually used in a survey, which requires a systematic way of collecting the data for the later to be able to analyze them statistically and obtain conclusions about the study population [15].

To measure the quality of life of patients diagnosed with type 2 diabetes mellitus, it will be applied with the diabetes 39 instrument, which includes 39 items that evaluate five domains of the patient's life: energy and mobility (15 items), control of diabetes (12 items), anxiety and worry (4 items), social burden (5 items) and sexual functioning (3 items). Each item is calculated from the evaluation made by the patient itself, in relation to its quality of life, how much was affected during the last month by action or activity that each item expresses- placing an "X" on a scale that is presented as a continuous line, with vertical marks that delimit spaces in which the numbers from 1 to 7 are identified, in which, on the value scales, the number 1 represents the quality of life that was not affected at all, and number 7, extremely affected. Two final items are incorporated into the five domains that rate the patient's perception about their quality of life in general, with a range from 1 (minimum) to 7 (maximum), and the severity of diabetes mellitus with a 1 (no severity) to 7 (extremely serious) [16].

The data collected was entered into a Microsoft Excel 2013 data matrix, to be later exported to the statistical program IBM SPSS Statistics Base 24.0.

Figure 1: Endocrinology area for conducting surveys at the Central Hospital of the Peruvian Air Force.

3. Results

To determine the validity of the instrument, the Kaiser-Meyer-Elkin sample adequacy index (KMO) and the Bartlett's test of sphericity were used. For the Quality-of-Life Test for patients with type 2 diabetes, a sample adequacy coefficient of 0.834 and a significance value of 0.005 (x^2 = 2633,620; gl = 741; p <0.05) were obtained in the test of Bartlett's sphericity.

The reliability of the instrument was determined based on the Cronbach's Alpha statistic. For the instrument Quality of life test

for patients with type 2 diabetes, it was determined that it presents an internal consistency index of 0.741 (α> 0.6); while the Morisky-Gree test instrument of adherence to pharmacological treatment has a coefficient of 0.591 (α <0.6). Therefore, a high level of general reliability of the Quality-of-Life Test is identified for patients with type 2 diabetes.

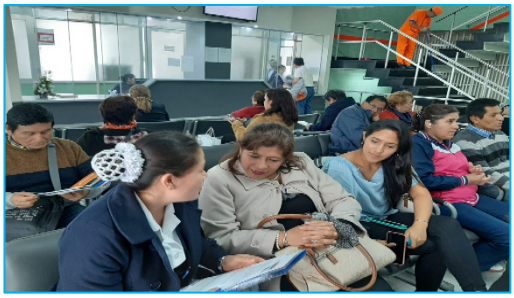

Figure 2: Application of the Survey in the Central Hospital of the Peruvian Air Force

3.1. Sociodemographic characteristics

Regarding the age of the study participants, it was determined that they fluctuate in an interval of 20 to 90 years, with an average of 56.45 (± 13,847) years old. Regarding sex, 60% of the sample is male. Likewise, 72.1% of the sample lives with their parents.

Table 1: Quality of life in patients with type 2 diabetes of the Central Hospital of the Peruvian Air Force, 2019 (N = 200)

Quality of life	N	%
Low Level	153	76,5
High Level	47	23,5
Total	200	100,0

In Table 1, it can observe the quality of life in patients with type 2 diabetes of the Central Hospital of the Peruvian Air Force, where 153 patients representing 76.5% have a low level followed by 47 patients representing 23, 5% have a high level.

In Table 2, it can see the quality of life according to its dimensions, in patients with type 2 diabetes of the Central Hospital of the Peruvian Air Force, where the most affected dimension was sexual functioning with 178 patients representing 89% have low level followed by 22 patients representing 11% have high level.

Table 2: Quality of life in patients with type 2 diabetes according to its dimensions, from the Central Hospital of the Peruvian Air Force, 2019 (N = 200)

Dimensions		N	%
Energy-mobility	**Low Level**	147	73,5
	High Level	53	26,5
Diabetes control	**Low Level**	132	66,0
	High Level	68	34,0
Control of anxiety - concern	**Low Level**	85	42,5
	High Level	115	57,5
Social burden	**Low Level**	156	78,0
	High Level	44	22,0
Sexual Functioning	**Low Level**	178	89,0
	High Level	22	11,0

The importance of obtaining these results in continuing patients with diabetes mellitus is to be able to identify in which of the dimensions are most affected by this disease and to be able to act in a timely manner in the dimension and above all to teach how to be responsible and aware of the disease. So, they could learn that diabetes is a chronic disease that involves the variation of lifestyles. For its treatment, it is essential that people learn to manage it correctly to have a good quality of life and avoid possible complications.

Table 3: Contingency table between the variables Quality of life and Adherence to pharmacological treatment and chi-square tests

			Quality of life		Total
			Low Level	High Level	
Adherence to pharmacological treatment	**Non-adherent**	Count	115	44	159
		% within APT	72,3%	27,7%	100,0 %
	Adherent	Count	38	3	41
		% within APT	92,7%	7,3%	100,0 %
Total		Count	153	47	200
		% within APT	76,5%	23,5%	100,0 %
Pearson's chi-square			Valor X^2	g.l.	Sig. (p)
			7,513	1	0,006

APT = Adherence to Pharmacological Treatment

In Table 3; on adherence, it can observe in patients with type 2 diabetes of the Central Hospital of the Peruvian Air Force, where the "Non-adherence" represents 159 patients, 115 of which is equivalent to 72.3% have low level and 44 patients 27.7% with

high level; "Adherence" 41 patients representing 92.7% have low level and 3 patients representing 7.3% have high level.

It is important that people with diabetes and their families should receive education about adherence and non-adherence; ignorance is one of the reasons for not achieving the necessary benefits that medications can provide in their disease; diabetes is a chronic disease that affects different organs of the human body.

4. Discussions

Quality of Life is a representative variable that allows us to measure the impact it has on a certain pathology (in this case Diabetes Mellitus type II) in the person's life, which has an impact on various biological and psychosocial levels in the individual health.

The results obtained according to the Diabetes 39 questionnaire demonstrate that of a population made up of 200 diagnosed continuing patients who are treated at the Central Hospital of the Peruvian Air Force, the dimensions most affected are determined that, regarding the Energy and mobility dimension, 147 is equivalent to 73.5% have low level. Likewise, regarding to social burden, 156 is equivalent to 78.0%, have low level. Lastly, regarding the Sexual Functioning dimension, 178 is equivalent to 89.0% have low level.

These results coincide and are reinforced by the study carried out in [17]. They show that patients with Diabetes Mellitus regarding their Quality of Life, who were surveyed with 101 diabetics; the most affected domains in order of score were: energy and mobility (60) equal 59.4%, anxiety-concern (62) equals 61.3% and sexual functioning (66) equals 65.3%.

Regarding adherence, it can observe in patients with type 2 diabetes of the Central Hospital of the Peruvian Air Force, where non-adherence represents 159 patients, 115 representing 72.3% have low level and 44 patients representing 27.7% have high level; adherence 41 patients representing 92.7% have low level and 3 patients representing 7.3% have high level. No relationship was found between the percentage of adherence to treatment with sex, age, educational level, and employment status; it is the lack of awareness about its treatment.

According to [18], it was found, the low level was 21 (32.8%) and with high level adherence 24 (37.5%). No relationship was found between the percentage of adherence to treatment with sex, age, educational level, and employment status.

In the analysis of each dimension of the instrument, it was observed that there were significant differences. In the dimension between quality of life and adherence to treatment in patients with treatment, as a strength of the study, it can be highlighted that there was no rejection by the patients, all the questionnaires were correctly filled out, with no missing data or loss in the sample. It is also important to note that a widely used instrument with a good internal consistency index was used.

Among the limitations of the study, the selection of patients is found, since as it is not a probabilistic sampling, there may be the possibility of selection bias. For future studies on the subject in primary care, it would be interesting to carry out a random sampling that provides greater reliability in the results obtained. Another important aspect to control would be trying to match the sample by sex.

5. Conclusions

It is concluded that the dimensions that highly affect patients are Energy and Mobility, Social Burden, Sexual Functioning, having a low level of more than 70% of the sampled cases.

In addition, the results of therapeutic adherence show that 72.3% of patients present a low level with respect to their quality of life, therefore, compliance with treatment, physical activities and a balanced diet help diabetic patients a better recovery and a balanced quality of life.

6. Recommendation

A restructuring of promotional preventive intervention programs targeting such patients with type II diabetes is recommended. This intervention program must involve a multidisciplinary team of professionals, who see aspects related to the disease and the environment of the person and are accelerators for their recovery from physical, biological, and psychosocial health.

It is suggested an awareness program, educational talks for both the patient and family members for their support and control, home health personnel visit programs.

Conflicts of Interest

The authors declare no conflict of interest.

ABSTRACT

Social skills are the behaviors that the individual adopts on a regular basis at specific moments in everyday life. Resilience is the way in which the individual faces the adversity that life imposes on them, as well as manages to overcome it. In adolescence, problems are perceived because important changes are generated in an accelerated way, many adolescents develop psychological disorders or alterations that could compromise their own lives, if not detected in time, therefore, the objective of this study is to determine the social skills and resilience in adolescents of secondary education of the Kumamoto Educational Institution I 3092, of the Puente Piedra district - Lima, 2019. Applying a quantitative, non-experimental, descriptive, and correlational study, with a population of 626 adolescents from the Kumamoto I 3092 educational institution in the Puente Piedra district, who answered a questionnaire with sociodemographic data and the instruments of the social skills scale and the Connor-Davidson questionnaire for resilience. In the results, the predominance of the medium level in both variables, in social skills with 87.5%, in resilience with 58.3%, concluding the need to carry out interventions in adolescent students, to prevent the inadequate development of their personality.

1. Introduction

The social skill or assertive behavior is a set of expressions that is manifested in a verbal and non-verbal way, where the person externalizes in an interpersonal way all his deficiencies, emotions, ideas, favoritism, rights, avoiding anxiety and hostility [1], [2]**.** Resilience is the ability that a subject or a group obtains that projects itself into the future despite difficult situations and on some occasions can generate trauma and serious consequences in its own life [3].

In adolescence, internal problems such as anxiety disorders, depression, post-traumatic disorders, and even obsessive-compulsive disorders can be perceived. They may also perceive external problems associated with abrupt behavior, conflicts with their environment and aggressive behavior [4]. Family problems can have a strong impact on the adolescent's life, which is why it is important that the family manages its problems correctly during this period, since otherwise this problem will affect the adolescent, diminishing his or her abilities in the academic aspect in society and in a personal way [5].

Worldwide, social skills are specifically oriented to prevent risk behavior and promote a healthy lifestyle [6]. Skills education has emerged since the increase of the problems that affects the community, but directly to adolescents as there are several events such as diseases generated through sex, drug addiction, bullying and even suicide [7].

According to the Pan American Health Organization, it promotes healthy lifestyle and the development of the adolescent stage in the Caribbean and Latin America. Regarding resilience, it establishes support for adolescents based on strategies to reduce various risk behaviors. This process will be continuous, where

*Corresponding Author: Brian Meneses-Claudio, Mr., +51 1 950159924 & bmeneses@uch.edu.pe

adolescents will use adaptation skills to seek adequate development within society, the family, school and culture [8].

PAHO establishes that social skills require the adoption of attitudes that are indispensable for optimal behavior to achieve success in the various challenges that life imposes. This favors healthy physical, social and mental behaviors, where adolescents have various possibilities for satisfying their needs, developing their aspirations and coping their environment [9].

In [10], un studio entre 170 adolescents between 15 to 17 years old participated in this study, to whom the social skills questionnaire was applied, where the predominance of the medium level is seen with 50.6%, continuing the low level with 38.2%, then the high level with 11.2%. In the explanation of the dimensions, it is observed that the self-expression factors in social situations predominate the low level with 40.6%, making requests 59.4%, while the high level corresponds to the expression of anger and disagreement with 45.3%. Regarding its study, it mentions the importance of developing social skills in an adequate way to reduce the risk of developing antisocial behaviors.

In [11], it developed the study with a population of 49 adolescents, where the prevalence of medium level resilience was found with 51%, then the low level with 43% and a high level of 6%. In its study, it was shown that adolescents have a medium capacity of resistance to remake and try to escape complex situations.

In [12], the present study had a population of 119 adolescents, where the results show that 71.75% is equivalent to the medium level, in their study, they determined to resort to development programs for teachers in order to include social skills topics in the training of adolescents.

In [13], they indicate that their total population was 160 adolescents, of whom the prevalence of medium-level resilience was obtained with 52.5%, continuing the high level with 46.9% and the low level of 0.6%. Regarding its control and purpose dimensions, they obtained a high level of 61.9%, while control under pressure had a medium level with 59.4% and spirituality a low level of 8.1%. Concluding that the present work will be use as reference to suggest precise interventions where the beneficiary will be the adolescent.

The main objective of this research study is to determine the relationship of social skills and resilience in adolescents because there is a deficit in research on this enigmatic topic in adolescence.

This study presents a quantitative approach, it will be carried out without manipulating the variable, which is why it is a non-experimental and descriptive cross-sectional design. The technique to be used in the research work will be the survey, since it is a measurement instrument which the data will be collected appropriately in a reliable, objective, and valid way.

The Elena Gismero Gonzales, E.H.S questionnaire includes 33 items, 28 of which are written in the sense of lack of assertion or deficit in social skills and 5 of them in the positive sense. The Connor –Davidson Questionnaire (CD-RISC) This test was created in 2003 and consists of two fundamental versions, one of 25 items and the other of 10, in which to carry out the research work the 25-item version was used. All the data collected was entered into the matrix designed by the statistical software SPSS 24.0., This procedure was carried out cautiously to not have errors and avoid values being lost.

This study is important because it will show us the capacity that adolescents have in the face of stimuli of changes in their personality and in their environment, in which it allows the adolescent to improve their capacity for understanding and adaptation both on a social, personal, and family level.

2. Methodology

Starting by making a request and receiving the authorization of the director of the educational institution, it was always established that ethical aspects were applied during the process, respectively, the students voluntarily answered the questionnaires. It is worth mentioning that these questionnaires were provided by the researchers, in the different classrooms, in the presence of the teachers from each grade. The descriptive cross-sectional and correlational methodological design was chosen. Once the database was assembled, the descriptive analysis began, where the percentages achieved, as well as its dimensions, are emphasized by the contingency table that will later be reflected in the bar charts. The stages of data collection are shown in Figure 1 where the processes by which the students were part are shown.

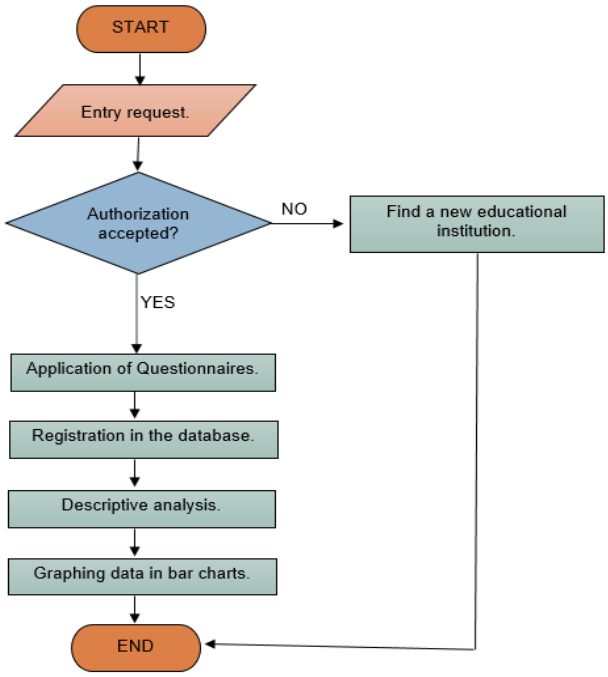

Figure 1: Flowchart for data collection

1.1. Population and sample

For this research, a vulnerable population was selected from a state school in the Puente Piedra district, where 626 students participated, they are the total population, ranging in age from 11 to 18 years old, who are in 1st to 5th grade of secondary education.

1.2. Type of study

In the present research work, due to its characteristics, data collection and the measurement of the variables involved is a quantitative approach. Regarding the methodological design, it is a non-experimental, descriptive, and correlational study.

Table 1: Distribution of classrooms at the secondary level of the Kumamoto I 3092 educational institution

Grade	Shifts	Classrooms	Total Students
1st	Afternoon	5	145
2nd	Afternoon	5	135
3rd	Afternoon	6	133
4th	Afternoon	4	103
5th	Afternoon	4	110
TOTAL		24	626

1.3. Inclusion and exclusion criteria

Inclusion:

- Adolescents who study in 1st to 5th grade of high school.
- Adolescents who have signed the informed consent.
- Parents who have signed the informed consent for the application of the survey in the adolescent.

Exclusion:

- Adolescents and parents who have missed classes and who have not signed the informed consent.
- Parents who have not signed the informed consent.

1.4. Analysis of the variable

The following study has two main variables, social skills, and resilience in adolescents, both variables according to their nature, are qualitative or categorical, and their measurement scale is ordinal.

The technique for data collection in the educational institution was the survey, which is very useful to collect data appropriately in a reliable, objective and valid way [14].

To assess social skills, the instrument of Elena Gismero Gonzales E.H.S was used, which comprises 33 items, 28 of which are written in the sense of lack of assertion or deficit in social skills and 5 of them in the positive sense. The final factor analysis has revealed 6 factors: self-expression in social situations, defense of their own rights as a consumer, expression of anger or disagreement, saying no and cutting interactions, making requests and initiating positive interactions with the opposite sex [15]. This instrument has been valid in different Latin American countries and in other countries, as well as in Peru that has construct validity, the meaning attributed to the measured construct (assertion) is correct. Regarding statistical validity, it was obtained using the Kaiser-Meyer-Olkin (KMO) obtained a sample adequacy coefficient of 0.923 and the Bartlett's Sphericity Test of 0,000 (x^2 = 4036,183; g.l. = 300; $p < 0,05$). Regarding the reliability of the instrument, it was determined based on the Cronbach's Alpha statistic. For the Social Skills Scale instrument, it was determined that it presents an internal consistency index of 0.805 ($\alpha>0.6$).

The Connor –Davidson questionnaire (CD-RISC) was used to assess resilience. This test was created in 2003 and consists of two fundamental versions, one of 25 items and the other of 10 in which the 25-item version was used to carry out the research work. The construct consists of five factors: persistence-tenacity-self-efficacy (items: 10-12, 16, 17, 23-25); control under pressure (6, 7, 14, 15, 18, 19, 20); adaptability and support networks (1, 2, 4, 5, 8); control and purpose (13, 21, 22) and spirituality (3, 9). The scores for each item are added together and it is interpreted that the higher the score in each dimension, the more indicators of resilience the individual shows. Measurement scale 0 - 33 Low resilience, 34 - 66 Medium resilience, 67 - 100 High resilience [16][17]. The Spanish translation was carried out by two members of the research team and supervised by a bilingual person with training in Psychology. Regarding the statistical reliability of the data collection instrument, a coefficient of 0.882 ($\alpha>0.6$) was obtained.

All the collected data will be entered into the matrix designed by the statistical software SPSS 24.0., this procedure was carried out cautiously to not have errors and avoid the values being lost.

1.5. Place and Application of the Instrument

To start the process, the followed steps were taken, making a request document attaching the letter of presentation provided by the nursing professional school of the Universidad de Ciencias y Humanidades, addressed to the director of the educational institution Kumamoto I 3092, located in the department de Lima, Puente Piedra district, in the AA. HH Laderas de Chillón, to access the permit and be able to apply the questionnaires formally, also it coordinated a meeting with the director, in the interview the authors explained in detail about the importance of conducting such research, which was accepted for the director and allowed the study to be carried out.

On July 19, 2019, the informed consent and assent was delivered to all students from the 1st to the 5th grade of secondary education, on July 22 the documents were collected verifying the correct filling, then the authors proceeded with the delivery of the surveys. The time elapsed in each classroom was 25 minutes. They were informed of the importance of their participation, in a brief explanation of the instrument, also it was mentioned that the confidentiality of their responses would be respected, the doubts they presented were also clarified. The students voluntarily answered the questionnaire provided. At the end of the application of the instrument, each of the surveys was verified with the correct completion and they were thanked for their participation in the research.

3. Results

After applying the surveys, the data was processed in a statistical program, resulting in the summary tables presented below.

Table 2 shows the results of the gender of the high school adolescents, where 306 (48.9%) of the adolescents are female and 320 (51.5%) of the adolescents are male.

Table 3 shows the mean age of secondary school adolescents, where the minimum age of adolescents is 11 years and the

maximum age of adolescents is 18 years, therefore the average age of adolescents in primary education is 14 years old.

Table 2. Gender of secondary education adolescents from the Kumamoto I 3092 educational institution, from the Puente Piedra district - Lima, 2019 (N = 626)

Gender of the adolescents			
		Frequency	**Percentage**
Valid	Female	306	48,9
	Male	320	51,1
	Total	626	100,0

Table 3. Age of secondary education adolescents from the Kumamoto I 3092 educational institution, from the Puente Piedra district - Lima, 2019 (N = 626)

Adolescents Age					
	N	**Minimum**	**Maximum**	**Mean**	**SD**
Adolescent Age	626	11	18	14,33	1,485
Valid N (per list)	626				

Table 4: Social Skills in adolescents of Secondary Education of The Kumamoto I 3092 Educational Institution, of The Puente Piedra District - Lima, 2019 (N = 626)

		N	**%**
Social Skills	**Low Level**	76	12,1
	Medium Level	548	87,5
	High Level	2	0,3
Total		626	100,0

In Table 4, the social skills in the adolescents of secondary education of the Kumamoto I 3092Educational Institution, of the Puente Piedra district - Lima, 548 adolescents that represent 87.5% have a medium level, followed by 76 adolescents representing 12.1% have a low level and finally 2 adolescents representing 0.3% have a high level.

Table 5: Resilience in adolescents of Secondary Education of The Kumamoto I 3092 Educational Institution, of The Puente Piedra District - Lima, 2019 (N = 626)

		N	**%**
Resilience	**Low Level**	24	3,8
	Medium Level	365	58,3
	High Level	237	37,9
Total		626	100,0

In Table 5, it can see the resilience of adolescents in secondary education at the Kumamoto I 3092 Educational Institution, in the Puente Piedra district - Lima, where 365 adolescents representing 58.3% have a medium level, 237 adolescents representing 37.9% have a high level and finally 24 adolescents representing 3.8% have a low level.

Table 6: Social Skills and Resilience in adolescents of Secondary Education of The Kumamoto I 3092 Educational Institution, of The Puente Piedra District - Lima, 2019 (N = 626)

			Social Skills			**Total**
			Low Level	**Medium Level**	**High Level**	
Resilience	**Low level**	Count	4	20	0	24
		% Resilience	16,7%	83,3%	0,0%	100,0%
	Medium Level	Count	34	330	1	365
		% Resilience	9,3%	90,4%	0,3%	100,0%
	High Level	Count	38	198	1	237
		% Resilience	16,0%	83,5%	0,4%	100,0%
Total		Count	76	548	2	626
		% Resilience	12,1%	87,5%	0,3%	100,0%
Pearson's chi-square			X^2 Value	g.l.		Sig. (p)
			6,767	4		0,149

In Table 6, the relationship between the variables Social Skills and Resilience was determined based on the Pearson's Chi square (X^2) statistical test. The significance level of the test obtained a value of 0.149 ($p>0.05$) ($X^2 = 6.767$; g.l. = 4). Therefore, the dissociation hypothesis cannot be rejected, for which there is no statistical evidence of a significant relationship between social skills and resilience of a sample of students from the Kumamoto I 3092 Educational Institution, in the Puente Piedra District - Lima. 2019.

4. Discussion

In this research study, the issue of social skills and resilience was raised, promoting adolescent mental health, therefore, it seeks to collaborate with educational institutions that are linked to education as part of the global training of adolescents, where they must incorporate plans or programs that allow the adolescent to strengthen and improve all the capacity to interrelate and be able to face better in daily life and social aspect.

Regarding social skills in adolescents at the secondary level of the Kumamoto I 3092 Educational Institution, in the Puente Piedra district - Lima, the medium level stands out, then the low and finally the high. This study is similar to [10], in which they found medium scores of 50.6% as the predominant average, however, it differs in terms of dimensions, the lowest level most affected is making requests with 59.4% and in our study shows a low score in the expression of anger or disagreement with 34.3%. At the same time, in [12], it presents a percentage of 44.54%, being the predominant medium level, for this reason we agree with the proposal of resorting to development programs for educators and this allows covering topics of social skills within the training of students.

Regarding resilience, it was evident that the medium level predominates, a similar value was found in the study [11], where a greater proportion of the medium level of resilience is evident, represented by 51% followed by 43% of low level and 6% of the high level. At the same time, it shows the average capacity of adolescents to cope with complicated situations. Similarly, in [13], the author determine that the predominant level of resilience was

the medium, and also proposes to carry out interventions with a multidisciplinary vision to comprehensively address adolescents, in the same way, it is evidenced in the study [18], who argue that the resilience in the participants was 17.5% low resilience, 67.1% medium resilience and 15.4% high resilience.

The research study shows that the results obtained indicate the need to carry out an intervention to the adolescent population with social skills and medium-level resilience, otherwise they would present an inadequate development in their personality.

5. Conclusions

Eighty-seven-point five percent of the study participants reported to have medium level of social skills, twelve point one, medium level and cero point three, high level. Regarding social skills according to their dimensions, where the most affected dimension was the expression of anger or disagreement with 215 representing thirty-four-point three percent of adolescents. All students from 1st to 6th grade of secondary level presented medium level resilience with fifty-eight-point three percent, high level with thirty-seven-point nine percent and low level with three-point eight percent.

Regarding resilience according to its dimensions, the most affected dimension was spirituality with 132 representing twenty-one-point one percent of adolescents.

As future work, it is expected that health professionals will have a greater interest in conducting more research, in vulnerable locations, that cover the adolescent stage in a holistic way, physically, emotionally, and socially, where adolescents can develop in an intrapersonal or interpersonal context.

The limitation in the present research work is that some adolescents were not present at the time of conducting the surveys also the interpretation of some questions, so nurse professionals were taking the survey to help school students understanding the questions.

Likewise, educators must assume the responsibility they have regarding the adolescent's physical, affective, psychological-cognitive, social development, guiding them to increase their activities to contribute to the management of good self-esteem, social skills, resilience, among others.

Conflicts of Interest

The authors declare that they have no conflict of interest.

ABSTRACT

Social skills are a set of partially independent and situationally specific verbal or nonverbal responses, in terms of resilience, it is the set of qualities, resources or strengths that favor adolescents to face the adversities of life, therefore the objective of the research work is to determine the social skills and resilience in adolescents of an educational institution in Lima - North. It is a non-experimental study, descriptive of a quantitative approach, it is a cross-sectional correlational research, with a population of 706 students of the secondary level, also with demographic data, and the Social Skills Scale (SSS), and the scale of Resilience (CD-RISC) that will measure the level of resilience of adolescents. The relationship between the variables Social Skills and Resilience. It was determined based on the Pearson's Chi square test (X^2). The significance level of the test obtained a value of 0.000 ($p<0.05$) ($X^2 = 28.626$; g.l. = 4). So, the dissociation hypothesis is rejected and it can be affirmed with statistical evidence that there is a significant relationship between social skills and resilience. The predominant level of social skills is medium with 648 (91.8%) participants and in terms of resilience, the predominant level is high with 366 (51.8%) of participants. Social skills and resilience are mutually related since both allow the adolescent to face situations of daily life looking the ability to develop their coping capacity.

1. Introduction

Social skills or assertive behaviors are understood as a set of partially independent and situationally specific verbal and nonverbal responses, through which adolescents express in an interpersonal their needs, feelings, preferences, right opinions without excessive anxiety and in a non-aversive way, expressing itself in self-expression of social situations, defense of its own rights as a consumer, expression of anger or disagreement, saying no and cutting interactions, initiating positive interactions with the opposite sex and making requests. Social skills are involved in many areas of a person's life, such as adaptation to the environment in which they live and health protection, both physical and mental. It helps to solve various situations such as appropriateness in behavior, decision making, facing difficult situations, assigned essential responsibilities in the development of learning [1].

Regarding resilience, it is the set of qualities, resources or strengths that favor adolescents to face life's adversities, overcome them or even be transformed by it, which is characterized by presenting traits of persistence-tenacity-self-efficiency, control under pressure, adaptation and support environments, control and purpose and spirituality [2].

Social skills and resilience can prevent problems that may affect adolescents in their daily life, where risky conditions such as family problems, drug abuse or abandonment make it evident that resilient factors are looking for a way to excel in risky conditions in an adolescent-friendly way [3], [4].

Therefore, social skills and resilience play an important role in the adolescent since it will allow them to develop on a social and emotional level so that they can adapt to their environment and at the same time they can face adverse situations in their daily life [5].

In Peru, according to the report of the Instituto Nacional de Estadística e Informática, 32.9% of households are made up of

*Corresponding Author: Brian Meneses-Claudio, Mr., +51 1 950159924 & bmeneses@uch.edu.pe

girls and boys and/or adolescents, of whom there is at least one child under 18 with a caloric deficit, being higher in rural areas (33.5%) than in urban areas (33.2%) and Metropolitan Lima (32.0%). On the other hand, 41.4% of children under 18 years of age had a problem that affected their health such as a new disease, a relapse or an accident. Health problems occurred more frequently in children and adolescents in the urban area, not including Metropolitan Lima (42.5%), Metropolitan Lima (41.4%) and rural areas (39.8%) [6].

In [7], the authors presented a research work carried out in Colombia, significant differences were shown in emotional intelligence. In the high social acceptance group, low scores were found in the social skills evaluated, being the ability to make requests lower. Likewise, statistically significant correlations were found between several of the factors of the Baron test and those of the Social Skills Scale.

In [5], the authors described a study carried out in Spain, in the sample made up of 844 participants of both sexes, it shows that the most resilient adolescents have better results in all dimensions of quality of life and the effect of resilience is greater in the dimensions related to mental health and in all those that measure social relationships.

In [3], the authors described a study carried out in Colombia, a study was presented regarding the ability to listen, the ability to start a conversation, the ability to hold a conversation and the ability to ask for help, it is evident that most of people obtained scores between high and medium level. On the other hand, in the expression subscale of feelings, it is stated that most men have a medium level, while women are between the medium level and a high level.

The objective of the study is to determine the social skills and resilience in adolescents of an educational institution in North Lima in which it will allow to give important data about the social skills and resilience of adolescent students at the secondary level because nowadays, adolescents tend to have little communication with others in which this behavior cannot help them in a social situation effectively.

The study applied the data collection instrument Social Skills Scale (SSS), it was created by Elena Gismero Gonzales and the Connor-Davidson Resilience Scale (CD-RISC), which has been useful to assess social skills and resilience of adolescents at the secondary level of an educational institution.

The data collection was processed through the survey of adolescents at the secondary level, the data was entered in a data matrix that will be designed in the statistical program SPSS (Statistical Package for the Social Sciences) in its version 24.0 , in which it will allow a better data processing to make statistical tables and graphs so that they can be described and interpreted in results and discussions, respectively.

The following research work is structured as follows: In section II, the development of data collection processing for each adolescent at the secondary level will be presented, as well as the guidelines to consider so that they are included in the research work. In section III, the results will show the social skills and resilience of adolescents at the secondary level of the educational institution according to the specified dimensions of the instruments in the measurement of the variables. In section IV, it presents the discussions of the research work, in section V, the conclusions and in section VI the recommendations as well as the future work that is intended to be reached with the research work.

2. Methodology

In this section, the type and design of the research will be evidenced, as well as the population and sample that will be carried out in the research work, in addition to the inclusion and exclusion criteria and finally the technique and the instrument of data collection.

2.1. Research Type and Design

The present research is non-experimental, descriptive of a quantitative approach, it is a cross-sectional correlational research.

2.2. Population and sample

The population is made up of 706 students from 1st to 5th secondary level of the educational institution 3049 Imperio Del Tahuantinsuyo.

Inclusion Criteria

- Students who normally attend the educational institution.
- Students who have informed consent and assent.
- Students who have the authorization signed by their parents and agree to voluntarily join the study.

Exclusion Criteria

- Students who do not regularly attend to the institution.
- Students who do not have the authorization of their parents.

2.3. Technique and instrument

The technique used is the survey, using the questionnaire or instrument for collecting data on social skills and resilience, which aims to measure social skills and resilience in adolescents of an educational institution in North Lima.

The Social Skills Scale (SSS) was created by Elena Gismero Gonzales, from the Universidad Pontificia de Comillas (Madrid) in 1997, its application is given individually and collectively, with an approximate duration of 10 to 15 minutes, it is focused in adults and adolescents. The social skills scale consists of 33 items grouped into 6 dimensions, self-expression in social situations (8 items), defense of one's rights as a consumer (5 items), expression of anger or disagreement (4 items), saying do not cut off interactions (6 items), make requests (5 items) and initiate positive interactions with the opposite sex (5 items) that are evaluated by a Likert-type scale where “1 = I do not identify myself, in most times it does not happen to me or it does not I would do ”,“ 2 = it has nothing to do with me, even if it happens to me sometime ”,“ 3 = describes me roughly, even if I don't always act that way or feel that way ”and“ 4 = strongly agree, I would feel that way or act that way in most cases". The scale range varies from 33 to 132, the higher the score, the higher the adolescent's social skills [8].

The Connor-Davidson Resilience Scale (CD-RISC) was built by Connor and Davidson in the United States in 2003.

Its application is focus for the adolescent and adult population from 11 to 80 years old, the resilience scale consists of 25 items grouped into 5 dimensions, persistence-tenacity-self-efficacy (8 items), control under pressure (7 items), adaptation and ability to recover (5 items), control and purpose (3 items) and spirituality (2 items) that are evaluated with a Likert-type scale where "0 = never", "1 = rarely", "2 = sometimes", "3 = often" and "4 = almost always". The range of the scale varies from 0 to 100, the higher the score, the higher the resilience in the adolescent [9].

2.4. Place and Application of the Instrument

The survey to measure social skills and resilience in adolescents was carried out at the 3049 educational institution of Imperio del Tahuantinsuyo in North Lima.

The survey was carried out in two consecutive shifts, morning and afternoon according to the schedule of the students of the secondary level, the questionnaire was taken to the secondary level students with a time of 20 minutes to each selected section (1st from high school to 5th grade according to the inclusion criteria), it was concluded with a good satisfaction at the time of collecting the surveys since support from high school students was presented to carry out this research work.

It is very important to emphasize the presence of classroom teachers at the time of completing the surveys, because this helps students to relay on making questions using the sign of upper hand. In addition to the presence of nursing professionals since the mental health of adolescents is very important, because they are the future where the ways of communication tend to be high and that allow them to generate self-confidence and be able to perform effectively to any situation that is happening.

Figure 1: Application of the Survey to the students of the Educational Institution

Figure 2: Nursing staff is supporting in carrying out the survey

In Figure 1, the resolution of survey is shown in a classroom of the educational institution at the secondary level by the students, the collaboration of the students can be seen since this allows interaction with them.

In Figure 2, the reader can see the direct interaction with the adolescent student for the research process, it should be noted that the students gave confidence when explaining about the completion of the surveys.

3. Results

The table 1 is a summary of the surveys carried out following the guidelines corresponding to the research work:

Table 1: Social Skills and Resilience in secondary level students of Independencia Educational Institution – North Lima, 2019 (N = 706)

			Social Skills			Total
			Low level	Mediu m level	High level	
Resilience	Low level	Count	0	16	0	16
		% within Resilienc e	0,0%	100,0%	0,0%	100,0 %
	Mediu m level	Count	6	312	6	324
		% within Resilienc e	1,9%	96,3%	1,9%	100,0 %
	High level	Count	3	320	43	366
		% within Resilienc e	0,8%	87,4%	11,7 %	100,0 %
Total		Count	9	648	49	706
		% within Resilienc e	1,3%	91,8%	6,9%	100,0 %
Pearson's Chi-square			Value X^2	g.l.	Sig. (p)	
			28,626	4	0,000	

The significance level of the test obtained a value of 0.000 ($p < 0.05$) ($X^2 = 28.626$; g.l. = 4). This indicates that there is a significant relationship between social skills and resilience.

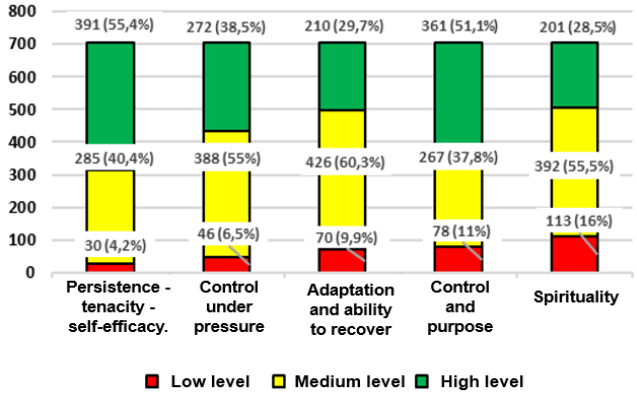

Figure 3: Social skills according to their dimensions in secondary level students in an Educational Institution of Independencia – North Lima, 2019 (N = 706)

In Table 2, it can see the social skills in secondary level students in an Educational Institution of Independencia – North Lima, where the middle level predominates with 648 (91.8%) students.

Table 2: Social Skills in secondary level students in an Educational Institution of Independencia – North Lima, 2019 (N = 706)

		N	%
Social Skills	**Low Level**	9	1,3
	Medium Level	648	91,8
	High Level	49	6,9
Total		706	100,0

In Figure 3, it can observe social skills according to their dimensions, where the most affected dimension was the expression of anger or disagreement with 97 (13.7%) students.

Table 3: Resilience in secondary level students in an Educational Institution of Independencia – North Lima, 2019 (N = 706)

		N	%
Resilience	**Low Level**	16	2,3
	Medium Level	324	45,9
	High Level	366	51,8
Total		706	100,0

In Table 3, it can see the resilience of secondary level students in an Educational Institution of Independence, where the high level predominated with 366 (51.8%) students.

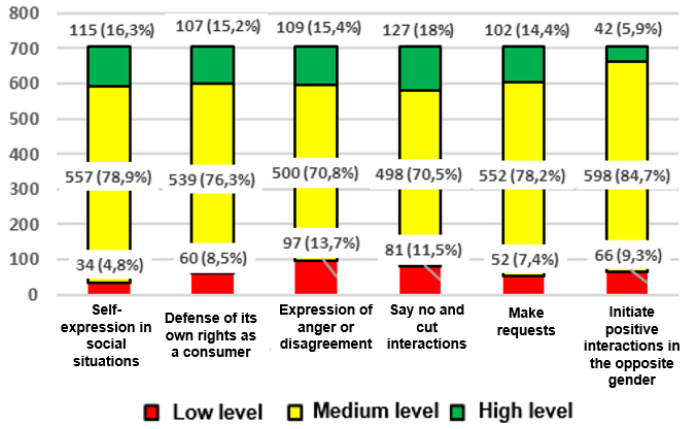

Figure 4: Resilience in secondary level students in an Educational Institution of Independence - North Lima, 2019 (N = 706)

In Figure 4, it can see the resilience according to its dimensions in secondary level students in an Educational Institution of Independence, where the most affected dimension was spirituality with 113 (16%) students.

Both studies can be interpreted that social skills and resilience in adolescents are linked to the promotion of mental and physical health of adolescents, knowing that resilience is relevant because it will allow the person to respond appropriately to negative events or situations. It also focuses on social skills because it is an essential element to achieve the socio-emotional development of the human being and favors school learning. It is vitally important to develop social skills and have a high level of resilience, but unfortunately there is a knowledge gap, reviewing the scientific information related to this topic.

These results will help to the educational institution since it will provide them with information that will allow to evaluate more concisely the adolescents of the secondary level, giving importance to the mental health of the student, in which it is beneficial for them and so they can communicate in an appropriate way that allows to have opportunities in the future.

4. Discussion

In the present study, the issue of social skills and resilience is raised from the point of view of promoting adolescent health, which seeks to contribute to institutions that are in the educational field as part of comprehensive adolescent training, including programs that allow adolescents to enhance their ability to interact, be extrovert, and cope with problems to improve their social life.

Based on the social skills in adolescents of the educational institution 3049 Imperio del Tahuantinsuyo, it prevailed in medium level followed by high and low. These results are based on two purposes: the first, if there are no interventions in the group with a medium level of social skills, these will not have a full development their personality. On the other hand, making interventions can raise the level of social skills, which would be beneficial for adolescent development. In [10], the authors showed that adolescents are normally receptive to new ideas, and are eager to take full advantage of their growing capacity to make decisions; their curiosity and interest lead to a great openness to new possibilities and among them could be considered relating to their peers. Engaging in positive and constructive activities offers opportunities to build relationships with adults and peers. The reason for these findings is due to the fact that in the institution there are no teachers prepared for the tutoring course, they are the teachers of different courses who are in charge of some sections and the participation of parents in the meetings is required.

By implementing well-designed social skills programs, the level of social skills can be raised for the benefit of adolescents and mental health. In these processes of strengthening social skills, the family must also be involved, since this constitutes an important Socialization space and parents play an important role as Trainers and counselors. Conditions must be implemented in schools such as not saturating student classrooms and having the necessary infrastructure for the work of the teacher and tutor; favoring the work of professionals for the benefit of adolescents [11].

Regarding social skills in its self-expression dimension in social situations in adolescents of the educational institution 3049 Imperio del Tahuantinsuyo-Independencia 2019, the medium level prevailed followed by the high and low. It reflects the ability of each individual to express themselves spontaneously in different social and work events. We agree with what was stated by Pérez, who points out in its study that an institutional intervention program can significantly improve social skills in adolescents.

Regarding to social skills in their defense of their rights as a consumer dimension in adolescents of the educational institution 3049 Imperio del Tahuantinsuyo-Independencia 2019, the medium level prevailed followed by the high and the low. Obtaining a high score reflects the expression of assertive behavior towards strangers in defense of their own rights in situations of consumption. Regarding social skills in their dimension defending their own rights as consumers in adolescents from a pre-university center in Lima Norte, the medium level predominated, followed by the low and high. This dimension is related to being an active participant in social life that allows to exercise full citizenship. In [12], the author deduces in his study that the development of social skills and their dimensions, play a protective role for the adolescent, away from risky doings and behaviors such as marijuana use.

Regarding to social skills in its expression of anger or disagreement dimension in adolescents from the educational institution 3049 Imperio del Tahuantinsuyo-Independencia. 2019, the medium level prevailed followed by the high and low. It rates the individual's ability to handle their conflicts with another person in a negative or positive way. In [13], the authors point out from the findings of their study, that the training institution must assume a leading role in promoting social skills; teachers play an important role, so they must be permanently trained to join and contribute to the promotion of social skills in them.

In relation to social skills in it say no and cut interactions dimension in adolescents of the Educational Institution 3049 Imperio del Tahuantinsuyo-Independencia 2019, the medium level prevailed followed by the low and high. This dimension reflects the ability of the individual to cut off interactions that they do not want to maintain, as well as refusing to lend something when dislike doing so, it was found that the vulnerable adolescents who are victims of bullying do not know how to respond to these situations and they have a hard time saying “enough” or “not”.

Respecting of social skills in its making requests dimension in adolescents from the educational institution 3049 Imperio del Tahuantinsuyo-Independencia 2019, the medium level prevailed followed by the low and high. This dimension reflects the ability of the individual to make a request without difficulties, it should be noted that in cooperative learning processes they promote the development of social skills and can enhance the ability to make requests in an appropriate and timely manner.

Regarding social skills in its dimension, initiating positive interactions with the opposite sex in adolescents from the educational institution 3049 Imperio del Tahuantinsuyo-Independencia 2019, the medium level prevailed followed by the low and high [10]. This dimension qualifies the ability of the individual to relate, interact with the opposite sex. This dimension presented a higher percentage in the low level of social skills.

Concerning the level of resilience in adolescents of the educational institution 3049 Imperio del Tahuantinsuyo-Independencia 2019, the high level predominated, followed by a minimal difference from the medium and low level. The results would be explained in different ways, one of the advantages is that the highest percentage lives with their parents, they share family experiences, which favors them as a protective factor so that they can overcome adversities and get out with great ease. The adolescence plays a very important role in resilience since at this stage of life, it goes through various changes such as: biological, psychological and social. This is where most conflicts, rebellions are generated, testing their ability to adapt [12].

In relation to its spiritual dimension, it has a higher percentage in the low level of resilience. The role of spirituality in improving an adolescent's ability to cope with stressful life situations is often under-appreciated, especially in the context of mental health services within a juvenile detention environment.

5. Conclusions

We can conclude that social skills and resilience are mutually related since both allow adolescents to develop functions that allow them to have resources or strengths to cope with situations of daily life.

It is concluded that the social skills are very important for adolescents since it is fundamental for their daily life because they can get success, have proper communication with other people and not only of verbally as well as affectively and emotionally.

It is concluded that resilience is very favorable for adolescents since, within their social environment, they will have the capacity to solve stressful situations and will make them vulnerable to any situation, since resilience will allow adolescents to adapt to these situations and be able to solve them effectively.

6. Recommendations

It is recommended in this institution to have programs that help improve communication between the students themselves so that they can improve their communication with other people.

It is recommended in this institution that it be carried out annually with a control system on social skills and resilience since these are essential for the adolescents so this will allow them to communicate with society and also with their environment.

It is also recommended that health professionals attend educational institutions where they can observe certain deficiencies in social skills and resilience in order to allow them to carry out psycho-affective programs where the adolescent can interact with their social environment and also develop both verbal and non-verbal skills.

Conflicts of Interest

The authors declare no conflict of interest.

ABSTRACT

The article discusses the possibility of using solar energy for street lighting systems in the city of Gitega, in the Republic of Burundi. Analysis of weather and climate conditions of the city was carried out and an effective street lighting system based on solar mini-power plants using an intelligent control system developed. Calculations of technical and economic efficiencies are made and the principle of operation of the developed system is described. A comparison of the methods of transmitting control signals and the performance of different types of lamps was made as well as an assessment of the battery discharge process. The different attachment types of solar panels to their supports were highlighted, the illumination received on a public space according to the installation height of the luminaire and the used LED power as well as the requirements in terms of illumination and brightness depending on the place to be lit were discussed. The system developed consists of two solar panels, connected in parallel, one battery and six LED lamps with adjustable power. At present, the problem of modernizing the lighting of public places and roads of regional and local significance in Gitega city remains relevant. With the aim of promoting clean energy and reducing energy consumption due to global concern about climate change, the use of modern, cost-effective lighting systems based on the use of LED technology and is one of the most dynamic trends in the world at present and in the near future for the well-being of the population.

1. Introduction

Light is a fundamental element for human activity, the day is lit by the sun but when night comes artificial light becomes mandatory. Since solar energy is available all over the globe, the city of Gitega, now the political capital of the Republic of Burundi, located in the center of the country, is privileged to have a strong solar deposit. This work is an extended version of the report [1] presented in 2020 IEEE Conference of Russian Young Researchers in Electrical and Electronic Engineering (EIConRus), where a public Lighting by Mini Solar Power Plants in the Republic of BURUNDI is proposed. With a duration of insolation exceeding 3000 hours per year and a considerable annual average daily irradiation, this region can be a pole of excellence for the use and promotion of photovoltaic solar energy [1, 2]. In this work, we propose a design and dimensioning of autonomous systems for street lighting using solar photovoltaic energy as the primary source. Obtaining information about the intensity of solar radiation in a specific geographic and climatic zone gives an idea of the possibility of using solar energy to generate a certain amount of electricity. The climatic conditions of the city of Gitega make this value almost constant throughout the year [2]. This is an important parameter when calculating any type of solar power plant (SPP). However, in order to improve the energy efficiency of photovoltaic lighting systems, it is necessary to use both high-efficiency photovoltaic modules as well as efficient batteries and charge regulators for energy storage and management; but also it is essential to use luminaires with high energetic efficiency (number of lumens/Watt) [3–7].

Nowadays, artificial lighting has become more than a means of obtaining light; it is an indispensable element of human life in general and in urban areas in particular [8]. The lighting of public places, traffic lanes, monuments and sites in cities and the countryside has now become a major concern for electricity

*Corresponding Author: Ntawuhorakomeye Noel, noentaw1@mail.ru

distributors and administrative and political authorities. Public lighting plays a very important role in various places of attendance both economically and socially [8, 9]. It is above all a measure aimed at increasing the safety of public spaces, whether in traffic areas or in relaxation and recreation areas. The objective is not to provide light only for safety purposes, but also to create a pleasant nighttime atmosphere giving a new vision and approach to the spaces [9]. To produce light, there are three main techniques [1, 8]: incandescent (classical and halogen), fluorescence and LED (Light-emitting diode). Due to the high efficiency and the absence of infrared radiation, LED lamps practically do not heat up during operation. Currently existing LED lamps consist of dozens, and sometimes hundreds of LEDs. The quality of colored light is still an unrivaled achievement of LED technology. The main difference between LED luminaires (lamps) and all others is their unprecedented long service life (up to 100,000 hours) [5, 8]. For electric lighting systems that operate at night, the period of electricity accumulation during daylight hours is a very important. A 120 amp-hours (120 Ah) accumulator battery with two 200-watt solar panels (200 W) were used in the design of this mini SPP to power the six public lighting LEDs. The developed intelligent system is a solution for remote control of street lighting, which has the ability to control the lamps and the lighting level of each street lamp. Increasing the reliability of street lighting networks will ensure energy saving, uninterrupted power supply, and as a result, ensure road safety as the number of accidents and illegal actions is significantly reduced when the city is well lit. The use of an intelligent street lighting control system will ensure safer traffic conditions, pedestrian safety, and significantly improve the city's architectural, tourist, and commercial aspects [10, 11]. All this with the aim of promoting clean energy, and reducing energy consumption due to global concern on climate change.

2. Characteristics and Features of Gitega City Climate

Gitega city is located in the center of the country about 100 km east of the economic capital Bujumbura. Its geographical coordinates are 3° 25' South, 29° 55' East according to Meteonorm 7.3, Sat = 100% of PVSYST. It is part of Africa in the southern hemisphere. This region is characterized by hills composed of metamorphic rocks such as schists, quartzites and phyllites. The Gitega province is located in the Central Plateau area with an altitude ranging from 1600 to 2000 m. It has a tropical climate tempered by altitude. Under normal conditions, the climate of the Gitega city is characterized by two (2) well-marked seasons namely the dry season, which begins in May and continues until October with minimas in June and July as well as the rainy season. The average precipitation is 1200 mm and the average temperature over the year 22.6°C (As shown in Table 1). The main nearby river is the Ruvubu with two main tributaries namely the Ruvyironza and the Mubarazi. Several districts make up the town of Gitega for about 10 km, along and around the RN2 (national road № 2) that crosses it: Magarama, Nyamugari (Swahili district), the commercial district, the administrative district, Musinzira, Shantanya, Rutonde, Nyabiharage, Nyabututsi and Mushasha (religious district). Located on an important relief, there is significant solar irradiation whose average value received annually is estimated at 1800 kWh/m^2/year. The following Table shows the average temperatures, solar radiation and wind velocity, by months according to Meteonorm 7.3, Sat = 100% of PVSYST.

Table 1: Temperature, Average irradiation, Wind velocity and Relative humidity at Gitega

	Average temperature (^{0}C)	Average irradiation (kWh/m^2/mth)	Wind velocity (m/s)	Relative humidity (%)
January	23.3	149.5	3.30	64.0
February	24.3	134.3	3.49	57.5
March	24.4	156.9	3.50	61.1
April	23.2	147.6	3.39	68.6
May	22.7	151	3.70	66.5
June	21.3	151.1	3.80	65.7
July	20.7	158.5	3.80	64.9
August	21.0	156.2	3.80	63.6
September	21.6	149.7	3.99	62.5
October	22.8	154	3.80	62.0
November	22.7	136.0	3.10	68.3
December	23.4	146.5	3.19	65.8
Year	**22.6**	**1791.3**	**3.6**	**64.2**

Based on the abovementioned and presented data in the table, we can conclude that the climatic conditions of the city of Gitega are ideal for the effective use of electricity from solar panels (SP). The Figure1 shows the temperature and irradiation variation according to the months of the year.

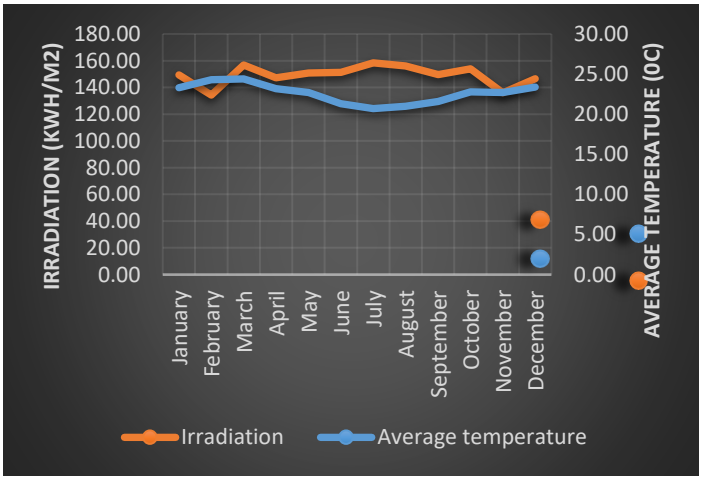

Figure 1: Temperature and Irradiation variation

Figure 2 Shows the Sun Path and Horizon Line respectively at Gitega. It is noted that the city of Gitega sees 9 hours of sunshine per day. Large solar irradiation begins to be observed at 10 o'clock, and begins to decrease at 15 o'clock with a maximum at 12 o'clock [1].

Knowing that there is no public lighting in general in this city and that the only light that the streets and public squares receive comes from the exterior lights of the surrounding houses and buildings, the development of a public lighting system is very important for the well-being of residents and passers-by, especially at night.

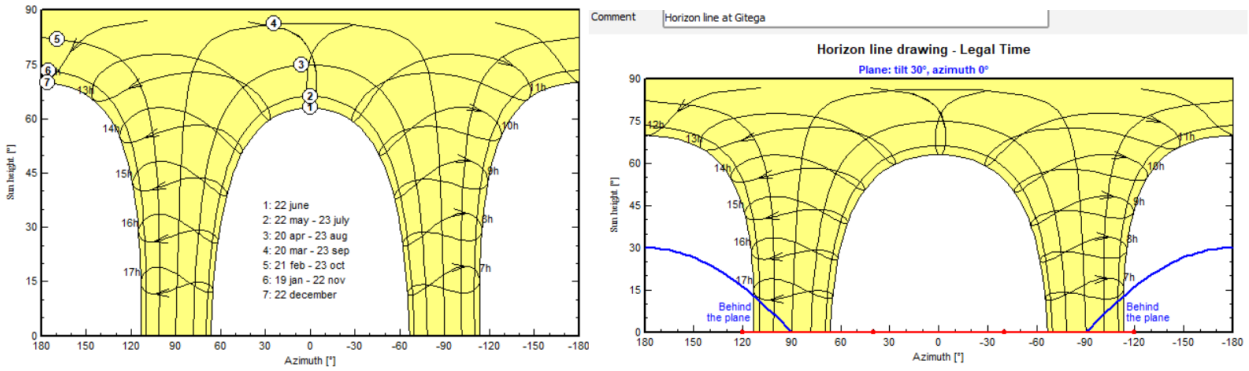

Figure 2: Sun Path Shape Horizon Line

Table 2: Requirements for Roads and Streets Lighting

Lighting Category	Streets and Roads	The Highest Traffic Intensity in Both Directions, units / h	Coating Average Brightness, Cd /m^2	Coating Average Horizontal Illumination, lx
A	Main roads, main streets of citywide significance	More than 3000	1,6	20
		1000 to 3000	1,2	20
		500 to 1000	0,8	15
B	Main streets of district significance	More than 2000	1,0	15
		1000 to 2000	0,8	15
		500 to 1000	0,6	10
		Less than 500	0,4	10
C	Local streets and roads	500 and more	0,4	6
		Less than 500	0,3	4
		Single cars	0,2	4

Table 3: Horizontal Illumination of Some Places

Places to light	Average horizontal illumination, Lx
Main pedestrian streets, impassable parts of squares of categories A and B, and pre-factory squares	10
Pedestrian streets: -within community centers	6
-in other territories	4
Sidewalks separated from the roadway on streets	2-4
Public transport boarding areas on all categories of streets	10
Pedestrian bridges, Children's playgrounds where outdoor games equipment is located	10
Pedestrian tunnel: -in the daytime	100
- evening and night	50
Pedestrian tunnel stairs in the evening and at night	20
Household sites and waste collection sites	2

3. Main Requirements for Public Lighting Systems

When developing solar street lighting, it is possible to achieve maximum efficiency of the system only using, so-called "smart" technical means, which would not only control operation modes, but also control the operation of the entire system in automatic mode. Additional maintenance of street lighting should be carried out in case of violation of the recommended lighting standards (lamps fail, stop shining or Shine dimly). The working hours of

lamps are regulated by municipal services, which approve the schedule for switching on and off lighting.

In cities and rural settlements, the requirements for lighting streets and roads vary significantly. Table 2 shows the standards for artificial lighting of roads and streets in cities and rural settlements. At the same time, the average brightness of a highway's coverage is 1.6 cd/m^2 in cities and at least 1.0 Cd/m^2 outside of cities at the main entrances to airports, river and sea ports, regardless of traffic intensity [8, 12].

The average horizontal illumination at the level of coverage of impassable parts of streets, roads and squares, boulevards and squares, pedestrian streets and territories of micro districts in urban settlements should be taken according to table 3.

At night, lighting level of city streets, roads and squares can be reduced to a standardized average brightness of more than 0.4 cd/m^2 or an average illumination of more than 4 lux by switching on no more than half of the lamps. It is allowed to reduce the lighting level with the regulator in order to obtain additional energy savings in the evening and morning hours of the day [3, 6]: by 30% with a decrease in traffic intensity to 1/3 of the maximum value; and by 50% with a decrease in traffic intensity to 1/5 of the maximum value.

On streets and roads at standardized values of an average brightness of 0.3 cd/m^2 or an average illumination of 4 lux or less, on pedestrian bridges, parking lots, pedestrian walkways and roads, internal, service and fire-fighting passages, as well as on rural streets and roads settlements, partial or complete switching off of lighting at night is not allowed. The following Table (Table 4) shows the variation of the illumination received (lux) on a public space according to the luminaire installation height and the power of the used Led (W) [13].

4. Automatic Control Systems of Public Lighting

Switching street lights on and off as needed is an excellent measure to save energy consumption. However, the various systems are not equally suited to this rapidly evolving technology. It is particularly interesting for public spaces used infrequently, such as public toilets, public waste collection points, and rural roads with little traffic. For areas with high safety sensitivity, it is not recommended (e.g. for busy roads, areas of heavy road or pedestrian traffic, and areas requiring overnight surveillance). On the other hand, for autonomous solar lighting systems, a regular and homogeneous consumption cycle is ideal. Uneven battery discharge due to erratic interruptions leads to rapid degradation and the need to replace them before the end of their normal lifespan. Therefore, measures to interrupt the nighttime lighting duration of such systems are only suitable to a limited extent. For solar systems, regular long-term interruptions are feasible to be managed through programmable astronomical clocks. Motion detectors are only recommended for small isolated spotlights. Automatic street lighting control systems usually operate under the control of a zone controller or server. Depending on the control algorithm, the controller generates a signal, for example, turning on a group of streetlights [10, 13, 14]. To transmit this signal to actuators, the following means are used: -low-current signal lines (twisted pair, RS-485, Ethernet, etc.); -radio channel; -GSM-channel; -signal transmission via power cable.

Table 4: Examples of illumination data for a lighting unit

Installation height of the luminaire	**Illuminated area**	**Maximum illumination (lux) received on a road**					
		LED 18 W	LED 30 W	LED 50 W	LED 65 W	LED 80 W	LED 120 W
6 m	8×20 m	10 Lux	19 Lux	30 Lux	39 Lux	49 Lux	59 Lux
8m	10×25 m	6 Lux	12 Lux	18 Lux	23 Lux	29 Lux	35 Lux
10m	13×30 m	4 Lux	8 Lux	12 Lux	15 Lux	19 Lux	24 Lux
12 m	16×35 m	2 Lux	5 Lux	8 Lux	11 Lux	14 Lux	17 Lux

Table 5: Comparison of control signal transmission methods

	1. Low Current Control	**2. GSM-Channel**	**3. Power Transmission Lines**	**4.Radio Channel**
Addressing (Economically Feasible)	possible Individual lamp controls	Group control only	Group control only	Group control only
Control Method	Digital control Protocol for example based on a calendar schedule	Phone call or SMS to the controller in the control Cabinet	Control via a power cable connected to the controller in the control Cabinet	Radio signal transmission from the control room to the receiver in the control cabinet
Factors Affecting the Reliability	Accumulation of timing error	Dependence on the workload of the public network of the GSM operator.	Upon failure of the required manual switching cable.	Radio interference may cause the control signal to be unable to be received
Labor Costs	High labor costs	Low labor costs through public use network	With individual lamp control, cable laying is labor-intensive	High labor costs when installing transceivers

Territory Coverage	Snap to city / region	Cellular coverage area	The length of the control power cable cannot exceed 1 km	Control is possible only in the area of confident reception of the radio signal.
Territory Size	City district, small settlement	City and nearest suburb	Limited territory	City and suburbs, area along the motorways
Cost Factors	Individual control unit in each lamp	Subscription and connection fees, messaging	The cost of individual power cables installation	Cost of dispatcher's equipment, relay stations and receivers
Factors Affecting Maintenance Cost	Timer adjustment is constantly needed		High repair costs for electrical equipment	A qualified dispatcher is required

Setting up the public lighting network is easier with a computerized centralized management system. Among other functions, this system normally allows: a) Easy and quick re-setting of the whole or parts of the network, for example during extraordinary events, which require a temporary adaptation of the lighting duration in a commune area. b) Accurate detection of faults and malfunctions in light points and electrical cabinets. c) Monitoring of energy consumption by the lighting network. d) Linking of network operation with climatic conditions and traffic volume. e) Management of equipment and human resources related to network maintenance.

Such a system consists of having controllers integrated into the electrical cabinets with a link to the light points or individual controllers integrated into the light points themselves. The controllers communicate with the remote management station (a computer, a tablet or a smartphone) via a wireless network, for example WIFI or radio. Note that for the control of the lighting time of streetlights, programmable time switches preferably of the so-called astronomical, digital or mechanical clock kind which are normally integrated in the control boxes as well as twilight detectors with a photoelectric cell (sensor) which are either integrated in the equipment (for example a regulator), or they are stand-alone units. Lighting controlled by a twilight switch automatically activates the switching off and switching on of public lighting according to daylight. To ensure the reliability and accuracy of the switch, it is essential to correctly position and orient the sensor so that it is not affected by random light sources or disturbed by shadows. It should also be checked and cleaned regularly to prevent dust accumulation. Twilight switches can be associated with clocks in order to cut off the control during part of the nighttime. The programmable time switches control the switching off and switching on of public lighting at specific times. They are installed in public lighting cabinets. If it is not an astronomical clock, it must be adjusted and updated regularly in order to approximate sunrise and sunset times [8, 10].

5. Design Features of the Developed System and its Operation Principle

The functional scheme of the solar-powered street lighting system developed is shown in Figure 3. It is an economical lighting system with intelligent control operating with an intelligent lamp having a step change of the luminous flux.

1. Solar panel; 2. Block of Sensor; 3. Lamp with Progressive Adjustment of the Luminous Flux; 4. Control Block; 5. Storage Battery; 6. Diagnostic Connector.

The photovoltaic solar panel (1) generates an electric current passing through the control block 4, which includes the charge controller of the storage battery. A "smart lamp" (3) is a lamp with stepwise adjustment of the light output power. Depending on its capacity, a battery to be charged by the solar panel ensures the operation of the entire system without recharging for a period corresponding to the duration of the night. The Block (2) consisting of temperature and light sensors sends accurate temperature and illumination data to the Control Unit 4, thereby controlling the operation mode of the lamp. The light sensors in block 2 will turn on the lamp at nightfall, and turn it off as soon as the first rays of the sun appear. Lamp operates in three different modes namely: maximum power mode, average power and economy mode depending on the time of year, the solar radiation intensity and the battery charge level. In addition, if the system notices a long lamp operation in Economy mode, it evaluates the battery charge level and can switch to timer mode in which the lamp turns on in Economy mode for a time T1, after which it turns off and turns on during time T2 before sunrise. Depending on the battery charge level, the T1 and T2 times may vary in the direction of decrease or increase. A computer is connected to the public lighting system via a serial interface according to the USB 2.0 standard from the diagnostic connector 6 to allow the use of software specially designed to control all the parameters of the system, program its operation, determine the dirt level from the solar panel, change the operating modes etc.

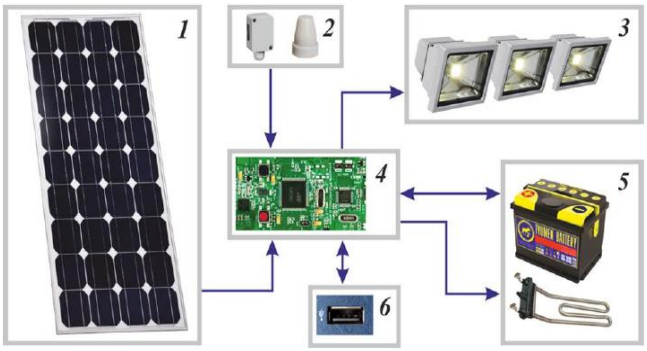

Figure 3: Block Diagram of the Developed Public Lighting

6. Proposed System Description and Operation

The developed street lighting system consists of smart lamps-lamp with a three-stage adjustment of the luminous flux: 10 W-20 W-30 W (the maximum power of each lamp is 30 watts). Each mini-SPP uses two solar panels of 120 W each to power six (6) smart lamps mounted 2 by 2 on three metal poles (As shown in Figure 4). The minimum total power of these lamps will be P_{min} =

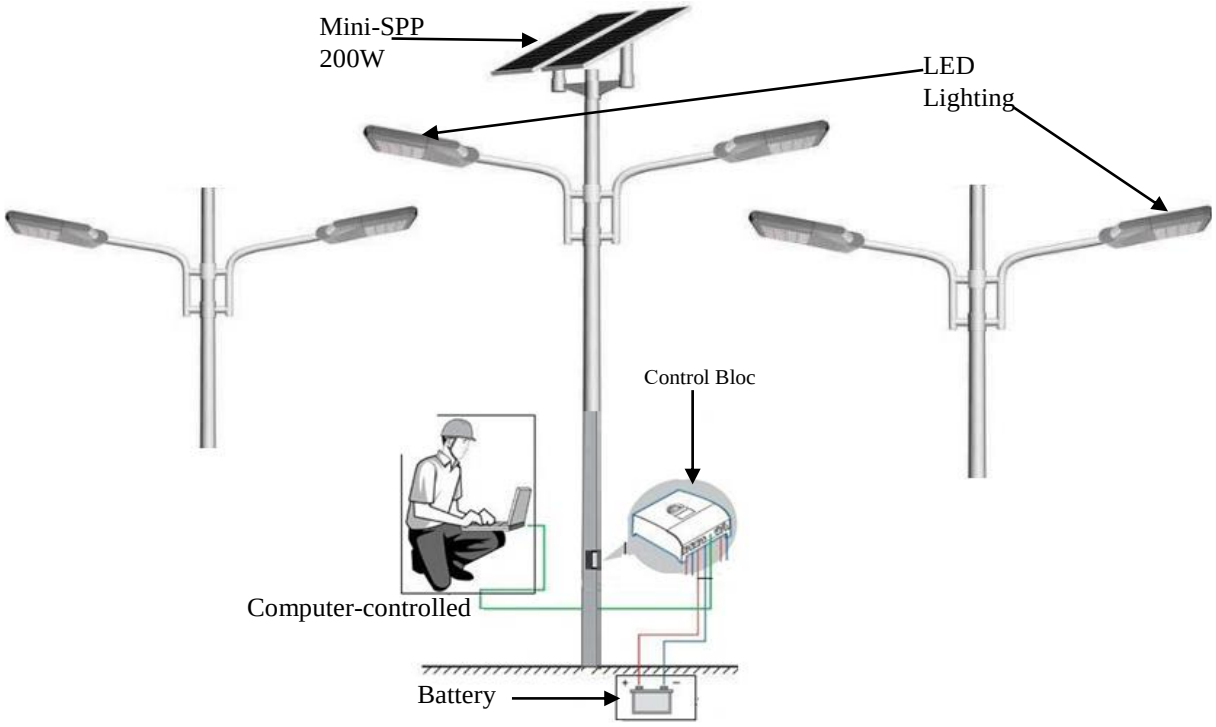

Figure 4: Developed Solar Mini-Power Plant 200 W

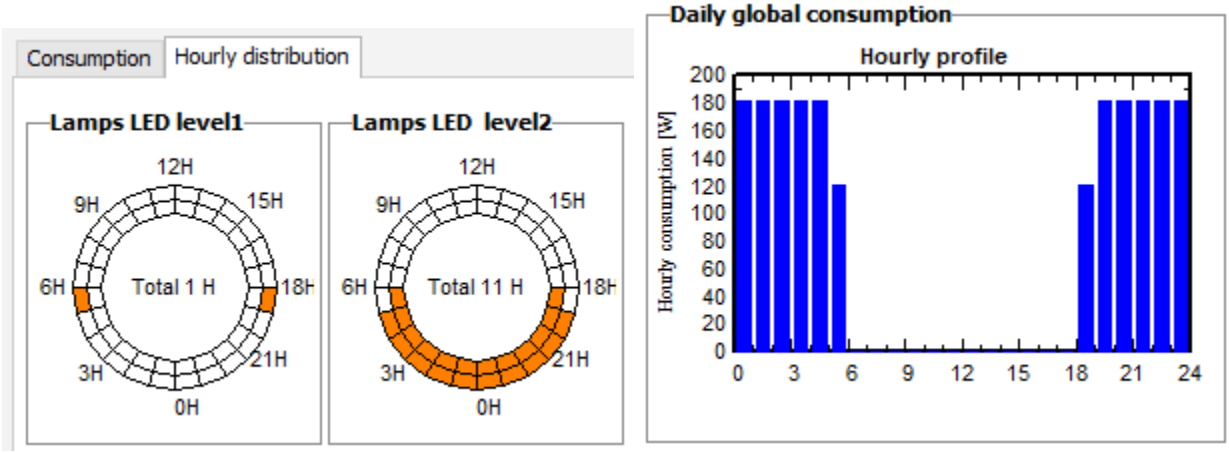

Figure 5: Lighting System hourly Distribution and Daily Consumption

60 W, with a maximum of P_{max} = 180 W. As Shown in the Figure 4, two of the lamps are installed on the central pole supporting the solar panels, the other 4 on the other 2 poles surrounding the first. A voltage of 24 V is transmitted from the battery of the mini solar power plant to the lamps via an underground power line. It should be noted that LED lamps are more advantageous than luminescence or incandescent lamps used in lighting systems in general. The following Table shows the relationship between the power of some lamps (W) and their luminous flux (lumen) [12].

The street lighting system shown in Figure 4 is designed to illuminate boulevards, public areas, etc. The distance between the supports on which the lamps are installed will be about 50 m. In order to reduce the cost of design and installation of the developed system, modernized conventional LED spotlights with systematic adjustment of the luminous flux are used. The following Diagram (As Shown in the Figure 5) shows the use state of this lighting over 24 hours (one day).

The diagram of operation and energy consumption of these lighting lamps shows that from 18: 00 (assumed time of the beginning of the night time),the lamps illuminate under a minimum power of 10 W for 30 minutes after which they illuminate at their maximum power of 30 W each.This minimum power which lasts 30 minutes will also be observed in the morning at the end of the night time so at 05h30 minutes.

7. Solar Panels Orientation and Positioning

In this street lighting system, the electrical energy source is usually located on the same support on which the luminaire is fixed. In this regard, special attention should be paid to the design of attachment of the solar panel to the support, since the amount

of electricity generated will also depend on its orientation. Most often, solar panels are installed at a certain angle (declination) to the sun, in the direction of azimuth to the South or South-East (As Shown in Figure 6) [12, 15].

Table 6: Power Ratio of Various Lamps Types

Incandescent lamp, W	Fluorescent lamp, W	LED lamp, W	Luminous flux, Lm
60	15-16	8-10	700
75	18-20	10-12	1200
100	25-30	12-15	1200
150	40-50	18-20	1800
200	60-80	25-30	2500

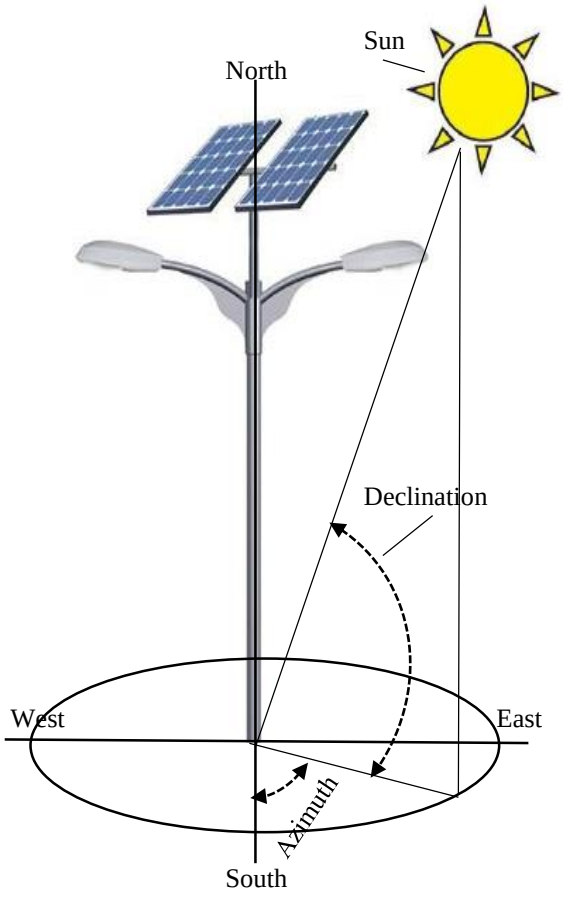

Figure 6: Solar Panel Orientation in Space

It is known that solar panels generate electricity in the absence of direct solar radiation, in cloudy weather, when the sunlight is weak and diffused, the photovoltaic system will produce electricity. The influence of various conditions on the production of solar panels as a percentage of the rated power is shown in Table 7 [12].

The tilt angle of solar panels relative to the earth's surface depends on geographical coordinates. Moreover, to increase the performance of the system, this angle must be changed during the year. As shown in Figure 7, for a fixed orientation throughout the year, the optimal tilt angle for the city of Gitega is 30 degrees.

Table 7: Dependence of Solar Panel Power on Different Conditions

Conditions	**Percentage of the Maximum Radiation (%)**
Bright sun	100
Light cloudy	60-80
Window glass, one layer	91
Overcast weather	20-30
Artificial light indoors	0,2-1,5

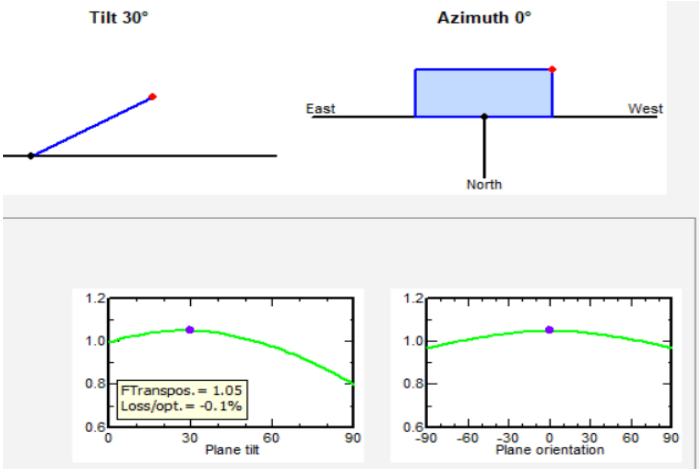

Figure 7: Tilt angle and Azimuth at Gitega

The tilt angle of a solar panel plays an important role, however small changes in the range of 0 to 5 degrees cannot have a serious effect on the system performance. Therefore, the tilt angle for localities (communes) of this region such as Bugendana, Bukirasazi, Buraza, Giheta, Gishubi, Itaba, Makebuko, Mutaho, Nyanrusange and Ryansoro will also be the same.

8. Solar Panels Fixings to Their Supports

Ideally, the luminaire support is fixed to a concrete footing through a metal plate to facilitate its replacement, if necessary. Depending on the function, the aesthetic appearance, the space and the environment, several types of supports can be identified, for example, poles made of steel, aluminum, cast iron, concrete, wooden etc. [12].

At present, metal supports are the most often used. Their manufacturing is more technologically advanced; they have a relatively small mass and retain their operating characteristics for a sufficiently long time. As the metal support is hollow inside, it is possible to run cables through it, connecting the solar panel to the control block and to the storage battery. In general, four (4) fixing points are used to fix a solar panel on a metal support. It is also taken into account that the panel should be oriented vertically, not horizontally. Table 8 shows some standard methods of solar panels fixing.

Table 8: Solar Panels Fixing

Denomination	Solar Module Width	Landing Dimensions	Image
MSU51585 Universal fastening of the solar module 50-150 W to the pipe up to 85 mm	up to 700 mm	Pipe Ø45-85 mm or on the wall	MSU515220 Universal fastening of solar modules 50150 W to the pipe up to 220mm	up to 700 mm	Pipe Ø80-220 mm	
MSU153085 Universal fastening of solar modules 150-300W on a pipe up to 85mm	up to 1000 mm	Pipe Ø45-85 mm or on the wall	
MSU1530240 Universal fastening of the solar module 150-300 W on the pipe up to 220mm	up to 1000 mm	Pipe Ø80-240 mm	
MSU2x1530280 Universal fastening of two solar modules 150-300W on a pipe (wall) 50-280mm	up to 1000 mm	Pipe Ø 50-280 mm or on the wall	

Note that it is necessary to use a design that facilitates the changeability of the tilt angle of the solar panels according to the time of day or year in order to increase the efficiency of the mini-solar power plant for public lighting.

9. Solar Panels Power Calculation

The energy generated by a solar panel with a power Pw for a selected period is calculated as follows [16, 17]:

$$W = \frac{k \cdot E \cdot P_w}{1000}$$

E – insolation value for the selected period; Pw – solar panel power, k - coefficient equal to 0.5 and 0.7 in summer and winter periods, respectively. This factor takes into account the solar panels heating by the sun, as well as the incidence angle during the day. The insolation value E = 4.91 kWh/day.

The solar panel power to be used is calculated taking into account the daily consumption of all the LED lamps operating during the night hours. Remembering that they are of the adjustable power type and therefore their minimum power $P_{\Sigma lamp}$ will be 60watts, their maximum 180 W. Their maximum daily energy consumption $W_{cons.}$ is given by (1) as follow:

$$W_{cons.} = P_{\Sigma lamp} \cdot t_{\max} \quad (1)$$

где $t_{\max}$ – the operating time of the lamps

The latitude of the city of Gitega and the sun declination on which the average longitude of the day depends, give an interval of the day equal to 12 hours. Accordingly, the maximum daily energy consumption of the system will be 2040 Wh/day according to (1). Since the average number of hours of sunshine is estimated at 9 hours (9h) per day, to determine the daily energy production (generation) of solar panels, it is necessary to multiply their rated power P_n by their operating time per day: $W_{gen} = P_n \cdot t_{op.}$

Where $t_{op.}$ – Operating time (9h), W_{gen} – Daily energy generation. This daily energy produced by the solar panels will be 2016 Wh/day. The 120 W 24 V solar panels that will be chosen from the ranges produced by different manufacturers must have an optimal operating current of at least 6.7 A.

10. Battery Capacity Assessment and Calculation

The developed public lighting systems are intended to work during the night hours, while during this time the solar panels do not generate the electric energy, the electricity stored in the batteries is used. The capacity of the battery to be used, i.e. the amount of energy it can store, plays a big role. Their total capacity depends on the number of storage batteries, and therefore the power of the solar power plant in general. Storage batteries in a solar power plant must meet a number of requirements. They must withstand a large number of charge-discharge cycles. When calculating the parameters of the storage battery, it is necessary to take into account the energy losses during its storage and transformation. Conventional car batteries do not withstand a large number of cycles and have significant self-discharge. Most often, special storage batteries are used for solar power plants. Table 9 shows the states of charge (Battery charge levels) of a 12-volt battery depending on the temperature [12, 18].

Table 9: 12V- Battery Charge Status Assessment

Battery charge level, %	Electromotive force (EMF) , depending on temperature		
	+20…+25°C	+5…–5°C	–10…–15°C
100	12,70 – 2,120	12,80 – 13,00	12,9 – 13,10
75	12,55 – 12,65	12,65 – 12,75	12,75– 12,85
50	12,20 – 12,30	12,30 – 12,40	12,40 – 12,50
25	12,00 – 12,10	12,10 – 12,20	12,20 – 12,30
0	11,70 – 12,00	11,80 – 12,00	11,120 – 12,10

The energy generated and stored in the battery during the day is used at night to power the load (streetlights) of public lighting. This energy shows the capacity of the battery; i.e. how long it can power the load if it is fully charged. The change in battery capacity ΔC during the load supply time $\Delta t_{nig.}$ is determined by the expression (2):

$$\Delta C = \frac{P_n}{U_n} \cdot \Delta t_{nig.} = \frac{P_n}{U_n} \cdot (24 - \Delta t_{dayl.}) \qquad (2)$$

где P_n – rated load power; U_n – rated load voltage; $\Delta t_{nig.}$ – the night time interval (12hours); $\Delta t_{dayl.}$ – day time interval

Battery manufacturers define the final discharge voltage, once reached, the battery must be disconnected from the load and charged, this because deep discharge can damage it. A battery should not be more than 70-80% discharged for it to work for a long time. The battery discharge level is determined by the expression [16]:

$$S_r = \frac{C_n - C_{\min}}{C_n} \cdot 100\% = \frac{\Delta C}{C_n} \cdot 100\% \qquad (3)$$

The required capacity C_n of the accumulator battery is obtained from (3) while taking into account (2):

$$C_n = \frac{100}{S_r} \cdot \frac{P_n}{U_n} \cdot \Delta t_{nig.} \qquad (4)$$

In the city of Gitega, taking into account that the nighttime interval is 12hours, with the 200-Watt solar panels as it was said above, a 120 Ah will be ideal for this mini solar power plant consisting of six LEDs of street lighting. Its energy capacity will be 2880 Wh. The higher the voltage supplied to the load, the lower the capacity can be, since the discharge current $I_r = \frac{P_n}{U_n}$ of the storage battery will be lower. For conventional lead acid batteries, the maximum discharge current is limited to a value that, in amperes, is between 5 and 25 times the battery capacities. The lower the discharge current, the lower the power loss, and therefore the higher the efficiency of the system. It is the increase in voltage and decrease in current that explains the use of voltage 24 V instead of 12 V, when placing "smart lights" at a significant distance from the solar mini-power plant.

11. Conclusions

The task of our research was to develop and study the public lighting system of the city of Gitega using mini solar power plants as a source of renewable energy. This project was designed taking into account the current state of the lighting in Gitega, the current global trends, as well as the great importance of public lighting in general and through photovoltaic solar power plants in particular such as: increasing the citizens' safety, reducing the number of crimes and offenses and increasing their detection potential, reducing cabling costs for transmission systems, reducing the burden on emergency services and electrical technicians. This public lighting system with an automated solar power plant will regulate energy consumption, monitor the integrity of the equipment and quickly send a signal to operating personnel on emergencies on the network. The current state of public lighting in the city of Gitega and its surroundings is poor due to the lack of financial resources needed using traditional energy sources. The development of such solar street lighting systems that would not require large investment costs, promote clean energy, reduce energy consumption and which maintenance would be carried out once or twice a year, is very relevant.

Conflict of Interest

The authors declare no conflict of interest regarding the publication of this paper.

ABSTRACT

Nowadays, robots are an important learning tool in education and are increasingly used inside and outside the classroom to foster the development of students' knowledge, skills, and attitudes connecting to a real-world situation. In past years, using robots in STEM (science, technology, engineering, and mathematics) education has been proposed as one of the strategies to integrate the different fields in order to construct more effective projects and innovations. Especially, engineering is the combination of math and science in solving a problem. Nevertheless, students could not understand and appreciate how to apply the knowledge of interdisciplinary integration to operate certain tasks by the engineering method. This research article presents STEM robot-based learning activities (STEM-RoLA) with sixty high-school students who were studying science and engineering. The obtained results show that the proposed STEM-RoLA is beneficial for students, especially when compared with high and low robotics performance students. The results found that high robotics performance students have higher computational thinking than low robot performance students, and they have a positive engagement response in the learning activity.

1. Introduction

At present, there is a proposal to increase robot usage in educational establishments undoubtedly because the robots have been integrated into the learning process to encourage students to think and connect to a real-world situation. Hence, using robots for education has gained a lot of attention from researchers and educators. This paper is an extension of work originally presented in the 7th International Congress on Advanced Applied Informatics (IIAI-AAI 2018) [1].

Nowadays, many studies focus on educational robots that help students develop essential skills inside and outside the classrooms that are significant in connecting the concept to real-life. Moreover, the learning activities were designed in consideration of promoting STEM discipline (Science, Technology, Engineering, and Mathematics) with a challenging learning mission in different situations [2]. Computational thinking (CT) is one of the essential core skills for students in the 21st century that is often regarded as the basic skill of computer science. CT is a kind of analytical thinking that uses the general way of thinking mathematically to solve real-life situations with scientific thinking [3]. The robot kit is a learning tool for use in the educational system, it is easy to use for students and enables them to have hands-on experience of activities and allows for a number of challenges for students to give them opportunities of robotics experience [4].

In the education context of Thailand, the students in high school have learned various subjects independently, such as Science (Physics, Chemistry, Biology, Mathematics), and Computer Programming. However, they may not understand how to apply the knowledge of interdisciplinary integration to perform or operate certain tasks in the engineering process [5].

The Thai government has attempted to push STEM education to enhance learning seamlessly for a new generation of students. Also, with the growing interest in STEM, educational robots have several benefits. Many educators have indicated that STEM integration would help enhance engineering students' learning performance with a flexible learning process. Besides, using

[*]Corresponding Author Sasithorn Chookaew, Faculty of Technical Education, King Mongkut's University of Technology North Bangkok, Thailand, Email: sasithorn.c@fte.kmutnb.ac.th

appropriate robotics-based STEM activities can be an effective way to introduce students' thinking to operate tasks systematically [6].

With the swift development of the field of robotics, it was proposed that robotics not only engage in active learning environments but also develop computational thinking knowledge and skills for students [7]. Of course, educational robotics was popular to bring an adaptive instrument for learning. Therefore, the robotics has been to promote STEM content, innovation, and creativity among students through an educational robotics competition [8].

This learning activity has integrated the benefits of robotics with the STEM education framework to promote senior high school students' computational thinking with the learning engagement process of students that was held outside the classroom for three days. This study aims at addressing the following research study:

- Do students who participate in STEM robot-based learning activities have computational thinking?
- What are the students' engagements in the STEM robot-based learning activities?

2. Literature Review Literature Review

2.1. Using Robots in Education

Robotics is a branch of engineering that includes a variety of subject matters that combine with STEM disciplines (science, technology, engineering, and mathematics). A robot is a machine applied in a variety of tasks such as industrial systems, medicinal purposes, and educational tools. Too many researchers state that educational robotics is a core element when STEM is a significant tool to integrate into the curriculum for students in the 21st century. A recent study has found that using a robot in education is increasingly being defined as an excellent instrument of teaching and learning that integrates STEM education, which is crucial for the future success of students [9].

Many studies proposed the benefit of an educational robot able to motivate students' learning with authentic learning activities based on real-world problems [10-11]. In [12], the author proposed robotic cooperative learning to promote students' critical thinking, and STEM interest indicates that students participating in robotic service-learning can benefit from this experience. Besides, robot hands-on activities can be easily adopted in classrooms to connect interdisciplinary core ideas for engineering design and STEM learning [13-14]. A robot in education can be used not only inside and outside of the classroom but also in meaningful learning activities for students as well.

Robotics makes the students able to connect and find relevance in the experience, together with the complexity of the global situation. So, it can be suggested that this is how to apply the concept of a robot for enhancing computational thinking skills.

2.2. Computational Thinking

The computational thinking basis concept of mathematics education research by Seymour Papert [15] proposed the aspects of computation that are: how to use computation to create new knowledge; how to use computers to enhance thinking and how to change patterns of access to knowledge. There is the basic concept that using technology can provide new ways to learn and teach with the logical thinking process. After that, computational thinking was described often by many researchers worldwide. In the last twenty years, computational thinking has become a fundamental skill for everyone in every field, not just for computer scientists, especially for students in the 21st-century who need skills such as analytical ability, reading, writing, and arithmetic to be processed systematically.

Based on the core concepts of computational thinking as a fundamental skill for everyone's analytical ability along with reading, writing and arithmetic, in [16], the author proposed that these should include decomposition, pattern recognition, abstractions, and algorithm design. In [17], the author classified computational thinking core components into three dimensions, including computational concepts which focus on the concepts that students employ when they are learning. Computational practices focus on problem-solving practices that occur in the learning process. Computational perspectives focus on the students' understanding of themselves and can connect learning with the world around them.

Measuring students' computational thinking is complicated, but it is a necessary task for understanding the effectiveness of the STEM-RoLA project. Our investigation focused on the implications of claims about three computational thinking dimensions consisting of computational concepts: the scientific concepts that students employ to learn and understand during activities, computational practices: problem-solving practices that occur in the learning process, and computational perspectives: students' understanding of themselves and the relationships between group members.

3. Methodology

3.1. Participants

The study was implemented in a public school in central Thailand. We selected a curriculum that prepares all students to be a scientist or an engineer. The participants in this study were sixty high school students, grades 10-12 (all males). The students were separated into twenty groups, so that each group had three members, and they learned and worked together in those groups.

3.2. Instruments

- The items in this observation checklist were developed to the three dimensions of computational thinking that cover all concepts of the robot activities including fourteen items: computational concept (4 items), computational practices (5 items), and computational perspectives (4 items). For this observation checklist, the mentors have rated the students on a 5-point Likert scale (1 = Failed, 2 = Passed, 3 = Acceptable, 4 = Good, 5 = Excellent). The scale validity was evaluated by five professors and teachers of educational robotics with more than seven years of experience. The internal consistency for the overall scale was 0.82.

- The items in this engagement questionnaire were adopted from a revised version in [5]. There are three dimensions of students' engagements after attending the robot learning activity that consist of eleven items asking about students' experiences toward STEM-RoLA. Three dimensions included behavioral engagement (3 items), cognitive engagement (4 items), and emotional engagement (4 items). The Likert scale is a five-point scale that allows the individual to express how much they agree or disagree with each item (1 = Strongly Disagree, 2 = Disagree, 3 = Neutral, 4 = agree, 5 = Strongly Agree). The internal consistency for the overall scale was 0.79.

3.3. Robot-based learning activity

The commercial robotic kits chosen in this study were mBot platform that operates and engages the students' learning experience of the mechanics, electronics, control systems, and computer programming [18]. The mBot is the easiest educational robot kit for student learning in robotics. The robot shape is easy to assemble and contains approximately 45 pieces in total, so students have a sense of achievement when they are able to assemble it quickly.

Normally, the components of mBot included the body, main control board, sensors, communication (Bluetooth), and power supply (battery). Also, it has three pre-set control modes of supporting student learning, consisting of obstacle avoidance mode, line-follow mode, and manual control mode. The students could feel that they had achieved and feel proud when they could program the mBot easily without writing difficult codes and language.

In addition, mBlock is a block-based coding platform for Scratch programming. It is easy-to-use software that makes teaching and learning coding fun and interactive. Scratch 2.0 is a very popular graphical logical programming software for teachers and students' learning. It has been proved to be one of the easiestto use graphical programming tool. Therefore, we have appled mBlock software to use Scratch coding to program Arduino and robots. Also, graphical programming is a visual programming technique where visual block connections are used for a student to code instead of texts, making it easy for non-coders to implement algorithms. It plays a meaningful role in enhancing computational thinking in the learning process.

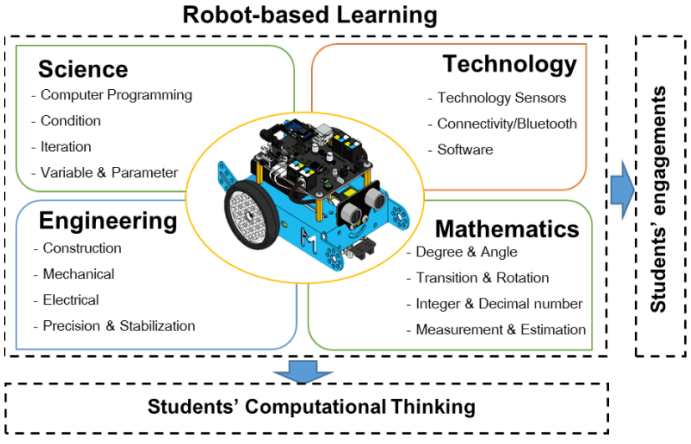

Figure 1: The STEM robot-based learning framework

Figure 1 shows the overall research of STEM-RoLA. We attempted to design the learning activity with STEM integrated. The students have learned about the mBot kits in a stepwise manner that describes its components with scientific understanding.

To achieve the tasks in this learning activity, students are encouraged to employ knowledge, skills, experience, and a teamwork process based on three dimensions of computational thinking:

- Computational thinking concepts, the students employ the knowledge when they code or control the robot for operating the mission and competition.
- Computational thinking practices, the students solve the problems that occur in activities: experimenting, iterating, and testing.
- Computational thinking perspectives, the students' understanding of themselves and their relationships with a group member.

Figure 2: The steps of STEM robot-based learning activity

To be an effective activity, we provide mentors who are pre-service engineering teachers. The mentor will help students while they work in a group during the activity. The mentors can provide

technical consultation and can be a source of support when students need it most. For the time being, each group has to come up with better solutions by integrating the knowledge of STEM and robotics, while their computational thinking is promoted accordingly.

The eight-steps to facilitate their learning process with hands-on experience lasts approximately twenty-one hours as follows:

- *Step 1: Robot introduction*: the first step addresses motivation to student-related robots that are important in daily life. After that, they introduce the functions of the robot and the introduction of the robot's components based on the engineering design process. At this moment, the students have to get acquainted with the robot components through several mini-labs such as the main control board, sensors, communication options (USB cable, Bluetooth, Wireless), and power supply (battery). In addition, the robot has three different modes of functionalities.
  - Mode A – Remote control driving or mobile device: the robot can be controlled by arrow buttons on the device to drive it forwards and backwards as well as to turn left or right.
  - Mode B – Obstacle avoidance: the robot is driven forward on its own until it detects an obstacle. If the robot detects an obstacle, it turns then continues driving forward.
  - Mode C – Line following: the robot drives forward while following a line
- *Step 2: Robot assembly:* The students were separated into twenty groups (3 students per group) then students of each group worked together. They can be learning at their own pace with support from the group mentor. This step requires students to get acquainted with each part and start to join each part together by robot function. Then, they learn three pre-set modes consisting of IR control mode, obstacle avoidance mode, and line-following mode. After that, they get the robot started by pressing on-board and push the button to change the mode.
- *Step 3: Primary programming*: the students can learn an easy programming language to control the robot. They use mBlock based on Scratch 2.0 software that is graphical programming for writing on a laptop or personal computer. The student receives the coding questions for programming practice. For example, how to control the robot to move forward or to turn left or right. They can drag the module block to move the robot area. During this step, the students in each group must analyze the facing proposition and situation in which they require to test-run-revise the code in a stepwise manner.
- *Step 4: Robot in the field:* the students from each group work together on the given tasks, a range of tasks designed to test the robot in the field. Each group has to adapt the physical robot as well as the programming instructions to overcome different challenges. This step is the basis for improving reliable robot working. The robot was assembled by students who programmed it to perform certain tasks and then there is the testing to operate, prove system functionality, and gain confidence that a system will perform as expected. Testing in the field also allows the student to learn the weaknesses, problems, and constraints of the robot and improve upon them.
- *Step 5: Robot mission:* the students learned to analyze and solve the problems in a logical way by taking the knowledge integration of STEM. The adjustment of one point will affect the related points. In this step, each group is faced with different problems in their robot's settings and programming. For example, the robot starts to move at a certain speed. When there is a barrier in front, the robot will turn right; when there is not, the robot keeps moving forward.
- *Step 6: Sharing:* The students have opportunities to share knowledge. What they have learned about each other helps build positive thinking. The representative student presents ideas to organize and control the robot to carry out each task in the missions. The students in each group help to justify the approach to solving the problems and present their ideas.
- *Step 7: Practice before the battle:* the students in each group have a rehearsal before the competition. They have analyzed and discussed opportunities and weaknesses to compete in the competition. This will increase their team's confidence in the final robot, while the final configuration may be needed. They receive the robot tasks for learning line-follow and obstacle avoidance and find a solution and strategy for solving the problem. For example, the students have learned how to program robots to take one step at a time. Meanwhile, students get to know the mechanical structure and understand how to control a robot.
- *Step 8: The robot competition:* the robot competition requires students to control the robot that makes learning robot programming simple and fun. The student members in each group are encouraged to apply knowledge of what they have learned to accomplish the goal effectively on the robot competition. There are two separate modes, including an autonomous robot following a task and a control robot via a mobile application on the Balloon Battle Game. They have to use the Makeblock open-source to control the robot with a mobile device, as shown in Figure 3.

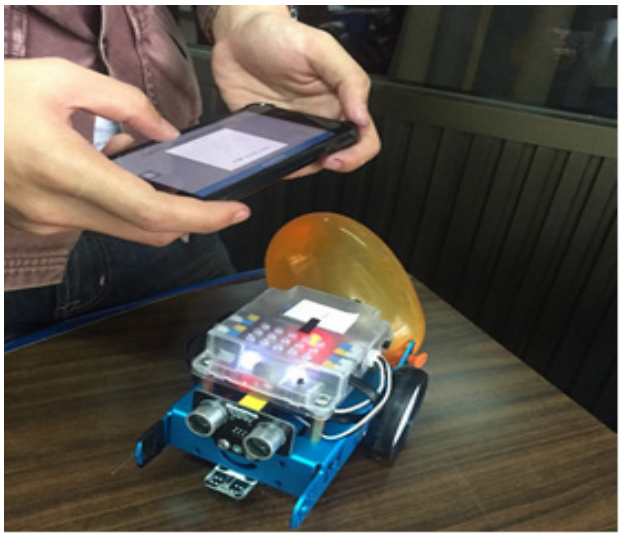

Figure 3: Illustration of a robot controlled by a mobile device

This moment is vital to each group since the robot's performance during rehearsal may be ineffective when competing with others. For this step, each robot has a needle and a balloon attached to the front and back of its body. Then each group's robot tries to stab the balloon's competitor while maintaining their

attached balloon. The loser is eliminated from the competition. For the final of the competition, each qualified group has ten minutes to come up with a better strategy for controlling the robot in a battle while maintaining their balloons. The last group to have a balloon at the end of the competition is the winner.

4. Findings

To understand better the effects of this part of the study, we compared the results with two separate groups of students' data consisting of a tasks score (30 points) and the robot competition score (70 points) total 100 points. Therefore, twenty groups demonstrated the difference between a high robotics performance group (HIRP) for the top ten groups with M=79.00 (SD =12.10) and a low robotics performance group (LORP) for the bottom ten groups. These were elaborated with M= 29.50 (SD =2.69). The findings related to the research questions were demonstrated.

4.1. The students' computational thinking

To analyze the differences between the students' robotics performances in two groups of three computational thinking components included computational thinking concepts (CTC), computational thinking practices (CTP), and computational thinking perspectives (CTPP), and these are shown in Table 1.

Table 1: Means and SDs of the students' computational thinking

CT Component	LORP		HIRP	
	M (SD)	***Remark***	***M (SD)***	***Remark***
CTC	4.01 (0.72)	Good	4.13 (0.22)	Good
CTP	2.88 (0.74)	Acceptable	4.75 (0.43)	Excellent
CTPP	3.25 (0.83)	Acceptable	4.13 (0.54)	Good

As the descriptive statistics in Table 1 show for the proposed STEM-RoLA in computational thinking concepts (CTC), both the HIRP and LORP students have concepts of the robot at a good level with M = 4.01 (SD = 0.72), and M = 4.13 (SD = 0.22), respectively.

Based on the results in computational thinking practices (CTP), the HIRP students performed tasks in each mission at an excellent level (M = 4.75, SD = 0.43), better than the LORP students at an acceptable level (M = 2.88, SD = 0.74).

Furthermore, in computational thinking perspectives (CTPP), the HIRP students tended to have positive perspectives at a good level (M = 4.13, SD = 0.22) while those who were LORP students, it was at an acceptable level (M = 3.25, SD = 0.83).

4.2. The term of students' engagements

The students' engagement results were analyzed based on quantitative and qualitative data for proposing STEM integrated robotics learning. We have presented three different aspects consisting of behavioral, cognitive, and emotional engagement as presented in Table 2.

In the first dimension, the HIRP students revealed behavioral engagement in that they could manage the function of members and have confidence in learning (M=4.63, SD=0.53). The entry indicated that the HIRP students were good at time management and working well together, as they expressed during the interviews, for example:

Table 2: Means and SDs of the students' engagements

Component	LORP		HIRP	
	M (SD)	***Remark***	***M (SD)***	***Remark***
Behavioral	4.32 (0.77)	Agree	4.63 (0.53)	Strongly Agree
Cognitive	4.47 (0.64)	Agree	4.45 (0.67)	Agree
Emotional	4.40 (0.71)	Agree	4.62 (0.51)	Strongly Agree

"Through this activity, we helped in my group about the coding program and explained to each other. I think I have learned a lot about cooperation and teamwork. I attend a robot activity with my friends, it made me have so much fun." (Student A)

"I am so excited about the robot because it is admirable to have this experience that I can construct a robot by myself. Besides, we have an opportunity to cooperate and share the ideas for working." (Student B)

While the LORP students had trouble with cooperating and working together, they did not enjoy learning in a group with members very much, and they had less time because they could not manage time (M=4.32, SD=0.77), for example:

"In my group, we have many members, so somebody does not involve in some activities. We can't organize the tasks and events on time." (Student C)

"I have less time to work on many tasks. It must spend a lot of time to solve the problems. Sometimes, I think I like to work without my friends." (Student D)

For cognitive engagement, the entry indicated that the HIRP students can reflect higher thinking skills on applications in their daily lives (M=4.45, SD=0.67), for example:

"I apply multiple tasking skills, and I can try when not sure. It is important to know how to employ the basic engineering principles for this activity." (Student A)

"For this activity, I think I have a thinking process and much knowledge I play it again when I come back home. Unfortunately, while I have learned a lot of programming, I never took any classes on robotics" (Student B)

While the LORP students just reflected what they had experienced from the activity by putting more effort before the success (M=4.47, SD=0.64), for example:

"I am upset about how to complete the work. However, I think I attempt to find the solution myself." (Student C)

"In the activity, I do not plan, it's not a success. I have attempted, but still failed, again and again, so I consulted the mentor." (Student D)

In the end, the HIRP students have emotional engagement. They enjoyed the learning activities (M=4.62, SD=0.51), especially the students in HIRP who have positive responses such as:

"I think it could be an interesting experience. I like to control a robot to follow my instructions. Each task, I am quite confident that a robot can do some pretty fun stuff." (Student A)

"I very enjoyed the activities in the activity because I think a robot can be a good assistant in the future. It helps me to be more productive in performing daily activities." (Student B)

On the other hand, the LORP students did not concentrate on some activities. However, they exposed their emotions towards the assistance of peer members in the group that could encourage them to proceed with the tasks. So, they have an attitude towards this (M=4.44, SD=0.71), as they expressed during the interviews, for example:

"I think a robot is difficult to use because it was always programmed. I'm running into a lot of infrared sensor issues. I'm attempt to do the typical line follower activity and also go ahead and stop when it finds a black line." (Student C)

"This activity was held during the semester. I have a lot of homework, so I don't concentrate on some activities. I think it should be held in my free time." (Student D)

There was unanimous agreement from the students present that, as a result of this robot activity, the students had significantly developed their computational thinking to solve the problems and challenges, their ability to work as a group, and their resilience. Also, students said they greatly enjoyed participating in the challenges and wanted more opportunities to participate in such STEM-RoLA.

5. Conclusions

Within Thailand's educational context, the integration of interdisciplinary knowledge to enhance crucial skills thinking, and a positive attitude are also important to realize goal. So the robotics STEM was integrated through active learning and the new learning tool has an effective strategy. The robotics challenges allow students to grasp the fundamentals of basic programming and develop their computational thinking with STEM education in an engaging way. The STEM-RoLA was held to motivate the senior high school students in three days (21 hours), consisting of eight steps in total, from robot introduction, assembly, programming, testing in the field, robot mission, sharing, practice before the battle, and final robot competition. The students established their robotics knowledge with hands-on experience based on the STEM strategy. Therefore, the obtained results show that the proposed STEM-RoLA is beneficial for the students, especially when compared with high and low robotics performance students. The results find that high robotics performance students have higher computational thinking than low robotics performance students. Also, they have positive engagement responses to the learning activity.

Nevertheless, the learning activities have shown that there are some limitations due to the availability of the school context, the information, and the educational context students already have before they learn robot information that might affect effectiveness. Also, the number of robot kits are quite expensive and inflexible to learning in some contexts. Future studies may explore whether there are specific learning strategies and learning tools that are particularly useful based on the attitudes of the students. Based on the result, the present research involved all males. So, future studies should clarify the results that can be described by gender differences in learning outcomes and assess the long-term effects on attitudes.

Dialdehyde starch
Hydrogels
Polyvinyl alcohol
Swelling
Controlled drug release

ABSTRACT

Starches have been applied as biomaterials due to their wide availability and biocompatibility. These have also been modified by oxidation, resulting in dialdehyde starch (DAS), to improve their stability in water and mechanical properties. Cassava starch with a low oxidation degree has been introduced into hydrogels based on polyvinyl alcohol (PVA) to improve their properties. However, the behavior of these materials with starch at different oxidation levels has not been previously explored. In the present work, the effect of the oxidation degree of cassava starch on the physical and chemical properties of DAS-PVA hydrogels was evaluated. To modify the degree of oxidation, different concentrations of H_2O_2 were used, and a high degree of oxidation was achieved by incorporating copper sulfate II as a catalyst. Oxidation was confirmed by quantification of carbonyl groups and Fourier Transformed Infrared Spectroscopy. Hydrogels with low and medium oxidation DAS displayed greater swelling, but also lower stability over time. Similarly, scanning electron microscopy confirmed greater porosity in them. On the other hand, hydrogels with high oxidation DAS had lower water absorption capacity, but greater stability over time. Regarding the controlled release of ibuprofen, as a model drug, hydrogels formulated with low and medium oxidation DAS presented a greater and faster release, compared to the formulations with high oxidation DAS. These results showed that the degree of starch oxidation, for the PVA-DAS hydrogel synthesis has a significant effect on the behavior of the polymeric network.

1. Introduction

Hydrogels are three-dimensional polymeric networks that are capable of containing significant amounts of water. They have been used in biomedical applications, such as tissue engineering and controlled drug release [1]. Furthermore, hydrogels have tunable biocompatibility, and respond to external stimuli such as pH, temperature, and concentrations of species, among others [2]. Thus, their porous structures are suitable for the encapsulation of drugs for a subsequent controlled release [3].

Hydrogels can be synthetized from virtually any water-soluble polymer, either natural or synthetic, such as alginic acid, pectin, carrageenan, dextran sulfate, chitosan, poly-lysine, and agarose [4]. Poly(vinyl) alcohol (PVA), is a hydrophilic, synthetic biodegradable polymer that has been widely used, due to its proved biocompatibility [5]. An additional benefit is that this polymer can be crosslinked physically, without the need of potentially toxic chemical agents . This can be achieved through freezing / thawing cycles, where the polymer in aqueous solution depending on its concentration and freeze cycles, form polymer microcrystals [1]. Nevertheless, since it is a petroleum derivative, PVA has limited availability. At the same time, in order to obtain stable structures, PVA concentrations must be high, up to 35% w/v, with molecular weights of 98000 Da or greater [2]. Therefore, its use poses an economical limitation for the creation of new technologies, especially in developing countries.

Starch, on the other hand, is one of the most abundant and cheapest polysaccharides [6]. It is comprised of two main molecules: amylose, a linear macromolecule composed of 250-300

[*]Corresponding Author: José Francisco Alvarez-Barreto, Email: jalvarezb@usfq.edu.ec

α(1→4)-linked-D-glucose, amylopectin, a less hydrophilic and branched macromolecule, and constitutes about 80% of the granular structure. To form starch hydrogels, it is possible to chemically modify its structure in order to have a greater number of functional groups [4,7]. Oxidation, for example, breaks the long glucose chains of the polymer molecules, replacing the hydroxyl groups for carbonyl and carboxyl groups . This results in reduced viscosity [8]. In drug-release applications, integrity and stability in a humid environment are required over a relatively long period of time. It has been shown that the use of dialdehyde starch (DAS), resulting from oxidation, exhibits a substantially lower solubility in water, making it more suitable for this application [9].

In [9], the authors developed protein-based films with dialdehyde starch (DAS), PVA and feather keratin. They found that if DAS was not added, an increase of the PVA concentration in the blended films resulted in a slight decrease of the film's solubility in water. By adding 5% of DAS, the total solubility mass of the film was reduced, which indicates an increase in the degree of cross-linking.

The most commonly used modifier in starch oxidation is hypochlorite, but despite being chemically efficient, it results in the formation of chlorinated products, that could potentially be toxic [10]. Several comparative studies have been carried out on the properties of starches at different degrees of oxidation with hypochlorite[10]; nevertheless, no comparative study is found in the literature on the effect that hydrogen peroxide has on different degrees of oxidation in cassava starch, and thereby in the formulations of hydrogels [11].

In [12], the authors synthesized hydrogels based on PVA and modified cassava starch as carriers for controlled drug delivery. In this research, the oxidation of starch was done with sodium hypochlorite solution containing 5% active chlorine. The hydrogels synthetized with DAS/PVA, showed an enhanced stability in water; nevertheless, the oxidation degree was maintained constant through the entire research. However, it has been demonstrated that, for other biomaterial applications, starch oxidation degree has important implications, such as bioplastics, in material behavior [13,14]. For this reason, the present study proposes to determine the effects of the oxidation degree of cassava starch on the physical and chemical properties of DAS-PVA hydrogels.

2. Materials and Methods

2.1. Chemical materials

Cassava starch was obtained from Ecuador's local stores. Hydroxylamine hydrochloride (ACS Reagent Grade, 5470-11, ACROS Organics), Poly vinyl alcohol (PVA, Mowiol 28-99, MW 145000, 99.0-99.8 mol% hydrolysis, Millipore Sigma, Cat. 10849), Sodium Phosphate, Dibasic, Anhydrous (3828-01, J.T.Baker), Potassium chloride (6858, Mallinckrodt), di-Potassium hydrogen phosphate, anhydrous GR for analysis (1.05104.1000, MERCK), Ibuprofen (≥98% GC, Millipore Sigma, Cat. I4883) were used as received.

2.2. Starch Oxidation

Starch oxidation was performed with hydrogen peroxide (H_2O_2), through adaptation of the methodology proposed by [15]. Briefly, H_2O_2 solutions at 3, 5 and 10% v/v were prepared in distilled water. For the chemical modification, a 2% w/v solution of starch in distilled water was gelatinized at 80ºC for 30 minutes, under moderate stirring. Later, the solution was cooled until room temperature, and its pH was adjusted to 7. For every 2g of gelatinized starch, 6.25mL of H_2O_2 solution were added,, drop wise during 1h at 25ºC, under continuous stirring, maintaining pH at 7.0. When the oxidation process was done, an equal volume of 70% v/v ethanol was added, and starch precipitation was allowed for 1 hour. The supernatant was discarded, and the remaining mixture was centrifuged at 1000g for 5 minutes. Five rinsing cycles were carried out with diH_2O, in a similar fashion. The resulting dialdehyde starch (DAS) was dried at 40ºC until constant weight.

To obtain a high degree of oxidation DAS, copper (II) sulfate was used as a catalyst, as proposed by [16]. Starch was gelatinized with the same methodology described above. Before adding the H_2O_2 solution at 10% v/v, the catalyst was incorporated at 0.1% w/v, and the reaction was allowed to take place for 1 hour at 25 ºC. Subsequently, precipitation and washing were done as previously mentioned.

2.3. Starch characterization

Carbonyl groups were quantified based on the method proposed by [17], with some modifications. Briefly, 1g of DAS was mixed with 25mL of distilled water, gelatinized at 80ºC under constant stirring, and then, cooled at room temperature. The pH was adjusted to 3.2, and, immediately, 3,75mL of hydroxylamine hydrochloride (25g of hydroxylamine hydrochloride in 100 mL of NaOH 0.5M in a 500mL solution) were added to the gelatinized solution, with subsequent incubation at 40ºC for 4h. A potentiometric titration followed, with 0.1M HCl until pH 3.2. The amount of carbonyl groups per 100 glucose units (CO/100GU), was calculated through equation 1:

$$\frac{CO}{100GU} = \frac{(Vb-Vs)\times M\times 0{,}028\times 100}{W} \quad (1)$$

where, Vb and Vs are the volumes (mL) of HCL used to titrate the blank (native starch) and the oxidized starch, respectively; M is the molar concentration of HCl (mol/L), and W is the weight of the sample on a dry basis (g).

On the other hand, carboxyl groups were determined using the protocol proposed by [15]. Briefly, 1g of DAS was suspended in 60mL of distilled water, gelatinized and cooled, as previously mentioned. Later, a potentiometric titration took place until pH 8.2, using NaOH 0.01M. The amount of carboxyl groups per 100 glucose units (CO/100GU), was calculated through equation 2:

$$\frac{COOH}{100GU} = \frac{(Vs-Vb)\times M\times 0{,}045\times 100}{W} \quad (2)$$

where, Vs and Vb are the titration volumes (mL) of the oxidized starch and the blank (native starch), respectively; M is the molarity of NaOH (mol/L), and W is the sample weight (g).

2.4. Hydrogel preparation

Hybrid hydrogels with Polyvinyl Alcohol (PVA) and dialdehyde starch were synthetized through a freezing/thawing method, by adaptation of the protocol reported by [2]. The

common protocol for the preparation was to completely dissolve PVA in distillated water under continuous stirring at 95ºC, at 20% w/v. In parallel, a starch suspension, at a given concentration, was gelatinized as previously mentioned. Both solutions were then mixed at a 1:1 ratio in a vortex homogenizer, with alternation with heating in a water bath at 70 ºC, for a total time of 30 min. Then, 5 mL of the polymeric mixture were poured into 1-inch petri-dishes.

Crosslinking was induced through freezing/thawing cycles; the polymeric mixture in the petri dish was frozen at -20ºC for 12 h, followed by thawing at 25ºC for 3h. Table 1 specifies the variables that were modified for the different conditions of hydrogel preparation in order to identify the formulations that could be suitable for the subsequent ibuprofen encapsulation and release. It was decided to vary the number of freeze/thawing cycles because through every cycle, there is a formation of microcrystals through the polymeric network, allowing a high crosslinking degree. Consequently, after thawing, the mixture was frozen again, and this process was repeated according to the chosen number of cycles. Since one of the objectives of this research is to partially substitute the amount of PVA in hydrogels formulations, the final concentration of the latter was maintained constant at 10% w/v. Hydrogels with native starch were used as controls.

Table 1: Variables for the synthesis of hybrid DAS/PVA hydrogels

Variable	**Values (nomenclature)**		
Oxidation degree ($\%H_2O_2$)	3 (3DAS)	5 (5DAS)	10, 10* (10DAS, 10DASC)
DAS concentration (% w/v)	5	10	15
Crosslinking cycles	1	2	3

*Copper (II) sulfate was added to obtain high oxidation DAS

According to the protocol described by [18], after crosslinking, hydrogels were cut in 5mm diameter discs, and placed in 24-well plates with 2mL of 1X phosphate buffered saline (PBS, pH 7.3), in an incubator, at 37ºC. The hydrogel weight was registered at 0, 5, 15, 60 min, 2, 3, 4, 5, 24, 48 and 72h. Water-uptake was calculated according to equation 3.

$$Water-uptake\ (\%) = \frac{(W_t - W_1)}{W_1} \times 100 \quad (3)$$

where W_1 is the initial weight of the hidrogel, and W_t its weight at a given time.

2.5. FTIR Analysis

Analyses were conducted in a Fourier transformed infrared spectrometer; model Cary 630 FTIR-ATR (Agilent Technologies) for the native and oxidized starches, as well as for the different hydrogel formulations [15]. Spectra were acquired in the region of 4000-500 cm-1.

2.6. Scanning Electron Microscopy (SEM)

Hydrogel morphological analyses were carried out in a JEOL JSM-IT300 Scanning Electron Microscope (Tokyo, Japan) with lyophilized hydrogels. Samples were cut and placed on metallic stubs with carbon tape. Images were obtained at 5kV and 50 Pa, at different magnifications..

2.7. Ibuprofen encapsulation and release

Ibuprofen was incorporated into the hydrogels at a concentration of 10 mg/mL, as proposed by [18], by adding the drug into the PVA solution at 50ºC. The same process described above for hydrogel preparation was followed. The release was performed as previously described [18]. DAS/PVA hydrogels with ibuprofen were cut into 5 mm diameter and placed in 2 mL of PBS at 37 ºC. Later, 400 µL of supernatant were collected and replaced with fresh PBS at 15, 30, 60, 120, 180, 240, 300, 360 min, 24, 48 and 72 h. Four samples of each hydrogel formulation were tested for Ibuprofen release.

Each supernatant was placed in 2.6 mL of PBS, in a quartz cuvette, and the optical density of this final solution was determined at 222 nm in a CECIL CE 2041 UV-VIS spectrophotometer. The sample concentration was calculated with a calibration curve done with known solutions of ibuprofen in PBS. The release kinetics was expressed as the percent cumulative release of ibuprofen over time.

2.8. Statistical analyses

All assays were performed with three samples of each formulation, and four in the case of ibuprofen release. The results are expressed as the average ± standard deviation. A two-way analysis of variance (ANOVA) was also applied, and multiple pairwise comparisons were carried out using Turkey-HSD, with a 95% confidence level ($p<0.05$).

3. Results and discussion

3.1. Oxidized starch characterization

Carbonyl and carboxyl contents of native and oxidized starches (dialdehyde starch, DAS) with low and high degrees of oxidation are shown in Table 2. It can be observed that carbonyl was the primary functional group produced during the oxidation process, whereas, a significantly minor amount of carboxyl groups was formed. It has been reported that the reaction mechanism of hydrogen peroxide with starch proceeds via a radical chain reaction [19] . It is more evident in dialdehyde catalyzed starch with copper sulfate, since, in the presence of the metal catalyst, the H_2O_2 is decomposed into a hydroxyl radical. Then, this radical rapidly reacts with the carbohydrate by eliminating hydrogen from a C-H group on the sugar ring, forming a R*CHOH radical, which further undergoes acid or base catalyzed rearrangement resulting in the cleavage of the glycosidic bond and formation of a carbonyl group [19].

One assumption that the authors in [19] proposed, is that the reaction between starch and hydrogen peroxide is so rapid that the major quantity of reagent was consumed for hydrogen abstraction, affording high amounts of carbonyl groups during the early period of time; therefore, less oxidant was available for the oxidation of

carbonyl to carboxyl groups. At the same time, the reaction time on the current research was stablished at one hour; which is in accordance with the literature since it has been shown that the oxidation of hydroxyl groups in starch molecules by H_2O_2 was almost completed within the first 30 minutes.

Table 2: Carbonyl and carboxyl contents of dialdehyde cassava starch at different oxidation levels

H_2O_2 Concentration (%v/v)	Carbonyl content [CO/100 GU]	Carboxyl content [CO/100 GU]
3	0.255 ± 0.091	0.046±0.010
5	0.419 ± 0.124	0.034±0.009
10	0.209 ± 0.108	0.052±0.010
10 (Catalyzed)	2.875 ± 0.089	0.025±0.003

GU: Glucose units

Oxidation degree is determined by carbonyl and carboxyl content. The relatively bulky carbonyl and carboxyl groups are introduced with a partial depolymerization of the starch chains; for this reason, the determination of these values shows the degree of oxidation degree. A major carbonyl content is an indication of a higher oxidation degree [20].In this study, a low degree of oxidation will be considered as having a carbonyl content of less than 1CO/100GU; thus, all starches oxidized without catalyst will be within this category.

3.2. Hydrogel morphological analyses

It was important to evaluate hydrogel morphology as it can have important implications in swelling behavior and controlled released, for which a porous structure is desired. Lyophilized hydrogels with the same compositions, but different DAS are presented in Figure 1. Natural porous materials have no uniform porosity; rather, it is distributed allowing to maximize the overall performance of the structure [21]. For drug delivery applications, a balance between adequate porosity and mechanical stability is required.. At comparing the different images, it is possible to recognize that hydrogels with low oxidation degree have flatter and larger pores; while, in high oxidation DAS, the pores seem to be smaller and rounded. There is clear indication that pore arrangement is altered by the incorporation of starch, and that the oxidation degree further influences pore morphology and structure. Additionally, PVA only hydrogels (without starch) appeared to less porous.

Hybrid hydrogels composed with hydrophilic-hydrophobic polymers have been reported previously in literature. It has been shown that one of the major issues in obtaining porosity is due to the intrinsic immiscibility of hydrophilic (i.e. PVA) and hydrophobic (i.e. DAS) polymers, which, in turn, affect pore structure, and potentially, distribution..

3.3. FTIR analysis

The Fourier transformed infrared absorption spectra of lyophilized hydrogels composed with 10% w/v PVA and 10% w/v starch is presented in Figure 2. In the case of FTIR spectra for different hydrogel formulations with oxidized starch, there is a decreased intensity. As previously reported in the literature, this lower intensity corresponds to crosslinked polymer structures, probably associated with a major bond vibration restriction [22]. A stretching band can be observed at 2850 cm^{-1} due to C-H broad alkyl. Another lower intensity stretching is because of the strong-OH group band for free unreacted alcohol and hydrogen bonded bands at 3600-3200 cm-1, which are associated with freeze-thawed PVA [23]. As expected, the peak of dialdehyde starch appears at 1630 cm^{-1} - 1710 cm^{-1}, due to C=O and C=C stretching frequency groups that are present in DAS [24].

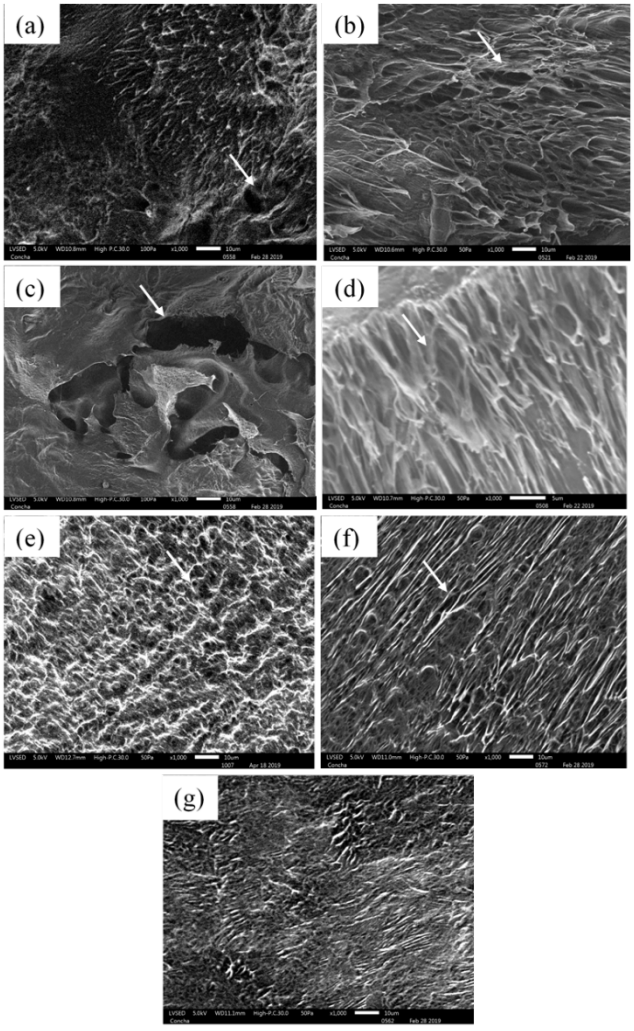

Figure 1: Scanning electron micrographs of lyophilized hydrogels composed of 10% w/v PVA, 10% w/v Starch and 1 crosslinking cycle: (a) NS, (b) 3DAS, (c) 5 DAS, (d) 10 DAS, (e) 10DASC, (f) Solely 20% w/v PVA and (g) Solely 10% w/v PVA. Calibration bar: 10 µm. Figure 1d was reported at 3000X (Calibration bar: 5 µm) in order to better observe the porous structure.

When comparing the spectra of hydrogels composed solely with PVA to hybrid hydrogels, there is lower intensity absorbance in the different bands; nevertheless, those associated with -OH groups, could be related to a strong interaction between both polymers forming a tight network, as suggested by [22]. PVA addition enhances the elasticity of hydrogels, which is corroborated by the increased intensity of the C-H stretching

absorption band at 2031 cm-1, and the C-C stretching vibrational band at 1200-1400 cm^{-1} [25].

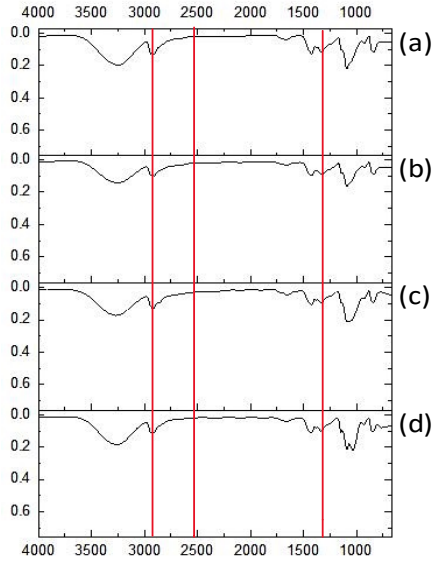

Figure 2: FT-IR spectra of lyophilized hydrogels formulations with 10% w/v PVA, 10% w/v starch and 1 crosslinking cycle: (a) Native starch, (b) 5DAS, (c) 10DAS and (d) 10DASC.

3.4. Hydrogel Water-uptake

Hydrogel water-uptake, or swelling ratio, is one of their most important characteristics, since this parameter is directly related to drug release mechanisms, as well as structure stability in aqueous media [1]. Water uptake capacity (%) of the different hydrogel formulations specified in table 1 are presented in Figure 3 through 5, where PVA composition remained constant at 10%. All assays where performed at 37ºC in PBS to emulate physiologic conditions. Since one of the objectives of this research was to partially substitute the weight/volume percentage of PVA in hydrogels formulations, it was necessary to compare the water-uptake percentage vs. time, according to hydrogels composed solely with PVA. In general, it was observed that 1 crosslinking cycle presented the largest swelling capacity; nevertheless, they showed the lower stability in time, with important swelling reduction toward the end of the assay. Two and three crosslinking cycles exhibited similar behaviors. At the same time, by increasing the quantity of PVA, hydrogels displayed greater stability (data not shown).

According to the analysis of variance, hydrogel formulation (both starch content and oxidation degree), number of crosslinking cycles and time had significant effects on water uptake ($p<0.05$). Figure 3a shows the swelling kinetics of hydrogels with 15% starch. There were no statistical differences between native and low oxidation DAS (3, 5 and 10DAS), which displayed fast water uptake, with important fluctuations over time with one crosslinking cycle. This could be due to degradation effects that, ultimately, become relevant, as the swelling decrease after a maximum at 48h. When increasing the number of cycles (Figure 3a and b), however, these fluctuations become less apparent, and decreases in water uptake are lower. These changes could indicate an improvement in hydrogel stability. In the case of 10DASC, on the other hand, had rapid swelling and seemed to reach equilibrium after 15h. This high oxidation DAS resulted in significantly lower swelling than the other formulations; moreover, this parameter tends to decrease with greater number of crosslinking cycles.

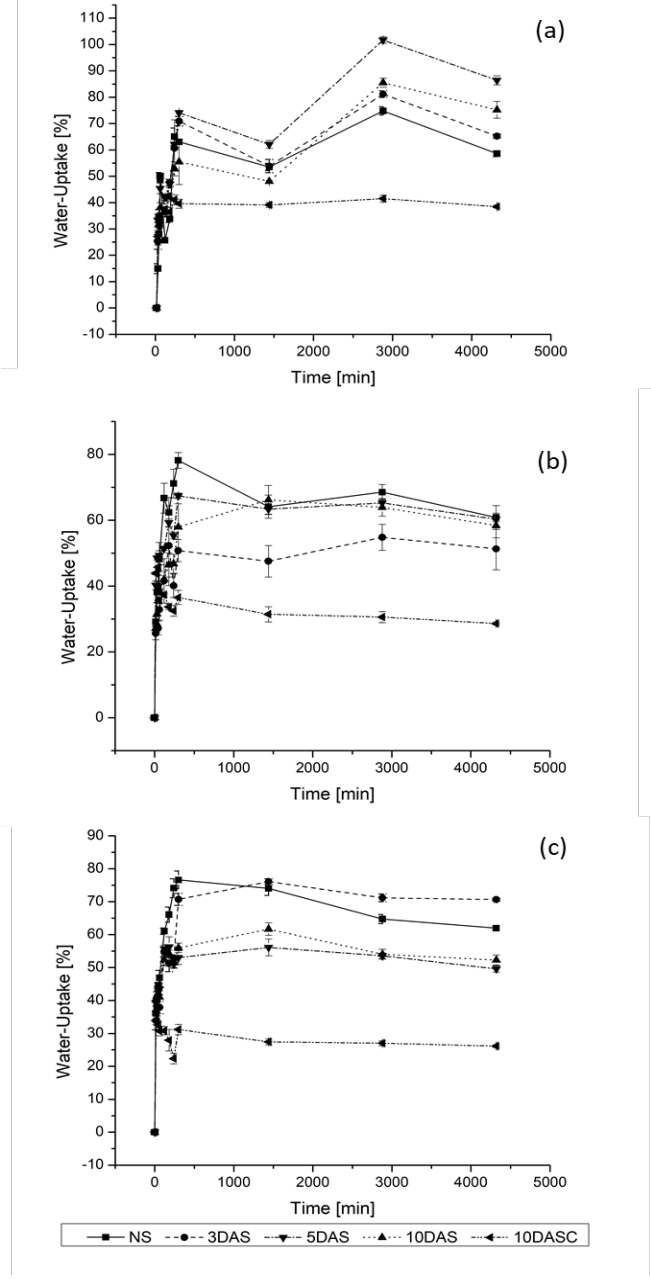

Figure 3: Swelling kinetics, expressed as water uptake percentage in time, for hydrogels composed of 10% w/v PVA and 15% w/v starch, either native (NS) of dialdehyde (3DAS, 5DAS, 10DAS and 10DASC). Formulations with (a) one crosslinking cycle, (b) two crosslinking cycles, and (c) three crosslinking cycles.

Figure 4 shows water-uptake capacity for hydrogels with 10% starch, in which, after an analysis of variance, it is determined that formulation and time affect water-uptake percentage ($p<0.05$). Once again, the major water-uptake is obtained with one freeze-thaw cycle. The stability in this case is significantly reduced in comparison with Figure 3(a), where hydrogel degradation, regardless of formulation, begins at 240 min until 72h. After the

statistical analysis, it was confirmed that oxidation degree had a significant effect on swelling ratio ($p<0.05$); nevertheless, there is not a clear pattern in the way the amount of carbonyl groups affects the swelling degree.

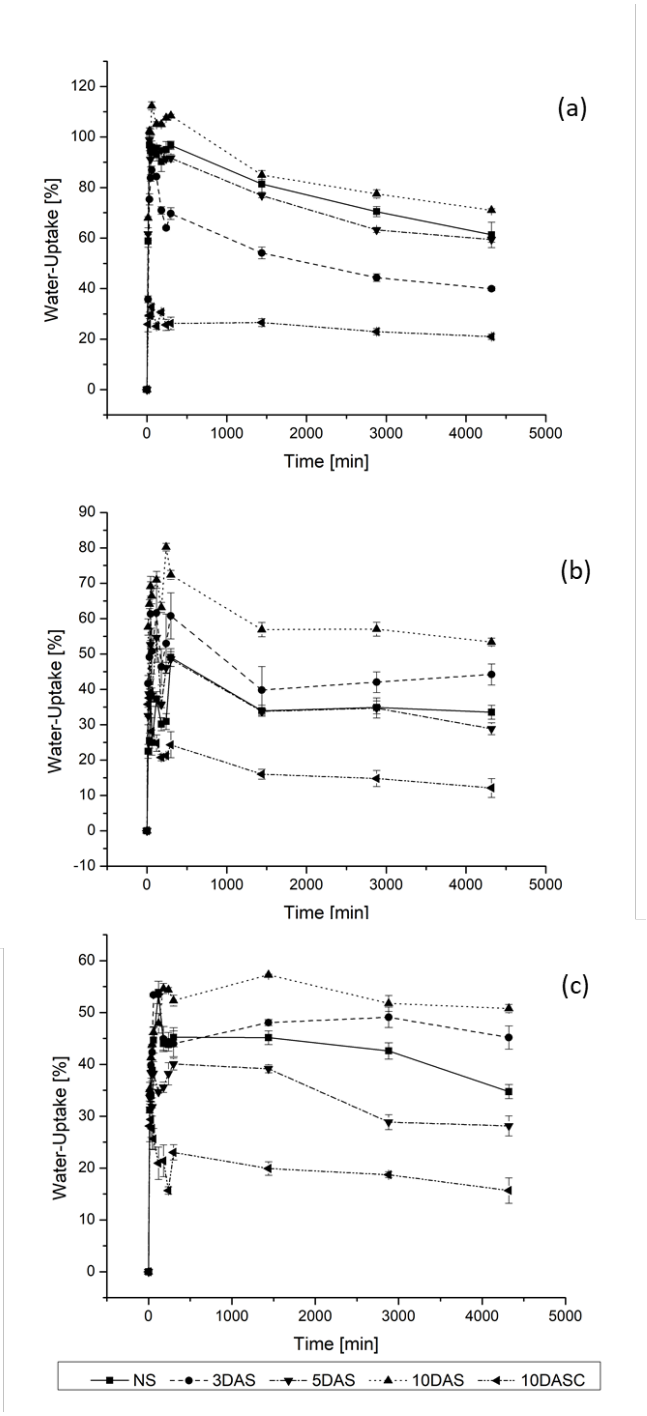

Figure 4: Swelling kinetics, expressed as water uptake percentage in time, for hydrogels composed of 10% w/v PVA and 10% w/v starch, either native (NS) of dialdehyde (3DAS, 5DAS, 10DAS and 10DASC). Formulations with (a) one crosslinking cycle, (b) two crosslinking cycles, and (c) three crosslinking cycles.

Figures 4(b) and (c) show a more accurate pattern within the effect of DAS, where starch with lower carbonyl content presents the greater swelling degree. After a Tuckey comparison on values of Figure 4(b), all the formulations are significantly different between them; nevertheless, the greatest water uptake was obtained in formulations with 3DAS and 10DAS, which agrees with lower carbonyl content. At three freeze-thaw cycles, Figure 4(c), Tukey analysis shows that there is not a difference between formulations with 3% DAS and 10% DAS. In all cases, the way time affects swelling degree, establishes an equilibrium tendency up to 72h. Finally, the number of cycles does affect hydrogel response, being inversely proportional to the swelling degree. However, the swelling degree within a time greater than 24 h, is not statistically different between formulations with 2 and 3 freeze-thaw cycles.

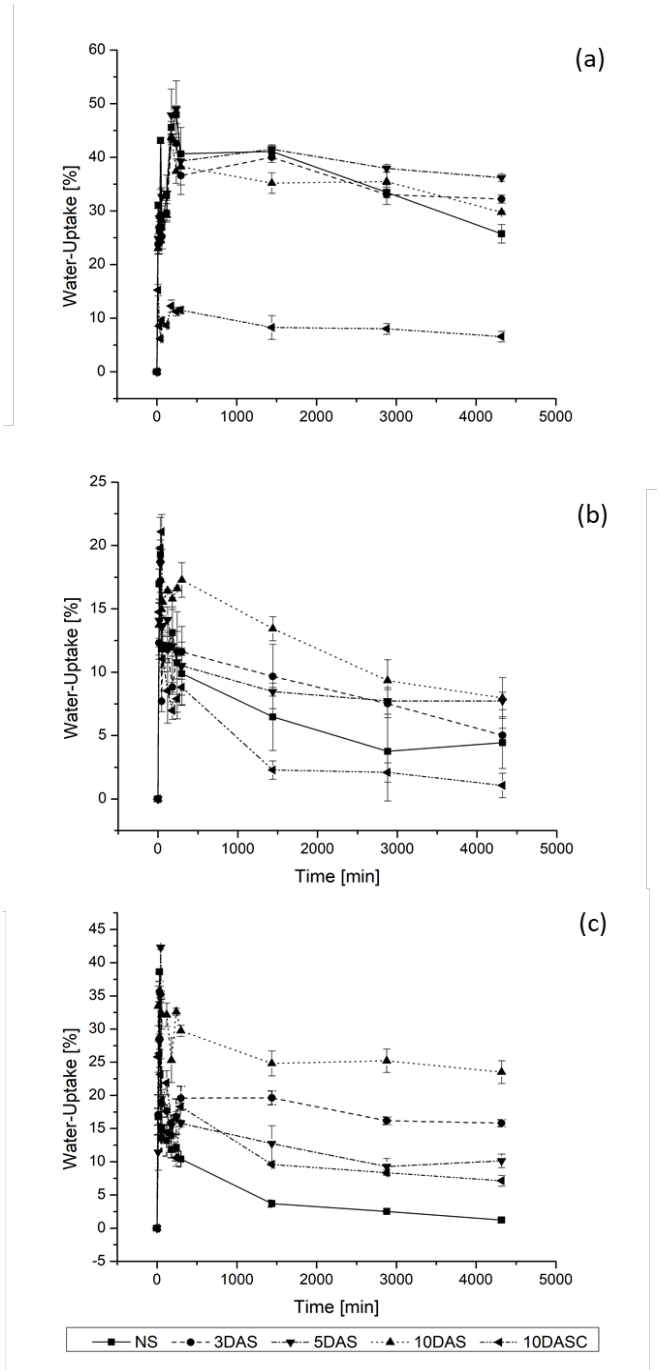

Figure 5: Swelling kinetics, expressed as water uptake percentage in time, for hydrogels composed of 10% w/v PVA and 5% w/v starch, either native (NS) of dialdehyde (3DAS, 5DAS, 10DAS and 10DASC). Formulations with (a) one crosslinking cycle, (b) two crosslinking cycles, and (c) three crosslinking cycles.

By comparing hydrogels with 15% and 10w/v starch (Figures 3 and 4, respectively), there are clear differences. The greater water-uptake in the first case is presented at 300 min; while, for the latter, this value is obtained at 180 min. There is a major hydrogel degradation within the first 24 h at a lower starch content. These results suggest that oxidized starch content affects swelling.

Finally, swelling kinetics for hydrogels formulations with 5% starch are shown in Figure 5. Considering factors such as formulations and number of cycles, swelling degree in all cases was considerably lower, compared with 15 and 10% starch (Figures 3 and 4), due to the decrease of polymer content in the structure. The statistical analysis resolved that there is not a significant variation on swelling, considering the formulation of the hydrogel as a swelling response. At this low concentration of starch, there is not a clear pattern on the effect of the oxidation degree on swelling, which could be due to a predominant effect of PVA, independent of the starch´s characteristics.

Literature shows that starch oxidation affects the surface in the granule by increasing the porosity and presence of holes in the structure [20,26]. This could explain the reason behind a large water-uptake in hydrogels formulations with dialdehyde starch. Even if there is a significant presence of hydrophobic groups in modified starch, this porosity helps hydrogels to increase not only their swelling degree, but also their stability during a period of time.

After the statistical analysis, it was possible to show that there is a major increasing swelling degree during the first 5 hours in hydrogels with a lower carbonyl content; which agrees with previous literature reported by [27]. According to previous works, higher PVA composition would result in hydrogels with lower swelling ratio due to its higher degree of crystallinity [25]. Nonetheless, the opposite effect occurs after the addition of dialdehyde starch. In [28], the authors reported that oxidation occurs mainly in the amorphous lamella of the semi-crystalline growth rings in starch granules. They evaluated the effect of different degrees of oxidation with sodium hypochlorite on bean starch. A higher carbonyl content in dialdehyde bean starch resulted in a decrease of the crystallinity, suggesting that the amylopectin chains were damaged and therefore, there is a degradation of the crystalline region. The conclusion proposed in the current research behind the large water-uptake of hydrogels composed with PVA and dialdehyde starch, is due to the significant presence of less crystalline polymer.

An important fact about dialdehyde starch at a high oxidation degree was evidenced through a Tukey analysis. The way in which time affects swelling degree, in all cases, follows a tendency in which water uptake within the first hour is rather high. Suddenly, there is a significant de-swelling until 240 min. Beyond this time, hydrogels exhibit stability. In [10], the authors reported that at higher carbonyl content, the crystallinity decreases, and at a certain point, starch structure becomes amorphous. It can be assumed that this de-swelling is due to the less crystallinity arrangement, even though, there is stability during times greater than 240 min.

Finally, swelling degree is related with the porosity of hydrogels, evidenced through the scanning electron micrographs of lyophilized hydrogels. As presented in Figure 1, oxidation degree does affect the morphology of hydrogels, by allowing flatter and seemingly larger pores in the case of modified starch at a low oxidation degree. The behavior according to porosity and swelling degree is as expected, since 10DAS presents not only large porosity, but also greater water-uptake; unlike, 10DASC, which exhibits a lower porosity and so was the swelling degree with these formulations.

3.5. Ibuprofen release

Hydrogels have sparked interest in drug delivery applications due to their porous structures, that assists drug loading in the polymeric matrix, for a subsequent sustained release. In the present work, ibuprofen was used as a model drug that can give insights into potential applications for other non-steroidal anti-inflammatory drugs (NSAIDs). In this case, control hydrogels were done at 20% PVA, since those at 10% were rather unstable and disintegrated quickly. According to ANOVA, ibuprofen release was significantly affected by composition, time and number of freeze-thaw, or crosslinking, cycles. Release assays are presented in Figure 6.

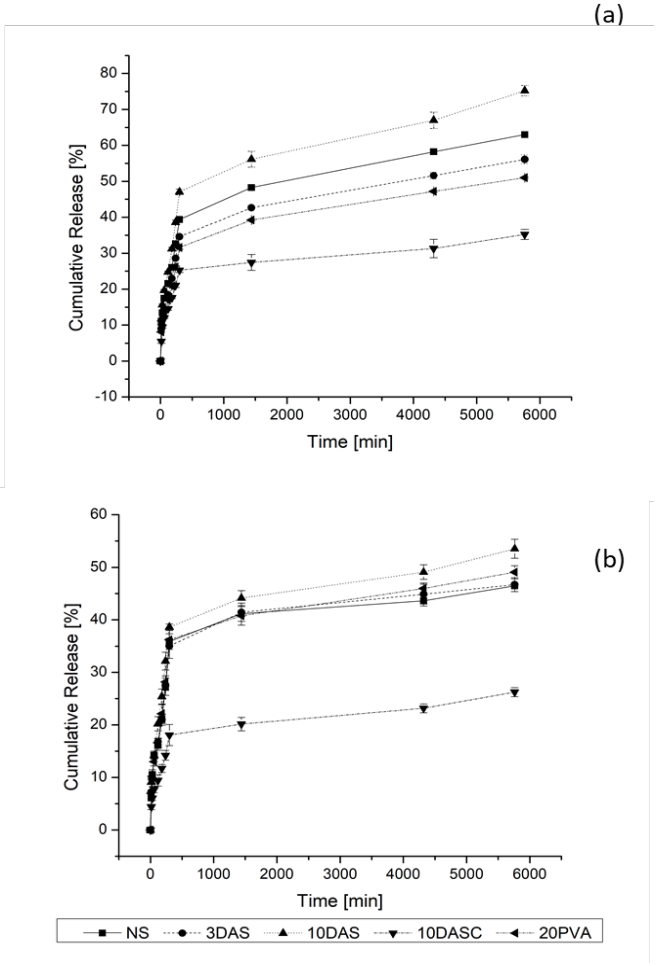

Figure 6: Ibuprofen cumulative release profiles from hydrogels with 10% /v PVA and 10% starch at different oxidation levels. Only PVA at 20% was used as control. (a) One crosslinking cycle and (b) Two crosslinking cycles.

For all formulations, there was a fast release in the first 6 hours, followed by small, not statistically significant, increases, indicating a tendency toward equilibrium. In hydrogels with one crosslinking cycle (Figure 6a), there is a very similar ibuprofen

profile in every hydrogel formulation. After Tukey comparison, it was shown that formulations with native starch, 3DAS, 10DAS and solely 20% PVA have no significant differences between them. Interestingly, hydrogels with native starch and low oxidation DAS displayed greater swelling, and some degradation that played an important role in the release. Hydrogels with 10DASC, on the other hand, did present significantly lower cumulative release at every time point. All these previous formulations exhibit the same behavior; the largest drug release was performed within the first 6 hours of contact with PBS; and, there is an equilibrium tendency at 72h.

Values of ibuprofen release in hydrogels with two crosslinking cycles, Figure 6b, were significantly affected by formulations and time. Again, Tukey comparisons indicated that formulations with 3DAS, 10DAS and solely 20% PVA are similar among them, representing the formulations with largest drug release percentage. Similar to what occurred with one cycle, 10DASC resulted in hydrogels with the lowest levels of release. This time, nonetheless, values of cumulative release were lower than those found with one crosslinking cycle, which relates to the lower swelling capacities found at greater number of freeze-thaw cycles. Moreover, there was a tendency to a more sustained release, possible due to the greater stability provided by more crosslinking

When comparing Figures 6a and b, it is possible to affirm that as presented in literature, the high-water content of hydrogels results in an increased release of drugs from the polymeric matrix [3]. This is confirmed by the statistical analysis. The tendency in both cases is that hydrogels with 10DAS exhibit the largest drug release, and the lowest is attributed to those with 10DASC.

In hydrogels, the rate of drug diffusion through the polymeric structure depends on the extent of cross-linking. Converting the ensemble of individual polymer chains into a macromolecular network allows the water diffusion into the interstices of the network. Comparing Figures 6a and b, there is indication that the extent of cross-linking minimizes the swelling and, thereby, the diffusion of the drug. The reason behind this behavior is due to the fact that ibuprofen is an entrapped drug, and the rate of diffusion depends on the interchain separation and the size of the diffusing drug [29].

4. Conclusions

The oxidation degree of cassava starch has important effects on the properties of hydrogels with PVA, particularly at larger carbonyl contents. At a low oxidation degree obtained with 10% v/v H_2O_2 and 3% v/v H_2O_2, hydrogels showed the major suitable characteristics of hydrogels for drug delivery applications, since the water-uptake percentage was higher, as it was drug release. Considering hydrogels formulations with DAS catalyzed with copper sulfate (II), and the largest carbonyl content, there was a significant reduction of water-uptake through the polymeric structure, due to strong intermolecular bonds, which resulted in a reduced swelling degree, but, as expected, those showed the major stability during time, proving an improved stability in physiological environment. It is possible that, for the latter formulation, the hydrogels could be more appropriate for tissue engineering because, given that they do not swell significantly, their mechanical properties could be superior to those that presented higher swelling ratios. Additionally, being more stable in time, they could potentially meet mechanical demands for longer periods, and we recommend doing this assessment in future studies.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

The huge number of images on the image sharing websites poses challenges for classification and retrieval of the images. On many image sharing websites, tags can be assigned by the users to an image that describes the contextual and visual description of an image. However, ambiguous or incorrect tags have appeared in frequent tags that affect the performance of an image retrieval system. Thus, assigning appropriate tags to the images plays a very important role in image retrieval and classification. In this paper, the ITR-WTF image tag recommendation method is proposed which explores tags from ranked nearest neighbors of each category. For a given input image, the method first determines the neighbors from training images of each category and ranks the neighbors according to the distance from the input image. In the second step, the weight is assigned to each tag based on the vote from each neighbor. Finally, the weighted tag frequency is determined to recommend appropriate tags to a given image. The experimentation is done on two datasets self-generated and NUS-WIDE. The results obtained using the proposed method ITR-WTF gives good results as compared with the existing methods of tag recommendation.

1. Introduction

The rapid development of advanced technology and the high usage of social media have created a large repository of images which poses many challenges for an image retrieval system. On many image sharing social websites, the users are uploading images for faster communication or to find the people with the same interest. The images on the image sharing social websites are associated with the tags which are assigned by the users. The tags describe the visual content of the images along with the context information such as the location and time the images are captured. These tags are used indexing during an image search. Thus, tags play a very important role in tag-based image retrieval systems and classification.

Many times, users assign tags that are imprecise and irrelevant to the image. According to the survey, only 50% of the Flickr tags describe the content of the images [1]. The presence of irrelevant tags affects the performance of the classification and image retrieval system. Hence, it is necessary to design an algorithm that assigns correct tags to the images. It improves the accuracy of the image retrieval system by suggesting proper tags for the images. The advantages of tag suggestions are: it reduces the cost of manual annotation of the images, spelling mistakes. Several studies have been done on tag recommendation using visual contents, tags and metadata. Still, the performance of tag recommendation is not satisfactory due to personalized tags as shown in Figure 1. The tags may not describe the content of the images and may be assigned as per the user perspective. The tags Denmark, 2011 does not describe visual content of an image as shown in Figure 1 (a).

In this paper, the ITR-WTF image tag recommendation method is proposed which contributes in the following way:

- Obtained ranked visual neighbor of each category for each feature
- The tag score is calculated by combining weighted tf-idf value and vote from rank categorical nearest neighbor to recommend top k tags

The paper is organized as follows: existing methods for tag recommendation are described in section 2. Section 3 explains the ITR-WTF proposed method for image tag recommendation. Section 4 and 5 describe the metric used for evaluating the performance of the proposed method and dataset used for experimentation. Section 6 describes the experimental results. Finally, in section 7 the conclusion and future work is given.

2. Work Done

The methods for tag recommendation are categorized into three methods: classification, semantic and nearest neighbor based.

In classification-based methods, the features of the images are extracted and classified into a category using a classification algorithm. The classifier trained for multiple class result in a multi-class problem. Finally, the tags are recommended based on the category of an input image. In [2] the method was proposed labeling of the images. The images were segmented into regions and identified salient region. Based on particle swarm optimization, the SVDD trained to assign labels to the images by assigning more weights to the salient regions. In [3] the method was proposed using probability and weight based SVM classifier for annotation of images. Given an image with tag, the method identifies the related and unrelated images using majority of voting from SVM in [4]. The system named 'SheepDog' was developed to which identifies the suitable group for the inclusion of photos and suggest appropriate tags to the users on Flickr dataset in [5].

In the semantic method, the tags are recommended based on the joint distribution of image and tag features. The method was proposed in [6] for annotation of images using KCCA framework by constructing semantic space in which the correlation was built between image feature and tag features. In [7] an approach for retagging of social images with diverse semantics was presented. Both the relevance of a tag and the semantic compensation to the already determined tags was fused to determine the final tag list for a given image. The method was proposed in [8] to recommend tags for geotagged images using unified subspace which correlates the textual and visual features. The hyper-graph-based method was proposed for tag-based image retrieval using image features and tag features simultaneously [9].

The nearest neighbor-based tag recommendation methods are very popular due to its effectiveness. The model is based on the assumption that feature based similar images tend to have the same tags. Given an input image, the method determines k nearest neighbors by combining various features either by using early or late fusion and calculates the tag relevance score by collecting votes of a tag from its nearest neighbors. The advantages of the method are: it is scalable and model building is not needed as it makes an assumption based on training data. The tag recommendation method was proposed in [10] using random walk on bipartite graph constructed based on weighted user and image nearest neighbor. In [11], the Bayesian based image annotation model was proposed based on semantic nearest neighbors. The method was proposed in [12] for annotation of images using a variation of traditional kNN algorithm by defining matrix which shows the relationship between labels and images. In [13] the method was proposed in which the given an image the similar images were determined using k nearest neighbor and tag graph was created from tags of neighbors and clustered to assign label to an image. The personalized image tag recommendation method was proposed based on neighbor voting scheme by building tripartite graph to show relationship between user, tags and images in [14]. The VS-KNN method was proposed in [15] for image labeling by exploring image features and label features simultaneously as a maximum posterior estimation. Given an image with label l, the method was proposed which identify the images labeled with l using kNN and denote it by set S [16]. Finally, the labels were assigned to the images by calculating the similarity between the input image and set S. The tag relevance method was proposed by assigning weight to each neighbor based on distance using kNN [17]. The method was proposed in [18] to suggest tags for an image based on visual features and tag correlations using neighbor voting scheme. Photo tagging method was proposed in [19] using history of the users. The method finds the geographical, visual and time neighbors for a given image and recommends tags by counting accumulating votes for each tag from three types of neighbors. In [20], the method was proposed to suggest tags to the images with and without labels. The method first identifies a set of k images using feature-based k nearest neighbor. Finally, assign or recommends the tags by counting the difference between tag frequency count from the entire database and k neighbor. The image annotation algorithm in [21] identifies rank based and weight based nearest neighbor and suggests the label for an input image using a probabilistic model.

In this paper, the proposed method recommends tags based on the nearest neighbor method. Compared with the classification and semantic based method, the nearest neighbor method is popular due to its effectiveness and scalability. Also, it does not require any training.

However, the performance of the existing nearest neighbor-based tag recommendation methods depends on the number of k neighbors and may be affected due to the equal weight and voting irrespective of the class. This observation motivated us to develop a method which improves the performance of tag recommendation. The method first determines the weighted categorical nearest neighbors and suggest the tags based on the ranked categorical neighbor and weighted tag frequency.

3. Research Methodology

In this section, ITR-WTF proposed tag recommendation algorithm is described. The main objective of the proposed algorithm is to improve the accuracy of tag recommendation by identifying distance based nearest neighbor and rank the tags by combining image score and tag score.

3.1. ITR-WTF Tag Recommendation Method

The block diagram of the proposed method for tag recommendation is shown in Figure 2. The proposed method consists of three main modules: feature representation, classification and tag recommendation.

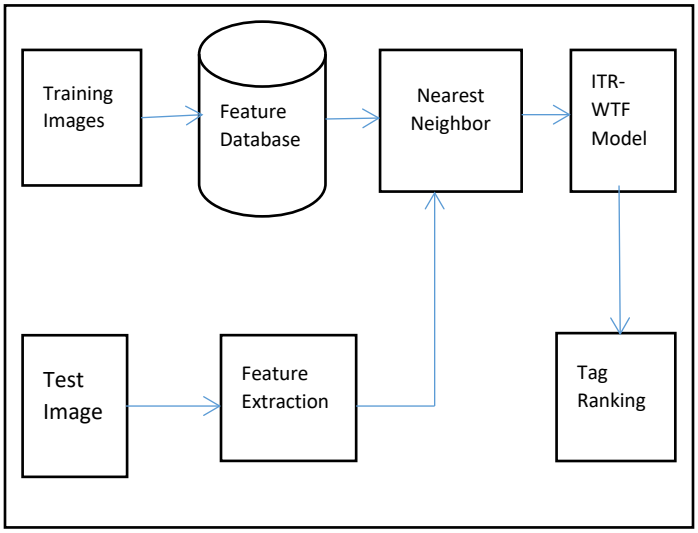

Figure 2: System Diagram of Proposed Method

3.1.1. Feature Representation:

Features play a very important role in image representation. Several researchers have worked on feature extraction methods for image retrieval using color, texture and shape features. Extracting an effective feature and represent them efficiently is very important.

Color is the most used feature in an image retrieval system. Using color features, a human can recognize most images and objects included in the images. Also, the color features are invariant to scaling, translation and rotation of an image. Another important feature is texture. Texture measures look for visual patterns in images and how they are spatially defined.

During the training phase, the features are extracted using color moment and wavelet packet transform [22, 23]. The first, second and third moments are extracted as color features in L*a*b* color space by segmenting an image into two by two sub-block along with a centralized sub-block of the same size resulting into 9 features for each sub-block. For texture features are extraction using wavelet packet transform, an image is decomposed into sub-bands up to level three using daubechies wavelet. The energy and standard deviation of each band are determined as texture features using eq.1 and 2.

$$M_i = \frac{1}{HT*WT} \sum_{h=1}^{HT} \sum_{w=1}^{WT} |Coeff_i(h,w)| \quad (1)$$

$$SD_i = \sqrt{\frac{1}{HT*WT} \sum_{h=1}^{HT} \sum_{w=1}^{WT} (|Coeff_i(h,w)| - M_i)^2} \quad (2)$$

where i = 1 to 4^L and L=3, $Coeff_i(h,w)$ represents the coefficient values of i^{th} decomposed sub-band image at level L, WT and HT are the width and height of the decomposed sub-band image $Coeff_i$.

Each feature has a different range of values. To avoid the influence of one feature due to variation in a range of values, the features are normalized between 0 and 1 range using min-max normalization method.

There are two methods used for combining features: early and late fusion. In early fusion, the individual features are combined before image similarity score calculation. In late fusion, the image similarity score determines for each feature and combine the individual score to calculate the final score. The late fusion method needs more cost of computation [24]. For this reason, the early fusion technique is used to determine the image similarity score.

3.1.2. Nearest neighbor:

After feature extraction, the nearest neighbor classifier determines the neighbors of a test image. In the nearest neighbor classifier, the neighbors for each class/category are determined as shown in Figure 3 and combined to form the final neighbors. The harmonic mean of the neighbors of each category is determined and finally predicts the category with the smallest mean [25].

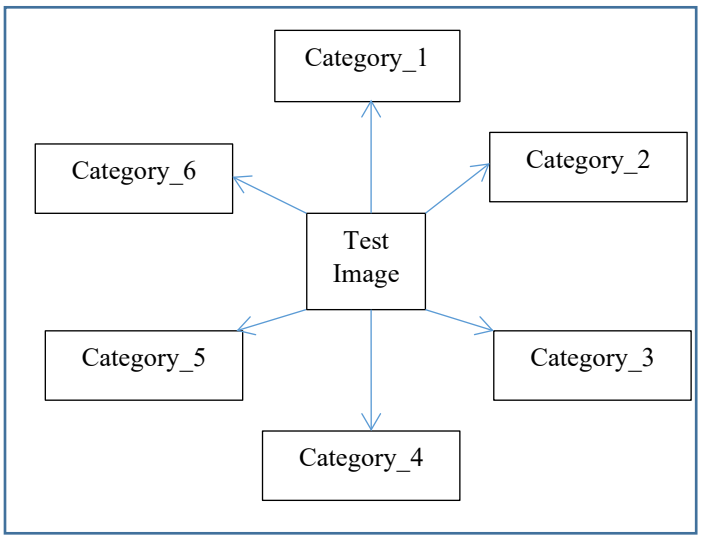

Figure 3: Nearest Neighbor from Each Category

To improve the effectiveness of feature-based neighbors, the weight is assigned to each neighbor so that nearby training image will get more weight and the training images which are farther away will be assigned less weight.

3.1.3. ITR-WTF Model:

Once the feature based neighbors are determined, the method assign an importance to each tag based on image similarity score as follow:

$$P(t) = \sum_{x_i \in NN} sim(I_q, x_i).\delta(x_i, t) \quad (3)$$

where $sim(I_q, x_i)$ denotes the importance of image x_i in predicting tag t according to their visual similarity; $\delta(x_i, t)$ is equal to one if tag is associated with an image x_i, otherwise $\delta(x_i, t)$ is equal to zero. Finally, the score of tag t is calculated as follow:

$$w - tfidf(t) = \left[1 + \log(N_t) * \log\left(\frac{NN}{N_t}\right) * P(t)\right] \quad (4)$$

where N_t represents the number of images associated with t and NN represents the total number of nearest neighbors.

3.2. Algorithm

Algorithm 1: The proposed ITR-WTF Algorithm

Input:

CV: Color feature vector of an input image
TV: Texture feature vector of an input image
$TFV_j = (y_i^j, C_i^j)_1^{NF_j}$: j[th] class texture feature vector of training images
$CFV_j = (x_i^j, C_i^j)_1^{NF_j}$: j[th] class color feature vector of training images
M = $C_1, C_2, \ldots\ldots C_M$: the number of class labels
$T_{mn} = \{T_{1n}, T_{2n}, T_{3n}, \ldots\ldots\ldots T_{mn}\}$: Tag associated with n[th] image

Output: Ranking of Tags

Step 1: Calculate the distance between CV and CFV_j using eq. (3). The set of m number of nearest neighbor for each class C_j is denoted as $CD_{mj}^{NF} = [x_{1j}^{NF}, x_{2j}^{NF}, \ldots\ldots, x_{mj}^{NF}]$

$$dist(CV, x_i^j) = \sqrt{\sum_{l=1}^{m}(CV_l - x_{il}^j)^2} \quad (5)$$

where $x_i^j \epsilon\, CFV_j$

Step 2: Calculate the distance between TV and TFV_j using eq. (4). The set of n number of nearest neighbor for each class C_j is denoted as $TD_{nj}^{NF} = [y_{1j}^{NF}, y_{2j}^{NF}, \ldots\ldots, y_{nj}^{NF}]$

$$dist(TV, y_i^j) = \sqrt{\sum_{l=1}^{n}(TV_l - y_{il}^j)^2} \quad (6)$$

where $y_i^j \epsilon\, TVF_j$

Step 3: Merge the nearest neighbors obtained using color and texture features

$NN = \{CD_{ij}^{NF} \cup TD_{ij}^{NF}\}$ where i = 1……M

Step 4: Assign an importance to each tag based on image similarity score as follows:

$$P(t) = \sum_{x_i \in NN} sim(I_q, x_i).\delta(x_i, t)$$

where

$$sim(I_q, x_i) = dist(I_q, x_i) * wt_j^i$$

$$wt_j^i = \frac{1}{j} \qquad i = 1, \ldots\ldots, m$$

Step 5: Calculate the w-tfidf of each tag as follows

$$w - tfidf(t) = \left[1 + \log(N_t) * \log\left(\frac{NN}{N_t}\right) * P(t)\right]$$

Step 6: Rank the tags according to the w- tfidf values and select top k values

4. Performance Metric

To evaluate the performance of proposed method, we use NDGC, Precision, Recall and F1-score.

Given an image with ranked tag list $T_1, T_2, \ldots, T_n$, the NDCG is computed as where r(i) is the relevance level of the i[th] tag and Z_n is a normalization constant that is chosen so that the optimal ranking's NDCG score is 1. After computing the NDCG measures of each image's tag list, we can average them to obtain an overall performance evaluation of the tag ranking method.

$$NDCG@k = \frac{1}{z}\sum_{i=1}^{k}\frac{2^{rel(i)} - 1}{\log(1+i)} \quad (7)$$

rel(i) is a binary indicator, which is equal to one if the i[th] tag in the ranking list is relevant to an input image, and zero otherwise.

$$Precision = \frac{TP}{TP + FP} \quad (8)$$

$$Recall = \frac{TP}{TP + FN} \quad (9)$$

$$F1 - Score = \frac{2 * precision * recall}{precision + recall} \quad (10)$$

5. Dataset

Two datasets are used: self-generated and NUS-WIDE. The self-generated dataset consists of images collected from Flickr image sharing website belonging different categories such as fish,

actor, aeroplane, butterfly, autumn etc. and each category consists of 300 images. The size of the images is fixed with maximum width or height to 320 pixels. The eight categories of the images from NUS-WIDE dataset are used for experimentation. The images are divided into two groups: training and testing images after 10-fold cross validation.

For self-generated dataset, the tags associated with the images are collected from Flickr using public API. However, some tags are do not describe the image content. Therefore, tags related to year, camera and brands are excluded from the tag list.

6. Experimental Results

The performance of traditional K nearest neighbor and nearest neighbor is shown in Table 1 and 2 respectively.

Table 1: Performance of traditional K nearest neighbor

Method	Self-generated dataset	NUS-WIDE dataset
Precision	84.33 %	65.87 %
Recall	84.50%	60.75 %
F1-Score	84.00%	61.37 %

Table 2: Performance of Nearest Neighbor

Method	Self-generated dataset	NUS-WIDE dataset
Precision	87.73 %	69.88 %
Recall	88.66 %	67.00 %
F1-Score	88.00 %	67.13 %

From Table 1 and Table 2 it is observed that the performance of nearest neighbor based on each category achieves good performance as compared to traditional k nearest neighbor.

The Figure 4 shows that the NDGC value is high for tag recommendation result when no of the tags recommended is 5 for self-generated dataset and 15 for NUS-WIDE dataset.

Table 3 shows the performance of the existing and proposed tag recommendation algorithm. The performance of proposed tag recommendation algorithm is better as it can recommend/suggest tags with higher NDGC score.

Tagvoting method [18]: In this method, the feature based similar images are determined and the tags are recommended to an input image based on the frequency of tags that appeared in k visually similar images. The method assigns a uniform weight to each neighbor.

TagProp method [20]: In TagProp method, the weights are assigned each visual neighbor of a query image. The weights are assigned using rank based and distance-based method.

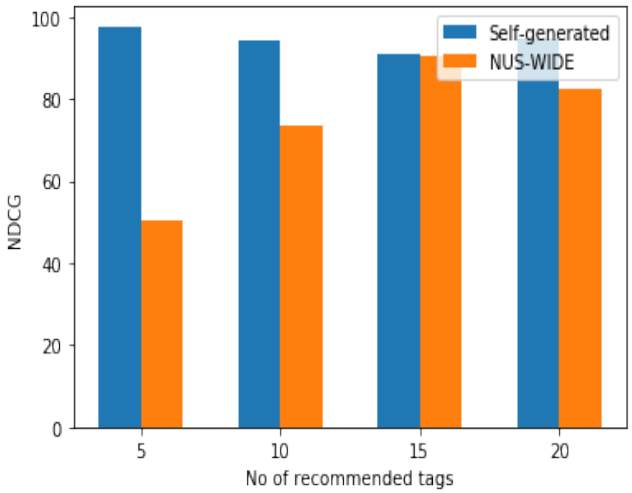

Figure 4: The NDCG values for different number of tags

NVote method [19]: In Nvote method, the tags are recommended based on the difference between global and local tag frequency by assigning equal weight to each neighbor.

Table 3: Performance of different tag recommendation algorithm

Method	Self-generated dataset	NUS-WIDE dataset
Tagvoting	84.45 %	85.20 %
TagProp	89.67 %	68.50 %
NVote	92.07 %	68.96 %
ITR-WTF	95.43 %	88.90%

From Table 3, it is observed that the methods for tag recommendation using the nearest neighbor depend on the value of k which indicates the count of neighbors. The existing methods first identify the uniform/weighted neighbors and then consider only tag information for tag voting which affects the accuracy of tag recommendation. The proposed method improves the accuracy of tag recommendation by combining the image score and tag score.

Table 4: Result of Tag Recommendation

Image	Initial Tags	Recommended Tags
	Brainedge Background Celebration Closeup Clover	Clover Green Nature Leaves Macro

	Bracom (Bram) Bracom Forest Bos Autumn Herfst	Autumn Trees Leaves Path Forest
	Mikepaws London Airport Aircraft Aeroplane	Flying Aircraft Aeroplane Plane Air
	Demerarah Fishalive Tropical-Fish Fish Tropical Fish-Tank Underwater	Fish Aquarium Tropical-Fish Underwater Fishalive

Table 4 shows the result of tag recommendation obtained using the proposed algorithm on self-generated dataset. The initial tag does not describe the entire image content. The proposed algorithm recommends relevant tags to the images. For the second image in table 4 initial tags do not cover the trees, forest and path between the trees which are added by the proposed algorithm.

Therefore, the effectiveness of the proposed method ITR-WTF for tag recommendation is demonstrated using examples in Table 4.

7. Conclusion and future work

In the paper, a method is proposed for tag recommendation of the images by identifying rank neighbors from each category. The method improves the accuracy of tag recommendation by combining the tag frequency score and weighted similarity score of the nearest neighbor images of each category. The experimentation is done two datasets: self-generated and NUS-WIDE dataset. The effectiveness of the proposed method is demonstrated in the experimental results.

The future work will focus on: i) exploring the relationship between tags obtained using from nearest neighbor ii) developing a more optimized approach which works on large dataset iii) exploring metadata associated with the images.

ABSTRACT

This article shows the possibility of creating high wear-resistant and corrosion-resistant coating by plasma electrolytic oxidation (PEO) on the AlSi12Cu aluminum alloy. The combination of influencing parameters during processing allows to influencing of the set of quality indicators of coating, such as the thickness of the coating layer, microhardness, porosity, phase and elemental composition. The influence of technological modes and electrolyte composition on the structure and composition of the resulting coating has been established. The structural features of the modified layers was investigated, the effect of the capacitor capacitance on the installation and the duration of treatment on the structure and microhardness of the resulting coating was established. The tribological properties of the different PEO surfaces had been evaluated by usage of the 'pin-on-disk' method. Different current densities were chosen to represent the arrangement component of the PEO layer. Wear test results were used to evaluate the wear resistance ability of the various PEO layers and for establishing a wear model. The surface morphology, porosity distribution on cross-section, and worn surface of the PEO layers were characterized using a scanning electron microscope (SEM). Different material counterparts and contact conditions were applied to simulate a variety of practical states. The results show that the hardness of the PEO layer formed on sample M5 was the highest among the five kinds of samples. The PEO layer formed at sample M5 has the best wear resistance. This can be ascribed to the different size and appropriation of the pores and the diverse proportion of α to the γ stage in the PEO layers when exposed to various limitations during the PEO cycle.

1. Introduction

During the operation of the internal combustion engine, the parts of the cylinder-piston group wear out most quickly. The wear of the cylinder-piston group of the engine takes place in conditions of high temperature, significant cyclic mechanical loads and an aggressive gas environment. One of the effective ways to increase the service life and reliability of the rotor group of an internal combustion engine is *PEO*, which leads to the formation of multifunctional wear- resistant coating based on ceramics on the working surface, which are characterized by high adhesion to the base [1].

PEO is a modern promising technology for electrochemical oxidation of valve group metals, including aluminum, titanium, zirconium, magnesium, niobium, beryllium, and tantalum, as well as their alloys in order to form a uniform ceramic coating with a thickness of 80 - 300 (μm) with high performance and protective properties. The environmentally friendly *PEO* method is optimal for processing and hardening the surfaces of products with complex-shaped parts and limited units of the electrical, aviation, oil and gas processing industries, instrument, and mechanical engineering, as well as shipbuilding, medicine, and utilities [2, 3]. The *PEO* method makes it possible to obtain a coating on the surface of aluminum alloys, which includes the γ- and α-phases of aluminum oxide, mullite (in the case of alloying the alloy with silicon). Corundum (α-phase) has a low coefficient of friction (0.04 and less) and low thermal conductivity, which increases the wear resistance of the friction pair, reduces heat transfer from the working chamber, and provides high corrosion resistance. Moreover, it has a higher hardness compared to the γ-phase of aluminum oxide. On the other hand, the presence of the γ-phase makes it possible to somewhat increase the coating resistance for cyclic mechanical and thermal loads. Mullite, in turn, has a low density, high thermal stability and corrosion resistance, low thermal conductivity, acceptable values of strength characteristics

[4, 5]. Many previous studies that have discussed the effect of coating thickness [6], solution concentrations [7], and porosity size [8] on corrosion performance and hardness. In this work, suitable thicknesses between 80 -100(μm) were chosen to obtain high hardness. In an attempt to get the lowest possible porosity, but impossible to obtain a coating that does not contain pores, due to the nature of the process. If necessary, the porosity can be reduced by saturating the surface layer with the application of a polymer. The coating produced had the best results for the lowest possible wear rate and thus reduce the friction coefficient to a minimum.

Favorable factors for the widespread of the PEO process in the industry are a set of such advantages as the possibility of obtaining high-quality wear-resistant, heat-protective coatings in combination with sufficiently high productivity, simplicity of hardware design, environmental friendliness, and cost-effectiveness of process automation [9]. The aim of the study is the influence of the parameters of the PEO process on the structure, mechanical and physical properties of the coating applied to the aluminum alloy AlSi12Cu to get high wear resistance.

Also, the goal of this study was formulated: to assess the possibility of applying GPM to the aluminum alloy AK12MMGH, Modification with the help of GPM makes it possible to increase the resource and reliability of parts of the Internal Combustion Engine (ICE), also protect them from high-temperature gas erosion and reduce the temperature of the base metal by 1.5 times [10]. To work out the modes and to study the structure and properties of the obtained coatings

2. Materials and Research Methods

Prepared AlSi12Cu Samples for coating were made in the form of a ring with a surface area of (3.6) dm^2. The external diameter size of such rings was 200 mm and the internal diameter was 164 mm and the thickness were 10 mm. An ELS device MDO-50-AKT-001 was used to form the coating. Two regimes were used to start the process, the anode regime was used, which made it possible to accelerate the formation of the primary oxide layer on the surface of the samples. After two minutes of anodic treatment, the capacitor-state regime was started, as the most suitable for the formation of a coating with the reduction of micro stresses, which controls energy dissipation due to the coupling of mechanical and thermal fields.

Cross-sections were prepared by mechanical grinding and polishing on a LaboPol - 5 (Struers) machine using abrasive paper and a silicon oxide slurry. The microstructure of the cross-sections of the coating obtained was investigated using Quanta 200 scanning electron microscope (*SEM*) in the backscattered electron mode, with an accelerating voltage of 30 and 15 kV. The thickness and porosity of the coating were determined on a cross-sectional image using the Digimizer program.

The electrolyte of *PEO* consists of Potassium Hydroxide (*KOH*) and Sodium Silicate (Na_2SiO_3). In preliminary experiments various composition of the electrolyte was tested in terms of *KOH* content in the range from 4 to 20 g/L, and in terms of Sodium Silicate content in the range from 4 to 20 g/L. It was found that coatings with less porosity and maximal thickness are obtained in the range 6.4 - 9 g/L for *KOH*, and 5 - 10 g/L for Sodium Silicate. So, this range was chosen for carrying out more detailed experiments to study the structure, elemental and phase composition, etc.

The study was carried out on five samples, the obtaining technological regimes of which are indicated in Table 1.

The duration of the processing was determined by a decrease in the intensity of the process, which means a possible transition of the process from the micro-arc stage to the arc stage. The last limitation is associated with the onset of etching and the destruction of the coating. The samples were cleaned with water for 3 min after treatment to prevent the deposition of electrolyte components during drying.

Table 1: The value of the thickness formed coating under different processing conditions

Sample	A/ dm^2	τ, min	Electrolyte, g/L	
			KOH	Na_2SiO_3
M0	($AlSi_{12}Cu$) Without coating			
M1	30	120	9	10
M2	30	120	9	5
M3	22	120	6.4	10
M4	22	120	9	10
M5	22	120	6.4	5

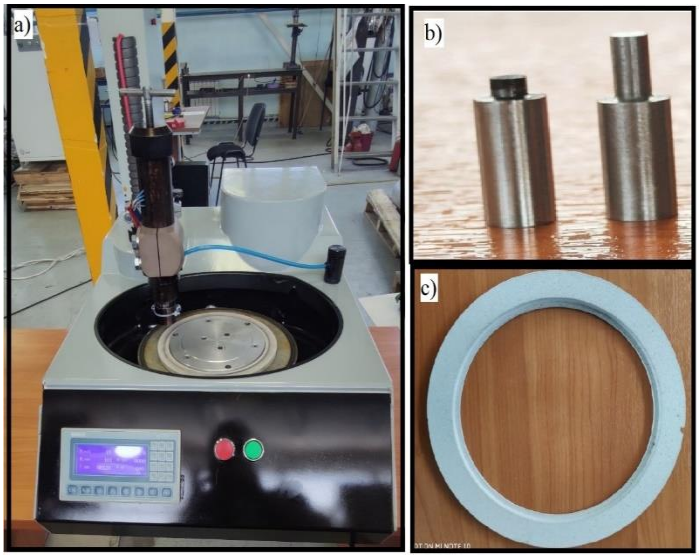

Figure 1: a) Image of the experimental setup for determining wear resistance; b) pin after testing (left), original (right) and c) coated substrate.

The 'pin on disc' wear testing machine used to study the mechanisms, wear rate and for determination of friction coefficients between the composite coating on a ring and the pin acting as a counterbody. The image of this machine is represented in Figure 1. Standard technical oil for a diesel engine was used as a lubricant for such wear tests. An aluminum alloy ring with a coating which deposited on its surface was fixed to the annular disc of the tribometer, and a 6 mm or 10 mm diameter cast iron pin was brought in contact. The load applied by the pin on the coating, as well as the rotation speed of the coated ring, were set and controlled during the experiment. The time of the experiment, the load on the pin, and the rotational speed of the coated ring

were 180 min, 90 N, and 1500 rpm, respectively fixed for all experiments. All tests were carried out at room temperature and atmospheric pressure. The wear rate was determined by evaluating the cross-sectional area of the wear grooves [11]. This data was obtained by analyzing the surface profile across the wear track using a SURTRONIC 25 profilometer. Wear rate was defined as volume loss under a unit load at a unit rotating distance.

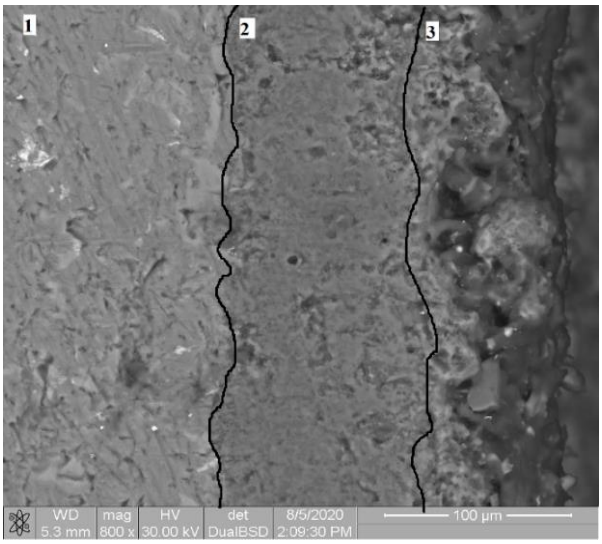

Figure 2: The coatings structure layers on the example of sample M1, obtained by the PEO method: 1-transition layer; 2- working layer; 3- technological layer.

3. Results and Discussion

SEM image of a cross-section of a sample *M1* with a 210 µm thick coating on the AlSi12Cu aluminum alloy is shown in Fig. 2. The ceramic coating contains three layers: a 5 µm thin transition layer, a 120 µm thin working layer and a Technological layer with a thickness of 70 µm. The coatings obtained are characterized by good interfacial adhesion between the aluminum substrate and the ceramic coating. The same result was shown in previous work [12, 13]. Analyzing the cross-section image of the coatings show that the growth of the coating occurs in two directions. The first direction from the surface of the substrate to its depth (working layer) and this take place in the direction of the aluminum substrate, this forms a dense layer with good mechanical properties. The second one is the growth of the coating in the direction of the outer surface accompanied by the formation of a loose structure (Technological layer). The wear resistance of the coating obtained by the *PEO* method will be almost completely determined by the properties of the inner working layer. Therefore, the upper porous layer of the coatings was grinded to the working layer for tribological measurements, as well as for X-ray phase studies.

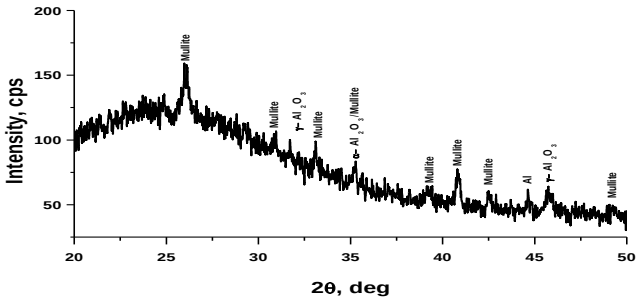

Figure 3: X-ray diffraction pattern of the technological layer of the coating applied according to mode sample *M5*

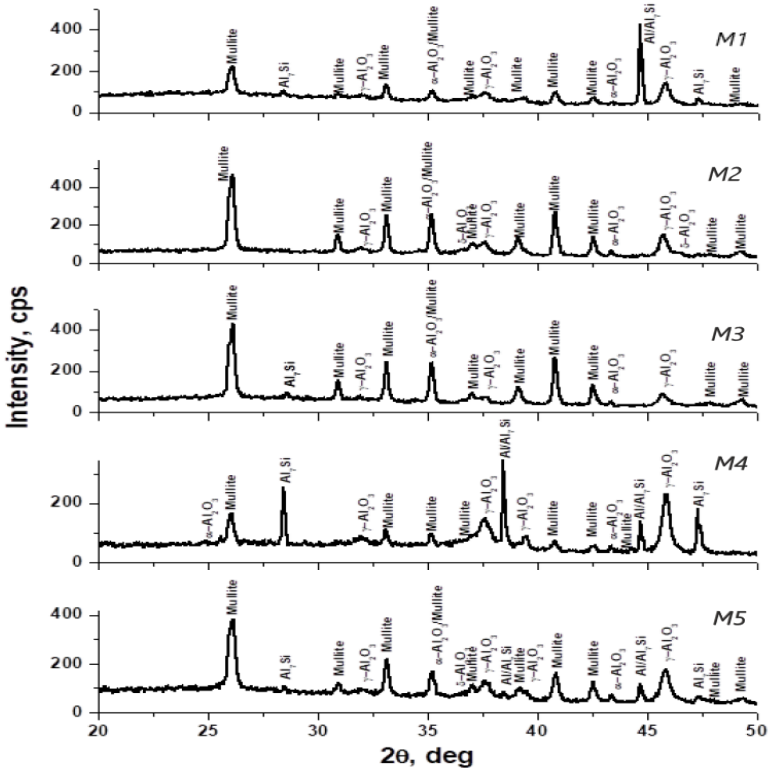

Figure 4: X-ray diffraction patterns of the working layer for applied coatings for the samples represented in table 1.

In (Figure 4) X-ray phase studies have shown the absence of pure aluminum in the composition of the coatings. It is seen that the coatings obtained by the *PEO* method on the AlSi12Cu alloy consist mainly of 3 phases: α- Al_2O_3, γ- Al_2O_3 and mullite. Diffraction reflections (105) α, (200) γ, and (400) mullite with high reflection intensity are identified as characteristic diffraction peaks of α- Al_2O_3 and γ- Al_2O_3, respectively. The working layer of the coating mainly consists of α- Al_2O_3 phase the content of which is much higher than that of γ- Al_2O_3 (see Fig. 4 *M2*). It can be seen that the content of the α- Al_2O_3 phase correspondingly increases from the working layer to the technological layer of the coating comparing the ratio of the intensities of reflection (105) α to reflection (200) γ at different depths of the coating. We assumed that this is due to a change in the cooling rate of molten aluminum oxide in the microarc discharge channel [14].

The presence of porosity is a positive moment when the coating is operating under oil starvation conditions, the lubricant enters the pores of the coating and provides a permanent oil film. The value of volumetric porosity and average pore size for different coatings are represented in Figure 5.

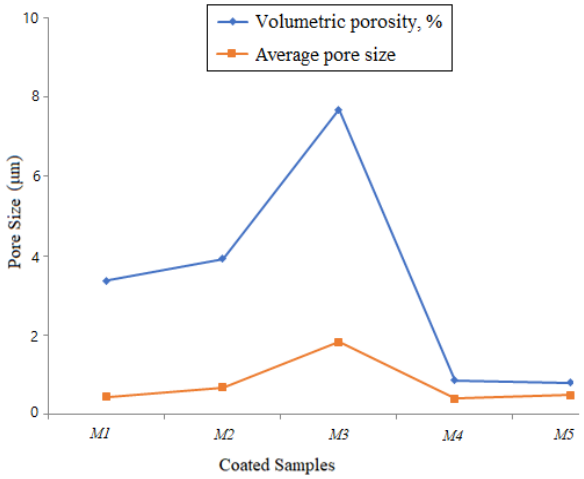

Figure 5: Volumetric porosity and average pore size of various processing modes.

The microhardness of the working layer is 1000-1500 HV (Fig. 6). A piston with a coating based on oxyceramic with a hardness of 6.3–11.5 GPa was tested in [15, 16]. It was also found in previous works that the wear rate of coated pistons is 3.86 times lower than that of uncoated ones [17,18].

Measurement of the microhardness of the applied coatings was carried out on cross-sections surfaces. This was done on the one hand, because it was impossible to make a correct measurement on the surface with the irregularity height comparable to diamond pyramid size and on the other hand it makes it possible to measure the change in microhardness over the thickness of the coating.

Figure 6 shows a graph of the distribution of the microhardness of the coating along with its thickness for example sample *M3*. Zero on the abscissa in this graph corresponds to the surface of the aluminum substrate on which the coating was applied. The microhardness of the coating increases first relatively slowly in the transition layer and then rapidly during the transition to the working layer until it reaches its maximum value at a depth of 40 µm from the substrate-coating interface is 1600 HV. After reaching the maximum value, it begins to gradually decrease with thickness increasing. The hardness of the coating does not exceed the value of 1600 HV in the distances range of 25–100 µm from the Al / Al_2O_3 interface. The microhardness of the aluminum alloy substrate near the Al / Al_2O_3 interface is only 210 HV [19] which is close to the hardness of 185 HV in the substrate, measured far from the interface.

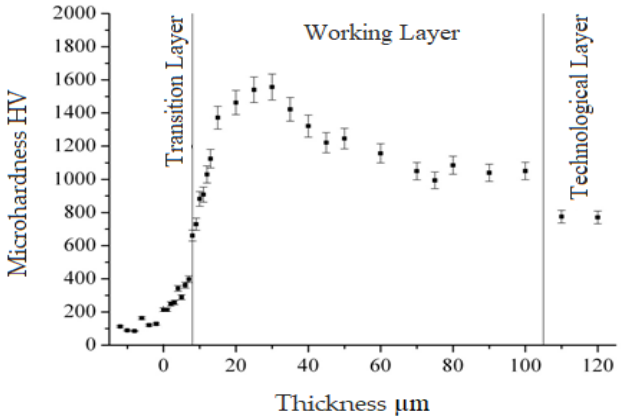

Figure 6: Typical distribution of microhardness over the coating thickness (shown for sample *M3*).

Figure 7 shows the cross-sectional profiles of the surface across the wear track of the a) initial substrate made of the AlSi12Cu alloy sample *M0* and c) polished coating of the sample *M5*. The wear track of the substrate made of AlSi12Cu alloy as shown in Figure 7b has a depth of 61 µm and a height of 23.2 µm, which is much deeper than that of a coated ring whose depth is 30.9 µm and a height of 6.9 µm as shown in Figure 7d. This means that the surface wear rate decreases significantly after the coating deposition on the AlSi12Cu alloy by the *PEO* method. Figure 7b shows the parabolic shaped profile of the wear groove with superficial changes in depth. This profile is formed with uniform abrasive wear of the material. Figure 7d, shows that there is no wear of the coating material over the entire width of the track, but instead there are narrow furrows that could occur if a very small fragment of the coating breaks off during testing and therefore forms a scratch in the area of the friction track.

Roughness profile parameters are showing in Figure 7. The roughness profile parameters for all samples were measured. It was observed that the maximum profile valley depth (*Rv*) and the average roughness (*Ra*) are more than two times higher for the uncoated sample in comparison to the coated one.

As it was mentioned above, the coatings were ground to remove the transition loose layer, which has poor mechanical properties. Since the thickness of the transition and the working layers were different for different samples and it was necessary to grind different amounts of materials. As a result, the remaining coating thickness was different for different samples. So, the microhardness distribution over the thickness (the thickness was determined from the interface between the metallic substrate and the coating) was carried out for different sample thicknesses. Table 2 shows the value of the coating wear rate for different samples obtained at a fixed operating time and applied load. It was

found that the smallest wear rate for coating samples is only 3.4295×10^{-7} mm^3 / Nm, which is a thousand times less than for the uncoated Al substrate. This means that the wear resistance surface of an aluminum alloy by *PEO* can be improved by three orders of magnitude by oxide coating deposition. The loss of coating thickness during the wear test is much less than the thickness of their working layer, so table 2 describes the results of wear of the working layers of coatings.

As shown for coating samples *M2* - *M5*, the wear rate gradually decreases as the remaining coating thickness decreases. However, the difference in the wear rate of samples *M4* and *M5* is small, which indicates a similar wear resistance at different thicknesses of the working layer of the coating. It should be noted that in the process of wear, some of the metal chips can be clogged in the pores of the ceramic coating, which leads to the effect of lubrication, which reduces the coefficient of friction. This leads to the fact that the wear of the coating is greater at the initial stage, however, when the friction couples reach stable wear, the tribocontact zone of the coating and the pin becomes very smooth, and the aluminum oxide coating practically does not wear out.

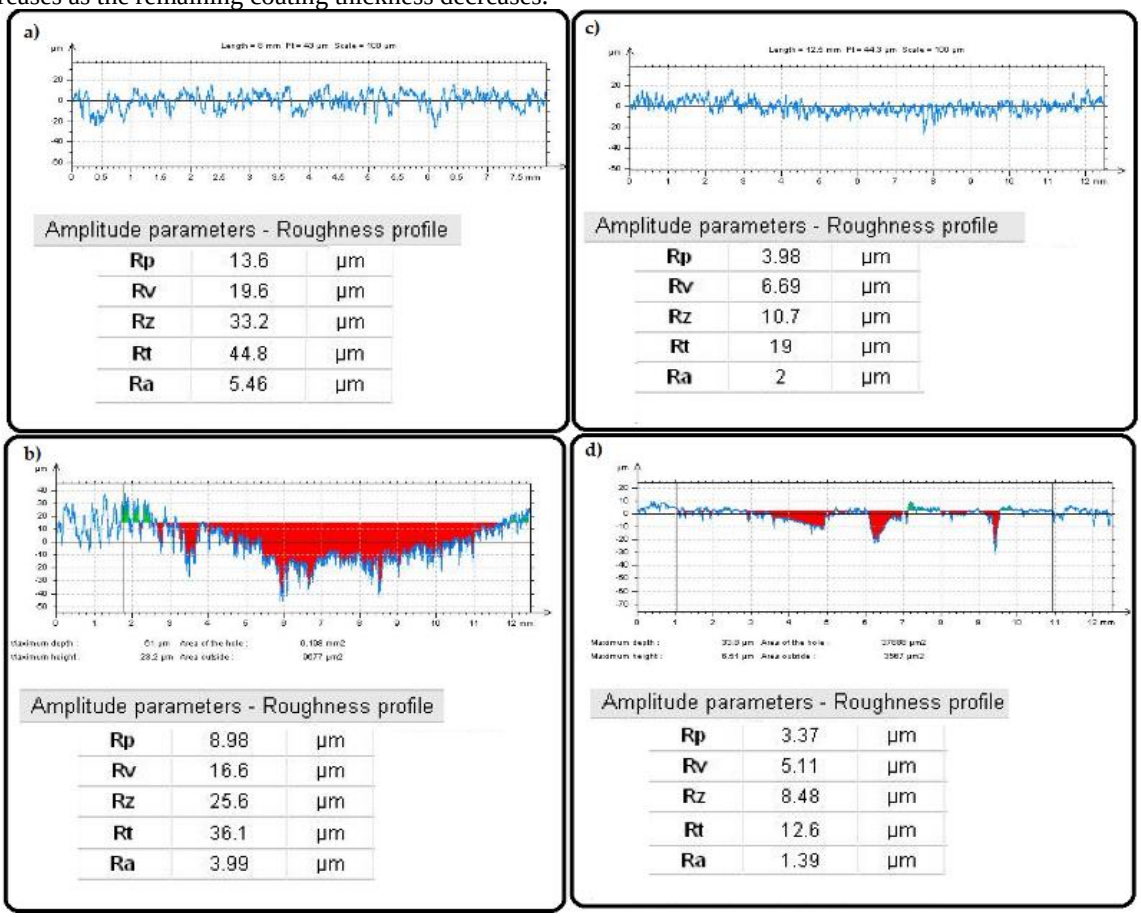

Figure 7: Typical cross-sectional profiles of the surface on an aluminum substrate (sample *M0)* before wear track (a); across the wear track (b); and on the polished coating with a remaining thickness of 180 µm (sample *M2*) before wear track (c); across the wear track (d).

Table 2: Wear rate of a substrate without coating and polished coating by tribological parameters.

Sample	Coating thickness (µm)	Loss of thickness in friction track (µm)	Wearing time (min)	Wear load (N)	Wear rate (mm^3/Nm)
M0	0	50	180	90	8.73016×10^{-4}
M1	210	38	180	90	1.38973×10^{-6}
M2	180	29	180	90	2.54766×10^{-7}
M3	160	27	180	90	3.4295×10^{-7}
M4	80	14	180	90	1.6183×10^{-6}
M5	90	10	180	90	1.4610×10^{-6}

The change of the friction coefficient for sample *M2* is paired with a cast iron pin depending on the time of wear is shown in Fig. 8. In the first minutes of the experiment, the lapping of a pair of rubbing bodies occurs. At this time, the contact area changes (increases), primary chips are formed, which in total leads to an increase of the friction coefficient up to 0.85. During 15 minutes of wear, the coefficient of friction (μ) is still high and remains at the level of about 0.75. At this stage, there is an intensive formation of α-Al_2O_3 and γ-Al_2O_3 microparticles, which cause intensive wear of both the coating and the counter body. This leads to the expansion and deepening of the wear mark on the coating. At the same time, there is an intensive formation of metal chips of the counter body material. In addition, the ceramic grains of α-Al_2O_3 and γ-Al_2O_3 in the coating become smoother, and part of the metal chips is driven into the pores of the coating. Thus, at this stage, the coefficient of friction remains at a high level. As we continue the experiment, the metal particles from the pin become clogged in the pores of the ceramic coating, which leads to the fact that the ceramic-to-metal contact turns into a metal-to-metal contact, as a result of which the coefficient of friction decreases. This contact looks like a thin lubricating layer of cast iron, which creates a lubricating effect between the pin and disc. In this case, the wear loss is very small, which results in a very low wear rate of coatings with longer test times.

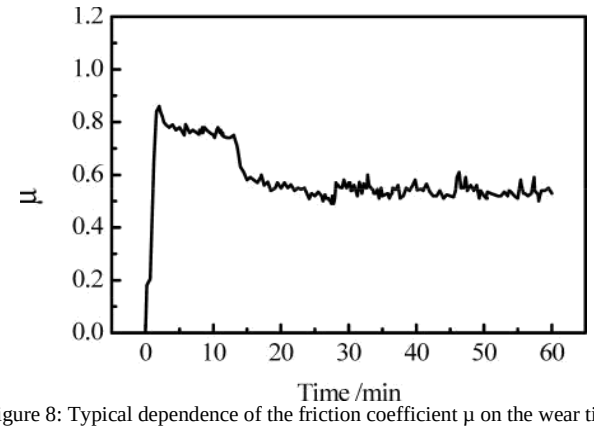

Figure 8: Typical dependence of the friction coefficient μ on the wear time (measured at *M1*).

Figure 9 and 10 shows images of signs of wear on the coating and the counterbody. As shown in figure 9, a wide wear path is formed in the tribological contact zone. The wear mark shows many grooves, which corresponds to the profile in Fig. 7. These grooves are the result of abrasive wear by small particles that have broken off from the coating. The wear trace of the counterbody as shown in figure 10 have more cracks than the coated ring because the hardness of a cast iron rod is less than oxide coating.

4. Conclusions

Wear tests were performed using standard technical oil for a diesel engine as a lubricant. The wear rates of the coatings and counterbody, as well as the friction coefficients for each condition at a normal load of 90 N for 180 min, were obtained. *SEM* and *XRD* were used to analyze the effect of process parameters and we founded that the best range of electrolyte composition for *KOH* (6.4-9 g/L) and Na_2SiO_3 (5-10 g/L) in order to get volumetric porosity less than 1% and hardness more than 1600 HV. Depend on in the intensity of the *PEO* process the selected time was 120 min and current density was in range (22 – 30 A/ dm2). When time or current density of Poe process increased this led to destruction of the coatings. A comparative analysis of the structure of experimental samples allows us to conclude that it is possible to provide different properties of coatings on the same material. In particular, the experimental sample *M5* has low porosity and a working layer thickness of 90 μm; therefore, it has higher mechanical strength and wears resistance. This makes the coating most suitable for resizing and increasing the wear resistance of the piston skirt.

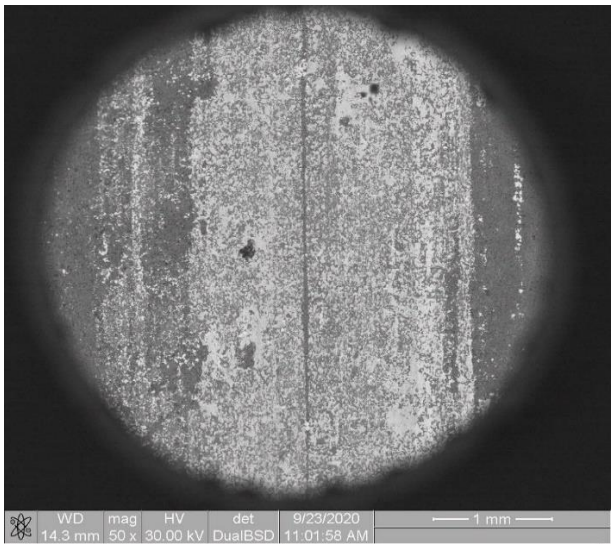

Figure 9: Electron microscopic images of the surface of the wear track for the aluminum coating sample *M4*

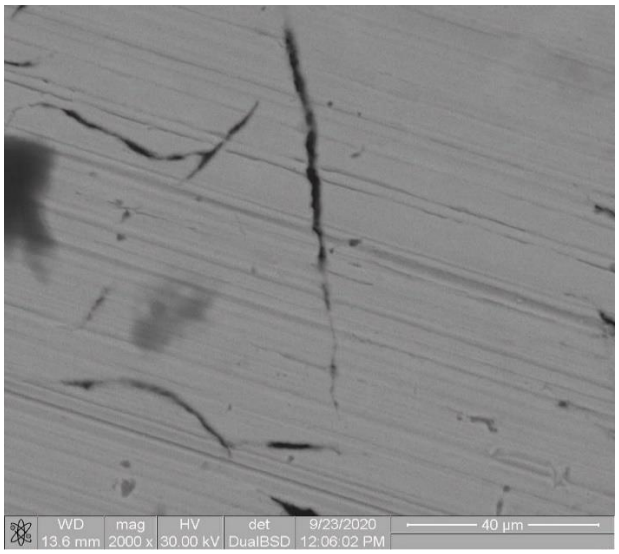

Figure 10: the wear track surface for the counterbody

It was found that the maximum profile valley depth (*Rv*) and the average roughness (*Ra*) for the uncoated sample are more than two times higher in comparison to other samples. Reducing roughness should have a positive effect on engine performance. The wear rate of the samples with oxide coatings is three orders of magnitude less than for uncoated one. Also, coefficient friction of coated samples was less than 0.04.

The *M5* sample has the best thermal insulation characteristics, which combines a low porosity about 10% depending on the concentration of Na_2SiO_3. In addition, the *M5*

sample compared to the other samples is more cost-effective in terms of the electrolyte composition. It is also noted that the wear loss of this sample is less than that of others, which is a consequence of the higher hardness.

Thus, it has been established that by the method of plasma electrolytic oxidation it is possible to obtain high-quality wear-resistant and heat-protective coatings on aluminum alloys with the high silicon content. By varying the technological modes and composition of the electrolyte, it is possible to change the structure, composition and thicknesses of coatings in a wide range from 80 to 300 (μm).

ABSTRACT

In this study, Taguchi method and ANOVA that are applied to determine the influence of several input parametrs on cutting force amplitude (F), vibration acceleration amplitude (a), and machining productivity (P) in the five-axis finish milling process of the spiral bevel gear. Taguchi orthogonal L_{27} array is used to design the experimental matrix with 27 experiments. During finish milling process of the spiral bevel gear (X40 steel) with a ball-end mill cutter (HSLB-2030), the parameter that has most influence on F was spindle speed (37.51 %). The parameter that has the second influence degree on F was feed rate (22.97 %). The parameter that has the third influence degree on F was maximum scallop height (16.45 %). Toolpath strategy has negligible influence on F (less than 1 %). Feed rate was the most influence factor on a (22.48 %). The parameter that has the second influence degree on a was the maximum scallop height (21.73 %). The parameter that has the third influence degree on a was the toolpath strategy (3.65 %). Spindle speed has negligible influence on a (less than 1 %). The parameter that has the most influence on the P was the maximum scallop height (54.90 %). The parameter that has the second influence degree on P was the feed rate (18.92 %). The spindle speed and toolpath strategy have negligible influence on P (less than 1 %). Quadratic regression that is determined as the most suitable regression of F, a, and P in the finish milling process of the spiral bevel gear with the determination coefficients (R^2) 86.72 % for cutting force amplitude, 93.46 % for vibration acceleration amplitude, and 99.85 % for machining productivity.

1. Introduction

In machining processes, milling processes are ones of the most common machining methods. Especial, the application of CNC technology with high precision and high machinability, milling processes have been used popularly to machine the surfaces with high precision and high productivity. Therefore, more and more studies on the application of milling method have been performed. These studies were performed to improve the quality of machining quality, reduce cutting heat, reduce cutting forces, reduce vibrations, increasing the material removal rate, etc. in milling processes. In application of machines such as for thermal power generation system, marine propulsion elements, mines and quarries, wind's kinetic energy system, automation, etc. the spiral bevel gears are the most important components of power transmission system [1, 2]

In the manufacturing of spiral bevel gears, many different methods were applied to cut the gear teeth of spiral bevel gears. In which, most of the machining of spiral bevel gears were conducted by the specialized machines. Some of machining systems for manufacturing of the spiral bevel gears consist of the Klingelnberg's Palliod system [3], Klingelnberg's and Oerlikon's Cyclo Palliod systems [4], and the Gleason's gearing [5] Several studies were conducted to machining the spiral bevel gears using five-axis CNC milling machines [6-8]

In machining processes, cutting forces, vibrations, material removal rate (MRR) are the most important factors. Cutting forces, vibrations, and MRR influence on the machining quality and machining productivity. So, many studies were performed to predict the cutting forces, vibrations, and MRR, and to determine the influence of cutting parameters on the cutting forces, vibrations, MRR. In milling processes, cutting forces can be modeled by theoretical method for ball end mill [9] or flat-end mill [10] and by experimental method [11] The vibrations also can

*Corresponding Author: Nhu-Tung Nguyen, Faculty of Mechanical Engineering, Hanoi University of Industry, Vietnam, 84988480490 & tungnn@haui.edu.vn

be modeled by theoretical methods [12, 13] and experimental method [14] Normally, the MRR is calculated based on the relationship of cutting parameters such as cutting time, feed rate, cutting velocity, etc.

In the manufacturing of spiral bevel gears using five-axis milling processes, many research directions were performed to improve the quality and productivity of machining processes. Using universal multitasking machines or five-axis milling centers, a large sized spiral bevel gears were manufacture. The different machining strategies, toolpath patterns, and parameters were conducted for both roughing and finishing operations. The machining time, tool wear, and gear surface were analyzed to determine which are the best strategies and parameters for large modulus gear manufacturing on universal machines. Cutting forces, vibrations, and MRR have not been mentioned in this study [6].

A unity transformation model (UTM) was proposed to machine the spiral bevel gears and hypoid gears. This model can be applied in machining process of Gleason spiral bevel gears and hypoid gears, including generation machining and formation machining for wheel or pinion on a universal five-axis machining center. However, this study only focused on the generation of NC program. So, the machining quality and machining productivity have not been mentioned [15].

By combined with the general five-axis NC machine tool, the general expressions of trajectory for five-axis NC machining for the circle bevel gears were proposed. The results of cutter positions and states were verified by 3D modeling. And then, the final tool trajectory was applied in experimental processes. In the milling process of this kind of gear, the cutting forces, vibrations, and MRR have also not been mentioned in this study [16] Besides, several studies were performed using four or five-axis CNC machines to analysis, plan, and manufacture the bevel gears to reduce the cost and time and to improvement of the machining quality in machining processes [15-17].

2. Material and Experimental Method

2.1. Material

In this study, 40X steel was used to perform the experiment. The equivalent signs of this steel are described in Table 1 according several standard. The chemical compositions of 40X steel are listed in Table 2. The properties of the 40X were the listed in Table 3. The geometry of workpiece (a gear was rough machined) is described in Figure 1.

40X steel is a structural alloy steel intended for use in heavy-duty components. Products made from this steel conform to DSTU 7806 and GOST 4543 standards. 40X structural alloy steel is used in heavy-duty components (shafts, axles, gear shafts, plungers, bars, crank and cam shafts, rings, spindles, drift pins, battens, cogs, bolts, half-shafts, bushings, screws etc.). 40X chromic steel is also used in forged, cold- and hot-stamped components, and the steel product is used in pipe, tank and other production.

2.2. Experimental Machine, Tool, and Measurement systems

A five-axis vertical machining center (DMU 50 - 5 Axis Milling) was used to perform the experiments as shown in Figure 1. A ball-end mill cutter (HSLB-2030) was used to finish milling the Spiral Bevel Gear with number of flutes of 2, helix angle of 30^0, rake angle of 5^0, and the diameter of 6 mm. In this study, the cutting forces were measured using a cutting force measurement system including a dynamometer (Kistler type 9139AA: force ranges: (-3 KN÷3 KN), a data processing box, and a PC with DynoWare software. Vibration measurement system including the acceleration sensor (type 4525-B-001), the data processing box, and the PLUSE software was used to measure the system vibration acceleration. The detail of measurement system was illustrated in Figure 2. The machining time of each gear teeth was determines based on the time machining from the control system of five-axis CNC machine. And then, the productivity was calculated by (1).

$$P = \frac{1}{T} \text{ (tooth/min)} \quad (1)$$

where T is the finish machining time of one gear teeth.

2.3. Experimental design

In this research, four factors that were used as the input parameters were spindle speed, feed rate, tool path strategy, and maximum scallop height, and their levels were expressed in Table 4. The toolpath strategies in five-axis milling process were described in Figure 3, and the scallop height in five-axis milling process was calculated by (2), (3), and presented in Figure 4 [18] In the experimental layout plan, with four factors and three levels, the most suitable Taguchi orthogonal array (L_{27}) was selected to design the experimental matrix as listed in Table 5.

$$h = R(1 - cos\beta) \quad (2)$$

$$\beta = sin^{-1}(\frac{S}{2R}) \quad (3)$$

where R is the tool radius.
S is the step over (radial depth of cut).

Table 4: The factors and their levels

Parameter	Unit	Coded sign	Levels		
			1	2	3

Strategy		C	Helical	Zig	Zig - Zig
Maximum Scallop Height (µm)	µm	D	1	3	5

3. Experimental Results and Discussion

3.1. Evaluation of the Cutting Force

ANOVA for Cutting Force Amplitude

The experimental results were listed in Table 5. The measured results of cutting force were listed in column 10 of this Table. Analysis results of variance of cutting force were listed in Table 6 and the main effect of cutting parameters, toolpath strategy, and the maximum scallop height on F was described in Figure 5. The ANOVA results that were used to evaluate the effect of input parameters on the output parameters with 95% confidence level and 5% significance level. The analysis results in Table 6 and Fig 3 showed that: During five-axis finish milling process of the spiral bevel gear, the parameter that has most influence on F was the spindle speed (37.51 %). The parameter that has the second influence degree on F was the feed rate (22.97 %). The parameter that has the third influence degree on F was the maximum scallop height (16.45 %). The toolpath strategy has negligible influence on the F (less than 1 %).
In addition, the influence of each input parameter on F was shown in Figure 5, the results from this figure showed that the spindle speed, feed rate, and maximum scallop height were the parameters that have significant effect on F And the influence degree of toolpath strategy on the F was quite small.

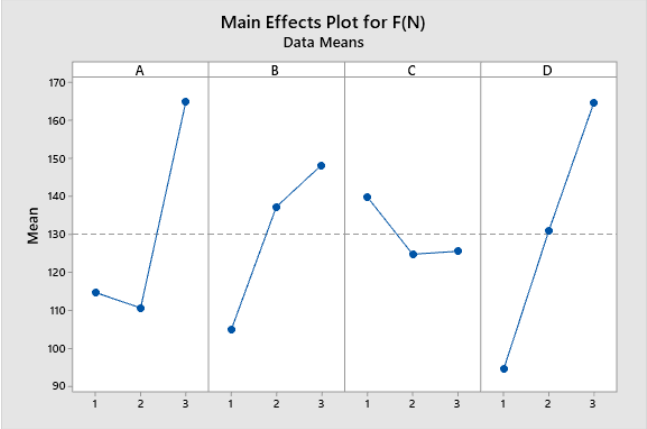

Figure 5: Main Effects Plot for Cutting Force

3.2. Regression of Cutting Force Amplitude Model

The measured data were used to model the cutting force amplitude. The regression model of cutting force amplitude is described by (4). The analysis results showed that the most suitable regression model for cutting force amplitude was a quadratic polynomial function of the spindle speed, feed rate, tool path strategy, and maximum scallop height. The regression model of cutting force amplitude was analyzed and built with high determination coefficients R^2 (86.72 %).

Cutting Force Regression Equation in coded variables

$$F = -109 + 66.1\,A + 109.5\,B - 103.9\,C + 111.0\,D - 6.5\,A*A - 11.7\,B*B + 34.1\,C*C - 17.1\,D*D + 8.4\,A*B + 2.9\,A*C - 6.1\,A*D - 17.2\,B*C - 2.8\,B*D \quad (4)$$

$$R^2 = 86.72\ \%, \quad R^2_{Ajd} = 73.44\ \%$$

3.3. Verification of Cutting Force Amplitude Model

The cutting force amplitude model was successfully verified by comparison of predicted and measured results of cutting force amplitude as described in Figure 6. The compared results from this figure showed that the predicted cutting force amplitude was quite close to the measured cutting force amplitude. It can be concluded that the quadratic regression model can be used to model the cutting force amplitude in in the finish milling process of the spiral bevel gear. The average difference between predicted and measured of cutting force amplitude is about 11.863 %.

3.4. Evaluation of the Vibration Acceleration

3.4.1. ANOVA for Vibration Acceleration Amplitude

The measured results of cutting force were listed in column 11 of Table 5. Analysis results of variance of vibration acceleration were listed in Table 7 and the main effect of cutting parameters, toolpath strategy, and the maximum scallop height on the vibration acceleration was described in Figure 7. In five-axis finish milling process of the spiral bevel gear, the parameter that has most influence on the vibration acceleration was the feed rate (22.48 %). The parameter that has the second influence degree on the vibration acceleration was the maximum scallop height (21.73 %). The parameter that has the third influence degree on the vibration acceleration was the toolpath strategy (3.65 %). The spindle speed has negligible influence on the vibration acceleration (less than 1 %).

In addition, the influence of each input parameter on vibration acceleration was shown in Figure 7, the results from this figure showed that the feed rate and maximum scallop height were the parameters that have significant effect on the vibration acceleration. And the influences degree of spindle speed and toolpath strategy on the vibration acceleration were quite small.

3.7. Evaluation of the Machining Productivity

3.7.1. ANOVA for Machining Productivity

The measured results of cutting force were listed in column 12 of Table 5. Analysis results of variance of machining productivity were listed in Table 8 and the main effect of cutting parameters, toolpath strategy, and the maximum scallop height on the machining productivity was described in Figure 9. In five-axis finish milling process of the spiral bevel gear, the parameter that has the most influence on the machining productivity was the maximum scallop height (54.90 %). The parameter that has the second influence degree on the machining productivity was the feed rate (18.92 %). The spindle speed and toolpath strategy have negligible influence on machining productivity (less than 1 %). The influence of each input parameter on the machining productivity was shown in Figure 9, the results from this figure showed that the feed rate and maximum scallop height were the parameters that have significant effect on the machining productivity. And the influence degree of spindle speed and toolpath strategy on the machining productivity were quite small.

3.8. Regression of Machining Productivity Model

The measured data of machining productivity were used to model the machining productivity. The regression model of machining productivity is described by (6). The analysis results showed that the most suitable regression model for the machining productivity was also a quadratic polynomial function of the spindle speed, feed rate, tool path strategy, and maximum scallop height. The regression model of machining productivity was analyzed and built with very high determination coefficients R^2 (99.85 %).

Productivity Regression Equation in coded variables

$$\begin{aligned} P = {} & 0.510 - 0.0359\,A - 0.1118\,B - 0.6723\,C + 0.3643\,D \\ & + 0.0065\,A*A + 0.0333\,B*B \\ & + 0.1691\,C*C - 0.0576\,D*D \\ & + 0.00976\,A*B - 0.01102\,A*C \\ & + 0.00992\,A*D + 0.0176\,B*C \\ & + 0.0107\,B*D \end{aligned} \quad (6)$$

$$R^2 = 99.85\ \%, \quad R^2_{Ajd} = 97.70\ \%$$

3.9. Verification of Machining Productivity Model

The machining productivity model was also successfully verified by comparison of predicted and measured results of machining productivity as described in Figure 10. The compared results from this figure showed that the predicted machining productivity was quite close to the that one of measured value. It can be also concluded that the quadratic regression model can be used to model the machining productivity in in the finish milling process of the spiral bevel gear. The average difference between predicted and measured of machining productivity is about 2.867 %.

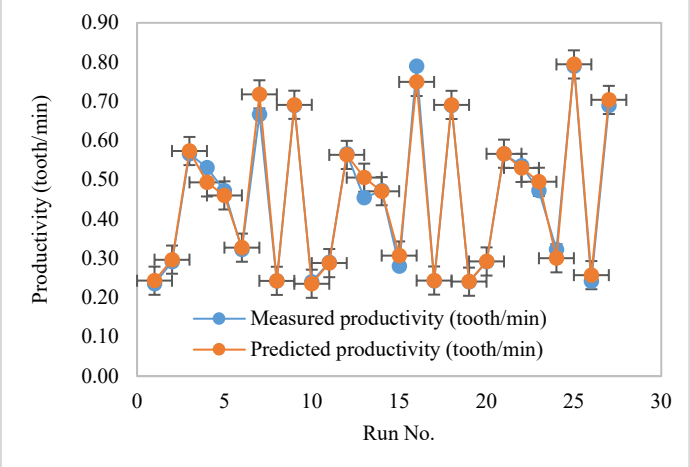

Figure 10: Comparison of predicted and measured productivity

4. Conclusion

In this study, the Taguchi method and ANOVA that were successfully applied to determine the influence of the spindle speed, feed rate, tool path strategy, and maximum scallop height on cutting forces, vibrations, productivity in the finish milling process of the spiral bevel gear. From the achieved results, the conclusions of this study were drawn as follows:

During the finish milling process of the spiral bevel gear with a ball-end mill cutter (HSLB-2030), the parameter that has most influence on the cutting force amplitude was the spindle speed (37.51 %). The parameter that has the second influence degree on the cutting force amplitude was the feed rate (22.97 %). The parameter that has the third influence degree on the cutting force was the maximum scallop height (16.45 %). The toolpath strategy has negligible influence on the cutting force (less than 1 %)

The feed rate was the most influence factor on the vibration acceleration (22.48 %). The parameter that has the second influence degree on the vibration acceleration was the maximum scallop height (21.73 %). The parameter that has the third influence degree on the vibration acceleration was the toolpath strategy (3.65 %). The spindle speed has negligible influence on the vibration acceleration (less than 1 %).

The parameter that has the most influence on the machining productivity was the maximum scallop height (54.90 %). The parameter that has the second influence degree on the machining productivity was the feed rate (18.92 %). The spindle speed and toolpath strategy have negligible influence on machining productivity (less than 1 %).

Quadratic regression that was determined as the most suitable regression of cutting force amplitude and vibration acceleration amplitude, and productivity in the finish milling process of the spiral bevel gear with the determination coefficients (R^2) 86.72 % for cutting force amplitude, 93.46 % for vibration acceleration amplitude, and 99.85 % for machining productivity. These regression models were successfully verified by comparison of predicted and experimental results of cutting force amplitude and vibration acceleration amplitude, and productivity.

Taguchi method, ANOVA, and these regression models in this study can be applied to improve the quality of the machining process by reducing the cutting force components, vibration components, and improve the productivity of machining process. There are the research directions in the next issues of this study.

ABSTRACT

In this paper, the investigated results on tool wear in milling process of a Gleason spiral bevel gear was investigated. The CVD Ti (C, N)-Al_2O_3-TiN coated carbide inserts were used in the experimental process. The cutting inserts clamped on the tool head of Gleason tool head system. The workpiece material that was used in this study was 20XM steel. In this experimental research, the experiments were carried out according to the Box-Behnken matrix. In this study, the cutting velocity, the feed rate, and the depth of cut were selected as the input parameters for the experimental processes. By analyzing the experimental results, the influence of cutting velocity, feed rate, and the depth of cut on the tool wear in machining process was investigated. Besides, the tool wear was successfully modelled as a quadratic polynomial function of the cutting velocity, the feed rate, and the depth of cut. Moreover, the optimization process was also conducted to determine the optimal values of input parameters. In this case, the minimum value of the tool wear that was 32.3679 µm was achieved at the cutting velocity of 93.0 m/min, at feed rate of 59.3939 s/tooth, and at the cutting depth of 0.553 mm. The obtained optimal values that were successfully verified by cutting test process. The difference between predicted and experimental values of tool wear was 2.9 %. This experimental method could be used to reduce the tool wear in the milling process of a Gleason spiral bevel gear.

1. Introduction

In recent years, the effect of cutting parameters on the tool wear and other machining characteristics was investigated to improve the quality and efficiency of machining processes many studies were performed to investigate. This research direction was performed in the different machining processes such as milling [1-3], turning [4-6], drilling [7], etc. to machine the different products. Milling is a popular machining method, providing high performance and widely used in mechanical machining. The milling method can be performed to machine many different types of surfaces, with many different materials.

In milling processes, the studies about tool wear and other machining characteristics that were carried out following two directions. In the first direction, the tool wear and other machining characteristics were modeled depending on the physical, chemical, and geometrical phenomena such as friction, temperature, cutting, Etc. [8, 9]. This approach is quite difficult to perform because many factors that influence on the wear of tool and other output parameters. In the second direction, the tool wear and surface roughness were modeled depending on the experimental data. This approach can be applied for specific cases in which only several factors were considered in the investigation of their influence on the tool wear and other machining characteristics [10-12].

In the experimental modelling method, several approaches were applied to model the tool wear and other machining characteristics depending on the cutting time or cutting conditions. The tool wear and other machining characteristics were investigated in milling process depending on the cutting time. This study was carried out to verify the change of machining surface roughness due to increasing tool wear. [13, 14]. The neural approach was applied to investigate the influence of cutting condition of tool wear and average surface roughness in turning process under minimum quantity lubrication (MQL) environment. [15]. The influence of the cutting parameters on the tool wear and the surface finish criteria have been determined through the

response surface methodology (RSM) prediction model. The prediction models of tool wear and surface roughness are also used to determine the combined effect of machining parameters on the tool wear and surface roughness [12, 15]. Taguchi experimental design was used to determine the influence of machining conditions on the tool wear and surface roughness. Besides, the investigation of relationship between tool wear and surface roughness was investigated in in dry pocket milling processes of aluminum alloy Al7075 [16].

In the milling process of a Gleason spiral bevel gear, the tool wear that is one of the important parameters to be selected as a criterion to evaluate the efficiency and quality of the cutting process. The tool wear not only influences on the quality of machined surfaces and the tool life, but also influences on the energy consumption (through cutting power). The studies on tool wear in the milling processes of the Gleason spiral bevel gear have been done by several authors. In order to determine the optimum values of the geometry parameters of cutting tools, the 3D simulation method was applied to ensure the minimum of tool wear value [17, 18]. The influence of the cutting velocity and feed rate on the tool wear was investigated when machining 6MnCr5 material using cutter insert coated (Al, Cr) N [19]. This study showed that cutting velocity and feed rate have significant influence on the tool wear. Tool wear was also was investigated based on the heat simulation in cutting processes [20].

In this study, the experimental of milling a Gleason spiral bevel gear (20XM steel) was performed using the CVD Ti(C, N) -Al2O3-TiN coated carbide inserts. This study was conducted to determine the effect of the cutting velocity, the feed rate, and cutting depth on the tool wear, and determine the optimum values of the cutting parameters to obtain the minimum of the tool wear.

2. Experimental method when milling a Gleason spiral bevel gear

2.1. Experimental machine

The semi-automatic gear milling machine with symbol 525 manufactured by the Russian Federation (figure 1) was used to perform the experiments.

Cool lubricant: Industrial oil 32, flow of 15 lit/min, lubricating directly.

Figure 1: Testing machine

2.2. Cutting insert and cutter head

The cutting inserts that were used in this study were the CVD Ti (C, N) - Al_2O_3 - TiN coated carbide inserts (SANDVIK). This type of cutting insert has many advantages in industry machining such as: heat resistance stability, mechanical stability, impact resistance, and suitable for final cutting conditions, etc. This material is widely used to manufacture cutting tools for machining process and for machining process the of the gears. The properties of this material in comparison to other cutter materials were presented in Table 1. The geometry of the cutting insert is shown in Figure 2.

Table 1: The properties of several cutter material [21]

No.	Cutter material	Cutting velocity V_c (m/ph)	Cutting limit temperature (°C)	Hardness (HRC)
1	High Speed Steel	20 ÷ 30	500 ÷ 650	60 ÷ 64
2	WC coated carbide	200	1000 ÷ 1200	91
3	WC + TiC coated carbide	300	1000 ÷ 1200	91 ÷ 92
4	TiC coated carbide	300	1000	92 ÷ 94
5	CVD Ti (C, N) -Al2O3-TiN) coated	370 ÷ 480	1000 ÷ 1100	90 ÷ 92

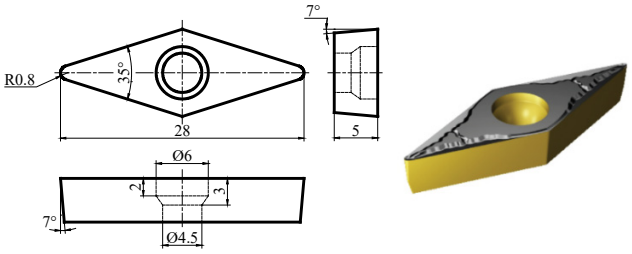

Figure 2: CVD Ti(C, N)-Al_2O_3-TiN coated carbide insert

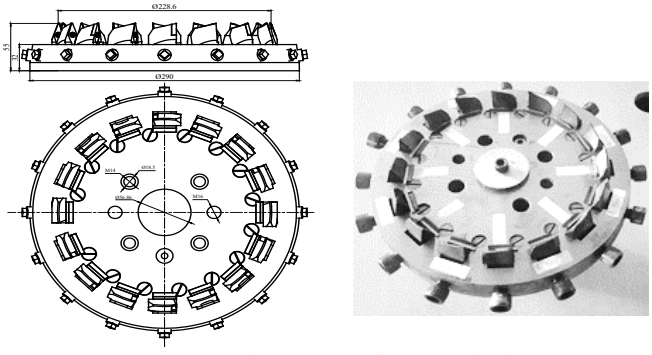

Figure 3: Gleason fine milling cutter head

The tool head for machining gears that was used in this study was a 9-inch Gleason final milling cutter head. This cutter head consists of 16 cutting flutes with 8 external flutes and 8 internal flutes. The tool can be used to machine the gears with module

from the module 4 to module 9 as shown in Fig. 3. The geometrical parameters of a flute were shown in Fig. 4 and Fig. 5.

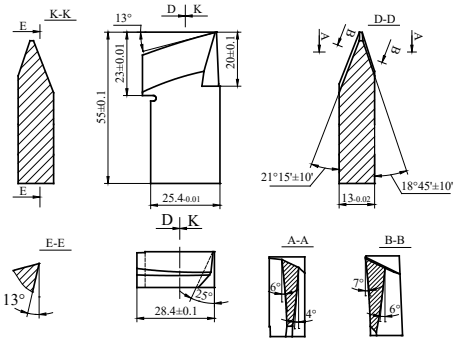

Figure 4: Geometrical parameters of the internal cutting flute of the Gleason cutter head

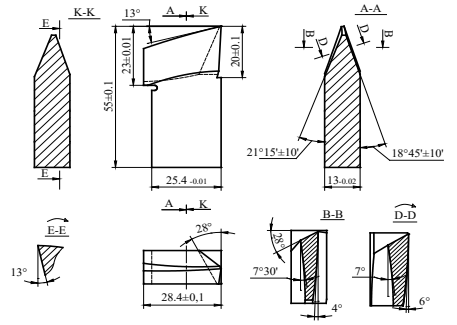

Figure 5: Geometrical parameters of the external cutting flute of the Gleason cutter head

2.3. Experimental workpieces

The workpiece material that was used in this study was 20XM steel (ГОСТ 4543-71). The workpiece chemical compositions are analyzed according to ASTM 415-99A-2005 standard was listed in Table 2. Before each experiment, the workpiece was machined according to the detailed drawing of a gear with the following basic parameters: Module: m_s = 4.5mm; helix angle $\beta_s = 35^0$; number of flutes Z = 27 as shown in Fig. 6 and Fig.7.

Table 2: Main chemical composition of workpiece material %

C	Si	Mn	Cr	Ni	Mo	Cu	S	P	Fe
0.23	0.19	0.68	0.93	0.18	0.24	0.15	0.03	0.03	Balanced

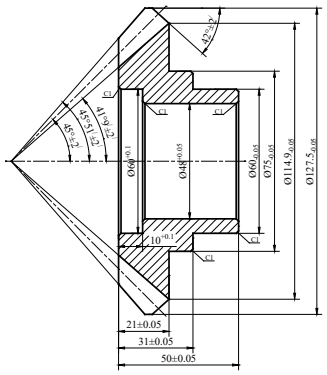

Figure 6: Detailed drawing of a gear workpiece

Figure 7: Experimental workpiece

2.4. Measuring system of tool wear

For each experiment, the tool wear was measured using the VHX-6000 digital microscope of Keyence Japan. Fig. 8 indicated the setup of the microscope for measurement of the tool wear. Fig. 9 indicates the measurement position of the flank tool wear (VB).

Figure 8: VHX-6000 digital microscope

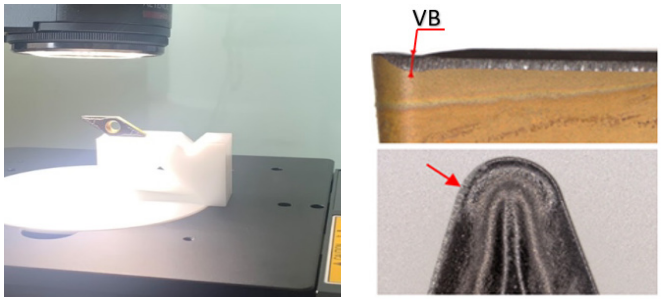

Figure 9: The tool wear of the back in a test

2.5. Experimental matrix

In this study, the experimental plan was designed using Box-Behnken matrix. In this form of planning, each input parameter had three value levels. The input parameters and their levels are presented in Table 3. The experimental matrix was presented in Table 4.

Table 3: Input parameters and their levels

Parameters	Symbol	Unit	Levels and values		
			1	2	3
Velocity of cut	V	m/min	93	117.5	142
Feed rate	S	s/tooth	40	50	60
Cutting depth	t	mm	0.25	0.50	0.75

Table 4: Test matrix and results

No.	Code value			Actual value			VB (µm)
	V	S	t	V(m/min)	S (s/tooth)	t (mm)	
1	-1	-1	0	93	40	0.5	57.22

15	0	0	0	117.5	50	0.5	30.24

3. Analyzed results and discussions

The experimental process was performed according to the experimental matrix as listed in Table 4. The values of tool wear (VB) that were obtained from the experimental process were also listed in this table. The results of ANOVA analysis for the tool wear were presented in Table 5. The influence degree of input parameters on the tool wear, and the influence of the interaction between parameters on the tool wear were shown in Fig. 10 and Fig. 11, respectively.

The analyzed results in table 5, Fig. 10, and Fig. 11 showed that:

The cutting velocity was a parameter with a great influence on the tool wear. When the cutting velocity increased from 93 to 117.5 (m/min), the tool wear decreases slowly, but when cutting velocity increased from 117.5 to 142 (m/min), the tool wear increased quickly.

Other parameter that has a significant influence on the tool wear was feed rate. This conclusion is also consistent with the statement of Fritz et al. [19]. When the feed rate increased, the wear of tool increased.

The cutting depth has little influence on the tool wear. Initially, when increasing the depth of cut, the tool wear decreased slowly, but further increasing the depth of cut, the tool wear increased slowly.

The interaction influence of V, the S, and t on VB were very complex influence. The in Fig. 11 showed clearly this statement.

From the experimental results in Table 4, a tool wear regression model was developed and expressed by Eq. (1). This model was built with a determination coefficient of 0.9169 (R^2 = 0.9169). This value was very close to one, which affirmed that this model had high compatibility with the testing data.

g) Interaction between V vs S when t = 0.075 (mm)
h) Interaction between V vs t when S = 60 (s/tooth)
i) Interaction between S vs t when V = 142 (m/min)

Figure 11: The interaction influence between input parameters on the tool wear

$$VB = 892.416 - 8.84014 * V - 12.7191 * S - 263.038 * t + 0.0230390 * V^2 + 0.042366 * S^2 + 80.7867 * t^2 + 0.0712551 * V * S + 0.636735 * V * t + 1.92500 * S * t \quad (1)$$

The tool wear model presented in Eq. (1) was the basis for choosing the value of the input parameters in the investigated area to obtain the minimum value of the tool wear. In addition, this equation may be used to predict the tool wear corresponding to specific values of the cutting velocity, feed rate and depth of cut. The comparing the tool wear in experimental and predicted processes was shown in Fig.12. It was shown that the predicted results of the tool wear were very close to the that one of experimental results. This showed that equation (1) can completely be used to predict the tool wear corresponding to specific values of the input parameters in the investigated area.

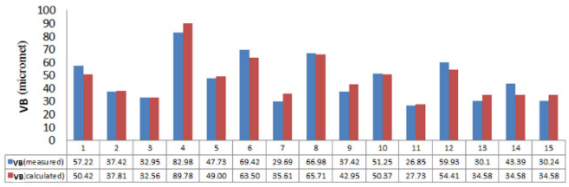

Figure 12: The tool wear when measuring and calculating

4. Optimization process

In order to obtain the optimal values of the cutting velocity, feed rate, and depth of cut to ensure the tool wear with minimum value (tools with maximum life), the constraints for input parameters and the constraints for evaluation criteria should be defined in solving the optimization problem.

The constraints values of the variables are the largest and lowest values of the Box-Behnken matrix. In particular, the constraints of experimental variables were expressed as Eq. (2).

$$\begin{cases} 93\ \left(\frac{m}{min}\right) \le V \le 142\ \left(\frac{m}{min}\right) \\ 40\ \left(\frac{s}{tooth}\right) \le S \le 60\ \left(\frac{s}{tooth}\right) \\ 0.25\ (mm) \le t \le 0.75\ (mm) \end{cases} \quad (2)$$

According to references [21, 22] and recommendation by the cutting tool manufacturer, and practical experience in the manufacturing processes, when the tool wear VB exceeds the value 250 (μm), the accuracy of each gear is not guaranteed. This value of VB is chosen as the constraint of VB when performing the optimization process in this study. Thus, the constraint for output parameter was selected by Eq. (3).

$$0 < VB \le 250(\mu m) \quad (3)$$

Using the Minitab 16 statistical software to solve the equation (1) to ensure the minimum of tool wear with the constraints as in equations (2) and (3), the optimization graph for the tool wear was obtained and shown in Fig. 13.

Fig. 13 showed that, the optimal value of the cutting velocity, feed rate, and depth of cut are 93.0 (m/min), 59.3939 (s/tooth), and 0.553 (mm), respectively. With the expectation function d = 1.000, it means the probability of this case is up to 100%, and then the tool wear has a minimum value of 32,3679 (μm).

The verified experiments were performed by using these optimized values of the cutting parameters. Based on the adjustment ability of the experimental machine, the value of cutting parameters were only selected in the percentage accuracy (two decimal places). The experiments were carried out with five tests in five gear samples with the workpiece velocity of 93.00 m/min, feed rate 59.40 s/tooth, and cutting depth of 0.55 mm. During the experimental process, other parameters were selected the same when performing the test according to the Box-Behnken matrix. The verified results were stored and listed in Table 6.

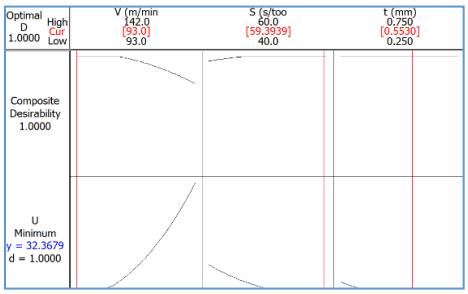

Figure 13: Optimization graph of objective functions for the tool wear

Table 6: Test results verifying the optimal value

The tool wear when testing, VB (μm)						Calculated VB (μm)	**% deviation**
Test 1	Test 2	Test 3	Test 4	Test 5	Average		
31.12	31.83	29.68	30.85	33.66	31.43	32.37	**2.9**

Table 6 indicates that in all 5 tests, the values of the tool wear during the tests are very close to the calculated values of tool wear, the average deviation between the test values and the calculated values was 0.94 μm (about 2.9%). The evaluated results showed that the optimal value of cutting parameters as well as the value of achieved tool wear when performing the optimization process ensured the high accuracy in compared to the actual value.

5. Conclusions

This study was performed to investigate the effect of milling parameters on the tool wear in milling process of the Gleason spiral bevel gear. The conclusion of this study was drawn as following.

(1) The cutting velocity has a great influence on the tool wear, the feed rate was the second factor that influence on the tool wear. The depth of cut has a negligible effect on the tool wear.

(2) The interaction between the velocity of cut, the feed rate, and cutting depth on the wear of tool is very complex.

(3) A regression model showing the relationship between the tool wear and the cutting velocity, feed rate, and the depth of cut was proposed in this study. This model was applied to determine the optimum values of cutting parameters to obtain the minimum value of tool wear. In addition, this model was also used to predict the tool wear in each specific case depending on the cutting parameters. The value of tool wear when calculating was very close to that one when performing experimental.

(4) In this study, by solving the optimization problem, the optimized results of the cutting parameters were determined as

following: The cutting velocity was 93.00 m/min, the feed rate was 59.40 s/tooth, and cutting depth was 0.55 mm. When machining with this set of cutting mode, the minimum tool wear that was obtained was about 31.43 (μm).

(5) The experimental method of this study can be used to improve the cost of the machining process through extending the tool life or reducing the tool wear.

ABSTRACT

The current online shopping system does not provide the actual shopping experience to the users where they scroll through the web pages and select an item to purchase, which becomes monotonous soon and lacks the shopping experience. This paper describes the development of the SmartMart, a 3D shopping mart where the user can navigate around the mart with the help of a virtual cart and interact with the products as they would do in real life. Further, this paper explains the integration of the recommendation system with the SmartMart that provides efficient and seamless customer experience. Here, the customers are recommended with various products based on their previous purchase history. This gives a more personalized touch to each user adding on to their shopping experience. This paper describes the implementation of recommendation system using three types of algorithms namely item-based collaborative filtering, popularity model and user-based collaborative filtering. These algorithms are integrated with Unity SmartMart application and tested with the open source dataset. This dataset is organized in three ways- original data, data with a dummy field and normalized data. Distance metrics such as Pearson co-relation co-efficient, Jaccard similarity, cosine similarity metrics are used to compute the similarity among customers. This paper presents a comparative study of these different similarity metrics for user-based recommendation algorithm based on precision, recall, F-value and accuracy. From results obtained it can be seen that the Pearson co-efficient metric gives the highest accuracy value (86.6%) but the F-value, mean precision and mean recall values are very less compared to Jaccard Similarity Metric. Hence, Jaccard similarity metric is preferred over Pearson co-relation co-efficient. The design and development of SmartMart along with the recommendation system adds a new dimension to both the existing online shopping system and provides better customer satisfaction.

1. Introduction

3D simulation software provides a rich training experience to the user for various end-user applications, without using any physical asset and loss to the company. This is a key factor of 3D simulation that is expected to boost market growth. The simulation software market was valued at USD 8.24 billion in 2019, and it is expected to reach USD 19.22 billion, by 2025. The 3D simulation enables users to immerse in a computer-generated environment where they can interact with various simulated objects in a way replicating the real-life process. These 3D objects can be generated automatically or manually created by deformation of the mesh structure, or otherwise manipulating vertices. Using 3D simulation for online shopping primarily enhances the customer experience and takes online shopping to a new level of sublimity.

This adds a realistic window which is absent with the existing online shopping websites where the user does not get to perceive the actual depiction of an item which they are inclined to purchase. Though the current websites try to minimize the hassle of the actual shopping process but it cuts away many privileges of a customer which would be helpful in selecting the appropriate item they want to purchase.

Currently, the e-commerce websites display 2D images of the products and facilitates the text-based search to seek out desired items to be purchased. But this does not allow customers to associate themselves with the real-world object experience. So, to replicate the real-world shopping experience for customers, this paper describes the design and development of a 3D shopping mart

*Corresponding Author: Poonam Ghuli, Department of Computer Science and Engineering, RV College of Engineering, 9986421230 & Email: poonamghuli@rvce.edu.in

called SmartMart. Here, each object is modeled in three dimensions to recreate the real-world object and also includes the other aspects of physics such as rotation, rolling, dragging of objects that makes the whole process more engaging. Due to this, the customer's experience of selecting an item from the SmartMart becomes more impeccable.

The SmartMart is designed using Unity along with its copious features to establish a smooth user interface. Also, the products to be bought are modeled and rendered in the gaming engine in way that provides the customers with a flawless online shopping experience. MySQL database used stores the information about the products, customers and their transaction details. MySQL database further enables to scale the number of products or customers without any inconvenience.

To broaden the scope of this proposed idea, a recommendation system has been implemented. To recommend appropriate products to customers the purchase history of multiple users is considered. A few factors that measures E-commerce success and customer satisfaction are as follows:

- What are the most trending products for sale?
- What are most suitable products for a particular customer based on his purchase history?
- What items are more often bought together?

Considering all the above-mentioned key factors, this paper describes implementation of recommendation system using three types of algorithms namely item-based collaborative filtering, popularity model and user-based collaborative filtering. Further, these algorithms are designed and integrated with Unity SmartMart application. For this, an open source dataset is used and organized in three ways- original data, data with a dummy field and normalized data. Further, Pearson co-relation co-efficient, Jaccard similarity, cosine similarity matrices are used to compute the similarity between purchase pattern usages among customers. Jaccard similarity metric provided the best result.

The admin of the SmartMart application is authorized to append the data of the ongoing transactions and periodically train the model with latest dataset. This ensures that the recommendation system takes into account the changing trends of customer's shopping patterns with proposed SmartMart application.

2. Literature Review

In [1], the author described a personalized Recommender System based on data clustering techniques to deal with the scalability problem. User-clusters are formed to categorize them based on their shopping behavior. The proposed work use DBSCAN clustering algorithm for clustering the users, and then implement voting algorithms to recommend items to the user depending on the cluster into which it belongs. Their idea was to partition the users of the Recommendation system using clustering algorithm and apply the Recommendation Algorithm separately to each partition. The system recommends item to a user in a specific cluster only using the rating statistics of the other users of that cluster. They have tested the algorithm on the Netflix prize dataset.

The work in [2], proposed two recommendation models for offline grocery/retail stores. The accumulated PoS (Point of Sales) data is used to understand the shopping behavior of different customers and recommend better products. The proposed recommendation models are-Direct recommendation of products and two step recommendation systems. These recommendation algorithms are analyzed based on precision and accuracy of the model.

In [3], the author presented a recommendation system in their 3D environment where they consider the pre-purchase ratings of users to suggest products. The pre-purchase ratings include the interaction of user with the 3D objects. The user's emotions are captured in the form of electroencephalogram (EEG) signals. This makes the recommendations more users specific and accurate. A combination of this and the already existing recommendation system makes it dynamic.

The study in [4] presents a Recommendation system which offers real-time personalized suggestions on offers to its customers. Using iBeacons personalized notifications telling about the offers which are pushed to the smart phones of the customer in real-time as they navigate through the shopping mart. This approach uses a Bayesian Inference and a Hard k-modes clustering approaches. Bayesian Inference approach uses Entropy-based algorithm to give accurate and user specific recommendations on the offers provided to each user.

In [5], the author has proposed a virtual shopping mart which simulates a real working of shopping mart. The virtual shopping mart enables a cost efficient and high flexible way to store data. Researchers can use this data to improve the shopping experience of the customers. The data can be used to accurately predict the reactions of the customers to price change and the reactions to availability of the products that the customers need. These reactions can be used to optimize the shopping mart in a way to efficiently serve the customer's requirements.

In virtual reality the customers have the exact 3D representation of the items unlike the other 2D shopping websites this helps in analyzing the exact reactions the customers have towards a product in the shopping mart which enables researchers to capture an accurate consumer behavior.

The architecture that is proposed in this paper stands out from the other existing prototypes in a way that it integrates the recommendation system with the 3D environment (Unity software) which makes it possible for the user to have a sublime shopping experience. This entire system is based on client server model that allows concurrent access to the SmartMart by the potential customers. The use of recommendation system which recommends the most popular items and the items that the user would purchase helps the user to manage his/her shopping time more efficiently. The interaction with the 3D environment using keyboard and mouse makes the customer's shopping experience realistic.

3. Proposed Design of Smart-Mart

The system architecture for the proposed SmartMart is illustrated in Figure 1. It manifests a computing model in which a server hosts, delivers and manages most of the resources and services to be utilized by the clients. The project aims at building a Client-Server architecture where the client application entails a 3D UI (User Interface) platform that would grant customers/users a real-time shopping experience at the click of a button.

The customer interacts with the environment through keyboard and mouse input controls to bring in various changes ranging from the state of a product to updating the fields in database in the server. The MySQL database stores all the information about products, customers, transaction details and billing information. A virtual shopping cart designed in unity platform can freely move around the SmartMart.

Also, customers are allowed to add products to shopping cart, thereby facilitating a user-friendly experience to the users, unlike the existing shopping platforms. As the user proceeds towards the billing section, the inventory is updated which would help administrators to track and maintain the stock efficiently.

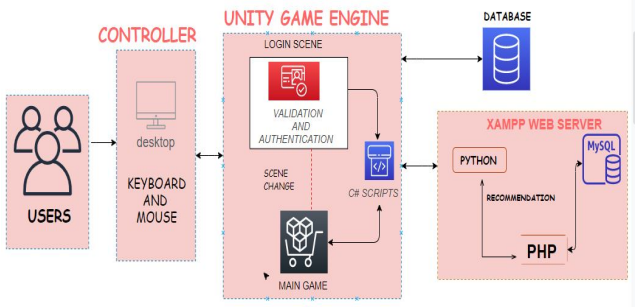

Figure 1: System Design of User interaction with SmartMart.

The Figure 1 describes about the Unity gaming engine that is used to host the entire shopping environment application. The Unity APIs used in the proposed work handle various user interactions and allow communication with third party scripts, namely, C# and PHP (Hypertext Preprocessor). The user interactions are translated into corresponding events by the interface. The application processes these events and triggers other events or updates the SQL database connected to it. A PHP script acts as an intermediary to communicate between the SQL database and the application.

The figure 2 describes the 3D view of the proposed SmartMart. This figure shows a virtual cart an products placed on shelves in the SmartMart. The user can move around virtual around the mart along with the Virtual-Cart.

The uniqueness of this paper is integration of SmartMart with the recommendation system. This recommendation system is deployed using the Python script and connected to the SmartMart application via PHP.

Figure 2. The 3D view of the SmartMart

4. Workflow of Proposed Work

Unity is a cross-platform game engine with a built-in IDE (Integrated Development Environment) used to develop video games for web plug-ins, desktop platforms, consoles and mobile devices. Pro-Builder is a tool that gives Unity the ability to edit the shape of primitive objects and model these 3D objects as per the requirements.

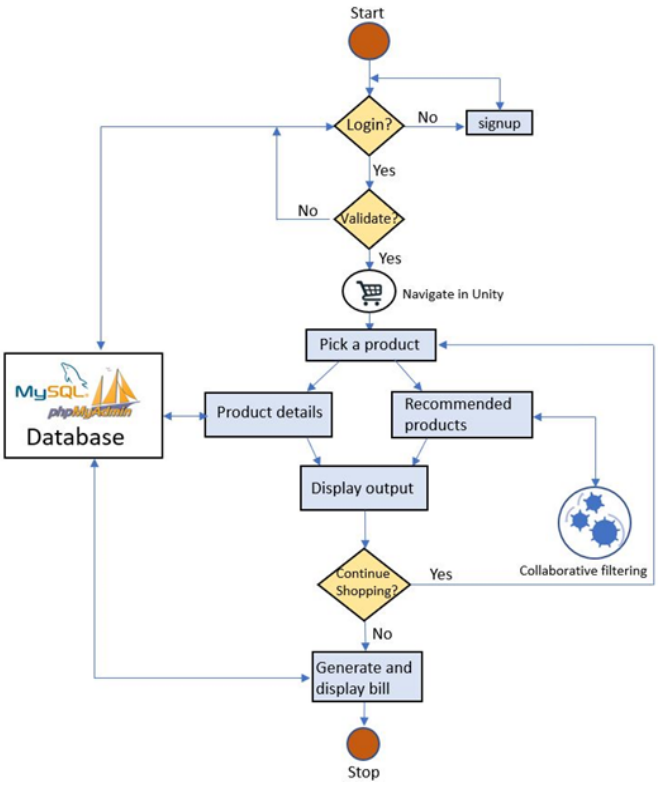

Figure 3: Workflow of Smart-Mart

The work flow of the Virtual Supermarket is depicted in the Figure 3. The application starts with the initial scene where user credentials are validated with username and password. If the credentials are correct, the user gets into the game scene, which is the main application. The user is placed at the entrance of the mart, with a virtual cart placed there. The cart is designed using Pro-Builder. The cart is scripted such that the customer can move it around the mart with the help of the mouse control.

Shelves at the virtual mart are rendered using unity platform and various products are placed on it. The products at the mart are built as 3D objects using Pro-builder platform in order to recreate the real-life products such as baseball bats or celery. These virtual products created in the Unity platform are nothing but Game Objects. Game Objects are the fundamental objects in Unity that represent characters, props and scenery. Every Game Object is associated with a tag which is used to identify, retrieve and store the information about a particular product. Each product/Game Object is associated with a script which allows the user to rotate, drag and drop it into the virtual cart. Whether the customer puts or removes the item to or from the cart, the inventory database is updated accordingly in real time. As soon as the user selects the product, the details of the product along with the recommendations are displayed on the monitor installed at the billing counter. This is accomplished using PHP server that communicates with MySQL and Unity.

Once the user completes the adding of products to the virtual cart, the cart can be dragged to the billing counter where appropriate billing information is displayed. This billing information includes the items purchased, per piece price, total quantity, total price, time of billing, customer id and customer details. These transaction details are stored in the database in real time. Once the billing details are generated, the user signs out and the session is over.

Thus, database manages all the transactions, user and product information efficiently. The details of the products are displayed to customers as required without any latency. The interactions, ranging from dragging and dropping of the items into virtual cart to its movement in 3D environment in the first-person view is flawless.

After the text edit has been completed, the paper is ready for the template. Duplicate the template file by using the Save As command, and use the naming convention prescribed by your conference for the name of your paper. In this newly created file, highlight all of the contents and import your prepared text file. You are now ready to style your paper; use the scroll down window on the left of the MS Word Formatting toolbar.

5. Recommendation System

Al the proposed virtual Super market is further integrated with a Recommendation System. In the field of e-commerce, recommendation systems are an attempt to bridge the gap between the online and in-store shopping experience reiterating the very aspect that made this project distinctive. Recommendation systems streamline our online shopping experience by suggesting products that customers might be interested in.

With the growing technological advancements in the fields of business intelligence and data science, recommendation systems have become increasingly popular. They help the customers to know and decide what to buy based on their previous purchase history, their feedbacks and features of the products to be purchased.

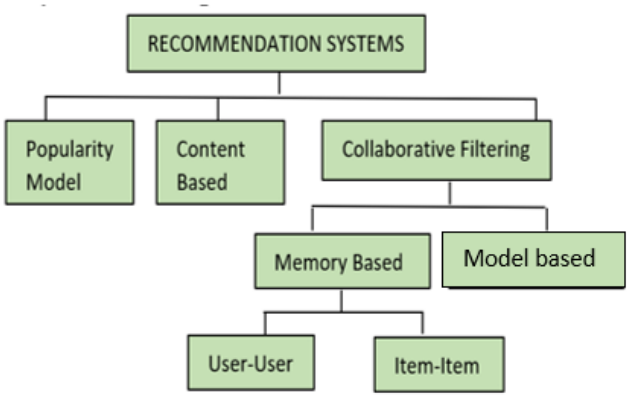

Figure 4: Classification of recommendation system

The two most popular approaches for building a recommendation system are Collaborative Filtering and Content-based algorithms as shown in Figure 4. While the former approach requires only the user's historical preferences over the existing inventory, the latter requires a fair amount of knowledge on the item's characteristics such as ingredients, trademark and features. Although Collaborative Filtering depends on only purchase history of users one assumption that this model makes is that the users who have purchased a certain set of products in the past also tend to agree with the same kind of products in the future.

Collaborative filtering algorithms [6] are mainly classified as model based and memory based approaches. Further there are two types of Memory based Collaborative filtering algorithms namely Item-based collaborative filtering and User-based collaborative filtering . Item-based collaborative filtering that depends on items and their similarity to other items. User-based collaborative filtering algorithm is more resource-intensive as it looks at customer behaviors and preferences. In memory based approach the similarities with the closest users or items are calculated by using Cosine similarity or Pearson correlation coefficients, which depend primarily on arithmetic operations. Model based collaborative filtering algorithms provide recommendations by developing a machine learning model on existing user ratings and then to predict user's rating of unrated items [7]. As building a model is both time and resource consuming. It is difficult to add data to model based systems. The quality of prediction for memory based algorithms is good as it uses the entire database every time it makes a prediction. Thus, we go with memory based algorithms for the proposed work.

The similarity metrics [8] used for recommending products in the SmartMart application are Cosine, Pearson Correlation Coefficient and Jaccard similarity methods.

- By measuring cosine of the angle between any two vectors, Cosine similarity technique calculates how these are related to each other. The Cosine similarity metric is computed as shown in equation 1.

$$\boldsymbol{CS(i,j)} = \frac{\sum_{u \in U_{ij}} \boldsymbol{r_{ui} r_{uj}}}{\left(\sqrt{\sum_{u \in U_{ij}} \boldsymbol{r_{ui}^2}}\right)\left(\sqrt{\sum_{u \in U_{ij}} \boldsymbol{r_{uj}^2}}\right)} \quad (1)$$

where Ui represents users, who have purchased only item i & Uij represents users who have purchased both i & j items.

- Pearson coefficient similarity technique calculates the similarity between two vectors by the linear correlation between them. The values resulting from PCC range from -1, representing negative correlation to +1, representing a high positive correlation. Zero order correlation is when the value is 0 and the vectors do not show any relation. The Pearson Correlation Coefficient similarity metric is computed as shown in equation 2.

$$\boldsymbol{PS(i,j)} = \frac{\sum_{u \in U_{ij}} \left(\boldsymbol{r_{ui}} - \overrightarrow{\boldsymbol{r_i}}\right)\left(\boldsymbol{r_{uj}} - \overrightarrow{\boldsymbol{r_j}}\right)}{\left(\sqrt{\sum_{u \in U_{ij}} \left(\boldsymbol{r_{ui}} - \overrightarrow{\boldsymbol{r_i}}\right)^2}\right)\left(\sqrt{\sum_{u \in U_{ij}} \left(\boldsymbol{r_{uj}} - \overrightarrow{\boldsymbol{r_j}}\right)^2}\right)} \quad (2)$$

where Ui represents users, who have purchased only item i & Uij represents users who have purchased both i & j item.

- Jaccard similarity technique calculates the extent of similarity between two users by taking number of preferences common between them and is shown in equation 3.

$$JS(i,j) = \frac{|U_i \cap U_i|}{|U_i \cup U_i|} \quad (3)$$

where Ui represents users, who have purchased only item i.

As mentioned in the previous section this paper implements recommendation system using three types of algorithms namely item-based collaborative filtering, popularity model and user-based collaborative filtering. Popularity based recommendation systems learn data in a certain way, after which, suggest items that are in trend at the moment. For instance, if there exists a product that is being purchased by many users then it is likely that it will be recommended to every user.

6. Details of Dataset and Data Pre-processing

The proposed work makes use of two datasets. First one is MySQL database created to store details pertaining to the customers, their transactions and product information. The other one is an open-source dataset [9].

The MySQL database being employed has the following tables that stores vital information – the validation details of the customers; the customer table contains the details of all the existing customers; the inventory table contains details like product ID, product name and their respective quantities that directly correlate to the stock available with the seller; the billing table which stores the bill generated during shopping and holds information like user ID, items bought, time of purchase, etc and the orders table that contains all the bills generated along with respective product information.

The open-source dataset that is used to build a recommendation system is available in .csv format. It has information regarding the purchase history of the customers. There are 3 approaches in terms of how data is being used.

Taking customer ID and product ID as they are.

Creating a dummy field for marking whether a customer bought an item or not.

Normalize purchase frequency of each item across users by first creating a user-item matrix.

Since normalization is always used as a basic component for the predictor models and most often produces the best results when it comes to recommender systems, it was decided to proceed with normalized data. We have normalized the purchase history of users on a scale of 0 to 1. 1 depicts the greatest number of purchases for an item and 0 depicts 0 purchase count for that item.

7. Results and Discussions

The proposed work evaluates the different Similarity Metrics for user-item recommendation algorithm based on recall, precision, and F-value with the number of recommended items for each user as 10 [10]. The results presented in Table 1 evaluate the different similarity matrices for user-item recommendation algorithm by using the average value of recall, precision, and F-value. Table 1 also provides the recall, precision, and F-value for popularity model variant of recommendation system. Cut-off 'K' is a user definable integer that is set by the user to match the top-N recommendations. The value of cut-off is kept as 10 (K=10).

Table 1: Performance comparison of Similarity Matrices

Recommendation System Models	Similarity Metrics	Precision	Recall	F-Value
Popularity Model	-	0.002685	0.014068	0.004509
User-based Collaborative Filtering Algorithm	Cosine similarity	0.026191	0.137444	0.043999
	Pearson similarity	0.002706	0.014176	0.004545
	Jaccard similarity	0.027089	0.141439	0.045469

Precision: The number of products bought by the customer out of all the recommended products. Precision at k is the proportion of recommended items in the top-k set that are relevant. Suppose if 10 products were recommended to this customer out of which he buys 5 products, then precision is 0.5. The precision at k is computed using equation 4.

$$\text{Precision} = \frac{\left(\begin{matrix}\text{Number of recommended items that}\\ \text{are relevant in the top k set}\end{matrix}\right)}{\text{Number of recommended items in the top k set}} \quad (4)$$

Recall: The number of products that are recommended out of all the products that a user buys. Recall at k is the proportion of relevant items found in the top-k recommendations. Suppose if a customer buys 10 products and the recommendation decided to show 4 of them, then recall is 0.4. Recall at k and F - value is computed as shown in equation 5 and equation 6 respectively.

$$\text{Recall at k} = \frac{\left(\begin{matrix}\text{Number of recommended items}\\ \text{that are relevant in the top k set}\end{matrix}\right)}{\text{Total number of relevant items}} \quad (5)$$

$$\text{F} - \text{value} = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \quad (6)$$

From Table-1 it can be inferred that the Jaccard similarity has the highest F-Value (0.04546) followed by cosine similarity (0.04399). The mean precision and mean recall are also the highest for Jaccard similarity (0.0271 and 0.1414 respectively). By the results it can be seen that Jaccard similarity is the best metrics to recommend products for the dataset used in this paper.

Table 2 presents the performance comparison of various similarity metrics based on RMSE (Root Mean Square Error) and accuracy. It also provides RMSE and accuracy values for the

popularity model variant of recommendation system. The Pearson metric gives the highest value (86.6%) but since the F-value, mean precision and mean recall values are very less, Jaccard metric is preferred. Note that the popularity model just recommends the most popular products and is similar for every user, so we don't consider it in user-item recommendation.

Table 2: Performance comparison of various similarity metrics based on RMSE and Accuracy

Recommendation System Models	Similarity Metrics	RMSE	Accuracy
Popularity model	-	13.3580%	86.6420%
User-based Collaborative Filtering Algorithm	Cosine similarity	16.1986%	83.8014%
	Pearson similarity	13.3915%	86.6085%
	Jaccard similarity	16.0924%	83.9076%

8. Conclusion

The Virtual SmartMart application is an innovative platform, which evolves the way people shop online when compared to different E-commerce websites. The above deployed recommendation models make sure that the customers never miss out on any current trending products (Popularity model), the most liked products by other users (user-item model) and best products related to the items present in the cart (item-based model). Therefore, the recommended products will provide customers a sense of satisfaction.

This paper presents a comparative study of different similarity metrics for user-based recommendation algorithm based on precision, recall, F-value and accuracy. From results obtained it can be seen that the Pearson co-efficient metric gives the highest accuracy value (86.6%) but since the F-value, mean precision and mean recall values are very less, Jaccard similarity metric is preferred.

From the dealer point of view, Unity Analytics (integrated with Unity game engine) with SmartMart will help him in monitoring the most selling products, the most active time during a day, the number of shoppers active at any point of time and the countries with leading number of shoppers. This helps dealer make appropriate decision at right time. Integration of Unity Analytics with the SmartMart can be considered as future work for this work proposed here.

For any company retaining customers and up scaling of business are two very important aspects. SmartMart Unity application successfully helps a company in doing so. The limitations of the virtual supermarket include cold start problem, data sparsity problem and scalability. This can be overcome by developing a hybrid recommendation system; a combination of collaborative and content-based filtering. This can be taken up as future work.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

We would like to express our special thanks to SCII (System Consultant Information India) for funding this work. We are grateful that they provided us an opportunity carry out this wonderful project which encouraged us to learn and explore unity platform to build virtual Smart-Mart application and integrate it with Recommendation system. Their constant guidance and suggestions helped us strive for sublimity and to expand our scope of learning.

Solid-State Devices

ABSTRACT

The one-dimensional form of some types of differential equations that appear in the modeling of solid-state devices, like, e.g., the Poisson and Schrödinger equations, can be solved numerically using the Numerov Process (NP). The accuracy of NP is superior by at least two orders of magnitude to that of commonly-used solution methods like, e.g., the finite-difference one. Another advantage of NP is that the increase in computational cost is modest. This paper investigates the possibility of extending the applicability of NP to the whole set of equations that constitute the mathematical model of semiconductor devices. It shows that the charge-continuity and charge-transport equations can be recast in a form suitable for NP. The performance of the method is tested on an n^+-n-n^+ *device, and the extension of the approach to the two-dimensional transport problem is worked out.*

1 Introduction

A number of physical problems are described by second-order differential equations of the form

$$-z'' = F(z, x) \tag{1}$$

(primes indicate derivatives with respect to x). When a uniform grid with grid size h is used, such a form can be tackled numerically, thanks to the absence of the first derivative, with an $O(h^4)$-accurate discretization method generally known as Numerov Process (NP); this in contrast to $O(h^2)$ of the finite-difference method (the derivation of the scheme is shown in the Appendix). Linearization of (1) yields

$$-z'' = Q(x)\,z + P(x)\,. \tag{2}$$

Scope of this paper is to extend the applicability of NP to the system of equations that describe the transport of electric charge in solid-state devices. This paper is an extension of work originally presented at the SISPAD 2019 Conference [1]; besides the Appendix, more details about NP are given, e.g., in [2] and references therein.

In some cases, (2) can be reduced to equations that appear in the model for semiconductors; for instance, letting $Q = 0$, and naming $z = u$ the electrostatic potential normalized to the thermal voltage $k_B T/q$, and $P = q/(\varepsilon k_B T)\,\varrho$, with ϱ the charge per unit volume, transforms (2) into the Poisson equation, which is one of the equations of the standard semiconductor-device model (in the above definitions, symbols q, ε, k_B, T denote the elementary charge, material permittivity, Boltzmann constant, and lattice temperature, respectively). If, instead, one lets $P = 0$, the form of the time-independent Schrödinger equation is recovered, which enters the semiconductor-device model when nanometer-scale devices are considered; in this case, $z = w$ is the time-independent wave function, whereas the form of Q reads $Q = 2\,m\,(E - V)/\hbar^2$, where $E = \text{const}$ is the total energy of the electron and $V(x)$ the potential energy; in turn, m is the electron effective mass and $\hbar$ the reduced Planck constant.

The elimination of the odd-order derivatives in the Taylor expansion (see Appendix), as required by NP, prescribes the use of a uniform grid; the better accuracy of the method largely compensates for this aspect. An application of NP to the analysis of a semiconductor device was shown in [2], where the coupled solution of the Schrödinger-Poisson system was dealt with; in that case, no manipulation of the equations was necessary because both have already the form (2).

Object of this paper is to show that, by a suitable choice of the unknowns, NP can be extended to the whole set of equations constituting the mathematical model of semiconductor devices. To this purpose it is convenient to briefly outline the recent progresses in modeling, following the semiconductor-device roadmap (now "International Roadmap for Devices and Systems — IRDS™" [3]) and the corresponding evolution of the mathematical models.

The standard model of semiconductor devices (*drift-diffusion* model) is made of the Poisson equation and, for each type of mobile charges (electrons and holes), of the continuity and transport

*Corresponding author:M. Rudan, Dept. DEI, Univ. of Bologna Viale del Risorgimento 2, I-40136 Bologna, Italy +39-051-209-3016, massimo.rudan@unibo.it

equations for the mobile-charge density; the transport equation has two terms: the first one is of the drift type, the second one of the diffusive type. For submicron devices the model is extended by adding another pair of continuity and transport equations, whose unknown is the energy density of the carriers (in this case, the model is termed *hydrodynamic*).

When the lateral extension of the device channel shrinks to the nanometer scale, the device can be described as a cylindrical structure. This makes it possible to separate the longitudinal and transversal directions; then, the calculation of the charge density is accomplished by solving the Schrödinger equation over each cross section, whereas the analysis along the longitudinal direction is still carried out in classical terms. An example is found in the solution of a cylindrical nanowire shown in [2]. Other examples of nanometer-size structures made of compound materials are illustrated in [4].

The n^+-n-n^+ structure considered in this paper is suitable for checking the extension of NP to the solution of the whole transport model of semiconductors. The structure is one of the benchmarks used in the literature (see, e.g., [5] and references therein): besides being one-dimensional, like a nanowire or a gate-all-around transistor, it has the advantage of being unipolar, namely, for its description it suffices to use only one type of carriers (electrons in this case), thus halving the number of continuity-transport pairs of equations to be solved.

The investigations on numerical methods for solving the semiconductor equations have gone in parallel with the strong development of the integrated-circuit technology of the last 50 years. At present, the most successful solution techniques for the drift-diffusion or hydrodynamic models are incorporated in huge device-analysis systems, whose update and maintenance is a concern of the semiconductor Companies in cooperation with specialized Software Houses. The advantage of NP is that it is applicable to the existing solution techniques without excessive changes in the organization of the software, and with a limited increase in the computational cost; for this reason, also considering the improvement in accuracy, the application of NP to the semiconductor equation is worth considering. The present investigation about the applicability of NP to the numerical solution of the semiconductor transport equations considers the drift-diffusion model for the sake of simplicity, since the hydrodynamic model and the other models of higher order, derived from the Boltzmann Transport Equation, have the same structure.

The paper is organized as follows: the model equations are shown in Section 2 along with the transformation that gives them an NP-suitable form; the NP-based discretization in the one-dimensional case is carried out in Section 3. A method for calculating the electric potential at each node independently of the coupling with the transport equation is outlined in Section 4, followed by a stability analysis of the iterative solution (Section 5). The results are shown in Section 6, and the extension of the method to the two-dimensional case, still over a uniform grid, is given in Section 7. Finally, the conclusions are drawn in Section 8, while a summary of the derivation of NP is provided in the Appendix.

2 Model Equations

The semiclassical, drift-diffusion equations describing the transport of carriers in solids is made of the Poisson equation and, for each type of charges (namely, electrons and holes), of a pair of equations made of the continuity and of the transport equations. Here a one-dimensional device of the unipolar type is analyzed, whose carriers are electrons. This situation is found, e.g., in n^+-n-n^+ structures like that shown in Figures 1 and 2, or in memory devices of the phase-change type (e.g., [6, 7]); in these devices, the Poisson equation reads

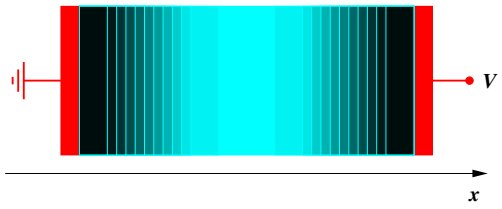

Figure 1: Lateral view of the simulated n^+-n-n^+ structure. The red regions indicate the contacts, while the shades of green mimic the non-uniform dopant concentration.

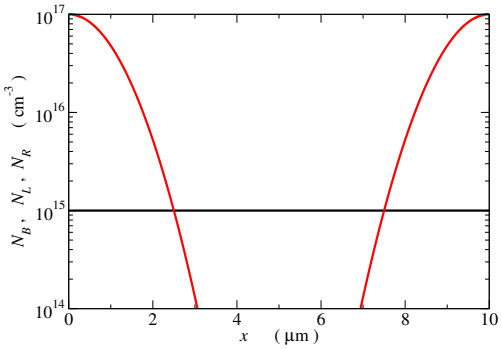

Figure 2: Dopant profiles of the simulated n^+-n-n^+ structure.

$$-u'' = P = \frac{q}{\varepsilon k_B T}\, \varrho(n, N_D)\,, \tag{3}$$

with n the electron concentration and $N_D(x)$ the concentration of ionized donors within the n^+-n-n^+ structure (when phase-change materials are considered, N_D is replaced with the concentration n_T of empty traps). The continuity equation of the electrons, and the corresponding drift-diffusion equation for the electron-current density read, respectively,

$$J_n' = q\,U\,, \qquad J_n = q\,D_n\,(n' - u'\,n)\,, \tag{4}$$

with $U = U(n)$, D_n being the net-recombination rate and the electron-diffusion coefficient, respectively (here a constant value of D_n is considered). Combining (4) yields

$$n'' - u'\,n' - u''\,n = \frac{U}{D_n}\,. \tag{5}$$

The Wronskian determinant of the homogeneous equation associated to (5) reads, by Abel's identity, $W = \text{const} \times \exp(u) \neq 0$.

The system of equations to be solved is then made of (3) and (5), whose boundary conditions are the values of u and n at the two ends of the (finite) integration interval. If the discretization of the interval

produces N internal nodes, the boundary conditions are u_0, u_{N+1} and n_0, n_{N+1}, respectively; in the analysis of solid-state devices it is assumed that the contacts force a condition of electric neutrality, so that n_0, n_{N+1} are such that $P_0 = P_{N+1} = 0$ (compare with (3)).

In a decoupled solution scheme, one assumes that n is given and solves (3) for u, then solves (5) for n using the form of u thus found; the procedure is iterated until convergence is reached. One notes that NP is not applicable to (5) as it stands, due to the presence of the first derivative; to give the equation a more suitable form one defines

$$s = -\frac{U}{D_n}\,\exp(-u/2)\,, \qquad g = n\,\exp(-u/2)\,, \tag{6}$$

this transforming (5) into

$$-\,g'' = c\,g + s\,, \qquad c = \frac{P}{2} - \frac{(u')^2}{4}\,. \tag{7}$$

Transformation (6) does not consist in a reduction to a self-adjoint form; in fact, the expression of the latter would be

$$[n'\,\exp(-u)]' = (U/D_n - P\,n)\,\exp(-u)\,; \tag{8}$$

transformation (6) is not either an "exponential fitting" of the type commonly adopted for solving the semiconductor equations: the exponential fitting would in fact yield

$$q\,D_n\,[n\,\exp(-u)]' = J_n\,\exp(-u)\,, \tag{9}$$

where the current density J_n is approximated with a different constant along each interval between two nodes (in the field of semiconductor-device modeling the scheme based on (9) is also known as *Scharfetter-Gummel method* [8]).

The homogeneous equation corresponding to (7) reads $g''+c\,g = 0$; in the iterative procedure by which the system made of (3) and (7) is solved within the finite integration interval, coefficient c is obtained from the electron concentration n and the normalized electrostatic potential u calculated at the previous iteration. As neither n nor u have poles, all points within the integration interval are ordinary.

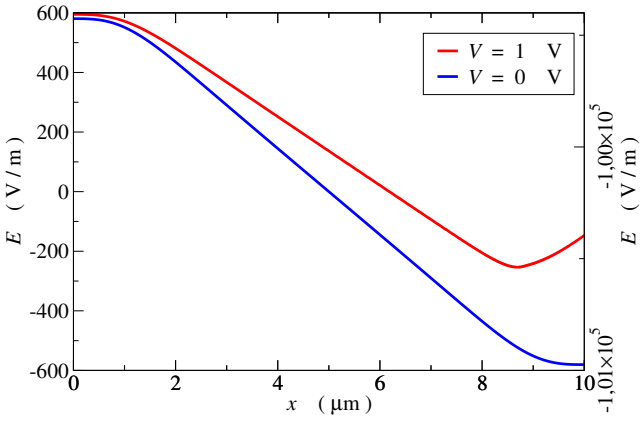

Figure 3: Electric field in the simulated n^+-n-n^+ structure, at different values of the applied bias; namely, 0 V (blue curve, left scale) and 1 V (red curve, right scale).

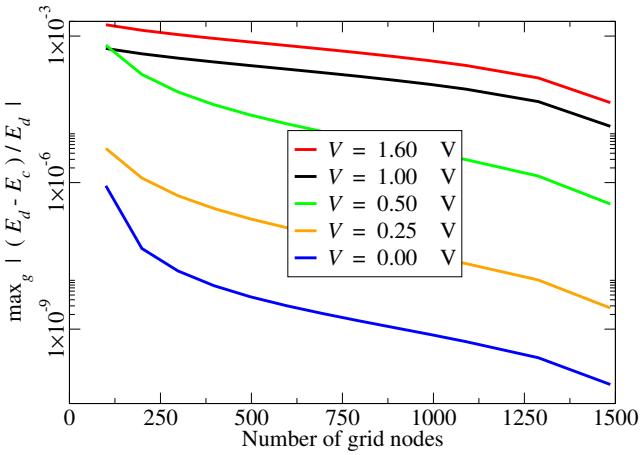

Figure 4: Maximum modulus of the relative variation $\max_g|(E_d - E_c)/E_d|$ of the electric field with respect to the densest grid (2000 nodes). The horizontal axis shows the number of nodes of each grid used in the comparison (more details are given in Section 6). The analysis has been repeated for different values of the applied voltage V, as shown in the inset.

3 Application of NP

In this Section, the Numerov Process is applied to (3) and (7) over a grid made of N, uniformly-spaced internal nodes with element size h. The Poisson equation (3) is transformed into the $N \times N$ algebraic system

$$-\,u_{i-1} + 2\,u_i - u_{i+1} = \frac{h^2}{12}\,(P_{i-1} + 10\,P_i + P_{i+1})\,, \tag{10}$$

$i = 1, 2, \ldots, N$, while (7) transforms into the $N \times N$ system

$$-\left(1 + \frac{h^2}{12}\,c_{i-1}\right) g_{i-1} + \left(2 - 10\,\frac{h^2}{12}\,c_i\right) g_i \tag{11}$$

$$-\left(1 + \frac{h^2}{12}\,c_{i+1}\right) g_{i+1} = \frac{h^2}{12}\,(s_{i-1} + 10\,s_i + s_{i+1})\,.$$

The matrix of the algebraic system (10) is symmetric, whereas that of (11) is non symmetric due to terms c_{i-1} and c_{i+1} at the left hand side. Although in the latter system the unknowns are $g_i = n_i\,\exp(-u_i/2)$, terms c_i and s_i still depend on the original unknown n; also, each g_i depends, through $\exp(-u_i/2)$, on the (arbitrary) zero of the electric potential; finally, due the presence of the exponentials of the electric potential, the matrix of the coefficients of (11) may become stiff. For the above reasons it is convenient to multiply both sides of (11) by $\exp(u_i/2)$. In this way, the following replacements are carried out in (11): $g_{i-1} \leftarrow n_{i-1}\,\exp[(u_i - u_{i-1})/2]$, $g_i \leftarrow n_i$, and $g_{i+1} \leftarrow n_{i+1}\,\exp[(u_i - u_{i+1})/2]$; by the same token, $s_{i-1} \leftarrow -(U_{i-1}/D_n)\,\exp[(u_i - u_{i-1})/2]$, $s_i \leftarrow -(U_i/D_n)$, and $s_{i+1} \leftarrow -(U_{i+1}/D_n)\,\exp[(u_i - u_{i+1})/2]$.

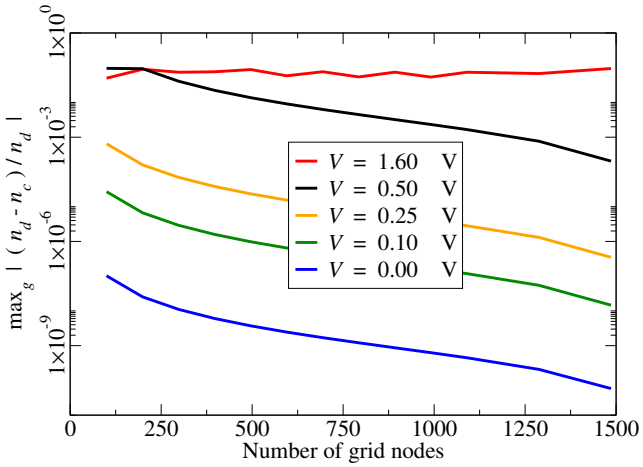

Figure 5: Maximum modulus of the relative variation $\max_g|(n_d - n_c)/n_d|$ of the electron concentration with respect to the densest grid (2000 nodes). Compare with Figure 4.

The new form of (11), where the original unknown appears, is preferable because the exponents bearing differences like, e.g., $u_i - u_{i-1}$, instead of a nodal potential alone, are expected to be relatively small. To complete the calculation it is necessary to express the derivative u' that appears in (7); this is also done using NP, so that the accuracy of the scheme is preserved, and yields

$$u'_i = \frac{u_{i+1} - u_{i-1}}{2\,h} + h\,\frac{P_{i+1} - P_{i-1}}{12}\,. \tag{12}$$

When $i = 2, \ldots N-1$, only the indices of internal nodes appear in (12); if, in contrast, $i = 1$ or $i = N$, then one boundary condition is present (u_0 and $P_0 = 0$ or, respectively, u_{N+1} and $P_{N+1} = 0$); the last possible case occurs when $i = 0$ or $i = N+1$, in which the values of the electric potential and charge in the interior of the contacts appear in (12); remembering that the contacts are equipotential and neutral, it is $u_{-1} = u_0$, $P_{-1} = 0$ and $u_{N+2} = u_{N+1}$, $P_{N+2} = 0$.

4 Decoupling the Model Equations

The model equations are solved by iterating between (10) and (11). In general, equations like these are tackled with algebraic solvers able to provide the values of the unknowns in a given sequence; for instance, considering the solution of (10) obtained through the $\boldsymbol{A} = \boldsymbol{L}\,\boldsymbol{U}$ decomposition, the ith nodal value of the normalized electric potential u is obtained only after calculating it at nodes 1 through $i-1$ (or at nodes N through $i+1$). Here a different approach is adopted, in which u_i is obtained as soon as necessary, without the need of calculating its other nodal values. Such a result is achievable for the discretized form (10) of the Poisson equation by solving it with the scheme of [9, p. 769], that provides each nodal value u_i independently of the others; using such a scheme after indicating with C_i the right hand side of (10) yields

$$u_1 = u_0 + R\,, \qquad u_i = u_0 + i\,R - Y_{i-1}\,, \qquad i = 2\,\ldots N\,, \tag{13}$$

where

$$Z_j = h^2 \sum_{k=1}^{j} C_k\,, \quad Y_i = \sum_{j=1}^{i} Z_j\,, \quad i = 1\,\ldots\,N\,, \tag{14}$$

$$R = \frac{u_{N+1} - u_0 + Y_N}{N+1}\,. \tag{15}$$

The differences that appear in (11) after carrying out the replacements outlined above, are easily evaluated from (13–15):

$$u_i - u_{i-1} = R - Z_{i-1}\,, \quad u_{i+1} - u_{i-1} = 2\,R - (Z_{i-1} + Z_i)\,.$$

In practice, this scheme decouples (10) from (11); it may appear that this result is due to the discretization: in fact, one can also eliminate the Poisson equation prior to the discretization, by recasting it in integral form [9, p. 781–784]. The calculation of the overall number of operations also shows that the method based on (13–15) requires fewer operations than the $\boldsymbol{A} = \boldsymbol{L}\,\boldsymbol{U}$ decomposition; specifically, for a matrix of order N the number of operations required by the $\boldsymbol{A} = \boldsymbol{L}\,\boldsymbol{U}$ decomposition is $6\,(N-1)$ multiplications and $3\,(N-1)$ additions, whereas the method based on (13–15) requires $N-1$ multiplications and $4\,(N-1)$ additions.

Another difference between the standard discretization schemes like, e.g., finite differences, and the present one is the following: here, the discretized functions and their derivatives of all orders "belong" to the nodes; as a consequence, no hypothesis is necessary about the form of the discretized functions over each element. In the finite-difference scheme the functions and their derivatives of even order belong to the nodes, whereas the derivatives of odd order belong to the elements.

5 Stability

Observing that the equations of the model are non linear, it is necessary to implement an iterative solution. Specifically, considering for instance the equilibrium case, the normalized charge concentrations P_{i-1}, P_i, P_{i+1} at the right hand side of (10) depend on the electric potential u; the dependence is exponential in a non-degenerate semiconductor, or via a Fermi integral in a degenerate one [9]. In both cases, the derivatives $\mathrm{d}P_i/\mathrm{d}u$ are negative irrespective of the type of carriers (electrons or holes) that is considered: in fact, electrons (holes) contribute negatively (positively) to the charge density, and the electron (hole) concentration increases (decreases) when u increases. This reasoning also applies in the non-equilibrium case, because the functional dependence of the concentration on the electric potential is the same. In conclusion, linearizing (10) with respect to u adds weight to the main diagonal of the system matrix, resulting in an improved convergence rate; this behavior, typical of the linearized Poisson equation in semiconductors, is due to the dependence of the carrier concentrations on the electrostatic potential and is common to a number of discretization schemes. In contrast, as shown below, the properties of the algebraic system obtained by discretizing the continuity and transport equations with the scheme shown in this paper are quite different from those obtained with the standard scheme.

Coming now to (11), when the expressions of c_{i-1}, c_i, c_{i+1} that appear in (7) are replaced in (11), one finds an algebraic system whose right hand side, in the ith row, is made of three summands: the structure of the first summand, $A_i = -g_{i-1} + 2\,g_i - g_{i+1}$, is the same as that of Poisson's equation (10). The form of the other two terms is

$$B_i = \frac{(u'_{i-1})^2\,g_{i-1} + 10\,(u'_i)^2\,g_i + (u'_{i+1})^2\,g_{i+1}}{48/h^2}\,, \tag{16}$$

$$C_i = -\frac{P_{i-1}\, g_{i-1} + 10\, P_i\, g_i + P_{i+1}\, g_{i+1}}{24/h^2}\,. \qquad (17)$$

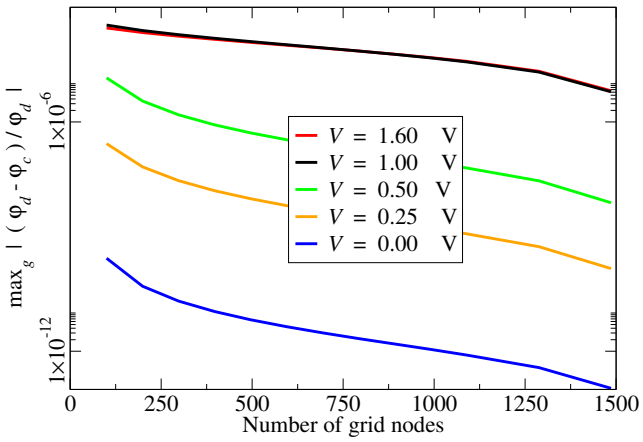

Figure 6: Maximum modulus of the relative variation $\max_g|(\varphi_d - \varphi_c)/\varphi_d|$ of the electric potential with respect to the densest grid (2000 nodes). Compare with Figures 4 and 5. The curves corresponding to $V = 1.0$ V and $V = 1.6$ V practically coincide.

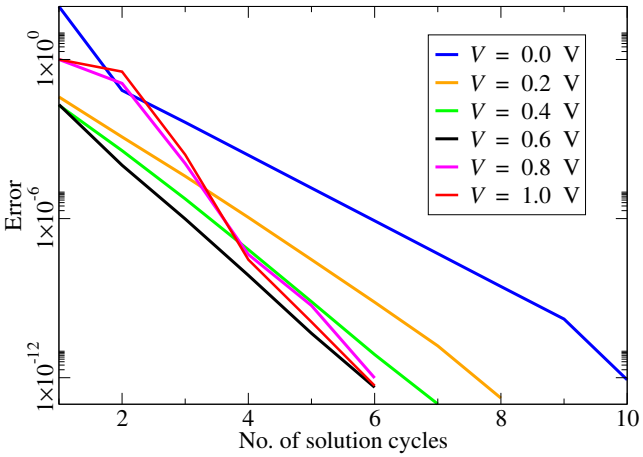

Figure 7: Number of calls to the solver that are necessary to bring the error below a prescribed value, for a given number of grid nodes. Here a 1500-node grid was used. The curves refer to the bias values shown in the inset.

The coefficients defined by (16) are non negative, therefore they add weight to all diagonals of the system matrix (11); due to factor 10, the weight added to the main diagonal is generally dominant, unless node i is near an extremum of u. As for (17), the presence in it of the normalized charge density P, which may have either sign, makes the analysis more complicated; on the other hand, (17) is of order 2 in h, whereas, due to a cancellation that takes place when (12) is replaced in (16), B_i is of the same order as A_i, namely, order 0 in h. In essence, the structure of the algebraic system (11) deriving from the present discretization scheme of the continuity and transport equations is similar to that deriving from the Poisson equation. In contrast, the standard exponential-fitting scheme for the continuity and transport equations, based on (9), approximates U as a piecewise-constant function at each node, and linearizes u between each pair of nodes; with these premises, the scheme yields

$$-K^i_{i-1}\, n_{i-1} + \left(K^{i-1}_i + K^{i+1}_i\right) n_i - K^i_{i+1}\, n_{i+1} = -h^2\, \frac{U_i}{D_n}\,, \qquad (18)$$

whose coefficients K^k_j depend on the normalized electric potential through the Bernoulli function B:

$$K^k_j = B(u_j - u_k)\,, \qquad B(\lambda) = \frac{\lambda}{\exp(\lambda) - 1}\,. \qquad (19)$$

Besides the approximations mentioned above, it is easily found that the main diagonal of the algebraic system (18) is not necessarily dominant [9, p. 781].

6 Results

As an example of application, the solution scheme based on NP is applied here to the n^+-n-n^+ structure whose lateral section and dopant profiles are shown in Figures 1 and 2, respectively. The device length is $L = 10$ μm, the concentration of the light, constant dopant (black line in Figure 2) is $N_B = 10^{15}$ cm^{-3}, while the two profiles (red lines) are given by $N_L = N_0 \exp(-x^2/x_0^2)$ and $N_R = N_0 \exp[-(L - x)^2/x_0^2]$, with $N_0 = 10^{17}$ cm^{-3} and $x_0 = 1.165$ μm, respectively. The total dopant distribution to be used in (3) is $N_D(x) = N_B + N_L + N_R$. The device is uniform in the direction normal to the field; the equations of the models have been solved at different applied voltages V, ranging from equilibrium (0 V) to 1.6 V. The form of the electric field E is shown in Figure 3 for $V = 0$ V and $V = 1$ V.

Each solution was repeated on different grids, starting with a reference grid having $N = 2000$ nodes and successively decreasing it down to $N = 100$. Figure 4 compares the electric field E calculated using the 2000-node grid with that calculated using coarser grids. As all grids are obtained by refining the 100-node one, for each node of the latter there exists a node of the denser grids having the same abscissa. Consider, e.g., the $V = 0$ curve of Figure 4, for which the 500-node grid yields about 4×10^{-9}; to obtain this value one considers two vectors, namely, the electric field E_c at each node of the 500-node grid and the electric field E_d at the corresponding abscissae of the 2000-node grid; from this vector one then extracts the maximum relative difference $\max_g|(E_d - E_c)/E_d|$, which is the strictest metric for the problem in hand. Figures 5 and 6 show the same type of comparison carried out for the electron concentration n and the electric potential φ, respectively. The worst case (about 9%) occurs for the electron concentration at the largest bias; this was to be expected, given the exponential dependence of the concentration on the electric potential.

Another part of the investigation aimed at determining the number of calls to the solver (i.e., iterations) that are necessary to bring the error below a prescribed value, given the number of grid nodes and the applied bias. The error is defined as

$$\text{Error} = \max_i |q_i^{(k+1)} - q_i^{(k)}|\,, \qquad (20)$$

where i is the node index, k is the iteration index, and q stands for φ or n. The number of calls is plotted in Figure 7 for a 1500-node grid, in Figure 8 for a 500-node grid and, finally, in Figure 9 for a 100-node grid, respectively; the bias values are the same in all cases. The curves show that the prescribed error is reached smoothly for all values of the applied bias, with no substantial difference from one grid to another; thus, the method provides a significant gain as far as the computational cost is concerned.

In [1], a different electronic device has been used to compare the error of the method presented here with that of the exponential-fitting one (the *Scharfetter-Gummel method*), in which the discretization scheme for the carrier concentration is based on (9). Like in the example above, after obtaining the reference solution over a dense grid ($N = 2000$), more solutions were calculated by making N to progressively decrease; after each solution, the maximum difference was calculated with respect to the reference solution. The improvement of the present method with respect to the standard one was found to be about one order of magnitude in all cases.

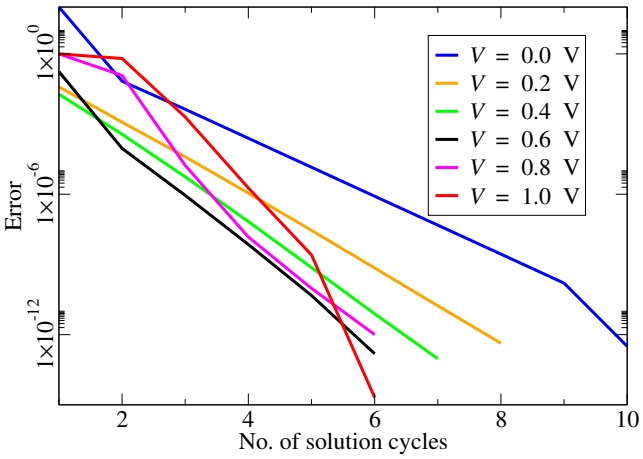

Figure 8: Same as Figure 7, using a 500-node grid.

7 Extension to Two Dimensions

It may be argued that a method for solving one-dimensional problems has a limited range of applicability. This is not so in the modeling of solid-state devices; in fact, when dealing with transport problems in structures like, e.g., carbon-nanotube transistors or nanowires, that are essentially cylindrical objects whose diameter is in the nanometer range, the restriction to the one-dimensional case is not too severe a constraint. In fact, for such devices the problem is typically separated by decoupling the longitudinal coordinate (the channel) from the transversal ones [11]; as no charge transport takes place in the directions transversal to the channel, separating the problem yields, for each transversal section, a system made of the Poisson and Schrödinger equations, which are further separated by exploiting the radial symmetry of the device. As shown in Section 1, the one-dimensional Poisson and Schrödinger equations are solvable by NP. In turn, the transport along the channel is described by equations of the form discussed here, also amenable to the NP scheme.

Clearly the NP method would gain in flexibility from the extension to a non-uniform grid. This issue is outside the scope of this paper; the interested reader may refer to a method for extending NP to a variable stepsize, still in one dimension, based on the k-step Cowell method, which has been tested on the Schrödinger equation (see [10] and references therein).

Another direction for evolving the NP scheme is the extension to more than one dimension using uniform grids of the tensor-product type. Such an extension, again applied to the case of the Schrödinger equation, is described in [12]. It is of interest to ascertain whether the approach of [12] can be extended to the class of equations investigated here. To this purpose, one must first determine the multi-dimensional form of (7); the latter is obtained as follows,

$$g'' \leftarrow \nabla^2 g\,, \qquad u' \leftarrow |\nabla u|\,, \tag{21}$$

this yielding

$$-\nabla^2 g = c\,g + s\,, \qquad c = \frac{P}{2} - \frac{|\nabla u|^2}{4}\,. \tag{22}$$

The multi-dimensional form (22) shows that the equations describing charge transport in a semiconductor can be reduced to a single second-order equation of the elliptic type.

The notation becomes rather awkward even if one limits the extension to the two-dimensional case; taking a uniform, tensor-product grid, and using the matrix notation of [12], namely,

$$a_{11}\,g_{i+1}^{j-1} + a_{12}\,g_{i+1}^{j} + a_{13}\,g_{i+1}^{j+1} + a_{21}\,g_{i}^{j-1} + \cdots \tag{23}$$

$$+\,a_{23}\,g_{i}^{j+1} + \cdots + a_{33}\,g_{i-1}^{j+1} = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix}_g\,,$$

in which the lower indices of $g_i^j, \ldots$ refer to the x axis, and the upper ones refer to the y axis, the two-dimensional expansion yields an interpolation of the form

$$\begin{bmatrix} 1 & 0 & 1 \\ 0 & -4 & 0 \\ 1 & 0 & 1 \end{bmatrix}_g = 2\,h^2\,(\nabla^2 g)_i^j + \tag{24}$$

$$+\,\frac{h^4}{6}\,[\nabla^2(\nabla^2 g)]_i^j + \frac{2}{3}\begin{bmatrix} 1 & -2 & 1 \\ -2 & 4 & -2 \\ 1 & -2 & 1 \end{bmatrix}_g\,.$$

Calculating the Laplacian of both sides of (24), eliminating $[\nabla^2(\nabla^2 g)]_i^j$ after neglecting the derivatives of the 6th-order and, finally, replacing $(\nabla^2 g)_i^j$ from (22) and defining the matrices

$$\boldsymbol{M} = -\begin{bmatrix} 1 & 4 & 1 \\ 4 & -20 & 4 \\ 1 & 4 & 1 \end{bmatrix}, \qquad \boldsymbol{J} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \tag{25}$$

eventually yields the two-dimensional generalization of (11):

$$\boldsymbol{M}_g - h^2\left(6\,\boldsymbol{J}_{cg} - \frac{\boldsymbol{M}_{cg}}{12}\right) = h^2\left(6\,\boldsymbol{J}_s - \frac{\boldsymbol{M}_s}{12}\right). \tag{26}$$

The result expressed by (26) shows that the approach of [12] can indeed be extended to the second-order equation of the general form; like in the one-dimensional case, no special assumption is necessary on the form of the discretized functions inside each elements or along its edges.

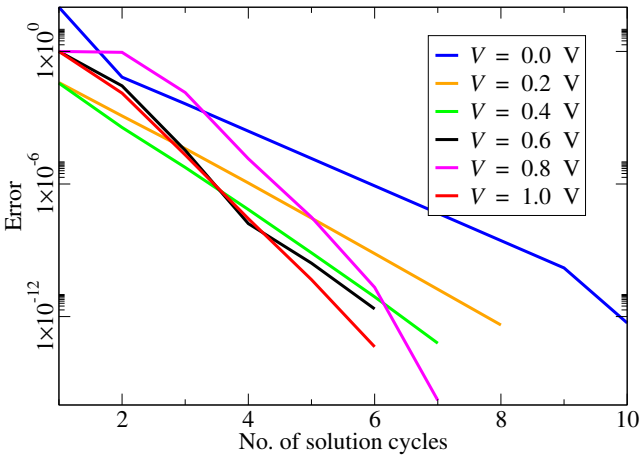

Figure 9: Same as Figures 7 and 8, using a 100-node grid.

8 Conclusions

It has been shown in this paper that the standard charge-transport model in solid-state devices, made of the continuity and transport equations for the charge, can be given a form suitable for the application of the NP scheme, using a uniform grid in one or two dimensions. With respect to the standard discretization schemes used in the analysis of semiconductor devices, the increase in the computational cost is modest; like in the case examined in [2], where the solution of the Schrödinger equation was takled, the NP approach has provided a simple tool for improving the solution of the equations.

In the field of semiconductor-device modeling, the results presented here are important from two points of view, already mentioned in Section 1: first, the NP approach, besides being able to significantly improve the solution, is applicable without excessive changes in the organization of the existing software; second, the drift-diffusion model on which NP has been tested is in fact the simplest level of description of solid-state devices; more sophisticated models exist, made of higher-order moments of the Boltzmann transport equation. On the other hand, such moments can always be grouped in pairs, each pair having the same structure: specifically, one equation of the pair is an even-order moment (order $2\,k$, with $k = 0, 1, \ldots$) whose general form, with a suitable meaning of symbols, reads [9]

$$-\operatorname{div} \boldsymbol{S} = C\,. \tag{27}$$

The next equation of the pair is the odd-order moment of order $2\,k + 1$, whose form is

$$\boldsymbol{S} = a\ \operatorname{grad}\sigma + \sigma\,\nabla b\,. \tag{28}$$

Comparing (27, 28) with (4) shows that all pairs of moments of the Boltzmann transport equation have the same structure. It follows that the method worked out in this paper applies to any order of transport models; also, considering that in the dynamic case the term C in (27) embeds the time derivative $\partial\sigma/\partial t$, the method is applicable also in the dynamic operating mode of solid-state devices.

Appendix

Letting $z_i = z(x_i)$, $z_{i+1} = z(x_i + h)$, $z_{i-1} = z(x_i - h)$, the series expansions around x_i yield

$$z_{i+1} = z_i + h\,z_i' + \frac{h^2}{2}\,z_i'' + \frac{h^3}{6}\,z_i''' + \frac{h^4}{24}\,z_i'''' + \cdots \tag{29}$$

$$z_{i-1} = z_i - h\,z_i' + \frac{h^2}{2}\,z_i'' - \frac{h^3}{6}\,z_i''' + \frac{h^4}{24}\,z_i'''' + \cdots \tag{30}$$

Adding up (29) and (30) and leaving out the terms of the sixth order or higher,

$$z_{i-1} + z_{i+1} \simeq 2\,z_i + h^2\,z_i'' + \frac{h^4}{12}\,z_i''''\,. \tag{31}$$

Multiplying (31) by $h^2/12$, taking the second derivative of both sides, and leaving out again the sixth-order term,

$$\frac{h^4}{12}\,z_i'''' \simeq \frac{h^2}{12}\left(z_{i-1}'' + z_{i+1}'' - 2\,z_i''\right). \tag{32}$$

Eliminating the fourth derivative between (31) and (32),

$$z_{i-1} + z_{i+1} = 2\,z_i + h^2\,z_i'' + \frac{h^2}{12}\left(z_{i-1}'' + z_{i+1}'' - 2\,z_i''\right), \tag{33}$$

or

$$z_{i-1} - 2\,z_i + z_{i+1} = \frac{h^2}{12}\left(z_{i-1}'' + 10\,z_i'' + z_{i+1}''\right). \tag{34}$$

Now one replaces the second derivatives in (34) using (2), to find the three-node interpolation

$$-\left(1 + \frac{h^2}{12}\,Q_{i-1}\right) z_{i-1} + \left(2 - \frac{h^2}{12}\,10\,Q_i\right) z_i - \tag{35}$$

$$-\left(1 + \frac{h^2}{12}\,Q_{i+1}\right) z_{i+1} = \frac{h^2}{12}(P_{i-1} + 10\,P_i + P_{i+1})\,.$$

The method originates from [13] (cited, e.g., in [14]). It provides a three-point interpolation where the terms of the expansion that are left out are those of order six or larger; for this reason, it is superior to the standard finite-difference interpolation, although the computational load is comparable.

The method can be extended to higher orders. For instance, leaving out of the expansion the terms of order eight or larger, and using the short-hand notation $-z'' = F(z, x)$, one finds the five-point interpolation

$$-\,z_{i-2} - 2\,z_{i-1} + 6\,z_i - 2\,z_{i+1} - z_{i+2} = \tag{36}$$

$$= \frac{h^2}{30}\,(F_{i-2} + 56\,F_{i-1} + 246\,F_i + 56\,F_{i+1} + F_{i+2})\,.$$

ABSTRACT

In an intelligent transportation system (ITS), time is a big challenge since processing a huge amount of data in a short time is very difficult, especially when the processed data is heterogeneous, consisting of a mixture of emergency data, normal data, and noise. In an ITS, an ambulance is one of the priority vehicles, and the data sent by the ambulance to the infrastructure and other vehicles must be treated first because if the ambulance does not receive a status of road from the infrastructure in time, it could take the wrong road or takes a road where there is a traffic jam has a high chance of arriving late, which could put the patient's life in danger.
Prioritizing treatment of this type of data has become paramount and vital in such cases. This paper proposes modifying the big data process to include handling the intelligent transport system's urgent data type. We will add a classification step that allows us to classify the data according to the priority degree. We use the SVM algorithm of machine learning because it has given good results concerning data classification.

1. Introduction

Nowadays, it seems that every city is trying to become a smart city. To make a city smarter, life necessities (water management, waste management, transport, and security) and technology need to be transformed into smart services. A simple definition of a smart city is an environment in which citizens can live smoothly and easily by developing their various facilities and making them smart [1].

In smart cities, sensors will be placed all around the city, and they will generate continuous data. The analysis of such data will be very helpful for the city with the potential to be smarter. As we will have many sensors installed in the city, we will have a very large amount of data generated called Big DATA, and big data is a very large amount of data and data that can come from different sources in different shapes and forms. In the intelligent transportation that will be our case study, data will be generated from sensors placed in the city and sensors placed in the car (traffic light, Lidar camera, etc.). Those sensors will generate a mass of data that will be analyzed to help the car to become autonomous on the one hand and on the other hand to make the ride a joyful experience in addition to reducing the rate of accidents on the road.

As mentioned before, the data will be generated from different sensors located in the city and the sensors placed in the vehicle. In addition to these data, we will also have another type of data circulating in the network, namely the data exchanged between the Road-Side Units and between the latter and the vehicles and between the vehicles and the network data. So the challenge will be which data should be processed first, which data should have a higher priority; we will answer these questions in the present article, which is an extended version of the work presented in [1] where we propose to make a change on big data analysis process to handle priority data.

In the first section of this paper, we will briefly review the intelligent transportation system we will define the autonomous vehicle, explore the sensors embedded in it. We will see the Vehicular Adhoc Network (VANET) and the type of communication in VANET network. In section three, we will define big data in smart transportation. We will apply the principle of classification of transportation data to see different types of data collected by sensors. In the fourth section, we will explain our contribution by explaining the case study and the different steps of the proposed process. We will also define the machine learning algorithm used. In the final section, we will present the experimental result, and we conclude our work.

2. Autonomous vehicle

An autonomous vehicle is defined as a vehicle with the capacity to detect the surrounding environment to drive without human intervention. The autonomous vehicle depends on sensors, a Cloud platform, advanced algorithms, Machine learning systems,

*Corresponding Author: Sara Ftaimi, Email: saraftaimi@gmail.com

and efficient CPUs to operate algorithms. Thanks to the sensors integrated into the vehicle as shown in figure 1, it can generate a map of its environment. The camera and the LiDar are the eyes of the vehicle. They detect traffic lights, obstacles, traffic signs; all this data is processed by an algorithm which allows reading the traffic lights and the traffic signs, to avoid obstacles and to trace the path of the vehicle, and finally to send instructions to the accelerators to accelerate or to brake depending on the existence of obstacles in the path.

2.1. Sensors

Car manufacturers have integrated several sensors into the vehicle, as shown in figure 1 so that it becomes autonomous and can move around safely by detecting obstacles and reading signal lights. For a vehicle to be able to see and understand its environment, at least eight cameras are placed in the vehicle in addition to the LiDar to detect obstacles as well as RADAR, GPS to determine the location of vehicles over and above authors sensors.

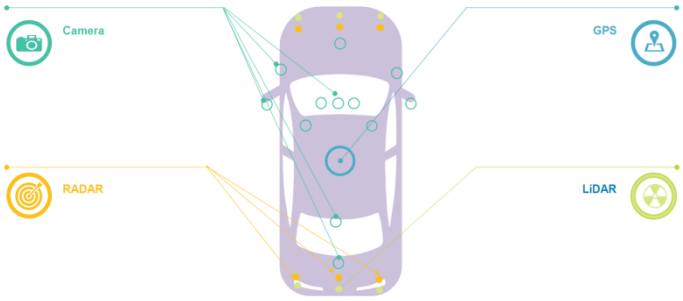

Figure 1: sensors in autonomous vehicle

2.2. VANET network

Vehicle Ad-hoc Networks (VANETs) emerged as one of the most relevant scientific research areas as they focused on supporting intelligent navigation and safe driving. It represents a specific type of MANET network that allows inter-node communication and organizes its communication system without any dependency on any other infrastructure. VANET is an intelligent building block of transport systems since vehicles interact with each other and infrastructure [2]. The high mobility of the nodes is one of the most relevant features of the VANET network vehicles are moving continuously in many directions and at varying speeds. The topology of the vanet network changes rapidly due to the fact that the vehicle can join or leave a cluster of vehicles in a very short time [3].Owing to the two above-mentioned features, combined with climate change and traffic congestion, vehicles can frequently become disconnected from the network. VANET has no energy or storage problems [4–6], unlike MANET networks, where energy constraint is a challenge. Besides having an unlimited network size since it has no geographical limits.The vehicles are referred to be communication nodes in VANET. To make communication possible between vehicles, the vehicle must be equipped with an On-Board Unit (OBU), and along the road, we must install the Roadside Unit (RSU).

The RSU is installed along the road based on the IEEE 802.11p radio technology to establish dedicated short-range communication (DSRC). It allows establishing local connectivity to the moving vehicle. It can also be used to communicate with other network devices in other infrastructure networks [7].

OBU is a device installed onboard the vehicle it allows to make a connection with the RSU, and with other OBUs via a wireless link IEEE 802.11p [8] The OBU gathers data from the sensors in the car, namely the Global Positioning System (GPS), the Event Data Recorder (EDR) and obtains the input power from the vehicle's battery [7].

2.3. Communication in Vanet

In the vanet network, Vehicles communicate with each other and with the infrastructure via three modes of communication

V2V: In V2V communication mode, a vehicle can directly communicate with other vehicles within the same range; for this mode, the architecture is decentralized. It is very efficient to transmit information on road safety services, but due to the changing speed and mobility of the nodes [7, 9] permanent connections between vehicles cannot be guaranteed.

V2I: In this mode of communication, the exchanges of information are between the vehicle and the infrastructure (RSU, antenna, satellite). The V2I mode offers a better use of the common resources,besides the connection status, which is more stable in this mode than V2V communication [7, 9, 10].

V2X means communication between vehicle and X where X can be a vehicle, a pedestrian, infrastructure, network, etc... In this diverse ecosystem, vehicles will communicate with other vehicles, with infrastructures such as traffic lights, pedestrians using smartphones, and data centers via cellular networks using short-range wireless signals [9].

3. Big data in smart transportation

In a smart city, an enormous amount of data will be generated by an intelligent transportation system (ITS). An autonomous vehicle driving around the city generates more than 25 gigabytes of data per hour. The sensors integrated into the vehicle (camera, GPS, Lidar, etc.) continuously generate information that is processed and sometimes sent to other vehicles or the infrastructure. Besides this data, there is also the data generated by the road infrastructure: RSUs (Road-Side Unit), traffic signs, traffic lights, and parking spaces.

All transport components are nowadays equipped with intelligent sensors that generate and send data continuously, e.g. a sensor is installed in a parking space and periodically sends the status of the space either it is empty or not. In addition to this data, there is also the data from the VANET network used for communication. [11, 12].

Figure2 resumes the data in a smart transportation system (ITS). Cars have to manage much larger amounts of data than ever before. Processing this data quickly and transparently is now and will continue to be one of the main challenges for car manufacturers in the future.

4. Taxonomy of data in a smart transportation system

Before classifying the data, we must know the sources of the data. In fact, in an intelligent transport system, the data generated and collected may come from a variety of sources:

- Data shared between vehicles.
- Data shared between the vehicle and the infrastructure
- The environmental data (climate)
- The data generated by the sensors placed on board the vehicles

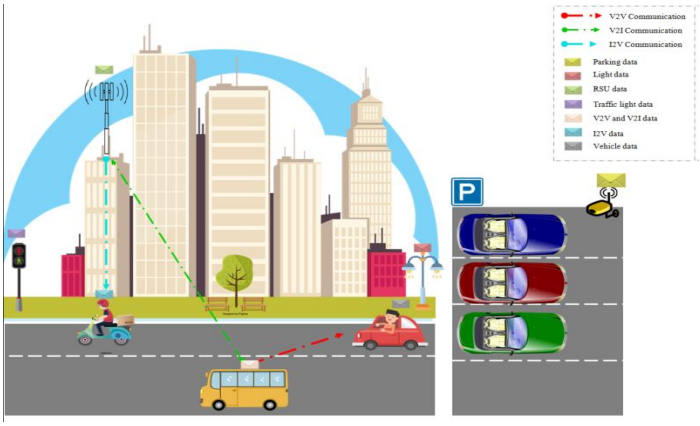

Figure 2: Communication and data type in ITS

Based on data collected from an intelligent transportation system and the taxonomy carried out in [1, 13], the data in an intelligent transportation system can be classified into three categories: the APP-level data, network-level data, and environmental data as shown in figure 3. APP-level data is the data generated by sensors installed in the ITS equipment (traffic light, etc) and the sensors integrated into the vehicles. The Network-level data is the data generated by the network that manages the communication between vehicles and road infrastructure besides the vehicles themselves (VANET network). The last type of data is environmental data.

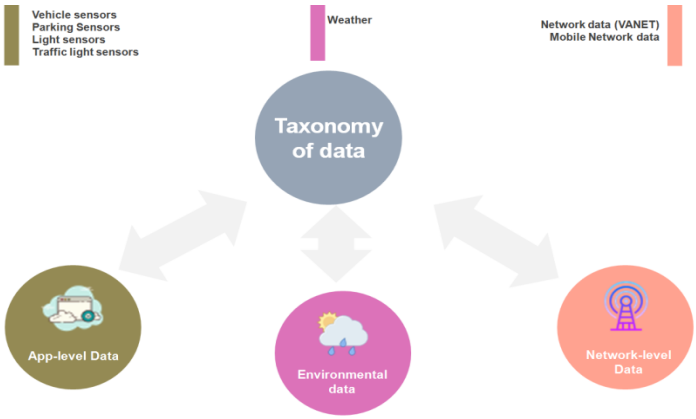

Figure 3: Taxonomy of data in ITS

5. Proposed Method

As the volume of data generated by the various intelligent transport equipment is large, processing has become vital. For a vehicle to move safely, it is necessary to collect, analyze, and transmit the information in short-time. When processing this data, the problem is to determine which data has the highest priority and needs to be processed first. To solve this problem, we propose to make a change in the Big data analysis process. Usually, the process of big data consists of the following steps: data collection, cleaning, analysis, and, finally comes the step of data interpretation[14]. However, to identify the data with the highest priority, we have added a step before the cleaning step, which will be the ordering and classifying step, and we will detail in the next sections.

5.1. Case study

In the intelligent transport system, we have several types of data that are assigned a priority. We are interested in the data shared between vehicles and RSUs, and our case study is as follows:

These RSUs will receive a large amount of data; amongst this data are the critical data that is of a higher priority than others. For instance, in the case of an accident on the road, or a fire engine trying to reach the scene of the incident, the messages sent by these vehicles have a higher priority than those sent by other vehicles, as shown in figure 4. In an intelligent transportation system, it must be able to broadcast information messages to alert road users about the accident on the road and advise them to change or turn back, as well as be able to alert the hospital through notifications, so it will send an ambulance if there is injury. The challenge here is the large number of messages received by the RSUs. The question we ask ourselves in this situation is how can we process this data and come out with the ordered data from the most critical to the least important. Figure 4 represents our case study;

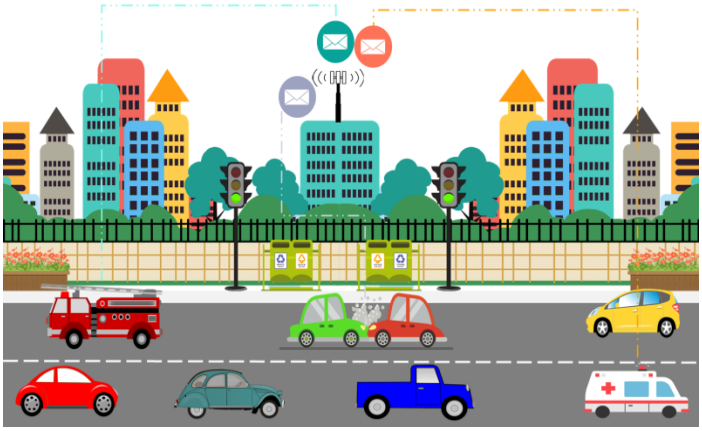

Figure 4: Case Study emergency data

We have three vehicles that have priority over the other vehicles, which are the fire engine, the accident vehicle and finally the ambulance. The messages received by these vehicles must be processed first to avoid causing traffic problems and other more serious consequences, such as loss of life.

5.2. Critical Data

To process the priority data, we must first determine the type of vehicles given priority [15]. In our case study, we have already listed three of them, and we add to them the police vehicles. Therefore, to process the priority data, we propose the following process.

First of all, it is necessary to collect the data received by the different vehicles and then apply a classification algorithm that allows us to determine the classes to which they belong. For this purpose, we have two levels of priority that are shown in figure five.

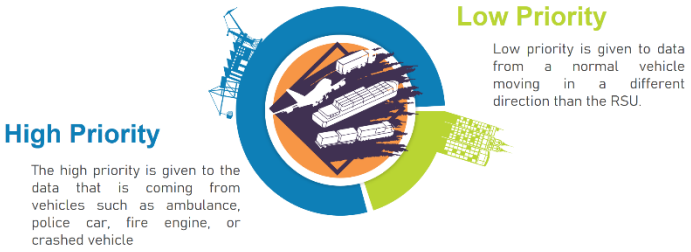

Figure 5: Levels of data priority in ITS

After the data classification step, we will have the possibility to know the data with priority, to process them first. The same process can be applied to the vehicles that will receive the data from other vehicles and the RSU data, and the data generated by the different sensors inside the vehicle. In the case of a vehicle traveling through the city at a given speed, if an accident occurs on its way, the priority must be given to the information of the change of path and the information of the change of the geolocalization map, whereas in the case of the ambulance, the alert must be given so that it passes first and requests the other vehicles in its area to clear the way.

5.3. Data packet

The communication that takes place between the infrastructure and the vehicle is communication managed by the RSU and the OBU. In an intelligent transportation system, the RSU is installed at the roadside to provide a local connection to the vehicle in motion, although it can also be used to communicate with other network devices in other infrastructure networks [7]. RSU uses short-range communication (DSRC), which is based on IEEE 802.11p radio technology. The RSU communicates to the OBU continuously. The main function of the OBU is to connect to the RSU or another OBU via the IEEE 802.11p wireless link [8]. Besides, the OBU gathers information from sensors embedded in the vehicle (e.g. Global Positioning System (GPS), Event Data Recorder (EDR)) and gets input power from the battery vehicles [16]. The packet from OBU to RSU contains the following fields OBU_ID, TIME_STAMP, POSITION, SPEED, DIR, ACC, VEHICLE_TYPE, DUTY_FLAG [15]. The table 1 represents an explanation of the fields.

Table 1: fields of the packet send between the OBU and the RSU

Fields	Explanation
OBU_ID	Contains the vehicle ID
TIME_STAMP	It is the time when the frame was sent.
POSITION	Is the position of the vehicle the value f position is gathered from the GPS sensor
SPEED	Is the speed of the vehicle
DIR	It is the direction of the vehicle.
ACC	Acceleration
VEHICLE_TYPE	Is the type of vehicle (Ambulance, fire engine, etc ...)
DUTY_FLAG	Contains information if there is an accident or the vehicle is on duty

The values of the fields above are calculated from GPS sensors that allow them to obtain directly the position, the speed, and the time. We can deduce the value of DIR from the GPS, the other values that identify the vehicle such as the id and the vehicle type are gathered from the latter.

5.4. Proposed algorithm

5.4.1. Support Vector Machine (SVM)

The SVM is a machine learning algorithm that belongs to the family of supervised learning algorithms. SVM can solve regression and classification problems besides outlier detection. The SVM algorithm can be used to classify linear and non-linear data. Therefore, it can carry out classification in a non-linear way using the kernel trick [3, 17].The SVM can be used to detect network intrusion [18] and spoofing attacks [19]. In [20], the author have used security messages to identify classes and types of attacks using SVM and KNN algorithms. In [20], the author noticed that KNN works better than SVM in some cases. When SVM has a reduction in performance, it is when the training base of both algorithms contains attacks that had extreme levels of misconduct and only a few attacks that were common errors. Also, judging the accuracy of recall, they found that SVM and KNN yield better results in some types of attacks, and SVM outperforms KNN in some attacks. In [21], the author have conducted an experiment on Support Vector Machine (SVM) and Feed Forward Neural Network (FFNN) to design intelligent IDSs that can detect two types of attacks, which are grey hole attacks and Rushing Attacks [21]. It is noted that FFNN-based IDSs could better detect malicious vehicles with lower false-negative alarm rates than SVM-based IDSs. However, the performance of SVM is much faster than FFNN. The choice of SVM algorithms was based on the comparative study conducted in [3] found that SVM is an algorithm that can handle multidimensional data and does not need much memory, and can detect outliers because the outlier detection is very important since the outliers can make false the classification model. Also, SVM can be used for both the separable and non-linearly separable data and work very well with a higher dimension. Besides, by using SVM we can replace the feature engineering, which is a very hard step for exploring data by kernelization.

5.5. Kernels

The SVM algorithm works by using a kernel technique to classify non-linear data, it maps data from the lower dimension data to the higher one and separates them with an optimal hyperplane. Therefore the kernel trick can help to transform non-linear problems into linear separable problems[17].

There are three types of kernel functions that are commonly used: linear kernel, Polynomial kernel, and Radial Basis Function Kernel (RBF). To choose which one to use, the SVM algorithm uses cross-validation to test several combinations of the kernel function and picks the one that gives the best results.

$$K(\bar{x}) = \begin{matrix} 1 & \text{if} \|\bar{x}\| \leq 1 \\ 0 & \text{otherwise} \end{matrix} \quad (1)$$

- Linear kernel: The linear kernel is commonly used to classify text and is also utilized in situations where the data is linearly separable. This means that the data may be separated with only one line. A linear kernel is generally faster to train due to the only optimization of the C regularization parameter.
- Polynomial Kernel(poly): The polynomial kernel is widely used for processing natural language (NLP). The standard degree is d = 2 (quadratic), since higher degrees over-adjust NLP problems.

- Radial Basis Function Kernel (RBF): The radial basis function kernel is the most used in SVM. This is because it has a localized and finite response along the whole x-axis. as well as being used when we have no previous knowledge of the data.

6. Experimental results

Our research results and their explanations, are presented in this section. First, we explain the methodology of our experiment and discuss the experimental result of using the SVM algorithm.

6.1. Methodology

Before starting the cleaning step, we will apply a classification algorithm to determine the type of data e.g, whether it is high-priority data or not.

The proposed process is schematically depicted in figuresix. Firstly, vehicles send every second packet, which is described in section 5.3. Each packet is read by the Machine Learning algorithm, which is the support vector machine (SVM) algorithm that we have chosen for this purpose. It has to classify data into two types see section 5.2. The classification is based on three criteria: the type of vehicle (e.g. ambulance, fire engine, police vehicle, accident vehicle, normal vehicle), the vehicle's direction, and finally, the duty flag field. If the type of vehicle is normal and the value of the duty flag mentions it as not crashed, then the algorithm will classify the data as not priority; otherwise, if the type of vehicle is an ambulance, fire engine, or police car, the algorithm must check the direction of the vehicle either it is the same as the one of the RSU, then the SVM classifies the data as a high priority. Once classified, the data can follow the standard BIG data process described in the figure six.

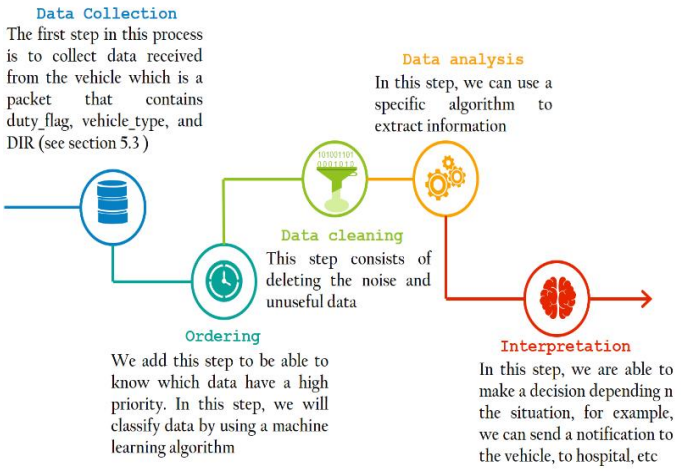

Figure 6: Proposed process

The urgent and priority data is a very challenging type of data in every domain, especially in the transportation system. If we do not treat them urgently, we can cause big damage and sometimes lose a life if the treatment was delayed. Our paper aims to handle this type of data. We propose an SVM algorithm that will read the packet sent to the vehicles or the RSUs and detect which packet has the priority to be treated first. Before starting the classification, we show in figure 7 the distribution of some vehicles based on their speed captured by the GPS sensor. We capture 100 packets sent from vehicles to RSU, and we use it to test our SVM algorithms. The SVM algorithm was applied to this database to classify the data into two types: priority and non-priority. We focused on three types of kernel poly, linear et RBF. The SVM algorithm uses two parameters to build the model, which are the gamma and the C value. In fact, the two variables, gamma, and C could change the classification model. So if the gamma value is very high, the algorithm will consider the closest points to build the limits and aims at it. We can fall into overfitting when C's value is very high and into underfitting if it is small.For this purpose, we applied a function that takes several input values for the C and Gamma parameters to find the optimal values that give the best classification results and high accuracy. The result was resumed in Table 2, where we represent C and Gamma's value that gives an accuracy that is equal to 0.90.

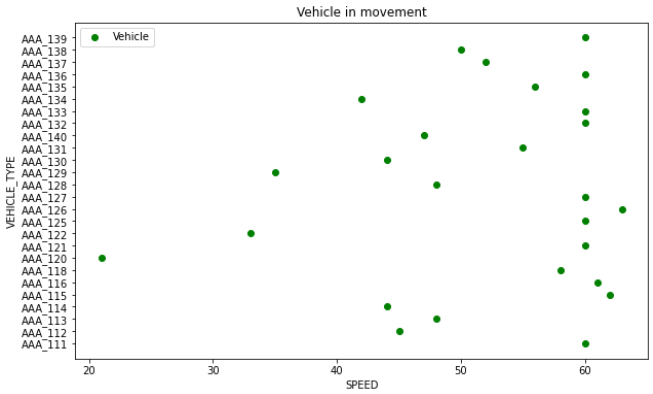

Figure 7: Distribution of vehicle based on speed

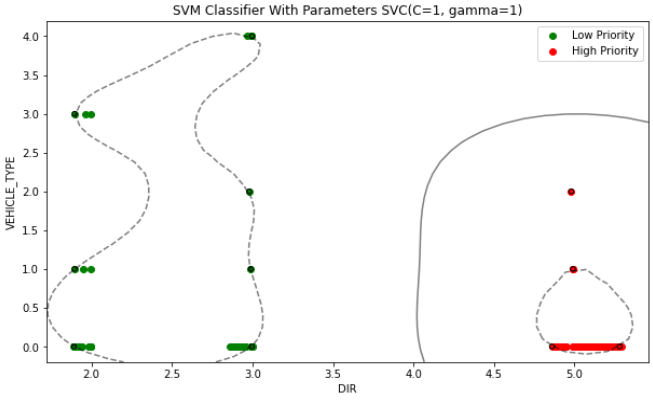

Figure 8 : SVM classifier with RBF kernel

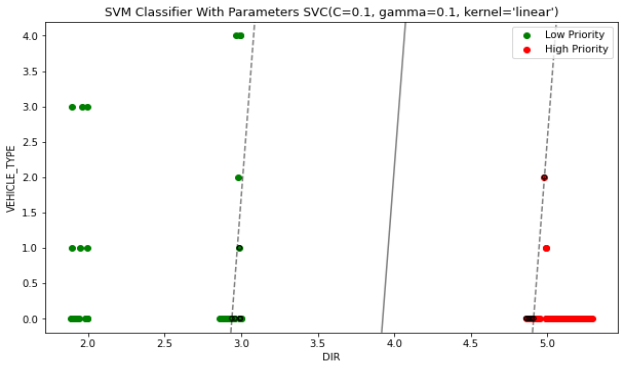

Figure 9: SVM classifier with Linear kernel

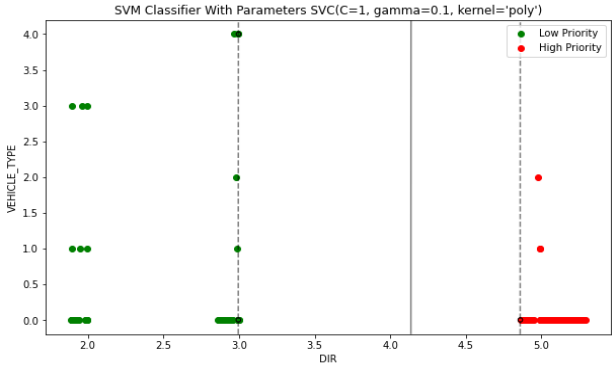

Figure 10: SVM classifier with polynomial kernel

Table 2: The best value of gamma and C

Gamma	C	accuracy	kernel
0.1	1	0.90	poly
0.1	0.1	0.9	linear
1	1	0.9	RBF

The figure 8,9 and 10 represents the classification results with each kernel. Figure 8 represents a two-dimensional classification problem. We plot the priority and the normal packet using two colors, red and green. There is a linear decision boundary for this dataset, but in figure 8, we can see how an RBF kernel can automatically decide a non-linear classification. In figure 9, we have three hyperplanes, and all of them separate the classes well. We can see that the margin between the continuous line and the data point is high compared to the dotted line. Therefore, we name the hyperplane that is represented by a continuous line as the good hyperplane. The reason for choosing the hyperplane with a higher margin is robustness, and if we choose the hyperplane with a low margin, then there is a high risk of wrong classification. The polynomial kernel is used with degree two, and he also gave a result close to the one with a linear kernel.

7. Conclusion

This paper proposes an SVM algorithm for classification problems in the context of the Vanet network. The contributions of this paper are as follows. First, we propose to add an additional step to the big data processing, which is the ordering step, and we have explained its role in identifying the data with high priority. This additional step can help to improve the cleaning step because by ordering data, we can remove the ones with low priority. It can also be employed to eliminate unused data namely the data of vehicle that is sent to the RSU and that possess a different direction from the latter. In the second part of this paper, we apply a machine learning algorithm to classify data. We select the SVM algorithm because of its high performance as a classifier, and we choose three kernels, which are the poly, linear, and the RBF. Since C and gamma's value can make a big change in the construction of the classifier, we apply a function that takes a different value of C and gamma for each kernel and return the value that gives the best accuracy. The paper aims to propose a process that can handle priority and urgent data and treat them at the right time. We propose adding a classification step that will allow us to classify data into two types: normal data and priority data. By using SVM, we achieve a good result. However, In future work, we will use the same proposed process, and we will apply the neural network to find the priority data. We will compare the SVM results with the neural network results. we chose to compare the neural network with SVM because, based on the comparative study conducted in [3], the neural network also gives good results in handling outliers, and also it is a very fast algorithm and can also handle multidimensional data and does not need much memory.

Volume and Shear viscosities

ABSTRACT

This paper covers the study of high-frequency (~ 1 GHz) ZnO piezoelectric transducer integrated on a silicon substrate able to generate both compressional and shear acoustic waves. First, to promote the longitudinal mode, an electrical matching of the transducer in this high-frequency range is effectuated. Second, to promote shear waves, new deposition conditions were applied, giving thin zinc oxide films of inclined c-axis. The RF microprobe was used to validate the transducer design and to conduct the viscosity measurements. Thus, the shear and the volume viscosity of a water droplet were measured.

1. Introduction

This paper is an extension of work originally presented in the International Conference on Design & Test of integrated micro & nano-System (DTS 2019) [1]. Piezoelectric sensors have many applications in different areas, like the medical, manufacturing, and research fields [2-5]. One of these applications is the piezoelectric ZnO transducer, which has been well known for about 50 years, mainly for its high-frequency applications. [6]. Compared to monocrystalline lithium niobate (LiNbO3) [7], ZnO has lower piezoelectric performances (coupling coefficients), but it is easier to be deposited with the classical sputtering process. The thickness of the deposited ZnO can be from 10s nm to several microns. Additionally, it is possible to lead to the right (C-axis) crystallite orientation for longitudinal acoustic wave emission with a relatively short process duration.

Prior publications have demonstrated that depending on the distance between the sample's axis and the sputtering target axis, the orientation of crystallites cannot be homogeneous over a large substrate surface [8]. The inclination of the C-axis can be modified by controlling this distance, which slightly increases the proportion of shear acoustic waves at the expense of compressional waves.

Only a few applications report using a transducer capable of generating longitudinal and shear acoustic waves simultaneously [9, 10]. The first step in this article is to present the manufacturing, the characterization and the electrical modeling of ZnO piezoelectric transducers that generate both shear and longitudinal waves in the solid. Then, an electrical matching was used in order to increase the longitudinal mode.

The deposition of layers with appropriate orientation for shear excitation has been mentioned in several articles using different methods and substrates [11-13]. Thus, to increase the shear mode, one of these methods, mainly based on the addition of a blind

[*]Corresponding Author: Hatem Dahmani, Email: hatem.issat342@gmail.com

positioned between the sputtering target and substrate, was used. The growth of ZnO films with inclined orientation makes it possible to generate shear waves.

Finally, to demonstrate the usability of this transducer**,** both longitudinal acoustic reflection and shear coefficients at the solid/liquid interface were used to characterize the viscous fluid (a sessile water droplet) properties from its shear and volume viscosity.

2. Manufacturing, characterization and modeling of ZnO transducers

2.1. The manufacturing steps of the ZnO transducers

The piezoelectric material used is ZnO. It is deposited between two metal electrodes. The deposition configuration is shown in Figure 1, and it is fabricated by a standard thin-film technology: deposition and lift-off.

The choice of ZnO as a piezoelectric material can be related to its ease of preparation and its increased scope in high-frequency applications. One can site, for example, the acoustic microscopy applications in 100s MHz to 1s GHz frequency range [14,15].

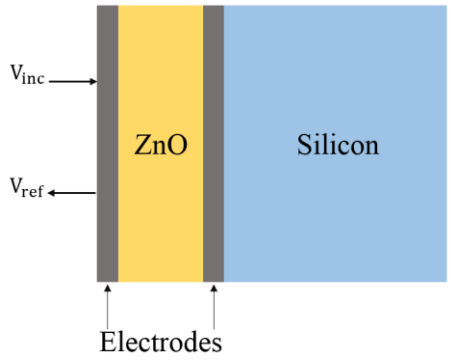

Figure 1: Multilayer Diagram of a Piezoelectric Transducer.

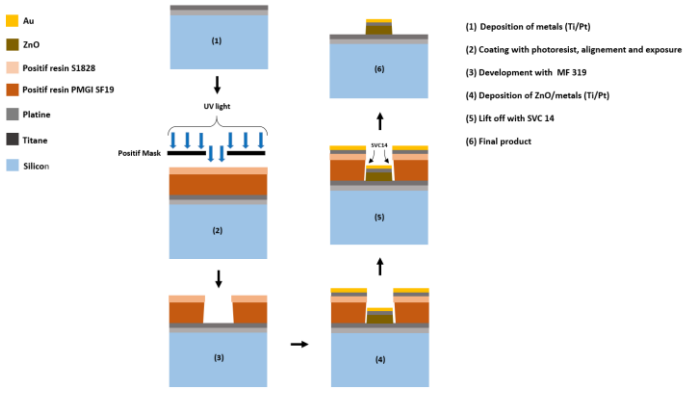

Figure 2: Piezoelectric transducer fabrication steps.

The ZnO piezoelectric transducer's fabrication starts with the deposition of 10 nm of a titanium layer by cathode sputtering on the surface of a 400 µm thick silicon wafer, followed by deposition of 80 nm of platinum. These two first layers will act as the lower electrode. A photolithography process is then performed to make the transducers pattern, where a thick 8 µm layer of PMGI SF19 (Microchem Corporation) is dispensed by spin coating on the lower electrode. Further, a layer of 1.5 µm of S1828 (Shipley Corporation) is appended. After ultraviolet exposure using a mask, a commercial developer MF 319 (Microposit) was used to obtain a pattern of different diameters in the PMGI layer. After that, a 2 µm thin ZnO layer was deposed. Finally, a 10 nm of titanium adhesion layer followed by 400 nm of gold were deposited. The gold layer is used to enable soldering of the contact electrode to a gold wire to connect the transducer to an external circuit. The last step is the lift-off process, where the UV exposed resin is removed to get the transducers pattern. The transducers have a diameter of 150 um. The microfabrication process is shown in Figure 2.

2.2. Characterization of the transducers

The ZnO transducers' characterization is carried out by a Rohde & Schwarz ZVA8 Vector Network Analyzer (VNA) as shown in Figure 3.a. The electrical contact is made using a radio-frequency measuring tip Z-probe, GS type (pitch = 1.25 mm) connected by a coaxial cable to the VNA (Figure 3.b). Since we are working within a high-frequency range in a Gigahertz order, a calibration must be done before each measurement to ensure reliable results. The silicon sample is fixed by suction (using a vacuum pump) on a circular plate.

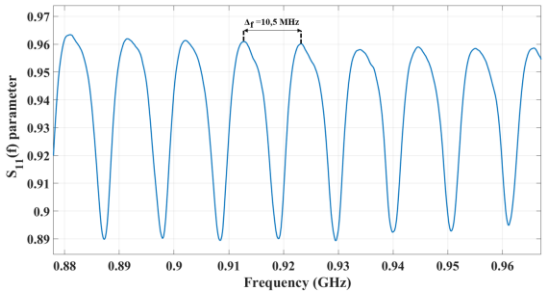
(a)



(b)

Figure 4: (a) Parameter S_{11} measured with the network analyzer, (b) Zoom around the longitudinal acoustic wave resonance.

The S_{11} parameter as a function of frequency, shown in Figure 4.a, is the output measured on a transducer located on the edge of the substrate. At this position, the crystal orientation of the ZnO is not perfectly vertical, thus, the generation of acoustic shear waves is clearly observed. This parameter given by Equation 1 is composed of two contributions [16,17]. The first one comes from the direct reflection of the electric wave on the transducer (S_{11}^{el}. The second is a result of all the acoustic wave reflections on the opposite side of the substrate. These acoustic reflections are then converted into electrical signal by the transducer.

$$S_{11}(f) = S_{11}^{el} + K_{11}S_{11}^{ac} \quad (1)$$

The coefficient K_{11} is the electro-acoustic-electrical coupling coefficient of the piezoelectric material used to convert energy from electric into acoustic for the emission then from acoustic into electrical for the reception.

The reflection transfer function of our system is represented by S_{11}. To obtain the temporal response, an inverse Fourier Transform is performed (Figure 5). In the time domain, the electrical term response appears shortly after the transducer's excitation while the acoustic term arises later.

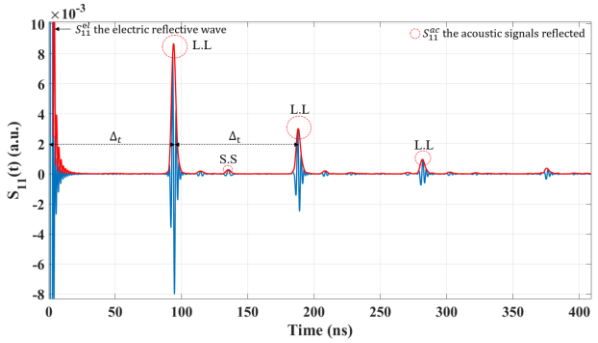


Figure 5: Impulse response $S_{11}(t)$ for f = [0.2 - 1.6 GHz].

The response shown in Figure 4 exhibits a rapid oscillation of $S_{11}(f)$ having a peak oscillation around the central frequency (f = 0.9 GHz). This is due to the fact that for each wavelength emitted in the substrate of a given thickness, the superposition of the emitted and received waves occurs with a variable phase shift. Thus, the total vibration amplitude acquired by the transducer (amplitude of the sum of the emitted and received waves) is greater for the case when the two waves (incident and reflected) are in phase and lower when they are in opposite phases (phase cancellation effect). This phenomenon is portrayed by the SWR standing wave ratio (between the highest and the lowest vibration levels). The frequency of these periodic interference ripples in $S_{11}(f)$ is $\Delta_f = c_{Si}/2e_{Si}$, where c_{Si} and e_{Si} are respectively the celerity of wave and the thickness of the silicon layer (400 µm) (Figure 4.b). The time-domain response corresponding to Figure 4.a is shown below in Figure 5. The multiple echoes are seen, the first one corresponding to the S_{11}^{el}. This electrical echo is directly due to the electrical mismatch between the transducer and the external circuit (50-Ohm load impedance of the VNA). The minor S_{11}^{el} delay corresponds to the electromagnetic wave propagation time in the cable portion between the network analyzer and the RF microprobe. The other echoes correspond to the different acoustic signals (S_{11}^{ac}) traveling back and forth in the silicon layer. They are separated by periods $\Delta_t = 1/\Delta_f = 94$ ns defined by the double Si wafer thickness's propagation time.

It is observed that the transducer emits both longitudinal and shear waves, which propagate in the silicon substrate at different speeds. The waves are denoted LL and SS for longitudinal/longitudinal or shear/shear propagation, respectively. The coupling of these 2 waves is very weak as the reflecting surface of the silicon is smooth and parallel to the transducer.

2.3. Transducer design using Auld's model

For checking the manufacturing quality of the transducers, we can model their impedance Zel and compare it to experiments. The piezoelectric layers being very thin compared to their lateral dimension (2 µm thick vs. 150 µm diameter), we can model them by a 1D model, like the Auld model [18].

As longitudinal and shear waves are emitted, we will use a modified Auld model that includes the two modes of emission. For that, it is necessary to consider the different mechanical impedances Z of the transducer's constituting layers. The analytical formulation for Zel of a transducer rigidly bounded to a semi-infinite solid is given by Equation 2; the mechanical impedances $Z^S_{(Air/Au/Ti)}$ and $Z^L_{(Air/Au/Ti)}$ in Equations 3 and 4 are hardly significant or negligible relatively to the other terms [16].

$$Z_{el} = \frac{1}{jC_0w} + \frac{K_S^2}{C_0w}A + \frac{K_L^2}{C_0w}B \quad (2)$$

where,

$$A = \frac{Z^S_{ZnO}}{\theta_S}\frac{2Z^S_{ZnO}[\cos(\theta_S)-1]+j\left[Z^S_{(Air/Au/Ti)}+Z^S_{(Si/Ti/Pt)}\right]\sin(\theta_S)}{Z^S_{ZnO}\left[Z^S_{(Air/Au/Ti)}+Z^S_{(Si/Ti/Pt)}\right]\cos(\theta_S)+j\left[(Z^S_{ZnO})^2+Z^S_{Air/Au/Ti)}.Z^S_{(Si/Ti/Pt)}\right]\sin(\theta_S)}$$

and

$$B = \frac{Z^L_{ZnO}}{\theta_L}\frac{2Z^L_{ZnO}[\cos(\theta_L)-1]+j\left[Z^L_{(Air/Au/Ti)}+Z^L_{(Si/Ti/Pt)}\right]\sin(\theta_L)}{Z^L_{ZnO}\left[Z^L_{(Air/Au/Ti)}+Z^L_{(Si/Ti/Pt)}\right]\cos(\theta_L)+j\left[(Z^L_{ZnO})^2+Z^L_{(Air/Au/Ti)}.Z^L_{(Si/Ti/Pt)}\right]\sin(\theta_L)}$$

L and S indices stand to the longitudinal and shear waves. $C_0 = \varepsilon_{ZnO}.S_{ZnO}/e_{ZnO}$ is the static capacitance of the ZnO transducer, ε_{ZnO} the dielectric permittivity of ZnO, e_{ZnO} and SZnO are the thickness and the active surface of the ZnO layer. K^2 is the square of the electromechanical coupling coefficient of the ZnO. $\theta = k_{ZnO}.e_{ZnO} = 2\pi f\,(e_{ZnO}/c_{ZnO})$ with k_{ZnO} the wave number in ZnO and c_{ZnO} the longitudinal or transverse wave's velocity the ZnO.

From an experimental point of view, the S-parameter is linked to the transducer impedance as follows:

$$S_{11} = \frac{Z_{el}-Z_0}{Z_{el}+Z_0} \quad (3)$$

Z_0 is the characteristic impedance of the network analyzer equal to 50 Ω.

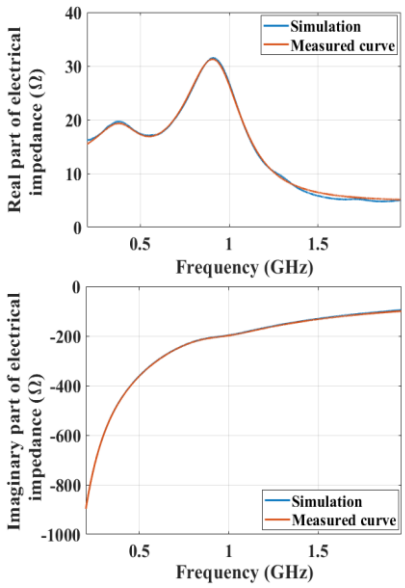

Figure 7: Simulated (blue curve) and measured (red curve) electrical impedance Z_{el} of the 150 µm diameter ZnO transducer.

The 150 µm diameter ZnO transducer's simulation results are shown in Figure 7 by the solid blue curves. The real part of Z_{el} (Figure 7.a) exhibits two peaks occurring at the resonance frequencies of the transverse (f_S= 0.38 GHz) and longitudinal (f_L= 0.9 GHz) waves.

A good fit between the simulation and the experimentation can be seen in Figure 7. So, the Auld model can be used to design a transducer for which the real part is close to 50 Ω by adjusting the thicknesses of the thin layers and the surface.

The manufacturing process is well calibrated which allows us to know the thicknesses of the different materials quite precisely. We were able, during various works, to measure the acoustic properties of ours deposited layers [17]. We therefore know the parameters on which the model depends, except the electro-mechanical coupling coefficients of the transducers which depend on the unknow orientation of the ZnO crystallites. We get them by an optimization routine using Nelder-Mead's algorithm. In the simulation, K_s and K_L were set to 0.10 and 0.23, respectively. The result of optimization for K_L is close to the theoretical one obtained for a perfect crystallite c-axis alignment (K_L = 0.27, according to [7]).

As shown in Figure 8, the pure electrical model we use represents the 2 modes of vibration of the transducer by the association of 2 RLC circuits shunted by the static capacitance C_0 . From a physical point of view, the capacity C_0 reflects the resonators electromagnetic behavior, while the two parallel resonant circuits exhibit the resonators acoustic behavior.

The electrical parameters of the circuit are determined by using the electrical impedance thanks to the measurement of the S_{11} parameter. As for the evaluation of the coupling coefficients, we obtained the electrical parameters by an optimization procedure.

The electrical parameters of the circuit are determined by using the S_{11} parameter:

$C_0 = 0.82$ pF, $L_L = 641$ nH, $C_L = 0.047$ pF, $R_L = 1645$ Ω, $L_S = 11.87$ µH, $C_S = 0.012$ pF, $R_S = 24$ kΩ.

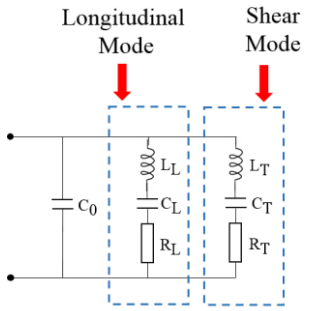

Figure 8: The equivalent electric circuit of the ZnO transducer.

3. Transducer optimization

3.1. Increasing the longitudinal acoustic waves emission by impedance matching

In any kind of application, we need to favor either one or both types of the generated waves. In the present study, regarding the matching network, promoting the longitudinal waves is sought [19].

The concept of electrical matching is to transfer the maximum power from the source to the transducer or, in other words, to eliminate electrical reflections on the transducer in a chosen frequency range. As piezoelectricity is a reciprocal phenomenon, the electrical matching network also acts as an acoustical matching layer. So, the electrical matching reduces the reflection of the acoustical waves returning on the piezoelectric layer, which increases the acoustical transmission coefficient at the piezoelectric device. Simultaneously, levels of both acoustic waves propagating in the device and electrical measurement signal increase.

There are two steps for the electrical impedance matching. The first one consists of connecting the transducer with a gold wire (25 µm of diameter). The second step uses an L-section impedance matching [20], consisting mainly of two reactive elements (capacitor and inductor). The capacity is used to adjust the real part of the impedance to 50 Ω, while the coil reduces the imaginary part. A capacitance has a significant loss effect at high-frequency, causing critical insertion losses [21]. For this reason, a chip inductor with a value of 8.6 nH was put in series with the load (transducer connected by the gold wire) at $f_{L,match}$ = 1.12 GHz. The real part of the load at this frequency is equal to 50 Ω.

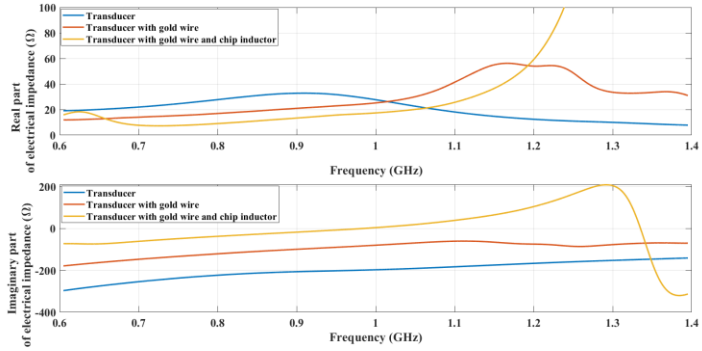

Figure 9: The real and imaginary parts of the electrical impedance of the ZnO transducer (blue curve), the transducer with gold wire (red curve) and transducer with gold wire and chip inductor (yellow curve).

It is clearly seen that the electrical response has been modified (Figure 9). This modification can be related to the losses and the parasite impedances of bonding wire and packaging. So, it has become complicated to choose a filter based on the equivalent electric circuit of the transducer, such as the Butterworth or Chebychev filters [22, 23, 24]. Therefore, the simplest solution is to use the transducer impedance's real and imaginary parts, including the wire.

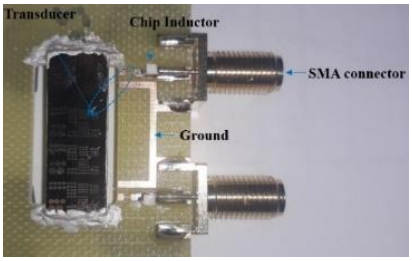

Figure 10: Image of the different elements of the circuit.

The expected result is the gain in longitudinal wave amplitude, which will make it easy to connect the transducer to the VNA or a generator via an SMA connector, as shown in Figure 10.

To verify that the electrical adaptation works as expected, we compare the insertion loss of the transducer before and after the adaptation, through an SMA connector. Afterwards, the responses in terms of received amplitude level will be compared. The electrical insertion losses L_e was calculated by the following equation:

$$L_e = -10 \log \left(1-\left|S_{11}^{el}\right|^2\right) \quad (4)$$

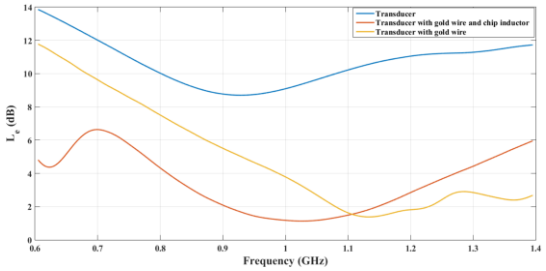

Figure 11: Measured electrical insertion losses.

As shown in Figure 11, the electrical adaptation has reduced the insertion losses. The matched transducer exhibits an amplitude gain of 8 dB and a bandwidth enlarged to 250 MHz.

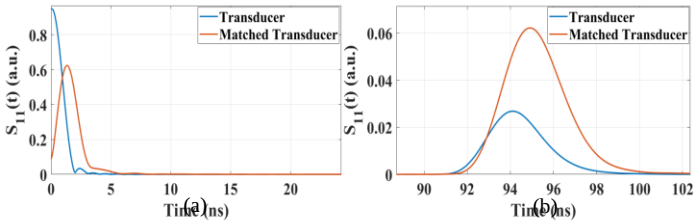

Figure 12: Impulse response $S_{11}(t)$, (a) the electrical reflection S_{11}^{el}, (b) the acoustic response S_{11}^{ac}.

The matching network's direct effect can be represented in Figure 12, showing the echoes before (blue curve) and after (red curve) the electrical matching. The attenuation of the reflected electrical signal is notably due to the conversion from electrical into acoustic energy. This conversion can be seen by the simultaneous amplitude decrease of the electrical echo S_{11}^{el} (Figure 12.a) and the increase of the first acoustical echo S_{11}^{ac} (Figure 12.b). However, this result only applies to $f_{L,match}$.

Although the electrical adaptation improves the transducer's acoustic sensitivity, the electrical reflection does not completely disappear because the use of an inductor is only at a single frequency $f_{L,match}$ and not over the bandwidth of the transducer.

3.2. Increasing the shear acoustic waves emission by deposition of ZnO inclined c-axis by R.F. magnetron sputtering

It appears difficult to use a matching network for increasing the level of shear waves as they are too weak. Previous measurements have been made with a transducer from a misaligned area (with respect to the ZnO target of the silicon wafer). By increasing that effect, it is possible to increase the shear level.

The ZnO thin film fabrication process was modified to balance the amplitude of generated longitudinal and shear waves by changing the material crystalline orientation. The film was deposited on three wafers with the following stack: Pt (80 nm) / Ti (10 nm) / Si (400 µm) by R.F. magnetron sputtering technique. The substrate was fixed in the chamber, whose total pressure was 0.02 mBar. A rectangular cover (the blind) is positioned between the target and the substrate, making it possible to obtain oblique incidence of the particles in order to locally influence the growth of the ZnO thin film (Figure 13). The blind was made of aluminum, had a height of 30 mm and a thickness of 1 mm. It was placed in the center of the substrate. The deposition rate of the ZnO films varied from 15 to 25 nm/min.

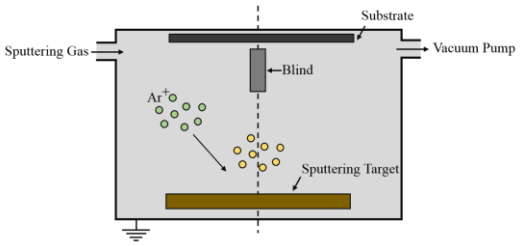

Figure 13: R.f. magnetron sputtering system with additional blind between substrate and target.

A cross-section SEM image of the ZnO deposited on the silicon substrate is shown in Figure 14. The inclination of the crystallite orientation is approximately 14.5° to the surface normal can be observed. So, shear and longitudinal waves can be excited. However, the inclination of the crystal orientation is strongly dependent on the distance between the blind and the transducer (in the substrate plane); therefore, the c-axis inclination will be higher in an area close to the blind or close to the edge of the substrate.

Figure 15.a shows the resonance diagram of the piezoelectric transducer; two distinguished downward peaks can be seen, the first one in the frequency range [0.35 - 1 GHz] which corresponds to critical transversal waves response compared to Figure 4 and the other peak in the range [1 - 2 GHz] corresponding to longitudinal

waves response. Two oscillations with different frequencies Δf = {S: 7.4 MHz, L: 10.5 MHz}, are presented in Figure 15.b. Each of them presents a different wave mode. This result directly reflects the transducers' ability sputtered with the inclined ZnO c-axis to generate both shear and longitudinal waves.

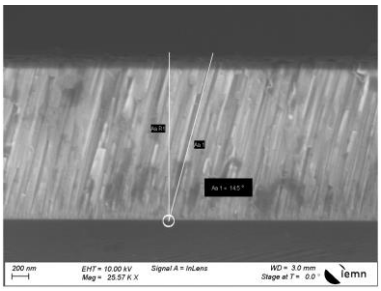

Figure 14: Cross-sectional SEM image of ZnO film with c-axis inclined of 14.5°.

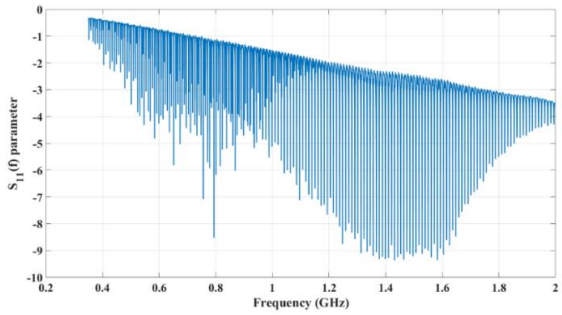
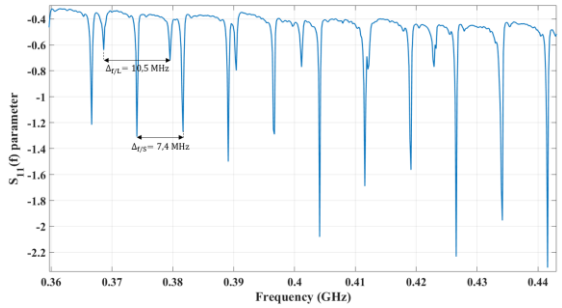


(a)



(b)

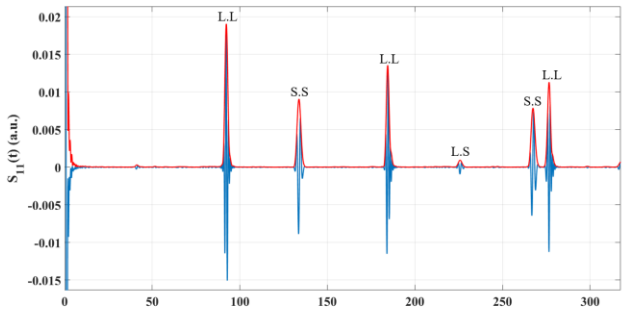
Figure 15: Impulse response $S_{11}(f)$, (a) for f=[0.35 - 2 GHz], (b) Zoom around the longitudinal and the shear acoustic waves resonance.

Figure 15 (b), as we expect each of them are close to the theoretical ones {Cs/2e = 5843/800e-6 = 7,3 MHz and Cl/2e = 8432/800e-6 = 10,54 MHz}.

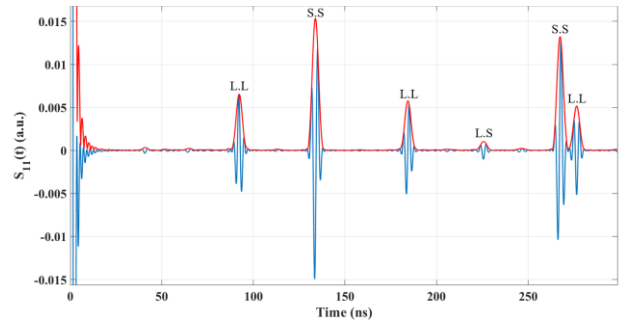
The time-domain representation is used below to check the level of both signals. Figure 16 shows the inverse Fourier transform of the S11 parameter. For [0.35 - 2 GHz], two different acoustic reflections LL, and SS, are the responses from the generated acoustic waves, with LL being a purely longitudinal response with longitudinal wave emitted and the longitudinal wave reflected. The longitudinal speed of sound in silicon (8432 m/s) is greater than the transversal one (5832 m/s); thus, the time of reception of the signal for the longitudinal waves should be the fastest (the first reflection on Figure. 16.a corresponds to LL). The second impulse SS is the purely transversal reflected signal with the time delay being significantly greater than LL. For a bandwidth of 1.65 GHz, the ratio of the shear wave to the longitudinal wave is 0.5.

We decreased the frequency range to [0.35 - 1 GHz] (Figure 16.b), the shear to shear (SS) reflection amplitude increases, and the longitudinal to longitudinal (LL) amplitude decreases, which what was expected to be seen since the lower frequency range favors the transversal waves (Figure 16.a). The ratio of shear to longitudinal amplitudes increases to 2.6.

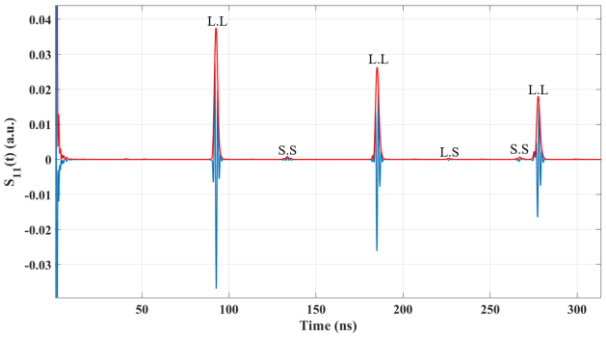
For f = [1 - 2 GHz] (Figure 16.c), the result is the profound decrease in the SS reflection amplitudes and the profound increase in the LL amplitudes, which is what to expect since the high frequencies favor the longitudinal waves. We now have a ratio of shear to longitudinal amplitudes decreased to 0.01.



(a)



(b)



(c)

Figure 16: Impulse response $S_{11}(t)$, the time delays $\Delta_{t/L} = 1/\Delta_{f/L} = 95$ ns and $\Delta_{t/S} = 1/\Delta_{f/S} = 135$ ns between them corresponds to the propagation delays of the longitudinal and transverse wave travelling twice the thickness of the wafer. (a) f = [0.35-2 GHz], (b) f = [0.35-1 GHz] and (c) f = [1-2 GHz].

Levels are weak, but all signals are out of the noise and can be used for measurements. If necessary, they can be increased using a convenient matching network, as demonstrated in part 1. Thus, we propose a method allowing the emission of both longitudinal and shear waves using only one fixed fabrication process.

However, the c-axis tilt is not the same on the wafer surface, so the transducers cannot generate the same wave level for each frequency range, so the ratio of shear to longitudinal amplitudes changes.

4. Application: Measurement of the viscosity of a liquid using both longitudinal and shear waves generated by the ZnO transducer

There are a vast number of applications that utilize physical parameters in relation to acoustic waves-material interactions. An application to measuring the fluid viscosity is presented below to demonstrate the usability of the proposed transducer design. Water is used as the reference fluid whose acoustic properties are given in [25, 26].

The total viscosity of water can be extracted from the shear and longitudinal waves generated at the liquid/ solid interface [27,28]. Our transducers can generate these two types of waves. We used the evaporation of 1 µL droplet of water to determine the two kinds of viscosities (namely shear and volume viscosities). The dynamic shear viscosity was extracted using the shear wave, while the volume viscosity from both waves.

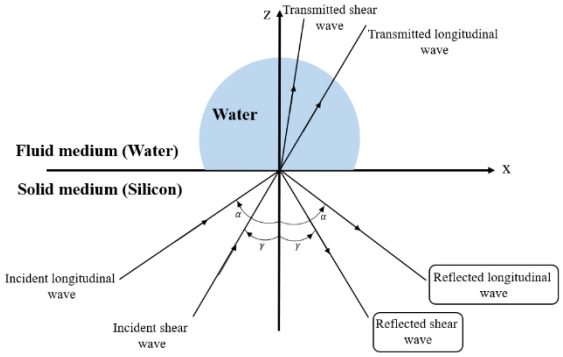


Figure 17: Incident acoustic waves interaction at droplet/silicon interface.

Figure 17 presents the direct contact of the acoustic waves to the water droplet/silicon interfaces. The acoustic waves reflect at the interface and generate two components, i.e., longitudinal and shear reflected waves.

Several mechanical properties at the silicon/water interface influence the measurement, and these are also strongly dependent on the temperature. The reflection coefficient at the solid/fluid interface is given by equation 5, Z_0 is the mechanical impedance of the silicon, considered purely elastic, so Z_0 is purely real [29], while water presents viscoelastic properties. As a consequence, its acoustic impedance Z_1^* is in a complex form.

$$r^* = \frac{Z_1^* - Z_0}{Z_1^* + Z_0} \tag{5}$$

where $Z = \rho C$, ρ is the density of the medium, and C is the acoustic velocity of the wave propagating inside of the medium. The reflection coefficients are determined for both longitudinal and shear reflected waves. So, the complex form of the shear reflection coefficient ($r_{SS}{}^*$) and the longitudinal reflection coefficient ($r_{LL}{}^*$) are shown in the Equations 6 and 7. These coefficients give access to the modulus and the phase angle of the two reflections acoustic wave at the interface.

$$r_{SS}^* = \frac{Z_w^{S*} - Z_{si}^S}{Z_w^{S*} + Z_{si}^S} = \frac{\rho_w C_S^* - Z_{si}^S}{\rho_w C_S^* + Z_{si}^S} \tag{6}$$

where,

$$C_S^* = \omega/k_S^* \quad \text{and} \quad k_S^* = \omega/C_S - i\alpha_S = \omega/C_S - i\sqrt{\frac{\rho_w \omega}{2\eta}}$$

$$r_{LL}^* = \frac{Z_w^{L*} - Z_{si}^L}{Z_w^{L*} + Z_{si}^L} = \frac{\rho_w C_L^* - Z_{si}^L}{\rho_w C_L^* + Z_{si}^L} \tag{7}$$

where,

$$C_L^* = \omega/k_L^* \text{ and } k_L^* = \omega/C_L - i\frac{\omega^2}{2\rho_w C_L^3}\left[\mu + \frac{4}{3}\eta\right]$$

where C_L^*, C_S^* are the complex longitudinal and shear velocity of water, ρ_w is the density, k_L^*, k_S^* the complex longitudinal and shear wave number, ω (rad/s) the angular velocity. η and μ are the shear and volume viscosity, respectively.

C_L and C_S are the effective longitudinal and shear phase velocities in water respectively, α_S is the shear attenuation. The kinetics of the shear and volume viscosity is shown in Figure 18. A sessile droplet of water evaporating at room temperature of 25°C is used. It is clearly seen that the consistency of the theoretical and experimental results.

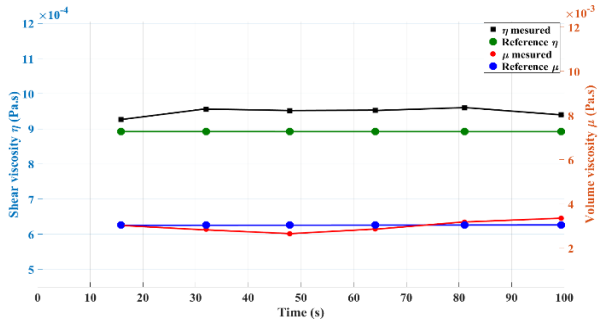

Figure 18: Kinetics of the shear and volume viscosity of a water droplet at T=25°C compared to the reference values.

It was essential to improve the shear waves emission to accurately measure the shear viscosity values for different complex fluids such as nanofluids. These nanofluids contain nanoparticles in suspension in a matrix fluid; that is why it is important to have a high sensitivity of these particles that settled above the surface.

5. Conclusion

This article is the extended version of a paper published in IEEE Xplore. We have studied the fabrication and the optimization of a ZnO high-frequency transducer able to generate both longitudinal and shear waves. To model the transducer's electrical response, we used the Auld model; we noticed a good agreement between electrical impedance measurements and simulations, allowing its use in the design of transducers. To

improve the sensitivity, we have used an electrical circuit including a chip inductor and an SMA connector so that it could be used without the requirements of an external RF microprobe. This matching circuit had been experimented with for the longitudinal mode and allowed us to gain ~ 8 dB on the electrical insertion losses.

In order to increase the shear wave level, the growth of ZnO films with tilting of the crystallite axis has been achieved using a blind of 10 mm that was positioned between the target and the substrate during the R.F. magnetron sputtering. The inclination of the crystal orientation was approximately 14.5°.

Both shear and longitudinal waves can be excited with this multi-mode transducer; the wave type can be selected by adjusting the emission frequency.

As to proof of the usability of this kind of measurement, an application has been proposed. We have exploited the simultaneous measurements of the two types of waves to extract both shear and volume viscosities of the water. Comparisons between the experimental and theoretical results show a good agreement.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

This work was partially supported by the French Renatech network. A part of the cost has also been supported by STMicroelectronics and Hauts-de-France region. The authors wish to thank all the members of the cleanroom at IEMN- UMR CNRS 8520. They are also grateful to the professor Bertrand Nongaillard for his encouragement and support in this work. Finally, the authors also thank the laboratory engineers, Dr. Malika Toubal, and Dr. Nikolay Smagin, for their help in preparing the article.

ABSTRACT

This work presents the analysis and formulation for optimizing the dynamic model and parameter estimation of all the six joints of a 6DOF industrial robot manipulator by utilizing swarm intelligence to optimize two excitation trajectories for the first three links at the arm and the last three links at the wrist of the robot manipulator. Numerical techniques were used to reduce the observation matrix to a minimum linear combination of parameters, thereby maximizing the identifiable parameters, and the Linear Least Square method was used for parameter identification. An improved particle swarm optimization algorithm with mutation and archived elite learning was proposed for solving the dynamic optimization problem of the industrial robotic manipulator. The basic parameters of the algorithm have been optimized for robotic manipulator analysis. The proposed algorithm is computationally economical while completely dominating other Evolutionary algorithms in solving robot optimization problems. The algorithm was further used to analyze 36 benchmark functions and produced competitive results.

1. Introduction

This paper is an extension of the work originally presented in the 2019 IEEE International Conference on Artificial Intelligence and Computer Applications [1], where a novel mutating Particle swarm optimization (MuPSO) based solution was proposed for analyzing the inverse kinematic problem of multi-degree-of-freedom robot manipulator. It was observed that the basic parameters of the Particle swarm optimization (PSO) algorithm are incapable of analyzing robot optimization problems, and it was established that the PSO parameters need to be modified for robot analysis. Further investigations were published in [2] where various parameters were used to analyse the inverse kinematic problem of four popular robot configurations and a new range of parameters for solving robot optimization problems was established, thereby an optimized mutating PSO algorithm for robot analysis was developed. If the algorithm runs into stagnation while solving a robot optimization problem, the mutation function is used to generate a completely new swarm and all the information regarding the previous swarm is lost. It is keen to note that if a particle from the previous swarm is retained, that particle becomes the global best particle for the new swarm, making the entire swarm converge again at the previous solution. It was observed that it would be beneficial to save previously non-dominated solutions in an archive for future reference. This work therefore seeks to further modify the mutating PSO algorithm by implementing it with an archived elite learning system, and using the new eMuPSO algorithm for dynamic parameter estimation of a 6 Degree-of-freedom (DOF) industrial manipulator and finally compare the improved algorithm with other state of the art algorithms in analyzing 36 benchmark functions. The rest of the paper is structured as follows; section 2 presents previous literature, section 3 introduces the new Mutating PSO algorithm, section 4 presents the results of parameter estimation of robot manipulators, and compares the new PSO algorithm with state of the art swarm-based algorithms on thirty-six benchmark functions and finally section 5 concludes the findings.

2. Literature

In industrial robotics, a dynamic model determines the actuator force required to achieve the desired joint configuration, coupling

*Corresponding Author: Zhanqun Shi, Hebei University of Technology, Tianjin-China, Tel.: +86-2260438217, z_shi@hebut.edu.cn

effects and non-linearity of the system introduces dynamic uncertainties. These errors degrade the robot's performance. Therefore, re-calibrating robot parameters are necessary for efficient robot analysis and control, that can only be achieved experimentally. In dynamic model estimation, obtaining experimental data requires that firstly, a linearized model of the robot manipulator is developed, then a trajectory that excites the robot's rigid body dynamics is developed, afterwards input torque and output joint configuration data is experimentally obtained and finally the dynamic parameters are estimated. The accuracy of the estimation method is largely dependent on the chosen trajectory and measuring accuracy. The actuator torque can be measured from input electric currents while optic encoders are incorporated for measuring joint output conditions. The recent improvement in technology makes available encoders and reduction gears that are capable of preventing cumulative errors and minimizing gearbox backlash. Therefore, carefully selecting an exciting trajectory is paramount in dynamic model estimation. Reference [3] observed that the excitation trajectory can be optimized by minimizing the condition number of the observation matrix. The observation matrix is a function of only the joint variables; it enables the solution of nonlinear systems to be presented as linear. The condition number of the observation matrix is a measure of noise immunity, a value closer to unity results in a better signal to noise ratio (SNR). The presence of unidentifiable parameters results in a high condition number of the observation matrix. References [4, 5] proposed techniques for categorizing dynamic parameters into identifiable parameters, unidentifiable parameters, and identifiable parameters in linear combinations. These works suggested that eliminating unidentifiable parameters from the observation matrix enhances estimation accuracy. In [6, 7] a set of Minimal Linear Combinations (MLC) of identifiable dynamic parameters from the total amount of parameters to be identified was generated. Reference [8] proposed formulating the periodic Finite Fourier series (FFS) as an excitation trajectory. FFS inhibits noise interference, if the identification experiment is repeated several times, averaging the measured data in the time domain improves SNR. Reference [9] used a modified Fourier series (MFS), where the FFS is implemented on a circular trajectory in the Cartesian space such that the initial and final conditions of the joints are the same, permitting continuity in the optimization experiment without necessarily stopping and restarting the manipulator. The particle swarm optimization algorithm (PSO) is a stochastic metaheuristic swarm-based evolutionary algorithm (EA), each particle in the swarm is attracted towards the global best particle's position and its personal best position denoted as (Gbest and Pbest). The velocity and position of canonical PSO are updated according to (1) and (2).

$$X_i^d(t+1) = X_i^d(t) + V_i^d(t+1)\,, \tag{1}$$

$$V_i^d(t+1) = wV_i^{\dim}(t) + c_1 r_1\left(Pbest_i^{\dim}(t) - X_i^{\dim}(t)\right)\cdots + c_2 r_2\left(Gbest^{\dim}(t) - X_i^{\dim}(t)\right)\,, \tag{2}$$

where i = 1, 2, 3…$nPop$ denotes for the index of each particle, $nPop$ is the swarm size, and dim = 1,2…dof denotes for the dimensionality of the solution space, dof is the degrees of freedom of the robot. V_i^{dim} and X_i^{dim} stand for the position and velocity vectors of the i^{th} particle, respectively. $V_i^{dim} = [v_i^1, v_i^2, \ldots, v_i^{dof}]$, $X_i^{dim} = [x_i^1, x_i^2, \ldots, x_i^{dof}]$. w is the inertia weight. c_1 and c_2 are cognitive and social learning coefficients. r_1 and r_2 are two uniformly distributed random numbers within the range of [0,1]. Over the years, PSO has undergone various modifications either to improve its internal dynamics (enhance convergence and exploitation characteristics) or to satisfy the requirement of a specific real-world optimization problem or both.

2.1. PSO with Improved Dynamics

An index based ring topology PSO was proposed by [10] for solving multimodal multi-objective optimization problems having more than one Pareto optimal solution corresponding to the same objective function. Reference [11] studied the impact of communication topology in PSO, the star topology (Gbest) where each particle communicates with every other particle, was found better in analyzing unimodal separable problems while the ring topology (LBest) where each particle communicates with only its two neighbor particles, is preferred for multimodal, non-separable and composite functions. The ring topology is more capable of jumping between optimum basins and it was also found to never converge at a local optimum, but with a considerably higher computational cost. Memetic algorithms (MA) are hybrid EAs that are a fusion of global and local search techniques. EAs are usually employed for global search while unconstrained optimizers are employed for local search. Adaptive MAs have been successfully combined with other EAs but not PSO, [12] proposed a co-evolutionary memetic PSO for solving multi-objective optimization problems. Feature selection (FS) is a combinatorial problem for large dimension data processing which requires large memory and high computational cost, [13] proposed a variable-length PSO for FS. The Proposed algorithm is flexible and simplifies large data analysis, and can jump out of local optima while narrowing the search space. The cooperative search strategy which prevents particle from being trapped in local optima was merged with PSO by [14] for unconstrained optimization, where cooperative multiple swarms were used to improve the convergence and efficiency of the canonical PSO.

2.2. Problem Oriented PSO

Medicine and medical healthcare are amongst the top beneficiaries of artificial intelligent swarm algorithms. Health care services are shifting from inpatients to outpatients. Reference [15] showed that accident and emergency centers in hospitals are currently being optimized to ensure 98% of patients get the required attention within 24 hours. The increasing demand for primary health care outlets has led to a requirement to optimize the operational efficiency of primary healthcare centers. Grouping the patients into an appropriate category optimizes time and manpower whereas patient no shows after grouping reduces operational efficiency of clinics. In [16], using PSO to improve the accuracy of traditional clustering techniques was proposed for analyzing real-time patient attendance data and group them into clusters, while [15] compared PSO with opposition based learning and self-adaptive cohort intelligence for identifying significant features capable of predicting no shows. Gene selection from microarray data for cancer diagnosis and testing also involve large data sets and are computationally expensive, support vector machines algorithm is a fast and efficient classification model

which requires its parameters tuned to satisfy specific problems. Reference [17] compared the performance of PSO-SVM and Memetic SVM for classification and feature selection of cancer cells. Alzheimer's disease is a primary stage of dementia which is a type of memory disorder that affects the brain. The structural changes of the brain's internal regions are the most commonly measured in diagnosing AD. Reference [18] compared the accuracy of PSO and other metaheuristic algorithms in segmenting the brain sub-regions. Air pollution is a major contributor to human mortality and a potential danger to the environment and ecological system [19]. Thermal power plants such as coal, petroleum, and natural gas are the main sources of air pollution, mercury contamination has been identified to be the most acute air pollutant produced by power plants [20]. In [21], a novel combination of modified genetic algorithm and the improved particle swarm optimization was proposed for minimizing the fuel cost of generating plants and emission simultaneously, by managing and controlling the integration of renewable energy and thermal power production, where an optimal generation plan for maximizing system efficiency can be achieved. Reference [22] proposed using an adaptive neuro-fuzzy inference system with PSO (ANFIS-PSO) for predicting mercury emission in power plants. Reference [23] sought to minimize the construction cost of reinforced concrete retaining walls (RCRW). These structures include bridges, railways, dams, etc., capable of withstanding the pressure resulting from the difference in level by an embankment, excavation, or natural processes. PSO was used to determine the optimum solution between popular techniques. In rural areas where the utility grid is unavailable, renewable energy is an attractive alternative for water pumping applications. The power-voltage curve of a photovoltaic cell was found to have multiple maximum power points under partial shading conditions, making the solar tracking mechanism unstable. In [24], the performance of PSO was compared with salp swarm algorithm for maximum power point tracking of solar panels. Electric motors are most popular for electrical-mechanical power conversion and employed in several industrial applications including robotics, because of their simplicity, durability, and low maintenance cost. They usually require a controller for high performance and efficiency. The electrical parameters of the electrical motor are very essential to design, performance assessment, and feasibility of the control technique, any difference in the actual motor parameters adversely affects the system performance. Reference [25] proposed using PSO for estimating the electrical parameters of induction motors.

3. Mutating PSO with Elite Archive Learning

The proposed PSO is equipped with a modified set of parameters and governing equations. The mutation function is used to generate a new swarm around the vicinity of the most promising particles when the algorithm runs into stagnation. The operation of the proposed mutating PSO with elite learning (eMuPSO) is divided into two, during the early stages, the algorithm searches the solution space for the minimum solution, then when it stagnates, elite solutions are being recalled from the archive and merged with the best solutions of the current run to generate a new population. The new population would be created either through Random or Gaussian mutation depending on the application. It was found that a mix of both was suitable for kinematic analysis while the Gaussian mutation was suitable for dynamic analysis.

3.1. Modified Parameters

It was established in [1] and [2] that the basic parameters of canonical PSO are not capable of ensuring converging solutions for robot optimization problems especially when the DOF is greater than three. The basic parameters of the mutating PSO were modified to satisfy the requirement for solving robot optimization problems. This was achieved by testing the performance of various PSO parameters on four popular robot configurations, and a relationship between the inertia weight and the social learning coefficient was derived. More details on modifying PSO parameters can be found in [2]. A non-linearly decreasing inertia weight is implemented with values between (2.1 – 0.6), the cognitive learning coefficient is constantly at 2.24, while the social learning coefficient is non-linearly increasing between (1.8 – 3.9). The equations for updating w and c2 are given in (3) and (4).

$$w_{iter} = w_{initial} * n^{iter} , \quad (3)$$

$$c_{2iter} = c_{2initial} / m^{iter} , \quad (4)$$

where *iter* is the iteration number, and *n* and *m* are coefficients. The coefficients *n* and *m* can be determined by setting *iter* to the maximum value. Robot configurations have complex dynamics described by highly coupled and non-linear, second-order differential equations, there are possibilities of numerous strong local minimizers in the solution space.

3.2. Mutation

In [26] it was shown that structural bias is a characteristic of swarm algorithms that tends to confine the algorithm to a region of the total search area. Mutation is a valid technique for overcoming such constraints. It was established in [2] that even the most intelligent swarm-based solutions are capable of running into stagnation, random mutation was used to push the algorithm out of stagnation and enhance convergence. The Gaussian mutation was used in [27] to improve swarm performance. Reference [28] also used a Gaussian mutation throw point strategy to redistribute the swarm at sparse positions. In the proposed algorithm, when the swarm stagnates at a local minimum solution, a Gaussian mutation is used to push the algorithm out of stagnation and redistribute the swarm to enhance unbiased coverage of the search space. The radius of the swarm is monitored according to (5). When the swarm radius becomes too small, it signifies that the swarm has lost diversity and might be stagnating, then the mutation function is initiated. The condition in (6) states that if there is no change in the swarm radius or when the change in the swarm radius is negligible, then the counter *g* increases sequentially otherwise the counter is reset to zero. A second condition in (7) terminates the algorithm when the minimum solution is achieved or the swarm is mutated when *g* is greater than a threshold value *G*.

Assuming there are *k* elite particles, the entire swarm population would be divided into *k+1* parts and each *k* part would be replaced by off-springs of the k^{th} elite particle, while the *k+1* part consists of particles generated from a random distribution, thereby maintaining diversity in the swarm. such that if x^{dim} is the

dimth dimension of the swarm, then all the elements in the *dim*th dimension shall mutate according to (8).

$$rad_{iter} = GlobalBestCost_{iter} - mean(BestCost)_{iter} , \quad (5)$$

$$g = \begin{cases} g+1, & if, (rad_{iter-1} - rad_{iter}) = 0 \\ 0 , & Else \end{cases} , \quad (6)$$

$$f(MuPSO) = \begin{cases} end & if \quad 1e^{-8} \\ mutate & if \quad g \geq G \end{cases} , \quad (7)$$

$$^{\dim} x_{mutate} = {}^{\dim} x_{elite} + gaussian(\sigma) , \quad (8)$$

where *rad* is the radius of the swarm, *iter* refers to the current iteration, $^{dim}x_{mutate}$ and x_{elite} are the mutated off-spring and the elite solution in the *dim*th dimension of the swarm, and σ is a variable between [0-1] multiplied by size of the search space.

3.3. Elite Archive

When the algorithm is searching for the best solution, the experiences of the best particle is transferred to the next iteration through the global best information, but at the beginning of subsequent generation or after mutation, all the information regarding the best particle from the previous generation is lost. This inspired the introduction of an archive where the experiences of the elite non-dominated solutions are saved and can be called in the future to enhance the search. Reference [29] applied a dynamic archive maintenance strategy to improve the diversity of solutions in multi-objective particle swarm optimization. In [30] an external archive was employed to preserve the non-dominated solutions visited by the particles to enable evolutionary search strategies to exchange useful information among them, and [31] used a grid-based approach for the archiving process and ε-dominance method to update the archive, which helps the algorithm to increase the diversity of solutions. Reference [32] used the cooperative archive to exploit the valuable information of the current swarm and archive. Information about the elite particles from dynamic sub swarms was used in [33] to improve the following sub-swarm, while [32] introduced a new velocity updating technique that explores the external archive of non-dominated solutions in the current swarm. In this article, an elite archive learning is used to refine the solution in the final stages of the algorithm. Elites from previous searches are saved as global elites, while elites of the current search are saved as local elites. When the algorithm stagnates, a combination of both elite vectors is used to generate a new population, and the global elites are updated with new solutions from the current local solutions

3.4. Robot Dynamics

Industrial robot manipulator

A 6 DOF industrial robot manipulator was analyzed, the structure of the robot manipulator is shown in Figure 1 and its D-H parameters are given in Table 1. A homogeneous transformation matrix describes the state (orientation and position coordinates) of a robot link with respect to the previous link in the Cartesian coordinate space and can be used to describe the state of the end-effector (tool) of the manipulator with respect to the base (global coordinate) frame. If all the joint parameters are known (D-H Parameters), the homogeneous matrix of each successive pair of frames for the forward and inverse directions can be obtained from (9). The robot manipulator's end-effector coordinates would be a product of post multiplication as shown in (10).

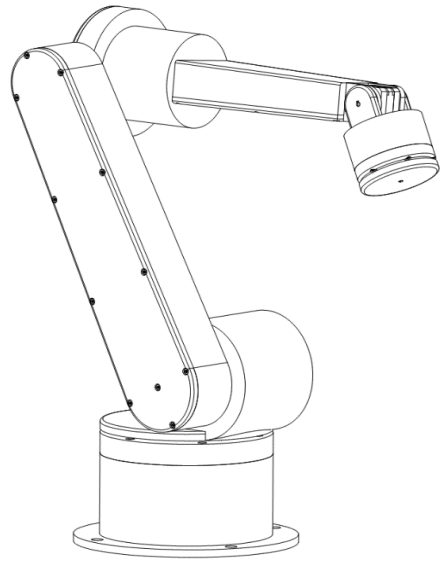

Figure 1: A 6 degree of freedom industrial robot manipulator

Table 1: D-H parameters of 6 degree of freedom industrial robot manipulator

Joint	Link	Off-set	Joint	Off-set
1	300	320	(-165 : +165)	-pi/2
2	700	0	(-110 : +110)	0

4	0	200+497.5	(-160 : +160)	pi/2
5	0	0	(-120 : +120)	-pi/2
6	0	97.5+30	(-242 : +242)	0

$$T_{\dim}^{\dim-1} = \begin{bmatrix} c\theta_{\dim} & s\theta_{\dim}c\alpha_{\dim-1} & s\theta_{\dim}s\alpha_{\dim-1} & a_{\dim}c\theta_{\dim} \\ -s\theta_{\dim} & c\theta_{\dim}c\alpha_{\dim-1} & c\theta_{\dim}s\alpha_{\dim-1} & a_{\dim}s\theta_{\dim} \\ 0 & -s\alpha_{\dim-1} & c\alpha_{\dim-1} & d_{\dim} \\ 0 & 0 & 0 & 1 \end{bmatrix}, \quad (9)$$

$$T_4^0 = \begin{bmatrix} t_{11} & t_{12} & t_{13} & t_{14} \\ t_{21} & t_{22} & t_{23} & t_{24} \\ t_{31} & t_{32} & t_{33} & t_{34} \\ 0 & 0 & 0 & 1 \end{bmatrix} = T_1^0 T_2^1 T_3^2 T_4^3 \quad (10)$$

where $c\theta$ and $s\theta$ refers to $cos\theta$ and $sin\theta$ respectively.

Dynamic parameter estimation

The Linear-least-square (LLS) method together with an optimized excitation trajectory was used for dynamic parameter estimation of the robot manipulator. LLS requires that the model equations are linear with respect to dynamic parameters and it is

sensitive to noise in the measured data. [34] observed that the actuator forces of an industrial manipulator are linear functions of dynamic parameters, [4] inferred that reformulating the Newton-Euler dynamic model such that the link inertia tensors are expressed about the link coordinate frames instead of the center of the links' mass, would result in a linearized Newton-Euler formulation. Equations (11-14) presents a summarized Newton-Euler formulation in the form of observation matrix. For detailed information on linearizing the Newton-Euler equation, see [4] and [34].

$$\Phi = \left(\Omega^T \Omega\right)^{-1} \Omega^T * \Gamma \ , \tag{11}$$

$$\Gamma = \left(\left(\Omega^T \Omega\right)^{-1} \Omega^T\right)^{inv} \Phi \ , \tag{12}$$

$$\Gamma = \begin{vmatrix} \tau_{\dim} \\ \vdots \\ \tau_{dof} \end{vmatrix} = \begin{vmatrix} \omega_{\dim}\left(q,\dot{q},\ddot{q}\right) \\ \vdots \\ \omega_{dof}\left(q,\dot{q},\ddot{q}\right) \end{vmatrix} * \begin{vmatrix} \phi_{\dim} \\ \vdots \\ \phi_{dof} \end{vmatrix} , \tag{13}$$

$$\phi_{\dim} = \begin{bmatrix} mm & mc_x & mc_y & mc_z & I_{XX} & I_{YY} & I_{ZZ} & I_{XY} & I_{XZ} & I_{YZ} \end{bmatrix}^T , \tag{14}$$

$$fitness = cond(\Omega) + \frac{1}{\varphi_{\min}(y)} + \varphi_{\max} y \ , \tag{15}$$

where Γ is the compound torque for the manipulator comprising of individual joint torques τ, the compound observation matrix Ω comprises of individual joint vectors $\omega(q, \dot{q}, \ddot{q})$, and is a function of the joint position, velocity, and acceleration only. ϕ is a vector of unknown robot parameters for each link that require to be identified, it includes link mass *mm*, first moments $[mc_x\ mc_y\ mc_z]^T$ along the x-y-z axis, and six inertia tensor I_{ij}, these compose the compound vector of unknown parameters Φ. The intelligent swarm-based algorithm would be required to minimize the condition number of the observation matrix while maximizing the smallest singular value and minimizing the largest singular value. Therefore, the fitness function would be as described in (15).

Exciting trajectory

A modified Fourier series (MFS) formulation was used to define the excitation trajectory with a cubic polynomial. The equation of motion for the trajectory of the first three joints are given in (16-18), a circular trajectory path was implemented so as to allow continuous trajectory tracking of the robot during experimentation. The trajectory is to be optimized by applying the eMuPSO algorithm to minimizing the condition number of the observation matrix. The trajectory is implemented in Cartesian space, and joint positions are determined from inverse kinematic solutions. The wrist of the manipulator has a z-x-z orientation, therefore the excitation trajectory along the *x* and *y* axis can be derived independently from (16) and (17) while that of the *z* axis is estimated from (19), where *d6* is the offset length of the sixth link of manipulator (see DH parameters) and t_{14} is the position coordinate of transformation matrix T_4^0 from the *Base* to *Link-04*.

$$Q_x(it) = d0_j^{it} + \sum_{j=1}^{N} \begin{pmatrix} \cos(P_{it}) * a0_j^{it} + \dots \\ \frac{b0_j^{it}}{freq * j} \sin(freq * j * tym) - \dots \\ \frac{c0_j^{it}}{freq * j} \cos(freq * j * tym) \end{pmatrix} , \tag{16}$$

$$Q_y(it) = e0_j^{it} + \sum_{j=1}^{N} \begin{pmatrix} \sin(P_{it}) * a0_j^{it} + \dots \\ \frac{b0_j^{it}}{freq * j} \sin(freq * j * tym) - \dots \\ \frac{c0_j^{it}}{freq * j} \cos(freq * j * tym) \end{pmatrix} , \tag{17}$$

$$Q_{z,arm}(it) = f0_j^{it} + \sum_{j=1}^{N} \begin{pmatrix} \frac{b0_j^{it}}{freq * j} \sin(freq * j * tym) - \dots \\ \frac{c0_j^{it}}{freq * j} \cos(freq * j * tym) \end{pmatrix} , \tag{18}$$

$$Q_{z,wrist}(it) = f0_j^{it} + \sqrt{d6^2 - \left(t_{14} - Q_x(it)\right)^2} \ , \tag{19}$$

$$Vector(it) = \begin{bmatrix} vec_{11} \\ vec_{21} \\ vec_{31} \end{bmatrix} = \begin{bmatrix} t_{14} \\ t_{24} \\ t_{34} \end{bmatrix} - \begin{bmatrix} Q_x(it) \\ Q_y(it) \\ Q_z(it) \end{bmatrix} , \tag{20}$$

$$\theta_4 = a\tan\left(vec_{31}, vec_{21}\right) , \tag{21}$$

$$\theta_5 = a\tan\left(norm\left(\left[0, vec_{21}, vec_{31}\right]^T\right), vec_{21}\right) , \tag{22}$$

$$\theta_6 = a\tan\left(\left(vec_{31}(it) - vec_{31}(it-1)\right),\ \left(vec_{21}(it) - vec_{21}(it-1)\right)\right) , \tag{23}$$

$$\left.\begin{array}{l} \min_{a_j, b_j, c_j} \ cond(\Omega) \quad such \quad that; \\ \quad \{s(Q(it))\} \subset S \\ if \quad Q_x = [q_{x1}, q_{x2}, \cdots q_{xk}] \\ \quad 0 \le Q_x(it) \le 2\pi \\ \quad 0 \le \dot{Q}_x(it) \le 0 \\ \quad 0 \le \ddot{Q}_x(it) \le 0 \end{array}\right\} , \tag{24}$$

where *Q* describes the trajectory in Cartesian space such that $[Q_x, Q_y, Q_z]^T$ are the *x-y-z* coordinates of *Q*, *P* is the polynomial, the variables *a0* is the radius, *b0* and *c0* are the coefficients of the MFS while the variables *d0*, *e0*, and *f0* are the x-y-z position coordinates of the excited trajectory. $j = 1,2 \dots N$ denotes the harmonics of the MFS, while the index of time segment/period is denoted as *it*; *freq* is the fundamental frequency and *tym* is the period. The joints 4, 5, and 6 coincident at the joint 5, described by the transformation matrix T_4^0 in (10). The inverse kinematic solution of these joints can be estimated given the orientation matrix, but in this case only the position vector is known (i.e. $[Qx, Qy, Qz]^T$). Therefore, the rotation angles of the joints at the wrist would be estimated from

(20-23), and the orientation matrix is evaluated by substituting θ in (9) then inverse kinematics can be subsequently evaluated. To achieve continuity along the tool-path, the initial and final conditions of the trajectory must be the same as described in the conditions in (24). The initial and final values for the circular trajectory *P* are set as *0* and *2π* radians, 3 harmonics for the coefficients of MFS were used (N=3), and the fundamental frequency is *0.6283* with a period of *10* seconds.

4. Results

The eMuPSO algorithm was first implemented together with the LLS for optimizing the observation matrix and dynamic parameter estimation of all the six links of the 6DOF robot manipulator. The ideal parameters of the manipulator are given in (25-32). Then the proposed algorithm was finally implemented in evaluating thirty-six benchmark functions including twenty-four variable-dimension benchmark functions and twelve constant-dimension benchmark functions. The variable dimension benchmark functions consist twelve functions each, of unimodal and multi-modal roles (a full description of all benchmark function used are given in the appendix).

The results were compared with the Standard PSO (PSO) [35] and four other swarm-based EAs including the Whale Optimization Algorithm (WOA) [36], Grey Wolf Optimization (GWO) [37], Grass-hopper Optimization Algorithm (GOA) [38], and the Differential Evolution (DE) algorithms [39].

4.1. Dynamic Parameter Estimation

Generating initial elite particles

Parameter estimation was in two stages; initial elite particles were first generated which were then used to generate the swarm for parameter estimation. This reduces the probability for the algorithm to run into stagnation. A swarm of ten particles was first generated for each variable *(a0, b0, ..., f0)*. From inverse kinematics, the joint conditions (position, velocity and acceleration) corresponding to the generated trajectory of each set of particle is estimated and compared with the stated constraints in (24). Trajectories that do not meet the constraints are flagged and a penalty was introduced.

The fitness function for this swarm is a measure of the degree of compliance of the generated trajectory with the stated robot constraints. If a trajectory is found to completely satisfy these constraints, the variables corresponding to such trajectory is elevated to elite status and a new particle is generated to replaces that particle, else, the entire swarm's velocity and position is updated in accordance with PSO. Elite particles should be generated within 5-10 iteration if the minimum and maximum limits of the variables are carefully selected. This algorithm is terminated when 5 elite particles have been generated. The variable limits are set at ±10. While the variables *a* and *b* span between negative and positive limits, others must always be positive.

$$\mathrm{Mm} = \begin{bmatrix} \mathrm{mm1} \\ \mathrm{mm2} \\ \mathrm{mm3} \\ \mathrm{mm4} \\ \mathrm{mm5} \\ \mathrm{mm6} \end{bmatrix} = \begin{bmatrix} 5.029912009 \\ 4.530794148 \\ 3.056783430 \\ 1.815211338 \\ 0.990530741 \\ 0.186899621 \end{bmatrix}, \tag{25}$$

$$\mathrm{Mc} = \begin{bmatrix} \mathrm{mcx1} & \mathrm{mcy1} & \mathrm{mcz1} \\ \mathrm{mcx2} & \mathrm{mcy2} & \mathrm{mcz2} \\ \mathrm{mcx3} & \mathrm{mcy3} & \mathrm{mcz3} \\ \mathrm{mcx4} & \mathrm{mcy4} & \mathrm{mcz4} \\ \mathrm{mcx5} & \mathrm{mcy5} & \mathrm{mcz5} \\ \mathrm{mcx6} & \mathrm{mcy6} & \mathrm{mcz6} \end{bmatrix} \cdots = \begin{bmatrix} 4.3956 & -15.8576 & 10.1804 \\ -44.1094 & 93.9465 & 183.7506 \\ 0.37299 & 0.001086 & 100.6463 \\ -0.01376 & 12.03674 & 18.1007 \\ -0.00300 & -0.00352 & -21.2584 \\ 0.004296 & 0.000028941 & 4.9163 \end{bmatrix}, \tag{26}$$

$$I_6 = \begin{bmatrix} Ixx6 & Ixy6 & Ixz6 \\ Ixy6 & Iyy6 & Iyz6 \\ Ixz6 & Iyz6 & Izz6 \end{bmatrix} \cdots = \begin{bmatrix} 103.8927 & 0 & 0 \\ 0 & 103.8903 & 0 \\ 0 & 0 & 204.5344 \end{bmatrix}, \quad (32)$$

Optimizing the excitation trajectory

A swarm of 20 particles is generated from the previously generated *initial elite particles* through Gaussian mutation. Similar to previous procedures, the boundary conditions are set, joint conditions corresponding to each generated trajectory is estimated, again penalties are introduced to make trajectories that do not satisfy the constraints in (24) less likely to be selected as exemplars. The fitness function for this swarm is evaluated according to (15). The swarm of the algorithm is mutated at 10 iterations after stagnation (i.e. G=10).

Parameter estimation

The dynamic parameters of a 6DOF manipulator was estimated in two stages, the last three links corresponding to the wrist were first estimated followed by the first three links corresponding to the arm of the manipulator. A numeric technique for reducing the observation matrix to a minimum linear combination of identifiable parameters was implemented as described in [40] where three empty matrices were created corresponding to *identifiable* parameters, *unidentifiable* parameters, and *identifiable parameters in linear combinations*. Understanding that the rank of the observation matrix is equal to the number of identifiable parameters, the norm of each column of the observation matrix is determined independently. The columns with zero norms represent coefficients of *unidentifiable* parameters and are moved to the matrix of *unidentifiable* parameters, else it is added to the matrix of *identifiable* parameters. Note that the initial rank of the empty matrix of *identifiable* parameters is zero, if the newly added column does not increase the rank of the matrix of *identifiable* parameters, it is moved to the matrix of *identifiable parameters in linear combination*. The eMuPSO was used to select the trajectory that best optimizes the observation matrix. Removing *unidentifiable* parameters from the observation matrix increases estimation accuracy. In the first estimation stage (wrist), out of the 30 unknown parameters at the wrist, 15 were independently identifiable, 7 were identifiable in linear combination, while 8 were unidentifiable. Out of the 7 parameters that were identifiable in linear combination, it was observed that for most elite particles, 5 were identifiable with lower errors. The 15 independently identifiable parameters include *Iyy4*, *Ixz4*, *mx5*, *Ixx5*, *Iyy5*, *Izz5*, *Ixy5*, *Ixz5*, *Iyz5*, *mcx6*, *mcy6*, *Iyy6*, *Izz6*, *Ixz6*, and *Iyz6*. The 7 parameters identifiable in linear combination include *mcy4*, *mcy5*, *mcz5*, *mm6*, *mcz6*, *Ixx6*, and *Iyz6*. It was found that *Ixx6* and *Iyz6* were identified with very large errors for most elite particles. In the second estimation stage (arm), 20 parameters were independently identifiable, 2 were identifiable in linear combinations while 8 were unidentifiable. All parameters were identified with little errors. The 22 identified parameters include *mcy1*, *Iyy1*, *mm2*, *mcx2*, *mcy2*, *mcz2*, *Iyy2*, *Izz2*, *Ixz2*, *Iyz2*, *mm3*, *mcx3*, *mcy3*, *mcz3*, *Ixx3*, *Iyy3*, *Izz3*, *Ixy3*, *Ixz3*, *Iyz3*, *Ixz1*, and *Ixx2*.

Figure 2.0 (a) and (b) show the convergence plot at the wrist and at the arm of the manipulator respectively. The eMuPSO was populated with twenty particles in thirty iterations and five runs. The Figure 2.0 shows all five runs, the sixth being the average of all five runs. It would be observed that in the third run of Figure 2.0 (a), the algorithm converges to the global minimum solution in eight iterations, then it is mutated in the 14th iteration where it stagnates until it is mutated again in the 24th iteration. The best solutions are stored in the archive before mutation. The Figure 2.0 (b) show less agitation of the algorithm signifying less mutation and simpler analysis.

Tables 2 and 3 presents the parameters of the non-dominated elite solutions for the joints at the arm and wrist of the manipulator, including the three harmonics each for *a0* and *b0*, with corresponding fitness values, condition number of the observation matrix and cumulative errors for the best 20 identified parameters and for all 22 identified parameters. Figure 3.0 (a) presents the resultant trajectory in Cartesian space for the 5th elite particle at the robot's wrist, showing a somewhat circular continuous trajectory with fluctuations that are typical of FFS. Figures 3.0 (b) and (c) show the position and velocity of the three joints at the robot's wrist in joint space, while Figure 4.0 shows the equivalent for the 1st elite particle at the robot's arm. From the results presented in Table 2 (at the wrist), it would be observed that while the *6th elite particle* has the lowest fitness value and the lowest cumulative estimation error for all the 22 identified parameters, the *2nd elite particle* presents the trajectory with the lowest condition number, and the *1st elite particle* presents the lowest cumulative estimation error for the 20 best identified parameters. Likewise, in Table 3 (at the arm), although all the 22 identifiable parameters were identified with higher accuracy, yet it would also be observed that the *6th elite particle* has the lowest fitness and presents the trajectory with the lowest condition number, but the *1st elite particle* presents the lowest cumulative estimation errors for both the 20 best identified parameter and the 22 identifiable parameters. This supports the observation of [41] that the best solution does not guarantee the global minimum solution because the dynamic optimization problem is not convex.

4.2. Benchmark Function Analysis

A total of thirty-six benchmark functions (BF) were evaluated, and the results presented in Tables 4-6. Reference [2] showed that accuracy and convergence time are paramount in robot analysis, the average and standard deviations alone do not completely describe the results, and some solutions with good averages are incapable of finding the global minimum solution (inaccurate). Therefore, the minimum values are also presented in the tables. The solution that best minimizes the function is presented in bolded font. From the Table 4, in the unimodal BF analysis, all the algorithms satisfactorily found the minimized solution for the function f6; eMuPSO, PSO, and DE equally minimized the function f7 while GWO and WOA equally minimized the function f11. WOA and GWO had the best performance, producing the best minimizing solutions for five out of twelve unimodal BF each. WOA dominated other algorithms in f1, f3, and f12 functions, tied with GWO in f11 and tied with all other metaheuristics in f6. While GWO dominated other metaheuristics in f8, f9, and f10. Therefore, WOA and GWO dominated other algorithms in three unimodal BF, tied in two BF and were dominated in seven BF each as elaborated in Table 7. The PSO dominated other metaheuristics in f4 and f5, while eMuPSO was dominant in f2. Both tied with other metaheuristics in f6 and f7 and were dominated in eight and nine unimodal BF respectively. From the Table 5, in the multimodal BF analysis, it can be observed that the eMuPSO and PSO tied in f1, f4, and f12; PSO, WOA, and GWO tied in f2; WOA and GWO tied in f3; eMuPSO, PSO and GOA tied in f5; all the metaheuristics except GWO and DE tied in f6, eMuPSO and DE tied in f9, and all the metaheuristics except GOA tied in f11. eMuPSO had the best performance producing the best minimum results on eight out of twelve multimodal BF, followed by PSO, WOA, and GWO producing the best minimum solutions for seven, five, and four multimodal BF respectively. eMuPSO dominated other metaheuristics on f10 and tied with other metaheuristics on seven multimodal BF. PSO did not dominate other metaheuristics on any of the multimodal BF, but tied on seven and was dominated in five BF, WOA was dominant on f7, tied with other metaheuristics on 4 Multimodal BF and was dominated in 7 BF. GWO was dominant on f8, tied with other metaheuristics on 3 BF, and was dominated on 8 BF. From the Table 6, in the constant dimension BF analysis, eMuPSO and PSO tied in producing the best minimizing solution for f1 and f6, all metaheuristics except GOA and GWO tied on f2; eMuPSO, PSO and DE tied on f3, f5, f7, f8, f9, f11. All the metaheuristics except WOA and GWO tied on f4 and f12. eMuPSO once again had the best performance producing the best minimum solutions for all twelve BF, dominated other metaheuristics in f10, and tied in eleven BF, followed by PSO and DE producing the best-minimized solution for eleven and nine BF respectively. Compared to other algorithms, WOA and GWO performed well in the unimodal BF analysis but performed poorly in the constant-dimension BF analysis. After numerous experiments, at various dimension sizes, it can be suggested that the WOA algorithm is convenient for analyzing optimization problems with high dimensionality (especially unimodal roles), but may not necessarily maintain its lead when the dimensionality is low, while the proposed eMuPSO is convenient for analyzing optimization problems with lower dimensionality. Compared to other EAs, the eMuPSO and PSO algorithms performed averagely in the unimodal BF evaluations but were excellent in analyzing multimodal and constant-dimension BF. DE performed poorly in the unimodal and multimodal BF, performed well in the constant-dimension BF analysis.

The Wilcoxon signed-rank test was performed at a 5% significance level to compare the results of each run and decide on the significance of the results, and the p-values are reported in Table 8. In the statistical analysis, the best algorithm in each test function is the algorithm with the best average value, the best algorithm is compared with other algorithms independently. For instance, if eMuPSO is the best algorithm, pairwise comparison is done between eMuPSO/PSO, eMuPSO/GOA, and so on. Observe that since the best algorithm cannot be compared with itself, N/A with bold font size has been assigned to it. From Table 8, in the unimodal statistical analysis (F1-F12) WOA algorithm was most significant in six out of twelve BF as elaborate in Table 9. SPSO and GWO were significant in four functions each, while DE and eMuPSO were significant in three and two of the functions respectively. In the multimodal statistical analysis (F13-F24), the eMuPSO and DE were most significant in six out of the twelve BF each, followed by WOA with five BF, while SPSO and GWO were most significant in 3 of the BF each. In the constant-dimension statistical analysis (F25-F36), the eMuPSO and DE remained most significant for ten out of the twelve BF each, followed by the SPSO with 8 BF, GOA was most significant in 2 of the BF, while others were significant in only one each of the benchmarks functions.

Table 4: Unimodal benchmark function analysis.

	Multimodal	2/4/6	0/3/9	1/4/7	0/3/9	0/1/11	2/4/6
	Constant Dim.	0/10/2	1/7/4	0/1/11	0/1/11	0/2/10	1/9/2
	Total	2/16/18	3/12/21	5/7/24	2/6/28	0/4/32	4/15/17

4.3. Convergence Analysis

In Figure 5, the unimodal convergence plot analysis, it can be observed that eMuPSO was dominant in f2, tied with other metaheuristics in f6 and f7, produced the second-best minimum solution for f4 and f5, and the third-best minimum solution for f8. A large overshoot can also be observed in the results of f7. In Figure 6, the multimodal convergence plots, eMuPSO dominated others in f10 and tied in f1, f4, f5, f6, f9, f10, f11. eMuPSO produced the second-best minimized solution in f8. All the algorithms except WOA stagnated at the local minimum in f7. In Figure 7, the Constant-dimension benchmark function convergence plots, eMuPSO best minimized all twelve BMF dominating others in f10. Overshoot can be observed in the results of eMuPSO in f25, f28, f29, f33, and f35. Similarly, an overshoot can also be observed in the results of WOA in f28 and f29. In the convergence plots presented, it can be seen that the GOA and GWO produced the slowest converging results, this is most evident in f13, f16, f18, f22, and most of the constant-dimension benchmark functions. This suggests good exploration capabilities of the swarms. Whereas eMuPSO, PSO, and DE produced the fastest converging results. In robot analysis speed and accuracy are required, therefore the best algorithm has to make a balance between fast convergence speed and good exploration tendencies.

5. Conclusion

An enhanced PSO algorithm was proposed with a Gaussian mutation and an archive elite learning (eMuPSO), the parameters and dynamic update technique were optimized for robot analysis. The parameter identification problem of robot manipulators is generally computationally demanding, therefore finding a computationally efficient solution is important for which swarm-based algorithms are suitable. In Dynamic parameter estimation, excitation trajectory was optimized using the proposed eMuPSO, it allowed the swarm to be populated with fewer particles thereby requiring less computational time. The mutation function allowed a wholesome search of the solution space. The LLS method was subsequently used to estimate the dynamic parameters of a 6DOF industrial robot manipulator where it was seen that estimation errors are larger at the wrist of the manipulator. Parameter estimation accuracy is better at the arm with less dexterity, while the total estimation accuracy for the 6DOF manipulator is deteriorated by the cumulative estimation errors at the wrist with increased dexterity. This suggests that larger DOF manipulators would be suitable for manufacturing, agriculture and other industrial applications, but may not be suitable for high end application that are keen on accuracy like medical operations, airplane manufacture, etc. The eMuPSO particularly gives a scientist the advantage of choosing from the set of elite particles, the solution that best solves the desired problem. The eMuPSO is therefore capable of analyzing both kinematic and dynamic robot problems of robot manipulators. Further experimentation showed that the landscape of the solution space for robot optimization problems are non-linear, non-separable and multi-modal with multiple possibilities of sub-optimal solutions (local minimizers) some of which are very steep. When a solution approaches the vicinity of these steep local minimizers, it easily falls into its trap and it is usually very difficult to break out of such stagnation without artificial perturbation, resulting to the failure of most evolutionary algorithms in analyzing robot optimization problems. The performance of the eMuPSO can be related to its origins. The parameters of the eMuPSO was derived experimentally by comparing the performance of various robot manipulator configurations as described in [2]. The robot optimization problem is a non-linear and multi-modal problem with dimension size usually less than twenty. Robot manipulator problems are generally computational demanding, therefore a fast convergence time and high accuracy are important. The eMuPSO best showed its veracity in analyzing multimodal and constant dimension BF. PSO and DE performed well in constant dimension BF. It would also be observed that the proposed eMuPSO cannot drill a solution below 1E-30, this is also suitable for robot analysis because the solution to robot optimization problems is usually in the range of 1E-10.

For a successful dynamic parameter estimation analysis, the following should be carefully observed.

- It is recommended to keep either *d0* or *e0* equal to zero to avoid singularity so that the excitation trajectory is limited two quadrants on the x-y plane.
- It would be keen to differentiate between dynamic and kinematic DH-parameters. When determining the position coordinated of the robot manipulator, the sum of lengths of the 3rd and 4th links make up *d4*, while during dynamic analysis this results in actuator torque errors. Likewise, the length *d6*.

- When determining the 6th joint angle from the excitation trajectory vector with (27), the initial joint position is unknown, so it is recommended to assume the initial joint position at the first segment (*@ it = 1*) is equal to the joint position at the last time segment to reduce the overshoot in velocity.

Funding

This research was funded by the National Natural Science Foundation of China, grant number 51875166.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

I would like to first acknowledge my late mum whose unflinching support kept me going against all odds and who unfortunately is no more with us to witness my achievements, my lovely wife and children who were patient with me through these trying times and finally to Prof. Shi for giving me the opportunity and finding me worthy.

The technics of maximum power point tracking is widely used in solar photovoltaic energy and electric power system applications. Traditionally, these technics are based on conventional methods like perturb and observe and incremental conductance. In this work, three methods based on particle swarms optimization, incremental conductance and adaptive neuro fuzzy inference system are presented. A comparative study is carried out. The study of this paper shows that there is a limitation in the incremental conductance method. To overcome the shortage of this last method, particle swarms and adaptive neuro fuzzy optimization methods are used. The behaviors of the three methods are compared and evaluated in simulation under matlab/simulink. Results demonstrate that the adaptive neuro fuzzy inference system is effective for photovoltaic power optimization even for non-uniform climatic conditions. It has the best performances followed by the particle swarms method.

NOMENCLATURE

ANFIS	Adaptive Neuro Fuzzy Inference System	Ipv [A]	PV current
PVS	Photovoltaic Solar	RMSE [-]	Root Mean Square Error
MPP	Maximum Power Point	MSE [-]	Mean Square Error
InC	Incrementale Conductance	MAPE [%]	*Mean Absolute Percentage Error*

1. Introduction

Today's world sees rapid industry development and this makes us more energy dependent. Fossil sources occupy the largest share of electricity production [1], [2]. The use of conventional energies (around 87% of global energy consumption) has an undesirable impact on the environment in terms of greenhouse gas (GHG) emissions and safety (nuclear accidents). 36.5 billion tons of CO_2 is emitted in 2020 [3]. To overcome these problems, it is necessary to resort to alternative energies [4–9]. Among them is Photovoltaic Modules (PVM) solar energy. Its annual growth rate over the last ten years is estimated at more than 40% [10]. Despite their low efficiency, PVM still have a high price. To get around this efficiency problem, techniques for optimizing the power generated by the PVM are proposed [11], [12–16]. This technique, makes it possible to run after the maximum power that the module is capable of supplying [17]. The generated power depends on weather conditions irradiation and temperature [18–20]. Under these latter conditions, the electrical characteristics of the PVM have only one optimal. So not too much trouble for the technique to converge the system to the MPP. Under non-uniform conditions of irradiation and temperature, the electrical characteristics of the PVM present several optimal points. The algorithm used must therefore be able to distinguish the global optimum from the local optima [21]. It therefore requires a sophisticated algorithm which will be able to make a global exploration of the search space in order to make the system converge towards the global MPP [22].

The most used of the classical methods are the P&O method and the InC method [5], [23–26]. Several researchers have used the P&O technique in their work. This method, based on the voltage disturbance and the observation of the variation of the power, is very widespread in the literature. Originally, it was designed to exceed the limits of other types of deterministic controls such as Hill Climbing, Open Circuit Voltage Fraction, etc. It also presents limits linked mainly to the response time and the numerous oscillations around the MPP. The InC method is proposed [3, 18, 25]. In [27], according to the results, the incremental conductance algorithm performs better than the perturb and observe algorithm. To overcome the problems linked to the limits of the methods mentioned above under variable of climatic conditions, Soft-Computing methods based on Meta-heuristic algorithms and Artificial Intelligence (AI) algorithms are proposed. MPPT techniques are based almost exclusively on these techniques. They are very numerous and diverse. They range from Evolutionary Algorithms (Genetic Algorithm), Meta-heuristic algorithms (Optimization by Particle Swarms) and AI algorithms (Artificial Neural Networks, Fuzzy Logic, ANFIS) [21], [10, 11, 28–31].

Artificial Neural Networks (ANN) have been used in several works to optimize the power delivered by a PVM. Its operating principle is inspired by that of the human brain. With their great generalization capacity, they are used for solving complex optimization problems [32], [33]. This is the case in [34] where MPPT method based on ANN is compared to MPPT method based on P&O. The results show that ANN method is more robust than P&O method, regardless of the operating conditions of the PVM. Its limits lie in its lack of interpretation and the difficulty of determining the appropriate number of Layer/Neurons. In addition, these latter limits represent strong points for the Fuzzy Logic (FL) algorithm. The interpretive inability encountered with ANN is resolved by the use of LF. It uses its linguistic variables to overcome this problem [35], [36]. Using the classical logic process, it has facility for extension and interaction [37], [38].

FL also has limits which can be circumvented. Which makes them two complementary techniques and the combination of which gives the Neuro-Fuzzy technique including ANFIS.

In reference [39], two ANFIS models are proposed for grid-connected PV system current injection and battery control. The results show that the proposed the models offered allow the battery charging/discharging process to be supervised and at the same time injecting good quality energy into the grid.

In [40] two MPPT techniques based on ANFIS and P&O are compared. Comparison results show that the technique based on the ANFIS algorithm is more robust.

In [5] Five MPPT techniques are proposed. A comparative study is carried out between them. The simulation results show that the best performances are obtain with ANFIS with an efficiency of 99.4%, against 98.1% and 97.5% respectively for FL and P&O.

The power optimization technique using the ANFIS algorithm is more robust than other techniques such as FL, ANN, InC and P&O. It overcomes the problems encountered with ANN and FL as it is a complementary technique linking the two [28, 38, 41].

Other types of techniques based on algorithms whose principle is inspired by the evolution of nature are presented in the literature [11, 42]. Among them there are methods based on the Particle Swarms Optimization (PSO) algorithm [43, 44].

In [45], a comparative study between techniques using PSO, InC and P&O is carried out. Results of simulation show that the PSO technique is the more robust with the most low response time compared to the two others techniques (InC and P&O). In [46], authors proposed a comparative study between PSO, P&O and FL techniques to optimize the MPP of the PVM. Results show that the MPPT technique based on PSO outperformed FL and P&O techniques.

The work in this paper is consisting to do a comparative study between MPPT techniques based on ANFIS, PSO and InC algorithms put under the same conditions in order to indicate the most efficient and the most robust for power optimization problems. A validation of these three commands is done using an experimental database. The scientific contribution of this paper is to design a MPPT technique based on ANFIS algorithm using database collected to solar power plant in tropical zone.

The rest of the article is organized as follows. Section II presents the MPPT proposed approaches. Section III the proposed approach for the MPPT techniques. Section IV presents the results of simulations and discussions. Finally, a conclusion is made in section V.

2. Proposed approach

In solar PV system, power delivered by the PVM is not always the maximum. This is due to the phenomenon of intermittence. As a result, the operating point of the PVM is not even the MPP. It so requires a technique which is able to extract the MPP of the PVM. This technique, called MPPT optimizes the power through the generation of a duty cycle for controlling the static converter.

The block diagram of the studied system is given in Figure 1.

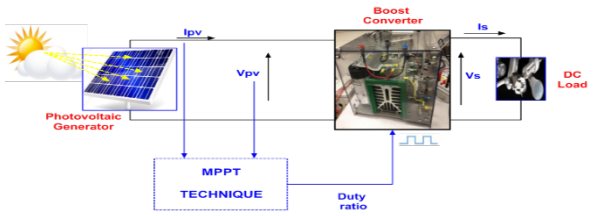

Figure 1: Schematic diagram of the MPPT technique

2.1. Incremental Conductance method based MPPT

The InC algorithm is among the most efficient of the classical algorithms. It is based on the cycle of the change in pressure to the change in voltage of the PVM (equation 1). At MPP, the slope is zero. The tracking is done according to the position of the operational point (or slope) (dPpv / dVpv) relative to the MPP (equation (3)). The latter depends on the value of the conductance (Ipv / Vpv). The sign of the latter indicates whether the MPP is reached or not (equation (2)). It is compared to its increment. This amounts to saying that the MPP depends on the voltage variation and that of the current [18,26],[47,48]. Thus, the algorithm increments or decrements the duty cycle of the static converter to continue the MPP. The flowchart is shown in Figure 2.

$$\frac{dP_{pv}}{dV_{pv}} = I_{pv} + V_{pv}\frac{dI_{pv}}{dV_{pv}} \quad (1)$$

The MPP is found when:

$$\frac{dP_{pv}}{dV_{pv}} = 0 \rightarrow \frac{dI_{pv}}{dV_{pv}} = -\frac{I_{pv}}{V_{pv}} \quad (2)$$

The sign of the slope indicates the direction of evolution of the MPP according to equation (3).

$$\begin{aligned} &\frac{dP_{pv}}{dV_{pv}} > 0, left\ side\ of\ MPP \\ &\frac{dP_{pv}}{dV_{pv}} < 0, for\ V_{pv} > V_{MPP}, right\ side\ of\ MPP \\ &\frac{dP_{pv}}{dV_{pv}} = 0, on\ the\ MPP \end{aligned} \quad (3)$$

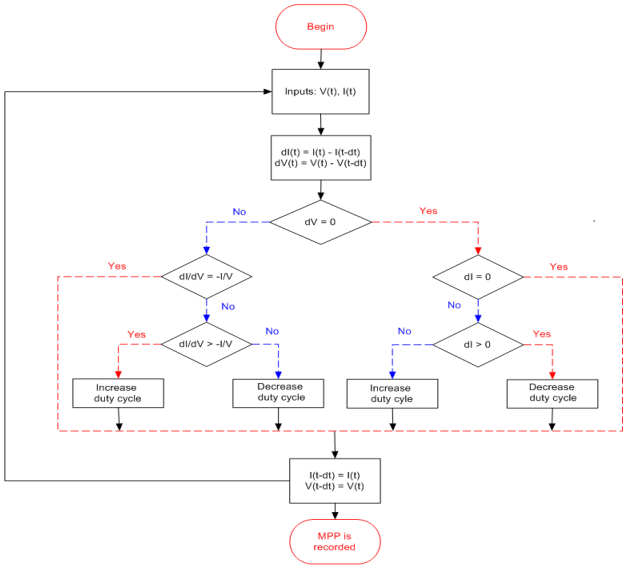

Figure 2: Incremental Conductance flowchart based MPPT

2.2. PSO method based MPPT

Particle Swarm Optimization is an evolutionary meta-heuristic approach. It is used for solving optimization problems. Its principle is based on the behavior of particles (individuals) [49]. In this paper we use a swarm of birds (Figure 3). In this type of swarm, collective intelligence is involved. Particles converge towards those with the best performance [50].

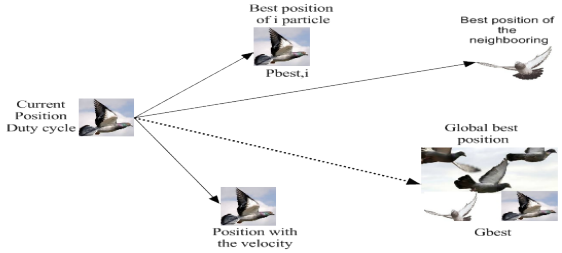

Figure 3: Movement of a particle in the swarm of birds

The duty cycle α of the boost converter represents the particles. Velocity and position are initialized to begin and the movement of the particles are described by equations (4) and (5). For evaluating the best position of the particles, fitness function is calculated according to the equation (6). Vpv and Ipv are calculated for each particle i with a fixed position in the search space [αmin, αmax]. The algorithm converges the system towards the global optimum. For this the duty cycle is initiated. This ratio, depending on P_{besti} and G_{best}, is corrected if it deviates from the best overall duty cycle as in the principle of Figure 3. The particles are then evaluated in terms of position and velocity according to equations (7) and (8). Updates are made to re-evaluate the optimum duty cycle for controlling the boost converter. Table 1 gives the parameters of the PSO. These parameters are defined for the PSO simulations. The flowchart is shown in Figure 4.

Table 1: PSO implementation parameters

Parameters	Values
Q_1	1,2000
Q_2	2
m	0,4000
Iterations	25

$$\alpha_i^{t+1} = \alpha_i^t + \left(\frac{d\alpha}{dt}\right)_i^{t+1} \quad (4)$$

$$\left(\frac{d\alpha}{dt}\right)_i^{t+1} = w\left(\frac{d\alpha}{dt}\right)_i^t + Q_1 r_1 (P_{besti} - \alpha_i^t) + Q_2 r_2 (G_{best} - \alpha_i^t) \quad (5)$$

$$F_i(\alpha^t) = P_{pv,i}^t \quad (6)$$

$$P_{besti} = \alpha_i^t \quad if \quad F_i(\alpha^t) \geq F_i(P_{besti}) \quad (7)$$

$$G_{best} = \max(P_{besti}) \quad (8)$$

F is the fitness function,

α is the duty cycle of the boost converter,

t is the time of simulation

r_1 and r_2: uniformly pull in [0,1].

w: coefficient of inertia.

Qi: acceleration coefficient

P_{besti} is the personal best position of particle *i*

G_{best} is the best position of the particles in the entire population.The MPPT technique based on PSO algorithm is described by equations (4) to (8).

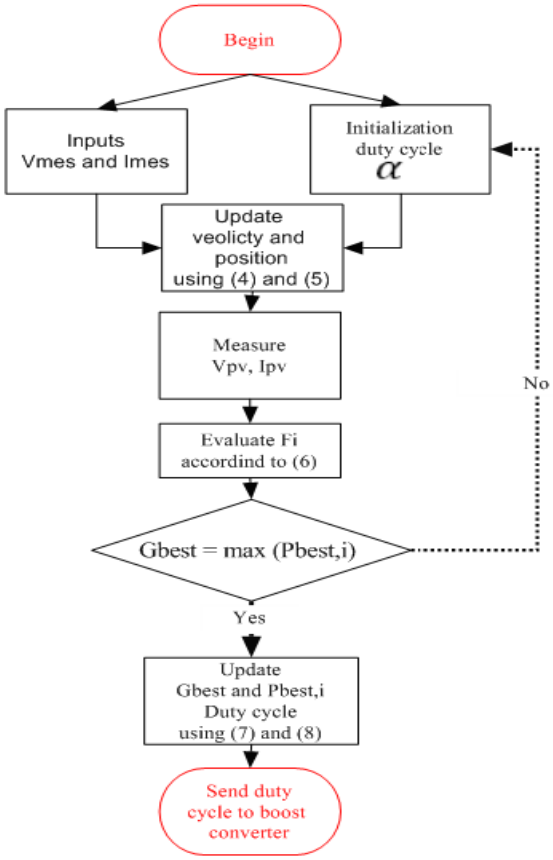

Figure 4: PSO flowchart based MPPT

2.3. ANFIS method based MPPT

ANFIS is an adaptive neuro-fuzzy inference system that has five layers in its structure. These layers refine the fuzzy rules already established by human experts and readjust the overlap between the different fuzzy subsets [51–54].

The neural structure replaces the hidden layers with fuzzy rules. This further simplifies learning and interpreting the results obtained. The structure proposed in this work receives the voltage and current from the PVM as inputs and supplies the output with an optimal power comparable to that of the PVM.

The architecture of the MPPT ANFIS technique is given in Figure 5.

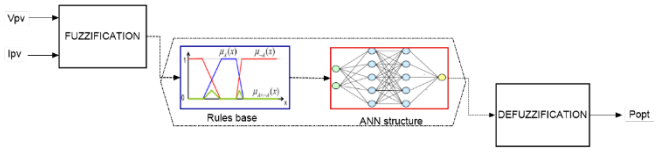

Figure 5. Architecture of the MPPT ANFIS technique

Layer 1: Each Neuron calculates the degree of truth of a fuzzy subset by its transfer function. It is called fuzzification layer. Numeric input values are converted to linguistic variables (equations 9 and 10) for high interpretability.

$$O_i^1 = \begin{cases} \mu_{Ai}(V_{pv}) & for \quad i = 1,2 \\ \mu_{B(i-2)}(I_{pv}) & for\ i = 3,4 \end{cases} \tag{9}$$

With:

$$\mu_{Ai}(V_{pv}) = exp\left[-\left(\frac{Vpv-a_i}{b_i}\right)^2\right] \tag{10}$$

Layer 2: It calculates the degree of activation of antecedents (premises). This is the layer of fuzzy rules (equation 11).

$$w_i = \mu_{Ai}(V_{pv}) * \mu_{Bi}(I_{pv}) \tag{11}$$

Layer 3: It normalizes the degree of activation of the rules: it is the normalization layer (equation 12).

$$G_i = \frac{w_i}{w1+w2} \tag{12}$$

Layer 4: It determines the parameters of the consequence of the fuzzy rules. Previous linguistic variables will be translated again into numeric values before being sent to the last layer. It is defuzzification (equation13).

$$O_i^4 = \frac{\sum_i w_i f_i}{\sum_i w_i} \tag{13}$$

Layer 5: It calculates the overall output of the system: it is the output layer. Equation (14) gives the expression of the optimal power generated by the PVM with the ANFIS technique for three fuzzy subsets.

$$P_{opt} = \sum_{i=1}^{nit}\left\{P_{opt,i}.\frac{e^{-\left[\left(\frac{Vpv-a_i}{b_i}\right)^2+\left(\frac{Ipv-a_{i-2}}{b_{i-2}}\right)^2\right]}}{\sum_{i=1}^{3}\left(e^{-\left[\left(\frac{Vpv-a_i}{b_i}\right)^2+\left(\frac{Ipv-a_{i-2}}{b_{i-2}}\right)^2\right]}\right)}\right\} \tag{14}$$

where ai and bi are the parameters of the premise of the MsF, and Popt is the optimal power delivered by the ANFIS controller.

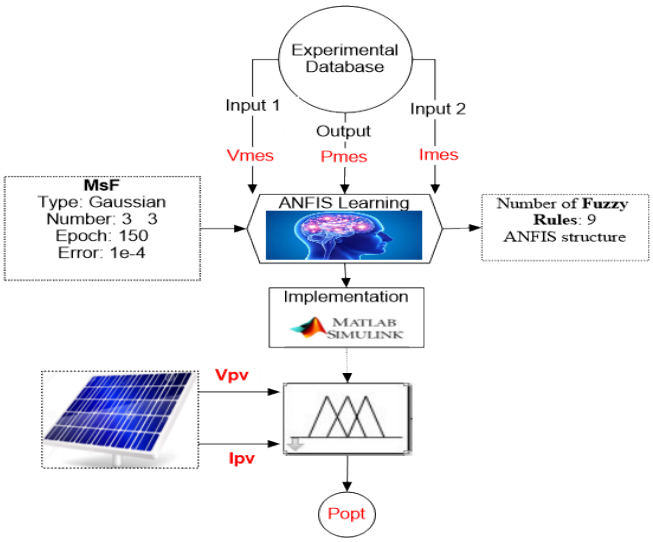
With nit the number of iterations when learning the ANFIS algorithm. Figure 6 gives the flowchart of the technique implemented in simulink and table 2 the learning parameters. The matlab "anfisedit" interface is used for learning the MPPT ANFIS command with a real database made up of two inputs (Vpv and Ipv) and one output. The number and type of MsF are fixed as well as the number of iterations. The hybrid learning algorithm is used and an error tolerance of 1e-4 is arbitrarily set.

Table 2 : ANFIS learning parameters

Parameters	Values
FIS	Takagui-Sugeno
MsF (Type)	Gaussian
MsF (Number)	3 3
Fuzzy rules	9
Epochs	10
RMSE (Training)	0.000123
RMSE (Checking)	0.002012

3. Simulation Results and Discussions

In this section, the results of simulations under matlab/simulink are presented. These simulations are performed with a real database. The latter first allowed to digitally characterize the PVM before being used for the validation of the three techniques presented in previous sections. The PVM consists of two PVs in series. The photovoltaic platform shown in Figure 7 is used in this study. The characteristics of the photovoltaic system being identified (Sharp Module) are given in Table 3. This platform is located at the Polytechnic high school of Cheikh Anta Diop University, Dakar, Senegal. This country is a tropical zone with an adequate rate of sunshine (5.7 kWh/m²/day) for the installation of solar PV plant.



ANFIS flowchart based MPPT

Table 3: Characteristics of the PV

Parameters	Values
V_{CO}	20 V
V_{MPP}	16 V
I_{SC}	2.5600 A
I_{MPP}	2.4300 A
P_{MPP}	38.3800 W

Experimental bench

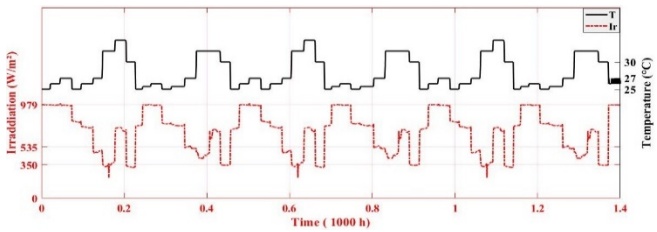


Figure 8: Experimental database of irradiation and temperature

In this subsection, the results obtained by the three MPPT methods are visualized. A comparative study is then carried out in order to detect the best order. Table 4 shows the simulation parameters and the Figure 9 gives the Simulink model.

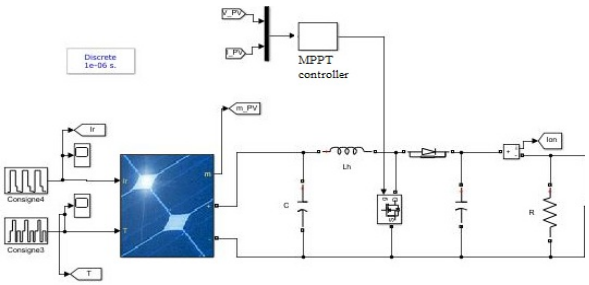

Figure 9: System simulated under matlab/simulink

Table 4: System electrical parameters

Parameters	Values
Input capacity	200.6230 µF
Inductance	1 mH
Output capacity	480 µF
Load	34.8000 Ω
Switching frequence	15 kHz

The RMSE and MAPE criteria are evaluated at the level of equations (17) and (18). They characterize the difference between the power generated by the control and the real power (Figure 14). The efficiency of the MPPT technique is given by equation (19).

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}\left(P_{ref} - P_{pv_i}\right)^2} \quad (17)$$

$$MAPE = 100 * \frac{1}{n}\sum_{i=1}^{n}\left|\frac{P_{ref} - P_{pv_i}}{P_{ref}}\right| \quad (18)$$

$$E_{MPPT}(\%) = \frac{P_{PV,MPPT}}{P_{Mesure}} \quad (19)$$

Figure 12 and Figure 13 respectively show the currents and voltages of the PVM obtained with the different MPPT techniques. They follow changes in weather conditions (Figure 8) which have a considerable influence on the point of operation of the PVM. In Figure 12, we see that the currents obtained with the PSO and ANFIS techniques are almost identical while that obtained with the InC technique is much lower. The opposite phenomenon is observed on the voltage curves in Figure 13. Indeed, the MPPT InC technique pursues the MPP first by comparing the voltage and the current of the PVM. Then, as the principle is based on conductance, the control performs compensation to achieve the desired MPP. Only, as it evaluates each time the variation of the power compared to the voltage, it often diverges with an enormous overshoot of the voltage. In addition, being also a static control, it takes a relatively long time to adapt to a climatic disturbance. This induces a small and slow variation in its duty cycle (Figure 10). As a result, it has difficulty extracting maximum power for these non-uniform irradiation and temperature conditions. Figure 11 represents the power curves of the three controls with respect to the measured power (reference). It reveals overruns for the PSO

and InC techniques while the ANFIS technique follows the set-point with an accuracy of 93.46%.

Furthermore, the performance criteria presented in Figure 14 show that the ANFIS technique is better with an extremely low RMSE (0.0194), no overshoot (D=0) and a higher efficiency of around 99.9984%. It is followed by the PSO technique with a RMSE of 1.7235 and an efficiency of 94.8748%.

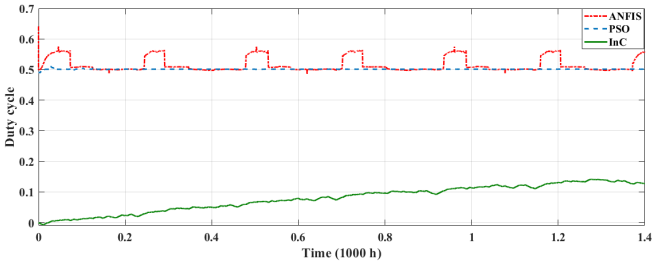

Figure 10: Variation in the duty cycle

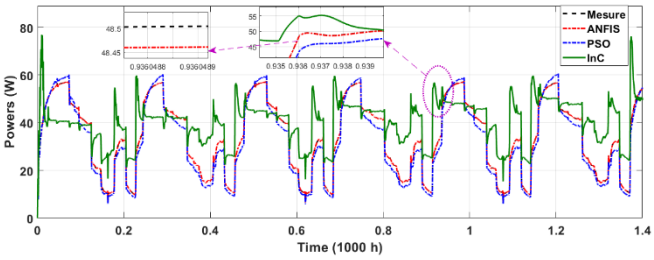

Figure 11: PVM powers

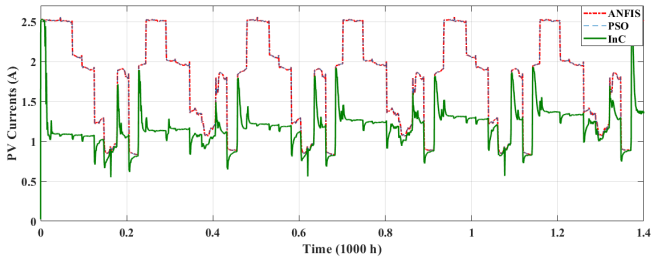

Figure 12: Currents of the PVM

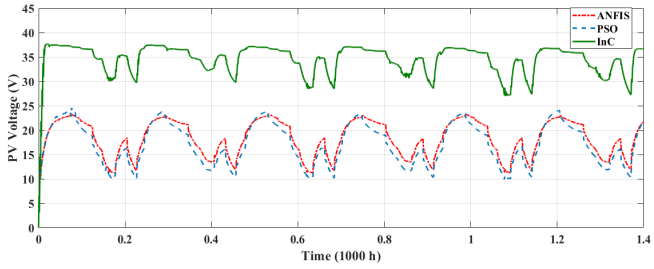

Figure 13: PVM voltages

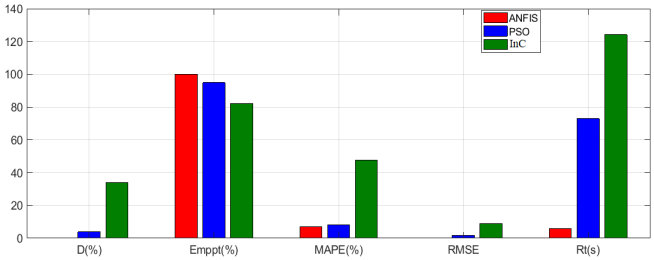

Figure 14: MPPT controller's performance parameters

These results corroborate those found in the literature which highlight the oscillating nature of the power obtained with the InC technique due to their inability to detect with precision the overall maximum in a situation of non-uniform climatic conditions [3]. They also confirm the results presented in [38] where the authors made a comparison between ANFIS and InC.

4. Conclusion

MPPT techniques are used to optimize power generated by PVM. In this work, a comparative studied between PSO, ANFIS and InC is done. An experimental validation of these MPPT techniques is also done using real database. The simulation results show that the MPPT technique based on ANFIS algorithm has the best performances. However, if we have to choose between these methods, the two parameters to consider are the complexity of the implementation and the performance of the method. For the first criterion, the choice will be relatively focused on the InC because of its great ease of implementation. For the second criterion, ANFIS will be chosen because of its best performance in terms of response time and accuracy. But we can conclude that the ANFIS and PSO methods give good results compared to the InC method.

Conflict of Interest

The authors declared that there is no conflict of interest.

ABSTRACT

In this paper, the effect of plane spacing between electrode planes on Electrical Impedance Tomography (EIT) reconstructed images is investigated. Image properties of models for various plane spacings between electrode planes on EIT imaging were investigated by applying conventional measurement strategies. Sensitivity analysis and spatial resolution analysis were used to study the influence of the different plane spacing between electrode planes on imaging properties. In the sensitivity analyses, the results indicate that there are insignificant differences in sensitivity level for the models with different plane spacings, regardless of measurement strategies applied. From the spatial resolution analyses, the findings are conclusive as there are visible differences in the spatial resolution across the off-electrode plane. A comparative study using reconstructed images was also done. The true distributions with the different number of objects are used as references to assess resulting reconstructed images obtained from models with different plane spacing between electrode planes. Results indicate the model with plane spacing between electrodes planes, which is one quarter to the height of the model, provides the better quality of reconstructed images, in terms of estimations of dimension, and colour contrast of the imaged object.

1. Introduction

Electrical Impedance Tomography (EIT) is useful for visualising the conductivity distributions of an imaged space. Due to its non-intrusiveness, low cost and versatility, EIT has been widely used in medical [1] and industrial [2] applications. Recently, EIT is gaining more attention in industrial applications as it provides intuitions and insights to the reaction and dynamic of the process, as well as useful information of flow characteristic in a pipeline or process vessel. However, EIT imaging suffers from relatively low spatial resolution, especially towards the centre of the imaged space, which is ultimately impacting the quality of the reconstructed images. This is due to the ill-posed nature of the EIT problem [3]. As a result, numerous efforts have been made to further understand this problem and explore ways to improve spatial resolution in EIT imaging.

In an EIT system, the planar arrangement is a commonly employed electrode configuration, where electrodes are mounted in an equally spaced manner, on the perimeter of the process tank or vessel, and the centre of electrodes are aligned on a defined height. In industrial applications, an effective electrode configuration system greatly depends on the vessel or tank size. The criteria of the electrode configuration include the plane spacing between electrode planes and the number and size of electrodes. So far, there is no past work that studied plane spacing of the multiple electrode planes in EIT applications systematically. Instead, the past publications are more focus on the electrode parameters, such as size and number of electrodes, in medical and industrial applications.

In [4], the authors investigated the optimal distance of the multiple sensor plane using a 3D EIT imaging technique based on simulation and experimental study. The investigation showed that the quality of the reconstructed images was accessed based on the correlation coefficient and the relative error. The results showed that 3.5 cm plane spacing between electrode planes, for a model with a diameter of 16 cm and a height of 21.5 cm, produced the highest value in correlation and achieved the lowest values in the relative errors as well as provided optimal performance in the distribution tests. In [5], the authors investigated the performance of drive and measurement electrode patterns using various plane spacing between electrode planes. The results highlighted that the Signal to Error (SNR) decreases as the spacing between two electrode planes decreases, regardless of the transverse and

*Corresponding Author: Renee Ka Yin Chin, Email: reneekychin@ums.edu.my

longitudinal current patterns applied. The transverse current patterns provided a better resolution than longitudinal current patterns but were more susceptible to noise and error, leading to poorer sensitivity in detecting impedance changes in the centre of imaged space. However, in industrial applications, the plane spacing between electrode planes may become a minor concern for the researchers.

Electrode parameters, such as size and number of electrodes, have been investigated in the past few decades. In [5], an experiment was carried out to examine the effect of the height of electrodes on the quality of reconstructed images. The findings indicated that the sensitivity or detectability of the EIT system reduced or remained the same as the height of electrodes was increased to twice the height of the imaged object or target. In [6], the authors investigated the optimum sized electrodes for Electrical Resistance Tomography (ERT). The findings highlighted that the optimum size of electrode coverage is 60% and 80% of the wall surface area of the model. In [7], [8], the authors investigated the electrode properties of ERT. They found that dot or point electrodes could eliminate the effect of contact impedance. Dot or point electrodes are more commonly applied in medical applications. However, it is impractical when implementing dot or point electrodes in industrial applications, as it is more costly to fabricate [9].

Electrodes used in applications are often in rectangular shape. This is not ideal, as narrow angles on the electrode corners result higher current densities in these areas. Circular electrodes are ideal for this purpose due to the uniformity of its shape [10]. However, forward solving requires discretisation of the model into tetrahedral elements in EIT. An accurate modelling of circular electrodes requires a large number of small elements to best represent the shape of electrodes, which results in an increased number of computational elements, and more importantly, these elements do not contribute to the representation of the imaged space. When the coarser mesh structure is used, the inaccurate representation of the shape of the electrode will occur and it leads to errors in forward and inverse solving. As a compromise, rectangular electrodes are often used.

In this paper, the influence of different plane spacing between electrode planes on EIT applications in industrial processes (e.g. pipeline flow and suspension monitoring, and mixing processes) on the quality of reconstructed images is studied. The main purpose of this investigation is to investigate a minimum requirement of space between electrode planes, such that information is not lost. This investigation was carried out through investigating the effect of different electrode configurations on imaging properties and reconstructed images. The rest of the paper consists of five (5) sections. The model setup for various plane spacing between electrode planes is described in Section II. Section III discusses the findings obtained from the comparative studies on image properties. Section IV describes the experimental setup for image reconstruction, as well as its results. Finally, Section V provides the conclusion of this study.

2. Model Setup

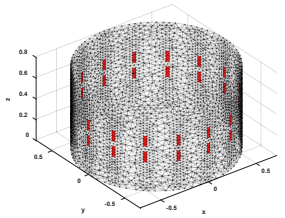
In this work, a cylindrical model with a radius of 71.4 cm and a height of 80 cm is used. The dimensions of the model are chosen to be sufficiently big, such that it can accommodate a variety of different electrode configurations, including spacing between electrode planes, which is the main focus of the work presented in this paper.

The electrode configuration used for this work consists of 32 electrodes arranged in two planes. Each plane consists of 16 electrodes arranged equi-spaced on the periphery of the model. The electrodes are rectangular in shape, with the dimensions of 3 cm in width and 10 cm in height. In this study, the spacing between planes is set as 5 cm (the smallest gap), 10 cm, 15 cm, 20 cm, 25 cm and 30 cm (largest gap). A summary of the plane spacing between electrode planes and the height of the centre of the upper and lower electrode planes is provided in Table I.

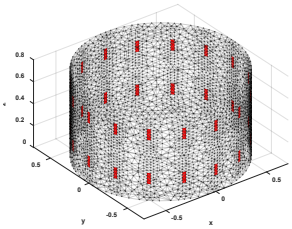
Table 1: Plane Spacing Between Two Electrode Planes and its Center of Upper and Lower Electrode Plane

Number of electrodes per plane	Plane spacing between two electrode planes	Center of upper electrode plane (cm)	Center of lower electrode plane (cm)
16	5 cm	47.5	32.5
	10 cm	50.0	30.0
	15 cm	52.5	27.5
	20 cm	55.0	25.0
	25 cm	57.5	22.5
	30 cm	60.0	20.0

The work presented in this paper is simulated using Electrical Impedance Tomography and Diffuse Optical Tomography Reconstruction Software (EIDORS), which is an open-source toolkit available for MATLAB [11]. The discretisation of the models was done by applying the Finite Element Method (FEM) through Netgen [12]. The FEM models with various spacing between electrodes planes are as depicted in Figure 1. It is should be noted that the number of elements for each of the models is the same as they are based on the same cylindrical model. The work presented in this paper is through simulation as it is a more feasible option due to the requirement of using electrodes with different plane spacing.



(a) 5 cm plane spacing between electrode planes model



(b) 30 cm plane spacing between electrode planes model

Figure 1: Examples of FEM models with varying plane spacing between electrode planes.

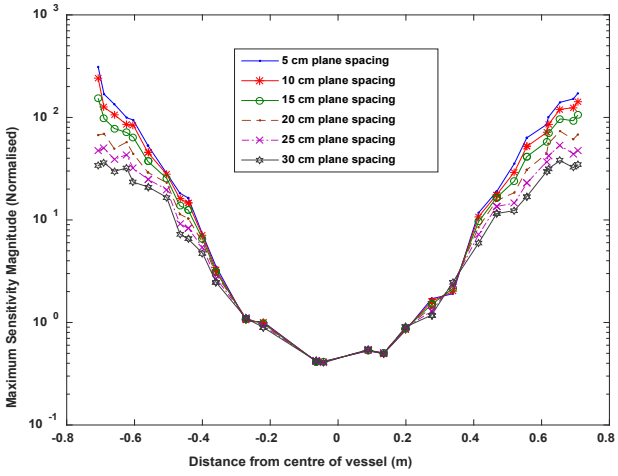
All measurements were simulated using the adjacent current injection protocol, which produces *N*(N-3)* number of

measurements, where *N* is the number of electrodes. In the case of two planes of 16-electrodes per plane model, 416 full-frame measurements were generated. Another set of measurement data were repeated to simulate by using another opposite current injection protocol, which produces *N*(N-4)* number of measurements. There are 384 full-frame measurements generated for a model with two planes of 16-electrodes per plane.

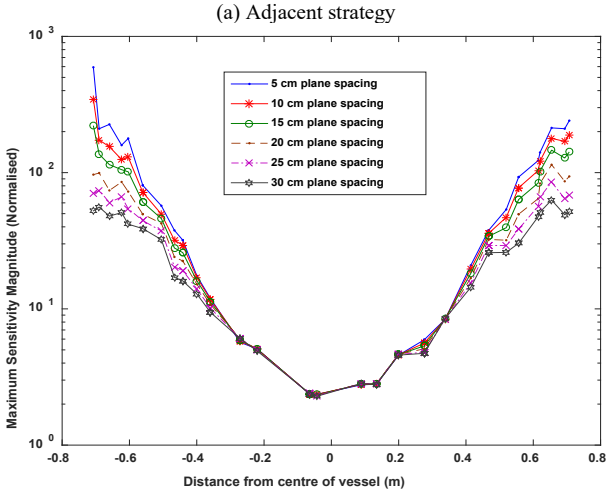
3. Experimental Results

3.1. Sensitivity Analysis

Sensitivity analysis provides information on the potential success of detecting any changes in conductivity in the imaged space. In the discretised model, each element has a sensitivity value for any measurement acquired, which makes up the sensitivity (Jacobian) matrix. For this comparative study, the maximum sensitivity for each discretised element for a full set of measurement, normalised to the volume of the element, is computed and compared, as shown in Figure 4 and Figure 5.



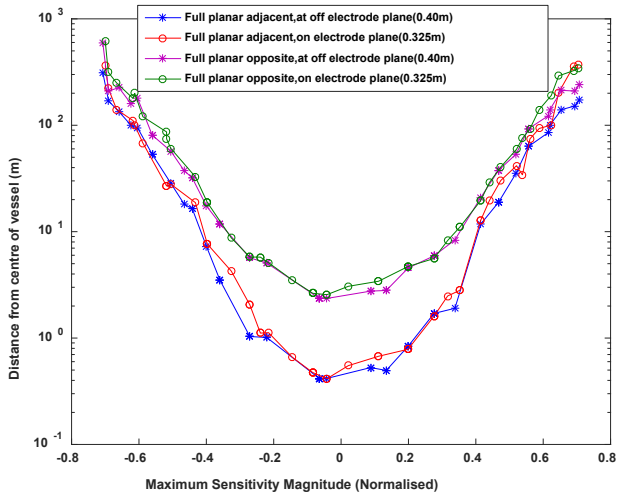
(a) Adjacent strategy



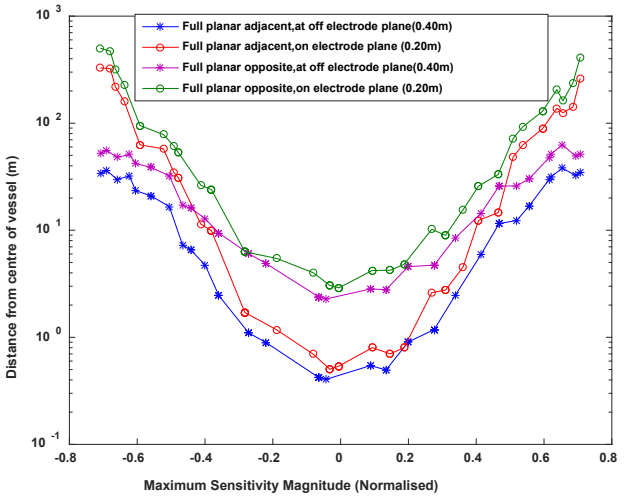
(b) Opposite strategy

Figure 4: Sensitivity comparison for models with different plane spacing electrode planes at the off-electrode plane (the height is taken at 0.40 m from the bottom of the model) by applying the (a) adjacent strategy and (b) opposite strategy.

Figure 4(a) shows the comparison of maximum sensitivity magnitude for the models with different spacing between electrode planes across an off-electrode plane when applying adjacent current injection protocol. From Figure 4(a), it can be seen that there are insignificant differences, as the spacing between electrode planes increases, especially towards the centre of the imaged space. Similar results are observed using the opposite current injection strategy, as reflected in Figure 4(b). This may due to the planar measurement strategy used, whereby measurements are only taken on the plane where the current source and sink pairs are located.



(a) The model with 5 cm plane spacing between electrode planes



(b) The model with 30 cm plane spacing between electrode planes

Figure 5: Sensitivity comparison for the models both (a) 5 cm and (b) 30 cm plane spacing between electrode planes, respectively, at the off-electrode plane and on the electrode plane.

From Figure 5, sensitivity is higher for opposite strategy due to the current penetrating through the imaged space, as opposed to the adjacent strategy, where current flowing typically tends to be more confined nearer to the periphery of the model [13]. The other obvious observation is that the sensitivity is higher on the electrode plane in comparison to those obtained off-electrode plane. This is expected, as the current signal is stronger on the electrode plane compared to the off-electrode plane [14]. This observation is similar to a previous study [15], where it indicates that the possibility of detecting a change in conductivity reduces when further away from the electrode plane.

Comparing Figure 5(a) and Figure 5(b), it can be observed that when the space between electrode planes are smaller (5 cm), there are insignificant differences between sensitivity on- and off-electrode planes. This is likely to be due to the closeness of the locations of the two electrode planes. In comparisons, when the space between electrode planes is bigger (30 cm), there are noticeable differences between sensitivity on- and off-electrode planes. Although the EIT image reconstruction problem is often treated as a 2D problem, where images and data are captured on a specific plane, it is essentially a 3D problem.

3.2. Spatial Resolution Analysis

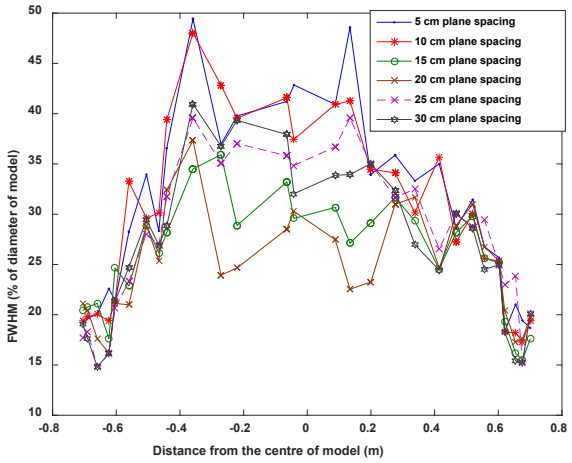
Spatial resolution analysis utilises information given in the resolution matrix, which contains the correlation between elements in a discretised model. In this analysis, the Full-Width Half-Maximum (FWHM) technique [16] is applied to investigate the spatial resolution of models with different spacing between electrode planes. The FWHM method applied in this paper is based on the technique, which was first proposed by [17] and later adopted by [18]. In spatial resolution analysis, the minimum distance between two point sources, which shares the same solution value in an image is measured. The same solution value shared is known as half the peak value. Spatial resolution for each point is computed and compared. The results are as shown in Figure 6 and Figure 7.

Figure 6 shows the spatial resolution comparing models with different spacing between electrode planes using both adjacent and opposite strategies. It is shown that the regions near the wall of the model, in general, have better resolution (low FWHM) in comparison with the area towards the centre of the model, which resulted in higher FWHM. This general trend obtained is consistent with the sensitivity analysis obtained in Figure 4(a) and Figure 4(b), where they indicate that sensitivity is lower in the centre of the model but is higher near the wall region of the model. With a higher possibility of detecting a change in conductivity, and thus it increases the chance of change detected to be reconstructed.

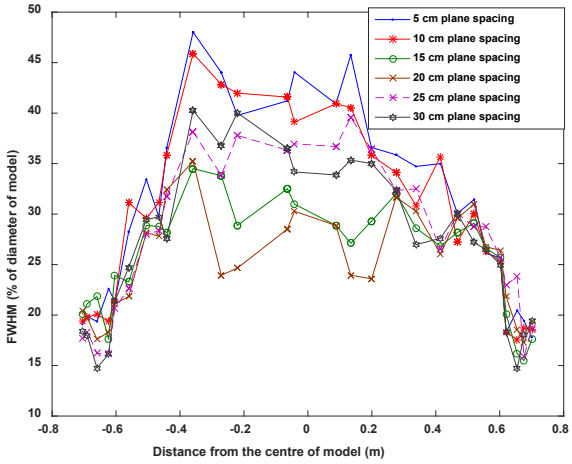
It is worth noting that unlike the sensitivity analysis, spatial resolutions do not show symmetry across the plane, and irregularities (i.e. peaks or valleys) are observed. One of the factors that affect spatial resolution is the size of the discretised element, and unlike sensitivity analysis, the computed spatial resolution for each discretised element is not normalized to the volume of the element, as it will provide misrepresentation on the visibility contrast.

From Figure 6(a), it can be observed that models with 5 and 10 cm plane spacing between electrode planes produced the worst resolution overall, especially in the centre region of the model. However, it is worth noticing that model with 20 cm plane spacing between electrode planes resulted in better spatial resolution in general. This finding is not anticipated as the sensitivity analyses are shown in Figure 4, where it indicates that there are insignificant differences in maximum sensitivity magnitude across the off-electrode plane, for both current injection strategies.

Referring to Figure 7, comparing spatial resolution for the on- and off-electrode planes, it is observed that there are insignificant differences in the resolution for an on-electrode plane, especially with the gap between the two electrode planes is small (5 cm). This result is consistent with the results observed in its corresponding comparative analysis, as shown in Figure 5. The spatial resolution analysis in Figure 7 also shows that the overall resolution is evenly matched for usable information which is available for image reconstruction.



(a) Adjacent strategy



(b) Opposite strategy

Figure 6: Spatial resolution comparison for models with different plane spacing by applying adjacent strategy in (a) and opposite strategy in (b) at 0.40 m height from the base of the model.

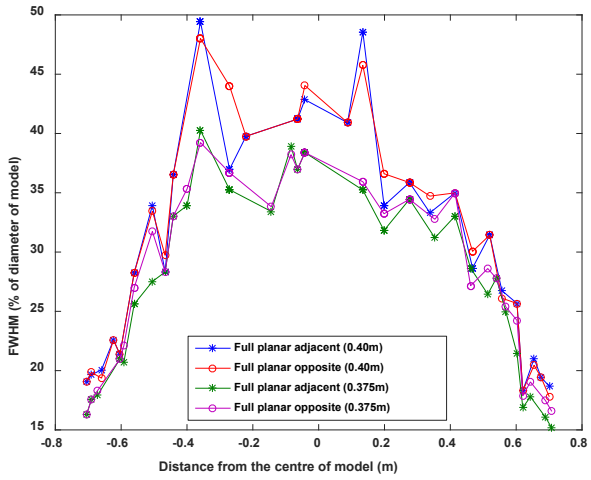
It is interesting to see in Figure 7(a) that there is very little difference in spatial resolution when comparing spatial resolutions for the adjacent and opposite strategies. This is unexpected, as shown in Figure 5, where there is a distinguishable difference in sensitivity between the two different measurement strategies. One of the reasons is likely to be due to both strategies producing a similar amount of usable (stable) information for reconstruction, which resulted in the spatial resolution for these two strategies to be evenly matched.

4. Experimental Set-up

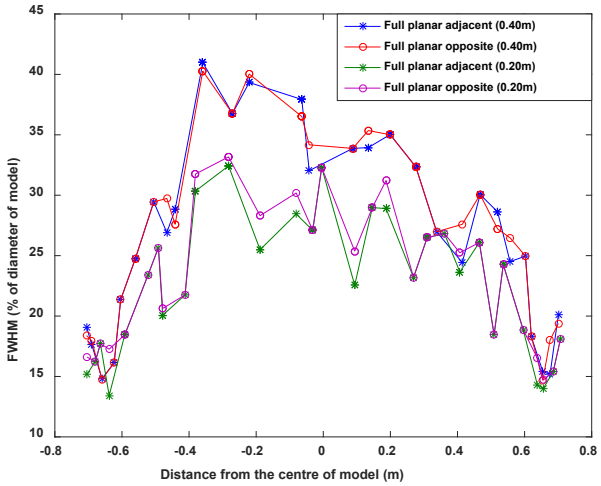
4.1. Experimental Set-Up

Measurements for image reconstruction are simulated using the EIDORS package [11], which is MATLAB-based. As

mentioned earlier, this study is more feasible to be done in simulation, as laboratory validation requires a process tank that allows multiple settings for electrodes configurations. For validation, two test distributions are used for experiment and comparison.



(a) The model with 5 cm plane spacing between electrode planes

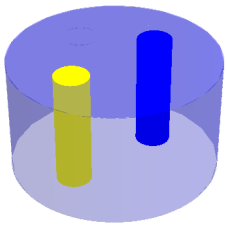


(b) The model with 30 cm plane spacing between electrode planes

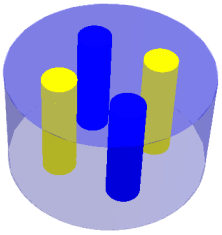
Figure 7: Spatial resolution comparison for the models both (a) 5 cm and (b) 30 cm plane spacing between electrode planes, respectively, at the off-electrode plane and on the electrode plane.

Measurements are simulated using a finely discretised FEM model. The level of discretization is chosen to be significantly higher than the discretized model used for forward and inverse solving, as it is intended to mimic a physical model. Two measurements are taken for each test distribution, for each electrode configuration, and each measurement strategy.

In this work, two test distributions are used for image reconstruction, as shown in Figure 8. The first test distribution consists of two cylinders, each with a radius of 12 cm. The conductivity of the background is 0.012 S/m (approximately the conductivity value of tap water). One of the cylinders has a higher conductivity than background conductivity, and the other is non-conducting. The arrangement of test objects is as shown in Figure 8(a). The second test distribution is similar to the first test distribution, with the addition of one conducting cylinder. The arrangement of test objects is as shown in Figure 8(b). All reconstructed images were obtained by applying the Non-Linear Gauss-Newton (NLGN) algorithm in inverse solving.



(a) True distribution with two cylindrical objects



(b) True distribution with four cylindrical objects

Figure 8: True distribution models with (a) two cylindrical objects, (b) four cylindrical objects and (c) four floating objects. The colour scale is applied, where yellow colour indicates the conducting object and blue colour indicates the non-conducting object.

4.2. Results and Discussions

The image reconstructions obtained from models with different spacing between electrode planes are shown in Figure 9 to Figure 12. The colour scale is maximised to show the best contrast. The reconstructed images are assessed and discussed based on the dimensions of the reconstructed objects and colour contrast of the reconstructed conductivity distribution.

Although sensitivity analyses indicated there are insignificant differences in the maximum sensitivity magnitude as the gap between electrode planes increases, this is not reflected in spatial resolution analysis and reconstructed images. When comparing the reconstructed images from Figure 9-12, it can be seen that there are visible differences in terms of shape and estimation of dimensions of the objects.

In Figures 9-12, it can be seen that the models with 5cm and 10 cm plane spacing between electrode planes generally produced the worst reconstruction images. The shape and the dimension of the cylindrical test objects are not reconstructed properly, especially towards the top and the bottom of the imaged space. There are also noticeable artefacts visible in the imaged space. The results are similar for experiments done using both the adjacent and opposite strategies.

(e) 25 cm plane spacing between electrode planes

(f) 30 cm plane spacing between electrode planes

Figure 12: Reconstructed images comparison for models with various plane spacing (a)-(f) by applying the opposite current protocol.

Models with 15 cm and 20 cm gaps generally produced better reconstructed images. With the exception of the reconstructed image using a test distribution with four cylindrical objects, the application of the adjacent strategy for the model with 20 cm gap, it can be seen in Figures 9-12 that the cylindrical test objects are reconstructed in the right configuration, with similar dimensions to the true distribution. There are also little to no artefacts visible in the imaged space.

For the widest gaps, namely the 25 cm and 30 cm electrode spacing models, the images reconstructed using the opposite strategy are better compared to those obtained using the adjacent strategy. The images obtained using the adjacent strategy has a significant amount of artefacts, and it is noticeable that the shape of the test objects are not reconstructed correctly where the gap of the electrodes are (i.e. space between electrode planes). It can be seen in Figures 9(e-f) and 11 (e-f) that the dimensions are overestimated in that space. In contrast, reconstructed images obtained using the opposite strategy turn out better, with the test objects shown to be cylindrical objects, and with less artefacts. This result is consistent with the results observed in the sensitivity analyses.

5. Conclusion

A summary of the results is tabulated in Table 2. This study is conducted through two methods: statistical method, through comparing sensitivity and spatial resolution of different models used; and through reconstructed images.

Table 2: Summarization of the results on image properties

Analysis	Best model	Worst model
Sensitivity Analysis	Results are inconclusive; Opposite strategy is better than adjacent strategy	
Spatial Resolution Analysis	15 and 20 cm gap (both strategies)	5 and 10 cm gap (both strategies)
Reconstructed Images	15 and 20 cm gap (opposite strategy)	5 and 10 cm gap (both strategies)

From Table 2, it can be seen that the results obtained through spatial resolution analysis are reflected in the reconstructed images, where the best quality and worst quality images are

reflective of the results obtained through spatial analysis. In this case, however, the sensitivity analysis results were inconclusive, as the sensitivity level in the centre region of the imaged space is indistinguishable.

It is worth noting that the results given in Table 2 are relative to the dimension of the model used for this study. When the model is scaled up or scaled down, an investigation similar to that carried out in this study should be conducted to ensure that the scaling effect does not deteriorate the quality of the reconstructed images.

Through this work, it is shown that it is important to investigate the spacing between electrode plane, to ensure that the information is not lost due to the inability to capture any changes that occur. It is impractical to have electrode planes close to each other, as it will result in a waste of resources. Therefore, a minimal distance ought to be set in order to ensure that any changes in conductivity can be measured and the information can be used to reconstruct and visualize the changes.

ABSTRACT

This study aims to discuss the establishment of digital culture in higher education as an effort of higher education to align themselves with the development of science and technology so that that higher education is always at the forefront in the enforcement and provide high-quality education. The method used in this study is a qualitative method, which analyzes the causal relationship between the dimensions studied. Observation and literature review used as the main source of data/ information analyzed in this study. The analysis results showed that social engineering is an effective medium of modifying values, subjective norms, and rules for the creation of digital culture. The implication of this research shows that social engineering is an important activity that must be scheduled periodically by higher education as a medium for strengthening organizational culture to increase the capacity of human resources.

1. Introduction

World civilization moves together with the rapid development of information technology. The utilization of digital technology in all aspects of social life enters almost all lines of activities that regulate community life, including in the education field [1, 2]. In Indonesia, higher education as an educational institution has the task of carrying out the *Tridharma Perguruan Tinggi*/ Higher Education *Tridharma*, namely education, research, and community service [3].

For carrying out functions optimally, higher education required to improve their business processes by adapting and adopting technology continually. The mastery of science and technology is substantive and elementary in the development of superior and modern universities. The diffusion of technology in business processes of higher education believed can create better performance in carrying out higher education *Tridharma*. Technology diffusion is an adaptation of higher education to its environment, by changing values, and making the work patterns of the academic community more systematic and efficient. One form of change from the diffusion of technology is the change of work culture into digital work patterns after this referred to as digital culture.

The digital culture was born from the phenomenon of digitalization in human civilization. Digital culture occurs because of the increasing uniqueness and importance of the technology application that encourages people to think about the importance of transforming significantly and dramatically [4]. Where finally, technology has an important role and becomes a necessity in the development of social culture [5,6]. Digitalization is a simplification of information material in the form of binary code or the integration of communication technology with computer logic. Data conversion methods have advantages in increasing the flexibility of handling, storing, processing, and sending data. The flexibility offered by the digitization process facilitates the process of transmitting and manipulating information materials that have an economic impact on a network, where information materials can be disseminated more efficiently among network users [7].

Several previous research that relevant to social engineering related to digital culture in higher education includes: (1) preparation of higher education in facing disruption of the digital era is a challenge in university branding, including adapting to the concept of virtual universities, virtual classes, artificial intelligent, and techno-entrepreneurship [8]; (2) guaranteeing the quality of education in the era of digital disruption in higher education is considered necessary, higher education which is one of the places to improve the quality of human resources needs to implement an internal guarantee system that is in line with the rapid development of digital technology [9]; (3) digital culture in higher education that the most frequently and widely used, especially for millennial students is e-learning/ digital learning/ virtual learning/ digital literacy [10–12], although on the other hand, learning in the classroom directly is still needed [13, 14]; (4) several models are created related to digital culture that will transform higher education into digital universities that are ready to compete in the era of technological disruption [15,16], even online education policies and practices have supported the concept of digital university past, present and in the future [17]; (5) even in some studies discussing that digital culture in higher education can support the development of the digital economy [18], because the educational revolution towards technological progress is a revolution for the long term [19, 20]. The novelty/ originality of this research lies in the focus of the study, which examines digital formation models for the development of the implementation of *Tridharma* in higher education.

2. Research Method

This research is policy research, where the product of this research expected to use as a foundation and consideration in the decision making of top university leaders. The methodology used in this study is qualitative research [21, 22] by collecting the literature review, observation, and Focus Group Discussion (FGD) [23]. The primary data source of this study refers to the results of observations, and literature reviews that have relevance to the objective conditions on the research object. Researchers use causal logic as a rational argument that connects the concepts which establish the organizational culture. Researchers in this study act as participant observers. This research conducted at UIN Sunan Gunung Djati Bandung (after this referred to as a university). This research puts digital culture as part of organizational culture. The main foundation used in this research is the need to shift the work culture that is manual towards digital culture as a consequence of technological developments and the demands of educational service users for technology-based prime services.

3. Result and Discussion

At the university, which is the object of research, 58 application programs have been designed and built as a modernization/ digitalization of the general business processes that run by the university. The design of the application program is aiming to optimize business processes carried out by the university. Figure 1 provides a detailed relationship between the main business process, supporting activities, and actors that run in the university.

Based on the results of discussions and interviews found the fact is not all application programs are running optimally. This case is allegedly due to low desire and the user's ability to run application programs. The integration of digital culture in the university's organizational culture is one solution to this problem. Organizational culture, according to many studies, can improve organizational performance [24–27].

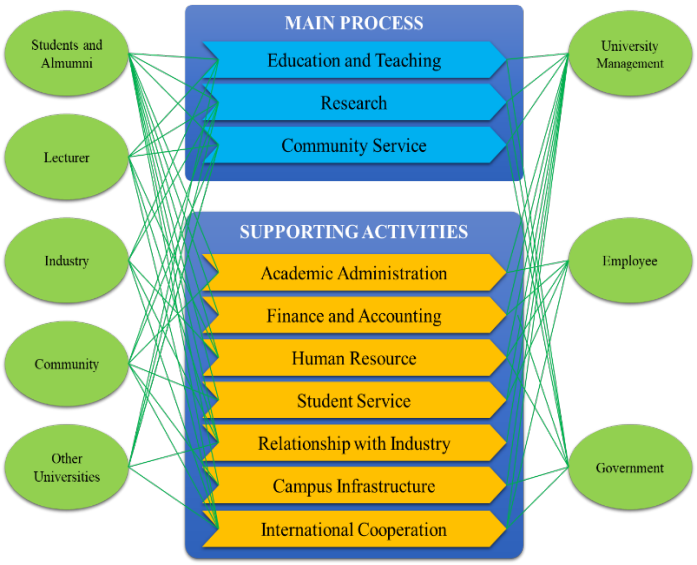

Figure 1: Process and Stakeholder Relations [28]

3.1. Organizational Culture

Organizational culture is a shared perception or a system of shared meanings shared by its members. The function of organizational culture is to determine the roles that distinguish organizations from others, define shared goals that are greater than individual interests, maintain social stability, enhance identity for members of the organization, and provide control mechanisms that provide guidelines for attitudes and behavior [29].

Organizational culture at the university will foster an individual's identity as a process of personal assimilation as part of the academic community. The similarity of embedded values will make it easier for every academic community to understand and appreciate every activity carried out by the university. An understanding of the organizational culture at the university will facilitate the resolution of internal problems such as giving awards, work ethics, and career development. This understanding will also help universities in overcoming external issues so that universities can do the best service.

Factors that lead to the development of organizational culture consists of internal and external factors, modifying/ changing the culture of the organization will create existing human resources will be of higher quality [30]. The organizational culture that is the color of the research object is the work culture of the Ministry of Religion (MORA) of Republic Indonesia. Structurally, the university which used as a research locus is a work unit that is under the authority of MORA. The work culture adopted at MORA includes integrity, professionalism, innovation, responsibility, and exemplary [31]. The alignment of work culture to a digital culture presented in Figure 2.

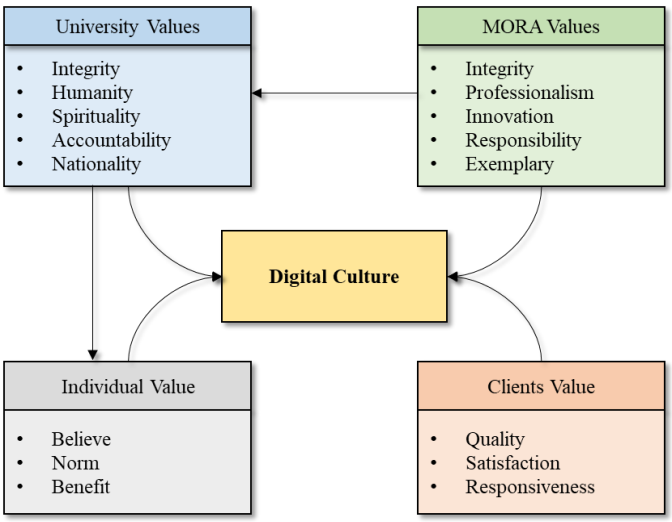

Figure 2: Alignment of Work Culture in Digital Culture

3.2. Digital Culture

Digital culture is a behavioral habit that utilizes digital technology as part of its work. The formation of digital culture is essential in sustaining the main tasks of the university. In general, individual activities motivated by the culture that influences their behavior. Culture requires individuals to behave and give instructions to them about what must be followed and learned. An influential culture can create a bond between the university and the academic community and inspire to create university excellence. The digital culture built by values, norms/ ethics, and regulations, which expressed in the form of behavior. Figure 3 describes the dimensions of forming behavior in digital culture.

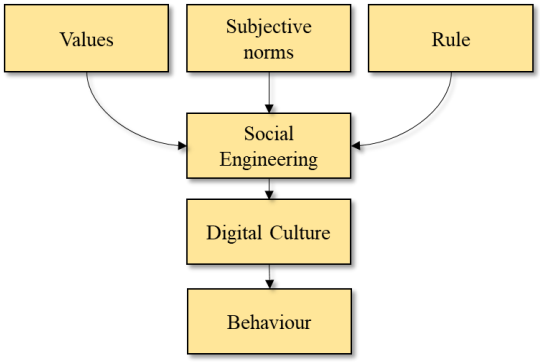

Figure 3: Dimensions of Forming Behavior in Digital Culture

3.2.1. Value

Values are all things related to human behavior regarding good or bad as measured by religion, tradition, ethics, morals, and culture that apply in society [32]. The definition of value used in this article is an individual's understanding of the elements of goodness that give meaning to his status.

Digital culture in the academic community requires value as an individual motivation to conduct digital-based behaviour. The value dedicated to the academic community includes strengthening personal beliefs about the value of goodness, which realized by working professionally and innovatively as part of worship. Digital culture will provide position and imaging for the academic community as individuals who are good at carrying out the activities in the social community.

3.2.2. Subjective Norm

Subjective norms are one's perceptions of the thoughts of those who considered to have a role and have hope for him to do something and the extent of the desire to fulfill these expectations. The concept of subjective norms is a representation of the demands or pressures of the environment lived by the individual and showed the individual's belief in the existence of approval or not from social figure [33], [34]. Norms generally formed on the convergence of the values of goodness to individuals in the group. The norm that developed in digital culture is the desire always to improve things. Norms implemented lead to forms of appreciation or social sanctions for the implementation of digital culture.

3.2.3. Regulation

Regulations are written decisions regarding binding behavior, which contain provisions regarding rights, obligations, functions, status, or order. Rules established and issued by the authorized institution [35]. Because it is binding, this regulation can shape digital culture as part of personal obligations in carrying out its activities on campus. The effectiveness of university regulations can do by applying formal awards and sanctions for the implementation or violation of its commitments as an academic community.

3.2.4. Behaviour

Behaviour in general terminology can translate as all actions or actions carried out by humans, which can be observed directly or indirectly [36]. Behaviour is a function of the relationship between the individual and his environment. Different environments can determine differences in human behaviour between one another [37]. Based on a biological perspective, the behaviour is an activity or activity of the organism in question. Behavioural symptoms that can observed directly from organisms influenced by environmental and genetic factors (heredity). The mechanism of fusion and the meeting between the two elements is called the learning process [38].

Behaviour is a mental condition (thinking, opinion, attitude, and etcetera) that reacts to the status that exists outside the object. The reaction can be in the form of an active response accompanied by action. Simply stated, behaviour can refer to as an action taken by a person or group of people based on particular interests or needs based on the values, knowledge, and norms of the group concerned.

Educational psychologist Benjamin Bloom divides human behavior into three elements [39], among others:

1) Cognitive. The cognitive item includes an individual's beliefs that are related to the way individuals perceive the object of attitude to the responses they see and know (knowledge) based on their views, thoughts, beliefs, emotional needs, personal experiences, and information from others.

2) Affective. The affective element refers to the subjective psychological aspects of individuals towards the object of attitude, both positive and negative. Emotional reactions are primarily determined by what believed to be good or harmful to the object of the attitude.

3) Psychomotor. The psychomotor element is also called the behavioural component, which is the attitude component related to predisposition or the tendency to act on the object of the attitude it faces.

In general, human behaviour is an instrument of response (operant response) as a response that is born and develops on specific stimuli. Therefore, certain conditions (operant conditioning) need to be created to form the type of response/ behaviour [39]. The stages of developing behaviour in operant conditioning carried out as part of digital culture are:

1) The introduction of reinforcement elements in the form of rewards/ prizes for the behaviour to be established;

2) Analysis of the components forming the desired behaviour, which arranged in sequence for the formation of the desired behaviour;

3) For the implementation phase the sequence of the components is accompanied by the determination of tentative (temporary) objectives and identification of reinforcements for each component;

4) Carry out a sequence of components that have arranged as a behaviour formation activity.

In the implementation of digital culture, it is necessary to emphasize the importance of collaboration between individuals, so the planned goals will run according to what desired.

3.3. Social Engineering

Humans created as individual creatures and social beings; socializing is a characteristic of humans and is a natural tendency in living the activities of human life. In the context of individual beings, human beings given physical characteristics and characters that make the difference between humans and other individuals; if they are part of a unified social group, they will experience the process of socialization [40]. In the process of socialization with groups/ communities, individuals often have different perspectives that can trigger conflicts of interest, which referred to as social problems. The social problem is the gap between how an individual behaves who seen as opposed to the norm agreed upon by the community members [41]. Social issues are closely related to norms, moral values, and social institutions [42].

The results of research observations can see the gap in the use of information systems applications that have been provided by the university. It is found groups who optimally use information systems, on the other hand, found the academic community who rarely use the information system as a work support tool. In addition to the problem of professionalism, in the context of organizational culture, researchers see this gap as a social problem. To overcome social issues, it is necessary to do the social transformation that emphasizes individual adaptation to social norms and institutions (digitizing policies) that apply. The next stage is changing one's behaviour as aligning itself with these values.

A more systematic and planned social transformation generally carried out through a process of social engineering. In social engineering, the object is the community to form a better system and system as desired by the engineer (the social engineer). Social engineering begins with the emergence of social problems, namely the imbalance between *das-sein* and *das-sollen*, or what happens is not following the expectations of the organization (university). Social engineering is a social planning that leads to the realization of social transformation, which is supported by the internalization of humanization values [40].

Social engineering is a process of social change that is systematic and planned to deal with social problems that implemented using various strategies and stages to make social change happen as desired. For social engineering to run effectively and efficiently, the planning, implementation, and evaluation activities of social engineering activities must involve all stakeholders [43]. Social engineering is not only used for inculcation and strengthening patterns of habits and behavior, but also used to direct the desired goals, eliminate habits that deemed unnecessary/ unsuitable, create new patterns of behavior, and etcetera [44]. Culture can form through formal assignments and habituation processes [45].

Education/ training, from a particular perspective, can be understood as social engineering, where education/ training will provide a fundamental influence in the process of social change. In education, there is a planting of universal values that will change the human paradigm so that humans can have the ability to think critically objectively [40, 46]. Education/ training in this context can be understood as a process of increasing understanding of professionalism and innovation that realized in digital culture.

The education/ training process can be useful if a learning module is available [47], open space for discussion/ debate [48], good implementation process, and involve all parties. The process of education/ training to create a work culture is to form workers' attitudes towards work (work attitudes). This attitude is determined and influenced by three factors, namely: involvement in work, job satisfaction, and work commitment. These three factors are interrelated with one another [49].

In higher education, to establish the digital culture of academic community (especially lecturer, educational personnel, and student as main stakeholders), social engineering is become one of important strategy. Research found that social responsibility attitude and behavior can influence the user satisfaction in higher education, especially for student [50]. More than just being "literate" in technology, social engineering including habits, attitudes and behavior of the academic community in higher education is a trigger to improve the digital culture. Starting from the policies and support of top management, to fostering habits in the use of technology and the creation of a digital culture atmosphere.

4. Lack of the Study

This study specific to the perspective of digitalization in Higher Education. While, one perspective could be the digitization of education by itself. Within this topic not only social engineering is important but also technical engineering of the used technology. Another perspective could be worldwide digital technology transformation which then becomes a central perspective for studying by the teachers and students. With this central perspective teachers and lecturers could be acquainted with the development of new digital technologies which are of will be used in the coming years.

5. Conclusion

A digital culture is a form of higher education adaptation in facing various dynamics of technological development. Digital culture is a modification of the organizational culture that has existed at higher education, with reinforcement in technology/ digital-based work behavior. This research creates a formulation model to enhance the digital culture for the development of main activities in higher education. This model of digital culture implements the university value, MORA value, individual value, and client (technology user) value. The process of cultural formation can carry out with social engineering by modifying values, subjective norms, and work rules. Then, social engineering can change the digital culture to be behavior. For the implementation of digital culture, social institutions take precedence over the formal administrative approach. Therefore, for the further works, the social engineering can be implemented and the behavior of digital culture in higher education can be evaluated and enhanced.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The authors would like to appreciate and thank UIN Sunan Gunung Djati Bandung academic community for supporting this research.

ABSTRACT

The world has turned in the modern era to reduce peak times for electricity consumption, where the peak times cause excessive load on the electricity grid and power stations. In Egypt air conditioning loads are considered the main contributing reasons for the peak time's problem due to presence of large unshaded glazed surfaces, which cause high thermal loads inside the buildings. In this study, various methods of energy rationalization in buildings are evaluated by using many scenarios, from the obtained results of this research study. It is found that the use of shading on windows is an effective strategy where the percentage of rationalization using scenarios integration reached 40%, and the financial returns have also been calculated based on this work.

Nomenclature

AHU	*Air Handling Unit*	LED	*Light Emitting Diodes*

DB	*Design Builder*	THD	*Total Harmonic Distortion*
GUI	*Graphical User Interface*	VFD	*Variable Frequency Drive*
HVAC	*Heating, Ventilation, and Air Conditioning Systems*	VSD	*Variable Speed Drive*

1. Introduction

The rise of 4G industry era in our nowadays life led to a great demand of efficient energy systems specially the requirements of the large-scale industrial systems. This led to a significant rise in electricity prices; therefore energy conservation became a crucial policy [1]. It is an influential reason for preserving the environment and climate [2]. Therefore the world has turned to energy efficiency [3]. With the continuous development of technology, the smart home applications appeared in its contribution to improve energy efficiency effectively. As the smart grid deals with the flow of energy in distribution networks whose objectives are to balance supply and demand [4]. The more energy transfers from one form to another, the more losses occur. With the increasing of energy transformations, it is found a reduced gab between production and the consumer also an increase in the efficiency of devices and equipment, the loss decreases, the consumption be more efficient, rationalization increases and helps in reducing the demand for increased power plants [5].

Energy management is the assessment and measurement of electrical energy consumption in buildings [4]. As the global economy develops, it is necessary to strengthen and improve research and development in building energy management. The association of energy classification methods in new buildings is also necessary to develop building policies that are of great importance. Therefore, the main functions of energy management systems are to monitor, control and improve energy flow in general [6]. Energy management systems start from the use of energy-

saving devices, through smart buildings to supervisory control applications [7].

Energy auditing is also a review and evaluation of building energy use and identification of energy saving measures to reduce consumption [6]. This is through the analysis of public service bills such as electricity bills [4]. Throughout this framework a professional power saving protocol is applied to reduce the electrical energy consumption in public buildings. This protocol includes - but not limited to - power factor correction, variable speed control, earth leakage current treatment, lighting management, heating, ventilation, and air conditioning (HVAC) system, load management and intelligent energy system. Correction of power factor has many economic benefits, one of those, is saving the financial fine that the electricity company imposes when the power factor drops below 0.90 [8], [9]. Technically, it reduces the overload on transformers and generators and reduces the overload on cables and switches [10]. The variable speed drive (VSD) and frequency speed drive (VFD) when used in the Air Handling Unit (AHU), it can save energy up to 18% and save energy at least 7.5% when used in Chiller pumps [10], [11]. Earthing leakage current treatment is obtained by isolating cables and conductors according to the Egyptian code for electrical installations and connections in buildings. Assuming that the ground leakage current in a residential or administrative unit is 30 mA, this means that the monthly energy loss is about 4.75 kilowatt hours [8].

The use of light emitting diodes (LED) bulbs technology, which is considered an improvement in lamp efficiency, leads to limited energy savings, but when maximizing daylight, it is one of the measures to achieve a low energy design [12]. Also, a study was conducted to study the effect of changing the power factor in the LED bulbs on the total harmonic distortion (THD), the study was conducted on a house and a hotel, and the result was that it contributes to increasing harmonics [13]. As well as in another study on the effect of changing the feeding voltage of the LED bulbs (160-240) volts on the quality of the bulb and the color characteristics of the bulb, it was found that the bulb of good and approved industry is not affected by this change [14]. A comparison of the LED bulbs feeding was done with a constant voltage (DC) and a variable voltage (AC) and the result was that the lamp efficiency increased from 5% to 10% in the case of feeding using DC more than AC [15]. Also, two of the typical methods for achieving effective energy management and lighting control are working to integrate natural and industrial lighting or using highly efficient bulbs [16].

HVAC systems are responsible for the occupants 'comfort in the building by saving internal temperature, humidity, and the total air quality inside the building. Therefore, they are responsible for a large part of the building's energy consumption [17]. It is noted that the use of technological developments increased the efficiency of HVAC systems and thus reduced energy consumption, for example, the use of automatic natural ventilation by using suction fans and automatic windows. When a strong wind or storm occurs, it closes automatically [17]. Various concepts and elements have been developed to reduce energy use for cooling and heating in buildings [16] Such as:

- Mixed method: Use natural ventilation when the external temperature is moderate and use mechanical if necessary.
- Air distribution system: there are fans that work when there are people to reduce the thermal loads inside the building. Therefore, it is noted that the application of this system in the German commercial bank building, Commerzbank, where the architect Norman Foster has used [16]:

Natural lighting from the surrounding windows with hinges and can be opened and shaded by a Building Management System (BMS) system.

Natural ventilation for approximately 60% of the total hours of use, and mechanical ventilation is used in extreme conditions. There is also a system for night ventilation where the temperature is moderate in summer for pre-cooling of the thermal mass and the possibility of using the heat switch for the ground and groundwater.

2. Methodology

The research aim is the possibility of using simulation programs to determine the energy consumption per square meter annually, whether the building is finished or in the design stage and Economic study of the methods of rationalization in the simulation program and the application of the most feasible method in practice. The workflow of this study will be structured as follows:

- Determining the study case to implement the energy rationalization mechanism.
- Preliminary evaluation of the case study using smart electricity meters.
- Evaluating using the DB simulation program with studying the following:
  - The effect of rationalization on change the Set Point of the Cooler device on consumption rationalization.
  - Effect of rationalization in lighting.
  - Rationalization by fixed shading.
  - The effect of rationalization in glass types on the rationalization of energy.
  - The effect of rationalization in the use of thermal insulation.
- presenting of simulation results for rationalization scenarios.
- Making a Comparison between actual consumption and results of simulation program consumption (DB) and then calculating the error.
- Discussing the rationalization scenarios used in the study.
- Evaluation of the economic return.

3. Model Description

Air conditioning engineers ASHRAE (the Energy Accounts Committee) completed a new project in the late 1990's to create mathematical algorithms that can be used for various building models (including the contents of a building's cover, appliances, and equipment in the building).It is also available to the simulation community [18]. Therefore, the Design Builder (DB) program is an easy-to-use design environment that helps in designing the construction model. Therefore, it loads heating, cooling and

lighting calculations using heat. Likewise, energy conservation indicators, annual consumption, thermal comfort indicators, temperature and humidity, heat transfer from walls and windows, air leakage and architectural shading calculations can be analyzed every hour and a study of rationalization methods more efficiently and with high accuracy [19]. DB is a GUI for Energy plus [20].

The case study was chosen on the western front of building of the National Center for Housing and Building Research, which is a government administrative building located in Giza Governorate, as shown in Table 1 and Figures 1 and 2. That by selecting the case that contains lighting and air conditioning loads only as shown in Table 1. As well as working hours start from 8 Am in the morning until 5 Pm in the afternoon.

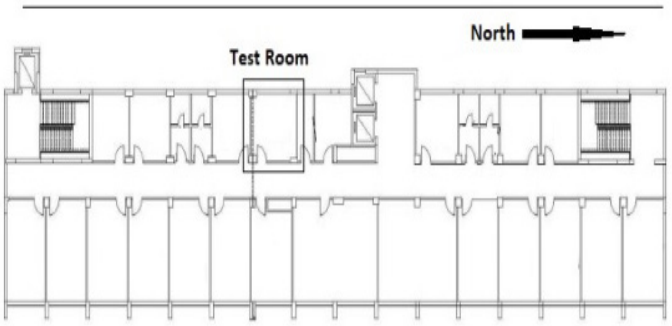

Figure 1: Case Study Location

Table 1: General Description of the Case Study

Item	Description
The building's name	The National Building and Housing Research Center (HBRC) is a government administrative building of the Ministry of Housing.
Building location	87 Tahrir Street - Dokki - Giza Governorate
The shape of the building design	As Figure 4
Case study location	As Figure 3 shows the location of the room on the fifth floor, where it overlooks the western façade, and there is another floor above this floor.
Room Area	14.5 m^2
Window	Open Area (Window): **2.95 m^2** Wall Area: **12.5 m^2** Window to wall ratio: 23% Sill Height for window (m): 1.3 Window Height (m): 1 Shading: no
Type window	TV: 0.88; SHGC: 0.82; U-Factor: 6.17; type: clear Single (6mm)
Construction	Physical properties of thermal Resistivity $m^2.C°/w$ / Specific heat (J/Kg.C°) / Conductivity (W/M.C°) / Density ρ ($k\ g/m^3$) / From the outside to the inside 0.37 / 840 / 1.6 / 1800 / Pink brick 0.02 / 730 / 1.25 / 1200 / Mortar paint 0.38 / Total resistivity
Activity	Density (people / m^2): 0.10 -0.11 Lighting energy (w/ m^2): 21.9 Computer Gain (w/ m^2): zero Office Equipment Gain (w/ m^2): zero
Climate region	Delta and Cairo region .As shown in the Figure No (3)
Room Details	cooling loads Equipment description / Quantity of equipment (unit) / Total power Unit (Watt) Air Condition window / 1 / 2000 lighting loads Quantity of fixture (units) / Fixture Type / Total power for Room (Watt) 2×4 lamp / Fluorescent lamp / 310 Watt ×9 Hours/day =2790 Watt

Figure 2: The Building Design

4. Simulation Results

4.1. Modeling and Validation Check

Case study simulation was done on DB program as shown in Figure 3. The validity of the simulation program was also confirmed by comparison between the simulation program results and the laboratory measurement of the energy consumption of the air conditioner by a smart open source electricity meter that measures every half a second and maintains these measurements in a built-in memory as shown in Figure 4. Also, the smart meter measurement was also compared with a certified clamp meter measurement and the error rate was 0.02%. As for lighting consumption, it was constant throughout working hours. Laboratory measurements of air conditioning loads were done on August 25, 2019 (8Am – 5Pm) and the measurement was done without using shading. Also on September 4, using 55% fixed shading. The beginning of laboratory registration was from 10 in the morning until 5 in the afternoon. Therefore, Table 2 Shows the result of comparison and the error rate between the simulation program and the laboratory measurement. From equation 1 the error associated with the energy models may be declared valid the CVRMSE within ±30% when using hourly data or 5% to 15% when using monthly data [20].

$$\text{CVRMSE} = 100 \times \frac{\sqrt{\overline{(Y_{measured} - Y_{modelled})^2}}}{\overline{Y}_{measured}} \quad (1)$$

Where, $Y_{measured}$ is the measure data point, $Y_{modelled}$ is the modeled data point and $\overline{Y}_{measured}$ is the average of all measured data points.

5. Discussions

5.1. Electricity Consumption for the Basic Case

After making the comparison and proving the error rate within the mathematically allowed, an annual consumption of the research study, shown in Figure 5 and Table 3, has been made. Also, it was taken into consideration that this case uses air conditioning in the period of 6 summer months, starting from May to October only. As for the lighting consumption, it is used throughout the year, and it turns out that the average consumption of electrical energy is 166 KWh/m^2. Where also by calculates the emission of carbon dioxide due to consumption 1383.8Kg CO2-eq / kWh considering that each kilowatts consumption is 0.57151 kgCo2 [21]. Also for calculate the emissions per square meter is 94.9kg-CO2-eq / m2.

5.2. The Effect of Set Point Change of Air Conditioning Device on the Rationalization of Energy Consumption

The effect of electrical consumption when using Set point for the air conditioning device on the following temperatures has been studied: (21°c - 22°c - 23°c - 24°c – 24.5°c). Table 4 shows the electrical consumption for each Set Point. Therefore, it was found that setting the temperature to 24.5 ° C saves energy consumption 38% compared to setting the temperature at 21 ° C as in Figure 6. Therefore, it is considered one of the best rationalization and not expensive. The annual consumption of the base case was also calculated by setting the temperature to 24.5° .

5.3. The Effect of Lighting Control on the Rationalization of Energy Consumption

In this case, the daylight factor was suitable. Therefore, the focus was on using rationalization by replacing fluorescent bulbs into low-watt LED bulbs [22]. Also, using a daylight sensor using the Step 1 method, as there is only one office in the case study, and from Table 5 it was found that rationalization of changing old lamps to LED technology saves 31% of the total consumption. Also, rationalization using a daylight sensor saves 36%, as in Figure 7.

5.4. The effect of glass types on the rationalization of energy consumption

Table 6 shows a study of rationalization in consumption by reducing solar heat gain coefficient (SHGC). Also in Figure 8, it is noted that the lower the SHGC, the lower consumption.

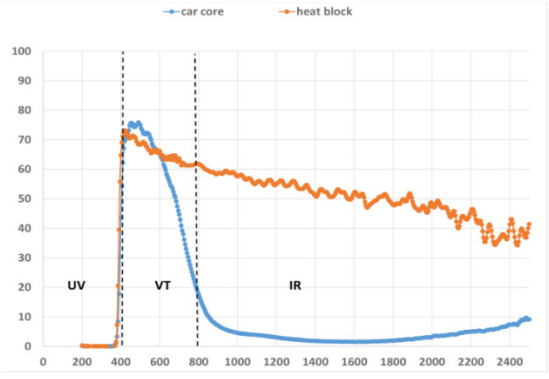

Figure 12: A Thin Film Car Core Characteristic

Also, with advanced technology, day by day, the focus will be on making materials that reduce SHGC and increase the visible transmission light as shown in Figure 12 for a thermoforming glass sample that shows its ability to reduce SHGC and increase the visible transmission light.

5.5. The Effect of Thermal Insulation on the Rationalization of Energy Consumption

From Table 7 it was found that using insulation in the western facade increases the energy consumption in summer due to the heat retention within the research study. Also Figure 9 shows the best resistance of the external wall

5.6. The Effect of Shading Control on the Rationalization of Energy Consumption

Figure 10 and Table 8 show the scenarios for rationalization by shading. Therefore, it was found that vertical shading by 55% as in Figure 13 of the window area is better in rationalization than horizontal and vertical shading on both sides of the window length of 1 m . Vertical shading is characterized by having a motor that can control the rate of openings for windows. Therefore, it is possible to maximize the benefit of the sun in winter and increase shading in summer. Also, observed decrease of the value of the flowing current in the wire was 14%.Also, the reason for choosing 55% shading is because at this point the lighting intensity was measured at the desktop level by lux meter in 4-sept -2019 during working hours (8am - 5pm) and the minimum was 300 lux. Accordingly, this shading was bought as in the Figure 13 and it is controlled according to occupant's desire. As lighting consumption constant, sureness of simulation program validity is by comparison of electric energy consumption that resulted from cooling as in the table 10

Figure 13: 55% Shading During the Summer Period

Table 10: The Comparison Between The Readings Recorded in the Simulation Program and Measured by Smart Meter

Time	Simulation (KWH)	Measure (KWH)	Error %
10 a.m.	2.312434	2.21625	5.16%
11 a.m.	1.775199	1.5	14.76%
12 p.m.	1.708757	1.575	7.17%
1 p.m.	1.681947	1.8375	8.34%
2 p.m.	1.725026	1.8	4.02%
3 p.m.	1.72124	2.0625	18.30%
4 p.m.	1.704831	2.0625	19.18%
Total	12.629434	13.05375	3.3%

5.7. The Effect of Integration on the Rationalization of Energy Consumption and Return on Investment (ROI)

Table 9 shows the methods of integration, the percentage of rationalization in each scenario, and the period for recovering capital from the energy saving (Assuming electricity tariff in Egypt is 1.5 EGP/kWh), the more integration scenarios of rationalization, the greater the savings rate as in Figure 11. It can be noted that the non-use of photovoltaic energy due to our approaching to the lowest station that can be connected to the distribution network in Egypt is 5 kilowatts. Therefore, it is not economically feasible in this case. The economic feasibility to rationalization can be measured by the following equation [18]:

$$\text{Expected payback period} = \frac{\text{initial cost+operation and maintenance costs}}{\text{cost operation saving}} \quad (2)$$

6. Conclusion

Optimizing the utilization of energy in buildings tends to save more power. The "Design Builder" simulation program is used for simulating the study building. In this paper, various energy saving methods are used to optimize the energy consumption in buildings. It can be found that the more integration between saving scenarios, the higher economic return. The behaviour of occupants poses a great challenge in implementing the rationalization methods. It can be noted that the percentage of rationalization that reached is large, that is due to lighting and air-condition loads only. Controlling the temperature of the refrigeration device represents the more simple and effective rationalization method with low cost and significant rationalization ratio. Also it is recommended to replace old bulbs with high efficiency bulbs because they have an economic return and reduce the consumption of cooling loads indirectly. Also rationalization can be achieved by the use of shading and lighting control using the daylight sensor. Shading helps in converging the average electrical energy consumption in the summer and winter seasons, as well as helps in reducing the consumed power by the air conditioners. Rationalization in air conditioning loads helps in achieving a balance in the average monthly consumption during the year where an annual energy saving about 39.6% is achieved. Comparison between the simulation results and the measured results shows that the simulation program can be reliable in studying the economic feasibility of rationalization scenarios before implementation.

ABSTRACT

Lime mortar, an age-long building material is primarily popular for its flexibility, the basis of its ability to accommodate masonry deformation, hence durability. However, lime's characteristic delayed setting/hardening time, low mechanical strength and poor internal cohesion often characterised by volumetric changes have put its use into decline. These shortcomings have therefore relegated relevance of this fundamental flexibility feature which underscores limes' excellent performance and durability characteristics. The research therefore attempted to leverage this feature through evaluation of synergised lime composites, using cement as a partial replacement for lime. This is with a view to integrating advantageous features of 'lime and cement' as a composite, at the expense of their known individual drawbacks. The methodology involved mortars with the same Binder/Aggregate (B/A) mix ratio (1:3) using five different compositions of 'cement-lime' binders (i.e. 1:1, 1:2, 1:3, 2:1 and 3:1). The research focused on comparative evaluations of each composition in both fresh and hardened states, with the latter covering twelve-month curing period. While Water/Binder ratio constituted the fresh state assessment parameters, mechanical characteristics and microstructural features were evaluated in the hardened state. Results of the investigation show that progressive addition of cement significantly changes pore size distribution (PSD) of lime mortar from predominant pore sizes between (0.5 – 5 µm) and (5 – 20 µm) into (10 nm – 2 µm) range. This alteration is associated with porosity reduction by up to 11%. Significant improvements in the mechanical strengths of the composite is recorded as both the compressive and flexural strengths of the composite with 75% of cement is 18 and 6 times higher respectively, compared with the reference mortar. However, progressive addition of cement is proportional to the E-value of the composite (with a clear linear relationship), leaving a negative impact on the flexibility. Nonetheless, all the composites investigated exhibit elastic behaviours relative to the basic lime mortar. In particular, composite with cement addition up to 33% of the binder compositions exhibits deformation tendencies under compression. However, mortars with higher cement compositions (i.e. above 33%) would strain linearly until failure occurs suddenly with minimal deformation. Substitution of lime with cement therefore has a significant impact on the microstructural compositions of lime mortar, and subsequent improvement on the performance of the composite. Despite the improved mechanical strengths, inherent flexibility of lime is maintained though negatively impacted, subject to the amount of lime substituted. Hence, relative to specific purposes, lime revival can be promoted in form of sustainable lime-cement composites.

1. Introduction

Lime mortar, an age-long building material [1], is primarily popular for its flexibility, the basis of its ability to accommodate masonry deformation. It has the flexibility to cushion masonry joints to absorb strains, prevent cracking and result in medium to high flexural bond strengths [2]. By virtue of its reasonably high flexibility, lime mortar exhibits low elastic modulus, thereby displaying capability to deform more on load application relative

*Corresponding Author: Sule Adeniyi Olaniyan, Email: saolaniyan@lautech.edu.ng

to Portland cement [3]. The modulus of rupture and the bond strength of an appropriate, well cured mature lime mortar are such that movement joints are not normally required in new (traditional) construction and any movement experienced (i.e. structural, seasonal and thermal) is taken up by minute adjustment over many joints due to their 'plastic' and 'self-healing' properties [4]-[6]. In addition, lime mortar possesses excellent permeability feature via its relatively large interconnected pore structures. These pore structures allow ice crystal growth in frost periods, thereby accommodating the crystals within the pore structures without causing deterioration of the matrix [7]-[9]. This feature enhances durability of lime mortars in a building fabric against environmental conditions. Lime mortar also exhibits phenomenal 'breathability' through which moisture and vapour transfer from the external environment are freely dissipated via its permeable material, in view of its capillary porosity. This enhances the performance of the materials and structure holistically [2, 7, 10, 11]. Lime mortars also have superior water retention as values from 94.2 to 99.5% have been consistently measured against those of 60-80% of Portland cement equivalents [2]. This property enhances workability which improves contact between mortar and substrate, thereby increasing bond.

With growing emphasis on the need for reduced energy consumption and minimised atmospheric CO2 concentration [12], continued use of lime mortar in building has significant environmental benefits: manufacture of limes consumes less energy and produces less greenhouse gases (compared with Portland cement); its exposure to the atmosphere as lime based mortars absorb most or all of the carbon dioxide that was driven off during its calcination, a phenomenon called re-carbonation; masonry laid using lime based mortar has lower bond strength (than cement) that the units can be prised off easily thereafter, thereby facilitating recycling of the materials, and; building structures finished with lime mortars are usually characterised with low thermal conductivity as this affects the interior surface temperatures of buildings, and may therefore perform better as an insulating material [8, 11, 13].

Despite the properties as stated above, lime mortar is connected with exaggeratedly long setting and hardening periods, low internal cohesion, volumetric changes (i.e. shrinkage, particularly, aerial lime), relatively low mechanical strengths and a high water absorption capacity through capillarity. These have substantially impacted negatively on project delivery periods and significantly resulted in its relegation and relative disuse [9], [14]-[17]. To leverage some of the remarkable features particularly, flexibility, this situation therefore leads to the study of blended binding materials, in form of lime-cement composites.

Cement is a hydraulic material in nature because of its ability to set and harden under water by virtue of a chemical reaction with it [18, 19]. It is characterised with high compressive strength and exhibits higher thermal expansion coefficient than most masonry. It hinders accommodation of movements resulting from creep or thermal effects, and exhibits negligible plastic deformation under load. Thus, it fails by brittle fracture [4], [20]-[26]. Effect of cement on porosity and pore size distribution of lime mortars is crucial since changes in microstructural features of lime can substantially modify its overall performances. In conservation works especially, cement is considered chemically incompatible with lime based mortars as it has low permeability, responsible for introduction of soluble salts and characterised with a high modulus of elasticity that is unfit for accommodation of masonry deformations [27]-[32]. It is also established that Portland cement reacts with carbonic acid to form alkali carbonate or bicarbonate salts which are undesirable. However if Portland cement is used in a small amount, this will remain a minor problem as previous works show that an increase in cement content does not proportionally increase the amount of soluble salts [30, 33].

The evolving lime-cement composite would therefore share in the advantages of lime and cement mortars, avoiding or reducing their individual disadvantages [34]. These blended materials will be characterized by faster setting than lime and better flexibility than cement mortars, which generally improves their application [34]-[40]. The underlying purpose of this effort is driven by the need to improve lime mortar performances and reduce carbon dioxide emissions related to the production of cement [41]. It would also facilitate protection of the environment and conservation of energy resources along with the advent of a sizable market, for renewed interest in the use of lime as a building material [14, 42, 43].

2. Experimental Procedure

2.1. Materials and mortar Preparation

Materials used for the present research have been products commercially available in the market. Natural Hydraulic Lime of the class NHL-5.0 (St Astiers, UK), characterised with the lime's highest compressive strength, based on the 28-day test [44] was adopted for this research. This lime type (NHL-5) was chosen based on its relatively short setting time for optimal strength yield, its availability, ease of handling, as well as the need to maximise lime performance behaviour [14, 45]. Table 1 shows Lime's average Particle Size Distribution obtained through laser diffraction method, using Laser Difractometry Xmastersize. This method is based on measurement of the laser beam scattered by the particle analysed. The distribution indicates particles with main equivalent diameter of 33.99 µm (by volume) and 10.19 µm (by Surface Area). 90% of these particles have sizes below 91.88 µm (by volume). Lime's chemical compositions (by elements) determined by Energy Dispersive Spectrometry are given in Table 2. Cement (CEM I 52.5) for this investigation was obtained from 'Hanson Cement', United Kingdom. Its average Particle Size Distribution shown in Table 1 indicates particles with main equivalent diameter of 21.08µm (by volume) and 10.64µm (by Surface Area). 90% of these particles have sizes below 41.55µm (by volume). Cement's chemical compositions (by elements) are given in Table 2. Siliceous fine kiln dried sand, obtained from Fife Silica Sands (a division of Patersons of Greenoackhill Ltd, United Kingdom) constituted the aggregates. The aggregate was passed through a sieve analysis in accordance with the requirements of [46], and the particle size distributions in compliance with ASTM C 136 [47] are shown in Figure 1. The sand had Particle Size Distribution of 0-2 mm (i.e. 0.05 mm < Ø < 2 mm) which is considered suitable, in accordance with ASTM C 33 [48].

Following the required standard (BSI, 2000) [49], the mortars were prepared as the binder-aggregate (B/A) ratio was maintained at 1:3 by volume. This was chosen from the commonest dosage

Table 1: Particle Size Diameters of the tested materials

Parameters		d(v,0.5)	d(v,0.1)	Mode	d(v,0.9)	D[4,3] (main equivalent diameter by volume)	D[3,2] (main equivalent diameter by Surface Area)
Specified Particle Diameter (µm)	**Lime**	10.78	5.28	6.50	91.88	33.99	10.19
	Cement	20.14	5.40	31.78	41.55	21.08	10.64

Table 2: Chemical Composition of the materials

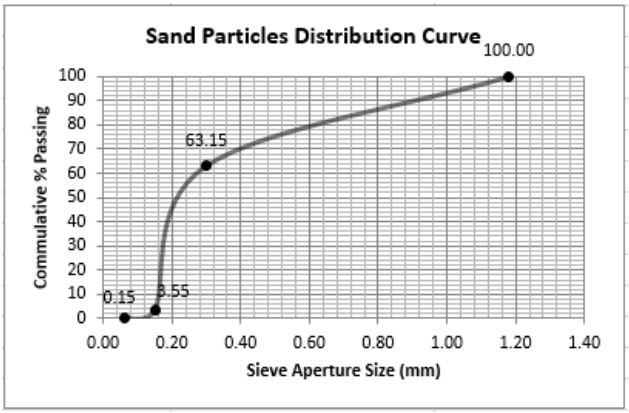

Figure 1: Grain size distribution of the aggregate

reported in the literature [15, 23, 33, 50]. To avoid measurement imprecision during batching processes, volume proportions of components were converted to weights [2]. Mortar mixtures were prepared using the correct amount of water required to obtain adopted workability of 145±5 mm (measured by the flow table test – BS EN 1015-3 (BSI, 2000) [49] as BS EN 1015-6 (BSI, 1999) [51] specifies a flow value of '140-200 mm' for 'plastic mortar'. Arising from visual and physical assessments of the mixes during the trial experimentation however, a flow value of 140 – 150mm (i.e. 145+5mm) was adopted. As observed, either higher or lower value tends towards stiffness or fluidity respectively. This was determined in accordance with (BSI, 2005) [52].

Using the stated B/A ratio (i.e. 1:3), each mortar formulation was prepared with progressively increasing/decreasing cement contents as indicated in Table 3. Mixing was done in the laboratory mixer of 30 litres maximum capacity. The mixing procedure was performed in a number of stages: Aggregates were placed first, followed by other dry materials (i.e. lime and cement, pre-mixed earlier, where applicable) and these were blended consistently for 60 seconds as best practice dictates that the NHL powder should be thoroughly mixed through the dry sand, ensuring batch colour consistency prior to gradually adding water. Water was added slowly during 30 seconds and mixing continued for another 30 seconds. Mixing was stopped for 90 seconds as mortar adhering to the wall and bottom of the mixer bowl was scraped off. Mixing then resumed to obtain consistent mixture. The entire mixing period lasted about 5minutes. For every mortar mix, minimum of three prismatic specimens of 40×40×160 mm were prepared, the average value of which represented the 'actual value' for consideration during the specimen evaluations afterwards (i.e. for microstructural analysis, and mechanical characteristics evaluations: Flexural and Compressive tests; Moduli of Elasticity determination). The specimens were compacted with a vibration table after mould filling in prismatic casts (BSI, 2010b) [53], removed from the moulds 2 days later and left to cure at the laboratory ambient conditions of 21+4ºC (temperature) and 40+5% (relative humidity), until the test dates of 1, 3, 6, 9 and 12 months.

2.2. Analytical methodology

This involved microstructural characteristics evaluation, mechanical properties assessment and some other relevant preliminary material testing. Microstructural characteristics of the mortar samples were evaluated in terms of the total porosity (in %), median pore diameter (by volume in nm), bulk density and pore size distribution, using Mercury Intrusion Porosimetry (MIP) technique. This was achieved with AutoPore IV 9500 by Micrometrics (with pressure range up to 60000 psi). The test was carried out with samples of approximately 1.5g that were extracted from the core of the crushed prisms. Under short term loading and at a relatively low rate of load application (approximately 2mm/min), the chance of micro crack propagation is minimum [33, 54]. These samples were obtained at the test ages of one and six months, and dried in an oven at temperature of 75 ± 1 ºC for 24 hours before the test, to ensure that the sample is devoid of moisture contents (which may otherwise affect its microstructural properties, thereby affecting the results). The mechanical properties were evaluated with regard to the three-point flexural tests, and compressive strength. While the flexural strength tests were performed on the ELE AutoTest 2000 apparatus with a load application pace of 50 N/s, compressive strength tests were conducted on the two fragments of each specimen (resulting from the preceding flexural test) using INSTRON 3367 with 30kN load capacity, moving at a loading rate of 2mm/min.

Table 3. Lime-Cement Mortars' Compositions by materials

Cement Contents	**0%**	**25%**	**33%**	**50%**	**66%**	**75%**
Mortar Reference I.D.	**L13**	**LC31**	**LC21**	**LC11**	**LC12**	**LC13**
Volumetric Ratio (L-C-Sd)	1-0-3	3-1-12	2-1-9	1-1-6	1-2-9	1-3-12
Lime (L): Volume (Volume in 'ml'/ mass in 'g')	1 (1700/ 1172)	3 (770/ 528)	2 (665/ 458)	1 (850/ 586)	1 (510/ 352)	1 (260/ 176)
Cement (C): Volume (Volume in 'ml'/ mass in 'g')	0 (0)	1 (415/ 442)	1 (540/ 574)	1 (830/ 883)	2 (995/ 1060)	3 (1250/ 1325)
Sand (Sd): Volume (Volume in 'ml'/ mass in 'g')	3 (4350/ 6444)	12 (4350/ 6444)	9 (4240/ 6283)	6 (4350/ 6444)	9 (3920/ 5800)	12 (4350/ 6444)

The results reported in this work were all taken as an average value of six similar specimen fragments. Additionally, INSTRON 3367 plots stress/strain graph on the screen, with the value for Modulus of Elasticity generated automatically. Other Preliminary Material Testing carried out included: application of Scanning Electron Microscopy/Energy Dispersive X-ray Spectrometry using 'Carl Zeiss EVO 50' Scanning Electron Microscope to examine and analyse the microstructure, morphology and chemical composition characterizations of the experimental materials (Lime and cement); Laser Difractometry Xmastersize with air dispersion was adopted for determination of the Pore Size Distribution of the tested materials (Lime and cement), and; Consistency of fresh mortars was examined using the flow table test in accordance with (BSI, 2000) [49].

3. Results and Discussion

3.1. Water/Binder Ratio

Table 4 shows the results of the W/B ratios obtained for lime, and lime-cement mortars batched using varying binders' contents. Water/Binder (W/B) ratio was adjusted appropriately to ensure the same mortar flow of 145±5 mm for all the mixes. For the reference mortar (lime mortar, L13), W/B ratio was recorded at 1.53.

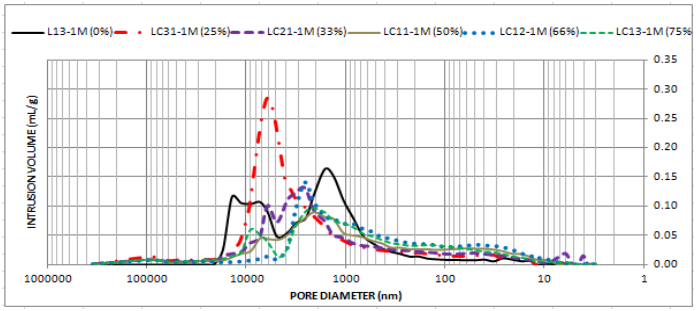
With progressive addition of cement content, a clear reduction of water demand was recorded, although non-linear. Thus, lime mortar exhibits its ability to retain water in the mix as it imparts plasticity and enhances workability [2, 4]. Besides, this reduction in water demand could be attributed to quicker formation of more hydration products of Calcium Silicate Hydrates (C–S–H) and resulting densification of the mortar matrix. It can therefore be inferred that increase in the percentage of lime with respect to cement mass requires a higher percentage of water in order to obtain a paste with the same consistency. This is because lime has smaller particle size with a higher specific surface. This leads to the mortar's finer pore system which results in higher suction and stronger water-retaining characteristics [55, 56].

Table 4: Lime-Cement Mortars' Compositions by materials and Water/Binder ratios.

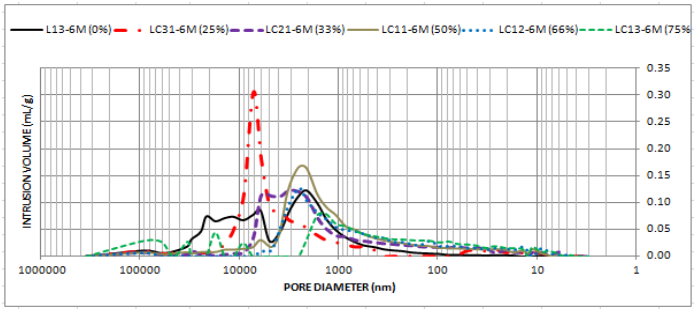
Cement Contents	**Mortar Reference I.D.**	**Water Content** (g)	**Water/ Binder Ratio**
0%	**L13**	1790	1.53
25%	**LC31**	1880	1.94
33%	**LC21**	1775	1.72
50%	**LC11**	1800	1.23
66%	**LC12**	1680	1.19
75%	**LC13**	1710	1.14

3.2. Microstructural features

Microstructural characteristics such as porosity and Pore Size Distribution (PSD) were evaluated for different mortars. Figures 2 (a) and (b), and Table 5 show the PSD curves and other microstructural data obtained by Mercury Intrusion Porosimetry (MIP) for the six different composites at 1 and 6 months of curing.



(a)



(b)

Figure 2: Pore size distribution for cured lime mortars with increasing cement contents: (a) At 1-month curing; (b) At 6-month curing

For lime only, at 1-month curing, the graph indicates a bimodal PSD with predominant sizes between (0.5-5 µm) and (5-20 µm) (Figure 2(a)). In this case, the mortar exhibits both gel pores (i.e. 1 nm – 3 µm) and substantial proportion of capillary pores (i.e. 3-30 µm). These large pores result from loss of excess unbound kneading water due to strong water-retaining characteristic of lime, and slow carbonation process [57]. The pores can also be related to fine cracks induced by associated drying shrinkage which can even expand and widen.

After 6 months, in spite of the continuous hydration and carbonation processes, the median pore diameter increased (from 2.16 to 3.96 µm) (Table 5) indicating more presence of larger pore sizes (i.e. between 0.5 µm and 40 µm) with the shift of the PSD curves to the left (Figure 2 (b)). However, a reduction is observed in the total pore volume (i.e. from 27.77 to 23.42%), which indicates filling of some of the capillary voids due to deposition of the hydration and carbonation products. The bulk density was also reduced (from 1.75 to 1.72 g/ml) due to evaporation of excess kneading water and subsequent drying shrinkage.

However, progressive addition of cement to the mortar resulted in unimodal PSD with lower median pore diameters and formation of finer pores at 6 months (Table 5). The graphs are shifted towards the right (relative to lime mortars), an indication of the dominance of smaller pore sizes.

The observed decrease in the median pore diameters is a consequence of lower W/B ratios used to achieve similar consistency. Also, it can be related to subsequent filling of larger pores by the hydration products particularly, C–S–H gel [58, 59, 60]. This can explain why the addition of cement led to predominance of smaller pore sizes in lime mortar. Usually, kneading water decreases with increasing cement content in the paste (as demonstrated in Section 3.2). This led to the densification of the mortar matrixes and consequent reduced porosities (21.45% for LC31) at 6 months (Table 5).

3.3. Mechanical Properties

The results of the mortars' mechanical assessments (flexural strength, compressive strength and modulus of elasticity) for a 12-month curing period are summarised in Appendix I. Each result was taken as an average value of three similar specimens for flexural strength and five similar specimens for both compressive strength and modulus of elasticity. The coefficients of variation (COV) fall substantially within the lower range (0 – 17%). This suggests consistent results. However, there were also few cases of higher COV, which indicate some degree of scatter in those cases. Appropriate error bars are also displayed on the respective graphs.

For lime only, Figure 3 and (Appendix I) show a flexural strength value of 0.70 MPa in the first month of curing which decreased to 0.61 MPa at the end of 12 months. This may be due to formation of different pore sizes resulting from loss of excess unbound kneading water as revealed in the microstructural analyses above.

Table 5: Extracted Mercury Intrusion Porosimetry data for composite mortars containing increasing cement contents

Specimen Reference I.D.	Curing Period	Median Pore Diameter (Volume) [nm]	Bulk Density at 0.52psia [g/mL]	Porosity [%]
L13 (0%)	1 Month	2163.6	1.75	27.77
	6 Months	3955.0	1.72	23.42
LC31 (25%)	1 Month	4276.0	1.78	29.17
	6 Months	6616.9	1.80	30.03
LC21 (33%)	1 Month	3036.1	1.78	27.54
	6 Months	2579.4	1.84	23.43
LC11 (50%)	1 Month	1487.3	1.83	24.35
	6 Months	1909.7	1.87	25.67
LC12 (66%)	1 Month	989.4	1.86	25.51
	6 Months	1340.8	1.92	20.81
LC13 (75%)	1 Month	1372.1	1.86	24.64
	6 Months	1033.7	1.90	21.45

As anticipated, progressive addition of cement to the mortar increased the flexural strength throughout the curing period, though not in a linear trend. Cement with faster hydration, quicker formation of C-S-H, reduced pore sizes and volume, attained higher flexural strength at a relatively shorter time. Notably, LC12 recorded the highest values of 4.12 MPa and 4.23 MPa at 1 month and 12 months respectively.

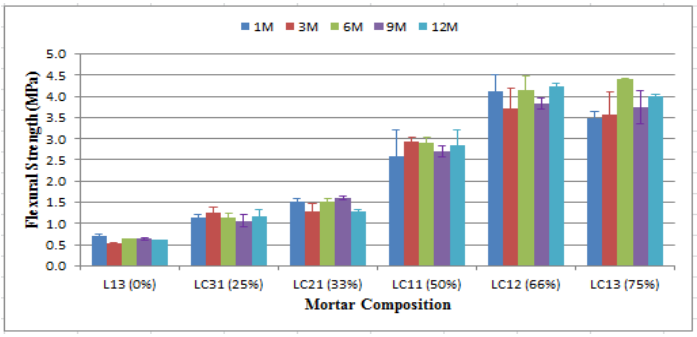


Figure 3: Flexural Strength developments for lime mortars with increasing cement contents

The compressive strength developments followed a similar trend to that of flexural strength. A marginal increase in the strength from 0.61 MPa at 1 month curing to 0.66 MPa at 12 months in the mix containing lime only was observed (Figure 4 and Appendix I).

Expectedly, these values significantly increased with progressive addition of cement. At 1 and 12 months of curing, highest values of 9.17 MPa and 12.34 MPa were recorded for the mix with triple cement content (LC13). This represents a significant increase (in each case) above the mix with no cement content (L13), over the same curing period.

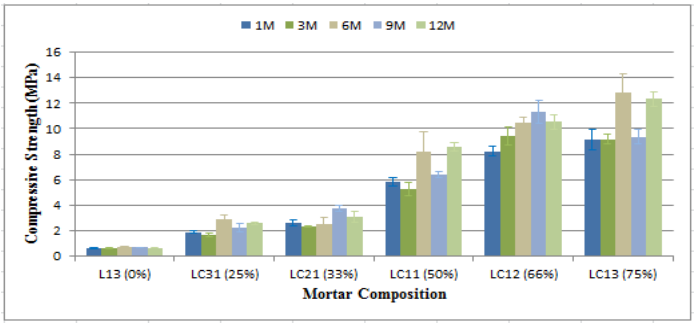

Figure 4: Compressive Strength developments for lime mortars with increasing cement contents

Despite increases recorded in both flexural and compressive strengths with increasing cement contents across the mixes, no significant increase was observed within each mix over the curing period. Being a hydraulic lime, the initial strength recorded may be related to the products of hydration reactions (i.e. formation of calcium silicate hydrates (C–S–H) and calcium aluminate hydrates (C–A–H)). Subsequently the remaining bulk calcium hydroxide would be expected to react with atmospheric carbon dioxide through carbonation over time, for further strength developments. However, rate of carbonation is found to be strongly dependent on relative humidity [61]-[63]. The laboratory curing condition of 45% relative humidity is considered possibly low and could have impacted negatively on the carbonation process thereby leading to the insignificant strength gains over time. Nonetheless, observed impact of the low humidity on the results may be applicable and relevant in some geographical regions, where the humidity is not always very high (e.g. tropical regions like Nigeria, among others).

The compressive strength recorded in each case is related to the mortars' practical performance. This is as reflected in their moduli of elasticity (E) values as shown in Appendix I and Figures 5 to 7.

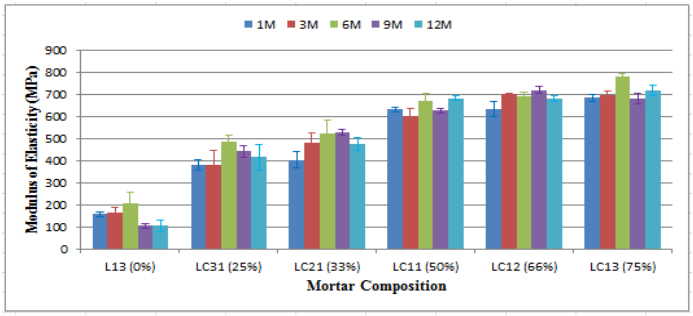

Figure 5: Moduli of elasticity (E) values for lime mortars with increasing cement contents

From Figure 5, L13 with the least compressive strength correspondingly recorded lowest 'E' value over the 12-month curing period. Also, LC13 with the highest compressive strength correspondingly recorded the highest 'E' value over the same curing period. Both LI3 and LC13 have the tendencies to display contrasting elastic behaviours (high and low) respectively. This is supported with the mortars' Compressive/Flexural strength ratios (f_c/f_f) and Moduli of Elasticity relationships with increasing cement contents as illustrated in Figure 6. It is well established that low compressive to flexural strength ratio (f_c/f_f) of similar materials is proportional to the Modulus of Elasticity (E-value) which is inversely proportional to its elastic behavior [64, 65]. Figure 6 presents the relationships between (f_c/f_f) and the E-values with cement contents for studied lime mortars. The dotted arrow on the graph indicates the general tendency of the E-values with respect to the increase in cement contents.

From Figure 6, it can be observed that both (f_c/f_f) and the E-values are proportional to cement content. However, these relationships are not linear over the 12-month curing period. Figures 7 (a) and (b) show further analyses to determine any potential pattern of relationships between the parameters

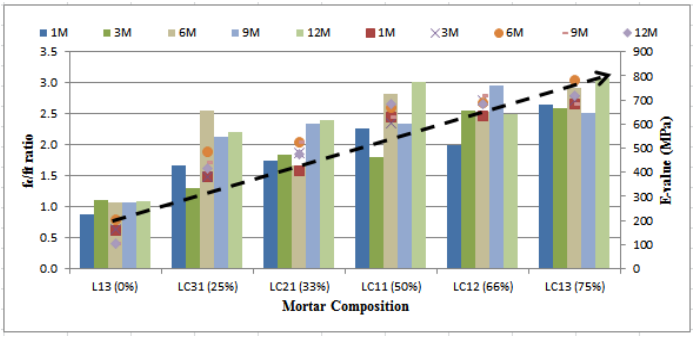

Figure 6: Compressive/Flexural strength ratios (fc/ff) and Moduli of Elasticity versus lime and cement mortars over 12-month curing (general relationships)

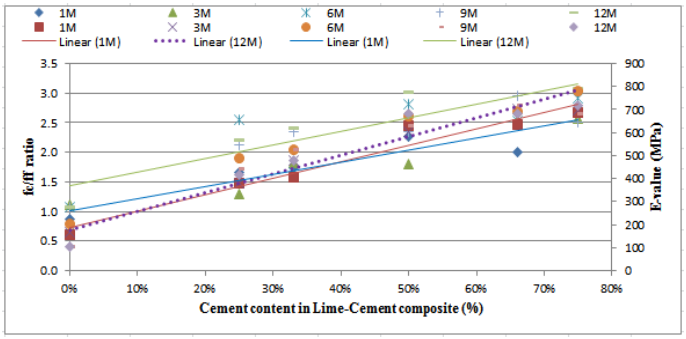
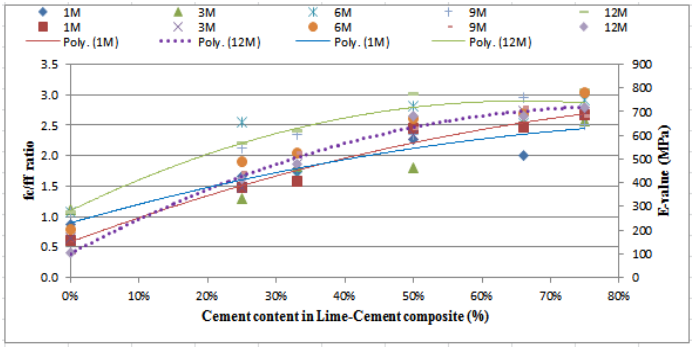
As can be observed from Figures 7 (a) and (b), good relationships could be established between (f_c/f_f) and cement

contents (with correlation coefficients above 0.80 obtained in each case). The relationship is described by the quadratic equation ($R^2 = 0.89$):

$$f_c/f_f = -4.14c^2 + 5.46c + 1.09 \quad (1)$$



f_c/f_f: Linear equation for the relationship at:
1-month ($f_c/f_f = 2.04c + 1.02$); $R^2 = 0.8715$;
12 months ($f_c/f_f = 2.28c + 1.44$); $R^2 = 0.765$
E-value: Linear equation for the relationship at:
1-month (Tc = 712.91E + 187);
12 months (Tc = 807.79E + 178.65); $R^2 = 0.9166$
(Note: Tc: Thermal Conductivity; c is cement content in %; E is E-value) (a)



f_c/f_f: Quadratic equation for the relationship at:
1-month ($f_c/f_f = -1.52c^2 + 3.21c + 0.89$); $R^2 = 0.8972$; 12 months ($f_c/f_f = -4.14c^2 + 5.46c + 1.09$); $R^2 = 0.8985$
E-value: Quadratic equation for the relationship at:
1-month ($E = -462.6c^2 + 1068.5c + 148.86$); $R^2 = 0.9674$; 12 months ($E = -964.31c^2 + 1549.1c + 99.155$); $R^2 = 0.9856$
(Note: Tc: Thermal Conductivity; c is cement content in %; E is E-value)
(b)

Figure 7: Compressive/Flexural strength ratios (f_c/f_f) and Moduli of Elasticity versus cement content for lime and cement mortars: (a) Through linear relationships; (b) Relationships using polynomial curves

However, a strong relationship could be established between the E-value and cement content. This relationship is described by the quadratic equation with a high correlation coefficient ($R^2 = 0.99$):

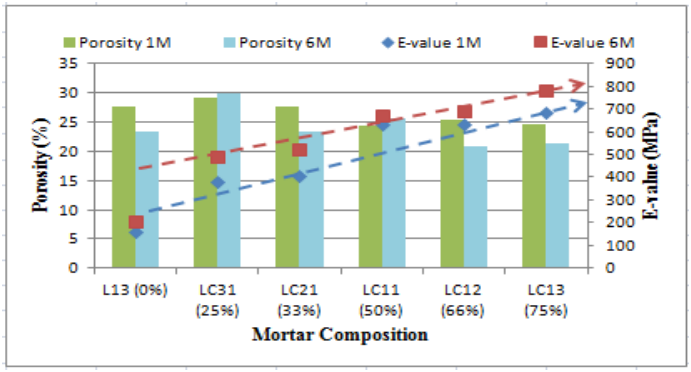
$$E = -964.31c^2 + 1549.1c + 99.155 \quad (2)$$

where E is E-value, and c is cement content in %.

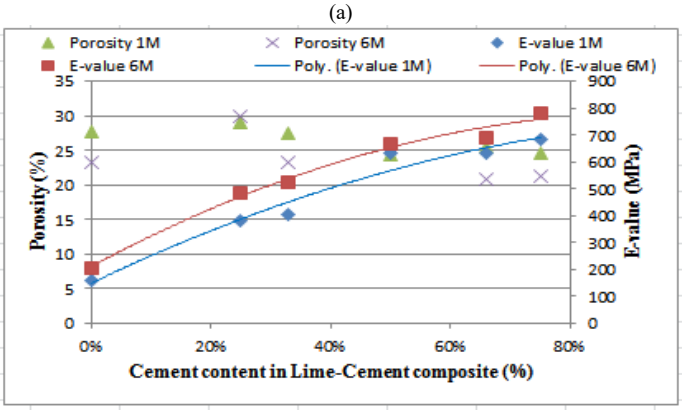
4. Further Results Synthesis: Changing Microstructural Compositions vis-à-vis Lime Composites' Flexibility

The changing microstructural characteristic features of the lime-based mortars are related to the mortar's modulus of elasticity (E-value).

Figure 8 (a) presents the effect of cement content, on both porosity and E-value. While porosity is inversely proportional to cement content, E-value is directly proportional. The dotted arrows on the graph indicate the increasing pattern of the E-values for 1 and 6 months curing.



(a)



E-value: Quadratic equation for the relationship at:
1-month (E = $-462.6c^2 + 1068.5c + 148.861$); $R^2 = 0.9674$;
6-months ($E = -626.12c^2 + 1199.6c + 210.65$); $R^2 = 0.9868$;
*(Note:*p *is porosity;c is cement content in %)*

(b)

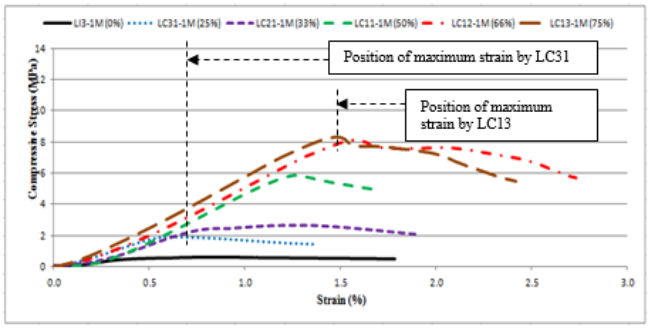
Figure 8: Relationships between increase in cement content, porosity and E-value of Lime mortar at 1 and 6-month curing: (a): General relationships; (b): Relationships using polynomial curves

An attempt was made to approximate these experimental results by establishing mathematical relationships between cement content and porosity as well as E-values, using quadratic equations (Figure 8 (b)). Considering composite performance at 6 months, a clear relationship can be established between cement content (c) and E-value (E) as expressed in the following equation:

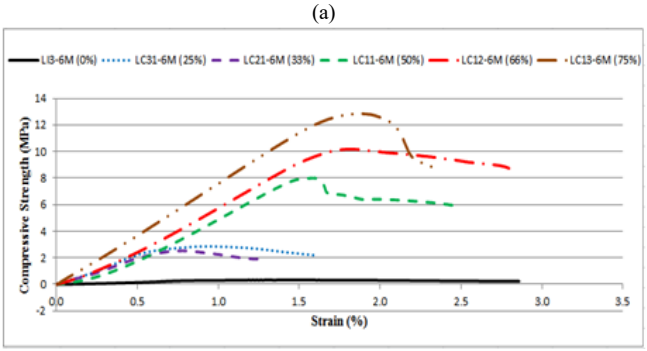
$$E = -626.12c^2 + 1199.6c + 210.65 \quad (3)$$

The coefficient of correlation in this case is very high (0.99), indicating a very strong relationship

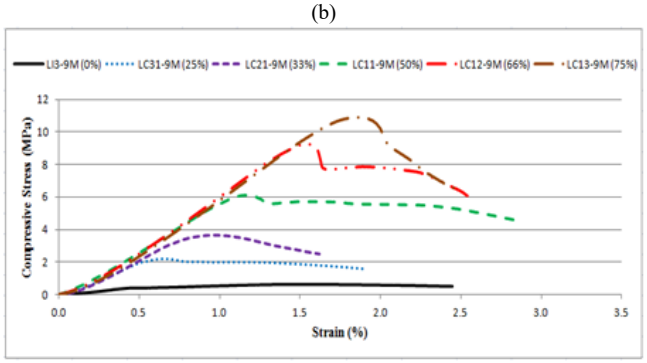
Lime mortar is primarily popular for its flexibility, the basis of its ability to accommodate masonry deformation. With the presence of lime (in varying compositions), both LI3 and LC13 (with the least lime content) have the tendencies to display contrasting elastic behaviours (high and low) respectively, as demonstrated in their stress-strain relationships at 1, 6, 9 and 12 months of curing respectively (Figures 9 (a) to (d)), with varying capacities to absorp deformation. The trend is also applicable to other mixes.



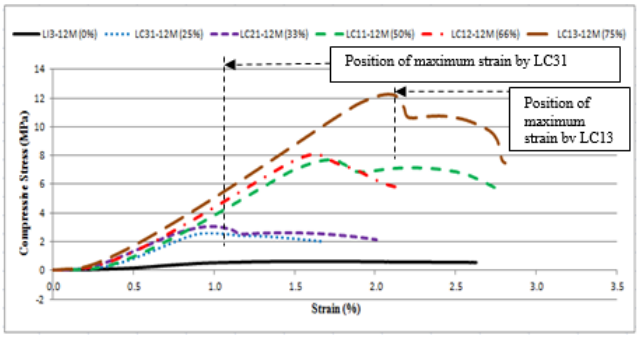
(a)



(b)



(c)



(d)

Figure 9: Compressive Strength versus Strain relationships for lime and lime-cement mortars at different curing ages: (a): At 1-month curing; (b): At 6-month curing; (c): At 9-month curing; (d): At 12-month curing

The smaller the slope of the curve, the better the elastic behaviour. All mortars exhibit comparably varying slopes relative to lime mortar's (L13). Compressive stress varies proportionally with increasing cement content as shown on the individual behavioural patterns for lime-cement composites (Figures 9 (a) to (d)). For example, the specimen with the highest cement content (75% cement content i.e. LC13) sustained about 8 MPa and 12 MPa maximum compressive stresses after 1 and 12 months respectively. This differs significantly from the maximum compressive stresses of 2 MPa and 3 MPa sustained by the composite with the least cement content (25% cement content i.e. LC31). However, increasing cement content is associated with higher slope of the curve, having attendant negative consequences on the strain, and the ability of the sample to sustain deformation. This results in decreasing flexibility.

Thus, LC13 curve with the highest gradient is characterised with the least flexibility, and thus, the least capability to sustain deformation before failure. Nevertheless, cement content at about 33% of the binders produces composite with comparable flexibility relative to lime mortar. This is evident in LC31 and LC21. In general, cement addition up to 33% of the binder compositions would enable the mortars under compression to exhibit some deformation tendencies. The smaller the slope of the curve, the better the elastic behaviour. All mortars exhibit comparably varying slopes relative to lime mortar's (L13). Compressive stress varies proportionally with increasing cement content as shown on the individual behavioural patterns for lime-cement composites (Figures 9 (a) to (d)). For example, the specimen with the highest cement content (75% cement content i.e. LC13) sustained about 8 MPa and 12 MPa maximum compressive stresses after 1 and 12 months respectively. This differs significantly from the maximum compressive stresses of 2 MPa and 3 MPa sustained by the composite with the least cement content (25% cement content i.e. LC31). However, increasing cement content is associated with higher slope of the curve, having attendant negative consequences on the strain, and the ability of the sample to sustain deformation. This results in decreasing flexibility. Thus LC13 curve with the highest gradient is characterised with the least flexibility, and thus, the least capability to sustain deformation before failure. Nevertheless, cement content at about 33% of the binders produces composite with comparable flexibility relative to lime mortar. This is evident in LC31 and LC21. In general, cement addition up to 33% of the binder compositions would enable the mortars under compression to exhibit some deformation tendencies. However, mortars with higher cement compositions (i.e. above 33%) would strain linearly until failure occurs, and failure appears suddenly with minimal deformation.

5. Conclusion

This study has presented empirical data to reveal synergies obtainable by taking the advantage of respective useful features of each of lime and cement, combined as mortar constituents. The study sought to evolve low carbon composite construction materials in forms of 'lime-cement' mortars with cement serving as a partial replacement for lime in each case. Through this process, potential benefits derivable from blending lime and cement are revealed, particularly, maximizing 'flexibility' feature of lime mortar. This is a primary lime property essentially responsible for its age-long durability. However, due to other prominent drawbacks associated with lime, its overall usage has gone to decline. Thus, it is clear from this study that the patterns exhibited by all the composites investigated suggest that they are relatively characterized by elastic behaviours comparable to the basic lime-based mortar. In particular, cement addition up to 33%

of the binder compositions would enable the mortars under compression exhibit some deformation tendencies. However, mortars with higher cement compositions (i.e. above 33%) would strain linearly until failure occurs suddenly, with minimal deformation. This study therefore is an attempt to revive sustainable lime mortar as a direct response to the climate change challenge in view of the material's sustainability characteristics. Conclusively, this effort would facilitate protection of the environment and conservation of energy resources along with the advent of a sizable market, for renewed interest in the use of lime as a building material.

Conflict of Interest

The author declares no conflict of interest.

Acknowledgment

The authors gratefully acknowledge the financial supports from 'TETFUND AST&D' Scheme, an educational development organ of The Federal Government of Nigeria. Thanks, are also due to Hanson Cement, United Kingdom, for the provision of the cement used for this work.

Local interpolation cubic spline

ABSTRACT

In this article, the Grebennikov cubic spline, the Ryabenky cubic spline, and we offer the local interpolation cubic spline models are selected. The construction details of the models were given and the processes of approximating the functions were performed using selected local cubic splines. We can also say that the local interpolation cubic spline models considered in this study provide high accuracy in digital processing of signals, which helps experts to make the right decision as a result of digital processing of signals. For instance, the initial values of the gastroentrological signal were calculated after that they digitally processed, and the error results were taken. Approximation of the considered models and digital processing of the gastroenterological signal by getting error results were specific analyzed comparatively based on numerical and graphical comparisons.

1. Introduction

Digital signal processing is one of the most pressing areas of science and technology today, which is developing from a practical point of view. The correct choice of mathematical apparatus in the digital processing of signals leads to a high degree of accuracy in making the right decisions by experts in the field. As an example, we can say that in medicine and geophysics accuracy is very important [1]. In medicine, accuracy plays an important role in such processes as determining the current condition of a patient brought to the hospital in a critical condition, determining the type of disease, clarify the degree of the disease. We know that in the field of geophysics, too, a large amount of money is spent on the extraction of mineral resources, so accuracy is important in confirm the location of minerals [2].

That is, according to the anomalous changes in the geophysical signal, it is possible to make predictions for the analysis the subsequent developmental activity of the object under study. Usually, as a result of forecasting, it is possible to predict such information as the location of the most accumulated minerals, the amount of their reserves in advance. As information can be used anomalous changes in the electromagnetic, gravitational fields of the earth, anomalous changes in the ionosphere, seismic noise, various acoustic vibrations.

Today, scientists are exploring new ways to process these signals using a variety of mathematical models and algorithms [3]. One of these methods is to recover the signals received in tabular form using local interpolation spline functions [4]. This is because the accuracy level of spline functions is higher than that of classical interpolation polynomials. And the algorithms derived from them require less computation [5]. Existing classical interpolation models, their application in signal recovery and digital processing algorithms are performed depending on the node points [6], [7]. The construction of classical interpolation polynomials is based on the idea of replacing functions with that are closer to it, in a sense, and simpler in structure [8], [9]. In this case, a large number of node points are required to obtain a high degree of convergence of these models [10], [11]. In the case of node points, the order of the system equations formed in the construction of the model under consideration increases, and the process of solving this system of equations becomes more complicated, which does not ensure a high level of accuracy of the model.

In order to solve this problem, in the article, the process of digital processing of signals was carried out using high-precision

spline models. The increase in the degree of convergence of the models under consideration does not depend on the increase in the order of the system of equations [12], [13].

That is, in the construction of the spline function considered in this work, the following node points are constructed on the basis of $x_{i-1}, x_i, x_{i+1}, x_{i+2}$ in the $[x_i, x_{i+1}]\ (i=\overline{0,n})$ interval S_i local interpolated cubic spline.

That is, the spline function divides the [*a, b*] interval into n parts and builds a spline function in a single interval (Figure 1).

To construct a spline function, the interval [a, b] is divided into n parts, and the spline function is constructed in a single interval [14].

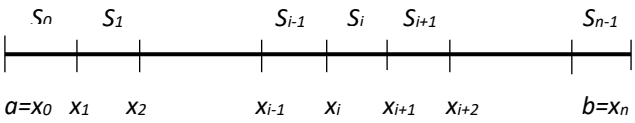

Figure 1: A view of the spaces where the cubic spline is built.

$$S_i(x_i) = S_{i+1}(x_i) \tag{1}$$

$$S_i^{(')}(x_i) = S_{i+1}^{(')}(x_i) \tag{2}$$

$$S_i^{(")}(x_i) = S_{i+1}^{(")}(x_i) \tag{3}$$

If conditions (1), (2) and (3) are met, the spline function defect is called a spline function that fully meets the actual level of demand, which is equal to 1.

The following is a study of cubic spline functions with high accuracy in digital processing of signals [15]-17].

2. Build cubic spline functions

In digital signal processing, cubic spline functions are a high-precision mathematical apparatus.

We know that the $\{x\}_{i=0}^{N}$ corresponding to the $f(x)$ function, the $S(x)$ function passing through the node points, is called the interpolation cubic spline and meets the following conditions [1],[9],[10]:

1) $S(x)$ function third-degree polynomial in each $[x_i, x_{i+1}]\ (i=\overline{0,n})$ interval;

2) The first and second-order derivatives of the $S(x)$ function must be continuous in the interval [a, b];

3) $S(x_i) = f(x_i), i=\overline{0,n}$.

The last condition is called the interpolation condition, and the function that satisfies the three conditions is called the interpolation cubic spline.

2.1. Build a cubic spline function based on basic functions

Let us be given the following function.

$$G(x,t) = (x-t)^3 = \begin{cases} (x-t)^3, & x \ge t \\ 0, & x < t \end{cases} \tag{4}$$

Assume that the $\{x_i\}$ node points on the OX axis are defined in steps h as follows [12].

$x_{i+1} = x_i + h,\ i = 1,2,...,M$, $G(x,t)$ we enter the fourth-order divisor of the function separately for the $x_{i-2}, x_{i-1}, x_i, x_{i+1}, x_{i+2}$ node points on the variable i:

$$\phi_i(x) = G(x_{i-2}, x_{i-1}, x_i, x_{i+1}, x_{i+2}),\ i = 3,4,...,M-2$$

The fourth-order difference of the $\varphi(x)$ function is determined by the following formula:

$$f(x_{i-2}, x_{i-1}, x_i, x_{i+1}, x_{i+2}) =$$

$$= \frac{f(x_{i-1}, x_i, x_{i+1}, x_{i+2}) - f(x_{i-2}, x_{i-1}, x_i, x_{i+1})}{x_{i-2} - x_{i+2}}$$

In turn, $x_{i-1}, x_i, x_{i+1}, x_{i+2}$ and $x_{i-2}, x_{i-1}, x_i, x_{i+1}$ are also calculated sequentially as above.

After some simplification, the calculation formula for the fourth-order subtraction difference of the $G(x,t)$ function will look like this:

$$\varphi_i(x) = G(x_{i-2}, x_{i-1}, x_i, x_{i+1}, x_{i+2}) =$$
$$\frac{1}{4!h^4}[(x-x_{i+2})_+^3 - 4(x-x_{i+1})_+^3 \tag{5}$$
$$+ 6(x-x_i)_+^3 - 4(x-x_{i-1})_+^3 + (x-x_{i-2})_+^3]$$

Based on the features discussed above, the following forms the basis in the space of tertiary splines

$$S_i(x) = \frac{\varphi_i(x)}{\varphi_i(x_i)},\quad i = 3,4,5,...,M-2 \tag{6}$$

Let's look at the features.

This function forms the basis in the space of cubic splines and has the following features:

1) Smoothness

$$S_i(x) \in C^2[x_1, x_M] \tag{6^1}$$

2) Locality

$$S_i(x) > 0, \quad x \in (x_{i-2}, x_{i+2})$$
$$S_i(x) \equiv 0, \quad x \notin (x_{i-2}, x_{i+2}), \qquad (6^2)$$
$$i = 3,4,5..., \quad M-2$$

The values of the $f(x)$ function at the $f_i = f(x_i),\ i = 3, M-2$ node points are given $x_4 = a, x_{M-3} = b$.

Consider the following function.

$$S(x) = \sum_{i=3}^{M-2} f_i S_i(x), \quad x \in (x_4, x_{M-3})$$

From this function

$$S_i(x) > 0, \quad x \in (x_{i-2}, x_{i+2})$$

$$S_i(x) \equiv 0, \quad x \notin (x_{i-2}, x_{i+2})$$

the local condition is required.

In that case, the values at the node point of the $S_i(x)$ function based on the localization condition are as follows.

$$S(x_i) = \sum_{j=i-1}^{i+1} f_j S_j(x_i), \quad i = 4, M-3$$

For simplicity

$$S(x_i) = \sum_{p=-1}^{1} f_{i+p} S_{i+p}(x_i)$$

That is

$$S(x_i) = f_{i-1} S_{i-1}(x_i) + f_i S_i(x_i) + f_{i+1} S_{i+1}(x_i),$$
$$i = \overline{4, M-3}$$

The $S_i(x)$ function at values p= 0.1 is as follows

$$S_{i+p}(x_i) = S_{i-p}(x_i) = S_i(x_{i+p}) = S_i(x_{i-p}) = a_p$$

has properties

$$a_p = \begin{cases} 1 & if \quad p = 0 \\ 0,25 & if \quad p = 1 \end{cases}$$

That is, at p = 0

$$S_i(x_i) = S_i(x_i) = S_i(x_i) = S_i(x_i) = 1$$

really

$$S_i(x) = \frac{\varphi_i(x)}{\varphi_i(x_i)},$$

in this

$$S_i(x_i) = \frac{\varphi_i(x_i)}{\varphi_i(x_i)} = 1,$$

The case p = 1 is similar.
As a result

$$S(x_i) = 0,25 f_{i-1} + 1 f_i + 0,25 f_{i+1} = f + 0,25(f_{i-1} + f_{i+1}),$$
$$i = \overline{4, M-3}$$

We now express the f_{i-1}, f_{i+1} through the f_i, for which we spread them to the Taylor series

$$f_{i-1} = f_i + h f_i' + \frac{h^2}{2} f_i''$$
$$f_{i+1} = f_i - h f_i' + \frac{h^2}{2} f_i''$$

By adding these expressions we get the following

$$f_{i-1} + f_{i+1} = 2 f_i + \frac{h^2}{2}(f_i'' + f_i'')$$

$$f_{i-1} + f_{i+1} = 2 f_i + O(h^2)$$

$$0,25(f_{i-1} + f_{i+1}) = 0,5 f_i + O(h^2)$$

In that case

$$S(x_i) = f_i + \frac{1}{4}(f_{i-1} + f_{i+1}) = f_i + \frac{1}{2} f_i + O(h^2),$$

From this

$$S(x_i) = \frac{3}{2} f_i + O(h^2)$$

We will have $S(x_i) = \frac{3}{2} f_i + O(h^2)$.

The smoother the $f(x)$ function, the closer it is to f_i in $(f_{i-1} + f_{i+1})/2$ calculations.

And the $S_i(x)$ spline function is close to the $k\frac{3}{2} f(x)$ at the node points then we find the next approximate function

$$S^*(x_i) = \frac{2}{3} S(x_i) = \frac{2}{3}[\frac{3}{2} f_i + O(h^2)]$$

$$S^*(x_i) = f_i + O(h^2)$$

in which case it can be obtained

$$S^*(x) = \frac{2}{3} \sum_{i=3}^{M-2} f_i S_i(x)$$

$$S^*(x) = \frac{2}{3} S_{i-1}(x) f_{i-1} + \frac{2}{3} S_i(x) f_i +$$

$$+\frac{2}{3} S_{i+1}(x) f_{i+1} + \frac{2}{3} S_{i+2}(x) f_{i+2}$$

We enter the following notation, where $t = \frac{x - x_i}{h}, x = x_i + th$,

$$\psi_1(t) = \frac{2}{3} S_{i-1}(x); \quad \psi_2(t) = \frac{2}{3} S_i(x);$$
$$\psi_3(t) = \frac{2}{3} S_{i+1}(x); \quad \psi_4(t) = \frac{2}{3} S_{i+2}(x)$$

In that case

$$S^*(x) = \psi_1(t) f_{i-1} + \psi_2(t) f_i +$$

$$+\psi_3(t) f_{i+1} + \psi_4(t) f_{i+2}$$

It is not difficult to calculate $\psi_i(t)$.
We will see one of them count

$$\psi_1(t) = \frac{2}{3} S_{i-1}(x) = \frac{2}{3}\frac{1}{4}(1-t)^3 = \frac{1}{6}(1-t)^3$$

the rest are calculated similarly.

$$\psi_2(t) = \frac{1}{6}(3t^3 - 6t^2 + 4)$$

$$\psi_3(t) = \frac{1}{6}(1 + 3t + 3t^2 + 3t^3)$$

$$\psi_4(t) = \frac{1}{6} t^3$$

As a result, we write the general view of a tertiary spline function that is independent of node points as follows

$$S^*(x) = \sum_{j=1}^{4} \psi_j(t) f_{i-2+j}$$

Here

$$\begin{cases} \psi_1(t) = \frac{1}{6}(1-t)^3 \\ \psi_2(t) = \frac{1}{6}\left(3t^3 - 6t^2 + 4\right) \\ \psi_3(t) = \frac{1}{6}\left(1 + 3t + 3t^2 + 3t^3\right) \\ \psi_4(t) = \frac{1}{6} t^3 \end{cases}$$

2.2. Local interpolation cubic spline function based on Ryabenky operator

If the function is smooth enough, then it is advisable to approximate this function with spline functions. The use of third degree Given the extreme nature of the spline function with a high approximation accuracy, a third-order Ryabenky spline can be used to approximate the function, which approximates better than classical interpolation polynomials [10].

The $f(x)$ function belongs to the class of continuous functions up to the $f(x) \in C^q(-\infty, \infty)$, q order derivative.

Where q> 0 is the fixed number. Let the values of the $f(x)$ function be given at nodes of equal spacing

$$f(x) = f(ih), \ (i = 0, \pm 1, \pm 2, ...)$$

In Ryabenky's article, a 2p+1 level $S_{ph}(x)$ spline function with defect p+1 was constructed based on the $f(ih)$ values of the $f(x)$ function. For the $\left|f(x) - S_{ph}(x)\right|$ error in the one-dimensional case (up to the derivative of order r < q), the following is appropriate.

$$\left|f^{(r)}(x) - S^r_{ph}(x)\right| \le h^{q-r} \ k(p) \sup_x \left|f^{(q)}(x)\right| \qquad (7)$$

Where k(p) is not variable, it only depends on p.

For the optional p, the $S_{ph}(x)$ spline can be written to see the exact appearance of the $f(x)$ function via $f(ih)$ values. It is therefore very convenient to apply in various fields. This spline function can also be approximated in *C[a,b]* to the advantage of the Hermit spline.

In the works of S.L. Sobolev the following Ryabenky operator is given for the $S_{ph}(x)$ function in the $[x_i, x_{i+1}]$ interval [14].

$$S_{ph}(x) = \sum_{j=0}^{p} \sum_{k=0}^{p-j} \frac{(p+k)!}{k!\,j!\,p!} [a_{pj}(x) t^{j+k} (1-t)^{p+1}$$

$$S_{ph}(x) = \sum_{j=0}^{p} \sum_{k=0}^{p-j} \frac{(p+k)!}{k!\,j!\,p!} [a_{pj}(x) t^{j+k} (1-t)^{p+1} \quad (8)$$

here $t = \frac{x - x_i}{h}$, $a_{p0}(x_i) = f(x_i)$.

The spline function given in (8) is a 2p+1 level spline with a defect defect p+1, which in general gives a local third-order interpolation spline of the special case Ryabenky given p = 1.

When p= 1, a local cubic spline is formed

$$S_{1h}(x) = a_{10}(x_i)(1-t)^2(1+2t) + a_{10}(x_{i+1})t^2(3-2t)$$

$$+ a_{11}(x_i)t(1-t)^2 - a_{11}(x_{i+1})t^2(1-t)$$

$$a_{10}(x_i) = f(x_i), \quad \Delta f(x_i) = f(x_{i+1}) - f(x_i)$$

$$a_{11}(x_i) = 1! \sum_{k=1}^{1} \frac{\Delta f(x_i)}{1!} S(1,1) = f(x_{i+1}) - f(x_i), \quad S(1,1) = 1$$

$$a_{11}(x_{i+1}) = f(x_{i+2}) - f(x_{i+1})$$

$$S_{1h}(x) - S_3(x) = f(x_i)(1-t)^2(1+2t) +$$

$$+ f(x_{i+1})t^2(3-2t) + (f(x_{i+1}) - f(x_i))t(1-t)^2 -$$

$$-(f(x_{i+2}) - f(x_{i+1}))t^2(1-t) = ((1-t)^2(1+2t)$$

$$-t(1-t)^2)f(x_i) + (t^2(3-2t) + t(1-t)^2 +$$

$$+ t^2(1-t))f(x_{i+1}) - t^2(1-t)f(x_{i+2}) =$$

$$= \phi_1(t)f(x_i) + \phi_2(t)f(x_{i+1}) + \phi_3(t)f(x_{i+2})$$

$$S_3(x) = \varphi_1(t)f(x_i) + \varphi_2(t)f(x_{i+1}) + \varphi_3(t)f(x_{i+2}). \quad (9)$$

here

$$\varphi_1(t) = (1-t)^2(1+t), \ \varphi_2(t) = t(1+2t-2t^2),$$

$$\varphi_3(t) = -t^2(1-t)$$

This function in the $[x_i, x_{i+1}]$ interval (9) can be called the "Ryabenky" cubic spline function.

2.3. Building of a local interpolation cubic spline function

Divide the $[a,b]$ interval into n equal parts

$$a = x_0 < x_1 < \ldots < x_i < x_{i+1} < \ldots < x_n = b$$

We construct the local interpolation cubic spline model under consideration using a linear combination of two $y_1(x)$ and $y_2(x)$ parabolas in the $x \in [x_i, x_{i+1}]$ $(i = \overline{0, n-1})$ interval [9],[13].

We have the following four points $A(x_{i-1}, y_{i-1}); B(x_i, y_i); C(x_{i+2}, y_{i+2}); D(x_{i+1}, y_{i+1});$ to build a $S_3(x)$ spline in the $x \in [x_i, x_{i+1}]$ $(i = \overline{0, n-1})$ range.

It should be noted that in this method, four points are of course used to construct the interpolation cubic spline model (Figure 2).

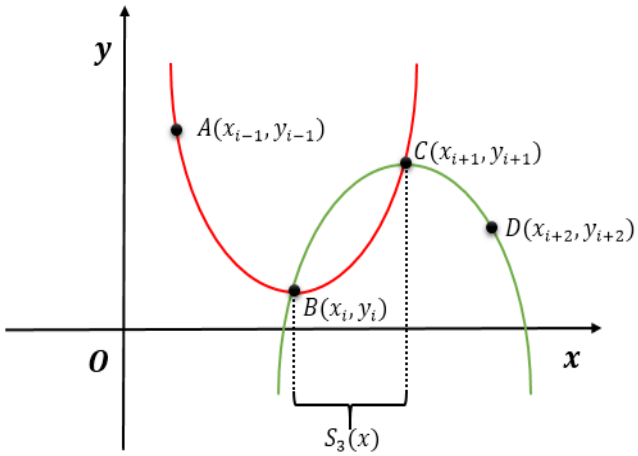

Figure 2: A view of the $S_3(x)$ local cubic spline construction range.

Using the interpolation condition to construct the following $y_1(x) = a_1x^2 + b_1x + c_1$ parabola passing through the points A, B, C, we construct the following system of equations [13], [18]:

$$\begin{cases} ax_{i-1}^2 + bx_{i-1} + c = y_{i-1} \\ ax_i^2 + bx_i + c = y_i \\ ax_{i+1}^2 + bx_{i+1} + c = y_{i+1} \end{cases} \quad (10)$$

(10) we find a, b, c from the system. And the following

$$y_1(x) = a_1x^2 + b_1x + c_1 \quad (11)$$

parabola will be formed.

We construct the following system of equations to construct the second $y_2(x) = a_2x^2 + b_2x + c_2$ parabola passing through the B, C, D points as above:

$$\begin{cases} ax_i^2 + bx_i + c = y_i \\ ax_{i+1}^2 + bx_{i+1} + c = y_{i+1} \\ ax_{i+2}^2 + bx_{i+2} + c = y_{i+2} \end{cases} \quad (12)$$

(12) we find a, b, c from the system. And the following

$$y_2(x) = a_2x^2 + b_2x + c_2 \quad (13)$$

parabola will be formed.

We perform the replacement to make it easier to estimate the error here $h_i = x_i - x_{i-1}$.

$$y_i(x) = y_i(t) = -0{,}5t(1-t)f_{i-1} + (1-t^2)f_i + 0{,}5(1+t)f_{i+1} \quad (14)$$

$$\begin{aligned} y_{i+1}(x) = y_{i+1}(t) = 0{,}5t(1-t)(2-t)f_i + \\ + t(2-t)f_{i+1} - 0{,}5t(2-t)f_{i+2} \end{aligned} \quad (15)$$

Through the combination of the above parabolas, we get the following view

$$S_i(x) = S_i(t) = (\alpha_1 + \alpha_2 t)y_i(x) + (\alpha_3 + \alpha_4 t)y_{i+1}(x).$$

From the interpolation condition

$$S_i(x_i) = f_i, \qquad S_i(x_{i+1}) = f_{i+1}$$

To determine the $\alpha_1, \alpha_2, \alpha_3$ *and* α_4, we construct equations (16):

$$\alpha_1 + \alpha_2 = 1, \quad \alpha_1 + \alpha_2 + \alpha_3 + \alpha_4 = 1, \quad (16)$$

where α_3 *and* α_4 are found $\alpha_3 = 1 - \alpha_1$, $\alpha_4 = -\alpha_2$

The system of equations (17) and (18) is formed after some simplification of the interpolation conditions of the first $S_i'(x)$, $S_{i+1}'(x)$ and the second $S_i''(x)$, $S_{i+1}''(x)$ at the x_{i+1} node point of the spline

$$\alpha_1(\Delta^2 f_{i+1} - \Delta^2 f_{i-1}) + \alpha_2\Delta^3 f_{i-1} = \Delta^3 f \quad (17)$$

$$\alpha_1(\Delta^4 f_{i-1}) - \alpha_2(\Delta^2 f_{i-1} + \Delta f_i - \Delta f_{i+2}) = \Delta^3 f \quad (18)$$

here Δ is the difference of operators.

If we say that the system of equations (16) - (18) is solved by $\alpha_1^*, \alpha_2^*, \alpha_3^*, \alpha_4^*$,

Then

$$S_3(x) = S_3(t) = (\alpha_1^* + \alpha_2^* t)y_i(t) + (\alpha_3^* + \alpha_4^* t)y_{i+1}(t).$$

Spline will have 1 defect. But $f_{i-1}, f_i, f_{i+1}, f_{i+2}, f_{i+3}$ coefficients are complex rational functions. Therefore, such splines are inconvenient for digital processing of signals.

If we say $\alpha_1 = 1$, $\alpha_2 = 1$, then $\alpha_3 = 0$, $\alpha_4 = 1$ These values satisfy equations (16) - (17) but do not satisfy equation (18)

The defect of the interpolation spline in the $[x_i, x_{i+1}]$ interval will be 2 [1],[13].

$$S_3(f;x) = S_3(t) = (1-t)y_i(t) + ty_{i+1}(t). \quad (19)$$

We will add these following formulas

$$\varphi_1(t) = -0{,}5t(1-t)^2, \quad \varphi_2(t) = 0{,}5(1-t)(2+2t-3t^2)$$

$$\varphi_3(t) = 0{,}5t(1+4t-3t^2), \quad \varphi_4(t) = -0{,}5(1-t)t^2$$

Substituting the expressions (14) and (15) for the $y_i(t)$ and $y_{i+1}(t)$ given in (19), we obtain the view (20) for the $[x_i, x_{i+1}]$ interval.

$$S_3(f;x) = \sum_{j=0}^{3} \varphi_{j+1}(t)f(x_{i+j-1}). \quad (20)$$

Based on the theory of splines, this function in the $[x_i, x_{i+1}]$ interval (20) can be called a local interpolation cubic spline function.

3. Approximation of functions using local cubic splines

The graph of the local interpolation cubic spline function generated in Section 2 was compared with the graph of the Ryabenky local cubic spline function and the graph of the Grebennikov local cubic spline function.

Let us compare the approximation of these three local cubic splines with the given function $f(x)$.

The local interpolation cubic spline function we propose has the appearance in y $[x_i, x_{i+1}]$ cross section as studied in Section 2.3:

$$S_3(f;x) = \sum_{j=0}^{3} \varphi_{j+1}(t) f(x_{i+j-1}),$$

here

$$\varphi_1(t) = -0,5t(1-t)^2,$$

$$\varphi_2(t) = 0,5(1-t)(2+2t-3t^2),$$

$$\varphi_3(t) = 0,5t(1+4t-3t^2),$$

$$\varphi_4(t) = -0,5(1-t)t^2.$$

here $t = (x - x_i)/h$, $h = \frac{b-a}{N}$, $N = 1,2,...$

We then define this spline function with $S_3(x)$ for convenience.

The second is the Ryabenky local cubic spline function and has the following appearance in y $[x_i, x_{i+1}]$ cross section:

$$S_3(f;x) = \sum_{j=1}^{3} \psi_j(t) f(x_{i+j-1}),$$

here

$$\psi_1(t) = (1-t)^2(1+t),$$

$$\psi_2(t) = t(1+2t-2t^2),$$

$$\psi_3(t) = -t^2(1-t),$$

here $t = (x - x_i)/h$, $h = \frac{b-a}{N}$, $N = 1,2,...$

We define the Ryabenky local cubic spline function by $RS_3(x)$

The third spline is the Grebennikov local cubic spline function, which has the following appearance in the $[x_i, x_{i+1}]$ cross section:

$$S_3(f;x) = \sum_{j=0}^{3} \phi_{j+1}(t) f(x_{i+j-1}).$$

here

$$\phi_1(t) = \frac{1}{6}(1-t)^3,\ \phi_2(t) = \frac{1}{6}(4-6t^2+3t^3),$$

$$\phi_3(t) = \frac{1}{6}(1+3t+3t^2-3t^3),\ \ \phi_4(t) = \frac{1}{6}t^3.$$

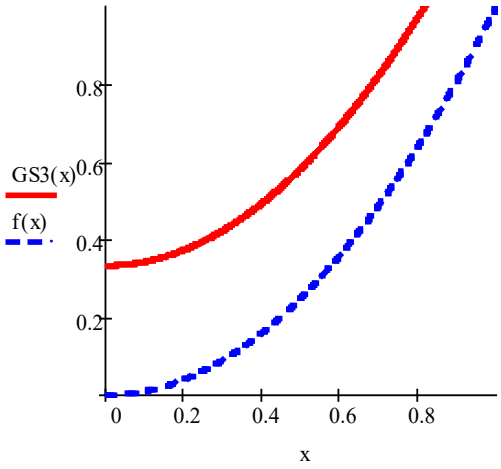
here $t = (x - x_i)/h$, $h = \frac{b-a}{N}$, $N = 1,2,...$

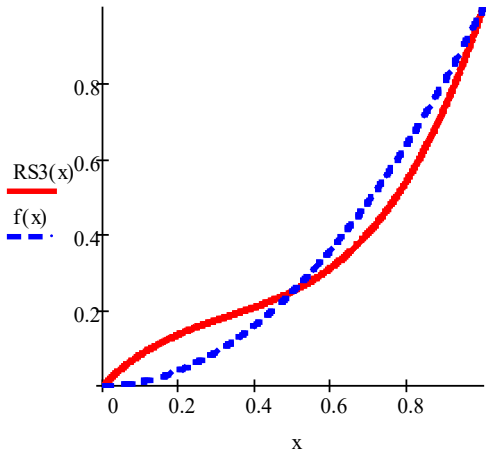
We define the Grebennikov local cubic spline function as $GS_3(x)$. In the examples, without losing generality, we only look at the situation when there is $[a,b] = [0,1]$ $N = 1$.

In this case, we consider the approximation of several functions in $t = x$ and graphs with three cubic splines (Figures 3,4,5 and 6):

1. In the case of $f(x) = x^2$ (examples given in Fig. 3)

As can be seen from the graph of the first example, the $S_3(x)$ spline graph overlaps with the $f(x) = x^2$ function graph, while the $GS_3(x)$ and $RS_3(x)$ spline graphs do not overlap.





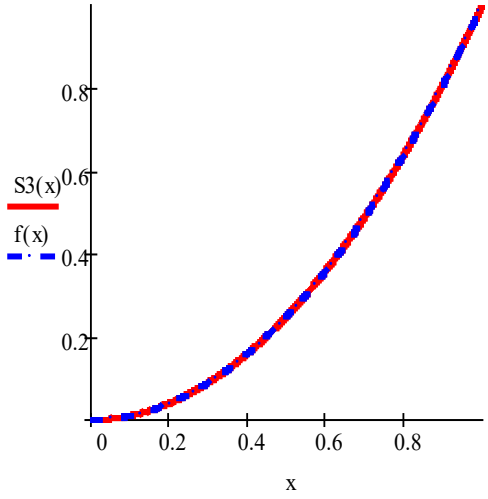


Figure 3: Results of approximation of the $f(x)=x^2$ function with three cubic splines.

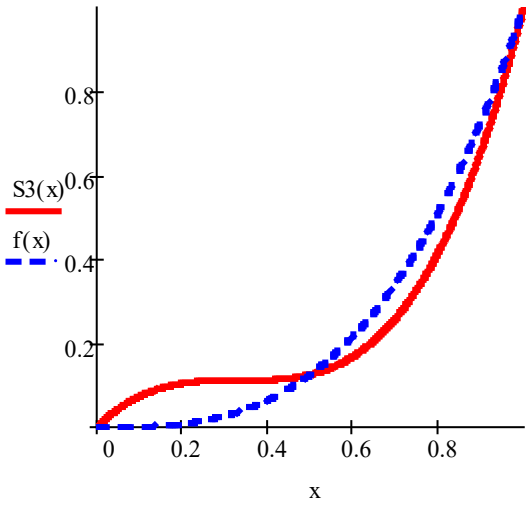

Figure 4: Results of approximation of the $f(x)=x^3$ function with three cubic splines.

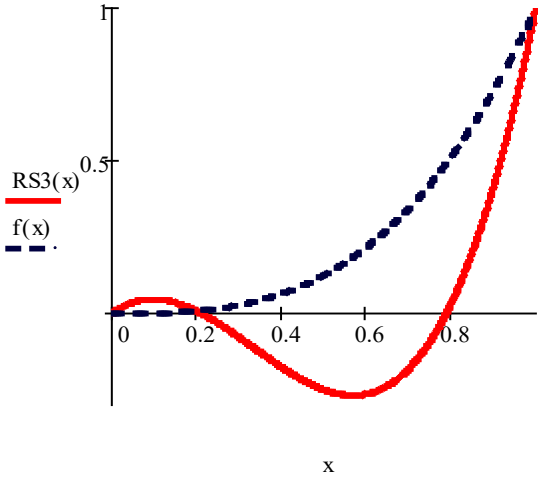
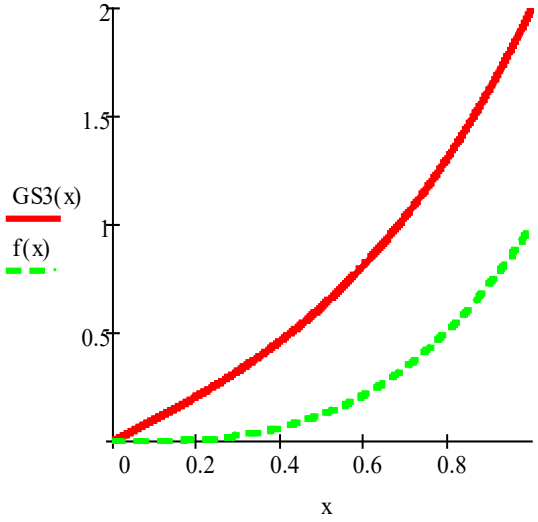
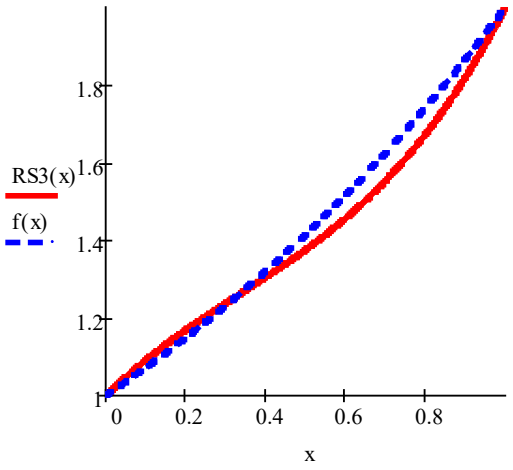
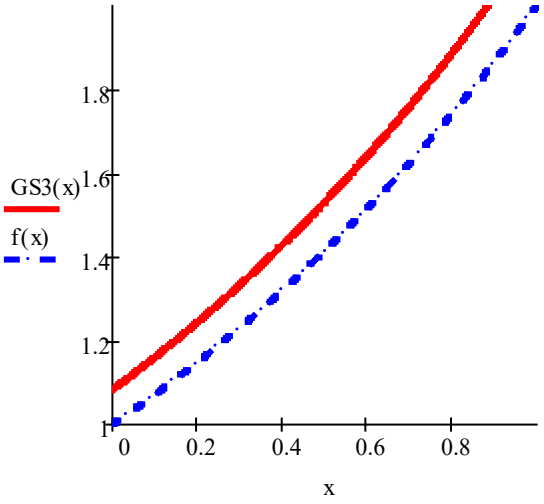
2. In the case of $f(x)=x^3$ (examples given in Fig. 4)





3. In the case of $f(x)=2^x$





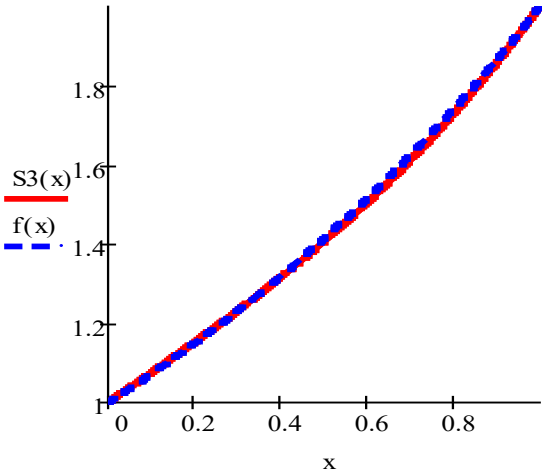


Figure 5: Results of approximation of the $f(x)=2^{x}$ function with three cubic splines

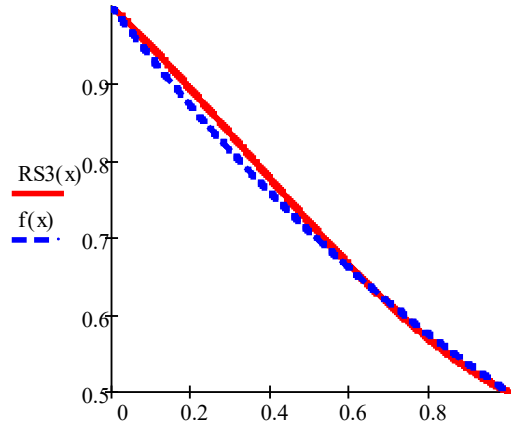
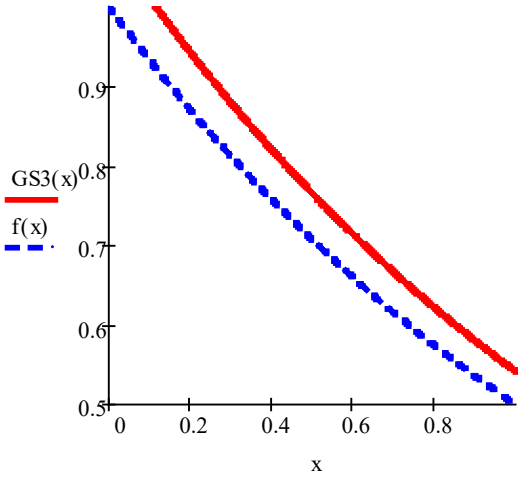
4. In the case of $f(x)=2^{-x}$





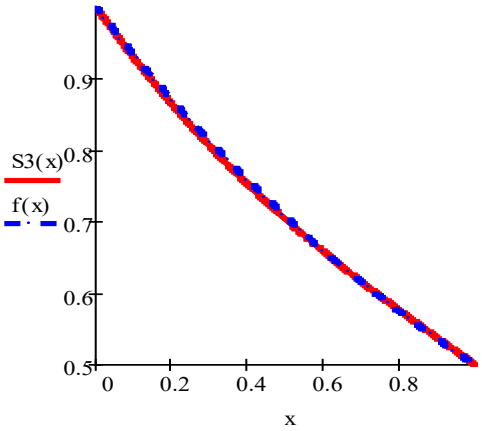


Figure 6: Results of approximation of the $f(x)=2^{-x}$ function with three cubic splines

Examples 1,2,3 and 4 show that the $S_3(x)$ spline function graph approximates the $f(x)$ function graph better than the $RS_3(x)$ and $GS_3(x)$ spline function graphs.

4. Digital processing of gastroenterological signals based on developed algorithms

Using the cubic spline models considered, the restoration of the gastroenterological signal given in Table 1 was considered. Based on the above sequence, a tertiary spline construction program was developed in the MATLAB software environment and used in signal processing (Figure 7). The algorithm of this program is shown in Figure 8.

5. Conclusion

In this article, spline functions with a high degree of accuracy in digital processing of signals which are Grebennikov cubic spline, the Ryabenky cubic spline, and the local interpolation cubic spline functions that we proposed.

The construction details selected cubic spline-functions in the equally distributed nets were given, and initially the processes of approximation functions were carried out.

Using selected cubic spline models, the gastroentrological signal was digitally processed and errors were evaluated.

According to results of approximation function using local cubic splines presented in Section 2, as well as the error results in Table 2 obtained from digital processing of the gastroenterological signal, it was found that the local interpolation cubic spline accuracy was high which .we proposed

It can be seen that the application of the mathematical model of the local interpolation cubic spline function we have considered in medicine, in geophysics, and in many areas where the level of accuracy is important in digital processing and recovery of signals leads to effective results.

ABSTRACT

Leachate generated from landfill Indonesia is typical has high salinity and organic matters during the dry season, potentially contaminating water and the environment. An increase in salinity might deteriorate the activity of the microorganisms on the decomposition process. This research aims to study the feasibility of the ozonation technique for treating stabilized leachate. The parameters tested were pH, COD, BOD_5 BOD_5/COD ratio, and TDS. Independent variables of this study were salinity with different concentration from ±0.4 ppt; ±5 ppt; ±10 ppt; and ±20 ppt and ozone contact time up to 60 minutes with an ozone dose of 600 mg/hour. Experimental results revealed that salinity ranging from 0.4 ppt to 20 ppt had little effect on COD removal, and the removal efficiency was around 30%. Further, the ozonation process exhibited better organic removal with an improved BOD_5 concentration from 426 mg/L to 887 mg/L in low salinity conditions (0.4 ppt). Meanwhile, it significantly affected the old leachate treatment, where the leachate biodegradability can be enhanced from 0.120 (initial condition) to 0.321 with salt addition of 20 ppt.

1. Introduction

The end of life of municipal solid waste (MSW) in landfills has always been expected because of its cost and operational efficiency [1]. Landfill leachate results from percolated rainwater and moisture passing through the layers of wastes in landfills [2]. The combination of pollutant parameters like BOD_5 (Biochemical Oxygen Demand), COD (Chemical Oxygen Demand), ammonia, and inorganic salts makes leachate a potential contamination source in river water and surface water. The characteristics and composition of leachate depend on the biological and chemical processes that occur during waste degradation, solid waste composition, rainfall density, groundwater percolation rate, and landfill age.

Government regulation requires minimizing the risk to public health, therefore all of the leachates generated from conventional landfills must be treated according to quality standards. The BOD_5/COD ratio can predict changes in the biodegradation rate in leachate. In general, the ratio of BOD_5/COD contained in leachate ranges from 0.4 - 0.6. This ratio range states that the organic compounds contained in leachate are biodegradable [3]. One of the causes of the low degradability of leachate is the high salinity value, where salinity is one of the inhibitors in the degradation process of microorganisms.

Lim et al. stated that salinity does not affect the hydrolysis and acid formation processes, but inhibits bacteria's activity carrying out the digestion process [4]. The effect of salinity on the waste degradation process can be measured through the COD content, the characteristics of the biogas produced, and methane gas production. Leachate salinity contain potassium (K^+), sodium (Na^+) and chloride (Cl^-) ions [5]. Chloride inhibits bacterial activity so that it can reduce COD content. High salinity content can reduce methane gas formation [6]. Due to the high complexity in its waste composition and characteristics, it is arduous to define a better leachate treatment strategy [7].

Apart from having a high salt concentration, leachate concentrate also contains large amounts of refractory organics [8].

*Corresponding Author: Novi Kartika Sari, Email: novi.sari@tl.itera.ac.id

In addition, old leachate consists primarily of refractory organics due to less volatile fatty acids, which is turn can lower the BOD_5/COD ratio [9]. The physical-chemical process can be applied to pretreatment, tertiary processing, and the overall leachate treatment process. The purpose of the oxidation process in leachate processing is to oxidize organic substances to the most stable form of oxidation, namely into carbon dioxide and water, and increase the biodegradability of organic pollutants suitable for economic, biological processing [10] Furthermore, in principle, physicochemical technologies are suitable for wastewater treatment with extremely low biodegradability, such as stabilized leachate [11] Ozone treatment is one of the strongest chemical processes in leachate processing, because it has the potential for oxidation to reduce stubborn organic fractions.

However, the variation of salinity in landfill leachate fluctuates, leading to further deteriorating treatment efficiency [12]. Several studies have reported on the influence of high salinity on the landfill leachate by the ozonation process [13-15]. This research was designed to examine the treatment performance subjected to different salinity by the ozonation process from stabilized landfill leachate by adopting those approaches. The scope of future research is to compare three types of leachate characteristics, namely young leachate, semi-old leachate, and stabilized leachate with variations in the concentration of salinity by processing with ozonation.

2. Material and Method

2.1. Properties of leachate

Mature leachate was obtained from an aged landfill in Batam City, Indonesia, which has been operating since 1992. This research was conducted in a research laboratory at Universal University in Batam City. Research sampling was carried out at the inlet section of the leachate treatment plant, namely the landfill in Batam City. The laboratory test results from sampling on the landfill are leachate belonging to the characteristics of old leachate which has a COD concentration of 3000-4000 mg/L.

The mature or stabilized leachate's COD concentration was 3,000-4,000 mg/L, ammonia concentration was 1,000-1,500 mg/L, and pH was 7.8. The leachate was categorized as stabilized leachate for this study due to the exceedingly low BOD_5/COD ratio (<0.15) and high salinity content. The leachate was pumped from the leachate collecting pond. After collection, the stabilized leachate was stored in a cool container (4°C) to maintain the inherent characteristics. Before subjected to the ozonation process, the leachate samples were prefiltered using a vacuum pump.

2.2. Laboratory scale reactor

An illustration of leachate treatment with ozonation can be seen in Figure 1. It is equipped with the ozone generator that can supply ozone with a flow rate of 0.25 g/hour in the frequency of 50/60 Hz, providing an ozone flow rate reaching 1.4 L/minute after calibration [9] . KI solution was prepared to absorb excess ozone gas and safety. The ozone concentration was determined according to the standard method by titration using KI solution. The processes in the reactor were run in a thoroughly complete mix condition with 10 L volume of the reactor.

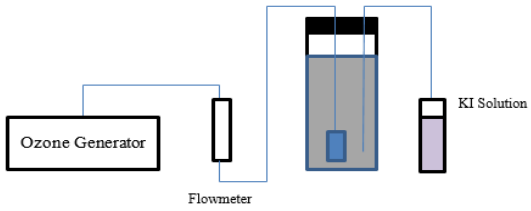

Figure 1: Schematic diagram of ozonation reactor

In Figure 1, a flow diagram of the leachate treatment process in the ozone reactor can be described. The first step is to prepare a KI (Potassium Iodide) solution by dissolving some potassium iodide powder with aquadest. Then, the solution was put into an iron tube with a tube and put into the ozone reactor. Stabilized leachate was put into the ozone reactor at a volume of 10 L. After that, prepared the flowmeter by adjusting the flowrate to 1.4 L / minute. The flowmeter was mounted on the ozone generator and connected to an ozone reactor which already contains old leachate.

2.3. Experimental procedure

The physicochemical treatment process in this study involved ozonation used in the batch operation. At the start of each experiment, the reactor was filled with 9 L of stabilized leachate. Samples were regularly taken at the specified time of 20 minutes, accounting for different applied salinity concentrations. These conditions were performed at a salt concentration of 0.4 ppt, 5 ppt, 10 ppt, and 20 ppt for 60 minutes. The ozonation for treating stabilized landfill leachate was operated for 20 minutes, 40 minutes, and 60 minutes, respectively. Different salt concentrations were adjusted by adding NaCl.

2.4. Sampling and analysis

The initial leachate quality was all measured to determine the original characteristics of the contaminants in the leachate. The initial characteristic parameters consisted of pH, temperature, conductivity, COD, BOD_5, and TDS as for leachate. The leachate used was certainly not low in salinity (as a control).

The leachate properties were analyzed for the following elements: COD, BOD_5, and TDS. The ozonation reactor was continuously monitored (online measuring of pH), and sampling was taken (COD, BOD_5, and BOD_5/COD ratio) during every cycle. Samples collected every operational cycle were filtered through a 0.45 µm filter before analysis. All the parameters were analyzed based on the procedure BOD_5 (APHA A-B 1995), COD (APHA B-C 1995), TSS (APHA N 1995), TKN (APHA C 1995), and salinity (APHA B&C 1995) [16].

3. Results and Discussion

3.1. Leachate characteristics

The collected leachates' initial characteristics depend on the municipal solid waste's waste composition and water content (MSW). The quality of stabilized leachate has not fulfilled the effluent standard, set by government regulation, and both are presented in Table 1. It can be ascertained that the salinity in leachate is only 0.4 ppt to be used as a control in research.

Table 1 shows that the untreated stabilized leachate sample possesses a high concentration of chemical parameters compared to government regulation. The leachate sample's pH value was

beyond the quality standards because anaerobic decomposition was attributed to decreased volatile fatty acid concentration. The electrical conductivity value (19.33 mS/cm) demonstrates dissolved inorganic materials in the samples. The concentration of TDS (4,100 mg/L) also fluctuates widely. The leachate's dark brown colors are mainly caused by ferrous oxide ferric form and the ferric hydroxide colloid formation and complexes with fulvic and humic substances [17]. The stabilized leachate has COD and BOD_5 concentration of 3,561 mg/L and 426 mg/L, respectively. This result reveals that organic matter in stabilized leachate is difficult to degrade biologically due to the complexity of organic compounds. The lower BOD_5/COD ratio in this leachate characteristic might be attributed to the leachate's biologically recalcitrant fraction.

Table 1: A comparison of untreated characteristics of the stabilized leachate and leachate quality standards

Parameter	Units	Stabilized Leachate	Government Regulation
pH		9.4	6.0 – 9.0
Temperature	°C	24.5	
Conductivity	mS/cm	19.3	
COD	mg/L	3,561.0	300
BOD_5	mg/L	426.0	150
BOD_5/COD		0.12	
TKN	mg/L	1,757.0	60
Salinity	ppt	0.4	
TDS	mg/L	4,100.0	

3.2. Stabilized leachate treatment: Effect of ozone contact time and salinity

The chemical oxidation process for the leachate treatment results in a better quality of stabilized leachate than the initial effluent. Ozonation with different salt concentrations contributes to the degradation of COD substances, the improvement of biodegradability ratio, the change in pH, and total dissolved solids.

3.3. The degradation of COD substances

Figure 2 compares the COD reduction in raw leachate at different salinity subjected to ozone treatment at a certain period. From the COD concentration obtained, the oxidation efficiency decreased slightly after 60 minutes. With 20 minutes of ozone exposure time, COD concentration decreased from 3,561 mg/L to 2,538 mg/L and 2,863 mg/L at salinity of 0.4 ppt and 20 ppt respectively. By adjusting the salt concentration of 5 ppt, the COD efficiency removal increases from 19.91% to 31.99% in ozonation time from 40 min to 60 min. Figure 2 shows that as ozone contact time increases, the COD content of stabilized leachate decreases faster than that of initial mature leachate. The initial COD value (3,561 mg/L) declines to 2,479 mg/L, 2,422 mg/L, 2,521 mg/L, and 2,434 mg/L respectively at the ozone contact time of 60 min and different salinity resulting in removal efficiencies of 30.38%, 31.99%, 29.21% and 31.65%.

These results suggested that COD removal efficiencies remained largely unaffected due to variations in salinity from 0.4 ppt to 20 ppt. Moreover, a minor decline in COD content removal was obtained when the ozone contact time was prolonged from 20 min to 60 min. Salinity variations showed a negligible effect on organics removal, while it influenced the nitrification and denitrification efficiency to a more considerable extent. The salt inhibition can be diminished significantly after the long acclimatization time of the biomass [18].

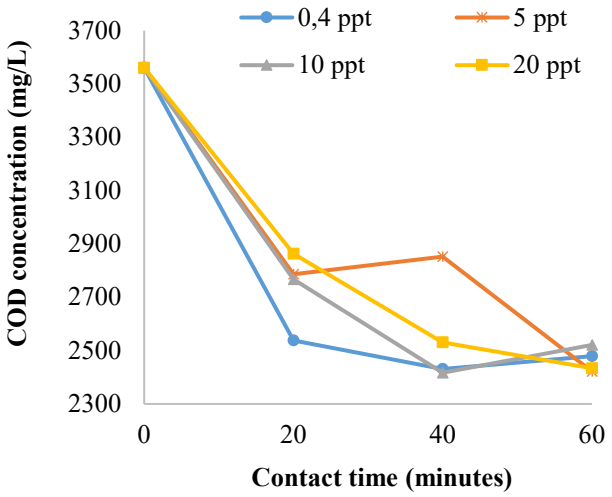

Figure 2: Effect of ozone contact time and the salinity on the COD concentration

The ozonation process and the further oxidation process by accelerating the decomposition of ozone to OH, is one of the wise efforts to be effective in treating leachate. The ozone decomposition reaction is

$$O_3 + HO^- \rightarrow HO_2^- + O_2 \quad (1)$$

$$O_3 + HO_2^- \rightarrow OH^* + O_2^* + O_2 \quad (2)$$

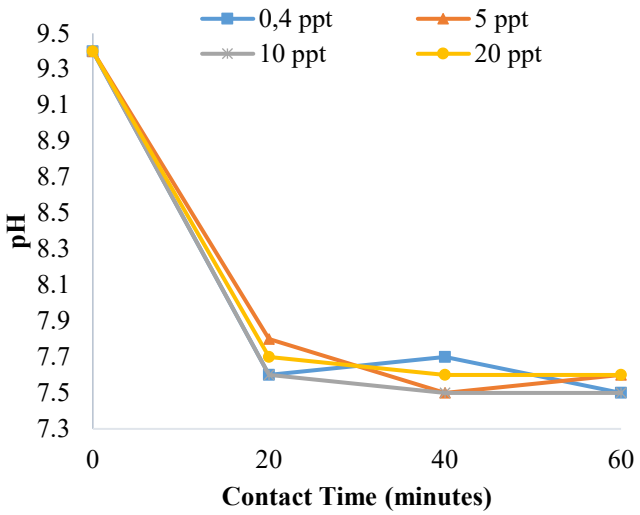

Figure 3: Effect of ozone contact time and the salinity variation on pH

3.4. The change of pH

Applying ozonation at a high leachate pH of 9.4 will most probably lead to a faster ozonation decomposition, therefore a significant enhancement of HO* production which is a more reactive compared to ozone itself, maybe achieved [19]. It is possible that at lower pH, organic pollutants are shifted toward their non-ionized forms. This promotes a lower reactivity toward

ozone compared to the ionized or dissociated form [20]. The conversions of the recalcitrant compound will also alter the occurring pH. The pH gradually decreased as ozone contact time increased, and the variation of effluent pH is depicted in Figure 3. When the salt concentration was 0.4 ppt, effluent pH slowly declined from 9.4 to 7.5 as ozonation time was increased from 0 to 60 min. Furthermore, salts of 5 ppt effluent pH gradually decreased from 9.4 to 7.6 after 60 min of ozone contact time. This might be due to the degradation of macromolecular organic content by ozone to form aliphatic acids, alcohols, and aldehydes and subsequently lead to lower pH.

3.5. The improvement of the biodegradability ratio

From Figure 4, it can be seen that ozonation leads to an increase in the BOD^5/COD ratio. On the other hand, biodegradability changes one indicator to evaluate the ozone's efficiency to treat wastewater [21].

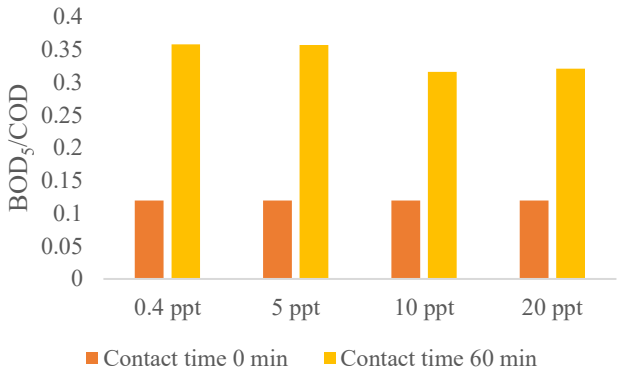

Figure 4: Effect of ozone contact time and the salinity variation on BOD_5/COD ratio of stabilized leachate

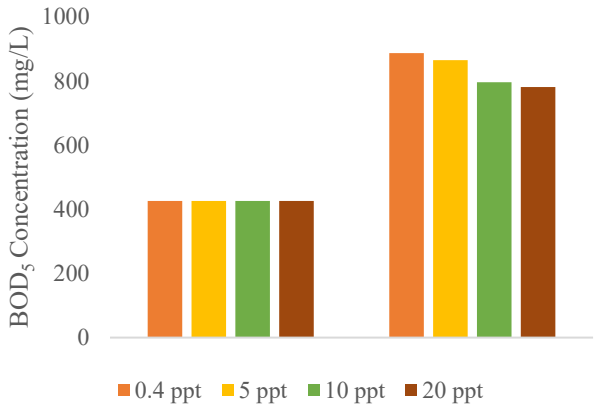

Figure 5: Effect of ozone contact time and the salinity variation on BOD_5 concentration of stabilized leachate

The improvement of biodegradability as measured by the BOD_5/COD ratio are shown in Figure 4. For a 60 min ozone contact time, COD concentration gradually decreased, and BOD_5 concentration slowly increased from 426 mg/L to 865 mg/L at a salinity concentration of 5 ppt (Figure 5). When salinity concentration is adjusted to 20 ppt, biodegradability rises from 0.12 to 0.321. Furthermore, the effect of ozonation is visible at the salinity of 0.4 ppt, and the biodegradability is improved from 0.12 to 0.358. These results indicate that ozonation technology can destruct macromolecular organics into lower molecular weight substances [22, 23] Consequently, the ozonation process yielded a more favorable effluent for biological treatment with a BOD_5/COD ratio of more than 0.3 [24].

Advanced treatment with ozone/persulfate oxidation lowered pH from herbal decoction pieces wastewater and improved biodegradability from 0.16 to 0.55 [25]. Another study with ozone/hydrogen peroxide also enhanced the biodegradability of textile wastewater [22, 23] and color removal [26], as well as the efficiency of biological wastewater treatment [27]. Figure 6 shows that there is a close relationship between salinity and biodegradability values. The higher the salinity in leachate, the non-biodegradable food will be processed biologically.

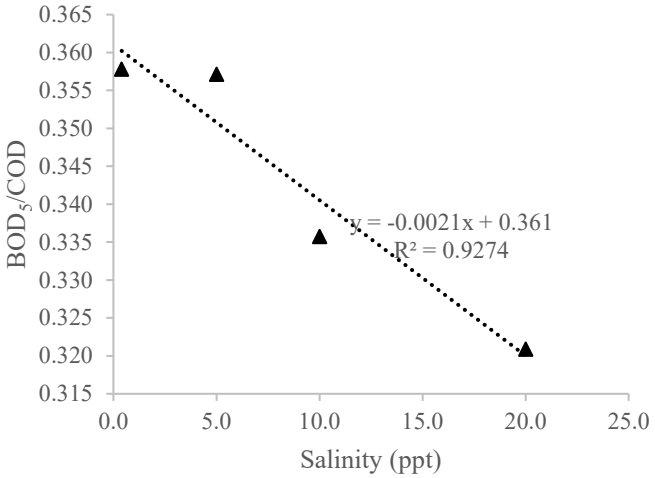

Figure 6: Correlation of ozone salinity and BOD_5/COD ratio of stabilized leachate

3.6. Total dissolved solids (TDS) analysis

Leachate generally contains high salinity and TDS. The TDS values of samples subjected to ozone treatment are presented in Figure 7. In Figure 7, the initial concentration of total dissolved solids (TDS) ranged from 4,000 – 7,000 mg/L depending on salt concentrations. TDS in leachate shows the presence of inorganic salts, organic compounds dissolved in leachate. The higher the salinity due to the higher TDS can increase leachate's toxicity because it can change the ion composition [28]. TDS can be sodium (salt), calcium, magnesium, potassium, carbonate, nitrate, bicarbonate, chloride, and sulfate [29].

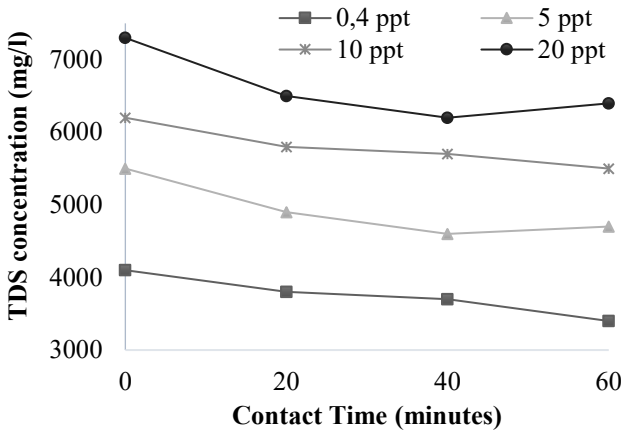

Figure 7: Effect of ozone contact time and the salinity variation on the TDS concentration

TDS primarily revealed the presence of inorganic salts and dissolved organics. The increase in salinity provokes an increase in TDS concentration. The final TDS concentrations increase for all different salinity from 0.4 ppt to 20 ppt. The amount of TDS reflects the availability of the mineralization process and becomes one of the parameters considered for the licensing discharge of landfill leachate. It can be detected in Fig.4 that following the ozone treatment for 60 min of ozone contact time at each salt concentration, the TDS values are 3,400 mg/L, 4,700 mg/L, 5,500 mg/L, and 6,400 mg/L respectively. Overall, ozonation does not significantly contribute to the reduction of TDS.

4. Conclusions

The influence of different salinity conditions on the ozonation of stabilized landfill leachate was studied for several physicochemical characteristics such as COD, BOD_5, pH, and TDS. In this project, ozonation technology was employed to treat stabilized leachate to study the COD removal efficiencies at different salinity concentrations. However, the COD value in the stabilized leachate is still above the discharge standard in conformance with the Indonesian regulation. The results indicated that significant removal of the COD parameter could achieve 31.65% for 60 minutes of ozone contact time with 20 ppt salinity. The estimated COD removal in all conditions (0.4 ppt, 5 ppt, and 10 ppt of salinity variation) was 30.38%, 31.99%, and 29.21%, respectively. Though slight difference of COD removal was obtained, biodegradability, as indicated by BOD_5/COD ratio, can be significantly enhanced by ozonation.

ABSTRACT

The need to update the news at this time is very important. Journalists have responsibilities as their job. Apart from conveying the correct news to the public, they must also deliver it quickly. Journalists who are tasked as news seekers must always be updated about the latest news that is viral, therefore a journalist must be fast and reliable in finding news sources. With this research, it can help journalists work in finding news sources by utilizing public information from Twitter, as one of social media platforms. Social media is considered a source of public information that can involve everyone. In previous research, a system has been created to collect tweets from several news accounts on Twitter which are then grouped into various themes based on cosine similarity. Continuing from the results of previous research, this research obtained data from crawlers stored in the database server can be displayed in the form of a report on a business intelligence application dashboard using a data warehouse. Thus, there is some information that can be used to make decisions. This information includes how much news engagement is, how active users are in commenting, trending posts categories, etc. The results of the research will show how much news is generated based on users who actively like, comment and share news on news accounts that are on Twitter. These results will be used as a reference by journalists to cover live news that is viral.

1. Introduction

Along with technological developments, the distribution and exchange of information are becoming faster and kept growing. Social media is the answer towards conveying information quickly in effective and efficient ways, reaching many people. It is an open media that grants access to all people all over the world, regardless of age, occupation, or social level. Social media such as Twitter, Facebook, MySpace, YoutTube, Flickr, and others have been growing at a tremendous rate and the adoption rate of such media has been skyrocketing, which in turn, has delivered astronomical numbers of users in less than 10 years [1].

Through social media, people can create or participate in the making of every content that can be shared and discussed. The freeness and openness which social media offers were very different and more convenient, compared to other media.

In 2012, six years after Twitter got launched, Twitter had already 140 million active users and was still growing. There were 340 million tweets uploaded in a day [2], which creates a high possibility that social media will give a significant impact on gaining and reaching a lot of worthy news from a lot of people. Aware of this opportunity, we realize the worthy news that is obtained can give a huge impact to journalism. But in this case, social media will require a monitoring system to find out the latest news, which is currently discussed in society through social media. Therefore, journalists will be able to find the latest news effectively and efficiently. Monitoring directly through social media will also help journalists to understand the bigger picture of the latest trending news. The story can be told in many different points of view and also accompanied by several other people's opinions. Of course, social media also has the possibility of spreading false information or hoax news, but this is where the role of journalists is needed. Journalists can help the public to identify and inform the true version of the news or news that is trending.

Social media will become a bridge to connect journalism with public stories and opinions which contain worthy news. There is little doubt that social media has an important role to play in the future of journalism and that it has functioned to be the source of ideas and information [3].

2. Related Work

Social media technology takes many forms, including internet forums, weblogs, social blogs, microblogging, wikis, podcasts, photos or images, videos, ratings and social bookmarking. By applying a set of theories in the areas of media research (social presence, media wealth) and social processes (self-presentation, self-disclosure) Kaplan and Haenlein created classification schemes for different types of social media in their article Business Horizons published in 2010. According to Kaplan and Haenlein there are six types of social media collaborative projects, blogs, content communities, social networking sites, virtual game worlds, and virtual social worlds [4].

Social media has vast growth and clearly matters for society [5]. After interviews with 53 digital journalists, some public Figureures, extra media organizations, opinion leaders, and others in social media were shown to affect news production [6] Journalists use social media to find story leads and to share their work with audiences, which has made journalism more interactive [7].

As one of social media platform, Twitter can be seen as a modern version of person-on-the-street interviews, or even a journalistic stand-in for actual polling. While this was never a reliable way of gauging public opinion, the fact that Twitter makes these vox populi searchable and embeddable vastly reduces the effort that it takes to collect and call upon them. Its use has proliferated to the point that journalists see Twitter as a reliable source of news [5]. An online survey for US journalists with participation of 212 journalists, shows that journalists who use Twitter, potentially causing them to dismiss information that many of their colleagues identify as newsworthy [8].

Investigation in 2012, presidential primary which was the first presidential election where Twitter was used as candidate and party reactions for what was broadcasted in news media, which makes Twitter become a field of new sources for journalistic content [9]. On London Olympic 2012, @London2012 account served as the official account of London Olympic and became another news source for journalistic [10]. Austria's national selection campaign proved that Twitter feeds significantly increase the parties agenda-building power, compared with the impact of parties' news releases [8].

Analyzing the content of tweets in Twitter has also been done outside the journalistic view however performing a similar function. In the context of promoting biking, hashtags become the key point of Natural Language Processing (NLP) tools implementation of the study. Generally, NLP refers to the process of understanding how each word correlates to each other to produce a certain meaning, from the text grammar [11]. In this study, selected hashtags are determined in the first place to assemble the dataset associated with bike commuting. By performing data cleaning to the raw data from Twitter, the tweet frequency could be deduced by a text mining process. To further infer the meaning behind the tweets, sentiment analysis is conducted to determine the polarity of opinions regarding biking. The results show a majority of positive remarks. Biking communities and other related instances could then benefit from the result of the analysis to generate ideas in stimulating more people to bike by understanding the past biking motivations [12]. This also further elaborates how Twitter is a major platform to gain insights on the public's interests.

Another example of tweet classification, is used to analyze user feedback and its impact on a business. The analysis was based on influential term groups that are determined specifically for each different type of business. Then the relationship between the content of tweets and real-world outcomes could be established [13].

Processing data from Twitter means relying towards short texts as tweets only consist of very brief messages. This might be one of the causes of inaccuracy when making inference or classification based on tweets. Researchers on the study of Arabic Twitter users classification also concerned about the issue when performing classification using Twitter data [14]. There are several methods that could be implemented in reducing that by selecting the appropriate method. One of them would be a support vector machine or known as SVM (Support Vector Machine) [15]. In terms of NLP, SVM is one of the machine learning models that is often used. Category classification is the main purpose of SVM implementation [11]. In relation to journalism, trending topics can be classified using SVM. Another study has implemented SVM in classifying tweets into real news or rumour. The consideration that took part in the classification includes the content of the tweet, information about the user that posted the tweet and like numbers [16].

With the same context of this paper, a research has been done on news classification [17]. The news are classified based on religion, business, entertainment, law, health, motivation, sports, government, education, politics and technology as the chosen topics. Although different machine learning approaches are implemented in the research, overall, Naive Bayes Multinomial (NBM), as one of the algorithms for classifying texts, achieved the best performance with 77.47% of accuracy. However, the result of the news data classification only focuses on segmenting the news and does not further provide insight for news trend analysis.

By making use of the data from social media, trend analysis can be done further with the implementation of business intelligence through designing the data warehouse. The process of designing the data warehouse has been introduced in a study which consists of data preprocessing with the objective to clean the data obtained from two social media, Facebook and Twitter altogether, then determining the facts and dimension [18]. Dimension tables are results of denormalization and fact tables consist of the keys that lead to each dimension, along with fact attributes [19]. In that study specifically, before facts and dimensions are determined, as there are two origins from where the data is being collected, data mapping should be performed in ensuring a valid integration of data. The next step would be the transform and load process to complete the whole Extract, Transform and Load (ETL) procedure before proceeding into the data warehouse.

Another research involving the integration of business intelligence on social media analytics has been explored in the case of brand personality analysis [20]. The details about the brand followers, tweets related to the brand, reviews from the employee of the respective brand, tweets posted by the brand

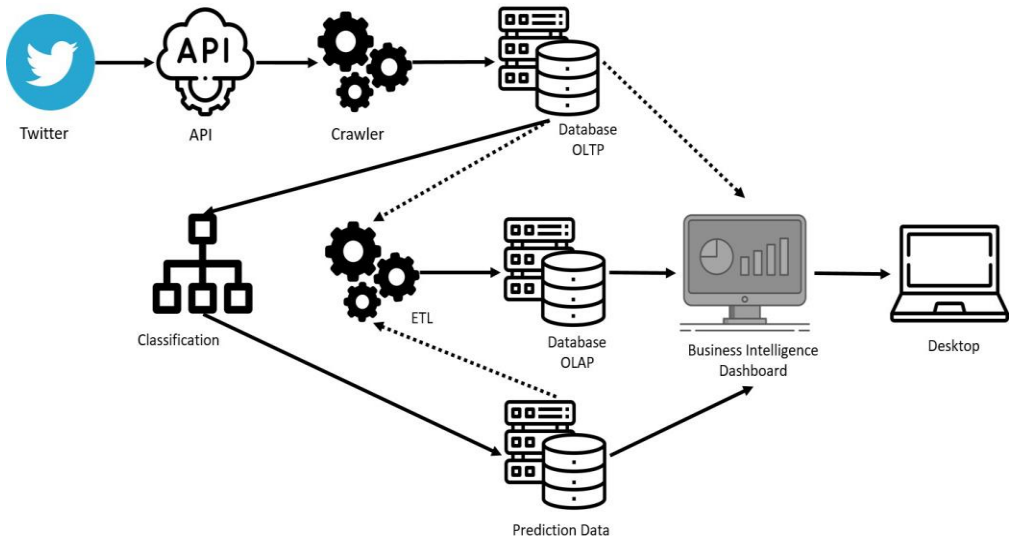

Figure 1: Business Intelligence Architecture

themselves comprise the dataset used in the research. Classification of the data into five brand personality categories supports the analysis on the chosen brands. The researchers suggested that decision making strategies can be improved with a sufficient business metrics measurement, in this context, gained from the activities associated with the brand on social media. This result could be achieved as trends are provided within social media data and useful for many types of organization [21]. Hence, classification of social media data incorporated with business intelligence could present more insight for enhancement in business strategies.

3. Proposed Method

In this research, a Business Intelligence application will be built into the architecture shown in Figure 1.

The following steps should be taken to develop the system as shown on the image above:

3.1. Data collection

At this data collection stage, there are processes including:

- Collecting data from selected Social Media Platforms such as Twitter through the Social Media Application Programming Interface (API) available on each platform.
- Data retrieval will be carried out periodically by crawlers who have been created with the Social Media API Token input which is useful for authentication and authorization in data retrieval.
- Thus, the results of data retrieval will be saved on the database as raw data.

3.2. Content Analysis

At this stage of content analysis there is an intermediate process including:

- Retrieving data for content analysis from each data on each Social Media platform.
- The data taken is then processed for text classification using SVM into 10 news categories.
- The results of text processing will be stored in the database as analysis data.

3.3. Data warehouse process

At this stage of the data warehouse process, there are processes including:

- Retrieving data for the ETL process that comes from the results of content analysis (in the content analysis database) and the results from the crawler (in the raw data database).
- The data that has been loaded will then be carried out by ETL, such as counting comments, posts, likes, and so on.
- Data resulting from the ETL process is then stored in the data warehouse.

3.4. Client Side

On the client side, there are several processes that are carried out so that the application dashboard can be accessed by users, including:

- API is used as a bridge between applications and data (both raw data and finished data in the data warehouse)
- The application will request data to the API by inputting the API Token as authorization and authentication, so that with this API people are not able to access data directly.

4. Analysis Results

4.1. Setting Variables

There are some variables used in this study as shown Table 1. In Figure 2 shown the ERD (Entity Relationship Diagram) from the transaction database of the scrapping system or can be called OLTP (Online Transaction Processing), before ETL (Extract, Transform, Load) process.

Table 1: Setting Parameter

Variable	Value	Description
Number of Twitter Account	10	Kompascom, Detikcom, BeritaSatu, MediaIndonesia, Tempo.co, BreakingNews, TMCPoldaMetro (Traffic Management Center Polda Metro), MNCNewsChannel (Media Nusantara Citra News Channel), TribunIndonesia and CnnIndonesia
Duration	20 days	Ranges from 27th November 2020 - 17th December 2020
Batch	8/days	Each batch has a three-houred range
Threshold Cosine	0.7	For measuring similarity of two comments
Threshold number comments	10	If number comments more than 10, it can be considered as top news

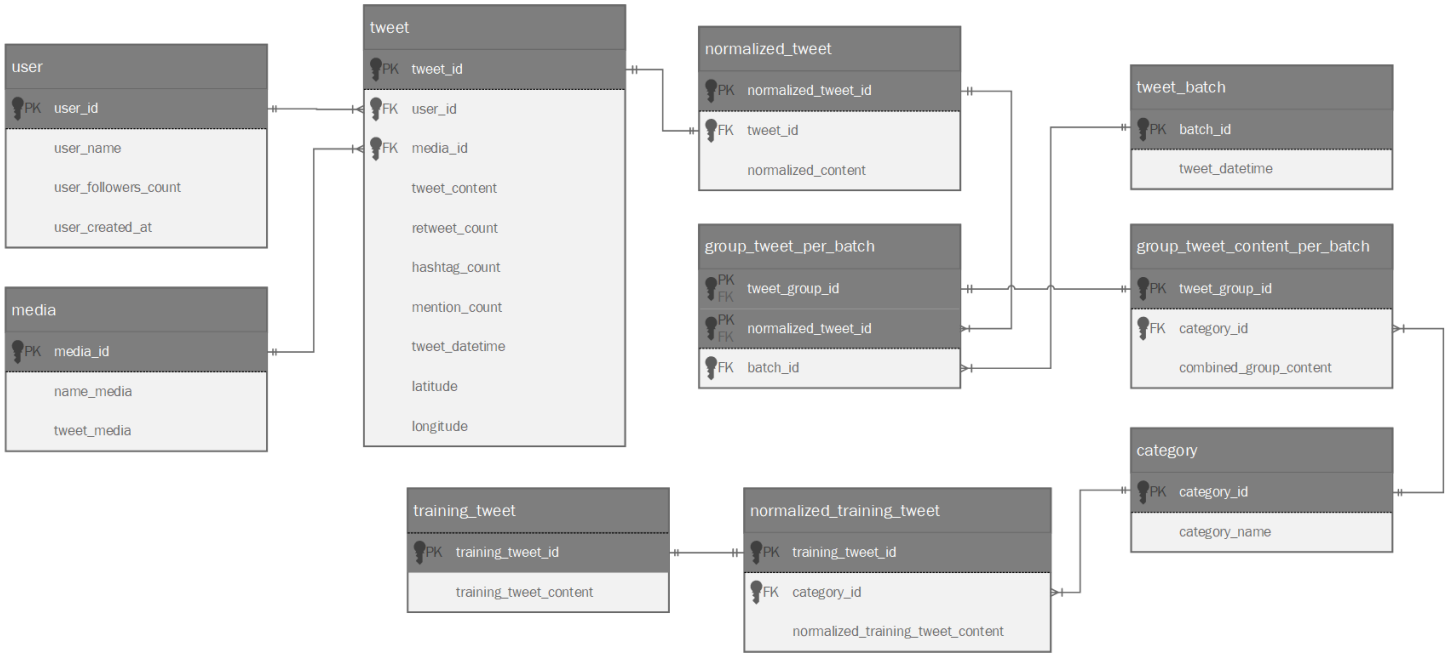

Figure 2: ERD

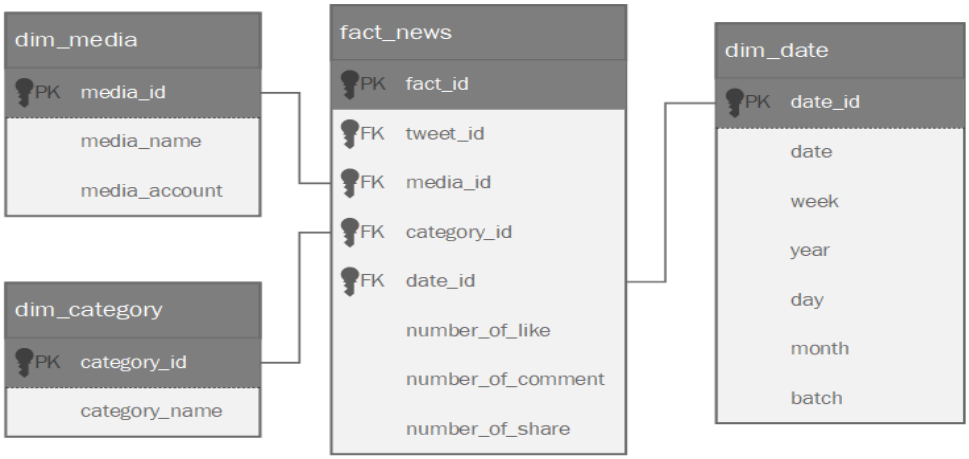

Figure 3: Star Schema

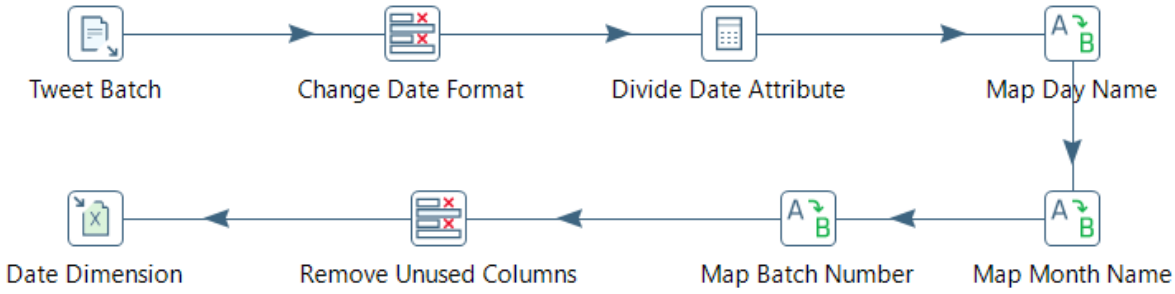

Figure 4: Date Dimension

4.2. ETL Process

In Figure 2 shown the Star Schema from OLAP (Online Analytical Processing), after ETL (Extract, Transform, Load) process. During the tweet extraction, when the time has entered the new batch, the datetime is directly inserted into the database in the server using a Python script. In order to generate the date dimension as shown in the star schema, the date obtained from the tweet extraction which started from 27th November to 17th December 2020 and shown as Tweet Batch data in Figure 3, is processed further using Pentaho. In Pentaho, the datetime format requires conversion as an error is encountered on the existing datetime from the database. Afterwards, the datetime is then divided into days, week, month, year, and batch. Week and year are represented in numbers, whereas days and month are mapped to their corresponding names. Batch itself is obtained from the hour of date, where it is then mapped into batch numbers ranging from 1 to 8. Date dimension is finally created after removing unused columns that are only used for processing purposes but not necessarily needed in the date dimension.

4.3. Performance Analysis

Each three hours, called a batch, data is evaluated. The batches are at 0-3, 3-6, 6-9, 9-12, 12-15, 15-18 and 21-24 having eight batches in total for each day as shown in Table 2. Table 3 showed tweets distribution for each category after classification with SVM. Table 4 showed the top three categories in each batch on the first day of extraction.

Table 2: Batch Time Detail

Batch	Created Time
1	00.01-03.00
2	03.01-06.00
3	06.01-09.00
4	09.01-12.00
5	12.01-15.00
6	15.01-18.00
7	18.01-21.00
8	21.01-24.00

Table 3: Tweets Distribution

Category	Number of news
Economy	11
Health	10
Entertainment	4137
Culinary	0
Lifestyle	317
Automotive	11
Politics	1991
Sport	0
Technology	284
Travel	0
Total	6761

Table 4: Distribution Top News in First Day

Day	Batch (Time)	Number top news (Based on Shares)
Day 1	Batch 1	Entertainment, Politics, Automotive
	Batch 2	Politics, Entertainment, Lifestyle
	Batch 3	Entertainment, Life, Politics
	Batch 4	Entertainment, Politics, Lifestyle

	Batch 5	Politics, Entertainment, Automotive
	Batch 6	Politics, Entertainment, Automotive
	Batch 7	Entertainment, Poliis, Technology
	Batch 8	Politics, Entertainment, Lifestyle

After all the data has been loaded to the data warehouse consisting of three dimensions, the data stored is transformed into a business intelligence dashboard. Figure 5, 6, 7, and 8 were shown as an overview and example of a business intelligence dashboard. Some insights that were taken based on chart analytics in the business intelligence dashboard in Figure 5, 6, 7, and 8 will be discussed further. Figure 5 and 6 shows the first part of the business intelligence dashboard which contains some analytics with higher quality information retrieval than Figure 7 and Figure 8, such as Total Number of Like, Comment and Share, Number of Share by Batch and Category, Number of Like, Comment, and Share by Category and Media, etc.

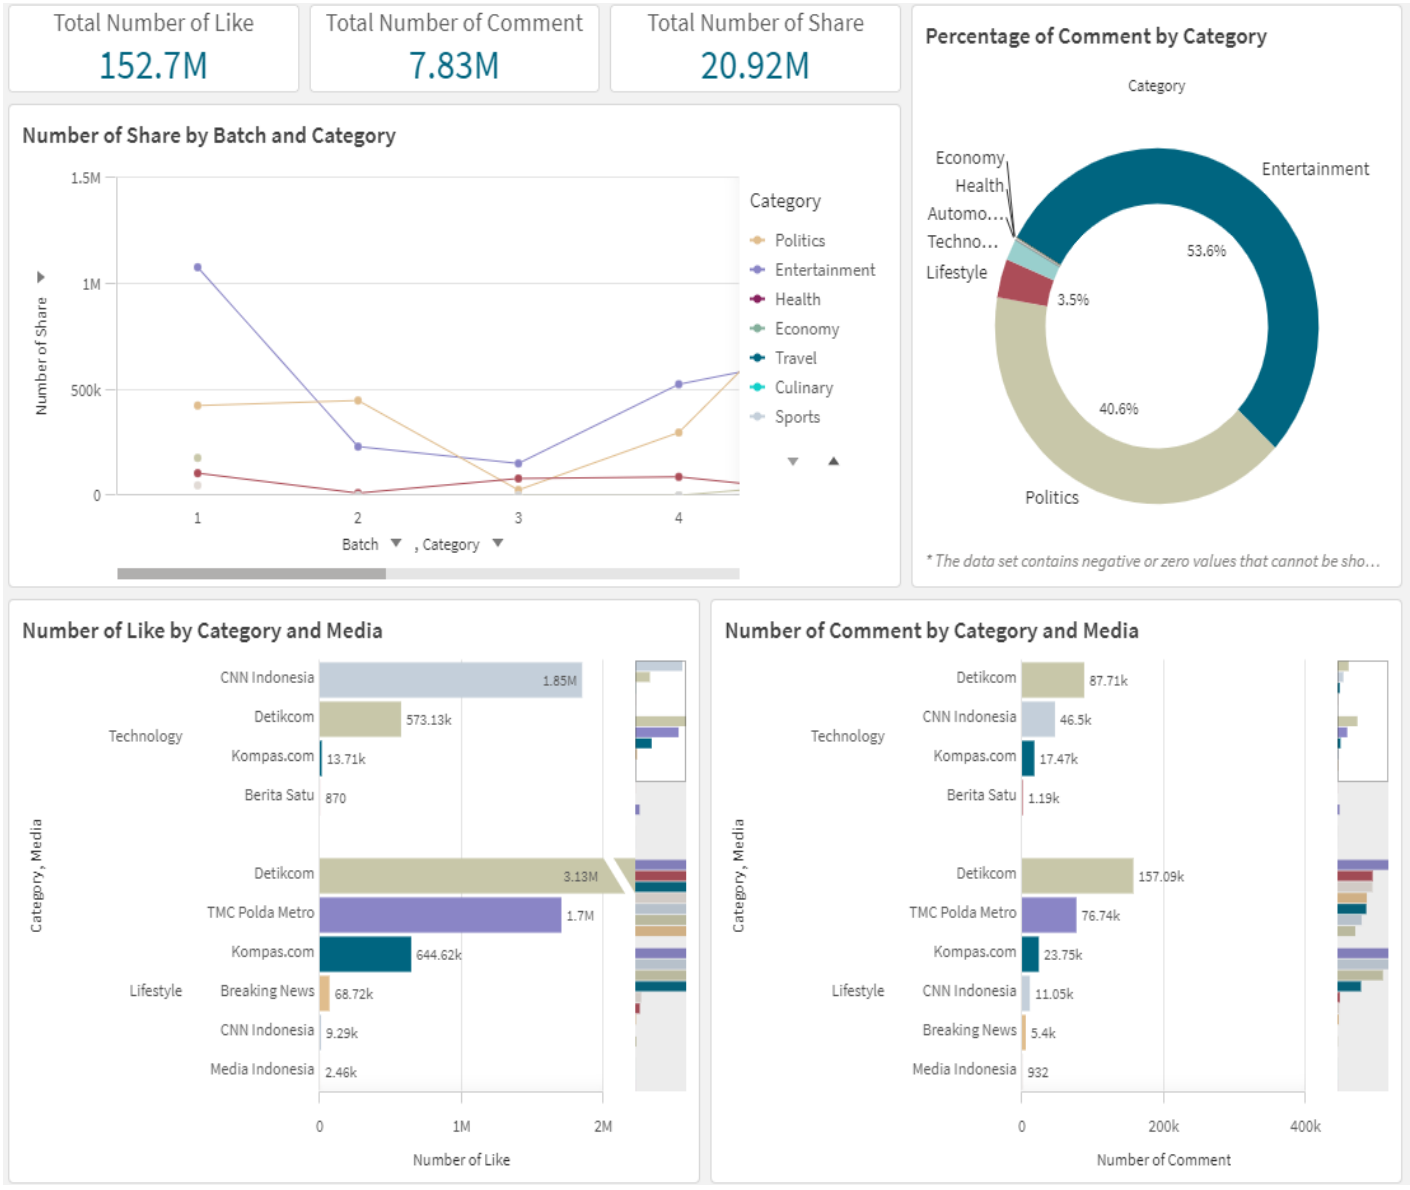

Figure 5: Business Intelligence Dashboard I

Figure 6: Business Intelligence Dashboard II

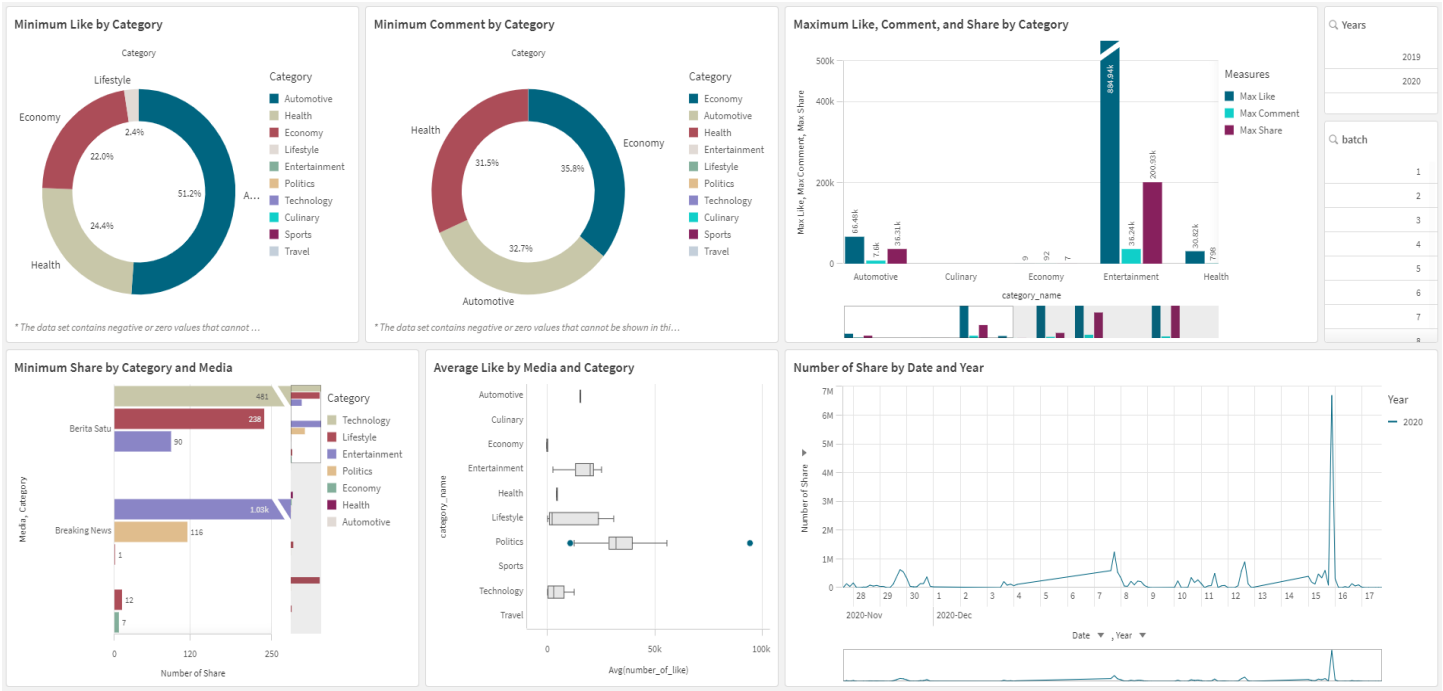

Figure 7: Business Intelligence Dashboard III

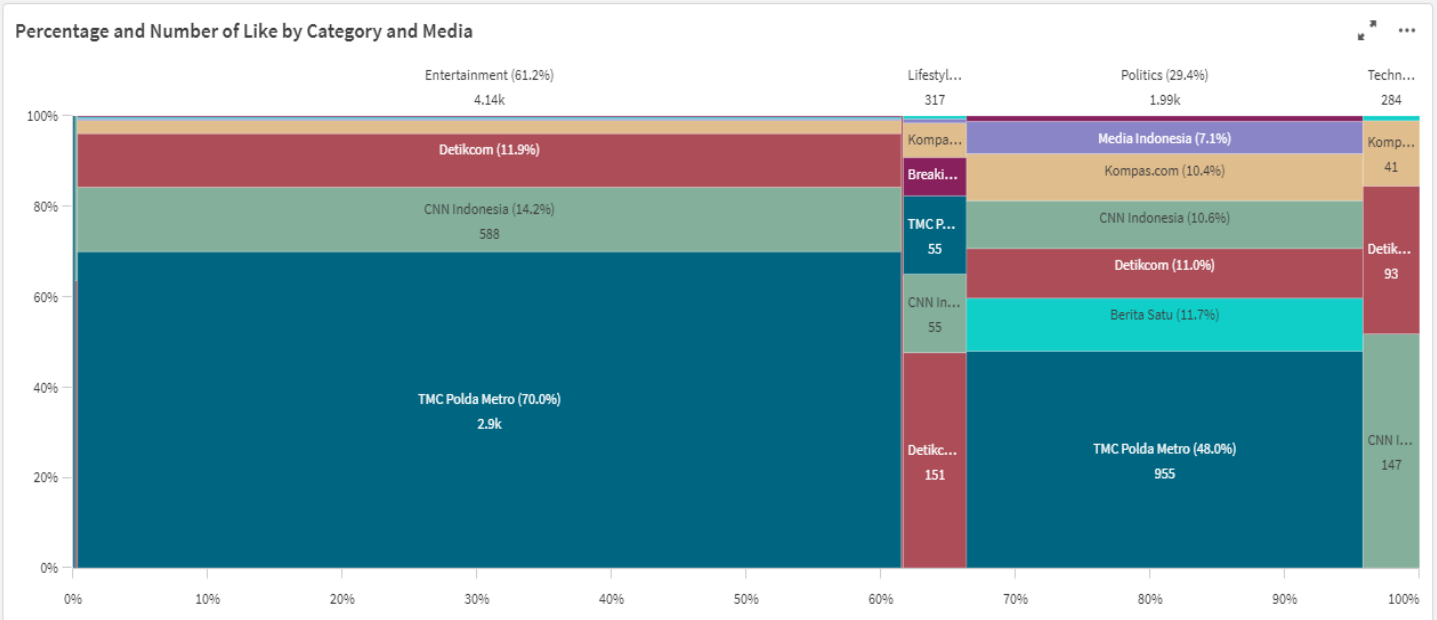

Figure 8: Business Intelligence Dashboard IV

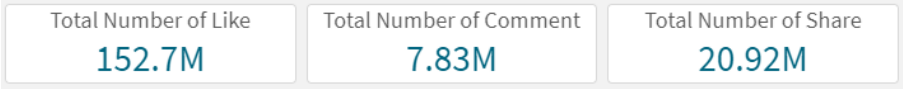

Figure 9: Total Number of Like, Comment, and Share

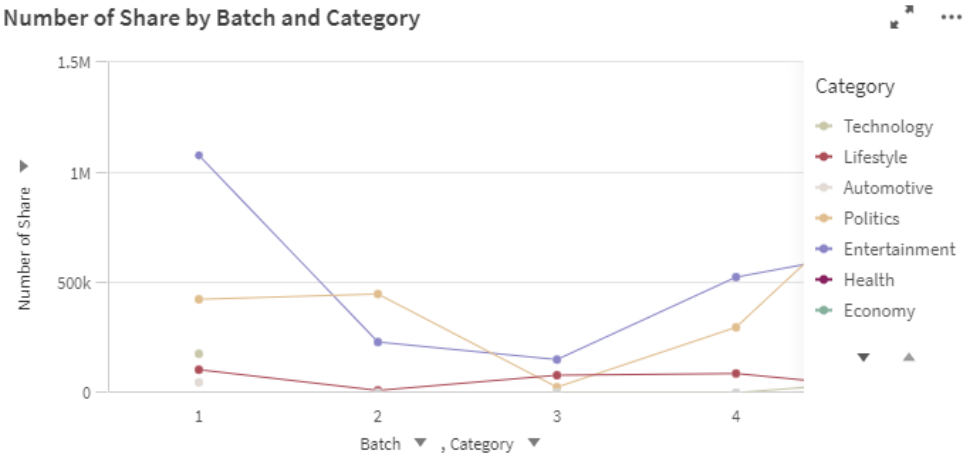

Figure 10: Number of Share by Batch and Category

Figure 9 shows a detailed screenshot on the total number of likes, comments and shares from the whole dataset. They represent the amount of engagement involved in Twitter for the specific period in 20 days. From the description in Figure 8, it could be seen that the total number of comments have the lowest value compared to the other two. This indicates how less frequently users leave replies on tweets they are interested in, whereas users mostly are prone to leave likes on a tweet as it requires less effort. Shares in another case require a moderate effort and in Figureure 10, it shows that entertainment is leading in batch 1. Data presentation in terms of batches, allows journalists to observe more about what kind of news attracts engagement of the public in specific time of day. Hence, it could provide understanding of what content type is at peak on certain hours, as well as how active users are participating in sharing information.

In terms of percentage, users have commented the most on tweets related to entertainment, politics and lifestyle. Considering the COVID-19 pandemic outbreak that started since the last month of 2019 and is still ongoing, the circumstances have impacted people's lifestyle, one of them would be staying at home more. This resulted in Twitter users behavior which is exploring more regarding something fun despite being mostly at home, as represented by the entertainment category in the top first position in terms of comment percentage shown in Figure 11. Politics category with a close comment percentage, is positioned second. During the specific chosen time period of tweet extraction, there are several political issues that users are intrigued about, leading

to higher interest in the topic. On the other side, the least percentage of comment is obtained from the economy category, indicating that the critical economic condition in the present is either quite a sensitive issue or nothing very significant, resulting in a fewer interaction between social media users.

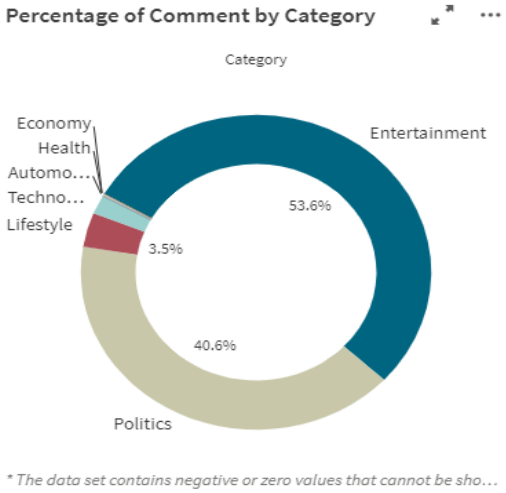

Figure 11: Percentage of Comment by Category

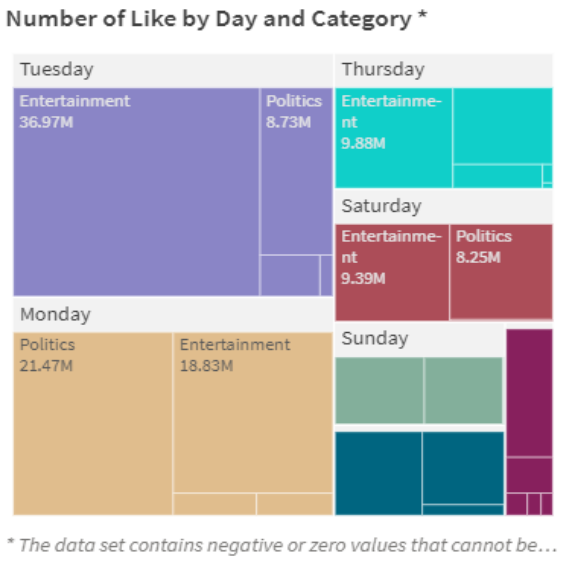

Figure 12: Number of Like by Day and Category

On a larger scale, the data can be further observed in terms of days. If batches tend to be very specific, days would display more generic data. This kind of data functions to assist and give insight on users' engagement routines. From Figure 12, on a daily basis, mostly weekdays, Twitter users frequently like tweets related to entertainment. This indicates that the users' daily interest is mostly fixed to the entertainment category. Hence, journalists can create more opportunities in searching for news that are able to raise high engagement from the public by being aware of entertainment updates during the specific period.

Number of likes within the politics category as shown in Figure 13 represented a quite unbalanced trend among the listed media. High engagement on politics category only appears to be most applicable for TMC Polda Metro, but specifically not much for Breaking News. There are two factors that allow this to occur: the number of tweets posted on that category or the attention that the tweet is able to acquire (by providing a more engaging tweet although the content is similar that triggers further response from other users, etc). Obviously if there are more tweets posted on the category, they will record a higher number of likes. However, this does not bring the possibility of having fewer tweets related to the category on the specific media, but still obtaining numerous likes down to the drain, as long as the tweets conform to the preferences of the users. In this case, Breaking News seems not to be focusing on the politics category. However, on the other side, it could be seen that most media did not cover much about the economy category. Based on this analysis, for more references regarding potential news on a specific category, journalists might be able to learn from the top media with the greatest number of likes, as the engagement towards a certain category does not apply to every media.

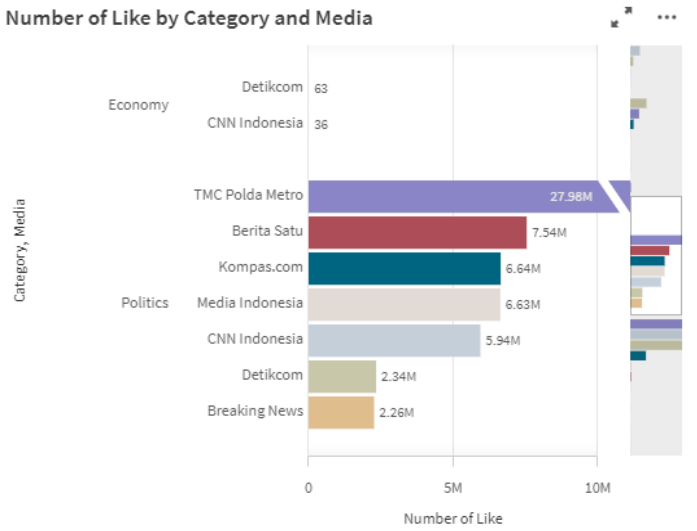

Figure 13: Number of Like by Category and Media

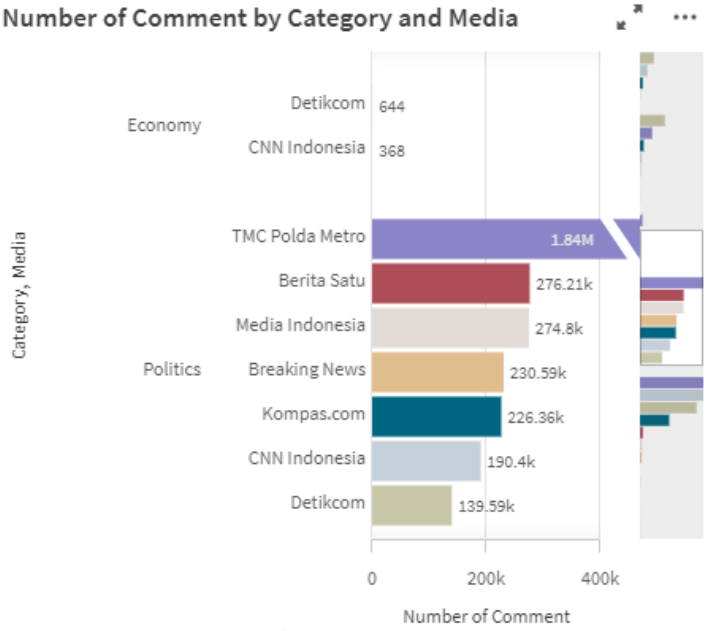

Figure 14: Number of Comment by Category and Media

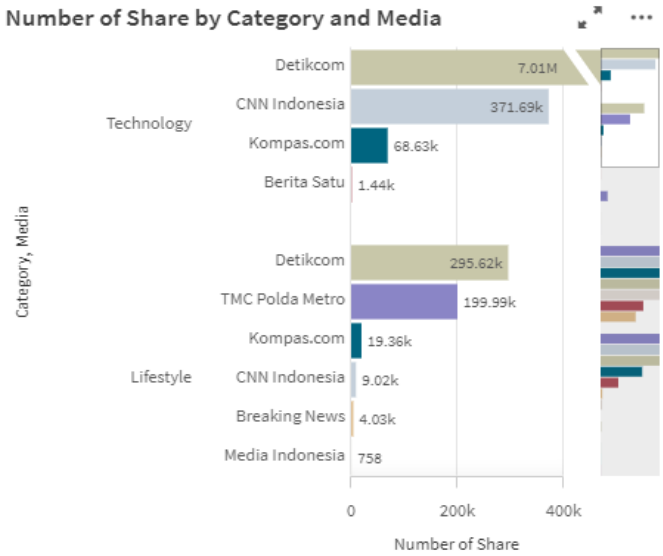

Figure 15. Number of Share by Category and Media

In Figure 14, it showed there is a significant difference between two categories for some media. The top Five Media and the others media in terms of the politics category, which was TMC Polda Metro, Berita Satu, Media Indonesia, Breaking News, and Kompas.com had the most commented tweet, which means people are more likely to reply and retweet these top five media. It also can be seen that at the certain time, there was no critical news related to the economy category. Comments can serve as discussion boards with unlimited sources and participants, limited by the need to validate information. Hence, journalists can dig and validate further information from the candidate news through comments. The comments will help provide more insight into news. If there was some big or high-quality news that occurred and uploaded to Twitter, it is speculated that the number of comments will be a balanced number for each media, either it will be a large amount of number or some range amount of number. Therefore, journalists can identify how worthy the news is but in more efficient and effective ways.

In Figure 15 can be seen the number of shares by category and media which can help decide trending news to look furthermore. Categories with a balanced number of shares in the chart have a bigger probability of containing a good quality and worthy of sharing news. With a lot of people sharing or retweeting the tweet, it concluded the news is well-known by a large number of both segmented users and other users on Twitter. Then, it will be useful for journalists to catch up nowadays trending topics in every category that is available.

Maximum like, comment, and share for each category will represent the most trending category discussed in society which can be seen in Figure 16. Showing the quantity data of the maximum engagement will be useful for journalists in defining the standard quality of news in the trending category news. At a certain time, Politics was the top trending category with 891.82k number of likes, 50.25k number of comments, and 394.71k number of shares. Therefore, when Politics hits the top trending in another certain time, the engagement's amount can be compared to gain comparison and insight. Over time, journalists can define the average of maximum engagement of the trending category which contains high-quality tweets that are worthy of sharing especially as news. Meanwhile, the lower limits of maximum engagement can also be defined by these circumstances. Hence, journalists will be able to choose the best quality of news in the category and process the news.

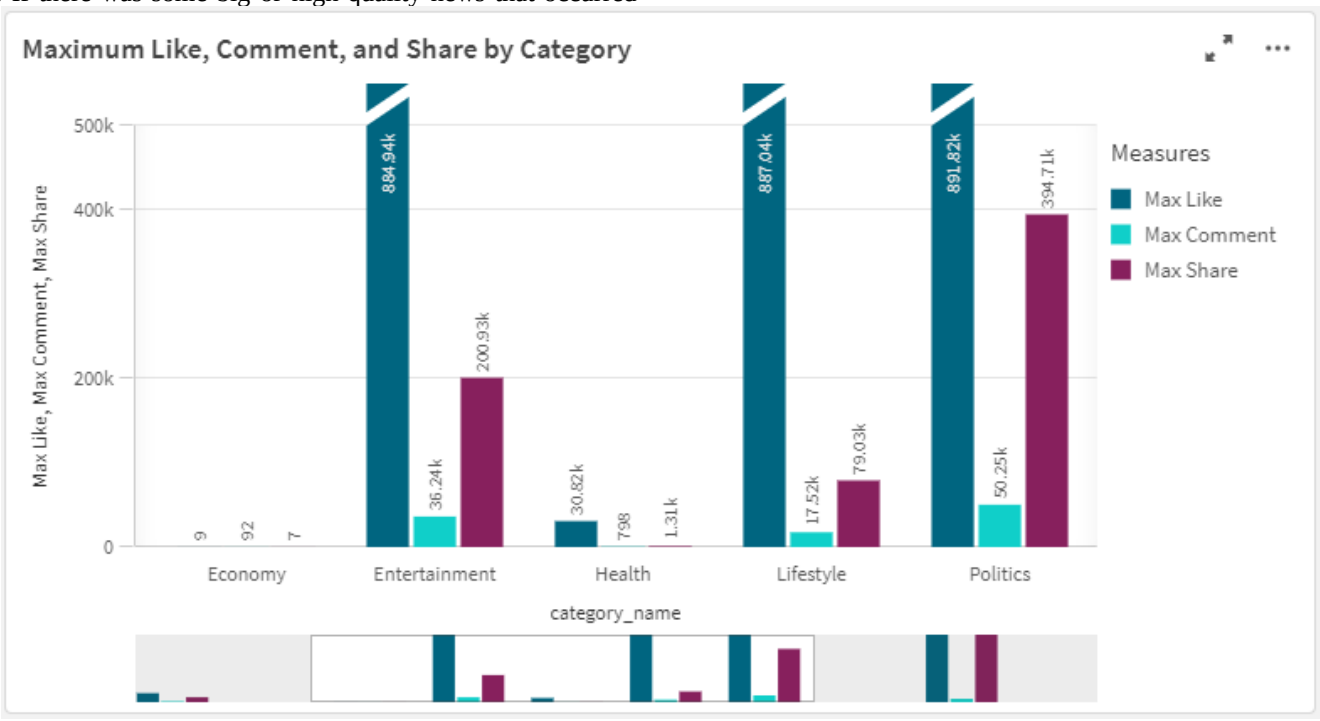

Figure 16. Maximum Like, Comment, and Share by Category

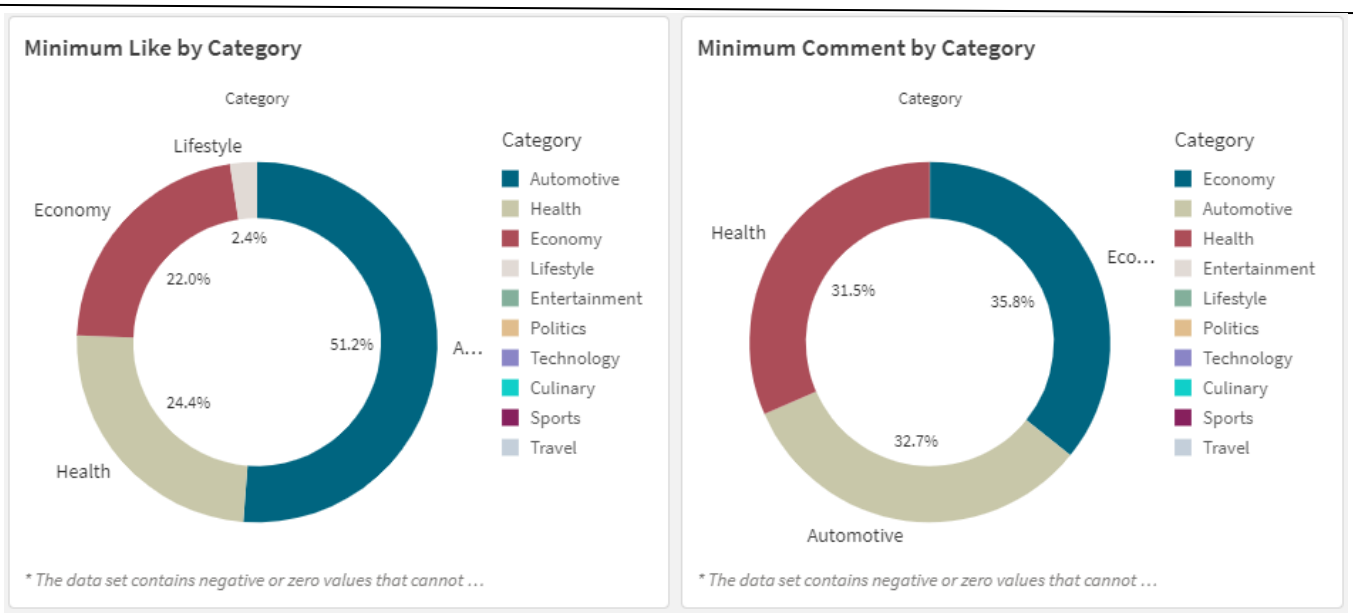

Figure 17: Minimum Like, Comment by Category

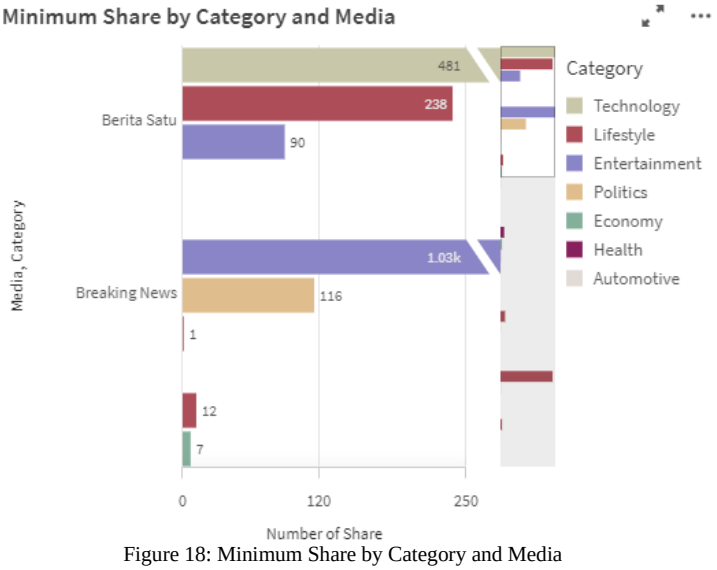

Figure 18: Minimum Share by Category and Media

Figure 17 and Figure 18 shows minimum count data of likes, comments, and shares by Category and Media which are able to help choose and exclude the certain category with the smallest percentage of likes and comments or smallest number of shares. With the standard defined, furthermore, the process of choosing the category and news will be easier. On the other hand, a big number of percentage and amount define that the certain category news was one of trending topics. In Figure 17 the entertainment category in Berita Satu minimum likes was 90, it can be seen there a large number difference to compare with the technology category. It concluded Berita Satu is not the right media to find entertainment news.

5. Conclusion

With processed and presented data at the dashboard, journalism will be helped a lot, for viral news information, through batch, date, day, news's category, news media and others. Through many data mining and other processes, Twitter was proven capable of providing and helping journalists with news sources and conveying the correct news to the public in effective and efficient ways. This process will help and give the journalism world a solution for effective, efficient, and unlimited news sources.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Normalized Metered Energy Consumption (NMEC) is a solution for investors in determining the best energy-saving strategy for buildings. But on the other hand, investors need a fast and reliable evaluation results in measuring how effective the savings methods they use without wasting money. To address this issue, we selected Facebook's latest predictive time series method called Prophet Algorithm's which adapts the regression modular additive model with hyperparameter advantages that can be optimized based on time series parameters by automation. Although the Prophet is a relatively new method in time series predicition, but it can show promising results that offer even more easily implemented by beginners for business purposes. Furthermore, it allows gaining insight into each periodic component of the forecast separately and helping to assess energy management issues. At the end of the experiment, the Prophet model achieved an excellent result by showing the Root Mean Square Error (RMSE) below 10 points for the next two-month forecast.

1. Introduction

Energy wastage is still an enormous problem around the world, even about 40% due to inefficient city building energy management systems [1,2]. Challenges in the recent energy industry are cost-effective deficiencies, model inaccuracy, and lack of prediction procedures determining the use of energy that can be measured periodically to make significant decisions [3]. Investors have invested a lot of money to improve sustainable building's energy efficiency to reduce costs and emissions. The question is whether energy efficiency has worked success effectively reducing energy consumption to the maximum? Then the next question is how effectively the method works in the influence of various external factors? In previous research on energy efficiency, it concluded that the best strategy is not only to apply energy-saving technology. But energy management strategies can also be an effective solution in minimizing energy disposal [4].

Energy benchmarks are still a consideration for building owners to be able to measure the energy consumption performance of building with similar structures to different geographical or weather conditions. Based on the results of energy benchmark analysis, building developers can implement appropriate and proven energy-saving methods by the best practice of other buildings. The core keys to knowing the maximum energy savings are by determining the energy demand model before the development action (baseline model) and determining the energy demand prediction model after the implementation of the energy-saving method (report model) [5]. Meanwhile, the new energy benchmark introduced in California Energy Policy for verifying the success of energy-saving in 2017, namely NMEC. The NMEC considers the weather and building characteristics to normalize energy consumption data. Normalization indicates a statistical process for adjusting energy use before and after energy management improvements in a wide range of conditions related to independent variables for more sensible results that can describe actual energy consumption patterns [6].

Previously researchers successfully used the Hybrid model Artificial Neural Network (ANN) with an average Mean Absolute Percent Error (MAPE) value of 4.2% [7]. On the other hand, the model still has limitations where it can give a decent prediction for only the next 72 hours. Another research uses LSTM performs well in terms of accuracy, but it requires more data compared to other methods [8]. Until now, various algorithms have been explored widely for predicting building energy consumption. However, many external factors such as holidays or high season trends that change occasionally in many cases, which cannot capture by models. And it's hard practically to produce feasible analysis results for many business users.

In this research, the authors had the idea to implement the Prophet method to predict building energy use based on historical

*Corresponding Author: Abba Suganda Girsang, Email: agirsang@binus.edu

trends that address dynamic business needs and require time efficiency. Prophet demonstrates higher accuracy and ease of implementation to see movement trends periodically for business purposes with flexible requirements after studying the evaluation results in several previous studies such as Autoregressive Integrated Moving Average (ARIMA) [9], and Seasonal Trend Decomposition using LOESS (STL), ARIMA, Neural Network Autoregressive (NNAR), Trigonometric Exponential Smoothing State-Space model with Box-Cox transformation (TBATS), Linear, S. Naïve in [10]. Prophet can also effectively solve the problem of easy forgery using real-time prediction of the user behavior to determine the right time to switch on the security sensor on the smartphone [11].

We believe that there are still fewer applications for prophet methods, especially in predicting energy consumption in buildings. Although it is still new development methods, the prophet method can surpass various other approaches with the concept of an additive model to estimate predictions based on historical trend patterns. For further development, the authors combine affecting normalization techniques to improve the quality of the model. The purpose of the research will later contribute to producing baseline models that can minimize external effects (e.g., weather, building characteristics, etc.) as an accurate evaluation model of building energy savings in the future. And it could be a consideration for investors to prepare a strategy for the implementation of high-value prolonged energy savings.

2. Literature Review

2.1. Energy Consumption Performance Indicators

Factors that affect energy consumption in buildings generalized into 7 categories [12]:

- Weather (e.g., air temperature, wind speed, solar radiation, humidity),
- Building characteristics (e.g., building functionality, square area, number of floor levels),
- Characteristics of occupants (e.g., presence of residents on weekdays and holidays),
- Building service system (e.g., cooling/heating conditions, availability of water heaters),
- Activities and habits of residents (e.g., turning off lights during the day),
- Social and economic factors (e.g., education level, energy cost), and
- Needs for indoor air temperature.

The behavior and habits of the occupants are quite difficult parameters to identify regarding the complexity and differences of each occupant observed [12]. One of the most possibles solutions is to use real measurement data such as historical data on KWH electricity usage of the previous period. Based on four energy consumption performance methodologies on buildings explained in [13], we chose to use statistical analysis (regression model-based) as the best option to overwhelm the time limitation problem. Statistical analysis methodology refers to the measurement of Energy Performance Intensity (EPIs) in buildings derived from a combination of supportive variables with robust relationships to energy usage.

2.2. Structure Dependent Energy Usage /Loss (SDE U/L) Overview

Energy consumption estimates in buildings usually consider dry-bulb temperature, known as normalization of weather Heating and Cooling Degree Days (HDD/CDD) [14]. HDD/CDD is the standard term of measurement units for conducting weather modeling. However, this method can provide misleading solutions because unable to keep up with the dynamics of extreme weather changes by limited inputs and ratio concept. The development of this method continued to be carried out throughout until recently the SDE U/L method introduced to the public. The SDE U/L method uses the concept of linear or nonlinear models considering the coefficients of wind speed, humidity, radiation, and outdoor temperature. Moreover, several important building factors such as building size, window size, construction connection that ignored in the application of various previously normalization methods [15]. SDE U/L consists of 3 main factors, namely weather, characteristics of buildings, and behavior or habits of building occupants.

$$g_{bl}(T, W, R,H, P)=a+aT+bR+cW+dH+eP, \quad (1)$$

In steady-state, (1) represent linear models to calculate the heat balance of the building denoted by $g_{bl}(\cdot)$ function. The equation made base on heat/cool generated by building appliances that improve overall electricity use. Coefficients *a*, *b*, *c*, and *d* are parameters that depend on the building's characteristics. Parameter *a* relates to insulation, building size, etc. that affect air temperature. Parameter *b* associates to the direction of entry of sunlight, the size of the window, the material of the window that affects the intensity of radiation. While parameter *c* is related to air ventilation, the height of the building, the open space that affects wind speed. And parameter *d* relates to the infrastructure that affects the humidity of the room. Parameter *e* could consider as the number of residents of the building. While non-linear models have the same concept as linear models, but the application of methods developed with Multi-Layer Perceptron. Where each input node consists of T, R, W, H, P, and when the data do not exist, then the node input will be omitted. The model is optimally attached when the RMSE result is smaller than 10^{-10}.

2.3. Prophet Overview

The prophet method concept is adapting the Generative Additive Model (GAM) method that emphasizes regression models with non-linear smoothers on the regressor [16]. As a difference, Prophet only uses time as a regressor when there is the possibility of some linear and non-linear functions of time as essential components. Prophet can generally meet the main criteria of good time series models described further in [17] such as forecasting, modeling, and characterization. One of the advantages adapted from the GAM model is the flexibility in accepting trend changes in the data source and quickly in the process of model fittings so that users can change the parameter model interactively to improve accuracy results [18]. Prophet's model base on the concept of a decomposable time series with three main components: trend, seasonality, and holidays that represent in (2) [19]. The additive regressive model result of

combination decomposable time series denotes as $y(t)$, which will describe per movement how the Prophet model fits data distribution.

$$y(t)=g(t)+s(t)+h(t)+\varepsilon_t, \quad (2)$$

In (2), $g(t)$ describes the trend of non-periodic changes in the time series model. $s(t)$ describes periodic changes such as weekly, yearly. And $h(t)$ depicts the continued effect of holidays on a nation that has the potential to cause unusual trends and sometimes effects occurring over one day. Notation errors are distinct changes that the model cannot predict. The fundamental in a decent non-linear model is to make sure the model can describe the growth trend and how the continuation corresponds to the addition of data. With dynamic trend movements, the basic approach used is the logistic growth model follows in (3).

$$g(t)= \frac{C}{1+exp(-k\,(t-m))}, \quad (3)$$

C represents carrying capacity, k is the growth rate, and m is the offset parameter. Carrying capacity is the maximum number of individuals that can be supported resources in an ecosystem. One of the modifications implemented in the Prophet method is to define changepoints, which variable C changes to $C(t)$ defines carrying capacity expected at any given time. Then Prophet defines a vector containing a rate adjustment of $\delta \in R^S$, where δ_j is the change in the rate at the time of s_j. Then base k will be couple with adjustment at that point: $k + a(t)^T\delta$. Where vector $a(t)$ - $\{0, 1^S$ is defined in (4) to limiting that the k rate increase will only occur when the t measurement time exceeds the changepoint time occurred.

$$a_j(t)=\begin{cases} 1\ ,if\ t \geq s_j \\ 0\ ,otherwise, \end{cases} \quad (4)$$

The k rate variation is also followed by an offset parameter change to connect the endpoints of the segments. The correct adjustment at changepoint $\boldsymbol{j}$ is easily computed as and presented as follows in (5):

$$\gamma_j=\left(s_j-m-\sum_{l<j}\gamma_l\right)\left(1-\frac{k+\sum_{l<j}\delta_l}{k+\sum_{l\leq j}\delta_l}\right) \quad (5)$$

The result of modification of prophet model is presented in (6):

$$g(t)= \frac{C(t)}{1+exp(-k+a(t)^T\delta\,(t-(m+a(t)^T\gamma)))}, \quad (6)$$

In determining the changepoint on the model, the analyst can perform manually by defining a specific potential signifiant date as an example of a national holiday. Or automatic by applying the principle of historical trends to variable δ and sets the flexibility rate in the model by parameter τ. For the record, the application of historical trends in δ will not influence the central point growth rate of k. Thus, when the parameter τ value is 0, the curve of the fitting model will be linear or basic logistics. Accuracy in the prediction model becomes the final parameter as the evaluation material, but the error value of uncertainty would still occur due to the unconstant growth rate. Uncertainty calculates assuming that future predictions will have an average pattern of frequency and enormous changes in growth rates in history. To increase accuracy, we can configure the τ parameter based on the variant result of the data. The increasing value of the τ parameter will also increase the flexibility of the model fitting to historical patterns and reduce the error loss value. However, high flexibility is directly proportional to the increased interval of uncertainty.

In the Prophet model, the seasonal component $s(t)$ provides adaptability by permitting periodic changes in a different kind of seasonality. There are many cases of multi-period seasonality as a capture result of human behaviors. For instance, a 5-days workweek implies effects on a time series that repeat each week for over a month, while vacation schedules at the weekend and school breaks can generate a trend that repeats each year. To fit and forecast these effects we must specify seasonality models that are periodic functions of [time] t. Prophet relies on the Fourier series to provide a lenient model of periodic effect. P is the regular period the time series will have (e.g., P = 365.25 for yearly data or P = 7 for weekly data when time scale in days).

The impact of a particular holiday on the time series is often similar year after year, making it important incorporation into the forecast. The component $h(t)$ indicates predictable events of the year including those on irregular schedules (e.g., Halloween or Labor day). To utilize this feature, the user needs to provide a custom list of events. Fusing this list of holidays into the model is made straightforward by assuming that the effects of holidays are independent. After the model fitting process, the model will make predictions based on trends and seasonality that successfully captured previously in (1). Trend assumptions are based on the same date in the previous period. The output of the model will be yhat variables that indicate the predicted results. And another component yhat_lower and yhat_upper, which describes uncertainty intervals of prediction.

2.4. Related Works

In this section, it will explain in more detail about the methods used along with the evaluation results obtained by the previous research. Previously researchers used four approaches as a comparison to create baseline models of energy prediction such as Support Vector Machine (SVM), Long Short-Term Memory (LSTM), Nonlinear Auto-Regressive (NAR), Autoregressive Moving Average (ARMA) [8]. It could conclude that each method tested can exceed ARMA performance. While LSTM performs well in terms of accuracy, it requires more data compared to other methods. Hybrid model Artificial Neural Network (ANN)-based Short Term Load Forecasting (STLF) models with a combination of boolean metering systems to convert input values into vector bit shapes carried out in [7]. The experiment conducted using energy consumption data on 93 homes in Portugal from 2000 to 2001. The experiment proved a pretty good result with an average Mean Absolute Percent Error (MAPE) value of 4.2% as well as a maximum MAPE of 18.1%. In the evaluation results, there are limitations where the model can give a decent prediction for only the next 72 hours. They suggest further development with variable use of air temperature and weather and consider the presence of residents by distinguishing routines on weekdays and weekends to improve the accuracy of

prediction models. Other research with the concept of short-term load forecasting for the next 24 hours had a comparison between ANN and SVM methods, with an accuracy rate of 62% for ANN and 60% for SVM [20].

Another comparison method based on a data-driven approach on two buildings to get predicted results of energy consumption per hour meet the model calibration criteria defined by the American Society of Heating, Refrigerating, and Air-Conditioning Engineers (ASHRAE). Various methods such as multiple linear regression, adaptive linear filter algorithms (least mean square (LMS), normalized least mean square (nLMS), and recursive least square (RLS)), and Gaussian mixture model regression (GMMR) used in this experiment [21]. Once evaluated, the GMMR method can go beyond a variety of other adaptive approaches. Cause GMMR is a non-linear method so it can better show the performance of building energy consumption. For an additional record, the data-driven method's large number of parameter inputs does not ensure better accuracy. It is due to the model's difficulty in achieving a convergence state in finding the best solution due to the combinatorial explosion problem. Table 1 shows the summary of related works, together with the dataset, method, and achieved experiment results.

Table 1: Summary of Related Works

Ref	Dataset	Method	Result
[7]	Energy Consumption on 93 Homes in Portugal	Hybrid ANN	Gives an average MAPE around 4.2 %.

		GMMR	

3. Experimental Design

In this section, we describe the framework that we used to perform data normalization until the implementation of prediction methods for a group of buildings with the same characteristics as the comparison with other groups. Moreover, we explain the steps and configuration parameters for the numerical assessments of Section 4.

3.1. Dataset

The data in this experiment consists of 3 datasets: weather, electrical consumption of buildings, and building characteristics. Dataset acquires from meter measurements of more than a thousand structures across the United States [22]. The data consist of measuring water, electricity, gas, hot water, and steam meters. ASHRAE's 1000-building electrical energy consumption data has an hourly interval with a measurement period from 2016 to 2017, thus meeting the regularly spaced criteria in the time series. Once the data are collected, the data going through the selection phase since some buildings do not have full sensors or there might construction conditions in certain areas, possibly making the sensor measurement value 0.

In ensuring a valid measurement where the building is inhabited, then the maximum missing data is set at 15%. Besides, missing values are replaced with a value of -999 or with interpolation automation techniques based on data of the previous and next day. To eliminate outliers on data, the plot analysis method used in looking at the trends of each district's building sensors. In this simulation, one building was randomly selected with an N/A value of less than 10 percent to provide the best results. The historical movement of energy consumption over a year with hour intervals could be seen in Figure 1.

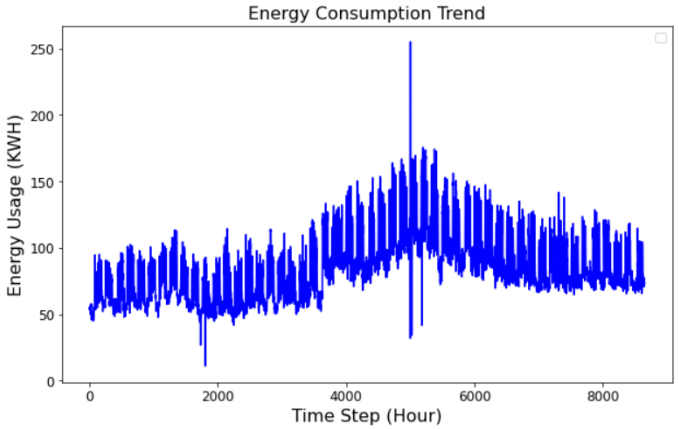

Figure 1: Electrical Energy Consumption Trend on Building with Id 1082.

3.2. Weather Normalization

Then in the stage of weather normalization, implementation is carried out by SDE U/L method to consider meter measurement with weather conditions as well as building characteristics as inputs. Normalization has done using a multi-layer perceptron with configuration four input nodes, two hidden layers, and one output node. For the normalization process, the base temperature sets to 9.6°C, which refers to the average temperature of the building area on measured year. The configuration of base variables used in normalization could be different depends on the needs of research in analyzing the most influential weather factors for the development of energy-saving methods in the future. The trend of electricity consumption after normalization could be seen in Figure 2. Differences in radiation normalization results through the same data could be seen in Figure 3. Because there is no additional information about the behavior of the occupant, thus the input node in parameter P be ignored on the model. For the

final training model configuration, we use two hidden layers with each consisting of seven nodes and a learning rate of 0.04.

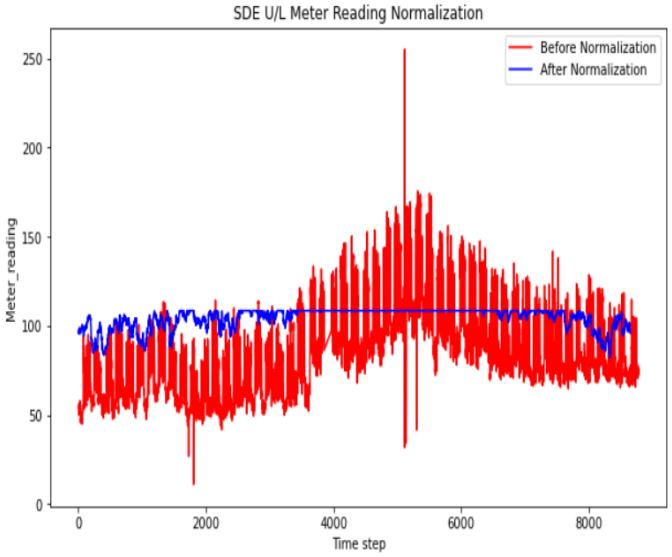

Figure 2: Temperature Base Normalization Implementation.

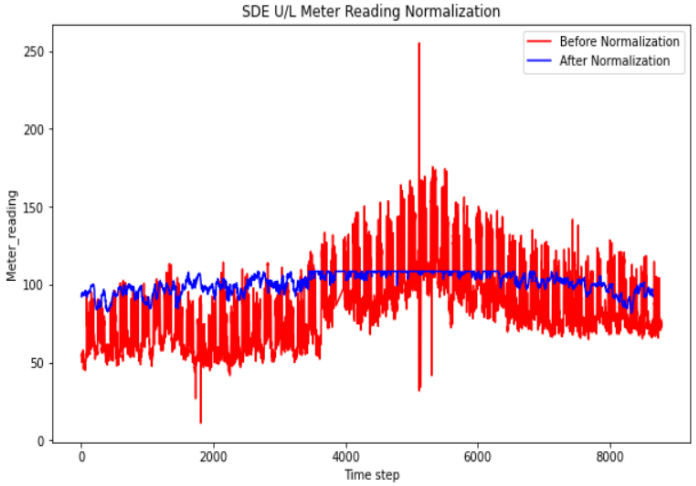

Figure 3: Radiation Base Normalization Implementation.

3.3. Prophet Framework

Preparation of the prophet prediction model carried out in the following stages:

- Split data into three sets, training set, validation set, and test set. The proportion we used in splitting the dataset into training, validation, and test sets is 80%, 10%, and 10%, respectively as a reasonable option given the sufficient amount of data [23]. Training sets were used to train models, while validation sets were used for tuning hyperparameters, and test sets were used for evaluation of models.
- Initialize the carrying capacity value for each row of data presented in the stamp column. The stamp value is not continuously adjusting to the market size at the time of measurement. The market size here refers to the maximum amount of energy consumption per hour. Therefore, carrying capacity plays a role to keep the curve of the model does not exceed the market size value specified before. For example, in the winter season (December - February), the carrying capacity value is determined based on the maximum value of energy consumption between those three months. For the implementation of carrying capacity, minimum value can be used floor variable.
- Defines specific dates such as national holidays that repeat periodically for each year in the form of data frames like Christmas, labor-day, etc.
- Add custom seasonalities such as school holidays in the long-term summer holidays for up to 3 months.
- Change the changepoint ratio on the model to set the flexibility of the model. By default, change points have automatically added to 80% of trends with the reason for creating more projection lines so that there is no overfitting at the end of the prediction. But to be aware, adding a changepoint ratio will make the model have too much flexibility and have overfitting side effects. The default changepoint ratio value in the Prophet method is *0.05*.
- Apply fouries series yearly seasonality tuning as a smoothing method when trend patterns have high fickle frequencies. For example in tropical conditions, the weather changes rapidly.
- Divide the data into 2 columns, ds for the date (timestamp) and y for the feature column which is the result of normalization of building energy consumption as input in the model.
- Repeat steps e through f to find the best model through a final evaluation using RMSE.

3.4. Evaluation Metrics

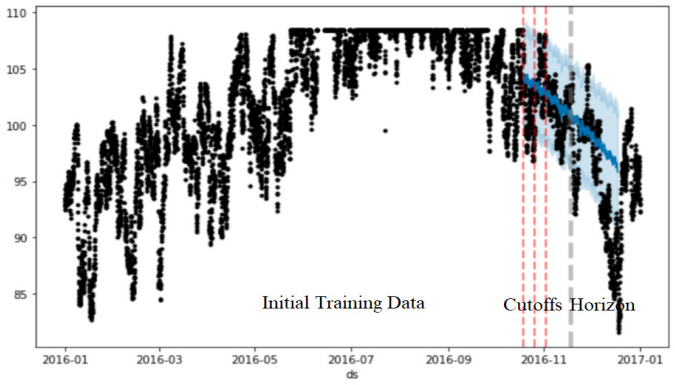

Figure 4: Cross Validation Periods.

3.5. Environment and Parameter Setting

These experiments were conducted on Google Colab using GPU accelerator with Python programming language. The models created using the Prophet forecasting model through the logistic growth model as a trend factor base. The final configuration of the Prophet model in this experiment could be seen in table 2.

Table 2: Prophet Parameter Setting

Parameter	Setting
Changepoint prior scale	0.1
Seasonality prior scale	10
Holidays prior scale	10
Seasonality mode	additive

4. Result

4.1. Analysis

An overview of the final prediction Prophet model could be seen in Figure 5. Prophet model movement trends illustrating through blue lines that can fit the pattern of data diversity well. The red vertical lines in this figure indicate where the potential changepoints placed, and by default, are uniformly placed in the first 80% of the time-series data. Looking at how the curve in fittings movement of the model, Prophet prove can handle a single outlier in the middle of the data. In the last section of Figure 5, we can also see how the prophet made predictions for the next two months.

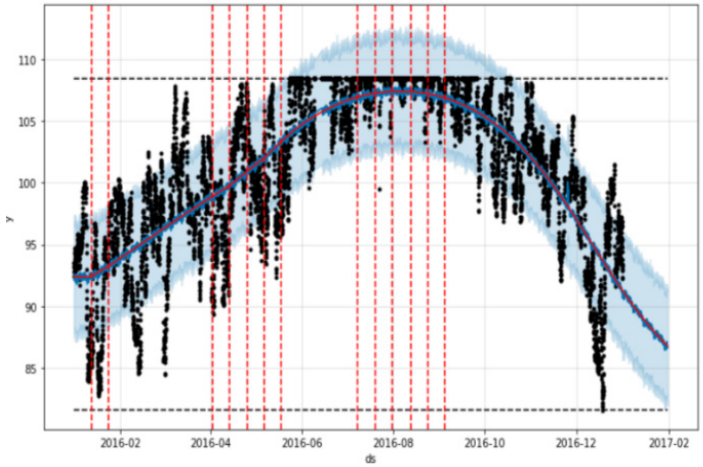

Figure 5: Forecast Plot with Prophet Built-in Method.

Observing the weekly plot provide by Prophet in Figure 6, we can conclude that the usage of electricity consumption in the building increased on weekdays following the function of the building as an office. Also, through advance analysis, we can see daily electricity usage in Figure 7 decreases at 8 p.m. and increases at 2 a.m. And the annual trend in Figure 8 shows energy usage increases in the mid-season and decreases in the late season.

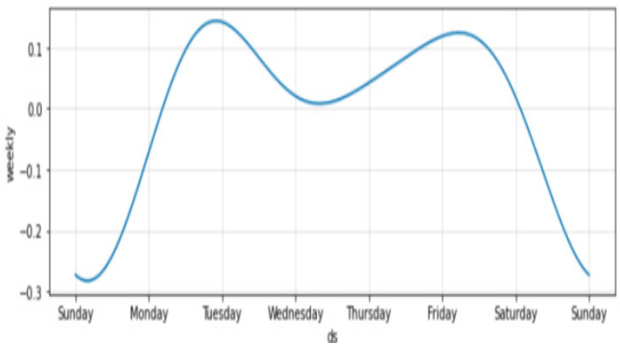

Figure 6: Weekly Plot of Energy Consumptions.

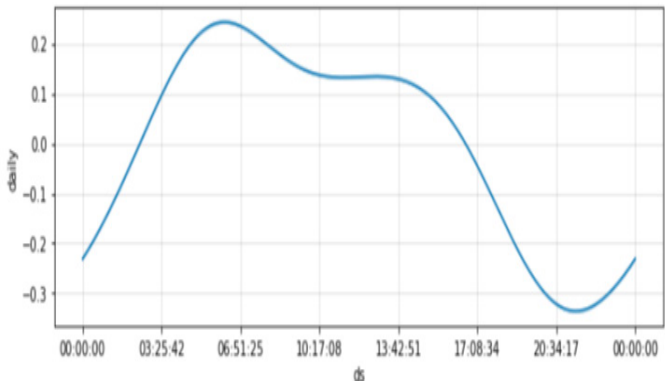

Figure 7: Daily Plot of Energy Consumptions.

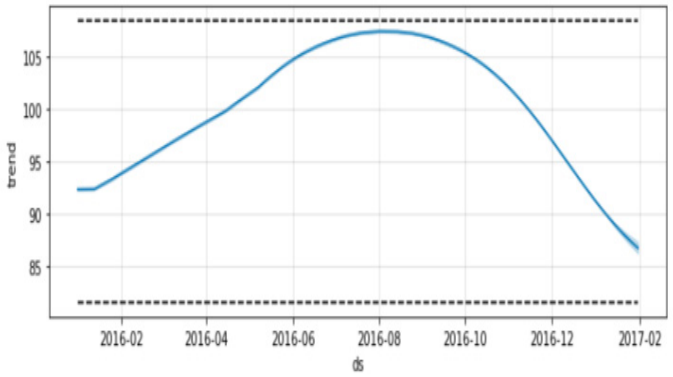

Figure 8: An Overview Plot of Energy Consumptions by Date.

4.2. Evaluation

We could investigate the trend of cross-validation errors for the next two months' predictions in Figure 9. The blue line shows the RMSE, where the mean takes over a rolling window of the dots. We realize that errors below 5 points are typical for predictions one month into the future and that errors increase up to around 8 points for predictions two months into the future.

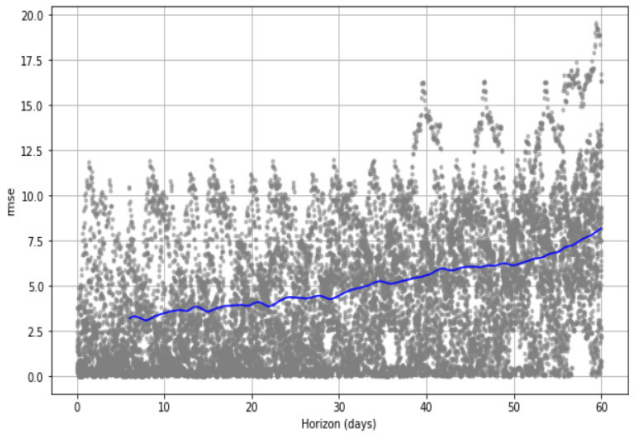

Figure 9: Cross Validation Visually Over Time.

Another experiment had conducted to further evaluate the Prophet's performance with another well-known time series algorithm, LSTM. For LSTM training model configuration, we use two hidden layers, with each consisting of 50 LSTM units,

dropout 0.25, batch size 32, and a sliding window of 720 as the accumulated number of hours in one month. And weather dimensions applied previously in the normalization process were used as inputs in the LSTM model.

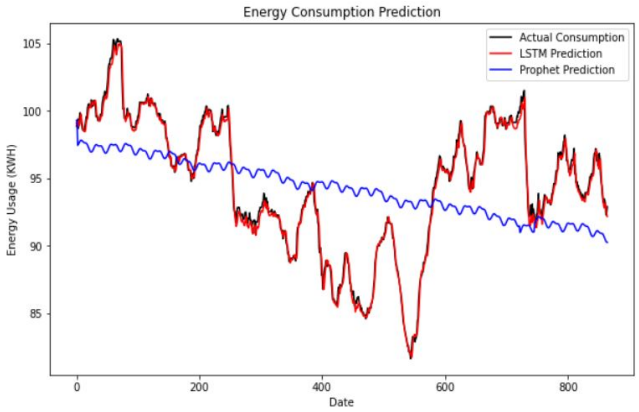

Figure 10: Prophet, LSTM Prediction and Actual Comparison.

Looking at the results on the graph in Figure 10, it appears prophet performs well in fitting data without overfitting. On the other hand, LSTM tends to shows easily overfitting results with RMSE around 0.005 points and training execution time around 330 s. Meanwhile, Prophet with just one-dimensional feature input showed a short training time of 20 s, 15 times faster than LSTM. Comprehensively LSTM still needs to apply an approach to minimize overfitting. Adding more data to LSTM maybe become the solution to have reasonable predictability results.

Cross-validation may be used for tuning hyperparameters of the model, as can be seen in Figure 11. Here parameters are evaluated on RMSE averaged over a 30-day horizon. However, different performance metrics may be acceptable for various problems. In this scenario, the changepoint prior scale is specified within [0.001; 0.01; 0.1; 0.5], while the seasonality prior scale within [0.01, 0.1, 1. 10]. Seeing the result, whereas an increase of changepoint ratio may offer minimum RMSE, nevertheless, it tends to form the model overfitting after all.

	changepoint_prior_scale	seasonality_prior_scale	rmse
0	0.001	0.01	6.932333
1	0.001	0.10	6.948724
2	0.001	1.00	6.928149

5. Conclusion

With the rapid advancement of machine learning-based techniques, especially deep learning algorithms, the Prophet method is gaining popularity as alternatives way among researchers across diverse disciplines. The objective of this study was to improve the baseline model by introducing the implementation of prophet methods with its practical advantages combine with weather normalization method SDE U/L. Furthermore, we would highlight some of its ability within this experiment in addressing a variety of external factors that affect electricity consumption, such as modeling holiday effects, custom seasonalities, and additional regressor. As a result, SDE U/L – Prophet models could considered successfully predicted values without overfitting in the 30-day forecast with maximum RMSE around 5 points. In advance, more data will make predictions give better results. In the future, the Prophet can be a leading solution that offers practically insightful, flexibility, accuracy, speed, and simplicity for many non-technical users in various time series cases.

We hope that this study result could be a consideration for the researcher by using Prophet methods in various time series cases, as many advantages that Prophet have compared to other time series prediction methods. And especially for practitioners to be more efficient in choosing the best energy-saving based on the prediction analysis result of the energy savings method used. So that in the future practitioner does not have to wait until months to evaluate the final results before further modification considering the many costs incurred in the method selection process. This provides a useful tool for analysts to gain insight into their forecasting problem, besides just producing a prediction.

ABSTRACT

Traditional networks have difficulty in meeting the technological developments and the continuous increase in the size of data to be processed. Software-Defined Network (SDN) approach has emerged as an alternative to traditional networks. SDN separates the control and data planes from each other and manages the network over the control plane with flexibility and cost advantages. In networks with large data flow, SDN with multiple controllers will be useful to manage the network because a single controller may cause network interruptions and data loss. After deciding on the use of multiple controllers in the SDN approach, problems are encountered with the number of controllers that should be used and the placement of these controllers. Due to the increase in the coronavirus epidemic that has affected the whole world in recent months, the need for pandemic hospitals has increased. However, considering the establishment costs of pandemic hospitals, it will not be possible to establish these hospitals in every desired location in the impact area. For this reason, positioning pandemic hospitals at more strategic points will provide these hospitals with a wider coverage area and more functionality at lower costs. In this paper, a genetic algorithm-based SDN is presented for pandemic hospital localization. The number of coronavirus infected people of each city in Turkey is taken into consideration as well as the city distances in the ULAKNET data set within the Topology Zoo database. For the best localization of pandemic hospitals, the Dijkstra algorithm is used to best cover the cities where the coronavirus epidemic is at a minimum distance from the cities. In this paper, the number of controllers is set as 10, and the experimental results are given with maps and graphics.

1. Introduction

This paper is an extension of work originally presented in 2019 4th International Conference on Computer Science and Engineering (UBMK) [1]. In this study, firstly, the coronavirus coefficients of the cities on a certain date are added to the data file of [1] in addition to the coordinates of each city in the Ulaknet data set within the Topology Zoo database. Secondly, the fitness function values are obtained by dividing the coronavirus coefficients of the cities in the selected solution set by the arithmetic averages, as well as the algorithm used to find the minimum distances of the incoming solution clusters to other cities. In this way, while developing random solutions during Genetic Algorithm (GA) generations, solution clusters at the minimum distance to cities are found based on Dijkstra Algorithm (DA), and the solution set with cities with a high number of coronaviruses become the optimum solution set. The aim is to find the locations of pandemic hospitals that are close to the cities on the map, have a high coronavirus coefficient, and best cover cities that need hospitals.

With the continuous development of information technologies, the Internet has turned into a complex and large-scale infrastructure that profoundly affects people's working and lifestyle [2]. However, the complexity of the traditional network makes the networks difficult to manage. SDN resolves these issues based on the principle of separating the data layers. SDN enables easy management of the traditional network seperating data and control planes. By this way, SDN provides many benefits such as simplifying network management, improve network utilization efficiency, support network innovation, reduce network delays.

*Corresponding Author: Eda Nur Hascokadar, edahsckdr@gmail.com

As the network structure expands, a single controller SDN architecture may be difficult to manage a comprehensive network. To increase the scalability and reliability of the network and to avoid a single point of failure, there is a need for a logically centralized [3], physically distributed multi-controller network architecture. In multi-controller architecture, the Controller Placement Problem (CPP) is encountered. With CPP, the number and location of the controllers have a large impact on end-to-end latency reduction and network performance within the network.

2. Related Works

CPP has been intensely studied in the literature. Papers [4-16] explain the different CPP problems in detail for the proper single controller or multiple distributions of controllers and clarify the benefits of SDN.

In [4], the authors present as a solution to CPP and minimize the response delays for a large-scale network using a hybrid GA-PSO algorithm. Using the hybrid algorithm, the best position is obtained in a shorter time compared to GA.

In [5], the authors solve the distributed controllers' placement problem and apply different scenarios in CPP for the distribution of the network load.

CPP with different aspects such as transmission delay, control plane utilization, and controller workload distribution are studied in [6]. A hybrid gradient descent optimization method with GA is implemented in two different network scenarios and effectively established the balance between the use of the control plane and the network response time.

In [7], the authors examine different controller placement models and their accuracies. Other goals of the study include maximizing the controller capacity, reliability, flexibility while minimizing the network latency, deployment cost, and energy consumption. Concerning CPP, the authors present a feature selection technique adopted in the literature to illustrate the search methods used by the controller placement models.

In [8], the authors present a hierarchical K-median algorithm for CPP. Also, by dividing the large number of single-controller network SDN, they attempt to provide efficient control of the area. They also consider the load balancing.

In [9], the authors consider the packets among the controllers and switches for wide area networks, argue that it is important to reduce the propagation delay. They propose a new approach called the Cluster-Based Network Division Algorithm (CNPA). CNPA divides the network into subnets in steps to shorten the propagation delay between the controller and the controller can place the associated switches to a sub-network. They aim at minimizing the network latency, maximizing reliability and durability, minimizing distribution cost and energy consumption. The solutions are searched for CPP with different purposes. They focus on cooperation between controllers for CPP, cost awareness with the use of multiple controllers, and increasing the number of parameters to be based on optimization.

In [10], the authors review the CPP, and analyze the solution techniques and their limitations. The solution techniques are generally based on objective functions. In obtaining the optimum solutions, various factors such as propagation latency between switches and controllers and constraints such as the capacity of controllers and switches are considered.

In [11], the authors present a cost-effective real-time monitoring and recording system to combat the crime committed on the Internet using SDN architecture. In [12], the authors implement a small scale and low-cost SDN design. The performance of two different load balancing algorithms (Round Robin and Dijkstra) is investigated in [13] using round-trip times for addressing the SDN load balancing problem.

In [14], the authors examine the factor of controllers' load into the problem of the controller placement. For this, they define the Capacitated Controller Placement Problem (CCPP). The evaluation shows that the new strategy can significantly reduce the number of required controllers and reduce the load of the maximum-load controller.

In [15], the authors propose a new mathematical model for the CPP in SDNs. The goal of the model is to minimize the cost of the network while considering different constraints. The simulation results show that the model can be used to plan small scale SDN.

In [16], a new expansion model is presented to introduce the network operators plan and to update the SDN infrastructure. For a given network design and switches, the model finds how many, where and which controllers to install to (re-)design the topology of the new network.

The coronavirus also called COVID-19 or SARS-CoV-2, is one of the worst pandemics in recent history [17]. Especially, in recent months, the financial and the social impacts of the COVID-19 pandemic on our lives and economies are very destructive. To stop the spread of COVID-19, billions of people need a vaccine for coronavirus. Many research teams in companies and researchers in universities try to develop vaccines against COVID-19. But it might not be physically possible to make enough vaccine for everyone and optimistically it could be available in 2 year-time but as scientists say it will be a while before the vaccine is as useful as hoped. To this end, governments take measures such as buy blood test kits, rules for wearing masks and social-distancing, flexible working hours, online schools, severe lockdowns, etc. to slow down the spread of COVID-19. Apart from these and besides, governments need effective resource management and coordination. Especially, the key challenges where to place the pandemic hospitals and what should be the number of pandemic hospitals to be placed in a city should be effectively addressed by governments.

The main contribution of this paper is the introduction and evaluation of an SDN-based approach for the best hospital localization against COVID-19. We propose and explain a GA with the DA method that considers the number of coronavirus patients of cities to reduce the insertion end-to-end delay controller. The proposal uses the ULAKNET data set for Turkey and provides the most appropriate placement for the pandemic hospitals. We experimentally show the controllers are located at the closest distance to all other cities and close to the places where the coronavirus outbreak is common, thus reducing the end-to-end delay significantly. Our approach can be used to analyze, validate, and to evaluate the localization of the countries' pandemic hospitals' demand. If more data support is satisfied especially at the level of villages, towns, cities, and districts better prediction models can be obtained.

3. Technical Concepts

3.1. Software-Defined Network (SDN)

SDN is a new networking paradigm emerging to improve the performance of existing network architecture [18]. SDN, by separating the control plane from the data plane, the switches become simple forwarding devices. Network control of SDN is provided with the help of a controller or controllers with logical management in the control layer. Controller, applications, network policy, network configuration, topology management, finding connections, is responsible for the process flow table entry. SDN architecture data, consisting of control and application layers. The communication between the layers is carried out by North and Southbound interfaces. The basic architecture of SDN is shown in Figure 1.

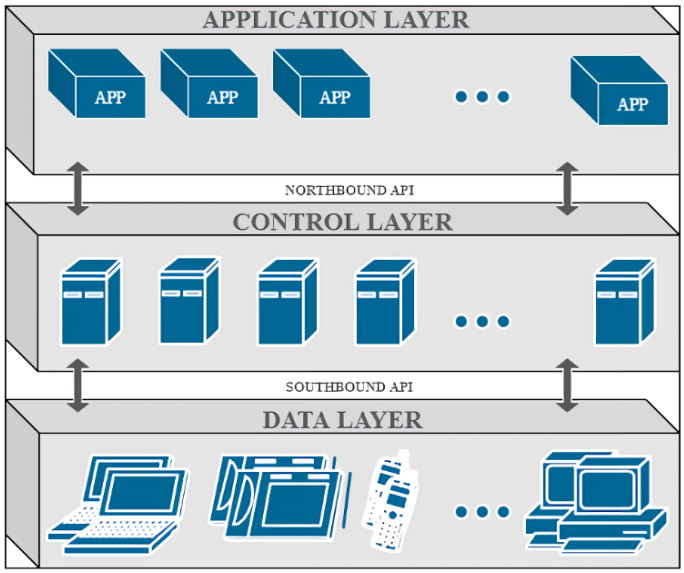

Figure 1: The Basic SDN Architecture

3.2. Multiple Controller Placement Problem

A single controller in the control layer of the SDN architecture may not be sufficient in large-scale networks. There are disadvantages such as a single checkpoint being a single point of failure, bottleneck, and delay in response time. A multi-controller structure is recommended to solve such problems in SDN. After deciding the number of controllers, the significant challenges of multi-controller SDNs to be addressed to increase performance are determining the locations of controllers and determining the number of controllers per module by evaluating the latency.

3.3. Genetic Algorithm (GA)

GA has three steps (selection, crossover, mutation) to have a successful gene. GA process starts with randomly selected individuals. After creating the initial population, it is necessary to determine the fitness function value of each individual. The value of the fitness function is directly proportional to the proximity to the solution according to the type of problem. The higher the fitness function value, the higher the chance of an individual to survive and to reproduce. Individuals that have high fitness function values are selected for crossover. In crossover step, two individuals are selected as a parent and then one or more individuals are produced using different types of crossover operators such as one-point, multi-point, uniform, etc. Then mutation is applied in a probabilistic manner to enrich the gene pool. After these steps, a new population is produced. This procedure is repeated until a specified termination condition is satisfied. The block diagram of GA is given in Figure 2.

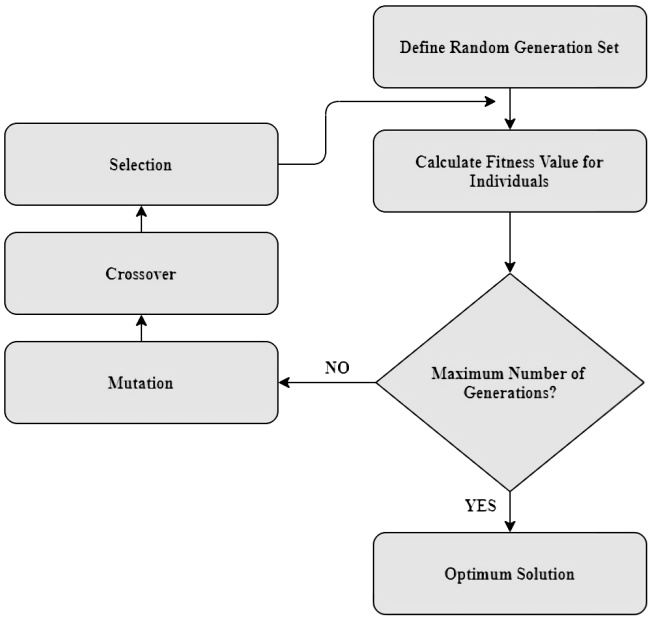

Figure 2: Genetic Algorithm Block Diagram

3.4. Dijkstra Algorithm (DA)

DA is one of the most commonly used algorithms for the shortest path searching. The purpose of DA is to find the shortest distance between nodes in a graph [19]. It uses the greedy search principle as it aims to find the most suitable solution at every step while searching for solutions to the problems it applies to. The input of the DA is the weighted graphs and its output is the shortest path from the origin node to each vertex in the graph.

4. Experiments

In this paper, the hospital placement problem for the coronavirus epidemic affecting the whole world is solved in the SDN infrastructure (see Figure 3) by applying GA and DA approach. In addition to the coordinates of the cities, the coronavirus parameter of each city is added to the ULAKNET database file used.

The ULAKNET data set for Turkey in the Topology Zoo database [20] shown in Figure 4 is used. The study is carried out with Python codes on a machine with Linux based Ubuntu 16.04 operating system, 8 GB RAM, and Core i7, 2.0 GHz processor. The Pycharm platform is used as a compiler for the Python codes.

First, a fixed node map for Turkey using latitude and longitude values in ULAKNET data sets is illustrated in Figure 5. In Figure 5, each city is also represented by a number. For example, 74 number is assigned for İstanbul. The data for İstanbul is as follows:

```
<node id="74">
<data key="d29">1</data>
```

<data key="d30">41.01384</data>
<data key="d31">Turkey</data>
<data key="d32">Red Colour</data>
<data key="d33">74</data>
<data key="d34">28.94966</data>
<data key="d35">Istanbul</data>
</node>

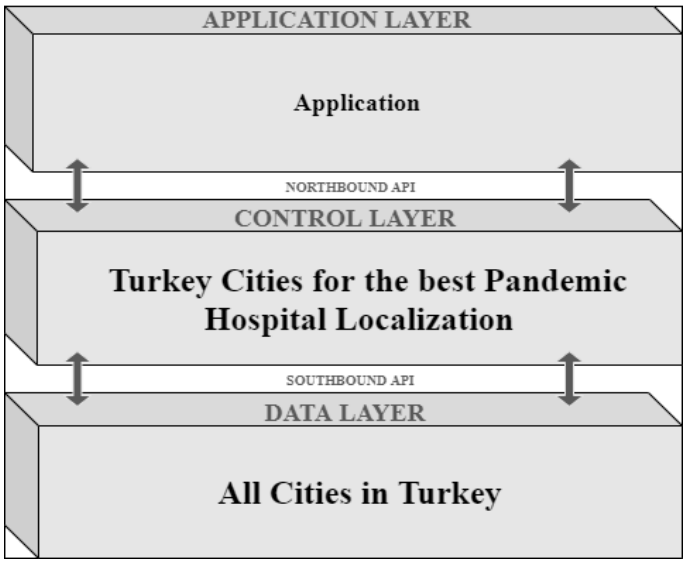

Figure 3: The SDN-based Structure Used for the Best Pandemic Hospital Localization

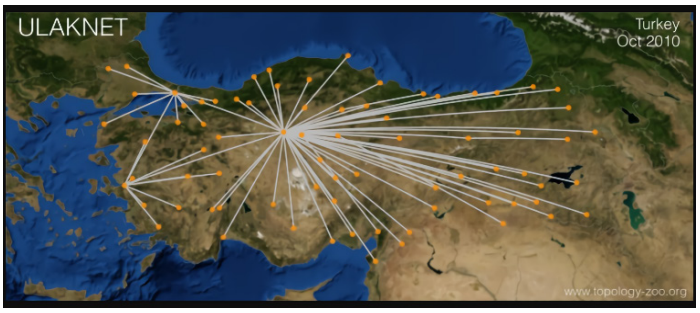

Figure 4: ULAKNET Turkey Map

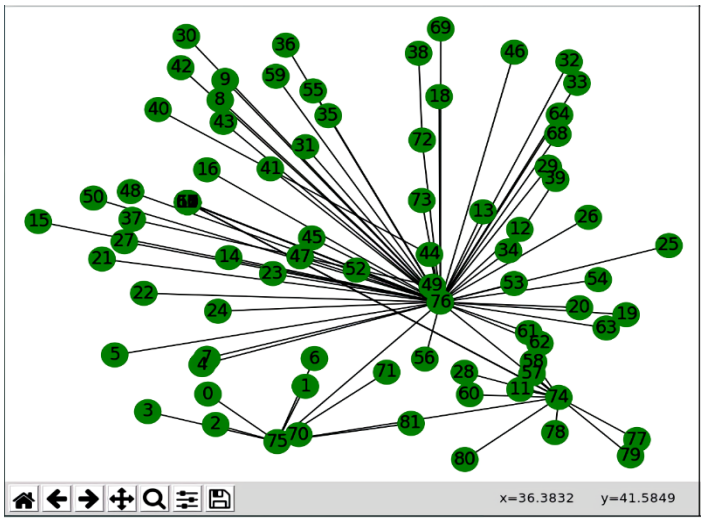

Figure 5: ULAKNET Turkey Map Before the Placement of Multi-Controllers

According to the coordinate data of the cities, the minimum distances of each city to other cities are calculated with DA. A distance matrix obtained for each city is shown in Figure 6.

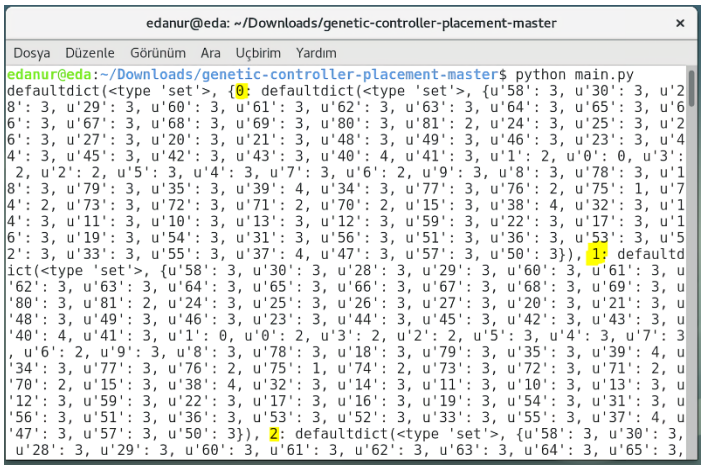

Figure 6: A City Distance Matrix

The number of coronavirus patients is assumed as the coronavirus coefficient of a city. So, the corresponding coronavirus coefficients are added for each city and are shown in Figure 7. The coronavirus patients' data of the cities of Turkey given in Figure 7 are the patients of the date 03/04/2020 [21]. For example, the city number 74 corresponds to Istanbul, and 76 corresponds to Ankara while the coronavirus coefficients of Istanbul and Ankara are 12231 and 860, respectively.

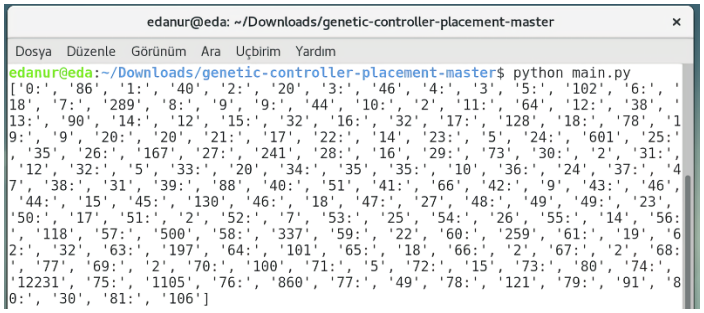

Figure 7: The Coronavirus Matrix of the Cities of Turkey

The parameter setting of GA are listed in Table 1 and the flowchart for the hospital placement problem is presented in Figure 8.

Table 1: GA parameter setting used in the simulations

Parameters	Value
Individuals in the Population	100
The Number of Controllers (Hospitals)	10
Parent Percentage	0.1
Mutation Rate	0.05
Random Selection Rate	0.01
The Number of Generations (Iterations)	1000

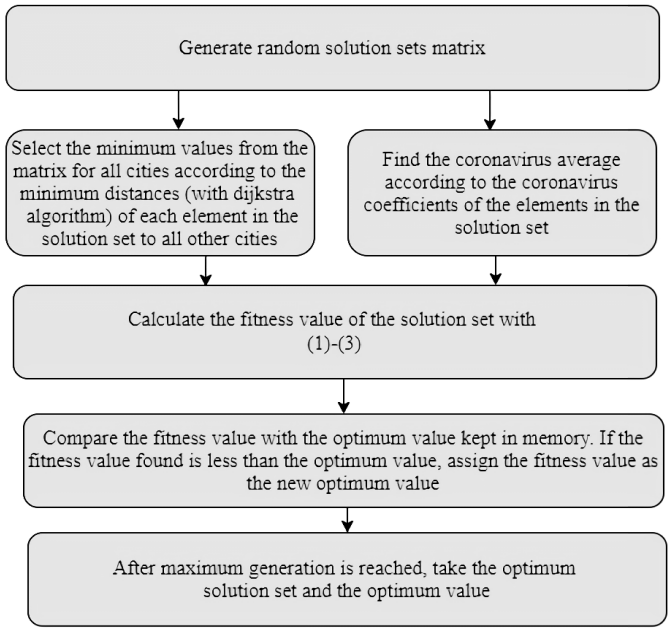

Figure 8: Flowchart for the Hospital Placement Problem

Using the parameters listed in Table 1, 100 random 1x10 solution clusters are created. The randomly generated solutions are illustrated in Figure 9.

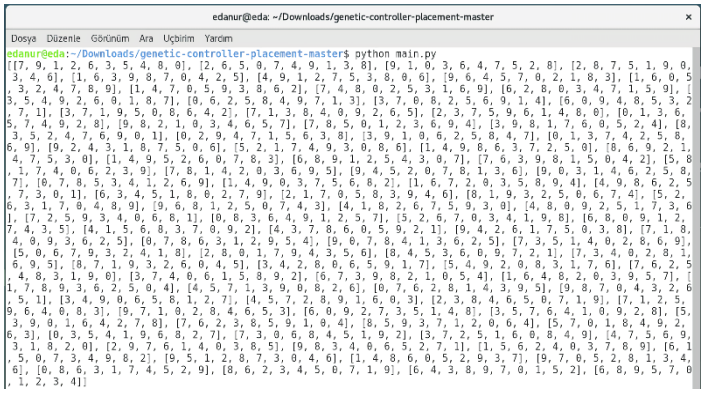

Figure 9: Random Startup Solutions

The fitness of each the random solution sets is calculated using the fitness function. The fitness function has two purposes:

- Choosing solution clusters at minimum distances to cover all cities on the map,
- Choosing solution sets that have higher coronavirus coefficients.

The fitness values of all cities are calculated according to the distance matrix created for each city according to the DA. The city in the random solution set that has a minimum distance from all other cities is selected. After calculating the optimum distance to all cities according to the minimum values in the solution set, the average of the distance from the solution set to all cities is calculated.

For the algorithm used in the simulation: n is the number of the controller (number of pandemic hospitals to be established) and set as 10. x_i is the solution set where $i = 1, 2, 3, \ldots, 10$. h is the weighted graph of cities. $f(x, h)$ is the Dijkstra function. A is the calculated value of the selected solution set with the shortest distances to all other cities. L_Opt and G_Opt are variables for Local Optimum and Global Optimum, respectively.

Equation (1) shows the arithmetic mean of the coronavirus coefficients of the elements in the solution set and (2) takes the average of the values produces according to which of the elements in the selected solution set for each city in the graph of the cities is closest. (2) calculates for the 100 solution sets. After (1) and (2) are calculated, the local optimum value of the selected solution set is obtained by dividing (1) by (2) and (3).

$$\bar{x} = \frac{\sum_{j=1}^{n} x_j}{n} \quad (1)$$

$$A = mean(min(f(x_i, h), i = 1, \ldots, n)) \quad (2)$$

$$L_Opt = \frac{A}{\bar{x}} \quad (3)$$

Initially, a global optimum value is defined by (4). In each iteration, the global optimum value is compared with the value in (3). If the value in (3) is better than the global optimum value, the new global optimum value will now be that value (5).

$$G_Opt = Maxint \quad (4)$$

If 'L_Opt' value is lower than 'G_Opt' then:

$$G_Opt = L_Opt \quad (5)$$

The aim of the study is to reach the optimum value when the average distance is minimum and the coronavirus arithmetic average is maximum. Thus, two criteria are taken into consideration for the establishment of pandemic hospitals:

- Solution clusters that are close to the cities on the map and will cover the maximum number of cities
- Solution clusters consisting of cities with a high number of coronavirus and needing hospitals more

Each experiment is run for 1000 iterations. After maximum iteration is reached, the optimum solution set and optimum value are taken. 30 experiments are conducted in the study. The best fitness values obtained of the 30 experiments are shown in Table 2. The number of the experiment and the solution set (cities) obtained during the experiment are also listed in the first and the second column of the Table 2.

The iterations and the convergence graph of the 9th experiment is shown in Figures 10 and 11, respectively. The proposed algorithm is converged faster, as iterations proceed the output gets closer to the optimum value at every iteration.

Each number in the solution set that gives the global optimum value corresponds to a city and represents the most suitable cities for the construction of pandemic hospitals. In Figure 12, the cities obtained from the 9th experiment, which gives the most optimum solution set in Table 2, are shown on the map obtained from the ULAKNET data set within the Topology Zoo database. According to the results we have obtained, the pandemic hospitals that should

be placed in the cities [74, 57, 8, 28, 0, 39, 15, 74, 18, 45]. The names of these cities obtained are as follows:

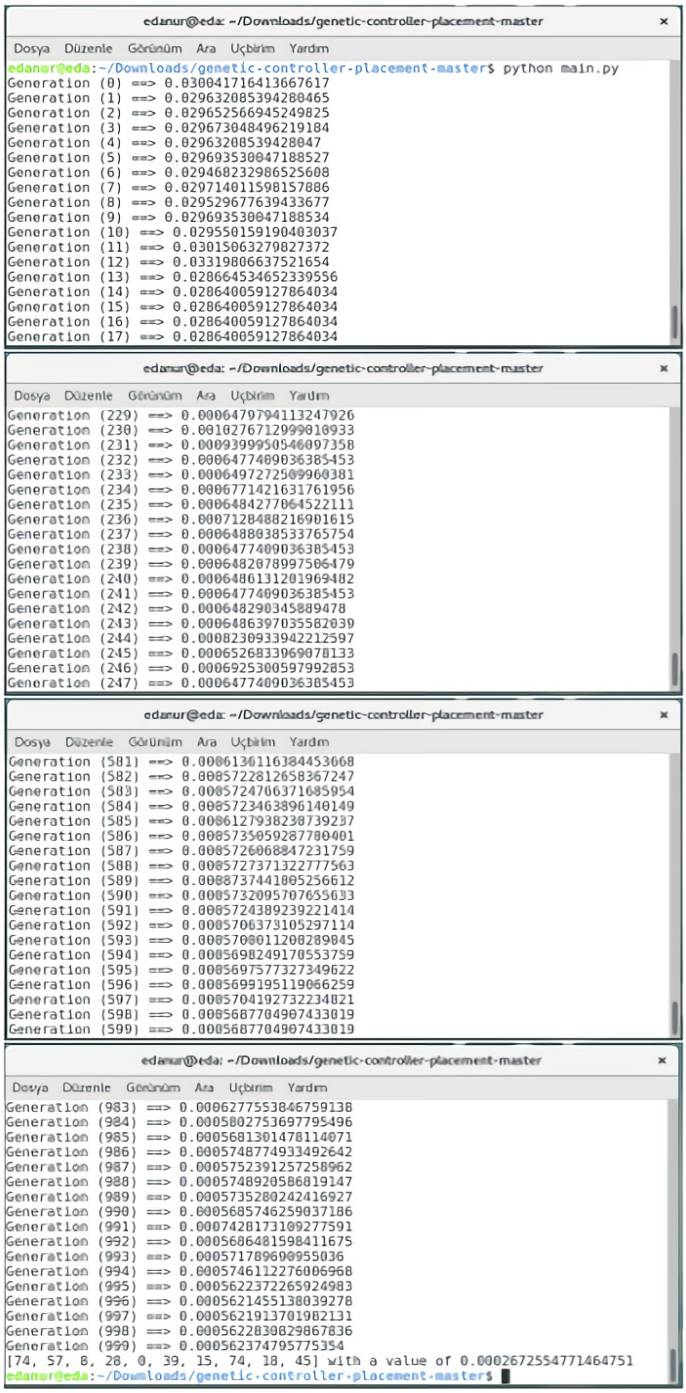

Figure 10: The Optimum Solution for the 9th Experiment

and demonstrated in the SDN structure in Figure 13. The observation is that in the solution set, there are two Istanbul cities. This corresponds Istanbul needs two pandemic hospitals. However, the capital Ankara is not in the obtained cities. But 24 of 30 experiments obtained Ankara. The cities are not obtained based on their economic, social, and cultural levels. The values obtained from the experiments should be evaluated together with the results obtained from the algorithm of all cities in the solution set, not as a single city.

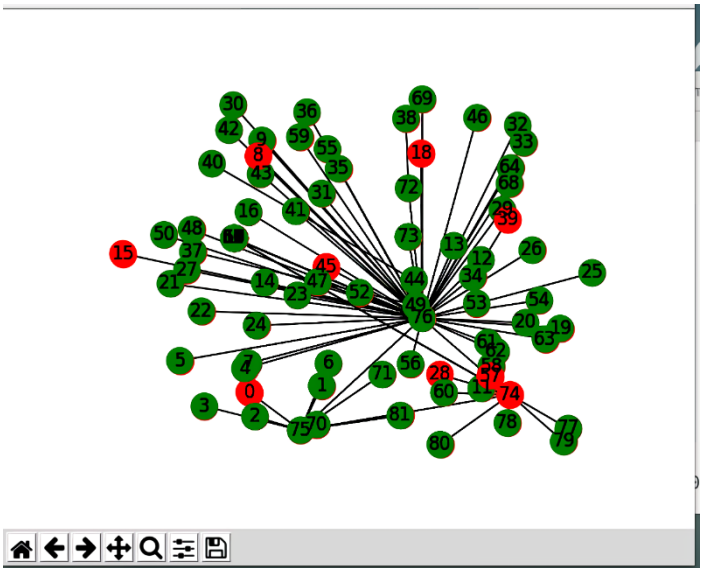

Figure 12: The Best Hospital Localization

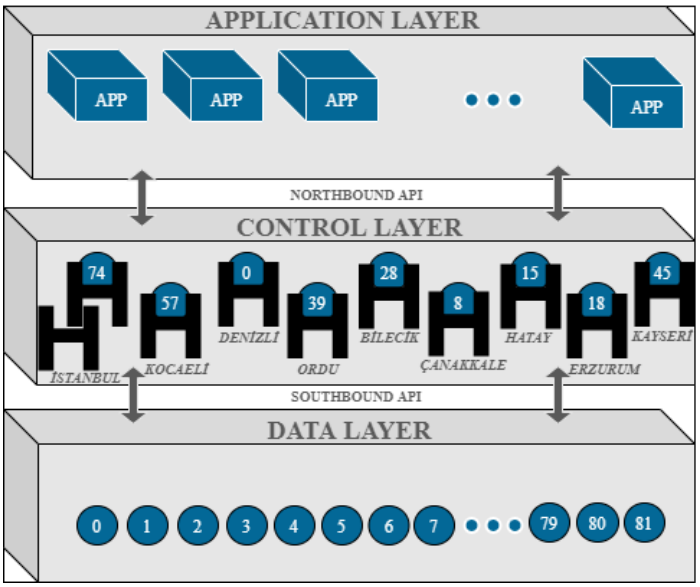

Figure 13: The Obtained Cities for the Pandemic Hospitals in the SDN Structure

5. Conclusion and Future Study

In this paper, we have studied the placement of the pandemic hospitals which should be established against the coronavirus. As it is not possible to establish the pandemic hospitals in every desired location due to the high cost of setting up the pandemic hospitals, the placement of the pandemic hospitals is of great importance. To solve the pandemic hospital placement problem, in this paper, an SDN-based solution has been proposed by applying a GA with DA method according to the distance and coronavirus parameters to the maps obtained from the ULAKNET data set.

From the experimental results, the hospital location found has the closest distance to cover all cities in the selected data set and in places where there is a high coronavirus. Ten pandemic hospitals are placed with maximum coverage.

We need more data at the level of villages, towns, cities, and districts. But now, data for coronavirus in many countries of the World are still limited and even it is very difficult to get the shared data of the countries. Such better data will help us to achieve better prediction models as future work.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Biological networks represent biological systems, and various graph analysis algorithms have been applied to solve various real-world problems. Network motif analysis, as one of network analyses, is detecting frequently and uniquely over-occurring subgraph patterns in a network. The detection process requires high computational resources, and various tools have been developed to provide efficient solutions. However, they still lack extensible output options and easy accessibility, which restricts substantial scale of experiments for many biological applications. Therefore, we provide NemoSuite (Network Motif in a Suite) as a web-interactive tool for detection and analysis of network motifs. Including both of network-centric and motif-centric approaches, it is a greatly accessible tool emphasizing on efficiency, usability, and extensibility.

1 Introduction

Systems biology focuses more on the interconnections between molecules, such as DNA, RNA, or proteins, than individual components. Biological systems are often represented as biological networks, including protein-protein interaction (PPI), metabolic, or gene-regulatory networks. Biological networks, which model the data in -ome level or in ecosystem level, show individual molecules as graph nodes and their interactions as edges. Researchers applied various graph analysis algorithms to understand biological systems in networks, and we are focusing on network motif analysis as one of graph algorithms. Here, we present an online program extending an original work presented in 2019 IEEE International Conference on Bioinformatics and Biomedicine (BIBM) [1], which introduces NemoMapPy as an online tool to detect network motifs.

Network motifs are defined as statistically over-recurring subgraph patterns in a network, which are assumed to have biological significance in biological systems. They are defined in line with "sequence motifs" that are playing a key role in analyzing DNA/RNA or protein sequences with the goal of, for example, controlling the translation of the encoding mRNA, characterizing protein families, detecting DNA binding sites, or controlling tumor suppressor gene expression.

Analysis of network motifs have applied to various applications such as predicting protein-protein interactions [2], determining protein functions [3], detecting breast-cancer susceptibility genes [4], investigating evolutionary conservation [5, 6], and discovering essential proteins [7, 8]. Furthermore, a broad spectrum of network motif applications has been explored: "motif clustering" [9], "motif themes" [10], "relative graphlet frequency distances" [11], "motif modes" [12], and "MotifScores" [13].

However, currently existing tools lack the easy accessibility, and flexible scalability, which restrict their range of applications, and thereupon cause some amount of faithlessness on the analysis [14]. Most tools are unable to collect instances of network motifs and lack of functionality, usability, and extensibility. Therefore, we provide NemoSuite (Network Motif in a Suite) to resolve these problems: it includes Nemo and NemoMapPy programs. Nemo program implements a network-centric approach using NemoLib [15, 16]. NemoMapPy implements NemoMap [17] algorithm which is one of the motif-centric methods.

The contributions of NemoSuite include the followings: (1) As a web-interactive graphical user interface (GUI) program, it provides easily accessible tools with great efficiency and usability; (2) It provides various output results based on users' choice, which will explore network motif analysis to various real-world applications; (3) It provides both network-centric and motif-centric tools. As far as the authors' knowledge, NemoSuite is the first program providing both network-centric and motif-centric methods as an web-interactive, and GUI format.

The rest of the paper starts providing the review of various detection algorithms and tools in Section 2. Thereafter, Section

3 describes NemoSuite, followed by experiments and results in Section 4, and Section 5 respectively, and conclusion in the last section.

2 Related Works

2.1 Network Motif

Recent survey of network motifs showed that there are different types of network motifs [18]. Originally, Milo et al. [19] introduced network motifs as the "patterns of interconnections occurring in complex networks at numbers that are significantly higher than those in randomized networks" in 2002. After discovering the under-represented patterns could also delineate some features of networks, 'anti-motifs' are defined as the subgraphs with significantly less frequencies in the input network compared in a random pool [20]. On the other hand, 'colored-motifs' are introduced as the network motifs in multi-label networks such as metabolic, social or traffic networks [21]. Additionally, Parida proposed 'maximal-motif' as the network motifs with maximal nodes and edges in a given size [22].

However, as we focus on biological networks, we use the original network motifs in this work, whose mathematical definition follows. A network motif M is a connected subgraph of size k which can be found frequently and uniquely in an input network G. To determine the uniqueness, P-value (Eq. (1)) or Z-score (Eq. (2)) of the recurrence of M is calculated within a huge pool of randomly generated graphs.

$$\text{P-value}(M) = \frac{1}{N}\sum_{n=1}^{N} c(n), c(n) = \begin{cases} 1, \text{if } f_R(M) \geq f_G(M). \\ 0, \text{otherwise} \end{cases} \quad (1)$$

$$\text{Z-score}(M) = \frac{f_G(M) - \mu(f_R(M))}{\sigma(f_R(M))} \quad (2)$$

Here, N refers to the number of random graphs, and $f_G(M)$ is the frequency of M in the input G while $f_R(M)$is the frequency of M in the random network R. $\mu(f_R(M))$ is the mean of frequencies of M in the random networks and $\sigma(f_R(M))$ is the standard deviation of frequencies of M in the random networks. For a fair comparison, the random graphs are generated given the same degree sequences as the original graph. In general, a subgraph with P-value less than 0.01 or Z-score greater than 2.0 is considered as a network motif after compared with $1,000$ random networks [23].

2.2 Algorithms

Grow and Kellis classified various algorithms of discovering network motifs into network-centric and motif-centric approaches [24]. The former method first searches all possible patterns from the input graph, then determines which patterns are network motifs through a statistical testing, whereas the latter approach outputs the number of occurrences of the given query pattern in the input network without statistical testing results.

Various algorithms and software programs implement network-centric approach, which include MAVisto [25], MFinder [26], Kavosh [27], NemoFinder [28], NetMODE [29], QuateXelero [30], Motif-Discovery[31], MotifNet [32], ESU algorithm[33], and FANMOD program [34]. Network-centric approach, requiring an input network and the size of motif to search, involves enumerating non-isomorphic k-size subgraph patterns in the original network. It then compares the frequency of each pattern in a number of generated random graphs. The uniqueness of each pattern is determined based on the P-value or Z-score. This approach is specifically useful if the goal is to determine which pattern is a network motif. However, enumeration process limits the size of detectable motifs due to the time-consuming process of scanning for every nodes and edges of the network. Consequently, network-centric algorithms using exhaustive enumeration of k-size subgraphs in the network does not exceed size 8 nodes [24]. Larger size of network motifs can be detected if searched approximately .

Vertices	Number of non-isomorphic subgraphs	
	Undirected	Directed
1	1	1
2	1	2
3	2	13
4	6	199
5	21	9 364
6	112	1 530 843
7	853	880 471 142
8	11 117	1 792 473 955 306
9	261 080	13 026 161 682 466 200
10	11 716 571	341 247 400 399 400 000 000

Table 1: It shows the number of non-isomorphic patterns in undirected or directed graphs increases exponentially with the size of pattern, courtesy of [23].

Focusing on detecting larger size of motifs, Grochow and Kellis introduced a motif-centric approach (GK method), which finds the frequency of each pattern in a given query set by mapping each query graph to all possible location in the input graph [24]. GK method, MODA[35], FASCIA [36], ISMAGS[31], ParaMODA[37], and NemoMap [17] are implementing this motif-centric approach. This approach was able to find motifs of up to 15 nodes with symmetry-breaking technique to significantly reduce isomorphic testing. One disadvantage is that it assumes that the user has pre-knowledge of what patterns are network motifs in the target graph as a set of query patterns have to be provided. Otherwise, this approach is not straightly applicable to finding network motifs. In fact, no algorithms or tools have described how to provide the query set. Therefore, if the goal is to find which pattern is significantly frequent than others, the user has to provide all possible k-size subgraph patterns as a query set to compare, which can suffer heavily since full list of all possible variations of k-size subgraphs grows exponentially with k. Table 1 shows the exponential growth of pattern variations of k-size subgraphs up to 10 nodes, and in the worst-case scenario the application would have to iterate over $341,247,400,399,400,000,000$ of 10-node patterns many of which might not even exist in the target graph.

Table 2 summarizes various aspects of these two approaches. Although both the network-centric and motif-centric approaches have

Table 2: Summary of network-centric and motif-centric approaches.

	Network-centric	Motif-centric
Input	An input network, a motif size k, the number of random graphs to generate	An input network and (a) query pattern(s)
Output	All discovered subgraph pattern's frequency in the input network, Z-score and/or P-values	Each query pattern's frequency in the input network
Processes	Enumerate or sample all possible non-isomorphic subgraphs, and each pattern's frequency is compared in a huge random pool	Search the instances of each query graph in the input network, and its frequency or the set of instances of the pattern is provided
Tools	FANMOD, MAVisto, MFinder, Kavosh, NemoFinder, NetMODE, QuateXelero, MotifNet, Motif Discovery	GK, MODA, FASCIA, ISMAGS, ParaMODA, NemoMap
Benefits	Can determine which patterns are network motifs. Non-existing patterns in the network will not be searched.	Can search large size (more than 8) of a pattern. Relatively fast to collect all instances of a given query graph.
Drawbacks	Exponential computational time growth with increasing size of motifs and networks. Statistical analysis adds more computational burden.	Exponential computing time increase on the number of possible query patterns with increasing size of motifs. It cannot be directly applied for discovering network motifs.

drawbacks, each approach can be respectively applied to different problems with appropriate goals. If the goal is determining which patterns will be network motifs in a target graph, then network-centric approach is appropriate. Motif-centric method would work better for a pattern matching. Therefore, we aimed to provide a tool with both approaches to maximize the usability and efficiency.

2.3 Tools

There are various tools that follow network-centric or motif-centric approaches. After careful review of the tools [18, 38, 39], we found out that most tools are out-dated, dependent on operating systems or other external tools, restricted output options, inaccessible, or lack of usability. As shown in Table 3, we tested the following tools such as mFinder, FANMOD, Kavosh, QuateXelero, Fascia, ISMAGS, MotifNet, and Motif-Discovery, because others are unable to locate, unable to install, out-dated, incompatible with current security setting, or inexecutable.

mFinder, FANMOD, Kavosh, and QuateXelero are network-centric based tools that accept a text file as an input graph, the size of network motifs, and the number of random graphs to generate. While others require a list of edges in the text graph file, Kavosh and QuateXelero additionally require the number of nodes at the first line in the file. Before running these programs, however, since each node should be labelled as an integer, non-integer labels should be converted to integer labels. They provide outputs consisting of each pattern's frequency, and its Z-score or P-value so that users can determine which patterns are network motifs. When we design our program, NemoSuite, we set FANMOD program as an example, since it is a GUI-based program, efficient, with additional filtering options, and can provide the set of instances as well. MotifNet, as a web-program, also succeeds FANMOD, taking two files (edge list and node list), the size of network motif, and the number of random graphs. However, it requires the user to submit the work in a queue, which seemed discontinued the service currently, as we never got the results back. Motif-Discovery, as a cytoscape[31] plug-in, can read string-labelled nodes, visualize the network, and provide the frequency and Z-score for each pattern. Unfortunately, since the Z-scores are significantly different from the ones by other tools, it is unclear how to determine network motifs.

Fascia and ISMAGS are motif-centric based motif discovery tools. Fascia requires two text files. One is the input graph and the other is a query graph. The input graph file should contain the number of nodes, the number of edges, and the list of edges where the node ID's are integers. A query text file is a list of edges. As a command-based program, it provides the number of occurrence of the query pattern in the input network. On the other hand, ISMAGS is cytoscape plug-in, which can visualize the input network. In this work, we excluded other tools including MODA, since we failed to install or run them properly.

Table 3 lists the tools, approach, year of publication, the input options, the output options, interface, and shortcomings. In general, current available tools lack of visualization, usability, easy accessibility, and comprehensive results. To overcome the shortcomings of other tools, we provide NemoSuite as a comprehensive and efficient web-interactive program.

3 Methods: NemoSuite

We developed 'NemoSuite' (Network Motif in a suite) to provide a unified access to network motif analysis including network-centric and motif-centric approaches. NemoSuite consists of two separate programs: 'Nemo' and 'NemoMapPy.' Nemo program employs a network-centric approach using a NemoLib [15, 16] that improves ESU (Enumerate SUbgraphs) algorithm [33]. NemoMapPy program follows a motif-centric method by implementing NemoMap [17] algorithm in Python and Flask framework. Figure 5 shows the NemoSuite homepage with Nemo and NemoMapPy program pages. The program is available at https://bioresearch.css.uwb.edu/biores/NemoSuite/.

Table 3: Network motif detection tools are compared based on their approach (network-centric vs. motif-centric), shortcoming, year, input, output, and interface options.

Tool	Approach	Year	Input	Output	Interface	Shortcoming
mFinder	network	2002	edge list file (integer ID)	text file: freq, z-score, p-value	command-line	restricted input and output options, command-line
FANMOD	network	2006	edge list file (integer ID)	html: freq, z-score, p-value, visual. Instance set	GUI	restricted input and output options
Kavosh	network	2009	#n,edge list file (integer ID)	text file: freq, z-score, motif matrix	command-line	restricted input and output options, command-line
QuateXelero	network	2013	#n,edge list file (integer ID)	text file: freq, z-score, motif matrix	command-line	restricted input and output options, command-line
Fascia	motif	2013	#n,#m,edge list file (integer ID)	count	command-line	restricted input and output options, command-line
ISMAGS	motif	2016	cytoscape input	count	cytoscape plug-in	exception error, plug-in

Motif-Discovery	network	2018	cytoscape input	text file: freq, z-score	cytoscape plug-in	restricted output options, significantly different Z-scores from others, cytoscape-dependent

3.1 *Nemo*

Nemo, as shown in Figure 5(b), follows a network-centric approach which includes the steps of enumeration, random graph generation, and statistical analysis. The user should select an input file (see Fig 1 (a) for the file format), along with the directness, the size of motif and the number of random graphs to generate. Nemo program works on both directed and undirected graphs, and the input graph's node can be represented as string or integer. There are three output options: NemoCount, NemoProfile, and NemoCollection, whose formats are introduced by Kim and Haukap [40], and illustrated in Figure 1 (b).

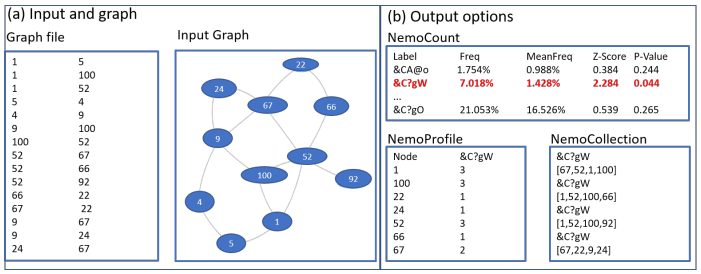

Figure 1: Nemo: (a) shows the input file format with visualized graph on the right; (b) shows the three output options including NemoCount, NemoProfile, and NemoCollection.

'NemoCount' is a default output format which lists the patterns of each detected subgraphs, along with its frequency in the input graph, average frequency in the random graphs, then finally shows its statistical results so that the user can determine which pattern is a network motif. Each pattern is labeled with g6 format which is used to identify isomorphic graphs in the Nauty program [41]. 'NemoProfile' option returns two files. One is a file of *NemoProfile* that contains two dimension of matrix of N rows and M columns, where N is the number of nodes and M is the number of network motifs. For example, from the Figure 1 (b), the node '100' is found in three instances of the motif **&C?gW**, and the node '67' belongs to two instances of the same motif. Wang and Kim showed that NemoProfile can be used as a data feature to detect essential genes [42]. Another file is a *SubgraphProfile*, which is an extended NemoProfile containing not only motifs but also non-motifs in the column. If none of patterns are network motifs, this option provides SubgraphPrifle only. Likewise, 'NemoCollection' also provides two files: *NemoCollection* and *SubgraphCollection*. While NemoCollection provides the set of network motif instances as a file, SubgraphCollection provides instances of all subgraph patterns.

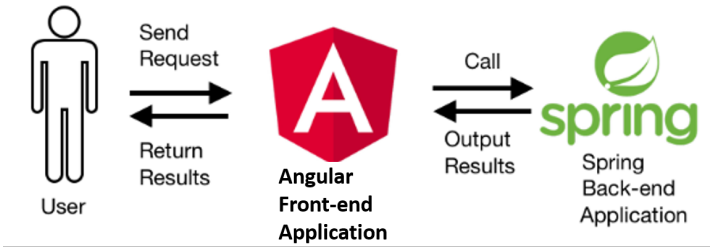

Figure 2: Block diagram for Nemo program.

Nemo program is using an angular application for the front-end, and a spring application for the back-end as shown in Figure 2. The front-end uses the angular framework, which takes advantage of

the Model-View-Controller (MVC) pattern. Developers can easily display the data and the model from the back-end and control the model with the 'appcomponent.' Also, it can be easily deployed with angular. The back-end uses the Spring framework, which produces RESTful APIs. With this simple and intuitive design, developers can easily update modules for additional purposes. Nemo program also has high maintainability with the REST architecture style. Developers can fix any defected part if any, and restart the Spring application on the server while the client application remains untouched. Figure 3 shows the overall architecture of the program.

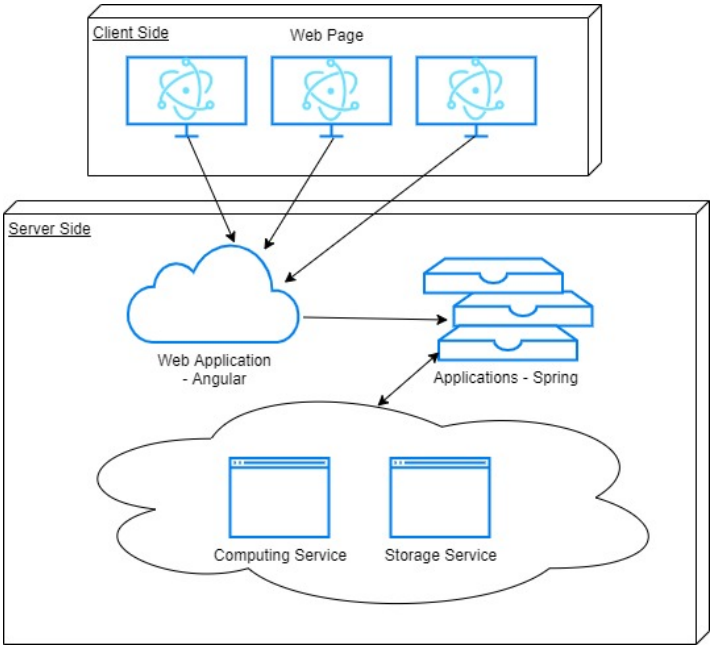

Figure 3: Descriptive architecture of Nemo program.

3.2 *NemoMapPy*

NemoMapPy implements a motif-centric approach which requires an input file, and a query pattern. While other motif-centric tools do not provide statistical results, NemoMapPy provides the frequency and statistical results of the query pattern in the input graph if the number of random graphs are entered, so that whether this pattern is a network motif can be determined with its P-value or Z-score.

NemoMapPy, as an online tool, refined and upgraded the features of NemoMap [17] that improved the performance of ParaMODA [37], which also increased the efficiency of the motif-centric algorithm introduced by Grochow and Kellis (GK) [24], and MODA program [35]. In fact, NemoMap improved the performance of ParaMODA, MODA and GK method by modifying the symmetry-breaking method. It removed the need of maintaining a list of all mappings to prevent duplicate occurrences. It also reduced some of symmetry-breaking conditions, thereafter, contributes on optimizing space and computational time. NemoMap has been proven to be more efficient than ParaMODA, MODA and GK in most cases, exception with some simple query patterns.

NemoMapPy ported NemoMap with additional features on the web [1], and was implemented in Python 3 with the Flask web framework [43]. As a consequence, NemoMapPy can accept streaming text inputs as well as file uploading. The query pattern can be provided as a text input, file uploading, or g6 format. Since Nemo program provides g6 format for detected pattern, the g6 format helps a quick transition from Nemo to NemoMapPy.

Figure 4 illustrates the overall architecture of NemoMapPy. Nginx [44] is used in the first layer, which is a reverse proxy for Gunicorn [45] that redirects incoming requests to Gunicorn with remarkable performance. Gunicorn is a WSGI server which allows multiple applications to run side-by-side in the same process. It handles the load balancing for a program, distributes incoming requests, and communicates with the Flask services accordingly. The back-end of NemoMapPy program is developed by python Flask framework, which takes advantages of simplicity and flexibility. It is convenient for developers to deploy or undeploy it from the server, and the simplified usability make Flask program faster to debug. Here we focused on providing an easy and accessible interface with multiple input options so that users can use NemoMapPy in a variety of situations.

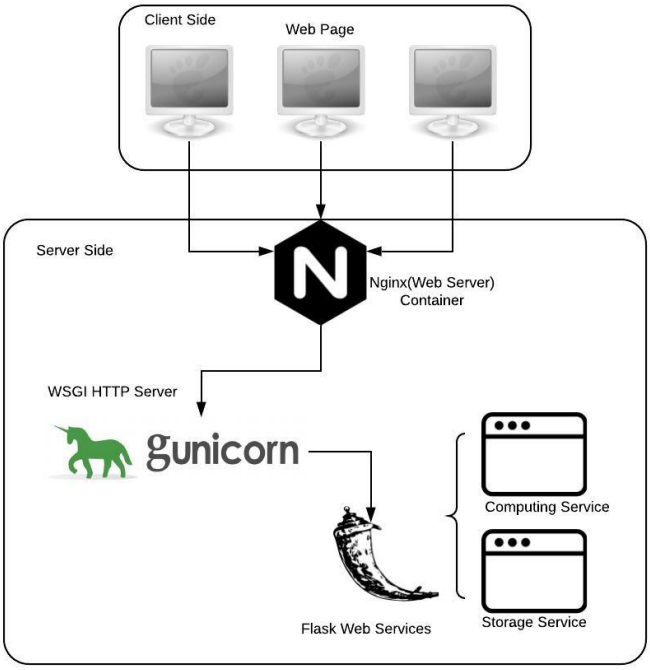

Figure 4: Descriptive architecture of NemoMapPy program

Initially, NemoMapPy only worked on undirected graph and the input file should have integer-labeled vertices [1]. Also, it only provided the frequency of the query pattern as a result. Here, we improved the initial NemoMapPy by adding the following features. (1) NemoMapPy now works both on directed and undirected graphs; (2) the vertices can be integer or string; (3) the query pattern's statistical significance is provided along with its frequency; (4) the input format of query graph pattern has three options. Input text, a file, or g6 format; and (5) the instances of the query pattern is provided as a file.

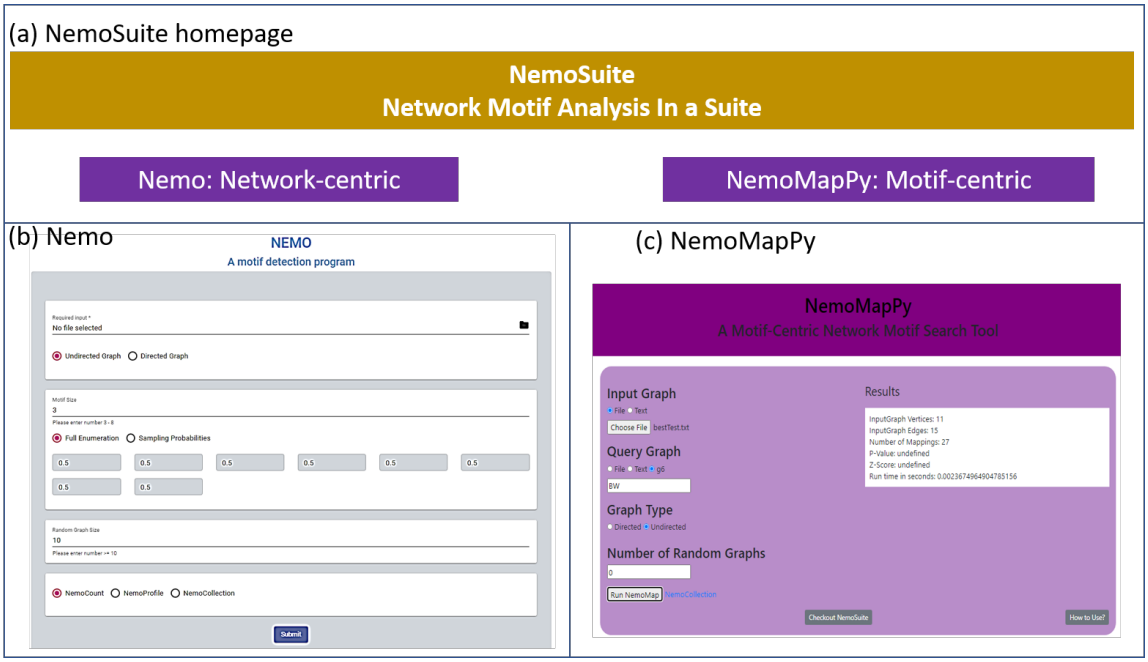

Figure 5: NemoSuite: (a) is the homepage view of NemoSuite program; (b) is the homepage of Nemo program with network-centric method; (c) shows the homepage for NemoMapPy with motif-centric method.

4 Experiments

NemoSuite is an online network motif detection program with both of network-centric and motif-centric methods. It is designed to satisfy the following functional and non-functional requirements.

Functional Requirements

- The user can use the program with any web browser.
- The user can upload the data file, which is an undirected or directed graph.
- The user can use the data file with string or integer type of nodes.
- The user can use both programs to detect the frequency of network motifs (NemoCount).
- The user can use both programs to obtain the instances of network motifs (NemoCollection).
- The user can use the Nemo program to obtain the network motif profile (NemoProfile).

Non-functional Requirements

- The returned results should be clear and easy to understand.
- The running time should be reasonably fast based on the size of the input data.
- The program works for any devices that have access to the internet and have a web browser.

In other words, as a web program, NemoSuite provides easy accessibility for users to detect network motifs, and apply them for various real-world problems. With additional features, the program provides good usability, functionality and computational efficiency. In the following section, we provide results of the comparison of NemoSuite with other programs to demonstrate its computational efficiency and good usability.

We compared Nemo with FANMOD [34] program, since both follow the motif-centric ESU algorithm in essence. Also, after reviewing all other tools, we found FANMOD is efficient and the most usable program among all others. Therefore, we compared Nemo program with FANMOD to evaluate the accessibility, usability, functionality and computational efficiency.

NemoMapPy is implementing a motif-centric approach, which is provided by Grochow and Kellis (GK), called GK method. Unlike network-centric methods, few programs are available that follow GK method, such as, MODA [35], ParaMODA, Fascia [36], ISMAGS[31] and NemoMap. They are available as source codes, cytoscape plug-in, or executable programs. However, the standalone MODA program is out-dated and had many restrictions on running the program, ISMAGS is cytoscape plug-in, and Fascia is a parallel and command-based program. Therefore, we compared NemoMapPy with NemoMap for its efficiency, assuming its easy accessibility and good usability are self-demonstrated with its web-interactive features.

5 Results and Analysis

5.1 Nemo vs. FANMOD

As a web program, Nemo program can be launched with any web-browser. Therefore it is easy to access, and easy to use. FANMOD

program is a stand-alone GUI (graphical-user-interface) program that can be downloaded from a website and it can be installed in Windows, Mac, and Linux operating systems. While both programs have good accessibility, Nemo has a better accessibility as the user can use it anytime and anywhere as long as there is an internet connection.

Nemo and FANMOD programs have good usability too. Usability measures "the capacity of a system to provide an environment for the users to perform the tasks safely, effectively, and efficiently [46]." With Nemo and FANMOD, network motifs are easily detected given an input graph, the size of motif, and the number of random graphs to generate. FANMOD has more options for the random graphs, and the user can see the progress of the task. However, Nemo program performs faster than FANMOD and has more input and output options.

Table 4: Input graph files used for testing

Type	**biological**			**collaboration**		**social**
File	Y2k	Y11k	MIPS	CA-GrQc	CA-HepTH	Face-book
#vertex	988	2401	4545	5241	9875	4545
#edge	2455	11000	12317	14484	25973	12317

We tested the performance of Nemo and FANMOD program with three biological networks, two collaboration networks, and one social network. The detail features of testing networks are described in Table 4. When we tested the run-time for network motif detection with different graphs, the size of network motif is set as four, and the number of random graphs as 100. All tests are performed in Windows OS. Table 5 and Figure 6 provide the comparison results.

Table 5: Nemo vs FANMOD run-time (rounded in seconds) comparison on the size of input graph

	Y2k	**Face-book**	**CA-GrQc**	**CA-HepTH**	**Y11k**	**MIPS**
Nemo	24	54	201	205	517	551
FANMOD	72	248	607	561	2,189	2,859

We can observe that Nemo runs relatively stable as the network size grows, while the run-time of FANMOD program increases abruptly. For the Y11k and MIPS networks, Nemo program runs roughly 5 times faster than FANMOD program.

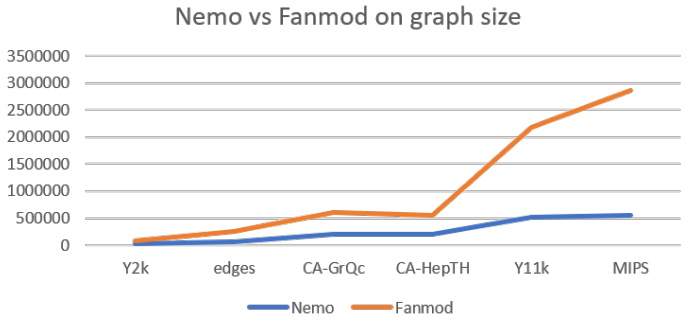

Figure 6: Graph of runtime vs. input graph size between Nemo and FANMOD in millisecond(ms)

We also tested the performance of two programs based on the size of motifs. To save time, we used Y2k data with only 10 number of random graphs, and used Windows OS.

Table 6: Nemo vs FANMOD run-time (in seconds) comparison on the size of motif

	3	**4**	**5**	**6**
Nemo	0.1	2.4	60.8	1,580.5
FANMOD	0.3	7.6	208.5	6,946.9

Table 6 and Figure 7 provide the results. We can observe that Nemo program runs consistently faster than FANMOD program, although the run-time of both programs still increases steeply with the increment of the size of motifs.

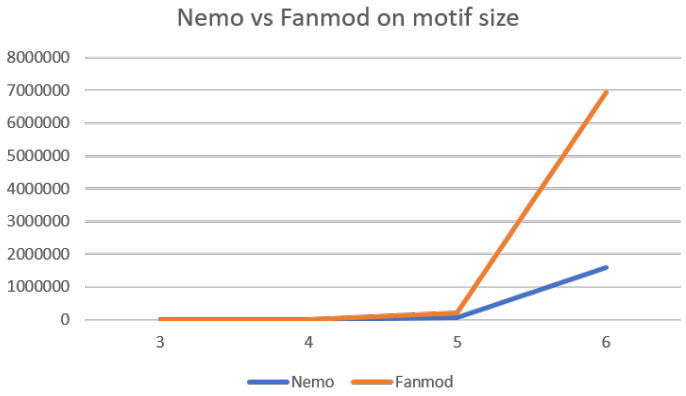

Figure 7: Graph of runtime vs. motif size between Nemo and FANMOD in millisecond(ms)

Through various experiments, we could see that Nemo program provides better accessibility, functionality, usability and computational efficiency than FANMOD program.

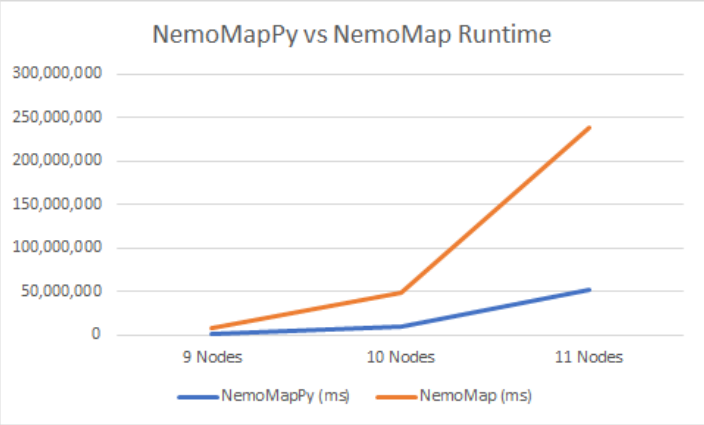

Figure 8: Graph of runtime vs. query graph size between NemoMapPy and NemoMap

5.2 *NemoMapPy vs. NemoMap*

We tested the efficiency of NemoMapPy by comparing with the NemoMap, as NemoMap is known the fastest program with motif-centric approach [17] in most of cases, when not considering parallelization. We tested NemoMapPy with a graph of 1,018 nodes and 1,331 edges, the query graphs that has 9, 10, 11 nodes with average complexity. The complexity of query graph was measured in node-to-edge ratio. We obtained NemoMap source code from the authors of [17] and compiled with Visual Studio 2017. We compared the performance with run-time.

The testing environment was on a desktop computer in Windows OS. In summary, NemoMapPy is approximately 70% faster than NemoMap on the graphs with average complexity and average density, as shown in Table 7, and Fig. 8.

Table 7: NemoMapPy vs NemoMap run-time (in seconds) Comparison

Query Graph	9 Nodes	10 Nodes	11 Nodes
NemoMapPy	1,728,213	9,923,137	51,904,930
NemoMap	8,599,994	48,674,827	239,088,982
% Reduction	79.90%	79.61%	78.29%
# Mappings	13,882,459	251,584,995	1,070,991,776

6 Conclusion

In this paper, we present NemoSuite that provides a combination of easy accessibility, usability, functionality, extensibility, and efficiency that the current network motif detection software programs lack. More specifically, we believe NemoSuite contribute greatly to development of network motif detection programs in the following reasons.

As a web-interactive program, it is easily accessible, and highly usable tool with great efficiency. The various input and output options enable for the users to apply the results to various real-world problems. It is also the first tool that provides both of network-centric and motif-centric approaches. We also demonstrated that NemoSuite is substantially designed to meet the functional and non-functional requirements, and showed its computational efficiency by comparing with other available tools.

Currently, NemoSuite includes Nemo and NemoMapPy programs to represent network-centric and motif-centric methods. Source codes of both programs are available in public github: Nemo is available at https://github.com/lytbfml/Nemolib_App and NemoMapPy at https://github.com/zicanl/NemoMapPy. We plan to add more online tools implementing recent algorithms such as QuateXelero [30], and utilize distributed computing to improve its efficiency further. Additional future works include adding more utility programs such as motif-visualization, graph file conversion, and generating random networks with various methods.

Conflict of Interest The authors declare no conflict of interest.

Acknowledgment We thank the Computing and Software Systems, School of STEM, at the University of Washington Bothell for the support of this research.

ABSTRACT

Forest mapping by remote sensing is a hot topics in forestry. At present, many researchers focus on the research of forest type classification or tree species identification using different machine learning methods and try to improve the accuracy of classification of satellite image. However, forest type classification using deep belief network (DBN) is still limited in previous literatures. Our research focuses on forest mapping in the western part of Dehua county in southern China. Most important objective was to assess the feasibility of forest mapping from hyperspectral data using deep learning. The HJ-1A hyperspectral data was adopted in this paper. We applied deep belief network and got a thematic map of four forest types, such as coniferous forest, broad-leaved forest, mixed forest and non-forest. Our finding shows that optimal network depth of DBN model is 3 and best node in each layer is 256 in our experiment. Overall accuracy is 85.8% and kappa coefficient is 0.785 with best-fit parameters in DBN model, while for SVM is 73% and 0.6447 respectively. DBN obtain better performance compared with support vector machine. Furthermore, network depth and number of nodes in each hidden layer in DBN model has a significant effect on overall accuracy and Kappa coefficient. In general, DBN is promised to be dominant method of forest mapping by hyperspectral data.

1. Introduction

It is very important to obtain the forest information timely and correctly for forest management and land cover mapping in forest ecosystems. For example, forest mapping plays an important role in the issues of forest restoration and forest degradation assessment [1]-[4]. Nowadays, it is an effective way to obtain forest structure from satellite image [5], [6]. Hyperspectral image is a typical data of satellite image and widely used in forest mapping because there are lots of spectral bands of this image and beneficial for forest type recognition. What's more, A series of achievements have been made based on hyperspectral remote sensing technology [7], [8]. However, it leads to the Hughes phenomenon because of redundant spectrum of hyperspectral image [9]. Normally, it needed to be reduced by different methods before image classification [10]. After dimension reduction, traditional classifiers were adopted, such as random forests [6] and support vector machines [7], SVM is the most popular and nonparametric supervised learning method. It is widely used in classifying forest ecosystems [11]. Fortunately, deep learning can extract feature automatically, past studies have showed that deep learning can achieve higher accuracy of image processing of remote sensing avoiding human intervention [12]. Deep belief network is typical model of deep learning. There is an input layer, one output layer and several restricted in Boltzmann machines [13]. Pre-training and fine-tuning are two important steps in DBN model. Pre-training is an unsupervised learning from bottom to up and output result with a classifier. Backpropagation was coined by Rumbelhart [14] and used to update the parameter of model for better result.

There are lots of references about image classification using DBN. It seems that DBN was first adopted by Lü et al. in 2014 year [15]. The experiments showed that the optimal network depth was three hidden layers and best nodes of each hidden layer were

*Corresponding Author: Songya Xu, 29974817@qq.com

64. In year 2015, Chen et al. created DBN model combing with principal component analysis and logistic regression. They confirmed better effect of DBN than that of SVM [12] adopting two Hypersperctral datasets, such as Indian Pines and University of Pavia. On the whole, there are a lot of application situation of deep learning [16], but few literatures is reported about forest mapping using deep learning from Hyperspectral image.

Therefore, one of our research objectives is to confirm the performance of forest mapping by DBN using hyperspectral data. Another objective of this study is to compare the classification performance of DBN model and SVM algorithm. Third objective is to investigate how optimal parameters of DBN affect overall accuracy and Kappa coefficient of forest type identification. The major contribution is to determine the optimal parameters of DBN for forest mapping from Hyperspectral data.

2. Methods

2.1. Restricted Boltzmann Machines (RBM)

RBM is a directionless, full connective model [17]. A RBM consists of two layers. One of them is an input layer, or visible units *v*. Output layer, or hidden units *h* is another layer of RBM. There are no connections within each layer. From Figure 1, we know that the units between visible and hidden are full connected by weight W. The energy of a joint configuration with *v* visible units and *h* hidden units is

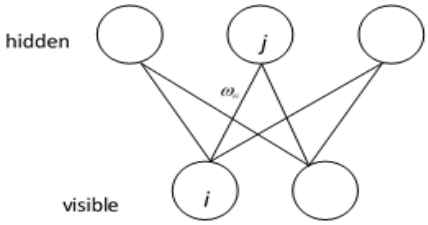

Figure 1: The model of an RBM

$$E(v,h|\theta)=-\sum_{i=1}^{I}a_i v_i-\sum_{j=1}^{J}b_j h_j-\sum_{i=1}^{I}\sum_{j=1}^{J}v_i h_j \omega_{ij} \quad (1)$$

Where $\theta=\{a_i,b_j,\omega_{ij}\}$ represents parameters of RBM. ω_{ij} is the weight between input layers *i* and hidden layers *j*. a_i is the bias of v_i, b_j is the bias of h_j. *I* and *J* are total numbers of input and output layers respectively. The probability of the joint configuration over both layers is

$$P(v,h|\theta)=\frac{e^{-E(v,h|\theta)}}{Z(\theta)} \quad (2)$$

where $Z(\theta)$ is the normalized factor, equals to $\sum_{v}\sum_{h}e^{-E(v,h|\theta)}$.

In the binary case where $h_j\in\{0,1\}$, given input layer, a conditional probability of an output layer being 1 is given as:

$$P(h_j=1|v,\theta)=\sigma\left(b_j+\sum_{i=1}^{I}v_i\omega_{ij}\right) \quad (3)$$

In the same way, the conditional probability of input layer given the output layer:

$$P(v_i=1|h,\theta)=\sigma\left(a_i+\sum_{j=1}^{J}h_j\omega_{ij}\right) \quad (4)$$

where $\sigma(x)$ is a function, such as a sigmoid function,

$$\sigma(x)=\frac{1}{1+e^{-x}}.$$

Normally, total error *E* is minimized to acquire the most favorable parameters θ, RBM.

$$E=\frac{1}{2}\sum_{k}^{K}(d_k-o_k)^2 \quad (5)$$

where the d_k stands for the true outputs, o_k corresponds real outputs. In general, there are *K* outputs. Gradient descent is a good method to minimize total error, it is ecessary to compute the partial derivative of *E* with respect to each weight in the network. The parameters, such as weights and biases will be iterated by stochastic gradient ascent which can be formulated as [18]:

$$\Delta\omega_{ij}=\varepsilon\left(\langle v_i h_j\rangle_{data}-\langle v_i h_j\rangle_{recon}\right) \quad (6)$$

$$\Delta a_i=\varepsilon\left(\langle v_i\rangle_{data}-\langle v_i\rangle_{recon}\right) \quad (7)$$

$$\Delta b_j=\varepsilon\left(\langle h_j\rangle_{data}-\langle h_j\rangle_{recon}\right) \quad (8)$$

where ε is a key parameter, that is learning rate. $\langle\bullet\rangle_{data}$ is expectation for data distribution and $\langle\bullet\rangle_{recon}$ is the expected value of the model distribution.

2.2. Deep Belief Network

Several RBMs stacked into a classical model of deep belief network. There are two important steps in the DBN [19]. One is pre-training and the other is fine-tuning, shown in the Figure 2. Initial parameters are produced in the pre-treatment by an unsupervised method, such as gradient descent method to avoid local optimum. Back-propagation is normally used to update model parameters according to error, such as squared error or cross entropy error.

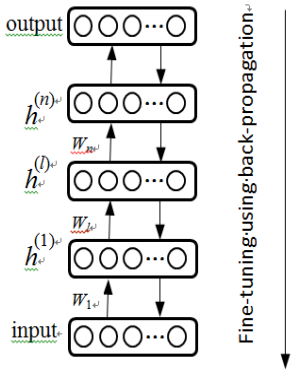

Figure 2: A generative model of deep belief network

2.2.1. Pre-training

Pre-training of DBN model is an unsupervised procedure. At the beginning, the input layer is initialized to a training vector. Then the subsequent hidden layer of RBM is trained through the output of the previous layer. Moreover, this whole process can be repeated until the final hidden layer. By doing so can the DBN extract more and deep feature from the original input data.

2.2.2. Fine-Tuning using Backpropagation algorithm

Backpropagation was coined by Rumbelhart [20]. Backpropagation update model parameters using cross entropy error because there is four kinds of outputs in this paper.

$$\delta_k = o_k(1-o_k)(d_k - o_k) \tag{9}$$

For the *l*th hidden layer,

$$\delta_i^l = (1-o_i)o_i \sum_j^n \omega_{ij}^l \delta_j^{l+1} \tag{10}$$

The batch update rules are

$$\omega_{ij}^l = \omega_{ij}^l + \varepsilon_{fine-tuning} o_i \delta_j^{l+1} \tag{11}$$

$$b_j^l = b_j^l + \varepsilon_{fine-tuning} \delta_j^{l+1} \tag{12}$$

2.3. Indicators of Evaluation of Classification

- *Overall accuracy*

The overall accuracy is total assessment of classified quality, which equals the total pixels sum divided by correctly classified pixels by total pixels. The formula for calculating the overall accuracy based on the confusion matrix can be listed as following:

$$p = \sum_{i=1}^{c} m_{ii} / N \tag{13}$$

here, *C* represents the number of categories, and m_{ii} represents the elements on the diagonal of the confusion matrix, and *N* represents the total number of test samples.

- *Kappa coefficient*

Kappa coefficient adopts a multivariate discrete analysis technique to reflect the consistency between classification results and reference data. It considers all factors of the confusion matrix, and it is a more objective evaluation index, which is defined as:

$$k = \frac{N\sum_{i=1}^{c} m_{ii} - \sum_{i=1}^{c}(m_{i+}m_{+i})}{N^2 - \sum_{i=1}^{c}(m_{i+}m_{+i})} \tag{14}$$

Among them, m_{i+} and m_{+i} represent the sum of the line *i* of the confusion matrix and the sum of the column *i* respectively. The higher the Kappa coefficient, the higher the classification precision.

3. Data and Process

3.1. Study site and hyperspectral data

Hyper Spectral Imager (HSI) is the first Chinese space-borne hyperspectral sensor aboard the HJ-1A satellite. In September 6, 2008, China launched the environmental and disaster monitoring and forecasting small satellite constellation A (HJ-1A), and the HJ-1A satellite was equipped with CCD camera and hyperspectral imager (HSI). With HSI interference imaging spectroscopy, the cutting width is 50km, the ground pixel resolution is 100 meters, 110-128 spectral bands, the spectral resolution of up to 2.08 nm, in the continuous spectral image of earth observation and available features to achieve the direct identification from the space object surface. HSI often produces certain stripe noise on the image. Satellite data was HJ-1A star HSI data 2 level products, imaging time is August 24, 2011, a total of 115 bands with working spectrum range 459 ~ 956 nm.

The research area has 8 downtowns in the west of Dehua county, Quanzhou City, Fujian Province. The administrative area of study site and its pseudo color synthetic imaging (105th, 7th, 40th band for pseudo colour synthesis) are shown in Figure 3. The image data of the product is geometrically corrected by previously corrected image with polynomial transform, and then orthorectified and outputted onto a fixed uniform spatial grid using nearest neighbour resampling. The correction error is not less than one pixel. The corrected image is unified into the specified map projection coordinate system (Xi'an 1980 coordinate system). There is obvious stripe noise in the part of the HSI image data, mainly in bands 1-29. Therefore, these 29 bands are eliminated from the HSI image. The remaining 86 bands are used for research within the wavelength range (529.6350-951.54 nm).

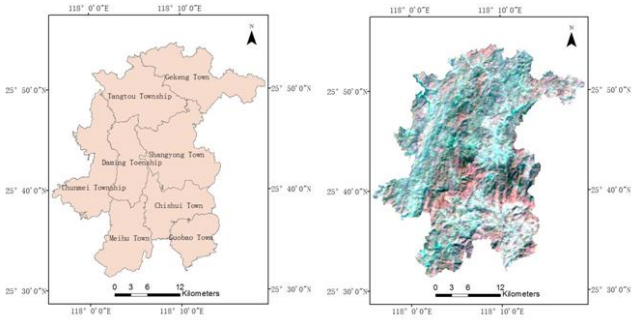

Figure 3: Study area and pseudo colour synthetic image

3.2. Experimental processing flow

According to the field data, the labelled samples were selected in the experiment. Then 86 bands of data were used as input of DBN. Before the training, these data were normalized by min-max normalization, which was mapped into the value between 0 and 1. Then, these data were shuffled and split into training and testing data randomly. After pre-training and fine tuning, categorical data was represented by one-hot coding, as shown in Table 1, 1 was Coniferous forest, 2 was Broad-leaved forest, 3 was Mixed forest, 4 was Non-forest.

The experiment is based on Windows 10 with 64-bit operating system. The processor is Intel (R) Core (TM) i5-8250U CPU @1.60GHz. The experiment is carried out in PyCharm 2018.3x64

editor to code and tune parameters. TensorFlow 1.11.0 framework was first set up as development environment. Also, The Python Extension Library is loaded, including Numpy, Pandas, Matplotlib, etc.

Then the selected samples were converted into a CSV file that is easy to be processed by Python program. All these samples were shuffled into training and testing data. Moreover, training samples were thrown into the DBN model. The trained parameters of model were stored into Tensorboar. Finally, the classified map of was outputted.

3.3. Distribution of samples

There are total 97258 pixels in the pseudo color synthetic image, shown in Table 1. The samples of four types in study site are selected manually. Different allocation of training samples and test samples are selected by experiments again and again. At last, 28000 pixels of known categories were selected as total samples. Among them, 51989 pixels pertain to the coniferous forest, 6142 pixels are broad-leaved forest, 16283 pixels are mixed forest, and the remaining 28986 pixels are non-forest. In the training process, there are 10,000 training samples for coniferous forest and 6,000 training samples for other forest type.

Table 1: Class code of dataset

Code of label	Forest type	Number of training samples	Number of testing samples	Number of all samples
1	Coniferous forest	10000	4000	45848
2	Broad-leaved forest	6000	4000	6142
3	Mixed forest	6000	4000	16283
4	Non-forest	6000	4000	28985
	total	28000	16000	97258

4. Experimental Results

4.1. Selection of super parameters

In the experiment, the dimension of the input data is 86. At the moment, network structure of DBN model is only designed by experience without theoretical basis. For simplicity, we assume that each hidden layer has the same number of nodes. The number of layers of the DBN is selected from {2, 3, 4, 5, 6, 7}, and the number of hidden layer nodes is selected from {16, 32, 64, 128, 256, 512}. According to the pre-experiments and references, several parameters are set as following: pre-training and fine-tuning of the learning rate is 0.001, the size of mini-batch is 100. Note that 10000 iteration times are run due to stability. Next, we discuss the influence of different network depth and the number of hidden layer nodes on the classification effect by fixing all these super parameters.

4.2. Network depth

Overall accuracy (OA) and Kappa coefficient were normally selected as the evaluation of image classification of remote sensing. The higher OA and Kappa coefficient, the better effect of classification precision. As we all know, network depth is key parameter of DBN. It is the number of hidden layers. Reference 21 summarized the range of optimal network depth is from 2 to 3 based on previous researches.

In experiment, we keep super parameters fixed and set the number of nodes in each hidden layer 256. Six different numbers (2, 3, 4, 5, 6, 7) of network depth were tested. Figure 4 shows that DBN with 3 hidden layers performs best, which both overall accuracy and Kappa coefficient are the largest. There is no obvious feature that how network depth affects the OA and Kappa coefficient. Reference [21] pointed out that there is no perfect theoretical basis for network structure selection. The optimal parameters should be given by experiments in different applications.

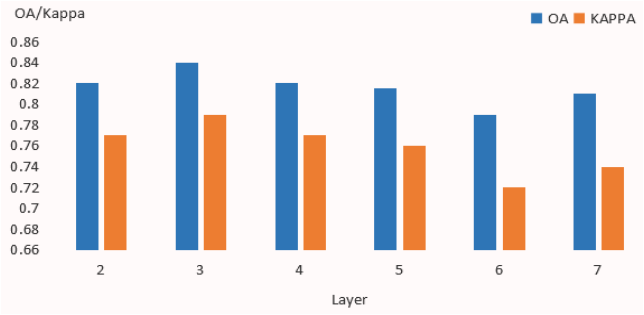

Figure 4: Effect of network depth on OA and Kappa coefficient

4.3. Number of nodes in each hidden layer

Number of nodes in the hidden layer is also import parameter in DBN model. When nodes are too large, it may cause the over-fitting problem. Oppositely, when nodes are too small, perhaps it will fail to extract deep information and gain high classification accuracy. Summarized by reference 21, the range of number of nodes in the hidden layer is from 50 to 500 according to previous research.

In experiment, we set super parameters unchanged and keep the network depth 3. Six various nodes (16, 32, 64, 128, 256, 512) were selected one by one and tested. Effect of number of nodes in each hidden layer on OA and Kappa coefficient is showed in Figure 5. It demonstrates that DBN with 256 nodes performs best, because it got the biggest overall accuracy and Kappa coefficient.

There is no obvious feature that how network depth affects the OA and Kappa coefficient. Reference [21-24] pointed out that there is no perfect theoretical basis for network structure selection. The optimal parameters should be given by experiments in different applications. Meanwhile, OA and Kappa coefficient keep relatively stable with changing nodes.

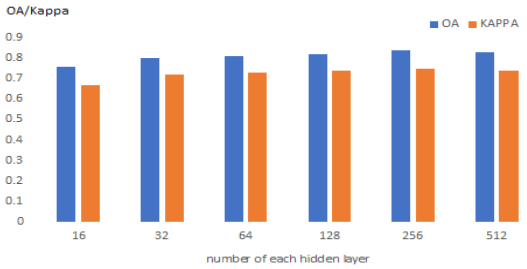

Figure 5: Effect of number of nodes in each hidden layer on OA and Kappa coefficient

4.4. Comparative analysis

SVM is a supervised and non-parametric machine learning algorithm. There is different type of kernels. A radial basis function (RBF) was adopted and has been used in some former works concerning forest type classification. The penalty factor C is selected from [1, 0.1, 0.001]. In order to keep the equit, the same samples are adopted between SVM and DBN method. Furthermore, to optimize of SVM method, five-fold cross validation and network search are adopted. When the C value is 1, the maximum overall accuracy is 73%, and the Kappa coefficient is 0.6447. For deep belief network, the optimal number of network depth is 3 and number of each node is 256.The classification process resulted in a thematic map of four kinds of forest types in Dehua county, as shown in Figure 6. As can be shown, the coniferous forest is green, broad-leaved forest is yellow, mixed forest is pink, and non-forest is blue.

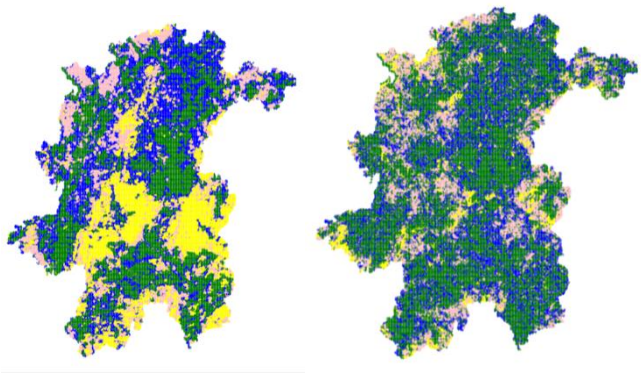
Table 2 reports the kappa values and the accuracy of forest types for both DBN and SVM classification algorithms. The accuracies of four kinds of forest types for SVM oscillated between 0.64 and 0.74 while DBN method varied from 0.82 to 0.89. Hyperspectral image classification using DBN algorithm yields the higher accuracy than that of SVM classifier for each forest type. Broad-leaved forest was generally better recognized than coniferous forest. Broad-leaved forest is classified with highest accuracy for both methods, 0.92 for DBN, while for SVM it is 0.84. The second top-classified forest type tends to be non-forest for DBN, while for SVM it is coniferous forest. Slightly lower result is obtained for mixed forest by DBN, while for non-forest by SVM. Furthermore, the worst effect performed by DBN algorithm is coniferous forest, compared to mixed forest for SVM. As the result, DBN model tends to attain better capability than SVM method from accuracy. There are two reasons due to it. One is that all feasible spectral features are thrown into input of DBN model, yet three bands or several components are selected as input for SVM method. The other is that there is large amount of data when all hyperspectal bands are considered. This is good for training of DBN model.

5. Conclusion and Discussion

This paper examined the capability DBN model in forest type classification with HJ/1A hyperspectral image. Many experiments are tested to obtain optimal parameter in DBN model. Conclusions can be drawing out as followed. At the beginning, the results showed that DBN model outperform SVM algorithm. Then, optimal network depth is 3 and best node in each layer is 256 in our experiment. Overall accuracy is 85.8% and kappa coefficient is 0.785 with best-fit parameters in DBN model.

Table 2: Comparison with SVM

Forest type	*SVM*	*DBN*
coniferous forest	0.74	0.82
broad-leaved forest	0.84	0.92
mixed forest	0.64	0.87
non-forest	0.70	0.89
OA	0.73	0.875
Kappa	0.6447	0.835



(a) SVM (b) DBN

Figure 6: Comparison of classification results based on different machine learning techniques

What makes our study unique is to make use of deep belief network to classify the forest type. Regardless of the spatial resolution of 100 m of HJ/1A hyperspectral image, our results provide satisfied recognition of four kinds of forest types. There are several open questions and future research directions remain worthy of investigation in the future. Firstly, in this paper, it is novative to adopt deep belief network to identify forest types. The classification accuracy of this method are better than that of support vector machine. However, it is still unclear that the mechanism of how this method can solve the traditional problem of "same object with different spectra" and "same spectra with different object ". Secondly, our results confirm the capability to map forest by deep belief network. Our experience in the study reveals that network depth and width affect accuracy of classification. The optimal structure needed to be adjusted according to different remote sensing data and further identification, such as tree species mapping. Finally, combining with field survey data, nearly one third of the samples are selected as training and testing samples to improve the classification effect. It is uncertain that how can we obtain the best result with so high number of total samples. It is a good idea to expand the sample by Generative Adversarial Network. Last but not least, optimal network structure is only for forest type recognition. The optimal network structure of specific forest type recognition needs further study. At the same time, it is urgent to establish the criteria and norms of forest classification using deep learning and remote sensing image.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

In this paper we propose an algorithmic approach for Convolutional Neural Network (CNN) for digital watermarking which outperforms the existing frequency domain techniques in all aspects including security along with the criteria in the neural networks such as conditions embedded, and types of watermarking attack. This research addresses digital watermarking in deep neural networks and with comprehensive experiments through computational modeling and algorithm design, we examine the performance of the built system to demonstrate the potential of watermarking neural networks. The inability of intruder towards the retrieval of data without the knowledge of architecture and keys is also discussed and results of the proposed method are compared with the state of the art methods at different noises and attacks.

1. Introduction

The research presented here is the extension of the work originally presented at International Conference on Artificial Intelligence and Signal Processing (AISP),2020 [1]. The digital revolution and the internet have paved a way to the creation of massive digital information containing images, videos, transactions, intellectual properties. The ease with which this digital data can be copied and reproduced has created avenues for copyright infringements. The massive explosion of digital multimedia devices has resulted in the creation of a large chunk of data and increased demand (and role) of data hiding techniques. Digital watermarking is employed for various applications such as copyright protection (ownership assertion), broadcast monitoring (really broadcasted or not), tamper detection (persistent item identification, forgery detection), data authentication and verification (integrity verification), fingerprinting (transaction tracking and privacy control), content description (labelling and captioning), publication monitoring and copy control (unauthorized distribution) covert communication (data hiding), Medical applications (Annotation and privacy control), and Legacy system enhancement (backward compatibility) [2]. All information hiding techniques revolve around 3 parameters: Imperceptibility, robustness and payload capacity [3]. While payload capacity is important in steganography, in digital watermarking the trade-off between imperceptibility and robustness is needed for the excellent quality of data hiding [4]. The ability of a data hiding technique to remain unchanged to human perception is called imperceptibility i.e. an unintended user should not be able to make out whether the image has undergone watermarking [5]. Robustness is the ability of watermarked data to be immune to attacks and threats. Other goals of digital watermarking are Security (watermark should be secret and undetectable by an unauthorized parties), effectiveness (ease of detection immediately after embedding), uniqueness (multiple watermarks to coexist), cost effectiveness (in terms of hardware and computational speed), and scalability [6]. Several Artificial Intelligent techniques such as neural network, evolutionary computation, fuzzy logic, swarm intelligence, Probabilistic reasoning and multi-agent systems were proposed to secure watermark in digital media [7]. These techniques will be employed at either the transmitter side during embedding the watermark or during the extraction stage at receiver. Recent approaches have also attempted to incorporate AI methods in the pre-processing stage [8].

With such diverse approaches and their unparalleled capabilities, the hiding of data in the digital image will be far more superior in terms of imperceptibility and robustness as compared to the existing ones [9].

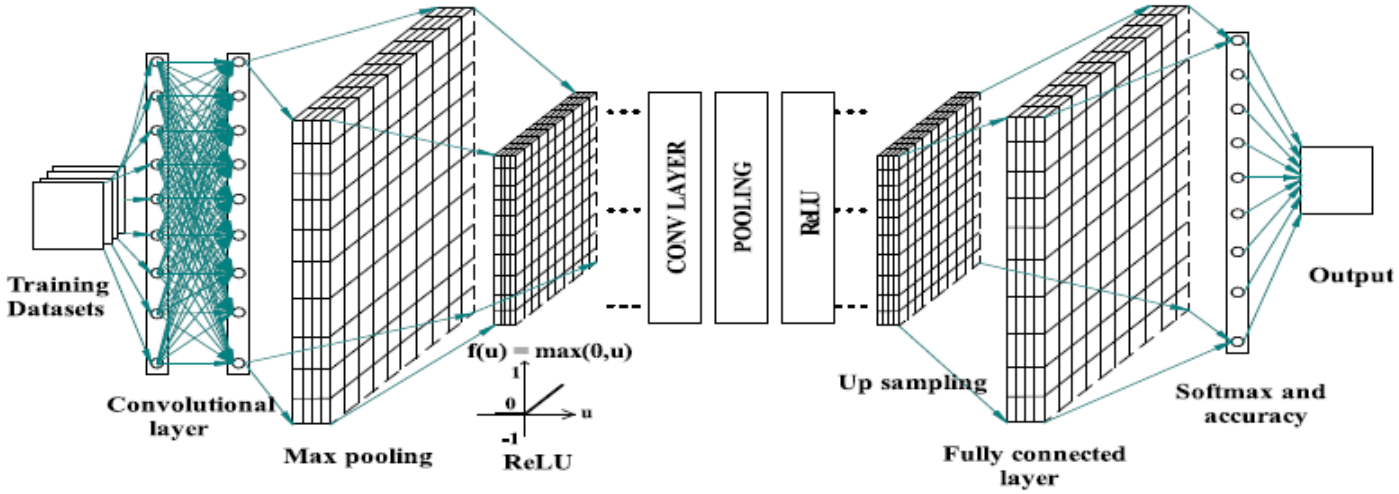

Figure 1: A typical digital watermarking process with Deep learning and its associated architectures

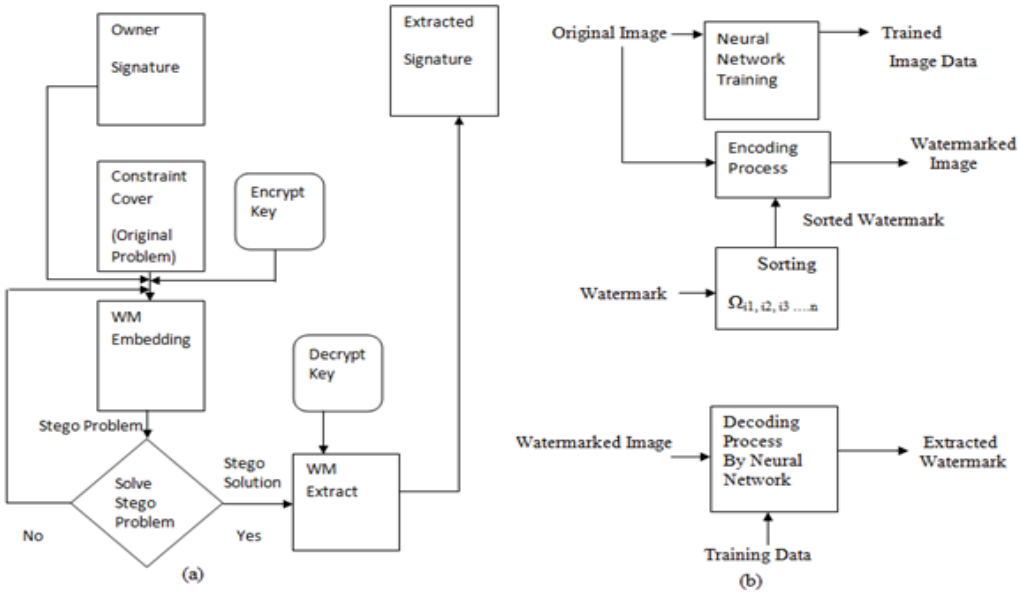

Figure 2: Experimental setup block diagram for digital watermarking process

A typical digital watermarking mechanism with embedding and extracting stages is depicted in Figure 1. It enables owners of the digital documents to embedded their copyright information for information security.

Digital watermarking can be done on text, image, audio, video and graphics in spatial or frequency domain. The watermark can be of noise type (pseudo noise, Gaussian random and chaotic sequences) or image type (binary image, stamp, logo and label) [10]. Based on the deployment conditions various watermarking techniques can be used. For public use, visible watermarks are preferred while for private applications and to arrest unauthorized copying invisible watermarking can be used [11]. Fragile watermarks are used in tamper-proof applications whereas robust watermarking is used in applications where the watermark should remain intact even after modification or tampered with [12]. According to the detection stage, visual watermarking is more robust which needs the original media and the embedded watermark for detection while blind watermarking does not require any of these. This is the most demanding type of watermarking as the watermarking is generated and embedded at the transmitter, while detection and extraction will happen at receiver as illustrated in Figure 2. Watermarking is also done even in prepossessing stage and the approach presented here does not impact the efficiency of the network in which a watermark is inserted as the embedded watermark while it is training the host network [13, 14].

The robustness of hard and soft decision detectors can be measured using Receiver Operating Characteristic graphs while Bit Error Rate is used for the detector response with bit sequence.

2. Literature Review

Many standard quantitative measures and metrics have been proposed to evaluate digital watermarking while comparing with their counterparts. Here we report all the standard methods found in the literature as illustrated in Table 1 and those used in this work to measure imperceptibility and robustness (along with capacity and computational cost) [34]. We use the methods for performance evaluation by ensuring

i) model and sources of distortion remain uniform
ii) All test images are 8-bit grey-scale images and are defined in same color space.

Quality assessment can also be done by comparing the original watermark and extracted watermark. This alternate metric is called a Normalized Correlation which exploits the correlation between the original watermark and the extracted one. The value lies between [0 1], any value nearer to 1 assures better quality. Another way of defining the similarity between the original watermark and the extracted one is accuracy ratio. It is the ratio of correct bits to the total bits. The architecture of CNN is different, unlike neural network where all layers are fully connected, here the layers are recognized in 3D: height, width, and depth. Further neurons in one layer are connected to only a small region of the next layer. Finally, the output is a single vector of probability scores, organized along the depth dimension [35]. The CNN consists of series of convolutional, pooling/sub-sampling layers followed by a fully connected layer. To implement the act of recognition in machines we need to show an algorithm of millions of images before it makes a pattern by generalizing the input and start making predictions for images it has never seen before [36]. The aim is to evolve a more robust and imperceptible watermarking scheme that can cater to the needs of content protection [37].

3. Algorithm Design

Watermarking can be achieved in any of the following two methods: either by changing the pixel values (least significant) of the image or by changing the coefficient values [38]. The quality of watermark depends on the method used. The first method where bits (representing the pixel values) are manipulated refers to a spatial domain which is very simple but not robust and can be easily perceived. In simple terms, spatial domain techniques refer to replacing pixels of the original image by watermark image [39]. In a given image first, the target pixels are identified and are replaced by pixels of watermark image. The spatial domain techniques are simple, fast and with less computational complexity [40]. They are immune to cropping and noising but are sensitive to signal processing attacks. In pursuit of enhancing robustness, if more pixels are manipulated we may end up with visible watermarks. These algorithms should carefully achieve a trade-off between robustness and imperceptibility [41]. In this section the experimental setup of watermarking a digital image is described with Algorithm 1 and Algorithm 2. At the various stages of digital watermarking from encoding of original image to decoding process and finally up to extracting the watermark and obtaining the high-resolution output decoded image. The aim is to evolve a more robust and imperceptible watermarking scheme that can cater to the needs of content protection and piracy prevention [42]. All the transform (and few hybrid approaches with NN) methods are good for watermarking but lack learning and adaptability [43]. We propose a digital watermarking method using deep learning methods which exploit the expressiveness of deep NN to securely embed invisible, imperceptible, attack-resilient binary signatures into the cover images. Coming to the

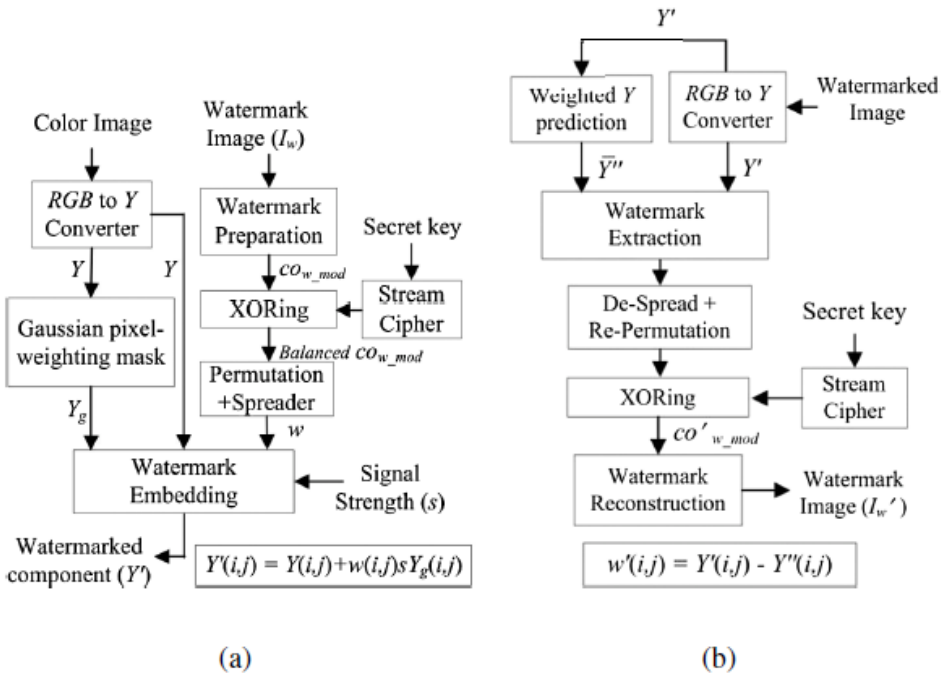

Figure 3: Block diagram representation of a typical digital watermarking process (a)Watermark Embedding and (b)Watermark Extraction.

decoder, we adopt adversarial model techniques to cause disorders to decode the desired signature [44]. We perform extended gradient descent under the Expectation over Transformation framework. In training the decoder network an Expectation-Maximization (EM) framework is employed to learn feature transformations that are more resilient to the attacks [45]. Experimental results indicate that our model achieves robustness across different transformations (all transformations, including scaling, rotation, adding noise, blurring, random cropping, and more) [46]. The aim is to evolve a more robust and imperceptible watermarking scheme that can cater to the needs of content protection and piracy prevention [47]. All the transform (and few hybrid approaches with NN) methods are good for watermarking but lack learning and adaptability [48]. We propose a digital watermarking method using deep learning methods which exploit the expressiveness of deep NN to securely embed an invisible, imperceptible, attack resilient binary signature into the cover images [49]. Coming to the decoder, we adopt adversarial model techniques to cause disorders to decode the desired signature.

Algorithm 1: Watermarking using Deep NN(Part-I)

Result: Encoding

  Else
    Given number of Iterations;
    Encode the set of images with specified binary targets;
    Image Encoding Process Ends;
  End Encoding Model
End

We perform extended gradient descent under the Expectation over Transformation framework. In training the decoder network an Expectation-Maximization (EM) framework is employed to learn feature transformations that are more resilient to the attacks. To implement the act of recognition in machines we need to show an algorithm of millions of images before it makes a pattern by generalizing the input and start making predictions for images it has never seen before [50]. The architecture of CNN is different, unlike NN where all layers are fully connected, here the layers are recognized in 3D: height, width, and depth. Further neurons in one layer are connected to only a small region of the next layer. Finally, the output is a single vector of probability scores, organized along the depth dimension. The CNN consists of series of convolutional, pooling/sub-sampling layers followed by a fully connected layer. The Figure 3 elucidates the block diagram representation of a typical digital watermarking process with Figure 3(a) as Watermark embedding process and Figure 3(b) watermark extraction phase. In this the input of the deep learning algorithm is the colour image and watermark to embed inside the colour image to watermark the deep Neural Network (DNN). The Algorithm 1 and Algorithm 2 are formulated based on the Figure 3(a) and 3(b).

Algorithm 2: Watermarking using Deep NN(Part-II)

Result: Decoding
Initialization;
While *setup* **do**
  Start the Decoding model;
  if *decoding network* **then**
    Initialize Decoding;

Extract Watermark;

Return predictions;
Return decoding model;
Image Decoding Process Ends;
End Decoding Model
End

The Algorithm 1 illustrates the encoding process of digital watermarking using deep neural network and the Algorithm 2 presents the decoding process of digital watermarking using deep neural network.

4. Performance Evaluation

Fair performance evaluation of any system is fundamental for its acceptance and accreditation. Many standard quantitative measures and metrics have been proposed to evaluate digital watermarking while comparing with their counterparts. Here we report all the standard methods found in the literature and those used in this work to measure imperceptibility and robustness (along with capacity and computational cost). We use the methods for performance evaluation by ensuring i) model and sources of distortion remain uniform ii) all test images are 8-bit gray-scale images and are defined in same color space. For an image size of M x N pixels, with a pixel value of O for original image (without watermark) and W for watermarked image, the performance metrics can be calculated as below:

MSRE:

$$MSRE(O,W) = \frac{1}{MN}\sum_{i=0}^{M-1}\sum_{J=0}^{N-1}[\mathrm{O(i,j)} - W(i,j)]e^2$$

PSNR:

$PSNR(O,W) = 10\log 10[\{255\}\,e^2/\mathrm{MSRE\ (O,W)}$

4.1. Robustness Metrics

Robustness Metrics: Robustness of a watermark is a measure of resistance to attacks. The detectors dictate the evaluation method to measure robustness. The three types of detector responses are i) hard decisions (true or false for the presence and absence of watermark respectively), ii) soft decisions (correlation or similarity coefficients in terms of real numbers) iii) bit sequence (if the embedded watermark is in form of a message). The robustness of hard and soft decision detectors can be measured using Receiver Operating Characteristic (ROC) graphs while Bit Error Rate (BER) is used for the detector response with bit sequence.

ROC:

True Positive Fraction (TPF): $\frac{Number\ of\ True\ Positive\ Results}{True\ Positive+False\ Negative\ Results}$

False Positive Fraction (FPF): $\frac{Number\ of\ False\ Positive\ Results}{Fasle\ \ Positive+True\ Negative\ Results}$

Quality assessment can also be done by comparing the original watermark and extracted watermark. This alternate metric is called a Normalized Correlation which exploits the correlation between the original watermark and the extracted one. The value lies between [0 1], any value nearer to 1 assures better quality. Another way of defining the similarity between the original watermark and the extracted one is accuracy ratio. It is the ratio of correct bits to the total bits. When the attack is not going to affect the commercial value then it is better to consider only the watermark-to-noise ratio. This ratio signifies the power of watermark signal against the noise introduced by such attacks. For a watermark of size m x n pixels, the performance metrics can be calculated as below:

$$NC(OW,EW) = \frac{1}{mn}\sum_{i=0}^{m-1}\sum_{J=0}^{n-1}[\delta[\mathrm{OW(i,j)} - EW(i,j)]$$

where,

δ (X,Y) = 1 if X=Y and 0 otherwise;

5. Results Obtained

In this section we discuss the watermarking in the presence of various attacks at different noise levels. We present the results in terms of robustness of the watermark (BER and NC). The CNN is trained using standard descent back propagation algorithm. The performance consistency of the proposed method is verified by considering 2 different cover images: Lena and Camera man as presented in Figure 4 shows the watermarking process with different transforms (scaling, rotation, adding noise, blurring, random cropping, and more)and also confirms that that the proposed method is applicable to any cover image and with any watermark. BER is a measure of noise injected when the

signal is received after transmission channel. The BER shows the signal loss and fading in a wireless channel. The BER for various noise levels is shown in Figure 5(a). Normalized (cross) correlation is a template-matching method in digital watermarking. The template will be an image that shows a critical feature; by repeatedly computing a statistic between the watermarked image and corresponding pixels of a subset of an original image presents the noise correlation for various noise levels of 2,5,10 and 15. The important parameter in watermarking is the loss of original information and the accuracy with which the watermark is hidden in the cover image. There is a fine balance between the robustness and imperceptibility. The trade-off is to achieve high robustness without showing any trace of watermark. The accuracy of our model is gradually increasing as the epochs increases, on the contrary loss is gradually decreasing. The models training and testing results are shown in Figure 6 with the over fit, under fit and good fit are shown in Figures 6(a), 6(b) and 6(c) respectively. Our model Adam performs well and is consistent as compared to other models as shown in Figure 7. The Figure 8 shows the noise injected/present and the model performance. In the Figure 8(a) noise in hidden layer is shown while Figure 8(b) depicts the noise in input layer.

Table 2: Comparison of Results

S.No	Noise/Attack	Parameter	[51]	[52]	[53]	[54]	[55]	[56]	[57]	[58]	Our Work
1	No Noise	PSNR(db)	58.91	48.29	48.47	51.45	34.33	56.47	35.6	47	**62.3**
		NC	1	1	1	1	1	1	0.99	0.98	**1.00**
2	With Noise	PSNR(db)	55.10	43.04	32.74	31.66	22.43	40.18	29.1	41.72	**58.78**
		NC	1	0.91	0.81	0.92	0.91	0.93	0.95	0.91	**1.00**

The graph shows that training and test results are in good accordance and validate the model used for training and optimization in digital watermarking. The proposed model is suitable for video too as the training is done off-line hence can be used in real-time applications. Hence the use of deep neural networks will enable us to realize complex features like learning weight sharing and update mechanism, noise-resilience and immunity towards attacks, and scaling. The proposed method has low loss and the accuracy goes on increasing as the number of epochs increases. The accuracy is 85% for 15 epochs and will slightly increase for more epochs. The level of high accuracy shows that the original image and watermarked image are indistinguishable.

This high performance of the model can be owed to the learning feature embedded in the watermarking. A digital watermarking task comprises embedding a signal into an image in accordance with robustness and quality constraints, it can be said that it is in essence a multi-objective optimization problem. The faster convergence of the algorithm (more accuracy with less epochs) can be achieved by introducing reinforcement learning or transfer learning method which has got huge attention in recent times. The current digital watermarking can also be validated by applying it to protect the copyrights of trained neural networks where ownership protection and piracy prevention is of utmost priority. The traditional approaches in digital watermarking are not fit for the digital data that can be stored efficiently and with very high quality and manipulated easily using computers [59, 60]. The aim is to evolve a secure digital communication that remarkably pushes forward the limits of legacy digital watermarking schemes across all dimensions of performance metrics. As this research space is ever increasing and innovations have spurred at all levels of communication, considerable progress is required in understanding the deep learning approaches for digital watermarking. The convergence of technological, economic and environmental forces is driving the digital watermarking and deep learning simultaneously, then each drives the other forward. Be it the deep neural networks driving digital watermarking or vice-versa, the continued expansion of each is good for the other. The complete suitability of digital watermarking for securing deep neural networks dataset is yet to be conducted. The trained models can be viewed as intellectual property, and it is a worthy challenge to provide copyright protection for trained models. We emphasis on how the copyrights of trained models can be protected computationally and propose for neural networks a digital watermarking technology. We propose a conceptual framework for integrating a watermark into models of deep neural networks to safeguard copyrights and identify violation of trained models of intellectual property. The Table 2 illustrates the comparison of obtained results with the previous works and it is noteworthy that the proposed work has shown an improvement of 5.75% in PSNR without noise and 6.68% in PSNR with noise = 5.

6. Conclusions

In this paper, we proposed a learning framework for robust digital image watermarking technique based on deep neural network. As observed, previous efforts in this space focused on optimization of embedding parameters with use of evolutionary computing. Demonstration of the watermarking under various noise and attacks is performed. The detailed experiments were carried out and we analyzed the performance of designed system. We have shown that our model could embed a watermark without impairing a deep neural network's efficiency. In future the research would continue in the direction towards digital watermarking based on intelligence.

ABSTRACT

The technological evolution and the frequent use of the Internet as a technology within the framework of the Internet of Things and Robotics has affected various fields such as Industry 4.0, smart agriculture, smart cities, home automation and autonomous cars. These advances applied to everyday life have facilitated the implementation of new concepts to minimize pollution, traffic jams and accidents while making life easier. In this article, we propose an intelligent parking concept based on embedded systems. In order to solve the problem of permanent traffic jams and their repercussions on large cities we have implemented this system. It is a complete platform allowing remote reservation from different platforms. It will also collect the various data obtained by parking sensors. These data will be processed and saved if necessary. This concept was first developed to highlight the feasibility and adaptability of this system in the context of smart cities. It has been realized using wireless sensor networks connected to embedded platforms. These platforms are not only connected to motors, sensors and actuators but also to servers to save data and deploy reservations. These reservations are made via web and mobile application.

1. Introduction

The robotics automation, wireless sensors, artificial intelligence and embedded systems are famous scientific research fields with a wide margin for innovation and growth. Although these are areas that are literally different and divergent. However, they remain compatible. One can thus join these different axes in order to carry out applications that make life easier for mankind.

In this framework, we can mention several types of uses such as smart houses [1], smart agriculture [2] and smart parking [3], which are smart city [4] applications. We can also talk about e-health [5] and Industry 4.0 [6] which are applications in constant development.

In this work, we're going to touch on smart parking. The automated systems for vehicle parking management [7] are widely available in the recent years. However, it is still an exclusive product that is not largely used for a couple of reasons including being very cost expensive and complex. These difficulties also contribute to other problems such as hard maintenance and resource management issues [8]. Nowadays, android applications and Arduino based technologies [9] are the mainstream and the most popular solution in numerous domains due to being open sourced. This attribute makes them easy to implement and heavily supported with the majority of hardware and software. For these reasons we used android based application for our embedded smart parking and management system that outperformed the other available options in resource optimization and performance.

In our previous work [10] we presented a fully embedded architecture for an automated intelligent parking system that communicates through an Android application, which delivered an intelligent parking management and a top-notch costumer service for smart parking.

In this paper, we describe in details our previous work [10] while we expand on the practical implementation and the communication interface. With the objective of having a functional prototype that develops the research work and can be integrated in the field of smart cities, we will present two platforms:

- an embedded platform that has the role of data acquisition and processing in our parking lot. The use and architecture will be described later on.
- a client/server platform with Android and Web applications: these will describe the reservation, confirmation and payment parts of the proposed service.

*Corresponding Author: Tarek Frikha, tarek.frikha@enis.tn

Our paper will be presented as follows. We start by an overview on the smart parking state of the art. In the theoretical analysis section, we will introduce the architectural design of the car parks on one hand and the developed computer application to be realized on the other. Then, we present the practical implementation section where we demonstrate the developed applications as well as the implemented embedded architecture. Finally, we compare between the implemented Intelligent Parking results before we declare the conclusion and perspectives.

2. State of Art

Several works have presented smart parking. In [11], they present a flexible and real time information system. This parking is easy to use for the client via web connexion. A CMOS cam is used to control the parking. The disadvantages of this system are the need to inquire for the available slot, the high implementation cost. The most important disadvantage is the bottlenecks due to an overload of incoming informations.

In [12], they use RFID technology. It permits to have not only secured but also an easy and fast checking out of the vehicles in less time. The data security is provided by ZigBee Wireless Technology. The data of the arrival and departure of the vehicle are stored in database. To inform the driver informations are displayed on the LCD proposed screens in the parking. Despite all the advantages, the system has many disadvantages. It allows one by one. That's why it consumes a lot of time and prevent multiple check out and check in at the same time. The drive can't make a reservation via mobile device. Another disadvantage of RFID is the increase of cost and of the node to node implementation time.

In [13], if the most important disadvantage is that the parking does not alarm the user about the car theft, the proposed smart parking use ultrasonic sensors and RFID. Needing for deployment ZigBee and 3G (or 4G, 5G…), the most important advantages of the proposed work are the use of the Car Parking Framework that gives two performance classes in term of financial and consumption cost deployment. In addition, the heterogeneous wireless sensor network cause energy fluctuations. To remedy they use LIBP gathering protocol.

In [14], they use Zigbee for deployment and ferromagnetic sensor. Suryady and al introduced another concept of smart parking based on cloud-based platforms as a service (PaaS). This technology gives the smart parking an interesting quality. The smart-parking system is faster to use. It reduces time, cost and system maintenance. The platform has the advantage of being flexible to collaborate with other platforms. This system has also disadvantaged. It does not provide neither guidance for the drive nor payment due to the application insecurity to protect user privacy. The user has no possibility to display spaces for user on smartphone or parking LCD.

In [15], the smart parking is more complete. It has many qualities like his flexibility and security increase. This security appears for the user because of less of human interaction for booking slots. The drive can find the availability of parking space and then books slots. The IoT's devices provide data storage. The data are processed and collected to be saved. The drive has another security aspect to preserve the user from steals by theft management.

As we already declared, there are numerous automated parking management systems, yet only three methods which are Park Assist [16], Hectronic [17] and Parking plus [18] that stand out and achieve respectable results. These intelligent car parks are available on the market but have some missing features that need to be addressed.

2.1. Park Assist smart parking system

the TKH group developed this smart parking system that have various traits including guiding the client to the empty parking space while providing access to a mobile application with the vehicle geolocation and the reliance on machine learning analysis for the parking spaces to insure the right exploitation.

2.2. Hectronic intelligent parking

Contrary to Park assist, this intelligent parking system delivered by the German international company Hectronic has a separate entrance and exit terminals. The main feature of this system is their powerful and well built security alongside other adequately constructed services.

2.3. Parking Plus mobile application

This parking system is based on a mobile application that delivers a central parking service by gathering information from a cluster of parking zones to provide the driver with the details about the nearest empty parking place and the possibility to reserve it and pay for it by the phone.

When we analyze these various methods, we found that some of them have security shortcomings both in capturing information for reservation and payment or in securing vehicles in case of theft. Therefore, in this work we present an intelligent car park allowing the capture of information on the different vehicles when they enter, exit and during their presence in our car park. An offline backup is made throughout the day before being transmitted to the cloud in order to maintain a trace if necessary.

Reservation, payment and placement of the car in the car park are done in a secure way via not only web but also mobile applications compatible on different types of terminals.

Given the lack of space proposed for parking lots and the permanent increase in the number of cars in large cities generally and particularly in Tunisia, our goal is to set up an intelligent system to give the user the choice, if possible, to choose his parking space, if not to allocate an automatic space to optimize the space.

Indeed, thanks to the automatic parking system chosen, we will have the possibility:

- to secure the parking lot by minimizing human intervention: cars will be closed and parked at the entrance of the parking lot. Their placement will be carried out automatically afterwards.
- to optimize space and minimize accidents: the cars will be parked automatically and therefore no space or accidents due to bad maneuvers will occur.
- to minimize pollution and traffic jams: by allowing the reservation system to not search for parking spaces in a

random way and therefore optimize fuel consumption and minimize pollution.

The innovation proposed in our paper is to create a fully automated parking system that solves the limitations described above.

This design will present not only the architecture of the realized prototype but also the technologies based on the IoT to allow the automatic placement of cars in the proposed concept.

There will be a design part, an IoT part and a hardware implementation part which will be described in parts 3 and 4.

3. Theoretical Analysis

Looking at the systems available on the market, we can initially assume that depending on their points of strength we can choose from them a tolerable approach [19]. However, these methods have many apparent concerns such as the inefficient space exploitation with Park Assist and Hectronic by the need for a driving pavement to connect the vehicle to the driving spot and the capacity problem caused by the lack of long term parking strategy [20]. We can also point out the high service cost and the absence of security plan for Parking Plus. In this section we will describe the different axis of our own parking architecture that fix these issues.

We begin with our proposed parking architecture for car parks that is set up in narrow plots of land. We present a cylinder shape architecture as shown in figure 1. The second part of this theoretical analysis introduce the proposed embedded system to collect, process and update the information before transmission step. The last part describes the frontend and the backend of the application architecture. It will describe different actors and secured reservation and payment service to be used by the driver.

3.1. Smart parking architecture

3.1.1. Proposed smart parking architecture

In order to solve the parking management concerns that the previous methods failed to answer, we conceptualized a structure with a cylinder-shaped architecture for vehicle parking as revealed in figure 1.

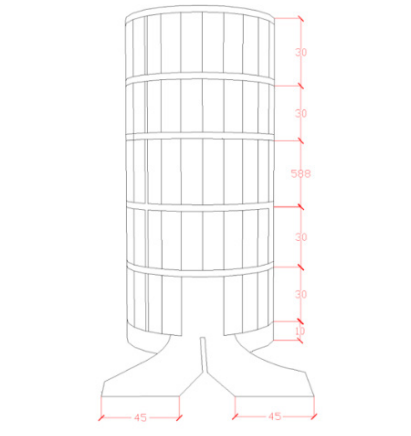

Figure 1: The front face display of the cylinder-shaped architecture for our parking

We choose using this architectural shape in an attempt to reduce the space spent on pavement allowing the vehicle movement within the structure and switching to a unique vehicle area, which is the mechanical component that act as an elevator and the selector for the parking place simultaneously.

3.1.2. Detailed units of the architecture

To simplify and optimize the driver's access to the proposed architecture, the parking place selection is done via the android mobile application. Afterwards, the driver has to station his vehicle on the entrance elevator panel that has the same size as standard parking place as shown in figure 2.

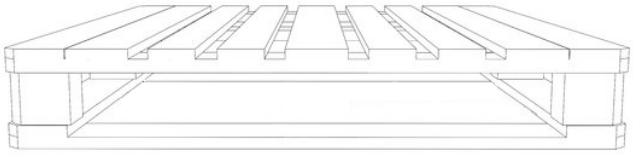

Figure 2: A side view of the entrance elevator panel

Having reserved a parking space via web or mobile application, the customer will provide the information for the car registration number. This number will be the reference to allow the car to enter the parking place.

Once the vehicle is checked to the entrance panel, a two-armed cart raise the panel as an elevator. Figure 3 present an example of this activity.

Afterwards, the vehicle will be directed directly to the parking space relying on the elevator's ability to rotate 360 degrees. This feature allows the system to set the vehicle in the appropriate location selected in advance by the customer. The exit process is also similar to the entry procedure but backwards. The customer has to do his check out and pay for the service via the mobile application and once he does the elevator selects the vehicle corresponding to the car registration number and bring it down to the exit of the parking lot.

The full automation of elevator with the minimization of manpower and human intervention in the parking process will make the process secure by avoiding human errors and effective by efficient exploitation of the parking facility.

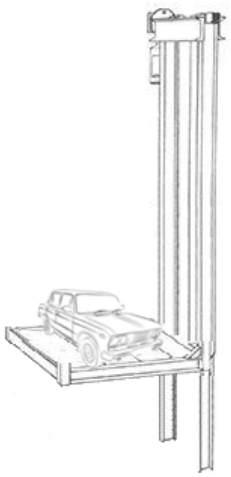

Figure 3: A sketch example of a vehicle elevator

3.2. Hardware embedded architecture

Having chosen a suitable architectural form for our intelligent car park, we will present the embedded implementation of our system in this section. It will, in fact, consist of three parts. Firstly, we have chosen a set of sensors and actuators that will be installed in order to obtain information about the parking spaces if they are available or occupied. Second, a system will collect this information from the installed sensors to update and save the occupancy in the parking lot. This data will be saved locally and subsequently updated in the cloud. In part C, we will present the software backup platform implemented.

3.2.1. Used set of sensors and actuators (SSA)

As described in the state-of-the-art section, our intelligent car park will not only make the driver's life easier by offering him an available space but will also provide him with a secure space for both him and his vehicle.

Thus, a surveillance camera at the entrance but also on each floor of the car park will detect the license plate of the car in order to validate its access to the car park but also to the reserved space.

As soon as the car reaches its space a sensor will transfer the information and cancel the space for any other reservation. At the exit of the car park, the information is transmitted directly to the driver and the space will be directly released for another reservation.

The billing for this operation will be proportional to the time occupied in our car park.

To sum up, we'll need:

- Surveillance cameras at the entrance and exit of the car park but also at the entrance and exit of each floor of our car park.

- Barrier level detection sensors to validate entry and exit to the car park.

- Infrared sensors to transmit information on the presence and absence of the car from the reserved space.

In parallel with the sensors, the need for actuators is equally important. Indeed, these will allow us to manage the different engines of our car park remotely. We can therefore mention the following:

- The motors of the car park barriers
- The engines of the car lift
- Vehicle placement jacks as shown in Figure 3.

Due to the importance of precision in the realization of our system. Different electrical voltage values must be received from the sensors and sent to the different motors. The accuracy of these data requires a system that can directly manipulate the analog data by minimizing the use of digital-to-analog and analog-to-digital converters. This will be detailed in the section sensor and actuators control and collection platform.

3.2.2. Sensor and actuators control and collection platform (SAC2P)

In order to control the various sensors and actuators present in our system, we will use an on-board platform that can receive and transmit analog data. In the prototype that will be described in section IV, part B, we will use an embedded Arduino platform that will allow us to validate the proposed approach.

This platform will be connected via Bluetooth to both actuators and sensors. It will thus control entry to the car park, the placement of the car and the sending of information to the information backup and transfer platform. Figure 4 describes sensor and actuators control and collection platform.

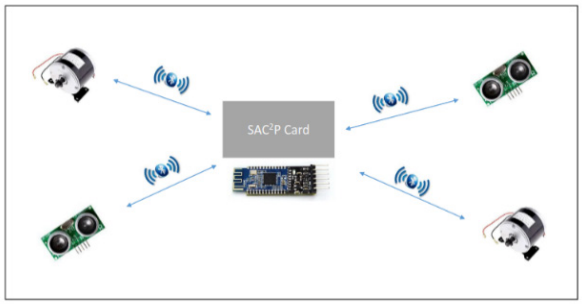

Figure 4: Sensor and actuators control and collection platform

3.2.3. Information backup and transfer platform (IBTP)

The Information backup and transfer platform part offers a digital embedded platform.

Several types of platforms can be proposed such as GPUs, FPGAs, ASICs. This platform will have four main tasks with the following priorities:

a) Acquisition and processing of information from surveillance cameras.

b) The administration of the Sensor and actuators control and collection platform via Bluetooth.

c) The offline backup and management of the various data recovered.

d) Updating information and saving it on the cloud server via wifi or 4G

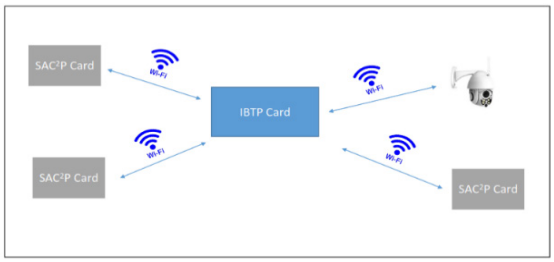

Figure 5: Information backup and transfer platform

Since, for our application, obtaining a real-time result is not paramount, it is not necessary to use GPUs that are quite expensive in terms of hardware and energy costs. Thus, a simple multiprocessor architecture based on 4 processors working in parallel is largely enough.

For our application, we decided to use a Raspberry Pi as a platform to meet the needs of our Smart Parking prototype. In part 4, we will describe in more detail the system implemented.

In figure 5, there is a description of information backup and transfer platform.

3.3. Software reservation platform architecture

After having described and set up the architecture part 3.1 and the hardware part 3.2, we will highlight in part 3.3 the software part and particularly the online booking platform.

In the reservation part we will have several interfaces.

Firstly, the administrator will access the different functionalities via the web. He will be able to modify the terms of payment, accept complaints, validate possible subscriptions from members and deal with disputes.

It is the administrator who will be able to manipulate the number of spaces, the availability as well as the occupation of the car park, the rates per hourly session, penalties for late payment.

The customer will access the online booking platform either via mobile application or via web.

Each customer must first register on the system either via mobile application or via the web. He will indicate his personal data (surname, first name, telephone number, e-mail, license plate, make and colour of the car, ...). He will then choose the method of payment either by credit card or in cash.

As a nominal scenario, a customer will be able to reserve a place on one or the other of the applications. He will indicate the duration of his parking period. At the time of reservation, the user will indicate the method of payment. At 15 minutes from the end of the indicated parking period, a SMS and an e-mail will be sent to inform the customer. He will be able to extend his reservation by reply or maintain the duration indicated at the time of reservation.

On leaving the car park, the parking space is released and is therefore open for a new reservation.

If the customer leaves the car park on time and has paid by credit card, they will leave the car park directly: the camera at the car park entrance will identify the car and open the entrance barrier. If he is going to pay in cash, a machine will take the coins or notes and give him the rest of the amount.

If the customer is late without replying to the SMS received, he will have to pay a penalty. The amount charged for leaving the car park will be the equivalent of a full day's parking.

If the customer is late and this delay has been indicated by message, the customer will pay the difference when leaving the car park.

4. Practical implementation

In this part we will present the parts describing the implementation and setup of our demonstrator. We will start with the modeling part including the class diagram and the use case diagram.

Then we propose the mobile SW part (Arduino application) and finally the implementation of the embedded part implemented on an Arduino platform.

4.1. Uses case diagram

In this section we will present the actors of our platform. The administrator, the client as a physical actor and the system as a logical actor.

0As shown in Figure 6, the administrator has the possibility to access to the different functionalities via the web. He will be able to accept claims, check the number of seats and set rates per hourly session.

The administrator can also be able to manipulate the penalties for late payment, validate the possible subscription of the member and change the terms of payment, etc.

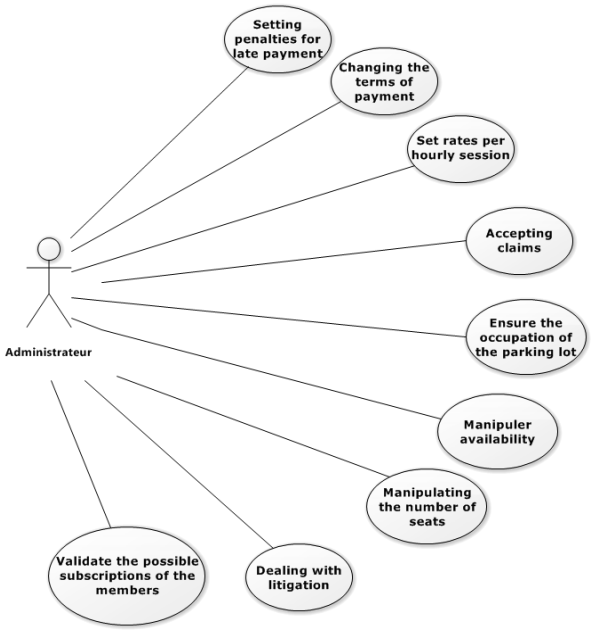

Figure 6: Admin Use Class Diagram

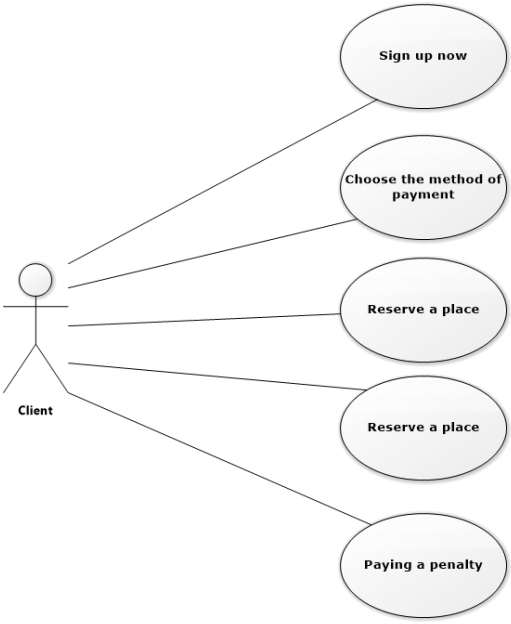

Figure 7: Client Use Class Diagram

The client, as mentioned in Figure 7, must start by registering on the system either via mobile application or via the web. He I indicate his personal data such as surname, first name, phone number, e-mail, license plate, make and color of the car, etc. After that, he chooses the method of payment either by credit card or cash. He will be able to reserve a place by indicate the duration of his parking period.

At the time of his reservation, the client will indicate the method of payment. He will be able to extend his reservation by reply or maintain the duration indicated at the time of reservation.

The last actor is the system, as represented in Figure 8, it must be able to identity the car, take coins or bills, remit the rest of the amount, open the entry barrier and before 15 minutes of the end of the period subscription, it sends a SMS to client to inform him; if he wants to extend the period or he free the space.

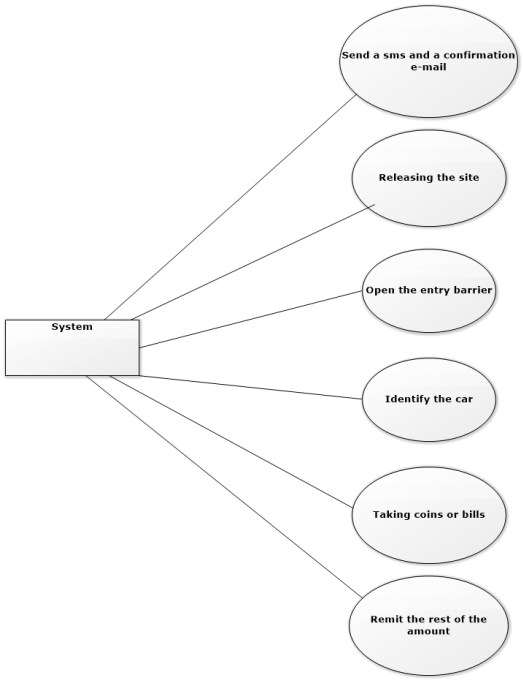

Figure 8: System Use Cas Diagram

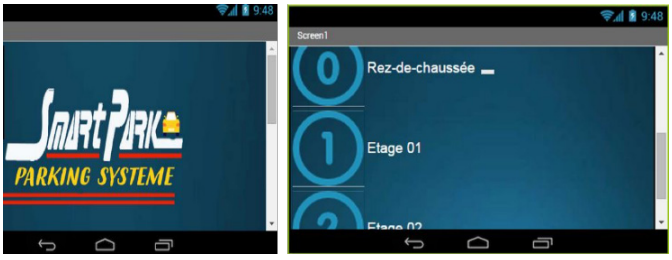

Figure 9: Our smart park application main menu

4.2. Android application

The Android operating system is by far the largest used operating system for smartphones in the world for the recent years. To communicate with our automated smart system, we developed an Android application to exploit the ease of implementation, compatibility and support [21]. We used the App Inventor development tool generate by Google to create our Android web application for smartphones [22]. Our application contains a main menu for the user to select the desired parking floor from the parking structure as shown in figure 9.

From this menu the driver first selects the floor and then searches for the empty parking location. Finally, the application creates a security code for the specific location to be used by the user when he exits the parking facility. It is also possible for the user to let the parking system to choose automatically which place to allocate.

4.3. Arduino technology embedded system:

To control the various parts of our system we choose to work with a simple Arduino board [23] and we have decided on the Arduino mega board. This embedded bored is responsible for the communication with the client commands coming from the Android application. It is also responsible for checking and monitoring the sensors that provide the information about empty locations and vehicle presence, while managing the mechanical elements of the elevator and the rotating panel.

For the communication part, the Arduino mega board needs the Arduino WIFI shield in order to connect to the network via WIFI [24]. As displayed in figure 10, this wifi shield is pin by pin compatible with the Arduino mega board, which makes it easy to work with.

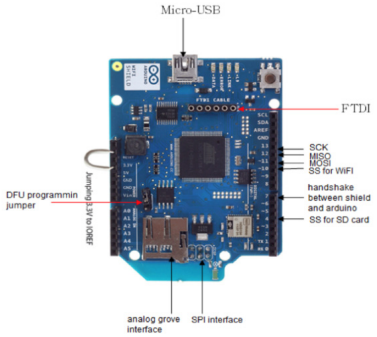

Figure 10: The Arduino WIFI shield

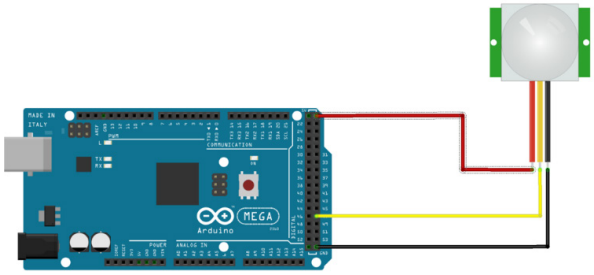

Figure 11: Arduino mega board and the PIR sensor wiring diagram

In order to collect the information about the availability of the parking locations and the elevator panel a cluster of spread out sensors is crucial for our system. Therefore, we decided to lay out a collection of the PIR (Passive Infrared Sensor) in every parking location, the entrance, the exit and in the elevator panel. As shown in figure 11, connecting the PIR sensor to our Arduino mega board is a very simple operation that demands the use of only three pins. We also considered using the HC-SR04 ultrasonic sensor for the same operation mainly for compatibility reasons since it is also an

Arduino technologies component. However, considering the low expensive PIR sensor was the optimal choice since it does not compromise the proficiency of our system [25].

To manage the mechanical part of our system, which are the elevator panel motor and the rotation motor, we also relied on our Arduino mega board. For our prototype , we sufficed with the use of simple direct current motor driver to emulate a real life situation where our Arduino mega board can also control the motor of the elevator using two relays and terminal levers for the 230V alternative current motor [26]. Our choice for a simple DC motor driver is the L298N circuit that grants our Arduino board full authority over the speed and the rotation direction of the direct current motor [27]. For the panel rotation motor, we used a servomotor connected to the Arduino mega. The servomotor delivers an immense management and control to every detail of the panel rotation and angular rotation manipulation [28]. With the use of the servomotor, we guarantee that our smart parking system is capable to reach all parking positions throughout the facility thanks to the 360 degrees of freedom available to the rotating panel. In figure 12 we present the wiring diagram for both the DC motor and the servomotor.

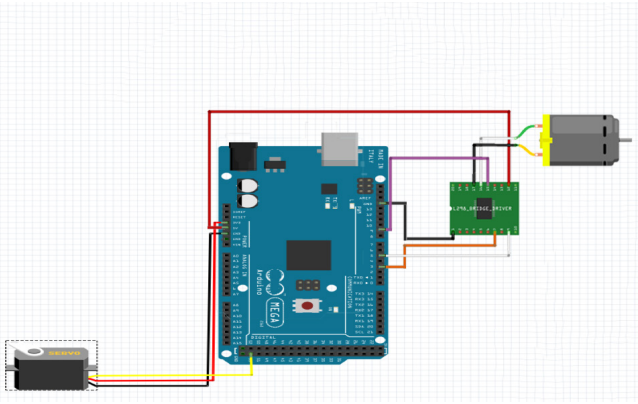

Figure 12: The Arduino mega board wiring diagram with the L298N motor driver, the DC motor and the servo motor.

4.4. Result comparison

Comparing the system we have set up with the different intelligent parking lots existing in the literature we notice that our system has several points in common with them but has advantages in terms of space optimization and automation of the system.

Table 1 illustrates this comparison.

Table 1: ESP2 parking comparison

	Mobile App	Automatic	Secured	Smart
Park Assist	Yes	No	*	No
Hectronic	Yes	No	***	No
Parking +	Yes	No	***	Yes
ESP2	Yes	Yes	*****	Yes

As shown in Table 1, it can be seen that all the systems described in the literature offer a mobile application for booking.

However, the car parking requires the intervention of the man (driver or parking manager) to park the car unlike our system which is fully automated based on sensors, IoT and embedded systems.

The minimization of human intervention makes it possible to secure the system against theft, minimize human errors and save energy consumption.

Finally, as Parking+, our system has an intelligent part to update the status of the parking lot and therefore make it easier to park the car while minimizing the waiting time for parking.

5. Conclusion

Throughout this paper we introduced a smart vehicle parking system that effectively manage the storage and automates vehicle parking using an Android application as the front-end user communication platform with our embedded control system. Our embedded control unit includes the main Arduino mega embedded board and the Arduino WIFI shield that ensures WIFI connection. The information for the presence of vehicles and the availability of empty parking location is acquired by the collection of PIR sensors and provided to the Arduino mega board to take the appropriate decision. This main control unit is also responsible for the management and control of the elevator panel and the rotation engine in charge of accessing the empty locations and stored vehicles.

Our novel smart parking system with the Android customer communication unit has delivered a better storage management capability than the previously mentioned commercially available competitors. The dominance of our developed system over Park Assist and Hectronic parking system is clearly manifested in the long term cost gained from the smart management of the allocated space that our competitors sacrifice in order to provide the driving pavement needed to connect the vehicle to the driving spot. The Parking Plus application also miss the security quality that our solution provides compared to their nonexistent answer to this problem.

Although our system is a great solution for smart parking, we do not deny the fact that it has a few shortcomings such as the need for more flexibility when it comes to the architectural structure of the facility and the power management of the mechanical parts (elevator panel and rotation engine). These limitations can be the subject of future research that can include introducing a sustainable energy resources and other architectural designs. we can also ensure a better security by implementing a decentralized Blockchain based security control system in case of an expansion to a multiple units of smart parking systems.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

The adoption and diffusion of mobile applications (mobile apps) has become the base of modern activities in Africa owing to the services and values that are obtained through mobile apps innovations. More emphasis has been on the development of mobile apps whereas the adoption and diffusion process as well as their predictors are ignored or given less attention. This study explores and develops a framework for the adoption and diffusion of mobile apps in Africa. A survey was conducted on the basis of the diffusion of innovation framework in five-selected African nations. A total of 1285 of the 2300 distributed questionnaires were returned, giving a response rate of 55.87%. The results indicated that many factors/predictors drive the acceptance and use of mobile apps and these factors were structured to develop a common framework for mobile apps adoption and diffusion in Africa.

1 Introduction

The advancement in mobile technology has had a major impact on the manner in which business and personal activities are performed. It could be said, in particular, that a radical evolution started with the advent of handheld devices such as mobile phones that caused the creation of distinct kinds of mobile apps that are used in separate activities [1, 2]. A number of mobile technology start-ups have been created in Africa to encourage mobile app innovation [2, 3]. Advances in digital technology have enhanced communication systems in Africa, leading to a growing amount of African communities linked to digital communications [4, 5]. The use of mobile apps are changing the African society, socially, economically and politically [1], [6, 7]. Despite the penetration and growth of mobile services, some mobile apps are rejected and discontinued to be used. Moreover, there are some non-users of mobile apps in Africa [8]. The process of acquiring and disseminating mobile app services in Africa must therefore be improved, particularly for those with local content.

It is imperative to information and communication technology (ICT) experts and scholars to know the flow of information technologies [3]. This can be achieved by conducting a research on adoption and diffusion, which implies accepting to use [2, 9, 10] and continuing the use of a new innovation [11, 12]. Various models have been proposed to aid this process including frameworks for mobile health [13], mobile banking [14] and e-government [15]. These models dealt on a particular mobile app in a specific country and cannot be generalised.

However, African mobile consumers are growing interest in home-grown mobile apps. Several mobile apps have originated in Africa, especially in South Africa, Nigeria and Kenya including social networking mobile apps like Mxit, 2go and How Far, entertainment mobile apps like Simfy Africa, Spinlet, iRokoTV and SOLO, and financial mobile apps like M-pesa [2]. These mobile apps are mostly used in the country where they are created whereas in the other countries of the continent, there is little or no adoption of the mobile apps. In other words, there is a significant difference between the rate of adoption of each respective mobile app between the country where it is created and the other countries in Africa.

This study proposes a general framework for mobile apps adoption and diffusion in African social system. Drawing from the literature on the adoption of mobile app innovation and deliveries, this research intends to address the following questions:

1. What are the factors that influences mobile apps adoption in

[*]Corresponding Author: Chinedu Wilfred Okonkwo, School of Consumer Intelligence and Information Systems, University of Johannesburg, Johannesburg, 2001, South Africa., +27 83 579 6557 & Email: chinedung@yahoo.com

Africa and

2. How can we structure these factors to form a general model to enhance the acceptance and use of mobile app innovation in Africa.

In order to achieve these goals, we conducted a survey in the five countries representing the five geographical locations in Africa to assess the user's view of mobile app use in order to explore the factors predicting the acceptance and use of mobile apps in Africa. These factors were structured to develop a framework. With leverage on the report that there is a need to know the diffusion of mobile technologies and the important of mobile technological services on developing nations such as African countries, this study would therefore make the following contributions. We have:

1. Examined and discovered the acceptance and use of mobile apps in Africa,
2. determined the factors/predictors that influence users' intention to adopt and use mobile apps innovations in Africa, and
3. developed a general framework that can improve the adoption and use of different kinds of mobile apps across African nations.

The remainder of this research work is organised as follows: Section 2 discusses the background information of the research work. Section 3 describes the related works and the gap. Section 4 shows the research conceptual model and Section 5 explains the research methodology. Section 6 describes the methods of analysis and Section 7 zooms into the survey results. Section 8 presents the regression analysis and Section 9 discusses analysis of variance (ANOVA) results. Section 10 interprets the results to validate the proposed framework. Section 11 concludes the study.

2 Background information

A brief theoretical overview of the study is presented in this part.

2.1 What are mobile apps?

Mobile app creativity has recently attracted scholars from different fields of study to carry out studies in their respective fields. As a consequence, mobile apps have been described by several writers, write-ups and web pages in many perspectives including Technology [16, 17], Educational [18], Context-aware Computing [19], Internet of Things [20], Business [21], Cloud Computing [22] and Social Services [23]. In this study, mobile apps are considered to be mobile technological innovations of a mobile computer software that allows users to carry out various activities including political, social, economic, and educational regardless of the user's location and background.

2.2 Features of mobile apps

There are five main characteristics of mobile apps, according to Rogers [9]. They are relative advantage,compatibility, complexity, observability and trialability. Such characteristics help to decrease the level of misunderstanding and increase the adoption rate of mobile apps. Technology reliability and cost are conceptualized in this study as important features of mobile apps [8].

2.3 Innovation decision process

This is a process of decision-making which includes an information-seeking and information-processing practices in which mobile app adopters are driven to reduce the confusion surrounding the effect of acceptance and use of a new mobile app innovation. Rogers's diffusion framework consists of five stages of the innovation decision process including knowledge, persuasion, decision-making, implementation and confirmation [9]. For this study implementation and confirmation are merged because they describe diffusion (putting into use and continue to use) and referred to as the diffusion stage. Thus, the innovation decision process of this research entails four phases including knowledge, persuasion, decision-making and diffusion. These stages are briefly discussed below.

Knowledge stage:The mobile apps adoption and diffusion begins with the knowledge about mobile apps. This stage involves acquisition, method and sharing of information about mobile apps. Having the right knowledge about mobile apps requires information sources, learning methods and information sharing. In Africa, there are two distinct sources of information about mobile apps including external initiated actions and personal initiated actions, learning methods are interpersonal communications, the Internet, operational manual and informal training, whereas information sharing involves organizations and events, and individual activities [8].

Persuasion stag: is shaping the minds of adopters towards adopting and using mobile apps. The main factor under this stage is the social influence [9]. Decision-making stage: This includes the adoption and rejection of mobile apps. In this stage, an individual/adopter of mobile apps chooses to adopt or reject the mobile apps. The adoption covers the adopter's category whereas rejection covers the reasons for non-adoption [9]. There are five categories of adopters in Africa including late majority and laggards, non-adopters, innovators, early adopters and early majority [8]. Also, the reasons for non-adoption of mobile apps in Africa are using mobile apps is time-consuming, using mobile apps takes a lot of phone memory, using mobile apps distracts attention from other activities and using mobile is expensive [8]. Diffusion stage: This involves the implementation and confirmation. That is putting mobile apps into use and continuing to use them. It covers the use of mobile apps, ways of using mobile apps and reasons for discontinuance of the use of mobile apps. There are two distinct ways of using mobile apps in Africa including business use and individual use, and the reasons for discontinuance include a better replacement, unsatisfactory performance, High complexity and lack of support [8].

2.4 Adopting Unit

The adopting unit consists of features of individual adoption, comprising personality variables, socioeconomic and communication behavior. [9].

Personality variables: Personality variables entail the individual characteristics (demographic) that are part of the factors influenc-

ing the outcome of the innovation decision process [9]. Adopters' attitudes, anxiety (degree of nervousness) and self-efficacy are conceptualized as part the personality variables. Attitude is measured by the feelings and reactions of the participants on the importance and contributions of mobile apps in Africa [24].

Socioeconomic characteristics: Socioeconomic characteristics involve the external factors that may influence individuals' adoption and diffusion of mobile apps. These characteristics include the contributions of mobile apps to the development of Africa [25], facilitating conditions and employment status[8] .

Communication behaviour: This covers the primary purpose of using and disseminating the information about a newly developed mobile app [9]. It is one of the primary goals that encourages a person to embrace and disseminate mobile apps. In this study, It deals with the function of information sharing as specified in the abstraction model of the research. This research deals with two key reasons of spreading the information about a newly created mobile app including: [8].

1. to facilitates both individual and business activities, and
2. to improve and make communications easier.

2.5 Adoption

According to Rogers [9], adoption is the absolute willingness to embrace and use new advanced technologies (mobile apps). GSMA [2] explained that adoption is embracing and using a new technology. It is the acceptance [10] and use [11] of an emerging product such as mobile apps by the consumer. Innovation is new when it is first introduced to a person. Therefore, we describe the adoption as the users' acceptance and use of a new invention.

2.6 Diffusion

Diffusion is a means of spreading the information and use of an innovation among the individuals of a social structure across certain networks [9, 3]. It is a mechanism by which a commodity is spread from one customer to another [11]. For this research, with regards to Rogers framework, we combine the implementation and confirmation phases to form diffusion. Thus, we defined diffusion as the method of sharing, uses and discontinued the uses of a product.

2.7 Usage of mobile applications in Africa

GSMA [26] recorded that, there are more than five billion mobile subscribers across the globe and the number is expected to rise to 5.9 billion by the year 2025. The spread of mobile technology is wider than any other technology [27]. Mobile service penetration is expanding at an extraordinary rate in Africa, and mobile apps are part of the main foundations of all mobile services. The introduction of mobile services in Africa is rapidly growing such that the mobile app is the driving force behind some of the emerging developments in African nations.[16, 7]. The African continent currently ranks among the world's largest adopters of mobile technology services, introducing new mobile services to the population [28, 29].

The beginning of mobile app development can be linked to the program required to operate the emerged mobile devices [30]. Over the years, telecommunications in Africa was primarily through a fixed-line system and the networks were regulated by the respective countries' central governments [31, 32]. In the late 1990s, the advent of mobile telecommunications brought significant changes to the African continent, so that countries like Nigeria, Cote d'Ivoire, and Uganda had more mobile phones than fixed lines [31]. In Africa, the mobile telecommunications system has a faster and broader penetration and deployment than fixed lines, and some nations, such as the South Africa, Comoros, Uganda, Kenya, Mauritius, Malawi, and the Seychelles, have increased their rural mobile network coverage as of 2010 [33]. The advancement of mobile technology has contributed to the creation, acceptance and dissemination of mobile apps to promote mobile services, leading to the production and rise in use of different kinds of mobile devices such as smartphones.

The procurement and service of a fixed-line telephone system is highly expensive. As a result, much of the African population in particular rural dwellers and low-income earners cannot afford or have access to it [4, 32]. A broad range of network coverage is provided by mobile technology enabling quick access to the African population to telecommunications services [34, 35]. Communication services are currently accessible and affordable and more than 70% of the African people is linked to the digital telecommunications network[27]. Thus, mobile technology services enable digital inclusion.

The development, delivery and use of mobile technology services included a group of interconnected network entities called the mobile ecosystem [16, 36, 37]. The African mobile ecosystem comprises of various entities that are involve in the development and delivery of mobile innovation services including mobile network operators, sales agencies, government and other stakeholders [16, 7]. Several facets of the mobile ecosystem in conjunction with a defined system development method are involved in the process of creating, delivering, implementing and disseminating mobile apps [38]. With regard to the stakeholder's priorities, aspirations, operational services, and some predicting factors [39] mobile apps are developed for different services. There are several types of mobile apps that offer unique services to their users, including: Mobile Learning [40], Mobile Commerce [41], Mobile Health [42], Mobile Agriculture [43], Mobile Banking [44], and Mobile Governance [45] used to offer different online services respectively. In this study, these various kinds of mobile apps are categorised as the classification of mobile apps. The use of mobile apps in Africa has added tremendously to the growth of Africa [1]. That is, mobile services are rising the living standards of the people of Africa, resulting in the promotion of the economic, social, political, and educational development of all African nations. [46, 47]. Thus, the ecosystem promotes mobile apps innovations which accelerate economic growth, though there are some issues to be considered.

While mobile app developments are growing in Africa, some areas, especially rural locations, are still experiencing a slow penetration of this advanced technology due to certain factors or issues of influence [29]. Around 60% of Africans resides in remote areas

where a large number of potential adopters are limited by the poor network connectivity, low income, unstable economic situations, and social and political instability [29]. In addition, some scholars have established numerous important factors that need to be addressed, including relative advantage, complexity, compatibility, trialability, observability, [9], [48]–[49], social influence, user perception, perceived technology reliability [49, 50], facilitating conditions [51], demographic, mobile technology self-efficacy, ICT anxiety, perceived financial cost [49, 52, 53] and culture [54], for greater acceptance and distribution of mobile apps in Africa.

However, in the African background, it is important to understand the whole procedures of adopting and disseminating mobile apps and to create a well-defined structure for this process. The goal of this study is to address these issues by developing a well-defined framework that can encourage the wider and more efficient use of home-made mobile apps, not only in the country of origin but also in other African nations. Through a survey conducted in five selected nations representing five geographical regions in Africa the process of mobile apps adoption and diffusion was examined. These countries include south (South Africa), west (Nigeria), north (Morocco), east (Kenya) and central (Democratic Republic of Congo).
These countries were selected because:

1. Each country is situated in one of Africa's five regions.
2. There is a significant population in each of the countries chosen.
3. More references were made to them in the literature review than to those in their respective regions.
4. Each region is presumed to have a similar lifestyle type.

2.8 What is a Framework?

A framework is a blueprint or guide consisting of principles, constructs and concept of a theory [55]. According to Fulton, Krainovich-Miller [55, 56], conceptual framework is a structure of concepts that offers the foundation for the development of an abstract idea. For this study, a framework is an abstraction for a successful mobile apps adoption and diffusion among entire African social system. This study seeks to develop a conceptual framework for mobile apps adoption and diffusion in Africa. Applying regression analysis to the research model, the relationships between the research constructs can be revealed.

3 Related Works

Although there is no general framework for the adoption and diffusion of mobile apps in all African geographical areas but some related works have been carried out. The existing frameworks apply to a particular category of mobile app and to a unique environment or country. A model for the adoption of mobile health in developing countries was proposed by Kiongo [13] using Kenya as a case study. In the framework, social influence, facilitating conditions, reliability, cost and simplicity are considered as determining factors of the intention to adopt and use mobile health. In a model for mobile banking adoption in Ghana, Crabbe, Standing [14] highlighted that usefulness, reliability and culture are factors shaping the attitudes and behavioural intention to use mobile banking. Bwalya and Healy [15] proposed a conceptual model for e-government adoption in the SADC region with consideration to the following factors; culture, user support, usefulness, ease of use and appropriate ICT infrastructure. Social influence, facilitating conditions, cost, culture and reliability are the predicting factors considered in a model for the adoption of e-commerce in Nigeria [57]. According to Moore and Benbasat [58], relative advantage and complexity are equivalent to usefulness and ease of use. In the light of the above-proposed frameworks, there is a need for a general model that can be applied to different domains and different regions/countries in Africa to increase the use of African-based mobile apps across all African nations.

3.1 The Gap

The development of mobile apps in Africa is growing rapidly [7]. A variety of mobile app start-ups have been introduced across several African countries to promote mobile app technologies. [2]. The African mobile ecosystem has promoted the creation of various kinds of mobile apps that are available on the African technology market. As a result, a large number of mobile apps originated in Africa [2]. From the literature, all the existing suggested frameworks are for specific kinds of mobile apps [13]–[15], [57] and there is no framework for the general mobile apps adoption and diffusion in Africa. In practice, most of the mobile apps created in Africa are actively used in the country where they are originated, while there is low or no acceptance of these mobile apps in other nations of the continent. It is necessary to have a common structure that will enable a wider adoption of mobile apps (especially local mobile apps) across African nations. This research will therefore assist to close the gap by suggesting an overall framework for mobile apps adoption and diffusion in Africa.

4 Research Conceptual Model (RCM)

Drawing from the diffusion of innovation framework, previous related studies on Africa context regarding the framework for adoption of mobile apps and their findings, a conceptual model for this study is, therefore, proposed as displayed in figure 1. The RCM demonstrates the methodological approach to accomplish the research aim. The model consists of three components including mobile apps innovations, innovation decision process and adopting unit. The mobile apps innovations component describes mobile apps and their features; innovation decision processes component deals with the acceptance, rejection, use, discontinuance and continues the use of mobile apps whereas adopting unit contains the influencing factors of mobile apps adoption and diffusion. Achieving the primary goals of this research work would validate this model.

The Mobile apps section describes that: as an innovation, a newly created mobile app should be considered to be better than the previous similar apps that it replaces, fits well with the intended potential users, easy to understand and use, tested before implemen-

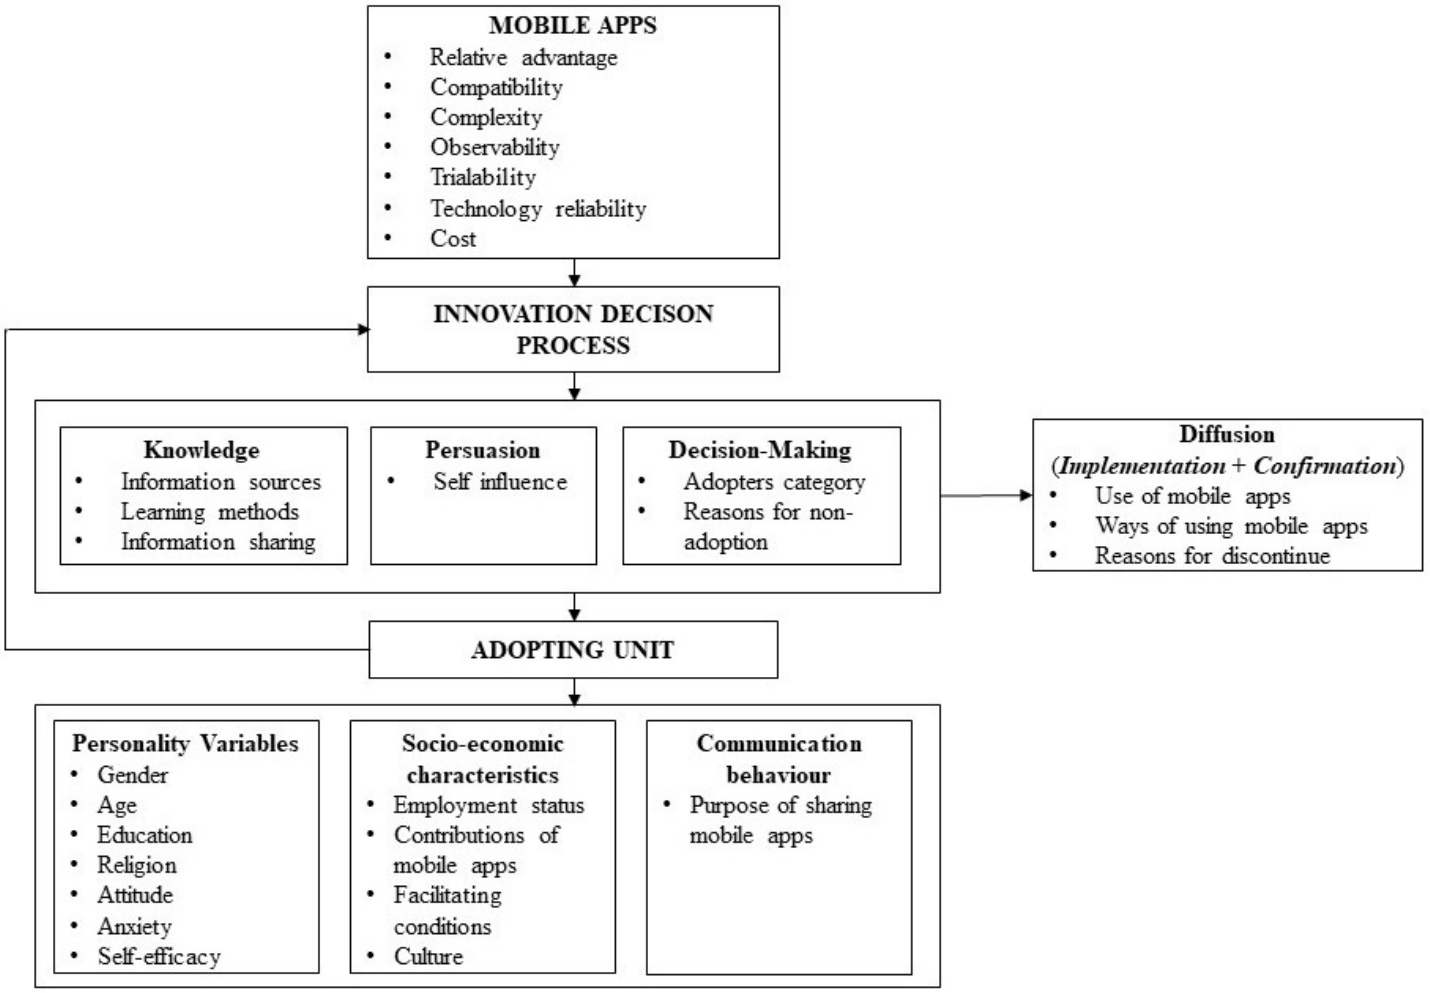

Figure 1: Research conceptual model

tation, accessible to people, and be credible. The innovation decision process explains the need for the public to be aware about the nature of a new mobile app, including source of information, the method of using the mobile app, and how to exchange information about it. Given these will help to influence the decision-making process of the adopters, either to accept or reject the mobile app. The adopting unit deals directly with the individual adopters, whereby certain personalized factors, such as personality variables, socio-economic characteristics, and communication behaviour, can affect the process of adoption. Overall, with the influence of good innovation characteristics, personalised factors and good decision-making process, a newly developed mobile app may gain widespread acceptance within the African social system.

5 Research Methodology

This research requires quantitative data from mobile apps users residing in five selected countries representing various African geographical regions. Hence, the positivism paradigm was adopted whereby a scientific method was used to gather self-determined data from the participants without the researcher's influence. The non-probabilistic technique of sampling was introduced since it is not easy in Africa to get the correct amount of mobile app users. In choosing the sample population for data gathering, purposive and convenience methods were considered. Purposive sampling involves the selection of a target audience based on a specific purpose. The study aims at the mobile apps adoption and diffusion and the population was selected from the area where there are large number of users of mobile apps for various activities. Convenience sampling is a particular type of data collection approach that entails the gathering of data from the participants that can be conveniently reached within the chosen population.

As the entire likely sample could not be covered by the researcher, therefore it was appropriate to pick a sample population containing all the desired participants. Thus, the purposive method was needed. The researcher was unable to reach everyone in the selected sample except those who were easily accessible; the convenience technique became essential at this juncture and was also applied. Educational institutions (universities) were selected with the purposeful method, and data was obtained from the participants with the convenience method. In order to achieve the research goals, the RCM formed the basis of the survey performed in the selected

nations.

5.1 The Research Instrument – The Questionnaire

The questionnaire was used as a data collection tool. It consists of seven sections containing close-ended questions with a 5-point scale rating of 1–5 (1 strongly disagreed and 5 strongly agreed). These sections are:

1. Background information – collects individuals (participants) details.
2. Mobile applications – examines the extent of participants' awareness of mobile app technologies.
3. mobile apps innovation Adoption and diffusion – examine Africa's acceptance and use of mobile apps.
4. Innovation features – examine the participants' perceptions of the importance of the characteristics of mobile apps.
5. Impact of mobile apps – examine the contributions of mobile apps to African growth.
6. Predicting factors – examine the factors influencing the acceptance and use of mobile apps in Africa.
7. Adopter's category – to determine the types of adopters of mobile apps existing in Africa.

A pilot or experimental test was conducted to make sure that the questionnaire can resloved the important parts of the study. All the recommendations were properly considered and effected. Also, the questionnaire was vetted and approved by a Statistical Consultant. The target population is the mobile apps users from the chosen nations in Africa. In the delivery of the study questionnaires, drop off and electronic/online approaches were applied. Participants were drawn from various age groups and job status to ensure that general views are covered by the collected data. A contact person was hired to help us in collecting responses from the respondents in each of the respective counties. The person was informed of the research process and the aim of the study was clarified. A total of 1285 of the 2300 distributed questionnaires were returned, providing a response rate of 55.87%. The responses comprise of 957 drop off and 328 electronically (online google forms) completed questionnaires. The responses obtained from the participants of each country was shown in Table 1.

Table 1: Participants' responses from each country

Early adopters	3.33	0.89	0.72
Early majority	3.34	0.88	0.71

6 Analysis

To explain the frequency and response percentage of the participants, statistical analysis was performed on all the study variables. Cronbach alpha reliability analysis was used to measure reliability coefficients of the investigating variables (criteria 0.6). In order to assess the difference in the groups of dependent variables, analysis of variance (ANOVA) was conducted on the study variables, involving individual profile data (criteria, $p < 0.05$). Finally, regression analysis was performed to measure the relationship among the dependent and the independent variables. The results obtained from the data analysis will be interpreted on the basis of the RCM components. See section 7

6.1 Reliability

Using Cronbach alpha coefficient analysis, the reliability of the study variables was checked and it was found that the factors were internally consistent ($\alpha = 0.67$). Also, the correlation scores of all the elements are the same (r=1), meaning that the factor elements

associate with each other. The reliability results are displayed in Table 2.

7 Survey Results

The main objective of this research is to develop a framework for mobile app adoption and diffusion in Africa. The quantitative data was obtained from 1,285 participants from five chosen nations representing the geographical regions of Africa. The data collected was carefully extracted, statistically analysed and the results were obtained. The outcomes of the survey are presented according to the mean values of the responses obtained from the participants with respect to scale rating except the participants' profiles which is presented on percentages.

7.1 Participants' profiles

The research sample population consists of 703 (54.71%) of males and 582 (45.29%) of females. This suggests a reasonably equal distribution of the gender categories (male and female). Mobile apps are designed to be used equally by all, regardless of gender [56]. It shows a good representation of the African population. Participants were of various age groups, from less than 20 to 70 years of age and above. The results revealed that the majority of participants were between the age groups of 20-30 and 31-40 with the proportions of 409 (31.8%) and 379 (29.5%) respectively. That is, >60% of the participating population was between the ages of 20 and 40 years. All levels of education, including Matrics, Diploma, University, Masters, Doctorate and others were involved in this study. 'Others' means the set of people that are deemed to be uneducated and could not fall into these classifications. 93.3% of respondents are educated, while 3.7% are uneducated. This shows that the responses were collected from individuals who had acquired some knowledge of mobile apps innovations and services. A large proportion of the participants are working class and students with 615 (47.9%) and 402 (31.3%) respectively. Such people have the capacity of embracing and using mobile apps, even though some financial costs are involved. In addition, students and workers are also more involved in many things than elderly and unemployed people, allowing more use of mobile apps for different tasks.

7.2 Mobile apps Component

This section investigated the participants' perceptions of the features of mobile apps.

Relative advantage - is the degree to which users of a specific mobile app considered it to be more improved than another equivalent mobile app. The mean value of the participants' responses is 3.74 meaning that relative advantage is an influencing feature of mobile apps.

Compatibility – is the extent to which mobile apps suit with the exiting values, practices and demands of the prospective adopters. The obtained mean value of the participants' responses is 3.78 suggesting that compatibility is a significant feature of mobile apps.

Complexity – the degree to which participants believe that the use of mobile apps is affected by how simple it is to use the mobile app. The obtained mean value of the participants' responses is 3.78 suggesting that complexity is an influencing characteristic of mobile apps.

Observability – is the degree to which participants believe that seeing the impact or what can be achieved with the mobile app will convince people to accept and use the mobile app. The obtained mean value is 3.52 suggesting that observability is an influencing feature of mobile apps.

Trialability – is the degree to which the participants believe that testing a mobile app before adopting can influence the adoption of the mobile app. The obtained mean value of the participants' responses is 3.72 suggesting that trialability is an influencing feature of mobile apps.

Perceived technology reliability - deals with the belief, danger, and credibility involved in using a new mobile app. The obtained mean value of the participants' responses is 3.38 suggesting that perceived technology reliability is an influencing characteristics of mobile apps.

Cost – are the financial costs involved with the adoption and usage of mobile app services. The obtained mean value of the participants' responses is 3.44 suggesting that cost is an influencing feature of mobile apps.

7.3 Innovation Decision Process Component

This section investigated the innovation decision process of mobile apps including the knowledge, persuasion, decision-making, and how the information about mobile apps are being spread in Africa.

Information sources – sources of disseminating information about the existence of mobile apps. The obtained mean values are external initiated actions, 3.21 and personal initiated actions, 3.61 indicating that the sources are important to the acceptance and use of mobile apps.

Learning methods – are the methods of learning how to use mobile apps correctly. The obtained mean values from the participants' responses are: interpersonal communications, 3.6; the internet, 3.5; operational manual, 3.3; informal training, 3.3 and formal training, 2.8. This implies that all the methods are significant except formal training method.

Information sharing – are the communication channels through which the participants share the information about mobile apps with one another. The obtained mean values from the participant's responses are: organizations and events, 3.36 and personal activities, 3.68 indicating that these are significant communication channels of mobile apps adoption diffusion.

Social influence – is the level to which the adopters of mobile apps are influence by others (family, friends, government, etc.). The obtained mean value is 3.56 indicating that social influence has a significant effect on the consumers intention to adopt and use mobile apps.

Late majority and Laggards category – are the most skeptical (wait and see) and most localized set of adopters of mobile apps. The obtained mean value is 3.25 indicating a significant group of mobile apps adopters in Africa.

Non-adopters category – are the set of participants that do not adopt and use mobile apps at all. The obtained mean value from the participants' responses is 3.18 indicating that there are non-users of

mobile services in Africa.

Innovators category – involve a group of users eager to experience or practice new innovation, regardless of the advantages or losses associated with it. The obtained mean value from the participants' responses is 3.19 indicating a significant group of mobile apps adopters in Africa.

Early adopters category – they are social system leaders and advisors and their acts are confined within the limits of the social system. The obtained mean value from the participants' responses is 3.34 indicating a significant group of mobile apps adopters in Africa.

Early majority category – they are non-leaders with strong social interactions who actively promote invention and they are neither the first nor the last to adopt the innovation. The obtained mean value from the participants' responses is 3.35 indicating a significant group of mobile apps adopters in Africa.

Reasons for non-adoption – are the factors that cause the rejection of mobile apps. The obtained mean values from the responses of the participants are: mobile apps occupies a large memory space in a phone, 3.4; use of mobile apps takes time, 3.3; use of mobile apps distracts focus from other tasks, 3.3; use of mobile apps is costly, 3.3. The results indicate that these reasons may cause the rejection of mobile apps.

Use of mobile apps – Ask to decide whether participants are mobile app adopters/users. The obtained mean value from the participants' responses is 4.0 indicating that most of the sample population are mobile apps users.

Ways of using mobile apps – determine the different aims of using mobile apps. From the responses of the participants, the obtained mean values are: business use, 3.20 and individual use, 3.83 indicating that these are the important ways of using mobile apps in Africa.

Reasons for discontinuance – are the causes of stopping the use mobile apps. The obtained mean values from the participants' answers are: a new improved one to replace the existing one, 3.5; unsatisfactory results, 3.5; not easy to use, 3.3; lack of support, 3.2. The results imply that these are significant motives that may cause users to stop using a particular mobile app.

7.4 Adopting Unit Component

Attitude – is the reaction (positive or negative) of adopters towards new mobile apps. The obtained mean value from the the answers of the participants is 3.39 suggesting that attitude has significant effect on the acceptance and use of mobile apps.

Nervousness/anxiety – is the degree of nervousness whenever a new mobile app is introduced. The obtained mean value from the participants' responses is 3.20 suggesting that anxiety has significant effect on the acceptance and use of mobile apps.

Predicting factors – are the factors that influence mobile apps adoption and diffusion. The obtained mean values from the participants' responses are: self-efficacy, 3.58; facilitating conditions, 3.56; culture, 3.31. The results imply that these are important factors that may impact mobile apps adoption and diffusion.

Contribution of mobile apps – are the effect of the use of mobile apps services on the growth of Africa. The obtained mean values from the participants' responses are: contributions to healthcare system, 3.52; contributions to education and social activities, 3.65; contributions to economy, 3.62; contributions to politics, 3.60; contributions to finance, 3.80; contributions to agriculture, 3.40.

Purpose of information sharing – are the motives for spreading the news about mobile apps. The obtained mean values from the participants' responses are: to enable easy communications, 3.88 and to facilitate ones activities, 3.55 indicating that these are significant purposes of information sharing regarding mobile apps.

8 Regression Analysis

To analyse the association among the dependent and independent variables, multiple regression analysis was conducted. Two regression techniques were used to ensure that more accurate results are produced, including Enter and Stepwise techniques. Because the proposed framework measures the adoption and diffusion of mobile apps, the variables in the adoption and diffusion sections of the RCM are the dependent variables, while the remaining research variables are the independent variables. Regression analysis determines how the variations in the independent variables are associated to the variations in the dependents variables. These variations are represented by the coefficients while the p-values show the significant level of the variations. P <0.05 is the appropriate significant level. It suggests a 95% confidence interval (the possibility of obtaining the accurate effect). Any of the variables (predictor) that has p <0.05 is potential to be included into the model. The R^2 shows the proportion of the variance accounted for by the independent variables in the dependent variable. In Table 3, the effect sizes and the significant level of R^2 are shown, according to Ellis and Steyn [59].

Table 3: Effect sizes and significant levels of R^2

Effect size	Effect	Values of R^2	Conclusions of R^2
<0.15	Small	<0.13	Non-significant
0.15-0.35	Medium	0.13-0.25	Significant
>0.35	Large	>0.25	Practically important

The dependent variables are; the Use of mobile apps, Business uses, Individual uses, and the five categories of adopters.

The independent variables are; External initiated actions, Personal initiated actions, Organizations and events, Individual activities, relative advantage and compatibility, Observability, Trialability, Perceived technology reliability, Self-efficacy, Social influence, Facilitating conditions, Cost, Cultural effect, Contributions to the healthcare system, Contributions to education and social activities, Contributions to the economy, Contributions to politics, Contributions to finance and Contributions to agriculture. Also included to the independent variables are Informal training, Operational manual, The Internet, Interpersonal communications, Good innovations and Add to development. The significant results obtained from the regression analysis performed are shown in Tables 4 – 11.

8.1 General Use of Mobile App

This model indicates that the R^2 is 0.291, thus, the important independent variables accounted for 29.1% of the dependent variable variance (*General use of mobile apps*). R^2 >0.25 which is practically significant. Eight variables/predictors entered into the model which accounted for 27.3% of the entire dependent variable variance. These variables are Add to development, Good innovations, Relative advantage and compatibility, Perceived technology reliability, Contributions to healthcare, Occupy phone memory, Satisfy user expectations and Social influence. Thus, R^2 = 28.2% suggesting that the variables added in this model are practically significant for the proposed framework. See Table 4

8.2 Business Use

It indicates that the R^2 is 0.380, thus, the important independent variables accounted for 38.0% of the dependent variable variance (*Business use*). R^2 >0.25 which is practically significant. Eighteen variables that accounted for 37.0% of the overall dependent variable variance entered the model. These variables are Enable work activities, Relative advantage and compatibility, Culture, Add to development, Anxiety, Informal training, Internet, Contributions to finance. Satisfy User expectations, Working manual, Interpersonal communications, Advantageous, Contributions to agriculture, Contributions to politics, Observability, Social influence, Contributions to educations and social activities and Enable easy communications. Thus, R^2 >25.0% showing that the variables added in this model are practically significant for the proposed framework. See Table 5

8.3 Individual use

This model indicates that the R^2 is 0.447, so the significant independent variables accounted for 44.7% of the dependent variable variance (*Individual use*). R^2 >0.25 which is practically significant. Also, 15 variables that accounted for 43.8% of the overall dependent variable were added into the model. These variables are Add to development, Self-efficacy, Good innovations, Trialability, Internet, Interpersonal communications, Time consuming, Contributions to finance, Tested correctly, Observability, Contributions to agriculture, Contributions to education and social activities, Individual activities, Fits well, and Contributions to healthcare. Thus, R^2 >25.0% suggesting that the variables added in this model are practically significant for the intended framework. See Table 6

8.4 Late Majority and Laggards

It indicates that the R^2 is 0.256, so the important independent variables accounted for 25.6% of the dependent variable variance (*Late majority and laggard*). R^2 >0.25, which is practically significant. Also, 12 variables that accounted for 26.7% of the dependent variables variance were added into the model. These variables are Contributions to agriculture, Contributions to politics, Formal training, Used by others, Self-efficacy, Contributions to economy, Satisfy user expectations, Organizations and events, High complexity, Social influence, Perceived technology reliability, A better replacement, Occupy phone memory, and Informal training. Thus, R^2 >25.0% suggesting that the variables added in this model are practically significant for the intended framework. See Table 7.

8.5 Non-adopters Category

This model indicates that the R^2 is 0.312, so the significant independent variables accounted for 31.2% of the dependent variable variance (*Non-adopters*). R^2 >0.25, which is practically significant. Also, 15 variables that accounted for 30.1% of the dependent variable variance were added into the model. These variables are Financial cost, Formal training, High complexity, Use by others, Culture, Satisfy user expectations, Facilitating conditions, Lack of support, Distraction of attention, Contributions to educations and social activities, Contributions to economy, Trialability, Observability, Good innovations, and Perceived technology reliability. Thus, R^2 >25.0% suggesting that the variables added in this model are practically significant for the intended framework. See Table 8.

8.6 Innovators Category

It suggest that the R^2 is 0.326, thus, the important independent variables accounted for 32.6% of the dependent variable variance (*Innovators*). R^2 >0.25, indicating practically significant. Also, 14 variables that accounted for 29.7% of the overall dependent variable variance were added into the model. These variables are Relative advantage and compatibility, Informal training, Contributions to healthcare, Perceived technology reliability, Formal training, Fits well, Add to development, Facilitating conditions, High complexity, Contributions to economy, Culture, Unsatisfactory performance, Tested correctly and Satisfy user expectations. Thus, R^2 >25.0% demonstrating that the variables added in this model are practically significant for the intended framework. See Table 9

8.7 Early Adopters Category

It indicates that the R^2 is 0.316, thus, the important independent variables accounted for 31.6% of the dependent variable variance (*Early Adopters*). R^2 >0.25, indicating practically significant. Also, 9 variables that accounted for 29.7% of the overall dependent variable variance were added into the model. These variables are Relative advantage and compatibility, Self-efficacy, Contributions to agriculture, Contributions to politics, Culture, Fits well, Contributions to education and social activities, Satisfy user expectations, and Facilitating conditions. Thus, R^2 >25.0% suggesting that the variables added in this model are practically significant for the suggested framework. See Table 10.

8.8 Early Majority Category

This model indicates that the R^2 is 0.271, thus, the important independent variables accounted for 27.1% of the dependent variable variance (*Early majority*). R^2 >0.25, which is practically significant. Also, 14 variables entered into the model which accounted for 25.7% of the total dependent variable variance. These variables are Self-efficacy, Financial cost, Contributions to education and social activities, Occupy phone memory, Informal training, Tested correctly, A better replacement, Advantageous, Contributions to

politics, Internet, External initiated actions, Culture, Satisfy user expectations and Trialability. Thus, R^2 >25.0% suggesting that the variables added in this model are practically significant for the proposed framework. See Table 11.

9 ANOVA Test

In order to examine the correlation among the profiles of the participants and the dependent variables, the ANOVA test was used. It helps to assess the impact or statistical importance of the participants' age, educational level, employment position and religion on the acceptance and distribution of mobile apps in Africa. The ANOVA results obtained are depicted in the Table 12 with regard to the five selected countries. This suggests that with the exception of innovators and early adopters, age has relevant impact on all the dependent variables. Education level indicated an important effect on Business use and Individual use. Employment status showed an important influence on business use and non-adopter's category while religion has a substantial impact on business use, individual use, non-adopter's and innovators categories concerning the acceptance and use of mobile apps within the African social system.

10 Interpretations and Validation of the Proposed Framework

The RCM was developed and used in this research as the basic principles. The model entails three parts or components, which include:

1. Mobile apps Innovations,
2. Innovation decision process, and
3. Adopting unit.

Each of these part contains a variety of factors that constituted the study variables. Various statistical analyses were conducted to measure the importance of the study variables from the perspectives of the participants. The obtained mean values from the responses of the participants show that the research variables are essential for mobile apps to be adopted and disseminated in Africa. With regard to the proposed framework, several analyses were also, carried out to confirm if the variable fits well in the model.

To examine the relationship between the model variables, multiple linear regression analysis was carried out. For dependent variables, eight factors were considered, including the Use of Mobile apps, Business uses, and Individual uses, Late majority and Laggards, Non-adopters, Innovators, Early adopters, and Early majority. These variables are derived form the adoption and diffusion component of the model. Regarding independent variables, the remaining factors were considered. The association among the variables was tested by regression analysis. After the analysis, the eight dependent variables resulted in the eight models. These models accounted over 25.0% of the variance (R^2 >25.0% <50.0%). With regards to the criteria for significant association namely the p-values, R^2, normality, tolerance and VIF, the output from regression analysis on the test of the relationships between the dependent and independent variables are interpreted below.

Model for the general use of mobile apps: R^2 = 0.273 suggests that the model is practically significant to the general use of mobile apps. This means that the model explained 27.3% of the variance concerning the general use of mobile apps in Africa. The model included a total of eight positive predictors: Add to development, Good innovations, Relative advantage and compatibility, Perceived technology reliability, Contributions to health care, Occupies phone memory, Satisfies user expectations and Social influence. All these variables have a positive impact on Africa's overall use of mobile apps.

The model therefore suggests that the dependent variable (general use of mobile apps) increases as predictive variables increase. this implies that that the adopters' attitude towards adoption and use of mobile apps can be shaped by good mobile apps that can contribute to Africa's development. Competitive benefit and usability increase the opportunity for mobile apps to be adopted and used. Safety assurance and decreased risk of using mobile apps, as well as the conviction of close friends and family increase the general use of mobile apps, even though the use of mobile apps takes up a great portion of phone storage.

Model for Business use: R^2 = 0.370 suggests that the model is practically significant to the use of mobile apps for business purposes. This means that the model explained 37.0% of the variance in the use of mobile apps in Africa for business purposes. In the model, 14 predictors, namely Enables work activities, Relative advantage and compatibility, Culture, Adds to development, Anxiety, Informal training, Internet, Satisfies user expectations, Working manual, Interpersonal communication, Contributions to agriculture, Observability, Social influence and Enables easy communication have a positive relationship with the use of mobile apps for business purposes, while four predictors, Contributions to finance, Advantageous, Contributions to politics, and Contributions to education and social activities have a negative relationship with the use of mobile apps for business purposes.

This means that the use of mobile apps for business purposes requires mobile apps to be good, beneficial and business-friendly in order to improve their meaningful business activities. Enables work activities and easy communications improve the use of mobile apps for business interactions. Organizations, such as banks are sharing the information about their mobile banking apps and other service-related mobile apps, such as FNB eWallet with their clients to improve their services. Increasing these predictors will increase the rate of adoption and diffusion of these mobile apps meant for business purposes.

African countries are developing nations, and developing mobile apps with local content containing social behaviour and norms will attract more adopters, especially rural dwellers and the less educated. Individuals can easily observe mobile apps created with local content, such as local language, and be convinced to use them. M-commerce apps in a local language can easily be adopted and used by people in remote areas to improve their lives in that area. Interestingly, anxiety about the use of mobile apps for business purposes has been positive. It is possible because most mobile app users were nervous when using mobile apps, especially for business transactions. Using the banking apps, as well as M-commerce apps

Table 12: ANOVA on Participants' profiles

Variables	p-values (ANOVA)			
	Age	Education level	Employment status	Religion
Use of mobile apps	0.023	0.598	0.442	0.066
Business use	0.000	0.000	0.000	0.000
Individual use	0.000	0.000	0.227	0.022
Late majority and laggards	0.000	0.746	0.990	0.264
Non-adopters	0.000	0.080	0.004	0.012
Innovators	0.176	0.835	0.777	0.023
Early adopters	0.063	0.607	0.197	0.065
Early majority	0.010	0.110	0.572	0.313

attracts some degree of fear and nervousness, but they facilitate easy, quick and comfortable transactions. Although people are anxious about using such apps, the number of users increases rapidly. Users need to learn how to use mobile apps adequately for business. Increasing the learning methods of how to use mobile apps will improve the adoption and diffusion of mobile apps. Unfortunately, the use of mobile apps for business is not profitable, and it attracts some costs. The more banking apps you use to carry out banking transactions, the more fees you pay. The use of mobile apps for business is also not affected by political, educational and social advancement.

Model for Individual use: $R^2 = 0.438$ suggests that the model is practically significant to the individual use of mobile apps. This shows that the model explained 43.8% of variance for individual use of mobile apps in Africa. The model included a total of 15 predictors, including 13 positive predictors (Adds to development, Self-efficacy, Good innovations, Trialability, Internet, Interpersonal communication, Time-consuming, Contributions to finance, Tested correctly, Observability, Contributions to education and social activities, Fits well, and Individual activities) and two negative predictors (Contributions to agriculture and Contributions to health care). Positive predictors have a positive relationship with the individual use of mobile apps, while negative predictors have a negative relationship with the use of mobile apps for individual purposes.

The model suggests that the attitude of mobile app adopters and their use thereof can be shaped by good mobile apps that can contribute to the development in Africa. The advantages of using mobile apps, including financial, educational and social benefits, affect the adoption and diffusion of mobile apps for individual purposes. The benefits of mobile social networking apps, for example have improved the adoption and use of mobile apps by individuals. Individual use of mobile apps involves the technical knowledge of how to use mobile technology, and the trial of new technology, as well as seeing others using it increases the adoption and diffusion of mobile apps. Users need to learn how to use mobile apps. The availability of learning methods, such as the Internet and interpersonal communication increase the rate of adoption and diffusion of mobile apps for individual use. The model also shows that, due to time and costs involved, there is less interest in using mobile apps to perform agricultural and health activities. In other words, the time and cost involved in using mobile apps reduces mobile app adoption and dissemination in Africa.

Model for Late majority and Laggards category: $R^2 = 0.265$ indicates that the model is practically significant to the Late and Laggards category of mobile app adopters. It implies that 26.5% of the variance can be explained by the adopters of mobile apps in Africa's Late majority and Laggards category model. The model included a total of 12 predictors, including nine positive (Contributions to agriculture, Contributions to politics, Formal training, Used by others, Self-efficacy, Contributions to the economy, Organizations and events, High complexity, Perceived technology reliability, Occupies phone memory, and Informal training) and three negative predictors (A better replacement, Satisfies user expectations and Social influence). Any increase in positive predictors leads to an increase in the Late majority and Laggards category, while any increase in negative predictors leads to a reduction in the category of the Late majority and Laggards adopters in Africa.

The Late majority and Laggards category of adopters is the set of adopters that is sceptical about adopting new mobile apps and they adopt a "wait and see" attitude towards adopting new technology. For this category to adopt and use mobile apps, they need proper information sources, such as organization and events, as well as seeing others using them and knowing the benefits of using mobile apps. In addition, they require training and reliability assurance on the adoption and diffusion of mobile apps. Since they are the local set in the social system, they become more discouraged by their close peers and are more afraid to adopt new mobile apps.

Model for Non-adopters category: $R^2 = 0.301$ indicates that the model is practically significant to the non-adopters' category of mobile apps adopters. This means that the model explained 30.1% of the variance. The model included a total of 15 significant predictors, containing 11 positive (Financial cost, Formal training, High complexity, Use by others, Culture, Facilitating conditions, Lack of support, Distraction of attention, Contributions to the economy, Observability, and Perceived technology reliability) and four negative predictors (Good innovations, Trialability, Satisfies user expectations and Contributions to education and social activities). The 11 predictors have a positive relationship with the category of non-adopters, while the four negative predictors have a negative relationship with the category of mobile app users in Africa who are not adopters.

The model explained that the high complexity, lack of support and the financial cost involved in the adoption and diffusion of mobile apps cause some adopters in the social system of Africa not to adopt and use mobile apps. The cultural beliefs, as well as the extent of support from government and other stakeholders, and dis-

traction from other activities increase the existence of non-adopters in Africa. It is expected that the perception of mobile apps as good innovations will change the attitudes of non-adopters. Providing a trial opportunity, satisfying users' expectations and the benefits of the use of mobile apps, especially in education and social activities, will reduce the number of non-adopters in Africa.

Model for Innovators category: $R^2 = 0.317$ indicates that the model is practically significant to the innovators' category of mobile apps adopters. It implies that the innovator category model explained 31.7% of the variance. The model is related to 14 important variables/predictors, including 12 positive variables (Relative advantage and compatibility, Informal training, Contributions to health care, Perceived technology reliability, Formal training, Fits well, Facilitating conditions, Contributions to the economy, Culture, Unsatisfactory performance, Tested correctly and Satisfies user expectations) and two negative variables (Adds to development and High complexity). The positive variables increase the category of innovators as they increase, while the negative variables reduce the category as they increase.

The model explained that the challenge of competitive advantage, availability of necessary environment from government and other stakeholders, as well as trying to satisfy the consumers' demands results in the increase of the innovators' category of adopters in Africa. The advancement of technology increases users' experience and requirements, thus there is a need for innovators to create mobile apps that will suit the new improvements. For purposes of improving the economy, poor performance of mobile apps and social behaviour, more improved mobile apps are needed. This encourages or raises more innovators in the social system. On the other hand, the higher the development progress and higher complication of mobile apps in Africa, the lesser innovators are required.

Model for Early adopters category: R2 = 0.297 suggests that the model is practically significant to the early adopters' category of mobile app adopters. It means that the model described 29.7% of the variance. The model is connected to nine predictors, including eight positive predictors (Relative advantage and compatibility, Self-efficacy, Contributions to agriculture, Contributions to politics, Culture, Fits well, Contributions to education and social activities and Satisfies user expectations) and one negative predictor (Facilitating conditions). Any rise in positive predictors leads to an increase in the early adopt category, while any increase in negative predictors leads to a decrease in the early adopt category.

The model shows that the ability to use a mobile app with advanced features will be of good interest and increase the potential adopters in the early adopter's category. In addition, the ability to use mobile apps to conduct educational, agricultural and political activities, as well as to fulfill consumer needs, is increasing the category of early adopters. Conversely, the availability of a suitable setting decreases the size of the group of early adopters.

Model for the Early majority category: $R^2 = 0.257$ shows that the model is practically important for mobile apps adopters in the early majority category. This means that 25.7% of the variance was explained by the model. The model is associated with 14 predictors, including 11 positive (Self-efficacy, Financial cost, Contributions to education and social activities, Occupies phone memory, Informal training, Tested correctly, Advantageous, Contributions to politics, Internet, Culture, and Trialability) and three negative predictors (A better replacement, External initiated actions, and Satisfies user expectations). A rise in positive predictors results to an increase to the size of early majority adopter category while an increase in negative predictors reduces the size of the category.

This shows that testing a new mobile app and finding it useful will increase the interest of consumers to embrace and use the mobile app without considering the impact on the phone's memory. The availability of methods of learning, such as the Internet and informal training, increases the user's skill and knowledge. The creation of better mobile apps and the acquisition of information from external sources, such as TV and radio, on the other hand increases consumer demand, thereby decreasing the acceptance of prior mobile apps.

Regarding the personality variables (age, education level, employment status and religion), ANOVA was conducted to examine the association among personality variables and the dependable variables. The findings showed that age has a statistically significant impact on all dependent variables, with the exception of the categories of Innovators and Early Adopters. The level of education showed a major effect on business and individual uses. A significant impact from the employment status was noticed on the business use and the non-adopters categories. Concerning religion, the impact was much on business use, individual use, non-adopters' and innovators' categories. Therefore, age, level of education, employment status and religion have an important impact on the acceptance and diffusion of mobile apps in Africa in various ways.

To explore the influence of gender on the acceptance and use of mobile apps, a t-test study was carried out. No noticeable effect was shown by the result. There are no variances among males and females in the adoption and delivery of mobile apps. Mobile apps are created for everyone regardless of the gender.

Overall, various substantial portions of the variance were explained by the eight models and all R^2 scores were over 25.0 points, (R^2 >25.0% <50.0%). This demonstrates that these models are practically important for the adoption and diffusion of mobile applications in Africa, and all the factors/predictors of the RCM can be applied to the proposed system. Some personality profiles have also been shown to have an effect on the adoption and distribution of mobile apps in Africa, including age, education, employment status and religion. As a consequence, a correlation occurs among them and the dependent variables. The association among the study variables typically shows that they are valuable predictors of mobile apps adoption and diffusion in Africa.

10.1 The Framework

Based on the findings obtained from various statistical studies and recommendations, Figure 2 presents the final proposed framework for the effective adoption and diffusion of mobile apps in Africa.

11 Conclusions and Future Work

11.1 Conclusion

This research aims to create a general framework for mobile apps adoption and diffusion in Africa. A three components model was conceptualized consisting of the research variables. The positivism

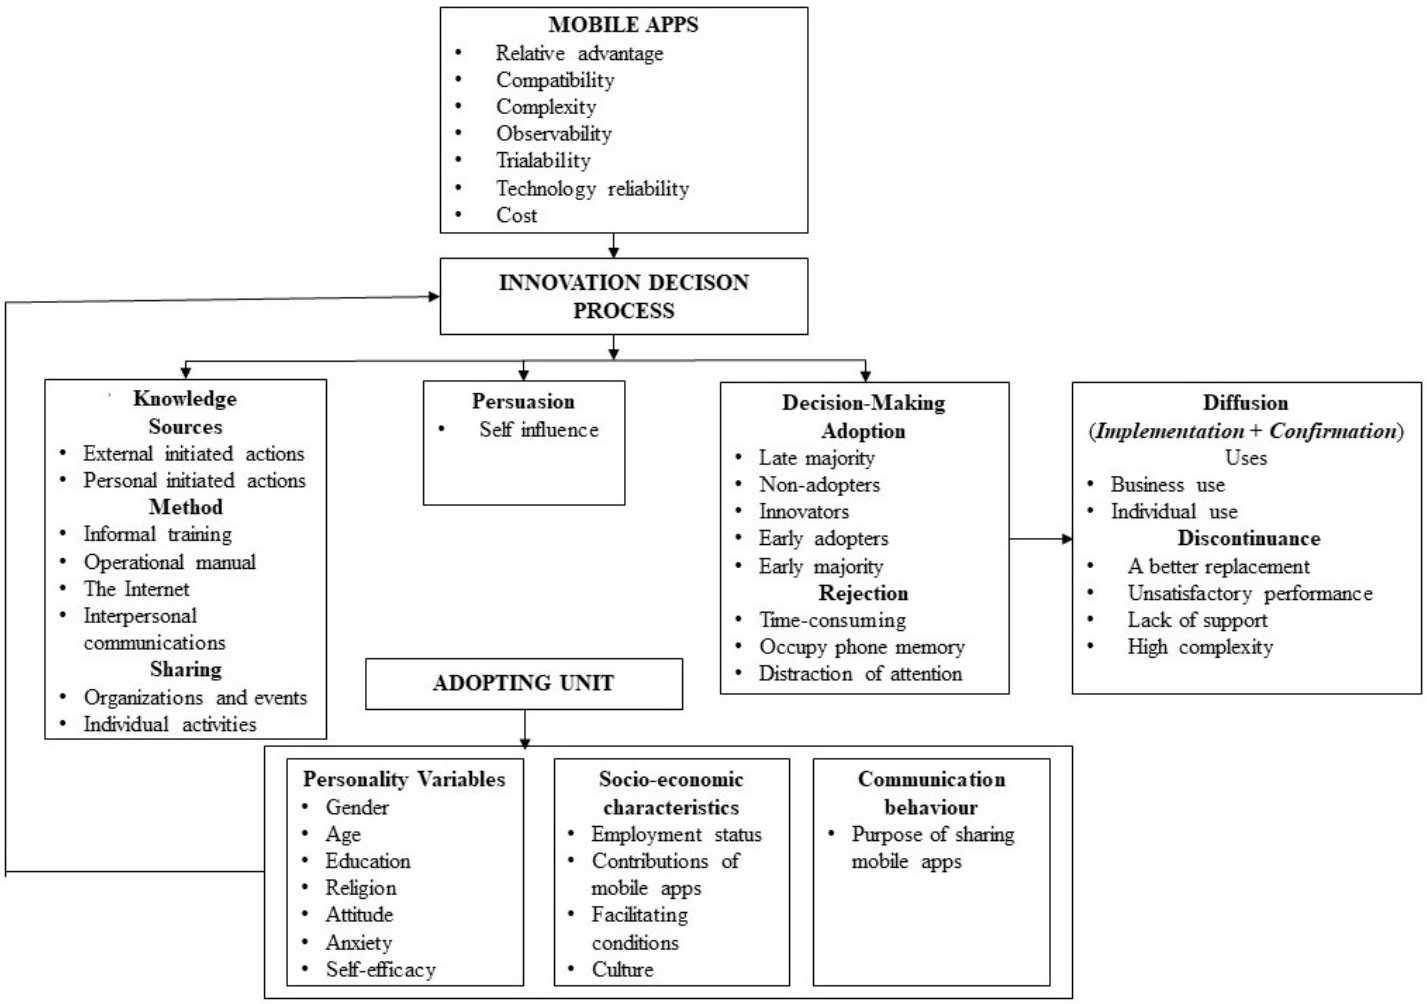

Figure 2: Validated Proposed Framework

research approach was applied. Through a survey, quantitative data were collected from the mobile apps users living in the five distinct nations representing the various regions in Africa. Various statistics analyses were carried out and the results show that the participants perceived these variables to be significant factors for mobile apps adoption and diffusion in Africa. Furthermore, a regression analysis was conducted to measure the relationships among these variables in association with mobile apps adoption and diffusion. The variable in the adoption and diffusion component of the RCM are the dependable variables whereas the remaining variables are the independent variables. The findings indicated that variables (predictors) explained more than 25.0% of the variance (R^2 >25.0% <50.0%) with appropriate level of significance ($p < 0.05$). These results suggest that the research variables are practically significant and they are potential or meaningful predictors of mobile apps adoption and diffusion in Africa. Thus, the variables fits well in the proposed framework. Also, the study revealed that some personality profiles such as age, education level, employment status , and religion have certain degree of influences on mobile apps adoption and diffusion in Africa. Therefore, there is a relationship among the personality variables and the dependent variables. Overall, the relationships existing among the research variables and their significant impact on mobile apps adoption and diffusion suggest that they are potential predictors of mobile apps adoption and diffusion in Africa. Consequently, the study proposed a three components framework for mobile apps adoption and diffusion in Africa.

11.2 Limitations

Africa is a region made up of multilingual nations and a variety of political challenges. Language gaps, cultural disparities and political uncertainty in most nations posed some serious limitations to this research work especially in Kenya, Morocco, and DRC. Also, due insufficient funding, it was not possible to reach all target audiences, particularly some rural dwellers, instead the convenient participants were used.

11.3 Future work

African nations are growing with potential population that are ready to embrace and use mobile technology innovations such as mobile apps. In order to further encourage mobile technology adoption, further research is needed on information awareness, the expansion of mobile services to unconnected areas, and how to bridge the gap

between educated and uneducated users of mobile apps in Africa.

ABSTRACT

With the features of the application system make it easier for users to transact, make the user feel comfortable in using the application system. The problem is that the intensity of application usage decreases judging by the application rating given by the user each time they perform a transaction, this is because the company initially make the features based on their urge without further investigating on user satisfaction level on similar social care e-marketplace, this causes users feel dissatisfied in using the application system on the same business system, and this is the reason why it is important to decide the feature preferences in the application development to meet user needs. The purposes of this study are to find out the feature preferences that would be used in the social care e-marketplace and to find out the actual result of user opinion related to the feature preferences found. The method used in this study are predictive accuracy conjoint analysis that can be measured by Pearson correlation to find out the correlation between respondent opinion and actual opinion. Respondents in this study are 521 users of the social care e-market, who filled out a distributed questionnaire to determine the feature priority in each functional category. The result is that six feature preferences have positive value namely Photo, Service Assistance Chat, Special Request, Worker Performance Rating, Application Rating, Tips & Articles. As well as Pearson's R Value is 0.558 with a significance rate of 0.002 and Kendall's Tau correlation value is 0.320 with significance level of 0.012. This indicates a correlation between the respondents opinion pattern (estimates part-worth) and the actual opinion (actual preferences) that answer the problem by determining the priority feature preferences from the result of user satisfaction level can help increase the intensity of using the e-marketplace social care.

1. Introduction

E-marketplace Social Care is an online business using the services of domestic workers who help users to meet their needs. One of user needs is the support of features which make it easier for user to transact [1]. The problem or the gap in this research is that the intensity of application usage decreases judging by the application rating given by the user each time they perform a transaction activity by the user [2], this is because of the company initially make the features based on their urge without further investigating on user satisfaction level and user experience [3] on similar social care e-marketplace, this causes users feel dissatisfied in using the company application system because they are considered not focus on improving the feature functionality in the same business, and this led a reason why it is important to decide the feature preferences in the application development of e-marketplace social care to meet their needs and help companies to increase user satisfaction on used feature functionality. Previous research supports the importance of assessing user satisfaction rating for information technology artifacts in this case is a feature of the whole system as an incentive for consumers to use the system intensely or loyal [2]. Other studies also support the assessment of user satisfaction with user experience in using the features of application system, where by the result of feature assessment provided by user can help companies to improve feature functionality on the company's application system [3]. The purposes of this study are to find out the feature preferences that will be used in the e-marketplace social care and to find out the

[*]Corresponding Author Angelina Egeten, Email: angelina.egeten@binus.ac.id

actual result of user opinion related to the feature preferences found. Thus, this research will answer the research questions about:

- Research Question 1 : what are the feature preferences in e-marketplace social care?
- Research Question 2 : are the result of the respondent opinion pattern much different from the result of the respondent actual opinion?

2. Theoretical Background

2.1. E-marketplace Social Care

E-marketplace is a place where sellers and buyers are brought together in the market demand and supply with various types of products and services that available and provide added value to companies [4]. E-marketplace acts as a third-party that brings together sellers and buyers to get the desired choices and at the same time reduces transaction cost in terms of products and services used [5].

E-marketplace social care provides a household services or health social care which aims to help users to meet with workers in helping meet the needs of the users themselves [6], where these workers are under the distribution agencies who cooperate with e-marketplace companies.

2.2. Customer Satisfaction

In general, customer satisfaction depends on the services used by users, as well as the purchased products. If users are satisfied with the products and services, user satisfaction is fulfilled, or the service exceeds user expectations, the user is very happy and satisfied. Likewise, if the service does not match the user's expectations, the user is not satisfied [7].

Customer Satisfaction is not only based on the user's assessment of the products and services used, but also on the user experience in using service application features and the system's ability to convey complete service information [3] and has an innovative feature [2].

2.3. Intention to Use

It is very important to maintain the intensity of reuse the services used in meeting user needs, because when users need the service they will always predict or surely use the service when they need assistance in meeting their needs [1]. Not only in terms of the offered services, but the system support of the services is also the main reason for users to use the services because it can be used anywhere, anytime and are supported with innovative features [2].

3. Research Method

This study uses a conjoint analysis method to determine the features preference used by users in the e-marketplace social care system. This method was chosen to evaluate the user's features preference of the services used [8] [9] and be able to produce accurate answer predictions that did not much different between the respondent's opinion pattern and the respondent's actual opinion. Conjoint analysis can be expressed in the following model as a part of the multivariate dependence method, namely [10]:

$$Y_1 = X_1 + X_2 + X_3 + ... + X_n$$

where:

X = Independence variables are often referred as factors and a non-metric data part of the factor called levels.

Y_1 = The overall opinion of respondents on the various factor and levels of a product or service.

The conjoint process is carried out to categorize the e-marketplace social care features against the functional attributes of the e-marketplace social care, which consist of Identity, Conversation, Information and Service, Reputation, dan Sharing. The process produces preference features for each functionality, so that each functionality has a feature that represent in need.

The population in this study was users of e-marketplace social care services in Indonesia where the data is collected from January-February 2020. 521 respondents are used as sample where the questionnaire is distributed using google docs and paper directly filled by users who already had experience in using similar e-marketplace social care applications. Users are asked to rate the 25 preferences that have been set out in the questionnaire based on the results of random features of the orthoplan using SPSS version 23. The questionnaire result that has been filled in by the user is collected and tabulated, then the data tested for validity and conjoint analysis to answer the research questions in accordance with the purpose of this study.

4. Result and Discussion

The following are the steps in conjoint analysis, namely:

4.1. E-marketplace Social Care Feature Preferences Based on Similar Application

Based on the feature functionality equation of 4 other similar e-marketplace social care applications that have been selected, they are mapped into the social care application functionality, which will be used for conjoint analysis test to identify the preferred features of the e-marketplace social care system.

Table 1: Feature Preferences of E-marketplace Social Care

Feature	**Functionality Social *Care* Application**	***App A***	***App B***	***App C***	***App D***

4	3	4	3	2

4.3. Orthoplan

In obtaining the minimum number of combinations stimuli that orthogonal respondent must evaluate, the orthoplan process or orthogonal array is used. Orthogonal is the absence of correlation between levels on an attribute [11]. Based on the orthoplan formula, the result of the calculation is:
N_Identity * N_Conversation * N_Information&Service * N_Reputation * N_Sharing

Orthoplan = 4 * 3 * 4 * 3 * 2 = 288 combination. The result of each component multiplication is 288 combination. Therefore, a randomized orthoplan was conduct in this study because it was not possible to test 288 combination.

The following is a table of random orthoplan results generated by the system using SPSS version 23 used in the questionnaire.

Table 3: Result of Random Feature Based on Orthoplan

Identity	Conversation	Information & Service	Reputation	Sharing
Photo	Chat Assistance Services	Special Request	Application Rating	Social Media
Forgot Password	Chat Assistance Services	Order and Order History	Application Rating	Tips & Articles
Photo	Chat Assistance Services	Special Request	Worker Performance Rating	Social Media
Photo	Like	Special Request	Application Rating	Social Media
Account Profile	Chat Assistance Services	List of Services & Detail of Services	Worker Performance Rating	Tips & Articles

Photo	Testimonial	Search	Application Rating	Social Media

Based on the random orthoplan result table above, the user must rate 1-25 of each row in the table, where the user can only fill in 1 rating number on each row and this number appear once on each line.

4.4. E-marketplace Social Care Feature Preferences

The following is the result of e-marketplace social care feature preferences based on conjoint analysis using SPSS version 23:

Table 4: The Result of E-marketplace Social Care Feature Preferences

Functionality	Features	Importance Value	Utility Estimate
Identity	Photo	21.996	**0.355**
	Sign Up		-0.013
	Account Profile		-0.080
	Forgot Password		-0.262
Conversation	Service Assistance Chat	25.026	**0.146**
	Testimonial		-0.058
	Like		-0.089
Information & Service	Special Request	24.402	**0.302**
	List of Services & Detail of Services		-0.068
	Order & Order History		-0.028
	Search		-0.205
Reputation	Worker Performance Rating	16.351	**0.027**
	Application Rating		**0.303**
	Best Dealer		-0.330
Sharing	Tips & Articles	12.226	**0.011**
	Social Media		-0.011
(Constant)			12.906
Correlations[a]		**Value**	**Sig.**
	Pearson's R	.558	.002
	Kendall's tau	.320	.012

Based on the result of conjoint analysis of 521 respondents on the attributes of social care functionality in the table above, the conclusions are as follows:

1. In the Identity section, based on the result of statistical test can be summed that the respondent prefers the form of feature photo. It can be seen from the utility value which shows a positive result with 0.355 for the photo feature. Meanwhile the Sign Up, Account Profile and Forgot Password have a negative utility value. It can be seen from the utility value which shows a negative result with -0.013 for Sign Up, -0.089 for Account Profile feature, -0.262 for Forgot Password feature.
2. In the Conversation section, based on the result of statistical test can be summed that the respondent prefers the form of Services Assistance Chat feature. It can be seen from the utility value which shows a positive result with 0.146 for the Services Assistance Chat feature. Meanwhile the Testimonial and Like features have a negative utility value. It can be seen from the utility value which shows a negative result with -0.058 for testimonial feature and -0.089 for Like feature.
3. In the Information and Service section, based on the result of statistical test can be summed that the respondent prefers the form of Special Request feature. It can be seen from the utility value which shows a positive result with 0.302 for the Special Request feature. Meanwhile the List of Service & Service Detail, Order & Order History and Search feature have a negative utility value. It can be seen from the utility value which shows a negative result with -0.068 for List of Service & Service Detail feature, -0.028 Order & Order History feature and -0.205 for Search feature.
4. In the Reputation section, based on the result of statistical test can be summed that the respondent prefers the form of Worker Performance Rating and Application Rating feature. It can be seen from the utility value which shows a positive result with 0.027 for the Worker Performance Rating feature and 0.303 for Application Rating feature. Meanwhile the Best Dealer feature has a negative utility value -0.330.
5. In the Sharing section, based on the result of statistical test can be summed that the respondent prefers the form of List of Tips & Articles feature. It can be seen from the utility value which shows a positive result with 0.011 for the List of Tips & Articles feature. Meanwhile the social media feature has a negative utility value -0.011.

4.5. Conjoint Analysis Hypothesis Test on Media Social Functionality

By using the predictive accuracy conjoint test can be measured using Pearson's R Correlation. In this study, the Pearson's R value was 0.558 with a significance level 0.002 and Kendall's Tau correlation showed a value 0.320 with a significance level 0.012. This indicates a correlation between the respondent opinion patterns (estimates part-worth) and actual preferences. For each respondent preference towards factors on social care functionality which is divided into five parts, namely Identity, Conversation, Information and Services, Reputation, Sharing.

H_0 = Estimated opinion patterns of respondents differ greatly
H_1 = Estimated opinion patterns of respondents do not differ that much

Based on the result, it can be concluded that H_0 is rejected and H_1 is accepted, because:

- The significance level of Pearson's R = 0.002 < 0.05
- The significance level of Kendall's Tau = 0.012 < 0.05

The result of conjoint analysis shows that the estimates of respondent opinion pattern (*estimates part-worth)* do not much differ from the respondent actual opinion (*actual preferences*) on the stimuli process.

5. Conclusion

The 6 features that have a positive value from the results of conjoint analysis, namely Photo, Chat Assistance Services, Special Requests, Worker Performance Ratings, Application Ratings, and Tips & Articles, are 6 features that are the main feature preferences in the social e-marketplace system. care and at the same time these 6 features answer the first research question.

As well as to answer the second research question, based on the results of the conjoint analysis can prove that the approximate opinion patterns of respondents are not much different from the actual opinion of the respondent which can be seen from the feature rating given by users as a result of user satisfaction in using the features, and it can answer the problem with determining feature preferences can help increase the intensity of the use of the e-marketplace social care system.

6. Limitation and Future Research

This research is limited to the feature preferences of the e-marketplace social care application system which users assess as a feature rating on the random orthoplan results which later on these features will be maintained and used in the other e-marketplace social care system development.

Further research activity needs to be reassessed in terms of the service capability in meeting user needs, from user satisfaction in using this type of service on the e-marketplace social care so that companies can improve the quality of services offered.

ABSTRACT

The world is witnessing unprecedented advancements in ICT (Information & Communication Technology) related fields. These advancements are further boosted with the emergence of big data. It goes without saying that big data requires two major operations: storage and processing. The latter is usually provided through High-Performance Computing (HPC) which is delivered through two main venues: supercomputers or clustering. The second venue has been widely opted for as a cost-effective alternative when compared to supercomputers. However, with the widespread increase in deploying ICT-based applications, the parallel increase in energy consumption has become a real issue. Thus, researchers have been exploring approaches to conceive big data analytics platforms that are both cost-effective and energy-efficient. In this paper, we present a cost-effective and energy-efficient HPC clustering that is based on Raspberry PIs. Our approach leverages the concept of Green Computing. We evaluated our cluster performance and its energy consumption and compared it to a commodity server. We leveraged on the Amdahl's law to set the maximum speedup of the proposed approach. Our approach can be easily deployed for usage in different ICT-based applications that consider energy efficiency as a priority.

1. Introduction

Nowadays, ICT is interweaving into the fabrics of everyday life and touches all aspects of our lives: smart homes, smart cities, smart grids, smart agriculture, eHealth, autonomous vehicles, etc. All these aspects been further enhanced by the emergence of big data.

Indeed, big data is now becoming wide data. By looking at the amount of data generated each day from different sources (e.g. social networks, Internet of Things, business transactions, etc.), we can infer that these data will eventually need large and advanced platforms that can accommodate for their constantly increasing amount.

It is very common that Big Data faces two major challenges: storage and processing. The storage of the big data can be challenging as it needs to be correctly performed in order to allow for an appropriate and efficient processing later on.

As the data becomes more massive and the applications more demanding, the processing becomes very heavy. This implies the use of High-Performance Computing (HPC) as the ultimate solution for the increasing demand on the computing power. The term refers to combining processing powers to deliver a higher performance. Throughout the years, HPC has been provided via either supercomputers, or cluster of commodity computers. The first venue is no longer opted for mainly because of its high cost and not-so-easy maintenance which leaves the clustering as the perfect alternative.

Cluster Computing involves combining similar type of computing machines that work, transparently, like a single computing unit. These machines are connected using dedicated network protocols and usually Local-area networks (LAN). The aggregation of computing powers allows for a better efficiency to

*Corresponding Author: Safae Bourhnane, Al Akhawayn University in Ifrane, +212610880040, Email: s.bourhnane@aui.ma

solve complex operations using faster processing speed than a single machine.

Cluster Computing can be divided into three main categories: load balancing cluster, high availability cluster, and high-performance cluster. The latter is what we are selecting for the work presented in this paper. Clusters of computers represent the environment for different distributed platforms to store and process the big data. Hadoop is the most widely used case in point and it can be utilized for a wide range of applications thanks to the number of benefits it presents.

Hadoop is a famous open-source framework that is conceived for storing and processing data. It serves to run applications on clusters of computers which help it make use of the great processing power provided by the cluster. Hadoop has two main components: MapReduce and HDFS. MapReduce is the programming model brought by the framework while HDFS refers to Hadoop Distributed File System and hence represents the underlying file system.

Testing the cluster with a specific number of nodes can give an idea about the performance as the number of nodes increases. This concept is called "Speedup" and can be given using the renowned Amdahl's Law.

Amdahl's law is a mathematical method that allows for having an idea about the maximum improvement that can be achieved through improving a particular part of the system. In our case, we are making use of Amdahl's law to theoretically find the maximum speed up with multiple processors. Also, it will allow us to infer whether the Raspberry Pi cluster will reach the performance of a single commodity hardware and determine the number of nodes needed in the positive case.

Since we are concerned by the energy efficiency and the cost-effectiveness of the entire system, we are opting for an approach that respects both features. Our approach is based on Raspberry Pis as an alternative to commodity computers and that is because it is known for its low cost and low energy consumption.

Currently, the world is trying to implement a solution that copes with the increasing demand on processing power due to the expanding amount of the data produced, without consuming a large amount of energy. Eventually, researchers have been trying to implement HPC clusters based on low-cost and low-energy hardware. There is a significant amount of work that has been carried in this direction. Most of it used Raspberry Pi as a basis of the cluster and tried to prove that the hardware supports the installation of different big data analytics platforms, e.g. Hadoop. However, this does not give an idea about the real performance of the Raspberry Pi cluster.

For the Raspberry Pi cluster to pass the performance test, it needs to be compared to a performant machine/server. This comparison should be accomplished using the same big data analytics platform and by running the same jobs. This does not only imply the use of the same dataset, but also the same dataset size.

In this paper, we are testing our Raspberry Pi approach and comparing it to a commodity server through benchmarking both setups against the Terasort which is one of the mostly used Hadoop benchmarks. In addition to keeping track of the performance, we are measuring the energy consumed by both setups as energy efficiency is one of the main pillars of our study.

Moreover, we are looking at the speedup of the cluster in order to find the maximum value it can reach. This will allow us to have an idea about the size of the cluster corresponding to a higher performance. For this, we are making use of the Amdahl's Law.

The rest of the paper is organized as follows: Section II presents the literature review; we present the background in III and our proposed approach in section IV. Section V contains the results related to the single-node cluster while section VI presents the results of Raspberry Pi multi-node cluster. We compare both setups and present a discussion in section VII. Finally, we present the conclusion and future work in section VIII.

2. Literature Review

During the last few years, implementing Green Computing using Raspberry Pi has been trending among practitioners in the domain.

Raspberry Pi clusters have been the center of different research works that tackled it as a cost-effective and energy-efficient solution to deliver Green Computing. In this section, we are shedding the light on some of the work that has been previously carried out in that sense.

In [1] the authors implemented a Raspberry Pi cluster that consists of 300 nodes. Through their paper, they walked us through the steps of deployment and set up of the hardware and software plus the maintenance and the monitoring of the overall system. Moreover, the work presents some of the limitations and the challenges that would block the deployment of the cluster. These include the overall performance of the card that is considered relatively low due to the design of the flash memory, in addition to the low processor speed.

The next work described another low-cost cluster named Iridis-pi and that was conceived for the sake of demonstration [2]. The cluster contains 64 Raspberry Pis Model B with 700MHz processor and 256MB of RAM. The authors chose to host the cluster on a Lego chassis. The nodes are connected together using Ethernet cables. The entire system has an overall RAM of 16GB and 1TB of storage. In order to assess the numerical computer power, this research used the LINPACK benchmark for the single-node performance, and the High-Performance LINPACK benchmark in order to measure the overall throughput of the cluster. The results revealed a computational performance peak of around 65000kflops. More results showed that the cluster delivers a good scalability with large problems, and a less significant one with small problems where the network overhead becomes more noticeable.

Glasgow Raspberry Pi cluster [3] depicted the use of Raspberry Pi in data processing. The cluster consists of 56 Model B Raspberry Pi that are supposed to emulate the entire stack of the cloud. The devices are interconnected in a tree topology. Each node uses a 16GB SD card that hosts up to three co-located virtualized hosts provided via Linux containers. According to this research, the deployment of this cluster is still not mature. The authors are still investigating an easier and more secure approach

to manage the virtual resources. Also, their future work includes the implementation of live migration through the PiCloud.

The work in [4] introduced a study of the feasibility of implementing Raspberry Pi based data centers for Big Data processing. The paper examined further the advantages using Raspberry Pi for big data applications through a micro data center. The authors conducted a study that tackles the performance, the scalability, energy consumption, ease of management, etc. For testing purposes, they used Hadoop framework. This allowed the authors to discover that the cluster delivers a moderate performance.

Th authors in [5] explored the use of low-power and low-cost devices for pervasive computing (Cloud and Fog computing). The work tests the performance of the cluster using Apache Spark and HDFS. It also uses the same setup for a real and a virtualized environment. The virtualization has proved to be more significant with large amounts of data. Moreover, the virtualization also affects the energy consumed by the Raspberry Pi when the workload becomes higher.

The research in [6] presented the evaluation and comparison of 24 ARM board energy consumption and performance wise. Finally the Raspberry Pi was chosen as the basis for ARM HPC after looking at the tradeoffs. The results of this study have shown that the overall performance of the cluster remains less than that of the x86 server. However, the authors mentioned that this was not the main end goal of the project. The low-cost of the Raspberry Pi allows for affordable and more accessible cluster computing for the public and especially for students. Hence, the work presented in this research encourages the use of low-power parallel programming in education.

In [7], the authors explained the use of Image Processing algorithms to test the performance of the Raspberry Pi cluster. Image processing is known to require a lot of processing power that is why it is being used to assess the performance of the Raspberry Pi cluster. The authors developed an application that counted the wheat grains presented in a given picture. The Raspberry Pi cluster hosted a parallel computing application that was coded in Python in addition to the use of MPI. The application was tested on a single node first and then on the cluster of four nodes. The purpose was to test the speed of the application. The results have shown that the processing time using both single-node and multi-node Raspberry Pi clusters depends on the number of images processed.

The work in [8] presented the design and creation of a high performance Beowulf cluster based on 12 Raspberry Pis. In order to test the cluster, some mathematical benchmarks have been used to measure the performance of the cluster. The authors used a program to calculate the scalar multiplication of a matrix. The runtime and the GFLOPS were logged. The authors have mainly noticed the following: the peak performance of the system went up as the number of nodes increased, the speedup also increased as more nodes were added to the cluster and increasing the problem size increased the performance. The authors also mentioned a number of limitations related to memory. However, according to the study, the cluster can be used to automate some testing operations.

In [9], the research extended some previously done work by comparing a cluster of Raspberry Pi to multi core processors like i5 and i7 processor machines. The results of this work have shown that the Raspberry Pi cluster is ranked third performance wise after the i7 and the i5 processors. The Raspberry Pi is very limited in terms of resources. Even with 14 nodes it could not reach the performance of its competitors. Core i5 architecture has better resources and eventually performs better than the Raspberry Pi cluster. The core i7 architecture remains with the highest performance.

Our paper aims to extend the previously discussed work by conducting a set of experiments in order to compare our cluster to one single performant commodity machine. The work presented here does not provide an ultimate solution, it rather serves as a baseline for researchers to decide on the most suitable configuration with regards to their applications.

3. Background

3.1. High Performance Computing

High Performance Computing (HPC) deals with the implementation of algorithms or code taking into consideration the hardware used for each application [10]. It was conceived by scientists and engineers to cope with the problems that require more resources (CPU, memory, etc.) than what one single machine can provide.

There are two very known venues to implement HPC: either through owning supercomputers, or clustering commodity computers. The second option is what is generally opted for. HPC is usually provided via a set of computers that have almost the same characteristics, and that are connected to each other. Each one of these machines is referred to as a node [11].

HPC-based solutions usually have three main components: Compute, Network, and Storage. Compute servers are connected forming a cluster which is also connected to the storage component. These connections are not visible to the user who deals with the entire system as a single machine in a transparent manner

HPC has several use cases that can either be deployed on premises, at the edge, or on the cloud [12]:

- Research: HPC clusters help researchers find solutions to very complex problems, and hence bring contributions to the community.
- Entertainment: HPC is also used in media in order to edit films and come up with mind-blowing special effects.
- Artificial Intelligence: HPC implements machine learning algorithms that requires huge processing power.
- Finance: HPC clusters can be used to track stocks, design new products, simulate test scenarios, etc.

3.2. Green Computing

Currently, Green Computing (GC) is considered a shift that is supposed to deal with the constantly increasing energy consumption of the existing computing solutions. This is due to the increasing demand on computing power by different applications.

Green Computing consists a tailor-made solution for many applications as it is based on energy-efficiency as one of the pillars. GC as a concept, refers to the deployment of efficient and eco-friendly computing solutions. It is provided through four main technologies: green data centers, virtualization, cloud computing, grid computing [13].

3.3. Hadoop

It goes without saying that data have been generated in a massive manner throughout the years due to the advancements in all the fields and industries. Talking about huge datasets implies bringing up storage. Storage capacities of hardware systems have increased to keep up with the amount of streaming data. However, access speeds did not keep up. Thus, the traditional Database Management Systems (DBMS) are no longer considered an option to go for. Also, hardware failure is a problem that needs to be overcome.

Hadoop was introduced to solve the previously mentioned problems in addition to others. It is an opensource framework that deals with big data through providing a platform for distributed storage and processing. As Hadoop is used over a set of clustered computers, the possibility of a machine failing is relatively high. This may imply serious data loss if not dealt with correctly. Data replication is a way to tackle this issue effectively: having redundant data all over the system.

3.4. Raspberry Pi

The Raspberry Pi is a computer with the size of a credit-card that can be plugged to a monitor, a keyboard, a mouse, and other devices. It provides a low-cost option to explore computing and programming in different languages (e.g. Python). It is also capable of providing all the options of a normal computer: internet browsing, playing games, etc. [14].

Moreover, the Raspberry Pi has the ability to interact with the outer world through the connection with sensors and actuators. This is done through what is called General-Purpose Input Output (GPIO). This allows the computer to be the best option for robotics related projects and prototypes.

Since its first launching, RP has gone through a set of changes that resulted in different versions and models available in the market. Table 1 presents the models of Raspberry Pi and their characteristics.

Table 1: Raspberry Pi Models [15]

Model	Date	Price ($)	Core	Num. Cores	RAM
RP B	15/2/2012	35	ARM1176JZF-S	1	512M
RP 2	1/2/2015	35	Cortex-A7	4	1G
RP Zero	30/11/2015	5	ARM1176JZF-S	1	512M
RP 3	26/2/2016	35	Cortex-A53 64-bit	4	1G

RP WH	12/1/2018	14	ARM1176JZF-S	1	512M
RP 3 B+	14/3/2018	39	Cortex-A53 64-bit	4	1G
RP 3 A+	15/11/2018	25	Cortex-A53 64-bit	4	512M
RP 4 B	24/6/2019	37	Cortex-A72 (ARM v8) 64-bit	4	1/2/4

3.5. Project Scope

The work presented in this paper falls under the scope of a USAID sponsored research project named MiGrid. The project aims at developing a holistic approach that couples renewable energy storage and production in smart buildings.

The general architecture of the project is depicted in the Figure 1 below:

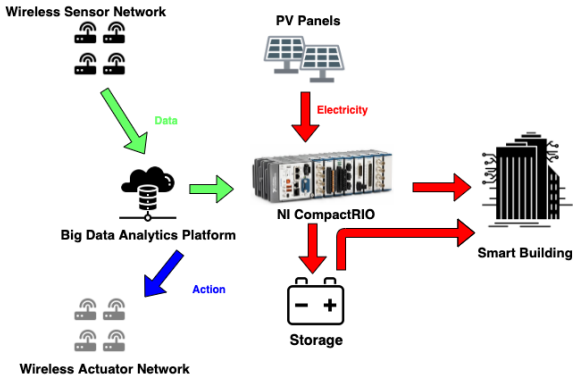

Figure 1: Smart Micro-Grid General Architecture

The architecture contains six main components [16]:

1. Wireless Sensor Network: (WSN) A number of wirelessly connected sensors that are supposed to sense data about the environment.
2. Wireless Actuator Network: Actuators that are connected and interfaced with the WSN. They are responsible for translating the digital signals into electrical ones.
3. Big Data Analytics Platform: A platform that implements a number of algorithms responsible for the processing and analysis of data provided by the WSN.
4. NI CompactRIO: the main controller of the system that decides whether the energy produced is to be stored, injected in the grid, or used to power appliances.
5. Storage: Batteries that store the excess of energy produced and make it available for later use.
6. Solar Panels: the main renewable energy source of the system.

The work tackled in this paper fits in the third (3) component as it presents and tests a potential implementation of the big data analytics platform that is based on Raspberry Pi as the main piece of hardware.

4. Proposed Approach

Our approach to the green cluster relies on using Raspberry Pis instead of commodity computers to deliver HPC. Our work consists of conducting a set of experiments that compare our green Raspberry Pi cluster to one single server. The comparison consists of looking at the performance in terms of CPU time, in addition to the energy cosumption of each solution. Furthermore, we are invistigating the impact of the number of CPUs and memory size on the performance of the single machine, and the impact of the number of nodes and the network performance on the Raspberry Pi cluster.

For the sake of this experiment we made use of two different architectures: a multinode Hadoop architecture, and a single node architecture.

4.1. Multi-node Hadoop Architecture

This setup consists of five Raspberry Pis. The hardware specifications are presented in Table 2:

Table 2 Raspberry Pi Specifications

SoC	Broadcom BCM2837
CPU	4xARM Cortex – A35, 1.2 GHz
GPU	Broadcom VideoCore IV
RAM	2GB
Networking	10/100 Ethernet, 2.4GHz 802.11n Wireless
GPIO	40-pin header, populated
Ports	HDMI, 3.5mm analogue audio-video jack, 4xUSB 2.0, Ethernet, Camera Serial
Price	$25-$195

The hardware architecture consists of the five Raspberry Pis connected together and to a switch through Ethernet connection. Figure 2 below describes the hardware architecture:

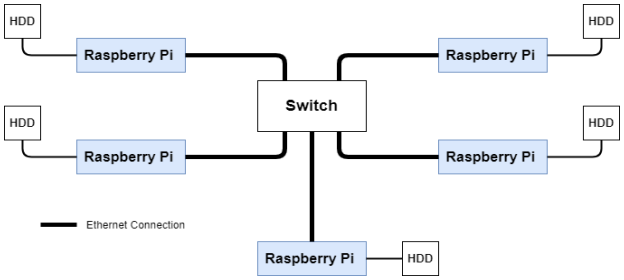

Figure 2: Multi-node Cluster Hardware Architecture

Each one of the Raspberry Pis has the software architecture presented in Figure 3:

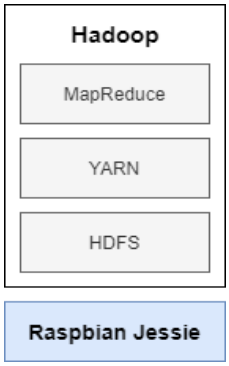

Figure 3: Multi-node Cluster Software Architecture

4.2. Single-node Cluster Architecture

The single node cluster consists of the following server with the specifications mentioned in Table 3 below. The corresponding software architecture is depicted in Figure 4:

Table 3: Single-Node Machine Specifications

Manufacturer	Dell, Inc
CPU	Intel Core i7 (6th Gen) 3.4 GHz
Number of cores	Octa-core
RAM	8GB
Hard Drive	SATA, HDD, 1TB
Networking	Ethernet, Fast Ethernet, Gigabit Ethernet
Graphic Controller	NVIDIA Quadro K620 2 GB
Price	$900

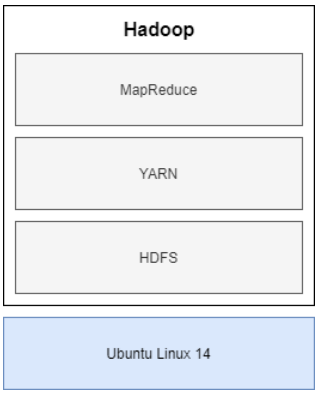

Figure 4: Single Node Machine Software Architecture

4.3. Benchmark

For this experiment, our setups were benchmarked against one of the most famous Hadoop benchmarks: Terasort.

The Terasort is a sorting algorithm implemented using MapReduce. There are two more functions related to Terasort that that are also implemented in Hadoop:

- Teragen: it generates the data to be sorted. We can specify the size of the dataset to be sorted.
- Terasort: the actual sorting jar that takes the result of the Teragen function.
- Teravalidate: it validates the output (the sorted result of the input data).

For the execution, we followed the steps presented in Figure 5:

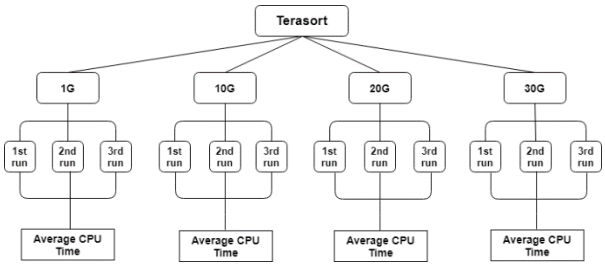

Figure 5: Terasort Execution Steps

We ran the experiment on four different dataset sizes: 1GB, 10GB, 20GB, and 30GB. For each run, and in order to avoid outliers in the results obtained, we ran each experiment many times and we kept the best (statistically) three results, and calculated the mean for both the energy consumption and the execution time.

4.4. Energy Consumption Measurement

In order to measure the energy consumed by each of the setups, we created a sensor node based on the Arduino Uno

microcontroller in addition to the SCT013 current sensor. Arduino is an open-source platform that is easy to use and mainly serves as a prototyping platform. The boards are able to read input form sensors and turn it into an output. We opted for Arduino due to its price affordability and accessibility user-experience wise [17].

The SCT013 sensor is a non-invasive current transformer that measures the intensity of the current in a conductor. These measurements are provided using the electromagnetic induction. They come in the form if clamps that can be wrapped around the equipment. The sensor is very accurate with an error rate of only 1-2% [18].

The Arduino circuit that we used is shown in Figure 6 below:

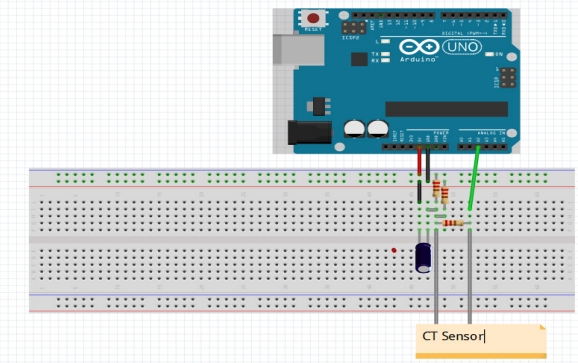

Figure 6: Current Sensor Arduino Circuit

5. Performance Evaluation

5.1. Single Node Cluster

a. Impact of the Number of CPUs

In this section, we are going to study the impact of the number of CPUs on the performance (i.e. the CPU time). The server we are working with is an octa-core machine. We ran the same job 8 times: limiting the number of CPUs from 1 to 8.

The results are given in Figure 7.

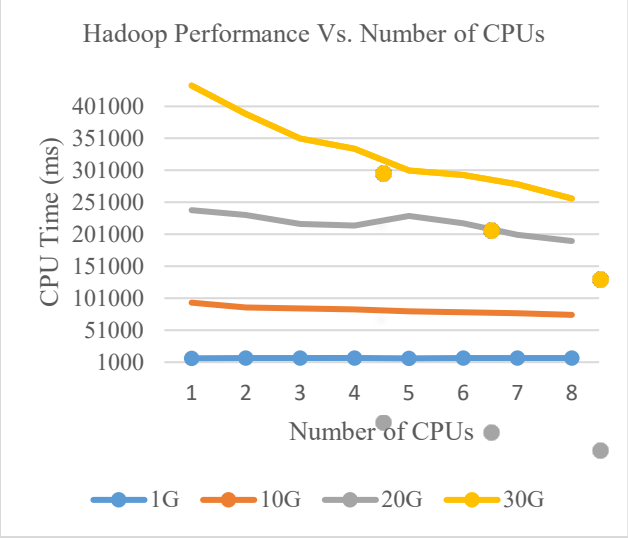

Figure 7: Hadoop Performance Vs. Number of CPUs

The job used in this comparison is the Terasort benchmark as mentioned previously in the paper. The sorting algorithm used as input files of different sizes.

As we can notice from the graph above, the difference in the CPU time when sorting 1Gb of data is not significant: it varies between 7350 ms and 7100 ms. For the CPU time corresponding to sorting 10Gb of data, it showed a slight decrease as the number of CPUs increased: it went from 94100 ms to 75005 ms. The most significant difference was shown in the performance of sorting 20Gb and 30Gb of data.

Concerning the CPU time resultant from sorting 20Gb of data, it scaled down from around 239000 ms to 191000 ms. Sorting 30Gb of data took eventually more time and went from 433590 ms using 1 CPU to about 251000 ms using 8 CPUs.

The number of CPUs used in the Dell Precision Tower machine has a significant impact on the performance of Hadoop jobs. This impact becomes more and more noticeable as the size of the job increases.

In the next section, we are going to have a closer look at the impact of memory size on the performance of Hadoop as a single node cluster.

b. Impact of Memory Size

In order to investigate the impact that the size of the memory has on the performance of Hadoop, we made use of the same benchmark (i.e. Terasort) and using the same input dataset sizes. The machine that we are working with in this experiment has a maximum of 8Gb of RAM. For each job, we had to limit the memory usage starting from 1Gb to 8Gb.

Figure 8 below shows the results of the experiment.

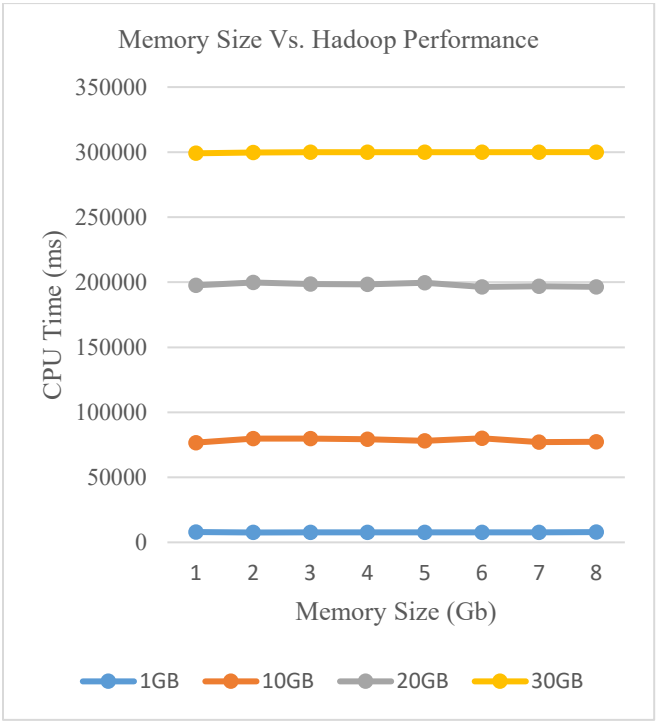

Figure 8: Memory Size Vs. Hadoop Performance

As shown in the figure above, scaling up in the size of the memory did not impact the performance of the cluster. The CPU

time remained the same throughout all the experiments. Sorting 1Gb of data took about 7500 ms with all the sizes of the memory. Concerning CPU time of sorting 10Gb of data, it was about 78000 ms and did not significantly change with all the memory sizes. Similarly, sorting 20Gb of data was stable at around 199000 ms. Also, the CPU time corresponding to sorting 30Gb of data was constant at around 300000 ms and was not impacted by the memory size. This mainly due to the nature of Hadoop and its technologies: they are disk-based and not memory-based. Unlike Spark, Hadoop does not work in memory, which somehow explains the delay that it presents compared to Spark platform.

c. Energy Consumption

Since we are concerned by the energy efficiency as a primary matter, we measured the energy consumed by the singe-node cluster for the same benchmark using 1Gb and 30Gb of input data. For the sake of this experiment, we used all 8 CPUs of the machine and unlimited memory resources.

The energy consumption measured is shown in Figure 9 and 10.

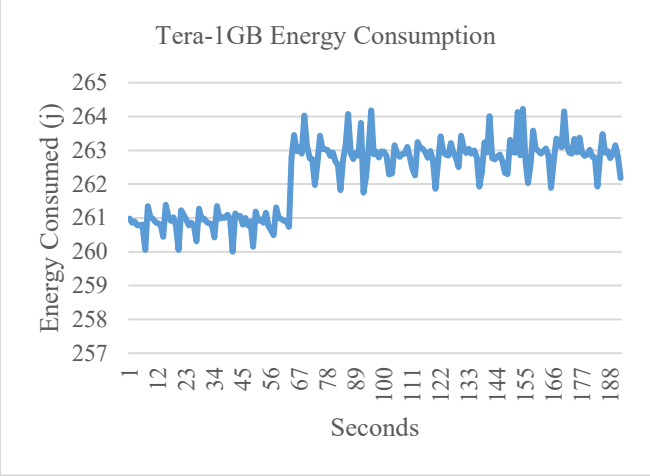

Figure 9: Tera-1GB Energy Consumption

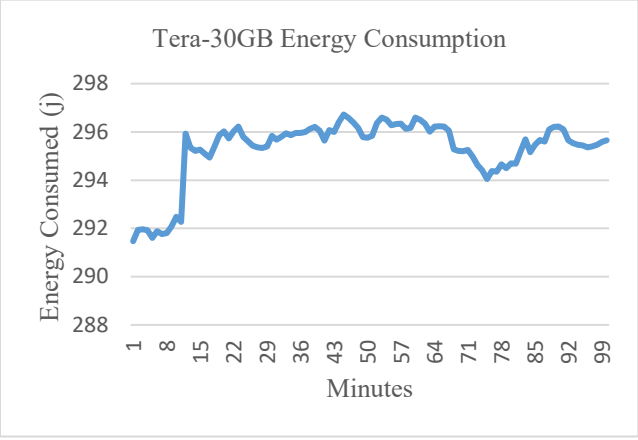

Figure 10: Tera-30Gb Energy Consumption

From the graphs above, we can notice that the energy consumption during the execution time of the Terasort benchmark with 1GB dataset went from 260 J/s to 290 J/s with an average of about 263 J/s. Running the same benchmark on a 30GB dataset size consumed an average of 295 J/s with the max being 296 J/s and the min 291 J/s.

5.2. Multi Node Raspberry Pi Cluster

a. Impact of the Number of Nodes

In this section, we are exploring the impact of the number of nodes in a multi-node cluster on the performance of Hadoop.

As described previously in the paper, we are dealing with a cluster of 5 Raspberry Pis that are connected together through ethernet. Each node has the same software architecture that is based on the same version of Hadoop.

For the sake of comparison, we are using the same benchmark as the previous experiment with the same dataset input sizes.

The result of running Terasort on Raspberry Pi is mentioned in the figure below.

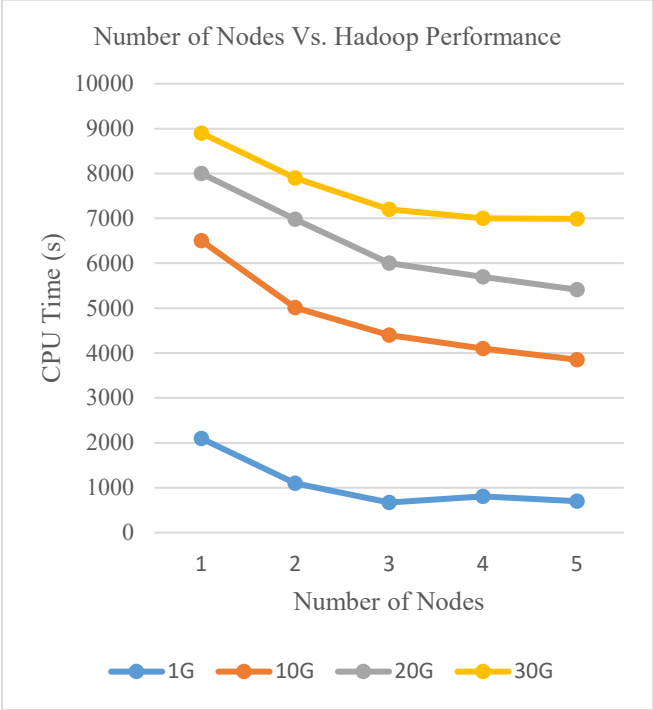

Figure 11: Number of Nodes Vs. Hadoop Performance

As we can infer from Figure 11, sorting all datasets using one node takes always longer than sorting them with more nodes. The time taken by the job using 1 node to sort 1Gb was about 2100s, and to sort 10Gb was 6500s, 8000s to sort 20Gb, and around 9000s to sort 30Gb of data. While using 5 nodes, the CPU time decreased significantly as it took only 700s to sort 1Gb of data, around 3800s to sort 10Gb of data, 5400s to sort 20Gb, and 6900s to sort 30Gb of data.

This means that adding Raspberry Pi nodes to the cluster increases the performance and reduces the CPU time taken by the jobs. Adding nodes means adding resources: memory size and CPUs. Knowing that each Raspberry Pi has 4 CPUs and 1Gb of RAM, working with 5 nodes implies working with 20 CPUs and 5Gb of RAM.

b. Impact of the Network

It goes without saying that any system that is distributed over a number of physical machines requires a network connection

between the nodes. This connection brings an overhead that affects the response time of the cluster.

In order to have a closer look at the impact of the network on the performance of Hadoop, we are connecting the 5 nodes of the cluster using two different types of switches with different throughputs: 100M and 1000M. Table 4 below describes both switches and presents their characteristics.

Table 4: NetGear Switch Vs. Fujitech Switch

	NetGear	**Fujitech**
Dimension	235.5x100.8x27	14.5x8.5x2.6
Network Characteristics	Gigabit Ethernet	Megabit Ethernet
Ports	8x10/100/1000	8x10/100
Energy Consumption	14W	-
Transfer Rate	1Gb/s	1Mbps
Weight	760g	-

Similar to the previous experiments, we are using the same benchmark and the same dataset sizes. The results of running Terasort using the two switches are shown in Figure 12.

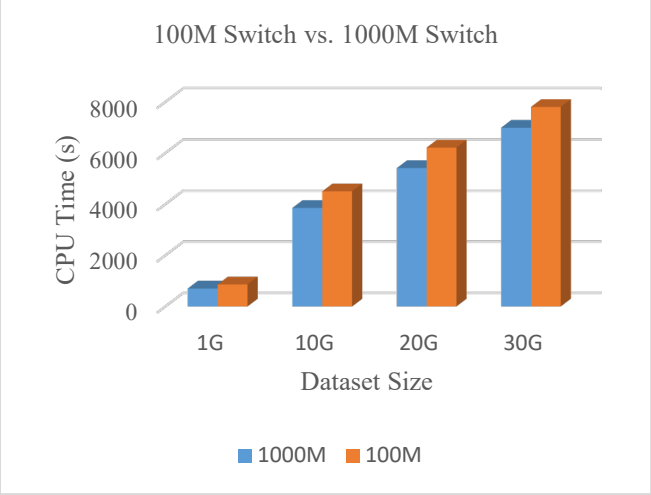

Figure 12: 100M Switch Vs. 1000M Switch

The results show the slight increase in the performance of the cluster as executing the same jobs using the 1000M switch takes less time than the other switch. The network clearly impacts the response time of the cluster. Hence, improving the network quality and equipment would result in a better performance.

c. Energy Consumption

Similar to the previous setup, we also looking at the energy consumption of the entire cluster.

Using the method described previously, we were able to measure the energy consumption of the cluster when sorting 1Gb of data and 30Gb of data. We used the same sensor for each of the slaves and we noticed that the power varies between 4W when jobs are being performed and 11W in an idle state. Regarding the master, the sensor showed a max of 6.7W and a min of 13W and that is because of the different external devices that are connected to it (i.e. mouse, keyboard, monitor, in addition to the external hard disk drive).

The sum of the values given by the sensors is shown in Figure 13 below.

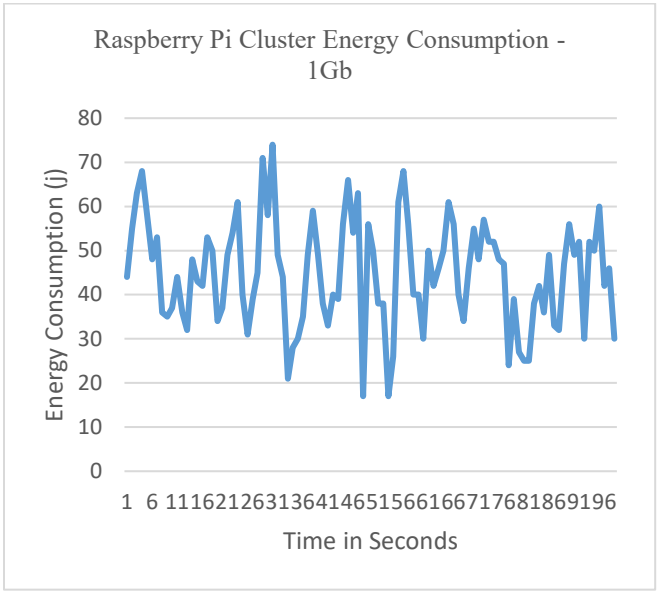

Figure 13: Raspberry Pi Cluster Energy Consumption - 1Gb

As we can notice, the entire 5-node cluster consumes between 17J/s and 70J/s. This is considered relatively low; we are looking into a detailed comparison later in this paper.

The energy consumed when sorting 30Gb of data using the same setup is shown in Figure 14.

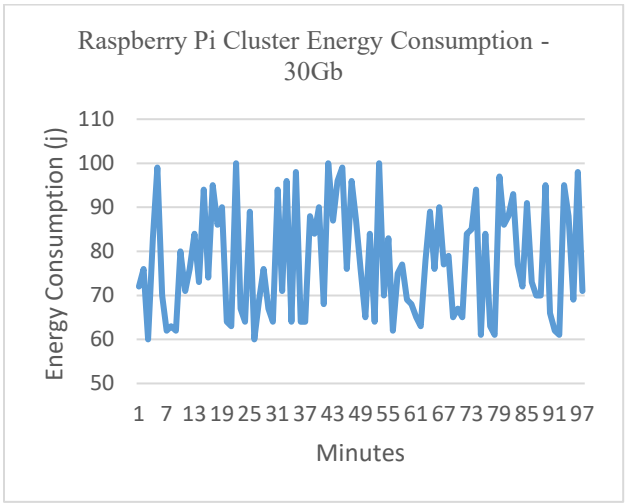

Figure 14: Raspberry Pi Cluster Energy Consumption - 30Gb

The energy consumed during the job is varying between 60J/s and 100J/s.

6. Comparison and Discussion

6.1. Performance Comparison: Single-node Vs. Multi-node Clusters

In order to have a general look over the difference between the two clusters, we are comparing the results given by all CPUs and full memory in the single-node cluster, and all nodes in the multi-node clusters.

The graph below shows the CPU time taken to sort all dataset sizes using both clusters.

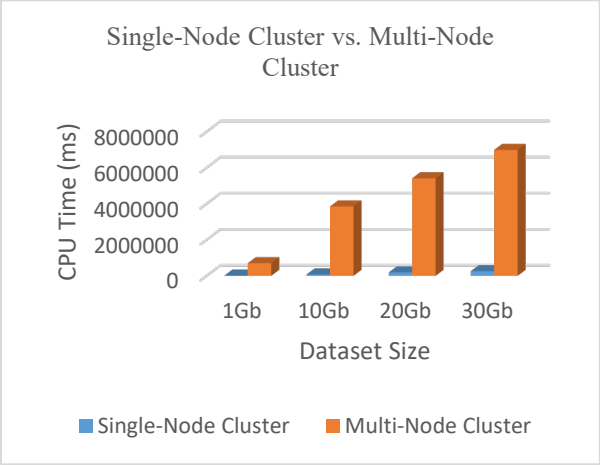

Figure 15: Single-Node vs. Multi-Node Cluster

Figure 15 above shows the clear difference between sorting the same dataset using the two different clusters. As the job becomes heavier (i.e. more data to be processed), the difference between the CPU times becomes more significant.

This implies that the 5-node cluster that we have is not enough to provide the same performance given by the single node cluster.

6.2. Energy Consumption Comparison: Single-node vs. Multi-node Clusters

As mentioned previously in this paper, our approach is supposed to be energy efficient as it tackles that concept of green computing. Thus, we are comparing the energy consumed by both clusters during the execution of the same job. We are comparing the first 100 seconds of sorting 1Gb of data using all CPUs and full memory for the single-node cluster, and all 5 nodes for the multi-node cluster. The result is shown in Figure 16.

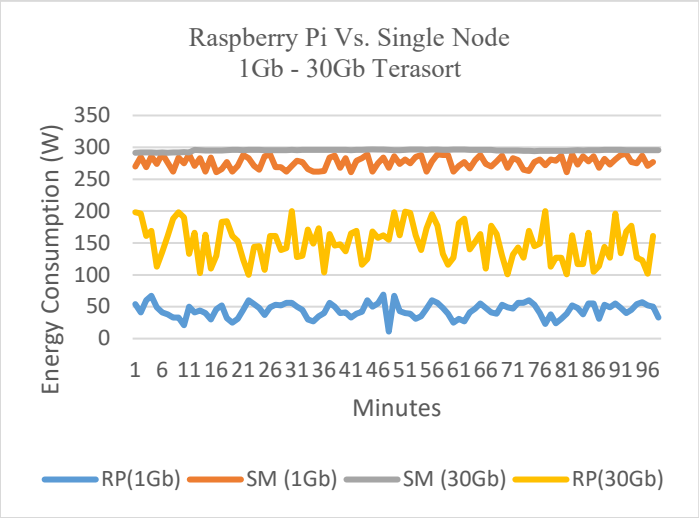

Figure 16: Raspberry Pi Cluster Vs. Single-Node Energy Consumption

The graph above shows the difference in the energy consumed by the two setups when sorting 1Gb and 30Gb of data using Hadoop. The results show that, not only the single machine consumes more energy, but also the RP cluster has a consumption that varies a lot compared to the single machine.

6.3. Discussion

The different experiments conducted in this paper were for the sake of determining how performant the Raspberry Pi green cluster can be.

According to the study conducted in [13] where the authors compared a commodity hardware cluster with a Raspberry Pi cluster using two different Hadoop benchmarks: Terasort and TestDFSIO. The results showed that the commodity hardware cluster outperformed the Raspberry Pi cluster. This was mainly due to the low computing power of the Raspberry Pi. The work performed in this paper sustains these results; In addition to that, since we are only using a single machine vs. a multi-node cluster, the network overhead is added and the performance is eventually decreased.

Another research has been done to test a Raspberry Pi Hadoop cluster against an image analysis in a cloud robotics environment [19]. Their research has proven that the Hadoop cluster lacks in performance compared to a Hadoop cluster that is based on virtual machines running on top of commodity computers.

Authors in [20] investigated the use of Raspberry Pi computers to implement an efficient solution for augmented computing performance. They used Hadoop along with benchmarks and compared the outcome to the one of a single commodity computer. The results showed that the single machine outperforms the clusters in almost all the operations. However, the low-cost and the light weight of the Raspberry Pi based solution makes it more suitable.

For the sake of our experiment, we are using the Amdahl's law to predict the performance of the Raspberry Pi cluster and decide on when the cluster will reach the performance of the single machine we are using.

According to the paralleled and serialized sections of the algorithm used, based on the Amdahl's law formula, the speedup is supposed to be as presented in Figure 17.

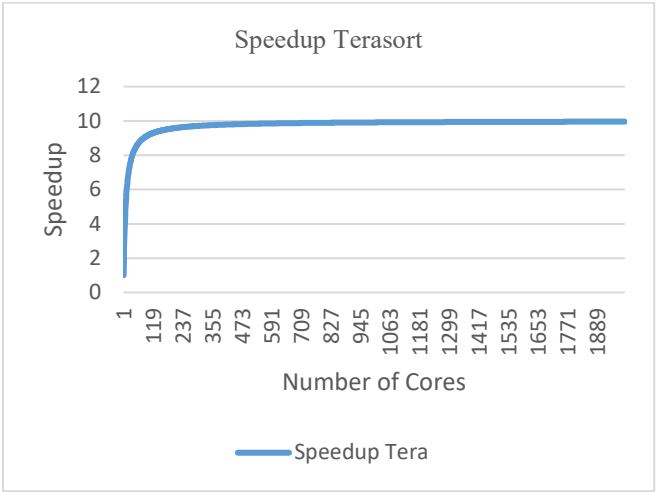

Figure 17: Speedup Terasort for Terasort Benchmark

We applied the formula for the number of cores from 1 to 2000 cores. Based on the speedup found, the performance is expected to increase according to the graph shown in Figure 18.

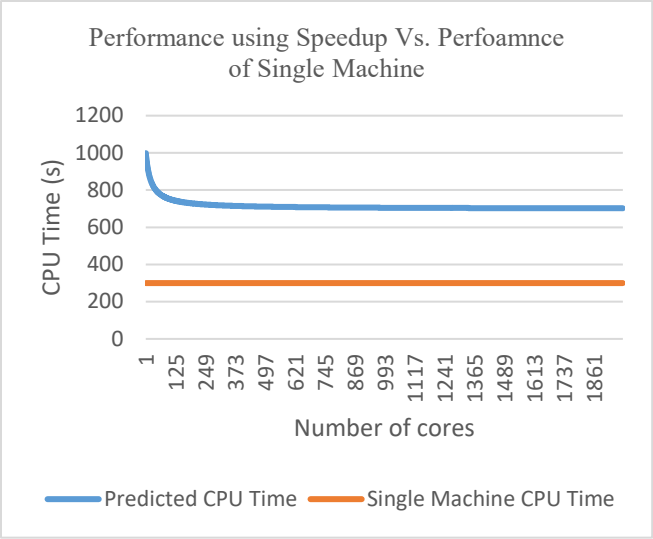

Figure 17: Performance of cluster using Speedup vs Performance of a Single Machine

Although we worked with 2000 cores (knowing that each RP has 4 cores, we are dealing with 500 Raspberry Pi nodes), we could not get the same performance as the single machine performance.

The best CPU time we achieved is 700 seconds using the Raspberry Pi cluster while the single machine performs the exact same job in 300 seconds.

At this level, we need to keep in mind that this study is theoretical, the real-world speedup can be given by the real measurements that we conducted and presented earlier in this paper. Also, the real-world measurements are affected by a number of other parameters and features: the network communication between the nodes that is, itself affected by the quality of the equipment used (i.e. switches as presented earlier).

The difference between the real-world and the theoretical results are shown in Figure 19.

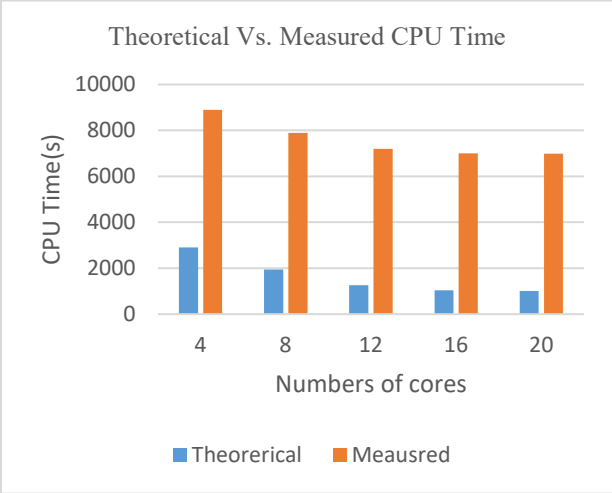

Figure 19: Theoretical vs. Measured CPU Time

Based on the theoretical approach that is built on Amdahl's law, the 500-node cluster will consume a minimum of 2000 W and 5000 W. In addition to that, the cluster will cost a minimum of $10000. Table 5 below summarizes the comparison between the single-node commodity computer and the Raspberry Pi 500-node cluster.

Table 5: Single-Node Vs. 500-Node RP Cluster

	Single-Node	**500-node RP cluster**
Price	$900	$10000
Max Energy Consumption	292W	Around 5000W
Min Energy Consumption	261W	Around 2000W
Scalability	Medium	Easy
Maintenance	Medium	Medium
Ease of use	Medium	Easy
Reliability	High	Medium

Oracle has been working on the world's largest Pi cluster where they used 1060 Raspberry Pi nodes to create a supercomputer.

According to [21], the cluster has 4240 cores for processing and it costs around $37100 without counting the external storage devices, the cables, 3D printed holders, etc.

7. Conclusion and Future Work

In this paper, we investigated the use of a Raspberry Pi clusters to provide High Performance Computing. The cluster performance was benchmarked against the Terasort algorithm and compared to a single legacy server machine. Both experimental setups run Hadoop. The experiments investigated the impact of the number of nodes and the network bandwidth on the performance of the Raspberry Pi cluster. Besides, we also tracked the impact of the number of cores and the RAM memory size on the performance of the single-node setup. We measured the energy consumed by both setups while performing the same operations.

The results of the experiments showed that the single-node cluster outperforms the Raspberry Pi cluster when sorting 1G, 10G, 20G, and 30G of data, but consumes less energy. However, and based on the Amdahl's law formula, the Raspberry Pi delivers a performance that is closer to the one of the single-node cluster when the number of cores reaches 2000. This implies having a cluster of 500 nodes that would cost around $10000 with a max energy consumption of 5000W. These results present a decent ground for researchers to base their choices on. If the performance is not a priority but the cost-effectiveness and the energy efficiency are, then the Raspberry Pi cluster is suitable. However, when the response time is essential, the most adequate solution is to opt for a more stable and performant solution.

As a future work, we are performing more projections on the number of CPUs used in a Raspberry Pi cluster, in order to determine (using prediction methods) the most suitable configuration according to the criteria/need of each application. Furthermore, we are examining more big data analytics solutions and investigating the possibility of putting in place a private cloud

that is based on Raspberry Pi. This will fall under the realm of green private clouds.

ABSTRACT

COVID-19 is a viral disease that became a pandemic representing a very great challenge worldwide. The purpose of this article is to analyze COVID-19 patients' data based on time-to-event analysis and identify the factors that affect the recovery time from COVID-19. The datasets that are used in this study are for cases that are clinically diagnosed and confirmed where the date of onset is recorded in Wuhan and elsewhere in China from Jan 1 to Feb 11, 2020. We used the regression imputation technique to replace the missing dates in the onset-symptoms based on the dates of the report. We fitted the Kaplan-Meier estimator and Cox regression model to our data. The predictor variables (factors) that we used are age, sex, and onset time to hospitalization. The results show that the young age group is better than the old age group in recovering from COVID-19 (the p-value of the log-rank is 0.00012) and at any time 1.9 as many patients in the young age group are having an event (recovery) proportionally to the old age group. Also, the results show that there is a non-significant difference between male and female groups in recovering from COVID-19 (the p-value of the log-rank is 0.63). The results also show that the early time to hospitalization group can recover from COVID-19 better than the late time to hospitalization group (the p-value of the log-rank is 0.0052). This study demonstrates the association of recovery time from COVID-19 with age, sex, and time to hospitalization.

1 Introduction

The novel coronavirus disease also known as COVID-19 is a viral disease that became a pandemic and turn out to be a great challenge that the world faced since world war two. This virus is originated in Wuhan city, which located in the Hubei province of China and it is spreading at a fast rate around the globe. The diseases caused by viral infection continue to emerge and raise a serious issue in public health worldwide. Several viral epidemics appeared in the last twenty years [1]. In 2002 the severe acute respiratory syndrome coronavirus, which is known as SARS-CoV, which is still circulating in China [2]–[4] has appeared followed by H1N1 influenza in 2009. Most recently in 2012, the Middle East respiratory syndrome coronavirus, which is known as MERS-CoV have been recorded. The main component of the viral genome is a positive-stranded RNA and it has a different structure [5]. There are four genera of Coronavirinae family: α, β, γ, and δ. it is believed that there is a viral gene in wild animals since it has been isolated from bats and other animals [6]. The novel COVID-19 causes mild to moderate respiratory illness, but some people and people with health problems can develop serious illness. Worldwide this disease affected more than five billion people and the number of people who died due to the infection with it exceeds five hundred thousand according to the World Health Organization (WHO) report on the time of writing this research. According to WHO the mild or asymptomatic COVID-19 infections represent 80% of the cases while the severe infections, which require oxygen and critical infections, which require ventilation represents 15% and 5% of the cases respectively. So far, the mortality for COVID-19, which is the total number of deaths divided by the total cases is 5% (this percentage is calculated according to figures that are taken from the WHO web site on 09 July 2020, which shows a total infection of (12,196,982) and total deaths of (552,781)). This mortality is higher than that of seasonal influenza, which is below 1% according to WHO.

Normally, data mining and machine learning methods can be used to analyze datasets of biomedical data [7]. When data include survival data, it requires a different analysis approach. This approach or the study of the time from the entry of a study until a subsequent event occurs is known as survival analysis. Survival analysis is applied in different disciplines such as medicine, engineering, social sciences or behavioral sciences and biology [8]–[16]. When it is applied to medicine, survival analysis is used to study people at risk of experiencing a negative event such as death, where the name survival analysis comes from. Survival analysis is also applicable to areas other than mortality such as analyzing the time taken to recover from certain diseases or the time taken to practice certain exercises to maximum tolerance [17]–[20]. Normally we compare two or more groups of patients with respect to the time of event. More than one event can be considered in the same analysis, but we normally take one event at a time as the event of interest in the study and it can be death or recovery [21].

Many methods can be used for survival analysis, these methods include Kaplan-Meier method which is an estimator of survival probabilities [19, 22] and the Cox regression model, which is now known as the Cox Proportional Hazard Model (CPHM) [23]. These two methods are considered among the methods that contribute significantly to the development of the survival analysis field.

Many studies were conducted to model the survival time and to predict the mortality risk for COVID-19. Guillermo Salinas-Escudero et al. applied survival analysis to study the effect of COVID-19 in the Mexican [24]. The factors they used include age, sex, comorbidities, hospitalization, and admission to the intensive care unit. They applied the Kaplan-Meier and Cox regression models to their data. Their results show that men and older people have higher mortality than women and young people respectively. Monira Mollazehi et al. modeled survival time to recover from COVID-19 [25]. They used data from Singapore in the period between January 23 and March 13, 2020. Their purpose is to identify the factors affecting the recovery time from COVID-19. They used patient's age and nationality as predictors and they found that younger patients can recover from COVID-19 faster than old patients and Singaporean patients can recover faster than non- Singaporean. They compared the results of different models and they found that the Weibull model is the best in fitting their data. Using the Weibull model, they obtained a Hazard rate of 1.01 and 0.76 for age and nationality respectively. Qinxia Wang et al. used survival-convolution models to model the duration of the patient remaining infectious to others [26]. Noam Barda et al proposed a hybrid methodology to construct a multivariable prediction model. In their hybrid method, they used a baseline model which they trained on population data to discriminate the risk then they used a multicalibration algorithm for the risk predation [27]

Different factors may have an influence on the mortality or the recovery time from COVID-19. These factors can be used to divide the patients into two or more groups and they include age, gender, and time from acquiring the illness to hospitalization. This study aims to investigate whether these factors affect recovery time. The datasets that are used in this study are downloaded from Github (`https://github.com/mrc-ide/COVID19_CFR_submission`). From these datasets, we used two datasets. The first one is for cases that died from COVID-19 in Hubei and the second dataset is for patients returning to their home, which obtained from six flights that departed between Jan 30 and Feb 1, 2020.

The rest of the paper is organized as follows: The next section describes the materials and methods. The material and methods section starts by showing how we prepared the dataset that we used followed by describing the imputation technique we used to replace the missing data. Kaplan–Meier survival curve, Log-rank test, and Cox proportional hazards (PH) model also are explained in the materials and methods section. we present the results and the discussion in the third section and the conclusion in the last section.

2 Material and Methods

2.1 Dataset

The datasets that we used in this study are for cases that are clinically diagnosed and confirmed where the date of onset is recorded in Wuhan and elsewhere in China from Jan 1 to Feb 11, 2020. From these datasets, we used two datasets. The first one is for cases that died from COVID-19 in Hubei. It contains the features: sex, age, date of symptom onset, date of hospitalization, and date of death or recovery from COVID-19. Some of the data for the date of symptom onset are not available for some cases so used imputation based on regression to replace the missing data. The second dataset is for patients returning to their home, which obtained from six flights that departed between Jan 30 and Feb 1, 2020. Also, the cases with incomplete date of symptom onset were replaced using regression imputation and then we merged the two datasets. We removed the cases where the sex or the age or date of hospitalization are not available and we end up with 693 cases, which represent recovered and died patients. The used datasets were downloaded from Github (`https://github.com/mrc-ide/COVID19_CFR_submission`). They were used by [28], which extracted it from WHO–China Joint Mission report to estimates the severity of COVID-19 based on the model-based analysis.

2.2 Regression imputation

The datasets that we downloaded has missing data on the date onset symptoms, therefore, instead of deleting all the cases that have missing data, we need imputation to replace these missing data with estimated values, because it is important to have the timing of the onset-symptoms to study the recovery time. We used regression imputation to preserves all cases by replacing the missing date onset symptoms with a probable value estimated by the date of the report because it is clear from Figure 1 that there is a strong correlation between these two dates. In Figure 2, the scatter plot shows the relationship between these two dates, and the value of R^2 (0.7266) emphasizes the strength of this relationship. The model that is used to estimate the missing data in the date onset symptoms is $y = 0.8227x - 0.5428$ also shown in Figure 2, where x and y represent the report date and the onset symptoms respectively. Preserving the cases with missing data using regression imputation has several advantages. In addition to avoiding the deletion of the cases with missing data that can alter the variance of the shape distribution, it can also substitute the missing value based on another variable and no novel information will be added therefore we will be having

an increased sample size and therefore a reduced standard error [29]–[31].

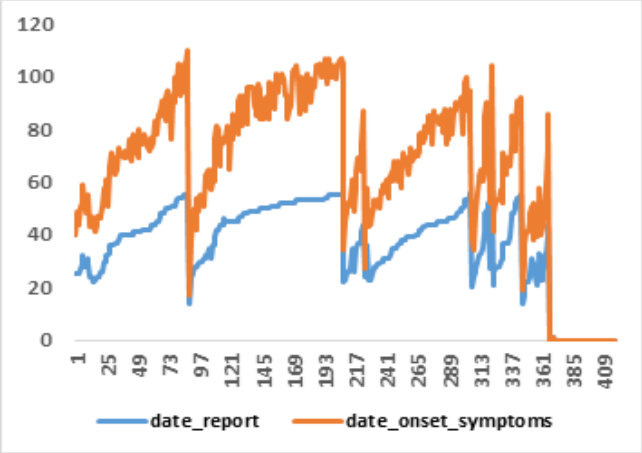

Figure 1: The correlation between date_report and date_onset_symptoms.

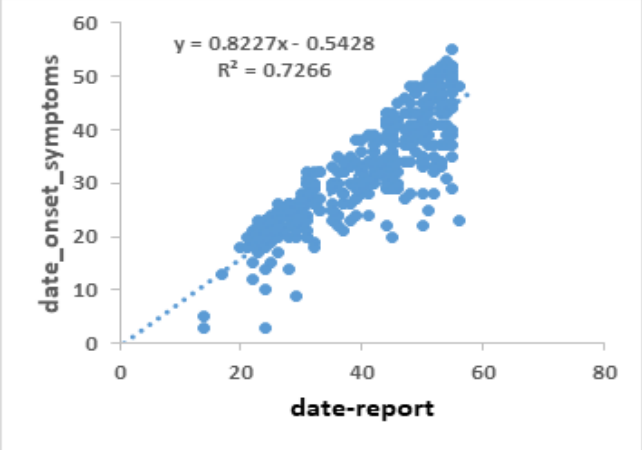

Figure 2: Regression prediction for date_onset_symptoms.

2.3 Kaplan–Meier survival curve

In Kaplan–Meier survival curve, the survival times that include the censored data (the observation that does not get the event) is assumed to be $t_1, t_2, ..., t_n$. These times are entered to the study ordered by increasing duration of a group of n subjects, We can estimate the proportion (survival rate) of subjects $S(t)$ surviving beyond any follow-up time t_p as [17]:

$$S(t) = \frac{(r_1 - d_1)}{r_1} \times \frac{(r_2 - d_2)}{r_2} ... \times ... \frac{(r_p - d_p)}{r_p} \quad (1)$$

Here r_i represents the number of subjects alive just before time t_i given that t_p is the largest survival time and i is any value between 1 and p, d_i represents the number of subjects who died at the time t_i, therefore $d_i = 0$ for censored observations. Before the occurrence of the first event all the patients are alive, therefore, $S(t) = 1$. Considering time t_i, where the number of events(deaths) is d_i and the number of alive is r_i just before t_i then $S(t_i)$ can be calculated as:

$$S(t_i) = \frac{(r_i - d_i)}{r_i} \times S(t_{i-1}) \quad (2)$$

In the censored data we will not have information about the survival time, therefore, $S(t_i)$ will not be calculated for censored observations since the survival curve will not change at the time of a censored observation. At the next event, the number of patients at risk is reduced by the number of censored observations between the two events [32].

2.4 Log-rank test

Normally, we need to compare two survival curves of two groups. For this sake, we use Log-rank test, which is related to a test that uses the logarithms of the ranks of the data and it is used under the assumptions: i) the survival times are continuous or ordinal, ii) one group's risk of an event relative to the other does not change with time. When the death event occurs at time t_i then we will consider the total number alive (r_i) and the total number still alive up to the time t_i in a specific group (say group A) r_{Ai}. Consider that d_i is the total number of deaths i.e event at the time t_i. Then the expected number of deaths in group A at time t_i can be calculated as

$$E_{Ai} = \frac{r_{Ai}}{r_i} \times d_i \quad (3)$$

Then the total number of expected deaths for group A can be calculated as:

$$E_A = \sum E_{Ai} \quad (4)$$

The total number of the expected deaths in group B can be calculated based on the total number of expected deaths for group A given that the total number of events is n as follows:

$$E_B = n - E_A \quad (5)$$

In the Log-rank test, the data for the two groups combined are ordered and then each event, in turn, is considered starting at time $t = 0$. Then the log-rank statistics is calculated for two groups based on the summed observed minus expected score for a given group and its variance estimate and it is given as follows:

$$\chi^2 = \frac{(O_A - E_A)^2}{E_A} + \frac{(O_B - E_B)^2}{E_B} \quad (6)$$

Here O_A and O_B represent the total number of events in groups A and B respectively and E_A and E_B represent the total number of expected events in group A and group B respectively. This statistic is compared with χ^2 statistics to decide whether there is a significant difference between the two groups or not using a specific confidence interval or level of significance.

2.5 Cox regression model

The Cox regression model also known as the Cox proportional hazards model (CPHM) is used to investigate the association between the survival time of patients and one or more predictor variables. CPHM is a regression model that has a dependent variable and independent variables and it is used to know the effect of specific

variables on the event. Its formula is written as shown in the following equation:

$$h(t, X) = h_0(t)e^{(\sum_{i=1}^{p} B_i x_i)} \quad (7)$$

where $h_0(t)$ is the baseline hazard, $X's$ here are time-independent, and B_i are the regression coefficients. It is important to note that Kaplan-Meier curves and log-rank tests work with categorical predictor variable and they can describe the survival according to only one factor under investigation. CPHM model can work for quantitative predictor variables as well as categorical predictor variables and it can assess at the same time the effect of several factors on the survival time of patients.

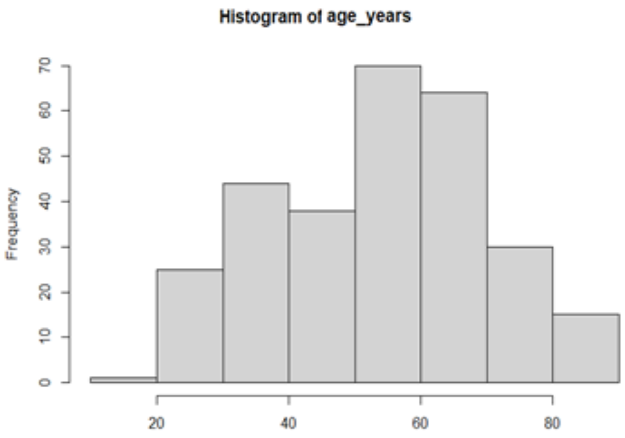

Figure 3: Histogram shows the distribution of age values.

3 Results and discussion

To analyze COVID-19 data, we used survival and survminer functions under R software. In this COVID-19 patients' data, the event of interest is the recovery of the patients and the outcome is time in days until the recovery. We must consider an important analytical problem called censoring, which occurs when we have sick people at risk who have died or the recovery time for them is not known due to losing their follow up, therefore the patients' exact recovery time will not be known at least in the period of the study so the patient survival time is considered censored. In other words, in this study, we will consider censoring if the patient is died or lost follow-up in the determined period given that the period of the study is from Jan 1 to Feb 11, 2020, as shown in the dataset subsection. After extracting the data and preparing it we read it in R software. We consider three predictive variables (patient gender, age, and time to hospitalization). The gender variable is a categorical variable and it can be easily analyzed using Kaplan–Meier survival curve and log-rank since we have two groups male and female. The patient age is a continuous variable, therefore, we need to convert it into categorical to be able to use it as a predictive variable. To do so we need to use a cutoff, where we will consider the age greater than this cutoff as old and the age less than the cutoff as young. To determine the cutoff, we should look at the overall distribution of age values using the histogram shown in Figure 3, where the cutoff of 50 is obviously suggested to be used. Also, we converted time to hospitalization to a categorical variable by considering hospitalization within 6 days as 'Early' and hospitalization in a time greater than 6 days as 'Late'.

Table 1: summary of the Kaplan-Meier estimates for the age groups up to day 16.

time	n. risk	n. event	non-recovery probability	std. err.	Lower. 95% CI	Upper. 95% CI
Old age group						
4	343	1	0.997	0.003	0.991	1.000
5	321	1	0.994	0.004	0.986	1.000

Young age group						
4	270	1	0.996	0.004	0.989	1.000
5	240	1	0.992	0.006	0.981	1.000
6	219	2	0.983	0.008	0.967	1.000
7	207	3	0.969	0.012	0.946	0.992
8	198	2	0.959	0.013	0.933	0.986
9	195	5	0.934	0.017	0.902	0.968
10	185	3	0.919	0.019	0.883	0.957
11	177	4	0.899	0.021	0.858	0.941
12	169	1	0.893	0.022	0.852	0.937
13	167	3	0.877	0.023	0.833	0.924
14	158	1	0.872	0.024	0.826	0.919
15	156	5	0.844	0.026	0.794	0.896
16	148	12	0.775	0.030	0.718	0.837

To analyze the data based on the age group, we created a survival object and we fit the Kaplan-Meier curves by passing the created survival object to survfit function. We obtained the results given in Table 1. Normally, the results obtained from the survfit function are the probability of non-recovery as shown in the 4th column of Table 1 i.e. death or negative event (Table 1 shows the results up to day 16). In this study, we are looking for a positive event (recovery) therefore we can calculate the recovery rate as (1- the probability of non-recovery). The results show that in the old age group over the four days period 1 recovered out of 343, therefore, the probability of non-recovery is (343-1)/343=0.997 (see Table 1 the first row) so the recovery rate is (1- 0.997) =0.003. Over the five days period as shown in the table (see Table 1 the second row), 21 patients of the remaining 342 patients lost follow-up (censored) so the number of remaining patients on the 5th day is 321. One of the remaining patients is recovered in the 5th day therefore, the proportion not recovered is 0.994. We could calculate the survival at a specific time t as the product of the observed survival rates until t i.e $S(t) = p.1 * p.2 * .... * p.t$, where $p.1$ is the rate of the surviving patients who past the first time point and $p.2$ is the rate of the surviving patients who past the second time point, and so forth.

It is very important to take into account that starting from $p.2$ we should consider only those patients who survived past the previous time point to calculate the survival rate for the following time point, in other words, $p.2$, $p.3\ldots$, $p.t$ are survival rates that are conditional on the previous survival rates. Given the assumption of independent and random censoring, we assume that the 21 patients who were censored were similar to the 321 who remain at risk regarding their survival experience. Since 1 of the 321 who remained and survived on the 5th day recovered and we have 1 recovered on the 4th day then the total number of patients who recovered on the course of 5 days is 2. Subtracting 2 from the original number, which is 343 will yield 341. Then the recovery rate in the 5th day will be (1-341/343) = 0.006. The same analysis for the old age group is applied to the young age group (the results up to day 16 out of 30 days are shown in Table 1). The lower 95% confidence interval and upper 95% confidence interval tell us how accurate the estimate of the mean is [33]. In the first row in Table 1 the lower 95%CI and the upper 95%CI show us that we are 95% confident that the interval (0.991, 1.000) contains the true value of the parameter. Also, we can see that this interval is very narrow, which means that the certainty of the results is very high. In other words, we are 95% certain about the results. This narrow interval is associated with a very small standard error (0.003).

The corresponding survival curve can be obtained using the function ggsurvplot on the survival object. The obtained curves (see Figure 4) are step functions that allow us to compare the survival time of two age groups. Typically, the curve starts at 1 representing the fact that all of the patients are not having the event at entry into the study (see Figure 4 A). Over time the curve represents the probability of remaining non-recovered patients. Since we are interested in the probability of the recovered patients, we drew the survival curve starting from 0 to represent the portion of the recovered patients as shown in Figure 4 B. It is clear from Figure 4 B that the survival function of the young age group consistently lies above that for the old age group. This indicates that the young age group is better in recovering from COVID-19 than the old age group. We note that the two functions are somewhat close to each other in the first few days. This indicates that the young age group can survive COVID-19 later after infection than its early one. The estimate of the median recovery time for the young age group can be obtained from Figure 4 by selecting the value in the time axis that corresponds to the survival probability of 0.5. From the figure, it is clear that the median recovery time is greater than 20 days. The p-value of the log-rank is 0.00012, which indicates that the results are significant considering $p < 0.05$ indicates statistical significance, in other words the results show that there is a significant difference between young and old patients regarding the recovery from COVID-19.

To analyze the data based on the gender (Male, Female), we directly created a survival object since we don't need to convert the gender of the patient to a categorical variable (it is already a categorical variable). Then we fit the Kaplan-Meier curves by passing the created survival object to survfit function. We obtained the results given in Table 2 (we showed the results for the first 15 days). The results show that in the Female group over the four days period 1 recovered out of 295 therefore the probability of non-recovery is 294/295=0.997 (see the first row). Then the recovery rate in the 4th day will be (1-0.997) = 0.003. The rest of the Female group results and the male group results can be described as we did with the age group results that are given in Table 1.

Table 2: summary of the Kaplan-Meier estimates for the sex groups up to day 15.

time	n. risk	n. event	non-recovery probability	std. err.	Lower. 95% CI	Upper. 95% CI
Female group						
4	295	1	0.997	0.003	0.990	1.000
5	261	3	0.985	0.007	0.971	1.000
6	234	1	0.981	0.008	0.964	0.998
7	216	4	0.963	0.012	0.939	0.987
8	210	1	0.958	0.013	0.933	0.984

10	193	3	0.920	0.018	0.885	0.956
11	184	5	0.895	0.021	0.855	0.937
13	169	2	0.884	0.022	0.842	0.928
15	160	1	0.879	0.022	0.836	0.924
Male group						
4	346	2	0.994	0.004	0.986	1.000
5	325	1	0.991	0.005	0.981	1.000
6	310	3	0.982	0.007	0.967	0.996
7	293	4	0.968	0.010	0.949	0.988
8	283	1	0.965	0.010	0.944	0.985
9	275	2	0.958	0.012	0.935	0.981
10	262	1	0.954	0.012	0.931	0.978
11	252	4	0.939	0.014	0.912	0.967
12	240	1	0.935	0.014	0.907	0.964
13	233	4	0.919	0.016	0.888	0.952
14	220	4	0.902	0.018	0.868	0.938
15	210	8	0.868	0.021	0.828	0.910

The corresponding survival curve for the sex is shown in Figure 5, where the step functions allow us to compare the survival time of two sex groups. Figure 5 A is the probability of remaining unrecovered patients based on gender. The survival function of the Female group and that for the male group from the time 0 up to 40 follow similar paths, therefore the p-value (0.63) from the log-rank test is not significant considering $p < 0.05$ indicates statistical significance. Figure 5 B shows the survival curves starting from 0 and they represent the proportion of the recovered patients based on sex.

We used Cox regression model to measure the effect of the different factors on the recovery from COVID-9. in Cox regression the measure of the effect is hazard rate. The hazard is the instantaneous event rate or the probability of a patient at time t has an event at that time. Here the assumption is non-recovery if the event does not occur up to time t [23, 34]. Hazard ratio of 1 means that event rates are the same in the members of the same group. Figure 7 shows that at any time 1.9 as many patients in the young age group are having an event (recovery) proportionally to the old age group, which is taken as a reference, and the value 0.001** shows that this result is statistically significant. The result of the hazard ratios supports the results that we obtained in the step functions that are depicted in Figure 4 B. Regarding the sex group, the results in the figure shows that the hazard ratio is 1 which indicate that three is no difference between male patients and female patients in recovery from

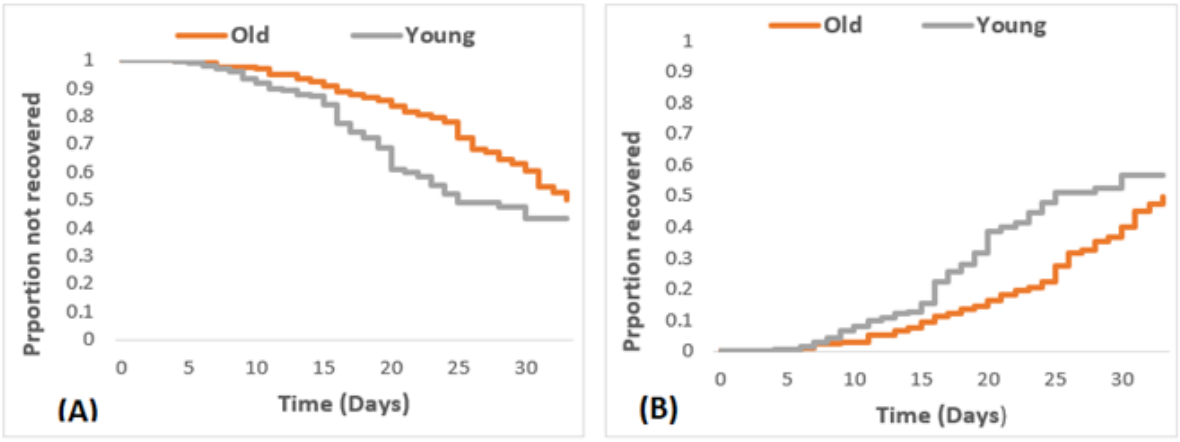

Figure 4: Survival curves for days to recovery from COVID-19 (age groups). A) Proportion not recovered; B) Proportion recovered.

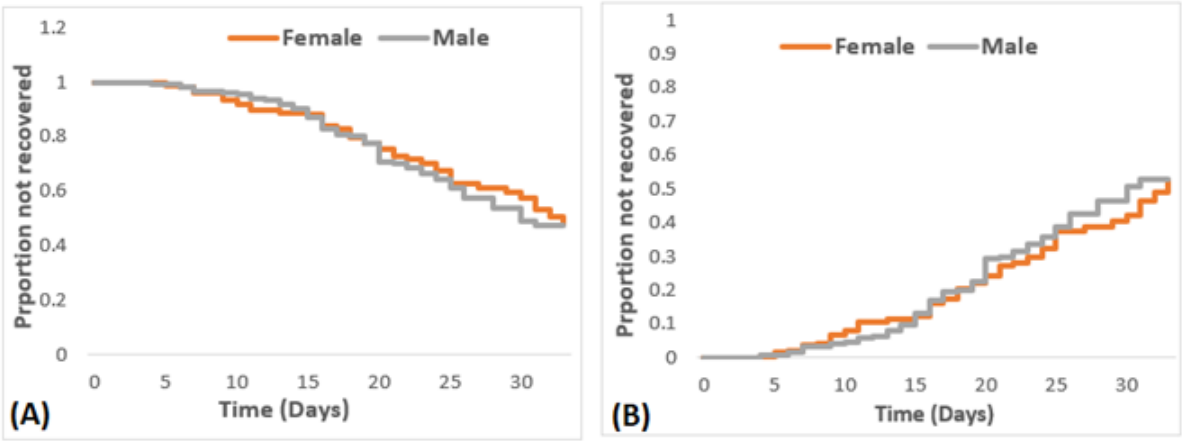

Figure 5: Survival curves for days to recovery from COVID-19 (sex groups). A) Proportion not recovered; B) Proportion recovered.

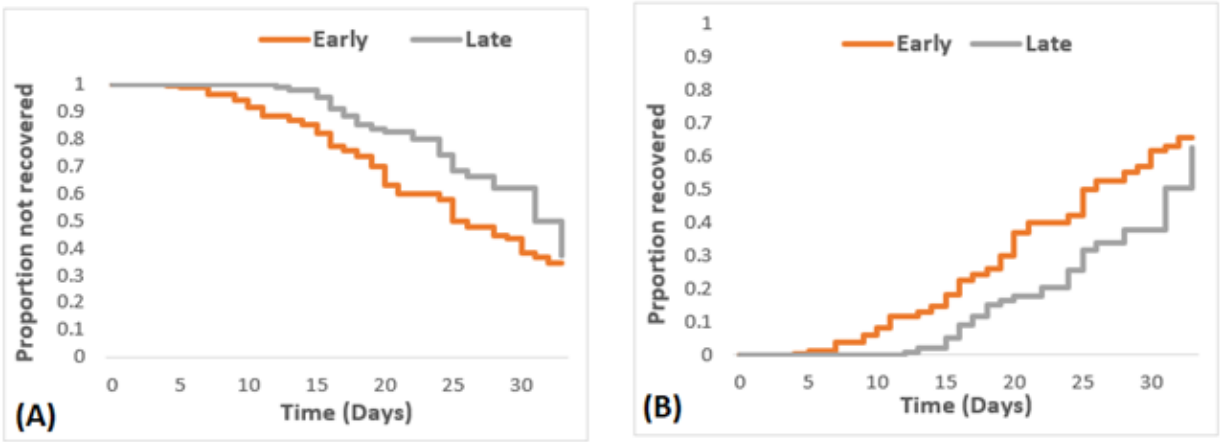

Figure 6: Survival curves for days to recovery from COVID-19 (time to hospitalization groups). A) Proportion not recovered; B) Proportion recovered.

COVID-19. This result supports the results that we obtained in the step functions. We note that the P-value is quite different from what is shown with the Kaplan-Meier estimator and the log-rank test that is because the hazard ratio calculates the hazard ratio and respective risk of death whereas Kaplan-Meier estimator and the log-rank test estimate the survival probability [35]. Therefore, we can see that the results yielded by these different methods are different in terms of significance.

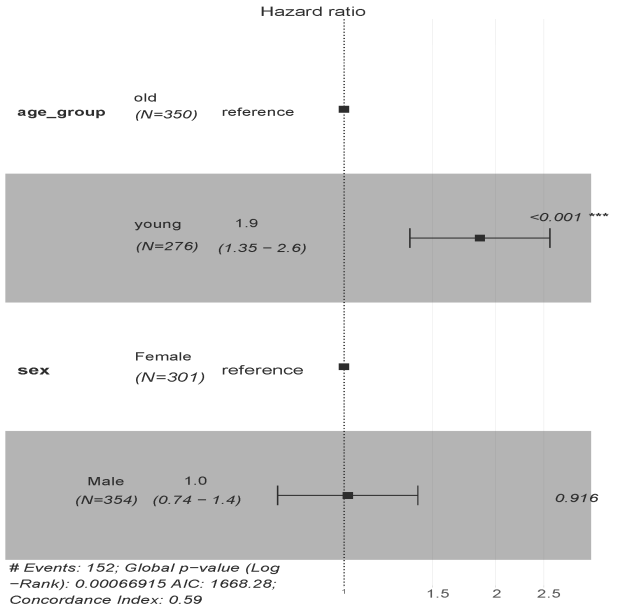

Figure 7: Forest plot shows the hazard ratios of the age and sex groups.

Also, we analyzed the data based on the time to hospitalization (early, late), we considered time to hospitalization as early if the patient is hospitalized within 6 days from catching the disease and as late if is hospitalized in a time greater than 6 days from catching the disease. Since not all the COVID-19 patients are hospitalized, we deleted the cases that have no hospitalization date. We then created a survival object and fit the Kaplan-Meier curves by passing the created survival object to survfit function. We obtained the results given in Table 3, which shows the results for the first 20 days. The results show that in the early time to hospitalization group over the four days period 1 recovered out of 159, therefore, the proportion not recovered rate is 158/159=0.994 (see Table 3 the first row), and therefore the proportion recovered rate is 1-0.994=0.006. In the late hospitalization group, the results show that over 12 days 1 recovered out of 103 so the proportion not recovered is 102/103=0.990 and hence the proportion recovered rate is 1-0.990=0.010. We note that in the early to hospitalization group the recovery starts at day 4, while in the late to hospitalization group the recovery starts at day 12.

The survival curve of the time to hospitalization groups is shown in Figure 6. It is clear from Figure 6 B that the survival function of the early time to hospitalization group consistently lies above that for the late time to hospitalization group. This indicates that the early time to hospitalization group is better recovering from COVID-19 than the late time to hospitalization group. Also, we note that the two functions are somewhat close to each other in the first few days (up to day 4). This indicates that the early time to hospitalization group can survive COVID-19 later after 4 days from infection than its early one. The p-value of the log-rank is 0.0052, which indicates that the results are significant considering $p < 0.05$ indicates statistical significance, in other words, the results show that there is a significant difference between the early time to hospitalization group and late time to hospitalization group.

Table 3: summary of the Kaplan-Meier estimates for the time to hospitalization groups.

time	n. risk	n. event	non-recovery probability	std. err.	Lower. 95% CI	Upper. 95% CI
Early time to hospitalization group						
4	159	1	0.994	0.006	0.981	1.000
5	157	1	0.987	0.009	0.970	1.000
7	147	4	0.961	0.016	0.930	0.992

19	77	4	0.698	0.042	0.620	0.786
20	70	7	0.629	0.046	0.545	0.724
Late time to hospitalization group						
12	103	1	0.990	0.010	0.010	0.972
13	100	1	0.980	0.020	0.014	0.954
15	96	3	0.950	0.050	0.022	0.908
16	89	4	0.907	0.093	0.030	0.851
17	82	2	0.885	0.115	0.033	0.823
18	74	3	0.849	0.151	0.037	0.779
19	68	1	0.837	0.163	0.039	0.764
20	63	1	0.823	0.177	0.040	0.748

Cox regression model for time to hospitalization yielded the hazard ratio, which represents relative that compares the early time to hospitalization group with the late time to hospitalization group as shown in Figure 8. A hazard ratio of 0.54 for the late hospitalization group tells us that patients who sent to hospital late have less opportunity of recovering compared to patients who sent to the hospital early, which served as a reference to calculate the hazard ratio. As shown by the forest plot, the respective 95% confidence interval is (0.35 – 0.84) and this result is significant (p-value=0.006). Using this model, we can see that the time to hospitalization variable significantly influences the patients' recovery from COVID-19. Also, We note that the obtained p-value is quite different from what is shown with the Kaplan-Meier estimator and the log-rank test and that is due to the same justification that we presented when analyzing the sex and age groups.

Salinas-Escudero et al. study [24], which applied Kaplan-Meier and Cox regression models to the Mexican found that the age factor has a significant effect in recovering from COVID-19. This finding agrees with our finding on the data we used. In another hand, their

study found that sex group has significant effects, which disagrees with our finding. Monira Mollazehi et al study [25] applied Weibull model in Singapore. The factors they used are age and nationality. Their finding agrees with ours regarding the age group.

The limitations that need to be declared in this research are: First, the dataset is for a specific region and in a specific period. Second, the dataset is relatively small compared to the total infected cases.

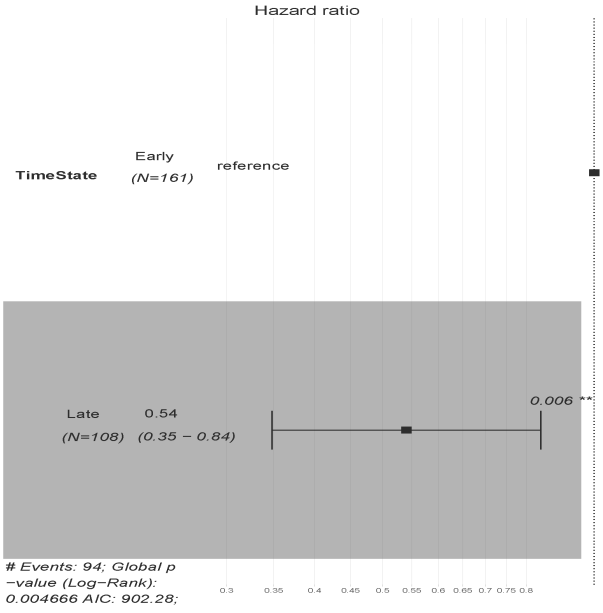

Figure 8: Forest plot shows the hazard ratios of time to hospitalization group.

4 Conclusion

In this work, we used survival analysis to analyze COVID-19 data that we obtained from the clinically diagnosed and confirmed cases where the date of onset is recorded in Wuhan and elsewhere in China from Jan 1 to Feb 11, 2020. We used the Kaplan-Meier method which is an estimator of survival probabilities and the Cox regression model, which is known as the Proportional Hazard Model for the analysis. The event of interest in our analysis is the recovery of the patients from COVID-19 and the outcome is time in days until the recovery. The predictor variables that we used are sex, age, and time to hospitalization. The results show that the young age group is better in recovering from COVID-19 than the old age group with a significant difference (P-value = 0.00012) and at any time 1.9 as many patients in the young age group is having an event (recovery) proportionally to the old age group. The step functions of the sex group show that the female and male groups are somewhat close to each other in recovering from COVID-19 and the p-value =0.63 indicates that there is a non-significant difference in the results between Male and Female considering $p < 0.05$ indicates statistical significance. The results also show that early time to hospitalization group can recover from COVID-19 better than late time to hospitalization group (the p-value of the log-rank is 0.0052)

Conflict of Interest The authors declare no conflict of interest.

Acknowledgment The authors would like to acknowledge the Jouf University for all the support that it provides.

ABSTRACT

Day to day huge medical data have been accumulating for diabetic diseases. The complexity of storing, processing ,analyzing and predicting the data related to diabetics is not so easy for healthcare professionals .The prediction of accurate results also has the limitation due to scale of data increasing worldwide for patients, symptoms and test results .In this paper ,it has been tried to considered the diabetic related data storage on cloud and adopt integrated computational algorithms of datamining for better prediction system to various diabetic types(Type 1, Type 2 and Gestational).Though many computational prediction model and recommended system have been proposed by many researchers ,the proposed model has the novelty of considering the elasticity in data analysis due to frequent data changes of patients due to diabetic test time to time. In this work, Elasticity based Med-Cloud Recommendation System (EMCRS) is proposed for predicting the diabetic disease types and providing recommendations for the patients diagnosed with diabetes. Moreover, elastic resource allocation mechanism is proposed to provide cloud resources an on-demand basis to EMCRS.Various computational algorithms have been used for different proposed to make EMCRS to predict results as compared other existing system. The Adaptively Toggle Genetic Algorithm (ATGA) is applied for elastic resource allocation while increase in the number of data sets. ATGA has taken toggle genetic algorithm that shifts between Roulette Wheel Selection Operator. Hybrid Classification and Clustering Algorithm (HC2A) is used for classifying and clustering the diseased patients as Type 1, Type 2 and Gestational Diabetic patients. Fuzzy C Means clustering based attribute weighting (FCMAW) was used for classifying the diabetic data set. The accuracy of the system tested on Pima Indian Diabetic Dataset (PID) and US Diabetic Dataset (USD) from UCI website which is approximately 98% classification accuracy.

1. Introduction

Diabetes is a chronic disease that begins with the failure of pancreas. The pancreas fails to produce sufficient insulin required by the body [1]. The internal changes prompt to an increased concentration of glucose in the blood. It is a condition of high blood glucose level in diabetic patients. It can cause either Type I or Type II diabetes. Type I is known as insulin dependent diabetes, which occurs when there is lack of insulin production. Type II diabetes is non-insulin dependent which is caused by the ineffective use of insulin by human body. This will result in excess body weight and physical inactivity. An earlier prediction or recommendation system is needed to save the patients from the risk of diabetes. In such a condition, Data Mining is suggested and found to be a better diagnostic tool which can be used by the medical practioners too.

Data Mining is the process of selecting, exploring and modeling large amounts of data [2], [3]. This process has become an increasingly pervasive activity in all areas of medical science research. Data mining has resulted in the discovery of useful hidden patterns from massive databases. Consequently, data mining tools are now being used for clinical data. The bottle neck in data analysis is now raising the most appropriate clinical questions and using proper data and analysis techniques to obtain

*Corresponding Author: Manas Ranjan Pradhan, School of IT, Skyline University College, Sharjah, UAE, manas.pradhan@skylineuniversity.ac.ae

clinically relevant answers [4]. But as the accumulated data is increasing abundantly, Data Mining algorithm alone is not enough to retrieve hidden pattern from the data.

In order to improve the existing algorithm performance, the computing and storage resources are insufficient in traditional data mining environment. In order to overcome the resource challenges, now day's resources are utilized on-demand elastic manner with the development of Cloud Computing [5]. National Institute of Standards and Technology (NIST) defines [6] "Cloud Computing is a model for enabling convenient, on-demand network access to a shared pool of configurable computing resources (eg., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction".

The main features of cloud computing are on-demand self-service, broad network access, resource pooling, rapid elasticity and measured service. Cloud computing has three service models such as Infrastructure as a Service (IaaS), Platform as a Service (PaaS) and Software as a Service (SaaS). It also has four deployment models such as public cloud, private cloud, hybrid cloud and community cloud. Elasticity is used to utilizing the cloud computing resources (Storage, Virtual machines, Servers, Platforms, network) in an elastic way based on the workload requirement. Elasticity manages the ability to increase or decrease the cloud system resources. Elasticity is defined by NIST [7], "Rapid elasticity: Capabilities can be elastically provisioned and released, in some cases automatically, to scale rapidly outward and inward commensurate with demand. To the consumer, the capabilities available for provisioning often appear to be unlimited and can be appropriated in any quantity at any time."

Elastic resource allocation is completed with the help of proper workload prediction and scheduling which are used to improve the performance of the cloud system. There are no existing algorithms that focus on workload prediction with elasticity in cloud computing environment [8]-[10].

In this research work, an Elastic Medical Cloud Recommendation System is proposed for diabetic classification, where Adaptively Toggle Genetic Algorithm is applied for the Elastic Resource Allocation. HC2A is involved to classify the diabetes patients and in case of diseased patients, they are clustered into three types and the recommendation system is suggested based on the cluster.

The remaining work of the paper is formed as follows. Related works are presented in section 2. In section 3, the proposed algorithm is explained. Results and discussions are presented in section 4. Section 5 shows the conclusion and future directions of the work.

2. Related Works

One of the important feature in cloud computing is elasticity which provides resources in an on-demand elastic manner for cloud users and providers. In [11]the authors concentrated energy consumption in cloud computing resources with the support of elasticity. In [12] the authors designed a CBIHCS (Cloud Based Intelligent Health Care Service) for supervising user health data for diabetic detection and proposed simple heuristic for dynamic resource elasticity.

Resource scaling methods are explained by in [13] based on the queuing models. It contains database level, application level and storage level. Each levels were analyzed with the parameters such as throughput, resource utilization rate and response time. Based on the results to scale applications in cloud environment, they recommended the elastic cloud resource allocation algorithm. In [14] authors proposed an improvised genetic approach for effective cloud resource allocation by maintaining vertical elasticity in cloud IaaS environment. They concentrated on vertical elasticity which focuses virtual machines allocation on cloud servers based on the workloads to improve resource allocation. The Enhanced Genetic algorithm concentrated only on cloud IaaS environment.

In [15], the scaling techniques of elastic resource management were classified as reactive or predictive imminent. Based on the workload requirements the system react without pre-planning in reactive imminent. In predictive imminent, the workload predicts the requirement of cloud servers that are allocated to handle the workload. In [16] it is proposed a cloud based framework with minimum resource setting for monitoring and diagnosis the PD (Parkinson's Disease). The framework used cloud database, voice data and FBANN (Feedforward Backpropagation based Artificial Neural Network) classifier in cloud platform.

The role played by evolutionary algorithms and Clustering algorithms in Medical Data Mining is incredible. K means algorithm was used in [17] to remove noisy data and Genetic Algorithm was applied to find the optimal set of features. Finally Support Vector Machine (SVM) was used for classifying the diabetic patients. The proposed method has obtained an accuracy of about 96.71%. Fuzzy C Means Algorithm (FCM) [18] was used to determine the small clusters in Diabetic data set and Outlier detection method was applied for classification. The accuracy was 93%. Attribute Weighting method [19] called Fuzzy C Means clustering based attribute weighting (FCMAW) was used for classifying the diabetic data set. This method reduced the variance within the attributes and improves the classification accuracy. It was done by transforming the non-linear separable datasets to linearly separable datasets. FCM was applied to find the center of the attributes and the dataset is weighted according to the ratios of the means of attributes to centers of theirs attributes. Then SVM and KNN classifiers were applied to classify the dataset. The accuracy of the method was 84.38%.

3. Proposed Work

3.1. The system design

In order to get maximum benefit from cloud computing, Cloud providers designed the architecture and deployment model. Various cloud architectures are designed by different cloud service providers. The conceptual diagram of cloud architecture is shown in Figure 1. Cloud service providers provide services to cloud users through internet and datacenter. Cloud servers contains memory utilization vector, processing unit and storage. Virtualization in cloud is to run multiple VMs on a single server and sharing these cloud resources among multiple cloud users. Based on the workloads, the VMs are allocated to process the data as per the command of elastic resource manager.

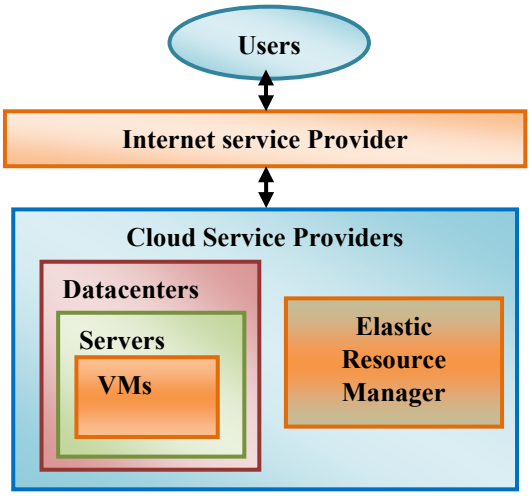

Figure 1: Conceptual diagram of Cloud Computing Architecture

In this work, the task of the ERM (Elastic Resource Manager) has been concentrated with the goal of elastic resource allocation for improving the resource utilization. ERM is responsible for VMs scheduling, Monitoring VMs and Workloads. Figure 2 explains the proposed framework of EMCRS and Figure 3 explains the flows of the proposed EMCRS for diabetic disease prediction.

3.2. The Elastic Resource Manager

The Elastic Load Manager task is to generate the schedule for the allotment of VM to the available cloud servers with the objective to improve the resource utilization. VM handler is responsible for handling VM queue which contains the user requests information. The scheduling algorithm brings the user request from VM queue and assigns it to the scheduler.

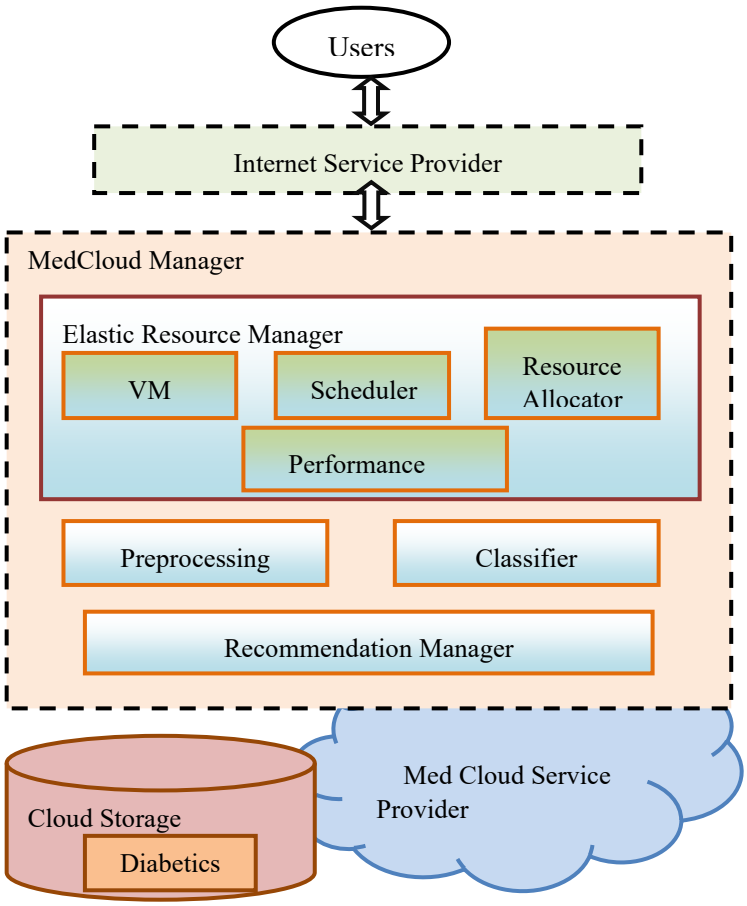

Figure 2: Framework for Elasticity based Med-Cloud Recommendation System

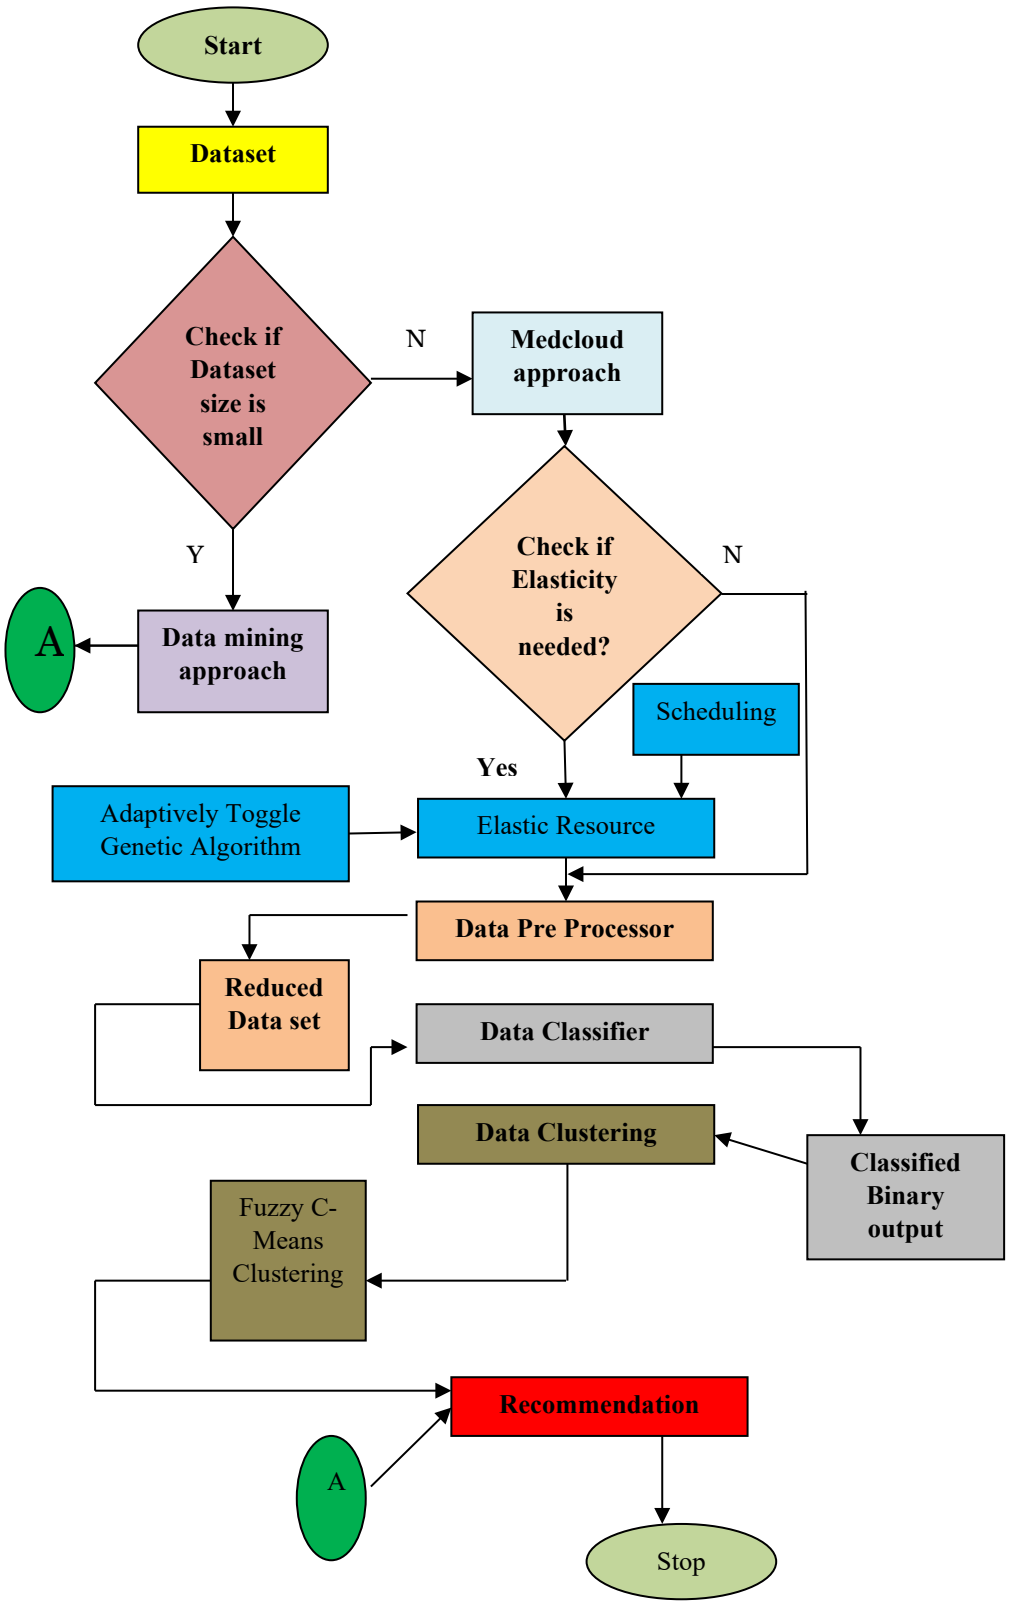

Figure 3: The EMCRS for predicting Diabetes

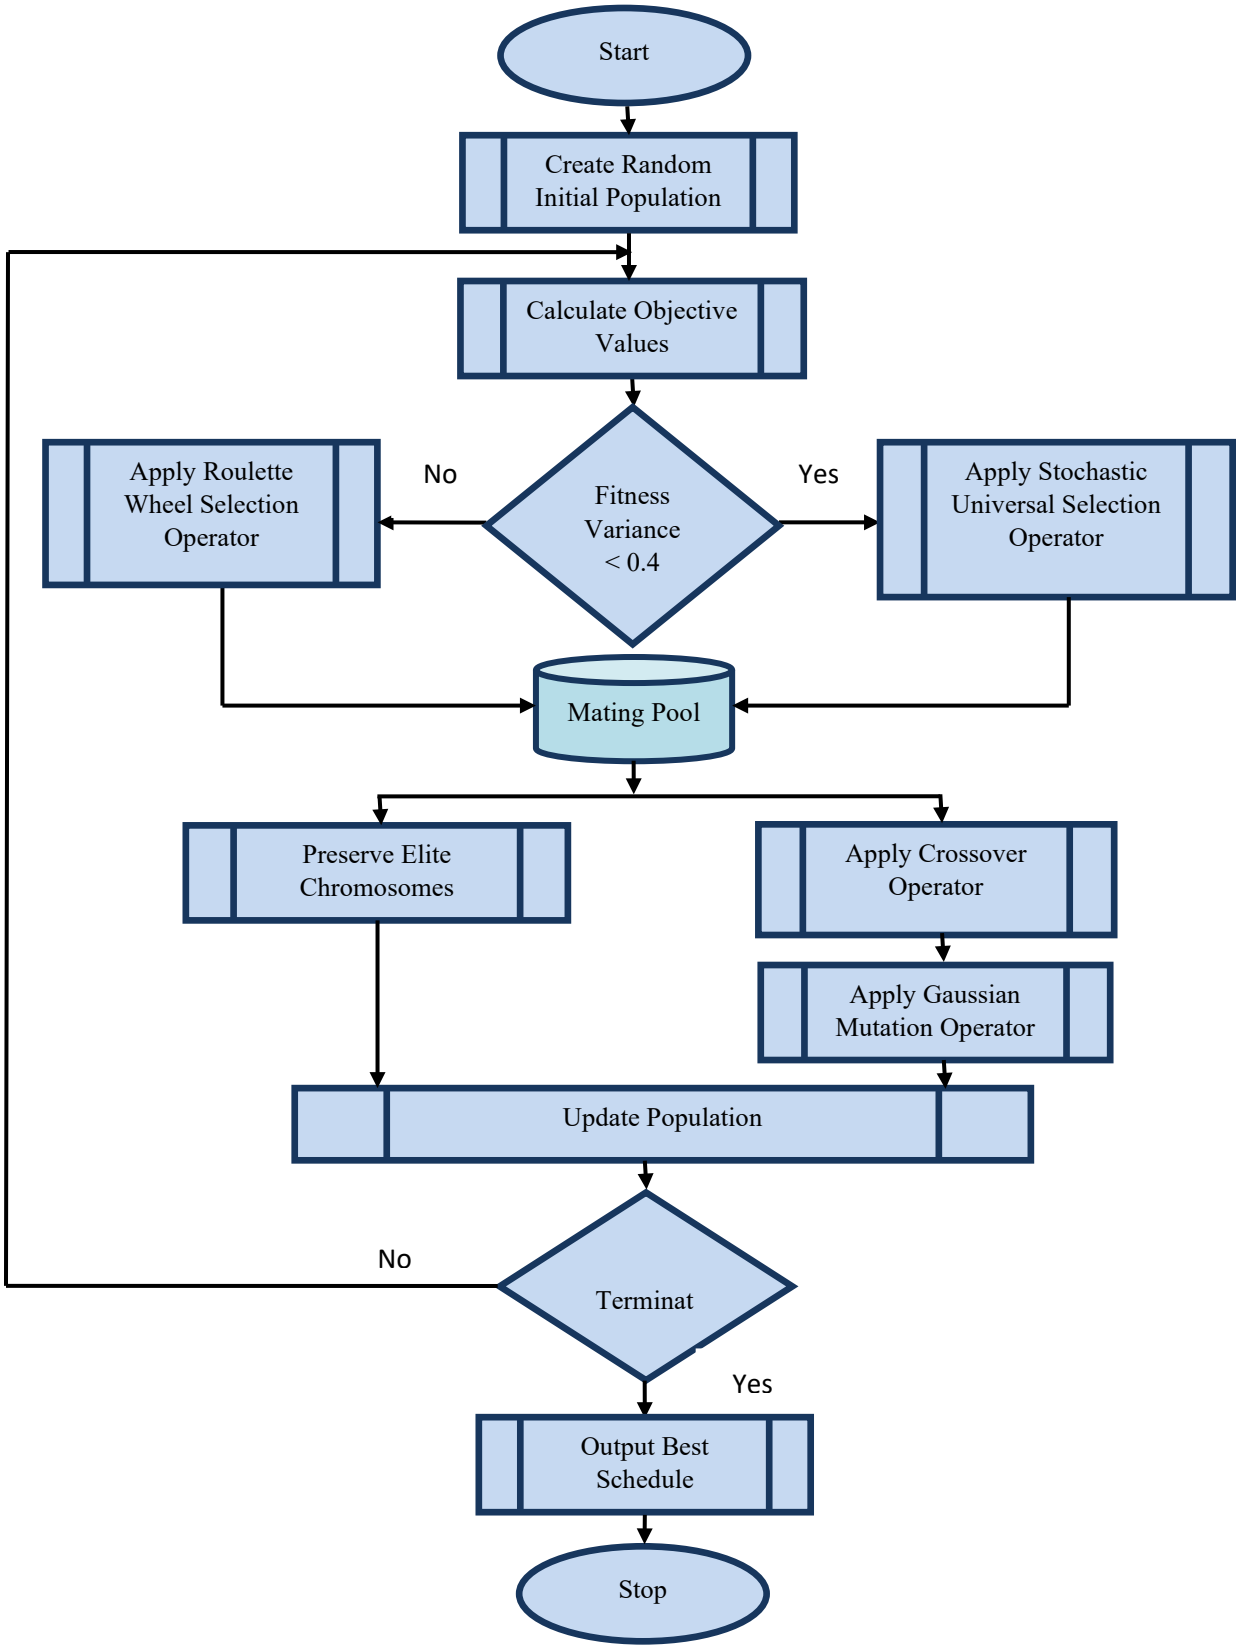

Figure 4: The flow of Adoptively Toggle Genetic Algorithm

3.3. Pseudocode of ATGA (Adaptively Toggle Genetic Algorithm)

Step 1: Begin

Step 2: Generate initial population with randomly generated chromosomes

Step 3: Calculate the objective Values for each chromosome in the current population

Step 4: Observe the fitness distribution of current population based on the fitness variance

Step 5: If the fitness variance is below 0.4

Step 6: Apply the Stochastic Universal Sampling Selection operator

Step 7: Else

Step 8: Apply the Roulette Wheel Selection operator

Step 9: End If

Step 10: Store the parent chromosomes in mating pool

Step 11: Store the best chromosomes from the current population as elite chromosomes

Step 12: Apply the crossover operator for generating offspring chromosomes

Step 13: Apply the Gaussian mutation operator to adaptively mutate genes

Step 14: Update the current population with the offspring chromosomes

Step 15: If termination condition is not reached

Step 16: Go to Step 3

Step 17: Else

Step 18: Output Best Chromosome

Step 19: End If

Step 20: End

3.3.1. Flow chart Adaptively Toggle Genetic Algorithm

The flow chart of adaptively toggle genetic algorithm is presented in figure 4.

3.3.2. Working Principle of Adaptively Toggle Genetic Algorithm

Even though it is a successful tool, many phenomena can affect the performance of Genetic Algorithm and such an important factor is the parameter settings of Genetic Algorithm. Most of the existing research works related to Genetic Algorithm were carried out with static parameter settings. But, inherently the Genetic Algorithm supports self-learning, parallelism and dynamism. Hence, this research work got the insight to improve the Genetic Algorithm by utilizing the adaptive nature of genetic operators. The core idea behind the development of the proposed Adaptively Toggle Genetic (ATG) algorithm is that to intelligently manipulate the selector operator and to adaptively control the mutation operator in order to enhance the performance of the algorithm. So, the two key operations of the proposed ATG algorithm are as follows.

- Toggle the selection operator
- Adaptively change the mutation probability

3.3.2.1. Toggle the selection operator

As selection operator is one of the crucial operators for the convergence of the Genetic Algorithm, the selector operator must be careful chosen and designed in order to make the best individuals to be survived in the successive generations. Various selection operators are already available, but the before applying the selection operators, the characteristics and suitability of them must be analyzed. In this research work, two selection operators are taken namely, roulette wheel selection and stochastic universal sampling selection operators. Though roulette wheel selection operator is the most commonly used selection operator in Genetic Algorithm, it fails when the fitness values of chromosomes in the population are highly scattered. This is due to the state that the high portion of the roulette wheel is assigned to the fittest chromosome where all the other chromosomes only obtain least sectors of the wheel. Therefore, the roulette wheel may provide biased output and it may lead to the premature convergence state. Hence, the proposed ATG algorithm calculates the fitness variance of the population at first and then it determines which selection operator to use at the current iteration of the algorithm. If the fitness variance is high the stochastic universal sampling selection is used, otherwise the roulette wheel selection is used. In this way, the proposed ATG algorithm intelligently toggles between the two selection operators and helps to conquer the premature convergence problem.

3.3.2.2. Adaptively change the mutation probability

The main task of the mutation operator is to provide exploitation in the search space. Further, it can also help to promote the gene diversity in the gene population. But, when the value of mutation probability is set as a constant, it may disturb the solutions in the global convergence state. Thus, the mutation probability value must be changed according to the convergence state of the algorithm. Hence, the mutation probability value in the proposed ATG algorithm is calculated based on the Gaussian curve as a function of the current iteration. In this way, the proposed ATG algorithm can escape from the local optima by adaptively changing the mutation probability value.

Therefore, the two frequent problems associated with Genetic Algorithm namely the local optimum and premature convergence are eliminated by the proposed ATG algorithm through the dynamic switching between selection operators and adaptive control of mutation operator with additional benefits. With help of ATG algorithm, the scheduler optimally allocates the virtual machines for processing the user requests. The user queries are processed for performing the classification task using the proposed HC2A algorithm.

3.4. Proposed Algorithm for Classification

The HC2A is proposed to classify the diabetic patient data set. The Framework works in three phases as Pre-Processing Phase, Classification Phase and Clustering Phase. Figure 5 explains the

flow of the proposed HC2A, In the Pre-Processing Phase, the Genetic-Relative Reduct (G-RR) Algorithm is applied to remove the noisy data and eliminate the irrelevant data. The output at this phase will be the reduced data set. The attributes are classified as Conditional and Decision Attributes. At the initial state the variable R is initialized to null value. And the variable γ_{best} is assigned to 0. The γ_{best} value is stored temporarily in another variable γ_{tmp} and R is stored in T.

The consistency of the data set is checked after removing every attributes. If the decision table is consistent, the attributes is removed and the reduced data set is stored. If the classification accuracy of the Conditional Attributes obtained is greater than the classification accuracy of the Decision attributes ($\gamma_{RU(X)}$ (C)>γ_X(D)), then the first Generation of Offspring is constructed. The obtained attributes are selected and then mutation and crossover operations taken place.

Input: Diabetic Data Set

Step 1 Start

Step 2 Load Diabetic dataset

Step 3 Initialize the parameters (R,))

Step 4 Call Genetic – Relative Reduct Algorithm

Step 5 Check for Reduced Data set

Step 6 **If** *the data set is reduced*

Go to Step 7

else

Go to step 3

Step 7 Initialize the attributes

Step 8 Apply Modified Particle Swarm Optimization – Neural Network Algorithm

Step 9 Check for maximum number of epoch

Step 10 Calculate error and accuracy

Step 11 **If** *the error is minimized*

Go to Step 12

else

Go to step 7

Step 12 Apply Fuzzy C Means Clustering Algorithm

Step 13 Check if the output is clustered and ready to suggest the recommendation system

Step 14 **If** *the clustered output is ready*

Go to step 15

Else

Go to step 12

Step 15 Stop

Output: Clustered output for the recommendation system

The obtained Reduct set is stored in T. The Decision Attributes which are best are stored in the variable γ_{best} . The obtained reduced set is stored in R. The process goes on repeating until the optimal data set is obtained. The obtained output is Reduct Set R. After obtaining the optimal data set, the algorithm terminates.

Step 1: Start

Step 2: R= ϕ

Step 3: γ_{best} = 0

Step 4: **do**

Step 5: $\gamma_{tmp} = \gamma_{best}$

Step 6: T=R

Step 7: **for** x in (C-R)

Step 8: ***If*** $\gamma_{RU(X)}$ (C)>γ_X(D)

Step 9: Construct the First Generation

Step 10: Selection

Step 11: Crossover

Step 12: Mutation

Step 13: T=RU{X}

Step 14: $\gamma_{best} = \gamma_c$(D)

Step 15: R=T

Step 16: *Until* $\gamma_{best} == \gamma_{tmp}$

Step 17: Return R

Step 18: **end**

The next phase is classification phase. In this phase, Modified Particle Swarm Optimization – Neural Network (MPSO-NN) Algorithm is employed to classify the dataset. This phase optimizes the reduced data set and classifies it.

Step 1: Initialize the population

Step 2: Evaluate the fitness of the attribute

Step 3: For each attribute, find the maximum fitness and compare it with the best found so far

Step 4: $Pbest_i$ is equal to the location of maximum fitness function

Step 5: Compare Fitness evaluation with population overall Pbest

Step 6: **If** particle best is greater than gbest, then reset gbest(i) is equal to the current Pbest's array index and value

Step 7: Calculate Convergence factor

Step 8: Calculate Inertia weight

Step 9: Update velocity and position and new population is generated

Step 10: Adjust acceleration

Step 11: **If** the data set is optimized

Go to Step 12

else Go to Step 2.

Step 12: Choose the initial weight

Step 13: **If** the error is minimum

Go to step 21

else

Go to Step 14

Step 14: Apply the optimized dataset to the network

Step 15:Calculate output for every neuron through hidden layer(s) to output layer

Step 16: Calculate Error value at the output layer

Step 17: Update the weight and bias at the output layer

Step 18: Calculate the Error value at the hidden layer

Step 19: Update the weight and bias at the hidden layer

Step 20: Check if the maximum number of epochs reaches

If yes

Go to Step 21

else

Go to Step 14

Step 21 Evaluate the network performance

Step 22: Classified output

At the preliminary stage, the population is initialized and the fitness of the population is calculated. The maximum fitness of each particles is compared with the best found so far as given in (1).

$$p_{best,i} = \begin{cases} P_{best,i} \; if \; f(x_i) > P_{best,i} \\ x_i \; if \; f(x_i) \le P_{best,i} \end{cases} \quad (1)$$

The P_{besti} obtained will be equal to the location of the maximum fitness function. The fitness evaluation is then compared with the population's overall best as in (2).

$$G_{best} = \{\min \{ P_{best,i} \} \quad (2)$$

$$i \in [1, ..., n] \text{ where } n > 1$$

The convergence factor is calculated as

$$\lambda = \frac{2}{\left\| 2 - C - \sqrt{C^2 - 4C} \right\|} \quad (3)$$

where C=C1-C2

C1 is the cognitive learning parameter and C2 is the social collaboration parameter. The C1 and C2 always lie between 0 and 2. Then the inertia value is calculated as given in (4). The inertia value provides the balance between the exploration and exploitation. Generally, the inertia value lies between 0.8 and 1.2. Lower value of inertia component speeds up the convergence of swarm to optima. Higher values encourage the exploration of entire search space.

$$\omega_{id} = \omega_{\max} - \frac{\omega_{\max} - \omega_{\min}}{iter_{\max}} \quad (4)$$

The velocity and position of the particle is updated using the (5).

$$V_{id} = \lambda(\omega_{id} V_{id} + c_1 r_1 (p_{id} - x_{id}) + c_2 r_2 (p_{gd} - x_{id}) \quad (5)$$
$$x_{id} = x_{id} + V_{id}$$

V_{id} is the momentum of the particle and r1, r2 is random numbers (0, 1). The acceleration of the particle is adjusted as

$$V_{id} = \begin{cases} V_{\max} \; if \; V_i > V_{\max} \\ -V_{\max} \; if \; V_i < V_{\max} \end{cases} \quad (6)$$

After the reduced data set is optimized, then the optimized data set is fed as input to Multi-Layer Perceptron Network. Back propagation learning is used to train the network. The output for very neuron is calculated in the hidden unit and output unit. It is calculated as

$$Z_{inj} = V_{oj} + \sum_{i=1}^{n} x_i v_{ij}$$
$$Z_j = f(Z_{inj}) \quad (7)$$

$$where \; f(Z_{inj}) = \frac{1}{1 + e^{-\lambda Zinj}}$$

The sigmoid activation function is applied in every layer. The number of neurons in the hidden layer is fixed by

$$N_h = \sqrt{N_i N_o} \quad (8)$$

where N_h is the number of hidden neurons in the hidden layer. N_i and N_o represent the number of neurons in the input layer and output layer. The error at the output layer is calculated using (9) and the weight and bias are updated using (10).

$$\delta_k = (t_k - y_k) f'(y_{ink}) where \; f'(Y_{ink}) = \lambda f(Y_{ink})[-f(Y_{ink})] \quad (9)$$

$$\Delta W_{jk} = \alpha \delta_k z_j \; \Delta w_{ok} = \alpha \delta_k \tag{10}$$

If the maximum number of epochs is reached and the error is minimized the training process is stopped, and the classified output and results are taken. The final output from this framework will be classified as binary output 0 or 1.

In Clustering Phase, the data with value 0, that is the non-diabetic patients are ignored and the diabetic patients with binary value 1 is again clustered using FCM to cluster the diabetes patients into three types as Type 1, Type 2 and Gestational Diabetes. Fuzzy C-Means (FCM) is a clustering method that allows each data point to belong to multiple clusters with varying degrees of membership. The objective function to minimize the FCM is:

$$J_m = \sum_{i=1}^{D} \sum_{j=1}^{N} \mu_{ij}^{m} \left\| x_i - c_j \right\|^2 \tag{11}$$

where

- D is the number of data points.
- N is the number of clusters.
- m is fuzzy partition matrix exponent for controlling the degree of fuzzy overlap, with $m > 1$. Fuzzy overlap refers to how fuzzy the boundaries between clusters are, that is the number of data points that have significant membership in more than one cluster.
- x_i is the ith data point.
- c_j is the center of the jth cluster.
- μ_{ij} is the degree of membership of x_i in the jth cluster. For a given data point, x_i, the sum of the membership values for all clusters is one.

FCM performs the following steps during clustering:

Step 1 Randomly initialize the cluster membership values, μij.

Step 2 Calculate the cluster centers:

$$c_j = \frac{\sum_{i=1}^{D} \mu_{ij}^{m} x_i}{\sum_{i=1}^{D} \mu_{ij}^{m}} \tag{12}$$

Step 3 Update μij according to the following:

$$\mu_{ij} = \frac{1}{\sum_{k=1}^{N} \left(\frac{\left\| x_j - c_j \right\|}{\left\| x_k - c_k \right\|} \right)^{\frac{2}{m-1}}} \tag{13}$$

Step 4 Calculate the objective function, Jm.

Step 5 Repeat steps 2–4 until Jm improves by less than a specified minimum threshold or until after a specified maximum number of iterations.

4. Experimental Setup

The proposed hybrid algorithm is implemented in Matrix Laboratory (MATLAB). The source code developed are run on system with Inter ® i5 with 8 GB RAM. The dataset required for experimentation is taken from the University of California (UCI) Website [20], [21].

5. Results and Discussion

The framework is implemented on Cloudsim and Matlab. The metrics like Sensitivity, Specificity, Precision or Positive Predictive Value (PPV), Negative Predictive Value, False Positive Rate (FPR), False Negative Rate and Accuracy is used to evaluate the performance of the network with different number of neurons. Sensitivity is also called as True Positive Rate which measures the proportions of positivies that are correctly identified. Specificity is defined as the measure of proportions of negatives that are correctly identified. It is also denoted as True Negative Rate.

Table 3: Comparison of results obtained using different algorithms for PID

Techniques	Sensitivity	Specificity	Precision	NPV	FPR	FNR	Accuracy

Pima Indian Diabetes (PID) Data Set is taken from UCI to evaluate the performance of the proposed algorithm. It consists of a total of 8 attributes and one output class A total of 768 instances are taken for experimentation. Table 1 depicts the results obtained using different algorithms. The proposed algorithm after scheduling using the ATGA has given more accuracy when compared with other algorithms.

The proposed HC2A is compared with Modified Particle Swarm Optimization – Artificial Neural Network (MPSO-ANN) Algorithm [22], Genetic Algorithm-Relative Reduct Algorithm combined with MPSO-ANN GA-RR+MPSO-ANN) Algorithm [23], GA-RR and MPSO-ANN combined with Fuzzy K-Means Clustering (GA-RR+MPSO-ANN+FKM). Table1, 2, 4 & 5 explains the Confusion Matrix obtained for different algorithms.

Below Table 3 shows the results that compares different algorithms for PID. Table 4 below shows the confusion matrix results.

Table 4: Confusion matrix for GA-RR+MPSO-ANN+FKM – PID

6. Conclusion

Elasticity-based Med Cloud Recommendation System(EMCRS) is proposed for diagnosing the diabetes disease and providing recommendation for the diabetic patients. This framework is implemented on Cloud and hence the resource sharing is made more comfortable. Adaptively Toggle Genetic Algorithm is applied to allocate the cloud resources in elastic manner. In the proposed algorithm when huge spikes of data occur, the classification process and clustering is handed over to virtual manager to scale the data across virtual machines while maintaining the security features of medical data. The proposed algorithm focuses on workload prediction with elasticity in cloud environment, in case of scaling conditions which is a unique feature of the algorithm. Hybrid Classification and Clustering algorithm is applied to classify and cluster the diabetic patients. The accuracy of about 98% is acquired for both PID and USD datasets. Performance metrics taken for evaluation also explores the effectiveness of EMCRS. Hence, it is evident that the proposed recommendation system is well suited for diabetic prediction. The limitation of the algorithm is the level of security on cloud data. The framework can be enhanced to predict and classify other types of financial and industrial data in future.

ABSTRACT

Manufacturing industry is facing several challenges in power quality and energy consumptions that play a significant role in the cost of goods sold in addition to the operational efficiency of manufacturing plants. The current techniques are not enough to manage the manufacturing processes from power perspectives as it is focusing only on the monitoring of the power grids using smart meters connected to SCADA systems. In this paper, a novel technique is proposed that is based on energy-aware manufacturing process control model using internet of things technology. The model is applied on cabling industry use case in addition to implementation of a MATLAB model for this purpose whereas the IoT physical layer is collecting , analyzing and communicating the electric power parameters correlated with the manufacturing process parameters received from PLC IoT nodes. Accordingly, the effective power quality is enhanced using manufacturing process control rather than additional correction nodes in traditional techniques. On applying the model on cabling use case, the Total Harmonic Distortion (THD-current) is improved 10 times to be 3.1% against 31.4% and the power factor is improved by 33% from 0.7 to 0.93 without additional correction nodes.

1. Introduction

This paper is an extension of work originally presented in 15th International Computer Engineering Conference (ICENCO) [1]. Power Quality (PQ) has recently become a very important topic because of its effect on energy producers, equipment's, manufacturers and consumers. There are so many industries nowadays that produce and use high technology for production thus high quality and high reliability are needed for these supplying strength [2]. The advantages of gathering real time monitoring is to develop the perception of awareness for power quality in factories.

Despite these circumstances, the executions of energy quality steps in improving energy efficiency have not yet satisfied expectations. The reason for the deficits in energy efficiency realization include lack of time and clarity on energy consumption [3]. The widespread use of non-linear loads leads to a huge distortion of voltage and especially current waveforms that affect any power electronic system [4]. In power systems, harmonic distortion and power factor disturbance increase on daily basis due to an increase in the use of nonlinear loads such as system resonances, voltage distortion, interference with communications networks, transformers overloading, a negative impact on energy metering and a decrease in the overall system efficiency. Thus, these two factors are set to be a serious problem in terms of power quality and this may affect other pieces of equipment connected to a particular system. The optimal performance between increasing in energy demand without severe increases in energy costs come to be our challenge now days. Hence, according to IEEE and International Electro-technical Commission (IEC) standards, industries must devote a greater attention to keeping harmonics and Power Factor (PF) within permissible limits [5, 6]. Furthermore, (IoT) could have significant contribution on energy management, hence several (IoT) applications to reduce the energy consumption have been developed [7, 8].

Power quality (PQ) monitoring methods that are recently produced have the capability to calculate and store data

[*]Corresponding Author: Khaled Y. Youssef, khalid_youssif@yahoo.com

https://dx.doi.org/10.25046/aj0506194

automatically with a high sampling rate. Significant quantities of measured data, such as current signals, voltage signals, total harmonic distortion, and power factor, can be obtained by monitoring devices. Yet, they do not identify distortions automatically, and involve off-line analysis of the data recorded. Consequently, in order to identify the type of end-use equipment, harmonic variations, and power factor detection a real time technique study is provided in this paper to develop the perception of awareness for power quality in factories and examine the impact of energy efficiency in industries. In today's power systems connected to nonlinear loads, voltage and current waveform distortion are more prevalent. The prevalence and interaction of loads of this kind with the power supply system increases the need to use power monitoring equipment to assess the quality of electric power. This paper proposes a new architecture which makes use of real-time data to ensure prediction of machine failure, using power quality data and ways to improve the energy efficient process. The algorithm proposed can be used for automated correction of industrial energy profile using Internet of Things (IoT) technology.

2. Literature review

Systematic approaches to eliminate the consumption of energy has been studied. Hence in order to explain the significance of problems with power quality, a detailed representation of any nonlinear system may be needed in the case of weak systems as interactions may occur between harmonics of different orders in such systems that are not predicted by linear time invariant models. Thus to identify and evaluate energy quality indices for various categories of electricity users, a fuzzy logic-based approach is suggested in [9]. Low energy quality is a serious concern for domestic, commercial and industrial users, in [10] issues of power quality in electrical systems is illustrated briefly.

Harmonics in electricity networks have recently gained even more attention from the power industry as a key cause of PQ problems, in [11], the total harmonic and unbalance distortion is well-defined to help factories to reduce harmonic distortion. In [12], an index is determined to represent the thermal effects on three phase induction motors as a result of harmonic distortions. Researchers in [13,14] illustrate other methods of PQ disturbances such as inter harmonics and voltage fluctuations. Furthermore , a Harmonic Trap Filter in conjunction with a line reactor designed and implemented by [15], using Simulink to demonstrate the principle of harmonic analysis in a three-phase system.

Additionally, the dramatic increase of electricity each year take the initiative on the aspect of energy efficiency in order to address the environmental issues. One of these aspects is the power factor correction. In [16], it is studied the importance of power factor which reflects how much the industries or organizations will consume the electricity efficiently. In [17], the authors investigate a system to carry out the effect of power factor on inductive loads using capacitor bank. Moreover, a system using a thyristor switching capacitor was proposed by [18], which helped to improve the quality of power and regulate the reactive power under the regularization of power factor.

Decreasing energy consumption is important for increasing productivity thus the relationship between electricity and economic growth is vital .To conserve energy and enhance its efficiency, smart grids (SG) were developed to do that [19]. John S. In [20], it is highlighted and clarified the different demand response (DR) programs. A number of DR-based programs are offered to organization managers and consumers, in general, where they choose which program they want to follow in order to decrease the overall energy consumption. Likewise, as energy saving has been one of the critical problems in designing electronic devices, Smart home appliance control system was developed in the IoT environment, a smart control system based on the technologies of internet of things has been proposed in [21].

3. Architecture for power quality management using IoT technology

In this paper a new architecture is proposed to increase the levels of power efficiency in industries. A smart energy management technique is illustrated in Figure 1. Using this block diagram will help factories to reduce their energy consumption. This architecture depends on tracking different loads in the downstream zone.

The architecture shown in Figure 1 is focused on monitoring the different loads attached in a Sensor Area Network (SAN), for the purpose of automated real-time monitoring of transient behaviour and accordingly the detection of anomalies related to power quality issues as voltage dwells, low power factor, and high order harmonics, that might happen as a result of grid's load non-linear behaviour. Most of this phenomenon is currently detected by capture of a measurement sample from the sub-system under test and that is usually reactive rather than proactive.

The concept emphasized by the study is about converting the grid system into an autonomous grid that has the ability to auto detect the phenomenon using a transit-time domain analysis and thus paves the way for artificial intelligence techniques on board to automatically detect the abnormal phenomena even on odd occurrence based on the intra-load communication, source-load communication and load on board processing. The concept also states the edge of machine to machine communications that is the core base of the well-known IoT technology.

According to Figure 1, the central processing server (CPS) is the node that is responsible for orchestration of the correction nodes on the correction plane according to the dynamicity of the load, and thus the CPS calculates and signals the configuration parameters to the corresponding correction nodes based on the measurements done by the IoT layer. The key difference between the existing techniques of correction and the proposed technique is mainly the holistic management of correction for the detected problem according to the multi-factor causal analysis.

One example is the power factor transient's detection that will be captured by IoT layer that is then escalated to CPS layer which in turn take the holistic decision to off –load the power factor capacitor bank and signal the synchronous power factor correction node to be in place in addition to active harmonic cancellation node in place of the passive one. The solution needs a level of intelligence as the classical capacitor bank response time to the change in loads will cause the failure of the classical technique. Moreover, the active cancellation will become effective due to the significant presence of several orders of harmonics rather than the

classical passive filter mode. The edge of the IoT layer in this example is in the consolidated view for the potential sources of problem with the decision of act on the optimum solution of correction.

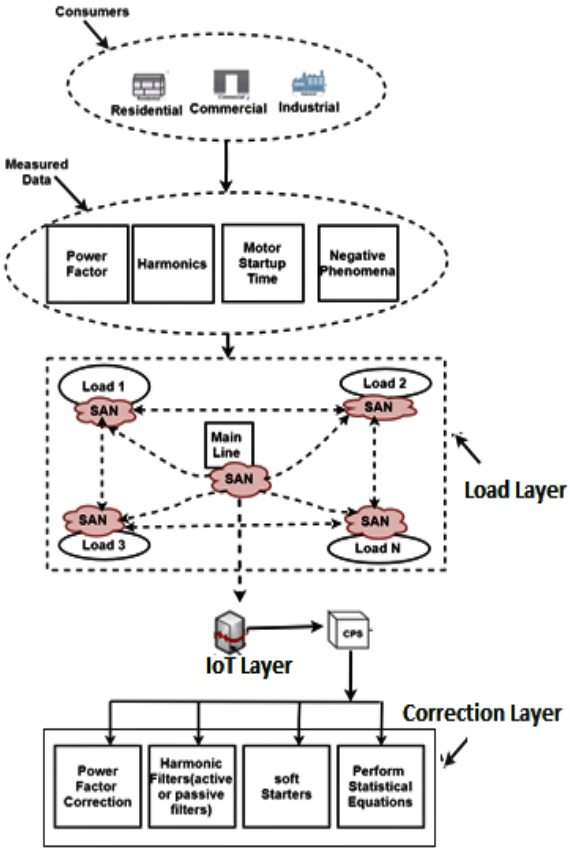

Figure 1: Schematic for the modules combining an intelligent energy management system in factories.

Illustrated in Figure 2 the concept of IoT smart grid which adds intelligence at each step by using online monitoring of transmission lines for disaster prevention and efficient use of power in order to decrease the overall energy consumption inspired by the factory. The three-layer architecture provides a high level framework through which different approaches might be implemented. The first layer consists of Machine drives, which are pumps, electric motors, and fans, account for about half of the manufacturing sector's delivered electricity, layer two is the IoT layer which consists of IoT beacon which are used as linking bridge that helps to provide total tracking and the last layer is named by correction plane layer in which the power factor correction bank and the harmonic filter exists.

The energy efficiency scheme is demonstrated by the flow chart in Figure 3, which begins by monitoring various production lines where each line has different load numbers, X is the order of each load, and N is the total number of loads. Two different parameters are evaluated on each load; power factor and harmonics. The CPS can detect if any of these parameters are not functioning effectively. A signal is sent to the CPS in the event of any errors. Where the problem can be overcome by the CPS,

4. Power Factor correction and Harmonics detection Matlab simulation model results and analysis

A Matlab Model is designed to limit the voltage and current harmonics to be applicable with the IEC standards and to improve the power factor value. A Three-phase harmonic filters with power factor correction model for High-Voltage Direct Current (HVDC) is designed in Figure 4, using Matlab Simulink platform to reduce the voltage and current distortion in the power system. The model is designed using a frequency of 60 HZ and a firing angle α= 19°. One capacitor bank C1 of 150 Mvar designed by a "Thee-Phase Series RLC Load". Three types of different filters combination were also used including one C-type high pass filter tuned to the 3rd F1 of 150 Mvar ,one doubled –tuned filter 11/13th F2 of 150 Mvar and one high pass filter tuned to the 24th F3 of 150 Mvar.

The model used a switch control device for reducing the load imbalance and improving the efficiency of data processing. This

switch control is used to switch on or off when the CPS detect that the data received from the load is not achieving the threshold. The filter can be activated and deactivated using the breaker in the circuit. When the breaker (i.e. CPS) is closed, the filter is activated, the current and voltage will pass through the filter and will successively be filtered. Conversely when the breaker is opened the filter will be deactivated and will have no effect on the output waveforms of the system.

After running the developed Simulink model with different values of α. A various responses are observed. The waveforms in Figure 5, 6 respectively illustrate that when the breaker is opened, the filter is deactivated, a highly distorted waveform was detected because of the nonlinear loads that can be existing in the system. Hence when the breaker is closed, the filter can remove the harmonics given the desired waveform which is free from distortion.

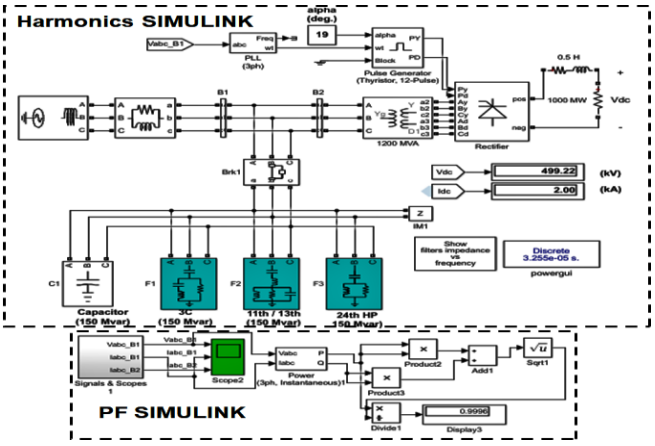

Figure 4: Three Phase Harmonic Filter with aid of PF correction (Simulink Design).

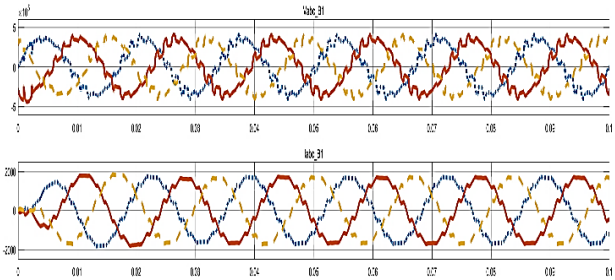

Figure 5: Output Waveforms when filter is disconnected.

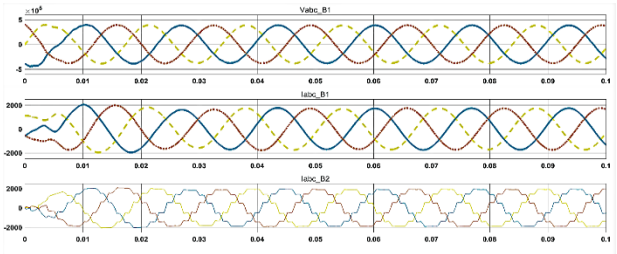

Figure 6: Output Waveforms when filter is connected.

Table 1 and table 2 illustrate that by using a suitable harmonic filter with the aid of a suitable capacitor value, we can control the flow of these fluctuations. From theses measureable results, it can be inferred that the system has worked successfully. As for example, it is clear that with the assistance of the harmonic filters and a capacitor, the THD voltage has fallen dramatically from 17.1 percent to 0.6 percent with an impedance of 407 Likewise, from 7.4 % to 0.3 percent, the new THD has decreased. The PF has risen from 0.3 to almost 0.9, coming close to the ideal 1.0.0. The proposed technique is therefore highly effective. 1.

5. Existing and future power quality system model for different loads

In the current technological transition scenario, power is very precious. A lot of researches need to improve the power quality system and find out the causes of power loss. In industries the huge increase in the use of inductive loads will leads to deficiency of the power system hence a routinely techniques have been used to detect the failures of their loads and correct it[22]. The classical approach shown in Figure 7 is to connect a direct act device with a current transformer (C.T) across the industrial input power lines. The C.T is directly installed at each load. In the classical scenarios, the technique of switching method (on/off) is used. Each load is supported by a controller device which is responsible for detection or cancellation to any failure on each line.

For example, to correct the power factor, these old techniques make use of a microcontroller to control the switching phase of the linked capacitor bank at the end of the main power supply. Each load has its specific control device connected to the main power supply close to the variable load. The controller's job is to read the power factor, voltage and current of the device. Then the controller determines, according to a proven algorithm, to cut off the power for the specified load and decide how many capacitors should be added to raise the power factor to the value required.

With this classical approach, there are two major problems: (1) the correction is a fixed one, so that if the industrial load differs , the correction becomes either less efficient or on the other hand, potentially overly efficient, resulting in an undesirable low leading power factor , (2) many industrial capacitor banks have inherently unpredictable maintenance problems. It would therefore be highly desirable to provide a device that would automatically correct the power factor of an induction motor in real time, so that as the applied mechanical load is varied, the motor runs at or near optimum efficiency continuously.

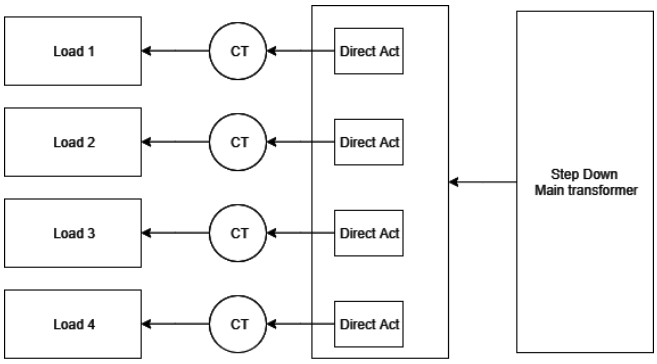

Figure 7: The classical power quality model for different load.

Substantial energy savings could be achieved through the Building Energy Management System (BEMS) within the Smart Electric Grid setting. A new technique based on IoT real time data acquisition using Message Queuing Telemetry Transport (MQTT) protocol which is the most commonly used protocols in IoT projects. The proposed architecture make use of real-time data to ensure prediction of machine failure using power quality data and ways to improve energy efficient process. The development of an energy monitoring system with the ability to acquire, process and store data in real-time is required for improving energy efficiency operations of the manufacturing industries and to enable proactive maintenance .This architecture prove the concept of sense, infer and act. As shown in Figure 8, the IoT beacons can contact with each other through the MQTT protocol. Thus, they can agree together that for example load number (2) will be compensated only. Consequently, tune tone generated by centralized harmonic cancellation to connect central node to a specific load.

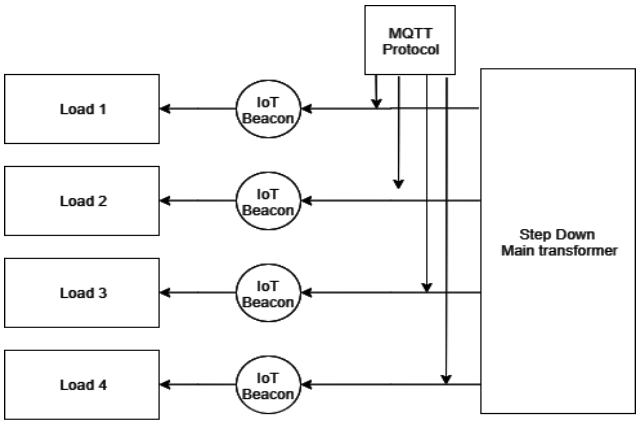

Figure 8: Future power quality system model for different loads.

6. Power factor and harmonics improvement: A Case study and Analysis of the processes of the production of a metals in Factories

This work is a case study and review of the technological and energy aspects of the recommended design of the metal factory production lines in Egypt. The study provide the factory with some technologies which can be integrated into the factory production

processes in order to improve the product quality, minimize the need for electrical energy, reduce maintenance time and cost, and increase reliability and real-time data accuracy.

This study reviewed the production line of metals in factories. The metal production line consists of four main process illustrated in Figure 9 which are drawing, stranding, insulation and assembly. In this power quality assessment, a power quality analysis of metal production process has been shown where power is given to different loads through transformer. Readings of power quality parameters such as voltage unbalance, current unbalance, power factor, harmonics and voltage fluctuation in each phase of the metal production have been studied.

The purpose of the electrical distribution system is to support proper operation of the loads. When any one of the loads fails to meet its purpose, it is time to investigate the problem, find the cause and initiate corrective action. When a load does not operate properly, the other loads agree together through the proposed architecture shown in Fig.9 that this load should be compensated only. Figure 10-13 show the average voltage distortion, average current distortion, average power factor and average harmonic in the drawing phase, stranding phase, insulation phase and assembly phase respectively from the metal factory. Finally all these parameters are measured at the main line, so that the power factor and the harmonics at the main line can be fixed directly. Thus, Figure 14 and Figure 15 illustrated the reading at the main line before and after correction correspondingly.

The proposed system shown in Figure 9 will monitor the load current to detect the harmonics wave up to 49 th order and performs the computing process to analyse and calculate the power factor, then to transfer them to the high current capacity rectifier module along with the module processor in order to generate the compensation current in reverse direction, with overall response time less than 10ms and perform exceeding 97%.

Furthermore, Figure 16 illustrated the power consumption for one of the loads in four days. The measuring is taken by calculating the consumption of power for the three phases of one of the loads over time. Thus, it can be concluded that when using the proposed architecture a daily real time monitoring can be conducted which offers an understanding of energy usage and efficiency across different loads.

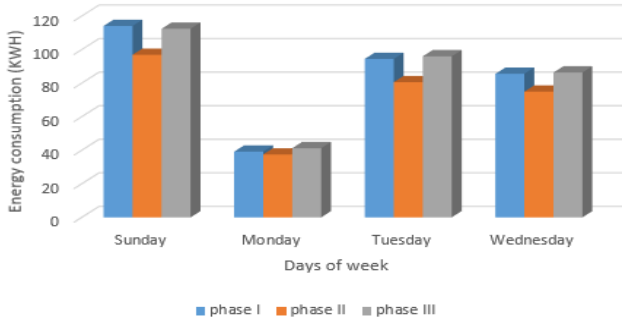

Figure 16: Energy consumption on one of the loads through four days

7. Discussion and conclusion

The manufacturing industry has been challenged with a lot of power quality problems in the overall including power factor, harmonics, unbalance ratios, power swells and dwells. Traditional techniques are moving towards correction steps as power factor correction using capacitor banks, synchronous power factor correction on individual loads, passive harmonic cancellations, active harmonic cancellations, soft switches to absorb spikes, voltage regulators, inverting technologies and others. However, those techniques are more focusing on correction of power rather than correction of manufacturing process that leads to the impact.

In the presented work , energy-aware process control model is proposed that is depended on IoT technology that enables the communication between PLC on machines and the energy management analytic platform on board to pinpoint the process that causes the phenomena to happen rather than the machine. For example, if two different machines working in parallel and doing the same operation type, machine x and machine y, that are installed in a factory. If the two machines are operating during three time shifts daily .Once the proposed model explore that machine x is doing wide spectrum of harmonic compared to machine y. The model will operate machine y for only two time shifts while machine x will operate for only one time shift. Hence the proposed model is able to stop the noisy machine and improve the overall power quality.

The model is simulated using MATLAB and is applied on a use case in factory that is specialized in cable industry. The results shows that the model pinpoints key areas of improvement of reducing the operation hours of a specific malfunctioning machine by one shift (eight hours) and increasing on the other side of operation hours of other two healthy machines doing the same operation type by 3 hours each has led to significant improvement of the power factor by 33% to reaches 0.93 versus 0.7 without impacting average OEE of the operation. On the other hand, the current total harmonic distortion is improved 10 times from 31.4% to 3.1% as shown in Figure 17 and 18 respectively.

The proposed model enables the cost-effective process management concept to achieve the same production results with better power quality and less energy consumption with minimum addition of correction nodes.

ABSTRACT

Quantum computers are heterogeneous device. It consists of a main CPU and a quantum accelerator. True quantum accelerator (or coprocessor) is analog and probabilistic device. Qubits are the basic building blocks of quantum computers. But qubits can be digital. A digital qubit is similar to RISC processor pipeline and is an unique chain of digital gates.

In this work, it is proposed to execute quantum routines in quantum computer not on the quantum chip but on the chip of a digital FPGA. This paper presents the architecture of such FPGA – an architecture of digital quantum coprocessor. The paper presents two types of digital quantum coprocessors - heterogeneous and homogeneous. The advantage of a homogeneous coprocessor is shown.

The IP Core generator was developed to create VHDL descriptions of digital quantum elements and digital quantum coprocessors in general.

In this paper heterogeneous quantum computer which consists of a main CPU and a FPGA-based quantum accelerator (coprocessor) has been proposed. And these FPGA-based digital quantum coprocessors can have a homogenous or heterogeneous structure. Quantum coprocessors have up to 1024 qubits in one FPGA. A homogeneous quantum coprocessor performs better than a heterogeneous one. Also, its implementation is easier.

The measured ratio of correct results for a 1024-qubit homogenous coprocessors is more then 50 %.

1. Introduction

This paper is an extension of work originally presented in IEEE 11th International Conference on Dependable Systems, Services and Technologies (DESSERT) [1].

Quantum algorithms are a mixture of classical logic and quantum routines which can be executed on the quantum chip. In [2] a heterogeneous quantum computer architecture was presented. According to [2] a quantum computer consists of both a classical and quantum computing part.

In this work, it is proposed to execute quantum routines in quantum computer not on the quantum chip but on the chip of a digital field programmable gate array, on a FPGA. This paper presents the architecture of such FPGA – an architecture of digital quantum coprocessor.

As an extension of the results described in [1] heterogeneous and homogeneous digital quantum coprocessors are considered. It is important to note that a heterogeneous quantum computer and proposed heterogeneous quantum coprocessor are completely different concepts.

Also, the number of digital qubits in the coprocessors under study was increased to 1024.

Von Neumann architecture had for a long time a single processor. Then homogeneous multi-core processor dominated the processor development. In the era of microprocessors, the understanding came that heterogeneity is the best way forward to improve the compute power. System architecture with heterogeneous accelerators includes the main CPU and heterogeneous coprocessors such as floating-point math coprocessors, graphics and neural accelerators, FPGAs. In [2] and [3] heterogeneous quantum computer which consists of a main CPU and a quantum accelerator has been proposed. In this paper heterogeneous quantum computer which consists of a main CPU and a FPGA-based quantum accelerator (coprocessor) has been proposed. And these FPGA-based digital quantum coprocessors can have a homogenous or heterogeneous structure and can be used at the lowest level of full-stack quantum accelerators along with quantum chips and quantum simulators [3].

A quantum computer contains N qubits and a digital quantum coprocessor contains N digital qubits. In both cases as a result of any calculations they can produce any of 2^N results. But the same

*Corresponding Author: Valeriy Hlukhov, Lviv Polytechnic National University, Computers Dept., Lviv, 79013, Ukraine, Glukhov@polynet.lviv.ua

calculations can lead to different results. And every i-th result will be produced with probability p_i.

A qubit can be thought of as a device that has a group of inputs for data and instructions that control its behavior. Unlike a real qubit, a digital qubit can have an additional group of outputs. The exact qubit state code is generated on this group of outputs. An important element of the digital qubit is a pseudo random number generator (PRNG). Together with the qubit state code, the pseudo-random code is used to generate a probabilistic result at the one-bit output of the qubit (Figure 1) [4].

Quantum volume VQ is a metric that measures the performance of a quantum computer's capabilities and error rates [5]. In the simplest case, the quantum volume is d·N. Now the quantum volume of a real quantum computers is very small (at the level of milliseconds), but for digital quantum coprocessors it is practically unlimited.

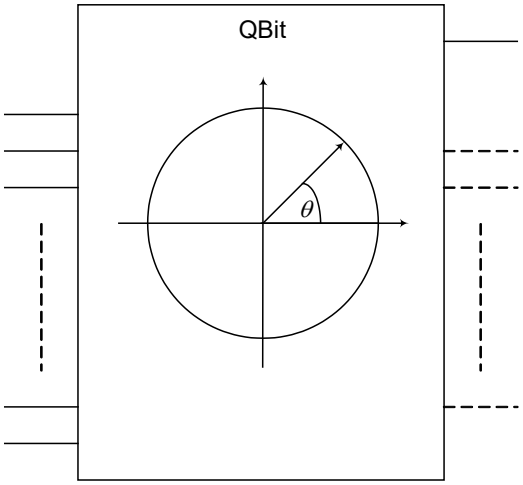

Figure 1: Digital qubit symbol

The DiVincenzo [6] criteria are conditions necessary for constructing quantum computer. Not a single word about the physical nature of a quantum computer is included in this criterion. Therefore, you can try to create digital quantum computer. It can be created either as a software model or as a hardware device.

"You can run a simulator on your phone that can run a 20-qubit system. But once you get up close to 50, the amount of memory you need to run a simulator gets into the petabytes [of memory]. Over 50 and there is no way you can pretend to be a quantum computer. At that point you really need a true quantum computer" [7].

The number of qubits required for solving practical problems is now estimated at several thousand [8]. Creating a true quantum computer with so many qubits is a very difficult task, and a digital quantum coprocessor can already be created on one FPGA.

The purpose of the article is to demonstrate the advantages of digital quantum computers over true ones. For this, it is necessary to develop a circuit for a digital qubit and a digital quantum coprocessor as part of a digital quantum computer. To compare different coprocessors, it is necessary to develop methods for their comparison. In this works digital quantum computers with 2^n qubits (n = 5, 6, …, 10) have been used for research.

Also, the purpose of the work is to determine the timing and hardware characteristics of the developed digital quantum coprocessors.

An important task is the problem of the reliability of the results of modeling the operation of digital quantum coprocessors. In this work, it was successfully solved, it was shown that simulation results coincide with the results obtained during prototyping.

2. Theoretical Foundations of Quantum Computing

$$|0\rangle, |1\rangle, ..., |N-1\rangle$$

$$|j\rangle$$

Along with measurement, the quantum superposition can be changed under external influence.

$$|\psi\rangle = \sum_{j=0}^{N-1} \lambda_i |j\rangle \quad p_j = \lambda_j^2 \quad P = \sum_{j=0}^{N-1} \lambda_i^2 = 1$$

$$p_0 = \cos^2\theta \qquad p_1 = \sin^2\theta$$

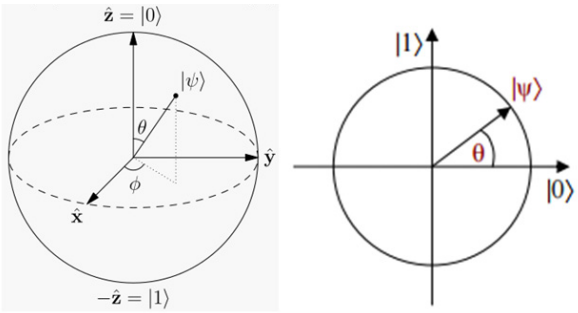

Figure 2: A Bloch sphere (left) and a unit circle (right)

A true quantum computer is an analog device and it has no memory. It has only gates. Therefore, there are no quantum programs. In the drawing of a true analog quantum computer, a sequence of quantum gates shows only the time sequence of qubit state changes. Software tool [14] allows to create circuits from quantum gates, simulate their work and manage it with C-like language instructions. This is very similar to the FPGA design.

In the schema of a digital quantum computer, a sequence of digital quantum gates shows both the time sequence of qubit state changes and the relative physical position of the gates themselves in the space.

A good illustration of a qubit can be an electron spin. An electron can change its spin in time from 1 to 20 nanoseconds [15]. This time can serve as a base operation time for compare the performance of true and digital quantum coprocessors.

To compare the capabilities of true and digital quantum computers, one can calculate the quantum volume as a metric that measures the performance of a quantum computer's capabilities and probability that the qubit will work for some time t without failure:

$$QV = N*p(t),$$

$p(t) = e^{-t/MTBF}$ is probability that the qubit will work for some time t without failure where (MTBF - Mean Time Between Failures);

N is qubits number.

For true qubits MTBF is microseconds and millisecond and p(t) run to 0 when t > 1 ms, QV << N.

For digital qubits MTBF is practically unlimited (MTBF of modern FPGA is at level 50 years) and p(t) run to 1. So, for digital quantum coprocessor QV = N.

The results of comparison of analog data processing methods, which are used in true quantum computers, and digital methods are summarized in the Table 1. All this speaks about the prospects of creating hardware digital quantum computers.

3. The Structure of FPGA-based Digital Quantum Coprocessor

A classical computer controls the operation of a quantum coprocessor (Figure 3) provides it with an input data, instructions and checks the result of its work [4]. This interaction is well described as a full-stack of the layers of an accelerator at [3].

A generalized functional diagram of full-stack hardware resources of quantum computer with realized in FPGA quantum coprocessor is given in Figure 4 [4].

Table 1: Comparison of analog and digital data processing methods

Characteristic	Analog processing methods	Digital processing methods
Speed	+	-
Versatility	-	+
Microminiaturization	-	+
Accuracy	-	+
Zoom	-	+
Transmission in space	-	+

Immunity	-	+
Reliability	-	+
Testing, debugging, diagnostics	-	+
Quantum volume	-	+

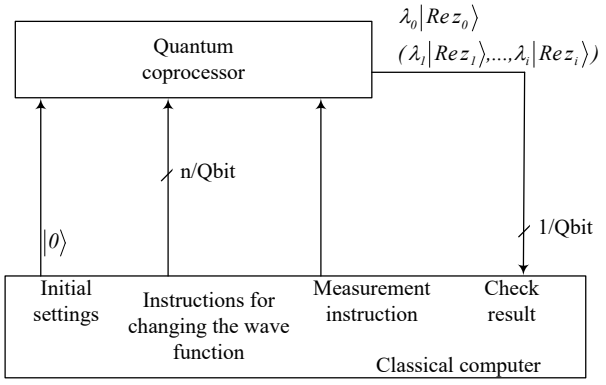

Figure 3: A classical computer with quantum coprocessor.

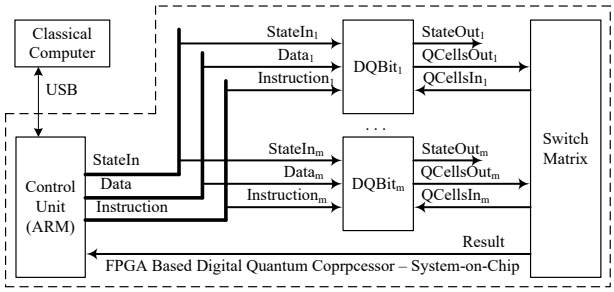

Figure 4: A digital quantum coprocessor for classical computer.

The top-level functionality of this stack is provided by the classic host computer. Functioning at the microarchitecture level is provided by embedded in FPGA microprocessor (AWP, control unit).

And directly quantum computing is provided by a set of digital qubits and a switch matrix which connects the qubits to each other and transmits the final state code of all of them or only those required at the moment to the control unit.

The connections between qubits can be static or dynamic. In this work static connections have been used. They do not change while the computer is running.

A digital qubit consists of j series-connected digital quantum cells (Figure 5).

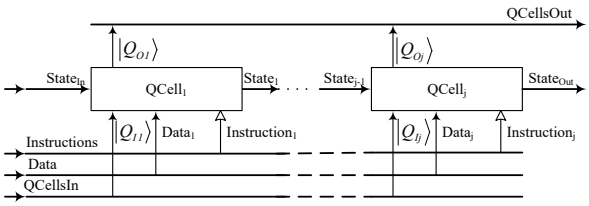

Figure 5: RISC processor-like structure of a digital qubit DQBit.

$|Q_{Oj}\rangle$

$|Q_{Ij}\rangle$

$D = arcsin\sqrt{A}$

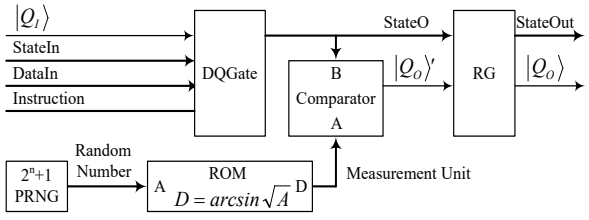

Figure 6: A digital quantum cell QCell.

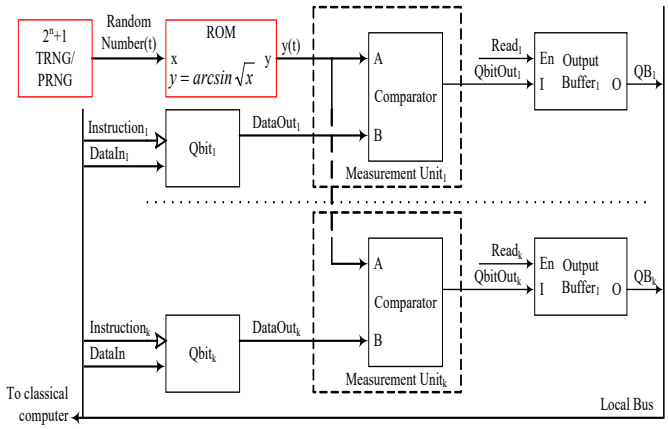

A digital quantum gate transforms the input qubit state code into the output code under the influence of the instructions and their data, as well as under the influence of measured states of another qubits.

Inverse functional transformation allows the creation and research of two types of digital quantum coprocessors:

each quantum cell of the heterogeneous coprocessor has its own pseudo-random number generator and its own functional transformer;

a homogeneous coprocessor contains only one pseudo-random number generator and only one functional transformer for all quantum cells, for all quantum qubits (Figure 7).

A simplified topology of a part of a FPGA chip with resources available to the user for design is shown in the Figure 8. These resources are sets of configurable logic blocks CLB, programmable switching machines PSW and I/O blocks IOB. The PSM and the wires laid on the chip between them and CLB make it possible to connect the CLB to each other. CLB can be programmed to act as a qubit (QB) or quantum cell (QC). This allows many digital qubits to be placed on one chip. The interaction of qubits and the control of qubits is carried out by digital methods using PSM. The use of COTS FPGAs makes it possible to create digital quantum coprocessors with a large number of qubits, which can operate for a long time under normal conditions.

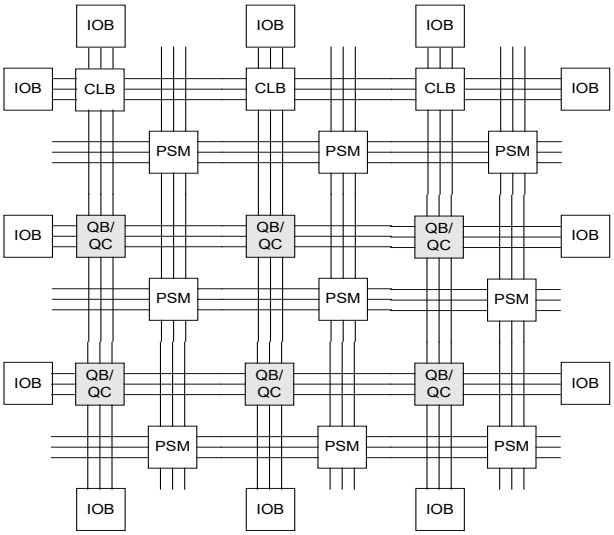

Figure 8: Simplified topology of digital quantum coprocessor FPGA chip

Recently, other developers have also tried to connect digital technologies with true quantum computers:

place true qubits on the crystal (similar to the Figure 8 shown) and organize interaction between them using digital methods [16]. It uses a custom crystal that can operate at ultra-low temperatures (near 4° K);

carry out optical control of true qubits embedded in the chip [17];

use a pseudo-random number generator in true quantum computers [18].

In this study digital quantum coprocessors were implemented for the case of wave function real amplitudes (Figure 2) and for polar coordinate system to represent the movement of the vector (Figure 13) [12].

Algorithm design steps for digital quantum computer design on FPGA are standard for FPGA design:

to create or to find an algorithm for solving the problem;

to find or to create a mathematical description of the solution to the problem;

for FPGA-based circuits to create graphic symbols of library elements and their descriptions in hardware description language;

- to create a schema from library elements;
- to simulate the created schema;
- to implement the project;
- to verify the project;
- to make a prototype project.

The IP Core generator was developed to create VHDL descriptions of digital quantum elements and schema of digital quantum coprocessors in general.

4. Testing Digital Quantum Coprocessors

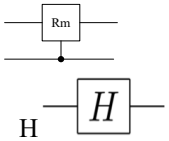
The quantum Fourier transform (QFT) as a part of Shor's algorithm [19] (Figure 9) for factorization [11] was chosen to compare different variants of quantum coprocessors.

The QFT is defined as

$$\sum_j \alpha_j |j\rangle \rightarrow \sum_k \tilde{\alpha}_k |k\rangle$$

$$\tilde{\alpha}_k \equiv \frac{1}{\sqrt{N}} \sum_{j=0}^{N-1} e^{2\pi i j k / N_{\alpha_j}}$$

Only 2 types of digital quantum gates are required during QFT (Figure 10, Figure 11):



- Hadamard transform H

$$R_m = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & e^{2\pi i / 2^m} \end{pmatrix}, \quad H = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}.$$

When implementing a digital qubit in the form of a chain of digital quantum gates and implementing only a QFT circuit on FPGA, there is no need to change the functions of the quantum gates. Therefore, the functions of each gate are determined only by their circuit. And there is no need for instructions that change the

function of the gates. Therefore, they are not shown in the Figure 12, but are shown in the general diagram Figure 4. And the data path in the Figure 12 is a chain of links named Q*, along which the changing qubit state code goes from one gate to another. The measured states of a qubit, which are called q*, are transferred from one gate to another as required by the algorithm for solving the problem. QFT determines spectrum of qubits states.

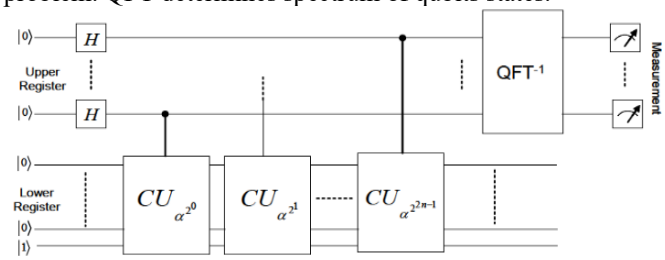


Figure 9: Quantum factorization by Shor's algorithm

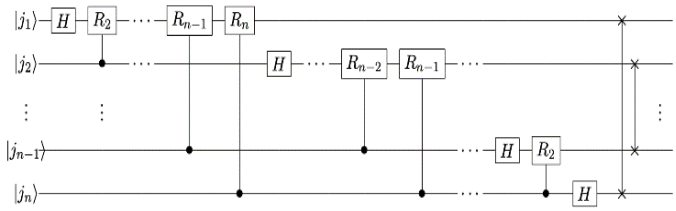

Figure 10: QFT drawing

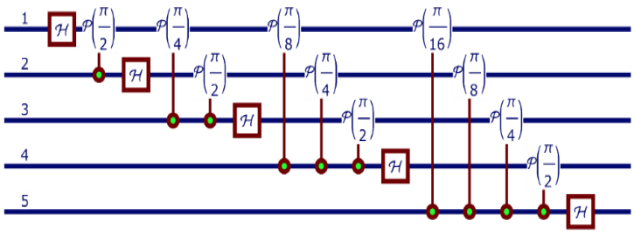

Figure 11: Simplified drawing of QFT (5-qubits)

The diagram for FPGAs corresponding to the Figure 11 is shown in the Figure 12.

The QFT results were obtained as described in [12] and [13].

5. Simulation and Verification of FPGA-based Digital Quantum Coprocessor

For analysis the input state of qubits, which can conditionally be described as |XXX..X0>, where X corresponds to the neutral position of the vector in the unit circle - at angle of π/4, was selected. The probability of measuring the input state with odd code is p_{odd}=0, and with even codes is $p_{even} = 100/2^{n-1}$ %, where n is qubits quantity and the spectrum of qubit states at the QFT input will look like in Figure 14 (for 4 qubits).

QFT simulation results for this case are shown in Figure 15. The 4 qubit digital quantum coprocessor determines the period of the input states spectrum with probability 38,5 %, so it correctly executes a QFT.

Also digital quantum coprocessors with up to 1024 qubits, have been investigated [13], [20]. Similar studies were performed for other periods in input states spectrum (for 0, 1, 2, 4, …, 2^{n-1} periods) [13].

Implementation results are summarized in Table 2.

Table 2: Implementation Results of Heterogonous Digital Quantum Co-Processors (2^{n-1} periods)

Qubit number, n	CLK period (ns)	LUT number	RAM number	FPGA resoirces, % R	FPGA 7z type [21].
128	2.353	32352		14	045
64	4.289	16043		15	010
32	3.874	7983			010
16	3.606	4000			010
10	3.976	2522			010
10	4.180	4307		24	010
10	5.137	3754			010
10	5.281	3650	20	16	010

32-qubit digital quantum coprocessor (Figure 18) was implemented on ZedBoard Zynq-7000 ARM_FPGA SoC Development Board (Digilent, Figure 17) for verification.

Verification and simulation results are almost the same (Table 3). This indicates the creation of both a high-quality model of a digital quantum coprocessor and its prototype, which can be used in further research. Each experiment was repeated 4000 times to determine the probability of getting the correct result (Figure 19). The average level of correct results during the verification of a heterogeneous coprocessor is 9%, during the simulation of a homogeneous processor is 61%, during the verification of a homogeneous processor is 58%.

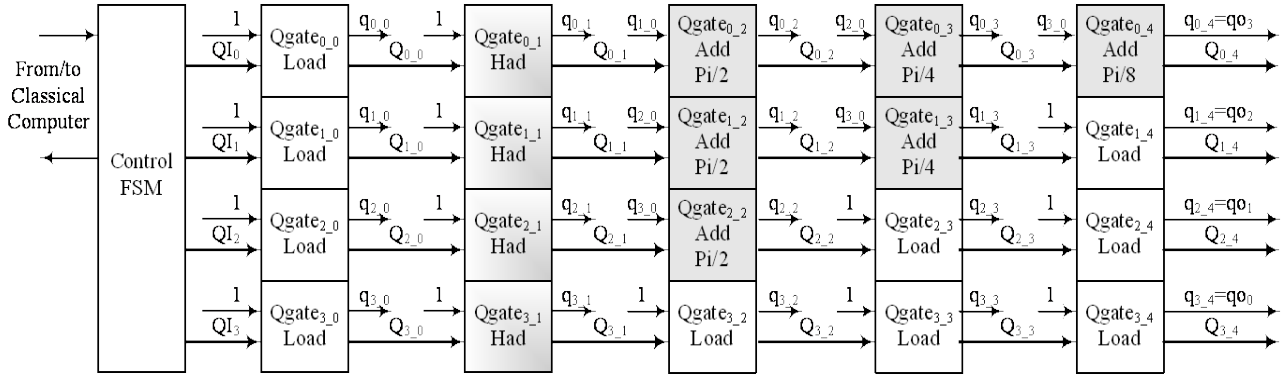

Figure 12: FPGA schema of QFT (4-qubits)

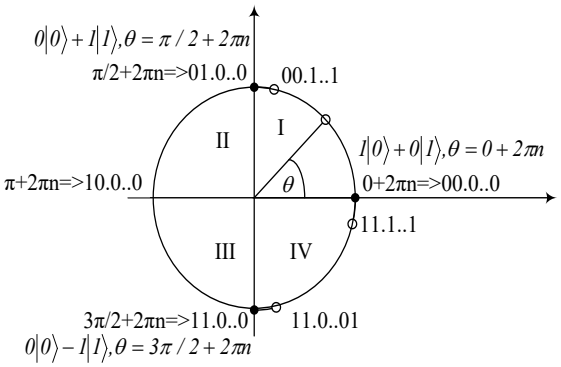

Figure 13: A polar coordinate system (angle θ codes)

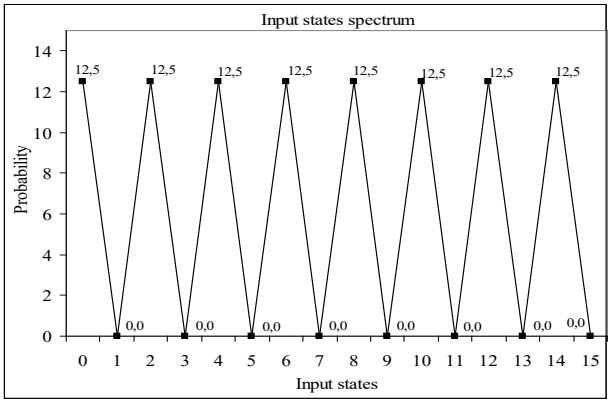

Figure 14: Input state spectrum

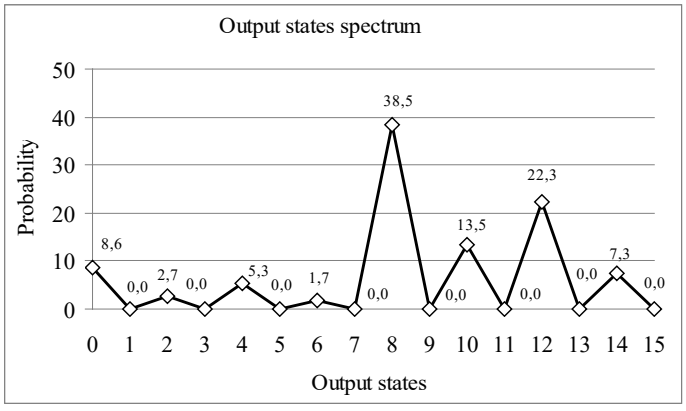
$$\theta_3 = \theta_2 = \theta_1 = 45°, \theta_0 = 0°$$

A homogeneous digital quantum coprocessor has shown better results than a heterogeneous one. Therefore, further research was carried out on a homogeneous digital quantum coprocessor.

The probabilities of obtaining correct results during the verification for the operation of multi-qubit homogeneous digital quantum coprocessors are shown in the Figure 21. The work of coprocessors with 32, 64, 128, 256, 512 and 1024 qubits were investigated.



$$\theta_3 = \theta_2 = \theta_1 = 45°, \theta_0 = 0°$$

# of logical nets	21575		28147	

6. Conclusion

The paper shows the advantage of digital quantum computers over true computers in terms of quantum volume. The paper presents heterogeneous quantum computer which consists of a main CPU and a FPGA-based quantum accelerator (coprocessor). This FPGA-based digital quantum coprocessors can have a homogenous or heterogeneous structure. Structures of digital quantum qubits and cells are also presented.

The IP Core generator was developed to create VHDL descriptions of digital quantum elements and digital quantum coprocessors in general.

32 qubits homogeneous digital quantum coprocessor generates correct quantum Fourier transform results with a probability of 61% during simulation and 58% during prototyping.

1024 qubits homogeneous digital quantum coprocessor generates correct quantum Fourier transform results with a probability more than 50 % during simulation.

Homogeneous digital quantum computer generates the correct results of the quantum Fourier transform 7 times more often than heterogeneous one.

The hardware cost of homogeneous digital quantum coprocessors is 20% less than that of heterogeneous coprocessors.

The number of logical nets in homogeneous digital quantum coprocessors is 20% less than in heterogeneous coprocessors.

Digital quantum coprocessors verification results are practically the same as simulation results. This indicates the creation of both a high-quality model of a digital quantum coprocessor and its prototype, which both can be used in further research.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Diabetes Mellitus Type 2 is a chronic disorder that affects the way the body metabolizes sugar (glucose) in the blood and depends on a combination of risk factors, such as genes and lifestyle. Although certain risk factors such as family history, age, or ethnicity cannot be changed, those related to diet, physical activity, and weight can be changed. These lifestyle changes can affect the probability of developing type 2 diabetes and its complications. In this research work, the prevention of the patient to develop type 2 diabetes with the option of leading a healthy lifestyle is proposed and reinforcing the population of each establishment with health education. It is a quantitative approach, a non-experimental, descriptive, and correlational study, with a population of 300 outpatients from a district of North Lima, who answered a questionnaire with sociodemographic data and the instruments of the level of physical activity IPAQ and risk of FINDRISK type 2 diabetes mellitus. In the results with respect to the level of physical activity, low 125 (41.7%) predominated and at risk of type 2 diabetes mellitus, 113 (27.7%) predominated. In conclusion, the population should be educated to have an adequate lifestyle by improving physical activity to prevent the risk of contracting diabetes.

1. Introduction

Type 2 diabetes is currently considered one of the non-communicable diseases with the greatest negative impact and projection on the quality of life of the world population and represents a world health problem [1]; it is diagnosed in 85-95% of all those who suffer from it, with a higher percentage in less developed regions (one in 14 adults will have diabetes mellitus). It is estimated that nearly four million deaths a year are directly related to this condition, based on changes in the lifestyle of the population, associated with sedentary lifestyle, obesity, high blood pressure and other cardiovascular risk factors [2]. For these reasons, it is the fourth cause of death in the entire universe [3].

Globally, the number of patients diagnosed with type 2 diabetes mellitus has exceeded the references by more than 100% increase in the last 20 years [4]. In its development, it is related to lifestyle, age, sex, ethnicity/race and family history of Diabetes Mellitus Type 2 (DMT2) [5]. The Body Mass Index (BMI) increased means the probability of developing DMT2, to a greater extent in individuals with a Normal BMI compared to the obese, identified physical activity as a fundamental strategy in its prevention [6].

In Peru, the number of people with diabetes mellitus is increasing very rapidly and the main cause of its rapid increase is the important change in the lifestyle of the Peruvian population, whose current characteristics represent an excessive intake of high-calorie foods (junk food and sugary drinks), and what is equally worrisome: a reduction in physical activity that directly leads to a high morbidity of overweight and obesity [7].

Regular physical activity is essential for disease prevention, particularly chronic non-communicable diseases; Health promotion; quality of life; and reduction of mortality [8].

In [9], the study prevalence and incidence of type 2 diabetes mellitus in the general adult population of Peru, they define the prevalence of type 2 diabetes mellitus nationwide according to the National Survey of Nutritional, Biochemical, Socioeconomic and Cultural Indicators study was 5.1% in 2004-2005, and it increased to 7.0% in 2010-12, Perú Diabetes (PERUDIAB, national study).

* Corresponding Author: Brian Meneses-Claudio, Sr., +51 1 950159924 & bmeneses@uch.edu.pe

The Risk Factors of Non-communicable Diseases study in Lima and Callao reported a prevalence of 3.9% in 2006, and in 2010-2012 the Centre of Excellence in Chronic Diseases (CRONICAS) study also in Lima found this indicator at 5.5%. Regarding the incidence, three of the nine studies analyzed PERUDIAB estimated the incidence of diabetes in 19.5 new cases per 1,000 person-years. The CRONICAS study, in selected populations of Lima, Puno and Tumbes, found the same result. The Perú's Rural to Urban Migrants (PERU MIGRANT) study estimated a 50% lower incidence than the previous two studies, although more than half of the population in this study lived in rural areas or were migrants from rural to urban areas.

In [10], the author studied physical activity in outpatients with diabetes mellitus type 2 concluded that 88% of diabetic patients had inactivity or minimal physical activity, estimating that patients with diabetes have a higher level of inactivity than the general population.

In [11], the author indicates that leading a healthy lifestyle pattern could lead to a lower risk of diabetes mellitus type 2, which identifies 142 associations related to the risk of developing DMT2. In which, they pointed out that Eleven associations (8%) presented evidence for the risk of DMT2 (low consumption of whole grains, metabolically healthy obesity, increased sedentary time). Thirty-four associations (24%) were associated with an increased risk of DMT2 and presented highly suggestive evidence, they were the following: high BMI, low educational level, gestational diabetes, increased consumption of processed meat, high level of total physical activity. Twenty-nine associations had suggestive evidence (20%), and 42 associations had weak evidence (30%) of DMT2 risk. All but six associations with convincing or highly suggestive evidence were based exclusively on prospective cohort studies.

The main objective of the study is to determine the risk of developing diabetes mellitus type 2 in relation to its level of physical activity in adults treated in health centers in a district of North Lima. It is important the need to modify the lifestyles of the population, associated with sedentary lifestyle, obesity, high blood pressure and other cardiovascular risk factors and thus identify physical activity as a fundamental strategy in its prevention.

Diabetes mellitus risk is understood as the probability of presenting or suffering from type 2 diabetes in adults attended in District-Rímac health centers, which can be evaluated by the presence of indicators such as age, body mass index, anthropometry waist, physical activity, consumption of vegetables or fruits, blood pressure medication, diagnosis of high glucose values and a history of diabetes mellitus [12].

The technique to be used in the research work will be the survey, which a significant amount of data will be obtained optimally and effectively. To measure the risk of type 2 diabetes mellitus, the data collection instrument will be used, the Finnish Diabetes Risk Score (FINDRISK) test that considers eight items grouped into eight dimensions and the level of physical activity will also be evaluated using the International Physical Activity Questionnaire (IPAQ), which considers 27 items grouped into three dimensions.

The data collection process will be carried out during the month of June through surveys, after the data will initially be entered into a data matrix designed in the Microsoft Excel 2013 program, then will be exported to the IBM SPSS Statistics version 24.0 program. It will apply descriptive statistical tests such as absolute frequencies, relative frequencies, and measures of central tendency, determining the risk of developing diabetes and the level of physical activity.

The following research work is structured as follows: In section II, the methodology that will determine the research work will be presented, with emphasis on the instrument, techniques to be used, scope of the study, valid inclusion, and exclusion criteria for the estimated population, among others. In section III, the results will show the tables and graphs obtained after data processing with an emphasis on determining the risk of developing type 2 diabetes mellitus and the level of physical activity of the studied population. In section IV, it will present the discussions of the research work and finally in section V, the conclusions obtained through the present research work, as well as the future work that leads to the timely detection of type 2 diabetes mellitus and the adoption of healthy styles.

2. Methods

The steps to carry out the survey as the population and sample were obtained, type of study, inclusion and exclusion criteria, analysis of the variables, data collection, location and application of the IPAQ and Finnish Diabetes Risk Score (FINDRISK) instruments. The paper before its application went through an ethics committee in which it was approved.

2.1. Population and Sample

It was applied to 300 outpatients at risk of developing diabetes, in the nine Health Centers of the Rimac district, considering the total distribution of patients who participated in the study, the sample corresponds to 35 participants from each center: H.C. Rímac, H.C. Caquetá and H.C. Flor de Amancaes. Likewise, 34 participants from Leoncio Prado, San Juan de Amancaes, Mariscal Castilla, Ciudad y Campo and Villa Los Ángeles.

2.2. Inclusion and Exclusion Criteria

Inclusion criterion is that all patients who receive regular care and wish to collaborate voluntarily in being evaluated to obtain a risk diagnosis participate and exclusion criteria; Patients who did not wish to participate in the study are excluded.

2.3. Type of study

The present work, due to its data collection characteristics and the measurement of the variables, has a quantitative approach, a non-experimental, descriptive and correlational study.

2.4. Analysis of the variables

The present study presents a main variable that is the risk of diabetes, the data collection instrument was used, the FINDRISK test that comprises eight items grouped into eight dimensions and also can be evaluated through the presence of indicators such as age, body mass index, anthropometry of the waist, physical activity, consumption of vegetables or fruits, medication for blood

pressure, diagnosis of high glucose values and a history of diabetes mellitus [13].

The level of physical activity will be evaluated using the IPAQ questionnaire. The short version evaluates three specific characteristics of activity: intensity (mild, moderate or vigorous), frequency (measured in days per week) and duration (time per day). Activity of moderate intensity is considered as which produces a moderate increase in respiration, heart rate and sweating for at least 10 continuous minutes, and vigorous activity, such as which produces a greater increase in the same variables, for 10 minutes or more [14].

2.5. Instruments

The data collection technique was the survey and the selected instruments were the FINDRISK test and the short version IPAQ questionnaire to measure the level of physical activity.

The data collection process will be carried out during the month of June through the surveys, later the data will be initially entered into a data matrix designed in the Microsoft Excel 2013 program, and then they will be exported to the IBM SPSS Statistics version 24.0 program. And the data analysis will apply descriptive statistical tests such as absolute frequencies, relative frequencies and measures of central tendency, determining the risk of developing diabetes and the level of physical activity.

The instrument was applied in the nine establishments of the Rímac district. The respective permission was requested from Directorate of Integrated Health Networks (DIRIS) Lima Norte, to have access to health centers, for this purpose an enrollment was made in the ethics committee to approve the instrument to apply; After approval, it was presented to the head of each establishment and permission was given to the triage health personnel in charge of the area to develop the questionnaire.

Figure 1: The patient is triage taking anthropometric measurements, before going to the external office to be evaluated

As shown in Figure 1, the instructions on how to carry out the respective filling in of the questionnaires are explained to the patients, they were informed to mark a single alternative in the questions avoiding smearing, and the patients were also consulted to ask before any doubt that they would not understand, to obtain real data.

Figure 2 considers the distribution according to sex of the total number of people who participated in the study, segmented by each health center in the Rímac district, an analysis that considers 35 HC respondents: Rímac, Caquetá and Flor de Amancaes; the second block considers the HC with 34 respondents: Leoncio Prado, San Juan de Amancaes, Mariscal Castilla, Ciudad y Campo and Villa Los Angeles; and finally the block of 25 respondents the HC Piedra Liza, an activity that was carried out according to schedule and considered the minimum established quota.

Figure 2: Filling out the survey of outpatients treated in the health center of a district of North Lima - 2019 (N = 300)

2.6. Developing the surveys

The patients were interested in reading the questionnaire; some patients were hesitant to answer because of their advanced age they did not understand the questions, they did not interpret it in the health field.

Based on good data collection in most of the patients with good attitude and with consent, they collaborated in the survey. In some patients, they did not give their consent because of the time or they had another meeting, the discomfort of the patient and/or relatives when waiting for care was also observed, so they arrived before the mentioned time and were not treated, since that this has an impact on answering the survey.

It is important in the data collection, the technical staff of the triage service since their function is to take the anthropometric measurements (weight, height) and the abdominal perimeter of all the patients before entering the medical office and thus be diagnosed and evaluated.

3. Result

After collecting the data, graphic tables were generated where it will synthesize the information and graphics so that the results obtained are easier to understand.

Table 1: Sociodemographic data on the risk of type 2 diabetes and physical activity in outpatients treated at health centers in a district of North Lima, 2019 (n=300)

Sex of hospitalized patient	**Frequency (f)**	**Percentage (%)**
Female	214	71.3
Male	86	28.7
Health Center	**Frequency (f)**	**Percentage (%)**
CMI Rímac	35	11.7
Caquetá	35	11.7
Flor de Amancaes	35	11.7
Leoncio Prado	34	11.3

San Juan de Amancaes	34	11.3
Mariscal Castilla	34	11.3
Ciudad y Campo	34	11.3
Villa los Ángeles	34	11.3
Piedra Liza	25	8.3
Degree of Study	**Frequency (f)**	**Percentage (%)**
No studies	2	0.7
Primary Incomplete	2	0.7
Primary Complete	4	1.3
High School Incomplete	18	6.0
High School Complete	91	30.3
University study Incomplete	41	13.7
University study Complete	142	47.3
Marital Status	**Frequency (f)**	**Percentage (%)**
Single	121	40.3
Cohabitant	87	29.0
Married	65	21.7
Separated	7	2.3
Divorced	6	2.0
Widowed	14	4.7
Type of Family	**Frequency (f)**	**Percentage (%)**
Nuclear	111	37.0
Single parent	36	12.0
Extended	71	23.7
Expanded	40	13.3
Reconstituted	7	2.3
Equivalent	9	3.0
Single Person	26	8.7
Mental health disorder	**Frequency (f)**	**Percentage (%)**
Depression	3	1.0
Family violence	3	1.0
Not have	294	98.0

Table 1 considers the socio-demographic data regarding the sex of the participants, most of the surveyed sample, equivalent to 71.3%, is female. There are nine health centers in North Lima that were part of the study, which between 34 and 35 patients (11.7% and 11.3% respectively) for each health center made up the study sample, except for Piedra Liza Center, which had 25 patients (8.3%). Likewise, the data of the surveyed sample (47.3%) has completed higher education, followed as a percentage of those with complete secondary education (30.3%). Regarding marital status, most respondents (40.3%) were "single". In a similar way, 37% of the surveyed patients denied having a mental health disorder.

Figure 3 considers the history of diabetes, which the risk is considered considering direct affinity, in which 108 patients are observed, representing 36% have no history, that is, relatives with a diagnosis of diabetes, followed by 104 patients representing 34.7% consider that there is a history of diabetes (grandparents, aunt, uncle, cousin, brother) and lastly 88 patients representing 29.3% consider that there is a history of diabetes (parents, siblings, children), they consider the line Transmissible with higher prevalence.

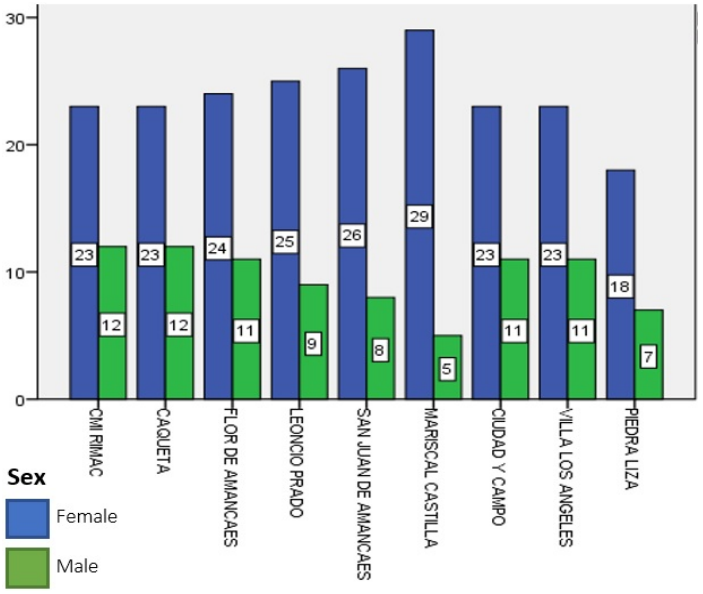

Figure 3: History of diabetes mellitus in outpatients attended in different health centers of a district of North Lima - 2019 (N = 300)

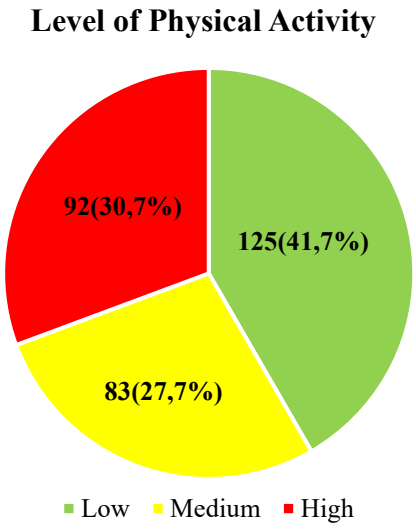

Figure 4: Patients surveyed who perform physical activity, cared for in the establishments of a District of North Lima - 2019 (n=300)

In Figure 4 regarding the level of physical activity, it is observed that 92 (30,7%) of the patients present a high level of physical activity, 83 (27,7%) a medium level of physical activity and 125 (41,7%) low level of physical activity.

In Figure 5 regarding the risk of type 2 diabetes mellitus, it is observed that 79 (26,3%) of the patients present a low risk, 113 (27,7%) present a slightly high risk, 46 (15,3%) present a moderate risk, 52 (17,3%) present a high risk and 10 (3,3%) of the patients present an extremely high risk.

Table 2: Relationship between the Risk of type 2 diabetes mellitus and Level of physical activity in outpatients attended in health centers of a district of North Lima, 2019 (n = 300) based on the Pearson's Chi-square statistical test (X^2)

			Level of physical activity			Total
			Low	Moderate	High	
Risk of type 2 diabetes mellitus	Low	Count	30	27	22	79
		% of total	10,0%	9,0%	7,3%	26,3%
	Slightly high	Count	55	28	30	113
		% of total	18,3%	9,3%	10,0%	37,7%
	Moderate	Count	17	10	19	46
		% of total	5,7%	3,3%	6,3%	15,3%
	High	Count	19	17	16	52
		% of total	6,3%	5,7%	5,3%	17,3%
	Very High	Count	4	1	5	10
		% of total	1,3%	0,3%	1,7%	3,3%
Total		Count	125	83	92	300
		% of total	41,7%	27,7%	30,7%	100,0%

Chi-square tests	Value	gl	Sig. (p)
	9,653	8	0,290

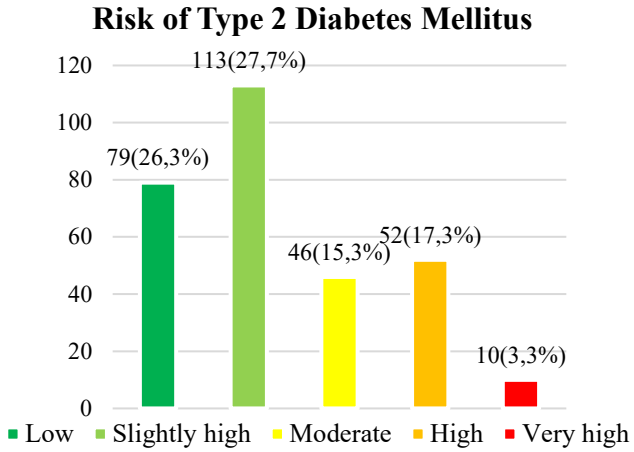

Figure 5: Risk of type 2 diabetes mellitus in patients treated in establishments in a District of North Lima - 2019 (n = 300)

Table 2 shows the relationship between risk of type 2 diabetes mellitus and level of physical activity in outpatients treated in health centers in a district of North Lima, where the significance value of the chi-square test is of 0,290 (p> 0.05) (X^2 = 9,653; g.l. = 8), therefore, there is insufficient evidence to deny the dissociation hypothesis. Given the above, it is concluded that there is no significant relationship between the risk of type 2 diabetes and physical activity in outpatients in health facilities in a district of northern Lima, 2019 with a confidence level of 0,05 (95%).

The importance of obtaining data allows us to identify the relationship between physical activity and the risk of T2DM and which factors are risk factors, which we can carry out prevention strategies that allow maintaining the well-being of the person, also serves for future research with studies that allow evaluating the relationship between physical activity and risk of T2DM in which they can look for the effectiveness of the strategies applied in this research work.

4. Discussion

For the present research work, the focus was given to the patient on their physical health, although we can affirm that the risk of having type 2 diabetes mellitus today is one of the problems in our country due to the sedentary lifestyle that people present due to physical inactivity.

In the results on the level of physical activity, the patients present a low level of physical activity 125 (41,7%), this is since the patients have an inappropriate lifestyle, where sedentary lifestyle is the first factor present when physical activities are not performed, therefore patients tend to have an increased risk of non-communicable diseases that can compromise their health throughout their lives. In [15], the author argues that sedentary lifestyle is a predisposing factor for metabolic diseases where long hours spent at a computer, being on the phone and the eating of fast-food foods that provides a high caloric index, that is not waste by not performing any physical activity, compromises the health of the person generating health problems.

In the risk results for T2DM, patients present a slight risk of having this disease 113 (27,7%), this is since the prevalence of morbidity for contracting T2DM is increasingly considered higher, because people nowadays they manage an inadequate lifestyle, a poor diet, diminished family activities, also family history, where the person who has a relative with this disease if it does not have

an adequate lifestyle can develop the disease. Therefore, adopting prevention and control strategies will reduce the risk of contracting T2DM. In [16], the author argue that family history of diabetes risk tends to increase the degree of susceptibility to the disease and that it is not possible to modify it, but also changes in the lifestyle of the person as a preventive measure by modifying food consumption, increasing physical activity and reducing body weight, are actions that allow the person to increase the benefits in their own health, ensuring well-being and trying to maintain a healthy life. Likewise, in [17], they argue that the self-care that patients with diabetes mellitus should exercise in themselves is important because it is related to the actions that each person take for their own benefit of their health including physical activity, proper nutrition, and self-control.

5. Conclusion

It is concluded that the population should be educated about the importance of increasing physical activity and of a healthy lifestyle where the well-being of health in the person is balanced.

It is concluded that nutritional counseling should be provided when making home visits to patients with diabetes mellitus.

It is concluded that the strengthening and control of prevention programs in primary care related to chronic diseases, including type 2 diabetes mellitus, should be considered.

It is concluded that preventive actions should be taken in the patient with diabetes mellitus such as a healthy lifestyle, a diet program that suits the patient and physical activity.

The main limitations in this research is the understanding that patients had about filling out the surveys, also, the time they had to fill out the surveys was also limited because the patients were waiting to be attended in the health centers and some did not want to fill out the survey; most of the patients voluntarily agreed to participate in the research work to find out if they had any risk of contracting T2DM.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Automatic Dependent Surveillance-Broadcast (ADS-B) is the future of aviation. It is a vast system that provides situational awareness for the aviator and regulator at a very low cost and does so with the aid of multiple disparate systems working closely together and communicating with one another. ADS-B uses the Global Navigation Satellite System (GNSS/ GPS) to locate elements. Weather information and ground-based information is also transmitted wirelessly. The system is designed to be open, unencrypted, and accessible to actors throughout the world. However, this leaves it open to attacks. The use of GNSS and other wireless technologies also carries over their security vulnerabilities into ADS-B. Certain issues have arisen due to both component-system failures and malicious attacks. Most obvious solutions impinge on the openness and transparency of the system. Past research has indicated that security must be built into a system design itself and cannot be retrofitted. We want to showcase such a design process for ADS-B. Our pathway to do so is to first create Universal Modeling Language (UML) diagrams to showcase security and safety issues and responses. These UML diagrams will then help us to model state and sequence diagrams. These will then be used to create a TLA+ model of one selected security methodology. We then run the TLC model checking on it to find loopholes and plug gaps in our scheme. We managed to create such models and prove deadlock-free running using only software tools. Our eventual goal is to develop a comprehensive formal specification for ADS-B model-creation and checking.

1. Introduction

This paper is an extension of work originally presented at the 2019 IEEE 62nd International Midwest Symposium on Circuits and Systems (MWSCAS), Dallas, TX, USA [1].

Under the 2020 ADS-B mandate [2, 3], the FAA has designated that all commercial traffic and most private traffic must make itself compatible with ADS-B by hardware and software upgrades by the date of January 1. 2020.

ADS-B will replace 'hard' sites like primary/secondary surveillance radar (PSR/SSR) stations with satellite-based GNSS. The onus to report position is now on the aircraft. Frequencies of 1090 MHz and 978 MHz will be used for the actual information transmission. Aircraft will also beam down velocity, altitude, and a host of other data. In exchange, weather data will be beamed up to them. Aircraft will share position information with each other as well, to prevent conflicts.

ADS-B is a lot more economical than the current system. In 2007 the cost to monitor 200 nautical miles of air space was estimated to be $10-14 million using PSR, $6 million using SSR, and $380,000 for ADS-B [4]. Cost savings occur due to not having to set up and maintain expensive PSR/SSR RADAR stations plus increased coverage of formerly 'RADAR-dark' areas, resulting in more safety dividends, among other advantages.

The cost factor makes the choice look easy, but the security and safety weaknesses of ADS-B present a conundrum. Security issues are noted in [5-7], and an example of a deliberate system shutdown is given in [8].

Any attempts to gatekeep ADS-B go against its ethos. Security thus becomes a challenge. Attempts are now being made to introduce security measures into an already deployed ADS-B. But in [9], the authors have postulated that security must be considered at the design phase itself and any attempts to fit it in later will result in underestimation of the system capacity required to run security.

The scope of ADS-B is not restricted to 1090/978 MHz. In [10], the authors talk about a future where the Internet Protocol is the communications backbone for this system, even for voice

* Corresponding Author: Pranay Bhardwaj, Email: bhardwpy@mail.uc.edu

communication for aircraft flying. The radio has not been the sole point of communication for an aircraft for a long time. Now component subsystems of an aircraft independently 'talk' to maintenance and route planning departments of the operator via Aircraft Communications Addressing and Reporting System [11]. IP is also slated to take this communication load.

Following [9], the goal of this research is to rethink the ADS-B system design from a security viewpoint. We want to show what models such a hypothetical design process could have made, and what tools they could have used. A similar methodology is adopted by the authors in [12]. Here we are not recommending specific solutions for the numerous safety and security problems, nor are we devising a way to 'fix' ADS-B as it exists. We want to model how the different subsystems that makeup ADS-B interact with each other when under attack.

Our methodology is to pick a particular attack, pick specific solutions to that attack, and then first model the attack and response using use case diagrams. These will be used to create state and sequence diagrams to give a step-by-step description of the security response process to that attack. Once the sequence of events is clear, we can develop a TLA+ model of our system and run it through the TLC model checker to see if there are any deadlocks or failure points.

The specific attack scenarios and response tools are not ours, nor do we want to create any. We just want to observe how these response tools would look if they were all designed into the system, rather than retrofitted and to see if their in-built design into the system will cause any problems with any other system.

To put it simply, we do not want a situation where, for example, a cyberattack is successfully stopped by the security system but with an unintended result that airplanes are left without GNSS coverage. This could happen if the inter-relationships of competing cybersecurity tools are not well- understood at design time. We want to showcase that our methodology can be followed to model all of ADS-B, and perhaps other large systems in this manner at a low cost to spot deadlocks and bugs early in the design process.

So why do we want to use UML?

In [13], the author has used UML, the Unified Modeling Language [14], to model the Controller Area Network Bus (CANBUS). It has also been used to create security parameters [15,16]. UML focuses on whole 'objects' and each component may be a whole system unto itself. Thus hardware, software, and cyber-physical systems can all be modeled in UML.

Looking from a very high level, we can visualize the ADS-B as similar to the CANBUS. Both are unencrypted, both have various 'nodes' in the system, both rely on messages, both use broadcast protocols and both have no 'central brain.' Finally, security was not a consideration in the original design of either.

In ADS-B, the 'nodes' are the aircraft, the GNSS is a 'sensor' and the bus itself could be the pathways of the 978/1080 MHz frequencies. This is quite an interesting comparison and can be made between ADS-B and many other systems of various sizes and scales.

If ADS-B analogies can be found with the CANBUS, then methodologies to secure the CANBUS can theoretically also be proposed for ADS-B. As in [13], we will begin by modeling selected security techniques in UML and create use case diagrams.

Aviation is a heavily regulated sector and the basic requirement in all these systems↓ operational and security↓ is that they all work well together. Thus, the early introduction of security into the design is necessary because a late addition may introduce unintended security flaws. That is exactly the model we suggest in this paper- a redesigned system that does not stray too much from the current design and does not require major changes in protocol or infrastructure.

Our inspiration to use TLA+ is to get a workable model of how a potential 'built-in security' ADS-B system will look and behave. If successful, we will also be able to spot any failure points or illegal states in our models.

We envision that our paper can be used as a guidebook to model any discrete distributed system and test it for security loopholes at a very low cost. This will lead to the introduction of formal methods in civil aviation cybersecurity.

Formal methods have been used for many years in modeling localized systems [17], and we believe large systems consisting of geographically discrete subsystems can also be modeled this way. ADS-B uses independent systems for position, weather, and collision avoidance↓and each one of these is important to ensuring security and safety.

Our end goal is to create an overall super-design of the ADS-B system incorporating all the different security measures we talked about. In the future, we will attempt to create state and sequence charts for all of ADS-B. We will seek to validate the TLA+ based model checking and formal methods for complete ADS-B design.

In section 2, we discuss some weaknesses of ADS-B security and some well-known attacks. We then do the same for its largest sub-system, GNSS in section 3. In section 4 we create UML use-case diagrams to show how some selected methods can protect us from a cyberattack, and we also look at many other methods specified in the literature and select some for the next stage. In Section 5, we create a state diagram and sequence diagram of how ADS-B could respond to an attack using tools described in section 4. This is not a general view↓ just a specific attack scenario↓ and it feeds into the next section. In section 6, we will finally convert the state diagram to an actual TLA+ text specification/model. We will run it through the TLC model checker in section 6.1 to look for deadlocks and failures. We will then suggest how to apply our method more broadly to deal with the safety and security issues we have identified for the ADS-B system in the concluding remarks and the future work described in section 7.

2. Major Weaknesses of ADS-B

Because of its accessible design, ADS-B is missing even minimal security features [5]. This makes attacking easy and defense complicated. Some overarching vulnerabilities are:

- Physical layer: The 1090 MHz channel used for commercial aircraft ADS-B is severely congested, with up to 50% message loss rate measured at 174 miles [5]. This will only get worse with time, and we are in a very early phase yet.
- Unencrypted: Because ADS-B is unencrypted, the positions of aircraft can be tracked by anyone with homemade equipment and a free open-source application like flightradar24.com (FR24). Eavesdropping is the first step for many attacks [5]. FR24 details a step-by-step guide to making an ADS-B 'snooper' and getting real-time aircraft identification, position, and performance data.
- Unauthenticated: ADS-B has no authentication on messages↓no signatures, no handshake protocol. Aircraft identifiers, like the 24-bit ICAO code, are publicly available in a platform like FR24. Thus, there is no way to identify the source of a message [3]. If the constraint of powerful transmission equipment is fulfilled, a well-funded actor can theoretically beam fake data about an existing contact, or a fake contact itself, to air traffic control. Even worse, it can remove data as well.

Some common attacks that can happen in the above environment are:

- Ghost contacts: Two works on cybersecurity [18,19] mention the possibility of fake, or 'ghost' targets in the system. An attacker could use the openness of the system to download authentic aircraft data and then broadcast it over the frequency with sufficient power. This would appear as a legitimate contact on the ATCS screen. Without confirmation of GPS position, it would be impossible to catch such an attack. An example that combined eavesdropping with ghost injection is described. The appearance of multiple ghost aircraft can cause system and sensory overload and can cause pilots and ATC to make dangerous decisions [6].
- Hybrid attacks: Hybrids of various attacks can be made. In [6], the authors talk about an attack that 'deletes' legitimate data from the system and injects false data in its place.
- Legacy systems: It is not uncommon to find aircraft flying today that are 20-30 years old or more. This is especially true in developing countries, cargo airlines, and various armed forces. Legacy aircraft systems were not designed with an interconnected super system like the ADS-B in mind. In the past, each aircraft was an independent entity. Legacy systems have always been a security challenge when hooked up to large networks. A determined adversary with ample support↓like a state-backed actor↓can overcome all compatibility and air gap barriers to infect an 'old' system with a 'new' bug, as was seen in [20].
- Physical access: Physical isolation or 'air- gapping' that ensured the protection of many systems before will cease to exist. In the past, the output of a PSR/SSR was inaccessible to the public. Now, the detection system, position system, and the results therein are all readable on a home computer in real-time. Physical isolation of infrastructure has given way to an open, unencrypted, unauthenticated setup.

Risks of GNSS Use in Aviation

- Survivability: As of today, four nations possess the capability to destroy satellites in orbit the USA, Russia, the PRC, and India [21]. These 4 nations have also all developed their own global or regional GNSS (GPS, GLONASS, BEIDOU, NAVIC respectively). All these nations have also militarized their GNSS systems↓to guide bombs, missiles, warplanes, naval vessels [22] and even to plan large-formation land maneuvers↓as was seen in the 1990 gulf war. Law enforcement and coast guarding also use GNSS. However, this also makes the GNSS a ripe target in the event of great power warfare. Knocking out GNSS satellites using anti-satellite (ASAT) missiles could lead to a mass blackout of ADS-B position reporting for all countries. This could have disastrous unintended consequences for civil aviation within seconds. In a future PSR/SSR-less world, this could mean crippling the global flight infrastructure. Although the probability of this is low, the authors find this to be one of the most disturbing eventualities.
- Deliberate shutdown: Like any other large system, GNSS may be on reduced performance from time to time, as noted, e.g., in [23]. Besides, deliberate shutdowns may be conducted for various purposes, like military training. The degraded signal quality sent an aircraft into high-speed oscillations in 2016 [24]. As the dependence of aircraft on GNSS grows, any shutdown or breakdown will become a safety issue for civilian aircraft. Dependence of autopilot systems on GNSS to navigate means aircraft could go into abnormal flight regimes without even alerting the crew if a sudden 'quiet death' of GNSS occurred locally during normal flight.
- Jamming and spoofing: GNSS is a satellite-based wireless system, and like every wireless system ever made, GNSS is susceptible to jamming of signals and spoofing↓incorrect location reporting. The Russian Federation has already demonstrated a GNSS spoofing/ jamming capability precise enough to make a single human difficult to locate [25]. It can be devastating for unsuspecting civilian aircraft in an ADS-B based system and could very well be the model of a terror attack.

3. Use Case Diagrams for ADS-B Security

For such a large and distributed system as ADS-B, it must be understood that no single solution exists. In [7], the authors tested the viability of many solutions and found none without a loophole. This is a glaring after-effect of not keeping security paramount in the design process. Of course, we cannot talk about a cybersecurity model without talking about the actual 'weapons' that will make it possible. We will now make UML diagrams of how the various cybersecurity tools we are familiar with could be deployed, in isolation or in combination, to ensure protection. Figure 1 provides the convention we use in the use case diagrams that follow.

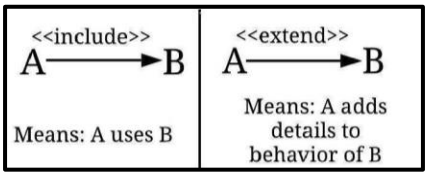

Figure 1: Convention for use case diagrams

In Figure 2, multilateration uses the time delay of signal arrival at multiple (>2) points to estimate the location of the transmitter [7]. Time Delay of Arrival (TDOA) of the signal is

calculated with the use of time stamps stamped on any message. Comparison of timestamps of transmission and reception gives a rough idea of the travel time, from which a rough distance can be calculated. If used at 3 receivers, a close X-Y-Z coordinate can be back-calculated. This is not very different from the SONAR equation.

If this back-calculated position is reasonably close to the reported GNSS coordinate of the transmitter, the allegiance of the message sender can be confirmed. Multilateration can be used to combat ghost aircraft, message modification, and man-in-the-middle attacks, and can provide a backup to GNSS breakdown in the absence of PSR.

Figure 3 is the most important here as it was the most complex one in our original paper. We have thus chosen to extend this diagram to the state diagram, sequence diagram, and later, to the TLA+ specification.

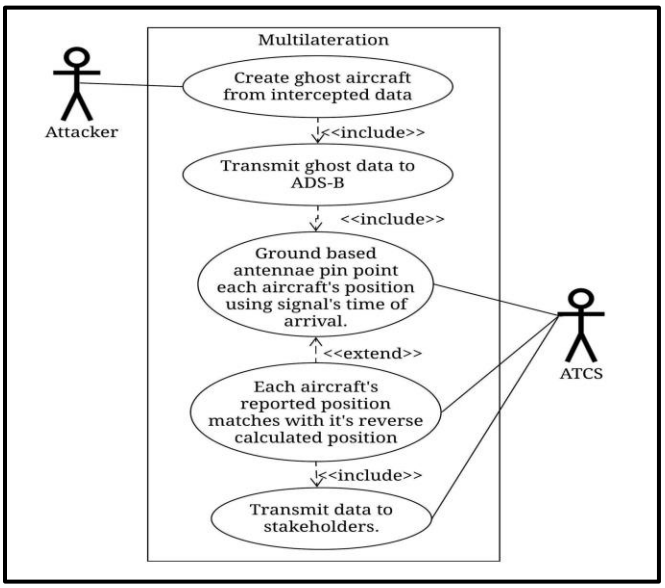

Figure 2: Multilateration and group verification can protect against ghost aircraft injections by matching the physical source of the signal to its reported one.

One of the weaknesses of using static ground posts as receivers for multilateration is that the system may be fooled by the attacker. If the location of these ground antennas is known, the attacker can tailor his transmission time stamps to present a 'false but accurate' picture to the multilateration-systems. A solution to this is to use dynamic receiver posts↓make the other, trusted aircraft in the airspace as multilateration, or triangulation points themselves!

Figure 3 shows multi-point multilateration. Group verification [7] is a kind of multilateration performed in the air. Aircraft already multilaterate each other using TDOA↓it is exactly how the Traffic Collision Avoidance System (TCAS) works. The equipment and algorithms are thus available on board already, and this is in line with our philosophy to cause minimal modification.

Each aircraft locates each member using TDOA of received ADS-B IN signals and estimates the others' positions. If the calculated position differs from the reported one, a 'suspect' airframe is identified, and group members move away from it. This can be successful only when 100% implementation of ADS-B is achieved. Location fixes from different sources are independent of GNSS. The fusion of this data can be an alternate method to locate aircraft. This will counter GNSS spoofing and GNSS jamming attacks.

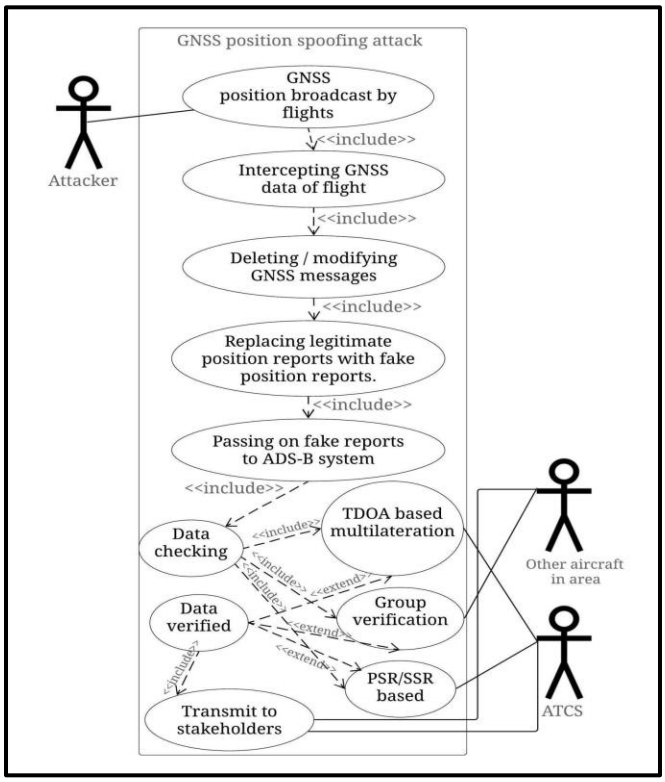

Figure 3: Multilateration may help with GNSS spoofing and unreliable position reports.

Other issues and solutions we will use in our overall model:

- Authentication of messages can be used to identify which messages are from what source. Authentication just confirms that the message is from who you think it to be. This directly allows us to trust or not trust it. Authentication of messages is the closest we come to a silver bullet solution for ADS-B as a single tool protects us from multiple issues↓Denial-of-Service (DOS) attacks and ghost aircraft attacks, just for starters. DOS attacks on airport or airline infrastructure are of concern as these are cheap to wage.
- Kalman filtering has many applications↓the ADS-B system can be 'taught' the typically correct values of airplane parameters [7]. According to their capabilities, scheduling, and operators, most aircraft will fly within a certain envelope of speed, heading, and locations usually. The Kalman filter can be rewarded whenever correct values are noticed, and not when unusual values are noticed. This will protect against ghost injection attacks and false data messages. The system will sense the departure from usual data trends and raise an alarm. If data trends change, it can be fed the new data trend and 'taught' any updates to the system this way. The only disadvantage is that the system is equally likely to be taught the 'wrong' way and thus become a 'bad child.'
- Hardware and software fingerprinting [26] have great potential to introduce economical authentication capability

without making major hardware or software changes. The authors in [26] provide a simple solution to 'fingerprint' the transmitters themselves. Every transmitter in the world is unique, just as every crystal is unique. Individual aircraft-borne ADS-B transmitters can be 'fingerprinted' either via unique hardware or through software properties. This can positively identify the transmitter and provide authentication.

- ADS-B as RADAR? A unique solution of using the ADS-B signal itself like a radar signal, by adding a random bi-phase modulation is proposed in [27]. This system can track other aircraft even with no GNSS. It can provide the much-needed reliability of radar at the low cost of ADS-B. This can counter issues of the survivability of GNSS. This agrees with [4], which talks of a fusion of GNSS and non- GNSS sources for locating aircraft. However, this will require changes to ADS-B transmitting recruitment and is thus low on our list of options.
- Weather RADAR for aircraft tracking: Weather RADAR is ubiquitous and big and small weather radar stations exist all over a developed country like the US. Since this RADAR can track small cloud formation, moisture, and bird/ locust flocks, can it be used to detect hard-skinned objects like airplane skin? Some research has been conducted in the use of weather RADAR to track aircraft and we believe that if it is properly developed, it can act as an emergency backup in the case of a major GNSS failure. For small general aviation (GA) aircraft at least, a method is suggested in [28]. This method can distinguish between small aircraft and large birds based on pressure waves created by aircraft propellers. In [29], the authors managed to detect aircraft with weather RADAR using some signal processing. More than 90% of aircraft in the USA are GA and most of these are propeller equipped [30]. Thus, a solution for GA aircraft as presented in [28] solves a huge chunk of aircraft tracking issues in case of GNSS blackout.
- Identification can be achieved by building a small ADS-B receiver like the ones FR24 uses, to receive aircraft data. Thus, in the event of a GNSS failure, weather RADAR can track the physical location of GA aircraft while an ADS-B receiver can identify them. One only must ignore the ADS-B location data in such a case. The use of a non-ADS-B source as a redundant backup is in the spirit of [7].
- TESLA protocol for encryption: In [31], the authors suggest a method that encrypts only the 24-bit ICAO aircraft identifier. It uses Timed Efficient Stream Loss-tolerant Authentication (TESLA) for authentication. It has performed well under testing without reducing security, performance, or affecting any major changes to ADS-B philosophy.

4. TLA+ conversion

TLA+ stands for 'Temporal Logic of Actions' [32]. It is a logical system or toolbox, developed by Leslie Lamport. which allows one to write formal specifications and to include scalable security protocols. The TLA+ specification can then serve as a formal 'model- checker' for any future realization of the ADS-B system and its components. It is not a classical programming 'language.' TLA+ is based on mathematics and uses set theory to model systems. Each system has states, and each state can be defined by a set of certain values. When these values change, so does the state. Any transition (step) is the change of one state to another or a change of one set of values to another set of values.

An entire system can be modeled as a superset of all possible state sets. We do not go too deep into the specifics of each state↓we are more concerned with the what rather than the how. Thus, abstraction and conciseness are a very important skill to master before modeling the system in TLA+. While economics and computer overhead would be major factors in practical systems design, we drop them when dealing with TLA+.

As a testimonial of its effectiveness, the application of TLA+ by Amazon revealed it to be excellent for bug detection [33,34]. Microsoft also used it to verify the design of a subsystem of the Alpha 21364 Microprocessor [17].

Our work here can be viewed as a guide on how to design large systems in the future↓by comparative analysis and extensive model-driven design.

ADS-B has many subsystems that make up the whole. GNSS is responsible for position reporting to aircraft. Aircraft then report their position to air traffic control.

Aircraft get weather and aerodrome information, and share position reposts with each other for collision avoidance. All this communication happens over the 978/1090 MHz spectrum. So not only are there several independent operations but also there are independent failure points. All these systems must be a part of any formal method examination of the ADS-B system. The specific solutions for responding to attack are not our own↓they are specified in section 4. What we are doing is modeling a security solution for the ADS-B system that will have safety and security included by design, and suggesting a procedure to design such a system and simulate it.

Several works on smart systems in TLA+ have been researched. In [35], the authors design a smart school system in TLA+. In [36], the authors model a sewerage system in UML and TLA+.

The authors in [35] start by making a UML specification, a sequence diagram, and a state diagram. These diagrams aid in making the sequence of events clear. The system's pathways, legal and illegal actions, and outcomes are modeled.

4.1. Why do we make sequence and state diagrams?

TLA+ defines every system as a sum of all the states it can exist in. A system can have multiple states, and there will be a defined 'step', or a sequence of events, to go from one state to another. Thus, we first develop a sequence diagram, which shows all the steps between states, and a state diagram which shows the states themselves. Only then can we draw a true TLA+ model.

Let us take the below example of applying methodologies of [35] and [36] to the ghost aircraft and GNSS spoofing issues as noted in Figure 3.

4.2. ADS-B response to Ghost aircraft and GNSS spoofing

In sections 2 and 4, we talked about security issues caused if an aircraft is either a fake contact or is reporting untruthful position information about itself to ADS-B, via GNSS spoofing. Since ADS-B envisions doing away with PSR/SSR, we had

examined some other backup systems that can physically locate an aircraft if GNSS reports are unreliable. The UML diagram for this was Figure 3. Let us now look at a sequence diagram for the situation, in Figure 4.

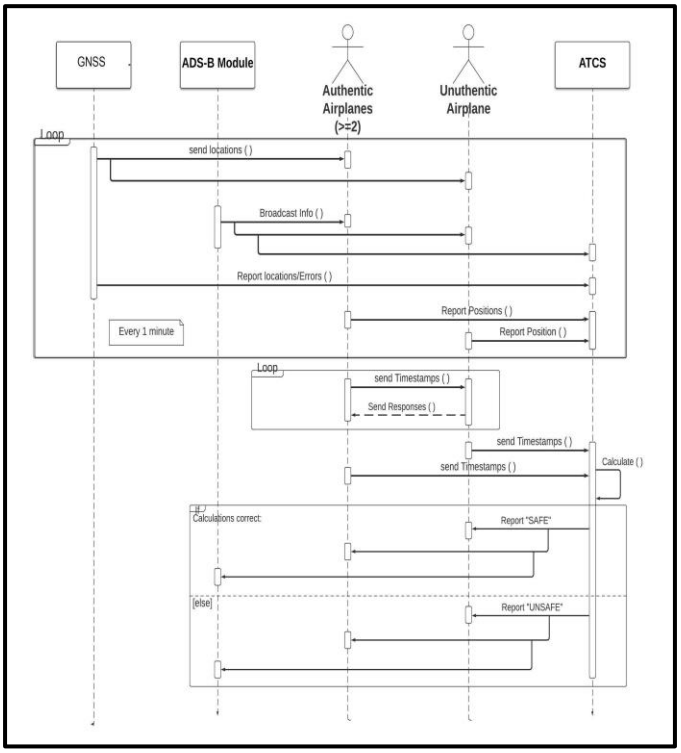

Figure 4: Sequence diagram: Reverse calculation of the aircraft's true position can be done using time-delay analysis of transmitted signals

GNSS reports aircraft position to airplanes, which includes both the 'good' and 'bad' airplane. All aircraft will then report their position to ATCS. A time delay analysis of the signals from all aircraft will be performed, and this will be used to get a location fix of the aircraft in physical space. Aircraft will also be able to perform multilateration and triangulation on each other in airspace↓within a '4-ship-cell' for example↓and get location fixes for each other's locations.

A comparison of the back-calculated position data with the GNSS reported position data will point out which contacts are reporting true data and which are not. Thus, aircraft can be labeled 'SAFE' or 'UNSAFE.' This information can then be provided to other aircraft in the area, and ATCS. Note here that 'ADS-B' stands for the system, but practically it may mean a supervisory body, like the FAA Technical Operations Services, or any other service which needs to be notified of security incidents. Let us now look at a state diagram of the same function in Figure 5.

This specifies an interval of 1 minute after which the whole cycle is repeated. This is arbitrary and will practically be a decision governed by radio traffic and economic factors. Since aircraft move fast and move in all 3 dimensions, this interval cannot be too long. Also, when we say 'ATCS', we mean a local or regional airspace manager. We do not envision a global central ATCS system in this paper.

Let us now use the 3 inputs, Figures 3,4, and 5 to start making the TLA+ formal specification for the above response.

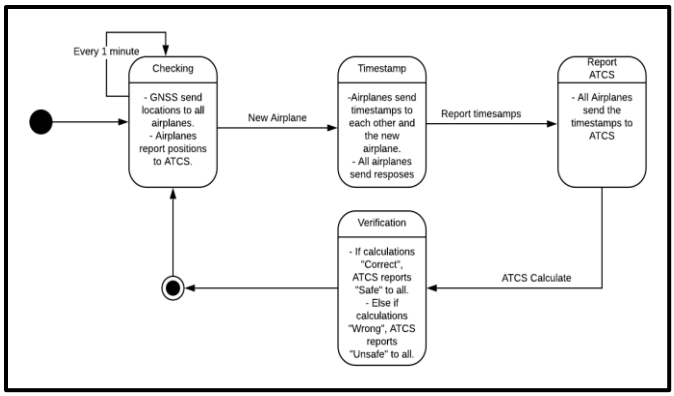

Figure 5: State Diagram of the system under Figure 4 conditions.

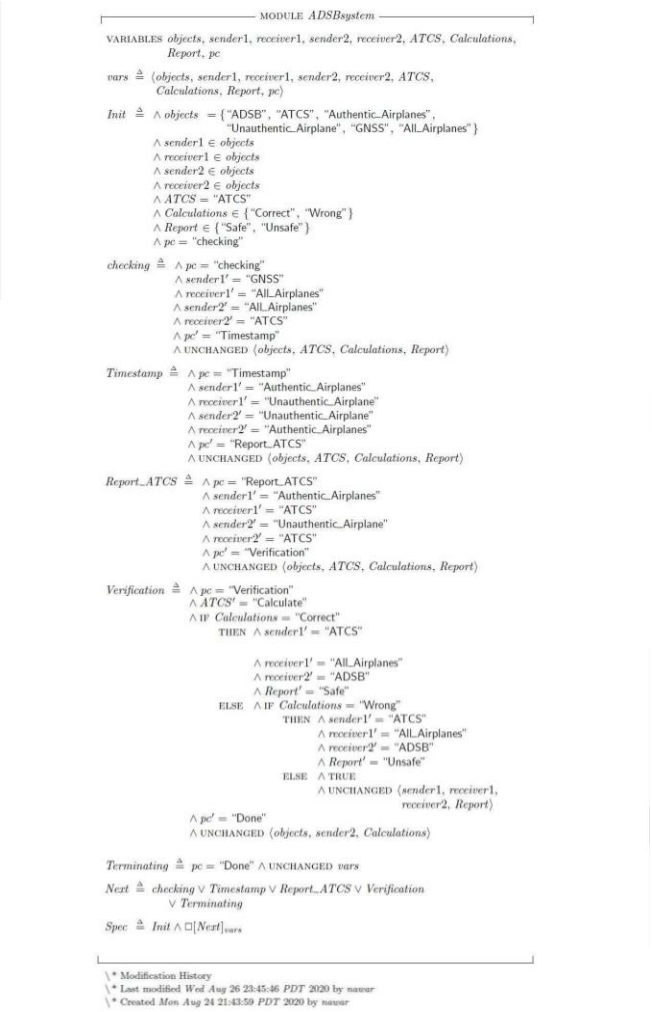
5. TLA+ Specification

We present now, the TLA+ specification for the attack response model sequenced in Figure 4 and stated in Figure 5. A block by block explanation follows.



MODULE *ADSBsystem*

VARIABLES *objects*, *sender1*, *receiver1*, *sender2*, *receiver2*, *ATCS*, *Calculations*, *Report*, *pc*

$vars \triangleq \langle objects, sender1, receiver1, sender2, receiver2, ATCS, Calculations, Report, pc \rangle$

$Init \triangleq \land objects = \{\text{"ADSB"}, \text{"ATCS"}, \text{"Authentic_Airplanes"}, \text{"Unauthentic_Airplane"}, \text{"GNSS"}, \text{"All_Airplanes"}\}$
$\land sender1 \in objects$
$\land receiver1 \in objects$
$\land sender2 \in objects$
$\land receiver2 \in objects$
$\land ATCS = \text{"ATCS"}$
$\land Calculations \in \{\text{"Correct"}, \text{"Wrong"}\}$
$\land Report \in \{\text{"Safe"}, \text{"Unsafe"}\}$
$\land pc = \text{"checking"}$

$checking \triangleq \land pc = \text{"checking"}$
$\land sender1' = \text{"GNSS"}$
$\land receiver1' = \text{"All_Airplanes"}$
$\land sender2' = \text{"All_Airplanes"}$
$\land receiver2' = \text{"ATCS"}$
$\land pc' = \text{"Timestamp"}$
$\land \text{UNCHANGED } \langle objects, ATCS, Calculations, Report \rangle$

$Timestamp \triangleq \land pc = \text{"Timestamp"}$
$\land sender1' = \text{"Authentic_Airplanes"}$
$\land receiver1' = \text{"Unauthentic_Airplane"}$
$\land sender2' = \text{"Unauthentic_Airplane"}$
$\land receiver2' = \text{"Authentic_Airplanes"}$
$\land pc' = \text{"Report_ATCS"}$
$\land \text{UNCHANGED } \langle objects, ATCS, Calculations, Report \rangle$

$Report_ATCS \triangleq \land pc = \text{"Report_ATCS"}$
$\land sender1' = \text{"Authentic_Airplanes"}$
$\land receiver1' = \text{"ATCS"}$
$\land sender2' = \text{"Unauthentic_Airplane"}$
$\land receiver2' = \text{"ATCS"}$
$\land pc' = \text{"Verification"}$
$\land \text{UNCHANGED } \langle objects, ATCS, Calculations, Report \rangle$

$Verification \triangleq \land pc = \text{"Verification"}$
$\land ATCS' = \text{"Calculate"}$
$\land \text{IF } Calculations = \text{"Correct"}$
$\text{THEN } \land sender1' = \text{"ATCS"}$
$\land receiver1' = \text{"All_Airplanes"}$
$\land receiver2' = \text{"ADSB"}$
$\land Report' = \text{"Safe"}$
$\text{ELSE } \land \text{IF } Calculations = \text{"Wrong"}$
$\text{THEN } \land sender1' = \text{"ATCS"}$
$\land receiver1' = \text{"All_Airplanes"}$
$\land receiver2' = \text{"ADSB"}$
$\land Report' = \text{"Unsafe"}$
$\text{ELSE } \land \text{TRUE}$
$\land \text{UNCHANGED } \langle sender1, receiver1, receiver2, Report \rangle$
$\land pc' = \text{"Done"}$
$\land \text{UNCHANGED } \langle objects, sender2, Calculations \rangle$

$Terminating \triangleq pc = \text{"Done"} \land \text{UNCHANGED } vars$

$Next \triangleq checking \lor Timestamp \lor Report_ATCS \lor Verification \lor Terminating$

$Spec \triangleq Init \land \Box[Next]_{vars}$

Figure 6: TLA+ model specification in literal form.

In the module, the keyword "VARIABLES" represents the variables in this module where "vars" is the tuple of variables:

<objects, sender1, receiver1, sender2, receiver2, ATCS, Calculations, Report, pc >

In every TLA+ module, there is an "Init" and a "Next" state. In the Init state, the variables get their initial values, while the next state represents all possible states that come next. In this module, the Next state represents:

Next == checking \/ Timestamp \/ Report_ATCS \/ Verification\/ Terminating

This includes 5 different states. The 'Checking' state occurs when the GNSS sends positioning data to all the airplanes, and then all the airplanes report their locations to ATCS.

In the group verification strategy noted in Figure 3, airplanes were using timestamps on exchanged signals to triangulate each other using time delay of transmission. The 'Timestamp' state represents this communication between airplanes. When a new airplane that possibly might be an attacker appears, it must communicate with other authentic airplanes (even if just for TCAS) and exchange timestamps.

In the 'Report_ATCS' state, all airplanes also report to ATCS with timestamps for routine operations↓and these can be used for position verification from a ground point of view.

The system must then enter the 'verification' state when ATCS does the time delay and radio directional calculations on these signals and compares them to the first GNSS location reports received from all airplanes. Based on these calculations the ATCS will identify which airplanes are reporting their position faithfully and which are not. It will then broadcast the result with a safe/unsafe report to everyone in the airspace.

The termination state allows infinite stuttering to prevent deadlock on the termination (when pc = "Done").

The statement:

Spec == Init /\ [][Next]_vars

represents the specification of the whole system, where Init means the starting state and []Next_vars means Next state must be true for the entire behavior with the option of keeping all variables unchanged.

5.1. TLC Result

The TLC model checker is a tool to validate the TLA+ module and check it for any errors. We run the TLC model checker for our TLA+ ADS-B module and it shows that the module is valid with no errors as well as no deadlock. Also, as appears in the figure below, the TLC model checker shows how many times each state was visited in the module, and what values changed to arrive at the next state.

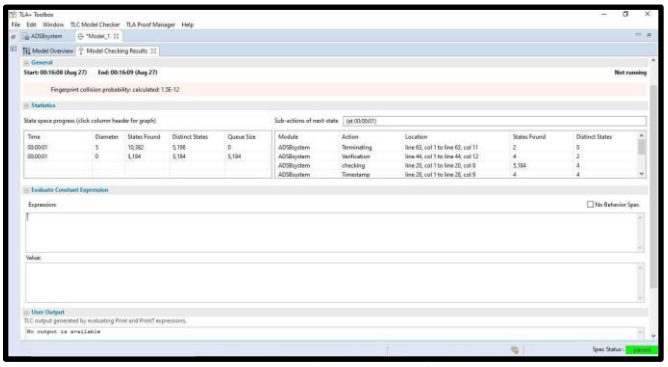

Figure 7: TLC Model check for validity of TLA+ spec in Figure 6.

6. Conclusion and Future Work

At this stage, our model for Figure 3 for verifying physical aircraft locations to combat ghost aircraft and incorrect position reporting issues shows no deadlock. We see that a security system using multilateration and time delay of arrival can identify which aircraft are ghosts and which are not, without getting into a deadlock for resources with the ADS-B system itself.

What this leads us to conclude is that this multi-level modeling of use case-> state diagram-> sequence diagram-> TLA+ specification-> TLC model check can be used to model a large and discrete system like ADS-B to see how it would function and what it would fail at. This is what TLC does it goes through iterations and finds failure points. It throws different numbers at the problem and sees what 'sticks to the wall,' what causes the system to break. We can conclude, at least on this level, that our procedure to model the ADS-B this way and the ability to test the model is valid.

It is always advisable to design security into a system from the beginning of the design process. We hope our method of using UML + state diagrams + sequence diagrams + TLA+ can not only provide the reader with a stable, practical ADS-B model that is secure and realistic but also act as a model of how to design security into other discrete systems in the future.

At the beginning of this paper, we compared the vast ADS-B to a small CANBUS. The roadmap we used here has already been used to formally model smart schools and sewerage systems. When a certain method is successfully used to design various systems of different sizes and scope successfully, it has the potential to develop into a standard. We hope other authors can expand on our work. Our diagrams can be used as an example of how to do this. They also provide a means to examine multiple solutions for strengths, weaknesses, and costs, before any detailed design or implementation takes place.

*6.1. Future work- **An Overall ADS-B** Model in TLA+*

The only weakness of our model is that it is not detailed enough. A true ADS-B system model with all subsystems and security systems and multiple attackers will be much larger in scope. While we model only one attack above, a real-world model will have all attacks and all security systems integrated and will run them in different ways and see when and where two security systems 'collide.'

And that is our future goal.

Following our methodology, the first step towards envisioning the entirety of ADS-B in TLA+ would start with a diagrammatic representation of what we want, as in Figure 8. We believe this will be an extensive task requiring more hands and time than we have right now. We can, however, think about what such a system would look like.

We make some basic assumptions.

No true communication can take place as long as the lines of communication remain unverified. We must find a way to secure the ADS-B physical layer without compromising on openness.

A lot of solutions impinge on trusting information systems like GNSS. Before we trust any data, we must know it came from the right source. Thus, a periodic 'wellness check' on vital infrastructures like transmission systems, radio frequencies, and GNSS should be the second step.

The third step will utilize the data gleaned from steps 1 and 2 to create a model of the system. We would get an idea of how safe or unsafe it is and would be able to deploy mitigation measures accordingly.

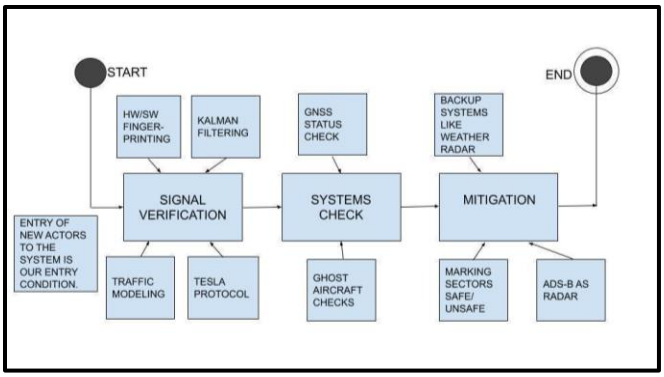

Figure 8: What an overall security solution for ADS-B might look like.

Once again, this would most probably happen on a local level. However, in the spirit of TLA+, we concern ourselves more with the 'what' than the 'how' and do not get too deep into details.

On a higher level, an overall ADS-B specification will consist of multiple figures like Figures 3,4,5, and 6, created for each security challenge, coming together and coalescing into one super-state diagram. This is why we see this paper as a stepping stone to achieving a formally designed ADS-B specification and showing the proper steps to carry out this process.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

All the use case diagrams in section 4 were made using chart-making tools at www.lucidchart.com and the authors would like to thank the website.
The authors would also like to thank Mr. Leslie Lamport for the TLA+ tool which is a fundamental part of this paper.
The authors would also like to thank the University of Cincinnati for its support.

Gas sensors node
Multi-variable environmental mapping

ABSTRACT

Environmental monitoring has gained significant importance in outdoor air quality measurement and assessment for fundamental survival as well as ambient assisted living. In real-time outdoor urban scale, instantaneous air quality index estimation, the electrochemical sensors warm-up time, cross-sensitivity computation-error, geo-location typography, instantaneous capacity or back up time; and energy efficiency are the six major challenges. These challenges lead to real-time gradient anomalies that effect the accuracy and pro-longed lags in air quality index mapping campaigns for state and environmental/meteorological agencies. In this work, a gradient-aware, multi-variable air quality sensing node is proposed with event-triggered sensing based on position, gas magnitudes, and cross-sensitivity interpolation. In this approach, temperature, humidity, pressure, geo-position, photovoltaic power, volatile organic compounds, particulate matter (2.5), ozone, Carbon mono-oxide, Nitrogen dioxide, and Sulphur dioxide are the principle variables. Results have shown that the proposed system optimized the real-time air quality monitoring for the chosen geo-spatial cluster (Qatar University).

1. Introduction

Living conditions or probability of life forms are dependent on environmental conditions, i.e. combination of gases, temperature, humidity, pressure, and light [1]. The quality of respiratory life processes is directly related to air quality at a particular geo-location [2]. Gradual deterioration in urban air quality is ambient each year due to the increasing population, chemical emissions from machinery, and depreciation in green ecology [3]. Air quality sustainability is a major concern in the age of imperialism [4] due to exponential development and construction density in the urban landscape.

An increase of 41% in the design and development of gas and pollutant sensing systems was observed in the environmental market since 2001 [5]. The top contributions AirNut, PA-I and PA-II, Egg, PATS+, and S-500, CairClip, Portable ASLUNG, AirSensEUR, Met One, AQY v0.5, Vaisala AQT410, 2B Tech, and AQMesh V3.0 systems had measurement capabilities in specific pollutants and gases presented in [6–8]. FIS SP-61 by FIS, O3-3E1F by CityTechnology, AirSensEUR v.2 by LiberaIntentio, and S-500 by Aeroqual, and AirSensEUR used a built-in AlphaSense OX-A431 limited to O3 [9–11]. The PMS1003 and PMS3003 by Plantower; DC1100 PRO and DC1700 by Dylos; OPC-N2 by AlphaSense had only sensing support for particulate matter (PM) [11–13]. The CO-3E300 by City Technology; CO-B4 by Alphasense, MICS-4515 by and SGX Sensortech, Smart Citizen Kit by Acrobotic and the RAMP had only abilities to measure carbon mono-oxide [4]. It illuminated the requirement of structure real-time sensor data processing framework for multiple gases sensing nodes with warm-up times below 5mins at ambient outdoor environmental conditions.

The top 10 environmental protection agencies (EPAs) unanimously agreed on the standard of four core gases for outdoor air quality [14] i.e. Ozone, Nitrogen Dioxide, Sulphur Dioxide, Carbon Monoxide, and two prime pollutants particulate matter PM2.5 and PM10. The concentration or ratio of four critical gases and air particles part per million (ppm) constitutes air quality index (AQI) is the fundamental design using Smart Rig [15]. The ratio of

Ozone (O3), Sulphur Dioxide (SO2), Carbon Monoxide (CO), and Nitrogen Dioxide (NO2) are the standard gases discussed in major environmental standards for AQI [4,14,15]. A standard outdoor air quality node (O-AQN) was needed to measure discrete and cumulative AQI with minimum data processing and power consumption.

Related Works

The existing O-AQNs, Urban AirQ, Smart Citizen Kit, SeReNo V1, AirQ Mesh needed improvement in energy efficiency, GPS, time-series vector structuring, and remote data transmission to ensure dynamic air quality mapping [16–20].

1.1. Urban AirQ

The AirQ platform [17] by Vishal et al was a smart and cost-effective solution for air quality monitoring. It supported wireless data communication technologies including WiFi, 4G, Bluetooth, LoRa, etc. It was supported by non-embedded data management and the implementation of smart data analytics algorithms exhibited at an AirQ Dashboard and Smartphone App. It had a dependency on external hardware and software with more processing needs with only air quality sensors.

1.2. Smart Citizen Kit

The Smart Citizen Kit [18] by Gullien et al was dependent on an additional resource named "Smart Citizen Station". Needed improvement in multi-variable time-series measurements and location accuracy, energy efficiency, and reduced data processing. Multi-variable sensing with simultaneous measurement of gases and environmental variables.

1.3. SeReNo V1

The Sensor Node (SeReNo) V1 [19] by Farid et al was the first node developed with indoor air quality monitoring and energy harvesting capabilities. SeReNo V2 presented in this work [20] is the improvement of [19] that needed to be upgraded with GSM and GPS, more Flash to perform AQI data processing needed for optimized energy efficiency, electrochemical gas sensors warm-up times, and outdoor air quality.

1.4. AirQ Mesh

The networked AirQ Mesh [21] by Nuria et al focused on the review and performance of existing AirQ platforms and their maximum utilization leading to credible results by EPA and Air Quality Directive (AQD). Data payloads were very high due to response time estimation errors leading to high storage requirements with energy challenges in the field were the gaps in the Nuria et al contribution.

Furthermore, the improvement potential in context-aware data processing model and thresholding for detection was discussed by Hasan et al in [22,23] for multi-sensor single-board node. The energy efficiency schemes were one major gap highlighted by [24]. The works Lebilium Waspmote [21] was Zigbee but needed GSM/GPRS support for outdoor sensing and have been more contributory if equipped with geo-spatial traces or cadastral layouts support for all the measured variables like AirBox [22]. An infrastructure embedded system was needed to accommodate the maximum sensing, minimum data processing, AQI estimation, and long-haul deployability [19–23].

2. Materials and Methods

This work proposed a smart AQM IoT system with three major components:

- The Real-time Gradient Aware Multi-Variable Sensing Model (GAM)
- The SeReNo V2 AQM Sensing Platform
- Real-time AQI Estimation Engine (AQM-EE)

First, we proposed the GAM and then the pillars of GAM led to the design and fabrication SeReNo V2 node.

3. The Real-time Gradient Aware Multi-Variable Sensing Model (GAM)

A real-time structured multi-variable structured data time-series vector was needed to proceed with AM. Let us consider an EPA standard outdoor air quality index (O-AQI) real-time variables as temperature T in centigrade, pressure P in pascals, humidity H in %, volatile organic compounds as VoC (ppm), particulate matter as PM (ug/m3), Ozone as $O3$ (ppm), Nitrogen Dioxide as $NO2$ (ppm), Carbon Monoxide as $CO2$ (ppm), and Sulphur Dioxide as $SO2$ (ppm). The real-time O-AQI data was proposed as a commutative time series multi-variable vector $V_{O\text{-}AQI}$ of two non-linear time-series with t_1 and t_2 of environmental E and gas G sensors data at a particular geo-location L given as:

$$V_{O\text{-}AQI}(t) = [E(t_1), G(t_2)] : L(t) \quad \text{where } t = (0, 1, 2, 3, \ldots\} \tag{1}$$

The practicality of response time of heterogeneous sensors was taken in account for non-linear time-series decomposition t, gas sensor response time t_2 is greater than the response time of environmental sensors t_1 with relationship $t_2 > t_1$ given as:

$$t_2 = 3t_1 \qquad where\ [t_1, t_2] \in t \tag{2}$$

The environmental sensor variables function E for sensor array $A_E(T, P, H, VoC, PM)$ as $E(A_E, t_1)$; and for gas sensors array $A_G(O3, NO2, SO2, CO)$ as $G(A_G, t_2)$ and position vector L as reference function GPS using GSM network cell locations (using $AT+CIPGSMLOC=1,1$) for L_{GPRS} and GPS module as L_{GPS} (using AT+CGPSINF). For precise AQM the L_{GPS} must belong to the slope of L_{GPRS1} and L_{GPRS2} in a particular slope format by NEMEA specifier for consecutive cells is given as:

$$L_{GPS}(X, Y) \in [L_{GPRS1}(X2, Y2), L_{GPRS2}(X1, Y1)] \tag{3}$$

The agreed L_{GPS} was termed as $L(t)$ where condition (3) was satisfied. From equations (1), (2), and (3) the finalized AQM vector of $V_{O\text{-}AQI}$ was derived as:

$$V_{O\text{-}AQI}(t) = [E(A_E(T, P, H, VoC, PM), t_1), G(A_G(O3, NO2, SO2, CO), t_2)] : L(t) \tag{4}$$

The transmission of this structured AQM vector can be power leeching. Here we introduce a gradient impact vector as a function of warm-up time t_W, cross-sensitivity classifier C_S, geo-location $L(t)$, and energy efficiency E_E. Three bounded value conditions we applied on GAM programmed in the SeReNo V2 firmware:

a) The mandatory system unit to stay on is the power is the micro-controller with power consumption P_M and at sleep mode, it has $P_{M\text{-}SLEEP}$ power with all the critical sensors active only.

b) For E_E the system has to have instantaneous power P_i varying between $P_{M\text{-}SLEEP} < P_i < P_M$.

c) The t_W had to be in the lower section of the curve of P_i. Likewise, at the constant magnitude of vector A_E at t_n and t_{n+1}, the difference cross-sensitivities had to stay constant at a particular $L(t)$.

4. The SeReNo V2 AQM Sensing Platform

A generic multi-variable AQM node consists of an EPA recommended sensors for $V_{O\text{-}AQI}$ based on equation (4), application-specific signal conditioning, power, and communication sections. The block diagram of a generic AQM node is given below in figure 1.

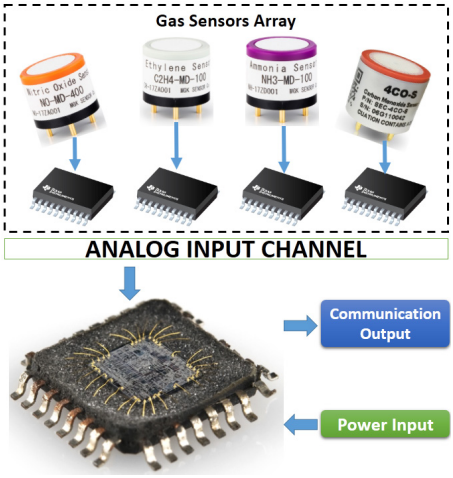

Figure 1: A Generic Multi-Variable AQM Sensing

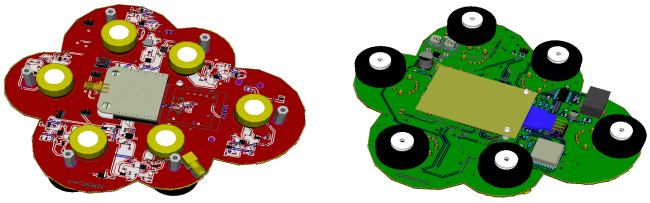
In our previous works [14,15,19,20], we had filled the design gaps in indoor air quality monitoring and developed a multi-sensor AQM node called Sensors V1 revision 1 and revision 2 presented in figure 1. In this work, work proposed a novel O-AQM node by improving the system architecture of SeReNo V1 as SeReNo V2. In our recent work [24] we had developed SeReNo V2 nodes tested for long-haul autonomous operations of 1.5 years that were improved in this work. The existing SeReNoV2 node was improved with GAM and AQI-EE to meet the state of the art needs.



a. Top View b. Bottom View

Figure 2: Two 3D Layouts of SeReNo V1 AQM Node

For outdoor AQM SeReNo V1 was improved to V2 as per global EPAs standards recommended sensors, energy harvesting long-range communication support. The comparison of major capabilities of SeReNo V1 and V2 is exhibited in the table below.

Table 1: SeReNo V1 and V2 Characteristics

Blocks	SeReNo V1	SeReNo V2
Energy Block	PV and Manual Charging + LiPo Battery 3.7V / 1200mAh + 6 Thermo-Electric Generators	Dual PV + Manual Charging
Communication Block	RF 433Mhz	GSM/GPRS
Sensors Block	6 Indoor Sensors Only interfaced with Analog Input	10 Outdoor Sensors Networked with I2C (4 Gas Sensors + 2 Pollutant Sensors + 4 Environmental Sensors)
Environmental Sensors Block	Absent	4 Sensors
Controller Block	RFC200	ATMega328P
Location Block	NIL	GPS
Local Display	NIL	Present
Energy Optimization	Partial	Full
Sensors Control	NIL	Present
Outdoor Cross Sensitivity	NIL	Present

GAM was a core engine driving the multi-sensor O-AQM IoT system. Mathematically modeled design and equations (1~4) parameters are addressed in the hardware blocks. A 1-1 correspondence electronics and instrumentation system was designed SeReNo V2 presented in figure 3 presented below.

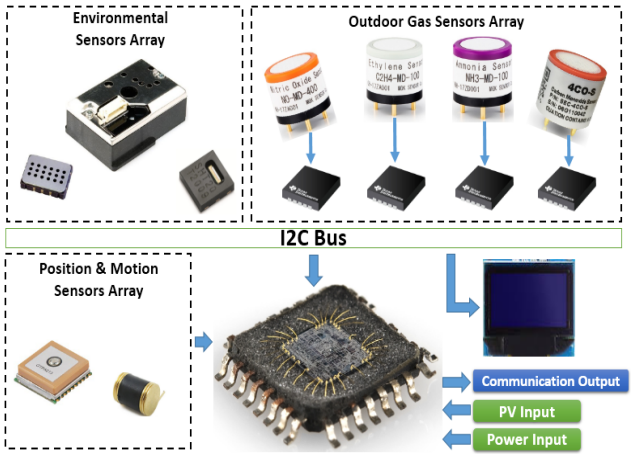


Figure 3: Block Diagram of SeReNo V2 AQM Node

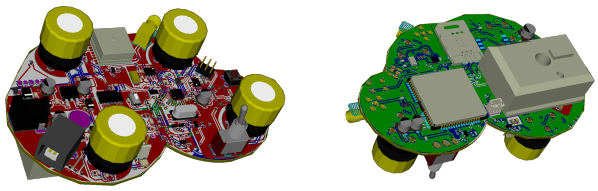
Fig 3 contains three sets of sensors The PCB design and completely assemble functional O-AQM node is presented in figure 4 given below.



a. Top View b. Bottom View

Figure 4: Two 3D Layouts of SeReNo V2 AQM Node

Three SeReNo V2 nodes with GAM and AQI-EE as improved firmware were deployed in QU for outdoor testing. The deployment was focused on the resolution of six key improvements mentioned in the abstract and literature review through proposed GAM and AQI-EE for six months, i.e. QU Greenhouse exhibited in figure 5 below.

Figure 5: SeReNo V2 Deployment in QU to utilize the GAM

This deployment was for six months and all the data was collected from Ubidots IoT platform as CSV files for further processing. The first month was stability assessment of GAM and AQI-EE firmware and the remaining 5 months were the measurement campaign.

5. Real-time AQI Estimation Engine (AQM-EE)

An AQI magnitude is estimated from 5 critical air variables or termed as pollutants, i.e. PM2.5, O3, NO2, SO2, and CO. The critical variable with the maximum AQI magnitude is termed as the "principle pollutant" and entire computation revolves around its significant figures among all the critical air variables. Let I_p be the index of the principal pollutant; C_p as the rounded-off concentration of pollutant p; $B_{P\text{-}high}$ as the breakpoint greater or equal to C_p; $B_{P\text{-}low}$ as the breakpoint less than or equal to C_p; I_{high} is the AQI corresponding to $B_{P\text{-}high}$; I_{low} is the AQI corresponding to $B_{P\text{-}low}$. The AQI is generically estimated as:

$$I_P = [(I_{high} - I_{low})/(B_{P-high} - B_{P-low})] \times (C_P - B_{P-low}) + I_{low} \quad (5)$$

Every pollutant was formulated in using equation (5) and given by in equations (6 to 10).

$$I_{O3} = [(I_{high} - I_{low})/(B_{O3-high} - B_{O3-low})] \times (C_{O3} - B_{O3-low}) + I_{low} \quad (6)$$

$$I_{SO2} = [(I_{high} - I_{low})/(B_{SO2-high} - B_{SO2-low})] \times (C_{SO2} - B_{SO2-low}) + I_{low} \quad (7)$$

$$I_{CO} = [(I_{high} - I_{low})/(B_{CO-high} - B_{CO-low})] \times (C_{CO} - B_{O3-low}) + I_{low} \quad (8)$$

$$I_{NO2} = [(I_{high} - I_{low})/(B_{NO2-high} - B_{NO2-low})] \times (C_{NO2} - B_{NO2-low}) + I_{low} \quad (9)$$

$$I_{PM} = [(I_{high} - I_{low})/(B_{PM-high} - B_{PM-low})] \times (C_{PM} - B_{PM-low}) + I_{low} \quad (10)$$

Furthermore, the standard AQI evaluation template for a specific region provided by EEA as Common Air Quality Index (CAQI) and US EPA as AQI were adapted in this AQM-EE and given as a cumulative state chart given below in figure 6 and 7.

Pollutant	Index level (based on pollutant concentrations in µg/m3)				
	Good	Fair	Moderate	Poor	Very poor
Particles less than 2.5 µm ($PM_{2.5}$)	0-10	10-20	20-25	25-50	50-800
Particles less than 10 µm (PM_{10})	0-20	20-35	35-50	50-100	100-1200
Nitrogen dioxide (NO_2)	0-40	40-100	100-200	200-400	400-1000
Ozone (O_3)	0-80	80-120	120-180	180-240	240-600
Sulphur dioxide (SO_2)	0-100	100-200	200-350	350-500	500-1250

Figure 6: CAQI EEA AQI Cumulative State Chart

The SeReNo V2 was successfully able to give real-time AQI-EE estimations that have plenty of environmental, metrological, and health applications and significance.

Breakpoints							AQI	Category
O_3 (ppm) 8-hour	O_3 (ppm) 8-hour[1]	PM_{10} (µg/m³)	$PM_{2.5}$ (µg/m³)	CO (ppm)	SO_2 (ppm)	NO_2 (ppm)		
0-0.064	–	0-54	0-15.4	0-4.4	0-0.034	(2)	0-50	Good
0.065 0.084	–	55 154	15.5 40.4	4.5 9.4	0.035 0.144	(2)	51 100	Moderate
0.085-0.104	0.125-0.164	155-254	40.5-65.4	9.5-12.4	0.145-0.224	(2)	101-150	Unhealthy for sensitive groups
0.105-0.124	0.165-204	255-354	65.5-150.4	12.5-15.4	0.225-0.304	(2)	151-200	Unhealthy
0.125-0.374 (0.155-0.404)[4]	0.205-0.404	355-424	150.5-250.4	15.5-30.4	0.305-0.604	0.65-1.24	201-300	Very unhealthy
(3)	0.405-504	425-504	250.5-350.4	30.5-40.4	0.605-0.804	1.25-1.64	301-400	Hazardous
(3)	0.505-0.604	505-604	350.5-500.4	40.5-50.4	0.805-1.004	1.65-2.04	401-500	Hazardous

Figure 7: US EPA AQI Cumulative State Chart

The EPA rated sensors produced the results in thresholds of the chart in figure 6.

The AQM-EE uses 5 KPIs to evaluate the performance of GAM given as:

5.1. Energy Efficiency:

The instantaneous energy consumed by node E_N for a minute is the sum of 60 secs for the product of supply voltage V_{DC}, instantaneous current I_i, and time T_i given in equation 11.

$$E_N = \sum_{i=0}^{n} V_{DC} * I_i * T_i \quad (11)$$

The difference between the maximum rated power consumption of node and minimum instantaneous power consumption in terms of watt-hour is termed as energy efficiency or E-Efficiency symbolized as E_e and given by:

$$E_e\ (Wh) \approx \left(\frac{N-M}{N}\right)(E_N) \quad (12)$$

5.2. Cross-Sensitivity Computation Error:

The cross-sensitivity computation error is the average of the total difference in a sensor's reaction to other gases being measured.

$$C_s\ (\%) \approx \left(\sum_{i=0}^{n} \Delta G_i\right)/n \quad (13)$$

It is used as the correction factor and must be in the range defined by the vendor.

5.3. Typo-graphic Error:

The difference in the GPS coordinates by GPS and AGPS was termed as typo-graphic or GPS error, presented in equation below:

$$T_E = |L_{GPS}(X, Y) - L_{AGPS}(X, Y)| \quad (14)$$

The acceptable value for this error was marked as 20 meters for precise AQM.

5.4. The ratio of Magnitude E_{BAT}/E_N or Instantaneous Capacity:

The ratio of instantaneous system battery energy E_{BAT} in watt-hour (Wh) and instantaneous node energy E_N in watt-hour (Wh) was termed the instantaneous capacity magnitude C_{MAG} of the node with current operations given as:

$$C_{MAG} = E_{BAT} / E_N \quad (15)$$

For long haul AQM, the C_{MAG} must be greater than 1 to ensure at least 1-hour autonomous operation.

5.5. Improved Warm-Up Time of Gas Sensors:

The start-up warm-up time is mandatory for the gas sensors to acquire chemical equilibrium with the atmosphere in which they are used. The warm-up time was improved by putting all the micro-controller, GPS, and GSM modules to sleep and then get active based on the gradient as mentioned in section 3.

6. Results and Discussion

After the long haul deployment of six months, the data results obtained were displayed on the Ubidots IoT platform as exhibited in figure 7.

The eleven real-time variables were exhibited in Figure 8 sending data through GSM model QuecTel M10. The application of GAM enabled only meaningful data to be sent to the cloud that made time-series more non-linear as only gradients impacted values were being transmitted. The following plots of individual variables give more insights of GAM in SeReNo V2.

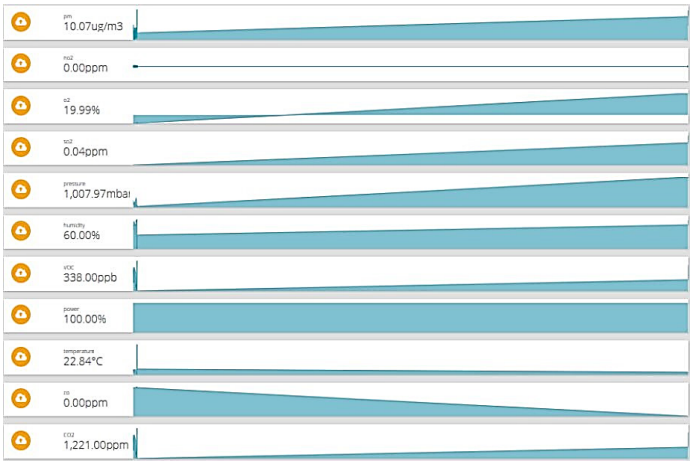


Figure 8: The SeReNo2 IoT Dashboard at Ubidots IoT

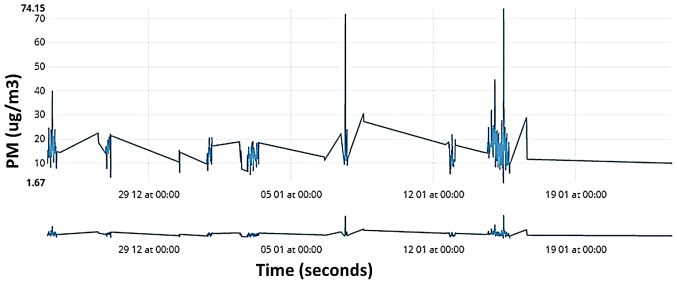

Figure 9: Illustration of Particulate Matter data due to GAM

Figure 9 explained the real-time measurement of PM from December 22, 2019, to January 22, 2020. The max of 74.15 µg/m^3 was observed on January 17, 2020, and a minimum of 1.67 µg/m^3 on December 27, 2019.

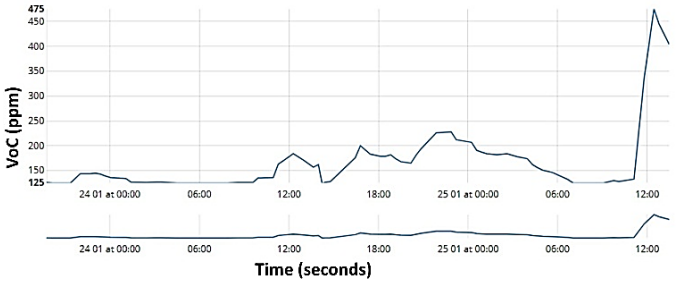

Figure 10: Illustration of VoC and Impact of GAM at 12:00 PM

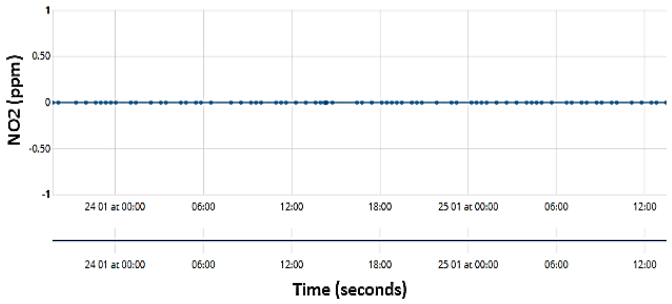

Figure 11: Illustration of Nitrogen Dioxide data due to GAM

In figure 10, it is ambient that amount of VoCs increased significantly due to day time traffic and air pollution in the atmosphere. This the special behavior common in all the days for 6 months.

In figure 11, it is eloquent that NO2 being extremely hazardous stayed zero and was transmitted to cloud whenever there was a signature of cross-sensitivity and time-series for NO2 was also non-linear.

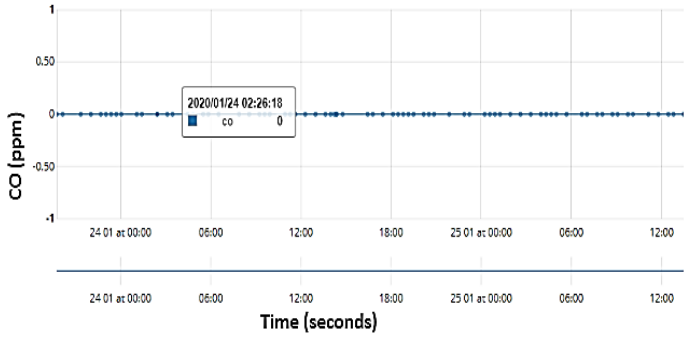

Figure 12: Illustration of Carbon Monoxide data due to GAM

In figure 12, it was observed that CO being hazardous was also observed as a non-linear time-series and the same as NO2 had cross-sensitivity signatures.

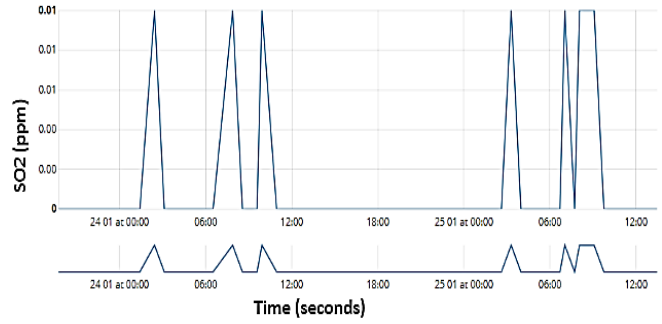

Figure 13: Sulphur Dioxide Signatures in Atmosphere

In figure 13, nominal magnitudes of SO2 were observed in the atmosphere due to plenty of gas processing plants that flare H2S and rest is preserved by Sulphur recovery units (SRUs).

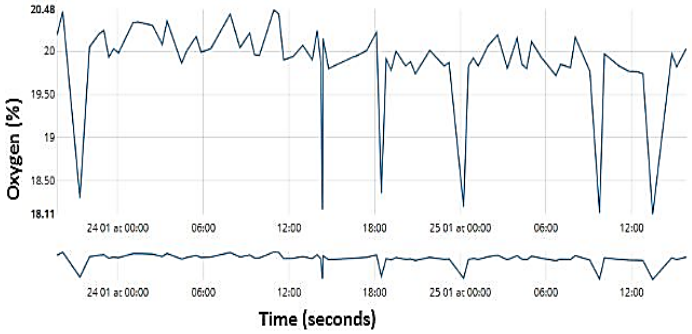

Figure 14: Presence of Oxygen Traces in Air

The SeReNo V2 node was initially equipped with an O2 sensor that was later on replaced by the O3 sensor for 2 years. The breathing conditions were favorable due to the measured average of 19.3 O2 in the air as obvious from figure 14.

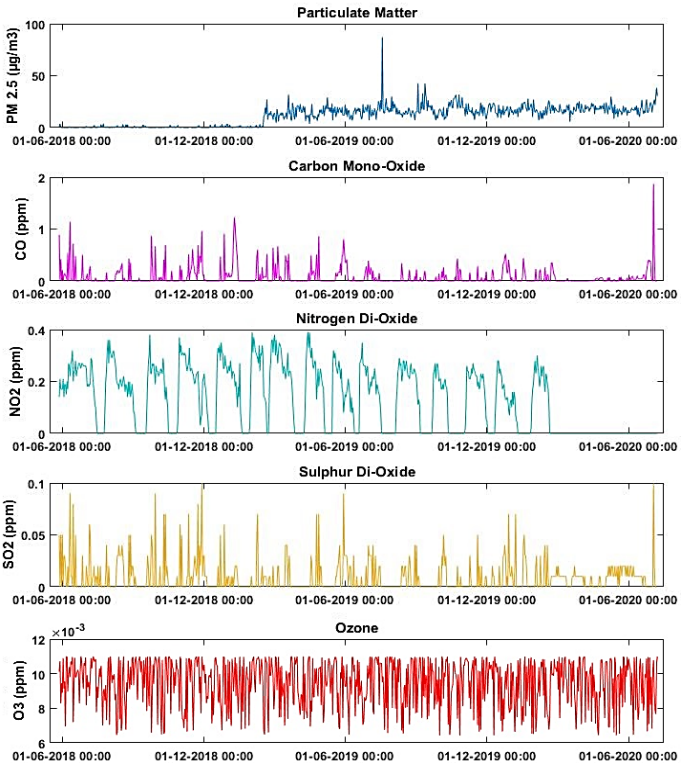

Figure 15: SeReNoV2 Total Deployment Data for EPAs recommended measurement

The first deployment of the SeReNoV2 node was 1.5 years to validate the autonomous operational capabilities as presented in figure 15 at the maximum sampling rate for pollutants and outdoor gases. This deployment was from June 1, 2018, to January 1, 2020.

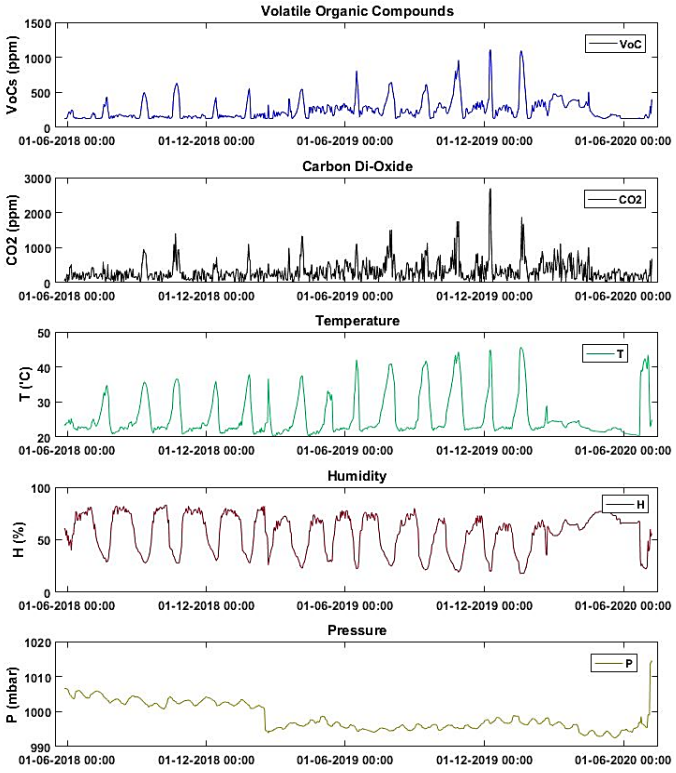

Figure 16: SeReNoV2 Total Deployment Data for EPAs Environmental Variables

In figure 16, the core 5 environmental variables, VoC, CO2, temperature, humidity, and pressure can be observed during the entire deployment tenure.

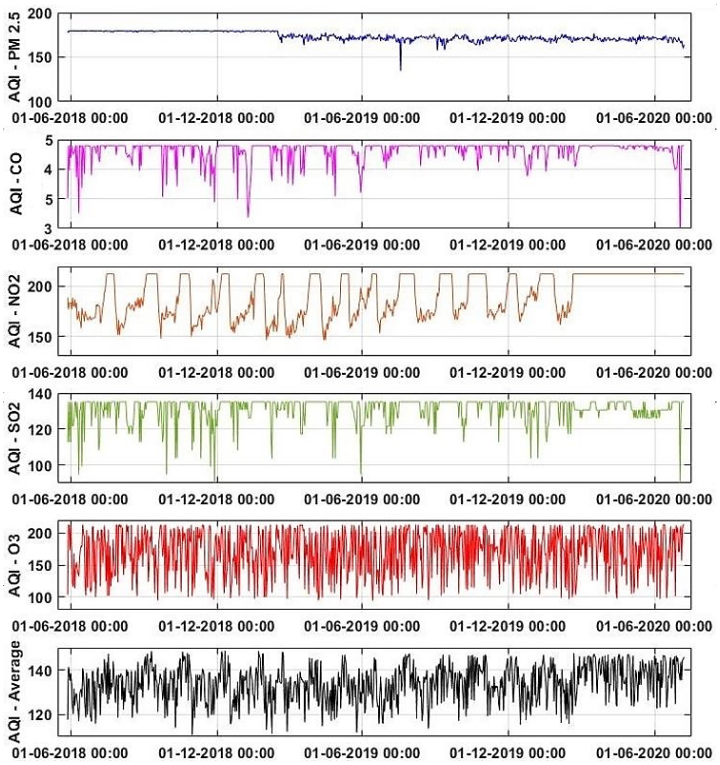

Figure 17: SeReNoV2 Estimation of real-time Discrete and Cumulative AQI

The AQI-EE key performance indicators (KPIs) were estimated for the programmed GAM on SeReNo V2 were the major contributions that enabled all the outcomes presented in figures 17 to 19. 80 meters typographic error can be observed in figure 18.

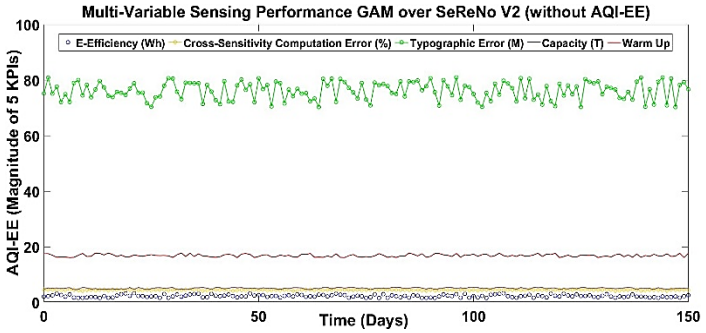

Figure 18: The GAM without AQI-EE KPIs for 5 months

The warm-up time of 18 minutes of electrochemical gas sensors was due to the average humidity of 63%. The warm-up time of electrochemical gas sensors is ideally 2 to 7. The cross-sensitivity error of 5% is normal. The E_e is near 0.8~1% is due to the extremely low power design on SeReNoV2.

The AQI-EE KPIs for GAM efficiency on SeReNo V2 can be observed in these recent 6 months deployment with 5 months of KPI assessment. The correlation of GPS and AGPS minimized typographic error to 3.5 meters. The cross-sensitivities error was also reduced to 2.7~4.8%. The E_e is aligned with the electrochemical gas sensors' operational instances. The capacity has improved to 1.4%. A significant reduction in warm-up times was observed due to the $P_{M\text{-}SLEEP}$ variable. Lastly, the measure data size with respect to power energy efficiency was mapped and significant amounts of data were observed even at very low power consumption as a landmark for future research.

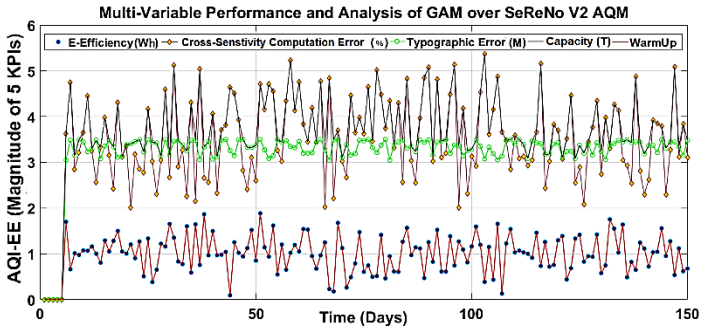

Figure 19: The GAM KPIs for SeReNo V2

7. Conclusion

A gradient-ware urban air quality index estimation multi-variable sensing IoT system was developed. The existing SeReNoV2 nodes were improved with the proposed system. The gradient-aware model and air quality estimation engine contributed to a significant and noticeable reduction in data processing for real-time AQI computation, electrochemical sensors warm-up times, cross-sensitivity errors, geo-location typographic-errors, and improved energy efficiency. The results can be summarized in four key milestones for accurate estimation of urban AQI estimation: 1) implemented gradient-aware sensing model as non-linear time series vector compensating the commutative anomalies in gases and environmental variables measurements; 2) the energy efficiency mechanism was able to keep the node up for 1.5 years constantly without any external charging source; 3) reduced warm times due to the proposed instantaneous power condition, and 4) precise estimation of AQI recommended air quality chart principal parameters. These novel air quality system results demonstrated the potential to handle redundancy in sensing time-triggers and non-linear timers as well.

Japanese text summarization

ABSTRACT

In this study, we developed and evaluated an automatic abstractive summarization algorithm in Japanese using a neural network. We used a sequence-to-sequence encoder-decoder model for practical purposes. The encoder obtained a feature-based input vector of sentences using the bidirectional encoder representations from transformers (BERT) technique. A transformer-based decoder returned the summary sentence from the output as generated by the encoder. This experiment was conducted using the Livedoor news corpus with the above model. However, two problems were revealed. One is the repetition of a specific phrase while the model is generating text. The other is that the model can not handle out-of-vocabulary words. As solutions, we use repeat block in n-gram words and WordPiece. In addition, to evaluate the performance of the model, we compared the summarization accuracy between our model and a long short term memory based pointer-generator network. As revealed by the results, our model comprehends the meanings of sentences better than a pointer-generator network but makes more word-based mistakes.

1 Introduction

This paper is an extension of work originally presented in 2019 International Conference on Technologies and Applications of Artificial Intelligence (TAAI) [1].

Societies with a highly developed information system make it easy for citizens to obtain the information they need. However, for this reason, the information obtained often has redundancy. Therefore, skills are needed to extract only the necessary information. In other words, a summarization skill is important. Thus, we need a system that automatically takes the necessary points of a text and applies deep learning with a neural network. At the present time, models using bidirectional encoder representations from transformers (BERT) [2] have achieved the highest scores in abstractive summarization tasks [3]. Although there are already many models using BERT in English and some other languages, a model in Japanese has yet to be found. We therefore developed models using BERT in Japanese and evaluated them through a comparison with another model. The code is available at `https://github.com/IwasakiYuuki/Bert-abstractive-text-summarization`.

Text summarization is one of the natural language processing that effectively summarizing long sentences. The Algorithms of text summarization used in machine learning are mainly divided into two types: extractive and abstractive summaries. In the extractive text summarization, a summary sentence is generated by combining important sentences in the source text. On the other hand, the latter, abstract type, understands the input sentences and generates the corresponding summary sentences by itself. Although both types are similar in that they summarize the main points of input sentences, they are more flexible in this respect because abstract abstract summarization generates the corresponding summary sentence by itself, while extractive summarization can only process sentences collected from input sentences. In this study, we focused on abstract summarization.

In recent years, various models have been proposed for abstractive summarization. An author proposed an abstractive summarization model using Bidirectional Encoder Representations from Transformers (BERT) [3]. Experimentation results as reported in [3] revealed that the developed model achieved a new state-of-the-art performance on both CNN/Daily Mail and New York Times datasets. Viswani et al. proposed an abstractive summarization model called a pointer-generator network based CopyNet [4]. This pointer-generator network model has advantages in terms of both abstractive and extractive summarizations.

The model developed in this study was built with reference to a text summarization model using BERT and has two stages. In the first stage, the input text was encoded into a contextual representation using BERT, and after processing the input text with BERT, a

[*]Corresponding Author: Yuuki Iwasaki, Tokyo College, s20607@tokyo.kosen-ac.jp

summary draft was generated using a transformer-based decoder. In the second stage, the draft summary text was re-validated using BERT to generate a crisper summary text, which was then processed with BERT. In this experiment, only the first stage was employed.

In section 2, we introduce the several well-know neural network models and layers used in this study, i.e., BERT and multi-head attention (the layers in BERT), and pointer-generator network used for comparison with our model. In section 3, we describe an overview of the proposed model along with its structure. In section 4, we detail the settings and dataset applied while training our model. In section 5, the results of the experiments described in section 4, are evaluated, along with those of another model, i.e., a pointer-generator network. Based on the evaluations, we compare our model with a pointer-generator network based on scores from the Extracted places and ROUGE-N [5]. In section 6, we provide some concluding remarks regarding our experiments and discuss areas of future study.

2 Related Studies

2.1 Pointer-Generator Networks

A pointer-generator network [6] is an LSTM-based model for an abstractive summarization. Long short term memory(LSTM) [7] is a neural network model that is often used for natural language processing. Figure 1 shows a model overview of a pointer-generator network. The most significant differences between this model and our approach are the structures, i.e., the “copy mechanism” and “coverage mechanism”. A pointer-generator network can-not compute in parallel owing to the structure of the model. In addition, it requires a long time and a large amount of data for training to obtain the meanings of both words and sentences at the same time.

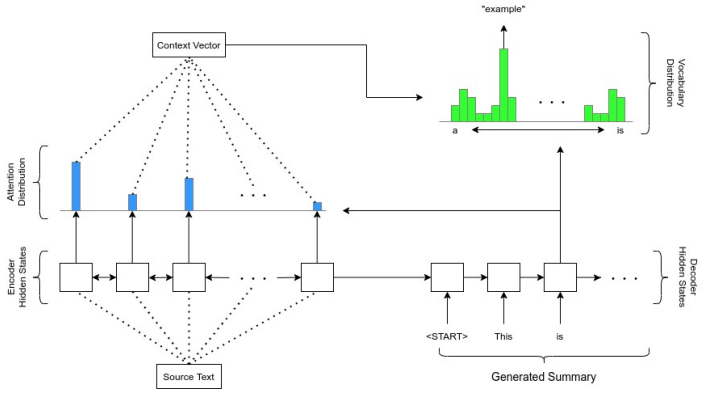

Figure 1: Overview of pointer-generator network. As shown on the left side of the figure, an ’Attention Distribution’ helps handle out-of-vocabulary words. In addition, as shown on the right side, the ’Vocabulary Distribution’ resolves the repeating problem. Referred to [6]

Copy mechanism A neural network outputs the probability of a predetermined group of words when generating them. Therefore, it cannot output proper nouns. However in sentence summaries, proper nouns are often important. Thus, a pointer-generator network dynamically allocates the words in the input text to the IDs using a copy mechanism and thus the model can handle out-of-vocabulary words.

Coverage mechanism Sentence summarization tasks occasionally have a problem of generating the same words repeatedly. A pointer-generator network incorporates a mechanism called a coverage mechanism to solve this problem. The coverage mechanism keeps the distribution of the words generated up to the t-step, and then penalizes them for producing the same word. The penalty is achieved by adding a new term to the loss function.

2.2 BERT

In recent years, pre-training models, such as BERT, have been widely incorporated into neural network models. In particular, models trained with BERT have achieved state-of-the-art performance in natural language processing tasks; BERT has been pre-trained with a large unlabeled corpus and can be fine-tuned with another corpus to achieve better performance. Figure 2 shows the process of pre-training and fine-tuning.

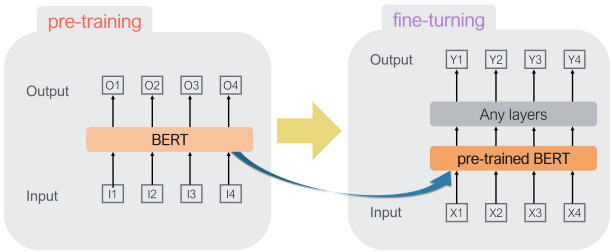

Figure 2: BERT pre-training and fine-tuning processes. A pre-training of the model is shown on the left side of this figure, and a fine-tuning is shown on the right side.

We briefly describe the structure of the BERT model with reference to [2]. BERT has several layers; each layer has a Multi-Head Attention and a linear affine with a residual connection. In our experiment, we utilize the BERT-based model which has 12-layers and 768-hidden sizes.

Pre-training In a general neural network model, the model is trained at once for the tasks. Then, the model is trained for each task at the same time as the meanings of the words and sentences are obtained. For this reason, a large amount of data is needed to train the model. However, there are two processes applied during BERT training, pre-training and fine-tuning. Pre-training tasks of BERT are called masked language model (MLM) and next sentence prediction (NSP). An MLM is a task for predicting masked words in an input text, and an NSP is a task for predicting the next sentence of an input sentence. Through a pre-training, the model obtains the meanings of the words and sentences, as well as the coherence of the texts.

Fine-turning After pre-training of the model, we re-train the model for a specified task, in this case, a summarization. A pre-trained model already has the obtained meanings of words and sentences, and thus we simply tune the model toward our task. This means it can be trained with a low data quantity. At the fine-tuning

stage, we use the pre-trained BERT model and some layers, as shown in Figure 2.

2.3 Multi-Head Attention

BERT and a transformer primarily comprise multi-head attention layers. The multi-head attention divides the attention input into multiple parts and concatenates them with multiple outputs. Multi-head attention is more accurate than attention and can be calculated through (1), (2), and (3) as described in reference [4].

$$Attention\,(Q,K,V) = softmax\left(\frac{QK^T}{\sqrt{d_k}}\right) \tag{1}$$

$$head_i = Attention\left(QW_i^Q, KW_i^K, VW_i^V\right) \tag{2}$$

$$MultiHead\,(Q,K,V) = Concat\,(head_i,\ldots,head_n)\cdot W^O \tag{3}$$

Equation (1) represents a formula for a single input query in multi-head attention, in which the input is split into units of a head as shown in (2), and each output is concatenated as shown in (3) to generate the overall output. In practice, we compute the attention function on a set of queries simultaneously, packed together into a matrix Q. The keys and values are also packed together into matrices K and V, and W_i^Q, and W_i^K, and W_i^V are the parameter matrices. Here, d_k used in (1) is the number of dimensions of key K.

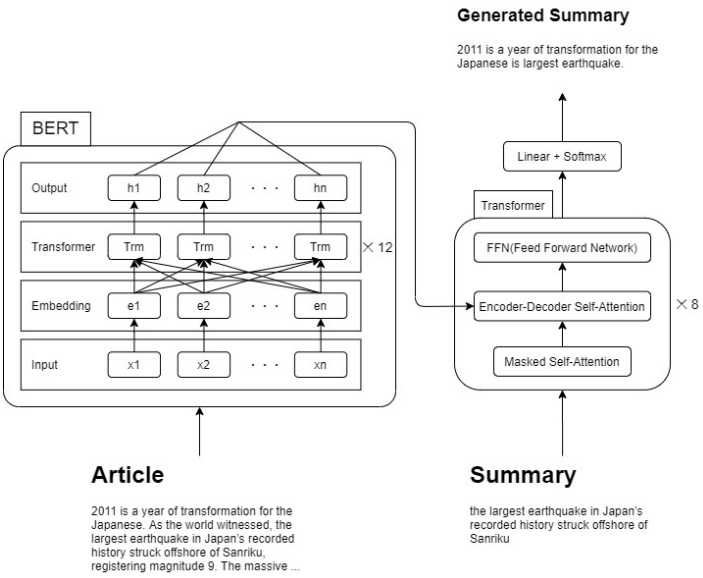

Figure 3: Overview of our text summarization model. Our model includes BERT in the encoder and a transformer in the decoder. During the training phase, we set the article body and summary into the encoder and decoder inputs, respectively.

3 Model

Figure 3 shows an overview of the model used in our experiment.

3.1 Encoder

Several pre-learning models, such as BERT, have been widely utilized in encoder-decoder models. Because BERT is efficient for fast training with high precision, it ensures a higher accuracy in existing models. In a study conducted by Zhang et al. [3], BERT is used as the encoder to achieve state-of-the-art performance for an abstract text summarization task. In this experiment we applied a pre-learning model BERT as the encoder.

3.2 Decoder

In our model, we configured a transformer-based decoder as an encoder. It was not the proposed decoder choice for BERT to send the output generated by the encoder to the input of the decoder at the same time.

Furthermore, we opted for a transformer-based decoder as opposed to a recurrent neural network (RNN) such as an LSTM [7] and GRU [8] for the following reasons: (1) Time for training - Transformer-based decoders are built using multi-head attention, which can perform parallel computations, and are, hence, faster. (2) Accuracy - Transformers are far more accurate than RNNs on machine translation tasks. (3) Long-range dependency - The attention used in the transformers makes it easier to learn long-range dependencies compared to RNNs such as an LSTM.

3.3 Abstractive summarization model

The input is denoted as $X = \{x_1, x_2, \ldots, x_n\}$, sequence representing sentence breaks is denoted as $S = \{s_1, s_2, \ldots, s_n\}$, and the corresponding summary is denoted as $A = \{a_1, a_2, \ldots, a_n\}$. We started by entering X and S into BERT.

If $f_{sen}(x)$ is assumed to be the number of sentence of x, sequence S is computed as $S = f_{sen}(X)\ mod\ 2$. The resulting BERT encoder output is denoted as H. Next, we input H and the output of the decoder at the t-th time step.

The probability of the vocabulary at the t-th time step can be obtained as shown in (4). This probability was conditioned on the decoder output until the t-th time step and the output of the encoder H.

$$P_t(w) = f_{decoder}(w \mid H, Y_{<t}) \tag{4}$$

The loss of training L, is calculated as shown in (4) using the probability of vocabulary $P_t(w)$.

$$L = -\sum_{i=0}^{n} \log P(y_t \mid H, a_{t-1}) \tag{5}$$

4 Experiments

4.1 Setting

During this experiment, we used a pre-trained model with BERT that was developed at the Kurohara and Kawahara laboratories of Kyoto College [9]. Most of the BERT hyperparameters were same as those of BERT-Base (i.e., 12-layers, 768-hidden, and 12heads) in [2]. The model was trained for 30 epochs with 1.8 billion Japanese Wikipedia corpuses. The input text was divided into sub-words with byte pair encoding (BPE [10]) using the morphological analysis system Juman++ [11].

The vocabulary size stood at 32,000 words. The decoder in our model comprises eight multi-head attention layers; the division of hidden size as 3,072; and the embedding vector as 768, similar to the encoder.

We used Adam as the model optimizer, and set the parameters as $\beta_1 = 0.9, \beta_2 = 0.999, and \epsilon = 1.0 \times 10^{-9}$. The maximum learning rate was set at 1.0×10^{-9}. In addition, the dynamic learning rate was adopted as the model learning rate in [4].

The learning rate is computed as shown in (6),

$$lr = max_learning_rate * \frac{min\left(cs^{-0.5}, ws^{-1.5} * cs\right)}{ws^{-0.5}} \quad (6)$$

In principle, the learning rate increases linearly up to the warmup step (ws). If the current step (cs) exceeds the warmup step, the learning rate gradually decreases. The learning rate peaks when the current step and warmup step are equal. At this point, the learning rate is denoted as $lr = max_learning_rate$. For our experiment, we set $warmup_step\,(ws) = 4000$ and $max_learning_rate = 0.0001$ for training. The model includes BERT with 12 multi-head attention layers. The batch size is set to 4 for GPU memory because the maximum input sequence was set to 512.

Figure 4: An example of Livedoor news corpus. Every article has three sections, a title, a summary and an article body. Each section is labeled in the above figure.

4.2 Dataset

The Livedoor News corpus contains 130,000 Japanese news articles from Livedoor News, each news article is accompanied by a three-line summary. The article text and summary are set as input and output of the experiment, respectively. From the dataset, 100,000 data points were used for training and 30,000 data points were used for validation. The maximum length of the input sequence was set to 512 tokens, but some data values exceeded this limit. In such cases, only the first 512 tokens were entered into the model.

Every article on the Livedoor news website has text and a three-line summary. Figure 4 shows an example of an article body and summary. In this example, the article body at the bottom of the figure is input into the model, and the summary at the middle of the figure is output to the model.

4.3 Training

If 100,000 live news corpus data points in 1 epoch were trained in 15 epochs, the loss of each lexicon in the validation data was about 6.5 words, and the accuracy of identifying the correct lexicon was about 67%. The graphics card used for training was a Titan X (Pascal) with 12 GB of memory. The training took about three days.

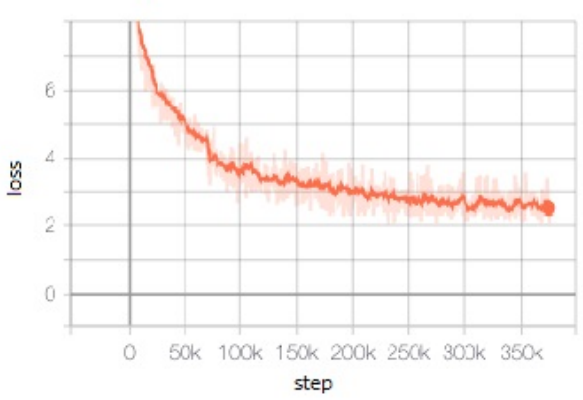

Figure 5: Outputs of loss function for every training step. A gradual decrease in the numbers of loss function outputs is implied in this figure.

5 Results and Discussions

In this section, we can see the evaluations of the generated summaries with two models, i.e., our model (BERT+Transformer) and a pointer-generator network. From the generated summaries, we evaluated the models on the following criteria:

- Grammatical Accuracy
- Vocabulary mistake
- importance level

To check the validity of the generated sentences, we focused on grammatical and vocabulary errors. We also extracted and checked which parts of the original text were important for the generation of the summary text. The above three points are evaluated subjectively. In addition, we calculated and compared their respective ROUGE-N scores.

5.1 Generated summaries

The texts in the appendix are the article bodies and their summaries that generated by the two trained models, our model and the pointer-generator network (translated from Japanese into English). The texts under "Input" are article bodies in the Livedoor news corpus, and the texts under "Output" are summaries generated by our model and the

pointer-generator network from each article body. In the appendix, we provide three article bodies and generated their summaries as examples. When generating the text, a beam search with a width of 4 was used. Prior to the training process, WordPiece [12] was used to further divide out-of-vocabulary words into multiple words. For example, the word "smoke" which is not in the vocabulary of the model, is able to represent the combination of "smo" and "ke" in the vocabulary. For the quantitative effect of WordPiece, refer to an ablation study [13].

One problem that arises during the summary sentence generation is the "repetition problem". This means that an arbitrary phrase will repeatedly appear in the summary sentence. We used a REPEAT block to get around this. The repeat block detects the repetition of a sentence in n-grams increments and returns to the (n-1)-steps before the repetition and reapplies the word generation. In this experiment, we used the repeat block of the tri-gram that had the highest ROUGE-N score.

For example, you can see the *t*-th step generated summaries by the model as follows:

summary : It is going to rain in **the(1) the(2) the(3)**

In the above example, the same three words are generated from the end of the word, and thus the approach returns to the two steps prior to "the(1)" and regenerates words other than the those previously generated.

summary : It is going to rain in **the(1) evening**

Input 1 in the appendix demonstrates that both models were able to learn correctly as, it can be seen, to some extent, that the summary text retained the key points of the input text. In addition, there are no errors in grammar or vocabulary. However, if we look at the summary of a pointer-generator network, the sentence "The Berlin International Film Festival Silver Bear Award is one of the three biggest film festivals in the world for "smoke". " is not extremely important. Therefore, in the above example, we thought the summary generated by our model was better than that of the pointer-generator network owing to the importance.

Input 2 in the appendix is regarding the risks to the human body from sitting for long periods of time. At first glance, both summaries appear to be correct, but the word "skillfully" is included in the summary of our model. This is not the word that should be used. Therefore, we felt that the pointer-generator network was able to produce a more accurate summary in this example than our approach.

Input 3 in the appendix deals with the response of a real estate company when a house is an accidental property. No erroneous words appear in either summary. However, the sentence "It is said that the building should be disliked because it is a place to live continuously." in the summary of our model, is not grammatically correct. In terms of content, however, we believe that our model is able to extract the more important parts. For example, the content regarding payment is fairly important but is not included in the summary of the pointer-generator network.

In the present example, our model extracts the more important parts, but the grammar was correct for the pointer-generator network. From the three examples provided in the appendix, it appears that the pointer-generator network has fewer vocabulary and grammatical errors, although our model is able to extract more of the important content. In addition, you can see that the locations that the pointer-generator network extract is mostly in the first half of the input text. By contrast, our model extracts from all throughout the input text. In other words, our model is more expressive, whereas the pointer-generator network is less prone to grammatical and vocabulary errors. In addition, because the pointer-generator network has a copy mechanism, we thought it might be related to the fact that the model is somewhere between abstract and extractive text.

5.2 *Extracted places*

We will now see which parts of the input text are extracted by the summary statement generated in the previous section. Figure 6, 7 and 8 shows the places that the model extracts from the input texts. Each horizontal axis represents the number of words, and the bar graph shows the word positions referenced by the models.

Figures 6, 7 and 8, indicate that the locations extracted by the pointer-generator network are mostly in the first half of the input texts. By contrast, those extracted by our model(BERT+Trasnformer) are scattered throughout the input text. This leads us to believe that our model may be able to understand the entire content of the input text better than the pointer-generator network.

Figure 6: Input 1 highlighting the extracted locations

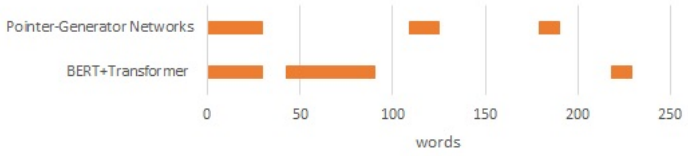

Figure 7: Input 2 highlighting the extracted locations

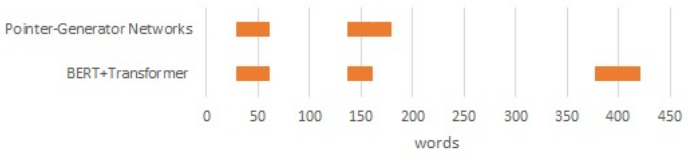

Figure 8: Input 3 highlighting the extracted locations

5.3 ROUGE-N socre

Next, we compare the pointer-generator network with our model using the ROUGE-N [5], which is an index frequently used in the evaluation of summary sentences, which represents the percentage of agreement between words in N-gram units.

As an example, let us try to calculate the ROUGE-N score of the following sentence.

summary : It is going to rain in the evening today
references : It is going to rain today

Referring to [5], the equation for obtaining the ROUGE-N score is shown below.

$$ROUGE_N = \frac{\sum_{C \in Reference} \sum_{Gram_n \in C} Count_{match}(Gram_n)}{\sum_{C \in Reference} \sum_{Gram_n \in C} Count(Gram_n)} \quad (7)$$

Considering the above example, we have the same six pairs on uni-gram, and four pairs on a bi-gram. From this, the ROUGE-1,2 score of the example could be derived as follows:

$$\begin{aligned} ROUGE_1 &= \frac{6}{9} \\ &= 0.667 \\ ROUGE_2 &= \frac{4}{8} \\ &\fallingdotseq 0.500 \end{aligned}$$

In our experiment, we calculated the ROUGE-1,2 scores with 1,000 Japanese news articles (sample size $n = 1,000$) chosen at random from the verification datasets. The standard error, *SE*, calculated using the unbiased standard deviation, u, and the sample size, n, is expressed as follows:

$$SE = \frac{u}{\sqrt{n}} \quad (8)$$

Using the above equation, the margin of error, e, for the 95% confidence interval (95% CI) is expressed as in Equation 9.

$$e = \pm 1.96 \times SE \quad (9)$$

The ROUGE-1,2 scores, the standard errors, *SE*, and the unbiased standard deviations, u, for both the models are presented in Table 1.

Table 1: ROUGE-1, 2 scores for pointer-generator networks and our model (BERT + transformer)

Model		Score	u	e
Pointer-Generator Networks	ROUGE-1	0.463	0.123	±0.008
	ROUGE-2	0.221	0.142	±0.009
BERT + Transformer	ROUGE-1	0.470	0.107	±0.007
	ROUGE-2	0.215	0.126	±0.008

Table 1 indicates that the ROUGE-1,2 scores of our model and the pointer-generator network were similar. However, our model's structure was designed for multiple tasks, whereas the pointer-generator network was a model designed for text summarization tasks because of the copy mechanism. In addition, our model generated all the words in the output sentences. Thus, we hypothesized that our model achieved a better comprehension of the text.

5.4 Word Mover's Distance

Next, we compared the pointer-generator network with our model using word mover's distance (WMD) [14] to evaluate their semantic similarity. The WMD is a novel distance function between text documents. The ROUGE scores are based on literal word overlap; hence, it is necessary to evaluate a score that is not based on literal word overlap. Among a number of recently proposed semantic similarity metrics, WMD is shown to be the most reasonable solution to measure semantic similarity in reformulated texts [15]. We evaluated the WMD for both models with 1,000 Japanese news articles chosen at random from the verification datasets and used the Japanese word embedding vectors [16] to calculate the WMD. Table 2 presents the WMD scores, unbiased standard deviation, and margin of error for the pointer-generator networks and our model.

Table 2: WMD of pointer-generator networks and our model (BERT + transformer)

Model	WMD	u	e
Pointer-Generator Networks	0.533	0.122	±0.008
BERT + Transformer	**0.521**	0.106	±0.007

As shown in Table 2, our model has a slightly lower WMD score than the pointer-generator network. This implies that the summaries generated by our model were more similar to the article's summaries than those generated by the pointer-generator network. Thus, the hypothecate that our model achieved a better comprehension of the text than the pointer-generator network was strengthened.

6 Conclusion and Future works

We conducted an experiment to demonstrate an abstractive summarization of Japanese text with a neural network model using BERT. In addition, we conducted a comparison between the qualitative and quantitative aspects of our model and a model frequently used for text summarization, i.e., a pointer-generator network. Our model is composed of a BERT encoder and a transformer-based decoder. The dataset used in this paper was the Livedoor news corpus consisting of 130,000 datapoints, of which 100,000 were used for training.

The results of the experiment revealed that the model was able to learn correctly as the summary sentence captured the key points of the text to a certain extent. However, the contents of the summary sentence were repeated, and the model could not handle unknown words. As a solution, we applied two mechanisms, a repeat block and WordPiece. The repeat block detects repeated n-grams in the generated summaries and regenerates summaries at the (t-n-1)-th step excluding the repeat word. To handle this, WordPiece further divides the out-of-vocabulary words into sub-words.

The results of evaluations of our model and the pointer-generator network revealed that their ROUGE-1,2 scores were similar. However, our model's structure was designed for multiple tasks, whereas the pointer-generator network was a model designed for text summarization tasks because of the copy mechanism. Therefore, we hypothesized that our model achieved a better comprehension of the text. In addition, the comparison of the two models to evaluate their semantic similarity, that is, the WMD, strengthened our hypothecate. While extracting phrases, the pointer-generator network extracted phrases from the first half of the input text, whereas our model extracted phrases from throughout the text. However, a qualitative evaluation of our model revealed that it made numerous grammatical and vocabulary mistakes. We believe that this problem can be solved by improving the model.

In the future, we will explore these recommendations through additional experiments and compare the results.

Appendix

The following are three articles from Livedoor news and a summary of our model and the pointer-generator network generated as examples. The examples below were used for the discussions provided in section 5.

Input 1 Director Wayne Wang from Hong Kong, who has won the Silver Bear Award at the Berlin International Film Festival, one of the three biggest film festivals in the world in the movie "Smoke" (1995), and Japan's world-famous Beat Takeshi and Nishijima Hidetoshi. The movie "When a Woman Sleeps" (published on February 27). It was the first time in 12 years since "Blood and Bone" starring in a film other than his own work in 2004, and said "I was so worried about my acting that I held my head," he said unexpectedly. Is it because of the mysterious style that the boundaries between dreams and delusions and reality are vague? Three people talked to each other. This film is a movie based on a short story by Javier Marias, a Spanish writer, and is set in a quiet resort hotel, and a mysterious couple (Takeshi and Shiori Nana Shiori), two years older than their parents and children. It is a mystery of love and hate that stares at a writer (Nishijima) who is obsessed with a relationship that has become obsessed with and has run out of curiosity. "I thought that the main character was Nishijima," said the smiling Takeshi, and read the script, "I thought I was foolish. A normal script would tell the story and the ending." He said that he had a hard time understanding a complicated story. Nishijima, who praises himself for being more acquainted with movie expressions, relieved, "If I say "good", I'm sure there will be no mistake." I watched all the acting all the time. When I finished watching, I didn't even remember what kind of movie it was," said an unknown side of Takeshi called "Kitano of the World." Nishijima, who immediately decided to appear, "Wayne Wang is a work that shoots Beat Takeshi, so it will come out (laughs)," said "This time especially Beat Takeshi is obsessed with love, even at the shooting site. I was shocked a lot and was really moved. It was wonderful." Director Wang, who worked on Japanese movies for the first time, also said, "I wanted to work with Takeshi rather than want to shoot in Japan." Takeshi played an unusual role in keeping a video recording of a young beautiful woman (Kana) sleeping. When asked, "What do

you want to leave your dear ones?", "I've been in the entertainment world for a long time, so I thought, "I thought that the gag of Takeshi at that time, that laugh was amazing." It's okay if you can leave one," he said. (Interview and text: Megumi Shibata)

Output 1 (Pointer-generator network) The Berlin International Film Festival Silver Bear Award is one of the three biggest film festivals in the world for "smoke." For the first time in 12 years, Takeshi said, "I was so worried about my performance that I held my head." "The boundaries between dreams and delusions and reality are vague and mysterious.

Output 1 (BERT+Transformer) A movie "When a Woman Sleeps", in which Takeshi Beat and Hidetoshi Nishijima formed a tag. Beat Takeshi was said to have been attached to love. "I'm worried about my performance, and I'm worried about the finished product, too," he said.

Input 2 "Mentai Wide-Fukuoka Broadcasting" At the corner of "Special News THE Slide Show" broadcasted on February 9, 2016, we covered the risks to your body from sitting for a long time. The image is an image (taken by Andrea Arbogast, from Flickr). A study of 220,000 men and women over the age of 45 in Australia found that the risk of death was 1.4 times higher for people sitting 11 hours or more a day than for those sitting less than 4 hours a day I got the result. It seems that the risk of obesity, diabetes, cancer, etc. increased, causing death. The detailed cause is unknown, but it is also said that "myokine" that suppresses heart disease is not secreted unless the muscles are contracted. This excessive sitting puts a heavy burden on the lower back, with 1.4 times being normally seated and 1.85 times being leaned forward. Even in Fukuoka, more and more offices are incorporating "sometimes standing work". More than 90% of the desks sold in Sweden and Denmark are of the type that can be moved up and down, and by using this you can do "occasionally standing work". Even in Japan, Rakuten has changed the desks of all employees so that they can be moved up and down, to avoid sitting down. Even in Fukuoka, some companies are making their desks movable up and down and changing the height of the desks themselves. When I asked when to change the height of the desk, this was the most common opinion. Because I may feel drowsy after lunch, switch to standing work at such times. When you are tired from working on a computer or lose your concentration, start a standing job. Stand up when your shoulders, waist, or neck hurts. It seemed that it was good to stand up, and there were interesting opinions. I have less stiff shoulders, lower back pain, and neck pain. Increased communication from the surroundings. When I sat down, I was staring at my computer, but by standing up, I was able to see my surroundings better and start talking. Since I also work as a deskwork worker, I sometimes feel pain in my lower back and shoulders after sitting for a long time. For this reason, I stand up and relax once every hour, but I found it useful to have a desk like this. If you keep sitting down, you may not be able to see the surroundings because you are staring at a desk or a personal computer, so I would like you to incorporate such desks in various offices. (Writer: Piyoko).

Output 2 (Pointer-generator network) At the "Special News THE Slide Show" on the 9th, I heard about the risks to the body from sitting for a long time. It is said that "myokine" that suppresses heart disease is not secreted unless the muscles are contracted. It is said that more and more offices in Fukuoka have adopted "sometimes standing work".

Output 2 (BERT+Transformer) In the program on the 9th, we discussed the risks to the body from sitting for a long time. The risk of obesity, diabetes, cancer, etc. is high, and the risk of death is 14 times higher. In addition, he changed the man's desk to something that can be skillfully moved up and down to avoid sitting.

Input 3 Last year, an incident that involved the illegal construction of a large-scale condominium construction project in Yokohama City reminded me of the difficulty of choosing a property, but I finally got the feeling that I could get a house. If it's a so-called "accident property", can you ask the real estate agent for a refund? Lawyer Masami Takeshita answers. (Consultation). At the end of last year, I bought a second-hand house, but when I looked up the reason because the neighborhood was strange, the previous owner was at home It seems that he tried to hang himself. The real estate company that introduced this property did not tell me that it was an accident property. In this case, is it possible to request the real estate agent to refund the purchase price in full? (Answer). The fact that a building purchased for residential use commits suicide and lacks "comfortable living" means that "a building is a place to live continuously, so there are also psychological flaws due to the historical background of the building that should be disliked. (Defect)" is understood. If the buyer makes a contract without knowing that there is a defect, the seller will be liable for the defect guarantee, and if the defect does not meet the contract purpose, the contract will be canceled, and if it does not reach that level, You are obliged to compensate the buyer for damages. In addition, there are court cases that the contract can be canceled if there is suicide and it is judged that it is reasonable to feel that it is not suitable for living because it lacks comfort to live in. .. It is the case that the cancellation of the sale of condominiums, which was found to have committed suicide six years ago when the deposit was paid, was approved. On the other hand, there are some cases in which the suicide was canceled 7 years ago, and there are also cases in the sale and purchase of a plan to demolish an old house in which the degree of dislike of suicide two years ago due to the removal of a building was not a defect. In your case, depending on the time of suicide and the degree of topicality, you may be able to cancel the contract and request a full refund of the price, and even if you do not go that far, the objective evaluation of the suicide building and the purchase price You can consider the difference claim for damages. The important things that the Homebuilding Act requires an intermediary to explain are not the history of the building, such as suicide, but if the trader knows suicide, which is an important factor in determining the buyer's contract decision, There is a statutory obligation to explain and if you remain silent, you will be liable. However, it is questionable to impose accountability forever, and there seems to be a guidance that sales are 5 years and rent is 3 years. In any case, when you buy a used building, you should ask about its provenance, etc., and you can pursue the default liability

of breach of accountability to the lying seller. (Attorney Profile). Masami Takeshita: Born in Osaka in 1946. Graduated from the Faculty of Law, the University of Tokyo. Registered as a lawyer in 1971. * Weekly post February 26, 2016 issue.

Output 3 (Pointer-generator network) Attorney Masami Takeshita explained why a real estate company can request a refund if the property is an ”accident.” It seems that the building purchased for residential use may lack ”comfortable living” due to suicide. ”There are also psychological flaws due to the disgusting historical background of buildings.

Output 3 (BERT+Transformer) A lawyer explains whether you can request a refund when you purchase the accident property in 2017. It is said that the building should be disliked because it is a place to live continuously. Regarding loans, it seems that there is a possibility that you can cancel the contract and request full refund.

Classification

ABSTRACT

The growing popularity of social media sites has generated a massive amount of data that attracted researchers, decision-makers, and companies to investigate people's opinions and thoughts in various fields. Sentiment analysis is considered an emerging topic recently. Decision-makers, companies, and service providers as well-considered sentiment analysis as a valuable tool for improvement. This research paper aims to obtain a dataset of tweets and apply different machine learning algorithms to analyze and classify texts. This research paper explored text classification accuracy while using different classifiers for classifying balanced and unbalanced datasets. It was found that the performance of different classifiers varied depending on the size of the dataset. The results also revealed that the Naive Byes and ID3 gave a better accuracy level than other classifiers, and the performance was better with the balanced datasets. The different classifiers (K-NN, Decision Tree, Random Forest, and Random Tree) gave a better performance with the unbalanced datasets.

1. Introduction

The recent widening expansion of social media has changed communication, sharing, and obtaining information [1–4]. In addition to this, many companies use social media to evaluate their business performance by analysing the conversations' contents [5]. This includes collecting customers' opinions about services, facilities, and products. Exploring this data plays a vital role in consumer retention by improving the quality of services [6,7]. Social media sites such as Instagram, Facebook, and Twitter offer valuable data that can be used by business owners not only to track and analyse customers' opinions about their businesses but also that of their competitors [8–11]. Moreover, these valuable data attracted decision-makers who seek to improve the services provided [8,9,12].

In this research paper, several research papers that studied Twitter's data classification and analysis for different purposes were surveyed to investigate the methodologies and approaches utilized for text classification. The authors of this research paper aim to obtain open-source datasets then conduct text classification experiments using machine learning approaches by applying different classification algorithms, i.e., classifiers. The authors utilized several classifiers to classify texts of two versions of datasets. The first version is unbalanced datasets, and the second is balanced datasets. The authors then compared the classification accuracy for each used classifier on classifying texts of both datasets.

2. Literature Review

As social media websites have attracted millions of users, these websites store a massive number of texts generated by users of these websites [13–20]. Researchers were interested in investigating these metadata for search purposes [16,17,21–24]. In this section, a number of research papers that explored the analysis and classification of Twitter metadata were surveyed to investigate different text classification approaches [25] and the text classification results.

Researchers of [26] investigated the user's gender of Twitter. Authors noticed that many Twitter users use the URL section of the profile to point to their blogs, and the blogs provided valuable demographic information about the users. Using this method, the authors created a corpus of about 184000 Twitter users labeled with their gender. Then authors arranged the dataset for

*Corresponding Author: Said Salloum, University of Sharjah, UAE. Tel: +971507679647 Email: ssalloum@sharjah.ac.ae

experiments as following: for each user; they specify four fields; the first field contains the text of the tweets and the remaining three fields from the user's profile on Twitter, i.e., full name, screen name, and description. After that, the authors conducted the experiments and found that using all of the dataset fields while classifying Twitter user's gender provides the best accuracy of 92%. Using tweets text only for classifying Twitter user's gender provides an accuracy of 76%. In [27], the authors used Machine Learning approaches for Sentiment Analysis. Authors constructed a dataset consisting of more than 151000 Arabic tweets labeled as "75,774 positive tweets and 75,774 negative tweets". Several Machine Learning Algorithms were applied, such as Naive Bayes (NB), AdaBoost, Support vector machine (SVM), ME, and Round Robin (RR). The authors found that RR provided the most accurate results on classifying texts, while AdaBoost classifier results were the least accurate results. A study by [28] interested as well in Sentiment Analysis of Arabic texts. The authors constructed the Arabic Sentiment Tweets Dataset ASTD, which consists of 84,000 Arabic tweets. The number of tweets remaining after annotation was around 10,000 tweets. The authors applied machine learning approaches using classifiers on the collected dataset. They reported the following: (1) The best classifier applied on the dataset is SVM, (2) Classifying a balanced set is challenging compared to the unbalanced set. The balanced set has fewer tweets than the unbalanced set, which may negatively affect the classification's reliability. In [29], the author investigated the effects of applying preprocessing methods before the sentiment classification of the text. The authors used classifiers and five datasets to evaluate the preprocessing method's effects on the classification. Experiments were conducted, and researchers reported the following findings: Removing URL has no much effect, Removing stop words have a slight effect, Removing Numbers have no effect, Expanding Acronym improved the classification performance, and the same preprocessing methods have the same effects on the classifier's performance, NB and RF classifiers showed more sensitivity than LR and SVM classifiers. In conclusion, the classifier's performance for sentiment analysis was improved after applying preprocessing methods. A study by [30] investigated Twitter geotagged data to construct a national database of people's health behavior. The authors compared indicators generated by machine learning algorithms to indicators generated by a human. The authors collected around 80 million geotagged tweets. Then Spatial Join procedures were applied, and 99.8% of tweets were successfully linked. Then tweets were processed. After that, machine learning approaches were used and successfully applied in classifying tweets into happy and not happy with high accuracy. In [31] explored classifying sentiments in movie reviews. The authors constructed a dataset of 21,000 tweets of movie reviews. Dataset split into train set and test set. Preprocessing methods applied, then two classifiers, i.e., NB and SVM, were used to classify tweets text into positive or negative sentiment. The authors found that better accuracy achieved using SVM of 75% while NB has 65% accuracy. Researchers of [32] used Machine Learning methods and Semantic Analysis for analyzing tweet's sentiments. Authors labeled tweets in a dataset that consists of 19340 sentences into positive or negative. They applied preprocessing methods after that features were extracted; authors applied Machine Learning approaches, i.e., Naïve Bayes, Maximum Entropy, and Support Vector Machine (SVM) classifiers after that Semantic Analysis were applied. The authors found that Naïve Bayes provided the best accuracy of 88.2, the next SVM of 85.5, and the last is Maximum entropy of 83.8. The authors reported as well that after applying Semantic Analysis, the accuracy increased to reach 89.9. In [33], the authors analyzed sentiments by utilizing games. Authors introduced TSentiment, which is a web-based game. TSentiment used for emotion identification in Italian tweets. TSentiment is an online game in which the users compete to classify tweets in the dataset consists of 59,446 tweets. Users first must evaluate the tweet's polarity, i.e., positive, negative, and neutral, then users have to select the tweet's sentiment from a pre-defined list of 9 sentiments in which 3 sentiments identified for the positive polarity, 3 sentiments identified for negative polarity. Neutral polarity is used for tweets that have no sentiment expressions. This approach for classifying tweets was effective.

A study by [34] examined the possibility of enhancing the accuracy of predictions of stock market indicators using Twitter data sentiment analysis. The authors used a lexicon-based approach to determine eight specific emotions in over 755 million tweets. The authors applied algorithms to predict DJIA and S&P500 indicators using Support Vectors Machine (SVM) and Neural Networks (NN). Using the SVM algorithm in DJIA indication, the best average precision rate of 64.10 percent was achieved. The authors indicated that the accuracy could be increased by increasing the straining period and by improving the algorithms for sentiment analysis. authors conclude that adding Twitter details does not improve accuracy significantly. In [35], the authors applied sentiment analysis on around 4,432 tweets to collect opinions on Oman tourism, they build a domain-specific ontology for Oman tourism using Concept Net. Researchers constructed a sentiment lexicon based on three existing lexicons, SentiStrength, SentWordNet, and Opinion lexicon. The authors randomly divide 80% of the data for the training set and 20% for testing. The researcher used two types of semantic sentiment, Contextual Semantic Sentiment Analysis, and Conceptual Semantic Sentiment Analysis. Authors applied Naïve Base supervised machine learning classifier and found that using conceptual semantic sentiment analysis expressively improves the sentiment analysis's performance. A study by [36] used sentiment analysis and subjectivity analysis methods to analyze French tweets and predict the French CAC40 stock market. The author used a French dataset that consists of 1000 positive and negative book reviews. The author trained the neural network by using three input features on 3/4 of the data, and he tested on the remaining quarter. The achieved accuracy 80% and a mean absolute percentage error (MAPE) of 2.97%, which is less than the work reported by Johan Bollen. The author suggested adding more features as input to improve the performance. In [37], the authors examined the relationship between Twitter's social emotion and the stock market. Researchers collected millions of tweets by Twitter API. Researchers retrieved the NASDAQ market closing price in the same period. The authors applied the correlation coefficient. Authors conclude that emotion-related terms have some degree of influence on the stock market overall trend, but it did not meet standards that can be used as a guide to stock-market prediction. While at the same time, there was a fairly close association between positive, negative, and angry mood-words. Particularly sad language tends to have a far greater influence on the stock market than other groups. In [38], the authors investigated telecommunications companies' conversation on

social media Twitter ('indihome,' in Indonesia). The authors collected 10,839 raw data for segmentation. The authors collected data: over 5 periods of time in the same year. Authors found that most of the tweets (7,253) do not contain customers' perception toward Indihome. Only 3,586 tweets are containing the perception of customers toward Indihome. Most of the data contained perception reveal that the customers have the negative perception (3,119) on Indihome and only 467 tweets contain positive perceptions; the biggest number of negative perceptions relate to the first product, the second relates to a process, third relate to people, and fourth relate to pricing. Researchers of [39] examined prevalence and geographic variations for opinion polarities about e-cigarettes on Twitter. Researchers collected data from Twitter by pre-defined seven keywords. They classified the tweets into four categories: Irrelevant to e-cigarettes, Commercial tweets, organic tweets with attitudes (supporting or against or neutral) the use of e-cigarettes, and the geographic locations information city and state. Researchers selected six socio-economic variables from Census data 2014 that are associated with smoking and health disparities. Researchers classified the tweets based on a combination of human judgment and machine-learning algorithms, and two coders classified a random sample of 2000 tweets into five categories. The researcher applied a multilabel Naïve Bayes classifier algorithm; the model achieved an accuracy of 93.6% on the training data. Then the researcher applied the machine learning algorithm to a full set of collected tweets and found the accuracy of the validation data was 83.4%. To evaluate the socio-economic impact related to public perception regarding e-cigarette use in the USA, researchers calculated the Pearson correlation between prevalence and percentage of opinion polarities and selected ACS variants for 50 states and the District of Columbia. In [40], the authors Investigated the link between any updates on certain brands and their reaction. Researchers gathered geographic locations based on the data to see consumer distribution. Researchers collected Twitter data by using the REST API. In total, 3,200, from ten different profiles, then used sentiment analysis to differentiate between clustered data expressed positively or negatively then resampled the result in an object model and cluster. For every answer, the researcher has been evaluated for the textual sentiment analysis from the object model. Researchers used AFINN based word list and Sentiments of Emojis to run comprehensive sentiment analysis; for the data that not existed in the word list, researcher added a separated layer to an analysis by using emoji analysis on top of sentiment analysis, and authors did not see any difference in the level of accuracy when applying this extra layer. The researcher found some Sentiment Analysis weaknesses related to the misuse of emoji, the use of abbreviated words or terms of slang, and the use of sarcasm. In [41], the authors proposed an application that can classify a Twitter content into spam or legitimate. Auhtors used an integrated approach, from URL analysis, Natural Language Processing, and Machine Learning techniques. Auhtors analyzed the URL that derived from the tweets, then convert URLs to their long-form, then compare URLs with Blacklisted URLs, then compare them with a set pre-defined expressions list as spam; the presence of any of these expressions can conclude that the URL is spam. After cleaning data, the stemmed keywords are compared with the per set of identified spam words and, if a pre-defined expressions list are found in the tweet, then the user is classified as spam. Six features were used for classification. The training set has 100 instances with six features and a label. The author used Naïve-Bayes algorithm. Authors manually examined 100 users and found (60 were legitimate and 40 were spam) then the sampled checked by the application and the result presented that 98 were classified correctly.

3. Proposed Approach

In this work, the authors implemented and evaluated different classifiers in classifying the sentiment of the tweets. It's by utilizing RapidMiner software. Classifiers were applied on both balanced and unbalanced datasets. Classifiers used are Decision Tree, Naïve Bayes, Random Forest, K-NN, ID3, and Random Tree.

4. Experiment Setup

In this section, the dataset is described as well as the settings and evaluation techniques are used in the experiments have been discussed. The prediction for the tweet category is tested twice—the first time on an unbalanced data set and the second time on a balanced dataset as below.

- **Experiments on the unbalanced dataset:** Decision Tree, Naïve Bayes, Random Forest, K-NN, ID3, and Random Tree classifiers were applied on six unbalanced datasets.
- **Experiments on the balanced dataset:** In this experiment, the challenges related to unbalanced datasets were tackled by manual procedures to avoid biased predictions and misleading accuracy. The majority class in each dataset almost equalized with the minority classes, i.e., many positive, negative, and neutral, practically the same in the balanced dataset as represented in Table 3.

4.1. Dataset Description

We obtained a dataset from Kaggle, one of the largest online data science communities in this work. It consists of more than 14000 tweets, labeled either (positive, negative, or neutral). The dataset was also split into six datasets; each dataset includes tweets about one of six American airline companies (United, Delta, Southwest, Virgin America, US Airways, and American). Firstly, we summarized the details about the obtained datasets, as illustrated in Table 1 below.

Table 1: Summary of obtained Dataset

	American Airline Companies					
	Virgin America	United	Delta	Southwest	US Airways	American
Number of Tweets	504	3822	2222	2420	2913	2759
Positive Tweets	152	492	544	570	269	336
Negative Tweets	181	2633	955	1186	2263	1960
Neutral Tweets	171	697	723	664	381	463

4.2. Dataset Cleansing

In this section, the authors described the followed procedure in the dataset preparation. The authors utilized RapidMinor software for tweet classification. Authors followed the methods described below:

1) Splitting the dataset into a training set and test set.

2) Loading the dataset, i.e., excel file into RapidMinor software using Read Excel operator.

3) Applying preprocessing by utilizing the below operators.

- Transform Cases operator to transform text to lowercase.
- Tokenize operator to split the text into a sequence of tokens.
- Filter Stop words operator to remove stop words such as: is, the, at, etc.
- Filter Tokens (by length) operator: to remove token based on the length, in this model, minimum characters are 3, and maximum characters are 20 any other tokens that don't match the rule will be removed.
- Stem operator: to convert words into base form.

4.3. Dataset Training

Each of the datasets was divided into two-part. The first part contains 66% of the total number of tweets of the data set, and it is used to train the machine to classify the data under one attribute, which is used to classify the tweets to either (positive or Negative or Neutral). The remaining 34% of tweets were used to classify tweets' attribute to (positive or Negative or Neutral), i.e., test set.

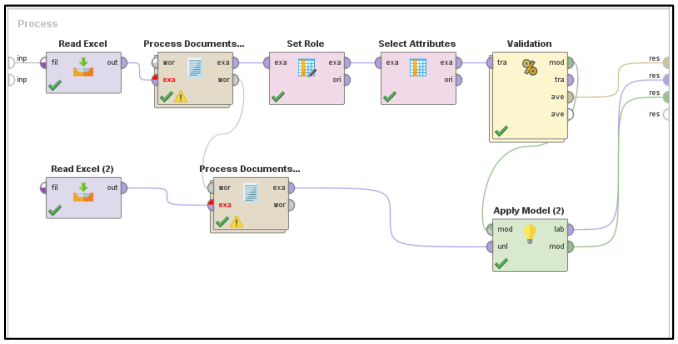

Figure 1: Summarization of the Process Model

4.4. Dataset Classifying

In this section, the authors described the steps in the tweet's classification techniques.

- Set Role operator is used to allow the system to identify sentiment as the target variable,
- Select Attributes operator is used to removing any attribute which has any missing values.
- Then in the validation operator, the dataset is divided into two parts (training and test). We used Two-thirds of the dataset to train the dataset and the last one-third to evaluate the model.
- Different machine learning algorithms are used for training the dataset (Decision Tree, Naïve Bayes, Random Forest, K-NN, ID3, and Random Tree).
- For testing the model, the Performance operator utilized to measure the performance of the model.

5. Experiment Results and Discussion

This section presented the experiment results in terms of accuracy level of prediction for each classifier on both types of datasets (balanced, unbalanced) and a comparison between the two experiments.

5.1. Experiment results for an unbalanced dataset

Figure 2 and Table 2 present the accuracy results of the utilized classifiers on the datasets.

Table 2: Accuracy results on unbalanced dataset

	Accuracy					
	Virgin America	United	Delta	Southwest	US Airways	American
Dataset	504	3822	2222	2420	2913	2759
Training set	333	2523	1467	1597	1923	1821
Test set	171	1299	755	823	990	938
Decision Tree	31.86%	72.03%	42.08%	50.46%	82.72%	68.98%
Naïve Bayes	32.74%	72.38%	42.28%	51.01%	82.72%	72.21%
Random Forest	31.86%	72.03%	42.08%	50.46%	82.72%	68.98%
K-NN	39.82%	11.66%	35.27%	50.46%	82.72%	69.43%
ID3	32.74%	72.38%	42.28%	51.01%	82.72%	72.21%
Random Tree	31.86%	72.03%	42.08%	50.46%	82.72%	68.98%

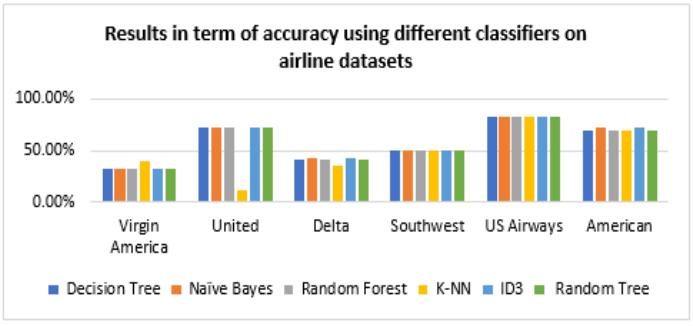

Figure 2: Accuracy results on unbalanced airline datasets using different classifiers

In some datasets, the classifier's accuracy results were very high, while it was low in others. All classifier's performance on the US airways dataset and United dataset provided the best accuracy due to the dataset's size, which was the largest. Naïve Bayes classifier, Decision Tree, and ID3 were mostly better than other classifiers and were given almost the same accuracy level. The classifiers with Virgin America dataset reported the lowest accuracy level due to the dataset's size, which is very small.

5.2. Experiment results for a balanced dataset

Decision Tree, Naïve Bayes, Random Forest, K-NN, ID3, and Random Tree classifiers were applied on the five obtained balanced datasets. (United, Delta, Southwest, and US Airways). The dataset for each was divided into two parts. The first part contains 66% of the total number of tweets of the data set, and it is used to train the machine to classify the data under one attribute, which is used to classify the tweets as either positive, Negative, or Neutral. The remaining 34% of tweets were used to classify tweets' attributes into (positive, Negative, or Neutral), i.e., test set.

Table 3: Number of tweets before and after balancing.

	Number of instances		Percentage		
	Total tweets before balancing	Total tweets after balancing	Positive	Negative	Neutral
United	3822	8276	33%	33%	34%
Delta	2222	2635	33%	33%	34%
Southwest	2420	5518	33%	33%	33%
US Airways	2913	6608	33%	33%	33%
American	2759	5924	34%	34%	33%

After applying different algorithms on the five balanced datasets, the performance, i.e., accuracy results, were reported in Table 4 and Figure 3 below:

Table 4: Accuracy results on the balanced dataset

	Accuracy					
	Virgin America	United	Delta	Southwest	US Airways	American
Dataset	8276	2635	5518	6608	5924	8276
Training set	5464	1743	3642	4363	3911	5464
Test set	2812	892	1876	2245	2013	2812
Decision Tree	35.06%	34.63%	34.35%	35.06%	33.98%	35.06%
Naïve Bayes	97.65%	36.99%	65.48%	97.65%	61.20%	97.65%
Random Forest	35.06%	34.63%	34.35%	35.06%	33.98%	35.06%
K-NN	38.79%	32.77%	35.32%	38.79%	39.47%	38.79%
ID3	97.65%	36.99%	65.48%	97.65%	61.20%	97.65%
Random Tree	35.06%	34.63%	34.35%	35.06%	33.98%	35.06%

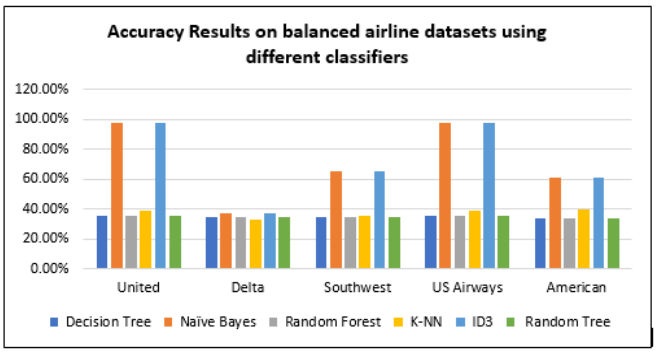

Figure 3: Accuracy results on balanced airline datasets using different classifiers

5.3. Comparison between two experiments results for each classifier

While comparing results between the performance of the classifiers on balanced and unbalanced datasets, it was found the following as seen in Figure 4 below:

5.3.1. Naive Byes and ID3

Gave the best accuracy than other classifiers in the two experiments. The accuracy level with the balanced datasets higher than unbalanced ones. In the unbalanced datasets, the maximum accuracy for both classifiers was 82.7%. In the balanced dataset, the accuracy reached 97.6%; these results confirm that these two classifiers are the best compared to the other selected classifiers in the two experiments:

5.3.2. K-NN and Decision Tree

Show better performance with the unbalanced datasets, and the difference is so apparent. The maximum accuracy with the balanced datasets is 39.4%, while it reached 82.7 % with the unbalanced datasets.

5.3.3. Random forest and Random Tree

It shows better performance with the unbalanced datasets, and the difference is so apparent. The maximum accuracy with the balanced datasets around 35%, while it reached 82.7% with the unbalanced datasets.

In conclusion, Naive Bayes and ID3 gave a better accuracy level than other classifiers, and the performance was better with the balanced datasets. The different classifiers (K-NN, Decision Tree, Random Forest, and Random Tree) gave a better understanding of the unbalanced datasets.

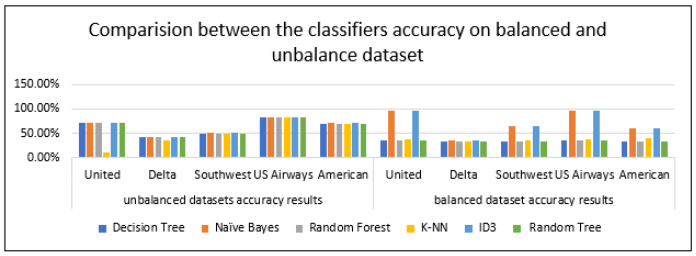

Figure 4: Accuracy results of classifiers on balanced and unbalanced datasets

6. Conclusions

Social media websites are gaining very big popularity among people of different ages. Platforms such as Twitter, Facebook, Instagram, and Snapchat allowed people to express their ideas, opinions, comments, and thoughts. Therefore, a huge amount of data is generated daily, and the written text is one of the most common forms of the generated data. Business owners, decision-makers, and researchers are increasingly attracted by the valuable and massive amounts of data generated and stored on social media websites. Sentiment Analysis is a Natural Language Processing field that increasingly attracted researchers, government authorities, business owners, services providers, and companies to improve products, services, and research. In this research paper, the authors aimed to survey sentiment analysis approaches. Therefore, 16 research papers that studied Twitter's text

classification and analysis were surveyed. The authors also aimed to evaluate different machine learning algorithms used to classify sentiment to either positive or negative, or neutral. This experiment aims to compare the efficiency and performance of different classifiers that have been used in the sixteen papers that are surveyed. These classifiers are (Decision Tree, Naïve Bayes, Random Forest, K-NN, ID3, and Random Tree). Besides, the authors investigated the balanced dataset factor by applying the same classifiers twice on the dataset, one on the unbalanced and the other, after balancing the dataset. The targeted dataset included six datasets about six American airline companies (United, Delta, Southwest, Virgin America, US Airways, and American); it consists of about 14000 tweets. The authors reported that the classifier's accuracy results were very high in some datasets while low in others. The authors indicated that the dataset size was the reason for that. On the balanced dataset, the Naïve Bayes classifier, Decision Tree, and ID3 were mostly better than other classifiers and have given the almost same level of accuracy. The classifiers with Virgin America dataset reported the lowest level of accuracy due to its small size. On the unbalanced dataset, results show that the Naive Byes and ID3 gave a better level of accuracy than other classifiers when it's applied on the balanced datasets. While (K-NN, Decision Tree, Random Forest, and Random Tree) gave a better understanding of the unbalanced datasets.

Conflict of Interest

The authors declare no conflict of interest

ABSTRACT

Tourism is relatively high profit, low-cost and high work opportunity industry. Medical tourism is special kind of business type in tourism industry. The characteristic of medical tourism is high threshold and high profit for hospital and government. But, fewer literatures research about competitiveness of medical tourism industry until now. Especially, medical tourism industry faces big challenge when COVID-19 occurs which stop patient to go abroad for treating in the world. This research arranges relative literatures and invite some expert's opinion to design criteria for evaluating competitiveness of medical tourism industry in each area. After that, linguistic VIKOR and Entropy will be integrated to analyze and evaluate performance of medical tourism industry among China, Taiwan, Japan and South Korea. Finally, some reasonable suggestion will be provided for Taiwan government and hospital.

1. Introduction

Compare with other area in Asia, medical service in Taiwan is relatively good whose price–performance ratio is high in the world. Based on health care index from CEOWORLD magazine, the rank of Taiwan is in top levels among eighty regions in the world (Please refer to Figure 1). This magazine investigates and believe that Taiwan's health care standard ranks first in medical equipment, medical personnel technology and medical expenses fields. Based on this information, Taiwan government can consider to apply this strength of Taiwan medical service to develop economics.

Business volume of tourism relative industry such as accommodation industry, transportation industry, catering industry and amusement industry will increase when government develop tourism industry [2]. Besides, a huge amount of work opportunity can be generated by tourism industry. Based on above reason, medical tourism become the main development business activity in Taiwan. However, medical tourism industry faces big challenge when COVID-19 occurs which stop tourist to travel in the world and foreign patient can't go to Taiwan for treatment [3]. It needs a novel criteria and framework to evaluate competitiveness of medical tourism industry for satisfying the sustainable development goal. The goal (research objectives) of this research is to develop a framework to evaluate and understand competitiveness of medical tourism industry under the sustainability development condition in Taiwan.

The content of this research is organized as follows. Some literatures about medical tourism evaluation will be arranged and discussed in chapter 2. After that, some operation content about linguistic variable and proposed method will be explained in chapter 3. The competitiveness of medical tourism industry among China, Taiwan, Japan and South Korea will be analyzed and evaluated based on proposed method and SWOT analysis about Taiwan medical tourism industry will be executed in chapter 4. Some management implementation will be token over in chapter 5. Finally, conclusion and future research will be discussed as ending.

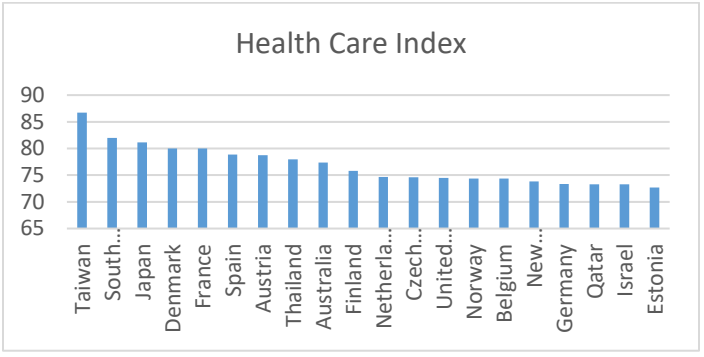

Figure 1: Rank of medical service in the world [1]

2. Literature Review

In 2005, the business volume of global medical market and healthcare market reached US$200-300 billion. In the same time point, the tourist volume of the global medical tourism industry market exceeds 19 million person per year and business volume of medical tourism industry approaches US$20 billion [4]. Enterprise in medical tourism industry should manage and evaluate its performance. So, there are various literatures research about medical tourism evaluation has been executed under this development trend. Below literatures are relative research about medical tourism evaluation.

In [5], the author collected relative literatures and surveyed relative experts' opinions to build 33 evaluation criteria. And then, fuzzy VIKOR were applied to evaluate service quality of public medical tourism hospital. In [6], the author developed a comprehensive framework to assess the factors affecting health tourism development in Yazd province in China. Their method integrated interpretive structural modeling (ISM) with fuzzy TOPSIS to evaluate medical tourism competitive ability. Research result showed that patient satisfaction is the most important factors for developing medical tourism. In [7], the author tried to validate the measurement model for medical tourism research. In their research, the research dimension about human capital, physical infrastructure and patient satisfaction had been validated by confirmatory factor analysis (CFA). Future scholar can use their questionnaire to test performance of medical tourism industry. In [8], the author used strengths, weaknesses, opportunities and threats (SWOT) analysis to evaluate business status of medical tourism industry in Turkey. After that, analytical hierarchy process (AHP) were applied to analyze and rank the importance of each factor which will influence the development of tourism industry in Turkey.

In [9], the author took Indian medical tourism hospital as research target. This scholar applied SWOT analysis to evaluate the development status of each organization. And then, technique for order preference by similarity to ideal solution (TOPSIS) were combined with AHP to rank the performance of each hospital. In [10], author considered that medical tourism industry is normal business phenomenon because some country face long waiting queues, high treatment costs or lack of insurance in some country. They applied SWOT model and best-worst techniques to develop and analyze medical tourism industry development strategy in Yazd province of Iran. In [11], the author collected relative information of different city in India and used rough number to integrate experts' opinions. Analytic hierarchy process was applied to evaluate weigh of each medical tourism criteria and multi‐attributive border approximation area comparison methods were used to rank performance of medical tourism site. According to analysis result, we can know that "quality of infrastructure of healthcare institutions", "supply of skilled human resources" and "new job creations" were three most important factor to select medical tourism destination. In [12], the author collected relative information to build medical tourism evaluation criteria and investigated fuzzy TOPSIS with decision making trial and evaluation laboratory (DEMATEL) to analyze the key factor for developing medical tourism industry in Malaysia. According to their research result, human and technological factors are most important key factors for medical tourism industry. In [13], author used SERVQUAL methodology to evaluate service quality of hospital and designed twenty-eight criteria to build hospital service quality. Fuzzy AHP and Elimination and Choice Translating Reality (ELECTRE-I) were employed to evaluate and rank performance of each hospitals. According to experiment result, trustworthiness and empathy were the most important dimension for patient to select hospital.

According to above information, we can know that a lot of literatures discuss about medical tourism in each dimension. They used each kind of multi criteria decision making technology to handle each kind medical tourism evaluation problem (such as importance factor analysis, medical service evaluation, hospital performance evaluation and hospital destination decision etc). However, past literatures investigative about medical tourism evaluation problem who usually lack to consider the dimension about sustainable development of medical tourism industry when some special event will stop development of medical tourism such as COVID-19. This study will fill this research gap.

3. Preliminary and Entropy-VIKOR Method

In this study, we will introduce the research tool – SWOT analysis, linguistic variable, entropy method and Entropy-VIKOR Method.

3.1. SWOT analysis

Strengths, Weaknesses, Opportunities and Threats Analysis (SWOT Analysis) are the most useful analysis tool. This tool has been applied in each kind of fields such as hospitality industry evaluation [14], tourism development strategy [15], medical tourism assessment [8] etc. SWOT is the comprehensive analysis tool which think over relative conditions of relevant competitors and external environmental conditions of research target. This method allows research target to analyze, examine and investigate external opportunities and potential threats. After that, research target will understand and recognize their own advantages and disadvantages for analyzing its competitiveness (Refer to Table 1).

Table 1: SWOT analysis concept

		Impact on Research Target	
		Good for Research Target	Harmful to Research Target
Sources of Influencing Factors	Within the Research Target	Strengths	Weaknesses
	External Environment	Opportunities	Threats

3.2. Linguistic Variable

Linguistic variable is useful tool. This tool can let expert to express their opinion under the same evaluation scale and integrate experts' opinion easily [16]. Below content are the definition, notation and operation about linguistic variable.

Definition 1. The η scale linguistic term set S is the set of linguistic variables. S can be described by following equation [17] and [18].

$$S=\{s_0^{\eta}, s_1^{\eta}, \dots, s_{\eta-1}^{\eta}\} \quad (1)$$

where $s_{\mathfrak{z}}^{\eta}$ ($\mathfrak{z} = 0,1, \dots, \eta-1$) is η scale linguistic variable and η is the total volume of linguistic variable in S.

Definition 2. △ is the linguistic transfer function. This function can transfer linguistic variable into crisp value n (n is between 0 and 1). This function can be described by following equation [17] and [18].

$$\Delta(s_z^{\eta}) = \frac{z}{\eta-1}=n \quad (2)$$

Definition 3. $\triangle^{-1}$ is the linguistic transfer inverse function. This function can transfer crisp value n (n is between 0 and 1) into linguistic variable. This function can be described by following equation [17] and [18].

$$\triangle^{-1}(n)=s_{n*(\eta-1)}^{\eta} \quad (3)$$

3.3. Entropy Method

Entropy Method is one kind of weight evaluation technology. Under this method, importance of each criterion will be decided according to information volume in each criterion. So, multi criteria decision making (MCDM) technology integrated with entropy method can distinguish the performance of each alternative easily [19]. Below content are notation and operation about entropy method.

Definition 4. Suppose that φ_q is entropy value for criterion q. If information in criterion q is low, then φ_q is low. Entropy function should be described by following equation [20] and [21].

$$\varphi_q=-1 * \frac{1}{lnM}\sum_{i=1}^{M} f_{iq} ln(f_{iq}) \quad (4)$$

where $f_{gq}=\frac{x_{gq}}{\sum_{i=1}^{M} x_{iq}}$.

Definition 5. Weight (importance) of each criterion should be decided by entropy value. The weight of criterion q will be acquired by following equation [20] and [21].

$$w_q=\frac{1-\varphi_q}{\sum_{z=1}^{N}(1-\varphi_z)} \quad (5)$$

where N is the total volume of criteria.

3.3. Entropy-VIKOR Method

In this research, Entropy-VIKOR Method are selected to cope with medical tourism competitiveness evaluation problem. In Entropy-VIKOR Method, some notation will be applied and can be described as Table 2.

Table 2: Notation in Entropy-VIKOR Method

Set	Notation	Detail Description
Research target	$T=\{T_1, T_2, \dots, T_m\}$	m represents volume of research target
Criteria	$C=\{C_1, C_2, \dots, C_n\}$	n represents volume of criteria
Weight criteria	$W=\{w_1, w_2, \dots, w_n\}$	n represents volume of criteria
Decision matrix	$X = \begin{matrix} & C_1 & C_2 & \dots & C_n \\ T_1 \\ T_2 \\ \dots \\ T_m \end{matrix} \begin{bmatrix} \tilde{x}_{11} & \tilde{x}_{12} & \dots & \tilde{x}_{1n} \\ \tilde{x}_{21} & \tilde{x}_{22} & \dots & \tilde{x}_{2n} \\ \dots & \dots & \dots & \dots \\ \tilde{x}_{m1} & \tilde{x}_{m2} & \dots & \tilde{x}_{mn} \end{bmatrix}$	$\tilde{x}_{ij}$ represents performance of research target T_i with respect to C_j.
Expert	$E=\{E_1, E_2, \dots, E_K\}$	K represents volume of experts

At first, research targets should be decided by organization. Organization should organize the evaluation project team. After that, some experts will be invited into this team. After experts discuss with each other, criteria for evaluating competitiveness of medical tourism industry can be arranged and selected. And then, experts' opinion will be gathered for evaluating performance of each research target respect to each criterion. At last, Entropy-VIKOR method will be used to evaluate competitiveness of medical tourism industry among each research target in Asia. SWOT analysis will be executed for detailly evaluating competitiveness of medical tourism industry among each research target. Research result will be provided to organization for reference. Relative execution process can refer to Figure 2.

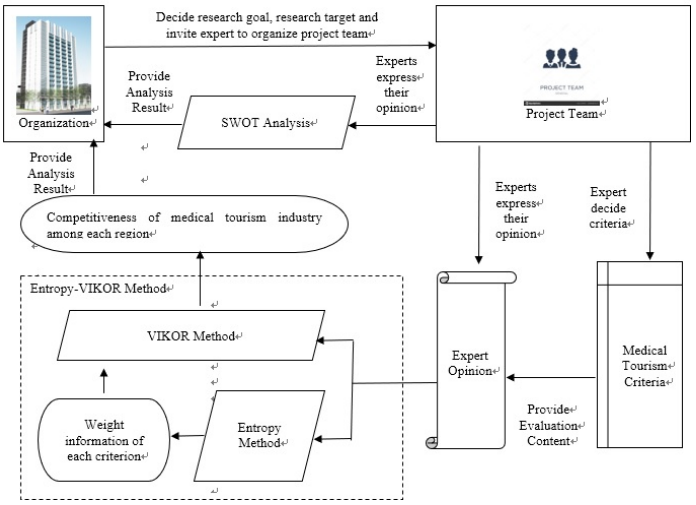

Figure 2: Execution process of proposed method

Let $\tilde{x}_{ijk}$ be expert k's opinion for performance of region i with respect to criterion j. Experts' opinion will be integrated by following equation.

$$\tilde{x}_{ij}=\triangle^{-1}\left(\sum_{k=1}^{K}\frac{\Delta(\tilde{x}_{ijk})}{K}\right) \quad (6)$$

In this research, weight of criteria will be calculated and acquired by entropy method. Weight evaluation function can be describing according to following equation.

$$w_q=\frac{1-\varphi_q}{\sum_{z=1}^{n}(1-\varphi_z)} \quad (7)$$

where $L_{iq}=\frac{\Delta(\tilde{x}_{iq})}{\sum_{i=1}^{m}\Delta(\tilde{x}_{iq})}$, $\varphi_q=-1 * \frac{1}{\ln(m)}\sum_{i=1}^{m} L_{iq} ln(L_{iq})$.

The advantage of using entropy method to acquire the weight of each criteria is that entropy method can decide the weight of each criteria automatically for reducing the evaluation burden of experts.

Below content is relative execution step in VIKOR method.

Positive ideal solution (PIS) is the importance index in VIKOR method. PIS represents the ideal performance of virtual best research target (alternative). PIS can be calculated according to following equation.

$$f_j^*=max_i \triangle^{-1}(\tilde{x}_{ij}) \quad (8)$$

Negative ideal solution (NIS) is another importance index in VIKOR. NIS represents the poorest performance of virtual worst research target (alternative). NIS can be calculated according to following equation.

$$f_j^-=min_i \triangle^{-1}(\tilde{x}_{ij}) \quad (9)$$

Total performance of research target (the largest group utility) S_i represents the overall performance of research target T_i. S_i can be calculated according to following equation.

$$S_i=\sum_{j=1}^{n} w_j * \frac{f_j^*-\triangle^{-1}(\tilde{x}_{ij})}{f_j^*-f_j^-} \quad (10)$$

The individual regret value of research target (the smallest individual regret) R_i represents the maximum regret degree of decision maker if he/she select research target T_i. R_i can be calculated according to following equation.

$$R_i=max_j\left[w_j * \frac{f_j^*-\triangle^{-1}(\tilde{x}_{ij})}{f_j^*-f_j^-}\right] \quad (11)$$

Total performance of research target S_i and individual regret value of research target R_i respectively means different consideration for making decision. So, expert can rank the performance of research target according to largest group utility S_i and smallest individual regret R_i simultaneously. Based above view point, it generates the compromise result Q_i. Q_i should be calculated for ranking performance of each research target based on following equation.

$$Q_i=v*\frac{S_i-S^*}{S^--S^*}+(1-v)*\frac{R_i-R^*}{R^--R^*} \quad (12)$$

where v represents decision parameter. This parameter is used to make decision for adjusting the importance between S_i and R_i. $S^*=min_i S_i$, $S^-=max_i S_i$, $R^*=min_i R_i$, $R^-=max_i R_i$.
Research target T_i will be better if Q_i is fewer.

4. Competitiveness Analysis of Medical Tourism Industry Among Asia Region

Competitiveness of medical tourism industry in Taiwan will be evaluated by an organization. After discussing and considering, four regions have been chosen as research target to evaluate their competitiveness. Those research targets are South Korea (T_1), Japan (T_2), Taiwan (T_3), China (T_4). Above research target are regions in Asia which are main medical tourism competitor for Taiwan.

The execution process of proposed method is as follows:
Step 1. Organize evaluation project team

In the beginning, Taiwan government organize evaluation project team and invite nine experts to execute this evaluation project. Experts in this team include government officer, employees in traditional hotel, employees in travel agency, nurse leader, doctor (hospital dean) and university professors. The investigation target covered already include tourism industry, medical industry, government and university. So, respondents in this survey are representative (Refer to Table 3).

Table 3: Interviewee related information

no	attribute	Content
1	Industry	Hospital dean
2	Industry	Nurse leader
3	Industry	High level employees in travel agency
4	Industry	High level employees in hotel
5	Government	Staff in the Ministry of Economy
6	Government	Staff in Tourism Bureau
7	Government	Staff in the Ministry of Health and Welfare
8	Academia	Professor in department of business management
9	Academia	Professor in department of nursing management

Step 2. Execute evaluation criteria decision

After collecting literatures and experts discuss with each other, eight criteria are employed to evaluate performance of research target. The criteria include medical industry image (C_1), medical ability (C_2), telemedicine ability (C_3), medical cost (C_4), financial status in hospital and travel agency (C_5), volume of medical tourism traveler per year (C_6), medical service speed in hospital (C_7) and maximum service volume in region (C_8). Above criteria are suitable to evaluate competitiveness of medical tourism industry because of below reason.

(a) medical industry image

Patient's medical industry image in this region will influence his/her intention to go to the region [22] and [23], foreign hospital does not have opportunity to service this patient if he/her do not go to this region.

(b) medical ability

Some patients want to receive high quality medical service, so medical ability of medical industry in this region is the main consideration when patients select medical tourism destination region [24] and [25].

(c) telemedicine ability

Hospitals need to treat their foreign patients and maintain relationship with those patients. However, COVID-19 causes that medical tourism patient cannot go abroad to receive face-to -face medical service. So, telemedicine ability is more and more important for region to develop medical tourism industry in order to maintain relationship with foreign patients and continuously treat those patients.

(d) medical cost

In some region, medical cost is very expensive for citizen [26] and [27]. So, patient has the intention to cure his/her disease in foreign region. Medical cost is the main consideration for choosing medical tourism destination region.

(e) financial status in hospital and travel agency

Some hospital's business volume decreases because COVID-19 occurs and foreign patient cannot go abroad to receive medical service. So, robust financial status in hospital and travel agency is key factor if medical tourism industry wants to sustainable development.

(f) volume of medical tourism traveler per year

Volume of medical tourism traveler in this region is the important index to evaluate medical tourism development in this region. High volume of medical tourism traveler not only can reduce medical cost but also can increase potential foreign patient because medical tourism traveler will execute "buzz marketing" if this traveler satisfies medical service in this region.

(g) medical service speed in hospital

Foreign patients go abroad for receiving medical service will request service quality. In some literatures, it justified that medical service time will negative influence patient safety and service quality perception [28]. So, controlling medical service speed in the reasonable range is the important competitiveness of hospital and it will influence the development of medical tourism industry in this region.

(h) maximum service volume in the region

The maximum medical service volume in the region is important index because this index will decide maximum business volume of medical tourism industry in this region. According to scale economics view point, high business volume of medical tourism industry can reduce medical cost in this region because hospital can purchase a huge amount of medicine and medicine price will reduce by bulk purchase [29].

Step 3. Collect information

In this study, nine scale linguistic variables are employed for experts to express their opinions [30] and [31]. Expert's opinion about competitiveness of each research target (region) in medical tourism industry respect to each criterion can refer to Table 4.

Table 4: Performance of each research target

	Expert 1's opinion				Expert 2's opinion			
	South Korea	Japan	Taiwan	China	South Korea	Japan	Taiwan	China
C_1	EG	EG	P	MG	MG	F	EG	VG
C_2	MP	MG	MP	EG	MG	EG	EG	EG
C_3	MP	MG	MG	EG	MG	F	EP	EG
C_4	G	EG	EG	MG	MP	MG	VG	MG
C_5	MG	F	MP	P	F	MG	EG	EP
C_6	EG	F	MP	EP	EG	F	EP	EP
C_7	EG	F	VG	F	G	MP	MP	EG
C_8	MG	G	MG	MP	MG	EG	EG	EP
	Expert 3's opinion				Expert 4's opinion			
	South Korea	Japan	Taiwan	China	South Korea	Japan	Taiwan	China
C_1	VG	MP	F	EP	MP	F	VG	F
C_2	EG	MG	MG	EP	F	G	VG	EP
C_3	MG	MG	G	G	MP	G	VG	MG
C_4	EP	MG	G	MG	F	G	G	F
C_5	MG	MP	EP	F	MG	MP	EG	VG
C_6	VG	F	VP	MP	G	MG	F	MP
C_7	MP	EG	MG	VG	EP	VG	F	P
C_8	EG	MG	F	MG	G	G	MG	G
	Expert 5's opinion				Expert 6's opinion			
	South Korea	Japan	Taiwan	China	South Korea	Japan	Taiwan	China
C_1	F	MG	F	MP	P	VG	VG	F
C_2	EG	VG	MP	F	EG	EG	MP	EG
C_3	MG	F	F	MG	MP	MG	EP	MG
C_4	EP	P	EG	VG	VG	VG	MP	MG
C_5	EG	VG	EP	EP	MP	P	MP	EG
C_6	MG	MG	P	EP	EP	MG	P	EP
C_7	F	EG	MG	F	F	MP	F	P
C_8	MP	F	MG	VG	VG	F	P	MG
	Expert 7's opinion				Expert 8's opinion			
	South Korea	Japan	Taiwan	China	South Korea	Japan	Taiwan	China
C_1	MP	F	VG	P	VG	G	P	MP
C_2	MG	VG	MP	MP	F	EG	MG	MP
C_3	EG	F	MG	EG	MG	VG	MG	VG
C_4	EP	P	F	F	F	F	EG	VG
C_5	EG	MG	MP	EP	MG	EG	F	VG
C_6	EP	F	EP	P	VG	MG	EP	MP
C_7	EP	MP	EG	P	MP	EG	VG	MG
C_8	EP	VG	P	VG	P	VG	F	P
	Expert 9's opinion							
	South Korea	Japan	Taiwan	China				
C_1	EG	G	MG	MG				
C_2	F	EG	MP	MP				
C_3	F	MG	F	VG				
C_4	MP	MP	VP	MG				
C_5	G	MP	MP	P				
C_6	VG	EG	EP	EP				
C_7	P	P	F	F				
C_8	MG	VG	VG	EG				

Step 4. Calculate weight (importance) of each criterion

In this work, we use entropy method (Refer to equation 7) to calculated weight of each criteria. Analysis result can refer to Table 5.

Table 5: Weight of each criterion

Criteria	C_1	C_2	C_3	C_4
Weight	0.1246	0.1902	0.1600	0.1190
Criteria	C_5	C_6	C_7	C_8
Weight	0.0656	0.1043	0.0906	0.1457

In this study, the rank of each research target (region) in medical tourism industry is decided by VIKOR method. The advantage of VIKOR is that VIKOR can solve decision problems with conflicting criteria. In this research, medical ability (C_2) and medical service speed in hospital (C_7) are conflicting criteria. Industry image (C_1) and medical cost (C_4) are conflicting criteria.

Step 5. Calculate PIS and NIS

Positive ideal solution (PIS) is the ideal status for medical tourism industry in Asia. On the opposite direction, negative ideal solution the worst status for medical tourism industry in Asia. PIS and NIS are reference points used to evaluate performance of each medical tourism industry (research target). Equation 8 and equation 9 are employed to calculate PIS and NIS. Analysis result can refer to Table 6.

Table 6: PIS and NIS

PIS	C_1	C_2	C_3	C_4
	0.7344	0.9688	0.9219	0.7969
	C_5	C_6	C_7	C_8
	0.7656	0.7500	0.7344	0.8438
NIS	C_1	C_2	C_3	C_4
	0.5156	0.5781	0.5625	0.4219
	C_5	C_6	C_7	C_8
	0.4688	0.1719	0.4688	0.6406

Step 6. Calculate total performance of research target S_i and the individual regret value of research target R_i .

Total performance of research target S_i means the entire performance of research target T_i. Individual regret value of research target R_i means the maximum regret degree of experts if he/she select research target T_i. S_i and R_i separately represents performance analysis result of research target based on different analysis direction. Equation 10 and equation 11 are employed to calculate S_i and R_i. Analysis result can refer to Table 7.

Step 7. Calculate Q value

In this research, decision parameter v is set up as 0.5. We consider that the evaluation index S_i and R_i is important equally. Equation 12 are employed to calculated Q value. Analysis result can refer to Table 7. According to analysis result, the rank of each region is T_2>T_1>T_3>T_4. The competitiveness rank sequence of medical tourism industry in Asia is Japan, South Korea, Taiwan and China.

Table 7: Total performance, individual regret value, Q value and rank among each medical tourism industry in Asia

	South Korea (T_1)	Japan (T_2)	Taiwan (T_3)	China (T_4)
Total performance of research target S_i	0.5795	0.1897	0.6310	0.6758
Individual regret value of research target R_i	0.1457	0.0974	0.1674	0.1902
Q value	0.6612	0.0000	0.8310	1.0000
Rank	2	1	3	4

Step 8. SWOT Analysis

According to experts' opinion (Refer to Figure 3), Taiwan medical industry possesses some strength is the dimension of medical cost (C_4) and medical service speed in hospital (C_7). However, Taiwan medical industry should take effort in the dimension of medical industry image (C_1), medical ability (C_2) and telemedicine ability (C_3). Medical ability and telemedicine ability of Taiwan medical industry will influence foreigners' medical industry image for Taiwan. Because volume of medical tourism traveler per year (C_6) in Taiwan is relatively small, Taiwan possesses high growth space to develop in the medical tourism market. Compare with south Korea, Japan and China, Taiwan lack scale economics in medical industry because financial status in hospital and travel agency (C_5), maximum service volume in region (C_8) is relatively small. The disadvantage of scale economics in Taiwan will cause that it is hard to reduce Taiwan's overall medical costs and is not easy to enhance Taiwan's overall medical industry image (Refer to Table 8).

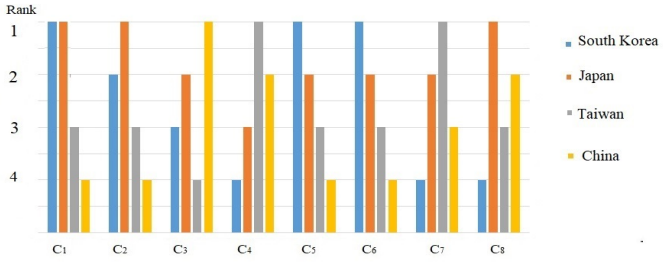

Figure 3: Rank of each region among different dimension

Table 8: SWOT analysis for Taiwan medical tourism industry

Strengths (1) Medical cost is relatively cheap. (2) Medical service speed is relatively fast.	Weaknesses (1) Taiwan medical industry image from tourism traveler is relatively less well-known. (2) Medical ability is weak. (3) Telemedicine ability is weak.
Opportunities (1) Volume of medical tourism traveler is relatively small.	Threats (1) Financial status in hospital and travel agency is relatively small (2) Maximum service volume in region is relatively small

5. Management Implementation

According to experts' opinion, Taiwan possesses high growth space to develop in the medical tourism market because medical cost in Taiwan is relatively cheap which can attract some foreigner whose economics ability is not good enough to receive high price medical service in Japan or South Korea. There are some policies which can promote the competitiveness for Taiwan tourism medical industry.

5.1. Increase volume of medical students each year

There are only 1,300 new students who can enter to study department of medicine in Taiwan each year. Under this total control policy, although Taiwan can maintain high medical standards, it cannot improve Taiwan's medical energy to meet the needs of additional medical services for foreign patients.

5.2. Build overseas medical zone

Taiwan has implemented universal health insurance. Therefore, Taiwan citizen can use low-cost medical services. However, the purpose of developing medical tourism industry is to increase Taiwan's overall GDP. It is unfair to Taiwan citizens if charging standards for foreign patients and Taiwan citizens are the same. Doctor and nurse should use English to serve foreign patients.

This is also a language threshold to develop medical tourism industry.

In order to compete with foreign medical institutions, this study suggests that Taiwan should set up an overseas medical zone. The hospitals in the zone are dedicated to treating foreign patients. It is beneficial to the development for Taiwan's medical tourism industry.

5.3. Development of telemedicine technology

The occurrence of COVID-19 in 2019 has caused the stagnation of the tourism industry in various countries around the world. This event has also affected the development of medical tourism. The medical tourism industry needs to maintain relationship with foreign patients. Telemedicine technology is an important means for hospitals to maintain relationship with foreign patients when international tourism activity cannot be implemented during 2019-2020. Taiwan's medical tourism industry should strengthen and improve telemedicine technology.

5.4. Develop overseas free clinic activities

Taiwan's medical industry is less well-known than south Korea and Japan. Taiwan should go to various countries in southeast Asia and central Asia for free consultations. This will not only enhance Taiwan's medical industry image but also increase the potential patience source for Taiwan's medical tourism industry. The world's low-end industrial manufacturing order may move from China to various countries in southeast Asia and central Asia. Therefore, people from countries in southeast asia and central asia will gradually have the ability to travel to Taiwan for receiving medical service.

6. Conclusion

Medical tourism is very important industry in many countries. A novel framework for evaluating competitiveness of medical tourism industry has been designed in this research. South Korea, Japan, Taiwan and China are selected as research target to evaluate their competitive ability. According to analysis result, we find out that Taiwan's medical tourism competitiveness falls in backward group. So, Taiwan government should provide more resource to improve its medical tourism competitive ability for developing medical tourism industry especially some citizen in other country such as America has high motivation to go abroad for medical treatment because medical expenses is too expensive in America. So, this research provides four suggestion to Taiwan government.

In the future, relative scholar can use this model to evaluate competitiveness of medical tourism industry among Asian countries and European countries. Scholar can analyze how the cultural difference can influence the rank of medical tourism competitiveness.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgement

I state that the data in this research collect from experts in each field and experts' occupation includes government officer, employees in traditional hotel, employees in travel agency, nurse leader, doctor (hospital dean) and university professors. Other scholars can use the data to execute extended research.

ABSTRACT

Blockchain is a solution to improve data integrity and minimize data manipulation. Blockchain technology can be used in student examination management in universities. The process of managing student examination produces some information that can be stored in a blockchain database such as information about the lecturer as the exam creator, exam proctor, student attendance, student exam scores, and the student study continuity status. Blockchain technology ensures student data is valid and reliable, therefore, the company's or organizational trust the teaching and learning process in higher education. This research was conducted using a qualitative approach, which is user center design (UCD) the goal is building a blockchain technology model that can be used by universities in the process of managing student examination, grading, and evaluation. This process will be repeated every semester until students graduate from the university. The propose of this research is to create a business process model based on blockchain technology that can improve data integrity in universities.

1. Introduction

In teaching and learning process in higher education, students will pass through midterm exams, final exams, lab exams, and certification exams [1]. This examination is carried out to measure the student comprehension during the teaching and learning process. Lecturer can also measure how far learning objectives achieved during the process [2].

After examination, students will get the score according to the criteria determined by the department or university. All grade will be recorded in Student Academic Transcript. This Academic Transcript is a reference for company to hired new graduate working in their company [3]. The company will filter the grade and choose the relevant position according to the student ability [4].

Valid and reliable grade will increase the company or organizational confidence and trust in the teaching and learning process that occurs in higher education [5]. However, in 2019 until now, there have been several cases of diploma certificate forgery. As the impact, the company or organization doubts about the data originality stated on the academic transcript and they need to crosscheck back the data to the university [6].

This is challenge by the university to keep the data integrity and security from any manipulation. According to the case happen in 2019, employee working in the company can also be a threat who manipulate the data [7].

This problem requires universities to updates the technology used, especially those concerning the data integrity and security. Blockchain technology is immutable, unchangeable. It also peer to peer, distributed (transparent), validated, and secured, which are very suitable for solving data integrity and security issues [7], [8].

One of the main processes in producing student grades is student examinations management process. This process has several sub processes, they are examination creation process, exam proctor attendance recapitulation, Student attendance recapitulation, the grading process (collecting exam answer and grading from lecture, and the evaluation process (to determine the student status for next semester).

All of the processes will produce data and information in academic transcript which are very important for students, the

*Corresponding Author: Meyliana, Meyliana@binus.edu

validity of data and information is a top priority for universities to For this reason, blockchain solutions are needed in managing student value data [9].

Based on the phenomena, the research question for this research is how to build an education value chain model in student exam management process based on blockchain technology in universities? The goal is to build an education value chain model for exam management process to ensure the data integrity.

2. Literature Review

2.1. Education Value Chain

This section discusses the Education value chain in general, starting from prospective students applying to the university, pass the test, and accepted as students. Students follow two types of activities during their study at higher education, they are intra-curricular and extra-curricular activities.

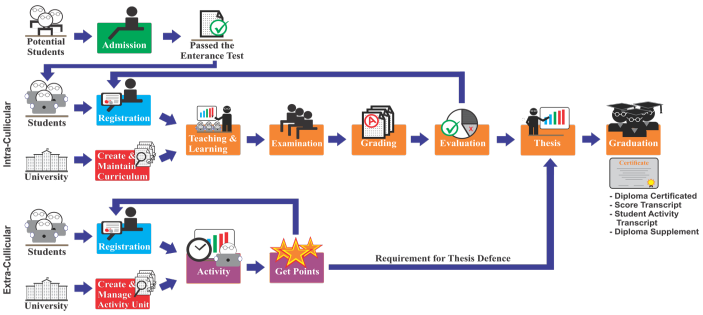

Figure 1: Education Value Chain

The intra-curricular activity starts from course registration for each semester. Then students will follow the teaching and learning process, students will take mid and final exams in each semester. For each exam, lecturer will give the score to students. Based on the results, students will be evaluated by the department and academic advisory unit so student status can be known every semester. In the final semester, students will take a final project or thesis, and thesis defense will be carried out at the end. Apart from following intra-curricular activities, students also take part in extra-curricular activities. Students will register to student organizations and participate in the organization activity. As a result of participating in the activities, students will get points. The points are collected into Student Activity Transcript (SAT). This SAT points is a pre-requisite for thesis defense [7].

2.2. Examination

In general, in one semester there are two exams, mid exam and final exam. With examination, the department or university can find out how far students can understand the overall material delivered and how far the learning objectives achieved. In addition, exam answers can provide feedback for lecturers, departments, and universities [10].

2.3. Grading

After the student takes the exam, the lecturer will give a score in accordance with the assessment measurement set by the university. Grading is the starting point for students to get a cumulative achievement index measured from the cognitive side of students during the teaching and learning process. Assessment may vary according to the type of exam being performed. The theory exam can be assessed based on the answers written by students. Oral exams or presentations are assessed directly based on the results of student presentations. Meanwhile, practical lab exams can be assessed based on the results of the practicum work made [11].

2.4. Evaluation of Study Progress

After students finish their semester, the department and academic supervisor unit will evaluate the learning progress. If students get the satisfactory results, the student may be got appreciation. However, if the evaluation process result is not good, Student will follow various coaching and guidance determined based on student cases and discussions between departments and student advisory units. On the other hand, if students get poor grades and less motivation, then the department and student advisory unit will try to provide solutions according to student interests [12].

2.5. Blockchain in Education

Blockchain research in education can provide new insights to education practitioners. Blockchain technology can be used to improve data integrity to minimize crimes such as diploma certificate forgery. In addition, previous research related to blockchain implementation is the application of smart contracts to business processes in universities [9][13].

3. Research Methodology

Research methodhology used in this research is user-centered design (UCD) [14]. In UCD methodology, research begins with an understanding of the context of use, at this stage a literature study is carried out related to the implementation of blockchain technology in universities. The next stage is to specify user requirements by conducting observations, interviews, and focus group discussions (FGD) to determine the teaching and learning process, especially in examination, grading, and evaluation.

Then a design solution was carried out by creating an education value chain model for the examination, grading and evaluation processes that apply to universities based on blockchain technology. At this stage, it is also described in detail the business processes and identify which activities need to store data and information to the blockchain database. The next stage is evaluate the requirements, FGD is conducted to see whether the model can be accepted and implemented in each university. This evaluation becomes input for validation on the design solution, specify user requirements and understand context of use. If there are things that are still not suitable, then it becomes feedback for the improvement of each stage in this research methodology.

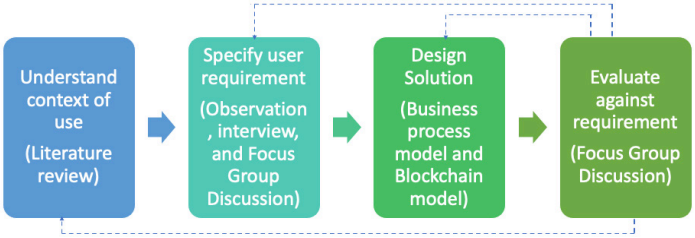

Figure 2: Research Methodology

4. Result and Discussion

The teaching and learning process in higher education which is discussed in this study is the examination, grading and evaluation process as shown in Figure 3.

These three processes are focused on the process of student examination management and evaluations starting from the preparation, execution, and evaluation of student study. All data generated in this process will be stored in a blockchain database so that universities can guarantee the data they have cannot be manipulated and have a good integrity.

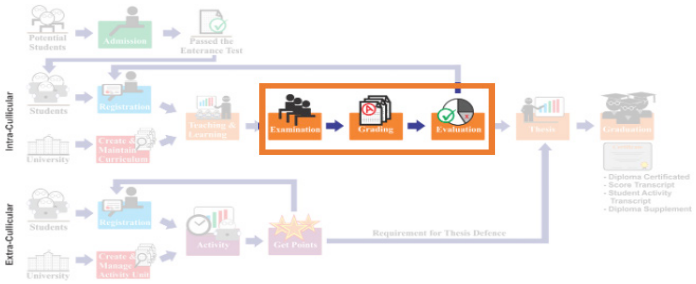

Figure 3: Focus of Research

The examination process begins with exam schedule by the student scheduling department. From the exam schedule, the department will determine the lecturer as the exam question creator. The lecturer will fill out an Exam Agreement Form that contains the topic of the questions and the learning outcomes that will be achieved by students after completing the exam. This form is filled to get the standardized exam questions and approval from the department. The data of the lecturer will be recorded on the blockchain database for honorarium.

The questions that have been completed will be examined by the department and given to the academic operations section to be distributed according to the exam schedule to students.

The exam scheduling section will also schedule the lecturers as exam proctor and the attendance realization data will be stored in a blockchain database as proof of payment of exam proctor fees.

Students take the exam twice per semester (mid exam and final exam). For a practicum course, students take a practicum exam. In each exam, the attendance will be recorded, and this data is stored in a blockchain database as proof of student attendance in the exam.

If the student is absent or cannot attend the exam, student can apply for a make-up exam in accordance with the applicable terms and conditions.

The exam answers are collected by the exam proctor to academic operations section. The academic operational section will validate the answer and distribute it to the lecturer. The lecturer will check the answers and gives score to each student. The score is entered by the lecturer through the system and will be validated by the department in the score judiciary. Student scores consist of several components, such as assignment scores, mid-test scores and final exam scores. This score is stored in the blockchain database. Lecturers will receive the examiner's honorarium according to the number of exam files corrected and proof of payment of this honorarium is stored in the blockchain database.

All grades entered in one semester will be evaluated by the academic supervisor and department. The results of the evaluation will determine the status of students in the continuity of the studies. The status will be stored in the blockchain database.

Figure 4 shows the transactions illustration from the education value chain model for the examination, grading and evaluation processes based on blockchain technology. Users who play a role in the examination, grading, and evaluation processes are students, lecturers, academic operations, scheduling units, student advisory units, and faculty / departments.

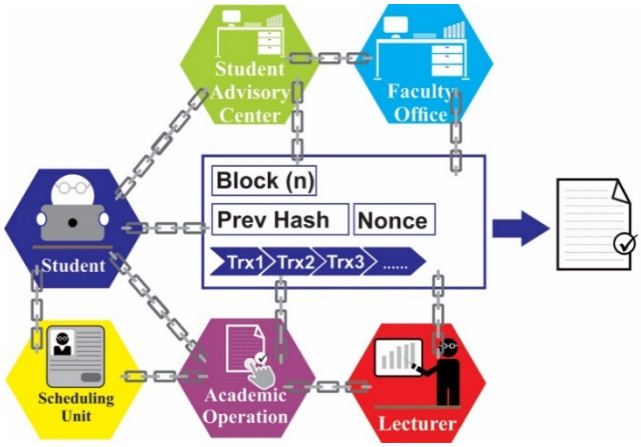

Figure 4: Transaction Illustration of Education Value Chain Model for Examination, Grading, and Evaluation for Higher Education based on Blockchain Technology

Figure 5 (a and b) shows the college's business process in teaching and learning activities focusing on the examination, grading, and evaluation processes. From the business process described in Figure 4 above, the data storage in the blockchain database is important in connection to the financial audit and payment process. The data are:

- Record name of lecturer as the exam creator
  - This data contains the semester period, lecturer code, course code, class code, exam date, and honorarium amount.
- Record name of Exam Proctor
  - This data contains the semester period, lecturer code, course code, class code, exam date, exam room.
- Record the attendance list of students and exam proctor
  - This data contains the semester period, lecturer code, course code, class code, exam date, exam room, student code, and the amount of the exam proctor fee.
- Record a score of students and Record the new score.
  - This data contains the semester period, course code, class code, exam date, exam room, student code, exam component code, and student scores.
- Record a payment of scoring honorarium to lecturer
  - This data contains the semester period, lecturer code, course code, class code, exam date, exam room, number of students and the amount of honorarium
- Record the student's evaluation for each semester
  - This data contains the semester period, course code, student code, component code grades, grades, social studies, and GPA

5. Conclusions

By using blockchain technology, it can be concluded that data integrity will be guaranteed, and data storage is more secure because the data has been validated and cannot be changed. Data changes can still occur by making new transactions without eliminating previous transactions, for example when students protest the score which causes the previous score to change. The Both scores are stored in the blockchain database.

Following the research methodology, we have conducted a focus group discussion to validate the model that has been made and the results are that all participants agree with this model and they think this study can be easily applied in universities in recording the academic transcript.

The process of examination, grading, and evaluation is very appropriate using blockchain technology, because this process is very crucial and requires data validity to produce the academic transcript for students.

In the current condition of the Covid-19 pandemic, using blockchain technology is more needed because the process input and evaluation are done digitally. With blockchain technology, universities make a digital transformation in the education sector and make education technology more effective, especially during the Covid-19 pandemic.

The limitations of this study are the process of interviewing and focus group discussion using virtual conferencing to get answers from the speakers and there is limited time in digging deeper into the information needed. So it is necessary to do the validity of the resulting model several times. Future research will build an integrated overall model to produce a value chain with data integrity starting from students entering higher education until students graduate and get diplomas, transcripts, diploma companion documents, and student activity transcripts.

Learning difficulty
Programming Language I
Systems Engineering Professional Career

ABSTRACT

The learning difficulties of Object-Oriented Programming can be one of the causes of failure in college students, which can even lead to student dropout. This article has the purpose of analyzing the main learning difficulties of object-oriented programming using the Java programming language in Systems Engineering students of the Universidad Nacional Tecnológica de Lima Sur (UNTELS), research that arises because the students reflect low academic performance in the subject of Programming Language I (object-oriented programming) that is developed in the fourth academic cycle with six hours of practice and zero hours of theory, because this is determined by the study curriculum. To collect data, first, the possible causes associated with learning difficulties have been identified through direct dialogue with the students of the second academic semester of 2019, then with these causes a questionnaire has been prepared to apply the survey technique. establishing indicators classified in the dimensions Teaching methodology, Previous knowledge of programming courses, reading materials, learning concepts and Process of learning to program. This research yielded as a result that students perceive with greater difficulty the indicators corresponding to the dimension "Learning concepts", in second place, the dimension Process of learning to program is presented, in third place the dimension Teaching methodology, in fourth place the Reading materials dimension and fifthly the dimension Previous knowledge of programming courses, the results of which will serve as a basis for the teachers of the subject to improve the strategies in the teaching / learning process in the students of the professional career of Engineering Systems.

1. Introduction

In [1], the author expresses due to the generalized use of the object-oriented programming paradigm, teaching is not without difficulties, since it is based on a solid base of elementary concepts on which to add experiences of design of applications oriented to objects. Currently, one of the most widely used paradigms in software development is Object Oriented Programming (OOP), it implements programs in terms of objects, includes concepts of inheritance, cohesion, abstraction, polymorphism, coupling and encapsulation.

In [2], the author indicates, the academic programs of Engineering in Systems, the learning of the programming oriented to objects is seen in relation to the scene of the life of their professional tasks. Students are very concerned that their learning is an element that allows them to act effectively and efficiently outside the university environment. Likewise, in [3] the author points out that it is necessary for the student to learn OOP and not the peculiarities of the chosen language, to present the theoretical contents in a way that facilitates their understanding and progressive learning.

In [4], the author points out, many times, even using languages that support OOP, the mistake is made of not programming in this methodology, because there are no clear concepts in this regard. Also in [5], the author indicates that, for many years, the emphasis in teaching was to transmit concepts and procedures whose meaning was often not understood. Also in [6], the author expresses the object-oriented paradigm includes a large number of concepts that allow the development of robust applications.

In [7], the author points out that currently there is a variety of programming languages, learning generally requires knowledge of flow diagrams, pseudo-code and the syntax of the programming language itself to build programs under the structured approach,

*Corresponding Author: Teodoro Neri Diaz Leyva, Sector 3 Grupo 1A 03, Av Central, Villa El Salvador-UNTELS, 982716223 & is_diazl@hotmail.com

that is, , using sequential, conditional and repetitive structures. Thus, learning to program at a professional level, regardless of the language used, is not a one-day task. There are students who fail to acquire the necessary programming skills, even after completing a Computer Science Programming Fundamentals course.

For many students, learning difficulty occurs as they move from structured programming to object-oriented programming and integrate various software development technologies. Thus, in [8], the author points out that the problem of learning object-oriented programming is manifested since it is a complex issue that involves the integration of many elements such as the object-oriented paradigm, the programming language, the environment development, development methodology, modeling language, development patterns. and programming logic. Therefore, students are faced with an overwhelming number of concepts in a short period of time, which makes it difficult to assimilate and develop skills to generate lines of code.

When studying complex courses such as computer programming, one should begin by understanding the fundamental concepts of programming, in this sense, in [9], the author indicates the search for strategies that allow improving the teaching and learning of programming. an indispensable task. Among the causes of failure, it has been concluded that they do not reside in the student's difficulty in translating the solution of a problem into the phrases of a programming language, but rather have to do with a lack of methodology, habit and skill. to solve problems.

In [10], the author explains that the learning of the disciplines of Algorithmic and Algorithmic Programming presents, perhaps, one of the highest levels of difficulty in the careers of Computer Science and Computer Science. Historically, students have faced problems assimilating abstract mathematical notions, particularly when these include the dynamics of how algorithms manipulate data (Acm and Ieee-Cs, 2009). Object-oriented programming courses require prior knowledge of programming logic that is generally learned in algorithm courses, however, this is where students already have learning difficulties.

In [11], the author points out that the problem of university dropouts is complex and includes various causes; Institutional characteristics would be the first dropout factor, followed by vocational, academic and, finally, economic interests. Likewise in [12], the authors point out that dropout is associated with academic capital, the perception of performance, skills gaps to face studies, time management and the incorporation of learning techniques and habits that affect the decision to drop out of students.

At the Universidad Nacional Tecnológica de Lima Sur (UNTELS) the Programming Language I subject refers to Object-Oriented Programming with Java programming language, it is dictated in the fourth cycle of the Professional Career of Systems Engineering, which is develops in six (6) hours of practice and zero (0) hours of theory; After having taken two structured programming subjects, the academic performance of the students is not optimal, in the first academic semester of 2019 of 28 students enrolled 64% failed the course and in the second academic semester of 2019 of 25 students enrolled 40%.

In this context, the present research aims to describe the factors that hinder the learning of Object-Oriented Programming with Java Language, since the student goes from studying programming with a structured approach to object-oriented and with little theory about the different topics addressed during its development. For this, a direct dialogue was established on the possible problems associated with learning difficulties, which have been ordered and reflected in a physical questionnaire regarding the teaching methodology, previous knowledge of programming courses, reading materials, learning concepts. and the process of learning to program with the purpose of improving the teaching and learning strategies in the students of the Programming I language course in the professional career of Systems Engineering at the National Technological University of Lima Sur.

2. Methodology

2.1. Research level

The research level of this article is descriptive / correlational. Descriptive because it specifies the characteristics of a group of students with respect to the learning difficulties of Object-Oriented Programming and is correlational since it seeks to know the degree of association between the dimensions Teaching methodology, Reading materials, Previous knowledge of courses Programming, Learning Concepts and Learning Process for Programming. In [13], the author describes the purpose of this type of study is to know the relationship or degree of association that exists between two or more concepts, categories or variables in a particular context.

To achieve these results, the following objectives have been set: to describe the main difficulties in learning object-oriented programming. Determine the dimension with the greatest learning difficulty of Object Oriented Programming.

2.2. Population and sample

The population is made up of 25 students of the Programming Language I subject of the second academic semester of 2019 of the Systems Engineering professional career of the National Technological University of Lima Sur.

The sample is equal to the population, because it was only considered to apply the questionnaire to students in the second academic semester of 2019, which corresponds to a number of 25 and who take the subject of Programming Language I (Object-Oriented Programming).

In [14], the authors in their article "The Proportionality of Women Graduated from the Professional Career of Mechanical and Electrical Engineering at UNTELS: Analysis of their Academic Performance and Field of Labor Action", point out that the sample will be equal to the population; Because the sample is less than 50, that is, the weighted average and the weighted average by specialty (Mechanical Subjects and Electrical Subjects) of the 38 women graduated from the Faculty of Mechanics and Electrical Engineering, until 2018 II. In this sense, in this research, the sample is equal to the population, since there is no other group of students studying the same Programming Language I subject in the second academic semester of 2019 that constitute a greater number in the population and therefore the sample is larger. Likewise, in [15], the authors highlight that the UNTELS University is an institution with a few years of operation, specifically it was founded in 2007, and its first promotion of graduates is registered

in 2011, to date the University does not have any report or information that allows relevant actions to be taken to improve the teaching and learning process of the subject Programming Language I.

2.3. Instrument used in data collection

The instrument used in data collection is the "survey", with questions about difficulties associated with learning object-oriented programming at UNTELS, considering the dimensions Teaching methodology, Reading materials, Previous knowledge of programming courses, Learning of concepts and Process of learning to program.

3. Result

Next, we proceed to describe the results obtained from the processing of the data collected in the survey "Learning difficulties of the Programming Language I course", of the second semester of 2019.

In Figure 1, the graphical representation of the results obtained with respect to the indicators that hinder the learning of object-oriented programming of the dimension "Teaching methodology" is shown.

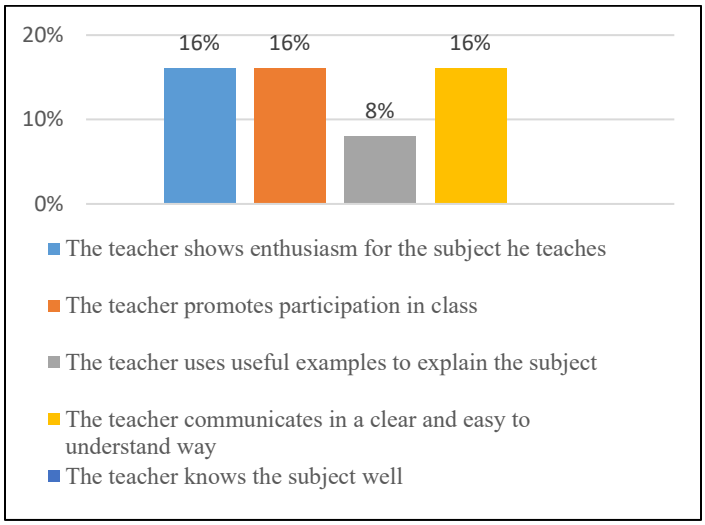

Figure 1: Higher indicators of the Teaching Methodology dimension that hinder the learning of OOP

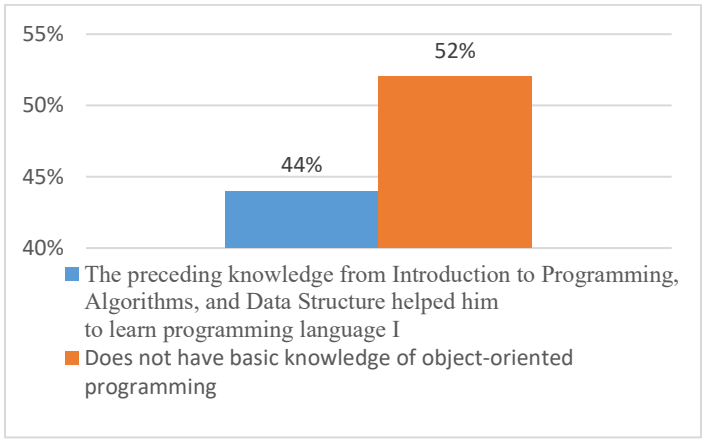

Figure 2: Indicator of the dimension Previous knowledge of programming courses that hinder the learning of OOP

As can be seen in the previous figure, the indicators that show the highest percentage are "The teacher shows enthusiasm for the subject he teaches", "The teacher promotes participation in class", "The teacher communicates in a clear and easy way understand "equivalent to 16% of the dimension" Teaching methodology "where students consider that it hinders learning OOP.

In Figure 2, the graphical representation of the result obtained with respect to the indicator that hinders the learning of object-oriented programming of the dimension "Previous knowledge of programming courses" is shown.

As can be seen in the previous figure, the indicator that shows the highest percentage is "Does not have basic knowledge of object-oriented programming", equivalent to 52% of the dimension "Previous knowledge of programming courses" where students consider it difficult to learn of the OOP.

Figure 3 shows the graphical representation of the results obtained with respect to the indicators that hinder the learning of object-oriented programming of the dimension "Reading materials".

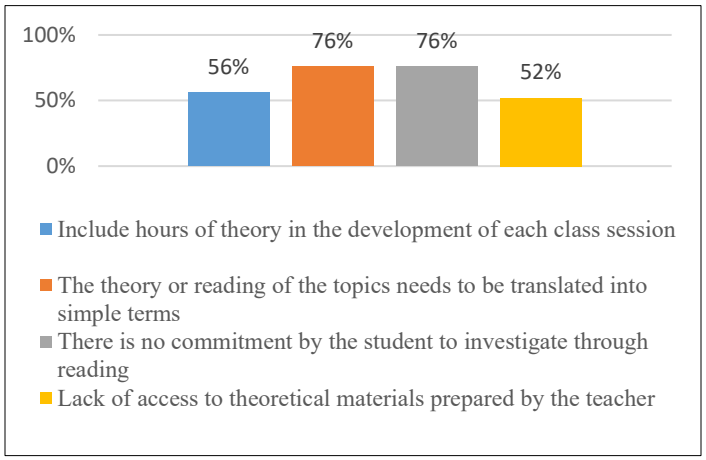

Figure 3: Higher indicators of the Reading Materials dimension that hinder the learning of OOP

As can be seen in the previous figure, the indicators that show the highest percentage are "The theory or reading of the topics needs to be translated in simple terms", "There is no commitment by the student to investigate through reading" equivalent to 76% of the dimension "Reading materials" where students consider that it hinders the learning of OOP.

Figure 4 shows the graphic representation of the results obtained with respect to the indicators that hinder the learning of object-oriented programming of the "Concept learning" dimension.

As can be seen in the previous figure, the indicator that shows the highest percentage is "Collections: Java Collection Framework, List and Array List, Map and Hash Map, Set and Hash Set, Iterator" equivalent to 60% of the dimension "Learning of concepts "where students consider it difficult to learn OOP.

Figure 5 shows the graphic representation of the results obtained with respect to the indicators that hinder the learning of object-oriented programming of the dimension "Process of learning to program".

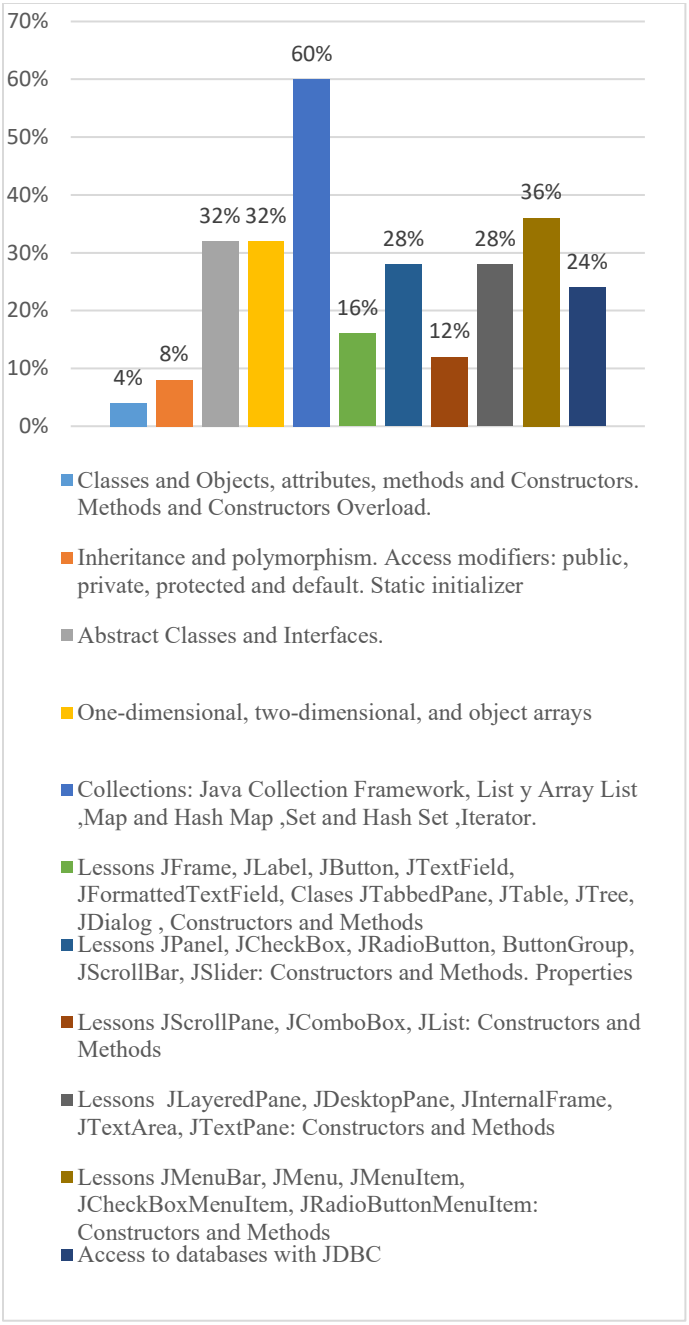

Figure 4: Highest indicator of the dimension "Learning concepts" that hinder the learning of OOP

As can be seen in the previous figure, the indicator that shows the highest percentage is “Develop programs using class libraries to create graphical user interfaces: AWT and Swing” equivalent to 48% of the dimension “Process of learning to program” where students consider it difficult to learn OOP.

To determine the dimension with the highest level of learning difficulty in OOP, we obtain the average for each dimension.

From the previous figure, we can determine that the highest percentage of difficulty associated with learning OOP is in the dimension "Learning concepts" equivalent to 8.20.

For the correlational analysis, we will classify the dimensions into two groups: Teaching Process Dimension and Program Development Dimension. The following table shows this classification.

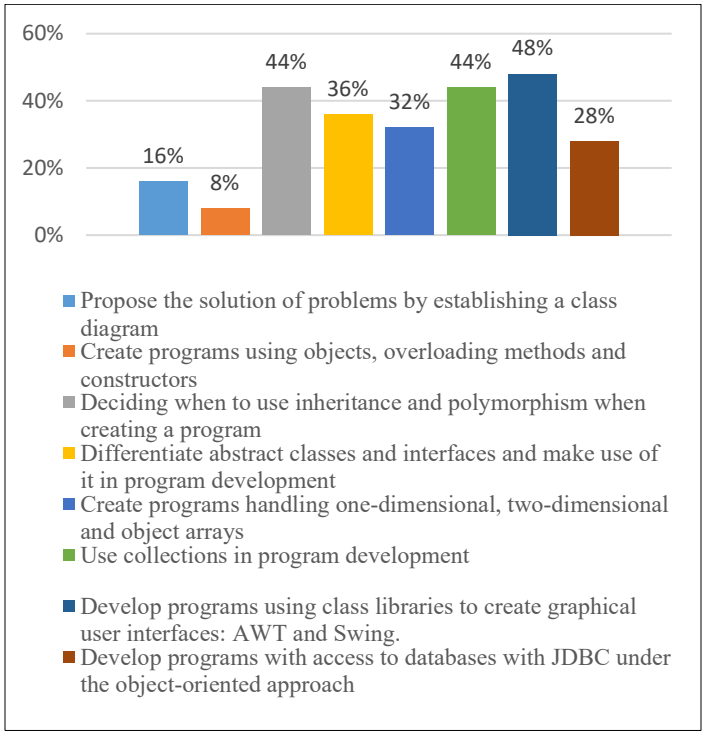

Figure 5: Highest indicator of the dimension “Process of learning to program” that hinder the learning of OOP

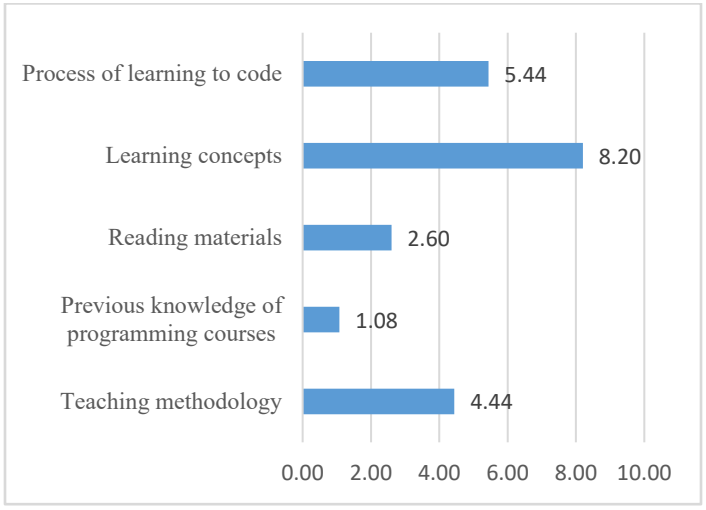

Figure 6: Average degree of difficulty for each dimension

Table 1: Classification of dimensions.

Teaching process	Program development
Teaching methodology	Process of learning to code
Reading materials	
Previous knowledge of programming courses	
Learning concepts	

In [16], the author points out to analyze the correlations, we have the interpretation of values expressed by various authors in scales, one of the most used being the Spearman rank correlation coefficient, which can score from -1.0 to +1.0 as detailed in table two

Table 2: Degree of relationship according to correlation coefficient.

Rank	Relationship
-0.91 a -1.00	Perfect negative correlation
-0.76 a -0.90	Very strong negative correlation
-0.51 a -0.75	Considerable negative correlation
-0.11 a -0.50	Mean negative correlation
-0.01 a -0.10	Weak negative correlation
0.00	There is no correlation
+0.01 a +0.10	Weak positive correlation
+0.11 a +0.50	Mean positive correlation
+0.51 a +0.75	Considerable positive correlation
+0.76 a +0.90	Very strong positive correlation
+0.91 a +1.00	Perfect positive correlation

In order to identify if there is a relationship or degree of association between the dimensions specified in Table 1, the Pearson Correlation coefficient is used, using the SPSS V25 statistical software.

Table 3: Pearson's correlation between the dimensions Learning concepts and Process of learning to program.

		Learning concepts	Process of learning to code
Learning concepts	Pearson correlation	1	0,659**
	Sig. (bilateral)		0.000
	N	25	25
Process of learning to code	Pearson correlation	0,659**	1
	Sig. (bilateral)	0.000	
	N	25	25
**. The correlation is significant at the 0.01 level (bilateral).			

In Table 3, we observe that the dimensions Learning concepts and Process of learning to program are directly related, that is, as there is more learning of the concepts of object-oriented programming with Java, there will be greater capacity in the process of learning to programming in Systems Engineering students, since a considerable positive correlation of 0.659 was obtained as a result.

Table 4: Pearson correlation between the dimensions Teaching methodology and Process of learning to program

		Process of learning to code	Teaching methodology
Process of learning to code	Pearson correlation	1	,235
	Sig. (bilateral)		,258
	N	25	25
Teaching methodology	Pearson correlation	,235	1
	Sig. (bilateral)	,258	
	N	25	25

In Table 4, we observe that the dimensions Teaching methodology and Process of learning to program present a mean positive correlation of 0.235.

Table 5: Pearson's correlation between the dimensions Reading materials and Process of learning to program.

		Process of learning to code	Reading Materials
Process of learning to code	Pearson correlation	1	-,014
	Sig. (bilateral)		,948
	N	25	25
Reading Materials	Pearson correlation	-,014	1
	Sig. (bilateral)	,948	
	N	25	25

In Table 5, we observe that the dimensions Reading materials and Process of learning to program are inversely related by presenting a mean negative correlation of -0.014, this implies that the number of reading materials on object-oriented programming can be increased, however , does not necessarily lead to increase their capacity of the process of learning to program in the students of Systems Engineering.

Table 6: Pearson correlation between the dimensions Previous knowledge of programming courses and Process of learning to program.

		Previous knowledge of programming courses	Process of learning to code
Previous knowledge of programming courses	Pearson correlation	1	0,036
	Sig. (bilateral)		0,863
	N	25	25
Process of learning to code	Pearson correlation	,036	1
	Sig. (bilateral)	0,863	
	N	25	25

In Table 6, we observe that the dimensions Previous knowledge of programming courses and Process of learning to program present a mean positive correlation of 0.036.

4. Discussion

In relation to the results of the present investigation, the following discussions are held below:

In [17], the author points out that starting in the world of object-oriented programming is a complex task for many students, the teacher plays an important role in student motivation, as evidenced by this research in its indicator "The teacher promotes participation in class ", where 16% of the students consider that it hinders their learning of OOP, it can be said that this result is consistent with the research entitled" Initiatives to motivate Programming students "in which it is concluded that motivation is low due to the novelty of the subject, the difficulty of students in learning abstract concepts and the lack of capacity for continuous work.

In [1], the author describes regarding the indicator “The theory or reading of the topics needs to be translated into simple terms”,

76% of the students consider that it hinders the learning of Object-Oriented Programming, coincides with the thesis doctoral degree entitled "Virtual environments based on active learning for the teaching of object orientation" in which he concludes that it is necessary for those who are starting in this paradigm to reach a clear understanding of its concepts, abstract in most cases, which represent in software development.

Regarding the indicator that students "do not have basic knowledge of object-oriented programming" before taking the Programming Language I course, 52% indicate that it makes learning difficult for them, this evidence agrees with the study entitled "Methodology of teaching by learning object-oriented programming logic "pointed out in [18] by the author, in which he concludes that there is a tendency to use Java as the first language directly with the object-oriented concept, without deepening the development of the bases logic of programming, this can be very harmful, because we are going to generate good programmers to code using languages, but without logical bases, that is, programmers who do not know how to program.

Regarding the indicator "Collections: Java Collection Framework, List and Array List, Map and Hash Map, Set and Hash Set, Iterator", 60% of the students consider a difficult topic to understand since it is related to classes, interfaces, inheritance, polymorphism for its understanding can be considered consistent since it coincides with the study entitled "Learning object-oriented programming: Experiences in technical and upper secondary education" indicated in [19] by the author, in which it is concluded that the subject of greater difficulty of understanding for the control groups is inheritance, while for experimental groups it is polymorphism.

5. Conclusions

It has been possible to determine the main difficulties associated with the learning of object-oriented programming (Programming Language I) in the students of the School of Systems Engineering of the National Technological University of Lima Sur, which are "The teacher shows enthusiasm for the subject he teaches", "The teacher promotes participation in class", "The teacher communicates in a clear and easy to understand way" with 16% indicators related to the teaching methodology". The indicators "Lack of translating the theory or reading of the topics into simple terms", "There is no commitment by the student to investigate through reading" with 76% related to the reading materials. The indicators "Does not have basic knowledge of object-oriented programming" with 52% related to Have prior knowledge. The indicator "Collections: Java Collection Framework, List and Array List, Map and Hash Map, Set and Hash Set, Iterator" with 60% in relation to Learning concepts. The indicator "Develop programs using class libraries to create graphical user interfaces: AWT and Swing" with 48% related to the Learn to program process.

It has been possible to determine the dimension that has the greatest learning difficulty of Object-Oriented Programming, which is "Learning concepts" with an average of 8.20, we can mention that this expresses that currently the curricular plan related to programming courses at school Systems Engineering do not have hours of theory to help manage fundamental concepts of Object Oriented Programming.

6. Recommendations

While developing the Programming Language I (OOP) course in its entirety in a practical way using the Java language, it is recommended to develop manuals or self-instructional videos that help the student understand concepts of object-oriented programming.

Since the curricular plans at the Universidad Nacional Tecnologicas de Lima Sur are updated every three years, it is recommended to include hours of theory in programming courses or, failing that, develop intelligent applications that help understand object-oriented programming concepts.

ABSTRACT

IoT integrates and connects intelligent devices or objects with varied architectures and resources. The number of IoT devices is growing exponentially. Due to the massive wave of IoT objects, their diversity and heterogeneity among their architectures, the existing communication protocols for wireless networks become ineffective in the context of IoT. Wireless Sensor Network (WSN) has the potential to be integrated to the internet of things (IoT). The issues of the routing of WSNs impose nearly similar prerequisites for IoT routing technique. Most of the traditional routing protocols are not appropriate for WSNs and IoT because of resource constraints, computational overhead and environmental interference and do not take into account the different factors affecting energy parameter and do not accommodate node mobility. Routing algorithms must ensure the data transmission in an efficient way, having proper knowledge of the IoT system. For this reason, many intelligent systems have been utilized to design routing algorithms to handle the network's dynamic state. In this paper, an ant colony optimization (ACO) based WSN routing algorithm for IoT has been proposed and analyzed to enhance scalability, to accommodate node mobility and to minimize initialization delay for time critical applications in the context of IoT to find the optimal path of data transmission, improvising efficient IoT communications. The proposed routing algorithm is simulated using MATLAB for performance evaluations. The evaluation results have recorded an improvement in conservation of energy, of almost 50% less consumed energy even with an increase in the number of nodes, by comparing with an existing routing technique based on ant system, a current routing protocol for IoT and the conventional ACO algorithm.

1. Introduction

With the widespread use of IoT devices, the issue of designing efficient routing protocol has attracted more attention in networking research. This paper is an extension of work originally presented in ICOM'19 [1].

According to the prediction of Cisco™ IBSG [2], by 2020, 50 billion devices will be connected to the Internet. IoT provides network connectivity between these smart devices everywhere and all times. The emergence of a new ubiquitous computing era has been created due to the evolution of wireless networks and sensor technologies, allied to the increasing demand for new IoT applications for the provision of smart services [3]. In this context, WSNs play an essential role to the expansion of IoT while providing ubiquity of networks with smart and low-cost devices that are easy to deploy. In an IoT system, a large collection of autonomous and dynamic sensor nodes are used to gather information by detecting physical parameters, communicate and cooperate with their environment and send their data to the internet. Sensor nodes have the ability of self-organization and sensor networks function in a distributed way [4]. IoT with the integration of WSNs, have a wide range of applications spaces that shape human life and also have impact on economic benefits. The physical domain of IoT is presented through the connected networks of objects and nodes utilizing wireless sensors. A large number of small devices surround the environment help to manage the physical world by sensing, processing, communicating and analyzing the data in the IoT network system [5]. The development of new applications and technologies are drawing attention from the research perspective, such as smart home, environmental monitoring, healthcare, transport, agriculture, offices, buildings and smart cities etc.

Designing efficient routing protocol is the key factor to improve the energy efficiency, data transmissions, scalability and prolong network lifetime in WSNs and IoT. However, several considerations are required for resource-constrained network system, such as energy efficiency, scalability, security, autonomy, computational complexity, environmental constraints for wireless link, node mobility, the QoS (quality of service) requirement for a particular application, during IoT routing. The sensed information ought to be sent to the base station for further operations in various IoT applications through the competent forwarding mechanism while keeping in consideration different functionalities of IoT objects states.

Until now, there is a large number of routing algorithms have been proposed by the research community, considering the energy parameter, yet its exploitation is not well thought-out [6]. The existing node energy and the distinctive components affecting this energy parameter need to be considered to spare node energy and enhance the communication quality of the network. The node's lifetime relies upon the battery-life to a huge range, and the irrational energy utilization will effectuate the system to expire early and decrease the lifetime of the network [7]. Hence the key research issue is the designing of efficient route calculation algorithm that can ensure efficient information communication within IoT while maintaining scalability. Most of the traditional routing protocols are not adaptable other than energy efficient, if the varied difficulties in various applications are considered or due to the dense and complex conditions and a wide range of radio obstruction. Many intelligent systems including the working mechanism of the biological systems have been employed for designing routing algorithms to handle the network's dynamic state while keeping pace with energy efficiency during information communication [8]. Ant colony optimization (ACO) based algorithms emphasize the design of routing protocols that are robust, adaptable and scalable [9]. The coordination of ants depends on the ability of self-organization that ant colony optimization based swarm intelligence techniques possess [10]. The probabilistic approach of ACO is used to determine the routes, and the pheromone update formulation is used for further updating of the pheromone trail [11].

An ant colony based routing technique, named EICAntS, for effective communications within IoT is presented in [12]. This algorithm considers the energetic parameters. The pheromone estimations in the ant system is related here by the calculated global efficacy factor. An improvement with regard to network lifetime and conservation of energy is shown from the evaluation results. The algorithm does not include the heuristic information and pheromone update strategy consisting of pheromone evaporation rate and/or the amount of pheromone deposited. The energy effect precisely addresses the data class handled by the node and does not specify the different factors affecting energy parameter such as the energy consumption in free-space and multi-path fading standard of wireless communication as well as no particulars are provided on how to compute the nodes' energy level. The REL routing technique for IoT applications, which is focused on energy and link quality information, is proposed in [13]. Testbed experiments are used besides simulation for the evaluation where REL increases the system and network lifetime, reliability, energy-efficiency, QoS of IoT applications and reduces packet loss rate. In addition, it offers a path determination system which is basically an end to end route. For this purpose, it depends on cross-layer data with insignificant overhead. Furthermore, it permits information transmission with a reasonable appropriation of wireless and remote assets. A piggyback and on-demand system guides nodes to become energy proficient where the residual energy is sent to their neighboring nodes. Nonetheless, no enhancement system is utilized in contradiction of ant based protocol, which utilizes the ant colony system.

In [14], LEACH-MA protocol is proposed which is based on modified ACO. The residual energy parameter is used along with LEACH (Low-energy adaptive cluster hierarchy routing) protocol for the selection of current cluster head. The measure of energy consumption is minimized by this algorithm. The energy and distances are combined in this approach for choosing the cluster head. But no facts have been provided on the threshold value for selecting the cluster head. In [15], a hybrid tree-based search approach, called ANT-BFS, is proposed to discover the optimum route for information communication. This scheme integrates breadth first search with ACO to minimize the amount of energy consumption. However, the memory and computational time requirements may arise some issues for this technique in case the cluster head and the sink are located far from each other, so it might not be suitable for large scale. Content based routing (CCR) protocol is presented in [16] that ensures reliability of information transmission for IoT applications. It utilizes the process of data aggregation and ensures good load balancing. This method transmits data based on the message content and incorporates link quality information. The traffic reduction gain is achieved by this technique, where an objective function is used by the nodes for routing of the heterogeneous sorts of content. Each node builds a distinct routing entry by using the content to select the next node for transferring the data via the certain reliable communication link. The energy consumption has been conserved by this method by forwarding aggregated data to selective nodes. However, no details were provided on the estimation of the reliability while taking into consideration of the parameters that are also unspecified for this reliability.

In [17], an ant-based routing algorithm considering the energy supervision is presented. Reward and punishment technique are adopted with the pheromone update rules. The energetic parameter is considered and this technique increases network lifetime and energy-efficiency. However, various factors of energy utilization are required to be addressed. The node delay parameter is used here, but no details were found on the delay factor. An improvised energy saving ant colony based routing protocol for sensor networks is proposed in [18]. Three phases are introduced in this multipath protocol, such as discovery of neighbor through link information, transmission of packets through EWMA (exponentially weighted moving average) technique and efficient & reliable end to end delivery. The simulation results indicate that the proposed routing protocol for dynamic networks stands efficient in general performance, particularly regarding energy efficiency and throughput when contrasted with standard and other novel proposed routing algorithms. A multi-constrained technique that ensures QoS, known as IAMQER focused on ant colony, is proposed in [19]. The simulation results show that average energy consumption is minimized and packet delivery ratio is increased by utilizing this technique. Also, a route evaluating function is presented here. But IAMQER strategy might suffer longer processing delay as it is based on traditional ACO method.

This paper is an extension of work initially reported in [20], where the necessary parameters for communication process have been taken into account by the proposed method, such as mobility and energy parameters. Most of the proposed routing algorithms have addressed merely some communication parameters that are not adequate enough to enhance the communication quality needed by the energy constrained IoT applications. The important communication parameters must be considered by the mechanisms that mediate in the correspondence procedure, for instance routing, for resolving the issues of routing and for efficient communications in the IoT network system. The proposed protocol has utilized the advantages of the ant system to discover the optimum path for information communication and to improve communication quality within an IoT system.

2. System Model

2.1. The Network Model

The considered network model consists of *M* sensor nodes with random distribution in an $L \times L$ rectangular area. The proposed algorithm comprises the system model for IoT communications which is designed with several nodes or sensors M_i. The adopted graph G with the nodes and connecting links has constructed the network. It is assumed that the sensor nodes have the same computation and preliminary energy. The nodes can update the information about its neighbors. The received signal strength indication (RSSI) is used to compute the approximate distance of the senders by the nodes. For that calculation, the transmitted power of the objective is acknowledged.

2.2. Proposed ACO Algorithm

The most pheromone path is chosen as the shortest and optimal path in the traditional ACO algorithm [11] and the energy parameter is not considered. Hence the network's node energy on that path reduces abruptly and lessens the entire network's lifespan. Furthermore, novel routing protocols are required to manage the overhead of mobility. As the topological changes for the mobility of the sensor nodes and the sink nodes generate frequent updates in the network, which may drain the node energy extremely in an energy-constrained system. This paper expands our research works presented in [1] in terms of network performance to improve communications within IoT. The proposed system of ours [21] has been investigated more here to enhance scalability, to accommodate node mobility, and to minimize initialization and processing delay for time critical applications in the context of IoT. An improved network routing algorithm based on ACO is proposed here by analyzing the nodes' balanced consumption of energy.

At the place of node *i* and time *t*, each ant *m* will adhere to the following probabilistic formula to select the next node *j* being the forwarding node of the subsequent route for the enhancement that is proposed of the ACO algorithm of ours [20] for the next hop routing:

$$P_{ij}^{m} = \begin{cases} \dfrac{[\tau_{ij}(t)]^{\alpha}[\eta_{ij}(t)]^{\beta}[\vartheta_{ij}(t)]^{\gamma}E_j}{\sum_{s\subset allowed_m}[\tau_{is}(t)]^{\alpha}[\eta_{is}(t)]^{\beta}[\vartheta_{is}(t)]^{\gamma}E_s}, & j \subset allowed_m \\ 0, \quad others \end{cases} \quad (1)$$

here,
$$\eta_{ij}(t) = \frac{1}{d_{ij}} \quad (2)$$

where $\tau_{ij}(t)$ and $\eta_{ij}(t)$ are the amount of pheromone and heuristic information on edge (*i, j*) respectively and $\eta_{ij}(t)$ is typically $1/d_{ij}$. α and β are two parameters that control the influence of the pheromone intensity and heuristic information respectively. d_{ij} is the distance between *i* and *j*. The average mobility parameter is used to calculate the stability factor, $\vartheta_{ij}(t)$, where γ is the mobility constant. E_j is the node residual energy that ant *m* will visit.

To avoid faster local convergence in case large amount of pheromone deposition happens on the routes, the pheromone update is required to improve as well. So, the amount of pheromone is updated and limited by incorporating a threshold value and can be obtained as follows:

$$\tau_{ij}(t+1) = \begin{cases} T, & \tau_{ij}(t+1) > T \\ (1-\rho)\tau_{ij}(t) + \Delta\tau_{ij}(t) & else \end{cases} \quad (3)$$

$$\Delta\tau_{ij}(t) = \sum_{k=1}^{m} \Delta\tau_{ij}^{k} \quad (4)$$

where ρ is the pheromone coefficient for evaporation, $\rho \in (0,1)$, T represents the threshold value used to limit excessive pheromone deposition, $\Delta\tau_{ij}(t)$ is the increased pheromone concentration of edge (*i, j*), usually given by,

$$\Delta\tau_{ij}^{k} = \begin{cases} \dfrac{R}{L_k} & if\ kth\ ant\ uses\ the\ edge\ (i,j) \\ 0 & otherwise \end{cases} \quad (5)$$

where *R* represents strength of pheromone, L_k denotes the path length of the k^{th} ant.

2.3. Energy Model

The energy model of wireless communications that is presented in [22] is incorporated by the proposed system. The free-space and multi-path fading model are utilized here depending upon the distance *d* in between the sending and receiving nodes and a threshold value, d_0. The following equations for energy consumption for the transmission (E_{tran}) of an *S*-bit data by the sensors are used:

$$E_{tran}(S,d) = \begin{cases} SE_{elec} + S\epsilon_{fs}d^2 & if\ d < d_0 \\ SE_{elec} + S\epsilon_{mp}d^4 & if\ d \geq d_0 \end{cases} \quad (6)$$

where E_{elec} indicates the energy dissipated to run electronic devise circuitry. The energy consumption in free-space and multi-path fading model are given by ϵ_{fs} and ϵ_{mp} respectively. *d* denotes distance and d_0 is the threshold value. The receiving energy, $E_{Rx}(S)$, for an *S*-bit data for a node is provided as follows:

$$E_{Rx}(S) = SE_{elec} \quad (7)$$

To calculate the residual energy of a node n_i, the following equation is used:

$$E_{res_i} = E_{tot_i} - E_{tran_i} \quad (8)$$

where E_{res_i} is the residual energy, E_{tot_i} is the total initial energy and E_{tran_i} is the transmission energy.

2.4. Fitness Function

A function for the evaluation of the routes, path assessing index, is provided here considering the current energy of the nodes, and the path of routing. If remaining energy is not assessed as in the conventional ACO algorithm, which causes early demise of some nodes and ultimately affects the whole network lifetime. The routing path is related to each particular ant after all the ants get to the destination node. The fitness value for the path can be computed as follows:

$$f_{(fitness)}{}_m^k = \frac{E_{res_i}}{L_m^k} \quad (9)$$

where the residual energy level of a sensor node n_i is E_{res_i}. L_m^k is the length of the route for m^{th} ant and k^{th} iteration. The pheromone is updated on the optimum path, having the highest fitness value.

2.5. Planning of Route Phases

Step 1. The route's arrangement phase. At first an initialization signaling is broadcasted by the sink node. Each node acquires its own neighboring node, then updates and adds it to its own routing table. The adjacent node link pheromone value is set to 1. The current node's ant packet is generated by each node that contains the number of nodes and the routing table. N_{max} is set to the maximum number of iterations, and the initial number of iterations is set to 1.

Step 2. The route's organization phase. The next node will be selected by the ant that locates in node *i* according to (1)-(2). Upon receiving the ant package, a node forwards ant package in accordance with the probability P_{ij}^m .

Step 3. The route's optimization phase. Once all ants get to the destination node, i.e. the sink node, the fitness function is used for optimal route selection where the fitness value is computed for the route according to (9) and the route with highest fitness value is chosen for optimal route for data transmission. The concentration of pheromones on this path is then updated according to (3)-(5).

In this route's optimization phase, once the ant package is received by the sink node, it will count how many ants packets each node sends. Let's assume that the total node number is *n* and the number of ants package sent by, for instance, node *i* is X_i (i =1,……., n).

Then the total sum of the network ant package can be expressed by means of:

$$T = \sum_{i=1}^{n} X_i \quad (10)$$

Back ant package is generated by each node. When back ant package is received by the nodes, the back ant package's adjacency linkage information is updated by (3)-(5). The node is selected as the next hop which resides in the back ant package. Following the information in the back ant packets, it is determined whether to send a new packet of ants at that same instance. When new ant package need to be sent, the route is established.

2.6. Proposed Improvement

Forming clusters associated with the group of nodes is deliberated on achieving scalability and robustness. For this reason, the routing protocol presented in [20] can be integrated with a clustering routing technique, such as LEACH (Low-energy adaptive clustering hierarchy) protocol [22]. It improves the selection strategy of optimal cluster head (CH), which is based on probability, node residual energy, and the distance of a node from the base station (BS). For selecting the cluster head node *j*, if it is assumed that node *i* is the current cluster head and next node is *j*, an ant *m* will use the probability calculation given by:

$$Prob_i(\mathrm{t}) = \frac{dist_i{}^{*\alpha} + [P_{ij}^m(t)]^{*\beta}}{\sum_1^{N_i} dist_i{}^{*\alpha} + [P_{ij}^m(t)]^{*\beta}} \quad (11)$$

Where $Prob_i$ provides the probability of each node to be selected as a CH (cluster head), $dist_i$ is the distance of node, α and β are two control parameters and N_i denotes the set of cluster nodes. P_{ij}^m is found from (1). Figure 1 shows the flow diagram of this suggested enhancement.

Using the proposed ACO based routing algorithm and the proposed improvement given above the initial optimal CH (cluster head) is selected. Then the final optimal CH is elected using the maximum fitness function value provided in (9). The optimal initial cluster head sends data to the optimal final cluster head. The optimal final cluster head transmitted data to the sink node.

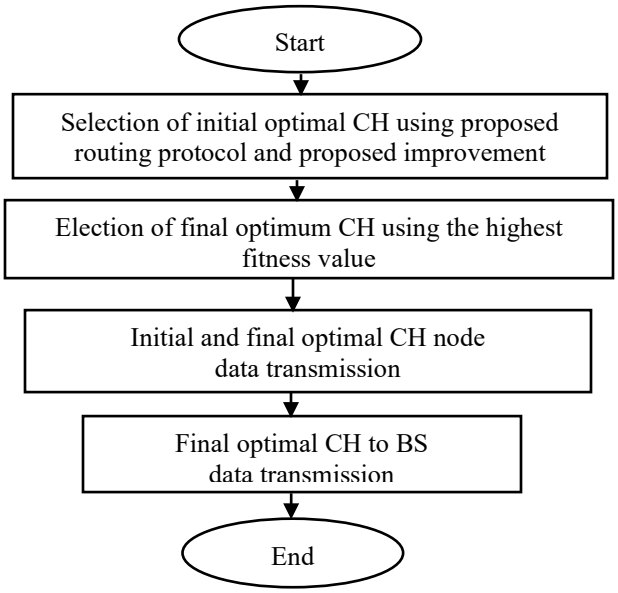

Figure 1: The flow diagram of the proposed improvement

Figure 2 shows the flow diagram of the proposed routing protocol operation.

3. Result and Discussion

The simulation is performed utilizing MATLAB where the proposed routing protocol is evaluated according to some important parameters, i.e., the consumed energy, the lifetimes of nodes, best cost, end-to-end delay, throughput and packet delivery

rate. The method represented here is evaluated against the conventional ACO, a current routing protocol for IoT, e.g., RPL (routing protocol for low power lossy network) [23] and an existing ant colony based algorithm, EICAntS algorithm [12] as benchmark protocols.

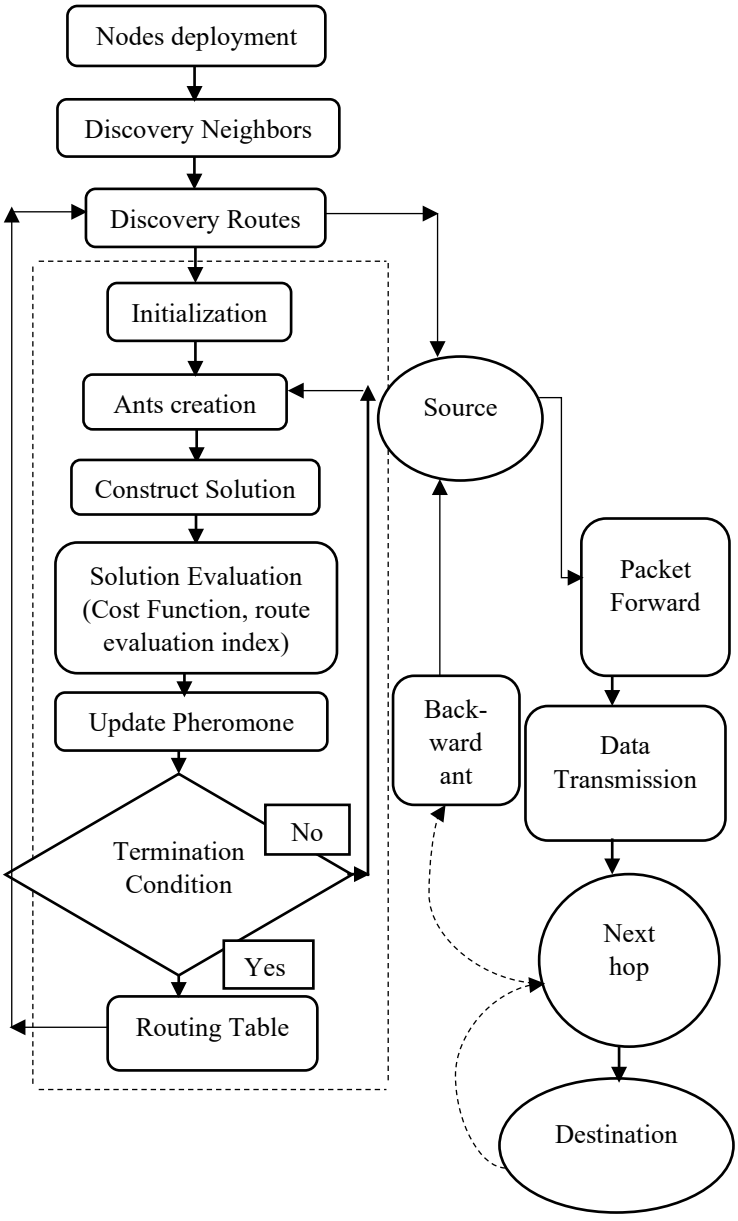

Figure 2: Overview Block Diagram demonstrating the Proposed ACO based Routing Algorithm Operation

The simulation parameters are based on the repeated tests and on the basis of simulation analysis of various parameters and set as: $\alpha = 1$, $\beta = 1$, $\gamma = 1$, $\rho = 0.05$. More parameters are provided in the Table 1.

The proposed system is supporting a mechanism permitting the selection of the best cost route for information communication from the source node to the destination, the base station. The network's parameters are dynamically adjusted to the network evolution, the growing number of nodes, the changed environment issues due to mobility, and outstanding node energy.

Table 1: Simulation Parameters

Parameters	Values
Simulation Region	100m×100m
Number of Nodes	40,50,60,70,80,90,100
T	100
No. of ants	40
Initial energy per node	0.5 joule
Node speed	2 m/s ~ 5 m/s
Message bits transmitted	4000 bits
Transmission distance	50 m

In Figure 3, for the proposed ACO based routing protocol and for the traditional ACO based protocol, the comparison of the node energy consumption per transmission is shown. The considerable improvement is shown for the proposed method. For majority of the nodes, contrasted with the conventional protocol, the proposed method has smaller energy consumption, almost 50% less. The proposed calculation has presented noticeable refinement for the total energy consumed of each node for individual discovery for the routes, contrasted with the benchmark protocol.

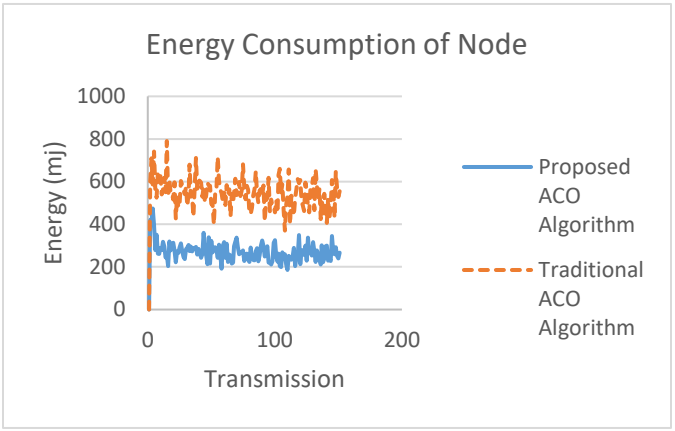

Figure 3: Comparison of node energy consumption per transmission

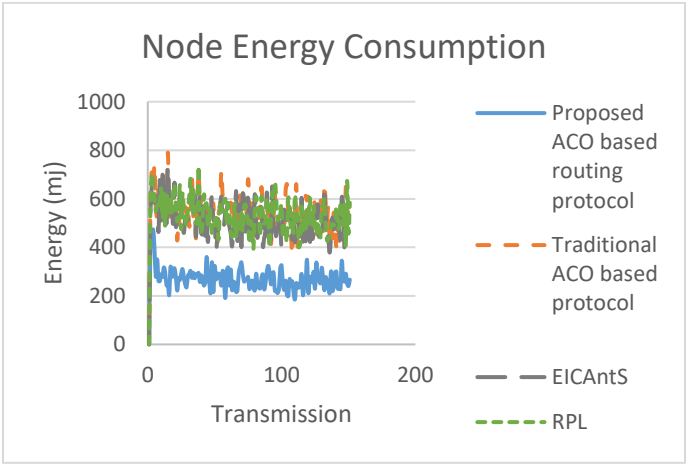

Figure 4: Comparison of node energy consumption per transmission

From Figure 4, we can see the node energy consumption per transmission based on improved method proposed here and other benchmark protocols, based on original ACO, RPL and EICAntS protocol. It is demonstrated from the evaluation results that

compared with the other two algorithms, the proposed ACO algorithm has attained a refinement, a much smaller energy consumption, almost 50% less.

The average energy consumption for the increasing quantity of nodes is represented in Figure 5 and Table 2. Figure 5 shows that the system using the proposed ACO based routing protocol as a resolution has minimized the average energy consumption, almost 50% less, by comparing with the original ant colony-based system, RPL and EICAntS technique. Since the proposed solution allows the determination of the optimal path for packet transmissions, and the retransmissions are avoided as well. Also, this presented method optimizes path selection strategy and minimizes updating phases. The scalability is maintained by the proposed system that has attained lower energy utilization contrasted with the benchmark protocols even when the number of nodes increases in the network.

Table 2: Average Energy Consumption (mj) with the Number of Nodes for 150 transmissions

No. of Nodes	Proposed ACO based routing protocol	Traditional ACO based protocol	EICAntS	RPL
40	270.49	545.89	516.65	532.65
50	281.67	570.07	566.42	574.78
60	303.76	620.61	606.97	632.29
70	330.97	650.51	660.42	679.46
80	350.65	686.47	695.87	692.01
90	372.42	739.92	744.55	735.55
100	401.21	791.33	799.01	768.49

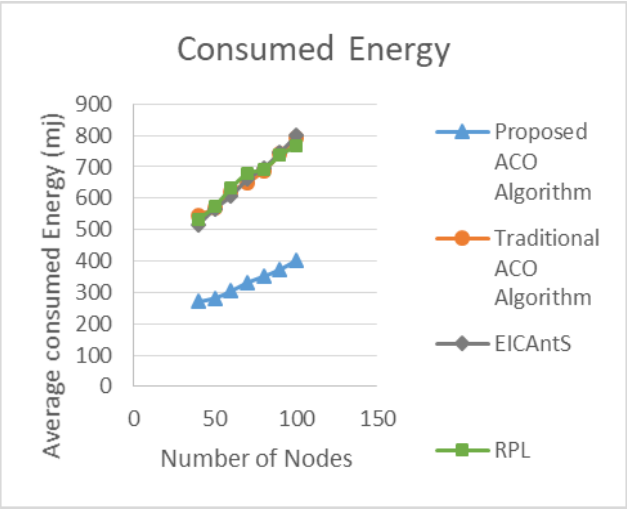

Figure 5: Comparison of the average energy consumption

The effective use of energy lead to increase of network lifetime. The percentage of survival nodes based on improved protocol proposed here and the traditional ACO based protocol are shown in Figure 6 and 7. The issues of ineffectiveness and uncertainty of the routes are alleviated as the protocol proposed here takes into account the energetic parameters. The energy utilization needs to be balanced and the present node energy needs to be deliberated; otherwise, the node energy is depleted and some nodes expire. The network lifetime is affected by this. The proposed approach deliberates the existing energy of the nodes besides the route path. Employing the suggested enhancement according to (11), the longevity, i.e. the nodes' lifetime and lifetime of the network, is increased by the offered ACO based technique.

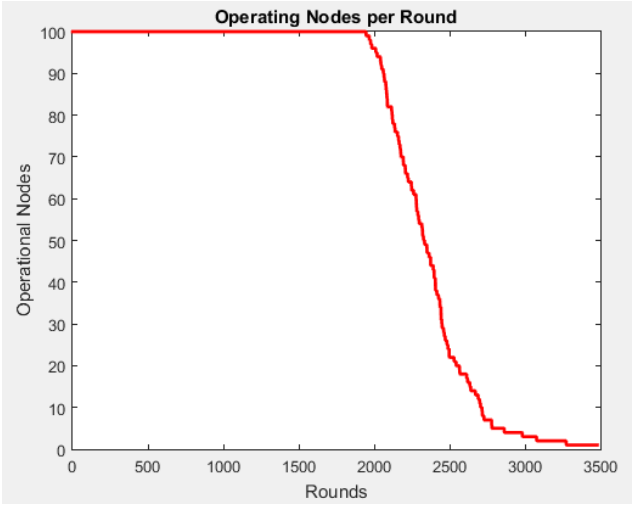

Figure 6: The percentage of survival nodes for the proposed method

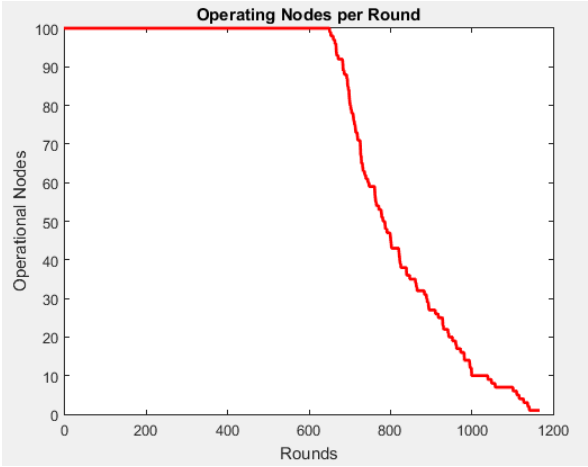

Figure 7: The percentage of survival nodes for the traditional ACO based protocol

We can see from the Table 3 and in the Figure 8 that the average end-to-end delay increases with an increase in the number of nodes. Route discovery and path selection stages affect this parameter, which are instated all the more regularly with an imperative number of nodes and with the topology evolution because of mobility of the nodes. Using the proposed algorithm the route discovery and selection stages are improved and the repetition problem is minimized when many packets should be resent to the destination in case the route might not be the best

always. The proposed system achieved better results with regard to average end to end delay, almost 40% reduced end to end delay, compared to the other benchmark techniques.

Table 3: Average End-to-End Delay (ms) with the Number of Nodes using Fitness Function

No. of Nodes	Proposed ACO based routing protocol	Traditional ACO based protocol	EICAntS	RPL
40	159.78	367.41	364.42	370.67
50	203.59	397.57	394.64	382.81
60	250.81	413.22	412.96	410.75
70	263.37	427.28	414.09	425.13
80	299.25	464.68	460.82	455.42
90	312.43	478.52	465.4	466.35
100	327.46	485.86	479.72	488.96

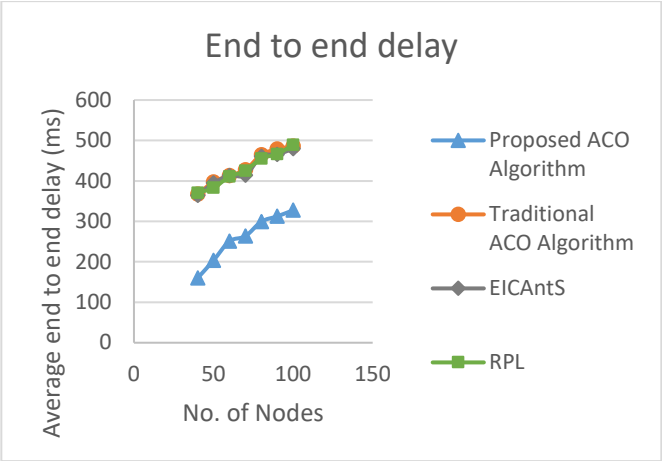

Figure 8: Evolution of average end to end delay with the number of nodes using fitness function

Throughput results are presented in Table 4 and depicted in Figure 9. The quantity of digital data, over a physical or logical connection per time unit, is the measure of the throughput in sensor networks. It is measured in bits/s or bps (bits per second), occasionally in per-second data packets or in per time-slot data packets. It can be defined mathematically, as the total number of packets delivered over the total simulation time:

$$\text{Throughput} = N / \text{Total simulation time} \quad (12)$$

where N is the number of bits received successfully by all destinations.

We can clearly see from the contrast that the results obtained are better than the results recorded by the other network.

Table 4: Throughput with the Number of Nodes over the Total Simulation Time

No. of Nodes	Simulation Time (Proposed Algorithm)	Simulation Time (EICAntS)	Proposed Algorithm	EICAntS
40	42 sec.	42 sec.	3809.52 (bps)	975.24 (bps)
50	45 sec.	45 sec.	4445.45 (bps)	1137.78 (bps)
60	48 sec.	49 sec.	5000 (bps)	1253.88 (bps)
70	51 sec.	51 sec.	5490.196 (bps)	1405.49 (bps)
80	54 sec.	53 sec.	5925.93 (bps)	1545.66 (bps)
90	55 sec.	55 sec.	6545.45 (bps)	1675.63 (bps)
100	57 sec.	57 sec.	7017.54 (bps)	1796.49 (bps)

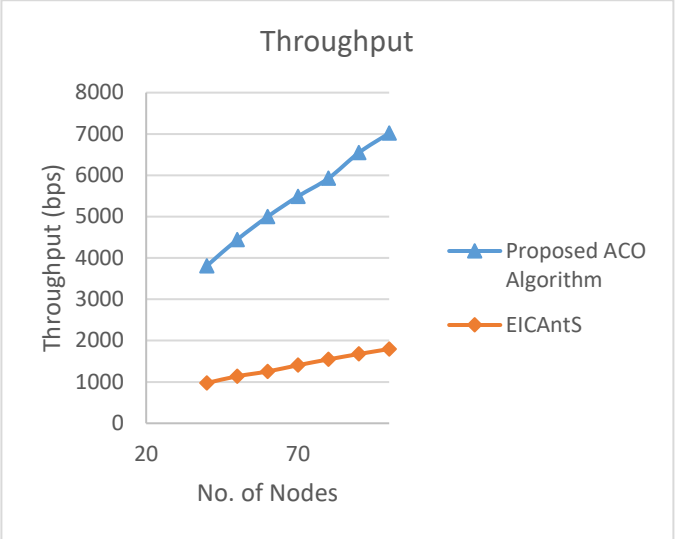

Figure 9: Throughput for the Proposed ACO and EICAntS algorithm

The calculation of the proposed algorithm in accordance with the delivery rates of the packets is provided in the Figure 10. The good results found with the proposed approach, even with an imperative number of nodes because the system has the capability that let many packets to send to get to the destination node in short time.

We can see from the comparison of the best cost as presented in Figure 11 that the network using proposed protocol has minimized initialization delay compared to the benchmark protocols. The network system achieved faster convergence for the initialization delay to discover the best cost route, which is about 30% improvement in convergence. Current node energy, mobility, route path, and cost function including route assessment index are

considered by the proposed method, making it preferable as a solution for the network system to improve communication quality. Figure 12 shows that utilizing the route evaluation calculation, about 60% enhancement can be recorded to find the optimum path with faster convergence in initialization delay.

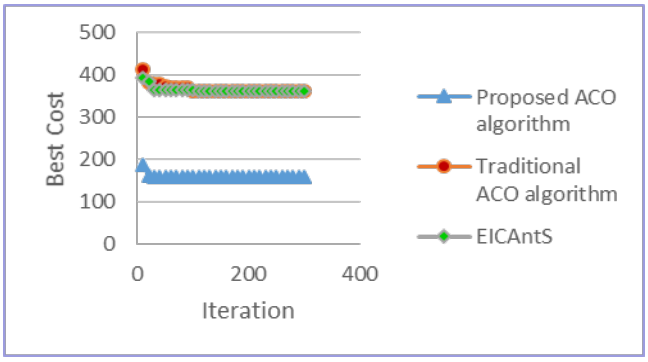

Figure 12: Comparison of the best cost with respect to the number of iterations using fitness function

4. Conclusions

The popularization of IoT-connected devices enabling development of IoT applications possess multiple and complex aspects of IoT while designing efficient communication protocols. The proposed system has utilized the beneficial features of an ant colony system to improve the route determination process and communication quality and mechanism in the context of IoT and to make IoT network system more scalable under varying load conditions. The parameters used in the selection of the routes are dynamically attuned to manage the network's dynamic condition. Current node energy, mobility, route path, and cost function including route assessment index are considered by the proposed method to enable efficient information communications within IoT. In the probability formula of ACO algorithm, the energy factor and the average mobility of the nodes are incorporated as well. It is demonstrated from the evaluation results that the proposed ACO based routing algorithm attained faster convergence for the initialization delay, about 30% improvement to discover the optimum route, and reduced energy consumption, of almost 50% less consumed energy even with the increasing number of nodes, compared with the benchmark algorithms. The proposed system achieved better results in terms of average end to end delay, almost 40% reduced end to end delay, compared to the other standard protocols. Also, it is confirmed that the proposed protocol as energy efficient method even for scalable networks, where the performance does not deteriorate abruptly as the number of nodes increases. Rather, it maintained improved network performance comparing with the other algorithms from the benchmark papers.

ABSTRACT

The demand on livestock as a source of protein is increasing with the dramatic increase of world population which approaches 8 billion. As a result, the monitoring of the performance of livestock breeding is becoming essential. The technique which could increase livestock production and improve the efficiency of operation is digitalization of livestock management .This could be achieved by models' realization that relates the rates of productivity and the parameters of operation which count on collecting big volume of data that results from digitalization process. In fact, the adoption of IoT technology in livestock environments is usually challenged by energy problems and power efficient communication technologies. In this paper a modified AODV protocol is proposed to enhance the traditional AODV protocol used in MANET networks that was mainly concerned with optimal route selection based on shortest path to send the data packets through it. The proposed technique models and simulates operational parameters of intermediate nodes as a factor to decide on the optimal path selection in IoT based MANET networks in addition to the shortest path that leads to transmission power gain of the source node. The results show a significant power performance enhancement that reaches average power saving of 33.3% compared to the traditional AODV protocol.

1. Introduction

This paper is an extension of work originally presented in 14th International Conference on Computer Engineering and Systems (ICCES) [1]. The increase in world population that reaches 8 billion increases the demand for livestock production. As a result, it is necessary to avoid livestock losses and protect it from diseases as this could threaten the countries' economy and food security. The process of observing livestock was difficult as it took a lot of time to detect if they had medical issues or not. Accordingly, researchers illustrated nowadays different advanced monitoring systems for livestock, these systems depend on remote sensors. Different types of sensors were used as: accelerometer, rumination, body temperature and humidity, and sound sensors. They were placed on the cattle to collect data and send it to the processing unit to take the appropriate action [2].

Today, Different technologies play an important role to increase livestock production and to save their losses as well as improving the operation efficiency in large farms. One of the recent technologies that offers the measure, actuate, sense and infer of physical and physiological parameters is the Internet of Things (IoT) technology. Livestock performance monitoring systems using IoT technology require special type of networks. Adhoc network is one of these special networks as it is energy efficient network and elongates the devices' lifetime. In the Adhoc network, different sensors are used to monitor behavior, stress, diseases and temperature. These sensors provide the IoT network with the collected data which allow the early detection of diseases. As a result, early treatment is offered which saves money and time.

The main problem in IoT technology is the energy source as it needs to work for a long time to reduce the need for replacement of sources or human collaboration. This paper concentrates on the study of suitable network topology that provides sensor network operation using energy efficiently. Accordingly, different

*Corresponding Author: Khaled Y. Youssef, Khaled.youssef@nsst.bsu.edu.eg

techniques against farms' environment are illustrated and simulated. Additionally, a Mobile Adhoc network (MANET) algorithm is introduced to decrease the source energy drainage and assure energy sustainability.

2. Literature Review

Several literatures are presented in previous work that proved the significance of IoT and sensor technologies to improve the livestock farm performance especially the large animal farming. In [3], the author presented a group of micro-sensors which were non-invasive sensors. They were mounted on the livestock using a collar that sent data via the internet wirelessly. As a result, a continuous connection between animals and veterinarian was established.

In [2], the author proposed a system using various sensors which were mounted on the cattle body. These sensors were used to monitor different parameters which allowed to detect the cattle body issues constantly. In [4], the author developed a system using misting systems for heat stress reduction. It was also developed to monitor humidity and temperature ranges. The system assured the avoidance of cattle death and the increase of producing high quality milk by preserving the ranges of the monitored parameters constant.

Although the literature above highlighted the use of rechargeable batteries as a main power source of the sensor nodes used in their studies, the researchers did not consider the battery recharging methodology especially for Adhoc wireless sensor networks. On the other side, the following literature developed techniques that enhance wireless sensor networks' performance.

In [5], the author focused on wireless sensor networks and proposed a gateway based Geographical Energy Aware Routing (M-Gear) protocol. In the system, the sensor nodes were distributed according to their location into four regions. Outside the sensing area, the base station was placed and at the center of the sensing area, the gateway node was located. Their developed protocol performance was compared to the performance of Low Energy Adaptive Clustering Hierarchy (LEACH) protocol. The compared performance was in terms of energy consumption and network lifetime. The comparison proved that M-Gear protocol was better than LEACH protocol.

In [6], the author developed a Modified Sensor Protocol for Information via Negotiation which is called M-SPIN. They made a comparison between the performance of M-SPIN and the traditional SPIN protocol using the broadcast communication. In the developed protocol, the hop distance between nodes and sink node was measured using a distance discovery phase. Additionally, the total number of transmitted packets was reduced as a result of transmitting data only to the sink node. As a result the consumption of total energy was minimized.

In [7], the author proposed an algorithm to modify the Dynamic Source Routing (DSR) protocol. The number of Route Reply (RREP) packets was decreased using the proposed algorithm and it also decreased the size of the header for the data packets which resulted in decreasing the overhead. They also developed an algorithm to reduce the energy consumed in data transmission.

In [8], the author presented a Dynamic MANET On-demand (DYMO) protocol and ant colony optimization algorithm which was capable of managing environmental changes. Graphs were used in ant colony optimization algorithm which was based on probabilities' method to find routes. Two factors were measured to evaluate the discovered routes. The measured factors were the route reliability and delay time. The software used to implement the algorithm was NS-2.

Accordingly, the proposed modified AODV technique capitalize on extending the enhancements in the literature to develop IoT operation aware Adhoc wireless sensor network that is suitable for use in livestock farm applications.

3. Overview on Energy-Efficient Routing Protocols

Mobile Adhoc network (MANET) is a group of self - configuring mobile nodes. These nodes can be used at the same time as router and end node, therefore a fail in the operation of some nodes affects the performance of the network. Energy deficiency of nodes is one of the main problems which affects the performance of network in MANET. As a result, it is important to use energy efficiently in MANET in order to increase the lifetime of node's battery [9]. There are several routing protocols in MANET such as Destination Sequenced Vector (DSDV), Dynamic Source Routing (DSR) and Adhoc On-demand Distance Vector (AODV). These protocols are used to select the optimal route between source and destination in order to send data through it.

3.1. Destination Sequenced Distance Vector

DSDV is one of the proactive routing protocols in MANET. It is a table driven routing protocol and it is based on Bellman-Ford algorithm. In this protocol, a routing table is used at each node to store all available destinations. Additionally, advertisements are made as a severe change may exist in the table's data. In this protocol, a sequence number is also sent to the destination in order to discriminate the old routes from the new ones which avoids the formation of loops. It isn't recommended for highly dynamic networks because it needs regular updates in its routing tables which lead to battery drainage [10].

3.2. Dynamic Source Routing

DSR protocol creates routes only when requested, therefore it is one of the reactive routing protocols. It doesn't use routing tables at the intermediate nodes as it uses source routing. In this protocol, the intermediate nodes send a Route Request (RREQ) packet with its own address identifier. The available routes in the DSR protocol are being tracked by a route cache. Two main mechanisms are used in DSR: route discovery and route maintenance. They are used to discover routes and to notice if any change occurs in the network topology [11].

3.3. Adhoc On-demand Distance Vector

AODV is one of the most known reactive routing protocols in MANET. It creates only a route when a source node needs to send data to a destination node therefore it is better than DSDV as it minimizes the number of broadcasts. It has a good performance in dealing with large number of mobile nodes as it creates dynamically at each intermediate node a routing table. It also has

a sequence number counter which prevents the formation of loops in its routing tables. This sequence number also keeps the nodes updated by comparing their routing tables to check how updated information they have about other nodes [12].

4. Performance Evaluation of Adhoc networks

There are different parameters measured to assess the performance of MANET protocols as summarized in Table 1.

4.1. Packet Delivery Fraction

The ratio between the number of broadcasted packets by the source node and the number of received packets at the destination node is known as PDF. In case of low number of nodes, DSR performs better in this metric but the performance declines with the increase of the number of nodes. On the contrary, DSDV performs better in case of large number of nodes but AODV showed that its performance is uniform in both cases [13].

4.2. Average end to end delay

It is the time it takes from the packet being created at the source node to the packet being delivered at the destination node. In this metric, DSDV performance declines with the increase of the number of nodes. However, the DSR and AODV performance is uniform [13].

4.3. Number of Packets Dropped

It is the failed data packets that couldn't reach the destination node. In case of large number of nodes, DSR and AODV have a good performance. On the other hand, DSDV has the worst performance as it declines with the increase of the number of nodes. The performance of AODV in this metric is the best as it exchanges information periodically between nodes which ensures connection [13].

Table 1: Performance of MANET Protocols

Metrics	AODV	DSDV	DSR
Average end to end delay	Uniform performance	Performance declines when number of nodes increase	Uniform Performance
PDF	Uniform Performance	Good performance when number of nodes increase	Performance declines when number of nodes increase
Number of packets dropped	Good performance when number of nodes increase	Performance declines when number of nodes increase	Good performance when number of nodes increase

5. Proposed Architecture for Livestock monitoring IoT networks

Figure 1 shows the architecture of a group of mobile nodes connected in MANET network. Each node in this network has different sensors such as accelerometer, skin temperature, humidity and ambient temperature, and respiratory rate. The data sensed from these sensors will be transmitted to a central processing server (CPS) to perform the proper action. In such a network, Power should be used efficiently to elongate the battery lifetime of each node. Accordingly, AODV protocol which is an energy efficient routing protocol is used to select the optimal route to send the collected data to the destination node. As a result, the total transmitted power of source node is reduced.

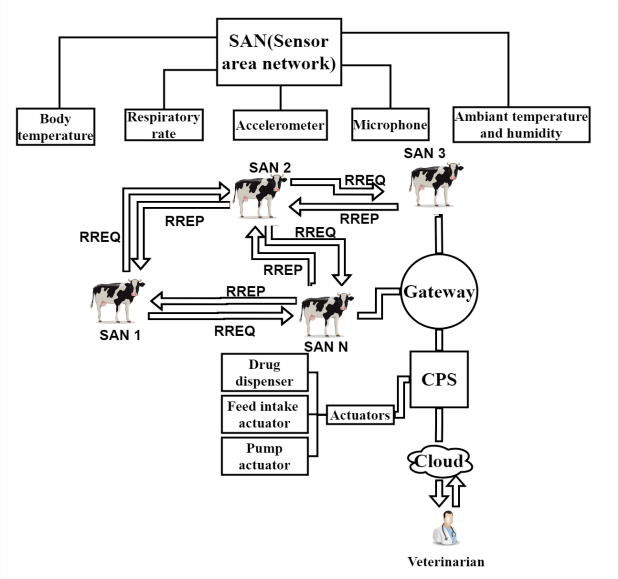

Figure 1: System Architecture for Monitoring livestock Performance

Figure 2 shows the flowchart of how AODV protocol is implemented. When a source node starts to search for a route to send its data through it to the destination node, it searches its routing table. If there is a route in its routing table to destination, it sends its data packets through this route. If there is no route to the destination node, it broadcasts a Route Request (RREQ) packet to all the neighbor nodes. If the node that received the RREQ packet is the destination node or it has in its routing table a route to the destination node, it sends a Route Reply (RREP) packet to the source node. If the receiving node isn't the destination node or there is no route for the destination in its routing table, it broadcasts a RREQ packet to all its neighbors. When the source node receives a RREP packet, it transmits its data packets through the same route where it received the RREP packet. If several RREP packets are received by the source node, it selects the RREP packet received from the shortest route and discard other packets. As a result, the power for transmitting the data packets is reduced which increases the source node battery lifetime.

A modified AODV protocol is proposed to enhance the overall network power performance. The optimal route in the modified protocol is selected depending on the index weight of the path rather than depending only on the shortest path. The index weight is a new factor measured to indicate the operation time of each node in a certain path. Each node is given a certain index

which represents its operation time. The index weight of the path is measured as the total index of nodes in a certain path divided by the number of nodes in this path. The path with the highest index weight has the lowest priority to be selected while the path with the lowest index weight has the highest priority to be selected.

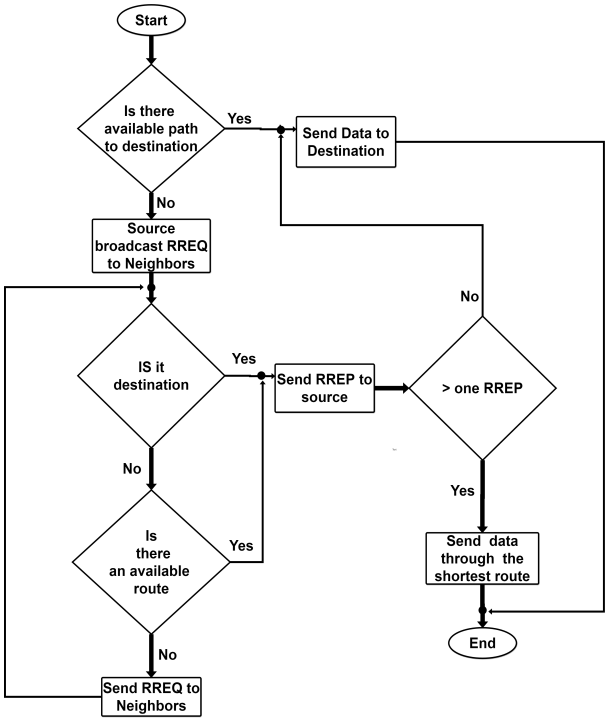

Figure 2: AODV Flowchart

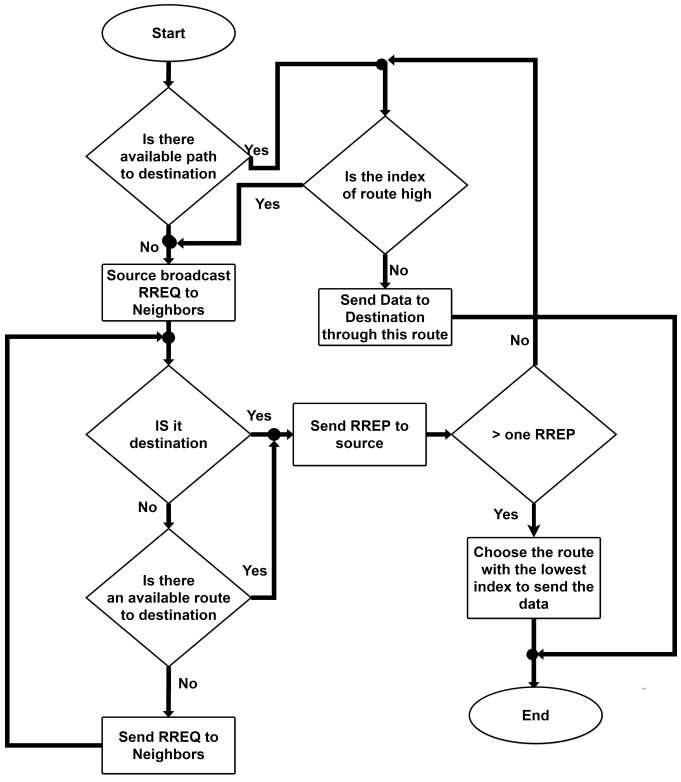

Figure 3: Modified AODV Flowchart

The flowchart in Figure 3 shows how the modified AODV protocol is executed. When a source node starts to search for a route to send its data through it to the destination node, it searches its routing table. If there is a route in its routing table to destination, it checks its index weight. If it is low, it sends its data packets through this route. If there is no route in its routing table or the index weight of the available route is high, it broadcasts a Route Request (RREQ) packet to all the neighbor nodes.

If the node that received the RREQ packet is the destination node or it has in its routing table a route to the destination node, it sends a Route Reply (RREP) packet to the source node. If the receiving node isn't the destination node or there is no route for the destination in its routing table, it broadcasts a RREQ packet to all its neighbors. When a RREP packet reaches the source node, it checks the index weight of the route. If it is high, it sends RREQ packet to all its neighbors searching for other routes with lower index weight. If it is low, it starts to send data packets to the destination through the same route where it received the RREP packet. If the source node receives more than one RREP packet. It selects the route with the lowest index weight to send data packets. As a result, it increases the lifetime of the serving nodes which enhances the overall network power performance.

6. Simulation Model Results

In this simulation, MATLAB software is used to simulate AODV protocol. In Figure 4, it is shown how the source node, destination node and the number of nodes are entered in this model. It is assumed in this simulation that the network has 20 mobile nodes randomly distributed in a farm size of 100 m^2 and a 20 m transmission range between nodes. The source node and the destination node are assumed to be node 2 and node 10 respectively. AODV protocol is implemented in this model to enable the source node to request different available paths to the destination node. The source node will receive RREP packet from the intermediate nodes if they have an available route to the destination node. In Figure 4, the available routes are shown.

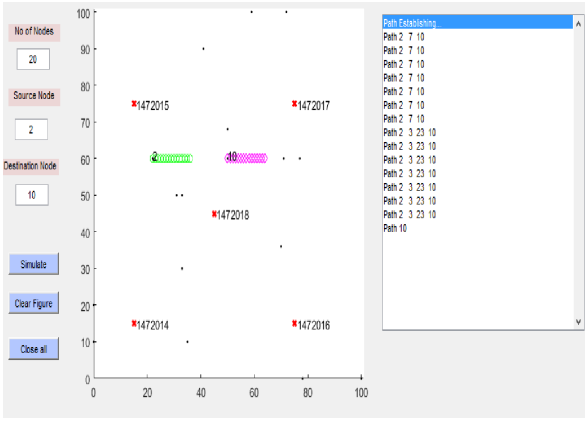

Figure 4: Simulation Model

In our work, two main performance indicators are used to measure the impact of the proposed advanced AODV protocol on the IoT network performance mainly the energy consumption and network lifetime.

i) Energy consumption is based on MATLAB model that is governed by the following equation

Energy Consumption (Joule) = Energy Consumption Rate (Joule/bit) * Transmission rate (packets per sec) * Packet size (bits) (1)

The multipath fading is also accounted in the simulator model given that the amount of Energy consumption rate considered in the model for the transmitter or receiver circuitry is 50 x 10^{-9} and amount of energy consumption for multipath fading is 0.0015 x 10^{-12}.

ii) Network lifetime that is defined as the ratio between its residual energy and the energy consumed to transmit data packets (i.e. the time spent until the node run out of energy). It is the third parameter calculated at each route as shown in Figure 7. In this case, the route with the longest network lifetime is the optimal route as it has the lowest energy consumption and the shortest distance. As a result, route 12 is the optimal route in terms of distance, energy consumption, and network lifetime.

The simulation results for applying AODV protocol in cows' performance monitoring system are shown in this section. The first parameter measured as shown in Figure 5 is the total distance between the source node and the destination node at each route. The optimal route is found based on this parameter as the optimal route is the shortest route which is selected to transmit data through it. In this case, the route with the shortest distance is route 12 so it is the optimal route.

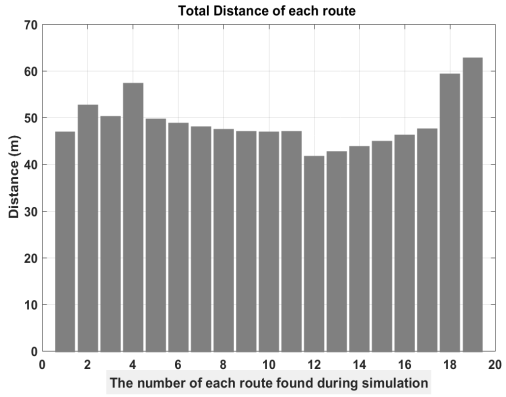

Figure 5: Total Distance versus The Number of Each Route Found During Simulation

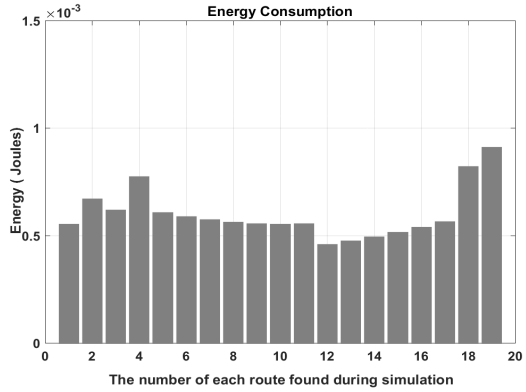

Figure 6: Energy Consumption versus The Number of Each Route Found During Simulation

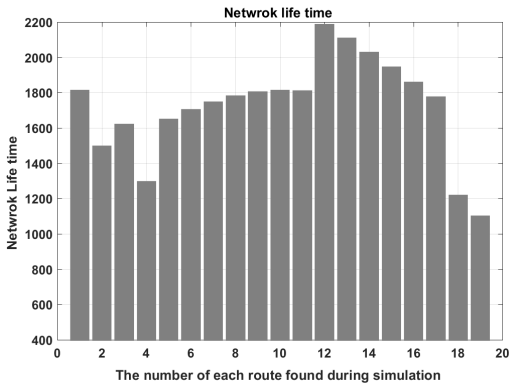

Figure 7: Network Life Time versus The Number of Each Route Found During Simulation

In this simulation, the energy consumption is the second parameter calculated at each route as shown in Figure 6. Equation 1 represents the energy consumption model. The route with the shortest distance has the lowest energy consumption. In this case, route 12 is the optimal route in terms of energy consumption and distance.

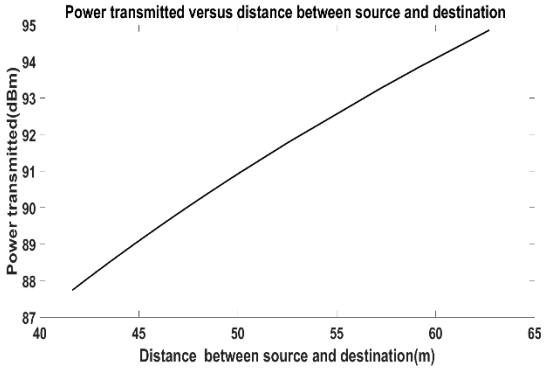

Figure 8: Transmitted Power versus Distance between Source and Destination During Simulation

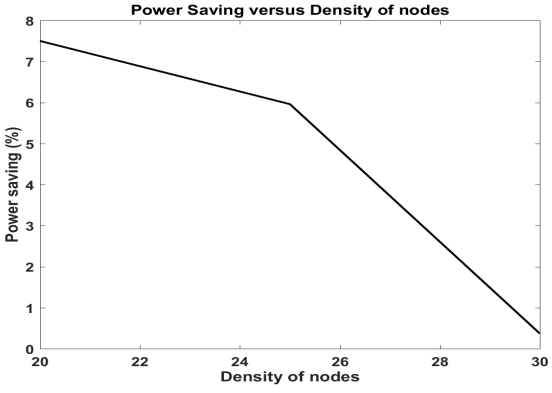

Figure 9: Power Saving versus Node Density in Mobile Adhoc Network

The fourth parameter calculated in this simulation as shown in Figure 8 is the transmitted power at each route. The data are transmitted with minimum power when transmitted through the shortest optimal route to the destination node. In this case, route 12 is the optimal route in terms of distance, energy consumption, network lifetime, and transmitted power.

The fifth parameter measured is the power saving as shown in Figure 9. It indicates when selecting the shortest optimal route in MANET how much transmitted power is saved. It is measured at different number of nodes as shown in Figure 9 to indicate that when the node density increases the power saving decreases. Figure 10 shows the power saving which indicates how much transmitted power is saved when selecting the shortest route in MANET compared to the transmitted power in fixed network. It is measured at different number of nodes to indicate that when the node density increases the power saving decreases as shown in Figure 10.

Table 2: Simulation Results

Route Number	Distance (meters)	Transmitted Power (dBm)	Power Gain
1	46.84294241	89.78211633	
2	52.58886799	91.79210254

7	47.90305917	90.1708796	
8	47.33955199	89.96531538	
9	46.97970233	89.83276007	
10	46.83013443	89.77736582	
11	46.894632	89.80127492	0.924
12 Optimal Route	41.64331698	87.73816223	
13	42.60107524	88.13317207	
14	43.66889973	88.56323963	
15	44.83914468	89.02264243	
16	46.10374679	89.50579849	
17	47.45489265	90.00758945	
18	59.20525888	93.85076102	
19 Worst Route	62.72062331	94.85276426	

Figure 11 shows different paths between source and destination which are path1 (P1), path2 (P2), path3 (P3), path4 (P4) and path5 (P5). It is assumed for each path that the distance between nodes is equal and the total transmitted power of the source node is 30 dBm. It also shows the transmitted power of each intermediate node in each path. There are some nodes which are common in more than one path such as nodes: 3, 4, 7 and 9. These nodes are called busy intermediate nodes as they could be used several times in the network which will lead to the drainage of their batteries. As a result, as mentioned earlier in section 5 a modified AODV protocol is proposed to save the battery of these busy nodes. There are different scenarios for node process shown in Table 3 as each intermediate node will have an index to indicate how busy this node in order to select the optimal path in terms of its index. In Table 4, it shows the transmitted power of each node and its index of processing. It also shows their index weight which is the total index of nodes divided by the number of nodes in each path. The selection of the optimal route will be based on its index weight, the route with lowest index weight is the optimal route to send data through it.

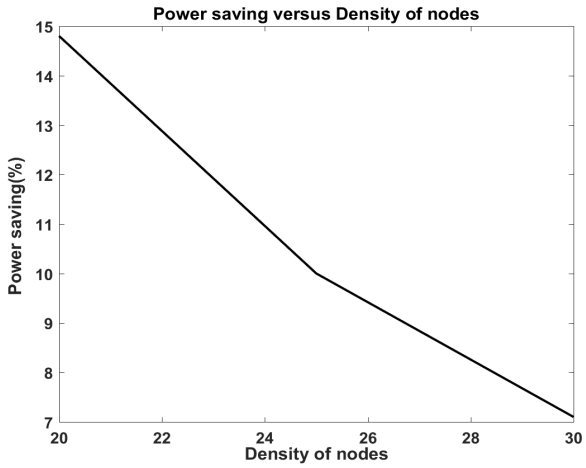

Figure 10: Power Saving versus Node Density in Fixed Network

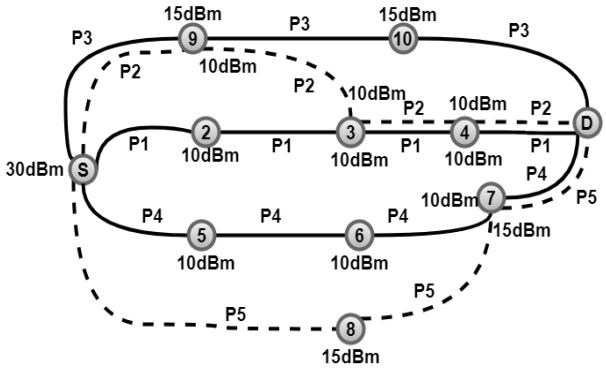

Figure 11: Different Paths Available to Send Data Packets from Source Node (S) to Destination Node (D)

Table 3: Different Scenarios for Node Process and Its Index

Node process	Duration of not processing node (T in hours)	Index(i)
Event Based	T >= 12	0
	6 =< T <12	1
	3 =< T < 6	2
	1 =< T < 3	3
	T < 1 hour	4
Periodic	Periodic Time (Tp in hours)	Index(i)
	Tp >= 12	5
	6 =< Tp <12	4
	3 =< Tp< 6	3
	1 =< Tp < 3	2
	Tp< 1 hour	1
	Data size (D in kilobyte(KB))	Index(i)
	D>=200	5
	100=<D<200	4
	50=<D<100	3
	10=<D<50	2
	D<10	1

Table 4: Parameters of Intermediate Nodes

Path	Intermediate Nodes	Power(dBm)	Index	Index Weight
P1	2	10	1	2.33
	3	10	3	
	4	10	3	
P2	9	10	5	3.67
	3	10	3	
	4	10	3	
P3	9	15	5	4
	10	15	3	
P4	5	10	1	2
	6	10	0	
	7	10	5	
P5	8	15	2	3.5
	7	15	5	

Figure 12 shows the index weight of each path which indicates the status of the intermediate nodes. If the index weight of a path is high, it indicates that its intermediate nodes were processing for long time therefore this path can't be selected to transmit data through it. As a result, this will save the lifetime of their batteries.

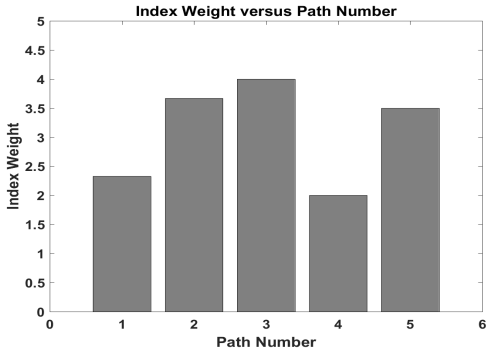

Figure 12: Index Weight versus Path Number

Figure 13 shows the power gain of each path which indicates how much power is saved by selecting a certain path. The optimal path shown in Figure 13 is path 4 as it has the highest power gain.

Figure 14 shows the power gain versus the index weight to indicate how much power is saved when selecting the path with the lowest index weight. As shown in Figure 14, the path with the lowest index weight has the highest power gain.

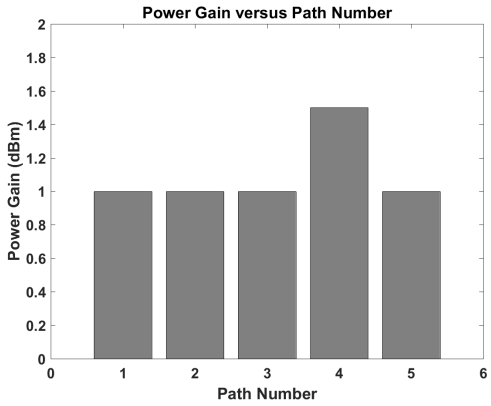

Figure 13: Power Gain versus Path Number

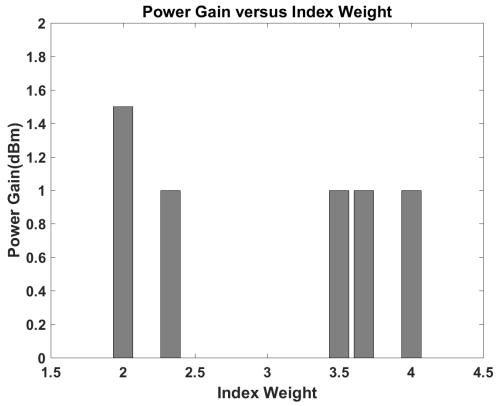

Figure 14: Power Gain versus Index Weight

7. Discussion and Conclusion

The results from applying the AODV routing protocol to select the shortest route showed that when the total distance between source and destination decreases, the energy consumption decreases which increases the network lifetime. It also showed that a decrease in the transmitted power occurs when the total distance decreases. For MANET and classical fixed networks, the power saving is calculated for each route found at different node densities. It showed that when the node density increases, the power saving decreases.

Table 5: Power Gain for Different Path Selection Scenarios

Busy intermediate nodes	Common in Path	Total Power(dBm) on busy node	Scenario	Power gain (dBm)
3	P1	20	1 (P1 selected)	10
	P2		2 (P2 selected)	10
4	P1	20	3 (P1 selected)	10
	P2		4 (P2 selected)	10
7	P4	25	5 (P4 selected)	15
	P5		6 (P5 selected)	10
9	P2	25	7(P2 selected)	15
	P3		8 (P3 selected)	10

Table 6: Traditional AODV versus Proposed Modified AODV Protocol

Routing Protocol	Optimal Path	Hop Count	Optimal Path Selection	Power Gain (dBm)	
Traditional AODV	3	3	Shortest Path	10	By comparing the traditional AODV and the proposed modified AODV, the results show a significant power performance enhancement that reaches average power saving of 33.3%
Proposed Modified AODV	4	4	Lowest Index Weight	15	

The traditional AODV protocol focused only on how to enhance the battery lifetime of the source node depending on selecting shortest optimal route. It didn't highlight the importance of the intermediate nodes which are serving nodes and their batteries could be drained quickly due to their operation time in the network. As a result a modified AODV protocol is proposed, this protocol added a new feature to select the optimal route. The selection of the optimal route in the modified AODV protocol is depending on the operation time of each node in the path. Each node is given an index which specifies its operation time as shown in Table 3. An index weight which is the total index of the nodes in a certain path divided by the number of nodes in this path is measured for each path. This factor indicates if the available path could be used or not. The path with a high index weight has the lowest priority to be selected because it indicates that the operation time of the intermediate nodes in this path is very high and thus the probability to have lower battery state of charge is higher.

Accordingly, the optimal path is the path that has the lowest index weight.

By applying the modified AODV protocol to select the optimal route depending on the index weight of the route as a priority to selection of the shortest route (i.e. if two routes have the same index, then the shortest one is selected). The protocol supports to give the intermediate node with longer operation time the opportunity to focus on sensed data processing. The networking processing function is then off loaded from this intermediate node to other nodes with lower operational time and accordingly higher probability of battery charge lifetime.

As observed in Table 5 the optimal path in terms of power gain is path2 and path4. It is also observed in Table 4 that the best path in terms of index weight is path 4. By comparing the power gain when selecting the shortest route (measured in hop counts) which is path 3 in Figure 11 to the power gain when selecting path4 which has the lowest index weight, it proved that the power is enhanced by 33.3% as shown in Table 6.

As a summary, a convenient network topology is studied in this paper to provide a network of sensors which has an energy efficient operation. Accordingly, in order to decrease the source energy drainage which assures energy sustainability, MANET algorithm is proposed. In MANET, AODV is the most common known routing protocol as its performance is the best compared to other MANET protocols. In this simulation, AODV was applied to allow the selection of the optimal route between source node and destination node. The optimal route is selected as it has the shortest distance, the lowest energy consumption and the longest lifetime.

A modified AODV algorithm is proposed in order to enhance the overall network power performance. The protocol depends on giving intermediate nodes with lower operation time a higher priority to share in the network routing even if the path could be longer which could lead to a power saving that reaches 33.3%. As a result, the paths in the modified AODV are selected based on the index weight of the path. The selected path is the path with the lowest index weight.

Virtual crime

ABSTRACT

Virtual reality is a technology that literally allows constructing of a new reality for its users. VR has huge potential, it is able to change social life, communications, and the academic sphere, but VR may also be applied by criminals. In the present paper properties of potentially committed crimes in VR are analyzed. It is concluded that VR provides criminals with some advantages. The first advantage is the multijurisdictional problem in prosecuting the offender that is usual for most of IT. The second advantage is that a virtual environment gives a realistic experience to the user and literally replaces the real world. The third advantage is an integration of virtual-world environments with haptic devices that may factually affect the user in the real world. All of these allow the commission of new kinds of crimes where properties of conventional and cybercrimes are combined. Among such kinds of crimes analyzed in the paper are cybercrimes that affect the body and mental state of victims. VR is researched as a first tool that in combination with haptic devices gives criminals the opportunity to commit crimes against sexual freedom and to cause physical harm. Thus, VR crimes need a special legal framework that will take into consideration this kind of crime.

1. Introduction

This paper is an extension of work originally presented in 2019 International Conference on Cybersecurity (ICoCSec) [1]. Virtual reality (VR) is one of the most promising breakthroughs. It literally replaces the real world. VR dips humans into an alternative reality where different aspects of human life are imitated. The tasks of introduction of any information technology may vary, for instance, technology could be applied to make the world around us better. At the time of the pandemic, it is the only way to visit new spaces that are so similar to the real world [2]. Virtual reality is not a single technology but a set of technologies that permit a developer to construct an environment that would be recognized by our body and mind as real. VR is a tool to create new realistic worlds. Sometimes this environment is used for work, very often for gaming and social interaction. There are some forecasts that soon people will prefer virtual worlds over reality.

Virtual reality is a widely used technology. The market of VR is anticipated to grow from US$27 billion in 2018 to US$209.2 billion in 2022 [3]. Some researchers noted that VR attracts a lot of investors' attention and large companies invest in the technology [4].

Virtual reality is technology that literally allows constructing a new reality for its users. VR has great potential, it is able to change our everyday life, communications, and academic sphere. Nowadays virtual reality is actively applied in different spheres. The biggest driver is the entrainment and computer games. Also, a VR application is noticeably beneficial in teaching [5,6]. Sometimes virtual reality helps to simulate real situations [7]. VR is widely applied in medicine [8]. Some cases of rehabilitation of felons in VR exist [9,10]. In addition, a virtual world can be tuned in accordance with the needs of the user that makes it more attractive than real.

Virtual reality technology is a variety of hardware and software tools, which help to imitate a real or fictional world for a user. It interacts with our senses (vision, hearing, touch, smell, sense of balance, etc.) and misleads the body and mind that they are in the real world [11]. Virtual reality is an environment that is imitated through technology. The main virtual reality device is a special

*Corresponding Author: Roman Dremliuga, Email: dremliuga.ri@dvfu.ru

helmet, that may mimic the outside world through rendering video and audio. There are also numerous additional devices such as controllers, joysticks, steering wheels, haptic interfaces which increase a realism of VR illusion. All devices are designed to make an imitated world as real as possible.

"Virtual reality" has a common-used definition of the term. It is considered that VR is an information technology with special characteristics. For example, the following definition is suitable for the goals of the research. Virtual reality term is interpreted as "a technically constructed interactive environment with the help of computer facilities; as the generation and operation of objects, real or imaginary, on the basis of their graphic representation, simulation of their physical properties and ability to influence and independent presence in space, as well as the creation of such objects by means of special computer equipment" [12].

Development and introduction of any technology depend on a legal framework that is applied. Investors, developers, and users have to understand current and future legal rules that concern application of technology. In terms of business, the legal expertise is necessary on the step of making the initial decision. Wrong assessment of legal risks could lead to a total misapplication of funds, time, and efforts. Thus, to understand development of VR it is necessary to understand the current and future legal frameworks in this sphere.

The question is whether VR is another technology to which existing cyberspace laws apply or whether entirely new rules need to be developed. In order to form the correct legal framework, it is necessary to understand the conceptual differences between this technology and other technologies.

The sufficient legal risk is to face criminal cases with new properties. Some technologies provide tremendous opportunities for commitment of crimes. If a developer understands which challenges would exist in terms of criminal application, he will design his products by taking into consideration potential risks. The key is understanding how VR could be used by criminals and how it could be treated from a legal point of view.

The idea of this paper is not directly to enumerate possibilities of illegal use of VR but assess future prevalence and social consequences. To achieve this goal, it is necessary to utilize some assumptions that research will rely on.

- If VR maintains to achieve the same illegal result as some other technology, this automation will be replaced by VR in case of higher effectiveness of VR.
- If some property bolsters to spread VR use in society, this property will be the key characteristic that makes VR useful for criminals.
- Enforcement is always behind leaders of the crime 'industry' since it is bound by strict regulation and bureaucracy.

Thus, three aspects were carried out in the present paper. Properties of VR as a tool of crime were analyzed; challenges for the development of regulation that is caused by the characteristics of VR were reviewed. Some recommendations for the development of a legal framework were provided.

2. Research methodology

Research methodology for studying legal challenges of VR technology that goes beyond both dogmatic analysis has to be applied in the research. Analysis in the research follows positions developed within the philosophy of law and legal theory. Among relevant methodologies are the hermeneutic and argumentative approaches.

As the research is interdisciplinary, there is a synergy between methodlogies of disciplines. Interdisciplinary research must extend beyond mere multiplication of disciplinary methods and perspectives, to incorporate some element of integration or, mutual dialogue between disciplines. Interdisciplinarity is absolutely essential for the research as its object lies on the intersection of disciplines. As fairly commented some authors "it is important to have a multidisciplinary approach inconstructing such a methodology as the tools analysed stem from different disciplines and domain of expertise" [13].

Factually the research is based on a comparison of current and future properties of VR technology with current and potential legal framework. The focus on the legal and societal impacts of VR use requires us to observe the results of researches in the sphere of influence of virtual environment on humans. It is clear that such an important question cannot be accepted only on the basis of one or several studies, therefore, it is necessary to use the results of a whole set of studies to draw conclusions about the characteristics of VR, important for the formation of legal norms for its regulation.

The expected results of the study are directions where the legal framework applied to VR has to be upgraded. Recommendations with a high level of abstract should be developed. In future, de lege ferenda proposals could be based on our results.

Despite analysis and conclusions of the paper could be applied in different legal systems, the study is mostly focused on legal practice and conceptions of the United States and EU states as leaders in introduction of VR. The reseacrh is less applicable to asian technological leaders due to sufficicent differences in legal frameworks. Some ways of VR applications that are usual in the United States and EU are prohibited in other countries. For instance, virtual sex or VR pornograhpy are illegal in China, Indonesia and Malaysia.

Thus, the methodology can be shortly described as the application of a legal case study to the research of technology with an enormous social impact. The paper as some others [14] utilized a case study methodology. It is manifested in gathering and analyzing proven effects of VR on a user in terms of social, ethical, and legal risks. As the area of risk is quite wide, the paper focuses on risks related to the commission of criminal offences in VR.

3. Legal challenges

3.1. Increasing significance of VR

The main purpose of VR is to provide an environment for spending time. The application of VR for gaming dominates nowadays but VR is also used for workshops and business meetings. It is actively applied for educational purposes and simulation of difficult tasks. The advantage of VR is clear: a

customized reality that provides a high level of similarity of human reactions with the real nature. It is effective for games where people pass through all spectrum of emotions as well as for training where people become ready for the stress of a real situation. Most VR applications in business communications or games imply audio and video information exchange in some virtual space that increases the level of participation.

The level of realism could be even improved when real appearance is applied. In virtual reality, a user is frequently seen by others as an anthropomorphic avatar whose appearance may be similar to the user's appearance in the real world or may be completely different. Despite the voice and personal appearance of the virtual world can be altered, this does not exclude the possibility that voice and visual appearance of the user would be the same as in the real world.

The big advantage of VR is that people are able to communicate in a realistic way even if they are separated in the real space. Thus, people, in the form of relatively realistic avatars, communicate as they would be face-to-face. VR provides the possibility to imitate eye contact and to manipulate virtual objects that participants see together. It is similar to a video call, but participants of VR meetings have a higher level of involvement.

VR technology is far from perfection. Headsets cannot track eye movement with high accuracy. VR Graphics is far from a full imitation of the representation of the real world and is rather applied to construct some simple spaces with a low quantity of details. Facial expressions are still rendered in virtual reality quite poorly.

Despite the above, virtual reality is a very popular environment for spending time and human interaction. Under different studies, the amount of VR's application for spending time and social interaction is fastly growing [15]. There are approximately 170 million users of virtual reality worldwide. A double increase in the number of VR consumers is evidenced in recent years.

The growth of legal applications of VR implies an increase in criminal use. It is anticipated that the number of virtual reality users should correlate with the number of crimes committed in VR, as this was observed with the growth of the number of Internet users. As more people use VR worldwide, there are more potential victims and criminals in VR. Some researchers found the proliferation of the use of the global network (the Internet) as a major factor in the growth of cybercrime. Thus, the number of criminal acts in VR is expected to increase due to the growth of the number of its users [16].

Wide use of VR leads to a classic dilemma. A legislator has to choose between the need for a free exchange of computer information, as a factor of digital economy growth and the need to defend state and social security by restrictions on IT use. To find the balance between public security and the necessary freedom of technology application for its development, a lot of different factors have to be taken into consideration.

As with any technology, VR may facilitate criminal activity. Virtual environment may be a tool or instrument to commit a crime as well as an additional factor that facilitates it. Recently, the use of high technology to commit crimes increases, and it concerns virtual reality. An opportunity how criminal law is applicable in case of crime in virtual environment should be studied.

3.2. VR as a potential tool to commit a crime

VR is in some sense a unique technology that makes crimes with the application of that technology dissimilar with others. It may constitute difficulties for the investigations of such offences. VR as a tool confers crimes by new properties. Virtual reality is not simply another new technology, which requires to design technical standards. Rather VR application requires to introduce a new legal framework. There are several reasons why a traditional legal framework does not qualify. Basically, due to its special characteristics, VR requires fundamentally new legal frameworks and solutions.

The first, commonly known problem is cross border jurisdiction. It is difficult to identify a person with whom the user interacts in VR. Virtual environment and its users are often in different jurisdictions. A world that is undivided in VR may exist regardless of borders of the concrete state in terms of its users. Millions VR users have no idea where the virtual reality platform is physically located, where their data are processed and stored. Thus, virtual space may be outside the jurisdiction of the state where the victim applies to law enforcement.

Some authors commented that: “It will take a lot to get domestic police interested in investigating a crime where the criminal is in a foreign country. … Still, the greater difficulties of extradition are likely to exceed the greater ease of proof. And many VR street crimes might thus be practically ignored by traditional police departments” [17]. Thus, the multijurisdictional challenge is the multidimensional problem. There are a lot of questions as from legal assessment of committed offence as well from criminal procedure rules.

Any digital cross border space poses a challenge to law enforcement and the legislator. People from states with different legal systems meet in a virtual environment. Cross border character of VR spaces creates a situation where the crime has anonymous, remote in space, and global character. When virtual reality is applied to commit a crime, deanonymization and pursuing criminals become very difficult and even impossible.

The second feature of virtual reality as a place, tool, or instrument of crime is the capability of a virtual environment to create an illusion of reality. Sometimes this property forces real consequences for the potential victims of crime in VR.

Studies demonstrate that people uploaded at VR may be afraid of walking across a wooden plank that is on the ground in the real world but placed in virtual reality between roofs of skyscrapers. The experimental environment forces similar psycho-emotional reactions of a probationer as if it happens in the real world [18]. Dizziness, nausea, stomachache, and shaking body are just a few of the reactions to virtual heights [17]. Thus, experience in a virtual environment, in turn, may bring real consequences for body and mind. The VR customer may be literally frightened to a state of heart attack by a game in which he (she) feels quite real [19]. In case of the absence of consequences for the body, it may be a difficult psychologically traumatic experience. Thus, a virtual experience could cause permanent physical or psychological harm.

The realism of virtual environments has also positive effects, for example, VR is successfully applied for autism control [20] or in treatment of phobias [21]. But the side effect of VR realism is

that it is a perfect tool for hackers or other cybercriminals to "hack" into the victim's heads. Earlier, cybercriminals only had distant access to property, business reputation, and other values, but now they can literally get inside the brain. Harm also could be caused by the application of VR in medical treatment without direct intention [22].

In comparison with the real world, VR provides certain advantages for criminals in terms of the range of psycho-emotional reactions that could be provoked. In the physical world, it is very difficult to place a victim into the "Grand Canyon" and is even impossible to organize a meeting with a monster from science fiction. Hence, it is possible to distantly manipulate consciousness and emotions through VR by imitating any real or fictional environment. [23]. The character of such intervention is limited only by the imagination of the criminals. Current studies demonstrate that with the help of VR any emotion for up to 8 minutes could be forced [24].

Virtual worlds become more realistic due to the development of VR software and hardware. Objects are rendered with a higher degree of detail. More sophisticated models are applied to imitate interaction between objects in virtual reality. The link between events in VR and the body of the user gets more channels. Some researchers underline that higher realism implies a more significant psycho-emotional response of the customer on events in the computer environment [25].

As some researchers claim “Multimodal inputs will be combined in unprecedented patterns of stimulation that will ultimately make a VR experience more real than reality. Strong social emotions, in turn, will likely reinforce the sense of presence and make it easier to ascribe mental states to other virtual characters” [26]. Thus, intervention into human mental state is conceivably even more aggressive in future because new developments in sphere of VR technology.

The next challenge is development of haptic devices or other devices that are capable to affect the customer in the reality. Haptic technology enhances, new ones appear each year [27]. For example, there are enough investments in technologies for remote sexual intercourse. In the case of virtual environment application, skin sensations are networked between the users. The widespread use of such technologies implies that a criminal is potentially able to commit illegal intimate contact.

In some studies, conducted in the United States, it is underlined that hacker’s replacement of another user in a sexual act or unauthorized access to the user’s body in VR with the use of a haptic interface has similar characteristics with crimes against sexual freedom. In the legal research papers, such act committed with intention is considered to be either sexual harassment or rape [28]. Before haptic technology, it would be impossible to commit a rape distantly. Thus, haptic devices and similar equipment provide the capability to intervene in body inviolability.

The opinion exists that the above challenge could be overcome by a technical solution. Some authors state that “the ability to define default consent in software can make VR safer than the real world—for instance, well-designed software may let me consent in advance to certain types of touching but not others, or touching by some people but not others, and touching that isn’t consented to won’t even be felt. The question that remains is to what extent, if at all, it should be viewed as the victim’s job to set software consent boundaries; more on that below” [17]. Thus, the questions here: who would be responsible for the introduction of defense from body encroachments, what would be the liability of the developer or the seller for negligent informing about such kind of risk? And the main question is whether it is still crime or not?

All discussed above presuppose that VR allows to committing crimes which are impossible to commit with traditional IT. For instance, homicide could be committed on the Internet without VR, but not rape. A victim who has been raped in VR may not immediately realize what happens. Thus, a victim may be in a helpless state. As the victim is unable to understand that some illegal actions happen, he (she) is unable to take measures against the criminal. In some sense, it implies that rape or harassment in VR is probably even more dangerous because it is latent even for the victim.

Moreover, software and hardware for distant sex have low security against cyberattacks [29]. Often developers in this sphere are focused on new user engagement than on fixing vulnerabilities. It indicates that such kind of products could be easily hacked. Potentially criminals even could provoke VR users to move outside their secure boundaries in the reality through application of malware [30].

Due to the innovations in the VR sphere criminals are able to encroach not only on the mind but also on the body of victims. It is a complicated question whether the sexual assault in VR is comparable with real-world crime in terms of consequences for a victim. Of note, in the case of VR, there is a great number of difficulties in the prosecution of the offender. In addition, criminal significantly reduces the sum of risks related to the act (risk to be caught at the crime scene, risk of suffering if the victim resists, risk of public censure even if the guilt is not proven, and some others).

Development of haptic suits with feedback poses a risk of increasing harm-related crimes. The suit by electrical impulses informs the body of what happens with it in VR. The haptic device stimulates skin when some object touches the user in virtual world. Currently, there are no regulations on the permissible power of impact on the body. It is not legally defined what the degree of pain and harm is possible in VR. Of note, such a rule has to depend on the individual characteristics and other parameters. Due to the absence of regulation a risk of inflicting real suffering from haptic suits in virtual reality exists.

For instance, «new peripherals and technologies enter the market supporting a variety of interaction fidelities, such as data glove controllers, skeletal motion capture suits, tracking systems, and haptic devices» [31].

3.3. Immoral acts

As described above some manifestations of VR are not covered by modern legal regulations but there are some difficulties in addressing the mentioned challenges even in terms of moral rules. As law and morality are both means of conducting control, they are strongly linked. It does not imply that both social regulators have to correlate each other, but at least legislator has to take into consideration the norms of molality. And if a gap in the legal framework exists, VR has to be assessed from a moral point of view. A moral system of norms is clearly often very dynamic and opaque, but it is often helpful to know what is good or what is bad from a moral point of view. Moreover, the last social initiative in countries of Western Europe and Northern America as MeToo and

BLM demonstrate that moral norms could have even bigger impact on society than legal rules.

The first question is arising from identity flexibility in a virtual environment. In VR any user can choose any appearance that is provided by a software, risk exists that a person will apply the wrong appearance. At the same time, avatars and names influence on the perception of the user by other persons. These characteristics that are very significant for the attitude of other persons could be easily changed. It raises some ethical questions that are significant from ethical and sometimes legal point of view.

Imagine a teenager who uses VR poses as an adult and engages in an intimate conversation or even virtual sexual contact with an adult person. Who would be liable for such actions? Who has to take precautionary measures? Who must be in charge of the customer's appearance? What would the legal consequences of similar action be? Probably the legislator has to oblige VR developers to incorporate technical solutions for this kind of case. If one person misleads another person by his/her appearance in VR, how does it correspond with moral or even legal rules?

Even if users represent themselves in VR without misleading other persons, appearance also could be an issue. A demonstrative example is an avatar that looks like a naked body. Public nudity is banned by ethical and legal norms in most of the states, but a video demonstration of a naked body is rather not. Whether the naked body in VR is regarded as pubic nudity or is it a demonstration of video content from an ethical and legal perspective? Does the legislator have to oblige the developer to add measures against the use of such avatars?

A prosecution of public nudity in VR is harder from a legal and ethical point of view. What is a nature of this act? Factually it is a rendering of video content. However, a demonstration is accompanied by emulating personal presence. Thus, nudity in VR is not the same as nudity in games or movies. At the same time in terms of the intent of a person, it could be considered as public nudity. Virtual avatar is able to be real human size, with real human movements, seemingly standing close to other users. Mentioned avatars are perceived much more like a real person than a picture on a screen. Such actions may offend someone's feelings or cause psychological trauma in a demonstration for minors.

The issue of a proper avatar in VR is not limited to the nudity problem. For instance, an avatar may offend someone's feelings in other ways. It may be intolerant of gender, race, religion, political beliefs. More ways to offend or to cause suffering exist in VR. Imagine that someone's deceased relative's face is used in VR. Some users are able to use Hitler or famous serial killer's face for their avatars.

It is able to harm, disgust, or provoke users which see the avatar in VR. Appearance could be chosen as intentionally as well as recklessly. Developers can clearly provide technical measures to filter or block graphical representation of a user in virtual reality. But as it is linked with additional costs of software development, special regulation obliging VR companies has to be enacted.

Another problem is compliance with ethical norms applied in reality. As users all come to VR from the real world, some expectation exists on the conduct of the user in a virtual environment. There is an enormous temptation to transpose the moral norms of the ordinary world into the virtual world. Is it appropriate from a moral point of view to scream, create a mess, etc. in the VR art gallery?

There is a suggestion that "VR environment operators can easily implement code that can deal with the screamers. The operator could, for instance, allow each user to control the perceived volume, for that user, of any other user. That is good not just to silence the screamers, but also to quiet down acquaintances who are a bit too loud, or to amplify acquaintances who mutter. And this should be technically trivial to code" [17]. But it provokes the same question who will oblige the operator or the developer of the application to bear additional expenses on the implementation of these rules. Any state that implements such rules will automatically decrease chances in the race for technological dominance in the sphere of VR.

Of note, the issue of content filtering in VR is within the scope of the free speech agenda. When the legislator imposes additional legal requirements on VR developers, it implies reducing–or elimination–of the ability of individuals to speak freely in VR [32]. It is difficult to differentiate harmful behavior from an expression of someone's freedom of speech right on the level of development, as any case depends on context, viewer, or environment. Thus, a restriction for the developer or the operator is a threat to the freedom of speech in a virtual environment.

Another issue related to legal restrictions in VR is enforcement. The developer that designs or supports VR software or hardware is able to incorporate restrictions in its products; however, it is inevitably linked with real-time tracking of the user's conduct. It is presumably a high price for secure VR.

Development of restrictive measures will face also technical issues. Experience of companies which control and process of big data shows that "training moderators to overcome cultural biases or emotional reactions in the application of rules to facts can be analogized to training lawyers or judges. Regardless of the label, training content moderators involves a repetitive process to override cultural or emotional reactions and replace them with rational valid resolutions" [33]. So, an automatic realization of rules could produce unjust decisions, discriminative ruling, and other negative effects. It is probably more difficult to automatically make just decisions about the character of VR scenes than to create a transparent judicial system. This part of companies' work is not limited by the assertion that technical decisions have to be developed, the company has to create a division to manage disputes with customers which are not enjoyed by rule application.

Big IT companies are often criticized for a lot of power, but the capabilities of a virtual environment will allow private companies to have almost unlimited power over customers and their data. Factually, companies get control over all channels of human perception in different spheres from gaming to sexual relations. "VR settings mimicking as close as possible the multisensory nature of real-world human interactions would be a welcome and powerful addition to the field. Experiments aligning auditory, vestibular, and tactile signals with the visual domain are already improving VR immersion and realism" [26]. Thus, some private companies will control our reality, minds, and bodies.

4. Discussion

The study is just the beginning. This paper describes the key challenges related to managing risks of virtual environment use. VR is in the spotlight of social attention and attracts more attention from researchers. The study could be developed in different directions. There are several topics for further research. First of all,

it is necessary to systematize theoretical and practical legal knowledge related to the regulation of VR. It could include but not be limited to the research literature, legal practice, and international public agreements, as well as case-study.

Also, it is necessary to define the term "VR" and differentiate its categories and types, depending on the depth of immersion. It is helpful in terms of systematization and unification of results of current and future studies. It is necessary to categorize types of crimes that could be committed in VR. As some authors fairly comment on significance of legal definition and categorization of VR "it will serve as a basis for choosing the optimum regime of their legal protection" [34].

In terms of multidisciplinary dialogue, it is necessary to find out categories of the permissible technical parameters of VR functioning. It is very supportive in terms of preventing the destructive impact of technology on the psychophysiological state of the subject. For instance, there is a need to regulate the frame rate to avoid: headache, nausea, dizziness, epilepsy, and other disorders. It is especially critical for the application of VR by minors and juveniles.

Some authors claim that it is necessary "to add additional investigation and analysis testing stages to the development of virtual reality technologies in efforts to protect the public. These tests might not focus on physical health and safety concerns, but rather on physiological and social influences" [35]. However, in accordance with the analysis, the main concerns are mental and physical health. Moreover, any measures that take into consideration social influences would be very local and depend on the volatile social environment.

There is a need to define and regulate the allowable limits of the subject's functional permissibility in virtual reality (virtual ethical standard). Moreover, it is necessary to study the potential consequences of non-compliance with the prescribed rules of conduct, in order to prevent the direct projection of actions in VR in real life, such as the loss of boundaries of objective reality and the unconscious killing of a person in the real world.

In some papers, authors conclude that current law is very flexible and could be also applied to VR [22]. These studies do not take into consideration the dual nature of VR, i.e. this cybertechnology is rapidly merged with real world. The question arises in this study that current law is not applicable in cases where VR manifests itself in cyberspace and space of the real world. For instance, illegal access to haptic devices is not the same as usual "hacking".

There is research on restrictions of speech in VR in terms of US legislation. However, there is no conclusion how it corresponds to the First amendment and leaves a lot of space for further discussion [36]. In accordance with the analysis of current research in the sphere of medicine and psychology, it is difficult to conclude whether it is appropriate to apply the law of real world or virtual worlds for VR. The main reason is that virtual space and behavior of users there are often perceived as reality by other users.

In addition, there are several problems related to VR regulation that have to fall within the scope of criminal law. For instance, rules for the regulation of rendering in VR, application of real-world standards in VR, total control of users' conduct by IT giants, and appearance that misleads other users.

5. Conclusion

In summary, our study demonstrates that the offender gets new opportunities in VR. It literally helps criminals to hack the head or body of the victim. VR allows to provoke the emotions and to manipulate the consciousness of the victim at a completely new level. It is proved in the research that VR use could not be regulated as any other IT technology as the effect of perception by the victim is comparable in strength with the effect of events in the real world. In the paper characteristics of the virtual environment that have to be taken into consideration during a process of VR, regulation development is underlined.

Moreover, VR combined with haptic devices requires even more sophisticated regulation as such environment merges with the real world. Due to the integration of skin-feedback devices into the virtual environment, the consequences of VR's actions also have an influence on the user in the real world that could not be considered as just illegal manipulation with computer information. As many types of criminal acts with harm to the victim's body can now be committed remotely, a new kind of crime with dual nature is originated.

The article shows that there are not enough criminal law measures to combat crimes in VR. First of all, the legislation should provide for the obligations of the developer of VR technologies in order to minimize the possibility of criminals. Development and adoption of such measures is not an easy task, it is necessary to minimize economic costs in the implementation of these measures, and to prevent serious restriction of freedom of speech.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Today, Drowning is the 3rd major cause for unintentional injury death accounting for 7% of deaths of all injury deaths. Drowning is a state of suffocation when water or other fluids accumulate the lungs, resulting in respiratory impairment, ultimately leading to death. The predominant problem during rescue operations of such accidental drowning is to locate or track the person underwater, facilitated with the help of our bare eye sight, which makes the process too cumbersome. Also, in case of moving water bodies such as rivers and sea, the process of tracking the person becomes too difficult. Thus, there is pressing need for development of an engineered solution to solve this problem. This research involves development of such a robotic technology which will facilitate the work of locating the position of the drowning person underwater. This method comprises of Image processing along with GPS tagging embedded on a Remote Operated Vehicle maneuvering underwater at the site of accident to detect the exact location of the drowning person along with the GPS coordinates in order to ease the process of rescue. This robotic system was tested on a real time environment in order to demonstrate the efficacy of the system under practical circumstances. Thus, this system can be used at places where emergency rescue operations are needed.

1. Introduction

Drowning accounts for 7% of all deaths that occur due to injury. It is also the 3rd major cause for unintentional injury death. As drowning is an unexpected event, there are neither any precautionary steps to prevent it, nor any existing technology to initiate rescue operations rapidly. According to stats from 2016 nearly 350000 people are reported dead due to drowning. In India, Drowning is the second largest cause of death for children below age of 15. The situation is even worse at Russia. The drowning mortality rate is of more than 3.9 per 10000 individuals.

Nowadays, few assistive technologies are available in the market to provide safety for humans in or under water. But these solutions are based on scenarios where people must use this technology before nearing any water bodies. But since Accidental Drowning are unpredictable and the underwater environment varies from place to place a solution adaptable to all water bodies is the main focus of this work. Development of this technology can be used not only on rescue operations of accidental drowning, but also to mitigate the risk of loosing track of people during natural calamities like heavy floods or Tsunamis. Thus, there is a urgent need to focus on development of a solution for the above mentioned scenario.

Our research work is to embedded Image Processing methodologies to detect drowning people underwater and to use GPS coordinates of their exact location with the use of a Robotic Remote Operated Vehicle which can by controlled autonomously or semi autonomously to navigate through water bodies during the rescue process. Also, this system uses a on board camera, live camera feed can also be surfaced over radio communications to the rescue team, which would prove to be great advantage to the people on the field for the rescue operations. All the existing methods are either not cost-effective or have installation issues at underwater environments.

2. Survey on Previous Researches

This paper is an extension of work [1] originally presented in 2019 IEEE International Conference on Distributed Computing, VLSI, Electrical Circuits and Robotics (DISCOVER), where a different method for the detection of humans drowning underwater was illustrated.

In [2], is a research work that involves development of an automated system that detects and tracks objects that are of potential interest for human video annotators. By pre-selecting salient targets for track initiation using a selective attention algorithm, we reduce the complexity of multi-target tracking, in

*Corresponding Author: Yaswanthkumar S K, Email: yaswanthsk4@gmail.com

particular of the assignment problem. Detection of low-contrast translucent targets is difficult due to variable lighting conditions and the presence of ubiquitous noise from high-contrast organic debris ("marine snow") particles.

In [3], the paper presents an attentional selection system for processing video streams from remotely operated underwater vehicles (ROVs). The system identifies potentially interesting visual events spanning multiple frames based on low-level spatial properties of salient tokens, which are associated with those events and tracked over time. Using video cameras, it is possible to make quantitative video transects (QVTs) through the water, providing high-resolution data at the scale of the individual animals and their natural aggregation patterns.

In [4], this paper explains an agent system is strategy to enhance the underwater manipulation. If the location of the agent can be measured, the end effector is able to be place to any position. To implement this system, the method of an agent vehicle localization is proposed. The method uses the sonar images of moving agent obtained by forward-looking sonar. To detect the location of the agent in the sonar images, the convolutional neural network is applied. Through field experiment, we confirm the proposed method can detect and track the agent in the successive sonar images.

In [5], This paper presents methods applied for automated detection of fish based on cascade classifiers of Haar-like features created using underwater images from a remotely operated vehicle under ocean survey conditions. The images are unconstrained, and the imaging environment is highly variable due to the moving imaging platform, a complex rocky seabed background, and still and moving cryptic fish targets. Several Haar cascades are developed from the training set and applied to the validation and test video images for evaluation.

In [6], This paper presents a robotics vision-based system for an underwater pipeline and cable tracker. This system is introduced to improve the level of automation of underwater remote operated vehicles (ROVs) operations which combines computer vision with an underwater robotics system to perform target tracking and intelligent navigation. This study focuses on developing image processing algorithms and nonlinear control method for tracking the pipeline or cable. By using the adaptive sliding mode controller, the ROV can easily track the cable or pipeline.

In [7], is a proposed system of a multi-step and all-round underwater image processing specially for the underwater images taken in succession to improve the image quality, remove the dynamic interference and reconstruct the image. For images with complex texture, the inpainting result brings out much smoothness, at the cost of massive details. For images with low resolution, the transition of color near the edge of the vacancy is abrupt

In [8], The paper presents a wavelet-based fusion method to enhance the hazy underwater images by addressing the low contrast and color alteration issues. The publicly available hazy underwater images are enhanced and analyzed qualitatively with some state-of-the-art methods. Green color dominates the Image in the evaluated set of images. In the results, it can be observed that the natural color profiles of Image are preserved by correcting the dominated color and it was hard before to distinguish the color of the water and objects

In [9], it shows that man-made objects in the image can be distinguished from natural objects. This paper proposes that a control strategy to adjust image processing parameters, and sequence multiple applications of tools, is especially important for digital processing of underwater images. This paper highlights the key difficulties in processing underwater images such as obscuration of objects of interest by fish / sand / coral / algae in the water and change of illumination, color balance and scale of fish images due to refraction, absorption in water and large range of distances of observation and different sizes of fish

3. Schematic & Working of ROV

As shown in Figure 1. The devised system consists of a on board camera embedded to the ROV to communicate the live video feed to the operator and also for the video to be processed by the on-board Processor to detect for humans underwater. The main system consists of sub units such as:

- Transmission & Receiving Unit
- Processor Unit
- Sensing Unit
- Maneuvering Unit
- Powering Unit

Each of which will be discussed on the following sections.

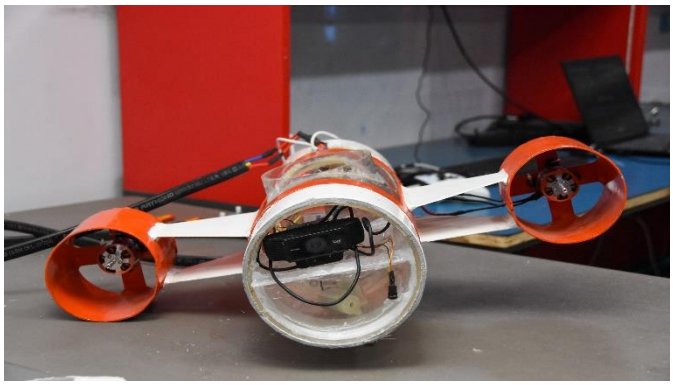

Figure 1: Hardware assembly of ROV

3.1. Transmission & Receiving Unit

A). Introduction

The transmission Unit consists of a Two axis controller to control the movement of the ROV along with a Screen or a monitor to view the live feed from the camera on-board which is interfaced to a Raspberry Pi through USB communication. A PC Joystick controller with TWO axis was used to provide the control signals as a input ls to the motor to control the movement of the ROV. Common PC monitor was used along with the raspberry PI to view the live feed from the ROV's on-board camera. The Receiver Unit Consists of a Raspberry PI which is on-board in the ROV. The Video data from the camera is given as an input to this raspberry pi from which is then transferred to the other raspberry pi through wireless communication.

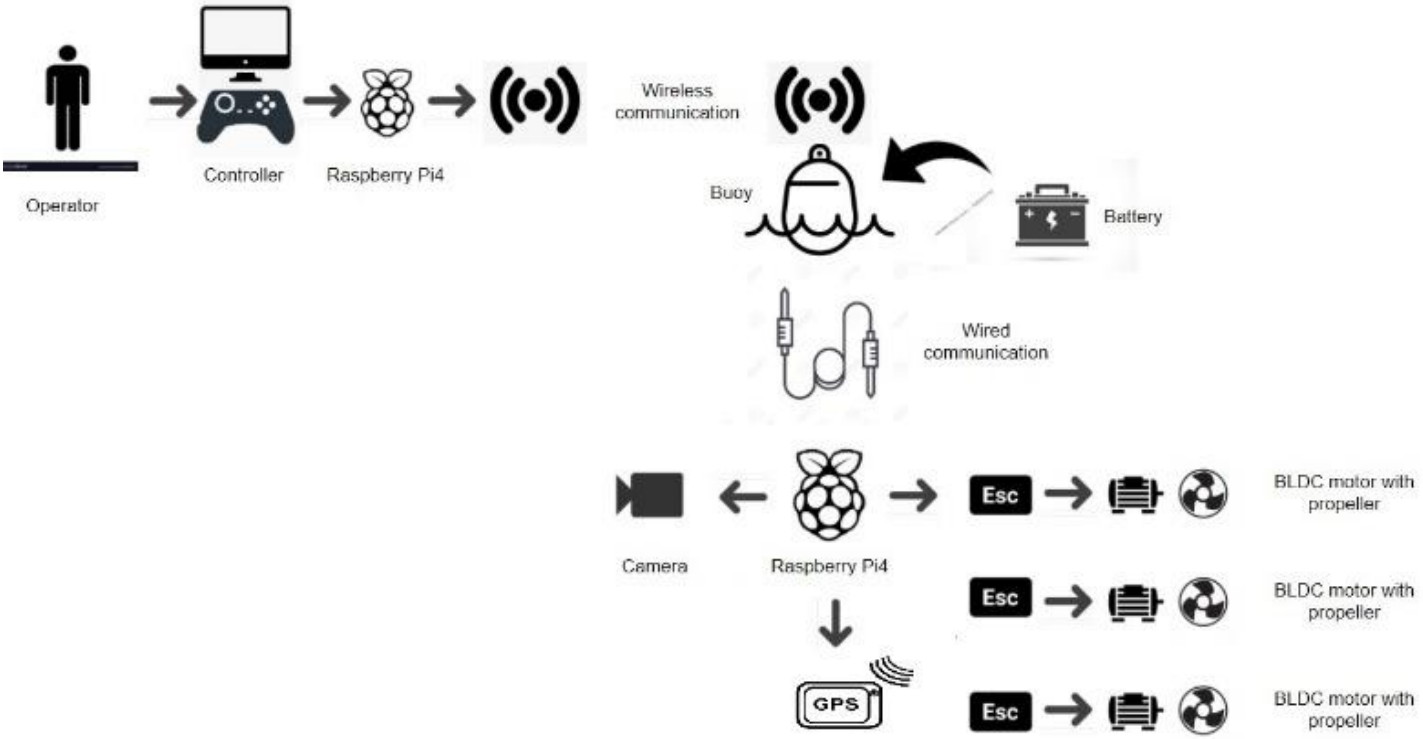

Figure 2: Schematic Diagram

B). Working

The control signals from the operator are provided as joystick input through USB communication to Raspberry PI on the Transmitter side. These signals are then transmitted to the other Raspberry PI on the Receiver side through WIFI Communication. This transfer of data can also be performed using RF transmission or MQTT via internet which will provide further distance range between the operator and the ROV. The operator can view the live feed in the monitor, to control the ROV effectively. The video feed from the USB Camera is also transmitted wirelessly through WIFI Communication from the Receiver Raspberry Pi to Transmitter Raspberry Pi.

3.2. Processor Unit

A). Introduction

The Processor unit consists of a Raspberry Pi (receiving unit) on-board in the ROV. This Receives the control signals from the Operator which is then used to control the movement of the ROV. This also receives data from the on-board camera and on-board GPS for further transmission.

B). Working

As the PWM from the Transmitter unit are received by the Processor Unit (receiving unit), these signals are the compared with the on-board accelerometer to measure the difference in the values. These values are again corresponded to respective PWM signals and then is given as an input to the respective Electronic Speed Controllers (ESC's) which control the spin of the motors. The Processor also performs the function of receiving the input data from camera and GPS on the ROV and transfer them to the operator.

3.3. Sensing Unit

A). Introduction:

The sensing unit consists of a IP68 waterproof high megapixel camera to be interfaced with the Processor. This will provide the video data for Image Processing and as well as send the live data from underwater to the operator. It also consists of a waterproof GPS chip to be enclosed in an air tight chamber of ROV. This provides the GPS coordinates of the ROV underwater.

B). Working

The camera transmits the data to the processor through USB communication, which is then used as the input for Image Processing algorithm and is also transmitted to the operator. The GPS module sends the signal to raspberry pi through SPI protocol which is also sent to the operator through wireless Communication.

3.4. Maneuvering Unit

A). Introduction

Maneuvering unit consists of 60 Amps ESC's, each individual for respective 500 kV BLDC motors. As the PWM control signals are given as an input into ESC, the speed of the motor varies accordingly the position and moment of the ROV also varies.

B). Working

As the operator provides the input signals through the JOYSTICK controller, this input data from the Transmitter Raspberry pi, reaches the Processor Raspberry pi (receiver unit). Those input signals are then provided as an input to the respective ESC after being compared with the current accelerometer value &

then the required amount of power will be delivered to the respective motor which is now being controlled by ESC.

3.5. Powering Unit

ROV is completely powered through wires as it is being tested for its buoyancy when battery pack is being placed inside the air tight enclosure of the ROV.

4. Imaging Methodology to Detect Drowning Humans in a - underwater environment

Image Processing has overcome the limits of its own discipline. Today, it is possible to process a live video feed right after few trained models. Due to this rapid increase in its uses, this technology is pressured to produce strong methodologies which would offer a wide variety of solutions for real time problems. Our methodology involves usage of Faster Region Convoluted Neural Network (FRCNN) algorithm.

4.1. Hardware Specification

The hardware specifications are illustrated in table 1.

Table 1: Hardware Specification

System	Dell G3 3579
GPU	Nvidia GeForce GTX 1050Ti
CPU	Intel Core i7-87507H
Memory (RAM)	8192 MB
Display Memory (VRAM)	4018 MB
Operating System	Windows 10 64-bit

4.2. Dataset

As only humans are to be detected underwater a dataset consisting of 800 images is used as dataset. These 800 images comprise a variety of underwater images with varying light intensity, water color, and humans in it. This dataset also contains images of halfway human pictures along with overlapping images too.

A). Data Preprocessing:

Reading

Using the matplotlib library on a python script is used to reading all the images from the dataset. This helps us to know whether all the all the images from the dataset are loadable and could be read by the algorithm.

Re-sizing

As larger images would take longer time to process, all the images collected are res-sized to be less than 200KB in size.

B). Data Labelling

The datasets must be labelled, since labelled images must be provided as input to train the training algorithm. In order to label the datasets, the images are first loaded onto the LabelImg tool. Now, humans in each image are to be bounded by drawing bounding boxes around them as shown in Figure 3. Then, the labelled data of all these images are to be stored in an XML format. Each image file would create individual XML files containing the File name, path, the label and coordinates for the bounding boxes. These are also called annotation files which will be used to train the algorithm.

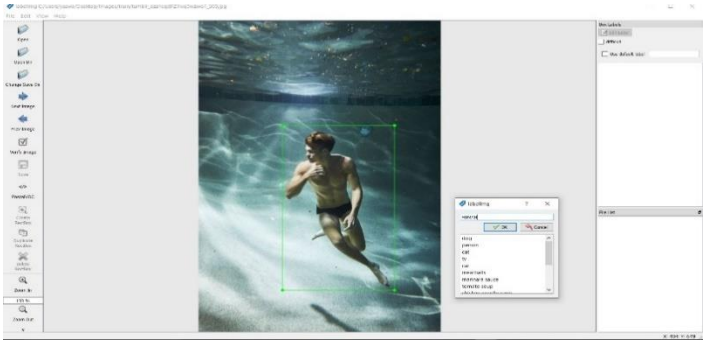

Figure 3: Labelling the datasets

4.3. Implementation

In order to bring out the best outcome, two algorithms were used 1). Faster RCNN and Yolo V3. Both these algorithms were implemented and trained using the TensorFlow Object Detection API. This makes the training process faster as TensorFlow object detection API comes with the model called ZOO which is a collection of models and algorithms.

A). Configuring the training algorithm

In order to detect the best algorithm which can be used, both the Faster RCNN and YOLO algorithms were configured to the same values.

Data Slicing

Both the algorithms were trained and tested using the same data sets. So, for both the algorithms 75% of the images and 25% of the images were used as training datasets and testing datasets respectively.

Classes

Since, humans were the only object to be detected by the algorithms, the class for these algorithms was set to 1.

Learning Rate

Learning rate is a parameter which allows us to control the model's response to estimated error each time the model weights are updated. The learning rate was set to a default value of 0.0002 while training both the algorithms.

Batch Size

The batch size corresponds to the consumption of VRAM, after looking into Table 1. The value set of batch size of the algorithms is set as 4.

4.4. Training Procedure

Figure 4 shows the training process of Faster RCNN algorithm along with the classification loss and the time taken after each iteration.

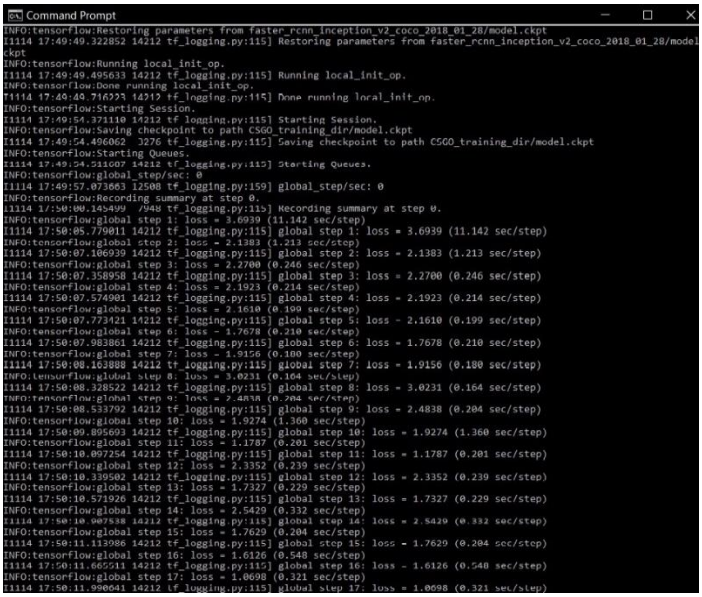

Figure 4: Training Process of Faster RCNN

As you can see, Classification loss is high when the training processes started. But after each step, there is a gradual decrease in the classification loss as the algorithm kept learning in each step. Figure 4. shows the exact decrease in classification loss during training process compared along with the testing process.

4.5. Performance Metrics

In order to compare the results of these two models, accuracy of these two models are to be contrasted. To calculate the accuracy few parameters are to be considered as metrics:

1. True Positive TP: A human is present in the Image and, the algorithm detects the human.
2. False Positive FP: No human is present in the Image, but the algorithm detects human.
3. False Negative FN: A human is present in the Image, but the algorithm does not detect the human.
4. True Negative TN: No human is present in the Image, and nothing is being detected.

A). Accuracy:

It is a measure to check whether the model or the algorithm is trained correctly to detect humans in an underwater environment or not. The formula to calculate the accuracy as follows:

$$\text{Accuracy} = \frac{(TP+TN)}{(TP+TN+FP+FN)}$$

B). Precision

It is a ratio of positively predicted images that contain humans in it to that of which actually contains humans in it. The formulae to calculate precision as follows:

$$\text{Precision} = \frac{TP}{(TP+FP)}$$

C). Recall

It is the ratio of images that actually contain human in it to that of which were predicted positively. The formula to calculate recall as follows:

$$\text{Recall} = \frac{TP}{(TP+FN)}$$

D). F_1 Score

It is the measure of accuracy of the model combining both precision and recall. A model or algorithm is considered to be perfect if it's F_1 Score is 1. The formula to calculate F1 Score as follows:

$$F_1 \text{ Score} = 2 * \left(\frac{\text{Percision} * \text{Recall}}{\text{Persion} + \text{Recall}}\right)$$

5. Results

The results for both the algorithms are summarized in this section. The analysis of results as follows:

5.1. Faster RCNN Results

Figure 5, Figure 6 & Figure 7 are a collection of test data from 3 different samples under varying light conditions and other environmental factors for faster RCNN algorithm.

Figure 5: RCNN Output 1

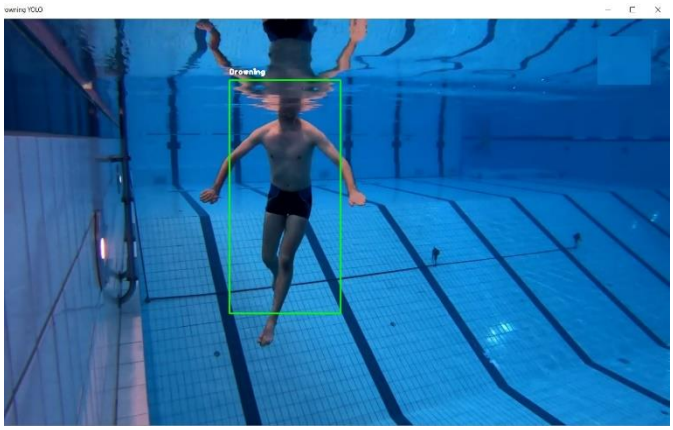

Figure 6: RCNN Output 2

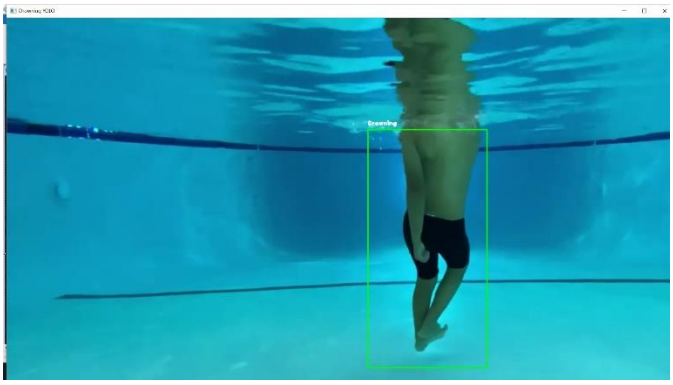

Figure 7: RCNN Output 3

The number of TP, TN, FP, FN from RCNN is tabulated in the table 2. These are further used to analysis the algorithms.

Table 2: RCNN Output Tabulation

#	True Positives	True Negative	False Positive	False Negative
Total	148	14	9	29

5.2. Yolo V3 Results

Figure 8, Figure 9 & Figure 10 are a collection of test data from 3 different samples under varying light conditions and other environmental factors for faster RCNN algorithm.

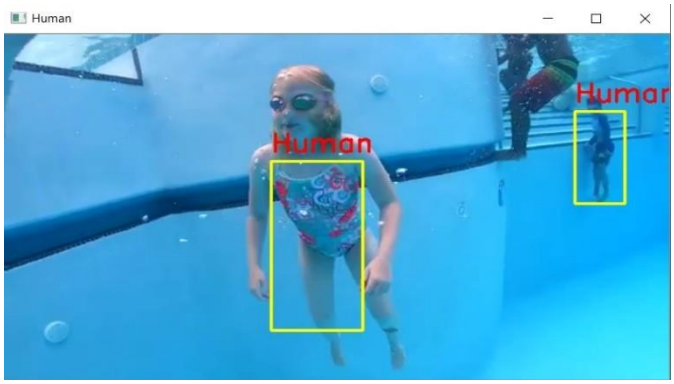

Figure 8: Yolo V3 Output 1

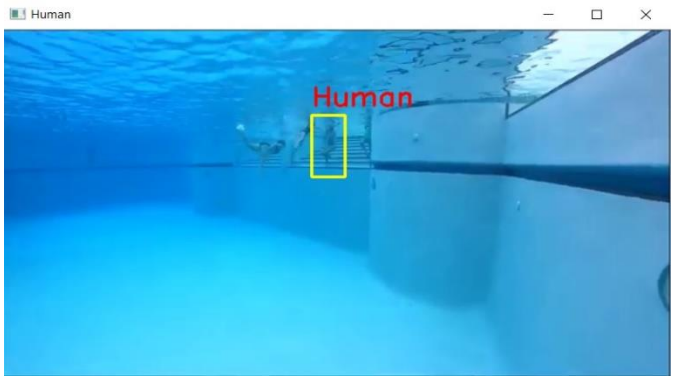

Figure 9: Yolo V3 Output 2

The number of TP, TN, FP, FN from YoloV3 is tabulated in the table 3. These are further used to analysis the algorithms.

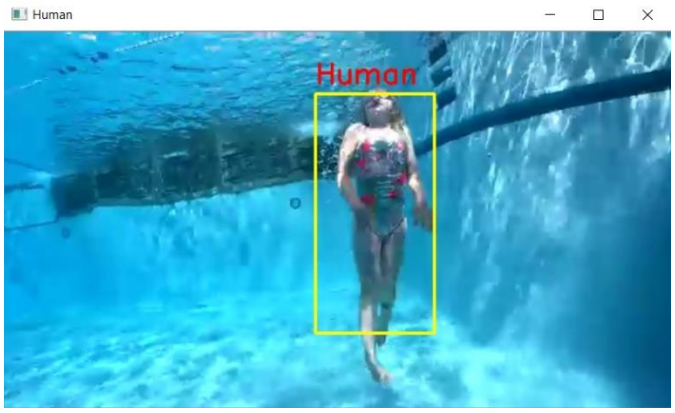

Figure 10: Yolo V3 Output 3

Table 3: YoloV3 Output Tabulation

#	True Positives	True Negative	False Positive	False Negative
Total	125	12	3	60

5.3. Analysis of Results

Table 4, provides us the collection of results containing the number of TP, TN, FP, FN parameters obtained by Faster RCNN and Yolo V3 algorithms.

Table 4

#	True Positives	True Negative	False Positive	False Negative
F - RCNN	148	14	9	29
YOLO V3	125	12	3	60

From this table, the accuracy of Faster RCNN and YOLO V3 algorithms are 81% and 68.5% respectively. Clearly, Faster RCNN is more Accurate than YOLO V3 in detecting humans in a underwater environment. It is also to note that Faster RCNN was able to consistently detect Humans if overlapping occurs. While, YOLO V3 failed to detect humans during overlapping frames.

Table 5

Algorithms	Precision	Recall	F_1 Score
Faster RCNN	0.94	0.83	0.881
YOLO V3	0.97	0.67	0.792

Table 5, Shows us that YOLO V3 is more precise compared to that of Faster RCNN, but then Faster RCNN has a high recall value than that of YOLO V3. To compare both the models, F_1 Score was calculated which also points out that Faster RCNN algorithm is the Best fitted algorithm to detect humans underwater. The results contribute to some preliminary findings to the growing field of underwater robotics in real time environments.

6. Future Work

The experimentation has been tested only on clear water bodies. The implementation of this ROV under real time circumstances such as lakes and river where the opacity will be translucent or opaque, it is better to use the thermal imaging as the

video input to this image processing models. As the body temperature of the aquatic species in that water body will be the similar, it will be easy to differentiate human body using thermal sensors and video feed of thermal imaging which will be performed in the near future.

7. Conclusion

This paper illustrates, an idea to develop a robotic system which will detect drowning people underwater at the times of an emergency. It also concludes that Faster RCNN is the best fit algorithm which can be used for this practical application. In our further research we plan to our work from a single ROV into a swarm of ROV's collectively working at a site of emergency to detect every drowning human underwater. We are also planning to enable full autonomous nature of the ROV in order to minimize the reaction time and communication time between the ROV and the Operator.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

We would like to thank Forge Accelerator for providing the necessary support to complete this research work. We also thank Mr. Ravi Shankar, Mr. Koushal & Miss. Poovika for contributing to this research work by building the ROV from Scratch.

ABSTRACT

Android Operating system (OS) has been used much more than all other mobile phone's OS turning android OS to a major point of attack. Android Application installation serves as a major avenue through which attacks can be perpetrated. Permissions must be first granted by the users seeking to install these third-party applications. Some permissions can be subtle escaping the attentions of the users. Some of these permissions can have adverse effects like spying on the users, unauthorized retrieval and transference of the data and so on. This calls for the need of a heuristic method for the identification and detection of malware. In this discourse, testing of classification algorithms including Random forest, Naïve Bayes, Random Tree, BayesNet, Decision Table, Multi-layer perceptron (MLP), Bagging, Sequential Minimal Optimization (SMO)/Support-Vector Machine (SVM), KStar and IBK (also known as K Nearest Neighbours classifier (KNN)) was carried out to decide which algorithm performs best in android malware detection. Two dataset was used in this study and were gotten from figshare. They were trained and tested in the Waikato Environment for Knowledge Analysis (WEKA). The performance metrics used are Root Mean Square Error (RMSE), Accuracy, Receiver Operating Curve (ROC), False positive rate, F-measure, Precision and recall. It was discovered that the best performance with an accuracy of 99.4% was the multi-layer perceptron on the first dataset. Random Forest has the best performance with accuracy, 98.9% on the second dataset. The implication of this is that MLP or random forest can be used to detect android application malwares.

1. Introduction

This work is an extension of [1] in which this work considers another dataset in carrying out the research. This research answers the questions from the comments received about the biasness of the algorithms used.

There has been a considerable increase in the usage of mobile phones year on year. Mobile phones have served as a medium of communication through calls and short mailing services (SMS) [2]. Technological advancement has increased the usage of mobile phones for various purposes. The operating system (OS) of mobile phones have evolved from java to Symbian with the current ones being android OS, windows OS and Apple OS – iOS [3]. The usage of mobile phones spans from individuals to organizations as well. This study focuses on Android OS. Mobile phones with Android OS comprises of some components which are; the

Android OS, the middleware and key applications [4]. The android OS has the biggest and fastest growing smartphone OS market, hence it has become a practical target for cyber criminals [5]. Large support to third party applications is also gotten from android. These third party applications can easily be downloaded on the popular Google Play store [6]. The developers of the Android OS do not develop third-party applications; it is done by software developers. Hence the name of the third party applications [6]. In [7], there are over 2.7 billion mobile users globally, and in 2022, 258.2 billion apps are projected to be downloaded. Android phones are useful for crucial functions ranging from financial transfers to e-commerce transactions

[*]Corresponding Author: Oluwaseyi Ezekiel Olorunshola, Electrical Electronics Engineering Department, Air Force Institute of Technology, Kaduna, 800283, Nigeria, +2348068341127 & seyisola25@yahoo.com

(goods payments) and so on [8]. It also allows other features, such as photo editing, game play, social media and messaging, internet searching, typing, listening, reading, and so on. Any of all these procedures are feasible due to the implementation of third-party apps.

The growth of android application malware has been made possible by the free application market for the Android OS [9]. The most severe and important threat to the Android OS arises as a result of malicious applications especially from unauthorized applications market that can easily be installed on any phone [9]. Android applications depend on users to grant permission to work optimally. Such permissions can forewarn users to the applications' secrecy and/or security [10]. Android malware can impersonate a legitimate program, but with intrusive permissions for which an agreement is required from the users before installation can be done [10]. The malware executes activity(s) that are malicious through these permissions. SMS spy pro is an example, masking itself as a tip calculator but forwarding all sent SMS and received SMS by the user to a third party [11]. Android malware can access and steal user data such as browsing history, SMS, location of GPS, phone records, e-mails, other application information (Like Facebook log-in details) and more [12]. Tasks such as snapping and sending photographs, sending unauthorized e-mails, conducting bank transfers without user awareness can also be executed [2]. The degree to which both malicious and innocuous applications can execute their functions is primarily dependent on the form of permissions that users grant them.

Considering the sensitivity of the data that can be colleted from users via the malwares combined with the kind of damage that can be done by these malwares (for example, spying, identity theft, extortion, logic bomb) [13], these malwares need to be identified effectively. Due to zero-day attacks, the conventional malware detection techniques that uses the malware signature to store them in a repository has proved to be ineffective [9]. Zero-day attacks are based on new flaws found by cyber attackers that the creator is unaware of and thus has not issued a patch [14]. Therefore, until the developers are aware, the attackers make the most of these vulnerabilities. Android malware with its corresponding permission requests must be found [9]. This study is focused on Olorunshola and Oluyomi's recommendations in [1]. An evaluation of the classification algorithms with regard to their performance in the identification of malicious software based on their manifested permission, command signature, API call signature and intents, is the aim of this study. This study aims to verify the conclusions drawn by Olorunshola and Oluyomi by training and testing the algorithms with additional datasets in this research. Two android datasets based on manifest permission, command signature, API call signature and intent are obtained from figshare created by [15] to achieve this aim. The algorithms are trained and tested on the datasets. The remaining portion of this work is structured as follows: review of literature, methodology, result and discussion, conclusion and future work.

2. Literature Review

2.1. History of Android

Android was created using the name of Android Inc company by Rich Miner, Nick Sears, Chris White, and Andy Rubin in 2003 [16]. Android began as a camera OS intended to enhance connectivity between personal computers (PCs) and cameras, allowing communication wireless between cameras and PCs. After a couple of months of the company's formation, the OS was adapted towards making mobile cell phones smarter [17]. Android was purchased by Google in August 2005. Android OS was created using the Linux kernel to make it free for mobile phone manufacturers [16,18]. The first version of Android OS (version 1.0) was released in November 2007, and the novel Android handset, T-Mobile, was deployed in September 2008. While it has a lot of feedback and appraisal, it ran with Android 1.0 OS, and it has other Google apps such as play store, charts, YouTube, etc. built on it. [16,18]. As the year passes by, android OS has evolved into improved models. Android 10 is the latest edition of Android, launched in September 2019 [19, 20].

The stack layers of Android apps contain applications, application framework, libraries and the Linux kernel, with each layer closely incorporated to offer stronger smartphone applications. Interoperability has also been provided for to make it easier for design developers to work and develop their applications at a cost-friendly level [4]. It made it possible for anyone to obtain due to the open source nature of the Android framework thus growing its users over the years. Android sales stood at 115 million units in 2011, and Android OS accounted for around 52.5 percent of the overall number of mobile phones [21]. The Apple App Store reportedly has 2.2 million applications [7]. Recently, about 68.71 percent of people use android OS while 29.60 percent use iOS, 0.30 percent use Windows devices, while 0.06 percent use Symbian [22]. The heavy use of android OS is attributed to several factors that include the reduced price relative to iOS, open source enabling third-party software installation unlike iOS. The sum total of applications available in the Android store (play store) as of 2017 was around 2,800,000 [22]. In March 2018, the applications in the play store crossed 3.600,000 [23].

2.2. Security in Android

IOS as a closed framework that offers more data protection and is more pristine than Android which is an open source. In the play store, developers can host the applications they have built giving rise to Android vulnerabilities [22]. The security enhancements in Android were clarified in [24]. They are public vs. private components, components open implicitly, permission for broadcast intent, permission for content provision, secure APIs, service hooks, pending intents, permission protection level, URIs permission. Security refinements such as these, aid the protection of the data of users from manipulation and abuse.

2.3. Android Malware

The skill to debone the code used in the development of Android applications and the open source nature of the applications also enabled the easy encoding of malicious codes and increased number of attacks [25]. In [26], Networks recorded that mobile malware rose to 155 percent in 2011, with a rise of 614 percent from March 2012 to March 2013, of which 92 percent of the malware is Android. When android devices are upgraded to the latest OS, about 77 percent of threats to android can be eliminated. Just one threat infected about 5,000 devices in the third quarter of 2018. This accelerated through phishing using download and

installation of a voice message application that is fake thereby sends all the user's data to a server or using text messages [27]. Report has it that 2,47 million of the latest mobile malware were discovered in 2013, indicating a 197 percent increase over 2012 [28].

From a simplistic SMS sending Trojan, Android malware has advanced to more futuristic codes that can corrupt other applications, encrypt user data, gain root privileges, download and install more applications that are malicious bypassing the knowledge of the users, and load a payload from a remote server to cellular phones [9,29]. In [29], the authors gave a complete malware for android analysis looking at the past, observing the present and predicting the potential android malware cases into the future. In [30], the author gave a thorough analysis of the models of mobile malware dissemination and explored potential future developments as well.

2.4. The dangers of android malware

Users are exposed to multiple attacks and may suffer from them if an android OS is compromised with malware. According to [25]. Many of the threats they face include but are not restricted to:

- Personal information theft which can lead to theft of identity
- Loss of privacy
- Monitoring of the users
- Financial loss through ransomware
- Remote operation of the phones

2.5. Android malware detection

Detection of Android malware can broadly be divided into;

- Signature-based: Detection using signature-based detection uses the malware's identity to determine the genuineness of the malware. The downside of this method is some form of attacks may be eluded. E.g., byte code level transformation [28].
- Machine-learning focused: The detection based on machine-learning uses an analytical method that includes extracting features from the application's behaviour [28]. These behaviours (permission request, API calls) are then developed into a dataset and then a machine learning algorithm is used to test and train. The measurement metrics used in the evaluation include: precision, accuracy, false positive, to mention a few.

Several approaches to android malware detection have been put forward; the use of applications' requested permissions, specific application programming interface for detection, the use of the applications' fundamental code (since most codes for malware are modifications of existent codes), sandboxing, components encapsulation, optional access control or signing of application [31,32].

This study is aimed at the usage of manifest permission, API call signature, intents and command signature for the android malware detection. The rights defined by the developer in the application to allow system interrelationship: to access system components (such as camera and GPS) or modules of other applications is permission [33]. There are four types of android permission with two classifications, according to [2,34]. These are:

- Signature permissions: These applications are authorized only if it is certified by the creator of the stipulated consents. It is used for component access restriction to a limited collection of application controlled and trusted only by the creator.
- System permissions: Once the application satisfies the signature criteria, these applications are authorized. Applications requesting these permissions are pre-installed by an advanced customer or system manufacturer.

The two permissions (Signature and System) are booked for applications that have signatures with keys accessible only to the creator of the firmware. This is not available for implementations from third party application.

- Normal permissions: These are software that do not need the involvement of the customer. They are immediately accepted.
- Dangerous permissions: These are software that prompts the user what system facility will be used before it can perform its function. Prior to installation, they must be issued by the consumers. [2, 34].

In [34] and [35], the studies titled "PScout: Analyzing the Android Permission Specification" and "Android Permissions Demystified" evaluated the different android OS permission specification. In [2], the author also examined certain motives for some evasive consents. Some are broadcast theft, malicious service launch, hijacking of activity, malicious activity launch, hijacking of service.

2.6. Review of Past Works

Some research has been conducted in the detection of malware, part of which includes:

A Naïve Bayes algorithm model for android malware detection system was proposed by Shang, Li, Deng, & He in [36]. By using the new permissions for malware and training permissions impact as the weight, the detection accuracy was enhanced. In order to strengthen the model, a detection model of information theory and permissions based on the enhanced Naive Bayes algorithm was used also. As a rate of detection for non-malicious applications, the proposed model earned 97.59 percent.

In [37], the authors proposed a hybrid intelligent model which evolves and uses support vector support (SVM). Genetic algorithm (GA) and particle swarm optimization (PSO) were used to resolve the optimization challenge in the SVM. This helped boost the classifier's accuracy. With the use of GA, 95.60 percent accuracy was obtained as the highest.

In [38], the authors performed a fixed evaluation of applications for android, tested the existence and occurrence of words that ae key in the manifest file of the applications, and established static feature sets from a dataset of 400 applications to yield superior results for malware detection. KNN and SVM classification algorithms were applied getting an average accuracy of 79.08 percent and 80.50 percent respectively.

In order to detect malware, Shohel Rana, Gudla, & Sung in [39] improved and analyzed certain algorithms through the implementation of a static analysis that is classifier based. When random forest was used on the dataset, 94.33 percent was obtained as the accuracy.

In [31], the authors proposed a technique of malware detection by first extracting the function call graphs from android applications and then embedding the function call graphs with a direct map feature. This was inspired by a linear-time graph kernel. They used the structural features of 12,158 samples of malware. SVM classifier was trained to differentiate between malicious and benign applications. 89% of the malware was detectable using this technique with minimal false alarms pin-pointing the code structures which are malicious within the android applications.

In [28], the authors extracted a weighted contextual API dependency graphs as program semantics which was used to create the feature sets. Authors also introduced graph similarity metrics to discover identical application behaviours for the purpose of discovering zero-day malware. In their work, a system called DroidSIFT was implemented to evaluate 2200 malwares and 13500 benign samples. It was able to correctly classify 93% malware instances while the detection of zero-day malware had a low false negative rate of 2% and false positive rate of 5.15%.

In [25], the authors presented a method of detecting malware in android by examining the manifest files of the android application since there are differences that are significant in the manifest files of benign and legitimate applications. Manifest files carry important information of the application like the name of the package, the version number of the application, the intent filter (action, category and priority), the API level, required permission, this approach was discovered to be effective by the use of real samples of android malwares. A total of 365 samples were used and the total correct detection was 90.0%.

In [5], the authors presented an automated detection system for the android platform (AMDA) where the behaviour analysis of the application was utilized. The features of both malicious and benign applications were first extracted to form the dataset used. Various algorithm in WEKA which include, Navies Bayes, decision tress and so on were used for the analysis.

In [40], the authors proposed a technique of applying the Bayesian classifier in a novel way. 1,000 samples each for both benign and malicious application was gotten. The accuracy obtained was 0.921 and true positive rate of 0.906.

In [41], the authors proposed a machine learning approach to the detection of malware in android using 200 features. These features were taken out of both the static and dynamic analysis of android applications. The deep learning technique used had an accuracy of 96.5%.

In [42], the authors used 17 supervised learning techniques to analyse adware in android devices and compared the result. It was discovered that Random Forest was the best classifier with an accuracy of 0.9838 and a false positive rate of 0.017.

This research was inspired by the recommendations in [1]. Their research study comprises of commonly and hardly used machine learning algorithms and it was found that multilayer perceptron (MLP) outperforms the other algorithm having an accuracy of 0.994. It was therefore recommended that other dataset should be put into consideration to confirm if MLP is dataset-specific.

3. Methodology

3.1. Environment Description

This research was conducted using the Waikato Environment for Information Analysis (WEKA) version 3.8.3 which was developed in [43]. Ten algorithms out of the available algorithms in WEKA were used in this research.

3.2. Dataset Description

From publicly available datasets, two datasets were used in the study. The first was gotten from figshare which was developed in [15]. The dataset contains a total of 215 characteristics which were extracted from 3,799 applications; 1,260, malicious and 2,539, benign. The second was also developed by Yerima in [44]. The dataset contains 215 attributes with 15,036 instances of which 5,560 was malware and 9,476 was benign.

Table 1: Description of the Android Malware Datasets

Description	Dataset	
	First	Second
Instances	3,799	15,036
Malware	1,260	5,560
Benign	2,539	9,476
Attributes	215	215

Attributes/characteristics are the applications' features that were extracted. The extracted features were gotten from the manifest permission, the API call signature, the commands signature and the Intents. Some features extracted under the manifest permission are SEND_SMS, RECORD_AUDIO, READ_PHONE STATE, WRITE_SMS, USE_CREDENTIALS, GET_ACCOUNTS, MANAGE_ACCOUNTS, RECEIVE_SMS. Some features under the API call signature are IBinder, Binder, createSubprocess android.os.IBinder, URLClassLoader. Some features under intents are android.intent.action.ACTION_POWER_DISCONNECTED, android.intent.action.NEW_OUTGOING_CALL, android.intent.action.CALL_BUTTON. The command signature has only the following features /system/app, mount, /system/bin, chmod, chown and remount.

3.3. Classification Algorithms application

The training and testing was carried out with the 10 algorithms chosen in the WEKA environment. The algorithms are Random forest, Naïve Bayes, Random Tree, BayesNet, Multi-layer perceptron (MLP), Decision Table, Sequential Minimal Optimization (SMO), Bagging, KStar and IBK (also known as K Nearest Neighbours classifier (KNN)). The 10-folds cross validation and 66% split were used to train and test in the condition. In the 10-folds cross-validation, the dataset is divided

into 10 folds or parts wherein each fold is divulged in almost equal sizes as the full dataset while the 9 remaining is used for training. This procedure is repeated for each fold, making it ten times. The mean for all the 10 folds is then calculated for each performance metric. The 66% split divides the dataset into 66% and 34%. It uses the 66% part of the data for training while using the 34% for testing. The 66% split was used to validate each algorithm.

3.4. Graphical Representation of the Methodology

Figure 1 shows the graphical representation of the how the research was carried out.

3.5. Performance Evaluation

Below are the performance metrics used in evaluating the algorithms.

- Accuracy: This calculates the rate of applications correctly classified, taking into account true positive, false negative, true negative and false positive [45].

$$\text{Accuracy} = \frac{TP + TN}{TP + FN + FP + TN}$$

where TP = True positive
FN = False Negative
FP = False Positive
TN = True Negative

- False Positive Rate (FPR). This calculates the rate incorrectly classified instances as benign. A low FP-rate implies that the classifier is good. [46]

$$\text{FPR} = \frac{FP}{FP + TN}$$

- Precision, Recall and F-measure. Precision is the ratio of instances that are positively predicted among the retrieved instances. Recall is the ratio of instances which were positively predicted among all the instances and F-measure is the harmonic mean of recall and precision.

A high F-measure is essential since both precision and recall are desired to be at high levels [47,48]. Therefore

$$\text{Precision} = \frac{TP}{TP + FP}$$

$$\text{Recall} = \frac{TP}{TP + FP}$$

$$\text{F-Measure} = 2\,x\,\frac{Precision}{Precision + Recall}$$

- Receiver Operating Characteristic (ROC) curve. A high ROC value means that the algorithms are good. The true positive rate is plotted against the false positive rate [46].

ROC Curve is Plot of FPR(x) vs TPR

where TPR is True Positive Rate

- Root mean square error (RMSE). This is the predicted error's standard deviation. The error between the training and the testing dataset is the predicted error. A low RMSE means that the classifier is good [49,50].

$$\text{RMSE} = \sqrt{1 - r^2}\; x\; SD$$

where SD = Standard Deviation

r = Predicted error

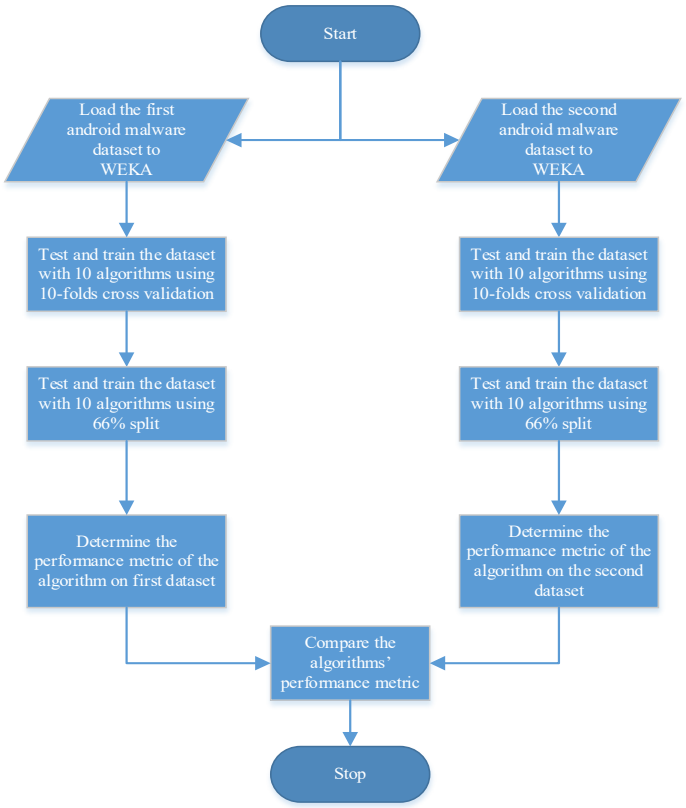

Figure 1: A graphical representation of the methodology

3.6. Algorithm Evaluated

Below are the description of two of the algorithms that stood during this research work

- Multilayer perceptron (MLP) is a perceptron that join up with extra perceptron, packed in many layers to figure out compound problems. Every perceptron in the input layer that is first layer to the left sends outputs to all the unseen layers that is the second layer perceptrons and all the second layer perceptrons send outputs to the output layer to the right that is the final layer [51].
- Random Forest: An additional dimension of randomness was introduced to bagging to create random forest in 2001. The algorithm creates tree predictors, and for all the trees in the forest, each tree depends on the random vector differently and autonomously sampled with the same dispersal. The best of these randomly chosen predictors is used in [52, 53].

4. Result and Discussion

This sections discusses the result gotten from the analysis done.

4.1. Analysis of the result

The dataset is made up of both malicious and innocuous applications. After the 10 algorithms have been trained and tested

with the 10 folds cross validation and 66 percent split in the WEKA environment, the obtained results is discussed in this section. Table 2 and table 3 show the performance metrics of dataset 1 and dataset 2 respectively. The performance metrics used are; accuracy, RMSE, false positive, ROC, precision, recall and f-measure. Figure 1 shows a display of the best performing algorithm in WEKA using the second dataset.

4.1.1. Discussion on the first dataset

While performance was optimal for all algorithms when trained and tested with the first dataset as seen in table 2, judging by accuracy, the top performing algorithm is the multilayer perceptron (MLP) having an accuracy of 99.4% when trained and tested under 66% split as previously stated in [1]. Under the 66% split, the MLP has the lowest false positive rate of 0.006 measured and also the highest recall (0.994), f-measure (0.994) and RMSE (00764).

Random Forest performs best measuring with respect to precision (0.993), accuracy (0.993), recall (0.993), f-measure (0.993) and ROC when trained and tested under the 10 folds cross validation [1]. MLP evaluated under the 66% split is, however, the best performing algorithm overall.

4.1.2. Discussion on the second dataset

In the second dataset, as seen in Table 3, while all algorithms perform well when evaluated with the dataset, the random forest had an accuracy of 98.9% when trained and tested under 10 folds cross validation making it the algorithm that performed best in terms of accuracy. The IBK has 0.013 as the lowest false positive rate. In comparison, the random forest has a reduced FPR of 0.016 and has the highest precision (0.989), recall (0.989), f-measure (0.989) and ROC (0.998). Kstar had the lowest RMSE of 0.0984.

Table 2: Showing the result of the performance metrics of the algorithms on the first datase

	Accuracy		**False Positive**		**Precision**		**Recall**		**F-Measure**		**ROC**		**RMSE**

BayesNet	0.828	0.829	0.124	0.128	0.862	0.861	0.828	0.829	0.831	0.831	0.928	0.925	0.4082	0.4081

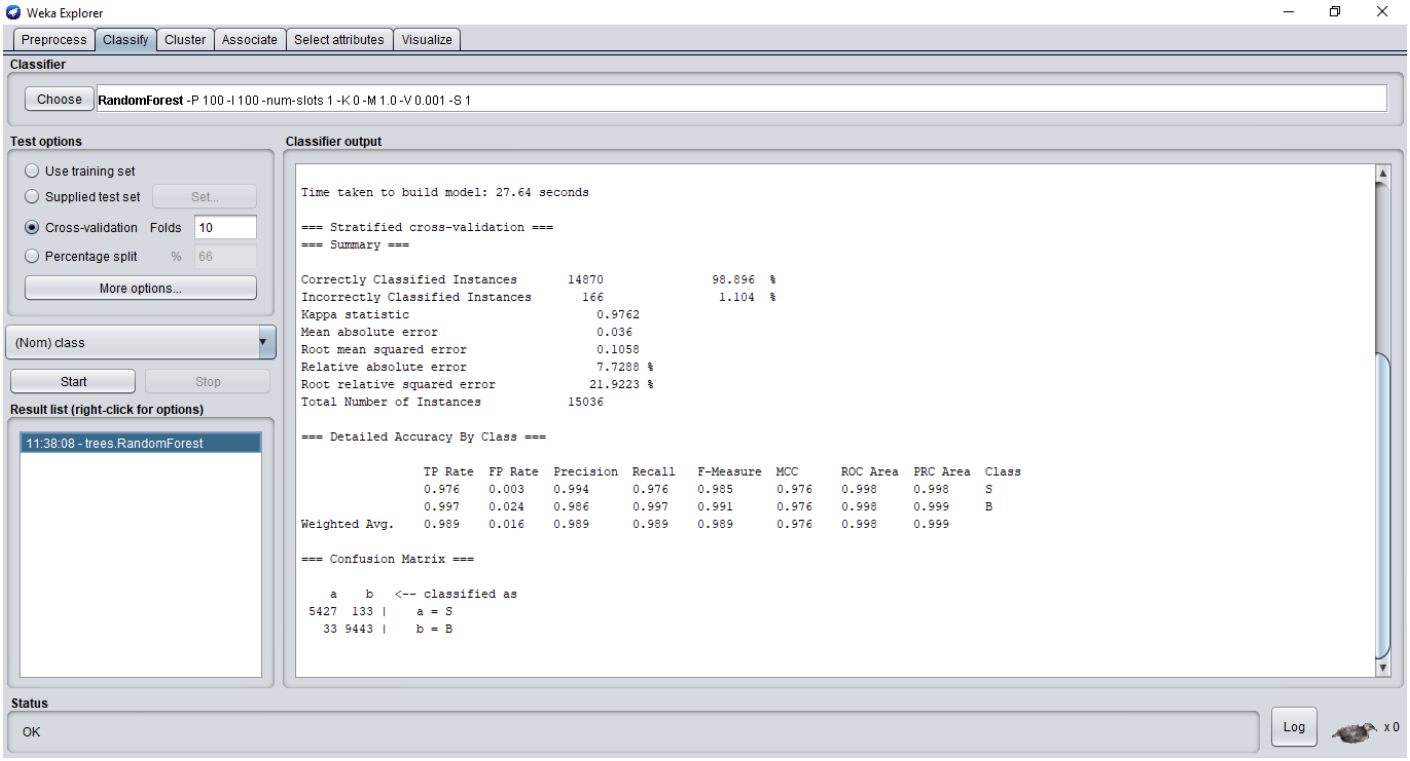

Figure 2: A display of Random forest in the environment using the second dataset.

Under the 66% split, KStar and IBK performs best with the same accuracy (98.5%), false negative (0.018), precision (0.985), recall (0.985) and f-measure (0.985). Kstar performs best in terms of ROC and RMSE with values of 0.998 and 0.1113 respectively. However, the overall best performing algorithm is Random forest tested under the 10 folds cross validation.

Although MLP was found to have the best performance under the 66% split when tested with the first dataset, it is seen that it was not able to maintain this performance when tested on the second dataset, this shows that MLP is data-set specific. This is as a result of the increased instances in the second dataset. The performance metrics of MLP was not maintained as a result of the increase in the instances. It is noteworthy in the classification of the first dataset that the analysis done under the 10 folds cross validation shows that random forest performs best with an accuracy of 99.3% having a difference of 0.001 when compared to MLP. The performance metric of random forest was further confirmed when analysis was done on the second dataset. It was observed that random forest performs best when trained and tested under the 10 folds cross validation. This therefore backs up the result of the first dataset analysis proving that random forest is not data specific.

5. Conclusion and Recommendations

Malicious applications has increasingly become sophisticated and complex with advancement in technological innovation. Models and methods for improved detection of such malware have been actively developed by various researchers in the field. The goal of this research study was to evaluate/appraise classification algorithms for malware in android detection. After the analysis in the WEKA domain, it was found that the performance metric of MLP was diminished with increased instances, making it dataset-specific. Random forest was found to perform better than the other algorithms with the first and second dataset when trained and tested under the 10 folds cross validation, having an accuracy of 99.3% and 98.9% respectively. Therefore, the contribution of this research is to determine that random forest

is the best performing algorithm in the detection of Android malware. Random forest is being proposed for use as the classification algorithm when building an android application for the purpose of android malware detection.

Further studies can consider selecting the best features of the dataset through feature selection or optimization for better performance. Other classification techniques under the reinforcement and unsupervised learning can be trained and tested. The studies should consider using Random forest as the classification and detection algorithm when developing anti-malwares, so as to provide a safe space for android users.

Conflict of Interest

The authors declare no conflict of interest.

Morocco

ABSTRACT

The objective of this article is to highlight the existing relationship between the tourist's destination brand image of the city of Rabat (Morocco) and its choice by foreign tourists to be visited once again. We suggest a reliable measurement scale able to measure the dimensions and associations of the brand image most memorized by tourists, so as to further attract the researchers and stakeholders curiosity in the tourism sector which face, every day, new challenges of attractiveness and sustainability of tourist destinations in the new Moroccan regionalization context. The survey is carried out on a sample of 454 foreign tourists in the city of Rabat because of the importance that this city requires in terms of overnight stays, that is to say nearly one million in 2018 according to the statistics of the Moroccan Tourism Observatory. The results obtained from the survey show that the functional and abstract associations jointly constitute the brand image of the city of Rabat in the foreign tourist's memory and that the abstract associations are more significant in the destination's choice.

1. Introduction

Today, tourism in all its forms is marked by strong competition between tourist destinations at national and international levels. The emergence of a large number of tourist destinations has compelled tourism managers to adopt new managerial approaches [1]. Faced with this situation, it is no longer easy to attract so many tourists because these people are more demanding and seek quality or even total satisfaction regarding a precise destination. Henceforth, in order to market their tourist sites, tourism professionals will have an interest in mastering territorial marketing in order to position themselves clearly on the most buoyant markets by adopting strategies with a political brand trend [2].

Indeed, likewise several destinations, Morocco is positioned as a country with a purely tourist vocation with 13 million non-resident tourists in 2019, according to the Moroccan Tourism Observatory, this is because of the country's geographical position, its natural and human resources, and its civilizational and historical heritage. Nevertheless, Morocco has been facing a fierce competition over the last decade with the emergence of countries such as Turkey with 39 million foreign tourists in 2018, Egypt with more than 8 million foreign tourists in 2017 and Tunisia with more than 8 million foreign tourists in 2018 (the Moroccan Tourism Observatory).

This is why our study focused on the study of the brand image of the tourist destination with the aim to analyze the measurement scale of the variable of the brand image of Rabat city tourist destination in order to define the different dimensions linked to it regarding the functional and abstract brand image. Consequently, we will present the concept of the Brand Image of the Tourist Destination and the multiple measurement instruments related to this concept in order to answer the following central questions: By which forms of perceived images can the attractiveness of Rabat city tourist destination be improved? And what are the associations with the brand image that have a greater impact on the choice of destination by tourists?

2. Territorial marketing: theoretical foundations

Territorial marketing research has experienced unprecedented growth over the last ten years. What all this research has in common is the application of marketing

[*]Corresponding Author: Abdellatif ELOUALI, Avenue le Prince Héritier BP. 227-Salé, Maroc+212663173006 – abdellatif.elouali@gmail.com

principles to the sphere, the territory, the city, and the destination [2]. In fact, several designations exist for territorial marketing: city marketing or public service marketing, urban marketing.

Territorial marketing does not only include communication strategies to promote the territory, but all the strategies that allow the attraction of tourists in relation to other territories. Territorial marketing is therefore based on effective, coherent and well-thought-out communication. The territorial brand plays a crucial role in this communication approach. From this point of view, the territorial brand is a means to attract not only tourists, but also investors, businesses and residents, who are also involved in the process of tourism development of a territory [3].

Although it is different from the enterprise, the territory will gain in adopting the strategies of the enterprise, especially the marketing strategy to be able to attract tourists in a context of strong competition [4].

3. The brand image: a multidimensional concept

The brand represents an intangible asset in order to attract new customers and subsequently building customer loyalty [1]. The brand fills numerous functions designed to support consumption. In this way, the brand carries a value and brings certain notoriety [5]. The brand is a product communication tool. For the consumer, the brand confers a reference point with which he can identify [6]. It makes it possible to identify and make the city desirable in the eyes of visitors [7]. At the level of a tourist destination, the brand takes the form of a name and a logo. For the destination, the brand carries its identity and protects its reputation [1]. The territorial brand is used as a lever of attractiveness of a tourist territory, within the framework of territorial marketing [8].

In [9], the author explains that the mark is both a signifier and a signified. It is a signifier because it enables the goods to be distinguished. Distinction does not only derive from sight, but also from other senses: touch, hearing, taste, smell. But as a signifier, the trade mark evokes a sense in the consumer. In [10], the author reports the characteristics of a brand at the territorial level, arguing that the territorial brand refers to the perception of the reputation of the territory by internal and external actors. The territorial brand therefore aims to convey the meaning of the city object. Furthermore, the city itself has always been considered a mark by nature, inasmuch as its name enables it to distinguish itself from others. Moreover, the name of a city already evokes its reputation and image in the mind. The territorial brand therefore encompasses all perceptions relating to a place and its inhabitants [11].

3.1. The notion of brand versus the notion of brand image

A differentiation is to be made between the brand and the brand image. The latter corresponds to the mental image that emerges in the individual when he hears, sees or evokes the brand [12]. In [13], the author explains that brand image corresponds to "all the associations and impressions that a consumer has in his memory about a brand. In other words, the brand image designates everything that comes to mind when talking about a brand. It can be tangible elements such as the goods or services bearing the brand, but it is also possible to associate the brand image with abstract elements from the producer's communication or from other competing brands [14]. As a result, the brand image could be assimilated to consumer representations or perceptions of a brand. It has emotional, rational and memory dimensions. However, for the consumer to be able to remember an attribute of the trade mark, he must have already experienced it or at least have been exposed to it on many occasions. The brand image is therefore the result of experiences resulting from the use of the product or exposure to it [15].

Within an enterprise context, the brand image is the perception of the brand by all stakeholders and the public [16]. From the marketing point of view, the touristic territory is assimilated to a product for sale and is associated with the brand. The territory becomes a brand that has its own image to promote through branding, but the brand image could also be considered as the characteristics that allow the individual to evaluate the brand in relation to others. The characteristics taken into account are in most cases concrete attributes [17].

The brand image of a tourist destination corresponds to its mental representation by the consumer. From this point of view, symbolic meanings are associated with the characteristics of the destination in question. This representation varies according to the experience or communications made by marketers and/or acquaintances who have previously experienced the tourist destination [18].

3.2. Brand image psychological approach

The branding process formation is split into four phases [19]: The first phase acts to express the process of the image perception by the individual's senses. It is primarily the physical characteristics of the product and the consumers' expectations and interests that affect or not the consumers' attention. If the consumer doesn't grasp the stimulus of the product by the senses, then the perception is not possible and ultimately the purchase will not occur.

During the second phase the consumer decodes the stimulus and interprets it according to his learning. This phase is unique to each individual.

The third phase deals with the perception's mental representation. The perceived image embodies a meaning and is somehow translated.

It is at the fourth phase that the individual can, through his evocation capacity, make a judgment, express an opinion, feel about the perception or simply take to purchase decision. The image itself can be divided into a desired image, transmitted image and perceived image [20].

3.3. Related associations to the brand image

In order for a brand to trigger a consumer's positive attitude, the consumer must develop strong and positive associations with the brand. It is therefore essential to create a strong image [14]. The structure of an image depends on the key attributes of the tourism product as well as the associations with the brand. However, the attributes and associations to the brand are derived from the different information retained in the consumer's mind after a consumption experience. Interactions at tourist destinations structure a complex image of the destination. The associations derive from this fact, from the confrontation between the image of the destination as perceived by the visitor before the experience, and the one developed after the tourism experience. Moreover, this complex image corresponds to the brand image perceived by visitors [21].

Branding consists of associations linking the individual to a brand. These associations can be functional or abstract. Functional associations group together attributes situations of use, benefits of using the product. Abstract associations, on the other hand, involve psychological phenomena such as affects, the attribution of a symbol to the trade mark or the emotions that the individual experiences in relation to the trade mark [18].

The functional or symbolic association with the image depends on the intensity and frequency of the positive experiences that the consumer has with the product [6].

4. Perception of destination's brand image as a communication strategy

The strong growth of the tourism industry has prompted many destinations to position themselves on this market [22], not only capital cities (Paris, London, Vienna, ...) but also cities that have developed a scientific (Cambridge) or cultural (New York, Aix-en-Provence, Dijon, ...) image, art cities such as Venice or emerging cities that have developed their own identity (Prague, Istanbul, Seville) [23].

Indeed, the competition between territories and even between cities has triggered the rise to an action mode which assumes the rise of reflections on attractiveness at several levels. Territories and destinations are the first willing to produce discourses to attract but also to retain a certain category of investors, tourists or residents.

In present day, the challenge for tourist destinations consists in differentiating themselves by developing a specific identity. They will carry out communication campaigns which may be reinforced by heritage images (culture, local customs, festivals, architecture, nature, etc.) intended to stage and perpetuate local traditions and culture [24].

Tourism communication therefore plays a capital role in the construction of the touristic destination image. Nevertheless, the multiplication of communication campaigns by the different territorial strata and the media coverage of the various events can blur the image of destinations.

Besides, it is important to study the effectiveness of communication between various territorial entities towards an urban destination in the light of the theory of social representations. Indeed, the development of destinations brands becomes compulsory for the cities' survival in the face of international competition. In order to differentiate themselves, they must develop their own identity brand and consequently create a good image.

Let us point out that touristic destinations are no longer perceived as mere entry points, boarding locations or transit points during a trip, but also, they are seen as eye-catching sites (natural or cultural resources) and attractions (appropriate development for tourism of these resources) [25] of fully-comprehensive destinations.

Previously, destinations promoted themselves thinking that the creation of tourist attractions would suffice to attract tourists (European Travel Commission). Nevertheless, exposed to tourism development, to the multiplication of communication campaigns at the different territorial levels (national, regional and city), as well as to the media coverage of the various events (terrorist attacks, strikes; riots in some countries; Pandemic, for example (Covid-19), the images and representations of destinations may be blurred.

In other words, the image keeps a very important place in the choice of a destination, and the different information sources play a crucial role in the tourists' minds regarding this image formation [26]-[28]. Consequently, the communication issued by destinations and touristic organizations influences the determination of the traveler's attitudes and behavior as well as in the formation of the tourist's image of a destination [29].

Typically, researches related to tourist destinations deal with the destination's image, which is an essential element in the choice of a touristic destination [27], as it provides information on the specific and unique attributes related to the destination before the potential stay [28].

As a result, the destination's image can, through its communication with tourists, generate a strong and distinctive image compared to its competitors. Moreover, many studies distinguish two types of images resulting from this formation process: the induced image resulting from the information of tourism actors (advertising and promotion of the destination and tourism organizations) and the organic image resulting from the consumers exposure to non-tourist information sources, such as the media outside the tourism sector [27], [28].

The organic image is often rooted in the tourists' minds because it is made up of shared representations which convey stereotypes [30].

5. Measurement scales of the Brand Image of the tourist destination

The measurement of brand image is based on the associations that consumers attribute to the brand. The stronger are the associations, the stronger is the brand equity. The associations should be strong and varied [31]. The measurement of destination branding is complex due to the fact that it is relative and dynamic and, therefore, varies over time. Thus, the models developed so far to measure the brand image of a tourist territory are based on tangible and intangible elements. Tangible elements include price, accommodation, different tourist services. The intangible elements refer to the ideas and sensations that consumers experience when they see or hear about the destination [32].

The measurement of the image of the destination is based on tourist activities and their needs, including transport, various amenities, food, services and travel prices. The image can also be measured through the characteristics of the destination and its inhabitants, such as their hospitality, the political stability of the country, economic development and environmental management. The image can also be measured through the attributes of the destination and its inhabitants. These different elements make it possible to gauge the image of a destination not only in the eyes of tourists, but also in the eyes of the whole world [33].

5.1. Quantitative and qualitative approaches

The quantitative and qualitative approaches make it possible to measure the brand image of a destination. Four scales have been indicated by [16] to measure brand image: the attitude scale, the ranking scale, purchasing intentions and turnover evolution. The attitude scale refers to the attractiveness of the

brand. The rating scale considers brand preference, as well as the characteristics that distinguish the destination from its competitors. Purchase intentions, on the other hand, provide information on the consumer's conviction about the brand. The evolution of turnover gives indications concerning the volume of purchases of the brand and, hence, the realization of the purchase intention [16].

5.2. Direct and indirect approaches

The measurement of brand image can be done indirectly through the study of perceptions, or directly, through the analysis of preferences and direct measurements. For the indirect measurement approach, it is possible to base the measurement on mental representation and the individual's ability to remember the brand. The consumer recognition or recalling of the brand allows the assessment of the brand's strength. The stronger is the brand equity, the stronger and more positive are the associations. Moreover, brand image is considered strong in this indirect measurement approach when consumers associate many attributes with it. In other words, the indirect approach to brand measurement refers to the measurement of brand awareness. The latter has six dimensions: brand acceptance, brand memorization, first brands that come to the consumer's mind, dominant brand (only one brand memorized), brand awareness and brand opinion [16].

6. Psychometric approach

Branding image is a multidimensional concept, particularly since it is often measured indirectly through its sources and its consequences. Unlike the various techniques already mentioned, psychometric measurements display the advantage of being more practical, more operational and above all more direct. In fact, it is a question of requesting consumers' opinions, through a pre-established questionnaire. In other words, satisfaction's surveys should be carried out among tourist consumers. The main measurement scale developed in this respect is the initiative of [34]. Nevertheless, the representations' mental extraction from the consumer's mind requires qualitative methods that are more rigorous than metric scales.

7. Brand's image other measures

7.1. Explicit measures

When the consumer proceeds to a purchase decision, he tries to remember the advertising message and what the brand represents. It is above all the level of learning of the message that varies the result of this consumer research in classic or so-called Territorial Marketing. The effectiveness of an advertisement and the product or territory brand will be evaluated on the basis of the words memorized. This is an explicit measure, as it focuses on a single person and on what that person has retained from an explicit message.

Sometimes there may be a distortion between what the consumer has memorized, and the information given. In this case, the person does not correctly restitute what he or she has "learned" from the advertisement but adds other incorrect associations or fractions.

7.2. Implicit measures

Implicit measurement is useful to advertisers to determine what consumers know about their brand, regardless of the information source. Different types of measurement can be distinguished [18]:

- Memorization: measuring the effect of advertising exposure on brand memorization;
- Spontaneous notoriety: consists of measuring of advertising effectiveness by asking consumers to name brands for a product category.

8. Attitude study

Consists of determining the perception of the brand and not what consumers know about it. In this method, they make a judgment on the basis of the various criteria of the brand.

The aim of these pre-tests is to determine what makes consumers change their brand preferences. We strive to single out the elements that build consumer's loyalty. Furthermore, classical theories indicate that there are strong and positive associations in the consumer's mind that influence the general positive attitude towards the brand [35], [36]. The literature then suggests that the strength of the image, i.e. its ability to translate itself into utility and loyalty behavior, depends mainly on four attributes according to [37]:

- The strength of associations;
- The dominance of associations;
- The valence of associations;
- The cohesion of the associations.

Therefore, in [37] the author described that only associations considered by the consumer as positive, strong, unique, and coherent, build the strength of the image. For instance, they affect the overall preference for the brand or a re-purchase or recommendation behavior. By analogy, and mentioning in [38], we suggest that attitudinal fidelity to a destination depends on the strength and valence of its image. Ultimately, it is expected that a tourist with strong and positive associations with the destination brand would be more inclined to revisit it and recommend it to others.

After our review of the literature, it appears that there is no agreement on the dimensions that form the brand image of the tourist destination. In addition, many of the brand features of the touristic destination have remained vague and lacking of clarity.

This generalism causes a certain ambiguity between certain concepts close but different from the brand image of the tourist destination, which causes a problem in terms of its determinants and its scales of measurement. Therefore, the design of a tool (scale) to measure the image of the tourist destination presents a real challenge in order to guide future research and support the professionals in order to better manage their management system of the brand image of the touristic destination.

9. Research methodology

In order to develop a standardized measurement tool, we will adopt the advocated approach known as the Churchill's paradigm [39]. The objective of this methodological approach is incorporating the knowledge of measurement theory and the appropriate techniques for improving it into an automatic procedure.

Similarly, Churchill's paradigm offers the possibility of rigorously designing measurement instruments such as multi-scale questionnaires. To this end, we deemed it appropriate to use, first of all, a qualitative approach to explore the characteristics of the brand image of the touristic destination.

In our field investigation, we used the semi-directive interview for data collection. This method is favored given its great flexibility and the wealth of information it can produce [40].

According to the literature, we have elaborated an interview guide that includes about the respondent's identification, age, gender and the determinants of the brand image of the touristic destination; the reputation of the touristic destination and ultimately the expectations of tourists towards (Rabat city).

The purpose of all these questions is to understand how the touristic destination is to understand how the brand image of the touristic destination is perceived by foreign tourists, and consequently to identify the different characteristics of the brand image of the touristic destination. Ten interviews were conducted with random tourists in Rabat city with average time duration of twenty (20) minutes. The population sample was characterized by female predominance (06 women and 04 men). The average age span is 28 years.

Afterwards, we have used a quantitative method. Indeed, in order to proceed in a methodological logic, we have formulated items based on all the items used in the different studies examined in the literature and the attributes collected after processing the information from the interviews (the results of the qualitative analysis will be dealt with in another research paper). Hence, a first version of the questionnaire was drawn up, then it was examined by two teacher-researchers in management sciences, and finally it was tested with 16 tourists from the city of Rabat.

The comments collected made it possible, on one hand, to improve the questionnaire, and on the other hand, to underline the latest version of the questionnaire which consists of 26 items on a five-point Likert's scale. Also, we also used exclusively affirmative sentences (positive statements) following Devellis' recommendations. The data were collected in paper format. 454 usable questionnaires were collected. The representative population of the control sample is composed of 64% men and 36% women. The majority of the tourists are situated in the age group of 25 to 60 years old.

The following figures present the various information about our sample population (gender, age, country of origin):

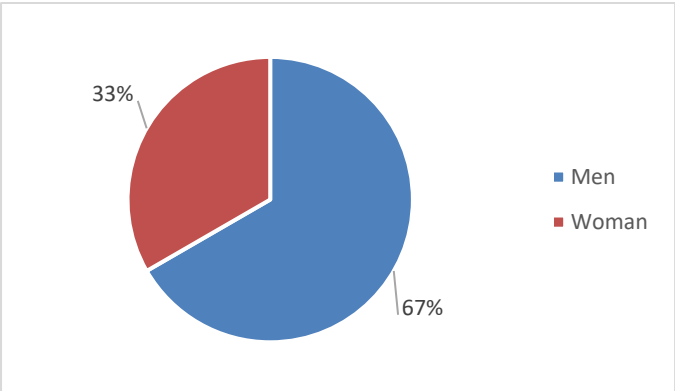

Figure 1: Tourists distribution according to the gender

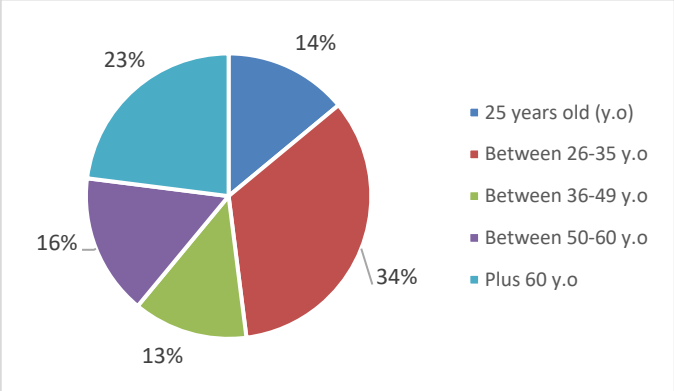

Figure 2: Tourists dispatching according to age

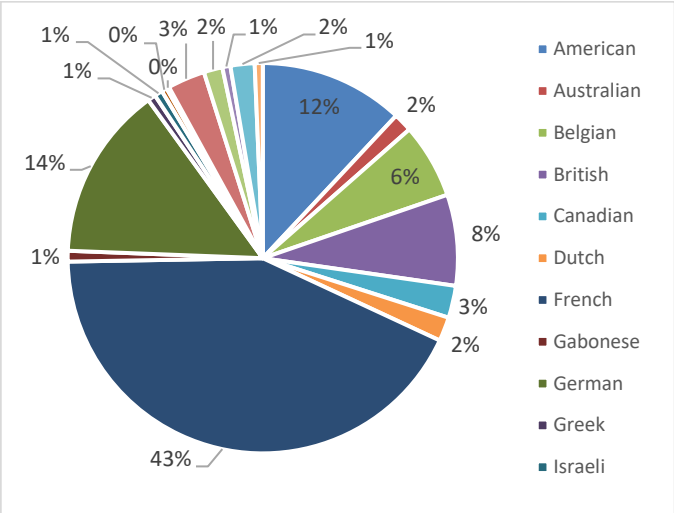

Figure 3: Tourists' dispatching according to their nationality

10. Exploratory Factor Analysis

To elaborate our measurement scale, we have gone through several steps. First, we have verified the content validity of the scale for measuring the brand image of the tourist destination. Content validity tests aims to check whether the questionnaire's different items are a good representation of the concept under consideration [41]. For this purpose, as explained before, we reviewed the academic literature to accompany and guide us in the questionnaire's elaboration and to reach a measuring scale of the brand image of the touristic destination beforehand. Indeed, the large number of items constituting the measurement scale (16 items), their heterogeneity and the way in which they can be taken out of the dimensions, offer the researcher a choice between three types of analysis' approaches:

- Independently, to examine each item by selecting only one item per theme;
- Aggregate all the items into a single scale;
- Undertake a factor analysis to identify the different underlying dimensions.

We have decided to introduce all items in a single scale without distinguishing between dimensions at the questionnaire level, in order to test the stability of the factor structure of the measurement scale we will use. The factor structure and the psychometric qualities of the scale of the tourist destination brand image were analyzed using SPSS (Statistical Social Sciences Package) 23 software, the data were subjected to

principal component factor analysis with Varimax rotation in order to test the dimensionality of the construct.

The Principal Component Analysis (PCA) is considered desirable in the development phase of a questionnaire in order to decrease the number of items and retain only keep those that allow the phenomenon to be characterized, particularly in order to identify the main factors [42].

The items purification deemed unsatisfactory was performed using the following elimination parameters: the rejection of items with a factor score of less than 0.3 and those with a high factor score on several factors [43]. The internal consistency reliability of the scale and its different dimensions was assessed by the Cronbach's alpha analysis as well as the correlation level for dimensions with at least two items.

11. Results and discussions

We undertook an exploratory approach to determine the dimensions of the tourism destination's brand. Firstly, we have prepared the number of variables, types of variables and finally the sample size.

Secondly, we looked at inter-item correlations. Then, we have measured the adequacy of sampling (KMO) and Bartlett's sphericity Test. The results showed that the KMO index is 0,758. It is qualified as good. This index shows that correlations between items are of good quality. After this, the result of the Bartlett's sphericity test is significant since $p < 0, 0005$ (Table 1).

Table 1: KMO Index and Bartlett's Test

Sampling precision measurement Kaiser-Meyer-Olkin	0,758
Approximate Khi-two	3664,384
Bartlett's sphericity test ddl	120
Bartlett's significance	0,000

In order to extract the appropriate of factors for our scale, we first have analyzed the table of total variance explained, and we have noticed that 4 components have an eigenvalue higher than 1. The 4 factors explain 66.38% of the variance (Table 2). These factors are considered significant.

Table 2: Initial eigenvalues

Component	Initial eigenvalues		
	Total	% of the variance	% cumulated
1	5,277	32,983	32,983
2	2,595	16,219	49,202
3	1,496	9,350	58,552
4	1,253	7,831	66,383
5	0,994	6,211	72,594
6	0,723	4,518	77,112
7	0,670	4,188	81,299
8	0,540	3,378	84,677
9	0,453	2,834	87,511
10	0,442	2,766	90,276
11	0,401	2,503	92,780
12	0,359	2,247	95,026
13	0,274	1,713	96,739
14	0,192	1,200	97,940
15	0,176	1,103	99,043
16	0,153	0,957	100,000

Secondly, and for more certainty, we have created a graphic from the eigenvalue using SPSS 23 (Figure 4) through the collapse layout and after examination of the Cattell's Elbow rupture. We have noticed that there is a change after the third factor. For this purpose, we retain three (03) factors that lie before the abrupt change in the slope of the Cattell's Elbow break for the analysis, since this criterion is precise than the eigenvalue criterion.

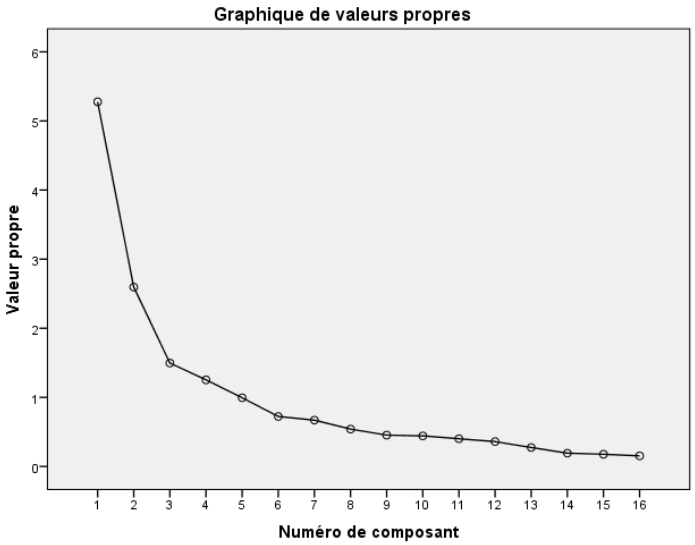

Figure 4: Initial eigenvalues

Table 3: Total variance explained through three dimensions (Extraction method: Principal Component Analysis)

Component	Initial eigenvalues		
	Total	% of the variance	% cumulated
1	3,537	32,153	32,153
2	2,125	19,320	51,473
3	1,327	12,064	63,537
4	0,901	8,193	71,731
5	0,808	7,345	79,076
6	0,630	5,731	84,807
7	0,463	4,210	89,017
8	0,382	3,470	92,488
9	0,340	3,087	95,575
10	0,303	2,754	98,328
11	0,184	1,672	100,000

The exploratory analysis in Table3, shows three (03) factors according to [44], which leads to the selection of the number of factors with a value of 1or greater. A clear factorial solution appears, without overlap. Factors are easily interpretable. In addition, the selected items appear to represent the brand image of the touristic destination in terms of content.

According to the component matrix (Table 4), the first factor consists of 5 items that represent the abstract brand image [45]. The latter characterizes the destination which is Rabat city as an adventures' destination judged by the foreign tourists interviewed, it is unique by its diverse touristic sites, A Sports destination because of the number of sporting events organized, namely the Rabat International Athletics Meeting, the Rabat International Marathon, the Hassan II Golf Trophy ,a city ranked second in the Maghreb region in terms of life quality after Tunis (capital of Tunisia), with a green belt of 1,063 hectares, Rabat

city managed to double the global area of green spaces for each individual given the standard of the World Health Organization set at 10 square meters per person (Tests garden), Nazhat Ibn Sina, Hilton forest, Maamora,... and ultimately, an events' destination (sporting, artistic and cultural).

In this regard, the author [46] argues that it is likely not all associations to the trademark have the same impact on behavior: associations involving symbolic benefits that are also abstract, would have a stronger influence than associations involving functional benefits.

The second factor represents the functional brand image, translated by the aspect of belonging to the territory and the local products, is composed of three items. These are related to the Peaks and Scents, Region City of the Rabat-Salé-Kénitra and the cultural activities namely Mawazine and the Rabat Jazz Festival for instance.

The third "Human and Intangible" factor is composed of three items. Rabat is a friendly city, a welcoming city, a wealthy city in terms of Historical Monuments (Mohammed-V Mausoleum, Oudayas Kasbah, Chellah, Rabat Saint-Pierre Cathedral, Hassan Tower, Mohammed VI Museum …)

Table 4: Components Matrix after rotation

	Component		
	1	2	3
IMA6	0,840		
IMA5	0,837		
IMF10	0,777		
IMA3	0,658		
IMF8	0,564		
IMF4		0,810	
IMA1		0,793	
IMF5		0,673	
IMA2			0,796
IMF9			0,769
IMF7			0,610

Table 5: Main Components' Analysis (Varimax Rotation) of the Rabat Destination Branding Scale (n=454)

Items	Components			Factors
	1	2	3	
IMA6. Adventures' destination	0,840			Brand image Marque Symbolic, Abstract
IMA5. Unique destination	0,837			
IMF10. Sports destination	0,777			
IMA3. Green city	0,658			
IMF8. Events (athletic, artistic, cultural).	0,564			
IMF4. Spices and scents		0,810		Belonging to the Territory and Local Products
IMA1. Region's city of Rabat Salé Kénitra		0,793		
IMF5. Cultural activities		0,673		
IMA2. Friendly city			0,796	Human capital
IMF9. Welcoming city			0,769	
IMF7. Historical monuments			0,610	Human, Capital Intangible

The three factors explain 63,537% (Table 3) of the total variance explained for a KMO of, 758 (Table 1). The internal consistency reliability for each component is mentioned in Table 5. After identifying the items that constitute our measurement scale (Table 5). We presently want to verify whether this scale is stable over time and whether it makes it possible to properly measure the brand image of the destination we have identified. So, we are going to perform an internal consistency analysis.

Table 6 displays the Cronbach's Alpha Index values for each component of the destination brand image. We observe that the value of the 1st component «Symbolic Brand Image» is 0,817, which is excellent, since it exceeds the minimum required threshold of 0,70 [47].

This beacon is arbitrary, but widely accepted by the scientific community. Consequently, we can claim that we obtain, for this scale composed of five elements, a satisfactory internal coherence. Similarly, the value of the 2nd component «Belonging to the Territory and Terroir Product» is 0,764, which is excellent. While the 3rd component's value «Human and intangible capital» is 0,673, which is acceptable.

Table 6: Cronbach's alpha coefficients

Components	Cronbach's alpha values
Symbolic brand image	0,817
Belonging to the territory and local product	0,764
Human and intangible capital	0,673

After examining the tables of total statistics of the elements corresponding to each dimension of the measurement scale of the Brand Image of Rabat Destination (Appendix 1), we have noticed that the Cronbach's alpha values of the first dimension improves (0,819 instead of 0,817) if we suppress item IMF8. Also, the Cronbach's alpha value of the third dimension improves (0,705 instead of 0,673) if we discard item IMF7. So our measurement scale of the Brand Image of the Final Destination of Rabat is presented as follows:

Table 7: City of Rabat Brand Image measurement scale

Factors	Items	Cronbach's Alpha
Symbolic brand image (abstract or functional)	IMA6. An adventures' destination	0,819
	IMA5.A unique destination	
	IMF10.Sports destination	
	IMA3. Green city	
Belonging to the territory and local products.	IMF4.Spices and scents	0,764
	IMA1.Region city of Rabat Salé Kénitra	
	IMF5. Cultural activities	
Human and intangible capital.	IMA2.Friendly city	0,705
	IMF9.Welcoming city	

11.1. Study results and implications

The results obtained show that functional and abstract associations jointly form the brand image of Rabat city in the foreign tourists' memory and that abstract associations are more significant in the choice of the destination. These results confirm that the brand image is constituted of several attributes linked to the associations, whether functional or abstract (the belonging to the territory and local product 0.764). The respondents consider that they are part of this destination and that local products remain a strong argument in the choice of destination. These data make it possible to mobilize a different approach in the management of the Rabat destination which prioritizes a diversified offer for foreign tourists capable of enriching this dimension of belonging and preference for local products and improving their quality.

The resources of the Rabat city destination mentioned in this study represent important distinctive and specific qualities in the overall satisfaction for the visit to a touristic location[48]. Moreover, the attributes linked to associations are a real means in order to develop and strengthen the brand image and, consequently, improving the attractiveness of the destination[49]. The results of this study represent a real reference for the managers of the Rabat destination and the Moroccan tourist sector for new prospects for the segmentation of the touristic offer and the opening up of new markets.

Conclusion

The aim of this research is suggesting a measurement scale of the touristic destination image in a Moroccan setting (Rabat city). To achieve this goal, we have conducted two empirical investigations. First, we have conducted a qualitative exploratory study in the form of ten semi-directive interviews, during July 2019, with a multi-nationality tourists visiting Rabat. Each interview lasted about twenty minutes. Then we have performed a quantitative study among 454 foreign tourists in Rabat during the time period from October to December 2019, and our results show:

- The existence of two different tourist's profiles based on the brand image they develop in their memory, a functional or abstract image and that the abstract brand image (Rabat unique city, city of adventure,0,819 of Cronbach's alpha) is more significant than the functional image (sports city...).These results are more compliant with those of [47] who suggested that not all associations with the brand have the same impact on tourist's behavior, with so-called symbolic or abstract associations having a stronger influence than those relating to functional benefits;
- The brand image, whether functional or abstract, constitutes an enormous potential for the Rabat destination (factor of belonging to the territory and terroir's product) of our model, 0,764);
- Our measurement scale suggests three (03) complementary factors, 9 items to measure the brand image of Rabat city. The three factors explain 63,537% (Table 3) of the total variance explained for a KMO of 0,758 (Table 1);
- At the managerial level, this study will enable the stakeholders of the national tourism sector to draw the necessary conclusions to segment the tourist's market at the level of Rabat city and at the national level according to the identified behaviors and preferences.

Likewise, all scientific research, our study displays some limitations which constitute as many threads of investigation. In fact, the scale has only been tested on one category of foreign tourists - those of Rabat city - and it is therefore appropriate to generalize the measure to several cities. Such an approach can improve the predictive validity of our scale at the national level.

Certain other research perspectives related to the results can be suggested. It would be interesting to study the structural relationships between the 3 factors of our model and to test their impact on other concepts such as attachment to the destination.

ABSTRACT

The purpose of this study is to show how to design the character used as the symbol or Mascot of the educational institution and how to apply the design results into advertising and Brand identity design such as printing art, poster, digital media, toy, and souvenir. In this study, the ideas of mascot design have been leaded to present a contemporary design under the conceptual framework from local culture, organizational culture, theories of society, arts and design through the analysis and synthesis of the organization, which is CAMT from Chiang Mai University, as the model of this study. CAMT has 7 bachelor's degree majors, namely Animation and Visual effects (ANI), Software Engineering (SE), Digital Film (DF). Modern Management and Information Technology (MMIT), Digital Game (DG), Digital Industry Integration (DII) and Knowledge Innovation Management (KIM). These Mascot design group were applied into Art product such as poster, Line sticker and end up with Toy product as a final stage, it was using digital 3D printing for action figure product in prototype level. This study including Toy creating concept designing and how the outcome product affected to Mascot identity, institution brand and the target groups of study which are widely from generation X to Z, mostly age range 18-23 years old. As a result, it founded that this Mascot package advertising becomes the distinctive character creating the new image of CAMT and the enhanced of Toy design product that raise CAMT remembered as a contemporary and digital organization in Chiang Mai University. Accordingly, it produced the impact results to receivers in many dimensions involving trend, creative behaviors such as Fan Art design, Doujinshi, or Caricature, Cosplay, Arts, and craft also Subculture from the public user.

1. Introduction

This paper is an extension of work originally presented in 2020 Joint International Conference on Digital Arts, Media and Technology with ECTI Northern Section Conference on Electrical, Electronics, Computer and Telecommunications Engineering [1]. In the lights of arts and designing, a mascot[1] is an effective public relation, promotion and marketing means of building brand images. A mascot is an extension of a logo in order to create the deeper dimension of image by building graphic identities or brand identities, it bears the responsibility of lifting the spirits of the group as well [2] which is highly popular nowadays. The building of a brand can rely on different techniques. However, most of the time, it involves the design of products such as shirts, hats or even collectibles that are memorable and tangible.

As for this project, it concerns the creation of new mascots based on the rebranding of College of Arts, Media, and Technology (CAMT[2]) Organization, Chiang Mai University,

Thailand. This college offers courses that are relating to Digital Contents in fields of Sciences and Arts focusing on innovation and digital technology. This project involves the designing of the new mascots for CAMT that correspond to the vision of the organization that emphasizes on digital innovation and advancement. Thus, the direction for the designing of the mascots/characters focuses on modernity and concurrence with the vision of CAMT and images of Chiang Mai University while

[1] Mascot is any person, object, animal used to represent a group of common identity mostly use for professional sport team also involve with advertising and marketing of organization or team.

*Corresponding Author: Nop Kongdee, Email : nopmerzy@gmail.com

building new images that focus on the dimension if arts and designing of Chiang Mai province simultaneously. Thus, it is apparent that the scope for the design corresponds to culture, images and perspectives that are overlapping on one another in various dimensions. Nevertheless, a new and meaningful image, which is the core outcome of this project, depends on the designing method, analysis and definition.

Marketing and promotional extensions an important element that leads to the memorization of brand identities. To achieve this requires images to consist of multi-dimensional perspectives that do not go beyond the conceptual framework, such as the design of envelope, letterhead, graphics on shirts and even graphic posters in the forms of digital media and digital image communication (stickers of Line application), as well as the design of toys and souvenirs, which are included as parts of the creation in this project. It is expected that the designed mascots will lead to the added value to the brand and the wide publication of promotional media and images in unique manners.

2. Literature Review of Mascot and Brand

In [3], it is stated that brand identity is how a company is being identified. The consistency of this brand identity is formed by its features like culture, vision, personality, positioning, presentations, relationships and other meaning beliefs followed by the entity. In term of commerce, brand identity is required to create costumers' awareness and remembrance in order to get access and chosen from consumers. However, there are many methods of brand identity expression which mascot is one of the potential paths.

It is quoted that the origin of the word "Mascot" is derived from "Mascara" or mask in the etymological dictionary [4], Corominas (1980, 1985) collected the first identifiable written use of the word "Mascota" or mascot in the year 1233. The word "Mascot" comes from the provincial language "Mascoto" which means magical things or amulets. Afterwards, it has been abbreviated to be "Masco" which roughly means which that relates to supernatural [5]. This is the linguistic and meaning background of the word "Mascot" which leads to the perception that "Mascot" is the representative of mask and magic.

"Mascot" would be a real person or animal or a character (or a group) used continuously and in different poses and attitudes to represent, advertise or promote a product, a brand, a company or institution, an event or a specific cause [6]. Therefore, mascot could be made of and could be representation of things for gaining awareness and recall and also could make the product alive and cause positive attitude for consumers.

"Mascot is being heralded as the magic bullet in the contemporary marcomms armoury [7]. Visual representation of a brand by using brand mascots is a technique which has been applied by organizations for many years. As the visual 'ambassador' of a brand, the mascot's goal is to strengthen the brand identity. The visual properties which are translated by these mascots can cause the distinctiveness of a brand [8]. It could be concluded that mascot is one of the most powerful tools for communication of brand's identity as we could see many famous brands with their identities' representation by mascots for instance: Michelin Man by Michelin, Mr. Peanut by Planters, The Laughing Cow by The Laughing Cow, Mickey Mouse by The Walt Disney Company, Jolly Green Giant by B&G Foods, etc. Therefore, it has assured that mascot is appropriate with intimate image with consumers setting organizations [9]. Another reaffirmation is that Mascot usage in Thailand tends to be usage for public relations mainly in events [10]. It has been mentioned that 60% of tourists in Shiga Province, Japan has been increased by the Hikonyan mascot. All this information insist that mascot is a very important instrument for communication, especially for brand identity representation.

3. Analysis of the Symbol

"Meaning" is defined that while everything has its meaning, meanwhile, everything does not have a chance to form its meaning by itself. Human is the entire meanings former which is not under human nature in an individual context to create meaning for things. It takes at least two or more humans to perform to make it meaningful where perception of meaning of things is based on experiences from the five senses. Since the past, interpretation and meaning transmission have been hidden in many visual languages [11]. Symbol is one of the hidden visual languages which is significantly influence interpretation and perception of human for a long time.

In general, mascot is a mean to create brand identity, and has the objective to enable people to remember an organization through a unique character in addition to logo design because a mascot is created within the similar framework of art concepts, such as the use of colors, shapes and forms. A mascot is one of the channels representing semiotics which denote sign and symbol that has been produced and sent or transmitted to indicate how the meaning of representation was formed, including its understanding of a thing or a process of giving such meaning. Semiology was a tool that could make individuals understand the formation of meaning and its application [12]. Semiotic theory is an "Interpretive" theory that can be applied to most aspects of everyday life although most people would not realise it.

However, a character has the complicated story, as well as emotions, characteristics, identities, style and overall image through the characteristics of the character. Meanwhile, logo design has the limitation; but to create a mascot requires creator to consider the campaigns that the mascot is used for and how to make people remember the mascot. In addition, mascot power can build harmony and unity in an organization such as the use of a mascot of sport teams to promote the organization and tourism of the local area. For instance, the use of the raccoon mascot of American football team of Tennessee, USA. Raccoon is a local animal of Tennessee State; thus, it is used as the mascot to express

[2] CAMT or College of Arts, Media and Technology is a Digital School located at Chiang Mai University, Thailand.

cultural identity. Therefore, mascot creation is a mean to present organizational culture and images based on the concept of artistic marketing or 'Graphic Identity, which is a branch of marketing strategy. In the education and academic society, it is known that in Thailand, animals are used for representing, which is relating to the contemporary society, and has endless development in accordance with the ever-changing trend in the global society. As for Chiang Mai University, the representing symbol is an elephant. However, the University has no exact or clear mascot. However, based on the definition of the symbol, it can be said that the keyword that is significant for the creation of core identity of Chiang Mai University is a violet elephant, which has been used for a long period of time although there has never been any exact or official mascot. Therefore, it can be said that a symbol needs people to drive it and time for cultural absorption until it is memorized and defined eventually.

In this case study, College of Arts, Media and Technology (CAMT) is an organization of the university. Thus, the culture of the university dominates the identity of this organization. Consequently, this organization has 2 logos of 2 different types. The first logo is the core logo of the university that is jointly used by all faculties, with the name changed in accordance with each faculty, and the defined logo that is especially designed for the organization (as shown in Figure.1) in order to express the definition of the organization that is contemporary and specific through the use of art compositions and designing.

Figure 1: Logos of College of Arts, Media and Technology (CAMT): Core Logo and Defined Logo

The aforementioned logos reflect different definitions. The core logo of the university is composed of the symbolic animal and violet color as the focal points of the local, which create identities of the university. Meanwhile, the shapes and forms of components in the logo clearly reflect the Thai style. Meanwhile, the defined logo of CAMT is completely different from the former because it reflects the modernity of the organization. The definition of CAMT is the emphasis on inventions through digital contents. This definition concurs with the courses that this organization opens; hence, the logo is designed to be in a modern form that is minimized, without any implication or symbol of Thai culture used at all. However, the status as being Thai has been defined in the name that is another defined image. In other words, the status as being Thai or Lanna Thai has already been inserted in the contexts of the organization already. However, images or representing symbol that are shown have the aim to reflect the status as a contemporary organization. In addition, the use of color of the organization (faculty) reflects the status as a luxurious and international organization. This logo has been developed from the previous logo that was defined 10 years ago (as shown in Figure 2).

Figure 2: Previous logo of College of Arts, Media and Technology (CAMT)

It is apparent that the contexts of CAMT have changed and the logo has been minimized with the different aim and in a different manner. Originally, the concept of the logo was to make people memorize the alphabets, but the current logo emphasizes on making people memorize an image with contexts. The letter 'Can has the form like a beehive or geometric form, which concurs with the previous definition. Nevertheless, the contexts of CAMT are flowing and changing along with the changes in different eras and the expansion of scientific and art concepts that still create the complexity of the organization.

Since symbols are changed in accordance with societal ideas and trends that serve as driving forces, mascot designing has been changed accordingly. Originally, there had been 3 mascots to represent the Department of Animation and Games, the Department of Software Engineering and the Department of Modern Management (MMIT) because there were 3 departments back then, which were divided into 6 branches in the bachelor level, as mentioned before. Thus, an interesting question is whether the contemporary design of mascot to reinforce the images of an organization should be for the timeline of 10 years in advance, together with the analysis on the nature and ideas of university students nowadays and in the future (Generations Y-Z) in the scope of organizations of university students or not. However, the implication of CAMT from previous mascot still has core definitions that include freshness, curiosity, contemporaneity and ethicality of students still remain in the symbol. Therefore, it is necessary to use the previous mascot as the basis for the analysis and development for designing a new mascot.

3.1. Previous Mascot

Originally, the previous mascots of CAMT had been designed with the focus on the education and the teaching and learning that was clearly separated by departments. Thus, the designed characters were students in the uniform that precisely reflect the characteristics of the 3 departments, namely, Animation and Game, Modern Management and Software Engineering in the bachelor level (as shown in Figure 3).

Analyzed in the aspect of arts, the 3 previous characters were designed to have color theme which was like an old logo that reflects moods through facial expressions of a board character[3], the characteristics of which are reflected through facial expression and shape and form of the eyes. As for the proportion, each of the characters have the proportion of a kid, with a big head, big hands

and a small body. This style of design is called Super Deformation (SD)[4], which is the deformation of a human body into a downsized body like a deformed body of a small kid. The advantage of this style is that the designed characters are trendy in accordance with the drawing style of Japanese graphic novel that is widely popular. Consequently, the characters are eye-catching and easy to remember.

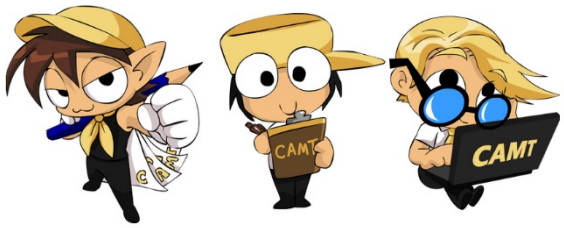

Figure 3: The previous Mascots of College of Arts, Media and Technology (CAMT)

Nevertheless, the mascots with the old definitions and policies have been used for more than 10 years since the establishment of the organization. With new policies and directions, there has been the need for extension and development of these characters so that they are contemporary while reflecting the identities of CAMT and CMU simultaneously.

3.2. Data Identification

College of Arts, Media and Technology has the educational approach that focuses on complexity which includes both sciences and arts, taught in a faculty that has learning method that is changed in accordance with eras, with the emphasis on innovation and digital technology as key principles. Therefore, the analysis and definition of the identities of the university are not fixed because the concepts and directions change annually in accordance with eras and trends. However, some keywords of the organization still remain. For instance, an organization that emphasizes on agriculture and technology may use lines and colors in organic art form in order to enable people to understand the definitions immediately. Alternatively, the Faculty of Political Science and Public Administration uses a scale and a lion as symbols that are related to Thai beliefs and symbolic definition which are combined together to form identities of the organization. As for CAMT, the symbol is designed to reflect the identities CAMT. However, such identities are under the domination of the identities of Chiang Mai University. Thus, there is the combination between identities of CAMT and identities of CMU, only for the identities from the social definition and graphic identities.

Chiang Mai University is an old complex university that provides courses of several subjects including medicine, sciences and arts in several branches, and extends and develops new curricula that fit modern era. From the view of the society, Chiang Mai University is a key University in the northern region of Thailand. At present, the university has the policy that focuses on digital technology and graduates of new generation with the competencies for diverse jobs, ethicality and promptness to the international level. However, such driving also leads to the change in the view of identities. In other words, this leads to the status as a contemporary university that accepts more foreign students, with the emphasis on linguistic aspect and tour system for foreigners in the university, or even the expansion of territory and branches in the northern region of Thailand, and the use of digital systems in the university, which turn the university Smart University, such as vehicle tracking system, game application for introducing places, class attendance (check-in) system with QR code and online method. Therefore, it is apparent that the current definition of the university is concurrent with the policy of CAMT because they are overlapping with each other and go in the same direction.

In addition, the definitions in the two aforementioned parts are also dominated by Lanna Thai status. It can be said that the Thai status and identities in terms of culture, thinking and traditions have control over the overall identity that cannot go out of this frame of social concept or definition. Consequently, the unique identity is created from the combination of several aspects such as media, people, policies, trends and politics, all of which are combined together. Therefore, the identity from the combination of the aforementioned aspects is a basis and component for designing a mascot with a clear scope that is different from a character that is a mascot of a private organization that has a broader scope. Nevertheless, this is no disadvantage. Rather, it enables the creation and designing of a character become clearer. However, there are several factors that are relevant, especially the concepts of the artist and the society which are key factors that lead to the building of the Character Style that are influenced by histories and the society as well.

3.3. Cultural Appropriation and Domination

Cultural Appropriation[5] is an approach concerning arts and society and is a key factor for the creation of art works. Therefore, it has both direct and indirect influences on the designing of mascots and characters based on experiences and societal perceptions of the artists or designers, as well as social trends, approaches referred to in a particular era and the implantation of ideas. For example, in this case, it is the creation of characters in the style of manga, which is a result from the great influences that Japanese manga works explored in Thailand to current. As for the designing, the thinking system of the artists focuses on applied art or extended arts, with the adherence to the origin. Therefore, the new identity reflects the combination among manga, original Thai arts and each artist's ideas. Not only does Thai status in arts and designing refer to lines and drawing but it also means identities, actions and stories that are added to a particular character. Thus, a character can be deemed to have identities that are based on Thai culture although it has culturally mutated or developed, which is called the 'mixed blood' or 'mongrel'. Nevertheless, based on the

[3] Board Character, according to the principle of character designing, is a character the characteristics and moods of which are mainly expressed with its look such as Scooby-Doo, 1969, Ruby J.

[4] Super Deformation Character (SD) is the style where by a character is deformed to look like a child, which originates from Japanese 'mangas'; and is sometimes called "Chibi" meaning a small thing, a petite person or a small kid.

approach of Culture Appropriation, the aforementioned phenomenon may be deemed a wrongdoing like plagiarism or copying of styles from any other culture in order to build and claim as our culture. Thus, the definitions of culture in various approaches are unclear. On the contrary, identity that is especially from the development of the aforementioned basic approach is accepted by people in the society and eventually becomes a symbol. Thus, the borrowing of culture that is caused from the domination over thinking occurs all the time, with the society acting like the judge and artists acting as presenters [13]. However, goals, objectives and approaches that newly occur have more significant implication. Hence, as for mascot designing at present, artists design their works to reflect the influences from mangas because of the aforementioned factors. It is not surprising that a newly designed character will look like a manga character. In addition, the key overlapping definitions, combined with styles, can create specific identity that serves as representation[6] of that society or organization as well. Therefore, cultural burrowing can occur all the time as a normal event in the society and in the field of designing.

3.4. Character Population and Demand

First of all, the target audiences for the mascot designing in this project are students in the age range of 15 – 25 years (Generation x) at present. From the survey, it is discovered that the characters that are popular are in the style of Manga[7] and have features of a kid (Manga Cute Characters). The advantage of this approach is the popularity of the style among the target audiences and audiences in other age ranges because cute characters do not mean manga style only; rather, it also means western characters such as Bug Bunny (W. Brothers, 1940). This character is used in western cartoon. It should be noted that this character is not originally created to serve as a symbol or logo but for producing animations for children audience. However, since the popularity of this character rises by dint of the expansion of media, Bug Bunny has become a symbol of western cartoon. Furthermore, Mickey Mouse (W. Disney, 1928) and Elza (C. Buck, 2013) have made Disney's cartoon characters memorable and great. In addition, may other characters from movies have also been popular and a societal factor. Examples of such characters are super hero group from Marvel Comics (1939), which have created trends that affect behaviors and thinking. Apart from memorable identities and looks, other attributes of these characters such as characteristics and thinking of the characters can generate new trends and thinking of people in the society. They can also trigger the building of social groups in accordance with personal preferences, which is concurrent with the concept of freedom of thinking nowadays. Looking back to Asian society that has manga characters as the foundations for thinking, one can say that manga characters were originally created to disseminate Japanese culture and thinking. However, with the popularity, manga characters have expanded to Thailand and become imprinted into many Thai artists during their childhood. Consequently, such artists design their works in the directions that they have been imprinted and in accordance with the popularity that evolves in each era.

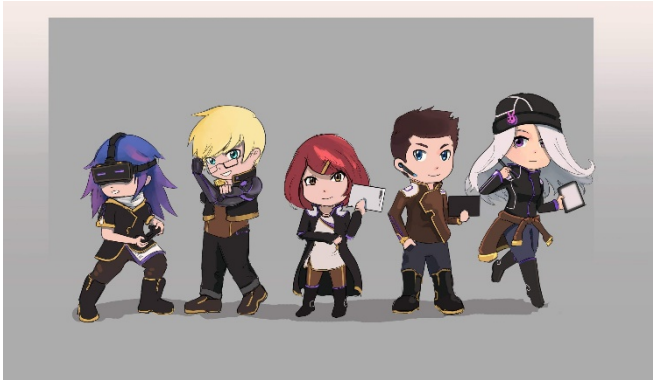

Figure 4: The Experimental Designs of Mascots:
DG – SE – MMIT - Dii – ANI draft 1

The mascots designed in this project belong to an educational organization. Thus, the outfits should be a uniform that reflects Thai culture in the improvised style and politeness in the society, mixed with the identities that the university wants to present, namely, digital technology, modernity and future world, with the basics of the identities from the identities of the university. In this case, violet, which is the color of the university, is used as a component of the design. Thus, in this designing experiment, culture domination and character population play prominent roles. As a result, there is a clear direction for the possible design.

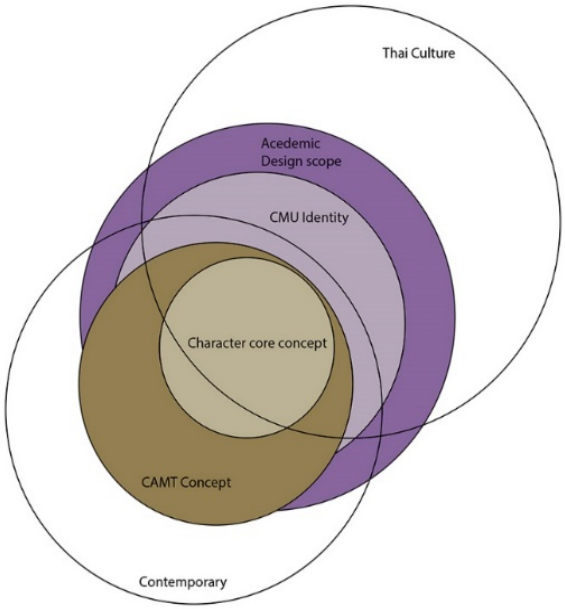

Figure 5: CAMT Mascot Design Scope, the overlapping area of contents analysis to finding of core concept design.

[5] Cultural Appropriation is the influenced of the artistìs background. In this case, it refers to Manga arts which applied to character design harmonious with Thai culture, CMU and CAMT.

[6] Representation in this case it intended merging of semiology and concept idea to presented something in specific purposed which approached to the meaning of Art work as a core concept.

[7] Manga are the Japanese comic or graphic novels style and become popular cultural in worldwide level since late 19th century.

Concerning the concept for designing the characters to represent the educational institute in this case, or CMU (as shown in Figure5), it is apparent that the scopes of the concepts are overlapping. Thai culture has partly taken part in the determination of the concepts of the characters because CAMT also has concepts in the international level. It cannot adhere to only Thai culture. Rather, foreign cultures have also partly played roles. At the same time, certain concepts that are the scopes of an educational organization, such as uniform, knowledge pursuit (curiosity), intelligence and friendliness. Such concepts belong to CMU and CAMT itself. The scopes of CMU have covered all the characters. At the same time, concepts of CAMT are slightly different from CMU because its identities are different from those of other faculties and are harmonious. In addition, such identities include contemporaneity that regards the directions of creation with all overlapping conceptual frameworks and scopes that cover the concepts of characters. Thus, it is apparent that the contemporary status and the Thai status are mixed together in the even ratio, with the concepts of characters as the cores for the designing and creation. In addition, feedback from audiences and users of the mascots is also taken into account. The most important aspect is the outcomes from the designing, which are regarded as the priority purpose.

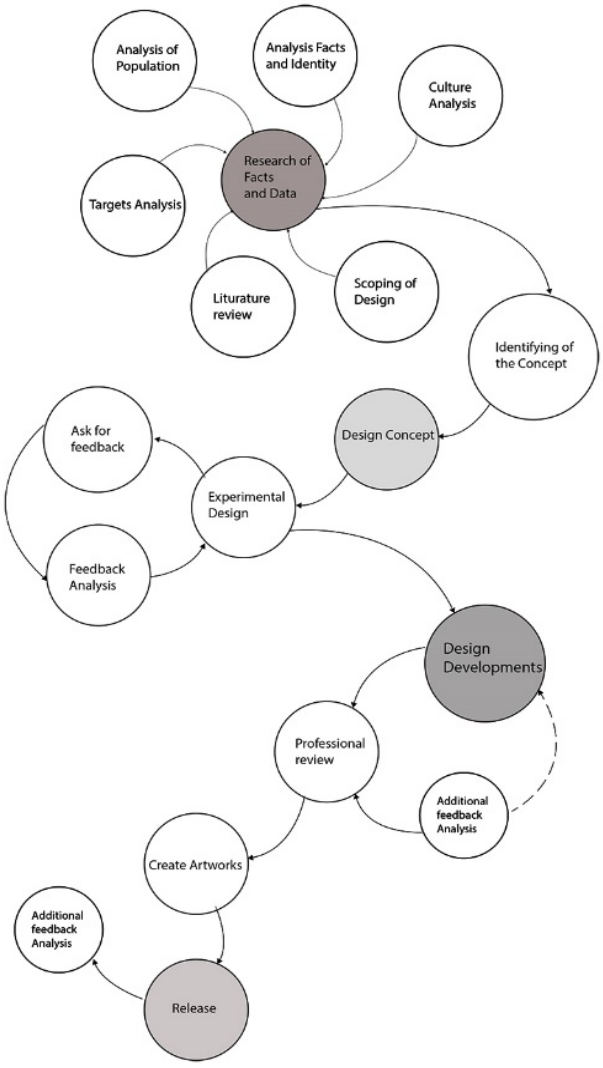

Figure 6: Design frameworks that specific for this project that require the audiences create an idea together with the artists.

4. Methodology

As for this study, the framework of the designing process consists of 4 phases that are 4 key steps, as follows. 1) Pre-production is the step that includes data research and analysis and determination for definitions and scope of the outputs and directions for designing, and study on the experiments by other artists. 2) Production is the step of the development of the designs that build images and patterns of the characters in ways that concur with principles of arts and designing and the concepts of contemporary design. Thus, this step incorporates experiments and creation of images in different dimensions. 3) Post-production is the step that includes the creation of media to present the outcomes from mascot designing, printed media to display in the building of CAMT, and promotional media including Line sticker and action figures. 4) Development and Conclusion is the step in which data are stored and products that have been released are refined in special occasions in order to add values to the brand in the consistent manner. In addition, new products are launched and new experiments in more diverse styles are conducted in accordance with social behaviors in each particular era.

In addition to product development, each of the aforementioned steps also includes the experiments that are based on the feedback from experts and some audience. The target audiences are divided into different age ranges, from people of generation Y or high school and university students to working adults. The designs of the mascots in this project must be neutral as possible whilst satisfaction and recognition should be supported by and concurrent with opinions and critics in social media as well.

5. Character Concept Identifying

The design definitions of each characters, Animation and Visual effects (ANI), Software Engineering (SE), Digital Film (DF). Modern Management and Information Technology (MMIT), Digital Game (DG), Industry Integration (DII) and Knowledge Innovation Management (KIM). The main concepts are contemporary and trendy including clothes and attitudes. The characters have their own distinctive characteristics, but work as a team. The same as CAMT concept that each major are related each other. The visions are combining which the words Honest, Discipline and Sharing (HOD)[8] which comes from the core values of CAMT (CMU CEO)[9] defining the current identity of CAMT. These definition and keywords are applied into Mascot mind and characteristic as a concept identity.

The definition of the Mascot of Animation and Visual Effect (ANI) is that this character has a high level of artistic features with individual thinking in digital technology-related arts. Therefore, the key instruments for creating the works in this project is the tablet pen painting plate, with the emphasis on creativity that allows the character to have high flexibility in terms of its appearances, which mean the character will not strictly adhere to any principle or rule.

As for the Mascot of Software Engineering (SE), this character is defined to be a scientific person who emphasizes on complex and systematic thinking with ability to create new software and

has literacy in special languages or digital ones (programming). Hence, this character relies mainly on left side brain (IQ) and truth.

As for the Mascot of Modern Management and Information Technology (MMIT), this character is defined as a person with leadership, innovativeness, capability of managing team members and planning, and ability to think and analyze, and intuition for forecasting things in the society through digital tools. This character is thus classified to have administrative skills and instant confidence for sound judgment.

In addition, the Mascot of Digital Game (DG) is defined separately from Software Engineering, but the emphasis is put on the creation of digital games. Thus, this character is both artistic and scientific and have more commitment than others. At present, there is a competition called E-sport. Hence, this character incorporates competitiveness, innovativeness and creativity.

Meanwhile, the Mascot of Digital Industry Integration (DII) is defined as a character who is based on facts and truth in the society, with the characteristics that are changing in accordance with the social trend. This character can learn from the issues in the digital industry; and thus, has diverse characteristic and ideas that are consistently changed. This character has diverse knowledge and ability to gather all knowledge in order to create new knowledge that is concise and easy to use.

The Mascot of Digital Film (DF) is defined as a character with creativity like the ANI Mascot, but this character focuses on the creation of cinematographic media, with combination between reality and imagination, and confidence. In addition, this character has capabilities and uniqueness in the field of entertainment arts because it has most prominent look of all members in the team. This character can be a director and an actor; thus, this character has as high confidence as MMIT Mascot, but in terms of entertainment only.

The definition of the Mascot Knowledge Innovation Management (KIM) is that it is the character that is regarded as the source of knowledge for the team because this subject is in Master Degree and Doctoral Degree levels only. The character is the eldest and most experienced of the team, with the characteristics to provide suggestions and advice to others in order to create new things from available information. Therefore, this character is prudent and does not show the emotion clearly. The special capability of this character is to analyze and file a great amount of information.

From the definitions of the characters, each character can be clearly and individually identified with values and policies of CAMT. Consequently, each character has specific definitions that are concurrent with the image and look of the character and different from another character depending on the subject. This is the concept for the designs of all the characters that has been combined with contemporaneity.

5.1. First Look of Design

After the data management is complete, in the Production Step, there will be the experiments of the art works by creating the mascots starting from forms, along with color designing, all of which are based on the definitions of the characters. In the image, it is apparent that gadgets that are related to each subject are added. For example, the ANI will hold a tablet and is floating all the time in order to show the implication of imagination and freedom in terms of arts. The experiments are still based in the feedback from the experts, which will be followed by the refinement of the designs because the designed characters are still not artfully perfect and are too complicated for the memorability.

Figure 7: CAMT early mascot part 2 design from artist A with digital gadget design e.g. tablet, gaming keyboard or smart phone.

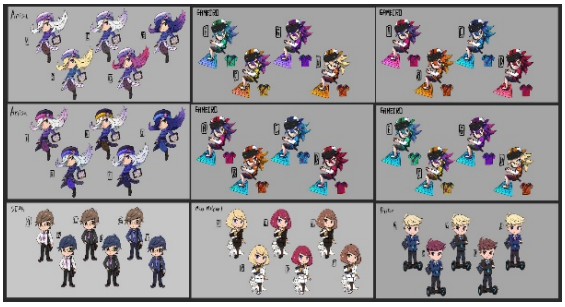

Figure 8: CAMT early Mascot design color alternative experiment

The using of color and shape, the trendy costume is also the key component by using the concept of Science fiction (Sci-Fi). The concept is that the costume design should indicate the futurism and the digital technology infused with CMU attributes and Lanna culture for representing the overall CAMT identity. In this process, there are experiments of color composition in various patterns (as shown in Figure7) as the attempts to clarify the identities of the mascot e.g. using red to portray danger and using blue to portray serenity.

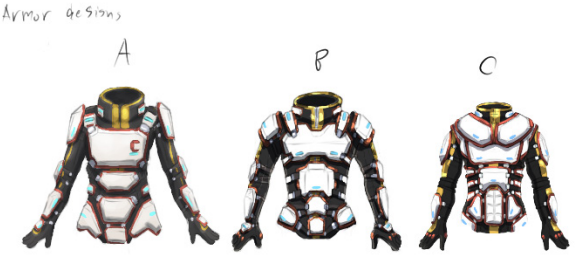

Figure 9: Early Digital CAMT Costume Design, Armor design

Concerning the designing of costumes of characters (as shown in Figure 9), initially, it is apparent that the look of the costume is too hard, which reduces the gentleness of the characters. In addition, the stories of characters are not agreeable. Thus, it is necessary that fabric materials are used as much as possible in order to create the costume that can be used in real life.

[8] HOD the definition of person who works at CAMT and part of CMU CEO representative words with honest, Discipline and Sharing used for personal mind at CAMT should have.

[9] CMU CEO the CAMT core values comprised with Community, Morality, Unity, Creativity, Excellence and Open for Challenge.

Furthermore, the proportion of the characters is changed from SD (Superhero Scale) in order to present charisma, confidence and implication of leadership, as well as the results from the analysis of the popular characters. As for this case, the characters from animation and game media are used. It is also apparent that characters from Ragnarok Online [10] Game have been highly popular for the past 20 years.

Figure 10: The example of ANI character transformation, *SD* re-scale design process.

Apart from rescaling, it is also vital to focus on the gestures of characters so that the identities and habits of each character will be presented more clearly. To do this, it is necessary to design the sketches in order to promote the mascots simultaneously by analyzing the characteristics of each character. For example, the Mascot of Digital Game (DG) (as shown in Figure 11) is reserved, loves playing games, and is not talkative. However, this character is keen on computer use and programming. This character is obsessed with some specific matters only. Such characteristics and habits are from the analysis of people of generation X who have complexity in thinking, individualism and introversion in high levels. However, with the light of the identities of CAMT people, this character also has optimism, which adds cheerfulness to this character until new identities are built. As a result, this character has gestures that show consistent movement and high responsiveness because most gamers have responsiveness rate that is faster than that of non-gamers. This is because of the main activities of the character.

Figure 11: The alternative of Character posing Design of CAMT DG Mascot

Unlike DG Mascot, Digital Industry Integration (DII) Mascot (as shown in Figure 12) is confident and capable of getting along with others easily. As a new character because the branch has been established this year, the character is designed to be still and prudent, with systematic thinking for management and confidence, but not in a great level as the confidence of MMIT and DF characters. In other words, this character can talk to, meet with and learn from other people all the time as reflected through the habit of the character whereby the character wears Bluetooth all the time with the promptness to discuss matters with people. At the same time, the character has still and stable gestures, with less movements than that of DG character.

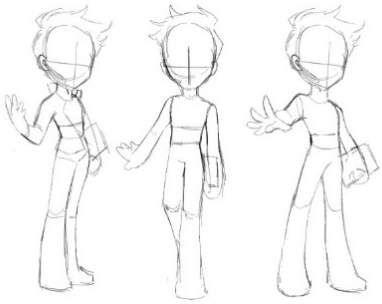

Figure 12: The alternative of Character posing design of CAMT DII Mascot: Confident Gestures.

Therefore, the creation of new postures that is carried out simultaneously with the rescaling is a significant step for adding personalities to each character. For instance, SE (Software Engineering) character (as shown in Figure 13) the uniqueness of which is the Smart Digital Arm. This character is the smartest one of the team, with expertise in language literacy and knowledge of programming. Hence, the gestures of this character represent confidence and uniqueness of the character. Initially, the postures emphasize on the Smart Digital Arm that is the unique feature of the character. Furthermore, the postures make the character look like a superhero but the child-like SD proportion make the character not much different from others in the team.

Figure 13: The alternative of Character posing design of CAMT SE Mascot

5.2. Detailing and Identifying

After designing the posing of characters, the next step is detailing and finishing the costumes by adding lines and details from the postures of the mascots. In this step, it is possible to create the graphics that can be actually used. In other words, there is the production of concept art which will be promoted in the step of publicity, which will shorten the period of time for media production. Nevertheless, there is a limitation that comes from a combination of organization synthesis. Besides, another limitation is that the costumes including hairs and faces have to be different and be infused with the gimmick[11] and the symbol. These are used to enhance the understanding of the receivers, e.g. Using of Digital suit look mixed Traditional Thai culture on fabric

[10] Ragnarok online is MMORPG game developed by Gravity interactive Company in Korea. The contents are based on manhwa Ragnarok by Lee Myung-jin. The game is the one of the most popular in the world and character design population.

form and texture with which can be seen in the details of the character, MMIT (as shown in Figure 14).

Figure 14: Detailing and Re-posing of design art concept, MMIT and ANI Characters

After the drawing process, more details are added to the characters. Each character is presented on different sides (in Character Sheet), together with expressions (in Expression Sheet) with details of gadget of each character in order to extend the story and details of the character in the future. In this step, the key action is to determine colors used for creating graphic identity without any deviation. The color system used is RGB that is concurrent with the color of the organization.

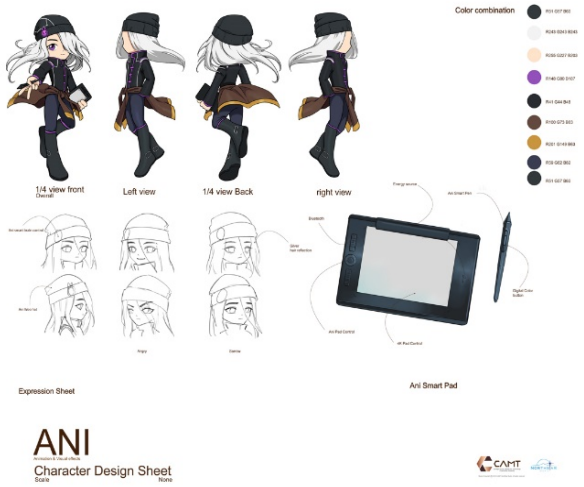

Figure 15: Character design Sheet of CAMT ANI (Animation and Visual Effects) Mascot

15, the ANI (Animation and visual effects) character is based on the personalities of the students of this branch and the body of knowledge from the analysis, the results from which reveal that the character is highly individual, especially in terms of art, or computer art, reserved, and outgoing, not for speaking but for presentation of arts and opinions. Therefore, the character is designed to have long silver hair, which reflects the obsession of independence. Thus, the character can fly, which is like the characteristics that is flexible, highly independent and sometimes introversive. The character carries a digital tablet as the important gadget that is used for drawing all the time. The eyes of the character are in violet color, which is a gimmick because violet is the color of CMU, which is inserted in the concept of the character. Meanwhile, the costume of the character is in the same direction as CAMT suit, with color tone limited to brown color and the character seems to be floating all the time.

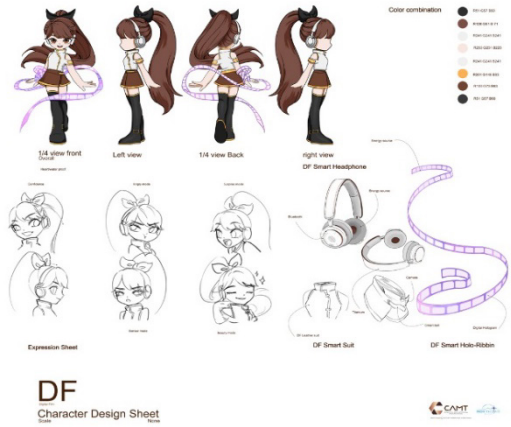

Figure 16: Character Sheet of CAMT DF (Digital Film) Mascot

Digital film) character is the combination of digital art and communication arts relating to entertainment art, especially cinematography. Therefore, the character has individualism as the ANI character and confidence to present self-identities because of capabilities and knowledge of acting and producing for films. Hence, this character is girly but confident, good looking and taking care of herself all the time, in terms of personalities and beauty. This is the only character of the team that is related to front stage. The accessory that represents this character is the Hologram Film Ribbon that is a traditional film roll. It symbolizes that although the character is in digital era, she still has knowledge of cinematography history. In addition, this symbol is easy to understand for propel in general, based on basic perception. In other words, when people see the symbol, they can immediately define the character. This character wears a miniskirt, but the miniskirt is also in the form of the contemporary uniform of the university, with the senses of fashion and sex appeal added. At the same time, the colors used are still related to the color of the organization, or brown in different shades.

Figure 17: Character Sheet of CAMT DG (Digital GAME) Mascot

[11] Gimmick, in this case is the way to input symbol identity into the design, including color, facial or accessories

DG (Digital Game) character is not much different from ANI one in terms of art statement with high levels of confidence and introversion. The differences are the love to competition and the capability of programming, which make this character inferior to ANI one in terms of arts. However, this character has complex thinking relating knowledge of digital interactive. This character is also inspired by e-sports that turn some game players to game producers. Hence, the character is highly obsessed and self-oriented. The key tool of this character is a traditional joystick that is linked to Oculus [2]. This tool is the key gimmick that presents a symbol that can hasten people's understanding on the concepts of the character. Meanwhile, the costume of the character has colors that are concurrent with the color of the organization. The costume is also designed to be agreeable to e-sport game team suit.

Figure 18: Character Sheet of CAMT DII (Digital Industry Integration) Mascot

Figure 19: Character Sheet of CAMT KIM (Knowledge Innovation Management) Mascot

DII (Digital Industry Integration) character is a male character and the only character of the team is has high confidence and skills of speaking and presentation, as well as concern with personality, which is reflected through the face and hairstyle that look polite and slick. The body of knowledge in this branch is related to the building of bodies of knowledge that can be implemented to contemporary industries in order to always catch up with current trends. Therefore, the character is confident and highly capable of communicating with others. The personal gadgets of this character are a smart Bluetooth and a notepad that the character carries all the time. This can manifest the implication of speaking and analytical skills, high are the key skills in this character. The costume of the character is adapted from suit jacket that makes the character looks more agile and active than other characters in the team.

Knowledge Innovation Management) character is the eldest character of the team. This character works at the back of the stager as the consultant of the team. This character collect and file all bodies of knowledge in every subject in the world. Thus, he is designed to have some gray hair as highlight, which is a tangible symbol to represent an aged person. Another unique point of this character is that he sits all the time, with the characteristics of a leadership who does not disclose himself or is the person secretly working at the back to ensure the success of the team. The significant skills of this character include the dissemination of knowledge, and the provision of advice in the fields of academy. The key gadget is the smart throne that is a tool to show and to store data like a hard disk. In addition, this gadget allows the character to communicate with others all the time. It is deemed as one of the most versatile digital gadgets because it can be used for creating, storing, and communicating. This throne is designed to have unique symbolic uniqueness of this character because it has violet color that is the thematic color of Chiang Mai University.

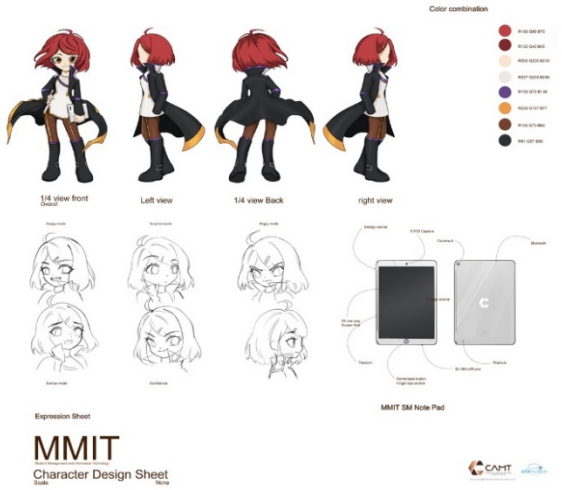

Figure 20: Character Sheet of CAMT MMIT (Modern Management and Information Technology) Mascot

As for MMIT (Modern Management and Information Technology) Mascot, this character is the leader of the team. She is capable of managing things quickly and efficiently. This character is also the key planner of the group and is also as capable of communication as DII character but has a greater level of leadership. Therefore, the character is designed to have the facial expression that reflects her confidence, with gestures that show high agility and delicacy, which are presented through the costume that consists of the cloak that waving all the time. The character has red hair which reflects boldness and confidence at the same

[12] Oculus is a VR game gadget from American technology company that used for visual reality in game specific support hardware and software in digital game.

time. Also, MMIT character has the key gadget of this character is the Smart Light Notebook that can store a lot of data but less than that of KIM character. However, the gadget of this character allows the character to have agility like a note pad does. Nevertheless, the concept of this character is inspired by the overall personality of the graduates of this branch, and the body of knowledge that has recently been developed.

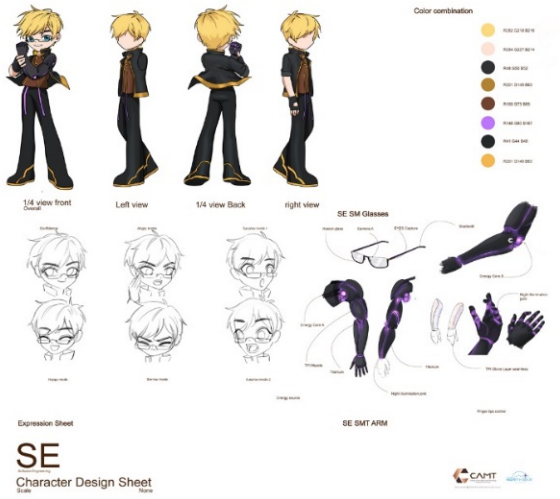

Figure 21: Character sheet of CAMT SE (Software Engineering) Mascot

Software Engineering) Mascot is deemed as the smartest character of the team, and has the knowledge of programming, production and language. This is the only character of the team that has mixed blood (a Thai – American person). The weakness of this character is the skills of arts. Even though being the smartest one, this character has to rely on ideas of ANI character as well. Therefore, SE character and ANI character are the closest friends of each other. The key tool of this is the Smart Digital Arms with AI at the finger tips, which allows the quick creation of programming works. This Smart Digital Arm was built by SE character himself, with color of CMU reflected through the violet light emitted from the tool. This gimmick has implication that can be widely understood with general perception in vision of color and arts.

Figure 22: Character Size Comparison when the character assemble as a team group.

6. Graphic for Advertising Product

The use of mascots for promoting an educational organization has more limitations than the use for a private organization in several aspects, including ethical images, definitions of education and organizational culture, all of which have to be taken into accounts and lead to the consideration of the types of media used. All media types, both physical and digital ones, are related to target groups and images of the organization. For instance, it may be deemed that the medium that is the symbol for memorization is a keychain souvenir because a general function of a keychain is to be a memorable symbol of an event or a place. However, at present, some functions may be added, such as to add a USB port flash drive to the keychain for multifunctional purpose. Likewise, designing the graphics that have mascots as the core element, it is necessary to present the images and tones that make the organization look like a lively and attractive place for every student like the students' second home that has modernity, and contemporaneity. In addition, the definitions of the term 'welcome' are reflected through the facial expressions of the characters. All the aforementioned concepts generate keywords that will be applied to all products under the principle of graphic identity in combination with the principle of graphic design in order to blend perception into arts perfectly without the need to sacrifice the identities of the organization. The building of such images needs the release of images in phases with the goals to allow audiences to send feedback and to enable all audience to perceive a little bit of new images of the organization at a time, starting from the display of the characters in the forms of posters in social media in special occasions such as New Year's Day, or in an event that has become a hot topic in the current society, such as the COVID-19 circumstance in 2020.

6.1. Poster Design

. rather, it includes the change of the head of the Facebook page of the organization, public announcements and question what the designed characters are representing. The chosen release day is the day for the celebration of 11th Anniversary of the University. This may have impacts on people in and outside of the University. In addition, this scheme al so makes students feel attached to the subjects they are majoring.

Figure 23: The Example of Character Poster Design

In 2020, there had been the outbreak of COVID-19 disease that caused Chiang Mai to be locked down for a certain period of time. At that moment, the professions that were worrisome were doctors and nurses who played key roles in taking care of patients, with the close encounter to the incurable disease. Therefore, the team designed a poster which was used in an online campaign to show the characters in the outfits of doctors and nurses in order to show the feelings of care and appreciation to doctors and nurses who worked hard. This design expressed the message that enabled people seeing the poster aware of the concern by the University with the situation, through the characters in the well-blended manner whilst expressing the perspectives that the organization had towards the country.

Figure 24: A Digital Poster using of Mascot on COVID-19 period in Thailand that also promoting a brand identity and policy at the same time.

Concerning the use of the poster design to deliver a message, at present the technique that has been found most effective currently is the creation of graphics that can be shown online. However, it is merely a one-way communication technique that can create awareness. Meanwhile, the use of mascots of the University to deliver messages to audience is a good way that reduces tension in certain situations along with presenting the images of the organization in new dimensions. Especially, in case of an educational organization, the delivered messages will be more reliable and accepted. All the aforementioned principles are related to social structure.

6.2. Line Sticker Design

To design characters to be used in social media communication is included in the marketing plan for building a brand in the modern era. This technique is to use characters that express emotions in the conversation to promote the key issue. In this case, the chosen media is Line[13] chat with is a popular mean of communication of people nowadays and is widely used in Thailand. Therefore, the team has created the mascots of CAMT to show emotions, appearances and symbols of human beings. This enables the users to choose the suitable characters that they like to complement their communications. Thus, designs of the gestures of the characters are related to currently popular messages such as 'congratulations', 'work hard' or 'thank you', all of which are still within the frameworks for designing the mascot of the organization without communicating messages that are too in-depth, allowing people of various age ranges, from high school students to middle-aged people, to use the designed characters and signs. In addition, the designed appearances and the used colors make users feel positive because the characters do not look too serious, which makes them fit the current trend.

The use of these character in digital communication (Line application in this case) has boosted the awareness of identity in deep and cognition because of each character has a differences personality for example, when they use MMIT emotion it can feel the leadership personality somehow from the face and body language, and that can show the identity of organization while using these symbols. The gender of the characters is also affected the user via using image or sticker chat, it makes the user more attractive on chat, same as using new patterns of language in

. Each version is designed to have a concept that is different from each other. The first version is for expressing common emotions such as 'thank you' and 'good' in 'good day'. At the same time, stickers in the other version are designed to be more specific with the works of the organization or professions, with new concepts and modern words, including slangs added, in order to make the designed characters become contemporary in the aspects of appearances, images and notions. In addition, facial expressions of the designed characters can look hilarious as well.

Figure 25: The example of Line Sticker CAMT mascot version 1-2 that already in the market.

-19 disease; hence, the research team has designed Line stickers in Thai language in order to use the designed mascots to promote and reinforce certain messages to the society. The mascots in this special version wear the outfits of doctors and nurses to show care and concerns with people in the society, which will spread positive vibe. Therefore, it is apparent that that the designed characters can be used for conveying diverse meanings and can be transformed into different styles whilst carrying the identities of the organization and their own identities at the same time, e.g., the KIM character, who is the source of knowledge or the team leader, wears a doctor uniform and has gray hair whilst other characters wears uniforms of PAs and nurses. At the same time, each character still shows his/her personal characteristics. For instance, the DF character, even though wearing a nurse uniform, shows cute and lively personalities as well. And that it makes people smile even in bad situation, this is a power of Mascot.

Figure 26: The examples of Line Sticker CAMT mascot COVID-19 version

[13] Line is a new communication application managed by a Japan company called Line Corporation. This application allows people to make free calls and free messaging. Invented by Naver Corporation Korea, it is the most popular

6.3. Architectural Decoration

The plan for the presentation of identities of the organisation is to increase the number of the woks consistently. One of the significant symbols is the L-shape building with glass wall at the main entrance. One thing that is indispensable is the decoration of the building, which will create the atmosphere and emphasize on the identities of the organization. The team designs big posters showing the designed characters to be displayed on the glass wall of the entrance in order to present new images of the organization and to renovate the building because the building is heated by the sunlight from the northern side. Pasted on the glass wall, the stickers will serve as blinds instead of curtains. The effects that happen are that the appearances of the building are completely changed because the colors and looks of the designed characters make the building of the organization look more exciting, active and delightful. The outcomes from this work lead to the discovery that to use bright and lively looks of the characters makes people visiting the building feel lively. These effects are like the ambience of Akihabara area in Japan, where some buildings are decorated with manga characters. Even though such manga characters are for advertising purposes, they make people in the space feel lively. Therefore, the decoration of the building, together with the design of landscape to have the building encompassed with a green garden, will also make students feel fresh and lively. At the same time, the decoration of the building builds unity in the organization. Also, the building of CAMT is the only building in Chiang Mai University, or even in Chiang Mai Province, that is decorated with images of contemporary characters in order to create the positive perception perfectly.

Figure 27 The use of Mascot for decoration, College of Arts Media and Technology, CMU.

7. Toy and Souvenir Product

As for the designing of characters, one of the indispensable elements is the creation of 3D models in order that the images and appearances of the designed characters will be more concrete. This concept of the creation of 3D models has led to the idea to create souvenirs to reinforce the identities of the organization through digital symbols and digital way of life. At present, many people, with artists and designers included, prefer to collect toys in the types of action figure, statue, Figma[4]. Therefore, the team has an idea to create souvenirs that are 3D models of the designed mascot characters with the framework to present the images of the organization along with the creation of aestheticism from small toys. The creation process starts with the creation of the characters in a computer before using a resin 3D printer which has the greater resolution than aplastic (PLA) 3D printer. The concept of this work is also based on some marketing principles concerning the presentation of images and symbols of the organization simultaneously.

7.1. Concept Design

This project is the creation of the set statue contained with 7 characters of CAMT in the sizes and scale were in accordance with the standard of Nendoroid[5], with the heights ranking between 5-15 cm, in the forms of SD characters [15]. Nendoroid is defined as a popular brand of small plastic figure replicas of manga and anime characters [16]. This is not too big statue but not too small based on population toys in the market. Mostly, for toys collector in worldwide so it become a standard size, scale and proportions. As a comparison of Nendoroid in the market place, there are the same scale and can replace the face and emotion but it lacks of group assembler product and light up system. This is an idea to create a difference type of Nendoroid figure. In this case, the works are created as statue figures, in order to set the gestures and looks to be presented that go in the same direction. The scopes of the design are as follows.

. Each collector must collect all the 7 models in order to get a complete logo.

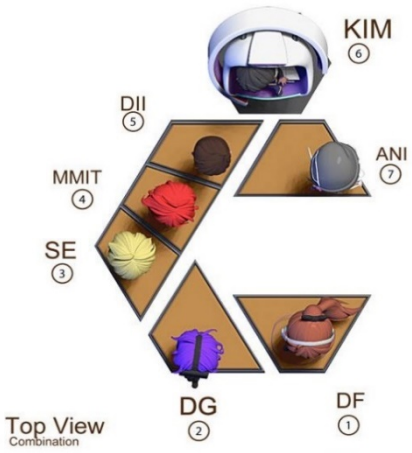

Figure 27: A Top view of 7 pieces of mascot combined into a CAMT logo

- The base is supported by a plate which is included in the model of KIM character, which is the team leader.
- The base of each model consists of the lighting system that related to the main plate, called LED light up base, which makes the display look more dimensional.
- The models are displayed in the stepped manner, with DF and DG characters sitting on the lowest steps whilst other characters are standing on the upper more steps. Thus, all characters will be seen from all angles without blocking one another.

Some characters, such as ANI, are floating all the time. Thus, the model of such a character consists of a metal pole that makes

[14] Figma Toy is a series of Japan toys invented by Max factory and distributed by Good Smile Company. The product focuses on highly articulated hand-sized figure of popular anime figure.

[15] Nendoroid is a series of plastic figures created by Japanese Good smile company in 2006. It becomes popular due to cute appearance. The figure has a function of articulation in appropriate scale for collectors.

the model look floating. In the future, the pole many be created with transparent material such as clear acrylic so that it will look more realistic. All the aforementioned ideas are complemented with the marketing design in order to make collectors desire to collect all the models in the set-in order to have a complete logo of the organization. In addition, the set of the models can serve as a lamp. As for toy designing, the most important elements are sizes and perspectives of the work in 3D view. Therefore, sizes are first set in the program of 3D image creation. The framework that is especially dedicated to this work is designed.

28: A Side view show the levels of the model steps

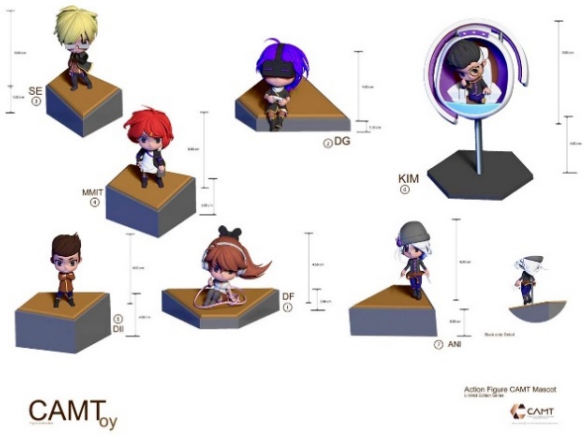

Figure 29: The separated details of each character

7.2. Methodology

The production of the toys can be divided into 3 main steps, namely, Pre-production, Production and Post-production, with the details of activities as follows.

- Pre-production is the step in which the initial design of each character and the concept for the assembly of the toys (Toy Mechanic Combination) are drafted. Also, details concerning used materials, postures, communication of the meanings and perspective are tested in the 3D space. In addition, the proportion and function for lighting systems can be adjusted in the step of the sketching in the 3D space. Furthermore, there is also the research for information of toys of the types of Statue and Nendoroid. If the size is bigger that 15 cm, the model set will need a great space, but a purpose of this model set is to be placed in any place such as at the space over the console of a car or a computer desk, which has no great space. Therefore, each model is designed to be 5-10 cm in accordance with the scale of each character.
- Production is the step that directly involves with the creation of the model set. This step starts with the creation of 3D model prototypes and the number of polygon is not taken into account. Thus, the design can have high quality subdivision, which will not affect the software for the printing. In this step, the focus is on the parts with joints that will be seriously taken into account because of the significant effects on the printing out. The consideration is also put on the designing of the colors for each character. Finally, the lighting system is added to the printed out model.
- Post-production is the step that still incorporates adjustment but the adjustment is more like the finishing of the details of each work in order to create the mold that will be used for mass production. This step also includes the taking of photographs to present the works and to get feedback which is used as statistical data of marketing demand. This step also includes activities in the production step if there is any suggestion from audience or expert. Most of the attained suggestions concern the use of mixed materials and the colors of the product.

From all the 3 steps as mentioned before, it is apparent that there are 2 keys activities in the production, which are the creation of products in 3D space and the printing out which require many experiments and adjustments.

This activity of the creation of the model is the experiment to determine the perspective and composition whereby all the models can be seen. From Figure 30, it is apparent that the SE character model is swapped with the DG character model in the final product. This is because SE model is in the standing posture whilst DG model is in the sitting posture. Hence, DG model is placed in the central area instead of SE model.

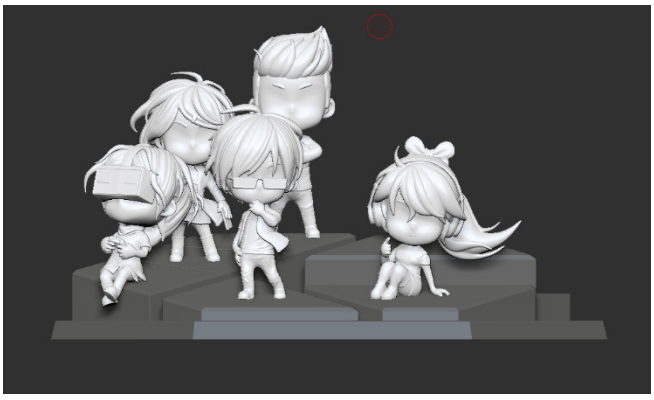

Figure 30: The First Draft 3D model in 3D Software.

This step also includes an important activity, which is the designing of separable parts such as faces, hair styles and bodies in order to let each model look seamless as possible. For instance, an SE model consists of 3 separable parts, namely, hair, head and body, which are easy for the assembly and the addition of details.

Figure 31: The test 3D model printing using resin separated 3 pieces.

. From the experiment, it is discovered that resin is very fragile especially in the parts of hair and small pieces in the model. Therefore, in this case, glasses are made of transparent plastic instead of resin.

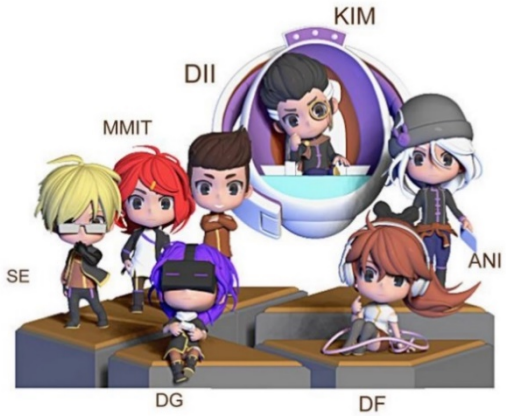

Figure 32: The Combination of the Mascot set in 3D vision.

After the test 3D printing of SE models, it has to make sure that when the character combine together, it in the right position and proportion. We use symmetrical in a feeling of mass and space, as you can see that KIM is blended to the right but on the left, there are 3 character standing on the step to make the composition look actually balance. The based system also designed in this step, in order to move on to printing a prototype step.

7.4. Printing a Product

This step involves the production of the models that have passed the test printing in 3D space already. All the pieces are put together, and the bases to support the works are also designed. The designing of the base to support each model is an important action in peeling the mold off the work. After the mold is peeled off, the work has to be scrubbed in order that the surface is smooth. In addition, a UV LED lamp is used for making the resin material hard and have smooth surface as expected. Instead of the lamp, sunlight can be used as well. Resin printing is different from PLA because it can show more details. In this case, a UV LED lamp is used for creating the prototypes, by using UV light to cause curing reaction on resin which makes resin hard.

. As shown in Figure 33, put together on the plate, the bases of the models do not fit well with one another. Therefore, the pieces of works have to be scrubbed with sand paper before the coloring process. Another problem is that the metal pole for holding the model is too high, disabling the model to stand by itself. In this step, there will be slight adjustment to the base. In the following step, the installation of lighting system will be focused on.

32: The Printed Resin Prototypes of Some Characters

Figure 33: The testing of LED light up system

As for the installation of lighting system, the switch is placed at the back of the plate to allow the connection with the adaptor for the light-up display. All the works in all the aforementioned steps have been described in posts on social media in order to attract feedback from message receivers. The attained feedback is satisfying to a certain degree but the light is too sharp and too bright. Therefore, the material of the base that cover the light bulb is changed to translucent one in white color in order to accumulate the light that hit the object. The opacity level of the material is 60 percent to deficit the light.

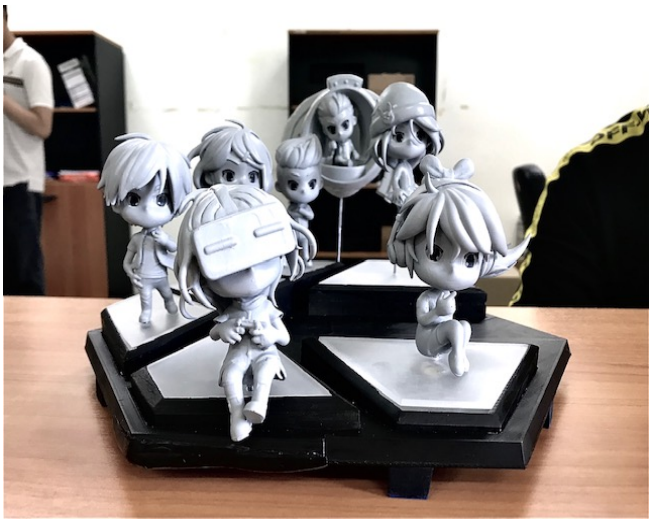

Figure 34: The Printed Prototypes Put Together on Plate in the Shape of the Logo of the Organization

7.5. Product Development

Based on suggestions and feedback from the experts and the audiences, the bases are modified to be in light gray color and the positions are changed, with KIM model pushed back of the plate. In case where a collector does not want to display all the models together, each model can be displayed separately. In addition, the KIM model is modified to show less seams because this model is the biggest and heaviest of all.

Figure 34: A prototype of the assembled product: picture for commercial released in October, 2020, on social media

After the product development leads to the satisfying outcomes, photographs of products are taken and shown on social media in order to get feedback in the Post-Production step. The results show that the satisfaction level is greater than 80 percent, but there are still requests for colored products, which are still in the course of experiment on different materials and colors.

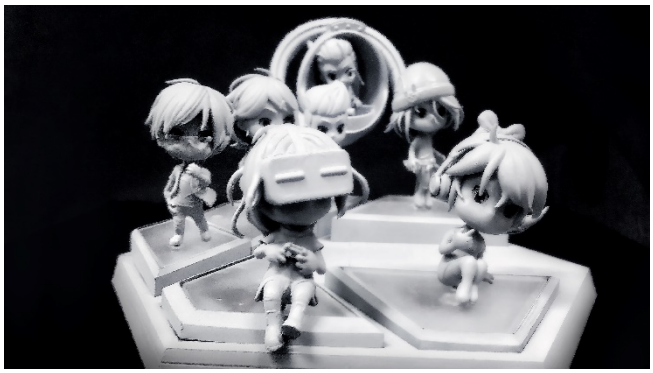

Figure 35: A prototype of the combination product and this picture is for commercial released in October, 2020 on social media.

7.6. Prototype

This final step involves the presentation of prototype products on social media. The presented prototype products are monotonously in the grayish white color. The products are presented in black and white color tone so that audiences can see the forms of all models, the lighting system of the base of each model and effects on the products. This style of presentation is popular among toy producers to present their works in a way to enable audiences to use additional imagination from experiences in primary perception and concept prior to the colored version.

Figure 36: A prototype of the combination product with LED light up test, released in October 2020 on social media.

In certain cases, consumers or audiences may want to see the prototypes in gray color, which can be optional. However, some audiences may p want to see just the colored version in order to consider the features of the products. Nevertheless, this style of prototype presentation will make audience consistently follow-up the updates of the products and give feedback. Afterwards, there is the primary virtual coloring so that audiences can imagine on the final products.

7.7. Product Publicity for Feedback

After the prototypes of the works are created, the next step is to create digital visualized images of the colored works to be presented to the audiences for their feedback. The colored works are presented with the concept of the overall product set in order to show clear identities of the designed mascots, which is the extension of the mascot designing.

Figure 37: A prototype in color version from digital visualization published for feedback

The issue relating to the works in this set is that they are just prototypes. This means the works can be modified in many other steps. There have been critics on material that the used material should be the mixed one that is composed of silicone because nowadays, silicone has been added as a component of materials to be used for creating works in the type of toy or statue in order to create the moods and dimensions of the surface that look more realistic. The extension of the product aims at the same goal, which is to extend the brand of the educational organization that is a choice for the promotion to make the brand sustainable.

Figure 38: A close-up shot of products of colored version

8. Results

As for the creation of elements of brand identity of the educational organization with various digital design-oriented media, namely, digital image, digital communication icon (sticker massage), poster, building decoration and toy (collectible) products, different feedback and opinions concerning different issues have been given by audiences and the experts.

In this project, many new characters (mascots) have been designed to have features different from original ones designed by artists/students. This means the characters in this project are re-versioned to have contemporaneity as other artists/students deem preferable. Theoretically, this style of drawing is called 'Dojinshi' [17] in Japanese language, which means the artists who are fond of certain characters to certain degrees re-create such characters in their own styles. Also, this style is called 'fan-art'.

The aforementioned fan-art phenomenon can be seen as the expression of feedback in the concrete and tangible manner.

Figure 39: Transformation of style of a character (ANI) into teen look can attract more favorable feedback.

Nevertheless, the designing of mascots for educational organizations still faces with certain limitations to designing, on the bases of target groups, organizational culture, spatial culture, and ethicality, which, all together, form the main scopes of the designing. Consequently, the designing cannot go beyond such scopes. This incident reflects the key difference between free comics and education comics because the designing has still had to embrace all the concept keywords. As a result, positive feedback and satisfaction are attained because more than 60% of the audiences (students and staff) deem that the designed mascots (characters) are related to themselves. Even though the uniform is designed to be more contemporary, the used symbolic colors of the organization, i.e., violet and brown, are implication that are hidden in the compositions of the designing and are comprehensible among target audiences.

The unique brand at CMU is a marketing concept for the creation in this project. The creation of the mascots that look contemporary and the extensive designing of other products in order to add values to the brand have led to the uniqueness of the University which results from this creation because the University is the only educational organization that applies platform and media usage in industrial level through the digital processing method in order to create versatile and tangible works. The ultimate result is qualitative and positive feedback that reflects a high level of satisfaction.

To create toy product is a key idea that enhances the strength of the brand of the organization because it reflects the versatile knowledge and skills acquire from learning. The concept of the University is to be a governmental university that is under regulations and conceptual frameworks but has been developed in the digital new normal era that follows the post-modern era. The designed products are tangible and create aestheticism while letting audiences absorb brand identities. This idea leads to a new direction of artwork creation that can be extended to industrial production. Furthermore, this experiment has received positive feedback from audiences in social media, which can be implied that it has market demand in a good level.

In techniques of creating these toys set, the using of digital methodology in ordinary which are follow step 1) 3D creating 2) Printing 3) Mass product creating is the same, but the idea of adding more option into the product such as light up figure or combination of set is the core of concept campaign if comparing with others Nendoroid in the marketplace and it keep develop and added more function into the product. However, the use of Toy

product in brand identity is a good idea of memorizing by touching, playing, and watching especially in institute's educational organization.

9. Conclusions and Discussion

From feedbacks from 3 groups of audiences, namely, CMU students, officer, staff and people in general, it is apparent that there are certain ideas that can be extensively applied to Institute's education brand designing and identity creation, with the main goal being to create tangible uniqueness for the organization through digital platform and digital media, in the form of products that people in the digital contemporary era can comprehend well an touched. Most of organization need a symbol present their identity. Logo is a good example, but it is lack of life and emotional in deep then that the idea of creating the Mascot was born. In this study, the scope idea does not include Digital Animation Film or game or any advance media, but it is the next step in advance once the brand is growing up and popular at certain level in social. Therefore, this study emphasize on to a new way of using Mascot design to enchanced and added value of the University brand in complicated cultural. It need many research of people mind, comments, feedback, population statices and demands, as well as analysis on behaviors of visitors who visited to the University and current students, which contributed to the creation of the new brand identity platform and the improvement of art identity in a future mindset. Key findings from the results analysis and presentation of the artwork product testing are as follows.

First, the designing of mascots for an education institute requires the connection among different dimensions of organizational culture, from the personal level that relies on the in-depth analysis on attitudes and specific personalities, the level of organizational image of the University, the level of provincial culture and the level of the country, under the conceptual framework that has limitations of dressing, ethicality, and purposes and policies of the organization. This is a contemporary study and creation project that creates new identities of the organization, which are reflected through characteristics of mascots (characters) that can be extensively designed as other products, based on the approaches of marketing strategies and advertising, all of which are systematically and sophisticatedly inter-related to one another. In addition, the trend of design is a factor for the creation. The results from the analysis point out that all the symbols designed in this project will be changed again in next ten years in order to sustain the values of the brand.

Secondly, the key factor for character designing is the target groups that are potential customers in term of marketing. Thus, it is significant to focus on students in order to study on trends and art population. From the study, it is discovered that 80 percent of the samples are interested in the styles of comic characters in animations and games rather than general photographs whilst 20 percent of the samples are interested in fashion in portrait style. It is also discovered that the cosplay and Korean pop (K-POP) fashion styles are most influential. Hence, the characters are designed in accordance with the aforementioned demands and trends, in combination with the spirits of digital era in order that they will have the ultimate looks that fit the trends while reflecting the organizational culture simultaneously.

Thirdly, the process of the creation of characters for an educational organization has conceptual framework that has more limitations than organizations of other types, including ethics, morals, and local culture. As for this case, it is Chiang Mai University which is a symbol of the city. Hence, it is necessary to create specific concept from analysis and synthesis. The aspect that must not be overlooked is the combination between organizational culture and local culture that is composed of ideas of people from local communities. Therefore, the outcomes are based on contemporary ideas that are more powerful than conservative perspective alone.

The fourth point of the findings is that toy product is a significant factor that affects imaginations for the audiences, people and provide beyond personal experience as we know that toys can make you imagine and more [18]. With this power, it is a powerful instrument for running promotional and marketing activities to promote brand identities perfectly. In general, people in this modern era, especially teenagers of generation Y people and younger people of following generations prefer to collect such products or any other products that features comic characters. From the analysis on the data of the market of Japan which known as the comic city as a culture, it is discovered that comic characters are used for presenting the tourism, and there have been new characters created until this style of art has become an element of culture since the post-modern era until the Bro-postmodern era when this art style is combined with the elements of the digital era. All the aforementioned cultural features have been absorbed by Thai youths. Consequently, modern artists can create manga-like art works, which can be regularly seen at present. From the analysis, it can be seen that this art style has also incorporated the features of traditional Chinese arts, especially the Chinese brush line drawing that has been developed to be digital line drawing that enables the creation of art works with new styles and contents. Eventually, the art works have been used as the bases for producing tangible mass products that, in turn, increase the popularity of the characters on which they are based. As for this project, the aforementioned product is the designed toy that also serves as a tool for measuring marketing outcomes, and effects in terms of art and culture simultaneously.

The final point from this study is that a perfect brand identity package should consist of tangible and intangible media that are contemporary, which will increase the values of brand and enable the brand to have versatility in terms of social statuses and positions so that the brand can effectively communicate with people in the current era. The findings from the analyses on consumer behaviors, products, trends, and positive ideas that have led to aesthetic perception which involve the awareness of artful beauty from sight and other senses. Hence, the design package for this study has incorporated digital art, and physical art and craft, which can reinforce the images of the organization in recognition and memories of audience in the easily comprehensible and quick manner, in addition to the use of ordinary graphic image or the logo of the organization.

These mascot design set and graphic brand identity project has been used in officially in Chiang Mai university, Thailand and its keep inspired to the people who visited CAMT as a school of new arts, media and technology at all the time.
