EDITORIAL BOARD
Editor-in-Chief

Prof. Passerini Kazmerski
University of Chicago, USA

Editorial Board Members

Prof. Rehan Ullah Khan
Qassim University, Saudi Arabia

Prof. María Jesús Espinosa
Universidad Tecnológica Metropolitana, Mexico

Dr. Hongbo Du
Prairie View A&M University, USA

Dr. Nguyen Tung Linh
Electric Power University, Vietnam

Tariq Kamal
University of Nottingham, UK

Sakarya University, Turkey

Dr. Mohmaed Abdel Fattah Ashabrawy
Prince Sattam bin Abdulaziz University, Saudi Arabia

Mohamed Mohamed Abdel-Daim
Suez Canal University, Egypt

Dr. Omeje Maxwell
Covenant University, Nigeria

Prof. Majida Ali Abed Meshari
Tikrit University Campus, Iraq

Dr. Heba Afify
MTI university, Cairo, Egypt

Regional Editors

Dr. Hung-Wei Wu
Kun Shan University, Taiwan

Dr. Maryam Asghari
Shahid Ashrafi Esfahani, Iran

Dr. Shakir Ali
Aligarh Muslim University, India

Dr. Ahmet Kayabasi
Karamanoglu Mehmetbey University, Turkey

Dr. Ebubekir Altuntas
Gaziosmanpasa University, Turkey

Dr. Sabry Ali Abdallah El-Naggar
Tanta University, Egypt

Aamir Nawaz
Gomal University, Pakistan

Dr. Gomathi Periasamy
Mekelle University, Ethiopia

Dr. Walid Wafik Mohamed Badawy
National Organization for Drug Control and Research, Egypt

Dr. Abhishek Shukla
R.D. Engineering College, India

Abdullah El-Bayoumi
Cairo University, Egypt

Ayham Hassan Abazid
Jordan university of science and technology, Jordan

Editorial

Advances in Science, Technology and Engineering Systems Journal (ASTESJ) is an online-only journal dedicated to publishing significant advances covering all aspects of technology relevant to the physical science and engineering communities. The journal regularly publishes articles covering specific topics of interest.

Current Issue features key papers related to multidisciplinary domains involving complex system stemming from numerous disciplines; this is exactly how this journal differs from other interdisciplinary and multidisciplinary engineering journals. This issue contains 208 accepted papers in Information System and Electrical Engineering domains.

Editor-in-chief
Prof. Passerini Kazmersk

ADVANCES IN SCIENCE, TECHNOLOGY AND ENGINEERING SYSTEMS JOURNAL

Volume 5 Issue 6 **November-December 2020**

CONTENTS

Qualitative Properties of a Cell Proliferating Model with Multi-phase Transition and Age Structure 01
Youssef El Alaoui, Larbi Alaoui

A Study on Intelligent Dialogue Agent for Older Adults' Preventive Care – Towards Development of a Comprehensive Preventive Care System – 09
Sho Hirose, Daisuke Kitakoshi, Akihiro Yamashita, Kentarou Suzuki, Masato Suzuki

Supervised Learning Techniques for Stress Detection in Car Drivers 22
Pamela Zontone, Antonio Affanni, Riccardo Bernardini, Leonida Del Linz, Alessandro Piras, Roberto Rinaldo

Analysis of Green Building Effect on Micro grid Based on Potential Energy Savings and BIM 30
Ihsan Mizher Baht, Petre Marian Nicolae, Ileana Diana, Nameer Baht

Effective Segmented Face Recognition (SFR) for IoT 36
Fei Gao, Jiangjiang Liu

Business Intelligence for Generating Comprehensive Report in Electronic Completion and Handover 45
Fadhillah Moulita Andiani, Faizal Abid, Hendri, Abba Suganda Girsang

Development of Group-Based Differentiated Learning (GBDL) Models 52
Toto Ruhimat, Deni Darmawan

The COVID-19 Effect in Mexican SMEs 63
Abel García-Villagrán, Patricia Cano-Olivos, José Luis Martínez-Flores, Diana Sánchez-Partida

Automated Extraction of Heavyweight and Lightweight Models of Urban Features from LiDAR Point Clouds by Specialized Web-Software 72
Sergiy Kostrikov, Rostyslav Pudlo, Dmytro Bubnov, Vladimir Vasiliev, Yury Fedyay

Using TOST in Teaching Operating Systems and Concurrent Programming Concepts 96
Tzanko Golemanov, Emilia Golemanova

Technology Adoption in Education: A Systematic Literature Review 108
Kayode Emmanuel Oyetade, Tranos Zuva, Anneke Harmse

Understanding the usage, Modifications, Limitations and Criticisms of Technology Acceptance Model (TAM) 113
William Ratjeana Malatji, Rene Van Eck, Tranos Zuva

The Impact Assessment of the Errors in Determining the Mass and Zero Lift-Drag Coefficient on the Aircraft's Performance Data 118
Klyagin Viktor Anatolievich, Laushin Dmitry Andreevich

Infrared Uplink Implementation for Software Defined Visible Light Communication Systems 127
Oswaldo René Banda-Sayco

Experimental Investigation of RC Footings Resting on Sand Strengthened with Concrete Jacketing 133
Mohamed Attia Fouda, Mahmoud Elkateb, Tamer Elkateb, Ayman Khalil

Electro-tactile Stimulation for Augmenting Finger Motoric Learning 143
Daniel Sutopo Pamungkas, Arjon Turnip

Aviation MRO: Impact of Physical Environment Factors on Job Performance in Aircraft Maintenance Organization 148
Kamal Jaiswal, Serdar Dalkilic, Evangelos Papageorgiou, Balgopal Singh

Inferring Topics within Social Networking Big Data, Towards an Alternative for Socio-Political Measurement 155
Khalid Ait Hadi, Rafik, Abdellatif El Abderrahmani

Research of the Effect of Rotation and Low-Frequency Vibration on the Robotic Assembly Process 160
Mikhail Vladimirovich Vartanov, Trung Ta Tran, Van Dung Nguyen

A Novel Approach to Augment the Opto-Electronic Properties of Stannic Oxide (SnO_2) Thin Films by Vanadium Doping 169
A. Victor Babu, S. Murugan, D.C. Bernice Victoria

Applications of the Heuristic Optimization Approach for Determining a Maximum Flow Problem Based on the Graphs' Theory 175
Simona Kirilova Filipova-Petrakieva

A Toolkit for the Automatic Analysis of Human Behavior in HCI Applications in the Wild 185
Andrea Generosi, Silvia Ceccacci, Samuele Faggiano, Luca Giraldi, Maura Mengoni

Real-Time Identification and Classification of Driving Maneuvers using Smartphone 193
Munaf Salim Najim Al-Din

The Effect of E-Service Quality on Customer Satisfaction and Loyalty (Case Study at E-Marketplace XYZ in Indonesia) 206
Hanny Juwitasary, Christian Christian, Edi Purnomo Putra, Hilman Baskara, Mohammad Wildan Firdaus

Trace-Driven Simulation of LoRaWAN Air Channel Propagation in an Urban Scenario 211
Eugen Harinda, Hadi Larijani, Ryan M. Gibson

Multi-Directional Light Sensing Using A Rotating Sensor 221
Hoang Anh Dung, Nguyen Manh Cuong, Nguyen Phan Kien

Vehicle Rollover Detection in Tripped and Untripped Rollovers using Recurrent Neural Networks 228
Kailerk Treetipsounthorn, Thanisorn Sriudomporn, Gridsada Phanomchoeng, Christian Dengler, Setha Panngum, Sunhapos Chantranuwathana, Ali Zemouche

Hybridization of Improved Binary Bat Algorithm for Optimizing Targeted Offers Problem in Direct Marketing Campaigns 239
Moulay Youssef Smaili, Hanaa Hachimi

IT GRC Smart Adviser: Process Driven Architecture Applying an Integrated Framework 247
Meriyem Chergui, Aziza Chakir

Multi Operated Virtual Power Plant in Smart Grid 256
Yevhen Fediv, Olha Sivakova, Mykhailo Korchak

A Fuzzy Controller Based SAPF for Power Quality Enhancement of Distribution System Integrated with Wind Energy Source 261
Vikas Kumar Sharma, Lata Gidwani

Pre-University Students' Learning Styles and Attitude towards Mathematics Achievements 269
Nurhilyana Anuar, Nurashikin Abdullah, Sharifah Norasikin Syed Hod

A Comprehensive Review of Traditional Video Processing 274
Helen Kottarathil Joy, Manjunath Ramachandra Kounte

Overmind: A Collaborative Decentralized Machine Learning Framework 280
Puttakul Sakul-Ung, Amornvit Vatcharaphrueksadee, Pitiporn Ruchanawet, Kanin Kearpimy, Hathairat Ketmaneechairat, Maleerat Maliyaem

The Role of Promotion in Mobile Wallet Adoption – A Research in Vietnam 290
Ha Hoang, Tan Trinh Le

Complex Order PI$^{?+j?}$ D$^{?+j?}$ Design for Surface Roughness Control in Machining CNT Al-Mg Hybrid Composites 299
Ravi Sekhar, Tejinder Paul Singh, Pritesh Shah

Dense Deep Neural Network Architecture for Keystroke Dynamics Authentication in Mobile Phone 307
Lubna Abdelkareim Gabralla

Emotion Recognition on FER-2013 Face Images Using Fine-Tuned VGG-16 315
Gede Putra Kusuma, Jonathan, Andreas Pangestu Lim

Multi-Model Security and Social Media Analytics of the Digital Twin 323
Jim Scheibmeir, Yashwant Malaiya

The Contribution of Wind Energy Capacity on Generation Systems Adequacy Reliability using Differential Evolution Optimization Algorithm 331
Athraa Ali Kadhem, Noor Izzri Abdul Wahab, Ahmed Abdalla

Enhanced Power Utilization for Grid Resource Providers 341
Tariq Alwada'n, Thair Khdour, Abdulsalam Alarabeyyat, Ali Rodan

DC-DC Buck Converter Driver with Variable Off-Time Peak Current Mode Control 347
Osvaldo Gasparri, Paolo Del Croce, Andrea Baschirotto

Blueprint Model: An Agile-Oriented Methodology for Tackling Global Software Development Challenges 353
Andre Figliuolo da Cruz, Cristiano Pereira Godoy, Lanier Menezes dos Santos, Lucas Frota Marinho, Marco Santarelle Jardim, Elisangela Paiva da Silva, C?cero Augusto Pahins, Paulo Fonseca, Felipe Taliar Giuntini

Vietnamese Text Classification with TextRank and Jaccard Similarity Coefficient 363
Hao Tuan Huynh, Nghia Duong-Trung, Dinh Quoc Truong, Hiep Xuan Huynh

Intrusion Detection and Classification using Decision Tree Based Key Feature Selection Classifiers 370
Manas Kumar Nanda, Manas Ranjan Patra

Comparison of Gaze Points Among Viewing Conditions (Resolution, Display Size, Viewer Position) During Video Viewing 391
Miho Shinohara, Yusuke Nosaka, Reiko Koyama, Riko Nakagawa, Takuya Sarugaku, Mitsuho Yamada

Method for Improving the Quality of the Product Obtained by Abrasive Treatment with Impregnated Tools 398
Viktor Butenko, Liana Gusakova, Dmitry Durov, Boris Safoklov, Oleg Dolgov

Level of Resilience and Family Functionality in Adolescents of two Educational Institutions of a Vulnerable Area in Lima Province 403
Rosa Perez-Siguas, Hernan Matta-Solis, Eduardo Matta-Solis, Melissa Yauri-Machaca, Anika Remuzgo-Artezano, Lourdes Matta-Zamudio

To the Question of Multi-Criteria Optimization of Aircraft Components in Order to Optimize its Life Cyclee 408
Sergey Alekseevich Serebryansky, Alexander Vladimirovich Barabanov

The Probe Mark Discoloration on Bond Pad and Wafer Storage 416
Wen-Fei Hsieh, Henry Lin, Vincent Chen, Irene Ou, & Yung-Song Lou

A Simulation Based Proactive Approach for Smart Capacity Estimation in the Context of Dynamic Positions and Events 423
Naeem Ahmed Haq Nawaz, Hamid Raza Malik, Ahmed Jaber Alshaor, Kamran Abid

Effective Learning of Tax Regulations using Different Chatbot Techniques 439
Rafael Mellado-Silva, Antonio Faúndez-Ugalde, María Blanco-Lobos

Electronic Warfare Methods Combatting UAVs 447
Miroslav Kratky, Vaclav Minarik, Michal Sustr, Jan Ivan

Fault-Tolerant Control of Permanent Magnet Synchronous Motor Drive under Open-Phase Fault 455
Amr Saleh, Nada Sayed, Ghada Ahmed Abdel, Mona Nagieb Eskander

Extending the Classifier Algorithms in Machine Learning to Improve the Performance in Spoken Language Understanding Systems Under Deficient Training Data 464
Sheetal Jagdale, Milind Shah

Reliability Improvement of Radial Distribution System by Reconfiguration 472
Srividhya. P, Mounika. K, Kirithikaa. S, Narayanan. K, Gulshan Sharma, Girish Ganesan. R, Tomonobu Senjyu

American Sign Language Recognition Based on MobileNetV2 481
Kin Yun Lum, Yeh Huann Goh, Yi Bin Lee

An Adaptive Nonlinear Sensorless Controller of Doubly Fed Induction Generator Driven By Wind Turbine 489
Radouane Ourhdir, Mohammed Rachidi

An Economic Theory Perspective for the Fight Against Poverty in the Peruvian Andes 497
Robert Antonio Romero-Flores

Microcontroller Based Data Acquisition and System Identification of a DC Servo Motor Using ARX, ARMAX, OE, and BJ Models 507
Mokhlis Salah-eddine, Said Sadki, Bahloul Bensassi

Facebook Translation Service (FTS) Usage among Jordanians during COVID-19 Lockdown 514
Zakaryia Almahasees, Helene Jaccomard

Accelerating Decision-Making in Transport Emergency with Artificial Intelligence 520
Alexander Raikov

Determinism of Replicated Distributed Systems–A Timing Analysis of the Data Passing Process 531
Adriano A. Santos, António Ferreira da Silva, António P. Magalhães, Mário de Sousa

Variation Between DDC and SCAMSMA for Clustering of Wireless MultipathWaves in Indoor and Semi-Urban Channel Scenarios 538
Jojo Blanza, Lawrence Materum

Interface for Visualization of Wireless Propagation Multipath Clustering Outcomes 544
Jojo Blanza, Lawrence Materum

The Effect of Different Starches in the Environmental and Mechanical Properties of Starch Blended Bioplastics 550
Adriana C. Neves, Tew Ming, Marta Mroczkowska, David Culliton

Proposal of a New Descriptive-Correlational Model of Population Lifestyle Analysis and Disease Diagnosis 555
Selene Tamayo Castro, Kristian Aldapa Salcido, Linda García Rodríguez

sharpniZer: A C# Static Code Analysis Tool for Mission Critical Systems 561
Arooba Shahoor, Rida Shaukat, Sumaira Sultan Minhas, Hina Awan, Kashif Saghar

Experimental Study on Mechanical Behavior of Polypropylene-based Blends with Talc Fillers 571
Pham Thi Hong Nga, Van-Thuc Nguyen

Ontology-based Data Management Tool for Studying Radon Concentration 577
Felix Fernandez-Pena, Alex Maigua-Quinteros, Pilar Urrutia-Urrutia, Diana Coello-Fiallos

Strategic Plan for the Achievement of the Competitiveness of Small Companies with Respect to Large Ones 584
Alan Guadalupe Ochoa Navarro, Juan De Dios Cota Apodaca, Dario Fuentes Guevara

"Traffic Congestion Triangle" Based on More than One-Month Real Traffic Big Data Analysis in India 588
Tsutomu Tsuboi

Effective Application of Information System for Purchase Process Optimization 594
Pearl Keitemoge, Daniel Tetteh Narh

Fast and Efficient Maximum Power Point Tracking Controller for Photovoltaic Modules 606
Khalid Chennoufi, Mohamed Ferfra

Inventory Management Practices during COVID 19 Pandemic to Maintain Liquidity Increasing Customer Service level in an Industrial Products Company in Mexico 613
Ignacio Alvarez-Placencia, Diana Sánchez-Partida, Patricia Cano-Olivos, José-Luis Martínez-Flores

Chatbot Developments in The Business World 627
Azani Cempaka Sari, Natashia Virnilia, Jasmine Tanti Susanto, Kent Anderson Phiedono, Thea Kevin Hartono

Burnout Among Primary School Teachers in the Wazzane Region in Morocco: Prevalence and Risk Factors 636
Abdeslam Amri, Zakaria Abidli, Mounir Bouzaaboul, Rabea Ziri, Ahmed Omar Touhami Ahami

Performance Analysis and Enhancement of Spline Adaptive Filtering based on Adaptive Step-size Variable Leaky Least Mean Square Algorithm 642
Sethakarn Prongnuch, Suchada Sitjongsataporn

Automatic Stochastic Dithering Techniques on GPU: Image Quality and Processing Time Improved 652
Giorgia Franchini, Roberto Cavicchioli, Jia Cheng Hu

Improved System Based on ANFIS for Determining the Degree of Polymerization 664
Marcel Nicola, Marian Du??, Maria-Cristina Ni?u, Ancu?a-Mihaela Aciu, Claudiu-Ionel Nicola

Network Modeling with ANP to Determine the Appropriate Area for the Development of Dry Port in Thailand 676
Jenjira Sukmanee, Ramil Kesvarakul, Nattawut Janthong

Social Influence Factor of e-Tourism Application Case Study University Student 684
Kristianus Oktriono, Surjandy Surjandy, Meyliana Meyliana, Michele Carolina, Stephanie Stephanie

Hand-Based Biometric Recognition Technique – Survey 689
Katerina Prihodova, Miloslav Hub

Automatic License Plate Detection and Recognition for Jordanian Vehicles 699
Khalil Mustafa Ahmad Yousef, Bassam Jamil Mohd, Yusra Abd-Al-Haleem Al-Khalaileh, Ahlam Hani Al-Hmeadat, Bushra Ibrahim El-Ziq

Adaptive Identification Method of Vehicle Model for Autonomous Driving Robust to Environmental Disturbances 710
Yohei Yamauchi, Mitsuyuki Saito

Cognitive Cybernetics in the Foresight of Globalitarianism 718
Zdenko Balaž, Krystian Wawrzynek

Ultra Wide Band-based Control of Emulated Autonomous Vehicles for Collision Avoidance in a Four-Way Intersection 724
Jashandeep Bhuller, Paolo Dela Peña, Vladimir Christian Ocampo II, Julio Simeon, Lawrence Materum

Minimizing Collisions of Self-Driving Cars by a Control System Using Predetermined Two-Dimensional Grid Localization 731
Jashandeep Bhuller, Paolo Dela Peña, Vladimir Christian Ocampo II, Julio Simeon, Lawrence Materum

Comparison of Support Vector Machine-Based Equalizer and Code-Aided Expectation Maximization on Fiber Optic Nonlinearity Compensation Using a Proposed BER Normalized by Power and Distance Index 738
Mark Renier M. Bailon, Lawrence Materum

Analysis of Long-term Equilibrium Relationship Between KRW, RMB, JPY Exchange Rates and International Financial Market Variables: Comparative Analysis of KRW, RMB, JPY 744
Moon-Kyum Kim, Woong Ryeol Kim, Moon-Kyum Kim

Optimization of Multi-user Face Identification Systems in Big Data Environments 762
Majdouline Meddad, Chouaib Moujahdi, Mounia Mikram, Mohammed Rziza

Surge Protection Device for Ex Application 768
Teik Hua Kuan, Kuew Wai Chew, Kein Huat Chua

Optimal Irrigation Strategy using Economic Model Predictive Control 781
Luisella Balbis

Dependency Head Annotation for Myanmar Dependency Treebank 788
Hnin Thu Zar Aye, Win Pa Pa

A Model-Driven Approach for Reconfigurable Systems Development 801
Ismail Ktata, Naoufel Kharroubi

Algorithm Design for Accurate Steps Counting Based on Smartphone Sensors for Indoor Applications 811
Hani Muhsen, Odeh Al-Amaydeh, Rakan Al-Hamlan

Polarity Switch within Social Networks 817
Sara Abas, Malika Addou, Zineb Rachik

Roadmap for Industrial Engineering Education Sustainability Withdrawn
Hani Shafeek

Towards a Smart Campus for Qassim University: An Investigation of Indoor Navigation System 831
Mohammed Hadwan, Rehan Uallah Khan, Khalil Ibrahim Mohammad Abuzanouneh

Effect of Heat Retention Time and Pouring Temperature on Graphite Shape and Mechanical Properties of Gray Cast Iron 838
Hong-Nga Thi Pham

Updated Analysis of Business Continuity Issues Underlying the Certification of Invoicing Software, Considering a Pandemic Scenario 845
Nelson Russo, Leonilde Reis

An Enhanced Conceptual Security Model for Autonomous Vehicles 853
Abdulla Obaid Al Zaabi, Chan Yeob Yeun, Ernesto Damiani, Gaemyoung

Low Power Fast Settling Switched Capacitor PTAT Current Reference Circuit for Low Frequency Applications 865
Muhammed Mansoor C. B., Hanumantha Rao G., Rekha S.

Blockchain Application in Higher Education Diploma Management and Results Analysis 871
Fernando Richter Vidal, Feliz Gouveia, Christophe Soares

Evaluating the Effectiveness of Query-Document Clustering Using the QDSM Measure 883
Claudio Gutierrez-Soto, Marco Palomino, Arturo Curiel, Hector Riquelme Cerda, Fernando Bejar Rain

Method of Analysis and Classification of Acoustic Emission Signals to Identify Pre-Seismic Anomalies 894
Marapulets Yury, Senkevich Yury, Lukovenkova Olga, Solodchuk Alexandra

A Fast Adaptive Time-delay-estimation Sliding Mode Controller for Robot Manipulators 904
Dang Xuan Ba

Investigation of the Effect of FBG Profiles, Temperature and Transmission Distance for Environmental Sensing & Monitoring 912
Muhammad Arif Riza, Yun Ii Go

Barriers and Supports in Engineering Career Development: An Exploration of First-Year Students 920
Rosmery Ramos-Sandoval, Jano Ramos-Diaz

Prediction of Vessel Dynamic Model Parameters using Computational Fluid Dynamics Simulation 926
Nu'man Amri Maliky, Nanda Pratama Putra, Mochamad Teguh Subarkah, Syarif Hidayat

Design and Implementation of DFT Technique to Verify LBIST at RTL Level 937
Nagaraj Vannal, Saroja V Siddamal

Empathy in Nursing Students that do the Non-Medical Internship in Three Universities in Lima, 2019 944
Liseth Acuña-Medina, Yumira Arias-Quispe, Yackeline Espeza-Veláquez, Brian Meneses-Claudio, Hernan Matta-Solis, Eduardo Matta-Solis

Investigating the Optical Behavior of Single/Multi-Dimensional Photonic Crystal Structures for Photovoltaic Applications 951
Gehad Ali Alsayed, Zahraa Ismail, Sameh O. Abdellatif

Standalone Operation of Modified Seven-Level Packed U-Cell Inverter for Solar Photovoltaic System 959
Kishan Bhushan Sahay, Pankaj Kumar Singh, Rakesh Maurya

Hand Gesture Classification using Inaudible Sound with Ensemble Method 967
Jinwon Cheon, Sunwoong Choi

Docker-C2A : Cost-Aware Autoscaler of Docker Containers for Microservicesbased Applications 972
Mohamed Hedi Fourati, Soumaya Marzouk, Mohamed Jmaiel, Tom Guerout

NPC five level inverter using SVPWM for Grid-Connected Hybrid Wind-Photovoltaic Generation System 981
Elamri Oumaymah, Oukassi Abdellah, Bouhali Omar, El Bahir Lhoussain

Mobile Money Wallet Attack Resistance using ID-based Signcryption Cryptosystem with Equality Test 988
Seth Alornyo, Mustapha Adamu Mohammed, Francis Botchey, Collinson Colin M. Agbesi

Advanced Design of Current-mode Pass-band Filter using Ant Colony Optimization Technique 995
Kritele Loubna, Benhala Bachir, Zorkani Izeddine

Feature Gate Computational Top-Down Model for Target Detection 1001
Aarthi Ramachandran, Amudha Joseph, Shunmuga Velayutham

Design of a Remote Real-time Groundwater Level and Water Quality Monitoring System for the Philippine Groundwater Management Plan Project 1007
Carlos M. Oppus, Maria Aileen Leah G. Guzman, Maria Leonora C. Guico, Jose Claro N. Monje, Mark Glenn F. Retirado, John Chris T. Kwong, Genevieve C. Ngo, Annael J. Domingo

Determinants of Technological and Innovation Performance of the Nepalese Cellular Telecommunications Industry from the Customers' Perspective 1013
Rewan Kumar Dahal, Ganesh Bhattarai, Dipendra Karki

An Analysts' Skills: Bespoke Software vs Packaged Software at Small Software Vendors 1021
Issam Jebreen

Ozone, Nitrogen Dioxide, and PM2.5 Measurement at Three Urban Parks in Manila, Philippines using Portable Sensors 1027
Maria Cecilia Galvez, Daniel Paulo Tipan, Angelo Ashtin Valera, Edgar Vallar, Alma Nacua

Evaluation of the Living Condition in Fishermen Settlement in the Coastal Area of Marisa City, Gorontalo Province 1033
Irwan Wunarlan, Sugiono Soetomo, Iwan Rudiarto

Design of a Mobile Application for the School Enrollment Process in Order to Prevent Covid-19 1042
Alexi Delgado, Enrique Lee Huamaní, Alfredo Chiara-Sotomayor, Florencio Roman-Casahuamán

Estimating LAI of Rice Using NDVI Derived from MODIS Surface Reflectance 1047
Rushikesh Kulkarni, Kiyoshi Honda

Developing a Modular Material-Based Independent Training Model for Primary School Teacher Training 1054
Asep Herry Hernawan, Mustari Bosra

Projection of Wireless Multipath Clusters Using Multi-Dimensional Visualization Techniques 1064
Aaron Don M. Africa, Emmanuel T. Trinidad, Lawrence Materum

Review of Different Methods for Optimal Placement of Phasor Measurement Unit on the Power System Network 1071
Ademola Abdulkareem, Divine Ogbe, Tobiloba Somefun

Human Emotion Recognition Based on EEG Signal Using Fast Fourier Transform and K-Nearest Neighbor 1082
Anton Yudhana, Akbar Muslim, Dewi Eko Wati, Intan Puspitasari, Ahmad Azhari, Murein Miksa Mardhia

5G, Vehicle to Everything Communication: Opportunities, Constraints and Future Directions 1089
Boughanja Manale, Tomader Mazri

Development of Secondary Processing Data Methods under Single Point Thunderstorm Activity Monitoring 1096
Anatoly Panyukov, Alexander

Evaluation of the Physico-Chemical Properties of Soil and Apple Leaves (Malus Domestica) in Beni Mellal-Khenifra Region, Morocco 1103
Berrid Nabyl, Lougraimzi Hanane, El-Khabbazi Houda, Abidli Zakaria, Hamidi Otman, Keltoum Rahali, El Mahjoub Aouane

Multi-Criteria Decision Analysis Coupled with GIS and Remote Sensing Techniques for Delineating Suitable Artificial Aquifer Recharge Sites in Tafilalet Plain (Morocco) 1109
Aicha Ousrhire, Hassane Oulidi Jarar, Abdessamad Ghafiri

Support Vector Machine Integrated with SASS-SM Approach for Parkinson's Disease Classification Withdrawn
Kadhem Al-Daffaie, Hadi Ratham Al-Ghayab

Experimental Analysis of Thin Layer Drying of Ginger Rhizome in Convective Environment 1132
Gbasouzor Austin Ikechukwu, Sabuj Mallik, Jude Ejikeme Ebem Njoku, Joshua Depriver

A Novel Approach of Smart Logistics for the Health-Care Sector Using Genetic Algorithm 1143
Marouane EL Midaoui, Mohammed Qbadou, Khalifa Mansouri

The Design of a Hybrid Model-Based Journal Recommendation System 1153
Adewale Opeoluwa Ogunde, Mba Obasi Odim, Oluwabunmi Omobolanle Olaniyan, Theresa Omolayo Ojewumi, Abosede Oyenike Oguntunde, Michael Adebisi Fayemiwo, Toluwase Ayobami Olowookere, Temitope Hannah Bolanle

An Efficient Performance of OFDM-Shaped Symbol for 5G Green Communication Compared to FBMC 1163
Mohamed Yasin Ibrahim Afifi, El-Sayed Soliman Ahmed Said, Abd El-Hady Abd El-Azim Ammar

PV Integrated Recursive Least Mean Square Estimation Based Shunt Active Power Filter 1171
Ragam Rajagopal, K. Palanisamy, S. Paramasivam

Defeating Anti-Debugging Techniques for Malware Analysis Using a Debugger 1178
Jong-Wouk Kim, Jiwon Bang, Mi-Jung Choi

Development of a Technology and Digital Transformation Adoption Framework of the Postal Industry in Southern Africa: From Critical Literature Review to a Theoretical Framework 1190
Kgabo Mokgohloa, Grace Kanakana-Katumba, Rendani Maladzhi

Evolution of Teaching Approaches for Science, Engineering and Technology within an Online Environment: A Review 1207
Rendani Wilson Maladzhi, Grace Mukondeleli Kanakana-Katumba

Development and Performance Analysis of HRPL Using 6LoWPAN CC2538 Module for IoT Ecosystem 1217
Nin Hayati Mohd Yusoff, Nurul Azma Zakaria

Priority-based Scheduling Algorithm for NOMA-integrated V2X 1225
Ala Din Trabelsi, Hend Marouane, Faouzi Zarai

Creativity in Prototypes Design and Sustainability – The case of Social Organizations 1237
Clara Silveira, Leonilde Reis, Vitor Santos, Henrique S. Mamede

Computer Vision for Industrial Robot in Planar Bin Picking Application 1244
Le Duc Hanh, Huynh Buu Tu

Crystallinity and Hardness Enhancement of Polypropylene using Atmospheric Pressure Plasma Discharge Treatment 1250
Oscar Xosocotla, Horacio Martinez, Bernardo Campillo

LEACH Based Protocols: A Survey 1258
Nour Najeeb Abdalkareem Qubbaj, Anas Abu Taleb, Walid Salameh

Towards a Documents Processing Tool using Traceability Information Retrieval and Content Recognition Through Machine Learning in a Big Data Context 1267
Othmane Rahmaoui, Kamal Souali, Mohammed Ouzzif

Time Granularity-based Privacy Protection for Cloud Metering Systems 1278
Hesham Aly El Zouka, Mustafa Mohamed Hosni

Analysis of the Operational Impact of ETC Lanes on Toll Station 1286
Alimam Mohammed Karim, Alimam Mohammed Abdellah, Seghiouer Hamid

Empirical Probability Distributions with Unknown Number of Components 1293
Marcin Kuropatwi´nski, Leonard Sikorski

Basic Study of 3-D Non-Invasive Measurement of Temperature Distribution using Ultrasound Images during HIFU Heating 1306
Ryosuke Sakakibara, Yasuhiro Shindo, Kazuo Kato, Pak Kon Choi, Akira Takeuchi

Wideband Active Switch for Electronic Warfare System Applications 1312
Mahadev Sarkar, Gaurav Anand, Sivakumar Ramadoss

Evaluation of Simple Space Interpolation Methods for the Depth of Precipitation: Application for Boyacá, Colombia 1322
Pedro Mauricio Acosta Castellanos, Alejandra Castro Ortegon, Hugo Fernando Guerrero Sierra

SH-CNN: Shearlet Convolutional Neural Network for Gender Classification 1328
Chaymae Ziani, Abdelalim Sadiq

Quality of Nursing Care in Hospitalized Patients of the Carlos Lanfranco La Hoz Hospital, 2019 1335
Amancio Izquierdo-Príncipe, Jaqueline Garcia-Núñez, Brian Meneses-Claudio, Hernan Solis-Matta, Lourdes Matta-Zamudio

Quality of Life in Patients with Type 2 Diabetes of the Central Hospital of the Peruvian Air Force, 2019 1340
Jared Zavala-Izaguirre, Fanny Mego-Llanos, Sarita Cornejo-Quispitongo, Brian Meneses-Claudio, Hernan Solis-Matta, Lourdes Matta-Zamudio

Social skills and Resilience in Adolescents of Secondary Education of the Kumamoto I 3092 Educational Institution, of the Puente Piedra District – Lima 2019 1345
Evelyn Roncal-Cespedes, Gloria Castillo-Laban, Brian Meneses-Claudio, Hernan Matta-Solis, Lourdes Matta-Zamudio, Eduardo Matta-Solis

Social Skills and Resilience in Adolescents of an Educational Institution in North Lima, 2019 1350
Lili Sifuentes-Gomez, Doris Vega-Davila, Betty Flores-Paz, Brian Meneses-Claudio, Hernan Matta-Solis, Eduardo Matta-Solis

Improved Design and Recommendations for Street Lighting in Gitega City 1356
Ntawuhorakomeye Noel, Ndayiragije Leonidas, Belov Mikhail Petrovich

Investigating Students' Computational Thinking through STEM Robot-based Learning Activities 1366
Sasithorn Chookaew, Suppachai Howimanporn, Santi Hutamarn

Effect of Starch Oxidation Degree on the Properties of Hydrogels from Dialdehyde Starch and Polyvinyl Alcohol 1372
Jahel Desire Carrera, Daniela Alejandra Viteri Narváez, Marco Leon, José Francisco Alvarez-Barreto

Image Tag Recommendation based on Ranked Categorical Nearest Neighbors and Weighted Tag Features 1381
Anupama D. Dondekar, Balwant A. Sonkamble

Analysis of Physical and Mechanical Properties of Galvanic-Plasma Wear-Resistant Coatings 1387
Mahmood Shaker Albdeiri, Sergey Sergeev, Vladimir V. Krasilnikov

A prediction of Cutting Force, System Vibration, and Productivity in Five-Axis Milling Process of the Spiral Bevel Gear 1394
Nguyen Van Thien, Dung Hoang Tien, Nhu-Tung Nguyen, Nguyen Van Que, Do Duc Trung, Pham Thi Thieu Thoa

A Study on the Tool Wear in Milling Process of the Gleason Spiral Bevel Gear 1402
Hoang Xuan Thinh, Pham Van Dong, Tran Ve Quoc

Recommendation System for SmartMart-A Virtual Supermarket 1408
Poonam Ghuli, Manoj Kartik R, Mohammed Amaan, Mridul Mohta, N Kruthik Bhushan, Poonam Ghuli, Shobha G

Solution of the Semiconductor-Device Equations by the Numerov Process 1414
Nicol`o Speciale, Rossella Brunetti, Massimo Rudan

Handling Priority Data in Smart Transportation System by using Support Vector Machine Algorithm 1422
Sara Ftaimi, Tomader Mazri

Fabrication and Optimization of High Frequency ZnO Transducers for Both Longitudinal and Shear Emission: Application of Viscosity Measurement using Ultrasound 1428
Hatem Dahmani, Ibrahim Zaaroura, Abbas Salhab, Pierre Campistron, Julien Carlier, Malika Toubal, Souad Harmand, Vincent Thomy, Marc Neyens, Bertrand Nongaillard

Parameter Estimation for Industrial Robot Manipulators Using an Improved Particle Swarm Optimization Algorithm with Gaussian Mutation and Archived Elite Learning 1436
Abubakar Umar, Zhanqun Shi, Lin Zheng, Alhadi Khlil, Zulfiqar Ibrahim Bibi Farouk

Comparative Study Between Three Methods for Optimizing the Power Produced from Photovoltaic Generator 1458
El hadji Mbaye Ndiaye, Mactar Faye, Alphousseyni Ndiaye

An Investigation of the Effect of Optimal Plane Spacing Between Electrode Planes for the EIT Industrial Applications 1466
Yew Lek Chong, Renee Ka Yin Chin

Social Engineering to Establish Digital Culture in Higher Education 1474
Tedi Priatna, Dian Sa'adillah Maylawati, Hamdan Sugilar, Muhammad Ali Ramdhani

Simulation Based Energy Consumption Optimization for Buildings by Using Various Energy Saving Methods 1480

Dual semigroup
Asynchronous exponential growth

ABSTRACT

In this paper we study a cell division cycle modeled by a system of partial differential equations with an age structure. This model translates the many regulatory mechanisms within the cell cycle where it introduces the notion of phases. The individual cell can be either in I phases where the transition between theses phases are ordered and unidirectional. The model is related to the suns and stars caluculus via the dual semigroups of operators that are considered as solution of an abstract integral equation equivalent to a Volterra type equation of the form $w(t) = \Phi(w_t)$. We will determine the core operator Φ and prove that the semigroup solution of the model possesses the asynchronous exponential property. The model permits different types of controls where the provided framework allows better control on the model parameters and yields the characterization of the intrinsic rate of natural increase through properties of the core operator Φ. Finally, we demonstrate that the asymptotic behavior of the model is governed by the simple dominant eigenvalue and its associated eigenvector, that leads to the dispersion of the cell structure through the future generations.

1 Introduction

This paper is considered as an extension of the work originally presented in 2019 International Conference of Computer Science and Renewable Energies ICCSRE [1], that represents more refined work where we investigated the long time behavior of a cell cycle model using a well founded mathematical theory.
The cell cycle is an ordered set of molecular events that a cell undergoes until it divides into two daughter cells. It has been recognized that the cell cycle can be divided into two major phase: The interphase and the mitosis phase denoted by M. The interphase is commonly composed of three phases : G_1, S, and G_2. It is the longest part of the cell cycle and is devoted to duplication of the cell's component. During the S phase, the chromosomes are duplicated. It is known that throughout the M phase, the cell split, producing two daughter cells [2]. In each phase the progression in the division cycle is reglemented by a serial of molecular regulation events which are ordered, directional and punctuated by checkpoints. These latter make use of some protein dephosphorylation and degradation where they are under control of the molecular circadian clocks. In fact, several animal experiments showed that the role of these clocks are essential to exert a rhythmic regulating control of each step [3], [4]. These steps are intracellular cascades which ensures the smooth conduct of the proliferation. The extracellular factors such growth factors play an important role in the controling strategy which ensures the environmental requirements are adapted to the proliferation of the cell. Thus, the regulation of the cell cycle is a crucial process to the survival of the cell. It is known that there exists two key classes of regulatory molecules: cyclins (regulatory subunits) and cyclin dependent kinases (catalytic subunits) denoted by CDKs where through phosphorylation activates or inactivates target proteins to permit entry in the next phase of the cell cycle.

Through the cell cycle, there exists different restriction points. The first one is called start checkpoint. It regulates the progression in the G1 phase. The transition from G_1 to S is regulated by CDK4/cyclin D and CDK6/cyclin D where CDK is expressed in cells and cyclin D is synthesized due to the growth factors. Various cyclins are produced at each phase: S, G_2 and M, resulting in the periodic formation of distinct combinations of cyclin-CDK complexes that trigger the cell cycle events [2, 5].

These various mechanisms of regulation are showed to be inefficient in cancer cells. In addition, the disruption of circadian clocks is showed to enhance the tumour growth [6]–[8]. In fact, the circadian rhythms play an important role in the cell cycle control where they contribute to the cell cycle regulation by the synchronisation of the

*Corresponding Author: Youssef EL ALAOUI, is.youssefelalaoui@gmail.com

control system. However, these dynamics have still to be understood and investigated. Further, various speculation tried to explain this phenomenon which give rise to the concept of synchronisation, that is, to the speculation that less synchronised phases are within cell population, the faster is proliferation. It is known that circadian proteins control CDKs and theses latter control phase transitions. In the following, we want to investigate the question if circadian clocks control the proliferation of the cell population.

The paper is concerned with a system of partial differential equations (PDE) describing the case of a multi transition phases cycle [9] in which cells can transit from one phase to the next one. The cell cycle is assumed to be divided into I different phases where the individual cell can be distinguished from one another according to their age a. These cells can growth, die and transit to the next phase where the rates describing the associated physiological process depend only on the cell's age. Then, the model read as follows (see figure 1)

$$\begin{aligned} &\frac{\partial}{\partial t}p_i(t,a)+\frac{\partial}{\partial a}p_i(t,a)=-\mu_i(a)p_i(t,a)-\mathcal{K}_{i\to i+1}(a)p_i(t,a)\\ &p_i(t,0)=\int_0^\infty \mathcal{K}_{i-1\to i}(a)p_{i-1}(t,a)da \quad \text{for } 2\le i\le I \\ &p_1(t,0)=2\int_0^\infty \mathcal{K}_{I\to 1}(a)p_I(t,a)da \end{aligned} \tag{1}$$

Here $p_i(t,a)$ is the density of the population of cells at the i^{th} phase of age a at the instant t, that is, $\int_{a_1}^{a_2} p_i(t,a)da$ is the number of cells at the i^{th} phase with an age in the interval (a_1,a_2) at the instant t. The transition from the state i to the state j is given by the rate $\mathcal{K}_{i\to j}(a)$, that is $\mathcal{K}_{i\to j}(a)dt$ is the probability that a cell having an age a at instant t in the phase i transit in the time interval $(t,t+dt)$ to the phase j, in which they start with age 0, the last phase when $i=I$ refer to mitosis as it is expressed by the boundary conditions in (1). At the i^{th} state, the cells go to apoptosis at the rate $\mu_i(a)$, that is $\mu_i(a)dt$ is the probability that a cell having age a at instant t die in the time interval $(t,t+dt)$ in the phase i. Since the effective separation of the mother cell into two daughter cells, that is, since the cell birth, the individual cell can quantitated by a continuous variable corresponding to cell age.

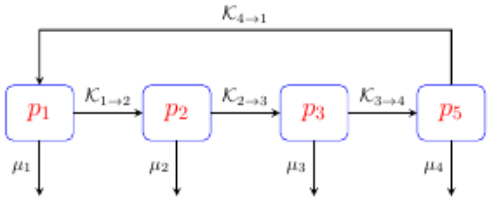

Figure 1: Flow chart of the model describing the evolution of cells along each phase of the cycle and the transition to the next phase between the cell densities. Here I=4, this corresponds to G1-S-G2-M.

It is known that cells transit through the cell cycle with variability in intermitotic times which correspond to different biological processes such the proteic (G_1 phase) or DNA (S phase) or microtuble (M phase) synthesis . As contrary to the model given in [9], the progression speed is assumed to be constant, that is one does not take into account the external growth factors. Indeed, the progression speed can be enhanced by the external growth factors in the early of the G_1 phase.

The authors in [9]–[16] considered a partial differential equations modeling a proliferating cell population with taking into consideration their external controls which can be hormonal, circadian, pharmacological . . . that leads to investigate the consequences of a periodic control on these models. Their results assert that the effect of circadian control on tumour proliferation is indirect.

Here, the death rates are supposed only age dependent. However, the case time-periodic death rates studied in [10, 11], using the Floquet theory, had shown a higher first eigenvalue and thus enhanced proliferation of the population.

For the one phase cell transition model [16, 17], it has been proved that if we influence the cell cycle with some control of a periodic function, we obtain that cells with cell cycle duration slightly lower than the control function period are selectively more advantageous, in addition, they hypothetize that the effect of disruption of circadian rhythms on tumour growth enhancement is indirect. The model for I phases was first introduced in [9], where the authors studied the long time behaviour of this model with the effect of a circadian control using an entropy method. Their results show that it imposes a circadian rythm to the cell cycle.

Mathematical cell cycle models have been treated since the 1960s by authors such as Fredrickson, Bell, Sinko and Streifer. These models were traditionally formulated as partial differential equations for the age and/or size distribution of the cell population. Diekmann et al. [18] used semigroup methods to give conditions for when there is, and also when there is not, asynchronous exponential growth of the population in a constant environment. More recently, Diekmann and coworkers have argued in favour of using (abstract) integral equations for the birth rate instead of PDE, also, and in particular, for the nonlinear models resulting from interaction via the environment.

The purpose of this paper is to create a mathematical framework for the analysis of this type of models by using the theoretically well established semigroup method based on the suns and stars calulcus using the perturbed dual semigroups of operators on the spaces of the form $\mathcal{E}:=L^1((-h,0),\mathcal{F})$. These semigroups are solutions of the integral equation [19]–[21] of the type :

$$p(t)=P_0(t)f+\int_0^t P_0^{\odot *}(t-\tau)\Phi(p(\tau))d\tau, \quad \text{for } t\ge 0 \tag{2}$$

where $h>0$, $\mathcal{F}$ is a Banach space and $\Phi:\mathcal{E}\to\mathcal{Z}$ and $\mathcal{Z}$ is some bigger Banach space. It has been proved that this method is well suited for applications, in particular in the field of cell biology models [22, 23].

In the following, the main result is to provide necessary and sufficient conditions on the parameters building the cell division cycle model (1) in order to yield the property of asynchronous exponential growth.The asynchronous exponential property is explained mathematically by the fact that a simple dominant eigenvalue govern the spectrum of the infinitesimal generator of the semigroup solution of the model. In the context of the semigroup theory, this operator will be the associated infinitesimal generator. We can say that the asynchronous exponential growth occurs when the following estimate $\|e^{-\lambda_0 t}p(t,\cdot)-\mathcal{P}p_0\|$ decreases to 0 exponentially as t tends to infinity, where the vector population is defined by $p(t,a)=(p_i(t,a))_{1\le i\le I}^{tr}$ and $p_0(a)$ is the initial given distribution of the population. This latter

means that when the cell population is multiplied by an exponential factor, know an asymptotic stabilization around a unidimensional projection. It is noted that this projection is only dependent on the initial structure of the concerned population.
We will use the theory developed in the works [19]–[21] to exhibit the link between the solutions of the model and the perturbed dual semigroups. First, we determine the operator Φ. Secondly, we derive different results, only based on the properties of the operator Φ ranging from existence to qualitative properties and particulary give a characterization of the Malthusian parameter as a spectral radius of some bounded operator.
Throughout this paper, the two parameters $\mathcal{K}_{i\to j}(a)$ and $\mu_i(a)$ are supposed to satisfy the assumption

$\left(\mathbf{H}_{\mathcal{K},\mu}\right)$: (1) The rates $\mathcal{K}_{i\to j}, \mu_i$ defined from $(0,\bar{a})$ to $\mathbb{R}$ are continuous.
(2) $\mathcal{K}, \mu \in L^\infty((0,\bar{a}),\mathbb{R})$ such that there exists $0 < \bar{\mathcal{K}} < \infty$ where $0 < \mathcal{K}_{i\to j}(a) \le \bar{\mathcal{K}}$ and$\mathcal{K} \not\equiv 0$ in addition there exists $\bar{\mu} > 0$ such that $0 \le \mu_i \le \bar{\mu}$

2 Well posedness

In this section, the mathematical analysis of the multi phases proliferating cell cycle model will be provided using the theory developed for the perturbed dual semigroups [24]–[27] associated to the equation of Volterra type :

$$p(t) = \phi(p_t) \tag{3}$$

where the Hale notation $p_t(s) := p(t+s)$ is used (see [28]–[35]), and the operator $\phi : \mathcal{E} := L^1((-h,0),\mathcal{F}) \to \mathcal{F}$. Our construction will permit to link the solutions of the model (1) to the solutions of the integral equation

$$p(t) = P_0(t)f + j^{-1}\left(\int_0^t P_0^{\odot *}(t-s)\Phi(p(s))ds\right) \tag{4}$$

where P_0 satisfies the properties of a semigroup of bounded linear operators on $\mathcal{E}$ with $\mathcal{E}^\odot \subset \mathcal{E}^*(\subset$ stands as the linear subspace) on which P_0^* yields the strong continuity, that is,

$$\mathcal{E}^\odot = \{f^* \in \mathcal{E}^* : \lim_{t\downarrow 0}\|P^*(t)f^* - f^*\| = 0\}$$

It can be shown that this subspace is closed in the norm topology of $\mathcal{E}^*$ and weak* dense subspace on $\mathcal{E}^*$ [24]. In addition, the semigroup on $\mathcal{E}^\odot$ is denoted by $P_0^\odot := P_0^*|_{\mathcal{E}^\odot}$. It is obvious that this restriction build a semigroup that is strongly continuous on the subspace $\mathcal{E}^\odot$. Since we consider an element of $\mathcal{E}$ as a bounded linear functional on $\mathcal{E}^\odot$. We can embed $\mathcal{E}$ into $\mathcal{E}^{\odot *}$ via the map q of $\mathcal{E}$ into $\mathcal{E}^{\odot *}$ defined by :

$$< f^\odot, qf >=< f, f^\odot >, \qquad \text{for } f \in \mathcal{E}, f^\odot \in \mathcal{E}^\odot$$

It is obvious that $q(\mathcal{E}) \subset \mathcal{E}^{\odot\odot}$. When $q(\mathcal{E}) = \mathcal{E}^{\odot\odot}$ then $\mathcal{E}$ is said to be $\odot$-reflexive with respect to $P(t)$.

Go back to the study of the model (1). The state space considered is $\mathcal{E} := L^1([0,\tilde{a}],\mathbb{R}^I)$. The parameter $\tilde{a} > 0$ is the maximal age that an individual cell can attain. This space is endowed with norm

$$\|f\|_{\mathcal{E}} = \int_0^{\tilde{a}} \|f(a)\|_{\mathbb{R}^I} da, \qquad f \in \mathcal{E}$$

Next, we introduce the operator $\chi(a)$ that yields the equation

$$\begin{aligned} \chi'(a) &= -\chi(a)\mathcal{M}(a) \\ \chi(0) &= Id(\text{ stands for identity}) \end{aligned} \tag{5}$$

with

$$\mathcal{M}(a) = \mathrm{Dg}\,(m_{i,i}(a))_i \qquad 1 \le i \le I \tag{6}$$

where Dg stands for the diagonal matrix and the entries of the matrix $\mathcal{M}$ hold

$$m_{i,j}(a) := \begin{cases} \mu_i(a) + \psi_{i\to i+1}(a) & \text{if } i = j \\ 0 & \text{else} \end{cases} \tag{7}$$

The aim of the introduction of this transformation is to demonstrate that $\{P(t)\}_{t\ge 0}$ the semigroup solution of the model (1) is equivalent to $(P_\phi(t))_{t\ge 0}$ the semigroup solution of (4). Thus, via this machinery and under the properties of the operator ϕ, we will establish the asynchronous exponential property only by handling with the equivalent semigroup and go back to the original one by using the cited transformation.
Before going to give the main results, we need some settings. First, let set $p(t,a) := (p_i(t,a))_{1\le i\le I}^{tr}$. So via this vector, our initial model (1) can be reformulated as an vector type Mckendrick Von Foerster model

$$\frac{\partial}{\partial t}p(t,a) + \frac{\partial}{\partial a}p(t,a) = -\mathcal{M}(a)p(t,a) \tag{8}$$

with the boundary condition at age 0

$$p(t,0) = \int_0^{\tilde{a}} \mathcal{B}(a)p(t,a)da \tag{9}$$

The matrix $\mathcal{M}$ is given above by (6) and (7) and the matrix $\mathcal{B}$ is given by

$$B(a) = \begin{pmatrix} 0 & 0 & 0 & \cdots & 0 & 2K_{I\to 1} \\ K_{1\to 2} & 0 & 0 & \cdots & 0 & 0 \\ 0 & K_{2\to 3} & 0 & \cdots & 0 & 0 \\ \vdots & 0 & \ddots & \ddots & \vdots & \vdots \\ \vdots & & \ddots & \ddots & 0 & \vdots \\ 0 & \cdots & \cdots & 0 & K_{I-1\to I} & 0 \end{pmatrix}$$

After we gave a compact form to the original model (1). Now, we consider the transformation

$$m(t,.) := \Gamma p(t,.) \tag{10}$$

where $(\Gamma g)(a) := \chi(a)g(a)$ with $a \in (0,\bar{a})$ and the operator χ satisfies the first order differential equation (5). Via this latter, we arrive at the equivalent system where it is more easily to handle than the original one (8). The model is formulated as given

$$\begin{aligned} \frac{\partial}{\partial t}m(t,a) + \frac{\partial}{\partial a}m(t,a) &= 0 \\ m(t,0) &= \int_0^{\tilde{a}} \theta(a)m(t,a)da \end{aligned} \tag{11}$$

The kernel θ is given by

$$\theta(a) = \mathcal{B}(a)\chi^{-1}(a), \quad \text{for } a \in (0,\tilde{a}) \tag{12}$$

The diagonal matrix χ^{-1} is given by

$$\chi^{-1}(a) = \mathrm{Dg}\left(\tilde{z}_{i,i}(a)\right)$$
$$\tilde{z}_{i,j} := \begin{cases} e^{-\int_0^a m_{i,i}(\tau)d\tau} & \text{if } i = j \\ 0 & \text{else} \end{cases} \tag{13}$$

Definition 2.1 *The strongly continuous semigroup $\{P(t)\}$ is said to be a translation semigroup on $L^1((-r,0),\mathcal{F})$ with $r > 0$ and $\mathcal{F}$ is a Banach space if the following $(P(t)f)(x) = f(x+t)$ is satisfied when $x + t < 0$.*

Diekmann et al. have demonstrated in [20] that the space $\mathcal{E}$ is $\odot$-reflexive with respect to P_0, where the operator P_0 is defined as the translation semigroup to the right and 0 on $\mathbb{R}^+$. Its generator $\mathcal{A}_0$ is given by

$$\mathcal{D}(\mathcal{A}_0) = \{f \in \mathcal{E} : f \in AC \text{ and } f(0) = 0\}$$
$$\mathcal{A}_0 f = -f'$$

where AC stands for the absolutely continuous space. We have the following identification (see [19] and [20])

$$L^1([0,\bar{a}],\mathbb{R}^I)^{\odot} \to C_0((-\tilde{a},0],\mathbb{R}^I)$$
$$L^1([0,\bar{a}],\mathbb{R}^I)^{\odot *} \to \mathrm{NBV}([0,\tilde{a});\mathbb{R}^I)$$

The semigroup $P_0^{\odot *}$ is the translation to the right and 0 on $\mathbb{R}^+$. Its generator $\mathcal{A}_0^{\odot *}$ is given by

$$\mathcal{D}(\mathcal{A}_0^{\odot *}) = \{f^{\odot *} \in \mathcal{E}^{\odot *} : f^{\odot *}(a) = \int_0^a g(s)ds \text{ and } g \in \mathcal{E}^{\odot *}\}$$
$$\mathcal{A}_0^{\odot *} f^{\odot *} = -f^{\odot *} = g$$

Using integration and the natural embedding q from $\mathcal{E}$ into $\mathcal{E}^{\odot *}$ and taking into account the boundary condition, we arrive at

$$m(t) = P_0(t)g + q^{-1}\int_0^t P_0^{\odot *}(t-s)\Phi(m(s))ds \tag{14}$$

where the core operator Φ defined from $\mathcal{E}$ to $\mathcal{E}^{\odot *}$ is given as a perturbation with finite dimensional range

$$\Phi(g) = \phi_1(g)\mathcal{H}_1 + \phi_2(g)\mathcal{H}_2 + \ldots + \phi_I(g)\mathcal{H}_I \tag{15}$$

The Heaviside function $\mathcal{H}_i$ is given by $\mathcal{H}_i(a) = e_i$ if $a \in (0,\tilde{a})$ else $\mathcal{H}_i(a) = 0$ where $\{e_1, e_2, \ldots, e_I\}$ is the canonical basis of $\mathbb{R}^I$. The canonical injection q is defined by $(qx)(a) = \int_0^a x(s)ds,\ s \in [0,\tilde{a})$ where the inverse is clearly differentiation.
The operator given in (11) is defined from $\mathcal{E}$ to $\mathbb{R}^I$ and it is given by the integral formula

$$\Phi g = \int_0^{\tilde{a}} \theta(s)g(s)ds \tag{16}$$

the kernel θ is given by (12). In the following, we adopt the following Hale notation

$$m_t(a) := m(t-a), \quad \text{for all } a \in [0,\tilde{a}]$$

with

$$m_0(a) = g(a) \qquad a \in [0,\tilde{a}] \tag{17}$$

In fact, the solutions of the formulation given by the integral equation (14) is proven to be equivalent to the solutions of the renewal equation [20]

$$\begin{aligned} m(t) &= \Phi(m_t), \quad \text{for } t > 0 \\ m_0(a) &= g(a), \quad a \in [0,\tilde{a}] \end{aligned} \tag{18}$$

where the latter generates a translation semigroup [28] given by

$$\mathcal{T}_\Phi g(a) = \begin{cases} g(a-t) & \text{if } a - t > 0 \\ \Phi(\mathcal{T}_\Phi(t-a)g) & \text{if } a - t \le 0 \end{cases}$$

The following result gives us the existence and uniqueness of the perturbed semigroup solution of the abstract integral equation (14)

Theorem 2.2 *Since the assumption $(\mathbf{H}_{\mathcal{K},\mu})$ holds. We obtain that $\phi \in \mathcal{L}(\mathcal{E},\mathcal{F})$. Then for the initial data $g \in \mathcal{E}$, the equation (14) has unique solution $m(t)$ on $[0,T)$ for some positive real number T where the operator $\mathcal{A}_\phi$ characterized as the following*

$$\begin{aligned} \mathcal{D}(\mathcal{A}_\phi) &= \{\varphi \in W^{1,1}((0,\bar{a}),\mathbb{R}^I), \varphi(0) = \phi\varphi\} \\ \mathcal{A}_\phi\varphi &= -\varphi', \qquad \varphi \in \mathcal{D}(\mathcal{A}_\phi) \end{aligned} \tag{19}$$

is the inifinitesimal generator of the semigroup P_ϕ on $\mathcal{E}$.

Proof. The hypothesis given by $(\mathbf{H}_{\mathcal{K},\mu})$ allows to us to obtain the first assertion about the boundedness of ϕ. Then, by using regular arguments on contraction mapping theory, we obtain the existence of the perturbed semigroup $(P_\phi(t))_{t\ge 0}$ solution of (14) on $\mathcal{E}$. □

3 Compactness and irreducibility

It is known that the eventual compactness result is often used to determine the asymptotic behavior of semigroups. In fact, it implies that the growth bound of the semigroup denoted by $\omega(T(t))$ equals the spectral bound denoted by $s(A)$, where

$$\omega(T) = \inf\{w : \|T(t)\| \le Me^{wt}, M \ge 0\}$$

and

$$s(A) = \begin{cases} \sup\{\Re e\lambda : \lambda \in \sigma(A)\} & \text{if } \sigma(A) \ne \emptyset \\ -\infty & \text{if } \sigma(A) = \emptyset \end{cases}$$

Definition 3.1 *We say that the semigroup $\{P(t)\}_{t\ge 0}$ is eventually compact if for some $t_0 \ge 0$ the operators $P(t)$ are compact for all $t \ge t_0$.*

We will give a criterion to obtain the compactness of the semigroup.

Lemma 3.2 *Since $\Phi \in \mathcal{L}(\mathcal{X},\mathbb{R}^I)$ is with finite Range. The semigroup $\{P(t)\}_{t\ge 0}$ given by (14) is eventually compact.*

Proof. The core operator Φ is spanned by the linearly independent set $\{\mathcal{H}_i\}_{1\le i\le I}$ in $\mathcal{X}^{\odot *}$, that is, Φ is with Range$(\Phi) < \infty$, where the core operator Φ takes the form given by (15). We know that there exists $\Phi_i^* \in L^\infty([-\tilde{a},0],\mathbb{R}^I)$ such that :

$$\Phi_i(\zeta) = \int_0^{\tilde{a}} < \zeta(a), \Phi_i^*(-a) > da, \qquad \forall \zeta \in \mathcal{X}$$

We conclude that :

$$\Phi(\zeta) = \sum_{i=1}^{n} \int_0^{\tilde{a}} < \zeta(a), \Phi_i^*(-a) > \mathcal{H}_i da, \qquad \forall \zeta \in \mathcal{X}$$

Let $t > 2\tilde{a}$, we have $\forall \tau, \tau' \in [0, \tilde{a}],\ \tau' < \tau$ for all f in the unit ball of $\mathcal{X}$. Then,

$$\begin{aligned}
&\|[P(t)\zeta](\tau) - [P(t)\zeta](\tau')\|_{\mathbb{R}^n} \\
&= \|q^{-1} \int_0^t P_0^{\odot *}(t-s) \left\{ (\Phi(P(s)\zeta)ds)(\tau) - (\Phi(P(s)\zeta)ds)(\tau') \right\} \|_{\mathbb{R}^n} \\
&= \|q^{-1} \left(- \int_{t-\max\{t,\tau\}}^{t} \Phi(P(s)\zeta)ds + \int_{t-\max\{t,\tau'\}}^{t} \Phi(P(s)\zeta)ds \right) \|_{\mathbb{R}^n} \\
&= \|q^{-1} \left(\int_{t-\max\{t,\tau'\}}^{t-\max\{t,\tau\}} \Phi(P(s)\zeta)ds \right) \|_{\mathbb{R}^n} \\
&= \|q^{-1} \left(\sum_{i=1}^{n} \int_0^{\tilde{a}} \int_{t-\max\{t,\tau'\}}^{t-\max\{t,\tau\}} < P(s)\zeta(a), \Phi_i^*(-a) > \mathcal{H}_i ds\, da \right) \|_{\mathbb{R}^n} \\
&= \|q^{-1} \left(\sum_{i=1}^{n} \int_0^{\tilde{a}} \int_{t-\max\{t,a+\tau'\}}^{t-\max\{t,a+\tau\}} < \Phi(P(s)\zeta), \Phi_i^*(-a) > \mathcal{H}_i ds\, da \right) \|_{\mathbb{R}^n}
\end{aligned}$$

Let $\alpha_1 = t - \tau$ and $\alpha_2 = t - \tau'$

$$\begin{aligned}
&\|[P(t)\zeta](\tau) - [P(t)\zeta](\tau')\|_{\mathbb{R}^n} \\
&= \|q^{-1} \left(\sum_{i=1}^{n} \int_{\alpha_1}^{\tilde{a}+\alpha_1} \int_0^a < \Phi(P(s)\zeta), \Phi_i^*(\alpha_1 - a) > \mathcal{H}_i ds\, da \right. \\
&\left. - \sum_{i=1}^{n} \int_{\alpha_2}^{\tilde{a}+\alpha_2} \int_0^a < \Phi(P(s)\zeta), \Phi_i^*(\alpha_2 - a) > \mathcal{H}_i ds\, da \right) \|_{\mathbb{R}^n} \\
&= \|q^{-1} \left(\sum_{i,j=1}^{n} \int_{\alpha_1}^{\tilde{a}+\alpha_1} \int_0^a < \Phi_j(P(s)\zeta)\mathcal{H}_j, \Phi_i^*(\alpha_1 - a) > \mathcal{H}_i ds\, da \right. \\
&\left. - \sum_{i,j=1}^{n} \int_{\alpha_2}^{\tilde{a}+\alpha_2} \int_0^a < \Phi_j(P(s)\zeta)\mathcal{H}_j, \Phi_i^*(\alpha_2 - a) > \mathcal{H}_i ds\, da \right) \|_{\mathbb{R}^n} \\
&= \|q^{-1} \left(\sum_{i,j=1}^{n} \int_0^a \left\{ \int_{\alpha_2}^{\tilde{a}+\alpha_2} < \Phi_j(P(s)\zeta)\mathcal{H}_j, \Phi_i^*(\alpha_1 - a) - \Phi_i^*(\alpha_2 - a) > \right. \right. \\
&\mathcal{H}_i da + \int_{\alpha_1}^{\alpha_2} < \Phi_j(P(s)\zeta)\mathcal{H}_j, \Phi_i^*(\alpha_2 - a) > \mathcal{H}_i da \\
&\left. \left. + \int_{\tilde{a}+\alpha_1}^{\tilde{a}+\alpha_2} < \Phi_j(P(s)\zeta)\mathcal{H}_j, \Phi_i^*(\alpha_2 - a) > \mathcal{H}_i da \right\} ds \right) \|_{\mathbb{R}^n} \\
&\leq \sup_{1 \leq i,j \leq n} \|\mathcal{H}_i\| \|\mathcal{H}_j\| \sum_{i,j=1}^{n} \left(\sup_{0 \leq s \leq 2\tilde{a}} |\Phi_j(P(s))\zeta)| \times \right. \\
&\left\{ \int_{\alpha_2}^{\alpha_2+\tilde{a}} |\Phi_j^*(\alpha_1 - a) - \Phi_j^*(\alpha_2 - a)| da + \int_{\alpha_1}^{\alpha_2} |\Phi_i^*(\alpha_2 - a)| da \right. \\
&\left. \left. + \int_{\tilde{a}+\alpha_1}^{\tilde{a}+\alpha_2} |\Phi_i^*(\alpha_2 - a)| da \right\} \right)
\end{aligned}$$

Hence, we obtain that $\{P(t)\zeta\}_{t\geq 0}$ is equicontinuous since $|\alpha_2 - \alpha_1|$ tends to zero uniformly for ζ in the unit ball of $C([0, \tilde{a}], \mathbb{R}^n)$. The rest of the proof is due to applying a famous result of Arzela-Ascoli, we obtain then that $\{P(t)\}_{t\geq 0}$ is eventually compact. □

Proposition 3.3 *Let assume that* $(\mathbf{H}_{\mathcal{K},\mu})$ *is satisfied. Then the strongly continuous semigroup P and* $\mathcal{T}_\Phi$ *are eventually compact.*

Proof. The core operator Φ given by the formula (15) is a perturbation of finite rank. Then by using the following result [35, Proposition 4], we obtain the eventual compactness of the semigroup solution $\{T_\Phi(t)\}_{t\geq 0}$. The perturbed semigroup $\{W(t)\}_{t\geq 0}$ is eventually compact by applying the result in Lemma3.2. □
In the follwing we define the family $(\tilde{\Psi}_\lambda)_{\lambda\in\mathbb{C}}$ of operators such that their entries are defined by

$$\tilde{\Psi}_{\lambda,i,j} := < \nabla_{\lambda,j}, \nabla_i^* >, \quad \lambda \in \rho(\mathcal{A}_0) \tag{20}$$

with

$$\nabla_{\lambda,i} = q^{-1} R(\lambda, \mathcal{A}_0^{\odot *}) \nabla_i^{\odot *}, \quad \lambda \in \rho(\mathcal{A}_0)$$
$$\{\nabla_i^{\odot *}\}_{1\leq i\leq I} \text{ is a linearly independent set in } \mathcal{X}^{\odot *}$$

If we adopt this formulation to the integral equation given by (14) such that

$$\begin{aligned}
\nabla_i^{\odot *} &= \mathcal{H}_i \\
\nabla_{\lambda,j} &= \left(q^{-1} R(\lambda, \mathcal{A}_0^{\odot *}) \mathcal{H}_j \right)(s) = e^{\lambda s} e_j \\
\nabla_i^* &= \Theta_{i,j}
\end{aligned}$$

where Θ is given by

$$\begin{pmatrix}
0 & 0 & \cdots & 0 & 2\psi_{I\to 1}\bar{z}_{I,I} \\
\psi_{1\to 2}\bar{z}_{1,1} & 0 & \cdots & \cdots & 0 \\
0 & \psi_{2\to 3}\bar{z}_{2,2} & \ddots & & \vdots \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
0 & \cdots & 0 & \psi_{I-1\to I}\bar{z}_{I-1,I} & 0
\end{pmatrix}$$

Therefore we obtain

$$\tilde{\Psi}_\lambda x = \Phi(e^{\lambda \cdot} \otimes x) \quad \text{for } x \in \mathbb{R}^I$$

where the relation $\otimes$ is defined by

$$(e^{\lambda \cdot} \otimes x)(s) := e^{\lambda s} x \quad \text{for } s \in \mathbb{R}.$$

Next we will give a characterization of the spectrum of the infinitesimal generator $\mathcal{A}_\Phi$ associated to the perturbed semigroup W_Φ by using the family of operators defined above. This characterization permits to show that the spectrum is a point spectrum and there exists a characteristic equation, the roots of which are the eigenvalue of the infinitesimal generator of the associated perturbed semigroup. Furthemore, we will give a criterion which assure the simplicity of these eigenvalues.

Proposition 3.4 *λ belongs to $\sigma(\mathcal{A}_\Phi)$ if and only if λ belongs to $\sigma_p(\mathcal{A}_\Phi)$ if and only if*

$$\prod_{i=1}^{I} \int_0^{\tilde{a}} \exp\left(- \int_0^x \lambda + m_i(\tau) d\tau \right) \mathcal{K}_{i\to i+1}(x) dx = \frac{1}{2} \tag{21}$$

Proof. By transforming the integral equation (14) using the Laplace transformation, we obtain the following resolvent equation

$$(I - q^{-1} R(\lambda, \mathcal{A}_0^{\odot *})\Phi) R(\lambda, \mathcal{A}) = R(\lambda, \mathcal{A}_0), \text{ for } \lambda \in \rho(\mathcal{A}_0)$$

Then it is clear that λ belongs to the spectrum of $\mathcal{A}_\Phi$ if and only if the operator $I - q^{-1} R(\lambda, \mathcal{A}_0^{\odot *})\Phi$ is not invertible. By straightforward computation it is turn out that it is satisfied if and only if $\det(\mathbb{I} - \tilde{\Psi}_\lambda) = 0$ that is equivalent to the assertion (21) since the term $q^{-1} R(\lambda, \mathcal{A}_0^{\odot *})\Phi$ is bounded and $\sigma(\mathcal{A}_0) = \emptyset$. By the eventual compactness of the semigroup the spectrum of $\mathcal{A}_\Phi$ is ponctual. □

Proposition 3.5 *The spectral bound of $\mathcal{A}_\Phi$ equal to the growth bound of W_Φ, that is,*

$$s(\mathcal{A}_\Phi) = \omega(W_\Phi)$$

such that there exists a real dominant eigenvalue $\tilde{\lambda}$ of $\mathcal{A}_\Phi$ solution of

$$\tilde{\lambda} = s(\mathcal{A}_\Phi)$$
$$\prod_{i=1}^{I} \int_0^{\tilde{a}} \exp\left(-\int_0^x \lambda + m_i(\tau)d\tau\right)\mathcal{K}_{i\to i+1}(x)dx = \frac{1}{2} \qquad (22)$$

Proof. Since our semigroup solution of (14) is eventually compact, the result given in [20, Theorem 2.7] provides to us that $s(\mathcal{A}_\phi) = \omega(W_\phi)$. The map given by the spectral radius of the operator $\tilde{\Psi}_\lambda$ is continuous. In addition, the operator $\tilde{\Psi}$ decreases and it satisfies

$$r(\tilde{\Psi}_\lambda) \text{ tends to } +\infty \quad \text{as } \lambda \text{ tends } -\infty$$
$$r(\tilde{\Psi}_\lambda) \text{ tends to } 0 \quad \text{as } \lambda \text{ tends } +\infty$$

Then there exists a unique real root $\tilde{\lambda}$ that holds (22) where $\tilde{\lambda}$ is an eigenvalue of $\mathcal{A}_\phi$. Using the fact that the spectral radius of $\tilde{\Psi}$ is monotone, we have the result

$$\tilde{\lambda} = \sup\{\Re e\lambda : \lambda \in \sigma(\mathcal{A}_\phi)\} = s(\mathcal{A}_\phi)$$

Finally, since the semigroup is eventually compact, the real eigenvalue $\tilde{\lambda}$ solution of (22) is dominant.□

We can say from the above result that less control on the transition and mortality rates, the higher the growth rate, that is the proliferation is faster within cells with less synchronised phases.

Proposition 3.6 *The operator $\tilde{\Psi}_\lambda$ is irreducible such that $\tilde{\lambda}$ is a pole of order 1.*

Proof. The irreducibility is a strong positivity property for the semigroup that provides to us a convenient criterion about the simplicity of the poles. Let $g, g^* \in \mathbb{R}^I$ we have

$$< \tilde{\Psi}_\lambda g, g^* >= \int_0^{\tilde{a}} \exp(-\lambda a) \sum_{i=1}^{I-1} \mathcal{K}_{i\to i+1} g_{i+1}^* \bar{z}_{i,i} g_i + 2\mathcal{K}_{I\to 1} g_1^* \bar{z}_{I,I} g_I da > 0$$

□

Next, we investigate the behavior in the long term of the perturbed semigroup solution of (14), where we show that the property of asynchronous exponential property is fufilled

Theorem 3.7 *The solution semigroup $\{P_\phi(t)\}_{t\geq 0}$ of* (14) *holds*

$$\|\exp(-\lambda_0 t)P_\phi(t) - Q\| \leq \beta e^{-\gamma t} \text{ for } \gamma > 0, \beta \geq 1, \forall t \geq 0$$

such that Q given by

$$Qg = \alpha(g)(e^{\lambda_0 \cdot} \otimes \varphi_{\lambda_0})$$

and

$$\alpha(g) = \frac{< \psi_{\lambda_0}^*, \phi(\theta \mapsto \int_0^\theta \exp(\lambda_0(\theta - s))g(s)ds >}{< \psi_{\lambda_0}^*, \phi(\theta \mapsto \theta \exp(-\lambda_0\theta) \otimes \psi_{\lambda_0} >}, \quad \psi \in \mathcal{E} \qquad (23)$$

where $\psi_{\lambda_0} > 0$ ($\psi_{\lambda_0}^* > 0$) is the eigenvector of $\tilde{\Psi}_{\lambda_0}$ (respectively of $\tilde{\Psi}_{\lambda_0}^*$) such that $< \psi_{\lambda_0}^*, \psi_{\lambda_0} >= 1$.

Proof. Our state space $\mathcal{X}$ can be decomposed as the following

$$\mathcal{X} = N_{\tilde{\lambda}} \oplus R_{\tilde{\lambda}}$$

where

$$\begin{cases} N_{\tilde{\lambda}} = \ker(\mathcal{A}_\Phi - \tilde{\lambda}I) = e^{\tilde{\lambda}\cdot} \otimes \ker(I - \tilde{\Psi}_{\tilde{\lambda}}) \\ \quad = \{\alpha e^{\tilde{\lambda}\cdot} \otimes \psi_{\tilde{\lambda}} : \alpha \in \mathbb{R}\} \\ R_{\tilde{\lambda}} = \text{Range}(\mathcal{A}_\Phi - \tilde{\lambda}\mathbb{I}) \end{cases}$$

where $\varphi_{\tilde{\lambda}}$ is the positive eigenvector of $\tilde{\Psi}_{\tilde{\lambda}}$ associated to the eigenvalue $\tilde{\lambda}$ solution of (22). The projection of g on the subspaces $N_{\tilde{\lambda}}$ and $R_{\tilde{\lambda}}$ gives us

$$g = \alpha(g)\exp(-\tilde{\lambda}.) \otimes \psi_{\tilde{\lambda}} + \rho$$

Then our semigroup solution of (14) can be rewritten as

$$P_\Phi(t)g = \alpha(g)\exp(-\tilde{\lambda}(t - .))\psi_{\tilde{\lambda}} + (P_\Phi(t)|_R)(\rho)$$

Using the fact that $\omega(P_\Phi(t)|_R) < \tilde{\lambda}$. Then we obtain that

$$P_\Phi(t)g = \alpha(g)\exp(-\tilde{\lambda}(t - .))\psi_{\tilde{\lambda}} + o(\exp(\tilde{\lambda}t))$$

Then we obtain

$$\|\exp(-\tilde{\lambda}t)P_\Phi(t)g - Qg\|_{\mathcal{E}} \leq \beta\exp(-\delta t)\|g\|_{\mathcal{E}} \quad \text{for } \gamma > 0, \beta \geq 1, g \in \mathcal{E}$$

where $Qg = \alpha(g)\exp(-\tilde{\lambda}.)\psi_{\tilde{\lambda}}$. Then

$$\alpha(g) = \frac{< \psi_{\tilde{\lambda}}^*, \phi(\theta \mapsto \int_0^\theta \exp(\tilde{\lambda}(\theta - s))g(s)ds >}{< \psi_{\tilde{\lambda}}^*, \phi(\theta \mapsto \theta\exp(-\tilde{\lambda}\theta) \otimes \psi_{\tilde{\lambda}} >}, \quad g \in \mathcal{E}$$

such that $\psi_{\tilde{\lambda}}^*$ is a positive eigenvector of $\tilde{\Psi}_{\tilde{\lambda}}^*$ that yields the condition $< \psi_{\tilde{\lambda}}^*, \psi_{\tilde{\lambda}} >= 1$. □

Proposition 3.8 *The semigroup solution of* (1) *possesses the asynchronous exponential property.*

Proof. Using the relation $(\Gamma f)(s) = \chi(s)f(s), \forall s \in (0, \tilde{a})$ we obtain the similar semigroup

$$P(t)f = \Gamma^{-1}(P_\Phi(t)\Gamma f), \quad \forall f \in \mathcal{E}$$

Then by considering the formula $\tilde{Q}f = \Gamma^{-1}(Q(\Gamma f))$ we obtain the estimate

$$\begin{aligned} &\|\exp(-\tilde{\lambda}t)P(t)f - \tilde{Q}f\|_{\mathcal{E}} = \|\Gamma(\exp(-\tilde{\lambda}t)P(t)f - Qf)\|_{\mathcal{E}} \\ &\leq \|\exp(-\tilde{\lambda}t)(P_\Phi(t)\Gamma f) - (\alpha(\Gamma f)\exp(-\tilde{\lambda}.)\psi_{\tilde{\lambda}})\|_{\mathcal{E}} \\ &\leq \beta\exp(-\gamma t)\|f\|_{\mathcal{E}} \end{aligned}$$

We can conclude that the solution of (1) yields the asynchronous exponential property. □

As generations follow one another, the synchronisation between phases are less expressed within the evolving cell population, that is we observe a variability in the structure when a cell transition from the i^{th} phase to the $(i+1)^{th}$ phase, and becomes fully desynchronised. In the following a threshold phenomenon appear and it can be formulated as the spectral radius of some integral operator

Proposition 3.9 *Let $r(\tilde{\Psi}_\lambda)$ be the spectral radius of $\tilde{\Psi}_\lambda$ defined by* (20)*. Then the following holds :*

1. *If $\int_0^{\tilde{a}} \exp\left(-\int_0^x m_i(\tau)d\tau\right)\mathcal{K}_{i\to i+1}(x)dx < \frac{1}{2}$ the trivial equilibrium state is asymptotically stable.*
2. *If $\int_0^{\tilde{a}} \exp\left(-\int_0^x m_i(\tau)d\tau\right)\mathcal{K}_{i\to i+1}(x)dx > \frac{1}{2}$ the trivial equilibrium state is unstable.*

Proof. We have shown that $\tilde{\lambda} = s(\mathcal{A}_\phi)$. Due to the monotonicity of the operator $\tilde{\Psi}_\lambda$ we have that the spectral bound $s(\mathcal{A}_\phi) < 0$ if

$$r(\tilde{\Psi}_0) = \int_0^{\tilde{a}} \exp\left(-\int_0^x m_i(\tau)d\tau\right)\mathcal{K}_{i\to i+1}(x)dx < \frac{1}{2}$$

which corresponds to the trivial equilibrium state. Then, since from

$$\|P(t)f\|_\mathcal{E} \leq e^{\tilde{\lambda}t}\|f\|_\mathcal{E}$$

we have $\lim_{t\to\infty} P(t)f = 0$ and it is unstable when

$$\int_0^{\tilde{a}} \exp\left(-\int_0^x m_i(\tau)d\tau\right)\mathcal{K}_{i\to i+1}(x)dx > 1/2 \quad \square$$

4 Conclusion

The study of the cell population dynamics by taking into account the proliferation process and generations overlapping take an important part in the mathematical modeling and analysis. Various analytical and probabilist methods were performed to this aim. In particular, the semigroup method, that demonstrate it is theoretically well established combining between different theories such as operator theory, functional analysis, spectral theory ...

In this paper, the dual semigroup theory provide a useful framework to examine these processes. In particular, the context of the control of the cell cycle where many complex regulatory processes are involved where the structuration by age permits to us to track the individual cell position through the multiple generations. We proved the asynchronous exponential property that consists as an important trait within the cell populations. In fact, the synchronisation or desynchronisation is essential in tumour therapy in which drugs can synchronize cell phases and others can destroy cells in the same phases.

Here, we investigated the role of the circadian clock in the control of the proliferation within the cell population. Mathematically, we can conclude that the disruption of the circadian clock, in particular the desynchronisation between the transition from a phase to another one has a major effect on the proliferation of cells. In addition, we demonstrate that as time evolves, the cells are more desynchronised than the younger generations. In this context, natural questions arise about the differences in synchronisation between healthy and cancerous cells. This question is essential in order to understand the cell cycle and to use such knowledge to make optimisation methods for cancer therapy.

In this paper, we consider only age dependent parameter, in perspective we want to examine the effect of time dependent and different periodic controls on the cell proliferation and to compare theses controls between them.

ABSTRACT

Preventive care approaches have attracted much attention in Japan, which is one of the world's most super-aged societies. These approaches aim to decrease the number of people who require nursing care or other human support. Our research group has developed several kinds of preventive care systems, including a fall prevention system, a cognitive training system, and an Intelligent Dialogue Agent (IDA). In this paper, we focus on familiarizing older adults with the IDA – a conversational agent that encourages older adults to engage it in natural conversations, while monitoring their health in the process – and we introduce a Speech Content Coordinating Function (SCCF) to the IDA to further improve older adult's familiarity with and interest in the agent. We also have a plan to develop a Comprehensive Preventive Care System (CPCS) which can encourage proactive conversation and provide effective monitoring of older adults as well as habitual cognitive training. To evaluate the basic characteristics and impressions of the CPCS, a prototype version that consists of the IDA and the Mechanism for Cognitive Training (MCT) is developed. The results of the experiments indicated that the SCCF can adequately adjust speech content depending on the user's circumstances. We also confirmed that the prototype CPCS achieves synergistic effects (e.g., more detailed monitoring of older adult's health condition, increased frequency of cognitive training) when its components are used together.

1 Introduction

This paper is an extension of work originally presented at the 2019 International Conference on Technologies and Applications of Artificial Intelligence [1].

Japan is currently known as the most advanced super-aged society. In 2018, Japanese people aged 65 and older accounted for 28.1% of the total population [2]. As the aging demographic increases, the number of people requiring long-term care also increases, as does the number of people who need nursing care or other human support, and that number in Japan has reached 6.41 million, as certified by the Long-Term Care Insurance Act [3]. Preventive care approaches, which aim to decrease the number of people who require nursing care or other human support by reducing the decline in individuals' mental and/or physical functions, have attracted a lot of attention. These approaches also aim to control increasing medical costs and the associated burden because the number of older adults is increasing while the working population is expected to decline due to declining total fertility rates. In recent years, many researchers in various fields have focused on the prevention not only of dementia but also of fall, one of the causes of the need for nursing care, and have shown a certain degree of effectiveness in preventive care [4]– [12]. However, some older adults experience physical and/or psychological distress due to preventive care activities, and therefore have trouble engaging in these activities on a regular basis.

At the same time, in the past decade, various voice-interaction-based devices and softwares (Dialogue Agents) such as smart speakers (e.g., Google Home and Amazon Echo) and voice assistants (e.g., Siri and Cortana) [13] have been developed and employed to provide useful information and a variety of services in response to users' prompts. In addition, there has been much research into the use of Dialogue Agents for older adults with dementia and mild cognitive impairment [14]– [17]. However, it should be noted that these devices and the Dialogue Agents generally do not talk to users

[*]Corresponding Author: Sho Hirose, Email: s20613@tokyo.kosen-ac.jp

without a specific request or prompt. However, we believe that introducing a function that makes it possible for Dialogue Agents to speak to users spontaneously in order to elicit a reaction will play an important role in endowing the agents with a sense of humanity and familiarity.

Against these backgrounds, previous studies examined Intelligent Dialogue Agents (IDAs) that allow natural and flexible communication with and monitoring of older adults by using a Smart Speaker, a friendly interface, to investigate older adults' impressions of the Smart Speaker and the basic characteristics of the IDA [18]. The IDA employed a Spontaneous Talking Function (STF) that allows the IDA to talk to older adults without users' requests to encourage them to actively dialogue. Our research group has shown that the STF is effective in some ways, particularly in providing increased convenience and familiarity to older adults. Our research group is also developing a cognitive training system based on a memory game on a tablet device [19] and a Fall Prevention System for regular preventive care exercise [3] to prevent dementia and fall, one of the main factors leading to a need for nursing care. Additionally, our research group is conducting a study to estimate the behavior of older adults who live alone from data gathered by supervision sensors installed in their homes [20]. In this paper, we introduce a Speech Content Coordinating Function (SCCF) into the IDA in order to further improve the user's familiarity with and interest in the IDA. The SCCF determines the content of speech by using a reinforcement learning algorithm according to the user's preferences and condition. In order to investigate the basic characteristics of the SCCF and users' impression of it, and to evaluate whether the SCCF was able to acquire appropriate policy depending on its users, several experiments were conducted. In the experiments, we developed a text-based agent in the form of a chat-bot and introduced the SCCF into it.

In addition, this paper considers the feasibility of a Comprehensive Preventive Care System (CPCS). Although we aim to develop the CPCS by integrating our preventive care systems, it is currently in the conceptual phase. Once fully developed, the CPCS will contribute to the encouragement of active conversation and the provision of not only effective monitoring of the health condition of older adults but also regular cognitive training and fall prevention exercise. As the first step to examine the adequacy and impressions of the CPCS, we conducted the experiment with a prototype version of the CPCS using both the IDA with a sensor and the Mechanism for Cognitive Training (MCT) which is at present equivalent to the cognitive training system.

At present, neither the IDA nor the prototype CPCS has been tested by older adults, because their basic characteristics and impressions have not been evaluated. Therefore, we enrolled students as participants in the experiments as the first phase to confirm the future applicability of the IDA and CPCS for older adults.

2 Preliminaries (Reinforcement Learning)

Before describing our study, we will first introduce the concept of Reinforcement Learning (RL). RL is a machine learning method [21]. An RL agent attempts to acquire an appropriate policy (a state-to-action map) based on observations and trial-and-error interactions with its environment. A policy characterizes an agent's behavior and is described using the function:

$$\pi : \mathcal{S} \times \mathcal{A} \rightarrow \boldsymbol{R}, \tag{1}$$

where $\mathcal{S}$ and $\mathcal{A}$ denote sets of states and actions, respectively. The pair $(s, a)(\forall s \in \mathcal{S}, \forall a \in \mathcal{A})$ is referred to as a rule, which states that "if an agent observes a state s, it outputs an action a". At each time step t, an agent observes state s_t, and selects action a_t using π.

RL algorithms are roughly classified into two approaches, exploration-oriented and exploitation-oriented approaches. The former approaches, which include Q-leaning, Sarsa, and so on, aim to optimize the total discounted reward typically in environments modeled by Markov Decision Process (MDP). The latter ones, such as Bucket Brigade and REINFORCE, are based on the notion of credit assignment and aim to increase learning speed and to acquire reasonable policies even in non-MDP environments although it is not ensured to acquire the optimal policy by using them. Because the environments we treat in this study seem to be non-MDP ones, the exploitation oriented RL algorithms are applied. Brief explanations about REINFORCE and Bucket Brigade, which are employed in the IDA and MCT (described later), respectively, are presented below.

2.1 REINFORCE

REINFORCE [22] is an exploitation-oriented approach based on a policy-gradient reinforcement learning algorithm. Policy-gradient reinforcement learning algorithms such as natural policy gradients [23], and stochastic gradient methods [24] learn policies directly by updating parameters θ that characterize a policy π_θ, as opposed to many conventional reinforcement learning algorithms such as Q-learning [25] or Sarsa [26]. The values of θ are related to conditional probabilities $p(a|s)$. In other words, the policy-gradient reinforcement learning algorithms aim to acquire a probability distribution that selects the optimal action to take in each state so as to maximize the sum of the rewards. The goal of these algorithms is thus to obtain the parameters θ, which characterize the probabilistic policy π_θ that maximizes the sum of rewards, updated according to the following formula (2):

$$\theta \leftarrow \theta + \eta \Delta J(\theta), \tag{2}$$

where η is the learning rate. REINFORCE updates θ by $\Delta J(\theta)$ shown below:

$$\Delta J(\theta) = \frac{1}{M} \sum_{m=1}^{M} \frac{1}{T} \sum_{t=1}^{T} \frac{\partial}{\partial \theta} \left(r_{m,t} - b\left(\theta\right) \right) \ln \pi_\theta(a_{m,t}|s_{m,t}), \tag{3}$$

where $s_{m,t}$, $a_{m,t}$, and $r_{m,t}$ are state, action and reward at the t-th time step in the m-th episode ($t = 1, ..., T; m = 1, ..., M$), respectively. In the above formula, an episode denotes the sequence of rules selected between rewards, and one time step is counted when the agent selects a rule. The term $b(\theta)$ reduces the variance of the estimate and serves to stabilize the policy learning process, called the baseline ($b(\theta) = \Sigma_{m=1}^{M} \Sigma_{t=1}^{T} r_{m,t}$), and π_θ denotes the agent's policy. In the present study, the probability that the IDA will select its action a given a state s is computed by the softmax function (4) with the

inverse temperature parameter β, because both the state and action spaces are discrete.

$$\pi_\theta(a|s)(= p(a|s)) = \frac{\exp(\beta\theta_{(a|s)})}{\sum_{a'}\exp(\beta\theta_{(a|s)})} \tag{4}$$

REINFORCE is used to coordinate the IDA's speech content depending on the user's circumstances in this study.

2.2 Bucket Brigade

In the Bucket Brigade algorithm [27], a policy is characterized by rule-weights $w(s_t, a_t)$, which are used as an agent's policy π. When an agent acquires reward R after it selects rule (s_t, a_t) at time step t, the weights of rule $w(s_t, a_t)$ and $w(s_{t-1}, a_{t-1})$ are reinforced as follows:

$$\begin{aligned} w(s_t, a_t) &= w(s_t, a_t) - C_{bid} \times w(s_t, a_t) - \\ &\quad C_{tax} \times w(s_t, a_t) + R, \qquad (5) \\ w(s_{t-1}, a_{t-1}) &= w(s_{t-1}, a_{t-1}) + \\ &\quad C_{bid} \times w(s_t, a_t), \qquad (6) \end{aligned}$$

where C_{bid} and C_{tax} denote a "bid" parameter specifying a degree of propagating the weight $w(s_t, a_t)$ to the weight $w(s_{t-1}, a_{t-1})$, in which the rule (s_{t-1}, a_{t-1}) plays a role of "trigger" to select the next rule (s_t, a_t), and a "tax" parameter which determines a discount rate for the weight of the rule selected at step t, respectively.

As described earlier, the Bucket Brigade is one of the algorithms categorized as an exploitation-oriented approach. The above formulae mean that this algorithm updates a rule weight at each step, even when no reward is given, and also that this algorithm is relatively easy to implement compared to other conventional RL methods. Moreover, the agent with the Bucket Brigade can acquire reasonable policies in many cases even if the agents do not have a sufficient number of trials because it actively employ rewarded past experience. This study applies the algorithm to the function for adjusting the difficulty level of cognitive training for respective users in the mechanism providing the users with cognitive training, which is described in the next section.

3 Preventive Care Systems

In this section, we present the preventive care systems that are currently under development or about to start development. We first overview the Intelligent Dialogue Agent (IDA), which our research group is currently developing, then introduce the Mechanism for Cognitive Training (MCT) as another preventive care framework, and finally provide brief outline of the Comprehensive Preventive Care System (CPCS), which will consist of the above two components and will be developed as our final goal.

3.1 Intelligent Dialogue Agent (IDA)

We have developed the Intelligent Dialogue Agent (IDA) with the aim of encouraging natural and flexible conversation with its users (older adults) and of monitoring older adult's health condition based on their behavior and dialogue history. The IDA talks spontaneously, using a variety of contents such as notification of daily routines (e.g., taking medicine, walking), trivia, news, weather and traffic information, and food information. The sensor mounted on the IDA also can monitor older adults within its detection area.

3.1.1 Architecture of the IDA

Figure 1 shows the final design of the IDA. The IDA consists primarily of an input/output (I/O) unit, a learning unit, and a database.

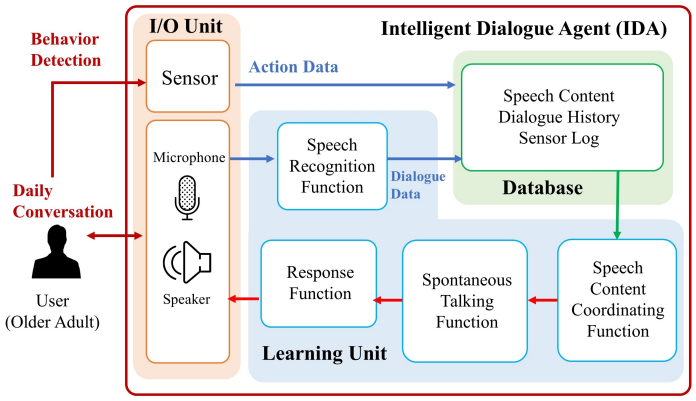

Figure 1: Final design of the IDA

(1) I/O Unit

The I/O unit is composed of a microphone, a speaker and a sensor. The user's motion is recorded by the sensor in order to track his or her characteristic behavior, such as lifestyle activities (e.g., waking and sleeping times, regular exercise). The pyroelectric sensor we adopted in this study, and which is embedded in the IDA, is both inexpensive and easy to use. Moreover, our research group has already employed a similar type of sensor and confirmed that it worked effectively to capture the motions of individuals [20]. This sensor can detect objects separate from the user, as well as even the slightest movement of people separate from the user. Although the IDA currently employs a microphone and speaker which are implemented by the included smart speaker (Google Home Mini) as its I/O unit, these components have certain limitations; for example, the smart speaker cannot acquire the user's response and dialogue history in real time. We thus plan to develop and implement an IDA that includes the highly desirable speech recognition and synthesis functions without using a smart speaker.

(2) Database

The database stores logs of the user's activity as detected by the sensors, and the history of dialogue between the IDA and the user, which is converted from speech information into text data by the Speech Recognition Function, a component of the Learning Unit. The data stored in the database are used to estimate the user's condition and to adjust the behavior of the IDA. We adopted a NoSQL cloud-hosted database known as the Firebase Realtime Database (https://firebase.google.com) for this component because it is compatible with Google Home Mini, which we employed in the IDA.

(3) Learning Unit

The learning unit has four functions: the Spontaneous Talking Function (STF), the Speech Recognition Function, the Response Function, and the Speech Content Coordinating Function (SCCF). A brief explanation of the four functions is as follows. The IDA can output its speech content without prompting by the user at the appropriate time by using the STF. The STF triggers speech to the user based on the user's daily routines and behavioral logs stored in the database. The Speech Recognition Function converts voice information obtained from the microphone, such as questions from the user or the user's responses to the IDA's speech, into textual information. The Response Function transforms the next speech content into voice information and transfers it to the speaker. In addition, the SCCF provides appropriate speech content depending on the user's preferences and condition. We expect that introducing the SCCF into the IDA will improve the convenience and familiarity of the IDA and hence the user's willingness to continue using the IDA. In order to adjust the content, timing, and frequency of speech, the following history information should be taken into account:

1. The behavioral history of the user (i.e., the frequency and number of times the user is detected) obtained by sensors on the I/O unit.
2. The history and frequency of dialogue between the user and the IDA.
3. What kinds of speech content were previously produced by the IDA and at which time slots.
4. Basic information about the user (e.g., age, gender, address, preferred topics for conversation)

3.1.2 The Speech Content Coordinating Function (SCCF)

The results of the experiments and questionnaires conducted in our previous study confirmed that the provision of appropriate information by the IDA increases the willingness of users to continue participating in dialogue with the IDA [1]. In the present study, we introduced the SCCF into the IDA and investigated its basic characteristics and performance.

In order to acquire the adequate behavior (policy) to determine natural responses depending on the particular user's preferences and/or circumstances, we apply the REINFORCE algorithm described in Section 2.1 to the SCCF as the policy learning algorithm. To conduct policy learning, we defined state, action, and reward for the IDA. The IDA's action is defined as the speech category $c \in \boldsymbol{C}$ that the agent employs to talk to the user ($\boldsymbol{C}$: A set of speech categories). There are 13 different speech categories: $\boldsymbol{C}$ = {time signal, greeting, today's weather, weekly weather forecast, today's trivia, domestic news, international news, economic news, technology news, science news, entertainment news, sports news, and each user's daily routine work}. The state of the IDA is defined as the pair of speech categories (c_1, c_2) that constituted the agent's output in the last two time steps. This state definition is based on the assumption that there is some relationship between past speech content and current content in human-to-human conversation ($c_1 \in \boldsymbol{C}, c_2 \in \boldsymbol{C}$). The user's feedback on the speech content spoken by the IDA is employed as the reward. All feedback is classified into one of three categories: positive (e.g., good, useful, beneficial), negative (e.g., bad, not useful, detrimental), or uninteresting, and the reward values obtained by the IDA are determined according to the feedback categories. Before establishing the reward setting, we asked a speech therapist at a long-term care insurance facility for older adults to comment on "how older adults come to have a good impression of speech content". She responded as follows:
[Comments of speech therapist]

"Even if older adults express negative responses to the information provided by the agent's speech, they may not necessarily have a negative evaluation of the corresponding speech (i.e., any user's reaction to the speech is evidence of being interested in the speech content)."

Based on this information from the speech therapist, we set up our SCCF to have two reward settings, one employing the speech therapist's comments and the other based on another assumption under which "the users' interest in speech directly corresponds to interest in the content of the speech." When the IDA acquires a reward, the weight parameter θ for each state and action are updated, and the probabilities for selecting actions are changed.

We substituted the softmax function (4) into the REINFORCE updating equation ((2), (3)) and the number of time steps T was set at one because we defined one episode as ending with one instance of speech. The following formula derived from (2), (3), and (4) is applied to the policy learning (parameter update) in the SCCF.

$$\theta \leftarrow \theta + \eta' \frac{1}{M} \sum_{m=1}^{M} (r_{m,t} - b(\theta))(1 - \pi_\theta(a|s)) \tag{7}$$

3.2 The Mechanism for Cognitive Training (MCT)

Our research group has developed the Mechanism for Cognitive Training (originally proposed as the cognitive training system) that encourages older adults to engage in cognitive training to help prevent dementia [19]. As shown in Figure 2, the MCT provides older adults with a brain-twister-based memory game as cognitive training, provided in such a way that they can regularly perform this memory game through repetitive interactions with a software agent on a tablet device. The software agent also serves as both an opponent who plays the game with the older adult users and a conversation partner; the goal of the latter function is to increase the familiarity of older adults with the MCT. Our system is expected to prevent dementia by preserving and improving cognitive functions such as short-term memory and encouraging and improving the user's motivations to use them. Furthermore, the MCT has a difficulty adjustment function that can set the appropriate game difficulty level according to differences between users and each individual user's current circumstances in order to create an environment that makes it easier for users to continue cognitive training for long periods of time, since they neither get bored because the game is too easy nor give up because it is too difficult. The database stores information on each user's game-playing conditions, such as memory time, response time, accuracy rate, and difficulty, and uses these data to adjust the difficulty level and provide feedback on the memory game results to the users.

The difficulty adjustment function employs the Bucket Brigade algorithm described in Section 2.2 in order to coordinate the game difficulty level. The Bucket Brigade algorithm is known to have two

characteristics: (i) advancing policy learning even when no reward is given; and (ii) additionally acquiring reasonable policies in many cases, even if the agents do not have a sufficient number of trials, by actively employing rewarded past experiences.

The software agent in the MCT is based on the concept of Human-Agent Interaction (HAI), which aims to design an appropriate framework of interactions between humans and agents. The MCT currently has a function to coordinate speech content depending on the game-playing frequency and/or time interval between bouts of gameplay so that a user can play the game (engage in the cognitive training exercise) comfortably. However, since it is intended that the software agent will be implemented on a tablet device, its functional and performance limitations may prevent it from fully achieving the desired functionality. Therefore, both functions for coordinating speech content and sensors for detecting the user's motions will be implemented in the IDA. In addition, the functions currently embedded in the software agent on the MCT will be implemented in the CPCS as functions of the IDA.

As a result of several experiments, we have confirmed that older adults were able to increase the difficulty level and the accuracy of the cognitive training by using the MCT. Furthermore, introducing the difficulty adjustment function made it possible to appropriately coordinate the training difficulty depending on the circumstances of the older adult playing the game. Although the use of MCT clearly had a positive effect on maintaining/improving the short term memory and cognitive function of older adults, we also confirmed that experiments over a longer period with a much large number of participants will be needed in order to make a detailed assessment of the MCT's effectiveness in dementia prevention.

3.3 Comprehensive Preventive Care System (CPCS)

The Comprehensive Preventive Care System (CPCS) aims to allow older adults to enjoy engaging in cognitive training while being monitored by their family and friends through active conversation. The CPCS consists of an IDA, which can carry out natural conversation with users, and an MCT (detailed in section 3.3) which provides users with a memory game on a tablet device as a kind of cognitive training (Figure 2).

Our research group is carrying out research on and development of each component with a view towards their eventual integration into the CPCS. Because the integration of the IDA and the MCT will allow the CPCS to employ the data stored in both in parallel, this system will be able to produce a synergistic effect between the cognitive training and monitoring functions. For example, the cognitive training status obtained by the MCT will be combined with the dialogue/behavior history acquired by the IDA, making possible a more detailed understanding of the user's condition (e.g., the user's degree of fatigue, whether he or she has taken a break while engaging in cognitive training, and so on). One of the final purposes of the CPCS is to notify family and friends of the circumstances of an older adult user obtained by the system, which also aims to accomplish the following three goals:

1. To maintain and improve the cognitive function of older adults;
2. To promote active conversation between older adults and their family, friends and the IDA; and
3. To create an effective environment where older adults and their families and/or community groups can be mutually involved to better monitor the older adult's health condition, and promote their care and dementia prevention.

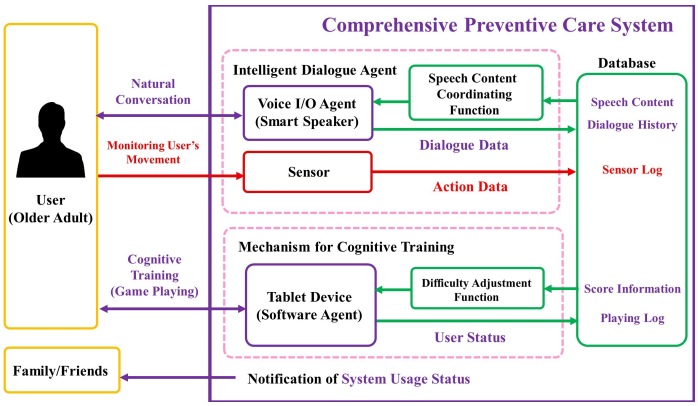

Figure 2: the Diagram of the CPCS

4 Experiments

As described in Section 1, we have not yet had an opportunity to employ older adults in the evaluation of the SCCF and the CPCS. In addition, many aged households lack a Wi-Fi environment which would be needed in order to use and evaluate the CPCS at home. For these reasons, we conducted several experiments with students to confirm that the SCCF can appropriately coordinate the speech content depending on the user's circumstances and to evaluate the basic characteristics and impressions of the CPCS. Moreover, we used the prototype version of the CPCS (described in a later section) in these experiments, because at present we have not evaluated the full version of the CPCS, but only its respective components (the IDA and the MCT).

Before conducting the experiment, a simple written questionnaire was administered to older adults in order to confirm their awareness of smartphones, the internet environment at their home, and the degree of interest/expectation in regard to spontaneous talking by the IDA (smart speaker). The questionnaire results showed that (i) older adults' degree of recognition of smart speakers was low; (ii) the majority of them did not have an internet (Wi-Fi) connection that would permit the use of a smart speaker at home; however, (iii) they had a high level of interest about conversation with the IDA (smart speaker), particularly its spontaneous talking function. Regarding item (iii), the older adults had on average 2.3 topics that they wanted the IDA to talk about, and no older adults answered that the talking function was "unnecessary" or that they had "no topics which they wanted to make the smart speaker talk about". The detailed results of the questionnaire are presented in Appendix (A).

4.1 Evaluation of the SCCF

In our first experiment, we aimed to evaluate the basic characteristics of the SCCF by employing a prototype of the IDA (henceforth referred to simply as the IDA) developed as a chat-bot using the Slack message application. The chat-bot periodically talks to provide information and learns from its users' feedback. The experiment was conducted for six days and our subjects were 10 students (average age: 18.9).

As the speech content of the chat-bot, six out of 13 categories were randomly selected before starting the experiment. The total number of states was $6 \times 6 = 36$ because the chat-bot had up to two previous categories (c_1, c_2) as pairs. From the set of selected speech categories $\boldsymbol{C'}$ ($|\boldsymbol{C'}| = 6$), the chat-bot selects speech category c according to the current policy. The initial value of the parameters θ which characterize a policy π_θ equals θ_0. Therefore, the chat-bot chooses a speech category with uniform probability at the first stage of the experimental period. Each participant responded to the speech content provided by the IDA with one of three kinds of feedback (P/N: positive/negative impression; U: uninterested). Reward values were determined by the collective feedback of users. The following two types of reward settings were utilized based on comments received from the speech therapist.

[Setting R_A]

Under this setting, in accordance with the speech therapist's assumption that "older adults would be interested in a topic if their evaluation was not U," a positive reward (+1) was assigned if the participant's feedback was P or N, and no reward was given otherwise.

[Setting R_B]

Under this setting, positive (+1) reward, negative (-1) reward, or no reward was given if the user's evaluation of a topic was P, N, or U, respectively.

The participants gave feedback for approximately 300 speech contents for each setting. To avoid any influence of the order of the participants' evaluations in settings R_A and R_B, the participants were grouped into two equally sized groups, and the order was changed in different groups. The parameters used in the policy learning and action selection are shown in Table 1.

Table 1: Parameters used in reinforcement learning

Parameter	Value
η'	0.22
M	3
θ_0	10
β	15

In addition, subjective evaluations was conducted after the end of the experimental period (three days) for each reward setting and after the end of the experiment to examine the participants' impressions of the SCCF. We also administered the questionnaire regarding the level of interest in each category at the end of the experiment because we did not want it to affect the participants' evaluation of the chat-bot's speech.

Which speech categories provided by the IDA were most preferred varied among users. The favorite speech categories and/or favored order of talking could also vary within the same user depending on the current circumstances (e.g., on holiday, at work, while eating, before bedtime, and so on). For these reasons, it was difficult to acquire a policy for providing optimal speech contents in the experiments; however, we can say that we were able to acquire a policy better expressing the user's preference by the learning in the SCCF if the speech categories preferred by the user were easy to be provided from the IDA compared to the other categories. The experiment thus confirmed the probability of the IDA generating speech for each category after learning the preferences of users while investigating the favorite categories of users via the questionnaire. By comparing the above results, we discuss the adequateness of the SCCF by evaluating whether the SCCF can learn the preference of users and how accurately the learning result matches the actual preference of users.

4.2 Preliminary Experiments with the CPCS

Several experiments were conducted to investigate the synergistic effect of using the MCT in conjunction with the IDA. As part of our preparation for conducting the experiment with older adults, we asked 10 students (the same as the participants in section 3.1) to participate in our preliminary experiments. However, after excluding one participant (participant F) due to an equipment malfunction that resulted in incomplete sensor data, a total of nine participants were included in these experiments.

A prototype version of the CPCS was employed for these experiments. The system consists primarily of the MCT and the IDA, but does not have functions that allow the two mechanisms to communicate or that allow either of the components to use data collected by the other. Using both mechanisms in parallel would contribute to the combined use of the log data obtained by each. We conducted two kinds of experiments to investigate differences in impressions of the CPCS when the IDA talked spontaneously and when it did not. This experiment was conducted in two periods, a speech period and a nonspeech period, of three days each for a total experimental duration of six days. However, to ensure that the order of the two periods did not affect the subjects' impressions of the CPCS, the order was randomized for each participant. The IDA employed in the experiment had a simple STF consisting of a smart speaker (Google Home Mini) and a pyroelectric sensor without introducing the SCCF, and provided information (speech content $c \in \boldsymbol{C''} = \boldsymbol{C} \backslash$ {each user's daily routine work}) selected randomly every 15 min between 9:00 and 23:00 during the speech period. Additionally, we asked participants to listen to the IDA's speech at least eight times a day. Sensors detected the participants' behavior throughout the experimental period (sampling interval: 1 s; detection range: 115° within a 2-m view range). The difficulty adjustment function was included in the MCT. We asked the participants to play a 10-min memory game every day near the location where the sensor was installed.

Written questionnaires were also administered after the first half of the experiment and at the end of the experiment to inquire about the number of times participants heard the IDA speaking, whether the difficulty level of the memory game was appropriate, and their

willingness to continue to use the CPCS.

Similarly to the case of IDA, how efficiently the CPCS prototype can monitor a user's behavior would be influenced by its installation site and the daily habits of the user. However, synergistic effects are also expected through the concomitant use of the IDA and the MCT, and could have a positive impact on the frequency with which users engage in cognitive training. To clarify these issues, we evaluated and discussed the impressions of users, the effectiveness of the system at monitoring users, and the relationships between dialogue with the IDA and the frequency of cognitive training by examining data such as the sensor log, the result of the questionnaire/interview with the participants, and the training frequency in parallel.

5 Results and Discussion

This section describes our experimental results and discusses our investigation of the basic characteristics and performance of the SCCF as well as the effectiveness of the CPCS prototype presented in Section 4.

5.1 Performance Evaluation of the SCCF

Let us first discuss the performance and adequacy of the SCCF in providing appropriate information according to the user's preferences and condition. Table 2 lists the probability of the chat-bot talking about each category over the last 100 times in the three-day experimental period. This table shows the results for all participants. In this table, "ranking" corresponds to the participants' interest levels for each speech category obtained by the questionnaire administered after the experiment. This table revealed that the probability of talking acquired by the learning tends to be high when the rank of the interest level is high, especially under the reward setting R_B. The bold digits in the table indicate areas in which probability increased from its initial value (16.66...%). Table 3 represents the results of the questionnaire concerning the participants' interest levels for each category on a five-point scale (the other questionnaire results are shown in Appendix (B)). Digits in boldface indicate areas with an interest level greater than 3. Table 2 shows that, for reward setting R_B, the probabilities of the top three speech categories tend to be larger than the initial probability value while the probabilities of the bottom three categories tend to be smaller. Additionally, the results presented in Tables 2 and 3 show that, under reward setting R_B, there is a positive correlation between the probabilities of speech from the chat-bot at the end of the experiment and interest in the actual content of the speech under reward setting R_B. In other words, the probability that the chat-bot provides the participants with topics of interest increased throughout the experiment, while the probability that it provided topics for which many participants' feedback was U (no interest) decreased. Therefore, we believe that the chat-bot with reward setting R_B was able to provide information that reflected the users' thoughts and states.

On the other hand, the chat-bot with reward setting R_A failed to acquire the appropriate policy. An important feature in the chat-bot with setting R_A was that the probability of a particular category being provided was too large (up to 98%) when targeting a specific participant compared to the results obtained with setting R_B (up to 41%). Critically, reward setting R_A does not include negative rewards; regardless of whether the user's feedback is positive or negative, a positive reward is given. Thus, it is much more likely that the chat-bot with the reward setting R_A will be given a positive reward than the chat-bot with reward setting R_B. However, it seems that the speech probability was changed too drastically for the chat-bot with reward setting R_A under the current parameter settings.

5.2 Basic Characteristics of the CPCS

This section discusses whether the prototype version of the CPCS can monitor and/or understand a user's circumstances in detail using the log data collected by the IDA and MCT, and evaluates users' impressions of the system as well. The sensor data of participant F were incomplete due to an equipment malfunction and are therefore not included in these results.

5.2.1 *Differences in the Participants' Amounts of Activity*

Let us consider the amount of activity detected by the pyroelectric sensor on the CPCS. A participant's amount of activity Act^x is defined as the number of times the sensor detects his/her motion for x min. The maximum and minimum values of Act^x equal $60x$ and 0, respectively. Since the sensor may also detect objects other than the user, the value of Act^x must be corrected depending on the experimental circumstances. Table 4 shows the maximum amount of activity per 30 min for each participant over the course of the experiment. As shown in the table, Participant B had the greatest amount of activity (number in red) while Participant A had the lowest amount (blue). Figure 3 also shows sketches of the rooms usually used by Participants A and B, and the location and orientation of the sensor in those rooms.

Installation of the sensor in a location where it can detect the participant's motion appropriately is essential in order for behavior to be estimated accurately. Since Participant B answered in the interview after the experimental period that she often reads for long periods of time at her desk, we believe that this caused her amount of activity to be greater than that of the other participants because she was active within the detection range of the sensor. These results suggest that environmental factors, such as the location and direction of the sensor, may influence the recorded amount of activity (some noise and error in sensing may also influence the results).

Therefore, in the case that the CPCS in its current form would be employed in practice by older adults, it is necessary to consider in advance where the sensors should be installed to effectively track the older adults' amount of activity. At the same time, if the CPCS could be installed at the appropriate location, we can expect to properly understand their behavior.

Table 4: Maximum amount of activity per 30 min for each participant.

Participant	Act^{30}	Participant	Act^{30}
A	1210	G	1301
B	1800	H	1353
C	1312	I	1711
D	1386	J	1503
E	1672		

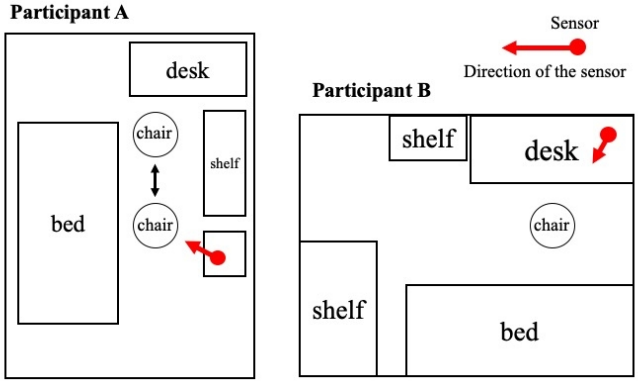

Figure 3: Diagram of the rooms where the experiment was conducted for Participants A and B

5.2.2 *Sensor Logs and Time Spent on the Memory Game*

Figure 4 depicts the average number of cognitive training memory games played every 30 min on weekdays (bar graph) and activity patterns (i.e., transition in the amount of activity) recorded by the sensor (line graph). The results shown in this figure are the average values for seven participants who showed similar behavioral trends. Participant I was excluded because his academic year and life patterns were different from those of the others. Here, interval (b) in Figure 4 is characterized by low activity because the participants were at school and not near the CPCS installation site. In addition, as can be seen at interval (c), there was an overall tendency for the participants to play the memory game more often at night, increasing their activity level at the same time. In contrast, interval (a) shows a larger amount of activity compared to interval (b), but almost no gameplay history except for Participant E. This result indicates that the participants were preparing to go to school during the corresponding period.

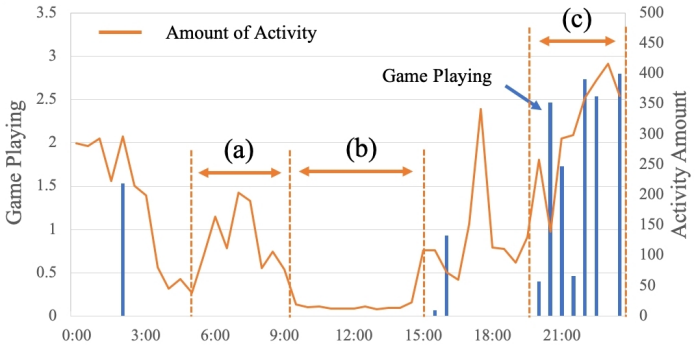

Figure 4: Average amount of game playing and activity patterns on weekdays.

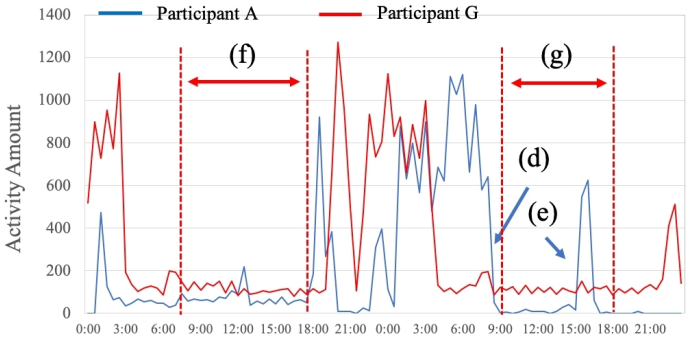

Figure 5: Weekend activity patterns for Participants A and G

At the same time, we can also see significant differences between the participants' behavior on weekday vs. weekends in terms of their life rhythms, such as sleeping hours and daily habits. Figure 5 shows the weekend activity patterns for Participants A and G, which were particularly distinctive. These patterns allow us to estimate the participants' awakening time and bedtime. For example, Participant A's activity decreased early Sunday morning ((d) in Figure 5) and increased around 15:00 ((e) in Figure 5). In the interview after the experiment, Participant A confirmed that this activity pattern corresponded to his sleep pattern. Similarly, the

other participants' sleep patterns could also be estimated from their activity logs. These results demonstrate the usefulness of the users' stored behavioral log data.

On the other hand, it was not possible to fully estimate Participant G's weekend sleep pattern. Figure 5 suggests that Participant G's bedtime was 3:00 on Saturday, and her waking time was around 19:00. However, in the interview after the experiment, we learned that she was awake but not in the room with the sensor at certain times of the day, such as from 7:30 to 17:00 (interval (f) in Figure 5) on Saturday and from 8:00 to around 18:00 (interval (g) in Figure 5) on Sunday. The fact that Participant G spent less time in the room where the CPCS was installed may have contributed to her lower amount of activity.

These results demonstrate that the use of sensor logs and gameplay histories obtained by the CPCS allows us to estimate not only daily habits such as waking and sleeping times but also whether users go out for long periods of time.

5.2.3 *Using Sensor Logs to Capture Users' Lifestyle Habits*

This section focuses on the sensor logs obtained in the IDA, a component of the CPCS, while playing the memory game on the MCT, and before and after playing. Figure 6 shows the amount of activity recorded every one minute for about 20 min while Participant B was playing the memory game. The memory game has 13 levels of difficulty and records three degrees of fatigue: 0, Bad; 1, Normal; 2, Good. Figure 7 shows the transitions in difficulty level and degrees of fatigue during the time that Participant B played the memory game. Note that all the intervals in Figure 7 correspond to interval (h) in Figure 6. The red circles on the red line plot in Figure 7 indicate the times at which the memory game was started. In Participant B's interview after the experimental period, she noted that she played the memory game at her desk (near the location where the CPCS was installed). During and after the gameplay (interval (h) and the second half of (h) in Figure 6), the amount of activity increased compared to the period of time before play, while after 22:12 (interval (i) in Figure 7), the participant temporarily stopped playing the memory game. Figure 6 confirms that the amount of activity remains high. We can speculate that the cause of this pattern was that Participant B was feeling fatigued from the memory game and may have stopped playing the game to do some other task or take a break.

Figure 8 depicts the amount of activity recorded every one min for about 20 min while Participant E was playing the memory game. In contrast to the results obtained for Participant B, Participant E's activity tended to decrease during the game-playing time ((j) in Figure 8) compared to his activity before and after playing. The interviews revealed that Participant E tended to play memory games on the bed. We inferred that this position was responsible for the low activity levels recorded by the system, since the location of the sensor would have made it difficult to detect someone on a bed. The interviews of the other participants indicated that the sensor logs adequately expressed their behaviors. It was clear from these results that the data obtained from the IDA and the MCT can be used to extrapolate detailed information about the user's circumstances.

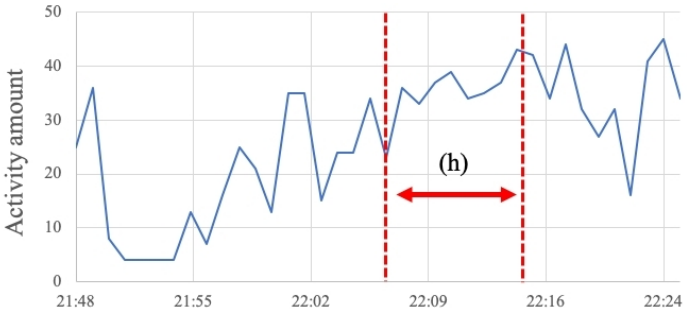

Figure 6: Activity before, during, and after Participant B's game playing.

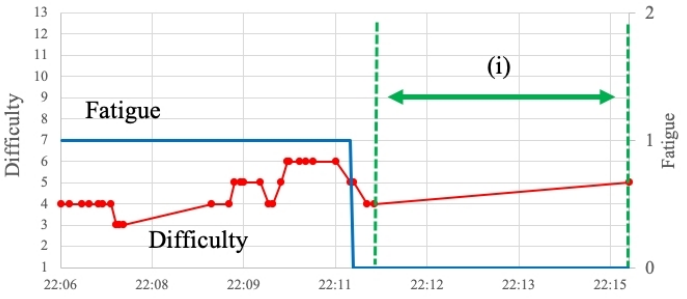

Figure 7: Changes in difficulty and fatigue during the memory game (Participant B).

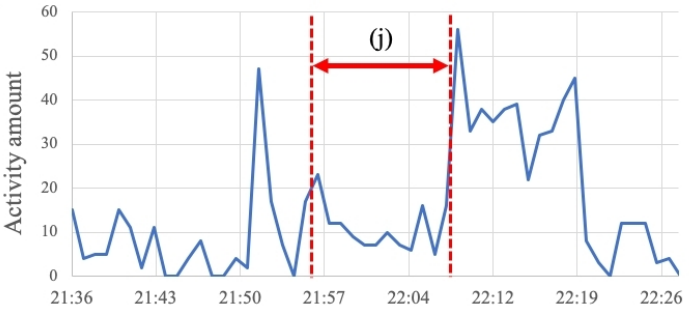

Figure 8: Activity patterns for Participant E.

5.2.4 *Questionnaire Investigation of the CPCS*

Next we will discuss the participants' impressions of the CPCS and the synergistic effects of combining the IDA and the MCT based on the results of subjective evaluations of the nine participants (college students) conducted after the experimental period. Among the nine participants, five stated that they felt there was a need to use the CPCS; however, there was only one participant who wanted to use both the IDA and the MCT as individual components of the CPCS. Thus, although in some cases the student participants expressed interest in the components of the CPCS, it can be said that, on the whole, they did not have a positive impression of the prototype version of the CPCS. One reason for this may be that students attend classes on a daily basis and have frequent opportunities to talk with the people around them. Further research needs to be conducted to investigate differences in the trends across age groups.

Table 5 shows the average number of times the memory game provided by the MCT was played per day by each participant with

Table 5: Differences in the number of times the memory game was played with and without speech from the IDA.

Participant	A	B	C	D	E	G	H	I	J	Average
Not talking	14.7	5.0	23.0	21.0	0.0	37.0	21.0	31.0	30.0	20.3
Talking	**20.7**	**10.0**	**26.7**	**31.0**	**15.7**	**41.0**	**29.0**	**40.3**	**41.3**	**28.4**
Difference (talking - not talking)	6.0	5.0	3.7	10.0	15.7	4.0	8.0	9.3	11.3	8.1

and without speech from the IDA. When the IDA spoke, the number of times each participant played was greater than that when the IDA did not speak (average: 8.1 times). We consider that the above result was caused by the synergy of the combination of the IDA and the MCT, because the dialogue between the IDA and the participant promoted their habitual game playing. The other questionnaire results can be seen in Appendix (C).

6 Conclusion

In the present study, we introduced the Speech Content Coordinating Function (SCCF) into the Intelligent Dialogue Agent (IDA), and developed a prototype version of the Comprehensive Preventive Care System (CPCS) consisting of the IDA and the Mechanism for Cognitive Training (MCT). The SCCF was developed as a text-based agent in the form of a chat-bot that employed reinforcement learning based on the policy gradient method. This system was tested in an experiment with student participants. The experimental results confirmed that the SCCF acquires appropriate policies based on the user's preferences and conditions. Furthermore, the results of experiments using the prototype version of the CPCS confirmed that taking advantage of data obtained from both the IDA and the MCT can lead to synergistic effects to monitor users in greater detail, better understand their circumstances, and increase the frequency of cognitive training.

In future research, we will further improve the convenience and familiarity of the SCCF by determining not only the content of speech but also the appropriate frequency and timing of speech based on the user's circumstances at any given time. At the same time, because this improvement may cause an exponential increase in the number of states and actions compared to the learning environment of the experiments conducted in the present study, we plan to improve the current learning algorithm or apply more powerful ones, such as deep reinforcement learning algorithms. The adaptability and familiarity of the improved SCCF will need to be evaluated through more practical experiments with older adults in a setting that more closely replicates real-life circumstances.

We also expect that further synergistic effects will occur by allowing the components of the prototype CPCS to communicate and share their data. It will also be necessary investigate the effects of the CPCS on older adults and their impressions of this system by fully examining the different trends in people of different age groups. We also plan to integrate a fall prevention system, which is currently being developed in parallel by our research group, into the CPCS; however, since this system involves physical exercise and a certain risk of injury, we will proceed with its integration in stages, starting with older adults who are at little risk of injury. Similarly, we will continue to work on the introduction of other preventive care systems and expect to see synergies similar to those obtained in the present study.

Acknowledgment The authors would like to thank the staff of the Fujisawa Care Center, and the members of the Hachioji Senior Citizens' Club and Cafe Kajiyashiki for their cooperation.

Appendix

We administered three questionnaires concerning (A) older adults' impression of the smart speaker and the IDA, (B) the evaluation of the SCCF, and (C) the preliminary experiments with the CPCS, before, during, or after the experiments described in Section 4. Several major results were already given in Section 4, and other results related to the discussion in Section 4 are shown below. Tables A1 - A4, B1 - B3, and C1 - C8 list the questions and typical answers for each.

(A) A questionnaire administered to investigate older adults' impression of the smart speakers and the IDA

Affiliation of the participants

A preventive care circle for older adults and a senior citizens' club

Number of participants

28 (9 from a preventive care circle, and 19 from the senior citizens' club)

Gender and age

male: 12; female: 16; average age: 76.6 (male: 76.4; female: 77.4)

Table A1: Items in the questionnaire administered to older adults.

Item	Question
Awareness of smart speakers.	(1) Are you familiar with smart speakers? (2) What kind of speech content would you like the IDA to spontaneously talk about? (multiple choice allowed) (3) Would you want to use a smart speaker if one was in your home?
Impression of the spontaneous talking function	(4) If a smart speaker talked to you spontaneously, what would be your reaction? Could you select all items applicable to you? (5) If a smart speaker could talk to you spontaneously, what would you like to talk about?
Information about the environment	(6) Do you have a Wi-Fi environment at home?
Information about the participant	(7) Could you tell me your daily routine? (8) Could you tell me your hobbies?

Table A2: Answers to question (1) in Table A1 (Answerer: 9 older adults in preventive care circle).

Answer	Percentage of respondents (%)
I know about them.	0.0
I have heard the name.	11.1
I don't know about them.	77.8
No answer	11.1

Table A3: The number of contents the older adults selected for question (2) in Table A1.

Index	Number of responses
Maximum	6.0
Minimum	1.0
Average	3.4

Table A4: Answers to question (6) in Table A1.

Answer	Percentage of respondents (%)
I have Wi-Fi.	35.7
I don't have Wi-Fi.	46.4
I don't know.	7.1
No answer	10.7

ABSTRACT

In this paper we propose the application of supervised learning techniques to recognize stress situations in drivers by analyzing their Skin Potential Response (SPR) and the Electrocardiogram (ECG). A sensing device is used to acquire the SPR from both hands of the drivers, and the ECG from their chest. We also consider a motion artifact removal algorithm that allows the generation of a single cleaned SPR signal, starting from the two SPR signals, which could be characterized by artifacts due to vibrations or movements of the hands on the wheel. From both the cleaned SPR and the ECG signals we compute some statistical features that are used as input to six Machine Learning Algorithms for stress or non-stress episodes classification. The SPR and ECG signals are also used as input to Deep Learning Algorithms, thus allowing us to compare the performance of the different classifiers. The experiments have been carried out in a firm specialized in developing professional car driving simulators. In particular, a dynamic driving simulator has been used, with subjects driving along a straight road affected by some unanticipated stress-evoking events, located at different positions. We obtain an accuracy of 88.13% in stress recognition using a Long Short-Term Memory (LSTM) network.

1 Introduction

Lately[1], the assessment of stress in car drivers is getting more attention, because a highly stressed driver could be less focused, more likely to drive in a risky way [1], and/or to get involved into accidents [2]. The emotional state, corresponding to a condition of tension and pressure in an individual, causes reactions of the sympathetic nervous system. These are defined as stress in literature [3].

Different approaches have been proposed to detect stress in individuals, using physical or physiological parameters [4]. Machine Learning (ML) algorithms are often employed [5]– [8]. In [9], a Support Vector Machine (SVM) classifier is used, with Skin Conductance Response (SCR), Electroencephalogram (EEG), and Heart Rate (HR) as inputs. In [10], various signals are utilized, such as Blood Volume Pulse (BVP), Skin Conductance (SC), Skin Temperature (ST), Electromyography (EMG), and Respiration (RESP). Deep Learning (DL) algorithms have also been successfully applied for stress recognition. Physiological signals are used, such as Electrocardiogram (ECG) [11] and Electrodermal Activity (EDA) [12], or facial expressions [13], or a collection of physiological and motion data, including ECG, EDA, EMG, RESP, Temperature (TEMP), and Acceleration (ACC) [14]. The system described in [15] uses the time differences between consecutive R-waves of QRS complexes, also called RR intervals, for mental stress identification in firefighters. In several works, a comparison between ML and DL methods for stress recognition has been carried out, also showing that Convolutional Neural Networks (CNNs) can outperform ML conventional methods [16, 17].

There are various stress analysis approaches when we consider car driving scenarios as well. Many use physical characteristics, e.g., facial or eye images [18, 19]. In others, physiological characteristics are considered [20–22]. Among these, EDA can be used jointly with different signals [23, 24]. Authors in [25] study the relation between the vehicle's acceleration and the driver's heart rate in elders. In [26], EEG patterns, belonging to different driving conditions, are classified using an SVM, a Neural Network (NN), and a Random Forest (RF). Some DL algorithms have also been successfully applied for stress recognition in the driving context as well, and are particularly relevant to this work. Authors in [27] present an end-to-end architecture, composed of convolutional layers, that uses ECG signals for stress detection. Their experiments are designed for identification of mental fatigue and for discrimina-

[1]This paper is an extension of the work originally presented in [43].

tion between driving and resting conditions. A multimodal system based on CNNs and Long Short-Term Memory (LSTM) networks, using ECG, vehicle data, and contextual data has been proposed in [28]. In [29], CNNs are considered to detect a driver's braking intention, in different driving conditions, using EEG data.

In this work we present a system that allows the recognition of the emotional and stress conditions of subjects while driving. The main features of our system, which differentiate our work from others in the literature, are the relative simplicity of the sensors used, the possibility of being used nearly in real time on 15 s signal blocks, and the ability to discriminate stressful events of short duration during driving. The experiments are organized in a company that designs professional driving simulators. We use a simulator that reproduces a road track in a 3D environment. Along the track we place different tasks to go through, which are expected to cause a reaction in the subjects. Two different signals are considered, the Skin Potential Response (SPR) and the ECG. We have proven that these signals are suitable for the analysis of the emotional condition of a driver and that can be acquired with an acceptably intrusive setup, with no intervention on the vehicle [30].

We analyze the SPR signal instead of the widely utilized SCR, because it can be logged in a more straightforward way, with no electric current in the skin. In addition, the electrode impedance and skin impedance changes have a lower impact on this signal [31]. In detail, our objective is to compare the performance of several ML algorithms in recognizing the stress responses of the drivers that undergo various stress situations. To do this, some features are extracted from both the SPR and ECG signals. In addition, we consider deep learning techniques for driver stress recognition. These require the raw recorded signals as input, contrary to what happens in traditional machine learning techniques, where a feature extraction process is needed. Specifically, we use a CNN and an LSTM network. Compared to other similar studies cited above [24, 27], we apply machine and deep learning techniques for detecting stress during short tasks in a controlled and simulated environment.

The paper is structured as follows. In the next section, a description of the fundamental blocks of the proposed system is provided. We introduce the sensing device utilized for both SPR and ECG recordings, the Motion Artifact (MA) removal algorithm developed to reduce motion artifacts, and the learning algorithms implemented for classification. Section 3 reviews the experimental setup. Section 4 presents the results of our comparative study, using different classification algorithms, on drivers' stress recognition. Finally, in Section 5 we draw some conclusions.

2 Description of the system

The block diagram of the developed system is shown in Figure 1. The inputs are the two SPR signals, recorded from the hands of a test subject ($s_1(t)$ and $s_2(t)$ in the figure), and the ECG signal recorded from the chest of the subject. The signals are acquired synchronously through a sensing device that uses a textile garment with electrodes, in addition to other electrodes placed under the gloves on both hands.

The two SPR signals can exhibit some artifacts that can be generated when the subject is driving, e.g., due to the hands movements or vibrations. To overcome this problem, we designed a MA removal algorithm that, taking into account the local energy of the two SPR signals, picks the smoother one, with the aim to remove spurious peaks and asymmetric signal spikes, possibly related to MA. As a matter of fact, the SPR component due to the sympathetic nervous system activity in the two hands is highly correlated. In the end, a learning classification algorithm is used to recognize the presence of stress in certain time intervals. In detail, every single time interval is classified into two possibile classes, which are the stress class (or "1") and the non-stress class (or "0"). In case of ML algorithms, this is carried out by selecting some statistical features from the cleaned SPR signal ($s(t)$ in Figure 1) and from the ECG signal. These features have been picked out, among others, since they well represent the stress signal peculiarities. In case of DL algorithms, instead, the raw SPR and ECG recordings are directly processed. In the next subsections, we will describe in detail each one of these fundamentals blocks.

2.1 The sensing device

The sensor used for data acquisition is the VI-BioTelemetry system (https://www.vi-grade.com/en/solutions/vi-biotelemetry/). This commercial sensor, shown in Figure 2, has been designed in our group and engineered by the VI-grade company. Its detailed description can be found in several recent scientific papers (e.g., [31, 32]).

Summarizing its features and specifications, the sensor is battery operated and transmits data to a laptop via WiFi connection. It acquires two SPR channels and three ECG channels. The SPR signals are acquired from the hands of the tested subject (through Ag/AgCl wet electrodes positioned on the palm and the back of each hand) and the ECG data are acquired using a commercial vest having textile electrodes in contact with the chest of the subject (using an adhesive conductive gel). The analog front end conditions the SPR and ECG signals with proper bandwidth and gain. Analog signals are converted using a 12-bit A/D and an on board DSP which acquires the signals at 1 kSa/s rate. The A/D converter is characterized by an Integral Nonlinearity (INL) lower than 1 LSB (Least Significant Bit) and an Effective number of bits (ENOB) equal to 11.1. The DSP sends the acquired signals to the WiFi module which is responsible to send all the time-aligned data to a server in the local area network.

Regarding the ECG channels, they are basically designed as band-pass differential amplifiers with maximum input range ± 5 mV (i.e., gain 370) and bandwidth in the [0.03, 160] Hz range. The input impedance of each channel is 100 MΩ, in order to reduce the load error to less than 1%, since the skin impedance is lower than 1 MΩ. The resolution of the ECG signals acquired on the chest skin results to be in the order of 2.5 μV and the accuracy of the ECG readout has been characterized in the past [32] to be as low as 0.1%. As for the ECG signal, we first detect the R-peak locations using the Pan-Tompkins algorithm [33].

The instantaneous RR signal is obtained by converting the RR interval time series with cubic spline interpolation at 100 Sa/s. Similarly to what is done in [34], where RR values and DL are used for Congestive Heart Failure (CHF) detection, interpolation is needed to synchronize signal segments, in our case with the SPR signal blocks. Note that this can be important to preserve correct time and

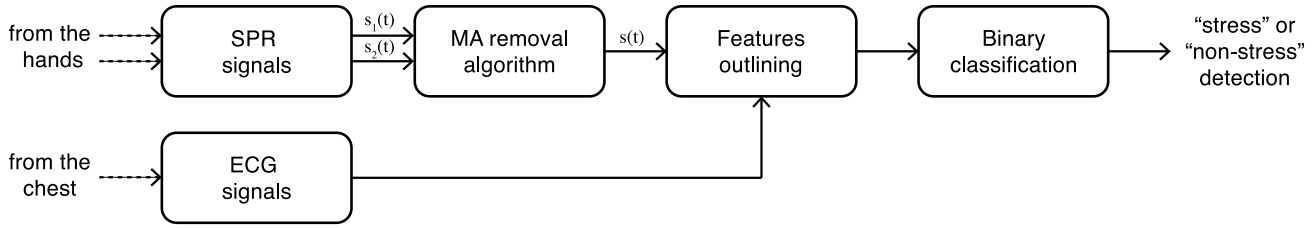

Figure 1: Block diagram of the presented system.

frequency information (see [35] and references therein), which the DL classifiers can possibly extrapolate from the data.

Regarding the SPR channels, the sensors acquire the electrodermal signals on both hands as differential voltages between the palm and the back of each hand. The SPR signals are supposed to be in the ±10 mV range. They are amplified with a gain equal to 160. The acquisition bandwidth is in the [0.08, 40] Hz range; the input impedance of each channel is 100 MΩ. The resolution of the SPR data acquired on the hands results in the order of 5 μV and the accuracy of the SPR readout has been characterized in the past [31] to be in the order of 0.2%. The SPR signals are subsampled at 100 Sa/s before further processing.

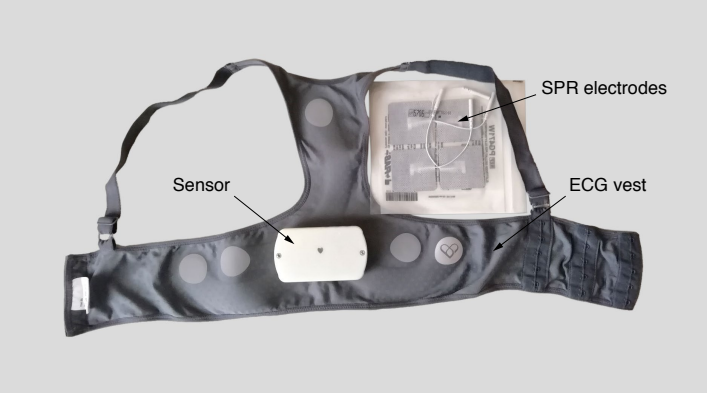

Figure 2: The VI-BioTelemetry sensor used in the experiments. The system is composed by an acquisition box, a vest with textile electrodes for ECG acquisition on the chest and Ag/AgCl electrodes for SPR acquisition on the hands.

2.2 Motion artifact removal block

As introduced above, some artifacts due to the movements and actions of the subject's hands while driving can become visible on the SPR signals, and could alter their shape. To take this issue into account, we propose an MA algorithm (see also [36, 37]) that is built on two assumptions: the first being that motion artifact enhances the local energy of the signal. The second being that the motion artifacts rarely appear simultaneously in the SPR signal of both hands. We observed this behaviour in our testing most of the time, and the proposed solution appears to be a good compromise to lessen the MA. Considering the RMS values σ_1 and σ_2 of the SPR input signals s_1 and s_2 on a $L = 100$ samples wide moving window, corresponding to 1 s at a sample rate of 100 Sa/s, we establish a smoothing threshold function $f(x)$ in order to obtain $f(x) \approx 0$ when $0 \leq x \ll 1$ and $f(x) \approx 1$ when $1 \ll x \leq 2$, namely,

$$f(x) = \frac{1}{1 + e^{-2(x-1)}} \tag{1}$$

This function is employed in a correction term β, that enables us to reduce motion artifacts. At the n^{th} sample, this correction term is calculated as:

$$\beta(n) = \begin{cases} f\left(\frac{\sigma_1(n)}{\sigma_2(n)}\right) & \text{if} \quad \sigma_2(n) \neq 0 \\ 1 & \text{if} \quad \sigma_2(n) = 0 \end{cases} \tag{2}$$

We can deduce that $\beta \to 0$ when $\sigma_1 < \sigma_2$ and $\beta \to 1$ when $\sigma_1 > \sigma_2$. The correction term β, as in (2), is then used to determine the clean single output $s(n)$ of the procedure as

$$s(n) = \beta(n) \cdot s_2(n) + \left[1 - \beta(n)\right] \cdot s_1(n) \tag{3}$$

In the end, the output in (3) imitates the signal characterized by the lower energy in the 1 s examined interval.

2.3 Classification algorithms

In the proposed system, we utilize a classification technique to detect the presence (or absence) of a driver's stress condition in a given time interval during a car driving simulation. For this classification task, we utilize and compare six different supervised machine learning algorithms: an SVM classifier, a Naïve Bayes classifier, a k-Nearest Neighbors (k-NN) classifier, a Decision Tree (DT), an RF classifier, and an Artificial Neural Network (ANN). All these algorithms have been widely used in the literature for classification purposes. We also use two deep learning algorithms, in particular a 1D CNN and an LSTM network.

Our goal is to classify all of the time intervals in two possible classes: the stress class (or "1") and the non-stress class (or "0"). For this, we use the processed and cleaned SPR signal, and the ECG signal, with the latter one processed to remove the ectopic beats similarly to what is proposed in [35]. In addition, a further normalization preprocessing step is applied to both SPR and RR signals, because they can differ considerably among the individuals. This step consists of the standardization of each signal, based on the mean and variance of the preceding 5 minutes of the current signal value. We decided to process a 15 s long interval at a time, and we take a new interval every 5 s. In this way each interval covers the preceding one by 10 s. We do this to keep a reasonably low processing delay. The overall number of features extracted from these time intervals is nine: five from the SPR signal and four from the ECG signal. The five statistical features considered for the SPR signal

are: the interval variance, the energy, the mean absolute value, the mean absolute derivative and the max absolute derivative. The four statistical features from the ECG signal are: the mean value of RR intervals, the standard deviation of RR intervals (SDNN), the root mean square of subsequent RR interval differences (RMSSD) and the mean value of the Heart Rate [38]. We gather the features of the two signals together to construct the feature vectors. Each feature is then normalized in the range [0, 1]. All of the ML classifiers have been set up using Matlab (2017.a), except for the ANN that has been set up using Python. Hyperparameters are optimized automatically by the Matlab routine functions used for classification. In addition, for the SVM classifier, a Radial Basis Function (RBF) kernel has been used. The Bayesian optimization has also been used during the training procedure. For the ANN, we implement a four-layer perceptron trained with the back-propagation algorithm. We utilize Keras and the optimization package called "hyperopt" [39], allowing the use of the Bayesian optimization in this case as well. The optimization process also allows us to select the number of nodes in the two hidden layers (ranging from 16 to 128). The drop-out percentage has also been computed by the optimization package. Regarding the cross validation methodology, the 10-fold cross validation is used for all of the ML algorithms. For the ANN classifier we set the batch-size equal to 128.

The DL algorithms are also set up using Python. In detail, the architecture of the CNN used for classification has been inspired by the one proposed in [28], and its parameters are briefly reported in Table 1. The CNN contains two identical sequences of four operations: a convolutional layer, an Exponential Linear Unit (ELU), a batch normalisation layer and a max pooling layer. These are followed by a fully-connected layer (of 128 nodes), and the output layer where the softmax activation function is used. As anticipated, the inputs of the CNN are no longer the feature vectors, but the unprocessed samples of both the SPR and RR signals recorded from the subject at the same moment, in time intervals 15 s long. For each time interval, the values of the SPR and the RR signals must be arranged side by side. Since each 15 s long time interval is made of N = 1500 samples, with a sample rate of 100 Sa/s for both the SPR and RR signals, we obtain an input matrix with a size of 1500×2, to be sent as input to the network. We proceed picking a new interval every 5 seconds and applying the same procedure. The labels corresponding to each interval are the same already derived for the ML algorithms. Other details about how the CNN model is defined are the following: we use the Adam optimizer, the learning rate has been set equal to 0.001, the categorical cross-entropy has been chosen as loss function, the number of epochs has been set equal to 20 and the batch-size to 64 (https://keras.io).

Another DL algorithm, i.e., an LSTM network, has been used in the experiments. This is a particular type of Recurrent Neural Network (RNN) that overcomes the issue of the short-term memory of the RNNs (also known as the vanishing gradient problem). The LSTM internal gates keep the relevant information in a long sequence of data, throwing away the non-relevant data, and this can help us recognizing stress with a long dynamic temporal behavior. The architecture of the implemented LSTM network is reported in Table 2. The same settings introduced before for the CNN (the learning rate, the number of epochs, etc.) have been used for the LSTM as well, with batch-size 128. Regarding this network, we also consider a variant of it which uses the hyperopt optimization package (it will be denoted as LSTM2 in Section 4). In this case the number of nodes (ranging from 16 to 128) and the dropout value (varying between 0 and 1), for each layer, have been computed by the optimization package.

Table 1: Architecture of the implemented CNN

CNN	
Convolutional layer	Filters = 20, Kernel size = 10, Stride = 2
Exponential Linear Units (ELU)	Alpha = 0.1
Batch norm. + dropout (0.15)	
Max pooling	Pool size = 2, Stride = 2
Convolutional layer	Filters = 20, Kernel size = 10, Stride = 2
Exponential Linear Units (ELU)	Alpha = 0.1
Batch norm. + dropout (0.15)	
Max pooling	Pool size = 2, Stride = 2
Flatten	
Dense + dropout (0.5)	Nodes = 128, Activation = ReLU
Dense	Nodes = 2, Activation = Softmax

We employ the "leave-one-person-out" technique for all of the learning algorithms, such that the training of each classifier is performed using the data of all individuals, except one, on which the classifiers will be tested. This process is carried out for each individual, and in the end the overall system performance is determined by computing the average of the results originated from all of the individuals.

Dropout	0.4
Dense	Nodes = 2, Activation = Softmax

3 Experimental setup

The experiments, as introduced above, are carried out in a firm that develops professional driving simulators, both in hardware and software. For our tests, we use a dynamic driving simulator that allows the reproduction of the same movements of a real car. In fact, it provides motion feedback to the drivers through a nine degrees-of-freedom moving platform. We enrolled 16 healthy individuals, 22-47 years old, some from the University of Udine and some from the University of Padua. The subjects were asked to drive on a 28 km long straight highway track, with four stress-inducing obstacles demanding some concentration to get over. These four obstacles are shown in Figure 3. From left to right and from top to bottom, they are: Sponsor block (from right to left), Tire labyrinth, Double lane change (right to left) and Sponsor block (from left to right).

All subjects prepare themselves before entering the simulator. They wear the sensing devices both on chest and hands. They gave consent having their physiological signals recorded, and the test were performed according to the principles of the Declaration of Helsinki.

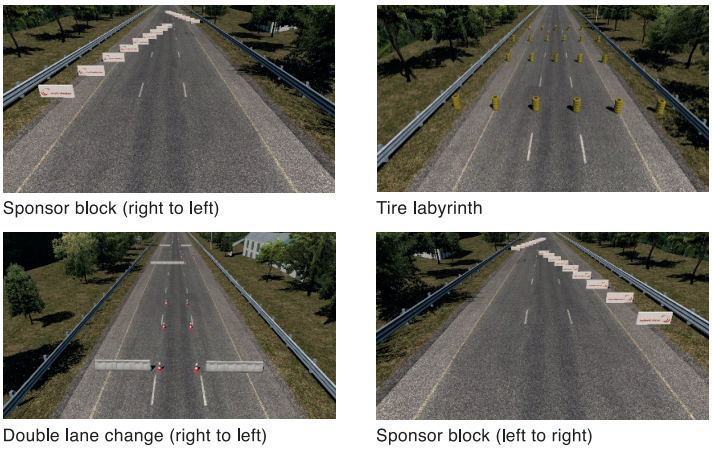

Figure 3: The four stress-inducing events located along the road.

Figure 4 displays the cleaned SPR signal, after the MA removal block, and the instantaneous HR signal of a subject (derived from the RR signal) during the simulation. The start of an event is signaled with a vertical line with a circle marker, and the end of an event with a vertical line with a square marker. We also assume an event starts when the obstacle enters the field of view of the subject (and this happens approaching a distance of 800 meters from the obstacle), and ends 30 seconds after surpassing the obstacle. Passing each obstacle takes approximately 65 seconds. The peculiar stress peaks shape in the SPR signal during the stress event can be seen evidently in the figure, just as the distinctive rise in Heart Rate.

4 Experimental Results

The classifiers, which allow the recognition of stress in each 15 s long interval, are built using the cleaned SPR signal and the ECG signal of each subject. For the traditional ML algorithms the features of the signals are extracted from each interval. For the DL algorithms there are no features to be extracted, and the raw signals themselves are considered for each interval. In all cases, the intervals overlap each other by 10 s as already specified.

We assume that all the intervals happening in a stretch of the road where obstacles are present, to have the value "1", with stress, and that all the intervals happening in a stretch of the road without obstacles to have the value "0", with no stress. As already mentioned, we employ the "leave-one-person-out" method in the classification process. So, for the training, we examine 15 subjects at a time out of the 16 in total. In this way, we obtain a total number of intervals ranging from 1176 to 1209, for both stress and non-stress classes. The total number of intervals for training is not fixed because each individual overcomes the obstacles with slightly different timing and speed. During the test we obtain approximately 187 intervals to analyze for each individual (this is an average value taking all of the subjects into consideration), where the majority of them, about two thirds, belong to the non-stress class.

According to the assumed ground-truth, the True Positives (TP), the False Negatives (FN), the True Negatives (TN) and the False Positives (FP) can be computed, as well as the performance indicators like Accuracy, Sensitivity and Specificity:

$$\text{Accuracy } (\%) = \frac{\text{TP+TN}}{\text{TP+TN+FP+FN}} \cdot 100 \tag{4}$$

$$\text{Sensitivity } (\%) = \frac{\text{TP}}{\text{TP+FN}} \cdot 100 \tag{5}$$

$$\text{Specificity } (\%) = \frac{\text{TN}}{\text{FP+TN}} \cdot 100 \tag{6}$$

Due to the fact that our test data are unbalanced (in fact we have less stress intervals than non-stress intervals), two additional indicators are also important, the Balanced Accuracy (BA) and the Geometric Mean (GM), defined as

$$\text{BA } (\%) = \frac{1}{2}\left(\frac{\text{TP}}{\text{TP+FN}} + \frac{\text{TN}}{\text{FP+TN}}\right) \cdot 100 \tag{7}$$

$$\text{GM } (\%) = \sqrt{\frac{\text{TP}}{\text{TP+FN}} \cdot \frac{\text{TN}}{\text{FP+TN}}} \cdot 100 \tag{8}$$

Table 3 presents the overall performance of our system (MEAN ± STD), calculated by averaging the results of the 16 subjects, for all of the considered ML algorithms. The accuracy and balanced accuracy values among the classifiers are close, even if the ANN classifier is slightly better than the other ones in terms of accuracy, and the RF in terms of balanced accuracy. Moreover, the sensitivity of the RF is higher than the others, as it is the specificity of the Naïve Bayes classifier. The GM values are similar for all of the ML algorithms, with the RF classifier still performing marginally better than the others.

As introduced before, as a first attempt to use a deep learning algorithm to recognize stress and non-stress episodes in our scenario, we set up a 1D CNN and an LSTM. We compute the overall performance of the CNN and the LSTM using the test set, and we obtain the values reported in Table 3. So, comparing the results of the DL algorithms with the ones obtained applying the aforementioned ML algorithms, we can notice that the CNN architecture performs similarly to the other ML architectures. In particular, the accuracy of the ANN and the specificity of the Naïve Bayes classifier exceed the values corresponding to the CNN classifier, whereas the CNN sensitivity is better than that obtained with the other ML classifiers. However, when looking at the LSTM, we can see that it works well in detecting the stress episodes, outperforming all the other algorithms in terms of accuracy, sensitivity, balance accuracy and geometric mean. The specificity of the LSTM, instead, is lower than the Naïve Bayes one. The variant LSTM2 performs even better, and all of the performance indicators are higher than the other DL and ML algorithms.

The overall performance of the system looks favourable. It should be noted that some of our hypotheses are critical and can affect the performance indicators. The first hypothesis we make is that all the time intervals happening during the overcoming of an obstacle by a driver should originate stress, even if it is possible that the driver is not constantly stressed during the manoeuvre. The second one is that a driver is not stressed when not overcoming an obstacle. This might not be true at all times, since a driver can be in a condition of stress during those time intervals for causes unknown to us.

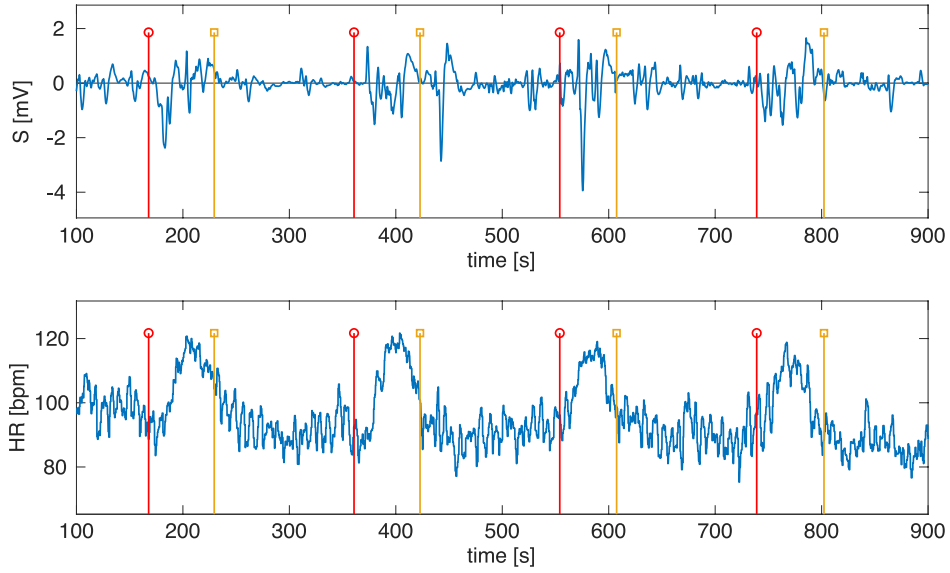

Figure 4: SPR and HR signals (at the top and the bottom, respectively) for a subject during the driving simulation. Each event onset is evidenced with a red vertical line with a circle marker, and each event offset with a yellow vertical line with a square marker.

Table 3: Performance of all the supervised learning algorithms

	Accuracy (%)	Sensitivity (%)	Specificity (%)	BA (%)	GM (%)
SVM	72.86 ± 8.77	86.69 ± 7.79	66.46 ± 13.02	76.57 ± 6.91	75.40 ± 7.85
Naïve Bayes	74.04 ± 6.53	82.83 ± 8.04	70.27 ± 10.85	76.55 ± 4.65	75.81 ±5.01
k-NN	72.07 ± 6.01	86.60 ± 8.30	65.99 ± 8.77	76.30 ± 4.96	75.26 ± 5.23
DT	70.76 ± 8.88	85.16 ± 6.61	64.80 ± 13.13	74.98 ± 5.98	73.69 ± 7.20
RF	74.25 ± 6.17	87.05 ± 7.60	68.83 ± 8.83	77.94 ± 5.03	77.11 ± 5.35
ANN	74.45 ± 8.65	86.19 ± 8.13	69.00 ± 13.38	77.59 ± 6.50	76.56 ± 7.30
CNN	73.97 ± 6.23	87.99 ± 6.40	67.76 ± 8.30	77.87 ± 4.82	76.99 ± 5.27
LSTM	82.56 ± 3.04	88.61 ± 7.55	69.79 ± 17.61	79.20 ± 5.96	77.46 ± 9.23
LSTM2	88.02 ± 0.97	93.60 ± 1.92	76.26 ± 4.22	84.93 ± 1.55	84.43 ± 1.78

Another possible critical aspect of our hypotheses is that part of the signal responses may be due to the increased physical effort during the events. However, in some previous works, e.g., [40], we observed that the intensities of the signals during designated stress events were significant, and could not be confused with the levels recorded during non-stress intervals, even if a comparable physical activity was required for driving. In [41], we also evaluated a car driver's stress condition in a simulated autonomous driving scenario. In that experiment, we submitted questionnaires to the drivers and evaluated other parameters such as the User Experience (UX) measure and the NASA Task Load Index. Questionnaires supported our findings derived by analyzing the SPR and ECG signals (see also [42]).

To account for these considerations, and enhance the stress recognition ability, we apply a re-label step to the output of the classifiers (see Figure 5). To do so, we assume stress is happening if a minimum of four consecutive intervals are marked as positive (thus covering a time span of 30 s). In the end, the blocks of four or more consecutive positive intervals are kept, whereas blocks of up to three consecutive positive intervals are instead re-labelled as negative.

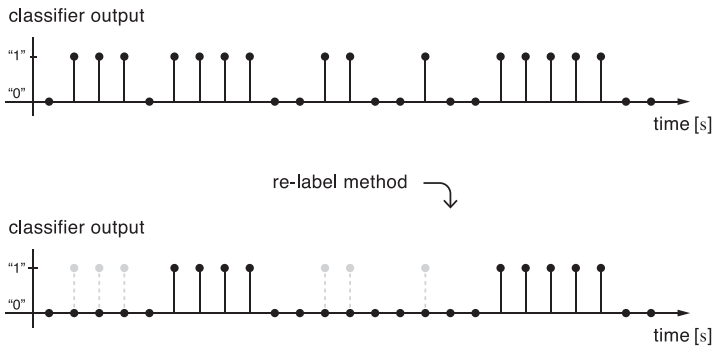

Figure 5: The re-label method applied to the output of each classifier.

In Table 4 the performance indicators applying the re-label method are presented. The values are slightly higher than the ones in Table 3. On the other hand, sensitivity is a little smaller for all of the classifiers, since we noticed that a number of stress intervals, which were correctly detected before, are now discarded by the re-label step. The performance indicators of the LSTM2 are clearly higher, when compared to the other algorithms, in this scenario as well.

Table 4: Performance of all the supervised learning techniques when the re-label method is applied to the output of each classifier

	Accuracy (%)	Sensitivity (%)	Specificity (%)	Balanced Accuracy (%)	Geometric Mean (%)
SVM	77.61 ± 8.14	85.11 ± 8.82	74.05 ± 11.67	79.58 ± 6.89	79.00 ± 7.30
Naïve Bayes	77.39 ± 6.69	82.83 ± 8.04	70.27 ± 10.85	76.55 ± 4.65	75.81 ±5.01
k-NN	75.86 ± 5.84	83.85 ± 11.04	72.61 ± 8.95	78.23 ± 5.47	77.56 ±5.63
DT	76.17 ± 7.87	82.42 ± 8.09	73.69 ± 11.41	78.06 ± 5.85	77.50 ±6.16
RF	77.15 ± 6.39	86.16 ± 7.42	73.32 ± 8.89	79.74 ± 5.35	79.22 ±5.59
ANN	78.17 ± 9.13	84.73 ± 9.72	75.16 ± 14.23	79.94 ± 6.88	79.15 ± 7.50
CNN	79.47 ± 6.45	85.31 ± 8.33	77.09 ± 8.48	81.20 ± 5.79	80.87 ± 5.90
LSTM	83.21 ± 3.27	88.23 ± 7.78	72.62 ± 17.39	80.42 ± 5.94	78.91 ± 9.00
LSTM2	88.13 ± 0.87	93.30 ± 1.92	77.20 ± 4.05	85.25 ± 1.42	84.83 ± 1.60

5 Conclusions

We presented a scheme to recognize individuals' stress while driving in a car driving simulator. The proposed system uses relatively simple sensors, with an acceptably intrusive setup. Due to the short signal block analysis, it can be used nearly in real time and can discriminate stressful events of short duration. In our system, we record two SPR signals for each individual, one for each hand, and the ECG signal. We then apply an MA removal algorithm to remove the artifacts that could appear in the SPR signals during the drive, so that the output is a single cleaned SPR signal. Some features are extracted from both the cleaned SPR signal and the ECG, and sent as input to an ML algorithm. The raw signals are instead directly used as input to DL algorithms. In particular, we evaluate the performance of an SVM classifier, a Naïve Bayes classifier, a *k*-NN classifier, a DT, an RF classifier and an ANN. The performance of all the ML classifiers are similar one to each other, however, the ANN classifier performs better than the others in terms of accuracy. The RF classifier outperforms the others in terms of sensitivity, balanced accuracy and geometric mean, while the Naïve Bayes classifier in terms of specificity. We also report the results obtained with a 1D CNN and an LSTM. The CNN outperforms the other ML classifiers in terms of sensitivity. The LSTM, when some parameters are selected by the optimization procedure, outperforms all the other learning algorithms. A re-labelling procedure is also considered, and the performance indicators of all of the algorithms are compared again in this case. We obtain the highest accuracy, equal to 88.13%, using the optimized LSTM.

Some critical aspects of the proposed experiment are due to the assumption that stress is present only during the arranged events, and that part of the signal responses may be due to the increased physical effort while driving through the events. We have observed that these issues still allow us to interpret the results with a good level of confidence. We conclude that the overall performance of our system is encouraging, showing that by using the SPR and ECG signals we can identify the stress in drivers, deriving from some demanding driving activities, with acceptable accuracy.

Conflict of Interest The authors declare no conflict of interest.

Acknowledgment We are grateful to VI-grade S.r.l., Tavagnacco (UD), Italy, and in particular to Fabio Formaggia, Diego Minen, Michela Minen, and Carlo Savorgnan, for their assistance in data acquisition with their professional driving simulator.

ABSTRACT

In this paper we are demonstrating the importance of building and achieving a renewable electrical power system that works in synchronization with the grid. The average of consumption, generation and the negative environmental effect of generating power were analyzed. This paper is divided into three parts, one was analyzed with Green Building Studio software and the other with Building Information software. Using BIM software, the levels of energy consumption were analyzed for a building in Baghdad – Iraq and in Craiova _ Romania, alongside pollution levels produced, and the possibility of energy generation utilizing PV cells and wind, the output power that can be achieved in respect to temperature and irradiance levels. Using Green Building software, energy consumption system was analyzed in the level of green building.

1. Introduction

The concept of power and energy management refers to the use of highly effective and reliable blueprints of managing the available power and energy in such a way that the outcomes are optimized while also preventing wastage. Despite the fact that there are many factors and issues that cause power and energy loss, the absence of an effective management blueprint is one of the main contributors [1]. When an effective blueprint is absence, it then follows that the framework of power loss is heighted. Following is an evaluation of the distinctive factors and issues affecting the management of power and energy. It is vitally important to accentuate the fact that there are numerous issues and factors that impact the management of power and energy. While some of the factors are preventable in the short-term, others can only be addressed in the long-term. Unless these factors are identified in the first place, the blueprint for management of power and energy cannot be enhanced. Over the years, many problems have characterized power and energy systems in different parts of the world because such systems were not aligned towards an effective management blueprint [2]. There is thus the need to identify the distinctive issues and factors that play a direct role in the framework of power and energy management.

2. Factors Effecting Power and Energy Management

As far as the factors affecting the management of power and energy are concerned, one of the most important issues of emphasis pertains to location. Depending on the location, a given blueprint for management of power and energy can either be effective or ineffective [3]. In line with this attribute, there is always the need to ensure that the process of management of power and energy is strongly aligned towards the specific needs and priorities of a given location. Such an approach is essential towards the prevention of potential problems such as power and energy loss. The factors affecting the framework of management of power and energy also encompass the source of power. Different sources of power are characterized by distinctive attributes and issues. It then follows that the specific source must be determined in order to develop a framework of management of power and energy that is effective in the short-term as well as in the long-term [4]. A notable way in which the source of power impacts the framework of management of power and energy is that it determines whether a given management strategy can help in the reduction of energy wastage or not. This goes a long way towards determining the quality of outcomes in the long-term as well as in the short-term.

Competence of personnel is a major issue that determines the approach used within the context of management of power and

energy. For instance, the competence of staff members in a power grid determines the manner in which they approach decision making processes concerning power management [5]. Additionally, it is also notable that the competence of personnel goes a long way towards determining whether they understand the technical elements of management of power and energy or not.

As far as the factors influencing the blueprint of management of power and energy are concerned, another notable aspect of emphasis pertains to the availability of resources. In some instances, the scarcity of resources can compromise the extent to which the management of power and energy is aligned towards the intended goals. This is because there are extensive resource requirements at any stage of managing energy and power. It is also vitally important to highlight the fact that the availability of resources impacts the manner in which planning is actualized into the blueprint for management of power and energy [6]. In view of these stipulations, it is hence evident that the availability of resources is always a notable aspect of emphasis that determines the manner in which the blueprint for management of power and energy is actualized. The engineering vision of analyzing and constructing green buildings is a foundation for energy management such as to guarantee the achieving of great economic benefits [7, 8].

3. Building Performance Analysis (BPA) and Optimization Energy (OE) in Green Building Studio (GBS)

The Green building studio (GBS) which powers the energy analysis through (cloud-based service), the GBS with Insight 360 Revit Autodesk is able to test daily and weekly then make review, comparing with the previous results, there are two types of testing in green building studio (GBS):

Service side: energy results from GBS compare against the baseline. Analytics: written the energy results as simulation and compared with the baseline. The green building studio analyze the performance of the building as total annual energy consumption (electrical, fuel, CO2), total annual cost and potential energy savings.

The GBS analyzes automatically 37 separate energy simulations that can run in the cloud through the weather data station (in Baghdad use for analyzing the weather station GBS_06M12_12_002295).

The performance factors of analysis are:

- Light efficiency (from 0.7w/sf-1.9w/sf)
- Plug load efficiency (from 0.6w/sf-2.6w/sf)
- Building orientation (0 degree, 135 degree….etc.)
- Operations schedule (24/7, 12/7, 12/5 ….etc.).
- Daylighting occupancy and non-control.
- Infiltration load.
- HVAC.
- Other (civil and mechanical parameters).

3.1. Green Building Analysis Based On Bulding Orientation

The first effective factor before creating the green building, the Building orientations, selects the optimum degree to the building construction to provide the best energy use intensity, total annual cost and total annual energy. Table 1 represents the orientation of a green building in Baghdad city.

Table 1: The Total Annual Energy Cost (Building Orientations)

Degree	EUI MJ/M^2 /YE.	Total annual cost $		
		Electrical	Fuel	Energy
0	1030	7233	120	7354
135	1054	7201	130	7332
180	1026	6752	136	6889
225	985	6401	134	6535
270	1024	6976	127	7104
315	1016	7057	121	7178
45	1012	6982	123	7106
90	1060	7346	127	7473

From the Table 1 at 225 degree building orientation, the energy use intensity (EUI) 985 MJ/m^2 /year, total annual cost electric 6401 and the energy cost for one year 6535. The solar irradiance, temperature, flow air, infiltrations etc. at 225 degree is the optimum point for construction of green building to save the cost of energy and fuel.

Table 2 represents the annual energy consumptions at a green building with the different degree orientation at the same location. At 225 degree the total annual energy consumption in kWh 46.590(minimum consumptions), and at 90-degree orientation 53.465(maximum consumptions)

Table 2: The Total Annual Energy Consumptions (Building Orientations)

Degree	Total annual energy	
	Electrical kWh	Fuel MJ
0	52.649	87.929
135	52.416	95.127
180	49.146	99.485
225	46.590	97.616
270	50.777	93.077
315	51.362	88.650
45	50.822	89.573
90	53.465	92.914

From the results (Table 1, Table 2) the minimum energy consumption, minimum EUI, and minimum energy fuel cost is at the 225 degree. Green Building Studio (GBS), Insight 360 is able to analyze the weather effect on the building to provide the best benefit from the environment and the effects of climate, wind …etc.

The parameters analysis extensions a scope of possibilities to find very active building as a green building, for example the climate can determine the type and capacity of the lighting installation depending on the degree of the building orientations.

Figure 1 and Figure 2 Represent the total annual energy consumption MJ and total annual electrical consumption. The Y-axis total energy (MJ), X-axis time (year) for example in Jan the red bar shows the space heat ,yellow bar area light, blue bar space cooling.

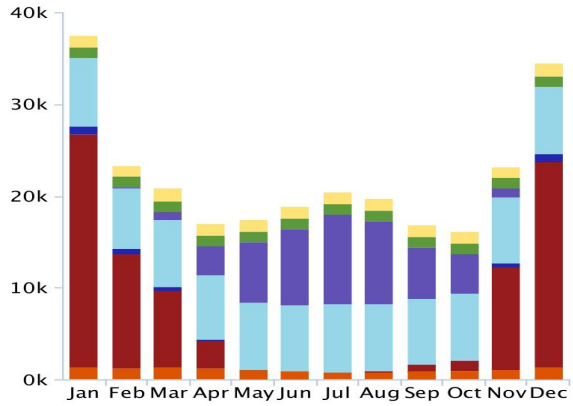

Figure 1: The Total Annual Energy Consumption (Mj)

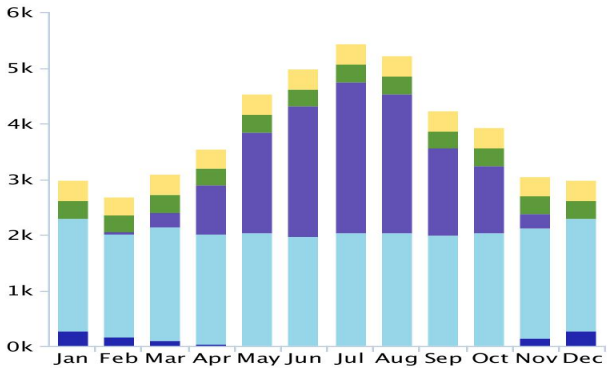

Figure 2: The Total Annual Electrical Consumption (Kwh)

3.2. Green Building Analysis Based On Daylighting

The second factor effect on the energy consumption in green building is daylighting analysis, the daylighting analysis is divided into four parts:

- Daylighting and occupancy control daylighting & occupancy control.
- Daylighting and occupancy control daylighting control.
- Daylighting and occupancy control none.
- Daylighting and occupancy control & occupancy control.

Table 3 presents the amount of total annual cost and total energy consumption for the four parts of daylights control regarding to GBS weather station (cloud-based service).

Table 3: The Amount of Total Annual Cost and Total Energy Consumption

		Total Annual Cost $			Total Annual Consumptions Energy	
Day Light	Eui Mj/M²/Y	Ele.	Fue.	Ener.	Elec. Kwh	Fuel Mj
1	1016	7.020	123	7.143	51.04	89.58
2	1021	7.105	122	7.227	51.710	88.89
3	1030	7.233	120	7.354	52.649	87.92
4	1023	7128	121	7250	51.883	88.74

From the Table 3 the green building studio analysis improves the maximum energy potential savings in Daylighting and occupancy control daylighting & occupancy control.

Figure. 3 and Figure. 4 represent the total energy (MJ), electrical consumption kwh for Daylighting and occupancy control daylighting & occupancy control for the one-year period.

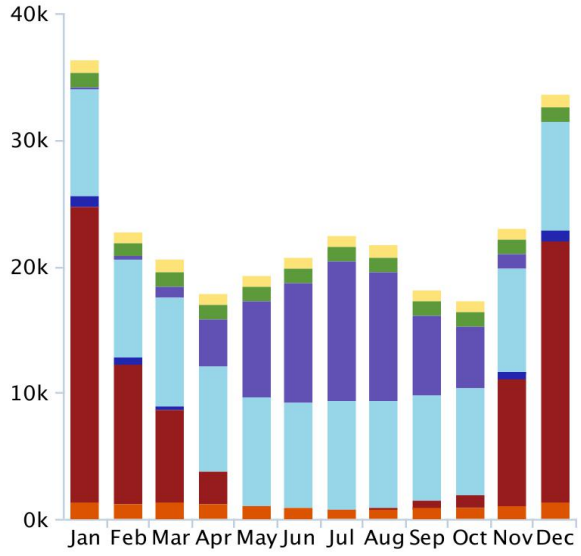

Figure. 3: The Total Energy (Mj)

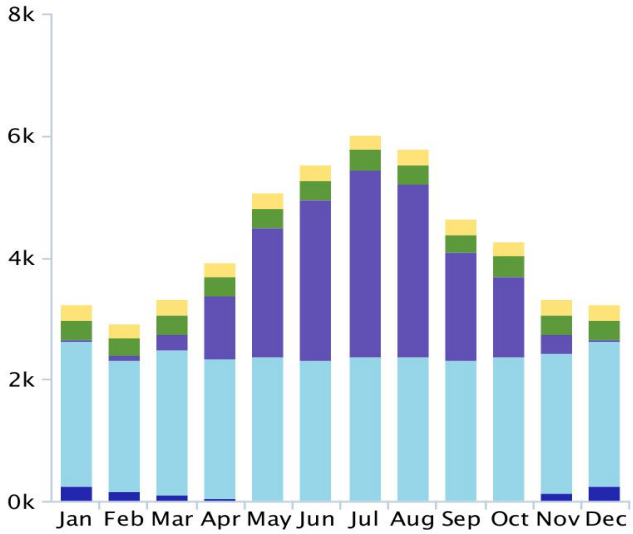

Figure 4: Electrical Consumption (Kwh)

3.3. Green Building Analysis Based On potantial energy (cost)savings

For the design of a green building and an existing building analysis, the reduce of the energy used is one of the main targets of the GBS, potential energy savings (PES) analyze all buildings energy performance (more than 37 separate energy simulations).

For the photovoltaics analysis (in Baghdad, weather station GBS_06M12_12_002295) at 225-degree orientation building, installed on the roof of the building, the panel type single crystalline -13.8 efficiency, installed panel cost 8$ per watt, applied electric cost 0.14$, the maximum payback period 50 years, installed panel cost 162.266$, installed panel area 147m^2, the annual energy production 36 kWh.

Table 4 presents the potential cost saving and annual energy with payback per surface per year, the annual energy produced depends on two factors, the panel area and solar exposure %, for example at the annual energy produce of 984(kWh), the panel area 4 m^2, solar exposure 69.9%.

Table 4: Potential Cost Saving and Annual Energy with Payback Per Surface Per Year

	Potential cost savings $		
Annual energy kWh	Per year/m^2	Per year	payback per surface per years
984	36.04	133	23.9
2914	36.04	408	23.9
364	36.04	51	23.9
447	36.04	63	23.9
16.703	32.23	2.338	26.1
3.251	32.14	455	26.2
3.207	31.80	499	26.3
3.563	31.8	499	26.3
2.767	31.80	387	26.3

3.4. Implications of Power and energy management

In view of the various factors and issues affecting the process of management of power and energy, there is also the need to identify the distinctive implications of management of power and energy [9]. These implications re essential in that they influence the planning process especially when it comes to decision making as well as allocation of resources [10]. Additionally, clarity of the implications helps in determining the best possible strategy to apply within the confines of management of power and energy.

The specific implications of management of power and energy also encompass sustainability. This refers to the use of energy resources in such a way that the needs of the future generations are considered even while scarce resources are being utilized by current generations [11]. Despite the fact that there are many factors and issues that contribute towards the sustainable use of power, the framework of management is always important. Additionally, the fact that the process enhances the extent to which energy and power is is optimized is also indicative of the manner in which the blueprint for management of power and energy enhances suitability.

3.5. Evaluation of CO2 emissions when only fuel is used for power generation

One of the most important criteria for creating a system that depends on improving the environmental levels is the effect of CO2 gas that is a by-product of electrical energy production.

Figure 5. Depicts the effect of energy production. Fuel consumption in Baghdad – Iraq is up to 6 tons [12] [13].

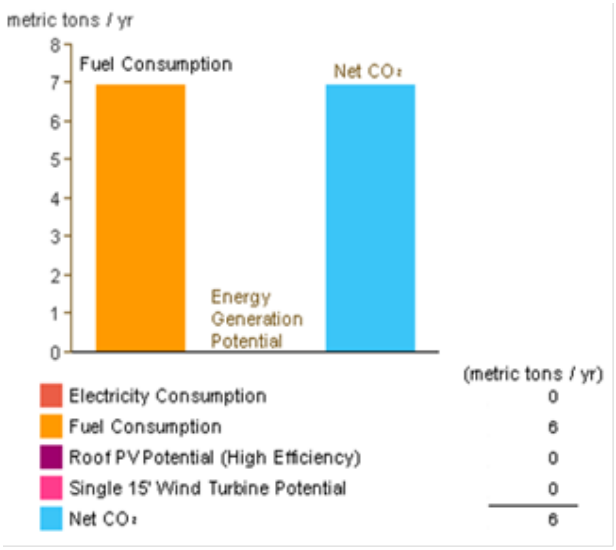

Figure 5: Energy and CO2 Consumptions (Baghdad)

Figure 6 depicts that fuel consumption is 4 tons in the city of Craiova – Romania. The generation system above was analyzed using BIM software for the same area, utilization and population. But the average effect in Craiova is less than Baghdad [12] [13].

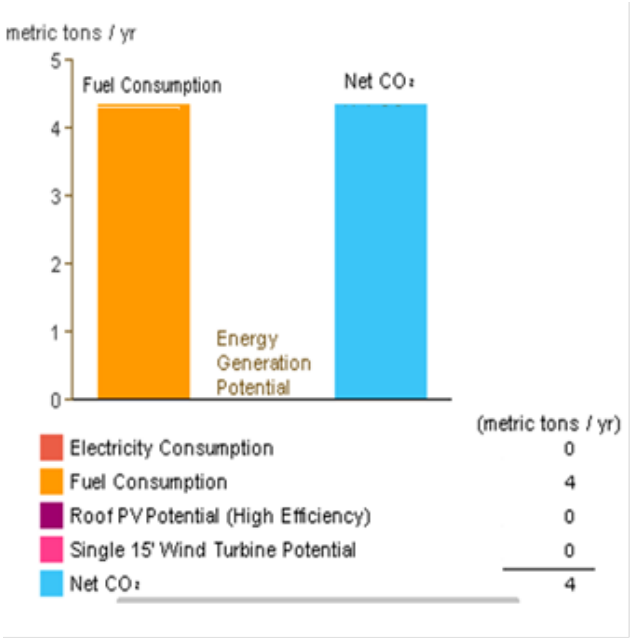

Figure 6: Energy and CO2 Consumptions (Craiova).

The table 5 below states the expected average electrical power generation if renewable energy (PV) is utilized, where these data were analyzed and average temperature and irradiance

were calculated for both cities of Baghdad and Craiova for several types of solar panels and also for wind turbine. The average production in Baghdad is higher than that in Craiova because of the nature of weather and intervals of sun energy availability and higher levels of irradiance [12] [13].

Table 5: Estimations energy produce by Pv cells And Wind

Energy Estimation	**BGW**(kwh/yer)	**CRA.** (kwh/yer)
PV cells (low efficiency)	12,377	9,009
PV cells (medium efficiency)	24,755	18,017
PV cells (high efficiency)	36,132	27,026
wind turbine Single 15’	1,956	691

4. Analysis by using BIM software

BIM software functions through analyzing of buildings and stating the effects of civil and mechanical works on the electrical power consumption. BIM software includes several criteria, in total 26 factors which improve grid performance and decrease consumption. Figure 7 illustrates the average annual energy consumption of the buildings taking into consideration building utilization, for example as a school, hospital or residence.

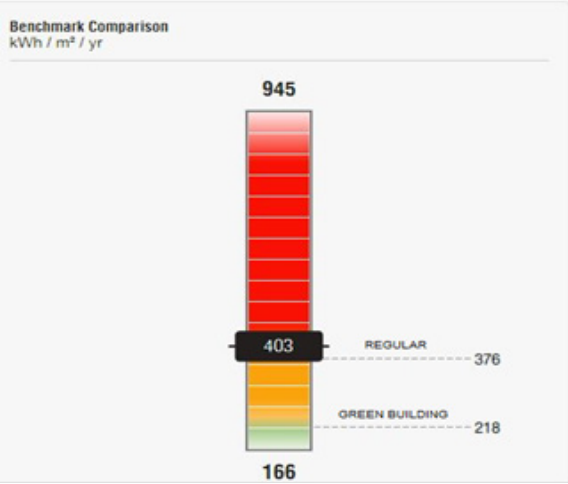

Figure 7: Energy Consumption

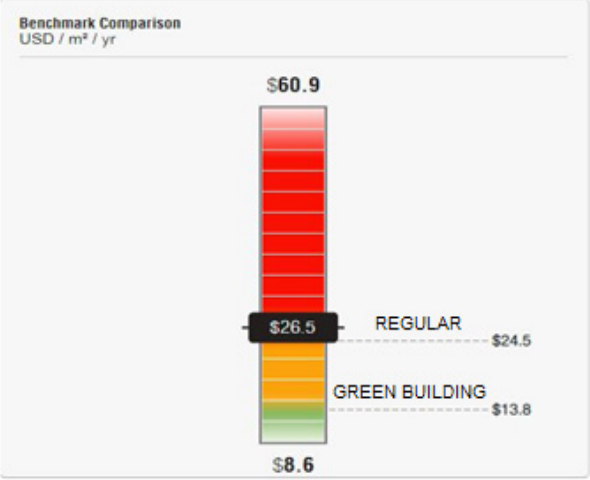

Figure 8: Costs Analysis

We can observe that average energy consumption reaches 376 kW, while when using BIM software analysis system consumption may be 218 kW/m^3 at the same efficiency. Estimated cost changes also from $24.5 to $13.6 (Figure. 8).

Figure 9 represents a comparison in analysis of a building in Baghdad where average consumption is highest through normal analysis, but when Green Building software is utilized as represented in yellow color which reaches a consumption of 310kwh/m^3, and green color when analyzed using BIM software with an annual consumption of up to 120kwh/m^3 [12], [13].

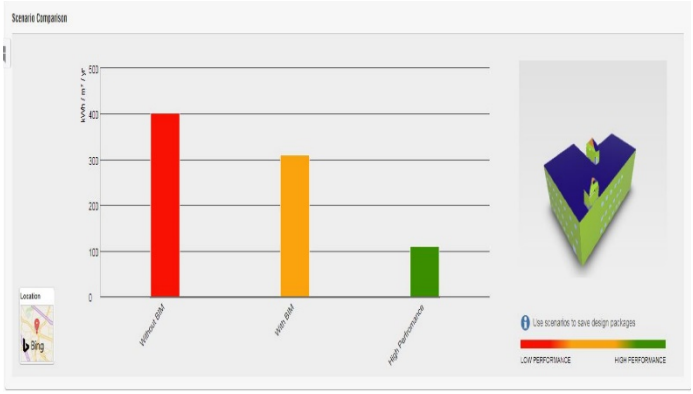

Figure 9: Analysis Performance

5. Conclusions

In this paper, the work was divided into three parts, first part analyzes a building and the effect of weather using Insight software. In the second part an analysis is done via Green Building, where a total cost was calculated to build a solar energy generation system to reduce electrical power consumption, and utilization of building angle which serves to better usage of weather. Third part is an analysis of the systems above. And depicting the economic value that BIM software provides to building efficiency, decrement of consumption, and decrement of costs

ABSTRACT

Face recognition technology becoming pervasive in the fields of computer vision, image processing, and pattern recognition. However, face recognition accuracy rates will decrease if training is done on disguised images with covered objects on a face area. This paper aims to propose a state-of-the-art face recognition methodology which could be applied in Internet of Things (IoT) devices as an input source; then face segmentation and training process will be executed in the cloud via internet; the recognition result will be sent to the connected applications which determines a safety check for personal or public security. This paper focuses on implementation of face segmentation and training process for IoT. Face extraction from the background and disguised part is applied by Fully Convolutional Networks (FCN), and then deep convolution neural network is employed for face training and testing process. This algorithm has been experimented on a challengeable face dataset. The proposed face recognition system is applied to IoT services which have multiple applications, such as, personal home security and public library space management. Compared to recognition without face segmentation, the results of proposed methodology indicate a better accuracy regarding recognition rate.

1. Introduction

IoT is the combination of hardware environment, software services and Internet. It is composed of sensors, servers, hardware equipment, software equipment, and Internet connections [1]. With the fast improvement of sensors and devices, IoT could be applied to multiple fields such as wearables, smart home, and city. Face recognition is one of the popular personal security topics for IoT system, which could be widely used in personal home and public places security fields. Also, it has been used as an identification task in different areas, especially in corresponding with computer-based security and safety systems in homes, criminal identification, and smart phone devices' face identification. For instance, cameras were used for image capturing and IoT processing devices, and Raspberry Pis, were used for comparing captured images with server database to provide directions over the GSM module and alert mobile phones [2]. Similar IoT systems with face recognition components were also proposed for security purposes in various applications, such as libraries and banks [3,4]. In this paper, we propose an effective segmented face recognition for IoT (SFR-IoT) shown in Figure 1.

Face recognition means recognize a specific person with a 2-D or 3-D face image or video base on available face data sets. If a camera is utilized to capture a suspect's face image, that image can then be used to identify the suspect by using biometrics. The application of biometrics technology such as face recognition could reduce crime rates. Instead, the lack of effective skills in capturing biometric data from face images will potentially increase the opportunity for criminal activity [1].

Figure 1: Segmented Face Recognition Architecture (SFR-IoT)

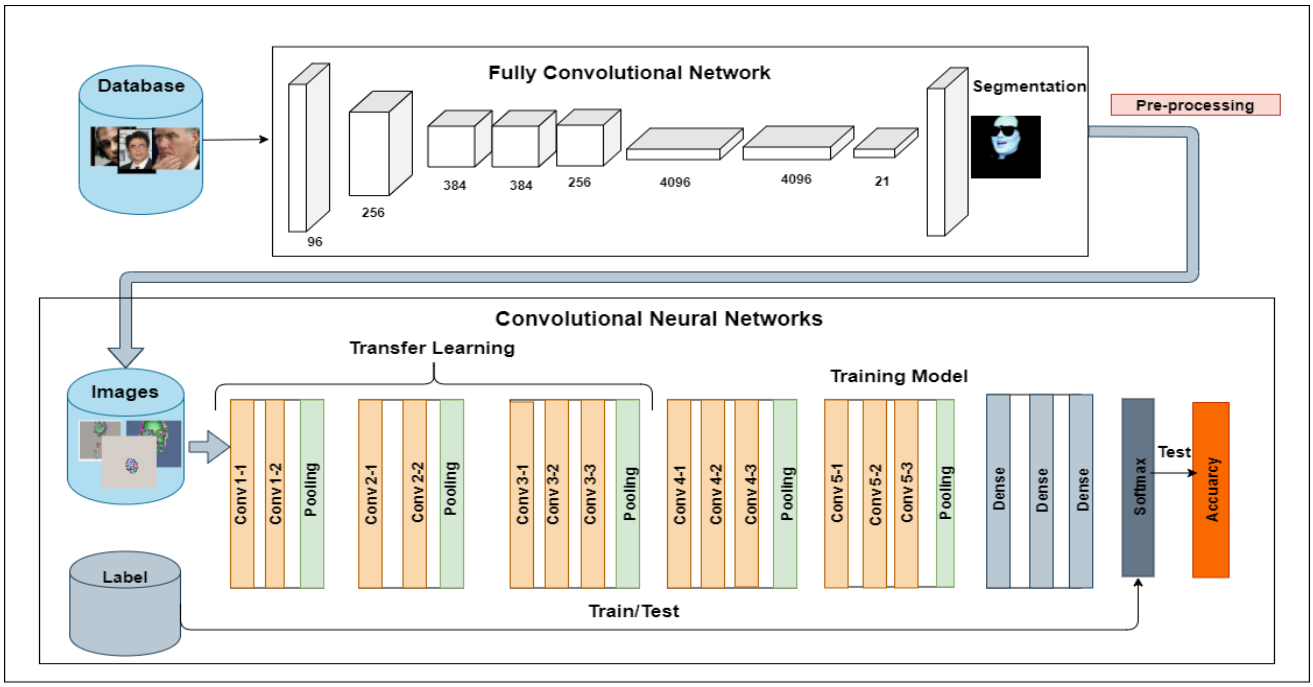

Figure 2: FCN-8Ss-VGG-16 System Architecture

Recently, a few researchers have published work related to crime detection. One study introduced a framework that first detects facial key points and then uses them to perform face recognition [2]. They mentioned that a larger number of images and camouflage images available in a data set can improve the training of the learning network and avoid the need to perform transfer learning. Results show that their framework outperforms the most advanced methods in critical point detection and facial camouflage classification.

For past investigation techniques, there are a few popular algorithms in regards to face cognition which include the geometric features method: principal component analysis (PCA) [3], linear discriminant analysis (LDA) [4], hidden Markov strategy (HMM) [5] and regular LBP features [6]. However, there are evident disadvantages in terms of utilizing these techniques. For instance, the accuracy rate of PCA will diminish significantly with lightness and a state of image change. Also, the strategy for inadequate data requires strict arrangement of information pictures, which is not applicable for basic application.

Due to the important factors of the accessibility of public data sets, as well as the improvement of Graphics Processing Unit (GPU) computation, neural networks has achieved a large renaissance, resulting in a significant increase in accuracy rates [7]. This leads to a major improvement in image recognition and finally in face recognition. For instance, Convolutional Neural Network (CNN) [8,9] is a popular model in neural networks. It is a state-of-the-art technique that has replaced the traditional algorithms on face recognition and consequently taken the network by storm, fundamentally enhancing the cutting edge in numerous applications. Several studies have applied CNN for face recognition purposes, such as Deep Face [10], DeepID3 [11] and Face Net [12]. They have achieved around 97%, 99.6%, and 99.5% success rates, respectively.

Recent studies that combined face segmentation and face recognition technology have provided an important concept for our research. For example, one study extracted face-like regions by using the extracted color information of an image in HSV color space, and the RHT algorithm is then applied to find face region [13]. Samantha proposed a technology of segmentation skin color through YcbCr as well, then applied artificial neural network classified face and non-face classes [14]. However, these researches did not integrate deep learning study for face segmentation and recognition, so this paper would like to propose a new methodology that improve the deficiency.

Even though current automated face recognition systems can recognize individual faces in controlled environments with a 99% accuracy, the accuracy drops to below 60% when images are in unconstrained environments [15].

This is caused by rich facial expressions and changing gestures; face movements with lights; angle; and distance [2].

In addition, disguised faces with glasses, scarves, and accessories will become challenging elements in face recognition tasks. Hence, in order to explore a more effective method to solve this problem, this study proposes a new system called FCN-8s-VGG-16, which is used for the segmentation technology face recognition before classification. The system contains two procedures, as shown in Figure 2. The process of this research is to build a training set of segmentation of the face area with FCN as an input of Convolution Neural Network (CNN), and then train the CNN network from VGG-Face with transfer learning. Lastly, the classification function SoftMax is applied for face probability distribution. The first step is to segment the original image for extracting face parts (eyes, nose, mouth, and skin) from the background, which applies a pre-trained FCN-8s model [16]. Secondly, the output images are fed into the network applying transfer learning [10] based on VGG-16 [8] with our fine-tuned

technology on face recognition task. Finally, the Softmax function calculates the probability distribution of the test image and generates the accuracy rate while comparing it to the label box.

2. Related Work

2.1. General Segmentation and Face Segmentation

Segmentation refers to the process of separating an image or frame into groups of pixels which are identical with respect to some standard. A few papers have applied segmentation for their research topic.

In [17], the author proposed a food calorie estimation model, which was applied on a smartphone to predicate calories of the food in images taken by a phone camera. Firstly, they estimated approximate positions of dishes by edge detection. Secondly, k-means based clustering was applied on the color pixels, thereby extracting a bounding box of a food area. Next, they used GrabCut [18] to obtain an accurate food area within the estimated bounding box. Then, they employed CNN as a calorie estimation task. They prepared 120-calorie annotated food photos as the data for the experiments. Finally, 60 test images with real food calories are estimated with the relative average error of 21.3%, regarding food calorie prediction achieved, and it is higher than the Japanese government definition.

In [19], the author applied different segmentation techniques in the aim of reorganization of the left ventricle in a VEF image. He compared two segmentation approaches: region-based segmentation and edge-based segmentation. The first detects homogeneities and the common features by simultaneously applying the chan_vese model and the thresholding techniques. In the second approach, he applied a certain algorithm such as Sobel, Canny, and Perwitt to obtain the interim between two related regions. Results showed that region-based segmentation using the chan_vese model in conjunction with thresholding gives a better performance.

Since Convolution Neural Network (CNN) has been widely researched by the scholarly field, various models and systems with different purposes are dramatically increased. Fully Convolution Network (FCN) [20] is one of most popular image segmentation technology that is widely used in studies. FCN extracts pixels from CNN layers of mixed scales, enlarges them to the size of the original image, and then applies a convolution layer to classify all this information.

There are research works pertaining to FCN for segmentation purposes that have achieved excellent results. One study presented a One-Shot Video Object Segmentation (OSVOS) based on the FCN network architecture, with transfer learned on ImageNet then fine-tuned on one training sample [21]. The performance was tested on DAVIS database, which consists of 50 full-HD video sequences and YouTube objects. The result shows that OSVOS is fast and improves the state-of-the-art technology by a significant margin (79.8% vs 68.0%). Based on these outstanding results, this paper chooses FCN as our face extraction segmentation tool.

In [22], the author proposed a method to achieve the segmentation of skin, hair, and background by applying FCN-8s and fully-connected CRF. Next, matting algorithm was facilitated in their experiment in order to receive clear hair and skin alpha masks. Finally, they demonstrated that state-of-the-art performance on LFW Parts dataset [23] holds more accurately than other approaches. The defect of the FCN algorithm influences our decision to apply Transfer Learning in our experiment, which we will talk about it in Chapter 3.

2.2. Face Recognition

Another study has shown that choosing an appropriate model in CNN architecture is vital for face recognition. This study evaluated two popular CNN architectures, Alex-Net [9] and VGG-16 [8], on face recognition. They accomplished their task by transferring learning idea to the networks trained for various classifying purposes. One study [24] used Alex-Net model to train the CASIA-WebFace [25] database, and the research shows that VGG performs better than Alex-Net. This paper inspired us to employ VGG-16 [8] as a face recognition model for our own experiment.

In [26], the author conducted face recognition by applying a CNN for feature extraction. First, they randomly selected patches from the STL-10 [27] database and used them to train a linear decoder and obtain a 400 × 192 learned weights matrix. The 64 × 64 RGB images are used to train the identifier through a convolutional layer, and then training features are extracted using these learned weights. Results show the proposed method reached a high rate of excellent sorting, ranging from about 80% to 100%.

There is another study [28] that has proposed a modified Convolutional Neural Network (CNN) architecture with the addition of two batch normalization operations on two of the layers. CNN architecture was utilized to separate particular face features, and Softmax classifier was utilized to recognize faces in the completely associated layer of CNN. The training and test process were tested on a Georgia Tech face database. After pre-processing, the researchers changed the sizes of input to 16×16×1, 16×16×3, 32×32×1, 32×32×3, 64×64×1, and 64×64×3 in order to receive the best result. Finally, 64x64x3 surpasses other sized images regarding the lowest Top-1 error rate. Our paper applied a similar strategy with this research, through altering the size of input in order to obtain the best result in our experiment.

However, to our knowledge, segmentation technology is not used in the face recognition field so far, except in our initial work [29]. This paper is an extension of work originally presented in the 2019 18th IEEE International Conference on Machine Learning and Applications. The accuracy rate will increase due to the interference decrease from unrelated face pixels, such as glasses. In order to decrease the useless effect pixels of disguised face parts, this study would like to propose an FCN-8s-VGG-16 system with segmented technology before classification. It only keeps face sections, and the other parts will be taken off. For the purpose of examination both before and after the change, the face section is sent to the classification model and accuracy will be tested for comparison.

3. The Proposed Approach

3.1. Methodology (CNN)

3.1.1. VGG-16

The core idea of convolutional networks is classifying target data samples to the different distances between classes. The

network structure includes three convolutions (conv1, conv2, conv3), two pooling layers (Pool1, Pool2), and a fully connected layer [8].

3.1.2. Convolution Layer

The input data is trained by employing a set of trainable neurons. The output of each of the feature maps corresponds to an image filter of the same size as the input of the convolution layer. The primary function of the convolution layer is to extract features from an image. Every convolution layer is trained on a feature map of the past layer, sequentially, and then it usually adds a bias parameter in order to increase accuracy by activating the function to translate results from linear to non-linear function. After that, the feature maps are fed into the next convolutional layer as input data.

3.1.3. Pooling Layer

Pooling layer decreases the dimensionality of each activation map but keeps the most vital data information. The input images are separated into a set of non-covering square shapes. Each field is downsampled by a non-linear function. For example, average or maximum is used the most. This layer accomplishes a better speculation and robust result for system.

3.1.4. ReLU Layer

Rectified linear units (ReLU) is a non-linear operation. It is an important function because it ends up with 0 if the input is less than 0. However, if the input is greater than 0, the output will be an original number. Research studies show that ReLU results can implement faster training for a huge network.

3.1.5. Fully Connected Layer

The output from convolution layer, pooling layer, and ReLU layer is high- level features of input data. The purpose of applying the Fully Connected Layer (FCL) is to sum these features for classifying the input data into different classes based on the probability of each class of each feature map. Next, FCL supports the features to a classifier, which is Softmax function. This function will conclude the probabilities of every target class over all possible target instances. Afterwards, the calculated probabilities will decide the target class for the given inputs.

3.1.6. Why VGG

There are a few CNN architectures, such as LeNet, AlexNet, Reset, and so on, which have been widely used since CNN was invented. Recently, the most state-of-the-art model [10] outperforms in the localization and recognition tracks, respectively, the ImageNet Challenge 2014 among them.

This VGG model is described by its simplicity, applying only 3×3 filters stacked over each other in increasing depth. Reducing parameter numbers and model size is employed by max pooling, two fully-connected layers, each with 4,096 nodes followed by a Softmax classifier.

3.1.7. Transfer Learning

Transfer learning is an area of artificial intelligence, which centers around the capacity for a machine learning calculation to enhance learning limits on a target data set through past exposure to an alternate way. The measured quality of a CNN implies that we can easily apply the weights from a pre-trained model and only re-prepare most elevated layers. In particular, we re-prepare all linear layers in the model and replace parameters of the highest layers in VGG-16 [8]. To get rid of the lack of geometric invariance of these approaches, fine-tuning [30] with an external data set can be utilized. The primary distinction between picture arrangement and picture recovery is the measure of information and its fluctuation. In classification, it is important to use huge data sets with high variability for different categories. However, in image recognition, the geometric invariance of an image is less essential for a training model. As the purpose of image recognition is to recognize the instance of example, less variability data will be needed.

In this paper, to use CNN functionally, we fine-tune the pre-trained CNN [10] a face data set for image recognition. Fine-tuning usually focuses on the higher layers while fixing the lower layers of a CNN. We use FCN-8s-VGG [16] architecture, which has been pre-fine-tuned for segmentation on PASCAL [31]. As the CNN model [16] is pre-trained on face dataset and performs an excellent result, we don't consider it for Fine-tuning while we are doing the same object segmentation purpose.

Table 1: The Architecture of VGG-Face Refined

Layer	Layer Type	Filters	Input	Training
1	Conv.	64	3x3x3	False
2	Conv.	64	3x3x64	False
3	Max-Pool	-	2x2	-

3.1.8. VGG-FACE

VGG-Face [10] is a model that was pre-trained based on the VGG-16 structure and set up on a face data set acquired by the Visual Geometry Group that is comprised of more than 2.5 million pictures and 2,622 different labels. Detailed information in terms of VGG-16 model was shown in Table 1, including layer types, number of filters, and input image size.

The architecture of VGG-face contains a total of 22 layers: 13 convolutional layers for image and filter calculation, 5 max pooling layers for keeping feature information, 3 fully connected layers for summing up all previous features, and later a Softmax layer for classification [10]. The normal image resolution of the input layer is 224x224. Table 1 shows the detailed architecture of the VGG-face, including filter numbers and input size at each layer applied in our research. In this experiment, we have fixed the previous 10 layers and changed 21 fully connected layers from 1,000 to 85, since we have 85 classes in the experiment, which means 85 labels will be generated. Additionally, we fixed the parameters of the lower convolutional layers from 1-9 but trained the higher convolutional layers from 11-17 and the FCN layers from 19-21. Applied changes are highlighted in the table.

3.2. Methodology (FCN)

FCN [16] uses the identical convolutional network based on VGG-16 layers [8] and converts the fully connected layer to a convolutional layer. In the traditional CNN structure, the first five layers are convolutional layers, and the sixth and seventh layers are a one-dimensional vector with a length of 4096. The eighth layer is a one-dimensional vector with a length of 1,000, corresponding to 1,000 different probabilities of the category. Instead, FCN represents these three layers as a convolutional layer whose size (number of channels, width, height) is (4096, 1, 1), (4096, 1, 1), (1000, 1, 1), respectively. There does not seem to be any difference in numbers, but convolution is not the same concept, and calculation process as a fully-connected layer. The convolutional layer uses the weights and biases that CNN has pre-trained, but the difference is that the weights and offsets are their own scope and belong to their own convolution kernel. Therefore, all layers in the FCN network are convolutional layers and are called fully convolutional networks.

3.2.1. Upsampling

Upsampling is also called deconvolution at some points, as both of their operations are multiplication and addition. The upsampling of the accompanying factor f is a convolution operation on a fractional input with a step size of 1/f.

Backward convolution is called deconvolution. Meanwhile, the forward and backward propagation of upsampling can only be achieved by reversing the forward and backward propagation of the convolution. Consequently, it performs well no matter the optimization or backward propagation. Deconvolution can enlarge input size by learning parameters while training [20].

3.2.2. Skip Layers

Now that we have a 1/32 size, a 1/16 size, and a 1/8 size feature map, after upsampling the 1/32 size heatmap, the image restored by this operation is a convolutional kernel of conv5. The features are limited to the accuracy, so they cannot restore the features in the image well; consequently, forward propagation will be applied. Detailed information could be complemented by upsampling the conv4. Afterwards, conv3 does the exact same calculation as conv4. Finally, the process completes the restoration of the entire image. According to different strides with 32, 16, and 8, FCN splits into three kinds of results: FAC-32s, FCN-16, and FCN-8s [20]. Obviously, FCN-8s combined previous FCN-32s and FCN-16 results, which gives FCN-8s more accuracy. We decided to choose FCN-8s in our experiment.

3.2.3. Why choosing FCN

The reason why this research employs FCN are below:

- Traditional segmentation method segmented the image into similar sections, including coherent area-independent, low-level clues based on categories, such as pixel color or proximity. Semantic segmentation, on the other hand, assigned each pixel of the image to a semantic tag. This usually means classifying each pixel (for example: the pixel 1 belongs to the glass, the pixel 2 belongs to the hair). Pixel-level classification seems more efficient than cutting out each patch [32]. The FCN-8s model brings state-of-the-art performance on PASCAL VOC in 2011 and 2012 [20].
- No fully connected layer is used in this kind of architecture, which reduces the number of parameters and the computation time. In addition, the network works regardless of the original image size. It could be trained from small and big images, and it does not require any particular number of units at any stage. Additionally, all connections are local [20]. FCN brought great breakthroughs on semantic segmentation tasks when implemented on image segmentation [20].

It is tough to obtain millions of diverse images with ground truth segmentation labels, which could be difficult and mostly performed manually. However, it is convenient to use a pre-trained model for research purposes. Our method applies the FCN segment to the visible parts of faces from their specific circumstance and impediments, which is a fine-tuned system for face segmentation on PASCAL [20] on the data set of IARPA Janus CS2 [33] with 9,818 segmented faces achieved.

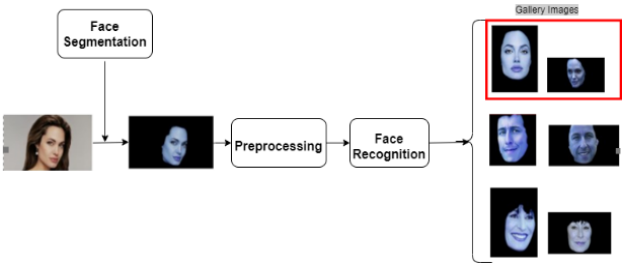

Figure 3: FCN-8s-VGG-16 System 2

This research has achieved an excellent segmentation performance that could be obtained with a standard FCN trained on plenty of rich and varied examples. FCN-8s combined previous FCN-32s and FCN-16s results, which gives FCN-8s more accuracy. We decided to choose FCN-8s in our experiment. Figure 3 shows the process of our experiment.

3.3. Methodology

3.3.1. Data selection

The ImageNet Large Scale Visual Recognition Challenge (ILSVRC) [34] was dominant in giving this information to the general picture classification task. Moreover, analysts have made data sets accessible for object recognition [35]. Labeled Faces in the Wild (LFW) [36], as the most popular benchmark data set has dominated in the field of face recognition for many years. It is a

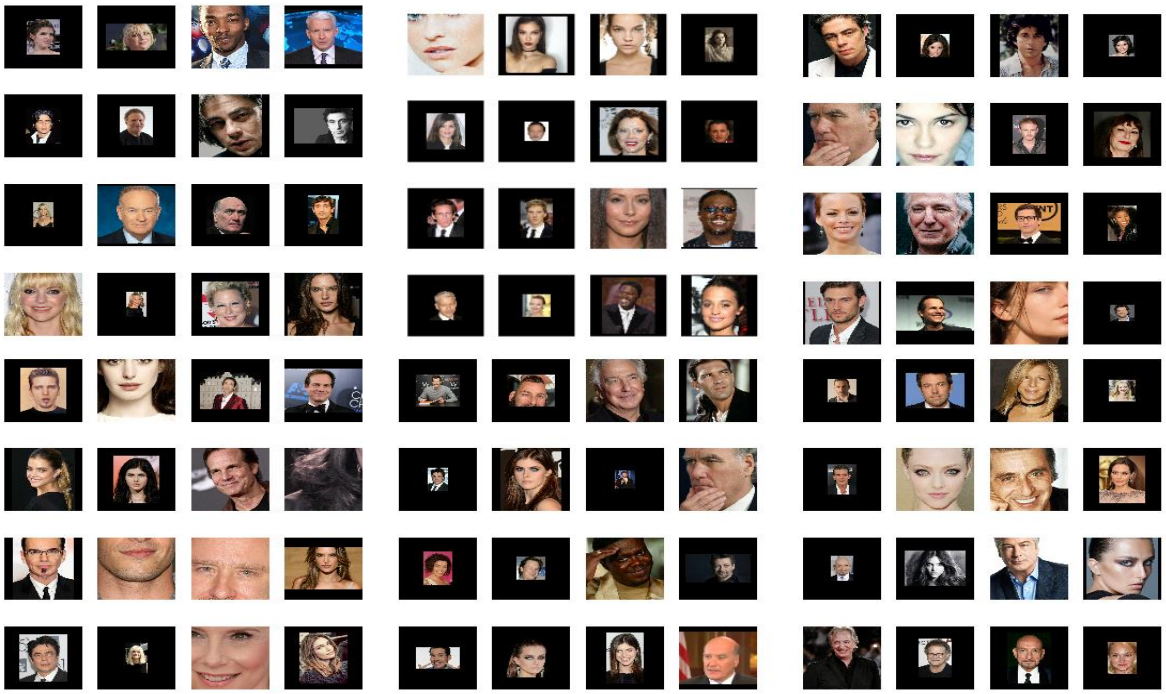

Figure 4: Gallery Images

huge scale open data set and the benchmark database of face photos intended for concentrating the issue of unconstrained face recognition, which has been widely applied in numerous research studies [10,12]. The data set contains more than 13,000 images of face pictures gathered from online.

Each face has been labeled according to the name of the individual envisioned. However, due to the shortage of obvious challenging face images, such as block face, tilt the head, wrinkle the eyebrows, and so on, it is not an ideal image set in terms of the purpose of the paper, which is to compare face recognition performance with and without segmentation. Furthermore, FRGC [37] MS-celeb-1M [38] and MOBIO [39] are other benchmark face data sets used to identify face images though various experiments with the same problem as LFW.

3.3.2. Applied Data Set

In this research, we decided to employ the Celebrity-Face-Recognition-Dataset, which consists of 1,100 famous celebrities with 8,000 images [40] in each. In this dataset, the total size of the data set is 172 GB with 800*800*3 pixels in each. Due to the limitations of our hard drive and memory, this research randomly and manually selected 85 individuals with 100 images for each as classes for the face recognition task.

Since accuracy difference along with and without segmentation face section from the background is in a significant index for the research, the images with obvious covers such as hats, accessories, or different poses and hairstyles, are our preferred selection among the 8,500 figures from the Celebrity-Face-Recognition dataset. Figure 4 shows partial data processed in our experiment.

3.3.3. Data Augmentation

Image recognition technology focuses on the work of few data sets and small variability in object images. This results in very few images that can train a particular CNN model, even with fine-tuning. One way to solve this problem is to augment the data, by randomly applying transformations, color perturbations, and other random transformations. Randomly rotating and flipping the images can make up the deficiency of diversity pixels of the model. In the experiment, the following values are applied:

- Brightness: Images are randomly changing brightness [-0.1, 0.1) [41].
- Flipping: Images are horizontally flipped from left to right.
- Scaling: The pixel values are scaled to the range [0, 1].
- Contrast: Images are randomly adding contrast to the range [0.2, 1.8].

The result shows below as Figure 5.

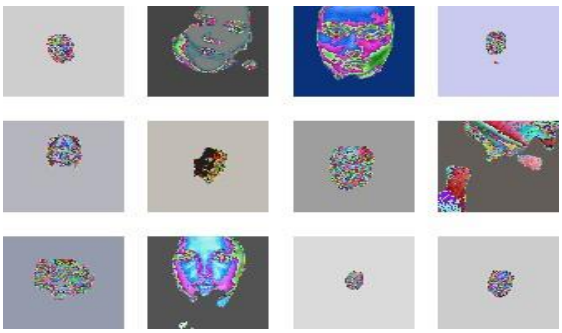

Figure 5: Pre-processing Result with FCN-8s Segmentation

3.3.4. Cross Validation

We found that in using the same data set, both training and model error estimation, the error estimation is mostly inaccurate, which is called the optimism of the model error estimation. To overcome this problem, cross-validation was proposed. According to Kohavi [42], cross-validation is a technology used to access predictive systems by dividing the original data set into a training set for training the parameters, with a test set for assessing the trained model. There are three more popular methods: leave-one-out, leave-P-out, and K-fold. Compared to the previous two technologies, K-fold only needs to calculate k times, which dramatically decreases code complexity. In K-fold cross-validation, the input data is split into k same size subsets, which is called folds as well. K-1 subset data will be trained into a system afterward, assessing the model on the subset that was not utilized for preparing. This procedure is repeated k times (the folds) until each subset has been used for evaluation purposes (and prohibited from training) each time finished. The results from k times calculation of K-folds can then be averaged (or joined) to receive a final estimation. The advantage of this method is that all data information is used for both training and evaluation, and each sub-dataset is used for validation exactly once. Based on the advantage of cross-validation, this paper has applied the 10-folds cross-validation on a data set.

3.3.5. Hardware Utility

Our implementation is based on Tensorflow Framework. AWS as a service platform that support the measurement of runtimes and performance. We implemented the experiment on the 16 GB memory of Nvidia Tesla 100V GPU.

4. Experimental Results

During this examination process, the implementation of the proposed method has been evaluated based on the percentage recognition rate of the identities on the testing data set. Initially, we set the learning rate as 0.001 for the CNN system, and a total of 10,000 steps are required for every k times calculation. Then for each step, 10 images (batch size) and 20 images (batch size) are sent for training through the network individually. At the same time, a 50% dropout was also been used in the experiment. Rectified Linear Unit (ReLU) as activation functions and Cross Entropy Loss function are applied to guide CNN training. The Adam algorithm calculates the gradient of entire data sets and updates values in the opposite direction to the gradients until a local minimum is found. Top-1 accuracy is applied to measure the performance of processes. This entire test experiment will be repeated ten times until the average of performance is obtained. The results of our experiment are used to compare with the performance of others. To check and analyze the implementation of the proposed method, 10 image samples from each category are collected into the test set.

According to the outstanding performance of our experiment, we took the best parameter as the final performance and compared it with the model consisting of original images. We performed various experiments by altering the image size. For example, we drafted the size of each picture after pre-processing as 350x350x3, 500x500x3, and 800x800x3. Among the data set, 90% of the data are the training set and 10% are the test set. 10,000 steps were applied for CNN training process ten times. Based on Top-1 error calculation, the result of the proposed system was acquired. According to whether the prediction is the same as the target category, the Top-1 error rate returns a Boolean value.

Table 2: Performance Comparison with Various Parameters

Input Image size	Numbers steps	Learning rate	Batch size	(VGG-16 System) Top1 Error	(Proposed FCN-8s-VGG-16 system) Top1 Error
350x350x3	10000	0.001	10	82.69%	92.15%
350x350x3	10000	0.001	20	84.34%	93.21%
500x500x3	10000	0.001	10	92.43%	97.25%
500x500x3	10000	0.001	20	93.54%	98.33%
800x800x3	10000	0.001	10	99.84%	99.57%
800x800x3	10000	0.001	20	99.88%	99.69%

Table 2 shows the comparison performance of various parameters. As seen from Table 2, the input size of 350x350x3 and 500x500x3 of the FCN-8s-VGG-16 system obtained a higher accuracy rate than the VGG-16 System which is trained without segmentation technology. Meanwhile, the accuracy rate of 800x800x3 input size achieved the closest result with the VGG-16 System. Furthermore, the running time has reduced on average 4.52% than the VGG-16 System in all three experiments owing to reduced pixel with segmentation technology. Figure 6 demonstrates the relationship between the batch size, image size and the system. We can conclude that as the batch size increased, both accuracy rate of VGG-16 System and FCN-8s-VGG-16 have increased slightly.

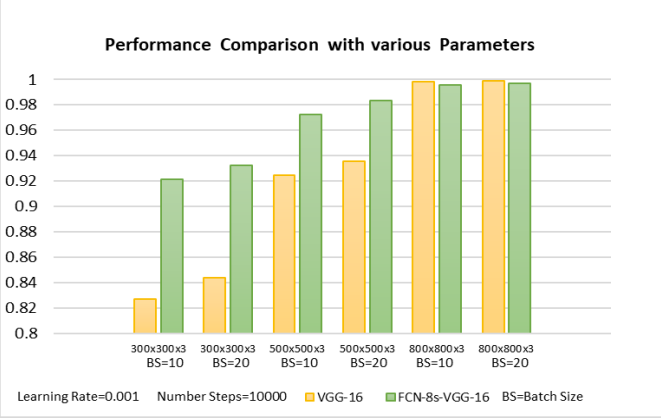

Figure 6: Performance Comparison with various Parameters

However, this will expand running time as well. Therefore, the batch size and running time could be a future trade off work for us. Above all, we could gather that image input size with high pixels will have a higher accuracy rate for recognition.

5. Conclusion and Future Work

In this paper, we proposed the FCN-8s-VGG-16 system to segment face images and recognize segmented images with high precision. Our face recognition system, FCN-8s-VGG-16 is composed of face image segmentation with FCN-8s [16] and

VGG-Face fine-tuning model recognition. Experiments were conducted on Celebrity-Face-Recognition dataset [40] for training and testing purposes. Compared with the original face recognition without segmentation accuracy, the effective classification rate using different parameters has been significantly improved from 92.15% to 99.69%, reaching a level of 82.69% to 99.88%. It also demonstrates that increasing the size of the input and batch number, while keeping the learning rate and number of steps constant, will improve the accuracy rate in certain situations. However, such observation is not completely ensured for other systems.

Accuracies on Top-1 in face recognition results means that some limitations happened in our algorithm, especially when applied to a wild data sets: First, even though FCN-8s has successfully segmented most face images, there were still a few images that did not achieve ideal results. For example, some small black areas occur after segmentation, which will affect the accuracy of performance. There are a few things that have triggered these failures. First, it takes three training processes to get the FCN-8s, which is not sensitive enough to combine the details of the image. This is because when the decoding is performed, that is, when the original image is restored, the label map of the input upsampling layer is too sparse. Secondly, FCN-8s does not consider the relationship between pixels during classification, and it lacks spatial consistency. Additionally, we only computed limited image input size, batch sizes, and learning rate, so it is very possible that we will receive a better accuracy rate if there are more parameters to choose from, with time allowed. Lastly, with the fine-tuning FCN model [16], the model will be more robust [43]. Only one recognition model processed in the experiment is limited. Some other CNN model has achieved an excellent performance in recent competition. For example, Google Net [44] is a winning architecture on ImageNet 2014. We will be applying it as our recognition system in future research for comparing with VGG-16. Besides, in reality, a human face is made of a 3D model; it's more realistic to segment and recognize images based on 3D faces. [45] has proposed a system of face recognition 3D based on segmentation by classifying fields of facial images before and after fusion of color and depth images. It brings us a potential research in face recognition study that we could investigate more about 3D image segmentation technologies instead of 2D.

Additionally, we will develop a mobile app such as [5], to complete the SFR-IoT architecture that could receive notification from our system though IoT devices when recognizing face in order to make contribution in real world application. In the future, data encoding and decoding will be applied to untrusted devices and servers to protect privacy data to make software more powerful and trustworthy [46].

Above all, the comparison reveals significant improvement in performance. Further experiments can be done by improving segmentation technology or by changing the recognition model.

Project Management System
Tree Model Structure

ABSTRACT

Project completion is a common and best practice for oil and gas and construction industry. It provides a comprehensive completion approach and gives total confidence to asset owner to operate the facility handed over by construction contractors. While the nature variation of asset hierarchy is unique from one type of asset to another, a project completion software must have prominent ability to adapt wide range of variations with unlimited level of hierarchy. One of the approaches to overcome this is implementing a tree-model concept to accommodate flexible hierarchy. Unfortunately, the package is loaded with complexity to retrieve data and takes longer join operation. This paper proposes a business intelligence approach to analyze and make an optimum reporting retrieval using data warehouse. This is implemented in 4 steps following Kimball methods. The objective of this paper is to generate model by using data warehouse starting the extract, transform and load process on the flexible tree model hierarchy. It can be used to generate report and comprehensive dashboard especially progress report of project and work schedule as needed in the oil and gas and construction industry.

1. Introduction

Project completion or commonly known as commission are one of critical activities for heavy industrial construction project. It gives total confidence for handing over the full facility from contractor to the operator or owner [1] . To support this activity, a project completion software is implemented. It is used to help the contractor's construction team to ensure that the facility is physically complete and made ready for handover to the commissioning team. Using the construction check sheets agreed by both parties (construction and commissioning), project management team can track, report and control all inspection and testing of workmanship and materials [2].

The barcoded, scanned documentation stored in the system helps to prove the complete and correct execution of all fabrication and installation work in accordance with the project specifications and design drawings. The phase of construction to Commissioning, eventually is continued to Commissioning to Operation provided that each phase requirements are fulfilled, completed, and verified by all related parties

The initial activity with respects to the system completions process is the installation and commissioning of the Electronic Completion and Handover (ECHO) as shown Figure1. An implementation plan should be produced to schedule all key activities necessary to deliver a commissioned PCMS.

The next process is to define the type of equipment or tag type deployed on the project, examples of tag types are: Compressor, Pump, Turbine, Filter, Heat Ex-changer, etc. When a Tagged Item is defined, check sheets can be allocated and generated in a form of Tag Type Matrix. Lead Discipline Engineers and Commissioning Engineers review the project's Piping and Instrument Diagram (P&ID)s and drawings to define by Discipline and assigned to the related folder, subsystem and eventually by system.

P & IDs structure are then represented in the ECHO system as shown Figure 2. Due to wide variety of both facilities and assets, ECHO is required to be flexible to adapt its level of hierarchy with no limitation, one project can consist of three (3) levels of hierarchy, another can be ten (10) levels as shown Figure 3. Most companies focuses in analysing its business mostly on structured data, and use a relational database [3]-[5]. To generate one report from that flexible hierarchy is such a tedious task, since the Structure Query Language (SQL) joint operation can be as many as required. One example of tree concept is illustrated as in Figure 4. ETL process is also used in some companies for processing data

*Corresponding Author: Abba Suganda Girsang, Jakarta, & agirsang@binus.edu

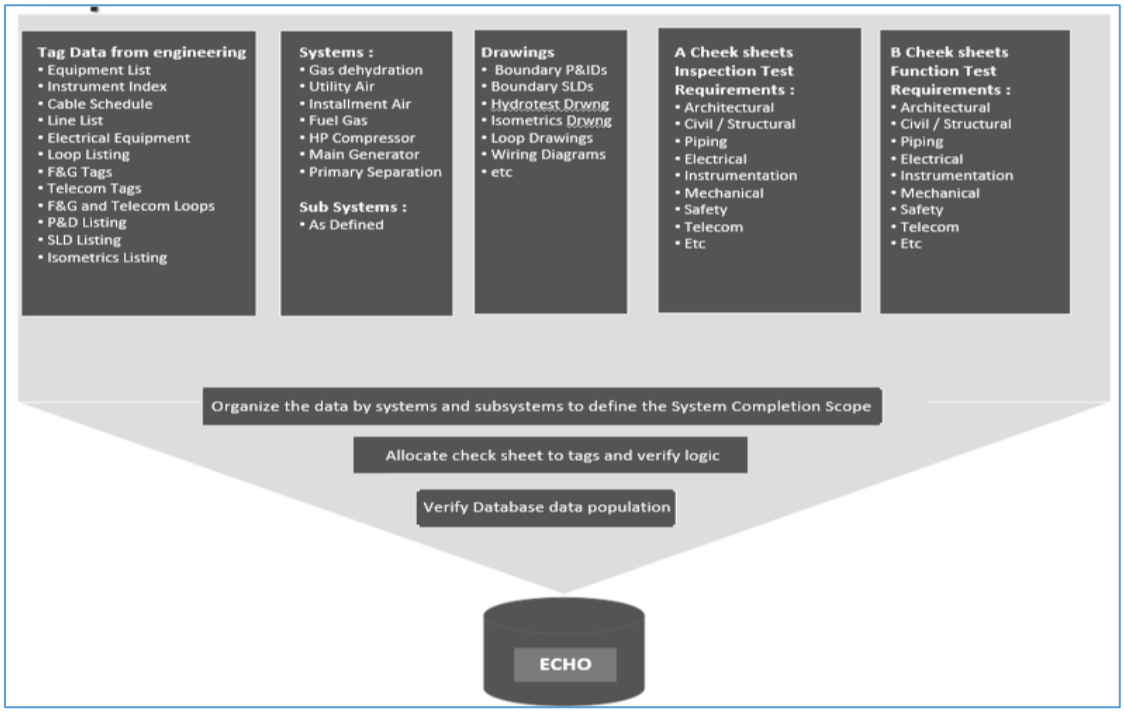

Figure 1: System Setup

warehouse, ETL processes extract data from various sources, transform the data to fit analytical needs and then load it into the database [6]. ETL Process as a part of the Data Warehouse implementation maybe a perfect solution for this and boost the performance of information retrieval of the ECHO system. An ETL tools can be used to extract data and uses business rules to transform the data into new formats [7]. It helps many companies to monitor its performance [8], [9].

This paper implements data warehouse system to the current system and propose a data warehouse model that can be used to make an online analytical processing through an interactive dashboard that can be drilled down, up and across [10]. The goals are to monitor the trend of the project completion and to get insight of the construction inter dependency between systems, disciplines and data-driven coordination among the contractors. It also can be used to obtain the strategy information for decision makers.

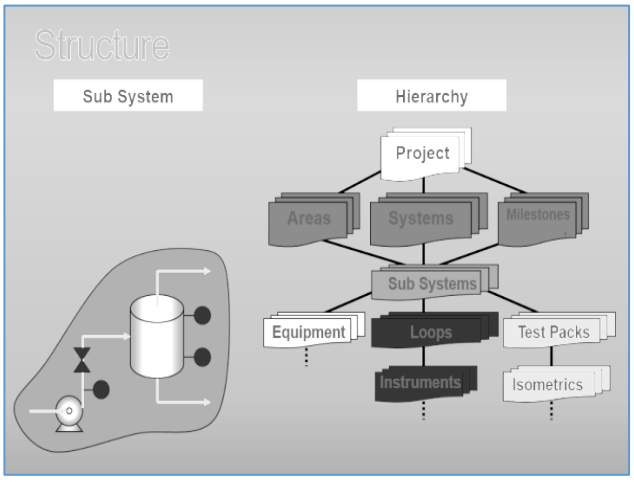

Figure 2: P&ID Structure in ECHO

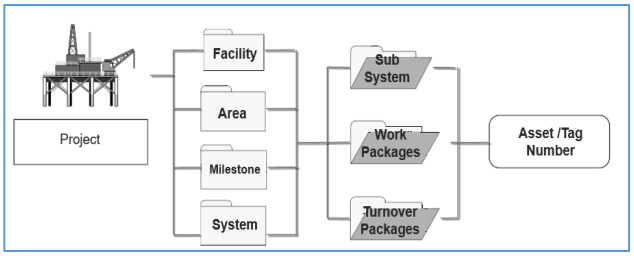

Figure 3: Project's level of hierarchy

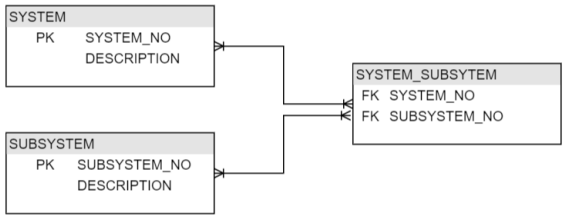

Figure 4: System and Subsystem Tree Structure

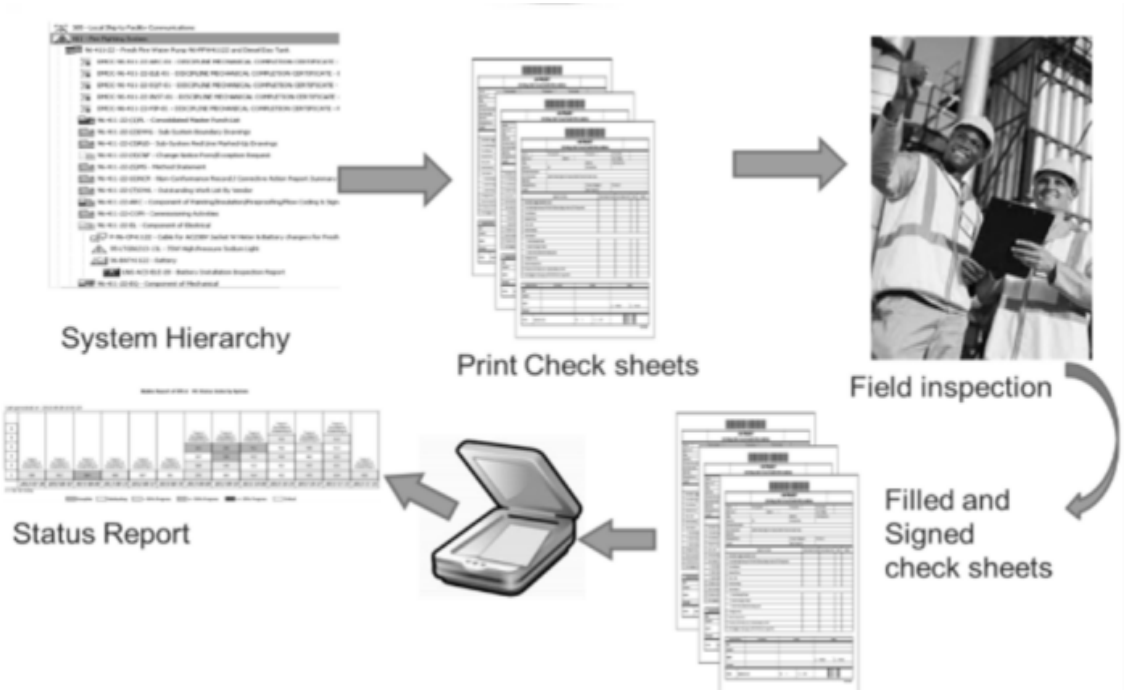
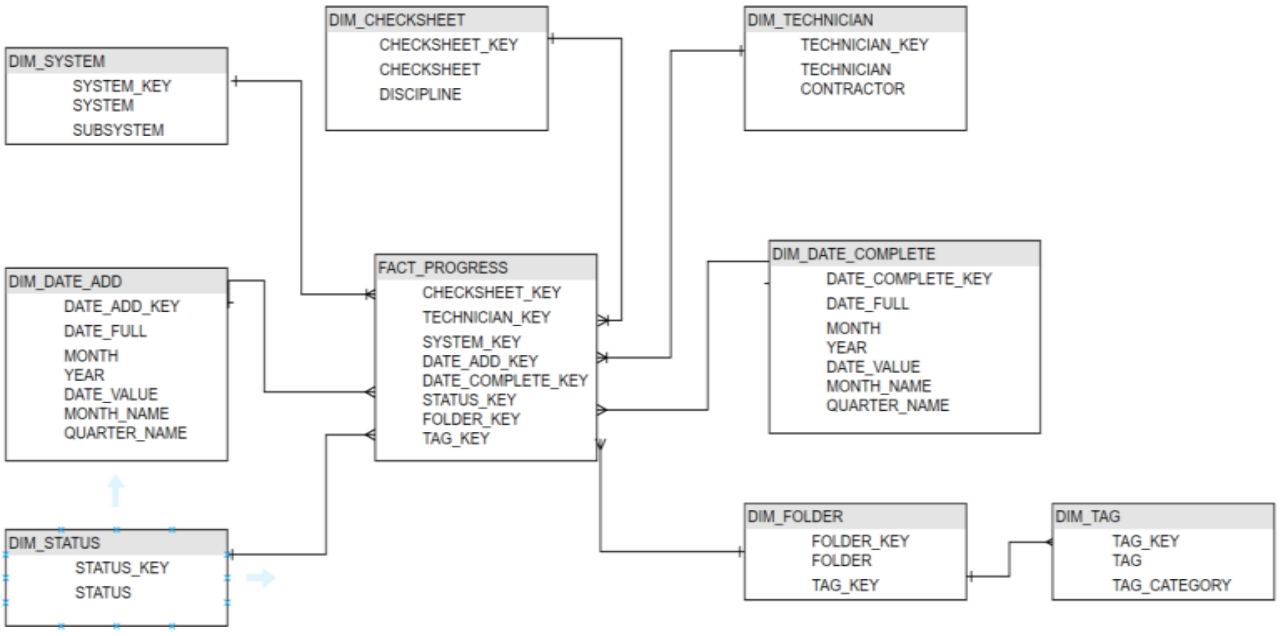
2. Literature Review

Since the amount of stored data is growing faster continuously, and the data processing brings many complications, the analytical databases (OLAP) based on the data warehouses rapidly gain popularity in analytical data processing [11]. The research of data warehouse is currently also developed by combining machine learning [12], [13]. The data warehouse is a preformatted data repository that consists of data collection from various format and structure in a particular way to expedite the information retrieval for analytical purposes [14] . Data warehouse is then loaded into a Business Intelligence (BI) platform which is then utilized as decision support technologies that aim to assist in a quick and data-driven decision making [15].





3. Proposed Method

As our guideline to develop a complete data warehouse system for ECHO, we are referring to industry widely known as Kimball four-step dimensional design process. Kimball presents a different vision of data warehouses. Kimball considers that the data warehouse be a set of consistent data marts and based on shared conformed dimensions.

Select the Business Process. The first step is to identify the business process. A business process is defined as a major operational process in an organization. Process in business is defined as a natural business activity in an organization supported by legacy source data-collection system (in this project database is used as data-collection). The business processes of this research are: 1. adding completion check sheet based on equipment's discipline into the project's scope of work and 2. Technician assigned to the project completes the work and turn the status of its check sheet to complete as shown Figure 5

Declare the Grain. The next step is to declare the grain. The goal of this step is to define the lowest detail on the fact table. The type of the fact table for this research is factless fact table which provide the status of one check sheet assigned to a tag or

equipment in a project hierarchy, system-wise and discipline-wise. It also shows the addition and its completion by technician from various contractors.

Identity the Dimension. With the business process selected and the declaration of the grain, we then observe and analyze the supporting information within the granularity of the data, which is called by a dimension, by defining it is a classification tables in original database that have correlation to each other into one table dimension. All the table in original database must be analyzed can classified into dimension tables. We observed that eight dimensions are identified, they are: dim_system, dim_checksheet, dim_technician, dim_date_add, dim_date_complete, dim_status, dim_date, dim_technican, dim_folder and dim_tag.

Identity the Fact. The last step is identifying the fact tables, the fact table normally store the transaction data, and it holds something that measurable. In our case, the fact table is indeed stores transaction data, the transaction of adding a completion check sheet into a project, and completing its work by assigned technician, by definition: A factless fact table is a fact table that does not have any measures. It is essentially an intersection of dimensions (it contains nothing but dimensional keys). There are two types of factless tables: One is for capturing an event, and one is for describing conditions, according to the definition above, we can conclude that the type of our fact table is factless. Figure6 shows the star scheme of the project completion progress where;

- system_key referred to DIM_SYSTEM,
- status_key referred to DIM_STATUS,
- date_add_key referred to DIM_DATE_ADD,
- checksheet_key referred to DIM_CHECKSHEET,
- technician_key referred to DIM_TECHNICIAN,
- date_complete_key referred to DIM_DATE_COMPLETE,
- folder_key referred to DIM_FOLDER,
- tag_key referred to DIM_SYSTEM,

They are respectively assigned into fact_progress as foreign keys.

4. Result and Discussion

In this section, we explain the ETL process for dimensions and for OLAP analysis. In brief, the process is getting data from csv exported from ECHO System, transformed as required then load them into dimensions and fact table, the transformation process is done by Pentaho Data Integration. ETL process consists converting some dimensions and fact process. It can be detailed as follows.

Dimension Add Date. This dimension is to store the addition check sheet date to the project as shown Table 1.

Table 1: Table structure of DIM_DATE_ADD

Field Name	Type	Description
DATE_ADD_KEY	INT	This is a surrogate key in a sequential number
DATE_FULL	DATE	Date with format: "dd-mm-yyyy"
MONTH	INT	Month index, i.e: 1,2,3,..12
YEAR	INT	Year value, i.e: 2015, 2016, … 2019
DATE_VALUE	INT	Date index in a month, i.e: 1,2,…30
MONTH_NAME	VARCHAR(20)	Month Name, i.e January, February, .. December
QUARTER_NAME	VARCHAR(2)	Quarter name, with the concatenation of Q and the number of Quarter, i.e: Q_1, Q2, .. Q4

Dimension Complete Date. This dimension is to store the complete date of check sheet to the project as shown Table 2.

Table 2: Table structure of DIM_DATE_COMPLETE

Field Name	Type	Description
DATE_COMPLETE_KEY	INT	This is a surrogate key in a sequential number
DATE_FULL	DATE	Date with format: "dd-mm-yyyy"
MONTH	INT	Month index, i.e: 1,2,3,..12
YEAR	INT	Year value, i.e: 2015, 2016, … 2019
DATE_VALUE	INT	Date index in a month, i.e: 1,2,…30
MONTH_NAME	VARCHAR (20)	Month Name, i.e January, February, .. December
QUARTER_NAME	VARCHAR (2)	Quarter name, with the concatenation of Q and the number of Quarter, i.e: Q1, Q2, .. Q4

The ETL process of Dim_Complete_data can be shown as shown in Figure 7.

Figure 7: Dimension Complete Date

Dimension Check Sheet. This dimension is to store the dimension of check sheet to the project as shown Table 3.

Table 3: Table structure of DIM_CHECKSHEET

Field Name	Type	Description
CHECKSHEET_KEY	INT	This is a surrogate key in a sequential number
DISCIPLINE	VARCHAR(20)	Code discipline of check sheet
CHECKSHEET	VARCHAR(95)	Description of discipline check sheet

The ETL process of Dim_CheckSheet can be shown as shown in Figure 8.

Figure 8: Dimension CheckSheet

Dimension Status. This dimension is to store list of status in the project as shown in Table 4

Table 4: Table structure of DIM_STATUS

Field Name	Type	Description
STATUS_KEY	INT	This is a surrogate key in a sequential number
STATUS	VARCHAR(20)	Detail of status, i.e: Outstanding, Completed, Accepted, etc.

Figure 9: Dimension Status

Dimension Tag. This dimension is to store the information tag in the project as shown Table 5

Table 5: Table structure of DIM_TAG

Field Name	Type	Description
TAG_KEY	INT	This is a surrogate key in a sequential number
TAG_CATEGORY	VARCHAR (20)	Consist of category tag, i.e: Building, Electrical cables, etc.
TAG	VARCHAR (100)	Detail of tag category, i.e: 1 phase transformer, AC Ups, etc.

The ETL process of Dim_Complete_data can be shown as shown in Figure 10.

Figure 10: Dimension Tag

Dimension Technician. This dimension is to store the information of technician and contractor in the project. It consists of:

Table 6: Table structure of DIM_TECHNICIAN

Field Name	Type	Description
TECHNICIAN_KEY	INT	This is a surrogate key in a sequential number
TECHNICIAN	VARCHAR (50)	Full name of technician
CONTRACTOR	VARCHAR (50)	Name of contractor

The ETL process of Dim_Technician can be shown as shown in Figure 11.

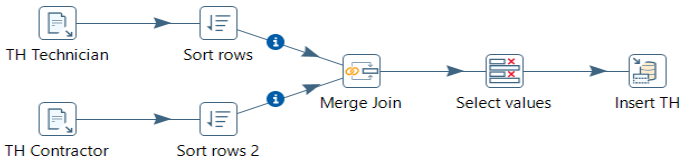


Figure 11: Dimension Technician

Table 7: Table structure of DIM_SYSTEM

Field Name	Type	Description
SYSTEM_KEY	INT	This is a surrogate key in a sequential number
SYSTEM	VARCHAR (20)	Description of system key, i.e: Water Spray System, Mooring Equipment
SUB_SYSTEM	VARCHAR (20)	Key of subsystem
SUBSYSTEM_DESC	VARCHAR (100)	Description of subsystem key, i.e : Mooring Equipment for Marine Terminal Control Shelter
TARGET_DATE	DATE	Target date with format: “dd-mm-yyyy”

The detail of Fact progress can be seen in Table 8.

Table 8: Table structure of FACT_PROGRESS

Field Name	Type	Description
CHECKSHEET_KEY	INT	cheecksheet_key is a key from dim_checksheet
TECHNICIAN_KEY	INT	technician_key is a key from dim_techncian
SYSTEM_KEY	INT	system_key is a key from dim_system
DATE_ADD_KEY	INT	date_add_key is a key from dim_date_add
DATE_COMPLETE_KEY	INT	date_complete_key is a key from dim_date_complete
STATUS_KEY	INT	status_key is a key from dim_status
FOLDER_KEY	INT	folder_key is a key from dim_folder
TAG_KEY	INT	tag_key is a key from dim_tag

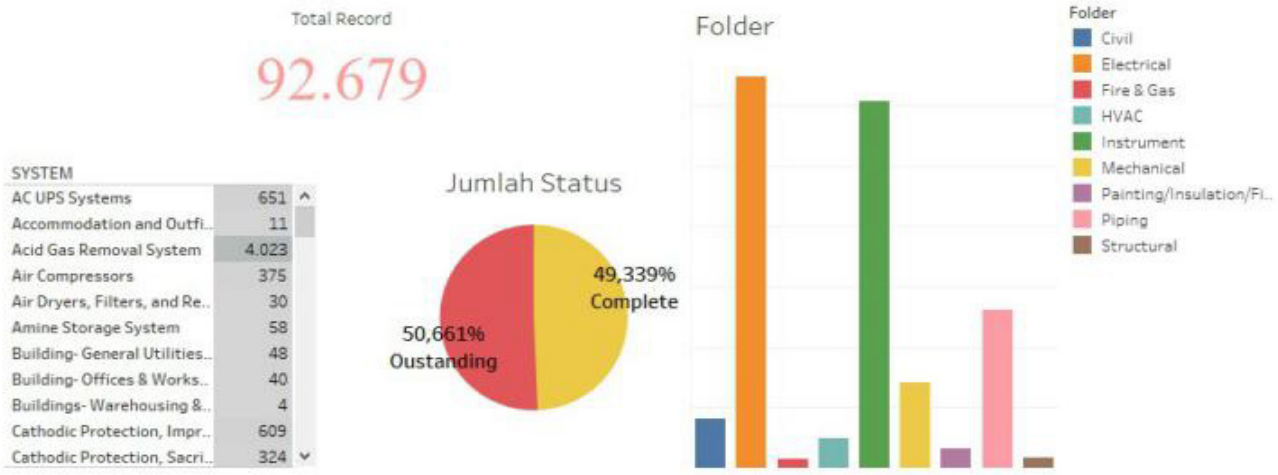

Figure 12: Dashboard Example

Report Generation. Once the star schema and its ETL Processes are defined, we then generate the report based on the new transformed table structure. One of the critical information required by the project is figuring the total number of check sheets required to be completed based on the project's system. We use Pentaho Report Generator as it is a dynamic and easy to use tool to generate dynamically from the database.

We can conclude in the project, that most of the work is in the Civil Onshore system which covered more than fifty percent, sixty six percent to be precise, and followed by the Dehydration System. Setting up the Dashboard. Beside report, dashboard can also be generated from tables in database. For data visualization and interactive dashboard, Tableau is used. Tableau's main products offered by Tableau are Tableau Desktop, Tableau Public, and Tableau Online, all offer Data Visual Creation and choice depends upon the type of work [16].

Figure 12 is an example dashboard that can be generated from all table in database. Bar chart shows how many folders that have been used. Bottom left is treemap, to select tenant name. And next to it is pie chart that shows which protocol is used. By clicking one of the charts, it will change the whole dashboard information based on the clicked condition. For example, if February is clicked tree map of tenant name will adjust which tenant sent bytes in February. The pie chart will do the same thing, it will show the protocol that is used in February.

From interactive dashboard, we instantly see the proportion of contractors assigned to a system as shown Figure 13. In this way we can see the interdependency between integrated project team with the contractors who are supporting the team on delivering their scope of work in an ordered manner.

5. Conclusion

By implementing data warehouse, ECHO with the dynamic tree table structure improves significantly to provide progress report and helps to provide informed decision making in managing the project completion by prioritizing on the work schedule and chasing the deadline by analyzing the best resource allocations.

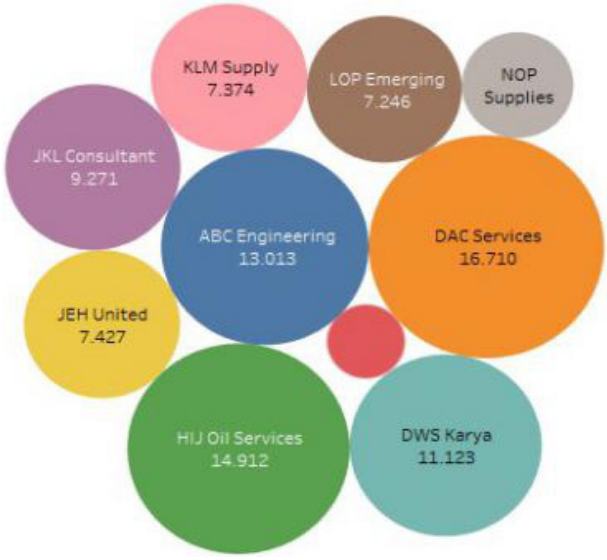

Figure 13: Progress Contractor Dashboard

For future research, the data warehouse then can be used to be analyzed with another method like projection on for another business process such as trend prediction, certificate completion, decision making on the resource allocation etc.

Differentiated Group Learning
Thinking Ability
Social Ability

ABSTRACT

The ability to think and the social abilities of junior high school students is a potential ability developed through learning based on the optimization of differences in learning abilities. For this reason, appropriate learning design and implementation model is needed in realizing this, especially in one of the social group subjects. This study uses research and development methods that begin with a preliminary study, develops a draft model, tests, and experiments to test model validation. Data collection techniques with observation, experimentation, and interviews. The results showed that aspects of the model of differentiated learning design based on groups put forward the process of analyzing the characteristics of students about readiness, interests learning profile, flexibility for curriculum elements of content (content), process (process), and results (product). Learning objectives are developed in the form of measurable and specific abilities that describe student behavior. In particular, the learning design components include; (a) Analysis of characteristics and curriculum elements; (b) Learning objectives or competencies to be achieved; (c) Essential material; (d) Learning Process, and (e) Learning Evaluation. The Implementation Model is carried out through learning syntax, namely: orientation, general exploration, learning techniques, investigation, evaluation, and follow-up. Group learning model, in which students learn individually to collaborate in the first group after completing the second group, after the second group rejoining the first group.

1. Introduction

Improving quality in the National Education System should be in line with globalization, which has an impact on changes in social life, political science, and technology in various countries quickly. Globalization has several impacts, including free markets, cooperation and competition between countries, democracy, and the implementation of human rights. This is in line with [1], which focused on Intelligence, Globalization, Complex, and Multi-Level Society. These forces have implications for national education, particularly in the effectiveness and relevance of the education system. It also relates to the need for efficiency, innovative, and creative movements in improving education quality.

To realize the education quality, schools need to develop attitudes, abilities and provide essential knowledge and skills needed to live in a global society. Learning needs to be pursued based on an individual approach, though it does not neglect the students' social abilities (sociability), such as relationships with peers, cooperative, tolerance, and respect the opinion of others. The learning characteristics are in line with the concept of a democratic education that uses a scientific approach both in groups and individually [2], [3]. According to [4], individuals have differences in intelligence diversity, and student's potential needs attention [5].

Learning methods need to be developed based on the characteristics that accommodate student differences. Their implications need to be flexible and oriented towards the formation of diverse competencies in students. Learning should focus on optimizing students' abilities individually and prioritize their differences. Moreover, learning activities should be flexible and dynamic, democratic, fun, and active [6]. Essential material that needs to be developed in diverse learning can be classified based on the level of learning, such as the classification of facts,

*Corresponding Author: Toto Ruhimat, Indonesia University of Education, Street of Dr. Setiabudi, 229 Bandung, 40154, Phone (022)2013163, email: toto.ruhimat@upi.edu

concepts, principles, attitudes, and skills [7]. In the selection of subject matter, it is necessary to pay attention to the balance of ethics, logic, aesthetics, and kinesthetic. It is vital to ensure that the subject matter is developed as expected.

The preliminary study on learning with the above competencies in the Social Sciences established that most junior high school students felt the learning process was not optimal, especially the method used, development of learning materials, the use of time, and the utilization of media as learning resources. The learning process tends to be expository or informative, and therefore students are more positioned learning objects.

Learning should prioritize the needs and differences of students based on the desired outcomes. This relates to the aspects of readiness, interests, needs, and learning profiles of students [7]. These aspects can be used as a basis for student differences. The results of these aspects are useful in developing education programs and determining learning materials and approaches, such as group learning, which develops students' social abilities, including cooperation, tolerance, and understanding the opinions of others. Additionally, it provides opportunities for students to recognize and develop their abilities based on multiple intelligences [8]. In this context, [9] established that learning involves 4 variables, including presage, context, process, and product.

Based on the background description, it is necessary to research and develop learning models that optimize the thinking and social abilities of students corresponding to differences in individual potential. This means that the resulting learning model needs to appreciate, accommodate, and facilitate the potential of students individually without neglecting social abilities. Therefore, this study focuses on the following questions (1) What kind of group learning design model optimizes students' thinking and social abilities based on their potential? ; (2) What kind of learning implementation model optimizes students' thinking and social abilities based individual potential ?; and (3) What kind of learning environment standards can optimize students' thinking and social abilities based on individual potential?.

2. Theoretical Review

2.1. The Essence of Student Differences

Students are individuals with unique differences from each other. [2] identified individual differences based on the multiple intelligences. The pattern of multiple intelligences is a form of curriculum organization that can be independently developed and guided by each individual. It can as well be perceived as an essential ability of each individual, which needs to be developed early for future survival. The characteristics of gifted students[10] can be identified from the abilities possessed, such as (1) general intellectual, (2) specific academic aptitude, (3) creative or productive thinking, (4) leadership skills, (5) visual and performing arts, (6) psychomotor abilities. According to Renzulli, a minimum of 3 to 5 percent of the students in schools have this ability.

2.2. Learning Procedures for the Development of Social Ability

The development of effective social abilities can be carried out using group or cooperative learning. [11] established that the teaching model can be grouped into 4, including information processing, personal, social, and behavioral groups. All student activities in learning programs have to be democratic, meaning that the learning process should develop the ability as individuals and have a beneficial social ability, which is beneficial for students. According to [12], social ability [13], including interpersonal intelligence, involves understanding and interacting with others.

The group learning approach is an alternative that can be developed in this regard. The stages of group investigation learning include (1) Students encounter puzzling situation (planned or unplanned); (2) exploring reactions to the situation; (3) formulating study tasks and organize for study (problem definition, role, assignment); (4) independent and group study; (5) analyzing progress and process and recycle activity [14].

Stages of learning are developed in ways that demand problem-solving and inquiry in learning. In general, students are organized into democratic problem-solving groups that attack academic problems and are taught procedures and scientific methods of inquiry [15]. This is in line with the concept of the group investigation approach, which involves placing students in the context of a social system with democratic and cooperative processes and provides opportunities for individuals to learn optimally. According to [16] students are provided the opportunity to learn based on higher-order thinking processes such as analytical, hypothesis, and scientific, especially in the learning process through problem-solving and inquiry. Cooperative learning is organized to conduct student activities in small groups in collaboration between students in learning [12].

3. Research Method

This study used research and development methods in education [17]. The implementation started from a preliminary study, developing a draft model, and testing and conducting experiments for model validation. Data collection techniques used include observation, experimentation, and interviews, while Relevant, Observable, useful, Realizable, Understandable, and demand by teachers and students tests were used for analysis.

Table 1: Research Samples Size

No	Name of School	Status	Size
1	State Junior High School 15	Experiment class	46
2	State Junior High School 10	Experiment class	46
3	State Junior High School 11	Control Class	46
4	Nugraha Junior High School	Control Class	46
		Total Sample	184

There were several reasons for choosing and using the junior high school level, including 1) according to the level of cognitive ability development, junior high school students (between 11-15 years old) have learned to think scientifically or rationally; 2) based on the level of social ability development, junior high school students can be independent, collaborate, socialize, lead and be responsible in groups; 3) junior high school students can carry out group activities; 4) their curriculum contains social science subjects especially geography; 5) in the social science curriculum

objectives, students need to develop the ability to reason, understand and solve problems; 6) social sciences allow variety, flexibility, and modification of learning content, process or product; and 7) junior high school already has a Subject Teacher Forum. Assessment technique of thinking and social abilities referred to the [18] model. The analysis data was used throughquantitative techniques with correlations, t-tests, and percentages.

4. Result and Discussion

4.1. Differentiated Group Learning Model Design

From the testing results conducted during the Research & Development [19], a learning design model matrix for Differentiated Group learning is formulated as follows.

Table 2: Syntax of Learning Design Stage

Component	Development Aspects	Criteria
Learning Purpose	- Able to identify and study the patterns of economic activity based on land use and region - Able to identify the distribution of forestry in Indonesia - Able to identify obstacles of forestry preservation in Indonesia - Able to identify the responsibility of the government in preserving forestry in Indonesia - Able to identify the responsibility of the community in preserving forestry in Indonesia - Able to identify problems and obstacles of forestry in Indonesia	- The design of learning purpose in the form of competencies - The purpose is developed in stages and flexibility - The purposes are oriented towards general learning programs
Learning Material	- Patterns of economic activity based on land use and region - Distribution of forestry in Indonesia - Constraints on forest preservation in Indonesia - Responsibility of the government in preserving forestry in Indonesia - Responsibility of the community in preserving forestry in Indonesia - Forestry issues and constraints in Indonesia	- Facilitating the choices of subject matter - Use various sources - Problem-based content - The material tends to be sought, built, or compiled by students - Contextual
Learning Activity	Development of Learning Design with Stages - Orientations : o The teacher creates the initial conditions for learning Social Sciences o The teacher conveys topics or sub-problems to be discussed on the patterns of economic activity based on land use and region o The teacher implements apperception, and students are allowed to ask questions or answer related to patterns of economic activity based on land use and region o The teacher provides a stimulus to be active in studying, discussing, and learning individually or in groups - General exploration o The teacher conveys a general description of the patterns of economic activity based on land use and region, explained in general to the sub-topics discussed o The teacher provides stimulus, motivation, and attention to students - Mastery of Learning Techniques (If students have mastered the learning technique, then this stage the teacher does not need to explain again unless deemed necessary) o The teacher explains learning techniques individually and in groups (cooperative) o The teacher explains effective learning individually and cooperatively o The teacher explains the stages of problem-solving or inquiry or group study.	The design of learning activities applies to the following principles : 1. Competency-oriented: the design of student activities is aimed at achieving competence in learning purpose 2. Problem-based learning: the design of student activities should be based on problems and issues to be studied. 3. Individual learning in a group. Student activities are designed individually and collaborate in groups 4. Students understand individual and group learning techniques. The teacher designs the implementation of activities, students should understand the learning techniques to be pursued 5. Flexibility. Both individual and group studies should be clear to students but can be flexible and modifiable 6. Position of teacher activity: facilitator and resource person collaborating

Learning Activity	○ The teacher explains how to use the worksheets or find learning resources related to Social Sciences, especially the topics discussed ○ The students are already in their respective groups. - Investigation (This is the core stage that needs to be carried out individually and cooperatively in assessing or solving problems) ○ Using groups and using student worksheets, students formulate general problems on "what is the pattern of economic activity based on land use and territory in Indonesia"? ○ The teacher restates the sub-topics in the form of problems that should be solved by students as follows • How is the distribution of forestry in Indonesia? • What are the obstacles to forestry preservation in Indonesia? • What effort needs to be carried out by the government in preserving forestry in Indonesia? • What efforts need to be carried out by the community in preserving forestry in Indonesia? • What are the problems and obstacles of forestry in Indonesia? ○ After understanding a general problem, students individually choose one or more sub-topics to solve or study the problem in the group. ○ Continuously monitored, guided, and assessed by the teacher, students follow the stages of learning Scientific thinking (problem-solving) according to the worksheet guidelines ○ After individual studies and problem-solving are completed, the results of individual work are discussed in groups (with discussions equating concepts, complementing each data and information) ○ Students individually process the results of the study of other members in the group and individually answer other sub-questions. ○ Each student makes a report (portfolio) of answers to common problems and all sub-problems. - Evaluations (Assessment is carried out continuously in the learning process) • Provide an essay or filling-gap test • Each group under the teacher's guidance summarizes the results of the discussion • Collecting the results of individual and group work. - Follow-up • Give assignments or enrichment individually to students deemed necessary • Announce the topics to be discussed in the next meeting	
Learning Outcomes	Assessment Procedure The assessment is carried out continuously IInnitial, process, and final tests Types of Assessment Forms, The assessment uses observation, written, oral, and portfolio forms.	- The assessment design prioritizes to assess the learning process apart from the input and results. - Assessment is designed as a basis for improvement, enrichment, and diagnostics. - The results of the assessment as a modifiable elements. Portfolio assessment. - Group and individual activities

The Group-Based Differentiated Learning Design was developed based on the aspects of Learning syntax as follows; (a) Analysis of students' characteristics of interest, readiness, and learning profile; (b) Analysis of curriculum elements (content, process, and product) that can be modified; (c) Conditions of the learning environment; (d) Assessment is designed continuously and integrated; (e) Objectives formulated and developed in the form of abilities; (f) Development of learning activities refers to the stages of orientation, general exploration, mastery of learning techniques, investigation, evaluation, and follow-up; (g) The curriculum components in learning design prioritizes the components of objectives, the content of subject matter, learning activities, and evaluation of learning developed systematically and systemically; (h) The format of the learning design can be developed flexibly depending on the needs of developing learning programs and the applicable curriculum. This finding is in line with [16], which focused on the balancing acts of building positive relationships with students.

Student Grouping Design was carried out in 2 stages, the first and the second groups. The first group resolves general problems with individuals who collaborate, and the product is a general problem-solving portfolio. This finding is supported by[16], which stated that learning outcomes serve as references for preceding teaching and assessment activities that help students construct learning. Furthermore, students in the first group choose one or two sub problems to be studied more deeply in the second group whose members chose the same sub-problem. The product of this second group is the portfolio of individual studies on selected sub-problems. Once the second group is completed, students return to join the first group to study and formulate more profound conclusions on the general problems.

Table 3: Syntax of Learning Implementation

Procedure	Details	Teacher's Scenario
Orientation (1)	Creating conditions for effective learning	- It starts from the beginning of learning by creating a conducive classroom atmosphere for readiness to take lessons. - Direct the concentration of students and encourage them to be interested in learning. - As a teacher, show attitude and enthusiasm with full of motivation.
	Apperception	- Observe the students' initial abilities on the topic to be studied
		- Allow students to ask questions and express opinions related to the topic.
	Delivering learning purpose	- Deliver the topics or purpose to be discussed in learning.
General exploration (2)	Delivering general explanation	- Deliver to the students the general description of the topic with or without learning media.
	Conducting question and answer (dialogue) about the topics to be discussed	- Give stimulus to students to make them respond, ask questions (dialogue), or give opinions on topics to be discussed.
		- Invite students to understand or discuss the topics briefly on the problem to be solved.
Mastery of learning techniques (3)	(*this stage should not always be conducted in case students master the learning techniques to be used or carried out at previous meetings. The teacher's task is only to provide an operational understanding of the learning techniques*)	
	Explain learning techniques	- Explain the techniques to be used, operational procedures, and an overview of learning outcomes.
		- Give stimulus to students for them to ask questions related to the learning method used.
		- Give direction and guidance to students on how to learn in groups, the importance of collaboration and responsibilities in groups.
	Explain students worksheet	- Briefly discuss the operational use of students worksheet
	Explain group - individual learning techniques	- Briefly explain the individual learning in groups. - Form groups using the jigsaw method
Investigation (4)	(*this stage is the core learning activity and should be carried out individually by students collaborating in groups*)	
	Preparation of learning activities	- Observe that students are ready in the 1st group to start learning.

		- When students discuss worksheets, re-explain to students about the problems that should be answered individually or in groups.
	Conditioning problem solving and collaboration activities	- Motivate students to be serious in solving the problem individually in a group.
	Implement the learning techniques and the process of mastering lesson content	- Guide students individually in the 1st group to solve problems with scientific thinking procedures (formulate problems and sub-problems, collect data, study data, and formulate conclusions). Individual student work is written in portfolio sheet 1
		- Conditioning help students choose one sub-topic or problem to be studied with other groups (second group)
		- With the teacher's direction, students join the second group studying the same sub-topic or problem. The results of individual studies are written in portfolio sheet 2
	Monitor the learning process	- Walk around each group to observe, and give individual or group direction.
	Helping students difficulties	- Help students if they need learning resources that are necessary for the class.
	Process / performance evaluation	- Conduct a process assessment of the activities carried out in groups.
		- Remind them in case time for the activity is almost up.
		- After completing the study in the second group, direct students to rejoin the 1st group to answer general problems. Make the group study results in portfolio sheet 3
Evaluation and follow up (5)	Carry out the final test	- Give questions to several students as a final oral test
	Collect the results of individual and group work	- Collection of student work individually or in groups
	Deliver the topic of the next subject	- Deliver the topic to be studied in the next meeting

4.2. Implementation Model

Learning Implementation Model with Differentiated Group Learning in social science subjects at junior high schools can be described as follows; (a) Teacher and student activities have increased compared to conventional learning; (b) Procedures to be carried out in implementation include orientation, general exploration, mastery of learning techniques, investigation, evaluation, and follow-up; (c) The flexibility of curriculum elements (content, process, and results) is likely to be more dominant during the learning process; (d) Eliminating the weaknesses of both individual and group approaches; (e) Students are more confident.

Table 4: Syntax of Learning Implementation

Procedure	Details	Teacher's Scenario
Orientation (1)	Creating conditions for effective learning	- It starts from the beginning of learning by creating a conducive classroom atmosphere for readiness to take lessons. - Direct the concentration of students and encourage them to be interested in learning. - As a teacher, show attitude and enthusiasm with full of motivation.
	Apperception	- Observe the students' initial abilities on the topic to be studied
		- Allow students to ask questions and express opinions related to the topic.
	Delivering learning purpose	- Deliver the topics or purpose to be discussed in learning.
	Delivering general explanation	- Deliver to the students the general description of the topic with or without learning media.

General exploration (2)	Conducting question and answer (dialogue) about the topics to be discussed	- Give stimulus to students to make them respond, ask questions (dialogue), or give opinions on topics to be discussed.
		- Invite students to understand or discuss the topics briefly on the problem to be solved.
Mastery of learning techniques (3)	(*this stage should not always be conducted in case students master the learning techniques to be used or carried out at previous meetings. The teacher's task is only to provide an operational understanding of the learning techniques*)	
	Explain learning techniques	- Explain the techniques to be used, operational procedures, and an overview of learning outcomes.
		- Give stimulus to students for them to ask questions related to the learning method used.
		- Give direction and guidance to students on how to learn in groups, the importance of collaboration and responsibilities in groups.
	Explain students worksheet	- Briefly discuss the operational use of students worksheet
	Explain group - individual learning techniques	- Briefly explain the individual learning in groups. - Form groups using the jigsaw method
Investigation (4)	(*this stage is the core learning activity and should be carried out individually by students collaborating in groups*)	
	Preparation of learning activities	- Observe that students are ready in the 1st group to start learning.
		- When students discuss worksheets, re-explain to students about the problems that should be answered individually or in groups.
	Conditioning problem solving and collaboration activities	- Motivate students to be serious in solving the problem individually in a group.
	Implement the learning techniques and the process of mastering lesson content	- Guide students individually in the 1st group to solve problems with scientific thinking procedures (formulate problems and sub-problems, collect data, study data, and formulate conclusions). Individual student work is written in portfolio sheet 1
		- Conditioning help students choose one sub-topic or problem to be studied with other groups (second group)
		- With the teacher's direction, students join the second group studying the same sub-topic or problem. The results of individual studies are written in portfolio sheet 2
	Monitor the learning process	- Walk around each group to observe, and give individual or group direction.
	Helping students difficulties	- Help students if they need learning resources that are necessary for the class.
	Process / performance evaluation	- Conduct a process assessment of the activities carried out in groups.
		- Remind them in case time for the activity is almost up.
		- After completing the study in the second group, direct students to rejoin the 1st group to answer general problems. Make the group study results in portfolio sheet 3
	Carry out the final test	- Give questions to several students as a final oral test
	Collect the results of individual and group work	- Collection of student work individually or in groups
	Deliver the topic of the next subject	- Deliver the topic to be studied in the next meeting

4.3. Learning Environment Model

The environmental condition contributes to the effectiveness of learning. The scope of the learning environment that supports starts from the conditions of the group, classroom, school, and community. Environmental standards and learning conditions that need attention include; 1) pleasant atmosphere in class; 2) activity and motivation in groups and class; 3) democratic class atmosphere; 4) discipline in the classroom; 5) effective school management; and 6) conducive community conditions. This finding is in line with [16] which detailed the support for learning environments, including a) pre-lesson conferences for joint lesson planning, b) core issues for lesson designs, c) both elements, or d) another educational topic (control group), effects on the quality of collaborative exchange in lesson conferences, student teachers' competency gains, and instructional quality.

Learning Environment Models [20] established in the differentiated group shows the existence of media empowerment and maximum learning resources support its success. Students are guided to search for and study data and information related to the topic, based on[21]. During the experiment class, especially at the second meeting, the data and information were obtained not only from textbooks but also from various sources. In general, the information contained in geography textbooks at that time tended to be less appropriate to the latest developments, such as charts, distribution maps, growth charts, and factual data [22]. During the second meeting, students and teachers were gradually encouraged to complete data and information that suits the latest developments.

4.4. Model Testing Results in measuring Students' Thinking and Social abilities

- Cognitive Ability

The level of students' ability to solve issues is evident in the process, and the results of problem-solving described in Using Metaphors to Aid Student Meta-Learning [16]. The results of problem-solving are classified by categories, including (1) knowledge ability, such as remembering data and information, (2) the ability to understand data and information, and (3) analysis and synthesis aptitude. From the first to the third learning on the large-scale testing of students' abilities, there was progress towards a higher level. In the first learning, students' ability mainly involved knowledge (cognitive; memory), while the ability of analysis, synthesis, or application was very little. In the subsequent learning, the analysis ability gradually increased. Many students showed an increase in the analysis and application ability in the third learning. This finding was in line with[16], which established that critical thinking is essential for success in all human endeavors. The details are shown in the table below.

Table 5: Recapitulation of Student Cognitive Ability Results Based on Study Large Scale Learning Testing Results

Ability level	Learning Stage		
	The First	The Second	The Third
Knowledge	62.16 %	39.61 %	22.86 %
Understanding	28.4 %	37.83%	48.98 %
Analysis & application.	9.42 %	22.5 %	28.15 %

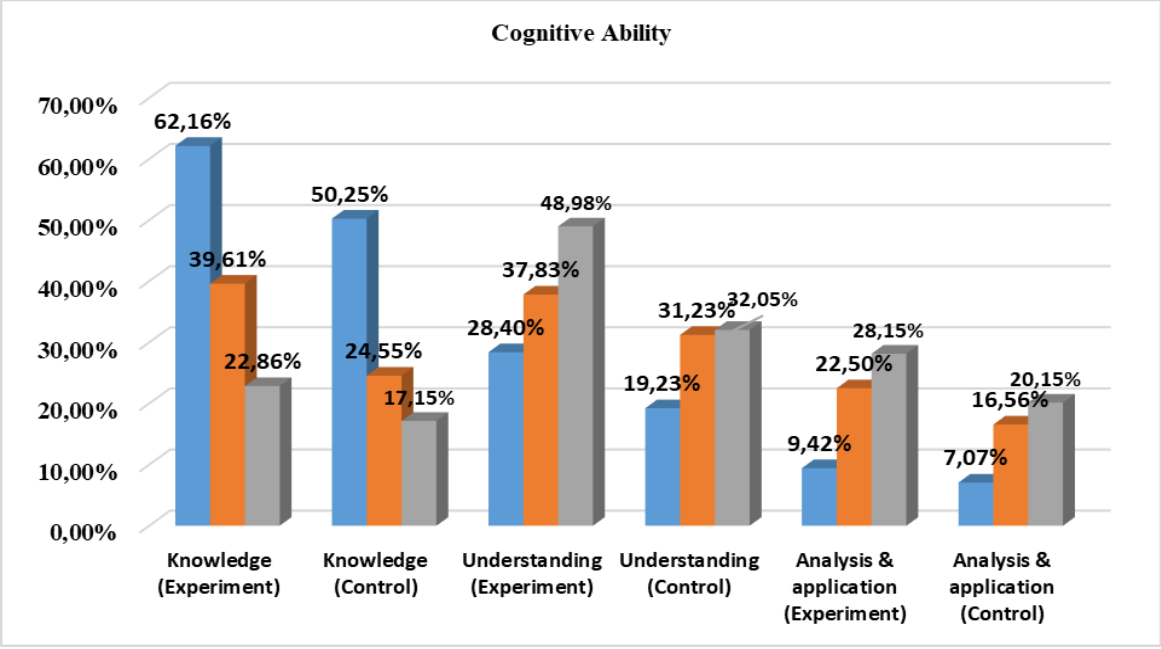

Figure 1: Student's Cognitive Ability Results Based on Experiment and Control Groups

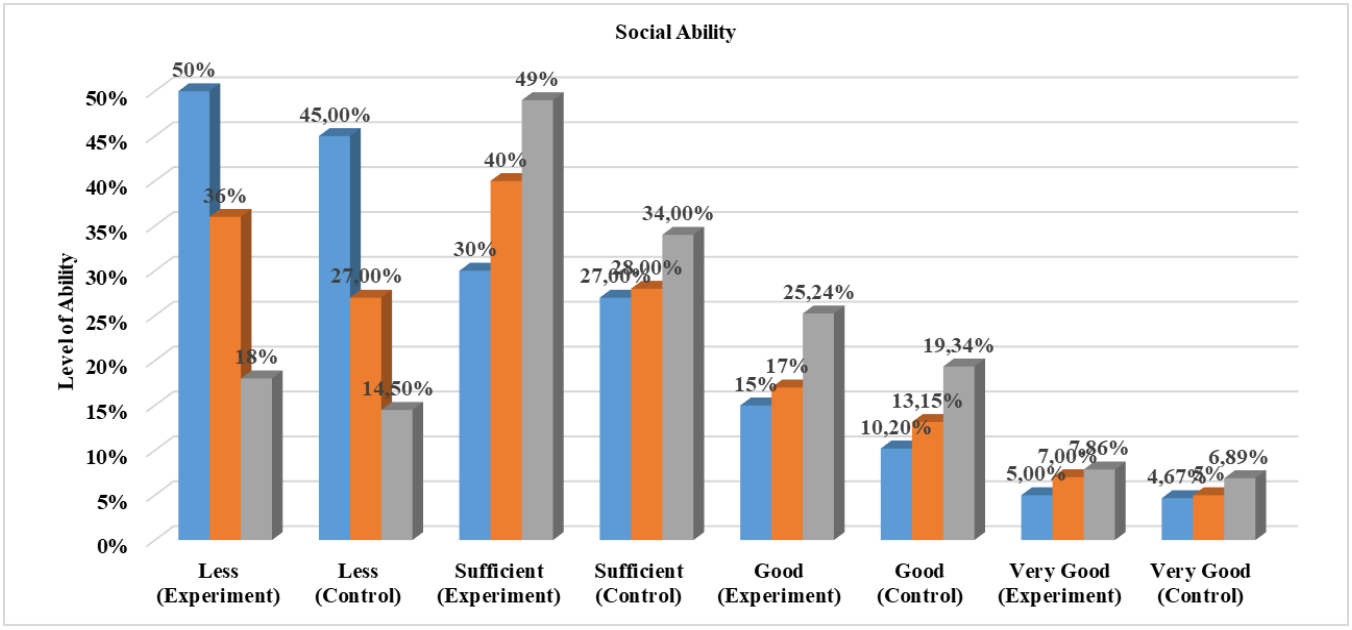

Figure 2: Student's Social Ability Results Based on Experiment and Control Groups

Table 6: Recapitulation of Students' Social Ability Results Based on the Study of Large Scale Learning Testing Results

Ability level	Learning Stage		
	The First	The Second	The Third
Less	50%	36%	18%
Sufficient	30%	40%	49%
Good	15%	17%	25.24%
Very Good	5	7	7.86

Table 7: Objective Test Results in Experiment and Control Groups

	N	Minimum	Maximum	Mean	Std.	Skewness		Kurtosis	
	Statistic	Statistic	Statistic	Statistic	Deviation Statistic	Statistic	Std. Error	Statistic	Std. Error
Pretest-Experiment	92	2.80	5.20	3.9641	.52927	-.063	.251	-.485	.498
Pretest-Control	92	2.80	5.00	3.7935	.61301	.404	.251	-.843	.498
Post Test-Experiment	92	6.00	8.40	7.4196	.50758	-.170	.251	-.683	.498
Posttest-Control	92	5.80	8.00	6.8717	.53807	-.030	.251	-.394	.498
School	92	1	2	1.50	.503.503	.000	.251	-2.045	.498
Gain-Experiment	92	.20	.71	.4891	.11282	-.600	.251	.153	.498
Gain-Control	92	.37	.74	.5693	.09251	-.283	.251	-.813	.498
Valid N (list wise)	92								

Table 8: Descriptive Test Result in Experimental and Control Groups

	N	Mean	Std.	Variance	Skewness		Kurtosis	
	Statistic	Statistic	Deviation Statistic	Statistic	Statistic	Std. Error	Statistic	Std. Error
Pretest-Experiment	92	4.2239	.57919	.335	-.027	.251	-.295	.498
Pretest-Control	92	4.1185	.64124	.11	.145	.251	-.893	.498
Post Test-Experiment	92	7.2978	1.0059	1.012	-.604	.251	-.009	.498
Posttest-Control	92	5.9793	1.04729	1.097	-.264	.251	-1.049	.498
Gain-Experiment	92	.5319	.15943	.025	-.359	.251	.263	.498
Gain-Control	92	.3179	.16273	.026	-.117	.251	-.188	.498
Valid N (list wise)	92							

Table 5 and figure 1, shows that in the first learning, the results of problem-solving by the student (individual) were more on knowledge (remembering) (62.16%). The ability to analyze was only around 39%. This finding was in line with (Savage 2019), which focused on student achievement and [23] on high-level thinking and learning outcomes of learners who have been analyzed using N-Gain.

- Social Ability

The table above shows that in learning, the level of social ability of some students was less (50%). Students with excellent social abilities were only 15%. In contrast to the third learning, the level of social ability of students was high.

The table.7 above shows that the averages for the pretest, posttest, and gain for the experimental group were 3.9641; 7.4196, and 0.5693, while the control groups had 3.7935; 6.8717, and 0.4891 respectively. Based on these results, the average ability of the experimental group both at pretest and posttest was slightly higher than the control group. Another aspect that should be considered is data dissemination. Data (pretest, posttest, and gain) in the control class tended to be more spread than in the experimental group. The description of learning outcomes data is shown in the following table 8.

Analysis of learning outcomes through tests with description is almost the same as the tests with an objective form, showing the consistency of students' abilities in learning outcomes. Based on the size of the central tendency, the average ability of the experimental group was higher than the control group, both in the pretest, post-test, and gain.

This research and development were meant to produce a learning model that could serve students' differences and optimize individual learners' potential in thinking and social abilities. The essence of the model was learning based on students' and cooperative differences. Several assumptions underlie this learning, including 1) Individual development is a matter that needs to be considered in teaching, in this case, the position of students as individuals and social beings who need to socialize [24], [25]; 2) in learning it is necessary to develop democratic processes that can be carried out by students through scientific methods, [26]; 3) through group study, students can exchange knowledge, experience, and views, develop feelings, attitudes, and beliefs, working together and increasing motivation[14]; 4) 11-15 years old children, including those in the formal operation phase, have stages of intellectual development that need problem-solving techniques in learning (Piaget); 5) learning implementation needs to recognize and develop students 'abilities based on their multiple intelligence [13].

This learning model can be implemented in regular classes or the Class of Excellence. It can optimize students' abilities through acceleration, escalation, or enrichment, and can serve learning activities that are compatible with the diversity of students' interests. It can assist teachers to develop and improve students' abilities in regular classes, this result support from [27]. This is proven by students who participated in the learning model. Many students (> 50%) gained improvement and deepening from the ability of basic level knowledge to analyze and synthesize, [28], [29]. The formation of rational abilities can be developed through problem-solving activities in teaching and learning events adjusted to the level of student progress, this result support by [30]. The problem-solving activities by investigating (reviewing) data and information from the media and learning resources,[31] were appropriate and can be implemented to junior high school students. The investigative approach in learning is an integral part of problem-solving activities that implement the principles of democracy to the scientific method and inquiry as a learning process,[32]. The characteristics of learning activities developed further provide opportunities for individual learning that synergizes with groups to be carried out optimally according to student potential. This finding was in line with [33], which discussed how to support learning for measurable positive impacts on teaching quality and teacher morale. Therefore, it is necessary to implement the principles of democracy, competitive, and cooperative developed in the learning process, which leads to the formation of higher-order thinking skills and social abilities.

5. Conclusion and Recommendation

GBDL models which optimize students' thinking and social abilities based on an individual potential focus on aspects of competency; Problem based learning and individual learning in groups. Students understand the individual and group learning techniques, as well as the teacher design. The learning objectives are developed in the form of measurable and specific abilities describing student behavior. The design of the learning process is developed in stages systematically and follows several activities, including orientation, general exploration; practice (mastery) of learning techniques; investigation, evaluation, and; follow-up. Learning design components of GDBL include (a) Analysis of characteristics and curriculum elements; (b) Learning objectives or competencies to be achieved; (c) Essential material; (d) Learning Process; (e) Learning Evaluation. Learning implementation models of GBDL which optimizes students' thinking and social abilities are developed in the following stages, (a) Learning syntax procedures; (b) An integrated manner guided by student worksheet (SW) and the teacher; (c) The group approach is implemented into 2 models, the first and the second groups. The process requires students to learn individually, collaborating in groups; (d) Alternative effective learning strategies used in this learning include problem-solving, inquiry, and group study. Learning environment standards that optimize students' thinking and social abilities based on an individual potential focus on the standard conditions of the learning environment relating to students, teachers, and essential subject matter. This makes the learning environment to be oriented to the activities of the study and the creation of relevant learning resources.

The findings of the GBDL model are expected to be used by teachers when teaching with the group learning method. Especially in social science learning which refers to the use of natural learning resources at the junior high school level.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The author would like to express gratitude to the Ministry of Research and Technology of Indonesia that has provided research

grants of Post graduate School of the Universitas Pendidikan Indonesia, who has permitted to complete this research to provide benefits in the world of education.

Supply Chain

ABSTRACT

This article presents a literature review on how the COVID-19 pandemic changed the way of managing risks in the supply chains of Mexican SMEs. Research was carried out in the most important scientific research databases. The spread of the pandemic in 2020 has affected public health and the world´s companies, including micro, small and medium enterprises (SMEs). The impact on business activities is tremendous, and stringent government policy and response to curb the disease are necessary. SMEs are more vulnerable to internal and external events and depend on the capacity of their owner-manager to run the businesses. The Coronavirus is already considered a factor that requires attention on the behalf of Mexican companies. It is now difficult to imagine a world that isn't permanently changed, and organizations need to adapt. The normality of 2019 is not going to return, and Mexico has a fragile economy and a low-budget health system. The SME supply chains contain many links. At the moment of being struck by a crisis such as the present one, we are experiencing that disruption is likely to occur at the weakest link. Supply chain resilience is the adaptive capacity to prepare for unexpected events, respond to disruption, and recover. A Mexican SME that wishes to be resilient must know all the risks that can affect it. An opportunity for SMEs due to the coronavirus refers to the possibility for continuous innovation through the development of new or better products, processes, and business models. Resilience and risk thinking are life-saving phenomena for Mexican SME´s.

1. Introduction

The coronavirus (COVID-19) is a viral infection that emerged at the end of 2019 in Wuhan, China, and has spread to all regions of the planet. It is highly transmissible and causes severe respiratory problems. The signs and symptoms are somewhat similar to influenza and seasonal allergies. There is no clinically approved antiviral drug or vaccine available at this moment. Many companies are working on the development of an effective cure [1]. The coronavirus outbreak is a tragedy that is affecting millions of the world's inhabitants. The pandemic also had negative impacts on the global economy, industries, corporations, and small and medium-sized businesses [2]. Many thousands have died, others have lost friends or family members, and many businesses have ceased to exist [3].

The World Health Organization (WHO) declared the problem a health emergency and classified it as a pandemic at the international level. Containment measures were put in place, such as the closing of factories and offices, cancellation of trips, and a mandatory at-home quarantine was even imposed, leading to an unprecedented economic crisis [4]. In all countries, people are asked to choose privacy and health, that is, protecting their health and staying home to stop the spread. When the population trusts the public authorities, they do the right thing and do not need to be monitored to comply with the quarantine. A motivated, well-informed society is often much more powerful and effective than an ignorant, government-monitored population [5].

The methodology used for this article was a literature review. The theme was the risks in SMEs with the appearance of COVID-19 and its impact in Mexico. Research was carried out in the databases of: Google Scholar, SpringerLink, and Elsevier, among others. Related topics were searched for in books, theses, and lectures. Research started with search formulas and the selection of keywords such as SMEs, COVID-19, Risks, Resilience, and Supply chain.

This situation affects not only the health of the planet but also the structure of the world economic order. As a result, many

*Corresponding Author: Abel García-Villagrán, ingabelgarvill@gmail.com

economies are in crisis and on the verge of a recession [2]. Although policies to contain the expansion of the pandemic such as quarantines and temporary closures are necessary, they cause a reduction of international trade, interruptions in supply chains, lower productivity, contraction of economic activity, less investment, closure of businesses and loss of jobs [6]. Coronavirus crudely shows us the limits of the system in which we live, the inequalities that we have wanted to ignore, and the urgent need to revalue and strengthen the public, frequently and collectively [7]. Small and medium-sized enterprises (SMEs) are organizations with fewer than 250 employees, and are the backbone of the world's economy. SMEs have characteristics that support them when there is a crisis. Being small organizations helps them to be flexible when new opportunities arise [8]. COVID-19 is a highly infectious and lethal virus; people's sense of insecurity is significant and may include feelings of severe panic. Fear and anxiety probably force consumers to avoid purchases in shops, restaurants and entertainment facilities, changing their lifestyle and behaviour. SMEs are not immune to this current and future situation [9].

With the disruptions caused to the world's SMEs, a great deal of research has been carried out by various authors on how these companies could successfully face this global crisis. In the case of Eggers [8], he investigated how SMEs had faced crises and disasters before COVID-19 to turn them into opportunities. In the case of authors Omar, Ishak, & Jusoh [2], they investigated how the pandemic affected SMEs in Malaysia to identify strategies to survive risks, based on the experiences of business owners. Thorgren & Williams [10] carried out a study in several SMEs in Sweden. They analyzed what actions they took to survive and prevent a major disaster, looking for how they could have a "better" or "critical" long-term impact. In this way, researching to understand the risks that affect SMEs in Mexico helps us to expand our knowledge of how these companies manage disruptions, seeking to be resilient to this pandemic that has changed the normality of how the world works.

2. Methodology

To prepare this research, a literature review was carried out. The search was guided by risks in the supply chains in Mexican SMEs with the appearance of COVID-19. The information investigated consisted mainly of articles published between March and September 2020. The methodology combined a systematic literature review with the most relevant articles. The literature review was augmented by the use of online computerized search engines including Google Scholar (350 articles), SpringerLink (105 articles), and Elsevier (252 articles). Information was also sought in books, theses, and lectures, using Keywords such as SMEs in Mexico, COVID-19, Risks, Resilience, and Supply Chains. Approximately 700 sources were retrieved and analyzed. In a careful analysis, the articles that contained the best information were selected. Based on this review, the main risks in Mexican SMEs and their effects during the COVID-19 pandemic were found.or the preparation of this investigation, a literature review was carried out.

3. Supply Chain in Mexican SMEs

The focus of a supply chain is to provide the right product to the consumer, at the right cost, with the correct quality and quantity. This network includes the manufacturing of a product or service, suppliers, retailers, transportation, and customers on both sides [11]. Supply chains work the same way our bodies do to fight the COVID-19 virus. If we imagine the human body as a medieval city to be defended, the immune system would be the army with all its strategies to take care of the safety of the inhabitants. The first line of defence is the wall. In the case of our body, it is the skin. But, there are other possible entrances, such as doors, cracks, water outlets, which are essential for the city to function. In our body, those entrances that are related to the outside are the nose, eyes, ears, mouth, and small wounds, which are the places through which the virus can enter to attack and end the person's life [12]. A supply chain contains many links. At the moment of being struck by a crisis like the present one, the weakest link is the place where the disruption that causes the failure or stoppage of the flow of materials, causing a drop in production, customer dissatisfaction or economic losses. If not corrected on time, these affect the chain and may cause the closure or weakening of any of the companies involved.

Our society seeks efficiency and economic benefit more than safety, a mindset that must change after the current outbreak. Many companies have closed, disrupting trade in most industrial sectors. Entrepreneurs and brands face many short-term challenges in areas such as health, safety, supply chains, workforce, cash flow, changes in demand, sales, and marketing [13]. The pandemic has several characteristics: it is a global phenomenon, with impacts on public health and the economy. It is spread between people, but also in commerce. The world economy is connected by value chains and international movements of people, capital, goods, and services [3]. The prolonged closure of companies in the world economy reduces inventory stock in supply chains. Companies must minimize disruption and adapt quickly to this new business landscape [14].

For Latin America, an increase in unemployment and poverty is anticipated as a result of the global economic slowdown, tourism decline, reduced remittances from immigrants, the interruption of value chains, and the lack of international investment [6]. As to the effects of COVID-19 on the real economy, there are already projections that assume an employment crisis in Mexico. Forecasts for negative growth rate are estimated to be between -3.9% (the most optimistic) and -9.6% (the most pessimistic). Therefore, the extent of the crisis and the duration of recovery depend on strategies implemented by the Mexican government at its three levels [15]. The Coronavirus crisis is projected to be a considerable economic crisis and the greatest challenge since the Great Recession. Unlike the 2008 crisis, it is not in the financial markets, but is now in the real economy, consisting of companies, mainly SMEs and their workers. Demand is expected to affect durable goods more than non-durable products, especially the manufacturing sector [4].

One characteristic of the crisis is that people have been confined to their homes. The population is trying to determine the best way to protect themselves and their loved ones. Many are fearful of losing their jobs or work around people who may be infected. Each country has adopted different actions to manage stress at work and supports its citizens in different ways [13]. Right now, we are in the hands of the decisions that people and governments will be making in the coming weeks that will shape

the world for years to come. And not only health systems, but also the economy, politics, and culture. What world will we inhabit once the storm passes? Even when all of this endsand we survive, the world we live in is going to be different [5]. Mexico, like the rest of the world, is at a crucial moment, in which the response of government and society will shape the future of the country. The challenge is enormous for a country which, in addition to having great inequalities, has received COVID-19 in a situation of great economic fragility, with a fragmented health system, little investment and a government that has not shown itself able to understand the magnitude of this crisis [16].

Contagion in supply chains leads to direct supply shocks among the countries least affected by the pandemic. It is more difficult and expensive to acquire the industrial materials necessary for manufacturing, and the most affected countries sell these inputs at a higher price due to the shortage of units [4]. Ways of consumption and purchase are going to change. We are having supply versus demand shocks. Companies and individuals are changing their consumption habits as regards many products. The demand for non-essential consumer goods is falling, even without supply restrictions [3]. Even if small manufacturers close their businesses temporarily, they continue to face payments such as rent and bank loans, in addition to debts for supplies they had ordered before the pandemic [17]. Despite these difficulties, supply chains are not broken. The global pandemic has been an opportunity to integrate a new set of skills, strategies, and innovations to develop a new chain model, one that is more resilient, more flexible, and with much less dependence on the Asian market [18].

Supply chain risk management only applied to first-tier suppliers, leaving companies blind and vulnerable to crises affecting their lower-tier "invisible" suppliers. Reality shows us that all suppliers are significant, and interruptions at any level can cause disruptions throughout the chain [14].

4. SMEs and the COVID-19 pandemic

In a globalized economy, small and medium-sized enterprises (SMEs) are the main source of dynamism, innovation, and flexibility in developing countries, as well as in industrialized nations. The economic development and job creation of a country are a consequence of the proper functioning of SMEs [11]. The spread of the COVID-19 pandemic has affected various sectors of the economy, including the micro, small and medium enterprises, which are usually resilient when economic problems occur. Currently, SMEs are at the forefront of crises becausemany employees are limited to doing activities outside the home. The disruption of business activities reduces business performance. Therefore, companies make layoffs and threats of bankruptcy, or they are unable to survive [19].

SMEs face the liability of being small. If a company is small, it controls fewer resources, which makes it more vulnerable to internal and external events, such as the resignation of an employee, a decrease in its finances, a reduction in demand, or a global economic crisis. [8]. Small businesses depend on the intelligence and ability of the owner to run them properly. The owner is a fundamental part of the organization, can develop the supply chain, alliances, performance indicators, and business vision [11].

Survival is difficult for small businesses, even under the best of circumstances. SMEs have limited cash and few reserves. They generally do not have access to credit or capital markets. A temporary interruption can mean the closure of the business. It is not surprising that the restrictions imposed by governments to combat the spread of the pandemic have become a risk for many of them [17]. The effect of the coronavirus on the business activities of SMEs around the world is tremendous. Governments have to put strict policies in place to curb the disease. These decisions cause challenges for SMEs such as cash flow, closure of the operation, dismissal of workers, changes in business strategies, and the search for new sources and opportunities [2]. In recent weeks, purchases of cleaning products have increased, and the population is recycling more garbage by staying at home. At the same time, they accumulate goods, make panic purchases, and some leave the cities to go to the countryside [13].

SMEs have to respond on multiple fronts. They must work to protect the safety of their workers and take care of the operations they perform. They are having an impact on the supply chain and need to move forward in these times of crisis [20]. The most common concern in SMEs we heard was a need for assistance in covering fixed operating costs: rent and mortgage payments, but also utilities and insurance [17]. Micro and small companies are less productive than large companies and have few financial resources to face this crisis. At this time of slowdown and possible loss of jobs, they must be prioritized as compared to large corporations. Forced to close in order to contain the contagion of COVID-19, some companies have announced layoffs and seek a way to reduce their costs during the suspension of activities [7]. It is essential to take action to ensure that fewer jobs are lost and to distribute subsidies to companies and workers to protect the most vulnerable.

The virus does not discriminate, but its economic impact does, so it is necessary to guarantee policies that have the following three priorities:

- Guaranteeing minimum income for the people most vulnerable to the crisis.
- Providing employment protection.
- Encouraging consumption, demand, production, and economic growth.

In Mexico, we had a fragile economy and a low-budget health system even before the health emergency caused by COVID-19 [16]. The President of the Republic, on two different dates, presented the list of welfare programs that minimize the economic and social effect of the pandemic. On April 23, a decree establishing austerity policies for the Secretariats and entities of the Republic until December 31, 2020, was issued [15]. In the case of SMEs, they receive benefits with the following points:

a) 3 million credits are granted to individuals and small family businesses.

b) Two million jobs are created.

c) Fuel prices and taxes are not to be increased.

The government has a very important role in disaster recovery. It manages aid and assistance programs, which provide a basis for

a faster recovery, and the economy should return to normal [21]. Predictions show us that the contagions will continue. It is the government's responsibility to have an adequate policy for the containment of COVID-19, in addition to ensuring that the country has better precautionary measures and preparations before the reopening of its borders [22].

The job loss trend from the first case of COVID-19 detected in Mexico on February 29 is as follows [15]:

- As of March 13, there has been a drop in the number of jobs covered by the IMSS (Mexican Institute of Social Security).
- 346,878 jobs were lost from March 13 to April 6, of which 62% no longer have access to health services, and the remaining 37.7% lose access after seven weeks.
- 47.5% of the jobs lost from March 13 to April 6 occurred in medium-sized companies with 51 to 500 workers.

5. SMEs Disruptions.

No supply chain is infallible; they are subject to different factors that affect their regular operation. Among the possible reasons for this are the closure of plants, the lack of supplies, a lack of information, unforeseen situations such as natural disasters, and epidemics that not only curtail supply but also affect demand [23]. There is a great difference between large companies and SMEs. Large companies have plans for almost all eventualities. It is commonly accepted that SMEs can be disproportionately impacted by extreme events [24]. With technological advances in information processing, there is a greater dependence on networks in supply chains. Companies must incorporate actions to mitigate risks, guaranteeing the safety of the chains and being able to compete effectively [25].

Organizations must be flexible to change. They need to have strategies as to managing the volatility, and ambiguity of the world. Knowing how to manage business risks improves resilience and can be useful for any organization. By knowing the most significant risks, companies implement actions that allow them to act early [26]. The ISO 9001: 2015 standard explicitly addresses the identification and intervention of risks as a preventive mechanism of the management system. This norm helps eliminate potential causes, preventing their occurrence, and minimizing disruptions. Organizations must determine the risks and opportunities to fulfil the purpose of the quality system and thereby increase the trust and satisfaction of the interested parties [27].

Speaking of higher risks, we have to refer to the events of greatest danger for an organization, which are those of High impact / low probability. The reason is that such activities are unimaginable or of such rare incidence that they have never happened in recent memory, and they are not on the "radar" of risk managers. These so-called black swans are events that were thought impossible or that had never been imagined until they happened; experts mistakenly assume that the probability of a black swan is zero, when in fact it is not [28].

Any disruption has consequences on the performance of SMEs, whether in sales, production level, or profits. The authors divide disruptions into eight different phases: Preparedness, Disruptive Event, First Response, Initial Impact, Total Impact, Preparedness for Recovery, Recovery, and Long-Term Impact. The measurement of business resilience to disruptive events should be carried out before the event so we can act more quickly and with distinct guides to the problem [29]. For successfully managing disruptions, both pre-disruption and post-disruption approaches are necessary and need to be taken into consideration [30].

Disruptions allow organizations to have experiences that help them to have answers to future problems. Analyzing an incident helps to identify lessons learned and to understand supply chain risks. In this way, future outages will be managed efficiently, and partners will have to collaborate to obtain better results [31]. In recent years, the manufacturing of companies has been disrupted by earthquakes in New Zealand, air traffic closures due to terrorism in France, and volcanic eruptions in Iceland. Researchers are concerned about the increase in disruptions of the supply chain and its implications [32]. Many SMEs cannot survive after a disaster, so ensuring their survival during and after crises is essential. Governments should also learn from past disasters [33]. On March 11, 2011, a great earthquake occurred in Japan and a tsunami that destroyed many houses and buildings. This event caused a 15% reduction in industrial production in the following months. Although the heaviest damage was on the east coast of the Tohoku and Kanto regions, companies in other parts of Japan were affected by supply chain disruptions [34].

Historically, many diseases, such as the plague, syphilis, smallpox, or influenza, have caused millions of deaths and caused panic in the world. In recent decades, the appearance of new diseases has created alarm and anxiety across the globe, affecting public health and the world economy. Countries with these problems must carry out inspections of all people at international airports, seaports, and land crossings [35]. In addition to human losses, epidemics threaten the free movement of people and goods in global supply chains. Contagious events almost always include medical and financial problems. They spread through human networks that are very often closely linked to supply chains. They affect several countries and multiple industries simultaneously. The weakest and least prepared companies are the most damaged [28].

Cholera in Peru, SARS in Vietnam, Ebola in Africa, and now COVID-19, which emerged in 2019 in China, are examples of global diseases that affect the economy of SMEs and cause fear among the population. The spread of the Coronavirus from China and its expansion to northern Italy, Korea, and the rest of the world, affects the industry in various ways. Mexican SMEs could be affected by the impact of the Chinese slowdown. Another risk factor is the possible shortage of products that affects the prices of many goods worldwide, so the Coronavirus is already considered a factor that Mexican companies have to pay attention to [36]. It is hard to imagine a world that is not changing because of coronavirus. The success of scientists, together with the political and social leadership, will determine the future. It is time to think about what we can do to help. It is a battle that tests our mutual responsibilities, our strengths, and our compassion [37].

Transportation risks are also a potential cause of disruption for SMEs in the supply chain. However, exporters (packers and wholesalers) are more vulnerable than other nodes in the supply chain [38]. Logistics is the engine of world trade; safety in the transport of goods appears as a critical element in its consolidation.

The World Customs Organization (WCO) developed a regulatory framework, to adopt the necessary measures to guarantee the integrity of transport throughout the supply chain against theft, piracy or terrorism [39]. In Mexican SMEs, the transportation of goods is a crucial element for the success of operations. Unfortunately, trucking theft has become a problem for entrepreneurs and a disruption for supply chains. According to the report of the Executive Secretariat of the National Public Security System [40] from January to September 2018, more than 8,727 thefts of carriers were registered, which meant an increase of 4.10% compared to the previous year, and 87% of these events were violent. These facts directly affect the competitiveness of SMEs, and managers must think about how to deal with it because now it is a risk every time their trucks hit the road to deliver to their customers.

The first research on the impact of natural disasters on business appeared in the 1980s. The first was carried out in the United States after the 1989 Loma Prieta earthquake. SMEs are more vulnerable to natural disasters and can be affected in many ways. There are also interruptions related to public services such as electricity, water supply, sewage, lack of fuel, transportation, and telecommunications. Failures in public infrastructure make companies look for alternative logistical support that allows SMEs to function after disruption of this type [41]. Risks from natural disasters in Mexico are many; the National Center for Disaster Prevention (CENAPRED) [42] mentions in its report for 2017 that the estimated damages and losses amounted to 73,862 million pesos, a figure that was 400% higher per year, which impacted 0.34% on GDP. The phenomena that most impacted the country were those of a geological type, with an earthquake of a magnitude of 7.1 degrees on September 19, representing 90.7% of the losses, and hydrometeorological events caused by cyclonic activity in the Pacific and Atlantic, representing 8.2 % of disasters. Manufacturing SMEs that were close to the epicenters were affected directly or indirectly without being able to do anything about it.

It may be that each of the causes that initiates a disruption is unique. Still, they may have some aspects in common, so that understanding them helps orient collective action towards efficient and effective situations. What is lacking for SMEs to remain is to create conditions for permanence, growth, and transformation into mature companies [43]. These different causes are similar to what happened on January 19, 2019, in which teachers from the Mexican state of Michoacán blocked in six different points and for more than eighteen consecutive days the railroad tracks that connect the main ports of the Pacific: Lázaro Cárdenas and Mazatlan. Eleven states of the Republic were affected, and results included 252 stopped trains, 10 thousand immobilized containers, and 2.1 million tons of cargo affected, leaving many SMEs without supplies for several days [44].

Many lessons can be learned, but one of special concern is that most companies fail to recognize high-impact risks and as a consequence are not able to respond adequately [45]. After a disruptive event, companies must react and control the situation to stop the effects of the disruption as much as possible, and preserve the business structure and the most valuable assets [46]. Disruptions usually occur suddenly, and their impact is experienced over a long period, requiring much effort and sometimes the help of others [33].

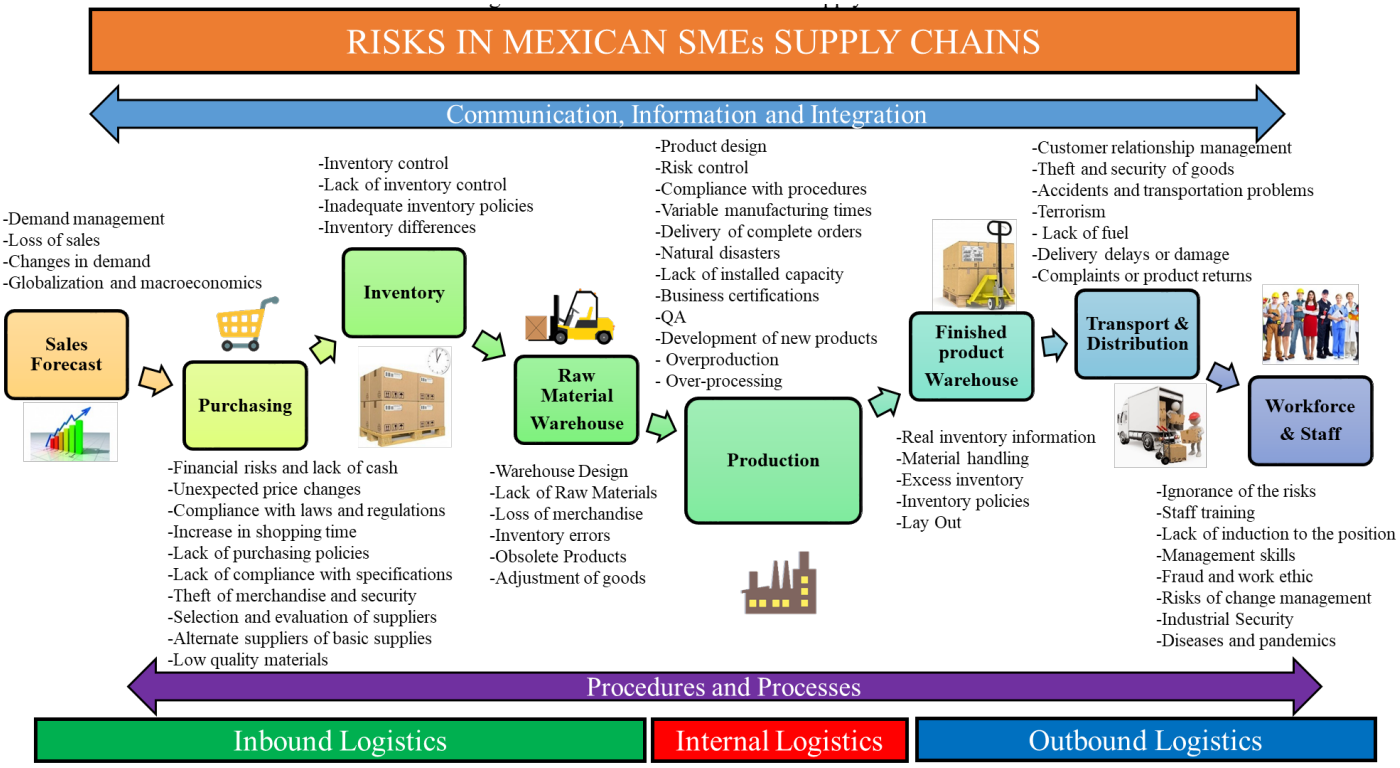
The design of a risk management strategy is the key to a well-functioning value chain. This strategy must identify the potential sources of risks and the appropriate actions to prevent them or reduce the impact of a disruption. As long as the risks are better known, entrepeneurs can identify and prioritize actions to have greater resilience, sustainability, and profitability [47]. SMEs face constant risks that negatively impact all areas, causing losses and endangering their survival in the market. Risk management in the different stages of an SME supply chain should not be an isolated program, but part of the business strategy. The magnitude of the efforts required to control them will depend on the complexity of the operational activities and the size of the company. Most of the time, Small Business owners do not pay attention to this issue because of their company's success in the market.

Risks are interconnected with each other. For example, factors such as natural disasters that affect the supplier increase the producer's risk of not receiving the raw material he needs. Logistics operators can be affected by lower demand, which translates into wasted production capacity with lower sales, increasing their risk of liquidity. Finally, distribution and transportation can be affected by the need to lower their inventories. It is essential for the operation and performance of SMEs' supply chain, to develop management strategies that identify the risks to which they are exposed, their probability of occurrence, and the effects they may have in a disruption such as COVID-19. In (Figure 1), a summary of the risks found in the literature review of each stage of the supply chain of SMEs in Mexico is made. The risks were classified into three areas: Inbound Logistics, Internal Logistics, and Outbound Logistics. In this way, it is easy to identify where outages may occur and take the necessary precautions.

6. Resilience in SME's in times of COVID-19.

In recent decades, resilience has become globally significant as the ability of a system to respond to change and continue to develop. This term has been used to describe and explain various life situations in different disciplines, and resilience is something that must be developed in the ecosystem, in humans, and therefore in organizations and specifically in supply chains [48]. The need for an "Antifragile" property is an imperative to ensure the business continuity and future success of SMEs in times of disruptive events. This concept originated from philosophy, and builds upon the Black Swan Theory, which describes unexpected and unpredictable events having a high impact in a world in which everyone believes that only white swans exist [9].

The word resilience comes from the English language and expresses the ability of a material to regain its original shape after being subjected to high pressure [49]. In the business world, resilience is understood as a crisis management and business continuity, as well as responding to all types of risks that organizations may face, ranging from cyberspace threats to natural disasters and many others [19]. Supply chain resilience is the adaptive capacity to prepare for unexpected events, respond to disruption, and recover from them by maintaining continuity of operations at the desired level of connectedness and control over structure and function [38].



The elements to measure business resilience are the adaptive capacity of the company, vulnerability, probability of occurrence of disruption, time, level of recovery, commitment, and responsibility of the supply chain [50]. Companies seek to become stronger and find the formula to continue despite adverse circumstances [46]. Therefore, they assume two primary missions:

1) Implementing strategies to face and overcome the adverse effects produced by those unexpected situations and,

2) Developing protective barriers to face eventual future circumstances.

Resilient companies are those that, in times of constant change such as economic-social crises or business globalization, perform better than others, and obtain benefits from adverse or unforeseen circumstances. Some companies are expected to emerge from intense crises, while others could weaken or even go bankrupt. In all these possibilities, those organizations that maintain a tendency to renew and perform better during the crisis are resilient [51]. An organization with these characteristics has a set of capabilities aimed at carrying out robust actions in the face of a specific condition generated by unexpected and powerful events that endanger the survival of the organization [49]. The majority of business resilience risks come from internal factors in the supply chain, thus requiring strong collaboration. The level of resilience risks and barriers varies in SMEs according to their size [19].

Many firms are struggling to survive during the pandemic, which focuses attention on the apparent failings of their business models and on how to build greater resilience in the future. There are new business opportunities [3]. Many questions that we could ask ourselves about the rapid closure of companies due to the pandemic have arisen. For example, how can we take better care of employees in such situations? Why weren't companies ready? How can companies and countries use this situation to improve their competitiveness? [13].

Diversified supply-chains across companies and geographies significantly reduce exposure. If firms are tied to single suppliers, the risk from disruptions should be carefully measured and contingency plans considered [14]. In most companies, inventories are stored for two to five weeks, with no additional deliveries. Each company has a different supply-chain strategy and ensures their delivery times. If the components do not arrive or their delivery is interrupted for a longer time, production stops. A resilient supply chain must align its strategy and operations to adapt to the risks that may affect it. Therefore, networking with providers is the key to resilience [20]. An SME that wishes to be resilient must carry out the following actions: recruit resilient personnel, define clear and precise positions and functions, have business strategies known by all members of the organization, establish quality systems, have an organizational culture with solid values, be attentive to economic trends, review consumer trends, and promote initiative and creativity among its staff [43].

Business certifications ensure that a business meets the requirements of governing industry standards. The pursuit of these certifications reinforces the commitment to continuous improvement, thus reducing risk in production and demand disruption and reducing trade barriers for firms. There is a positive impact of business certifications on firms' resilience. Certifications could be Hazard Analysis and Critical Control Point (HACCP), Good Manufacturing Practices (GMP), ISO 9000, among others [38]. Some Resilience Models have been used in SMEs worldwide. One of them is: "Healthy and Resilient Organization, HERO", a heuristic model that describes the functioning of healthy and resilient organizations. It is made up of three elements: Healthy organizational resources and practices, Healthy

employees, and Healthy corporate results. This model was created from the global context that refers to organizations that survive and adapt to crises, becoming more robust in the face of these negative experiences [52]. When evaluating risks in a Supply Chain, the SCOR (Supply Chain Operations Reference) reference model provides a common language in the areas of planning, manufacturing, distribution, and return. It includes a methodology that allows an analysis of the operations of the chain, helping them communicate company information, measure performance, and set improvement objectives. Being a reference model, it does not have a mathematical description or a specific method. Its usefulness lies in providing a standard of chain terms and processes to a model using performance indicators [25].

Using information technology during extreme interruptions can help people stay connected and ease their work situation. Lessons from the use of information technology by SMEs to support business continuity during COVID-19 help us minimize some of the risks of information flow throughout the supply chain [53]. The normality of December 2019 is not going to return. In many countries, the concept of omnichannel networks accelerated. People now work, buy, spend, and see their families digitally. Unexpectedly, COVID-19 has done more for digital acceleration than possibly anything seen in the last decade [18]. COVID-19 showed the weaknesses of the business model that existed. Some of the changes that are being experienced are: People involved in the physical distribution of goods can become infected with the virus and stop global value chains. International air travel is limited, but most ports and sea routes remain open. Social distancing and controls for the flow of people create delays. Companies and governments have a shortage of critical goods and services because foreign suppliers are looking for their products with local customers [3].

Some of the problems of lack of supply thanks to COVID-19 indicate that if there had been a previous study on these issues, many problems could have been foreseen: A lack of laws to control price increases due to a crisis; mapping the supply chain and ensuring certified suppliers and products. Government procurement of health products. International supply assessment, trade barriers, and market capacity [54].

Owners/managers must make the right decisions, which promote flexibility in SMEs and the ability to react rapidly in their markets. Another opportunity provided by COVID-19 refers to the possibility for continuous innovation through the development of new or better products, process and business models suggested by employees, customers and partners after the emergency. Also, SMEs could be redesigning and defining new strategies to meet the rising global demand for disinfectants, medical masks and other anti-Covid19 products [9].

In June the SoyLogístico Association of Mexico [55] shared some recommendations based on the experience of its partners and executives from different supply chains to return to the new normal. They issued a document called: "Ten Operational Tactical Actions towards the New Normal", in which some of the points that can support the logistical resilience and continuity of operations in Mexican SMEs are the following:

- Define health and safety protocols so that employees work safely.
- Analyze demand, align supply by adjusting sales and financial plans.
- Analyze the financial situation of the company, and also eliminate or reduce inventories.
- Review supply, and return to local suppliers instead of global suppliers.
- Define an operating strategy throughout the supply chain.
- Analyze the distribution of merchandise, review delivery restrictions, and ensure the requirements of distribution centres.
- Analyze the transport of goods and last-mile deliveries.
- Guarantee clear and continuous communication with collaborators, clients, suppliers, partners, and authorities.
- Have a leadership focused on the achievement of objectives and results of collaborators, seeking to "humanize" operations.
- Promote savings plans throughout the chain and define actions to digitize activities.

7. Conclusion

World political and economic scenarios in this century are leading us to collapse. Economic downturns, competition, corrupt governments, damage to the environment, natural catastrophes, and now global pandemics are leading the world into uncontrolled free fall. Disruptions are not only increasing but are also more potent; the possibility of bankruptcy or closure of companies is escalating. Resilient thinking is not a game; it is a life-saving phenomenon for organizations large and small [56]. Although viruses like COVID-19 have the potential to do much damage, they are very simple invaders. When a large number of them enter our body, our defences go into action to attack them and keep the person alive [12]. The global pandemic is striking Mexican supply chains, more than ever before, communication, timely information, innovation, best logistics practices, and the resilience of the most robust links help them to resist this time of crisis.

In the short term, the effects of the Coronavirus on the global economy are substantial. The temporary suspension of production and supply chains has also had an impact on the evolution of various financial indices. If the adverse effects of the epidemic persist, countries must adopt fiscal, monetary, and economic actions that support consumers and small businesses that are most affected. The COVID-19 emergency reminds the world that it must be prepared for a crisis with risks to the health of the population [6]. It was clear that SMEs' resilience requires partnerships and cooperation among firms, government, and other private organizations. It cannot be achieved by the business entity alone or by the government on its own [41].

In current conditions where demand is changing and customers are more interested in digital commerce, having the right information technologies is important for the sustainability of company operations. SMEs must make efforts to be part of the digital economic ecosystem and use social networks to promote products or businesses. By promoting their brands effectively, they create online communities, knowing the preferences of their

customers effectively and directly [57]. In these times of staying at home, consumer behavior has changed. Consumers are becoming more and more comfortable with digital technology and digital commerce. SMEs need to invest in data analysis technologies in order to know their customers effectively and offer them what they need [58]. The time has come for Mexican micro, small, and medium-sized companies to think about starting operations online. This option is the only way to guarantee their survival and development in the future. According to the Mexican Online Sales Association (AMVO), electronic commerce will grow by 59% due to the pandemic. If the benefits of electronic commerce are expected to be real in Mexican companies and consumers, some challenges have to be overcome, especially in logistics. The first is a lack of capacity of logistics infrastructure under normal conditions, and the second is the issue of the pandemic because demand continues to exceed expectations [59].

The Mexican government is in a race against time to implement a solid economic rescue plan. If it is not successful, the recession will be complicated, and access to financial markets will be restricted. The signs of President López Obrador are disturbing, placing the social and work life of citizens whose life has been altered by the pandemic at risk [16]. The priority must be to support individuals and small businesses urgently. Large companies are able to assume part of the cost of the crisis, especially those that are in sectors that may benefit. Companies with direct links to high government positions should be prevented from receiving financial support [7].

The challenges resulting from the COVID-19 are not disappearing quickly, and government policies for assisting small businesses and managing a return to some version of typical activities continue [17]. A global effort is needed for the production and distribution of medical equipment, test kits, and respirators. Rather than each country trying to achieve this locally, a coordinated effort could accelerate production and ensure that life-saving equipment is distributed fairly [5]. Recent articles debate what the future holds, considering questions such as how long social distancing needs to continue, the social and political consequences of lockdown, and implications for supply and demand chain structures [54].

Future expectations are anyone's guess. The COVID-19 crisis has consumers and companies in continuous uncertainty [4]. Articles published in the popular press or social media discuss how the crisis is changing the way we live and work, and this is driven mainly by small and medium-size organizations that create innovative solutions for problems. SMEs have a unique role in the macro-environment when it comes to creating a path forward [8].

Many changes have affected the supply chains of manufacturing SMEs in Mexico. One has to discover new ways of managing them if one wants to survive in the modern world context. The delivery times and availability of materials and goods are changing due to COVID-19 because no one is manufacturing them. The risks of diversifying with more suppliers globally or developing existing suppliers have to be considered. SMEs are increasing their inventory levels to face future disruptions. Electronic commerce is a new way of selling their products, forcing SMEs to strengthen electronic platforms and their information systems. The distribution, reception, and delivery of orders must be reinvented, so as to avoid any risk when inspecting or arranging products in the warehouses. What seemed unlikely to happen is happening now, and logistics managers, company staff, and researchers on these issues have to reinvent models to make companies resilient. It is necessary to consider every risk encountered throughout the supply chain.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

3D city modeling may be considered as one of the key applications, that are provided by the Automated Feature Extraction (AFE) techniques from LiDAR data. The authors attempt to prove that with growing availability of LiDAR surveying methods the resulted 3D city models become the most significant modeled features for any urban environment. Our paper represents the conceptual multifunctional approach within the AFE frameworks, that has been introduced through consequent steps of the phased methodological flowchart with its two branches: High Polyhedral Modeling (HPM) and the Low Polyhedral Modeling (LPM) of buildings. Both branches result in the heavyweight models, and in the lightweight ones, correspondingly. The research purpose of this paper is to outline our multifunctional approach (functionalities of Building Extraction, Building Extraction in Rural Areas, Change Detection, and Digital Elevation Model Generation) to the fully automated extraction of urban features, and present our original contributions to the relevant algorithmic solutions within both HPM, and LPM pipelines, as well as represent desktop, web-, and cloud-based software elaborated for these intentions. Original enhancements and optimizations of the adopted AFE-techniques have been bounded to the phases of the methodological flowchart, while some derivative results have been presented not only as the software description, but also in the discussion chapter. Joint implementation of various functionalities in a web-based application (the Server) is presented with several interface samples of research in urban block and district scopes, while a cloud-based application (the Geoportal) is an Internet-toolbox for solutions in the scope of a whole city.

1. Introduction

This text is a significantly changed extension of the work firstly presented as a conference paper [1].

The global world has been already transferring into the information society for several recent decades. It is quite acceptable to consider *a Geographic Information System – GIS* as one of the core tools of such transfer together with the relevant technologies of remote sensing, including *LiDAR (Light Detection and Ranging)* technique. It has been remarkable for few recent decades that exactly this period also has been featured by the continuing urbanization process, that still takes place nowadays in many developing countries. Numerous facts and phenomena indicate, that we may face the largest urban growth wave within the whole human history, which also concurs with prompt development of information technologies, remote sensing, computer sciences, geoinformatics, and *GIS-platforms / modules*. All listed entities could and should be involved in resolving of those drastic problems arisen within the urbanized areas, for example, by considering these territories as the *hierarchical urban geosystems* and making the corresponding decision support recommendations [2, 3]. Thus, even several highly challenging issues relevant to the Smart City development can be met in this way [4]. Moreover, the rapid growth of both remote sensing technique and GIS-technological involvement in surveying environmental consequences of the urbanization process has been

*Corresponding Author: Sergiy Kostrikov, sergiy.kostrikov@karazin.ua

clear evident over the past few decades [5], while quite a few both approaches, and methods, as well as user interfaces have been developed [6-15].

Urban features can be accepted as the core constituents of any virtual presentation for each digitally simulated city. A *3D City Model* is the key formalized entity of the mentioned city content, and it enables effective and accurate 3D modeling of the urbanized environment with respects to housing sets and infrastructures [16-23]. Within the urban studies perspectives it can be possible to accept a 3D object / feature model as a work-flow key issue of the GIS output completed from the urban remote sensing input. This assumption may be even more evident, while the discrete objects are considered as those modeled results, which are intended for a customized solution within the framework of one only, or several urban applications. In this meaning 3D modeling appears to become a key component within the common geoinformation paradigm [24]. It is considered be possible to accept a 3D city model of urban area as that entity, which corresponding environmental analog is placed within 3D urban environment described by routine urban features and structures with buildings as the dominant objects among them.

Exactly for a couple of latest decades LiDAR (Lidar) data collecting processing technique has become an alternative (to areal imageries) data source for generating a 3D representation of natural landscapes and housing environments as well as the overall human-environment intercourse [25, 26]. Being able to collect directly the accurate *3D point clouds* of various density over urban territories, the LiDAR technique proposes an effective and beneficial data source in this meaning. By the way, this is illustrated further in this text.

There are Airborne (ALS), Terrestrial (Mobile - MLS), and UAV-LS (Unmanned Aerial Vehicle Laser Scanning) LiDAR techniques within the common remote sensing technology, that measures distances on the base of the time intervals between the laser signal transmitting / receiving. All ALS / MLS /UAV-LS mapping are surveying and mapping tools based on hardware platforms and software solutions [27-30]. The ALS lidar normally completes low-average density measurements of the underlying topographic surface, that result in the georeferenced, but unstructured set of points – lidar Point Clouds, while the MLS technique usually captures the walls – with a high resolution of façade details for buildings of different sizes. The UAV-LS lidar accomplishes *high density measurements* and can provide surveys that may be considered as hybrid ones, since it combines those output data, which can be provided by both ALS, and MLS Lidars.

The *automated feature extraction* (AFE) methods are the derivatives of ALS / MLS / UAV-LS Lidar remote technique. AFE-procedures produce 3D city models mentioned above, that are positioned in three dimensions just because of the AFE-method implementation. Since a common three-dimensional urban model may be a subject of more, than one hundred applications in various industrial domains [24], the AFE-methodology itself can be hardly overvalued. Municipal management, urban emergency services, noise and other hazard mapping, visibility analysis city infrastructure inventory, population and energy demand estimation with building models are those key urban applications, in which 3D models obtained from LiDAR data through AFE procedures are in an evident growing marketing demand according to the obvious reasons. To meet this demand requirements an AFE-model should be of high accuracy [31], what in some cases implies *a hybrid data source*. The latter means either a "LiDAR + areal image" hybrid [32], or additional involvement of MLS / UAV-LS data processing procedures for detailed extractions of building façades [33].

The *main research purpose* of this text is to outline with the phased methodological flowchart our conceptual multifunctional approach to the fully automated extraction of urban features, and present the original contribution to relevant algorithmic solutions within the modeling pipeline, as well as represent the web- and cloud-based software elaborated for these intentions.

2. Previous Works Done due to Building Detection, Extraction, and 3D Reconstruction from LiDAR Data

Fully Automated Feature Extraction, building Point Cloud segmentation, rooftop modeling, and 3D reconstruction of buildings, all have been among the main topics of thematic discussions in the remote sensing community through the relevant papers and on forums of various scales especially for the latest decade [26, 32, 34-42].

Now, AFE is still a vitally crucial part of what is being done and what researchers and other professionals are attempting to do better within the LiDAR surveying / processing domain. How has it further been progressed with its technique recently? We may consider as a key issue for efficient AFE-results a provision of a bridge between MLS / UAV-LS lidars, from one side, and ALS lidar, from another, one and vice-versa. Without any further explanations just in this paper section, we may only express a somewhat trivial idea, according to which *the composite models* of urban features extracted may be considered as the most effective ones [43].

2.1. Overall AFE issues

Because of ALS / MLS / UAV-LS joint surveying methods the automated feature extraction as a generating procedure for 3D urban models has become an evident alternative to the urban photogrammetry. It is a well-known fact, that besides various direct processing of aerial images, the Urban Remote Sensing (URS) (e.g., multispectral, hyperspectral ones [44]) traditionally provides the 3D building model generation from airborne-mobile-drone photogrammetric point clouds, but the lidar surveying / processing approach deals with similar dataset structures. Moreover, the novel sensor technology with its lower cost in comparison with previous hardware has expedited Lidar involvement in urban studies. Significant pros for such solution may be that fact, according to which ALS / MLS / UAV-LS sensors can deliver point datasets with densities of huge range (from one up to several thousand points per sq. meter). Even with the lower edge of this density range, it is feasible to detect urban structures, their approximate boundaries, and other various man-made features. Those models can be generated, which correctly resemble both wall, and roof structures. Many relevant methods for ALS / MLS / UAV-LS surveyed data processing have been proposed due to building extraction, detection, and 3D reconstruction [45-54].

Once we already commonly classified the automated feature extraction approaches on the base of an input data source [1]. The first approach means processing the high-resolution airborne imageries with additional including of *digital elevation models* (DEM) into an AFE-pipeline [7, 55]. Although some significant results have been obtained, the "only aerial imagery" approach may be considered as that one, which does not perform well enough in the densely built-up urban areas, primarily because of shadows, landscape gaps, and unsatisfactory contrasts in various urban configurations. According to this, the AFE procedures based exclusively on the first approach may not be fully reliable for the robust practical usage [33, 56]. The second approach straightforwardly employs LiDAR data and produces improved AFE-results, if compared to the imagery-only methods [31, 35, 37, 56]. What is more, this second approach implies an employment of very different techniques for processing ALS point clouds [57-59]. Methods applied within the third approach combine in a common case both aerial imageries, and all kinds of LIDAR data (ALS / MLS / UAV-LS) so that to employ the complementary information from all data sources [33, 60].

The AFE complete algorithmic content implies the ground and vegetation detection, while the man-made feature AFE-technique has to use either single-, or multi-return ALS / MSL / UAV-LS range and intensity information with application of the various thematic algorithms, e.g., as: neural networks [61]; *RANSAC* (the *RANdom SAmple Consensus* algorithm) approach for extraction of feature plains [62] with its key modifications [63, 64], that have been successfully employed by the Polygonal Surface Reconstruction method (the *PolyFit*) for feature reconstruction [65]; 3D Standard / Randomized Hough Transform (SHT / RHT) methodology that generally consists of three main steps: building points' detection, detection of building planes, and these planes' refinement [66-68]; implementation of knowledge-based entities [69]; the multi-scale approach [70].

Besides all algorithmic solutions mentioned above it may be reasonable to emphasize the hierarchical terrain recovery algorithm, that may robustly provide distinguishing between ground and non-ground points within an input point cloud by implementing the "adaptive and robust filtering" method [50]. Within this approach it is necessary to consider the whole range of input data to evaluate a DEM of high resolution for further feature extraction steps using this relevant hierarchical strategy. Thus, road linear features can be identified by classifying signal intensity and elevation data. Not only discrete building boxes, but also network features can be detected and extracted then. For example, man-made features of the road networks can be derived using a customized transformation technique, and then validated with road lines and topographic shapes obtained from an initial Lidar point cloud. Further one can obtain the attributes of road segments such as their widths, lengths, and slopes by computing some derivative information and enhancing existing metadata in this way. Other man-made features, firstly, building models are created with the higher level of accuracy, which would correspond to various Levels of Detail (LODs), beginning from LOD1 simplified box models and up to the models with internal partitions [71]. City Geography Markup Language (*CityGML*) is employed as a geoinformation data standard for presentation of the geometry and geographical data in digital models related to city buildings.

We have already presented *the High Polyhedral* models *(HPM)* of buildings and *the Low Polyhedral* ones *(LPM)* [1]. These two categories not only are the components of the authors' Lidar data processing methodology but also they are mentioned in the surveying section of this text only because HPM / LPM definitions reflect two significant mainstreams in the existing automated feature extraction. Obviously, these two dominant trends can be named with other titles by different authors.

Mostly a literature survey already completed above concerns exactly the HPM issues. The latter imply the generation of building models consisting of numerous polyhedrons, and because of this the relevant modeled entities can be accepted as "heavy ones" – *the heavyweight (HW) models*, which are produced by *the High Polyhedral Modeling approach*. It means, an HPM-building model may be generated from up to more, than one hundred thousand of Lidar points. It may be reasonable to state that the HPM-procedures are primarily based on the *Lidar point classification* that one, which is not directly associated with clustering, while the LPM-operations – *on the Lidar point cloud segmentation* through *clustering.*

The common work-flow of the HPM building model generation can be outlined as follows on the base of those literature sources that we have already referred to.

At its *first stage*, the building footprints (building base boundaries) are detected by segmenting DEM data obtained from LiDAR for two general classes: *ground* class and *non-ground* ones. The bare ground as a grid is delineated upon this step. A well-known, so called "sequential linking technique" is often suggested to reconstruct building footprints into regular polygons. These polygons then are improved so that to reach the cartographical standards [52, 72].

The so-called *prismatic models* are generated for those urban structures, which roofs are flat, and *polyhedral models* are created for those structures, which roofs are non-flat, at the *second stage.* At last, at the *third stage*, the vertical wall rectification operations should be applied, if there are sufficient MSL / UAV-LS or other correcting data in a relevant geodatabase for processing of this *area-of-interest* (AOI).

These three introduced stages may overlap almost any LiDAR data processing workflow. Most urban attributes of these building models are obtained from ASL / MSL / UAV-LS data. All corresponding HPM AFE-algorithms, that conclude the three stages workflow referred to above, should be tested using several geodatabases of varying earth surface type, vegetation coverage type, urban area type and LiDAR point density. Afterwards, normally the most effective algorithm should be chosen.

If we complete the general summary even for several overviewed HPM AFE-algorithmic results, this summary may demonstrate that in many urban territories the derivative DEMs accumulate most topographic details and remove non-ground features reliably enough. The transportation infrastructural network features are also depicted mainly satisfactorily even within densely built-up city districts. The extracted building footprints demonstrate to have enough positioning accuracy. Their estimated values may be equal to the accuracy obtained from data surveyed in field monitoring, while this traditional

surveying technique in many cases is a routine procedure of Lidar processed result accuracy evaluation [73, 74].

2.2. Detection, Segmentation, and Reconstruction of Building Roofs

The relevant modeling software tools can provide by a Point Cloud segmentation and clustering procedures of building detection and extraction the models of low-rise buildings preferably through rural areas and suburbs [1]. Simulating procedures stay within the Low Polyhedral Modeling approach, which is based on procedures of planar segmentation of Lidar point clouds rather, than on their classification (the case of HPM). The LPM building models produced are composed of not many polyhedral facets, and the number of points intended for a single model generation is limited approximately by a range from five and up to thirty thousand points maximum. Thus, the low polyhedral models can be considered as *the lightweight (LW) ones*. Overall low polyhedral modeling frameworks adapted to our LPM methodological approach proceed from the series of seminal papers in roof segmentation and reconstruction, therefore we have named this algorithmic technique as the *SAS*-methodology (the title has been abbreviated according to the authors of the initial approach) [35, 37, 75-77].

Methodologically we can reasonably define HPM as the automated extraction of *a whole building*, while LPM – the automated extraction of *this building roof.* A *segmentation* procedure of roof plains may be a key one within a corresponding AFE-pipeline titled for this section of our paper. This data-driven procedure was initially adapted for Lidar data from imagery processing [78]. Segmentation normally starts with applying *clustering methods* to Lidar point clouds [37, 76, 77].

The automated extraction of a whole building can be normally fulfilled by three similar sub-procedures outlined above for roofs, i.e., *building detection*, *building segmentation*, and *building reconstruction* [50, 59, 70, 79]. Although, contrary to roof extraction, all three sub-procedures, which are related to a whole building, may not be evidently less distinguishable. The case is a completely automated process of a whole building extraction may not yet be reliable enough from a practical point of view, because of the great complexity of actual urban environment with tremendous variety of its configurations. Thus, a whole building fully automated processing may need to pass a longer distance to provide wider usage of available supplementary data sources, for instance, city ground plans or municipal architecture schemes, so that to significantly enhance an ultimate processed result.

Somewhat more simplified methods, which provide roof extraction as equal to roof detection, are based on a *Digital Surface Model (DSM).* This model contrary to a DEM includes not only the ground, but the discrete features also. According to existing references, the DSM is calculated using an imagery and feature pyramids [80]. The finalized surface is refined then on the base of local adaptive regularizations. The roof detection step is grounded on the fact that a roof should be higher, than the neighboring ground – the topographic surface. This is normally estimated applying tools of the mathematical morphology to this DSM. The sliding window size technique involves the input information about the maximum roof size in its existing geographical extent.

This "only DSM involved" method has been further specified, when the building roofs are segmented depending on their estimated complexity, and in the same way finally reconstructed [81]. Usually, two types of parametric models are used for simple building roofs in those cases, when a building possesses either a flat, or a symmetrically sloped roof [50, 82]. Within other variants prismatic models are applied for complex separate roof structures or to connected building roof sets.

Two general classes of the roof extraction approaches are either the *data-driven technique* (e.g., *SaS*-methodology already mentioned above, and this technique also known as *a generic of polyhedral technique*), or the *model-driven one* (also known as *a parametric technique*). The latter implies some assumptions about topological and geometrical properties of a whole building model, generally, and due to a roof model, particularly. Two methodologies can contrast one to another in a categorical perspective: the data-driven method can be accepted as the *geometrical approach* (due to creating the roof geometry from the points of a given cloud), and the *topological one*. It is necessary to emphasize, that there is no a clear boundary between these two approaches [83]. Some researchers report the Hough transform technique within the model-driven segmentation methods [37], while other scientists recall it as one from the key data driven approaches together with region growing and *RANSAC* [66]. By the way, in the opposite case some fully automated approach has been clearly defined as a model-driven one, which applied for the 3D model reconstruction with prototypical roof templates (*CityGML LOD2*) [84].

The invariant moment technique has been applied for generation of the roof template library according to various building classes [46]. It is a quite known fact, that the model-driven approach may fail, when the inhomogeneity of feature distribution within a point cloud leads to biased parameters. Therefore, extracted models of complicated, not ordinary building roofs are produced by using data-driven algorithms. These algorithms are normally based on segmented intersecting planes and operate with triangulated point clouds [35-38, 62-68, 85].

It is a commonly known fact for the data driven approach, that most critical errors occur upon the determination of a total building roof outline, when trees are placed near a building box [62, 64, 66-68]. To avoid this issue various algorithmic approaches have been modified independently based on the detection and outlining of planar facets, e.g. [46]. A facet plane is normally determined by the point clustering procedure. A roof scheme is outlined by a connected component analysis. A key related assumption is that all the geometric model boundaries for roof segments are either parallel, or perpendicular to the main building disposition.

Thus, it is necessary to emphasize once more, that it may be not reasonable at all to distinguish whole building modeling from its roof reconstruction, while only ALS data are involved. It can be the same or, at least, very similar procedure, if only façades are not generated from MSL / UAV-LS data sources. Also, this procedure may be both within the HPM, and the LPM frameworks. In the mentioned context various researches suggested a boundary-based building / its roof extraction and corresponding TIN-based modeling and reconstruction [50, 86]. The buildings and their roofs

are reconstructed within this approach by triangulating each point cluster of identified facet candidates and clustering those fragmentary triangles into small patches, concluding piecewise planar fragments. Finally, the reciprocal intersections of the summarized planar facets are employed for extraction of building corners and for definitions of corresponding extracted feature orientations. A quite resembling technique have been used in our high polyhedral modeling for the building extraction [1].

It may sound reasonable to conclude this literature review by mentioning again, slightly more in details, the Hough transform and *RANSAC* algorithms and making references to so-called "global solutions to building extraction and reconstruction" [87]. Most earlier reports of the Hough transform (HT) applications mainly concerned 2D mapping of point clouds, until the "extending generalized HT" was proposed that provided detection of 3D features in a point cloud [88]. Standard and Randomized Hough Transform methods are ones among the most popular techniques of plane detection [68], and it can be employed for the determination of more, or less precise roof plane parameters – the triplets selected are accepted as possible roof planes [89]. Comparison of one of the Hough methods – RHT with RANSAC demonstrates a significant advantage of the RHT in the processing accuracy versus computing time tradeoff [68].

The classic RANSAC (FB81 according to [65]), as it was already mentioned above extracts primitives from point datasets [62]. The high-quality geometric instances extracted are a subject for further polygonal surface reconstruction of various features with 3D geometry. Nonetheless there are still no proved evidence that either Hough, or RANSAC optimizations have been successfully applied for modeling urban areas [68], but even optimized RANSAC methods may lead to the numerous false plains [37]. Probably it would be right to affirm that RANSAC is that approach, which has faced almost the greatest number of its optimizing solutions among other point cloud detecting / segmenting methods. Even early optimizations of this algorithms provided the removal of up to a half the outliers resulted from a given data set [90]. Probably the best overview of this algorithm improvements together with one more original optimization has been given in [63].

Despite all optimizations followed by rising algorithmic efficiencies, both HT, and RANSAC still hardly could be applied to more, or less significant urbanized areas, e.g. to the city district scope. To meet such challenge among number of other purposes sophisticated methods have been elaborated within the paradigm of "global solutions to building segmentation and reconstruction" [87, 91]. Roof segmentation and reconstruction have been consequently developed within the frameworks of this methodology. Both these two stages should be recognized as a solution of the appropriate energy functions' minimization problem. Firstly, after an initial segmentation completed, every Lidar point has been accurately assigned to its optimal plane by minimization of a global energy function [87]. It was named "a global solution", because the method could define multiple roof plains concurrently. After it, on the base of the segmented in this way roof planes another "global solution" has been developed and applied already for the roof reconstruction stage. The building box has been partitioned into volumetric cells, what allows to construct the roofs of the sustainable topology and the correct geometry [91].

2.3. Generalizing LiDAR-Based Solutions in 3D Building Modelling

We have finalized with building reconstruction reviewing AFE steps in the previous subsection of the text, while shortly mentioning in subsection 2.1 processing integrated data sources. According to number of references, reconstruction of buildings can be accepted as a complicated procedure of the digital presentation generation for those physical urban features, that can be extracted from Point Clouds and transformed into effectively structured 3D models with various attributes, while the quality of these models should be evaluated further [58, 86, 92, 93]. Generalizing or *hybrid* solutions in the mentioned extent mean not only the data fusion involvement [94, 95], but also using this basis for *footprint extraction* in the automated mode and its *boundary regularization*, since both operations are the basis for a roof reconstruction, and even for wall raising, when MSL data are not available.

Four following groups of authors almost independently developed some interesting *hybrid* approach lied within the following workflow of five major algorithmic steps [37, 38, 96-98]: A density-based algorithm of clustering for the individual building segmentation, which begins with footprint delineation; A rectified boundary-tracing algorithm is applied; A hybrid method for footprint planar patches segmentation developed; these methods select so-called "seed points" in the parametric space and generate the regions in usual (spatial) space; A boundary regularization approach that examines point outliers; Finally, reconstructing procedures are accomplished due to the topological and geometrical information about building roofs and using the intersections of footprint planar patches.

This hybrid approach proceeds from that fact, according to which there are two main classes of methods applied to trace building footprint boundaries: *raster-based* method and *vector-based* one. By the raster-based technique, the point clouds are usually transformed into a regular grid, after it the image processing methods are employed to indicate, trace, delineate, and regularize the boundary and footprint edges [99, 100]. Upon the vector-based approach, that was developed quite long before, a simple string delimits the exterior boundary, while other parameters, representing the inner boundaries, are extracted from raw LiDAR data [101].

3. Original Methodological Approach

3.1. Phased Methodological Flowchart

While introducing the methodological basis of our complete R&D cycle (from raw ALS data processing to solutions of use cases with building models), we stand on that broadly accepted point of view, according to which LiDAR remote sensing can be defined as the research and technological approach primarily used to obtain for further processing the information about the topographic surface, vegetation, and various features of the human infrastructure at a certain distance from an observer's point (buildings, bridges, roads, powerlines, etc.) [25-27, 31].

Due to the options and the necessities to cover large areas in the cities the ALS surveys obtain data from very different urban configurations, that can be distinguished, initially, by building

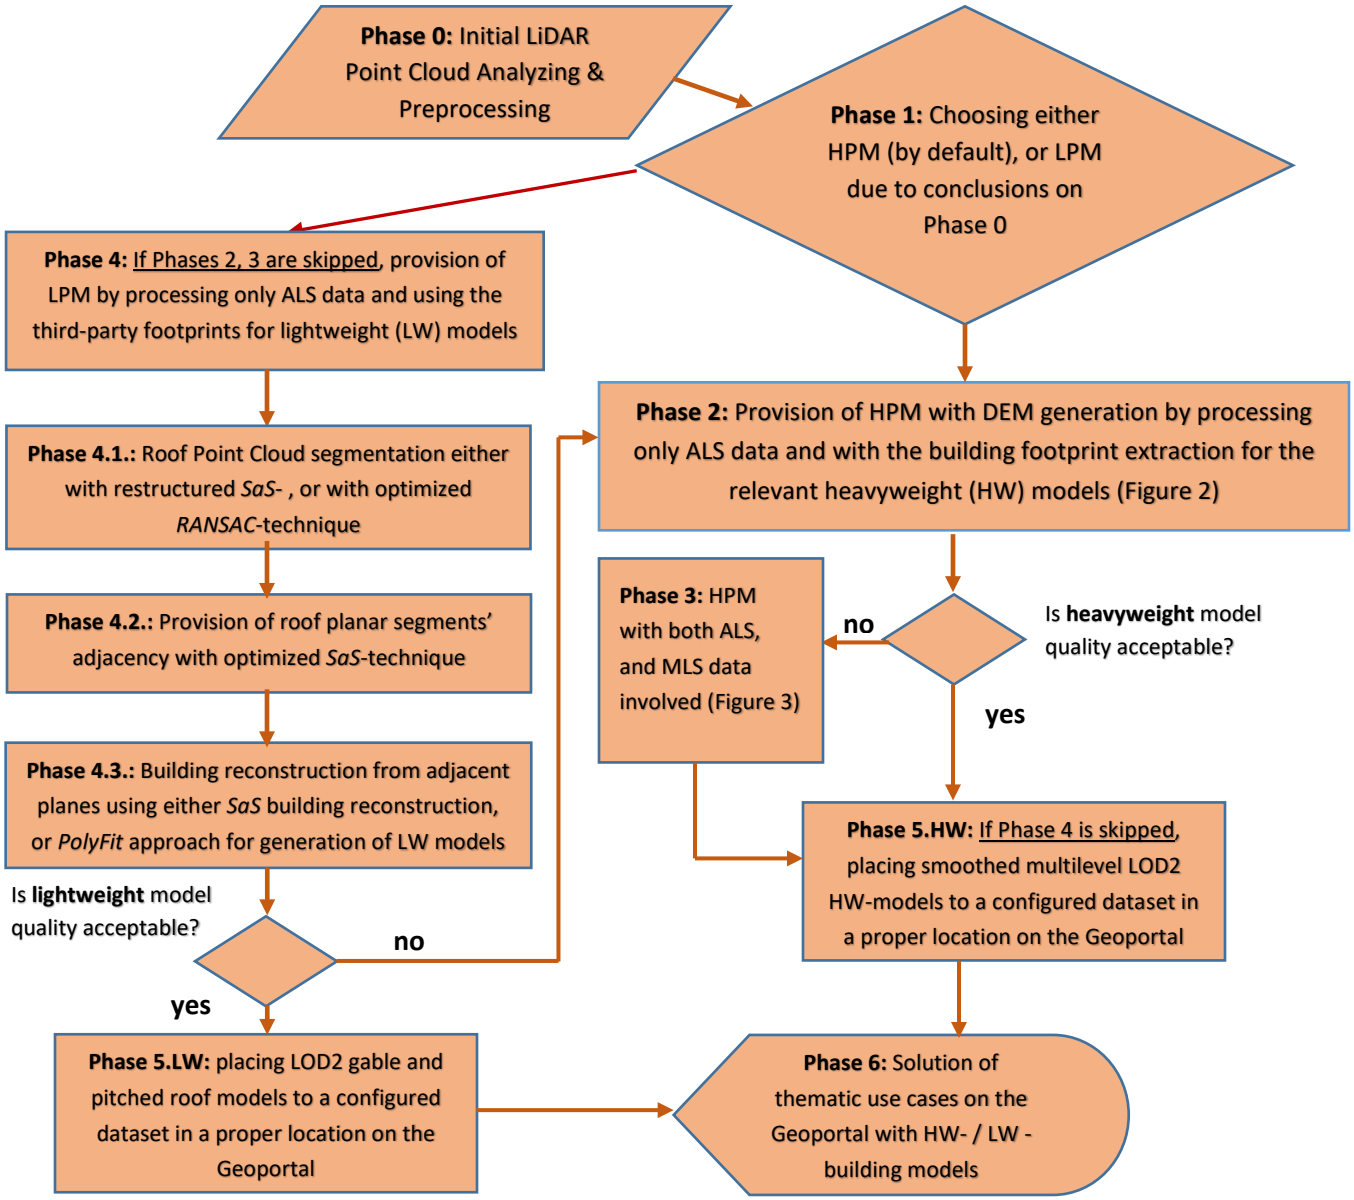

Figure 1: Phased flowchart of the overall methodological approach

geometries and by densities of sets of buildings. Probably two key types of the mentioned urban configurations are *high-rise buildings* of city downtowns and other central districts, on the one hand, and *low-rise buildings* of city suburbs / outskirts and neighboring rural areas, on the other hand. Two methodologically different AFE-techniques outlined in the previous chapter of literature review – the High Polyhedral Modeling of buildings and the Low Polyhedral Modeling – should be applied to these two urban configuration types exclusively – HPM to high-rise building sets, and LPM – to low-rise ones. We can emphasize as a strong point of our overall R&D approach just this joint employment of these two technically different methods within the united building detection, extraction, and modeling methodology, what is resulted further in the relevant software elaboration with two different tools – *Building Extraction (BE*, for a case of HPM), and *Building Extraction Rural Area* (*BERA*, for a case of LPM). Some common features of both approaches and relevant software tools have been already presented in some of our previous publications, although we have not made yet an emphasis on an allocation of both HPM, and LPM within a unified workflow [1, 4, 43, 102]. Since in many cases Airborne LiDAR survey relies on existing territorial regularities of urban areas, it is often provided consequently – from city central parts to outskirts. According to this, if presenting our general approach as *a phased methodological flowchart*, it would be reasonable to accept the HPM as *Previous AFE-Phase* and the LPM - as *Subsequent AFE-Phase* (Figure 1):

It is shown in Figure 1, that an activity diagram combines both HPM, and LPM issues, while an input is a raw LiDAR Point Cloud (*Phase 0). Analyzing & Preprocessing* phase implies evaluating point densities, survey induced and filtering induced errors, as well as checking a for a point cloud proper georeferencing. Two key

factors, that determine a solution to be made on *Phase 1* (either HPM, or LPM chosen) are the territories of specific urban configurations, that are overlapped by .LAS files, and if the third-party (*OpenStreetMap, Microsoft*, etc.) footprints are available for a given area.

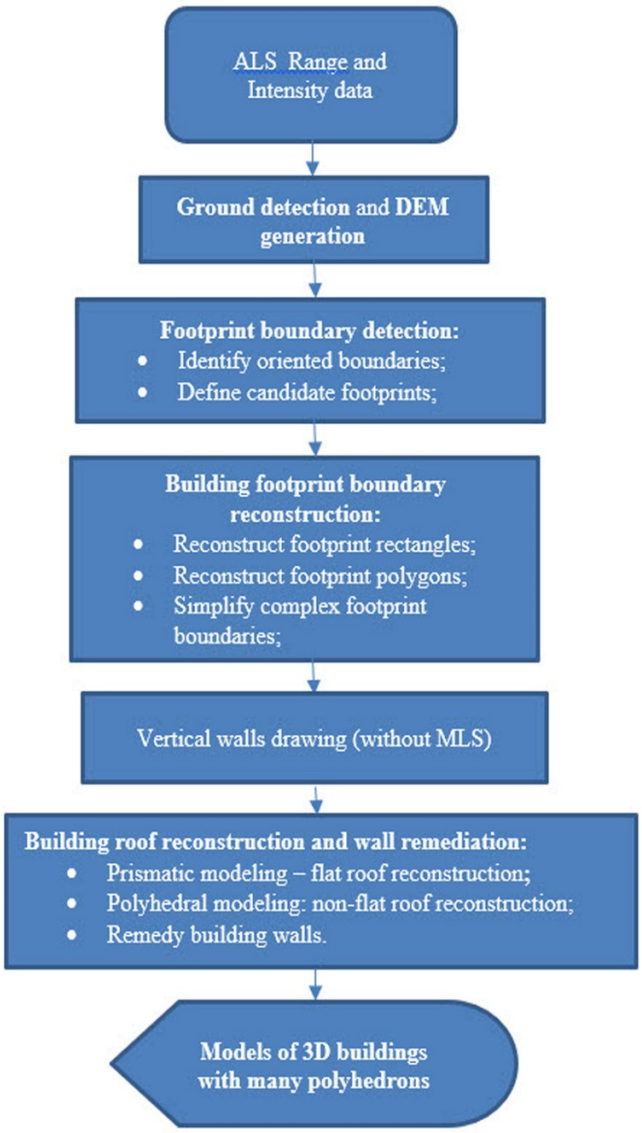
Phase 2 implies a provision of the phased flowchart HPM-branch by processing only ALS data with extraction of the original footprints and with generation of HW-building models, which surfaces consist of numerous polyhedral facets. The output model quality is estimated by several algorithmic evaluating parameters, and in the web-software UI (a user interface of the *Detailed Viewer* tool) by comparison of building surfaces' allocation in 3D space with their neighboring Lidar points. A procedure of such evaluation is illustrated further in this text. If model quality is accepted as either good, or satisfactory, it may be necessary to go directly to *Phase 5.HW*, since both *Phase 3* (involvement of MSL data in addition to ALS ones), and *Phase 4* (a whole LPM-branch) have to be skipped in this phased flowchart scenario. *Phase 3* is accomplished, if MLS data employment can substantially contribute to the quality of HPM-building models with not only precise reconstruction of their facades, but also with increasing of overall sustainability of the high polyhedral model of a building by adding supplementary facets of its minor surfaces. *Phase 5.HW* is also a further target, if acceptable model quality is obtained on *Phase 3*, and, in general, if the most of HW-models are of acceptable quality. Then on *Phase 5.HW* these models are place to a configured dataset to a proper location on our Geoportal. A digital elevation model is generated within the HPM branch only.

Phase 4 provides the LPM-workflow, which starts from *Phase 4.1*, within which surface normal determination as an initial step of roof surface reconstruction within the *SaS*-approach, is accomplished. It is followed by a roof point cloud segmentation either in the updated *SaS*-methodological frameworks, or by a segmentation provided with the optimized *RANSAC*-technique. Both these choices are described further in the text. *Phase 4.2* represents preliminary solutions for the LPM-building reconstruction stage with our original contribution to building a matrix of roof planar segment adjacency. *Phase 4.3* finalizes the building reconstruction stage by combining a building from geometric primitives extracted from a point cloud on the previous stages. If the most of LW-models of buildings with gable and pitched roofs are of acceptable quality, upon *Phase 5.LW* they are placed to a configured dataset of models to the Geoportal (it is defined further in this text). If the quality of the LPM output results is not acceptable, the HPM-pipeline is attempted as an alternative, and a repeated workflow starts again from *Phase 2.* The LPM branch of our overall methodological approach does not support the DEM generation functionality.

An accomplishment of the overall approach is normally finalized on *Stage 6* by solutions with HW- / LW- models of the thematic use cases on the Geoportal, what is briefly illustrated further in our paper.

Optimal LiDAR point density values that were empirically defined for processing techniques involved on *Phases 2* and *4* are between 5 and 140 ALS points per sq. m. If MSL / UAV-LS data are added to our HPM AFE-pipeline, these data are thinned out to acceptable values by sophisticated thinning algorithms, although *Phase 3* deals with up to several hundred of MSL points per sq. m.

A sketch of our core algorithmic workflow of High Polyhedral Modeling is depicted in two flowcharts below (Figures 2, 3). It has been elaborated within the frameworks of the integrated *Building Extraction (BE) / Change Detection (CD) / Digital Elevation Model-Generation (DEM-G)* pipeline of ALS / MLS / UAV-LS data processing. The complete algorithmic workflow depicted on the first flowchart (Figure 2) intends to extract both topographic surface, and urban features from ALS data arrays only, what corresponds to *Phase 2* of the overall methodological flowchart (Figure 1).



3.2. High Polyhedral Modeling for Building Extraction – Heavyweight Models

Thus, a flowchart depicted in Figure 2 does explain the thematic content of the *Phase 2* block of the phased

methodological diagram (Figure 1). Detailed consideration of this phase shows that initially the necessary preprocessing is accomplished within the first algorithmic block (*ALS Range…*). Then all Lidar points are separated for those, that belong to ground, and for other ones, that belong to non-ground features (block *Ground detection…*).

Delineation of the original building footprints (as a valuable alternative to the third-party ones) is a crucially important component of the HPM pipeline (*Phases 1-3, 5* Figure 1), and it is completed within the third block of the HPM ALS algorithmic flowchart (*Footprint boundary detection*) – Figure 2. The footprints extracted are a self-sufficient entity for a whole HPM-ALS pipeline of *Phase 2*, and the following block (*Building footprint boundary reconstruction*) predefines modeling of a whole building, but the preliminary to this reconstruction procedures of footprint boundary optimization and more precise allocation have to be accomplished according to three sub-blocks of this block indicated by the bulleted records (*Reconstruct footprint rectangles, Reconstruct footprint polygons, Simplify complex footprint boundaries*). Thus, through processing upon this fourth algorithmic block building footprints are determined as quadrangles, rectangles, or routine polygons. Then "pretended" walls are arisen from the defined boundaries of footprints (*Vertical walls…*block).

With the next algorithmic block (*Building roof reconstruction….*) the rooftops of buildings may be raised from these delineated boundaries and then corrected by the data of the same ALS point cloud used upon all five previous blocks of this flowchart (Figure 2). A building which has a flat roof is modeled in prismatic geometries (a bulleted record for a subblock *Prismatic modeling – flat roof reconstruction*). If a building possesses some complicated shape of its rooftop, it is modeled as a polyhedron (a bulleted record for a subblock *Polyhedral modeling: non-flat roof reconstruction*). As it was already mentioned above "HPM" means that initially reconstructed building facets consist of many polyhedrons and represent HW-models contrary to that solution ("LPM"), while LW-models can consist of few polygons only. According to the understandable reasons, HW-models are normally constructed and visualized as comparably heavier entities (from 20 to 150 thousand of points are processed per model). Thus, mandatory smoothing and noise removing should be evidently provided. For these aims our original contribution to a Delaunay refinement algorithm [100] has been employed. The corresponding "covering Delaunay TIN" is involved to algorithmic sub-blocks *Polyhedral modeling: non-flat roof reconstruction*, then – to a subblock *Remedy building walls.*

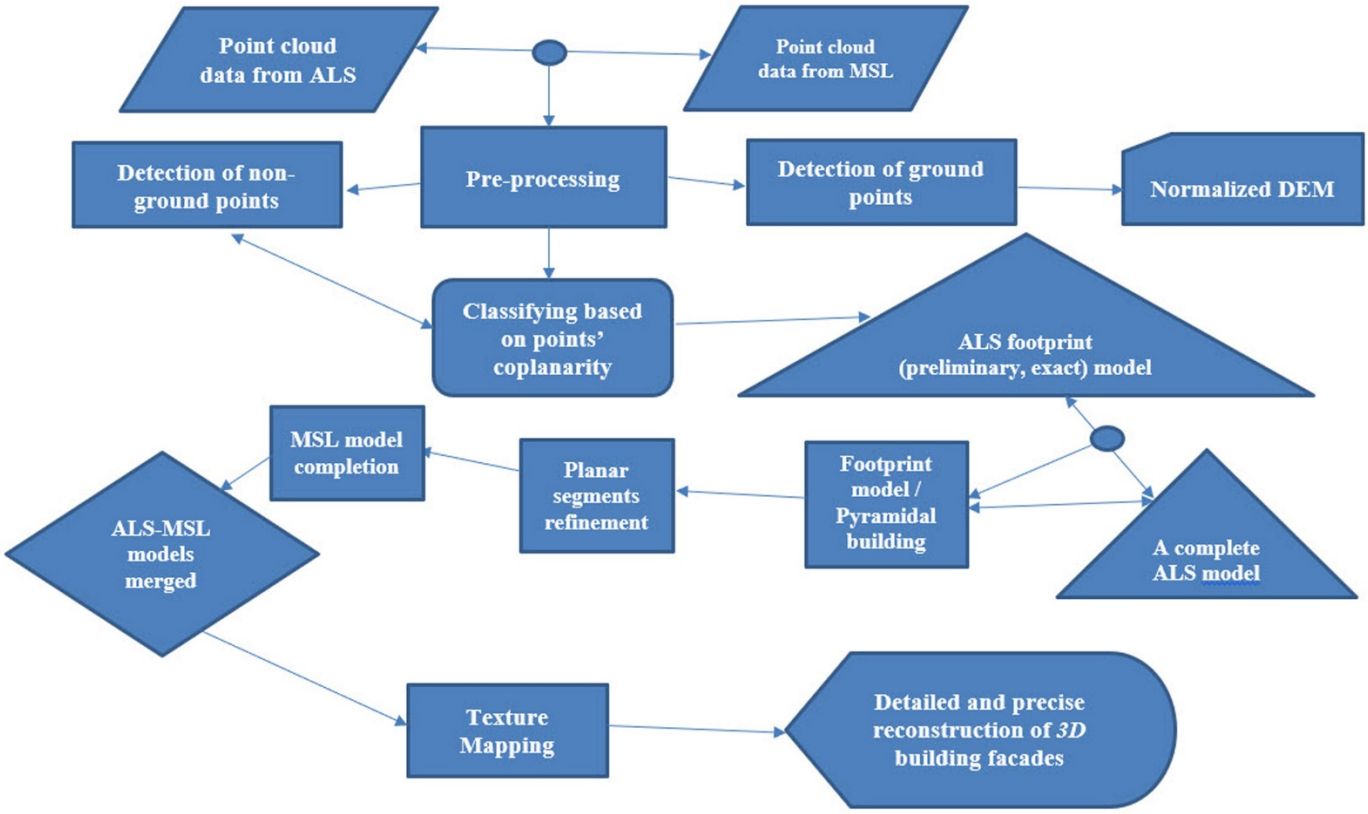
In the presented way we have just introduced the thematic content of *Phase 2*, which is in our methodological flowchart (Figure 1). As it has been emphasized above, if the output model quality (the finalized algorithmic block *Models of 3D buildings with many polyhedrons*) for the results based on the ALS data only is not acceptable *Phase 3* of the phased methodological diagram should be involved.

The initial input data for the HPM ALS / MLS / UAV-LS algorithm, which is core content of *Phase 3*, and which flowchart is presented in Figure 3, are as follows:

- The points that have been received by ALS (**x**, **y**, **z** coordinates and RGB color attributes) Lidar survey. It is geoprocessed as a set of 3D point layers;
- The points that have been received by either MSL, or by UAV-LS scanning, or by both (**x**, **y**, **z** coordinates and RGB color attributes). It is also geoprocessed as a set of 3D points layers;
- The regular earth surface (a grid layer - a DEM), that has been generated upon the first algorithmic steps with existing gaps within those locations, where ground data are absent, is also accepted as an initial input for further processing;
- The smoothed regular earth surface (a refined grid layer) as a DEM with gaps removed by chosen algorithmic procedures, therefore this surface is a continuous one.

On the base of points' distance to a smoothed DEM the HPM ALS / MLS algorithm of *Phase 3* (Figure 3) separates raw Lidar points into two categories, as it is done in those procedures completed by the HPM ALS algorithm of *Phase 2* (Figure 2). The first one contains the ground points that form "a ground level of this building footprint". The second category contains non-ground points that are clustered with this building footprint. The relevant point cluster normally represents a single building or a tree. The upper blocks of the ALS / MLS algorithmic flowchart display all preliminary pre-processing / classifying steps that are provided (*Detection of non-ground* and *ground points*; *Pre-processing; Classifying based on points' coplanarity*; *Delineation of preliminary footprints*) (Figure 3). On further classifying steps any Lidar point is assigned to be either a building point, or a non-building one. According to this binary labeling the primary footprint extraction is implemented as a technique of obtaining building footprint polygons from ALS data exclusively, thus this procedure is completely the same in both algorithmic workflows (Figures 2 and 3). This operation is normally performed in two steps: generating *preliminary footprints* from *existing grid gaps* and extracting the *exact finalized footprints* from these preliminary ones. The preliminary footprints are extracted as *No Data* holes in a grid. It is reasonable to examine this extraction slightly more in details in comparison with other components of both algorithmic workflows. It is the content of the flowchart block *ALS footprint (preliminary, exact) model* (Figure 1). The following modeling-extracting steps are performed for preliminary footprints:

1) An initial grid is divided into the blocks of a size not more than 4'000'000 cells. Neighboring blocks possess an intersecting part of the size, that is specified by the *Max building size* parameter. After this step each building block is processed detachedly;
2) Each cell either is marked as a ground (where the surface grid contains some value), or not classified at all (where a grid has no data);
3) Thus, assuming *expandCount = (params-> MaxCorridorSize / (2 * cellSize) + 1*; We expand the ground class on *expandCount* units in the urban metrics. Afterwards we expand *No Data* class on *expandCount***;** This step separates single long buildings in their ribbon sets connected by urban corridors;
4) Assuming *expandCount = params-> MaxCorniceSize / cellSize + 1*, we expand *No Data* class on *expandCount* to join semi-attached buildings;



5) Consequently, we find gaps in a grid through 1)-4) and each of these gaps retrieves its own index. In this way, only those holes that are completely isolated, i.e. surrounded by the bare ground, are expected to be found;
6) Afterwards, we should check each of gaps and store only those ones, that possess an area larger, than a certain threshold value specified in the preferences;

Thus, we obtain the areal boundary for each gap considered to be a preliminary footprint. The *exact footprints* are generated proceeding from the preliminary ones and from some supplementary information of this point cloud. For every "exact footprint" several following steps are provided.

1) All the points delineated by a geographical extent of some boundary (its size is the algorithmic parameter, which is equal to *MaxCorniceSize*) are selected for processing;
2) All Lidar points, that are above the ground surface, but lower than *2 m* above are classified as the *ground points*;
3) After this, through all points the triangulated network is being built. Within this network all edges, which possess at least one junction, that has been classified as the ground, should be deleted.
4) This triangulated network is divided for several connected segments by removing all the edges, that are longer than *MinDistanceBetweenBuildings.* All network segments that have an area more, than a minimal building footprint value (that is the algorithmic parameter), are assumed to be *the footprints* or *building parcels*;
5) The next algorithmic step is *filtering trees*. There are three possible customized options in this procedure:
a) Tree filtration is *turned off*. In such a case this step is skipped;
b) Applying *preliminary filtration*. The information about *trees* or *non/trees* is obtained from the classified source Lidar file;
c) Applying to a point cloud our own classifying technique.

Upon this fifth algorithmic step, the triangulated network is normally built through all points that are located inside those previously created footprints (preliminary ones). Then all vertical edges associated with this extracted from a point cloud entity are removed. The edge is supposed to be vertical, if its horizontal slope is more, than a certain threshold – a minimal angle, that is a parameter of the algorithm. After this procedure completed, the triangulated network is partitioned for several connected components. Then the points from components, which area is less than *MinBuildingPartArea*, are designated as non-building points, and are removed from the footprint entity.

6) At the next algorithmic step, a new triangulated network is built through the points that belong to building parcels only; moreover, those vertical edges, which 2D length is longer than *MinWallSize* (the key algorithmic parameter) should be removed. The jointed polyhedrons with their aggregated areas, which are more than minimal building parcel area, are accepted as *the footprints*.
7) The final step of the exact footprints extracting is expanding of their preliminary templates obtained through 1)-6). This step is necessary, since some building and infrastructural units, that are above the ground or above other constructive parts, are filtered out on the previous algorithmic step. To

expand a footprint template the iterative algorithm is applied. Upon every step of this algorithm those points, that have not been classified yet as a constructive building or the ground, are classified as *a building* in a case, when this point is nearer to a footprint, than some assigned threshold distance. Afterwards, all these points are added to a footprint, and the new expanded footprints are built as an external boundary, that crosses all points that were previously classified as building points.

After all *exact footprints* are extracted from the preliminary ones (footprint templates), each of them should be checked for intersection with a source preliminary footprint so that to avoid topology errors. All those ones that do no intersect have to be filtered out. At the end of the block *ALS footprint (preliminary*, *exact) model* all Lidar points, that are located inside the examined parcels, and that do intersect, should be marked as the *building points* (in this way avoiding an extraction of other footprints that may be located within the same area). Finally, we accept the exact footprints as some *planar parcels*. The algorithmic step of their refinement is completed at the next algorithmic block *A complete ALS model*. The procedure of the planar segment refinement is quite lengthy therefore it may be a subject of description in another text. Thus, summarizing all stated above, we should emphasize that a preliminary footprint is an entity, which is extrapolated through the ground points without filling corresponding gaps at perspective footprint locations. The exact footprints are built proceeding from preliminary ones and by providing outlined algorithmic steps.

Just as in the HPM ALS algorithmic pipeline of *Phase 2* (Figure 2) our update of a Delaunay refinement algorithm has been employed. The relevant "covering Delaunay TIN" creation is completed in the flowchart blocks of *Planar segment* refinement, *Footprint model / Pyramidal model*, *A complete ALS-model* (Figure 3). All algorithmic blocks mentioned above are provided for processing ALS data only and reconstructing only *HPM-building roofs* and some other supplementary constructive components.

The HPM AFE results of both *Phase 2*, and *Phase 3* obtained by the *Building Extraction* software tool is a set of building models, each of them, as a rule, consists of few façades. The textures may be placed on these façades. Each of these heavyweight models is stored by *.OBJ /.B3DM* ("Batched 3D Model") /*.KML* formats, but in the relevant software environment the main inner format is *.OBJ.* Each HW-model has its six mandatory components:

- *A footprint*. It represents a smoothed *2D* polygon, which allocates a building footprint;
- *A pyramidal model* that is *not draped*. This model consists of several horizontal polygons at different levels. From every layer a vertical building wall is dropped to the previous level. From the lowest level the walls are dropped to the ground level;
- *A draped pyramidal model*. This model is the previous one, but each of its polygons has *a texture*. ALS points are only used for creating textures due to quasi-horizontal polygons ("roofs"). As far as creating textures for vertical polygons ("walls") is concerned, preferably the MSL points should be applied to support a desirable level of details (*LOD*);
- *A complete model*. This model is generated either by using of the detailed TIN techniques on the Airborne Lidar points only (*A complete ALS model* block – Figure 3), or by combining ALS results with the wall segments reconstructed on the base of MSL data and obtaining a combined model (*ALS-MLS models merged*);
- *Texture Mapping:* draping textures on an ALS-MLS merged model;
- *Detailed and precise* reconstruction and visualization of the finalized model with 3D building façades.

The reconstructing operation for building façades is exposed by the *MLS model completion* block of the flowchart in Figure 3. The latter provides a necessary "noise clipping" procedure for building wall surfaces.Since if the distance threshold value, that means a metric length from a given Lidar point to an extracted façade, is either lower, or approximately equal to the points' density value, the reconstructed planar surface may be a set of outliers, e.g., small peaks. Exactly in this case a procedure of noise clipping should be provided.

As it has been aforementioned already, the ALS models, on the one hand, and the MLS models, on the other hand, are merged at a certain point of the flowchart in Figure 3, just after the *Planar segments refinement* and the *MSL model completion* blocks, and before the *Texture mapping* block. This block means the penultimate algorithmic step – texture draping on a merged model. In this way, for each modely component, every polygon in the pyramidal model, the textures are being built. All those Lidar points that are located near the texture extent can be found. These points are projected on the roof / façade plane, and the coloring of the texture pixel is initiated. All predeccor algorithmic blocks in the flowchart of are ended by the *Detailed 3D reconstruction of building façades* one. Finally, the results are being delivered into *.OBJ* and *.B3DM* formats, and a composite high polyhedral model can be displayed by the relevant visualizing software tools developed by the authors (Figure 4). It can be seen, that the HPM AFE results in numerous polygonal segments, which represent quite a rough surface, only while zoomed in. Even a model of numerous polyhedrons can be impressively displayed by our provided visualizing technique.

After completing the HPM-algorithmic workflow, a user obtains building models for display either in the *ElitCore* desktop application, or in the web-based *ELiT* (EOS LiDAR Tool) *Viewer* with three levels of detail (*LODs*): *LOD 0* represents a *model footprint* as its projection on the plane; *LOD 1* is a 3D object that exposes a building as a set of prisms - *a pyramidal model*;

LOD 2 displays smoothed multilevel models in minute details (Figure 5). We have expressed an idea in the introduction to this text, that the composite (ALS / MLS-UAV-LS) model of extracted features may be the most effective one, primarily, with respect to user' various applications in many industrial domains. Such a typically smoothed multilevel model of *LOD2*, a HW-model, may be like follows in the *ElitCore* desktop UI (a user interface) (Figure 5). Thus, despite visualizing rough building surfaces, if significantly zoomed in, while applying to the LiDAR data intentionally selected and refined by the ALS / MLS algorithmic workflow on *Phase 3* of the overall methodological flowchart (Figure 3).

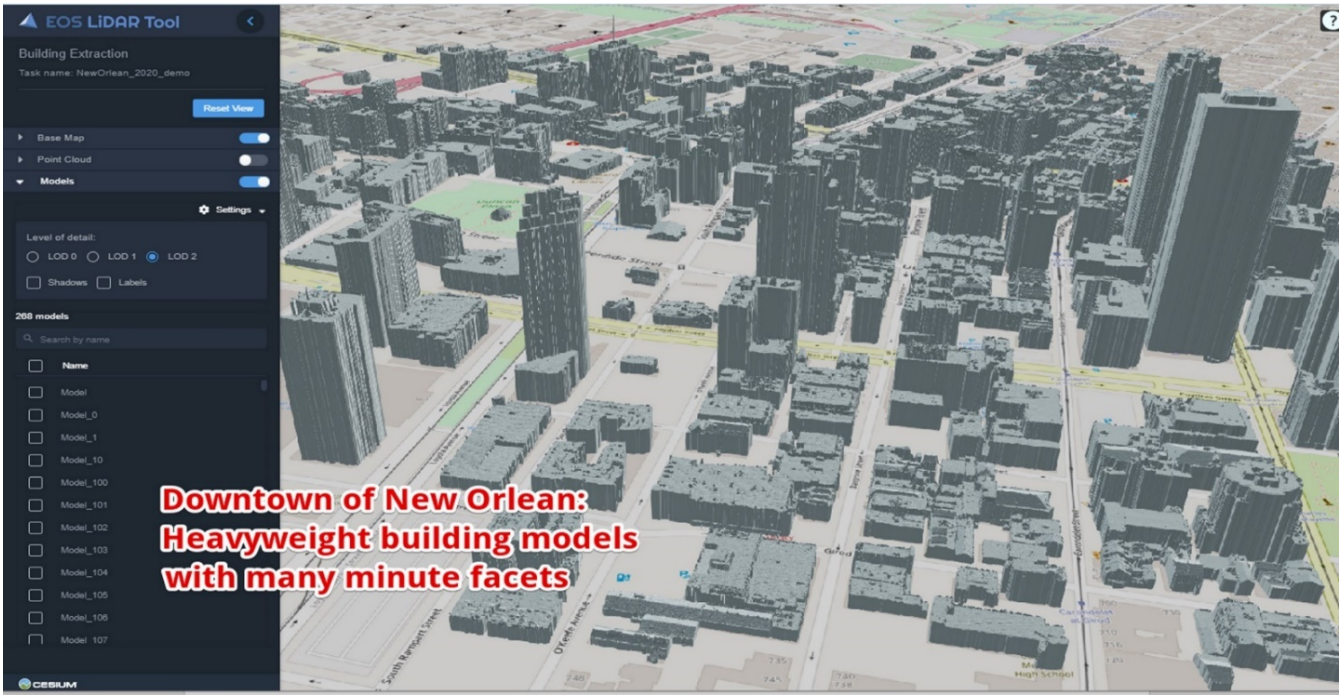


Figure 4: Results of the HPM ALS / MLS workflow displayed in the viewer of the web-based applications – building roofs of many polygonal segments. *The downtown of New Orlean, USA* (a dataset from the *EOS LIDAR Tool* landing page: https://eos.com/eos-lidar)

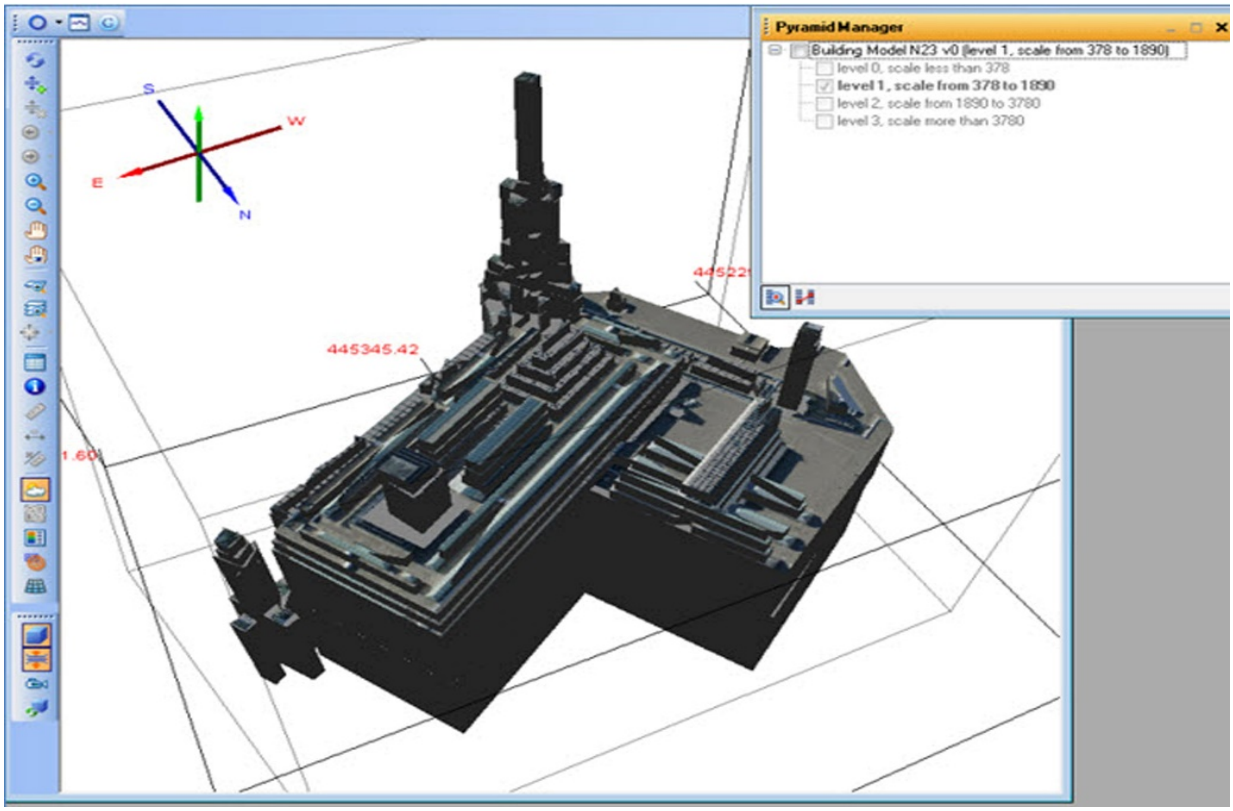

Figure 5: Model of one the historical buildings from the Ottawa downtown in the *ElitCore* desktop user interface

The presented methods of the HPM on *Phases 2, 3* is a completely original AFE-methodology elaborated by the authors. It has been implemented in *Building Extraction (BE)* (Figures 4, 5) and *Change Detection (CD)* (Figure 6) functionalities of our both desktop, and web-based applications.

3.3. Low Polyhedral Modeling for Building Extraction in Rural Areas – Lightweight Models

3.3.1. Common issues

Oppositely to the High Polyhedral Modeling technique our another AFE-approach is the Low Polyhedral Modeling method,

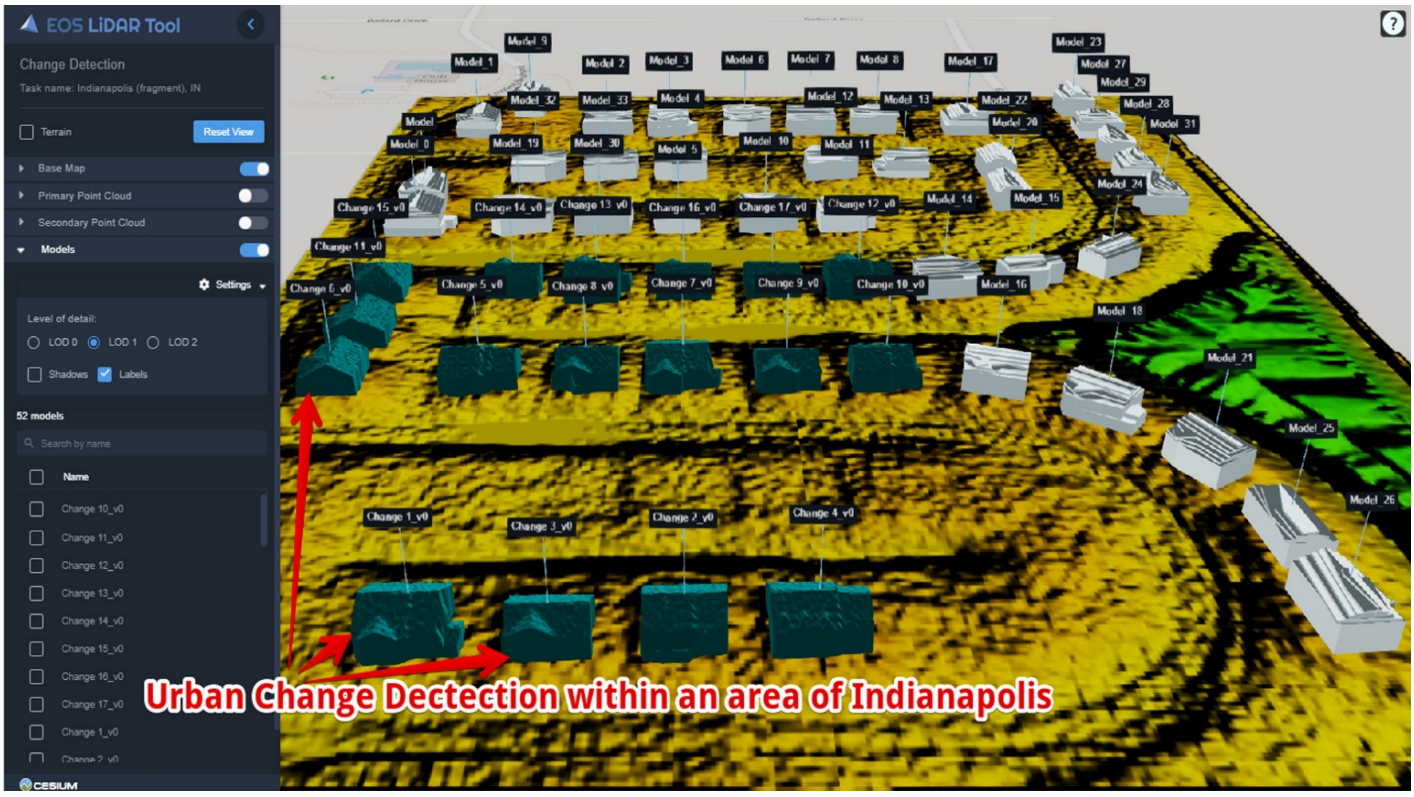

Figure 6: Results of the CD functionality application: new buildings (labeled as *Changes* in dark green color) as urban changes that appeared within one year's time. Models of both new, and old buildings (labeled as *Models* in light grey color) are placed on a DEM generated. *An area of Indianapolis, Indiana, USA* (a dataset from the *EOS LIDAR Tool* landing page: https://eos.com/eos-lidar)

On the finalizing building reconstruction stage theoretical basics of the *PolyFit* [65] have been effectively implemented in the applied solutions with web-software (*Phase 4.3*).

We have mentioned already, that initially the LPM is intended to extract low-rise buildings in either rural areas, or city suburbs. Nonetheless, it has been successfully applied to various urban configuration even within central parcels of the large city areas. Because of the segmenting / clustering procedures that drastically decrease a number of polyhedrons as constituents of a model extracted, such model is titled as "low polyhedral" one. We emphasized already, that these models are extracted, reconstructed, and visualized as the *LW-models* (approximately from 5 to 40 thousand of Lidar points processed per one entity). After completion these models are composed of only few polygonal planar segments. Models are reconstructed in this way, and each of them represents a lightweight modeled feature as a final solution.

Building reconstruction of low-rise constructive features is implemented as a finalizing procedure of building modeling (*Phase 4.3*). This algorithmic stage begins with the adjacency matrix of roof plains generation, that exposes the connectivity of the delineated planar segments. Our original contribution to the formation of the plane adjacency matrix is described in the one of the following subsections of this text.

Both roof interior, and exterior vertexes are determined. Topologically consistent and geometrically correct building models are obtained through implementation of the extended boundary regularization approach. The latter is based on multiple parallel and perpendicular line pairs, and just this approach expedites an achievement of the reliable building models. The model precision can be effectively tuned, despite it understandably still depends on the data precision. In any case the model precision may meet the strict customer requirements. The low polyhedral model implemented corresponds to *LOD 2* of the City GML standards [17, 19, 22]. The following visual presents the main content and some attribute information of this LPM algorithmic result in the interface of our cloud-based software (Figure 5). A number of acceptable models among all LW-models generated is a criterion of going either to *Phase 5.LW* with model output to the Geoportal, or *Phase 2* so that to repeat processing and modeling by shifting to the HPM branch (Figure 1).

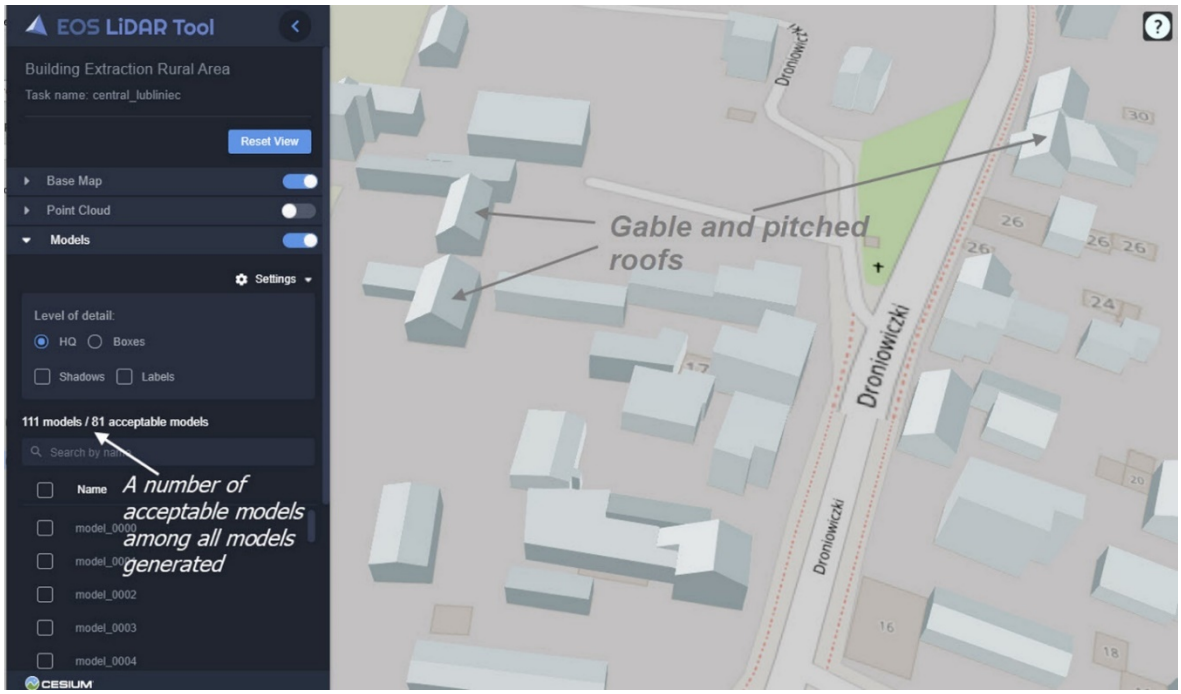

Figure 7: The LW-models of buildings with gable and pitched roofs (pointed to by grey arrows) in a small town. *The city of Lubliniec, Poland* (a dataset from the *EOS LIDAR Tool* landing page: https://eos.com/eos-lidar)

3.3.2. Enhancing SaS-segmentation by restructuring its pipeline

It is an initial content of *Phase 4.1* of the phased methodological flowchart (Figure 1).

2. To Assign unclassified points to the clusters. An addition of formerly unassigned points to a proper cluster might be a key procedure for various configurations of roof individual segment delineation. Some of these points might not be assigned to any cluster due to noise impact (a roof segment under a tree), or because of neighborhood nonplanarity on a seam between two or more roof slopes.

3. To Separate parallel planes inside each cluster. Surface normal vectors are being clustered initially. A clustered entity with the same normal vector is created. Thus, primarily a cluster is a set of planes, and a distribution of parallel planes into separate clusters inside this primary cluster takes place just on this step. The parameter ***D*** (from Item 1) is being computed for all points, and the latter are clustered. The output is a set of planes with the same normal vector, but on the different distance from the center of coordinates.

4. To Split coplanar clusters using the Voronoi neighborhood. A segmented plane may combine those roof segments, that are not connected spatially, but other segments are between them. Such coplanar planes are separated on this step. Commonly, these Items 5 and 6 correspond to the Separation of Parallel and Coplanar Planes step in [37].

5. To Remove small clusters (optionally – using the Voronoi neighborhood). Small area segments can be left after separation of parallel and coplanar clusters. These features should be eliminated as the noise and clustering errors.

6. To Remove the near-vertical clusters, because the modeling technique does not use them due to their unreliability.

It is reasonable to emphasize intentionally that the *Phase 4.1* initial content steps 1-6 can be completed only for a point cloud of some robust density, that may lie within the earlier mentioned range of 5-140 ALS points *per sq. m.*

3.3.3. Providing RANSAC enhancements

It is another content of *Phase 4.1*, and the optimized *RANSAC*-technique can be employed for a roof plane segmentation as an alternative to the *SaS*-approach, which has been somewhat restructured in comparison with an original issue in Item 1-6 in the previous subsection. We have already mentioned in the reviewing section of this text, that the RANSAC algorithm is able to extract a manifold of geometric primitives with different types of their shapes. RANSAC can deal with large number of outliers in the initial data, since this resampling method uses the smallest number of points necessary for estimation a given geometric primitive [62-64, 89, 103, 104]. Thus, the corresponding geometric primitives are obtained, if they approximate definite majority of points.

Some debatable issues present in the initially attempted *SaS*-segmentation, which appeared to be drastically sensitive to various outliers in the point clouds like, e.g., overhanging (above a building) trees. Because of this and due to the Lidar induced errors usually caused by sharp changes in the heights for the points belonging to the same feature, we have finally employed *RANSAC* with some editing of its general scheme. It may assist in meeting the challenges mentioned. For example, when the most points do not have the planar neighborhood, while the normal surface vectors, that are nonetheless found for the point minority, are located randomly, and this does not allow to delineate a corresponding point cluster for plane extraction.

In the outlined case, the *RANSAC* shape extraction strategy gives an opportunity to delineate a planar segment even facing the

challenges mentioned, because the sufficient condition is a randomly drawn point set, that can be quite feasible for this drawing, and employed then for constructing planar segment primitives. 2D planar points and 3D non-planar points can be separated ones from others using this technique. Figure 8 shows the example of a building model, which planes have been segmented with the optimized *RANSAC* from a point cloud with numerous outliers. Then this model has been refined and efficiently reconstructed, and even an overhanging tree, that is comparable in its size with a building, has been removed.

We have selected a following number of the basic *RANSAC* enhancements practicable for the ALS point cloud segmentation and implemented it in the relevant algorithmic pipeline embedded in our web-based software:

- *Number of iterations* upon the planar facet-candidate selection *is not a constant*, but it depends on a qualitative value that is the *Best Current Candidate Plane Index (BCCPI)*, a total number of Lidar points involved, and number of attempts completed yet. The purpose of the BCCPI value introduction is somewhat resembling to the RANSAC "score of the shape" [63], that also provides formalized estimation for the candidates of planar facets.
- Any BCCPI value is defined as *number of points within the delta-neighborhood of a plane minus the "penalty charges" for the point dispersion.* Thus, the less is point scattering from a detected plane, the higher is a qualitative

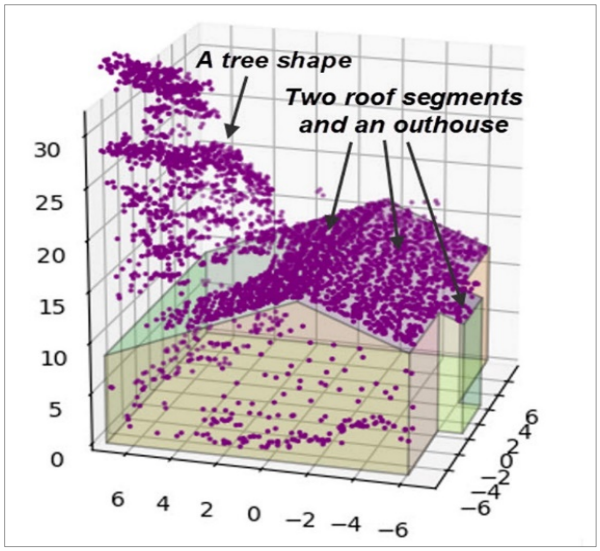

Figure 8: A building model reconstructed from the plains detected and segmented by the optimized *RANSAC*. A model is visualized by the *Matplotlib* python library. A building located in *the city of Lubliniec, Poland*

value of a candidate plane; the bigger is the scattering, the lower is a value mentioned. This technique reasonably allows to prefer those candidates, which approximate well even a relatively small point cluster, but not those random plains, that cross a whole extent of a model and overlap a big number of points in its delta-neighborhood. It is quite significant especially for the *gable roofs* with minor angles between its two slopes, or for *pitched roofs* with small angles within each pair of this roof slopes.

in point clouds with low data noise, but instead, a threshold for the BCCPI values may be intentionally decreased for overlapped strips resulted upon the airborne laser scanning, when a flight changes surveying direction.

- According to the improved *RANSAC* basics the point sampling for a plane-candidate may proceed from a whole point cloud with associated normal vectors, and the technique output is a set of planar primitives with corresponding point sets [105]. Such procedural content may cause some significant inaccuracy itself, while attempting to detect a plane, which may cross a whole cloud as explained above. Instead, we introduce *the point sampling from a randomly chosen limited neighborhood.* On the one hand, with this selection we still have the chances to approximate a big planar facet, if one does exist, on the other hand, we are expected to approximate some relatively small planar segment precisely enough, if a big one does not actually exist. If sampling neighborhood reduction is not provided, the probability that all three points, *a point triple*, would approximate (a key criterion of plane detection) one small planar facet has a low value.
- A point triple should be checked for *the degeneracy*: if an area of their triangle is too small, then the probability of processing error is high enough, and the whole computation cycle may fail. Therefore, *such triple is rejected*, and another one is sampled.

The overall structure of our optimizations of *RANSAC* is presented in the following *Algorithm Pseudo-Code* (Figure 9):

1. Main cycle:

```
working_set := input_points
result_planes := []
WHILE len(working_set) < threshold:
  plane_parameters, remaining_points := fit_plane_ransac(working_set)
   result_planes.append(plane_parameters)
   working_set := remaining_points
```

2. Selecting candidate plane function (fit_plane_ransac)

```
best_sample_quality := 0
best_sample_size := 0
best_sample := None
iteration := 0
WHILE probability(best_sample_size, points, iteration) <
quality_threshold:
  IF iteration >= iteration_threshold:
    reduce_dispersion_influence_on_quality_estimation()
```

```
  IF check_quality_limit_reached()
    BREAK
  iteration := 0
 p1, p2, p3 := select_candidate_points(points)
 iteration := iteration + 1
 IF NOT check_candidate_area(p1, p2, p3):
  CONTINUE
 candidate_sample, candidate_quality := get_best_candidate(p1, p2,
p3, points)
 IF candidate_quality > best_sample_quality:
  best_sample_quality := candidate_quality
  best_sample_size := size(candidate_sample)
  best_sample := candidate_sample
```

```
3. Assessing candidate quality function – BCCPI value
(get_best_candidate)
plane_parameters, sample_points := fit_plane(p1, p2, p3, points)
points_distance := get_distance_to_plane(plane_parameters,
sample_points)
distance_dispersion := mean(points_distance)
quality := quality_influence * (len(sample_points) / len(points)) + (1 -
quality_influence) * (1 - dispersion / plane capture_distance)
```

Figure 9: The Pseudocode of the optimized *RANSAC*

It has been determined that the optimal initial value of quality_influence may be 0.4, while the iteration step in reduce_dispersion_influence_on_quality_estimation is 0.1.

3.3.4. Optimizing SaS-reconstruction by Voronoi Neighborhood

One of our key contributions to the SAS-methodology corresponds to *Phase 4.2* of the phased methodological diagram (Figure 1). It consists in the refinement of the optimized adjacency matrix obtainment on the preliminary stage of building reconstruction. This matrix is the most significant issue for the delineation of the adjacent planar segments in the model generated. Thus, we have enhanced the *SaS*-workflow by *the extensive use of the Voronoi neighborhood* for computation of the roof segment cluster adjacency on the building *reconstruction stage.* Although the authors of the original workflow referred to the Voronoi diagram only on the point cloud *segmentation step* – the Voronoi neighborhood V_p has been employed for the surface normal computation only [37, 76]. Applying to the Voronoi diagram on the building reconstruction stage, we remove both horizontal, and vertical gaps in the processed data, as well as mitigate the nonhomogeneous point density of a primary point cloud.

The Voronoi diagram has been applied for the roof cluster adjacency determination and for separation of coplanar clusters, while the limited Voronoi diagram has been used for avoiding the side effects of the cluster adjacency determination. Also, the Voronoi diagram has been applied for the reliable identification of some traditional architectural constituents such as building awnings and or building overhands [102].

The Voronoi neighborhood for the roof cluster adjacency determination means the obtainment of the planar segment optimized adjacency, on the condition that these segments are preliminary delineated. The authors of the *SaS*-methodology use the Voronoi diagram while providing eigenvalue analysis, and each point of neighbors are being delineated. Nonetheless upon computing the cluster adjacency these authors apply a routine distance between all pairs of points using the following formula [37, P. 1562]:

$$d\,(P,Q) = min\,(d\,(p_i,q_j))\ \forall p_i \in P;\ \forall q_j \in Q, \qquad (1)$$

where: $\boldsymbol{d(p_i,q_j)}$ is a distance between any pair of points $\boldsymbol{p}_i$ and $\boldsymbol{q}_j$, which belongs to two different clusters $\boldsymbol{P}$ and $\boldsymbol{Q}$ correspondingly. The problematic issue of the *SaS*-approach like presented with (1) proceeds from a case of nonhomogeneous point cloud density that is a subject for clustering and segmenting. E.g., a sparse point cloud, which is also worsened by the faults of surveying technique, reasoned the case, according to which clustered points appear far from the boundary of a cluster. In such a case a distance value (from (1)) fails to be proved, if it is checked by a threshold parameter. Consequently, this may be a reason for the errored adjacency determination and for the consequent wrong model reconstruction. Nonetheless, it may be not so wrong to conclude, that because there are no Lidar points between two delineated planar segments, which would belong to other clusters, these two segments are sooner adjacent, than not and their seeming "non-connectivity" might be caused by the gaps and outliers in Lidar data only. This problem may be resolved by the adjacency determination with the Voronoi neighborhood.

The possible solution can be based on the following assumption. Even in a case, when two points lie far from each other, and there are no those points between them, which may belong to the third cluster (besides a given pair of clusters), and the Voronoi cells of these two points have common edges, then this pair of points can be determined by their Voronoi neighbors. In another case, when there are points of one more cluster between a given pair of points, these points are not considered as the adjacent ones even, if they pass a comparative test by applying a threshold parameter large enough.

On the base of all mentioned above and referring to an existing relevant example [106], we assume to consider as *adjacent ones* only those *clusters*, which points are *neighbors* within the Voronoi neighborhood. The only criterion is a case, when their Voronoi cells possess a *common edge*. Thus, we both solve a problem of data scarcity, gaps / outliers, and find a solution for a sparse point cloud. What is more, we get rid of a necessity of the enlarged threshold value introduction, but implement its definition by interpolating technique instead, since this value should be both big enough (not to remove the actual adjacent clusters), and small enough (not to define non-adjacent clusters as adjacent ones). In this way, we can significantly increase the applicability of our approach, and decrease its narrowness, e.g., when it strongly depends on point density and on the equitability or at least on the similarity of spatial distribution of the points that belong to two clusters. Moreover, the search of the Voronoi neighbors can be completed faster with such approach, because each point has a computed list of neighbors to be checked for their spatial acceptability. Thus, the overall algorithmic efficiency can be increased. It is only the first aspect of the overall LPM optimizing. The second one, that is not a less important solution, is introduced in the following paragraph.

While arranging the matrix adjacency in the frameworks of the *SaS*-technique, we define the distance between two clusters of planar points ***d* (*P*, *Q*)**, as the minimum of all point possible combinations between two clusters distance (1). Then, $m = |P|$ is a point number in the first cluster, and $n = |Q|$ - a point number in the second cluster. Hence, a whole number of possible combinations to be computed in such a case is the $m \cdot n$ value, the product of the point numbers.

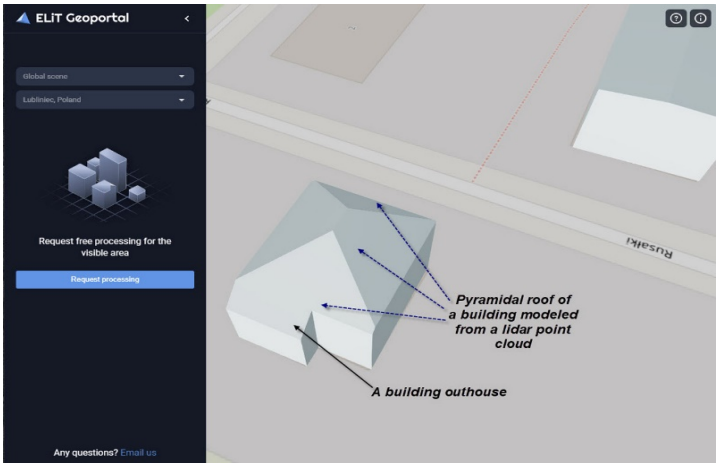

Figure 10: A lightweight model of a building with the pyramidal roof and an outhouse reconstructed at the *ElIT Geoportal* in the location of *the city of Lubliniec, Poland*

At this algorithmic step we suggest an alternative solution: to extend each of two clusters of planar points up to their mutual intersection, while a relevant linear segment of the cluster intersection is generated. Then we compute the distance between two clusters as the minimal distance of all possible measured combinations between points belonging to each of two clusters, from one side, and this linear segment of a cluster intersection, from another one. The statistical significance of difference between two mentioned values can be estimated. A combination number in this case becomes substantially fewer: the $m + n$ value only, the sum, but not the product. It defines the significant simplification of the overall LPM algorithmic complexity from the quadratic complexity $O(n^2)$ (a case of the *point product* that defines number of combinations) to the linear complexity $O(n)$ (a case of the *point sum*, that defines number of combinations). Decreased complexity provides the overall enhancement of the LPM-algorithmic efficiency.

It is evident, that the better a roof segment matrix is optimized, the more sustainable number of geometric primitives (e.g., vertices) is necessary for the robust building roof reconstruction. The introduced update of the adjacency matrix computation provides the definition of some threshold levels between two clusters of coplanar points within a footprint boundary, which is accepted as a geometric analogue of the roof edge. These clusters should never intersect, and this circumstance causes an indefinite exit of computing guaranteed, if the traditional approach is attempted to provide. Otherwise, the updated LPM technique, in its turn, completes the modeled topological sustainability and geometric correctness of a building footprint and of its roof as shown in Figure 10. It displays a model example from a fragment of one from modeled *CityGML LOD2* locations placed at our internet-resource – *ELiT (EOS LiDAR Tool) Geoportal* (http://elit-portal.eos.com/). The presented lightweight model has been selected for display, just because the relevant point cloud possesses quite a few non-intersecting planar segments, that is why the routine *SaS*-algorithm of reconstruction has failed while processing this data, but its update has succeeded – Figure10.

Phase 4.1 and partially *Phase 4.2* examined above deal with the point cloud segmentation stage in an overall processing workflow. Correspondingly, our prime LPM-concern has been a set of the roof segmentation operations, as it has been previously discussed for these two phases of the methodological diagram. *Phase 4.3* provides the finalized stage of building modeling – its reconstruction, while *Phase 4.2* grounds some substantial premises for it. We consider the urban feature reconstruction stage as presentation of building geometry and topology within a certain *LOD* with a defined number of feature segments. That is why we have attempted to implement in *Phase 4.3* one of the most interesting among other relevant theoretical technique – the polyhedral (polygonal) surface reconstruction (the *PolyFit* approach already mentioned in the literature review) [65, 107].

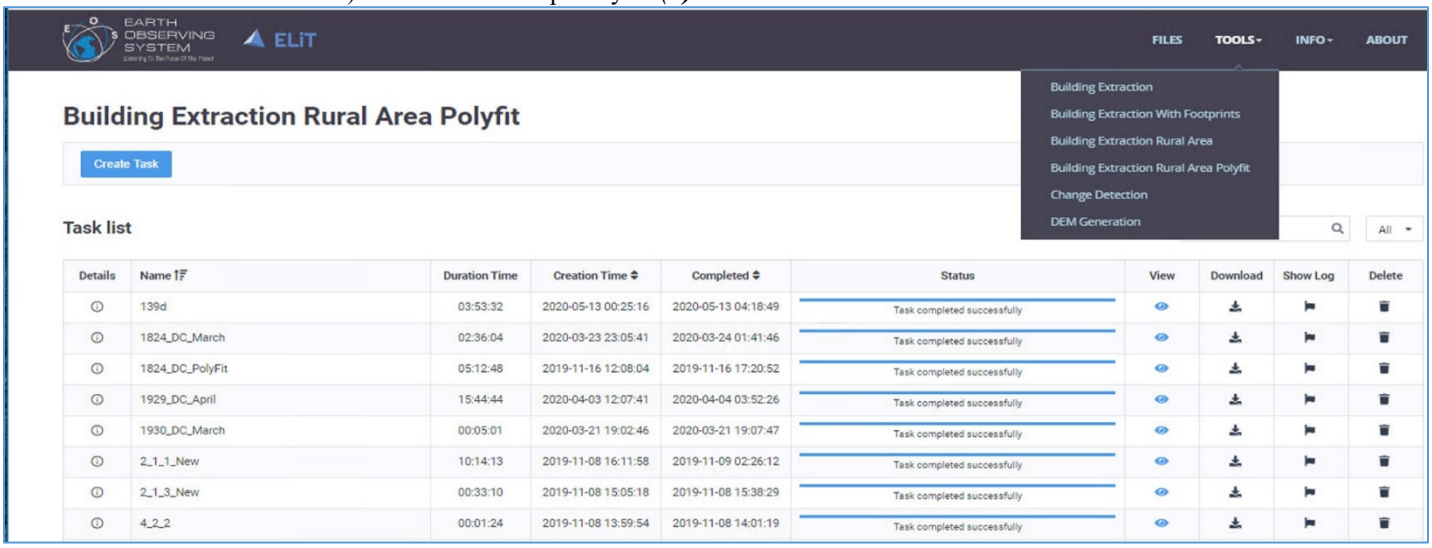

Figure 11: The *PolyFit* page selected among a list of other AFE-techniques in the menu *TOOLS* of the web-based software interface

This approach demonstrates, that reconstruction of geometric primitives from a point cloud can be treated as a binary labeling problem (what is, by the way, close enough to "global solutions" in the point cloud processing [87, 91]). The method proceeds from the hypothesizing and selecting strategy and provides intersecting the building planes already segmented, then seeking for a necessary combination of intersected planes and getting a manifold polygonal surface model. Since in its segmentation stage the method is strongly based exactly on the *RANSAC* algorithm for plane detection, then by enhancing *RANSAC* plane primitive extraction and refinement, what has been introduced in this text above, we understandably contribute to making the *PolyFit* solution more robust.

Therefore, constructing a whole pipeline for the *PolyFit* implementation in our web-based software, we attempted to employ on a relevant segmentation step both the original advances of the *SaS*-approach, and possibilities of enhanced *RANSAC*. Thus, the *PolyFit* appears to become one more AFE-option in the relevant menu option of our web-software package (Figure 11).

4. Results: Software Elaborated for AFE Purposes

The applied software solutions, that can be elaborated on the base of the presented multifunctional methodological approach to the generation of heavyweight and lightweight AFE-models (Figure 1) can be introduced as the robust results of this research. These software solutions are completed with the functionalities, which can provide the efficient support and realization of all three groups of advantages referred to above.

4.1. Desktop and Web-Based Applications

The ***ELiT*** (**E**OS **Li**dar **T**ool) Web-Based software is both a separate web-based (network) generator - *ELiT Server* (a landing demo-page available at https://eos.com/eos-lidar/), and an integrated component of EOS Platform-as-a-Service software - *ELiT Cloud.* The latter is the basis for *ELIT Geoportal* - a type of web portal used to find, access, and process LiDAR geospatial information, both primary, and resulted one, as well as provide the associated geographic services (display, editing, analysis, etc.) though the Web (http://elit-portal.eos.com/). Few examples of the *ELiT* Server interface have been already presented above (Figures 4, 6,7, 10, 11).

The congeneric to these two products is our desktop *ElitCore* package, which possesses even somewhat broader functionality, but can produce only the heavyweight polyhedral models (Figure 5). The *Building Extraction* functionality implemented in the standalone *ElitCore* provides detection, extraction, and reconstruction of heavyweight models according to our general methodological workflow of the HPM AFE (Figure 1) and its algorithmic content of *Phases 2* and *3* (Figures 2 and 3). It normally results in a DEM ("a bare ground class" delineated from an initial point cloud) and a set of urban features which are the discontinuous objects.

All three mentioned software products are based on the sophisticated HPM / LPM solutions based on those complicated algorithms for Lidar data processing that have been introduced in the previous section of this text. Both *ELiT Server*, which has been implemented as a distributed information system, and *ELiT Geoportal* usually operate from the Web browser installed on a user's workstation.

ELIT 3D city models as many other 3D models appear to be predominantly used for display; however, they are being increasingly employed in number of subject areas and for a large range of tasks beyond the visualization. In our previous publications, we sought to understand and present several use cases regarding their presentation not only on the *ELiT* Server, but also on the *ELiT* Geoportal with further utilization of these City GML LOD1 models for some tasks within and beyond model display [4, 102].

Our web-based software implies provision of the following *ELiT* tools as the functionalities of the distributed information system (these tools are shown in Figure 11 above):

- The *Building Extraction (BE)* tool (a sub-page *Building Extraction* of the *Tools* page – Figure 11) provides the HPM building detection, extraction, and reconstruction through various sub-procedures pursuing the final sub-procedure of building reconstruction for high-rise buildings, preferably in city downtowns. Thus, the *BE*-functionality accomplishes the generation of heavyweight models, which have been already grounded and presented above (Figures 2-4, 6). The building extraction functionality is that option, according to which any single building construction may be detected, extracted, and reconstructed as a heavyweight model with further visualization by the open source *Cesium 3DTiles* library with a certain *LOD* and with relevant spatial, geometric, and semantic attributes. Key components of the massive urban environment can be simulated as the heavyweight models with minor details (Figure 12);

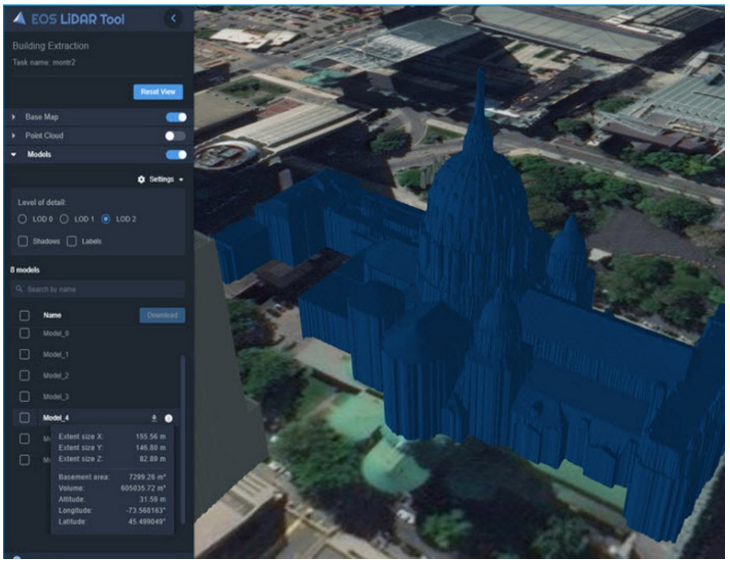

Figure 12: A historical building in *a downtown of Ottawa, Canada*, visualized in the *ELiT Server* interface

- The *Building Extraction with Footprints (BEwFP)* tool (a sub-page *Building Extraction with Footprints* of the *Tools* page – Figure 11) accomplishes the same HPM building extraction as the *BE*-tool producing the heavyweight building models. Oppositely to the previous tool, the *BEwFP*-functionality involves the third-party data – building footprints (global maps as *Open Street Maps*, *ESRI Imageries,*

Microsoft footprints, etc.) instead of accomplishing its own *ELiT* footprint delineation described in 3.2 Section of this text. Normally the footprints input is an archived ESRI *SHP* vector file;

- The *Building Extraction Rural Area* tool (*BERA* - a sub-page *Building Extraction Rural Area* located on the *Tools* page – Figure 11) provides "a classical pipeline", by which we implement the *SaS* point cloud segmentation / building reconstruction methods [37] of low polyhedral modeling introduced in *Phase 4.3* of the methodological flowchart (Figure 1). According to the *SaS*-pipeline and to its optimization described in subsections 3.3.2 and 3.3.4 the *BERA* tool accomplishes the hierarchical segmentation of a Lidar point cloud, refinement, and separation of extracted planes with further building reconstruction in rural areas and urban suburbs. As it has been already mentioned above (Subsection 2.2), the generated lightweight building models consist of not so many facets, and number of points involved in a single model generation is limited by a number from five to thirty thousand. Necessary limitation may be met by adaptive thinning at the cost of modeled details, if an initial value ranks over this quantity. The correspondence of a resulted model to an initial point cloud can be visually assessed for a conclusion, if it is modeled accurately or not, and if it is allowed to go to *Phase 5.LW* , or it is necessary to go back to *Phase 2*, and provide HPM instead of with LPM (Figure 1). This quality estimation is provided with the *ELiT Detailed Viewer* (Figure 13). In case of acceptable quality, the point locations should not deviate on more than a certain distance threshold value from the modeled surfaces. An exact threshold is introduced, basing on the point cloud characteristics, e.g., on its density.
- The *Building Extraction Rural Area Polyfit* tool (*BERA-P* - a sub-page *Building Extraction Rural Area Polyfit* located on the *Tools* page – Figure 7) implements somewhat another algorithmic pipeline in comparison with the *BERA* tool. The *RANSAC* optimized clustering and segmentation is used on the initial building modeling (subsection 3.3.3). The hypothesizing and sampling strategy of the *PolyFit* basics [65] together with its finalized reconstruction of polyhedral models is applied to concluding building modeling. Our optimization of the *RANSAC* segmentation described above is embedded in the relevant workflow, that fulfils the *BERA-P* tool. Its processing may take somewhat longer time, than the "ordinary" *BERA* tool does, but usually provides an increase of number of topologically correct and geometrically precise models among all output models in a dataset.
- The *Change Detection* tool (*CD* - a sub-page *Change Detection*, which is on the *Tools* page – Figure 11) automatically detects block-, district-, and city- scope alterations in an AOI selected. Changes in urban architectural morphology usually happen through city areas over some significant period, if only it is not any catastrophic event of either environmental, or social demolition. The *ELiT* CD tool detects locations of changes in positions and shapes of buildings and infrastructures as 3D models with additional spatial information. Usually two Point Clouds (the temporally primary, and the temporally secondary ones) are compared. It is not *BERA*, but the *BE*-functionality is the only one that is involved in preparing two resulted modeled sets. The difference between two input point clouds is computed as the *BE*-output of the high polyhedral modeling (Figure 6).

All those already listed *ELiT* functionalities are supported by the relevant web-API and by the Front-end web-interface for routine procedures of uploading, processing, and analyzing the initial data and for further downloading derivative data. The sets of modeled *.OBJ* and. *B3DM* entities (the latter are *Cesium 3D*

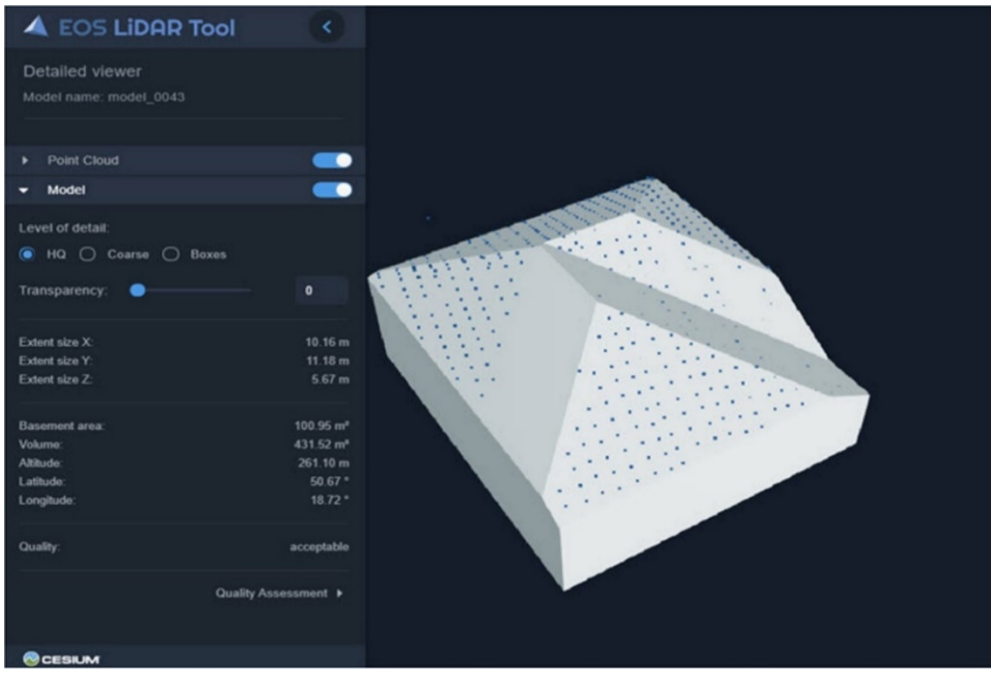

Figure 13: The *Detailed Viewer* Tool for examining accuracy of a lightweight model according to point cloud content

Tiles component) have to be delivered to 3D models, and can be stored and visualized in *.COLLADA, .KML,* and *glTF* formats.

According to the content of *3D Tiles* specification a *.glTF* is employed by *.B3DM* as *its payload* for delivering 3D building geometry. If data processed by *ELiT Server*, the results of all functionalities, *BE, BEwFP, BERA, BERA-P*, and *Change Detection,* are displayed by the *ELiT Viewer.*

- The *DEM Generation* tool (*DEM-G* - a sub-page of the *Tools* page Figure 11) runs a generation of a field of topographic heights making *a DEM / DSM grid* (Figure 17). It means we can create a gridded surface from sample data, what is commonly referred to as the interpolation. According to the contemporary basics of topographic modeling the most accurate uniformly spaced DEM matrix can be compiled directly either from photogrammetric processing of remote sensing imageries, or by processing results of LiDAR surveys [8]. In other words, a series of irregularly spaced height points are acquired, from which uniformly spaced elevation benchmarks are interpolated. A created DEM we understand as a synonym of a digital terrain model, which simulates the bare earth surface with uniformly spaced *z*-values of heights within a DEM neighborhood. Our automated processing for generation of a DEM of high precision provides modeling topography of various genetic types, e.g., sand-eolian (as shown in Figure 14), glacial, fluvial, volcanic, topography of human impact, etc. Results of the *DEM-G* functionality are visualized in *ELiT Viewer* by the *TerrainProvider* option of the open source *Cesium JavaScript* library (Figure 14).

4.2. Cloud-Based Application – ELiT Geoportal

A common definition of the *EliT Geoportal* (*EGP*) as a *cloud-based* application has been already done in the previous subsection of this text. We already explained in one of our previous publication the necessity of a geoportal as a robust solution for the web-GIS software promotion [102]. *EGP* is a kind of web portal used to transform occasional visitors of the EOS LiDAR web-site into the warm leads. The *EGP* site can be used to find and access the derivative Lidar information and relevant services for number of thematic use cases, that can be resolved through geospatial modeling, visualization, and GIS-analysis.

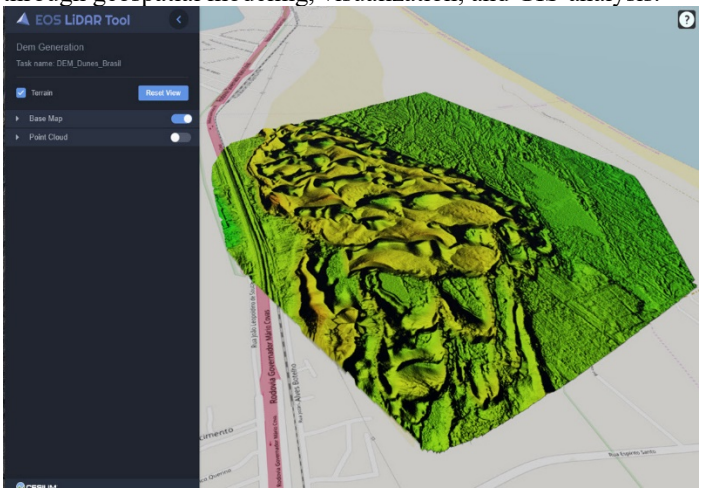

Figure 14: Topography of sand dunes in Brazil visualized in the *ELiT Viewer* interface (a dataset from the *EOS LIDAR Tool* landing page: https://eos.com/eos-lidar)

Thus, the Geoportal can be also defined as the Internet-toolbox for resolving local, regional, national, and even globalized urban problems, i.e., by performing at very different scales. A routine Web-based map-server software usually allows only backups of mapping results. Nonetheless, for various domains of Urban Studies, which can be provided with our research and modeling technique [1], we do need a Geoportal Internet-toolbox associated with a web-based Geodatabase, that would allow us to sort, query, update, and delete both different features and data associated with these features. Such architectural and structural web-software scheme differs towards its more efficiency if compared with solutions of a common case. Within these solutions some web-based GIS application generator is developed, and it provides on the base of the routine database scheme the number of web scripts. Then it deals with a map interface and with a database, as well as with provision of interactive maps defined by a user [19, 108, 109]. Otherwise, the EGP may support an effective integration of a Web-based GIS interface with a Geodatabase chosen within a web-architecture. Spatial references and 3D regional layers are automatically chosen for a given territory. What is more, semi-automatic generation of Web 3D Scenes according to a selected AOI can be provided. Owing to this architectural scheme, series of thematic EGP use cases are provided (http://elit-portal.eos.com/): *Population estimation in an AOI based on 3D building models; Energy consumption estimation based on 3D building models; Visibility analysis in urban environment for various city development scenarios' evaluation and comparison.*

5. Discussion

Choosing either the high polyhedral modeling, or the low polyhedral one with corresponding generation of either HW-, or LW-models may be selected as introductory topic of the discussion, which summarizes our research.

As explained above, in a common case, *Phase 1* of the methodological flowchart (Figure 1) suggests either one, or another option according to environmental and urban configurations of a selected AOI.

The LW-models are built exclusively on the base of ALS surveys together with input of the third-party footprints (Figure 7). The lightweight model accuracy exclusively depends on the segmentation quality and the reconstruction robustness. What is more, exactly clustering / segmenting procedures significantly define consequent LM-results. Application of the originally optimized *RANSAC* (Figure 9) has resulted not only in removal of

a point cloud outlier caused by a tree (Figure 8), but also in predetermined appearance of a building outhouse on the reconstruction stage in a finalized model, what cannot be guaranteed with the routine approach of segmentation (Figure 10).

The comparative evaluation of optimized clustering/segmenting technique with both restructuring *SaS*-pipeline (subsection 3.3.2), and with enhancing *RANSAC* (subsection 3.3.3) has been provided on the base of several ALS data surveys accomplished over the territory of the city of Lubliniec, Poland, in 2017-2018 (Figures 7, 8, 9). Table 1 is produced to compare the modeled results of the methods mentioned. Three different values of the key *RANSAC* parameter from Figure 9, *plane capture distance (PCD)*, are used in *meters*, evaluating the position uncertainty for each Lidar point. Consequent iterations are completed for *PCD=0.1*, *0.2*, and *0.3*. The model quality is evaluated both by a visual comparison with a processed point cloud (as in Figure 13), and by customized estimating of algorithmic parameters. Modeling warnings designate partially correct models that have some flaws.

Table 1: Comparison of the modeled results depending on clustering and segmenting method (a LiDAR point dataset on Lubliniec, Poland)

#	Method of clustering / segmentation	Pro-cessing time	Total number of models	Correct models	In-correct models	Modeling warnings
1	Original *SaS*	8 h 45 min	934	534	289	111
2	Original *RANSAC*	12 h 11 min	934	577	248	109
3	*SaS* with restructured pipeline	11 h 24 min	934	588	243	103
5	Optimized *RANSAC* with *PCD=**0.1***	15 h 57 min	934	662	167	105
6	Optimized *RANSAC* with *PCD=**0.2***	10 h 42 min	934	677	147	111
6	Optimized *RANSAC* with *PCD=**0.3***	7 h 42 min	934	699	133	102

Shown in Table 1 are the comparative statistics, which has stipulated the necessity development of the *BERA PolyFit* building modeling tool described above. *The total number of models* column has the same value for all records, since it is a number of building footprints obtained from a data provider for this AOI. Another almost constant column for all methods is number of partially correct models (*Modeling warnings*). The table shows, that for all other records the evidently best results are demonstrated by the optimized *RANSAC* with *PCD=0.3* (Method *# 6*). The accuracy of the segmented roof planes follows from a selected clustering-segmenting method thus it does predefine either a success, or not on the stage of reconstruction. Therefore, this technique has been selected for the *BERA-P* tool. Briefly the most efficient *RANSAC* method according to Table 1 can be illustrated in the following way, if examining only one model (*# 43*) from a dataset, what from Table (1) (Figure 15).

Two different iterations of Method # 6, which present resembling results (the same number of up to seven face candidates), are illustrated, because it is the only method, that produces an acceptable number of similar results through various iterations. Lidar point as color-coded segments have ratios for each coded class. Ratio numerator is the number of break-line (non-planar points that do not belong to this segment due to the *PCD* value) points, while ratio denominator – planar points (they satisfy the *PCD* threshold). Methods *##1-6* (Table 1) have been compared with respect to similarity of various iterations like in Figure 15. Method *# 6* meets criterion of the best efficiency in this respect. The following illustration shows that this technique is the only tool (among all other from Table 1), that can provide the clustering-segmenting premises for reconstruction of a problematic roof slope, that belongs to model # 21 in the considered Lubliniec dataset (Figure 16). All other five techniques missed this roof slope.

The finalized illustration of this text demonstrates an increase for up to 27% (*41 acceptable among 62 all models* versus *30 / 62 ratio*) in a number of acceptable models for a small urban area in Washington, D.C. by providing Method *# 6* as a software solution (Figure 17).

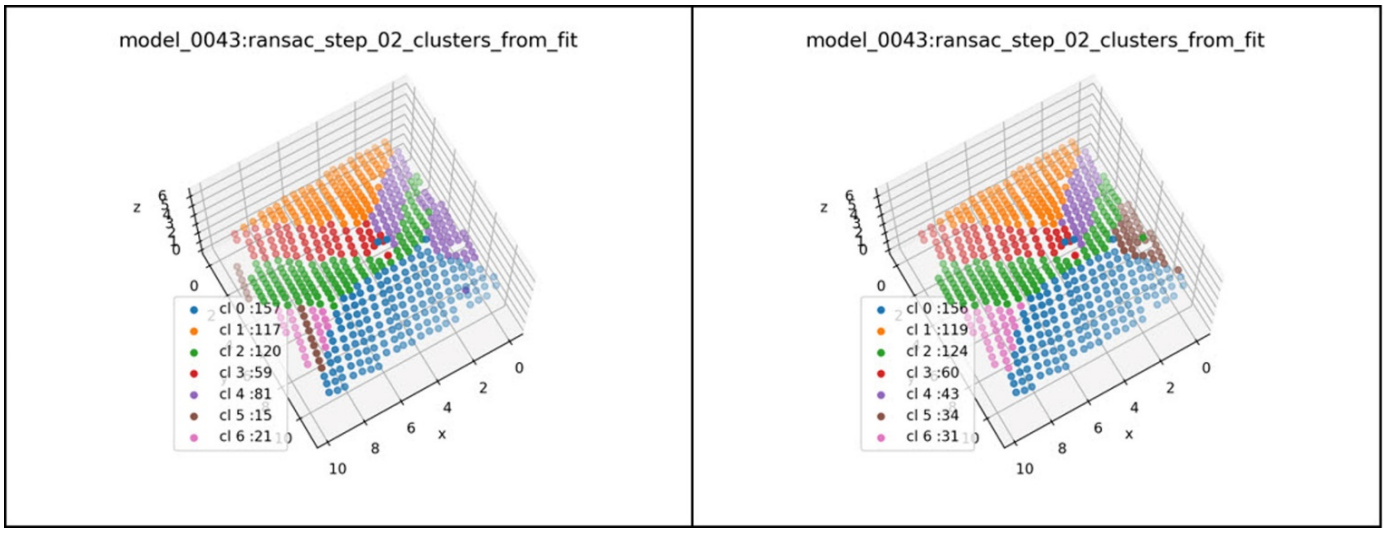

Figure 15: Two different clustering / segmenting iterations of Method # 6 (Table 1) to a point cloud of model # 43, that demonstrate resembling results

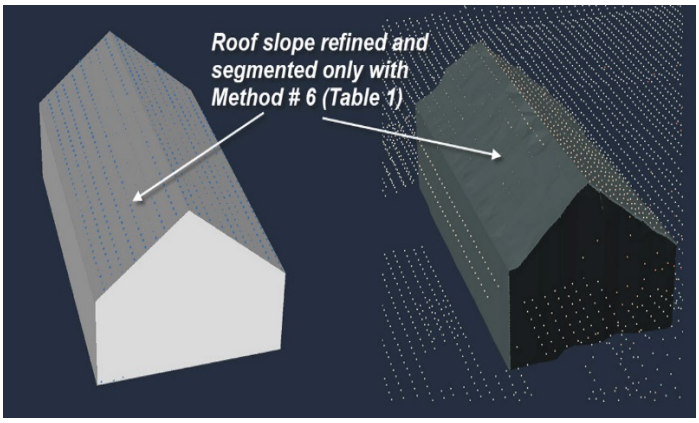

Figure 16: The roof slope pointed by arrows segmented by Method # *6* for further reconstruction. A CAD model built from a Google imagery (to the right) is compared with a point cloud with quite weak correlation for this building segment, while *ELiT* LW-model reconstructed is to the left

6. Conclusion

Our paper focuses on the conceptual multifunctional (functionalities of *Building Extraction*, *Building Extraction* in *Rural Areas*, *Change Detection*, and *DEM Generation*) approach within the AFE frameworks, that has been introduced through consequent steps of the phased methodological flowchart. In general, a workflow presented that has been completely automated for building detection, extraction and modeling by processing ALS and MLS point clouds. Two approaches of the high polyhedral modeling, and the low polyhedral one, have been proposed as two phased branches of a united overall workflow. These two modeling mainstreams have been compared on the base of their resulted models: the heavyweight models generated together with their original footprints within the HPM frameworks, and the lightweight models that employ the third-party footprints – with the LPM technique. With modeled results illustrated we have attempted to prove that the HPM branch can be appropriate for high-rise building reconstruction with either flat, or pitched roofs in densely build-up urban areas. The LPM branch – for modeling low-rise buildings with gable, or pitched roofs in either rural areas, or in city suburbs, as well as in small towns, i.e., in areas with thinned build-up.

A plot of our overall AFE workflow has been presented as the content of the methodological flowchart phases, while its *high polyhedral modeling* branch has been described by the relevant core algorithmic pipeline separately for phases of ALS and MLS data processing. The ALS block of footprint extraction and delineation has been presented in details. Visual samples of HPM-results processed by the *Building Extraction* and the *Change Detection* desktop and web-software tools have been provided.

The *low polyhedral modeling* has been explained as the technique consisting of two consequent stages: the point cloud clustering / segmenting stage, and the stage of building reconstruction. Our methodological flowchart has presented detailed phases of the LPM implementation. The *SaS*, *RANSAC*, and *PloyFit* approaches have been adopted, and selectively enhanced for implementation in the web-software as *Building Extraction Rural Areas* and *BERA-PolyFit* tools:

SaS-segmentation has been enhanced by restructuring its pipeline; *RANSAC*-segmentation has been optimized by both the introduction of the key BCCPI parameter, and by the adaptive alterations of rules due to the plane candidate "penalty charges", as well as by introducing the point sampling from a randomly chosen limited neighborhood; the optimized *RANSAC*-segmentation method with a certain parameter has been selected as the most efficient one among six compared methods on the base of results obtained for our key dataset;

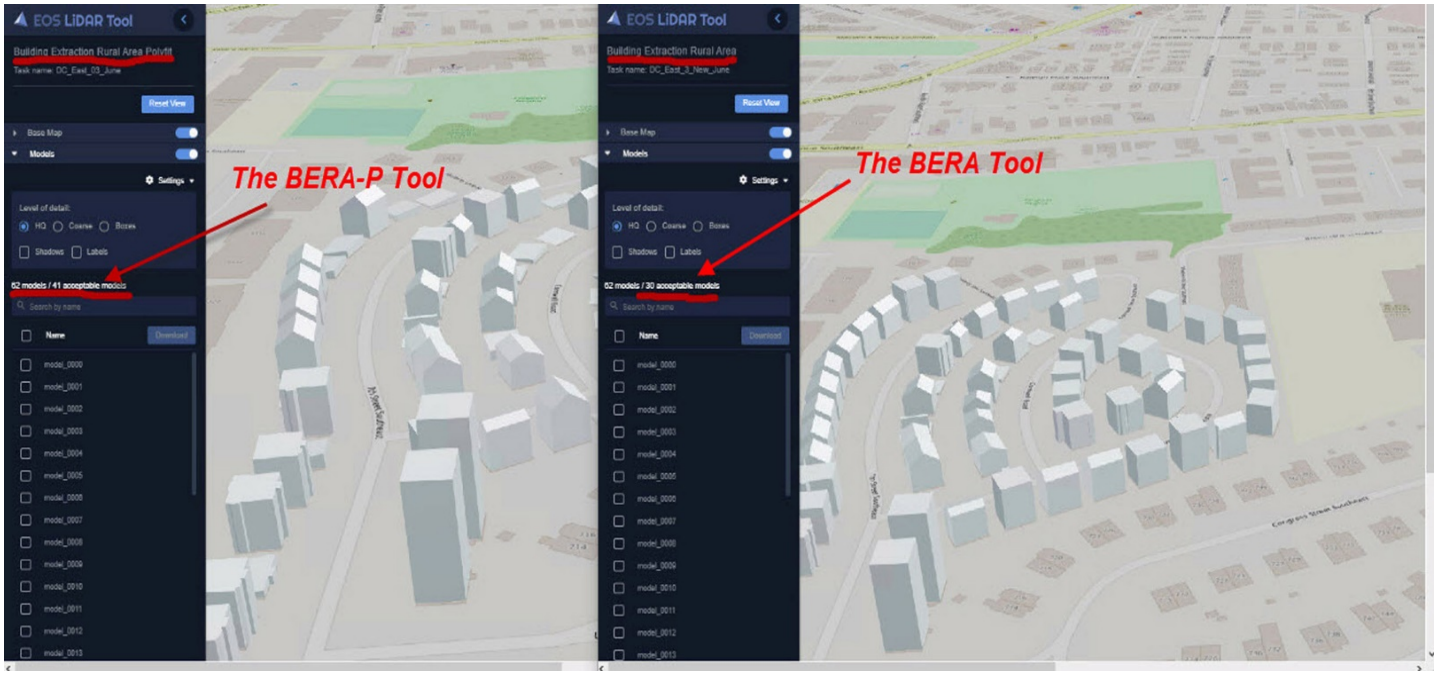

Figure 17: Comparison of modeled results, the number of acceptable models, produced by the *BERA Polyfit* Tool (with Method # *6* in clustering / segmenting algorithmic core - the left visual), on one hand, and by the *BERA* Tool (the right visual), on the other hand. *A small urban parcel in Washington, D.C., USA*

SaS-reconstruction has been optimized by the Voronoi neighborhood introduction, and thus obtaining the enhancement of overall algorithmic efficiency and the better optimization of the roof plane adjacency matrix. The Voronoi diagram can be accepted as a natural neighborhood without the necessity to specify its size. This property can be crucial for employing Voronoi neighbors within the reconstruction stage, while in the original methodology its usage is strictly limited to the stage of segmentation;

PolyFit approach has been implemented in the *BERA-P* web-software tool and proved to be as the most efficient one on the reconstruction stage if based on the optimized *RANSAC*. This issue has finalized our contributions to the low polyhedral modeling.

Besides all mentioned above functionalities the graphic user interface of the original family of software products for LiDAR data processing has been introduced as desktop, web-based, and cloud-based solutions: *ElitCore*, *ELiT Sever*, and *ELiT Geoportal*, correspondingly.

As far as future works are concerned the suggested algorithmic optimization and enhancements should be exercised through much more urban configurations, e.g., on those locations already placed on the *ELiT Geoportal.* Routine GIS-data consumers may employ the *ELiT Server* to search, access, and process their own Lidar data by the multifunctional tools in both block, and district scopes, and the data delivered to them by a provider. In such case, the *ELiT Geoportal*, as an Internet-toolbox, may serve an increasingly significant role in sharing derivative LiDAR information on the structure and spatiotemporal development of large human settlements, i.e., provide solution in a whole city scope.

Conflict of Interest

The authors declare no conflict of interest.

Teaching Tools

ABSTRACT

The paper is aimed as a concise and relatively self-contained description of the educational environment TOST, used in teaching and learning Operating Systems basics such as Processes, Multiprogramming, Timesharing, Scheduling strategies, and Memory management. TOST also aids education in some important IT concepts such as Deadlock, Mutual exclusion, and Concurrent processes synchronization. The presented integrated environment allows the students to develop and run programs in two simple programming languages, and at the same time, the data in the main system tables can be monitored. The paper consists of a description of TOST system, the features of the built-in programming languages, and demonstrations of teaching the basic Operating Systems principles. In addition, some of the well-known concurrent processing problems are solved to illustrate TOST usage in parallel programming teaching.

1. Introduction

This paper is an extension of work originally presented in 29th Annual Conference of the European Association for Education in Electrical and Information Engineering (EAEEIE) [1].

Operating Systems (OS) is one of the most fundamental courses in Computer Engineering, Computer Science, and Information Systems curricula. At the same time, students are faced with a lot of problems in learning OS basics, due to not fully understanding the wide range of techniques, strategies, and architectures involved in OS modules. The complexity and depth of concepts in this area requires a careful and detailed explanation from the educator in order to reach a better apprehending. Developing concurrent programs in an operating system environment (Unix, Linux, etc.) asks for students to already have prerequisite skills in both the C-programming and the operating system. Usually, such level of experience is difficult to be obtained at an undergraduate degree, thus a preferable approach would be to use a convenient and effective teaching tool that helps the students in their uneasy endeavor to apprehend and master the OS concepts.

We have assigned the widely spread tools for studying OS into the following two groups:

- Instructional Operating Systems
- Visual OS simulators

The systems from the first group (MINIX [2], Nachos [3], Xinu [4], Pintos [5], GeekOS [6]) run on real hardware and are too complicated to install and use. The main disadvantage of the instructional OS is the requirement students to be familiar with system-level programming in C, C++, Java or assembly language, and to be able to study large program codes (more than 4K program lines of Geek-OS and 15K of MINIX). Most of these systems do not have graphical visualizations, which makes them not very suitable for teaching purposes. In such cases, students spend a lot of time learning the systems themselves and how to use them properly.

In contrast, the visual tools from the second group (SOsim [7], SchedulerSim [8], CPU Sim [9]) are easier to use and convenient, however, they present rather restricted and pre-specified abilities (e.g. simulation of just one OS module or subsystem). For example, the TROJAN [10] simulator helps in teaching multiprocessor organization, the cache utilization, and the network traffic issues, while SIME [11] visualizations focus on memory management, but without shared memory concepts. Additionally, some of these systems (Proc OS [12], Alg OS [13]) do not connect theoretical concepts to a running code. Others present simulations of only one example problem (e.g. the Producer/Consumer problem [14]).

The authors propose a newly-developed by them OS teaching system named ***TOST*** *(Teaching in Operating Systems Tool)*. It has

*Corresponding Author: Tzanko Golemanov, Ruse University, Ruse, Bulgaria, tgolemanov@uni-ruse.bg

been created in response to the requirement of the educational tool to be straightforward to use, yet powerful enough, allowing the students to not only experiment with OS settings, architectures, and strategies but also to create and run any concurrent programs they want. This imposes the need for TOST to be developed as an integrated environment consisting of a code editor, a high-level language compiler, a virtual processor emulator, an interface for setting and modifying OS parameters, and a visualization of the content of the main OS tables.

The structure of the paper is as follows: Section 2 is an introduction to TOST giving an overview of the TOST interface, the grammars of the built-in programming languages, the manners to develop and execute concurrent processes, as well as the ways to set and modify system options, and to monitor the system tables' data. Section 3 is devoted to teaching Operating System basics, such as Process Management, Process Scheduling, and Memory Management. Section 4 describes the use of TOST in teaching Concurrent Programming concepts, specifically Mutual Exclusion (Dekker's algorithm, Peterson's algorithm, Test_And_Set instruction, and Semaphores), Interprocess Synchronization (Sleeping Barber problem), and Deadlock (Dining Philosophers problem). In Section 5, a student evaluation is presented. We conclude in Section 6 and discuss some further improvements to TOST.

2. The TOST System

The main objective of an educational tool in OS is to give students an inside view of the operating system. At the same time, in our opinion, the tool should meet the following basic requirements:

- to operate on an accessible hardware and software platform
- to support multiprogramming and concurrent processes
- to be with a well-known interface
- to support well-known programming languages with concurrency features
- to allow students the experimentation with the basic OS parameters and options.

TOST has been developed with exactly this idea in mind. It allows students to develop and execute concurrent processes, while at the same time they can change the basic settings of the OS (CPU scheduling, Quantum size, Memory management, Virtual memory strategies, etc.) and to monitor the main system tables (Processes, Blocked, Ready, Semaphores, etc.).

The proposed integrated environment includes:

- a multi-tasking, and a multi-window operating system
- editors and compilers for two simple programming languages
- a virtual processor emulator.

The last TOST version is developed with Embarcadero® Delphi within Embarcadero RAD Studio 10.3.3 Rio. It has no installation procedure, the executable file of the tool is very small in size (less than one MB), and it operates on any MS Windows environment. TOST is easy to learn and use, and allows students to become familiar with the capabilities and the limitations of the built-in programming languages within a short time (about an hour).

The first TOST environment is introduced in [15], while the focus of [1] is on using TOST in teaching mutual exclusion, synchronization, and deadlock. This paper expands the application area of TOST, describing its usage for teaching and learning OS concepts.

2.1. Programming in TOST

A general view of the current TOST main menu is depicted in Figure 1.

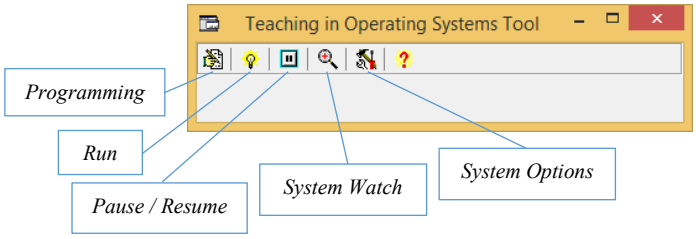

Figure 1: TOST interface

Using TOST, students can develop and execute concurrent programs in two simple programming languages - PASCAL-style and C-style. The grammars of these languages, consist of roughly twenty grammar productions only, which are presented in Figure 2 and Figure 3 in Extended BNF (ISO/IEC 14977).

```
program    = "void" "main" "(" ")" body
body       = [ { type identifier { "," identifier } } ] block
type       = "int" | "char" | "bool" | "shared" | "semaphore"
block      = "{" statement { ";" statement } "}"
statement  = block | assignment | if | while | read | write | lock | unlock |
             init | wait | signal
assignment = identifier "=" expression
expression = expr [ ( "<" | ">" | "==" ) expr ]
expr       = term { ( "+" | "-" | "or" ) term }
term       = factor { ( "*" | "/" | "and" ) factor }
factor     = [ "not" ] ( identifier | constant | random | "(" expression
             ")" )
constant   = number | """" char """" | "#" ascii_code | "true" | "false"
random     = "random" "(" expression ")"
if         = "if" "(" expression ")" statement
while      = "while" "(" expression ")" statement
read       = "cin" ">>" identifier
write      = "cout" "<<" expression { "<<" expression }
lock       = "lock" "(" identifier ")"
unlock     = "unlock" "(" identifier ")"
init       = "init" "(" identifier "," expression ")"
wait       = "wait" "(" identifier ")"
signal     = "signal" "(" identifier ")"
```

Figure 2: C-style language grammar productions

```
program    = [ "program" identifier ";" ] body "."
body       = [ "var" { identifier { "," identifier } ":" type ";" } ] block
type       = "integer" | "char" | "boolean" | "shared" | "semaphore"
block      = "begin" statement { ";" statement } "end"
statement  = block | assignment | if | while | read | write | lock | unlock |
             init | wait | signal
assignment = identifier ":=" expression
expression = expr { ( "<" | ">" | "=" ) expr }
expr       = term { ( "+" | "-" | "or" ) term }
term       = factor { ( "*" | "/" | "and" ) factor }
```

```
factor    = [ "not" ] ( identifier | constant | random | "(" expression
            ")" )
constant  = number | "'" char "'" | "#" ascii_code | "true" | "false"
random    = "random" "(" expression ")"
if        = "if" expression "then" statement
while     = "while" expression "do" statement
read      = "read" "(" identifier ")"
write     = "write" "(" expression { "," expression } ")"
lock      = "lock" "(" identifier ")"
unlock    = "unlock" "(" identifier ")"
init      = "init" "(" identifier "," expression ")"
wait      = "wait" "(" identifier ")"
signal    = "signal" "(" identifier ")"
```

Figure 3: PASCAL-style language grammar productions

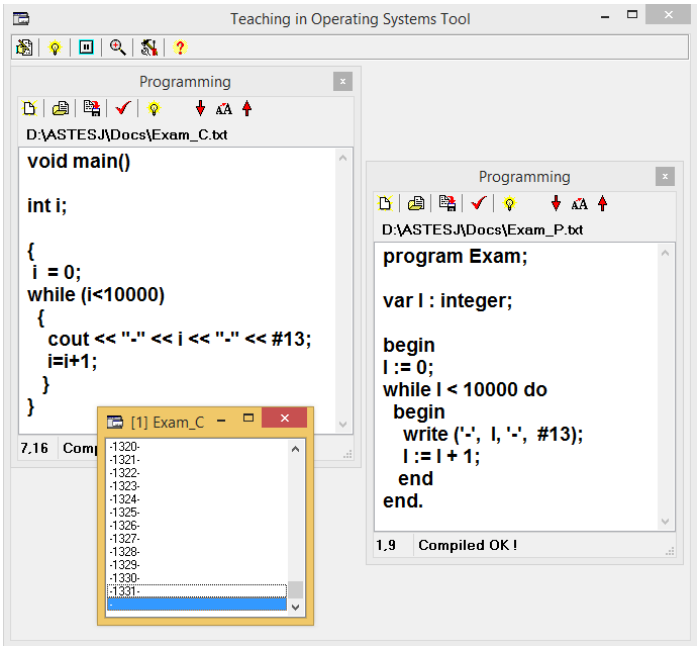

Figure 4: Process editing and executing in TOST

In the text bellow we will use C-style only for the programs' definition.

The programming languages in TOST are exclusively for learning purposes and while they are quite simple, there are some features that need to be addressed:

2.1.1. Types of variables

Only a few standard simple data types *integer*, *char* and *boolean* are available for local variables, nevertheless, some data types for concurrent programming purposes are also provided. Variables from the ***shared*** type can be declared in a TOST program. These variables become common for all concurrent processes running in the system. A shared variable is unified, i.e. it can accept any integer, char or boolean values, as well as any data can be extracted from it. As a result, passing through such variable can also be used in order to convert data from one type to another.

Another type of data used in parallel programming is the ***semaphore***. In TOST we implement the original Dijkstra's semaphores concept [16]. A semaphore variable ***S*** consists of two properties - ***S.value*** and ***S.queue***. The property S.value is a non-negative integer, while S.queue is a FIFO list of identifiers of the blocked processes (process ID).

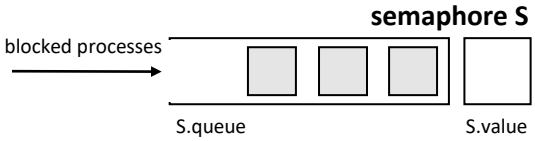

Figure 5: Semaphore's structure

2.1.2. Statements

Although TOST languages maintain only basic statements like assignment, conditional, loop and input/output, some statements for concurrent programming purposes are also available.

The semaphore operations ***init***, ***wait***, and ***signal***, which are defined below, are functions from the OS kernel:

init (S, value)

```
S.value = value
```

wait(S)

```
if (S.value > 0)
  decrement S.value;
else
  block this process and add it's ID in S.queue
```

signal (S)

```
if (S.queue is empty)
     increment S.value;
else
     unblock the first process from S.queue
```

Figure 6: Semaphore operations

Students can investigate the advantages and disadvantages of using the special assembly language instruction ***Test_and_Set*** [17] through the statements ***Lock*** (CS) and ***Unlock*** (CS), where CS (***C****ritical* ***S****ection*) is a boolean shared variable.

Function ***random***(*expression*) which returns a random integer value from *0* to *expression-1* can also be used in some synchronization primitives' implementations.

2.2. Processes Execution Management in TOST

After the successful compilation, an object code file is generated (with COD extension) and it is ready to be run in the environment. The compiled processes can be started from the ***Run*** at the main menu (as well as from the editing windows).

Figure 7 presents the general system view where in the ***Run*** dialog box students can select an object file to be executed, and set the initial parameters of the running process.

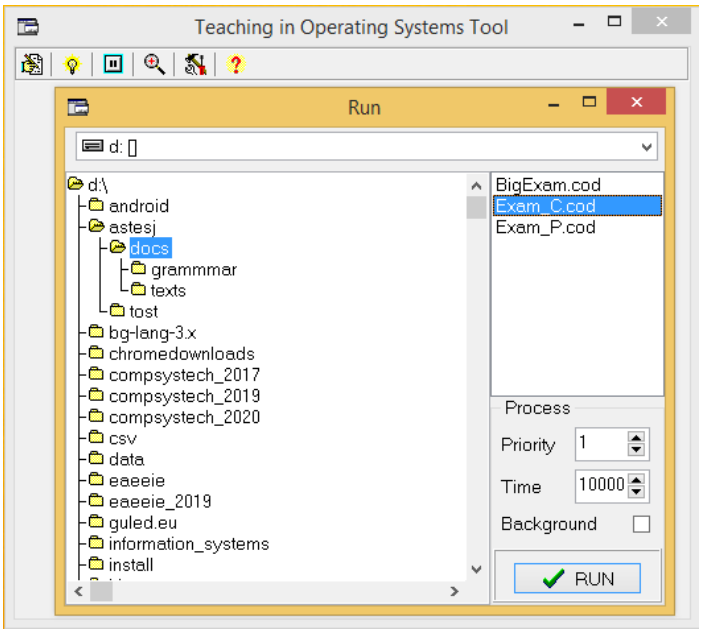

Figure 7: Process running

Priority spin-edit box sets the initial process priority while the total process execution time (used in some scheduling strategies) can be entered in ***Time***. By checking ***Background*** the students can specify the process visual mode (execution in a separate window or behind the scenes). Pressing the ***RUN*** button multiple times will cause the start of several concurrent processes.

If detailed monitoring of running processes is required, a temporary "freeze" can be performed via ***Pause / Resume*** at the main menu.

2.3. TOST System Options

Some basic OS parameters can be set and modified while several processes are executed in a concurrent mode.

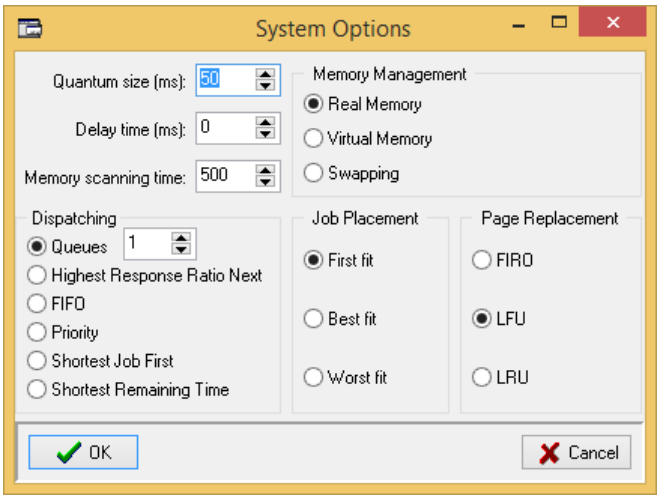

Figure 8: System Options dialog box

In System Options dialog box (Figure 8) students can modify:

- ***Quantum Size***: system time sharing quantum size in ms
- ***Delay time***: processes speed control
- ***Memory scanning time***: time interval of RAM scanning
- ***Dispatching***: current scheduling strategy
- ***Memory Management***: current memory management strategy – *Real Memory*, *Virtual Paging* or *Swapping*
- ***Job Placement***: jobs placement strategy in real memory mode
- ***Page Replacement***: page replacement strategy in virtual memory mode

These modifications of system parameters allow real-time monitoring of how each of them affects the processes executed.

2.4. TOST System Watch

For achieving an OS inside view, while several processes are executed in parallel mode, students can monitor the information dynamics in selected system tables (Figure 9): ***Processes***, ***Ready***, ***Blocked***, ***Memory Allocation*** map and ***Semaphores*** info. The information from each of the system tables is presented in a separate window, as it is shown in Figure 10.

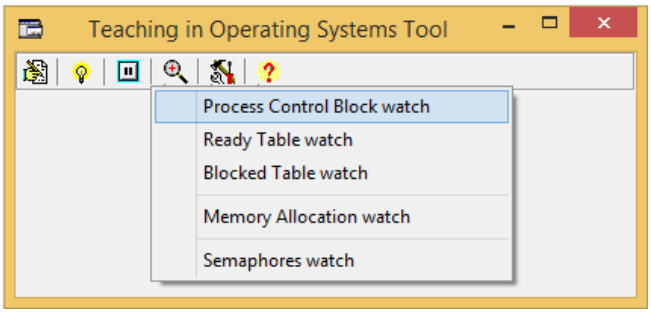

Figure 9: System tables Watch

2.4.1. Processes

The ***Processes*** table (Figure 10) contains the current ***Process Control Block*** of each of the existing concurrent processes.

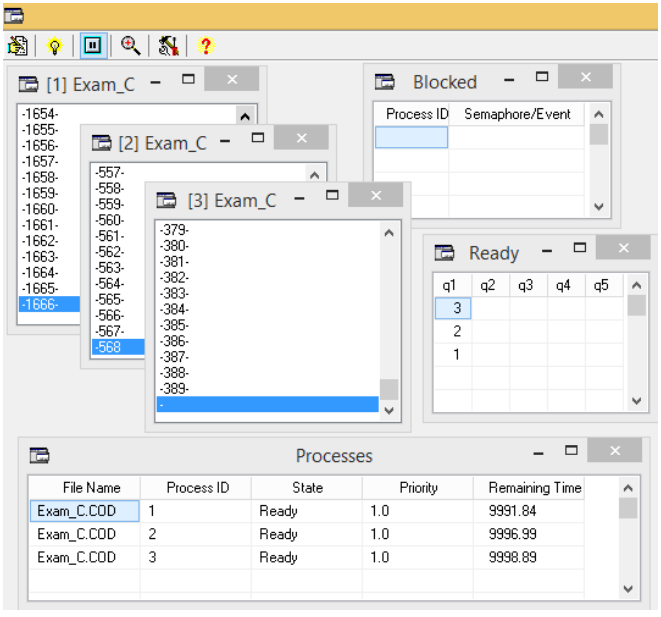

Figure 10: Processes execution and system tables monitoring

The information is presented in five fields:

- ***File Name***: the name of the compiled object file
- ***Process ID***: an integer unique identifier of the process
- ***State***: current process status – *Ready*, *Running* or *Blocked*
- ***Priority***: a real value determining the process priority
- ***Remaining Time***: the time remaining until the process completion.

In this table, students can manipulate the priority or the remaining time of the selected process.

2.4.2. Ready table

The ***Ready*** table contains IDs of all processes with status "Ready". It is possible (according the settings in System Options) to have up to 5 priority queues. Thus, students can experiment with scheduling strategies like ***Round Robin*** (one queue only) or ***Multilevel Feedback Queue*** [18] for the separation of the processes with different behavior (with more I/O operations or with more computations).

2.4.3. Blocked table

The identifiers of blocked processes and the names of semaphores/events, related to their blocking are presented in the ***Blocked*** table. In fact, these are FIFO-queues with blocked processes of all semaphores used. The information in this table is especially helpful when students have to monitor semaphores usage in processes ***synchronization***, ***mutual exclusion*** and ***deadlock*** prevention cases.

2.4.4. Memory Allocation map

Important information about memory allocation and referencing is given by ***Memory Allocation Watch***. When this submenu item is selected, the system periodically scans the TOST RAM and displays results in a separate window. This feature allows students to monitor a map of the memory blocks, where the occupied blocks are marked with the process' ID. The detailed referencing of the pages in the virtual memory is also displayed.

2.4.5. Semaphores information

Semaphores Watch submenu item can be selected for monitoring all semaphore variables' current values in a separate window. This helps students to master the mechanism of using both binary and counting semaphores.

3. Teaching Operating System Basics

3.1. Teaching Process Management

A process [2] is basically a program in execution. During its existence, the process goes through several different states, and the basic three are ***Ready***, ***Running***, and ***Blocked***.

Once students run several processes, they can monitor (as shown in Figure 10) their life cycles in the *Processes* (ID, the current State and the state changing), *Ready* (ID list of all ready processes), and *Blocked* (ID list of all blocked processes, and the event each process is waiting for) tables.

3.2. Teaching Process Scheduling

The act of choosing which of all the ready processes should be moved to the running state is not a trivial task [19]. It is known as Process Scheduling and is performed by OS Dispatcher.

There are several goals of the process scheduling system:

- to maximize the fairness according to the processes priorities
- to keep the CPU busy at all time
- to maximize throughput and to deliver minimum response time for all processes
- to minimize resource starvation
- to support a lot of interactive users
- to minimize system overheads (OS CPU time, OS RAM).

In fact, very often these goals contradict with each other, so the Dispatcher should implement an appropriate compromise [20]. Through experimentation, students are expected to gain understanding in the scheduling strategies and to be able to choose the most appropriate one, depending on the user's needs and objectives. In TOST students can change (at any time) the current scheduling strategy using ***Dispatching*** radio-buttons in ***System Options*** (see Figure 8).

Scheduling disciplines of the two general categories are supported in TOST:

Non-Preemptive Scheduling: once the OS assigns the CPU to a process, the process does not release the CPU until it has finished:

- ***FIFO:*** Simplest scheduling algorithm with only one queue (see queue q1 in *Ready*). New processes are appended in q1 where context switches only occur upon running process' termination. Then the top placed process in q1 becomes *Running*. Students can monitor:
  - scheduling overheads are minimal
  - throughput can be low
  - no starvation
  - waiting time and response time can be high
  - no prioritization occurs
  - interactive users are not allowed
- ***Priority:*** Whenever a scheduling event occurs, the *Processes* table will be searched for the process with the maximum priority number (the most important one), which will be the next one to be scheduled for execution. Students can monitor:
  - scheduling overheads are low
  - throughput can be low
  - starvation can occur in a busy system with many high-priority processes in the Ready table

- waiting time and response time can be high
- interactive users are not allowed

- ***Shortest Job First (SJF)***: Dispatcher selects the process with the least estimated processing time to be executed. The estimated processing time in TOST can be set while process is initialized (Figure 7). Students can monitor how the algorithm increases throughput, and how the starvation can become a problem, in a system with many short processes in the *Ready* table.
- ***Highest Response Ratio Next (HRRN):*** is a dynamic priority discipline proposed by Brinch Hansen to mitigate the problem of the large processes starvation. When CPU becomes free, Dispatcher calculates the priorities of all ready processes according to:

  Priority = 1 + waiting time / processing time

  and selects the high priority process to be executed. Students can monitor the priority calculations (in *Processes* table) which gives preference to short processes, but with each subsequent recalculation the priority of the large ones grows and they can be selected as well.

Preemptive Scheduling: Dispatcher can interrupt a running process any time in middle of the execution and the process is returned back in the *Ready* table:

- ***Shortest Remaining Time (SRT):*** is a modification of SJF with a preemption. When a new shortest process arrives Dispatcher interrupts the current process and assigns the CPU to the new one. Students can monitor that this discipline achieves maximum throughput in most cases, and the starvation is possible for large processes where a lot of small processes arrive.
- ***Queues:*** By specifying the number of queues (Figure 8), students can set two strategies:
  Queues (1): Round-robin (RR): is a FIFO modification with the process preempting where *Ready* table is a queue. Dispatcher assigns a small time interval (Quantum) per process, then interrupts and appends it at the end of the *Ready* queue. When students set *Delay time* in *System Settings* they can monitor processes preempting in the *Ready* table in detail. When students run processes with different priorities, they can monitor how the more important processes are with proportionally larger quantum and get a better service, and the starvation can never occur.
  Queues (2-5): Multilevel feedback queues: In this case, processes are grouped according to their behavior - interactive processes vs batch processes, and processes with more I/O vs. computational processes. In order to obtain a balance in system's resources utilization Dispatcher has to provide better service for interactive and I/O processes. Students can monitor in detail how processes pass into the multilevel set of priority queues (from 1 to 5) in *Ready* table.

3.3. Teaching Memory Management

In general, when discussing the topic of memory management [2], [19] the focus is on the virtual memory organization. However, before reaching this point, students need to understand in detail what the issues are in using the real memory organization. Only then they can comprehend why this kind of organization has been replaced everywhere by the virtual one.

3.3.1. Real Memory

Real memory organization is a classical (one of the oldest) memory allocation model according to which the process is placed in a consecutive memory blocks [21]. Each process takes up exactly as much memory as it needs, and due to the fact that the memory blocks have sequential addresses, process loading, executing and the memory releasing are extremely fast. Then *"Where is the problem?"* comes to be the next instructor's question towards the students.

Students are instructed to develop and try to run several large processes. Later, they run five small processes and with using the TOST feature ***Memory Allocation Watch,*** monitor the memory map with real memory organization. Then students kill the first, second and fourth process, so these memory blocks are freed. Figure 11 shows how the memory blocks occupied by a process are marked with its identifier.

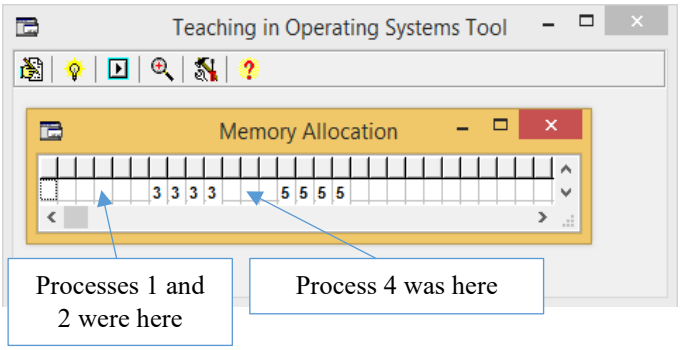

Figure 11: Memory allocation map

Following these instructions, students quickly realize the deficiencies of the real memory:

- A process cannot be started if it is even one byte larger than the available physical memory.
- There is a low CPU utilization, due to the low degree of multiprogramming (number of ready processes loaded in physical memory).
- The occurrence of memory fragmentation: In high dynamics of started and finished processes, the free memory area is broken into small parts, in which none of the ready processes can be allocated. Thus, a lot of memory blocks can remain unusable.

In order to minimize the problem of memory fragmentation, the placement strategies ***First-fit***, ***Best-fit*** and ***Worst-fit*** can be applied (Figure 8). To assess their usefulness students can run a new process and monitor its placement in the memory.

3.3.2. Virtual Memory

Although the problem of memory fragmentation can be solved, other serious problems of real memory remain: small maximum process size and low degree of multiprogramming.

Virtual memory organization allows each process to be divided into blocks (***pages***) while only a small part of the code and data (that are currently needed) are located in the physical memory. The physical memory is divided into blocks, which are called ***frames***. Figure 12 illustrates a moment in the execution of a large process where ***Virtual Memory*** as *Memory management* is set (Figure 8).

At that stage, students can monitor the occupation and references to the blocks (pages) in progress, with the memory scanned at a certain interval (0.5s for example). When the process starts, only a small part of its blocks are loaded - those that are needed at the beginning. Later, the OS loads additional blocks into the memory, those which are needed by the process but are not available. The blocks that the process refers to during the scan interval are colored red.

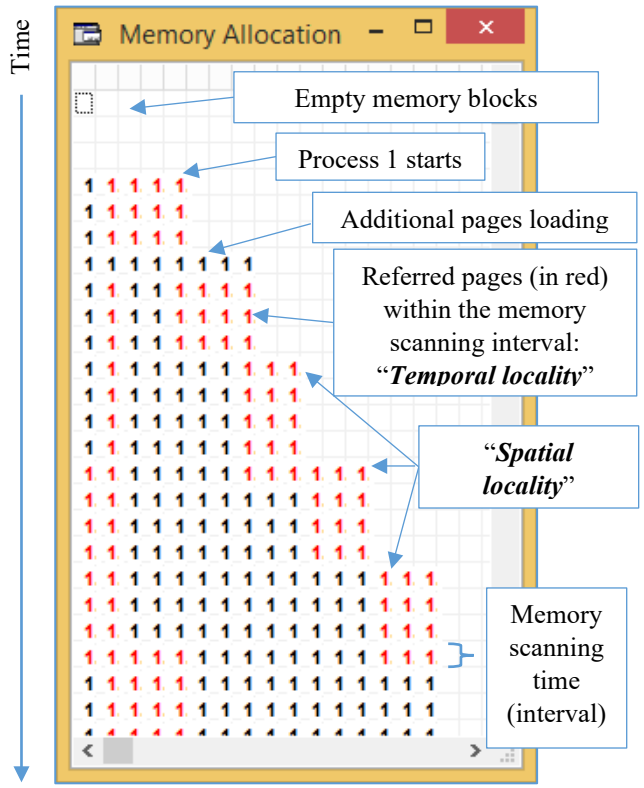

Figure 12: Memory allocation and pages referencing

Memory allocation map allows the instructor to clarify the ***principles of the locality*** [22] - ***Temporal locality*** and ***Spatial locality***.

Principles of the locality can be used for anticipatory paging (swap prefetch) to increase processes' execution speed. These principles are useful when the optimal replacement strategy has to be chosen.

In TOST students can set (Figure 8) and examine various replacement strategies such as *Least Recently Used* (***LRU***), *Least Frequently Used* (***LFU***) and ***FIFO***.

4. Teaching Concurrent Programming Concepts

Even if the students are familiar with the theoretical aspects of parallel programming, in order to gain intuition about the subject, it is vital to be provided with examples of incorrect operation of competitive processes. Therefore, our approach is to firstly develop concurrent programs without any protections and then, analyze the faulty actions of the processes. Consequently, modify the programs in order to achieve correct results. In addition, to strengthen this knowledge, we solve and program some of the well-known toy-problems in concurrent processing.

Representative examples of using TOST in teaching ***Mutual Exclusion***, ***Interprocess Synchronization*** and ***Deadlock*** are considered in the next sections.

4.1. Teaching Mutual Exclusion

The parts of the concurrent processes where they access a shared resource are called ***Critical Sections*** (CS) [23]. Critical Sections must be protected by synchronization primitives, assuring only one of the processes can be in the CS.

Figure 13 presents programs with no protection of the critical section. Students develop and execute an initialization process (init.txt), and two concurrent processes (p1.txt and p2.txt), incrementing the shared variable C 1000 times. After finishing the processes, the students can see the final result value of C = 1839, instead of the correct value of 2000.

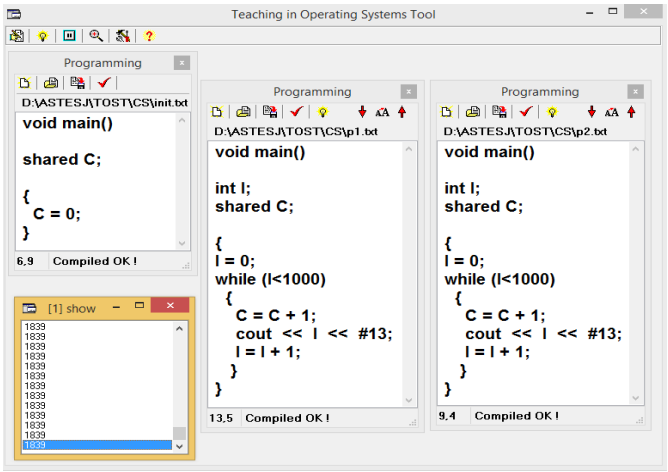

Figure 13: Concurrent processes with Critical Section

After examining the reasons for the wrong result, the students transform the programs gradually, seeking the correct solution for synchronization primitives. Thus, they examine program versions with one, two, and three shared variables, and at last, they come to the consideration of the ***Dekker's algorithm*** (Figure 14).

The ***Peterson's algorithm*** [24] is another well-known algorithm that students can try and compare with Dekker's algorithm. A simple solution of CS protection by the Peterson's algorithm is given in Figure 15.

In Figure 16 a simple example of CS protection, using primitives ***Lock*** and ***Unlock***, based on the hardware instruction ***Test_And_Set***, is presented.

The last example considered is the use of semaphores to protect the critical section (Figure 17).

```
void main()
shared C, ReqP1, ReqP2, Turn ;
{
 C = 0;
 ReqP1 = false;
 ReqP1 = false;
 Turn = 1;
}
```

```
void main()
int I;
shared C, ReqP1, ReqP2, Turn ;
{
I = 0;
while ( I < 1000 )
 {
  ReqP1 = true;
  while ( ReqP2 == true )
   If  (Turn  == 2)
    {
     ReqP1 = false;
       while (Turn  == 2) ;
     ReqP1 = true;
    };
        C = C + 1;
  ReqP1 = false;
  Turn  = 2;
  I = I + 1;
 }
}
```

(a) Initialization process (b) Process 1

Figure 14: Critical Section protection by Dekker's algorithm

```
void main()
shared C, ReqP1, ReqP2, Turn;
{
 C = 0;
 ReqP1 = false;
 ReqP1 = false;
}
```

```
void main()
int I;
shared C, ReqP1, ReqP2, Turn ;
{
I = 0;
while ( I < 1000 )
 {
  ReqP1 = true;
  Turn  = 2;
  while (ReqP2 and (Turn == 2)) ;
        C = C + 1;
  ReqP1 = false;
  I = I + 1;
 }
}
```

(a) Initialization process (b) Process 1

```
void main()
shared C, CS;
{
 C = 0;
 CS = false;
}
```

```
void main()
int I;
shared C, CS ;
{
I = 0;
while ( I < 1000 )
 {
  Lock (CS);
        C = C + 1;
  Unlock (CS);
  I = I + 1;
 }
}
```

(a) Initialization process (b) Process 1

Figure 16: Critical Section protection by Test_And_Set instruction

```
void main()
semaphore  CS;
shared  C;
{
 C = 0;
 init (CS, 1);
}
```

```
void main()
semaphore  CS;
shared  C;
int  I;
{
 I = 0;
 while (I<1000)
  {
   wait (CS);
     C = C + 1;
   signal (CS);
   I = I + 1;
  }
}
```

Figure 17: Critical Section protection by a semaphore

Figure 18 presents the contents of two main OS tables (Processes and Blocked) during the concurrent execution of three identical processes with the source code of Figure 17. Processes *P1_S* and *P2_S* are blocked, while the ready process *P2_3* is inside the critical section. Students also have the possibility of monitoring the semaphore variable CS in a separate window

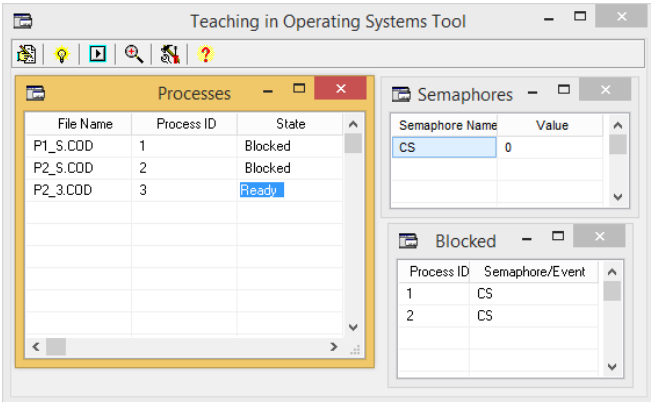

Figure 18: Monitoring TOST system tables

After finishing the processes, the value of the shared variable C is correct and equal to 3000.

4.2. Teaching Interprocess Synchronization

A good illustration of the Interprocess Synchronization is the. ***Sleeping Barber problem*** [25] depicted in Figure 19. As soon as the Barber or Client process reaches a certain point in the execution, it must stop and wait for an event to occur.

Figure 19: Sleeping Barber problem

The problem can be stated as follows: In a barbershop, there is a barber chair and an area for the waiting clients with five chairs. The algorithms of the concurrent processes of the Barber and the Client include the following steps:

Barber:

1) *The barber signals that he is ready to work (free).*
2) *The barber sits on the barber's chair and sleeps, waiting for a new client (indoor bell).*
3) *The barber gets up and waits for the client to sit on the barber's chair.*
4) *The barber begins the haircut and signals when he completes the work.*
5) *The barber waits until the client leaves the barbershop (outdoor bell).*
6) *Go to 1.*

```
void main()
semaphore Chairs, Barber,
          Client, Sit, Finish,
          Out;
{
   init ( Chairs, 5 );
   init ( Barber, 0 );
   init ( Client, 0 );
   init ( Sit, 0 );
   init ( Finish, 0 );
   init ( Out, 0 );
}
```

There are 5 chairs available
The barber is not available
No new client
No one is sitting in barber's chair
The barber has not finished work
The client has not come out

(a) Initialization

```
void main()
semaphore Chairs, Barber,
          Client, Sit, Finish,
          Out;
{
   while (true)
  {
    signal ( Barber );
    wait ( Client );
    wait ( Sit );
    signal (Finish );
    wait ( Out );
  }
}
```

(b) Barber

```
void main()
semaphore Chairs, Barber,
          Client, Sit, Finish,
          Out;
{
   wait ( Chairs );
   signal ( Client );
   wait ( Barber );
   signal ( Chairs );
   signal ( Sit );
   wait ( Finish );
   signal (Out );
}
```

(c) Client

Figure 20: Sleeping Barber solution

Client:

1) *The client checks if there is a free chair in the waiting room and eventually waits until a chair is available.*
2) *The client signals that there is a new client (input bell).*
3) *The client is waiting for the barber to be free.*
4) *The client frees the chair in the waiting room.*
5) *The client sits on the barber's chair and signals that he is ready for a haircut.*
6) *The client is waiting for the barber to complete the haircut.*
7) *The client gets out of the barber's chair and leaves the barbershop (output bell).*

The first thing students have to do is to identify processes synchronization events and implement one semaphore variable for each of the controlled events. Then they develop three programs - Initialization (for setting semaphore values), Barber, and Client (Figure 20).

The implementation of the synchronization of one barber's process and eight clients' processes are depicted in Figure 21.

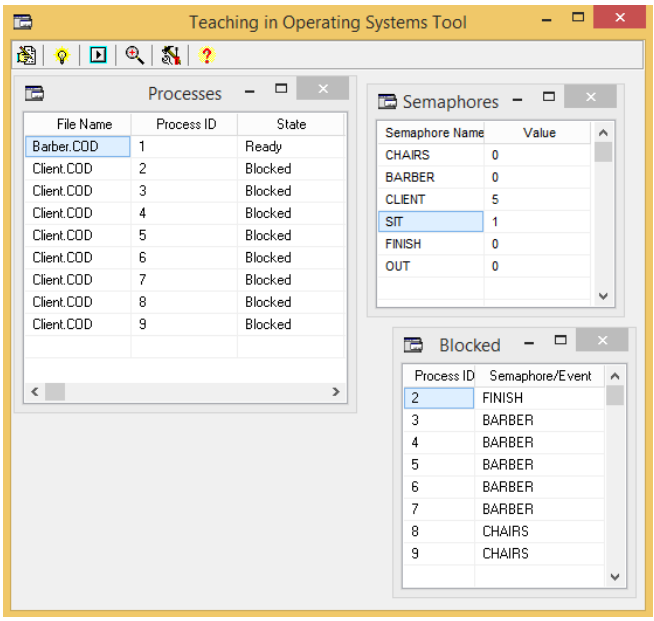

Figure 21: Sleeping Barber execution monitoring

According to the information in TOST system tables:

- the barber is busy (Semaphores: *Barber = 0*)
- a client is seated in the barber chair (Semaphores: *Sit = 1*) and waiting for the barber to complete the haircut (Blocked: *Finish*)
- five new clients are in the waiting room (Semaphores: *Clients = 5*) and all the chairs are occupied (Semaphores: *Chairs = 0*)
- all five new clients are waiting for the barber (Blocked: *Barber*)
- two clients are waiting for a chair outside of the barbershop (Blocked: *Chairs*).

4.3. Teaching Deadlock

The ***Dining Philosophers*** toy-example [26], depicted in Figure 22, is often used to analyze the synchronization and deadlock problems in the concurrent processes execution, as well as to demonstrate the approaches for solving them.

The students solve this problem by developing five programs (for the philosophers) while the correct access (mutual exclusion) to the shared objects (forks) is implemented by semaphores. The example programs for the first two philosophers are presented in Figure 23.

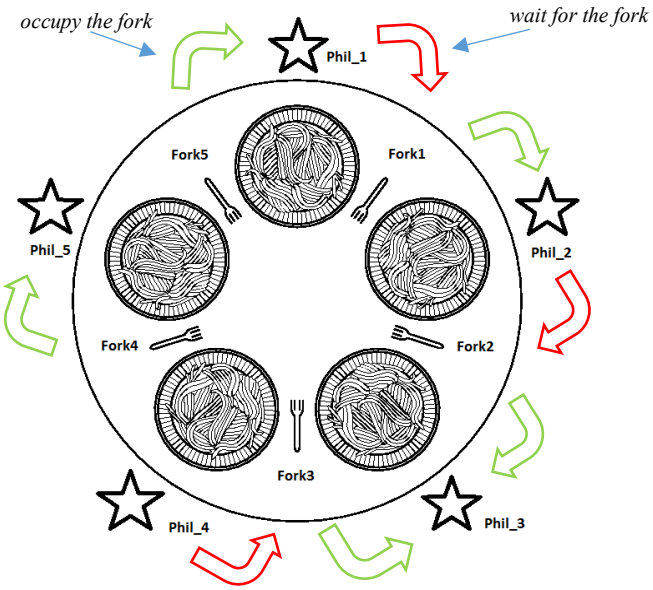

Figure 22: Dining Philosophers problem

```
void main()
semaphore FORK5, FORK1 ;
{
while ( true )
 {
    cout << "T" << #13;
   wait ( FORK5 );
   wait ( FORK1 );
    cout << "E" << #13;
   signal ( FORK1 );
   signal ( FORK5 );
 }
}
```

```
void main()
semaphore FORK1, FORK2 ;
{
while ( true )
 {
    cout << "T" << #13;
   wait ( FORK1 );
   wait ( FORK2 );
    cout << "E" << #13;
   signal ( FORK1 );
   signal ( FORK2 );
 }
}
```

Figure 23: Phil_1 and Phil_2 program samples

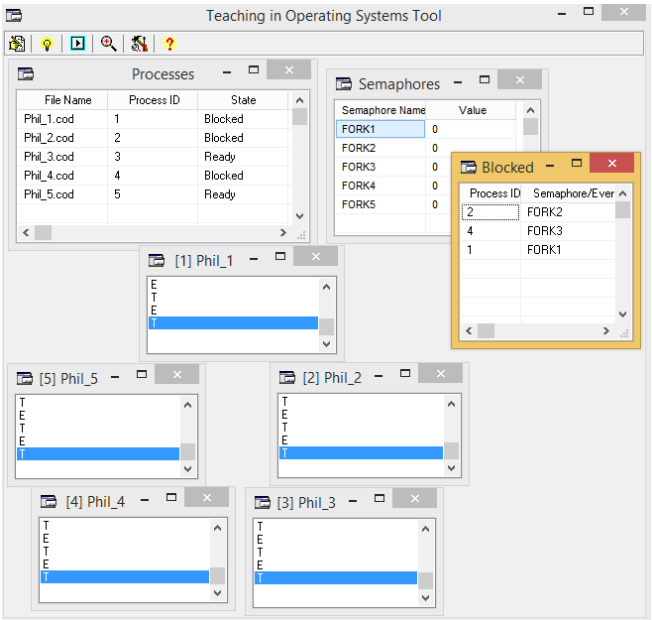

Figure 24: Dining Philosophers execution

TOST allows students to monitor (Figure 24) how philosophers are waiting for the forks (in *Processes* and *Blocked*) and how they take and put the forks on the table (in *Semaphores*).

Another aim of the Dining Philosophers problem is to demonstrate the prevention of ***Deadlock***.

Students can monitor how in the case of all philosophers taking a fork with their right hand, while expecting the release of a second fork, a *Deadlock* occurs (Figure 25 and Figure 26).

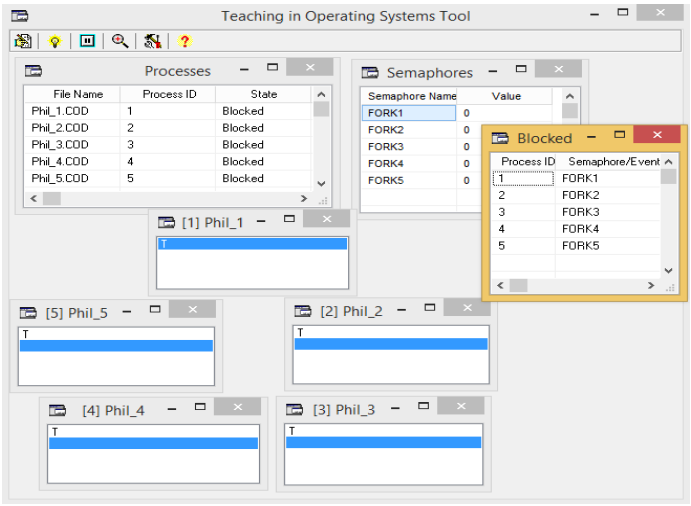

Figure 25: Dining Philosophers Deadlock example

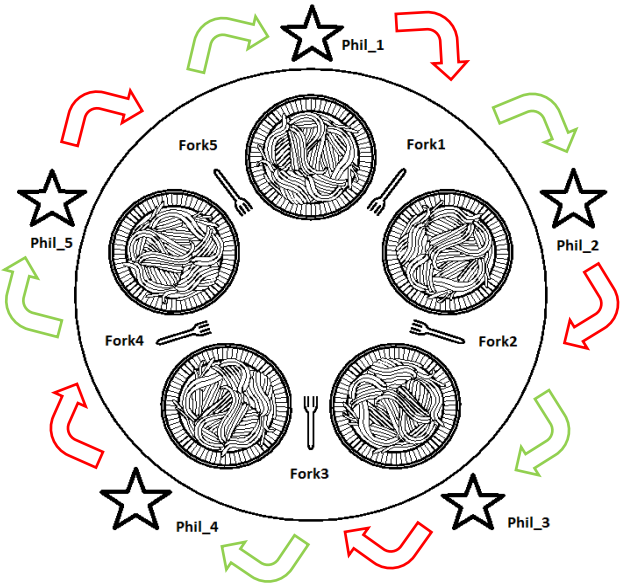

Figure 26: Dining Philosophers Deadlock example (Circular Wait)

Students have to find a solution and save philosophers from starvation dead. One idea is to break the fourth necessary condition for Deadlock - ***Circular Wait*** [27]. Students apply this approach by reprogramming Phil_1 (Figure 27) and introducing the general requirement for all processes to request resources in **ascending order only**.

```
void main()
semaphore FORK5, FORK1 ;
{
while ( true )
  {
      cout << "T" << #13;
     wait ( FORK5 );
     wait ( FORK1 );
       cout << "E" << #13;
     signal ( FORK1 );
     signal ( FORK5 );
   }
}
```

```
void main()
semaphore FORK5, FORK1 ;
{
while ( true )
  {
      cout << "T" << #13;
     wait ( FORK1 );
     wait ( FORK5 );
       cout << "E" << #13;
     signal ( FORK1 );
     signal ( FORK5 );
   }
}
```

Figure 27: Phil_1 program – **before** and **after** changes

5. Students' Opinion

Trying to improve the quality and usefulness of the integrated environment TOST, moreover to get better results from its usage, we also rely on end-users' opinions. For this reason, in a span of two consecutive years, we conduct qualitative surveys with students at the end of the course. The survey used a 5-point Likert scale and is based on a relatively small sample of 131 bachelor students. The summary data for user acceptance of the presented tool are in Table 1.

Table 1: Opinion Survey Results

Survey questions	**A**	**B**	**C**	**D**	**E**
I like TOST environment	2	13	30	55	31
TOST is easy to learn	0	3	15	40	73
I think that programming in TOST is complex	75	29	11	12	4
TOST is visually very attractive	7	22	26	61	15
Overall, I am satisfied with the TOST approach to studying Operating systems	5	11	15	41	59
Overall, I am satisfied with the performance of the TOST environment	9	9	12	21	80
The installation process of TOST is quick and easy	0	0	3	5	123

Overall, I am satisfied with the experimenting with TOST example solutions in understanding concepts related to Mutual Exclusion, Synchronization, Deadlock, and Operating system in general	4	2	3	111	11
I think the interface of the TOST environment is user-friendly	8	5	39	57	22
TOST is successful and effective in stimulating Operating system algorithms and strategies	0	0	0	95	36

A: *strongly disagree*
B: *disagree*
C: *undecided*
D: *agree*
E: *strongly agree*

Based on the data presented, it can be assumed that the responses are positive. According to the majority, the TOST environment is easy to learn and use, user-friendly, useful, and supportive for their understanding of the fundamental concepts of operating systems and the problems concerning concurrent programming.

6. Conclusions and Further Research

Learning the concept and basic principles of Operating systems poses a great challenge to Computer Systems and Technologies students. In this paper, the authors present an integrated environment named TOST, specially designed to be used in Operating systems and Concurrent programming courses at Ruse University. A description of the TOST environment and a demonstration of how it can be very effectively used in teaching Operating systems principles are discussed, as well as some of the TOST features that address the learning of Mutual Exclusion, Interprocess Synchronization, and Deadlock.

The TOST includes a time-sharing operating system with compilers for two simple and easy to use programming languages. There are shared variables and semaphores variables for concurrent algorithms development. The ability to monitor the real-time information from basic OS tables allow students to gain a better apprehending of the algorithms, concepts, and theories behind the design, construction, and insights of operating systems.

The presented environment might be extended in the following directions:

- developing a built-in file system with a set of file allocation methods and management strategies;
- developing a spooling system for mediation between a process and slow peripheral devices;
- implementing complex data types and subroutines for the programming languages integrated.

We have been using TOST for several years in the Department of Computer Systems and Technologies at Ruse University and the student's feedback and results are positive. The lack of any installation procedure, the small size, and the 'copyleft' license allow TOST to be obtained and used without limitation and with full inclusivity.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Technology is advancing faster today than ever before with evidence of its impact in all facets of our lives. With the spread of the novel COVID-19 pandemic across the world, schools were closed as part of lockdown measures to contain the virus thereby disrupting academic curricula. Academic institutions leveraged ICTs to virtually engage students and teachers. Technology adoption will become a new reality for teaching and learning processes. However, the choice of adopting and not adopting this technology is based on an individual's decision on the benefits or risks in using this technology. The objective of this study is to find topical and relevant studies that have been conducted on technology adoption in education. A systematic literature review was adopted to classify and evaluate articles that fits pre-specified selection criteria using Google Scholar and IEEE databases. 132 papers were found to match the search criteria and filtered to 17 articles using applied exclusion criteria. Current research highlights the trends in technology adoption and provide empirical evidence of applications that have been used to implement technology in educational settings. This research also adds to new literature on COVID-19 in relation to its effect on academic curriculum across the world. Future research will investigate areas that can be expanded and improved on to leverage the benefits of ICTs to limit the adverse impact on the performance of teachers and students in the event of a disruption to academic activities.

1. Introduction

Technology adoption is the choice of an individual to acquire and use an innovation. Technology is advancing faster today than ever before with developments such as cloud computing, robotics, Internet of Things (IoT), Artificial Intelligence (AI), Machine Learning (ML), etc., opening fresh opportunities for value creation and contributing to our life experiences. There is a consensus in both industry and academia on the growing importance of technology as a robust means for survival in today's fast-paced and knowledge-driven world [1]. Evidence abound of its success and impact on teaching and learning via documented research studies [2-4].

Moreover, adopting or rejecting a new technology is based on an individual's perception of the benefits of using the tool to achieve a goal [5, 6]. Although technologies are advancing, the decision not to adopt has been categorised by poor innovation implementation, high cost, high failure rates, maintenance, poor technological planning, inadequate stakeholder participation [6-8]. An understanding of the factors affecting an individual's choice to adopt technology is essential both for stakeholders using these technologies as well as creators and producers of such technologies. Several theories and models exist to allow us understand the acceptance or rejection of a technology by an individual: This includes but not limited to Technology Adoption Model (TAM), Innovation Diffusion Theory (IDT), Unified Theory of Acceptance and Use of Technology (UTAUT), etc. [9].

The present research aims to fulfil the objective: To provide a summary of studies to determine the level of technology adoption in an academic setting. On this basis, a systematic literature review approach was employed to achieve this objective. Google Scholar and IEEE databases were searched using the keyword 'technology adoption and education or learning'. One hundred and thirty-two articles were initially obtained from the search. Inclusion and exclusion criteria were applied which reduced the list to 17 articles. These 17 articles were further analysed to fulfil the purpose of this research.

The next section presents the research method for this study. The result section provides the outcome of the literature review

*Corresponding Author: Kayode Emmanuel Oyetade, VUT, +27846514453 & kayoyetade@gmail.com

and the analysis of the selected literature. This is followed by the conclusion and possible area of future research.

2. Methodology

This section provides an overview of the research method used in the present research. The approach stipulated by [10] to conduct systematic literature was adopted.

2.1. Data sources and selection criteria

This paper reviews the adoption of various technology used in schools for teaching and learning. Therefore, the combination of the following keywords was applied: "Technology Adoption AND education OR learning". The title and abstract were checked for the occurrence of the keywords to ensure results are for articles focused on the study's research objective. English language was used to conduct this search to obtain a global perspective on the topic as well as avoid narrow searches. We limited our search to peer-reviewed texts available in online published journals and conference proceedings from Google Scholar and IEEE electronic databases.

The following inclusion criteria were deemed relevant for the present research:

- Studies on technology adoption application in education
- Studies that engage in any kind of technologies to support learning
- Studies written in English

The following exclusion criteria to remove articles not deemed fit for the current study:

- Studies that are not published as peer-reviewed journal articles and conference papers
- Studies not originally written in English language
- Studies whose full text is not available online and
- Studies discussing technology adoption but not with an educational focus.

3. Result

As presented in Figure 1, the search and refinement process followed six steps.

Step 1: Database search was conducted using the above-mentioned keywords. A total of 132 articles was realised. Step 2 focused on the application of the selection criteria by checking to remove duplicates due to the search using dual databases resulting in 130 articles. Step 3 reviewed the abstract to determine whether the article focused on the study's research objective and relevance to technology adoption. This allowed the study to remove 81 articles and left with 49 articles.

In step 4, full-text review was done on the 49 literatures for eligibility to provide a clear understanding of the research objectives. This allowed the study to exclude 8 articles which do not fit with reason resulting in 41 articles. Further qualitative review for quality assurance to ensure appropriateness and relevance to the research study was applied on these 41 articles. This allowed this study to arrive at a final list of 17 articles to be considered for review.

3.1. Review of the Selected Literature

One of the well-known success areas of technology adoption is the usage of m-learning in education. One of the motivations is the provision and easy access to learning content [11].

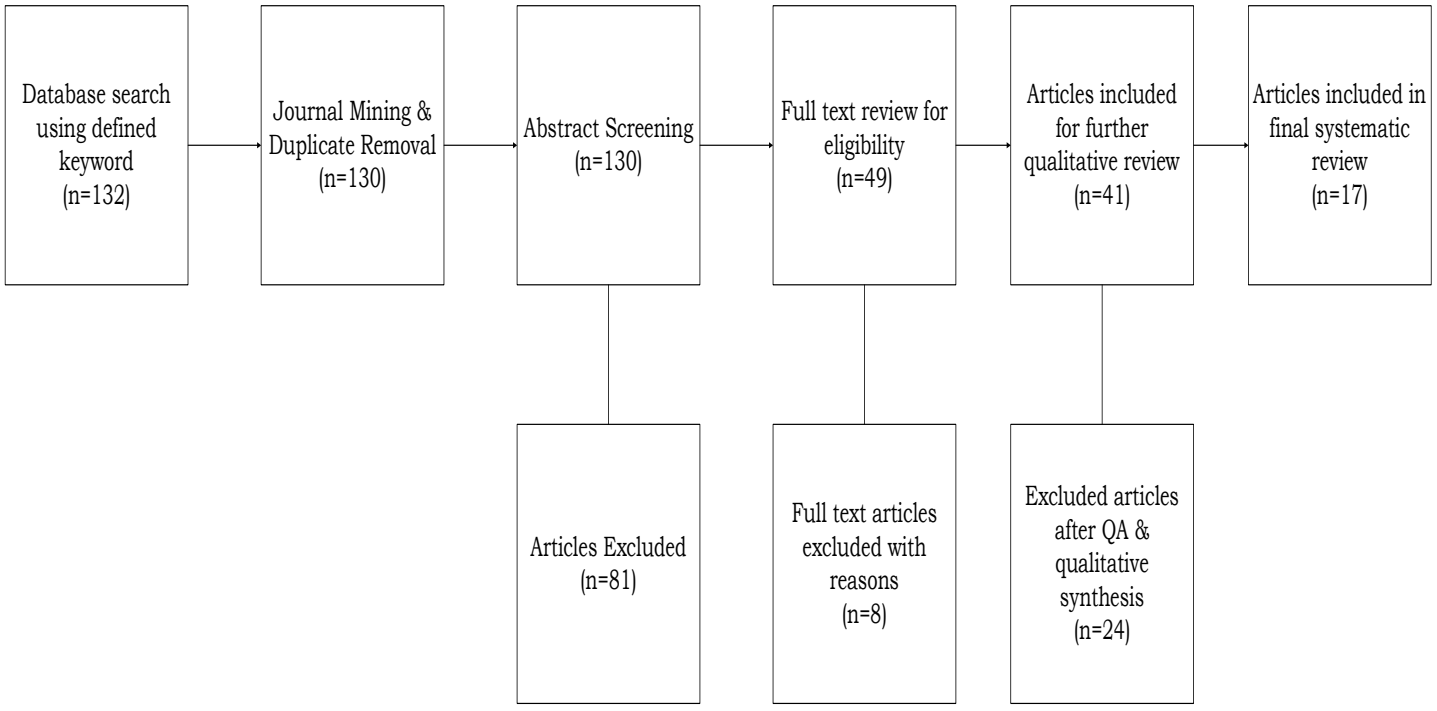

Figure 1: Steps to selection criteria and final outcome

A study by [12] used TAM to analyse factors that influence learner's technology adoption. They found that the factors economics, usefulness, suitability, ease of use, enjoyment, and social influence impact learners' adoption of m-learning to facilitate and promote learning. Likewise, [13] explored the capacity and acceptance of mobile instant messaging, an m-learning platform to increase student performance. They suggest that device portability, communication cost, collective capabilities, and learner control of the device are key factors of flexible learning in digital environments.

Evaluating the factors and effectiveness of e-learning adoption on student learning, [14] adopted the Interactivity Distance Education Web Learning (IDEWL), an enhanced online course creative and conferencing tool that integrates other add-on tools like online survey and e-blackboard for their study. There survey found e-learning effective with the enhancement of the interactivity modules in the students learning process.

On the other hand, [15] reported that the compulsory usage factor is essential for overall adoption of the e-learning system (ELS), either in a compulsory or voluntary setting. This is due to its effectiveness in promoting ELS as a core learning platform for students as well as discourage them from using other means to receive an education.

Similarly, [16] measured the factors that affect learners' adoption of blended ELS (BELS) and the perceived satisfaction of BELS according to their learning styles and gender differences. They report learning style did influence adoption of technology to provide flexible learning and improve understanding. In another related study, [17] examined the relationship between student's learning satisfaction and their use of video in a Moodle environment. He found that the use of video significantly impacted student's learning performance and satisfaction.

In answering student's willingness to learn using e-learning, [18] opines that designers of e-learning sites must ensure ease of navigating the web interface during the learning process. This designers must also ensure the quality of contents uploaded on the websites to enhance students learning while exploring college students learning attitudes with respect to their adoption of English e-tutoring websites. Using TAM as a theoretical framework for their study. There result showed that most users of English e-tutoring sites found online sources more effective and offer greater ease than traditional resources.

Furthermore, [19] conducted a study to examine key factors influencing the adoption of iPads using factors from extended TAM to design and deliver course content by academics. They found that University academics found iPads useful and easy to use with a high level of compatibility with their work.

Using the tablet devices in the classrooms, [20] reports that tablets impacts teaching and learning practices. This tablet devices provides a shift from the traditional way students learn to the media-rich and interactive environments. They therefore recommend stakeholders introduce educational and technical support to assist both educators' and learners' understanding of the benefit of these technologies in education.

Despite the growth and positive outcomes of technology adoption in education, [21] found that males and females do not differ in their belief about the usefulness of e-books. Usage of e-book in South African higher education corresponds to the effort and the external pressure exerted on students to promote the acceptance of e-books.

On mobile technology adoption for learning, [22] explored the correlation between students' ICT skills and factors that impact mobile technology adoption using the TAM framework. They found that basic and advanced ICT skills in mobile technology both played important roles in the intention to adopt m-learning.

Using mobile technology to enhance the convenience of teaching the English Language in Taiwan, [23] extended the factors of TAM to explain factors that affect the adoption of PDA. There result showed that extended TAM was effective in predicting and explaining the acceptance of English mobile learning.

To facilitate teaching and learning processes using the Learning Management Systems (LMSs) by University staffs, [24] used TAM extensions to identify factors that influence LMS usage behaviour and their underlying causal relationships. The analysis of data reveal that the proposed factors were significant predictors of faculty staff attitude towards LMSs. This confirms the validity of the extended TAM in determining users' technology acceptance.

In testing the effectiveness of a Blackboard (Bb) course management system (CMS), [25] used an experimental and control group to conduct his test on English writing instruction in and outside of the Bb environment. The experimental group achieved encouraging results than the control group thereby contributing to learning English writing using Bb. They also identified attitude, perceived usefulness, perceived ease of use, and technical support affect the adoption of CMS.

In [26], authors studied the effect of experience on students' intention to adopt webcast and found that students with previous experience in educational webcasts are most likely to adopt webcast. Ease of use and usefulness were found to be important factors in determining students' BI to use webcasts for learning purposes. They recommended that Webcast developers should pay attention to learners' intrinsic motivations and make them feel comfortable when using the environment for learning.

In conclusion, [27] extended the TAM model to explain the adoption and usage behaviour of social media users in higher education. It was found that subjective norm, perceived usefulness, perceived playfulness (happiness), and perceived ease of use strongly predict students' social media usage behaviour. Their findings suggest that social media use in classrooms should continue in higher institutions. This is because the intention to use translate to the actual use of this ICT tools.

The above review shows technology adoption has the potential to be used as an effective educational platform either directly or as an alternative tool for teaching and learning process.

4. Results of the Review

From the 17 articles examined, this section presents other findings from the above review and discusses the outcomes of the issues related to technology adoption as follows:

4.1. Publication History and Frequency

Figure 2 shows the history and frequency of the identified articles selected for review. We observe the number of articles remains reasonably constant (2006-2012) with a noticeable peak in 2015. The low volume of publications between 2016 and 2019 could be related to our exclusion criteria which may have led to the omission of recent literatures. However, the existence of up-to-date papers lends itself to continuing research efforts and trends of technology adoption in education.

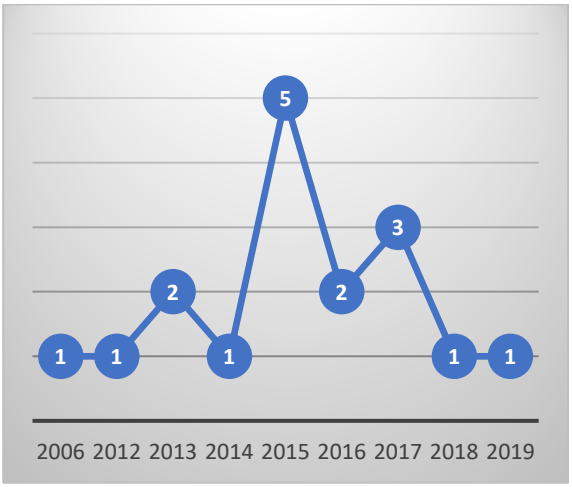

Figure 2: Publication History and Frequency

4.2. Publication Type

From the review of identified literature, Figure 3 presents the result of the articles reviewed by the publication type. It was observed that most of the articles (88%, 15 articles) were obtained from published journals and the remainder (12%, 2 articles) are conference proceedings. The different sources of articles for the current research eliminate possible publication bias.

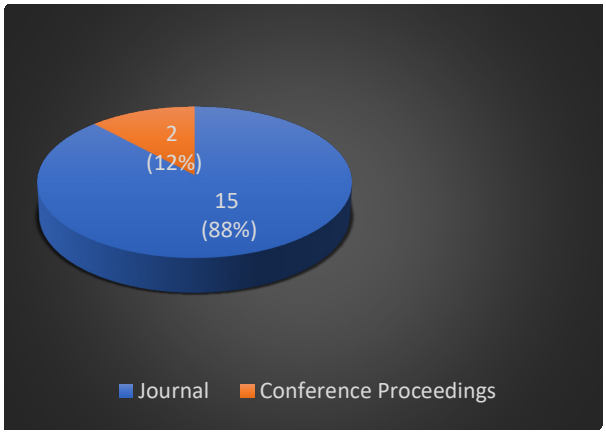

Figure 3: Publication Type

4.3. Word Cloud of technology adoption tools

As evidenced by the articles reviewed, Figure 4 shows the various technology adoption tools adopted for teaching and learning in education. M-learning and e-learning are mostly used technology. Other tools are classified into these two categories.

Figure 4: Word Cloud of Technology Adoption Tools

Even though, this research followed the steps for conducting a systematic review as specified by [10], it is not without limitations. For instance, the review results are limited to the search keywords used, and thus some studies may not have been included. However, we attempted to compensate for this by also relying on related recent literature reviews.

5. Future Research

Future research will investigate areas that can be expanded and improved on to increase the predictive performance of the Technology Adoption in education to support student's academic achievements.

6. Conclusion

The potential of technology has been identified in the above reviewed literature [14-17]. However, these technologies were blended with face to face interactions [25]. With the recent wave of the COVID-19 pandemic and the closure of schools, many schools were forced to seek alternative and virtual means of keeping the curriculum going using appropriate and connective technologies. This implies that technology adoption will gradually become a new normal in education as countries are gradually opening economic and academic activities that were affected by the COVID-19 pandemic.

Although a range of technologies is used in education, e-learning and m-learning are the major tools adopted by many institutions to enhance teaching and learning as identified in the reviewed literature. However, despite the usage of technology adoption as reported in this study, [28-29] reports present findings on the challenges faced with the adoption of technologies as related to COVID-19. This includes affordability and availability of connectivity to the internet to access academic resources while most educators lack the technical support needed to use this ICTs.

The current study implemented a systematic literature review approach to provide a general picture of the usage of technology in education. Google scholar and IEEE databases were searched for articles published in online journals or conference proceedings from 2006 to 2019. The keyword Technology Adoption AND

education OR learning was which resulted in an outcome of 132 articles. This was reduced to 17 articles for in-depth analysis using defined selection criteria. The researchers specifically conducted an analysis of contributions considering the research objectives that covered the year of publication, publication type, technology adoption platforms employed in the research study.

The findings highlight that technology is a relevant tool in schools to deliver the learning needs of 21st century students as learners prepare to return to schools with the lifting of barriers to academic activities. It is believed that the current COVID-19 challenge will change academic curricula and lead to the prevalent usage of technology in the future.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The present research has been prepared by Kayode Emmanuel under the supervision of Dr Anneke Harmse and Prof Tranos Zuva and supported by the Department of ICT at the Vaal University of Technology, Vaal, South Africa.

A B S T R A C T

Technology Acceptance Model (TAM) is broadly accepted and has proved applicable in identifying consumers' willingness to utilize information and communication technology (ICT). The theory proposes that Perceived Ease of Use (PEOU) and Perceived Usefulness (PU) are actually determining factors of individual attitudes, while attitude is a determining factor of Behavioural Intention (BI) and Behavioural Intention (BI) influences usage. It is necessary to understand the usage and modifications that have been made to Technology Acceptance Model (TAM) since user acceptance and confidence are of great importance for advance improvement and successful implementation of any new technology. Numerous frameworks and models have been designed and created to describe user acceptance of modern innovations. These models introduced factors that contribute towards user acceptance. This is a review paper on understanding the usage, modifications, limitations, and criticisms of Technology Acceptance Model (TAM). The model has been utilized to measure new different technologies for usage as well as adoption. The literature indicates that the modification of the model was mostly the addition or removal of variables and in some cases the addition of moderators or mediators. The model has limitations identified in literature such as the problem of reliably quantifying behaviour in an observed investigation. Moreover, there are notable criticisms identified in literature such as TAM's incapability of noticing other issues, for example, cost and structural imperatives that pushes users to adopt an innovation. TAM will continue to be accepted and modified according to the successful application of any new technology. This study can be used to enhance users' knowledge of usage, modifications, limitations, and criticisms of Technology Acceptance Model (TAM).

1. Introduction

Academics and practitioners have developed an interest in recognizing the factors that affect users' acceptance or denial of modern innovation [1]-[5]. Providing an answer to this question might assist them to improve techniques for assessing, predicting, and designing the feedback of customers to the new innovations [6]. Technology Acceptance Model (TAM) and frameworks were implemented in an expansive range of domains to comprehend and foretell users' behaviour for instance fasting, education, elections, etc. [7].

Numerous researchers in the discipline of technology acceptance, improved models, and frameworks to evaluate the utilization of modern innovations. These models introduced factors that contribute towards user acceptance [4]. TAM has been repeatedly studied and being extended to the two important upgrades named the TAM2 [8] and the Unified Theory of Acceptance and Use of Technology (UTAUT) [9]. TAM3 which includes the effects of use and perceived risk on system utilization in the circumstance of e-commerce was proposed by [10]. Numerous studies have utilized these traditional systems to carry out their studies and the remaining joint past models [11]. Great innovation and implementation may be planned and improved but if human beings do not partake and utilize it, the project is unsuccessful, therefore, user acceptance is not a deniable key of any continuous application and improvement of any innovation and implementation [4].

This paper aims to determine and understand usage and modifications, limitations, and criticisms of Technology

* Corresponding Author: William Ratjeana Malatji, villywr@gmail.com

Acceptance Model (TAM) for IT acceptance. User acceptance and confidence are of great importance for further improvement and to the successful application of any new innovation. Due to above-mentioned reason, it is necessary to determine and understand the usage and modifications that were made to Technology Acceptance Model (TAM). Therefore this paper is arranged as follows; Background, TAM criticisms and limitations, and conclusion.

2. Background

Growing the interest of customers' response toward Information Technology (IT) increased the significance of theories and models that foretell and describe information technology acceptance and utilization [4]. Researchers accepted and used theories and models such as Theory of Reasoned Action (TRA), Social Cognitive theory (SCT), Technology Acceptance Model (TAM), Theory of Interpersonal Behaviour (TIB) etc. to evaluate the usage of new innovations [4]. Several studies utilized these original frameworks to carry out their researches; however, in this paper TAM is the main focus.

2.1. Technology Acceptance Model

Technology Acceptance Model is one of the greatest leading extensions of [12]'s Theory of Reasoned Action (TRA) in the related works. In the 1980s TAM was created, given that employees were not utilizing Information Technologies made accessible to them [13]. Its founders highlighted that the way to multiplying the use was to initially multiply acceptance of information technology, which might be evaluated by questioning persons regarding their future intentions to utilize information technology [14]. Recognizing elements that formed a person's intentions might enable organisations to modify those factors so that they can improve acceptance and therefore multiply IT utilization [14].

An earlier TAM study found that three variables were required to describe, foretell and manage acceptance [15]. To reach this model, the founders adopted TRA, a universal social-psychological or behavioural theory which was confirmed suitable for comprehending different behaviours for example; exercise, condom use and voting [15]. As it was usual to adapt such theory to new circumstances, an introductory study was carried out to discover what could be the proper variables to add on comprehending IT utilization behaviour [12]. The variables chosen and created the first model of TAM are described in Table 1.

According to [16] TAM substitutes numerous attitude measures of the TRA with multiple technology acceptance measures namely, ease of use and usefulness. Moreover, TAM and TRA, which both contain powerful behavioural components, presume that when an individual develops a willingness to take action, that individual will act freely without any limitation. It is necessary to expand TAM to incorporate variables that are responsible for changing methods and that this can be attained by adopting the innovation Model into TAM [17].

2.2. Usage and Modifications of TAM

Numerous researchers have used TAM to carry out their studies. TAM was used by [18] to investigate the learning effectiveness of utilizing IT as a learning podium. The findings of the study highlighted that PEOU, PU, and perceived playfulness might all be utilized to efficiently foretell the learning behavioural intention of scholars (the variables are explained in detail in Table 1). The theory of planned behaviour and the expectation-confirmation model was used for two hundred and seven mobile information system users to investigate their behavioural intention to continue utilizing the system [19]. The findings of the study highlighted that consumer approval, PU, and perceived playfulness remained the main components for consumers to carry on utilizing the system.

TAM was used by [19] to examine Chinese clients' behavioural intention about instant messenger. The conclusion was reached that PU and perceived playfulness directly affect clients' attitudes. Using the theory of planned behaviour, it was found that social norm and perceived behavioural control might as well have a direct influence on BI. Moreover, [20] carried out a study on the utilization of emails and file processing software by one hundred and twenty workers in IBM Canada Laboratory. They discovered that workers' PU, PEOU, and software utilization were positively and significantly correlated.

TAM was used by [21] to study the behavioural intention (BI) of scholars in the higher institutions of learning and utilize a web-based application evaluation framework as an instrument to assess their specialised capability in e-book creation. The study discovered that participants' computer self-efficacy positively influence PEOU and PU. Participants' PU and PEOU also had considerable and direct influences on their intention to utilize the framework. Thus, when a person possesses greater computer self-efficacy with a greater point of view of the usefulness and ease of use of the web-based valuation framework, that individual will be more willing to utilize the framework.

TAM theory went through numerous changes. For example, an upgraded named TAM2 erased attitude (ATT) variable from the model, which initially arbitrated some of the effects of PU and PEOU. TAM2 also included a variable meant to capture the social influence that forces end-users to positively assess and welcome information technology, named subjective norm (SN) [9]. The connection amongst variables which were hypothesised from the theory that proposes and motivates the combination of TAM and DIT are:

- Social influence negatively impacts complexity of understanding.
- Social influence positively impact triability.

Lately, an impressive attempt to merge the information technology acceptance writings brought about the UTAUT (defined in Table 2), a theory with clear similarity to TAM [9]. UTAUT includes PU into a performance expectancy construct, PEOU into effort expectancy and SN as social influence (the terms are defined and explained later in Table 1). Modern to UTAUT, but not to the information technology acceptance study generally is the modelling of easing circumstances as one determining factor of behavioural intention [22]. UTAUT is a modern but capable theory; Prior experiments of UTAUT described a magnificent 70 percent of the variance in behavioural intention and at most 50 percent in actual use [22]. It has been embraced by current studies in healthcare, this include:

- The Modern Portfolio Theory (MPT): Independent of TAM, [23] designed the technology model and matching human being as part of national science foundation-funded dissertation research. The modern portfolio theory is fully explained in Scherer (2005)'s text.
- The Hedonic-Motivation System Adoption Model (HMSAM): TAM has been successful in describing multiple systems utilization (i.e. E-Learning, web portals, learning management system, etc.) [24, 25]. Nevertheless, TAM is not preferably relevant to describe the adoption of completely inherent or hedonic frameworks (e.g. learning for pleasure, music, online games etc.). HMSAM was developed to better the understanding of the Hedonic-Motivation System Adoption Model [26].
- Extended TAM: Numerous studies suggested an expansion of original TAM by including variables that are external on it with an intention of investigating the outcomes of factors that are external on user attitude, actual use and behavioural intention of an innovation [24, 25]. This model became implemented in acceptance of health care innovations [27].

Technology Acceptance Model and its improved versions are not appropriate for all applications since they exclude main constructs such as perceived risk[28]. Therefore TAM has also turned out to be an accepted model that can be expanded and adjusted [28, 29].

The table below lists and defines the variables in TAM and related models since TAM theory has undergone numerous changes.

Table 1: TAM variables and related models

Variable	Definition	Models that include the variable
Behaviour Use (BU).	One particular behaviour of interest made by persons with great consideration to a certain information system.	TRA/TPB, TAM, TAM2, UTAUT.
Behavioural Intention (BI)	A person's inspiration or intention to apply an effort to carry out the objective behaviour.	TRA/TPB, TAM2, TAM, UTAUT
Attitude (ATT)	A person's evaluative decision of the objective behaviour on a certain dimension.	TAM, TRA/TPB
Perceived Ease of Use (PEOU)	A being's point of view that utilizing an IT framework will be effortless	TAM, TAM2
Perceived Usefulness (PU)	A being's point of view that utilizing IT framework will improve job performance	TAM, TAM2
Subjective Norm (SN)	A person's point of view of the degree to which significant people favour or are not in favour of the objective behaviour	TAM2,TRA /TPB
Perceived Behavioural Control (PBC)	A being's point of view regarding how simple or hard it might be to make the objective the behaviour of elements that hinder or ease the behaviour, or of the amount of control that a person has above performing the behaviour	TPB
Effort Expectancy	(Refer PEOU)	UTAUT
Performance Expectancy	(Refer PU)	UTAUT
Social Influence	(Refer SN)	UTAUT
Facilitating Conditions	(Refer PBC)	UTAUT
Behavioural beliefs, normative believes and control beliefs	A person's point of view regarding particular positive or negative results of applying objective behaviour, particular groups or individuals who promote or depress the behaviour and particular factors or situations simplify behaviour or make it more complex	TRA/TPB

2.3. Summary of TAM and Modified versions

Technology Acceptance Model has been modified and the table below lists the summary of TAM and modified versions together with their aims.

Table 2: Summary of TAM and modified versions aims

TAM and modified versions	Model Aim	Source
TAM	TAM was created to understand the natural sequence joining external variables to its user acceptance and natural utilization in an establishment. TAM helps in comprehending the background of perceived ease of use.	[30]
TAM2	TAM2 intends to comprehend perceived usefulness in order to create working place involvements that would increase user acceptance of new framework.	[9]
UTAUT	UTAUT shapes a unified model as a suitable instrument for managers requiring to measure the probability of success for modern technology outlines.	[9]
TAM3	TAM3 offers a combined model with significance assigned on perceived usefulness and perceived ease of use so that it can address how managers and people who make decisions can make informed decisions regarding interventions	[10]

3. TAM criticisms and limitations

TAM has been cited by numerous researchers due to its simplicity without taking into consideration, an actual application in their researches. In this section, some of the TAM criticisms and limitations are presented considering, utilization of the model technology-related studies in various disciplines.

3.1. TAM criticisms

TAM has been broadly criticized, regardless of how it is being frequently used, leading the founders to try to re-explain it

numerously. TAM criticisms as a "theory" incorporate contentious heuristic value, restricted descriptive and foretelling capability, criticism triviality and short of any practical value [31]. TAM changed researchers' attention by moving it away from other significant research matters and it has caused the impression of progression in accumulating knowledge[31]. Moreover, various researchers have independently tried to extend TAM so that it can adapt to the continually changing information technology environments which resulted in a state of theoretical havoc and uncertainty [31].

Generally, TAM is based on a being's utilization of a computer, with an abstract idea of PU and disregarding essential social methods of Information Systems (IS) development and application, with no question that "where many technologies are actually best and social after-effects of using Information Systems (IS)" [31]. The system of PU and PEOU fail to notice other issues, for example, cost and structural imperatives that push users to adopt a new innovation [32].

According to [33] both TAM and TAM2 take responsibility for at most 40% of a technological framework's utilization. Some researchers gone through the limitations of TAM implementation under organisation setting into details, and indicated that better predictive capability can be reached even with the easy, simply applicable model when exact first screening methods are implemented [34].

Studies conducted by [35-37] found that PEOU is unlikely to become a determining factor of ATT and intention to use. Moreover, [34] reported the same results when researching on the adoption of Blockchain technology.

The study carried out by [38] revealed that PEOU has no impact on the adoption of multimedia online innovations for Malaysian small and medium-sized enterprises (SMEs). Similar findings were outlined by Hong Kong when evaluating small and medium-size enterprises (SMEs) [34].

3.2. TAM limitations

Several conditions must be taken into account so that a theoretical framework can be applied and researchers must be aware of the numerous limitations that exist. To better comprehend the factors that encourage improved utilization of information technology (IT), it is compulsory to have a broad theoretical and application knowledge of structures and frameworks through which IT utilization is investigated [39]. One of the restrictions of TAM relates to the variable that refer to the behaviour of clients, which is necessarily assessed over subjective measures like behavioural intention and interpersonal influence [39]. However, social influence as the subjective norm refers to when an individual is influenced by "word of mouth" from a fellow worker [39].

The second limitation of TAM is that underlines of behaviour is unable to be quantified reliably in an observed research, owing to various multiple subjective elements, for instance, values and norms of societies, individual features and personality attributes [40, 41]. Consequently, a relative, friend argument that could influence technology use through demanding social influence is extremely fabricated [40, 41] . Even though it might be correct in theory or for individual utilization of innovation, the concept might not be credible or precise in a working environment.

4. Conclusion

In the research area, many models and frameworks were proposed by researchers to explore the user acceptance behaviour on information technology and information systems. In the 1980s TAM was created, given that employees were not utilizing Information Technologies (ITs) made accessible to them. Numerous researchers in the discipline of technology acceptance, improved theories and frameworks to evaluate the utilization of recent innovations and these frameworks introduced factors that can influence user acceptance. This led TAM theory to go through numerous modifications. Writers and researchers have criticized the TAM model in terms of its variables. This study aims to determine and understand the usage and modifications of Technology Acceptance Model (TAM) for IT acceptance.

ABSTRACT

The adoption of technical decisions in the development of a new aircraft is carried out under the condition of insufficient information on the mass - dimensional and aerodynamic characteristics that will be achieved during the project. Insufficient information on the input parameters (weight and aerodynamic characteristics) leads to uncertainties in the values of the flying qualities and performances. When creating a new aircraft, the chief designer and specialists of the design bureaus establish certain reserves (limits) for mass and aerodynamic characteristics. The allocation of reserves for the characteristics of aircraft elements is carried out, as a rule, on the basis of experience gained from previous projects, and to a certain extent subjective. At the same time, it is not possible to quantify the risk of non-fulfillment of the tactical and technical task in terms of performance characteristics. Knowing the contribution of the uncertainties of the input parameters (for the values of which a margin is allocated) to the uncertainty of the final values of the flight characteristics will allow the person who makes the decision to reasonably establish reserves in the design of the aircraft and take a more reasonable risk. In this paper, the authors describe an approach that allows for a quantitative assessment of the impact assessment of the errors in determining the aircraft's characteristics on the tactical and technical task in terms of the aircraft's performance data. Using the example of the mass and zero lift-drag coefficient, analytical dependencies are derived that allow a quantitative assessment of the effect. To verify the obtained analytical dependencies, the calculation of weight coefficients was made for several aviation complexes of operational-tactical aviation. The analysis of the sensitivity of the aircraft's performance data to the parameters under consideration is carried out.

1. Introduction

When developing new aircraft, the most important decisions that determine the future fate of the project are made at the initial stages of work in conditions of uncertainty about the impact of these decisions on the performance of the – tactical and technical task (TTT). Mistakes in the early stages of design tend to cost more money and time for their elimination at the subsequent stages of the aircraft, and sometimes on the correctness of decisions depends on the feasibility of the project as a whole.

The uncertainty of the performance of the tactical and technical assignment in terms of flight characteristics at the stage of internal and external design is associated with many factors. For example, a delay in the receipt from related enterprises of reliable data on the characteristics of aircraft systems (such as engine, target equipment, etc.), insufficient knowledge of some physical laws, which is most pronounced when new technical solutions are introduced, and others.

When predicting the level of performance characteristics of a new aircraft, they rely on indicators of its technical perfection, which will be achieved as a result of the project. These include the relative mass of the structure and systems, specific engine thrust, specific fuel consumption, aerodynamic quality, and others. With the development of aviation, these indicators are constantly improving.

The choice of a reasonable level of technical excellence, and therefore TTT in the design of a new aircraft, is an important task. Excessive overestimation of the requirements for its weight and

*Corresponding Author: Laushin Dmitry Andreevich, 125993, Moscow, Volokolamskoe shosse, 4, Moscow Aviation Institute (National Research University), Email: laushin.d@yandex.ru; maksmai33@gmail.com

aerodynamic characteristics can lead not only to non-fulfillment of the promising requirements for flight performance, but also deterioration of the flight characteristics of the designed aircraft relative to the current level already achieved due to the mismatch of the characteristics of its elements. At the same time, the use of previously developed technical solutions and technologies, in which there is no risk, does not make it possible to ensure the required increase in flight performance and, as a consequence, efficiency in the development of new generation aircraft. Therefore, at the initial design stage, when applying certain technical solutions, it is necessary to have a clear idea of the real possibilities of performing the performance characteristics specified in the TTT.

In accordance with the existing design methodology, when creating a new aircraft, the chief designer and specialists of the design bureaus establish certain reserves (limits) for mass and aerodynamic characteristics. The reason for the allocation of such reserves is that at the initial design stage there is no exact idea of the final value of mass and aerodynamic characteristics, which will be obtained upon completion of the development stage. Each aircraft has its own targets. Therefore, the characteristic for which the reserve is allocated depends on the specific type of aircraft. For example, the characteristics of a commercially available engine are known values. If the power plant is at the development stage, there is a risk of non-implementation of the TTT of the engine, which may affect the non-implementation of the TTT of the aircraft. The use of insufficiently mastered materials or technologies in the aircraft structure can lead to a significant deviation in the mass characteristics of the airframe units, etc. Therefore, the identification of the main elements that introduce uncertainty in the level of aircraft performance should be made in each case specifically.

The allocation of reserves for the characteristics of aircraft elements is carried out, as a rule, on the basis of experience gained from previous projects, and to a certain extent subjective. At the same time, it is not possible to quantify the risk of non-fulfillment of TTT in terms of performance characteristics. Knowing the contribution of the uncertainties of the input parameters (for the values of which a margin is allocated) to the uncertainty of the final values of the flight characteristics will allow the person who makes the decision to reasonably establish reserves in the design of the aircraft and take a more reasonable risk.

Approaches to the formation of the appearance of an aircraft with inaccurate determination of the initial data are reflected in many scientific works, for example [1-10]. The relevance of this issue is also confirmed by scientific works [11-15].

To assess the technical solutions adopted in the design, it is necessary to associate particular changes in various parameters (weight, aerodynamic characteristics) with a change in the aircraft flight characteristics.

2. Materials and Methods

Let's introduce the concept of the influence coefficient (IC) – a dimensionless coefficient showing the ratio of the change in function (f) to the change in input parameters (x_i) in the relative form:

$$K_{x_i_f} = \frac{\Delta \hat{f}}{\Delta \hat{x}_i} \quad (1)$$

where $\hat{f} = \frac{\Delta f}{f_1}$, $\Delta \hat{x}_i = \frac{\Delta x_i}{x_{i_1}}$, Δf and Δx_i – uncertainty of the function and the input parameters, f_1 and x_{i_1} - expected value of the function and the input parameters.

In the absence of a relationship between the initial parameters, ICs are the coefficients of linear decomposition of the inaccuracy of determining the function from the errors in determining the parameters (in the relative form):

$$\frac{\Delta f}{f_{expect}} = \sum_{i=1}^{n} K_{x_i_f} \frac{\Delta x_i}{x_{i_{expect}}} \quad (2)$$

The numerical value of the IC is equal to the percentage change of flying qualities and performances (FQP) when the parameter changes to 1%.

This paper assesses the influence of such parameters as mass (m) and zero lift-drag coefficient (Cx_0) on:
- maximum flying speed - V_{max};
- service ceiling - H_{max};
- specific excess power (max) - V_y^*;
- sustained load factor - n_y;
- acceleration time - t_p.

For a comprehensive study of the considered IC, the research is carried out in two directions:
1. Analytically, by deriving IC from the formula dependencies of the FQP;
2. Numerical calculations of the IC by calculating the changes in FQP with varying mass and zero lift-drag coefficient.

The analytical method makes it possible to establish the dependence of IC on specific aircraft parameters. These dependencies are derived from the flight dynamics formulas and can be applied to absolutely any aircraft with a similar flight principle. However, to represent the dependencies in a relatively simple and easy-to-use form, it is necessary to introduce some assumptions that can be used to perform the required mathematical transformations. The formulas obtained require verification, since one and the same introduced assumption can give different errors in magnitude, depending on the type of aircraft and its purpose.

The verification of the derived formulas for IC can be carried out by the calculation method. The computational method, in contrast to the analytical one, allows one to obtain the exact value of IC (without assumptions), but does not allow one to establish the dependence of IC on the aircraft parameters. The IC is calculated using the FQP calculation program detailed in section 2.

Thus, comparison of the analytical findings with numerical calculations allows to prove the accuracy of the first.

3. Calculation of the influence coefficient by analytically method

For various parameters, the degree of their uncertainty can differ significantly depending on the level of elaboration of certain elements of the aircraft. The accuracy of calculating the mass of

aircraft at the stage of the preliminary project is 6-10%, outline design 3-5%, working draft 1-2% [5].

The influence coefficient, as described above, is indicated $K_{x_{i_f}}$. According to the IC mass for sustained load factor is indicated $K_{m_n_y}$, IC C_{x_0} to specific excess power - $K_{C_{x_0}_V_y^*}$, etc. We use the following notation:

$\Delta\widehat{m} = \frac{m_2 - m_1}{m_1}$ $\Delta\widehat{Cx}_0 = \frac{Cx_{0_2} - Cx_{0_1}}{Cx_{0_1}}$ – relative changes in mass and zero lift-drag coefficient.

3.1. The influence of parameters on maximum flying speed

The maximum flying speed can be expressed from the equality of thrust and drag:

$$V_{max} = \sqrt{\frac{2P_{max}}{(C_{x_0} + C_{x_i})\rho S}} \quad (3)$$

where C_{x_i} – inductive reactance coefficient, P_{max} – thrust at which maximum speed is reached, S – wing area, ρ – air density.

The inductive component of resistance when flying at maximum speed is small. In this case $C_{xi} \approx 0$ and the maximum flight speed can be calculated by the formula:

$$V_{max} = \sqrt{\frac{2P_{max}}{C_{x_0}\rho S}} \quad (4)$$

Let's get the formula for $K_{Cx_0 - V_{max}}$:

$$K_{Cx_0 - V_{max}} = \frac{\frac{V_{max2}}{V_{max1}} - 1}{\frac{Cx_{0_2}}{Cx_{0_1}} - 1} = \frac{\sqrt{\frac{Cx_{0_1}}{Cx_{0_2}}} * \sqrt{\frac{P_2}{P_1}} - 1}{\frac{Cx_{0_2}}{Cx_{0_1}} - 1}$$

Let $\tilde{c} = \frac{Cx_{0_2}}{Cx_{0_1}}$, and the coefficient $\tilde{p} = \frac{P_2}{P_1}$ will show the characteristics' flow of the altitude-speed performance (ASP) (with a change in V_{max}, the engine thrust will change). Then the influence coefficient Cx_0 to V_{max} will be equal to:

$$K_{Cx_0 - V_{max}} = -\frac{1 + \sqrt{\frac{\tilde{p}}{\tilde{c}}}}{\tilde{c} - 1} \quad (5)$$

The coefficient $\tilde{p}$ corresponds to a specific aircraft because its value is influenced by both the engine's ASP and the intake losses ($\Delta\bar{p}_{вх}$) and nozzle ($\Delta\bar{p}_c$):

$$\tilde{p} = f(\Delta\bar{p}_{вх}, \Delta\bar{p}_c, \tilde{c}) \quad (6)$$

The maximum flying speed is not always determined by the required and available thrusts. Limitations may include temperature, structural strength, stability and control of the aircraft.

As described above, it may be concluded that the biding of the coefficient $K_{Cx_0 - V_{max}}$ to the parameters of the aircraft is impractical, because it will not give a true picture of understanding the impact of the change Cx_0 to V_{max}.

3.2. The influence of parameters on service ceiling

The effect changes on the ceiling can be estimated by the formula [16]:

$$\Delta H_{max} = -6.3\Delta m\ [km] \quad (7)$$

In this case, IC will be equal to:

$$K_{m_H_{max}} = \frac{\frac{Hmax_2 - Hmax_1}{Hmax_1}}{\frac{m_2 - m_1}{m_1}} = \frac{\frac{-6.3\Delta\widehat{m}}{Hmax_1}}{\Delta\widehat{m}} = \frac{-6.3}{Hmax_1}$$

$$\boldsymbol{K_{m_H_{max}} = -\frac{6.3}{H_{max}}} \quad (8)$$

The value of the coefficient is related to the initial ceiling of the aircraft and does not depend on the percentage change in mass (Table 1).

Table 1: The dependence of $K_{m_H_{max}}$ on the service ceiling.

Initial ceiling H_{max}, km	$\boldsymbol{K_{m_H_{max}}}$	$\Delta\widehat{m}$	ΔH_{max}, %	ΔH_{max}, m
20	**-0.315**	0.01 (1%)	0.315	63
		0.05 (5%)	1.575	315
18	**-0.35**	0.01 (1%)	0.315	63
		0.05 (5%)	1.575	315
16	**-0.394**	0.01 (1%)	0.315	63

In order not to become attached to the initial ceiling, it makes sense to speak not about a relative change in H_{max}, but about the absolute. Therefore, with an increase in mass by 5% the ceiling decreases by 315 meters, 10% - 630 meters. An increase in the mass of 1% leads to a decrease in the ceiling of about 63 meters.

3.3. The influence of parameters on specific express power

In order not to become attached to the initial ceiling, it makes sense to speak not about a relative change in H_{max}, but about the absolute. Therefore, with an increase in mass by 5% the ceiling decreases by 315 meters, 10% - 630 meters. An increase in the mass of 1% leads to a decrease in the ceiling of about 63 meters. We write the specific excess power as follows [16]:

$$V_y^* = \frac{P - X}{G} V \quad (9)$$

where P – engine thrust, X – aircraft drag, G – aircraft weight, V – flight speed.

We assume that the flying speed at which the specific excess power is calculated is constant ($V_1 \approx V_2$), then $K_{m_V_y^*}$ will be equal to:

$$K_{m_V_y^*} = \frac{\frac{V_{y_2}^*}{V_{y_1}^*}-1}{\frac{m_2}{m_1}-1} = \frac{\frac{m_1}{m_2}\left(\frac{P-X_2}{P-X_1}\right)-1}{\frac{m_2}{m_1}-1} = \frac{\frac{m_1}{m_2}\left(\frac{P-X_1-\Delta X_i}{P-X_1}\right)-1}{\frac{m_2}{m_1}-1} = -\frac{1-\frac{m_1}{m_2}\left(1-\frac{\Delta X_i}{P-X_1}\right)}{\frac{m_2}{m_1}-1} = \left\langle t=\frac{m_2}{m_1}; K_{X_i}=1-\frac{\Delta X_i}{P-X_1}\right\rangle = -\frac{1-\frac{K_{X_i}}{t}}{t-1}$$

$$\boldsymbol{K_{m_V_y^*}} = -\frac{\mathbf{1}+\frac{\boldsymbol{K_{X_i}}}{\boldsymbol{t}}}{\boldsymbol{t-1}} \quad (10)$$

where $t=\frac{m_2}{m_1}; K_{X_i}=1-\frac{\Delta X_i}{P-X_1}, \Delta X_i$ - increase in inductive component due to mass increase, $\Delta P = P - X$ – abundance of power.

Note that the higher ΔP, the smaller contribution to the value of the IC makes ΔX_i. With small changes in mass (in this case $\Delta X_i \to 0$) and a relativity high value of ΔP we can assume that $K_{m_V_y^*} \approx -\frac{m_1}{m_2}$. Then at Δm=10% $K_{m_V_y^*} \approx -0.91$, and the coefficient value without the assumptions described above will be even less.

We similarly take out $K_{C_{x_0}_V_y^*}$:

$$K_{C_{x_0}_V_y^*} = \frac{\frac{V_{y_2}^*}{V_{y_1}^*}-1}{\frac{Cx_{0_2}}{Cx_{0_1}}-1} = \frac{\left(\frac{P-X_2}{P-X_1}\right)-1}{\frac{Cx_{0_2}-Cx_{0_1}}{Cx_{0_1}}} = \frac{\left(\frac{P-X_1-\Delta X_0}{P-X_1}\right)-1}{\frac{Cx_{0_2}-Cx_{0_1}}{Cx_{0_1}}} = -\frac{1-\frac{\Delta X_0}{P-X_1}-1}{\frac{Cx_{0_2}-Cx_{0_1}}{Cx_{0_1}}} =$$

$$\left\langle \tilde{c}=\frac{Cx_{0_2}}{Cx_{0_1}}\right\rangle = -\frac{\Delta X_0\, Cx_{0_1}}{\Delta P\left(Cx_{0_2}-Cx_{0_1}\right)} = -\frac{\left(Cx_{0_2}-Cx_{0_1}\right)\frac{\rho V^2 S}{2} Cx_{0_1}}{\Delta P\left(Cx_{0_2}-Cx_{0_1}\right)} = -\frac{X_0}{\Delta P}$$

$$K_{C_{x_0}_V_y^*} = -\frac{X_0}{\Delta P} \quad (11)$$

If we neglect the inductive component of the resistance, then the formula takes the form:

$$\boldsymbol{K_{C_{x_0}_V_y^*}} = -\frac{\mathbf{1}}{\frac{\boldsymbol{P}}{\boldsymbol{X_0}}-\mathbf{1}} \quad (12)$$

The value of the coefficient does not depend on the percentage change C_{x_0} and is associated with a specific aircraft.

The max value of the specific excess power for fighters is achieved as a rule at M=0.8-0.9 near the ground. We calculate the IC value according to the formula (11) and (12) for several aircraft. At M=0.85 ram airflow is q=51250 H/m^2, the IC excluding and taking into account the inductance is presented in Table 2.

Table 2: The values $K_{C_{x_0}_V_y^*}$ are calculated by the formula (4) and (5)

Air-craft	M	Cx_0	Cx_i	S, m^2	P, H	$\boldsymbol{K_{C_{x_0}_V_y^*}}$ **excluding** $\boldsymbol{Cx_i}$	$\boldsymbol{K_{C_{x_0}_V_y^*}}$ **taking into account** $\boldsymbol{Cx_i}$
Mig-29	0.9	0.025	0.0005	38	200000	**-0.398**	**-0.401**
Su-24 (69°)	0.8	0.0263	0.0029	51	230000	**-0.367**	**-0.383**
Mig-23 (72°)	0.9	0.0225	0.0026	34.2	150000	**-0.438**	**-0.460**

From Table 2 it is seen that the inductive component of the resistance makes an insignificant contribution to the value of the IC. When Cx_0 is changed by 10% the differences in the scatter of V_y^* excluding and taking into account Cx_i are about 0.2%, which can be considered a negligible value at the preliminary design stage. Therefore, to simplify, you can use the formula (5).

3.4. The influence of parameters on sustained load factor

The sustained load factor can be expressed through the formula [16]:

$$n_y = \sqrt{\frac{(P-X_0)qS}{A(mg)^2}} \quad (13)$$

where P – engine thrust, X_0 – non-inductive resistance, q – velocity head, A – drag-due-to-lift factor, g – acceleration of gravity, then:

$$K_{m_n_{y\,уст}} = \frac{\frac{n_{y_2}}{n_{y_1}}-1}{\frac{m_2}{m_1}-1} = \frac{\frac{m_1}{m_2}-1}{\frac{m_2}{m_1}-1} = \left\langle t=\frac{m_2}{m_1}\right\rangle = \frac{\frac{1}{t}-1}{t-1} = \frac{1-t}{t(t-1)} = -\frac{1}{t}$$

$$\boldsymbol{K_{m_n_y}} = -\frac{\boldsymbol{m_1}}{\boldsymbol{m_2}} \quad (14)$$

The value of the coefficient depends on the percentage change in mass (Table 3).

Table 3: Dependence of $K_{m_n_y}$ on Δm

Mass change Δm, %	$\boldsymbol{K_{m_n_y}}$	Change of the sustained load factor Δn_y, %
5	**-0.952**	*4.8*
10	**-0.909**	*9.1*
15	**-0.869**	*13*

Similarly, we get $K_{Cx_0_n_y}$:

$$K_{Cx_0_n_{y\,уст}} = \frac{\frac{n_{y_2}}{n_{y_1}}-1}{\frac{Cx_{0_2}}{Cx_{0_1}}-1} = \frac{\sqrt{\left(\frac{P-X_2}{P-X_1}\right)}-1}{\frac{Cx_{0_2}-Cx_{0_1}}{Cx_{0_1}}} = \frac{\sqrt{\left(\frac{P-X_1-\Delta X_0}{P-X_1}\right)}-1}{\frac{Cx_{0_2}-Cx_{0_1}}{Cx_{0_1}}} = \langle Cx_{0_2} - Cx_{0_1} > 0\rangle = \sqrt{\left(\frac{P-X_1-\Delta X_0}{P-X_1}\right)\frac{(Cx_{0_1})^2}{(Cx_{0_2}-Cx_{0_1})^2}} - \frac{1}{\Delta\widehat{Cx}_0} =$$

$$\sqrt{\left(1-\frac{\Delta X_0}{P-X_1}\right)\frac{{Cx_{0_1}}^2}{(Cx_{0_2}-Cx_{0_1})^2}} - \frac{1}{\Delta\widehat{Cx}_0} =$$

$$\sqrt{\frac{{Cx_{0_1}}^2}{(Cx_{0_2}-Cx_{0_1})^2} - \frac{qS(Cx_{0_2}-Cx_{0_1})}{qS\left(\frac{P}{Sq}-Cx_{0_1}\right)}\frac{{Cx_{0_1}}^2}{(Cx_{0_2}-Cx_{0_1})^2}} - \frac{1}{\Delta\widehat{Cx}_0} =$$

$$\sqrt{\frac{1}{(\Delta\widehat{Cx}_0)^2}-\frac{{Cx_{0_1}}^2}{(\frac{P}{Sq}-Cx_{0_1})(Cx_{0_2}-Cx_{0_1})}}-\frac{1}{\Delta\widehat{Cx}_0}=$$

$$\sqrt{\frac{1}{(\Delta\widehat{Cx}_0)^2}-\frac{Cx_{0_1}}{\left(\frac{P}{Sq}-Cx_{0_1}\right)(\Delta\widehat{Cx}_0)}}-\frac{1}{\Delta\widehat{Cx}_0}=$$

$$\sqrt{\frac{1}{(\Delta\widehat{Cx}_0)^2}-\frac{Cx_{0_1}\Delta\widehat{Cx}_0}{\left(\frac{P}{Sq}-Cx_{0_1}\right)}\frac{1}{(\Delta\widehat{Cx}_0)^2}}-\frac{1}{\Delta\widehat{Cx}_0}=\frac{1}{\Delta\widehat{Cx}_0}\sqrt{1-\frac{Cx_{0_1}\Delta\widehat{Cx}_0}{\frac{P}{Sq}-Cx_{0_1}}}-$$

$$\frac{1}{\Delta\widehat{Cx}_0}=\frac{1}{\Delta\widehat{Cx}_0}\left(\sqrt{1-\frac{Cx_{0_1}\Delta\widehat{Cx}_0}{\frac{P}{Sq}-Cx_{0_1}}}-1\right)$$

$$K_{Cx_{0_}n_y}=\frac{1}{\Delta\widehat{Cx}_0}\left(\sqrt{1-\frac{Cx_{0_1}\Delta\widehat{Cx}_0}{\frac{P}{Sq}-Cx_{0_1}}}-1\right) \qquad (14)$$

The coefficient value slightly depends on the percentage change Cx_0 (differences – in thousandths). When Cx_0 changes by 10%, the formula takes the form:

$$\boldsymbol{K_{Cx_{0_}n_y}=10\left(\sqrt{1-0.1\frac{Cx_{0_1}}{\frac{P}{Sq}-Cx_{0_1}}}-1\right)} \qquad (15)$$

For example, we calculate the IC for several AK. At M=0.8 at a higher H=1000m ram-air flow is equal q=41200 H/m^2, (Table 4).

Table 4: The values $K_{Cx_{0_}n_y}$

Aircraft	Cx_0	S, m^2	P (H=1000, M=0.8), H	$\boldsymbol{K_{Cx_{0_}n_y}}$
Mig-29	0.024	38	170000	**-0.16**
Su-24 (69°)	0.026	51	206000	**-0.21**
Mig-23 (72°)	0.022	34.16	130000	**-0.18**

3.5. The influence of parameters on acceleration time

Acceleration time in horizontal flight in within speed range is [17]:

$$t_p=\frac{1}{g}\int_{V_н}^{V_к}\frac{dV}{n_{xa}}\approx\frac{V_к-V_н}{g*(n_{xa})_{cp}} \qquad (16)$$

Where $V_н$ and $V_к$ – initial and final speed, $(n_{xa})_{cp}$ – averaged longitudinal g load for within speed range.

Let's get the formula for $K_{m_t_p}$:

$$\Delta(n_{xa})_{cp}=(n_{xa})_{cp2}-(n_{xa})_{cp1}=\frac{(P_{cp}-X_{2_{cp}})}{G_2}-\frac{(P_{cp}-X_{1_{cp}})}{G_1}=$$

$$\frac{\frac{m_1}{m_2}P_{cp}-\frac{m_1}{m_2}X_{1_{cp}}-\frac{m_1}{m_2}\Delta X-P_{cp}+X_{1_{cp}}}{G_1}=-\frac{P_{cp}\left(1-\frac{m_1}{m_2}\right)-X_{1_{cp}}\left(1-\frac{m_1}{m_2}\right)+\Delta X\frac{m_1}{m_2}}{G_1}=$$

$$-\frac{(P_{cp}-X_{1_{cp}})\left(1-\frac{m_1}{m_2}\right)+\Delta X\frac{m_1}{m_2}}{G_1}\text{, then:}$$

$$K_{m_t_p}=\frac{\frac{t_{p_2}}{t_{p_1}}-1}{\frac{m_2}{m_1}-1}=\left(\frac{t_{p_2}}{t_{p_1}}-1\right)\frac{1}{\Delta\hat{m}}=\left(\frac{(n_{xa})_{cp1}-(n_{xa})_{cp2}}{(n_{xa})_{cp2}}\right)\frac{1}{\Delta\hat{m}}=$$

$$\left(\frac{1}{\frac{(n_{xa})_{cp2}}{-\Delta(n_{xa})_{cp}}}\right)\frac{1}{\Delta\hat{m}}=\left(\frac{1}{-1-\frac{1}{\frac{\Delta(n_{xa})_{cp}}{(n_{xa})_{cp1}}}}\right)\frac{1}{\Delta\hat{m}}=$$

$$\left(\frac{1}{\frac{1}{\frac{(P_{cp}-X_{1_{cp}})\left(1-\frac{m_1}{m_2}\right)G_1}{(P_{cp}-X_1)G_1}+\frac{\Delta X*m_1*G_1}{m_2(P_{cp}-X_1)G_1}}-1}\right)\frac{1}{\Delta\hat{m}}=$$

$$\left(\frac{1}{\frac{1}{1-\frac{m_1}{m_2}+\frac{m_1}{m_2}\frac{\Delta X}{(P_{cp}-X_{1_{cp}})}}-1}\right)\frac{1}{\Delta\hat{m}}=\left(\frac{1}{\frac{1}{1-\frac{m_1}{m_2}\left(1-\frac{\Delta X}{(P_{cp}-X_{1_{cp}})}\right)}-1}\right)\frac{1}{\Delta\hat{m}}$$

$$\boldsymbol{K_{m_t_p}=\left(\frac{1}{\frac{1}{1-\frac{m_1}{m_2}\left(1-\frac{\Delta X_{i_{cp}}}{\Delta P_{cp}}\right)}-1}\right)\frac{1}{\Delta\hat{m}}} \qquad (17)$$

where ΔP_{cp} and $\Delta X_{i_{cp}}$ – the average engine thrust margin and the average increase of the induced drag for the speed range acceleration.

The value of the coefficient slightly depends on the percentage change in the mass. Assuming $\Delta X_{i_{cp}}/\Delta P_{cp}=0$ (ΔX_i is significantly less than the average available thrust ΔP_{cp}) $K_{m_t_p}$=1, and taking into account the influence of increased inductance (due to the increase in mass) the coefficient value will be slightly larger. For example, for Mig-29 during acceleration 600 – 1100 km/hour near the ground $K_{m_t_p}=1{,}12$ (Table 5).

Table 5: The values $K_{m_t_p}$ for Mig-29 (600 – 1100 km/hour on the deck)

m_1, kg	Δm, %	ΔC_y	ΔCx_i	P_{cp}, kgf	X_{cp}, kgf	ΔX_i, kgf	$\boldsymbol{K_{m_t_p}}$
15000	10	0.011	0.001	16000	4000	130	**1.12**

If accept $\Delta Cx_{0_{cp}}\approx\Delta Cx_0$ and $Cx_{0_{1cp}}\approx Cx_{0_1}$, $K_{Cx_{0_}t_p}$ takes the following form:

$$K_{Cx_{0_}t_p}=\frac{\frac{t_{p_2}}{t_{p_1}}-1}{\frac{Cx_{0_2}}{Cx_{0_1}}-1}=\left(\frac{t_{p_2}}{t_{p_1}}-1\right)\frac{1}{\Delta\widehat{Cx}_0}=\left(\frac{1}{-1-\frac{(n_{xa})_{cp1}}{\Delta(n_{xa})_{cp}}}\right)\frac{1}{\Delta\widehat{Cx}_0}=$$

$$\left\langle\Delta(n_{xa})_{cp}=\frac{-\Delta X_0}{G_1}\right\rangle=\left(\frac{1}{\frac{P_{cp}-X_{1_{cp}}}{\Delta X_{0_{cp}}}-1}\right)\frac{1}{\Delta\widehat{Cx}_0}=$$

$$\left(\frac{1}{\frac{P_{cp}-X_{1_{cp}}-\Delta X_{0_{cp}}}{\Delta X_{0_{cp}}}}\right)\frac{1}{\Delta\widehat{Cx}_0}=\left(\frac{\Delta Cx_{0_{cp}}qS}{qS\left(\frac{P_{cp}}{qS}-Cx_{0_{1cp}}-\Delta Cx_{0_{cp}}\right)}\right)\frac{Cx_{0_1}}{\Delta Cx_0}=$$

$$\left\langle\begin{matrix}\Delta Cx_{0_{cp}}\approx\Delta Cx_0\\ Cx_{0_{1cp}}\approx Cx_{0_1}\end{matrix}\right\rangle=\frac{Cx_{0_1}}{\frac{P_{cp}}{qS}-Cx_{0_{1cp}}-\Delta Cx_{0_{cp}}}=\frac{1}{\frac{P_{cp}}{X_{0_{1cp}}}-1-\Delta\widehat{Cx}_0}$$

$$K_{Cx_0_t_p} = \frac{1}{\frac{P_{cp}}{X_{0_{1cp}}} - 1 - \Delta\widehat{Cx_0}} \quad (18)$$

The coefficient value slightly depends on the percentage change Cx_0 and is associated with a specific aircraft. For Mig-29 $K_{Cx_0_t_p}$ = 0.27 (Table 6).

Table 6: The values $K_{Cx_0_t_p}$ for Mig-29 (600 – 1100 km/hour near the ground)

Cx0	Δ Cx0, %	Pcp, kgf	$X_{0_{1cp}}$, kgf	$K_{Cx_0_t_p}$
0.025	10	16000	3300	**0.27**

4. Calculation of the influent coefficients by numerical method

To confirm the derived dependencies (8), (10), (12), (14), (15), (17), (18), we calculate the IC using the "Program for preparing the initial data and calculating the FQP". This software product was developed by Sukhoi Design Bureau and verified by many years of the application practice. The program uses weight, aerodynamic characteristics (Cx_0(M), Cx_i (C_y, M), Cy_{max}(M), C_y^a) and propulsive characteristics P (H, M, Dr) Qc(H, M, Dr), as well as some limitations (q_{max}, ny_{max}) and constants. The graphs Cx_0(M), Cx_i (C_y, M), Cy_{max}(M) C_y^a, P (H, M), Qc(H, M) are digitized from books of practical aerodynamics [18-21]. ICs are calculated according to the algorithm shown in the Figure 1.

We calculate IC for the following aircraft of the class of operational - tactical aviation: fighter 4th generation Su-27; frontline bomber Su-24; strike-fighter Su-25; fighter 4th generation Mig-29; fighter 3rd generation Mig-23; interceptor jet 3rd generation Mig-25.

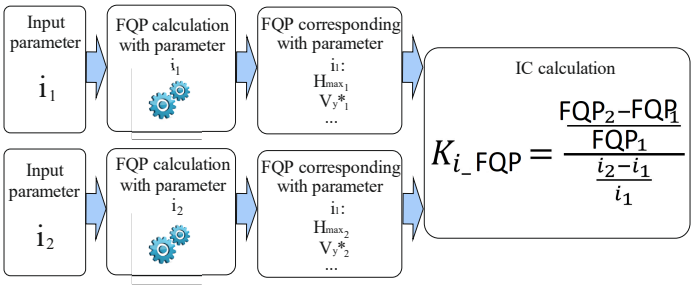

Figure 1: IC calculation scheme

Table 9 and Figures 2-11 show the results of calculating the IC programmatically. ICs were obtained when the mass changed by 10%, Cx_0 changed for M<1 by 10% and for M>1 by 18%. Such differences in the spread of Cx_0 are taken on the assumption that the inaccuracy of determining this parameter for the supersonic domain of flight is higher. Aircraft characteristics are taken in the calculations are presented in Table 7.

The effect on the service ceiling is shown in Figures 2 and 3, on the specific excess power - in Figures 4 and 5, on the sustained load factor - in Figures 6 and 7, for the acceleration time - in Figures 8 and 9. Figures 2-9 also show the values obtained from the above formulas.

5. Results and Discussions

As can be seen from Figures 2-10, the analytically obtained ICs are confirmed by numerical calculations. The absolute error when using the derived formulas is less than 0.1 of the IC value, which in terms of FQP values gives an error of less than 10%. At the initial stage of aircraft design (when the error of other constituent elements is comparable in magnitude), this is an acceptable indicator.

Summarize the calculated IC in Table 9, the percentage change in FQP is presented in Table 10.

Table 9: IC ranges for the considered OTA aircrafts

FQP	K_{m_FQP}	$K_{Cx_0_FQP}$	
		$M_{max}<1$	$M_{max}>1$
V_{max}	-0.1	-0.1…-0.25	-0.7…-0.85
H_{max}	0.25…0.6	-0.05…-0.2	-0.15…-0.5
$V_y^* max$	-0.9….-1.05	-0.35…-0.55	-
n_y (H=1000m, M=0.8)	-0.91	-0.05…-0.2	-
t_p (600-1100 km/h, H=200m)	1…1.25	-0.2…-0.35	-

Table 10: Percent change in the FQP

FQP	With an increase in mass by 10%, the FQP deteriorates by:	With an increase in Cx_0 in the subsonic area by 10% and by 18% in supersonic the FQP deteriorate by:	
		$M_{max}<1$	$M_{max}>1$
V_{max}	1%	1…2.5%	12…15.5%
H_{max}	decreases by 630 m	0.5…2%	3…8%
$V_y^* max$	9….10.5%	3.5…5.5%	-
n_y (H=1000m, M=0.8)	9.1%	0.5…2%	-
t_p (600-1100 km/h, H=200m)	10…12.5%	2…3.5%	-

From Tables 9 and 10 we can conclude that the considered FQP, such as the maximum specific excess power, sustained load factor, and acceleration time, are most sensitive to a change in mass. The inaccuracy in determining the mass in 1% gives a spread of these FQP in about 1% (more accurate values are given earlier). The IC of the mass on the practical ceiling depends on the absolute value of the ceiling, so it makes sense to talk about its absolute change. With an inaccuracy of mass of 1%, the ceiling is determined with an accuracy of about 60-70 meters.

To inaccuracy C_{x_0} is most sensitive to the maximum flying speed (for M>1). The numerical value of the IC on V_{max} is determined by the curve crossing nature of the required and available thrust (Figure 11). Graphs Cx_0 (M) for the studied aircrafts are shown in Figure 10.

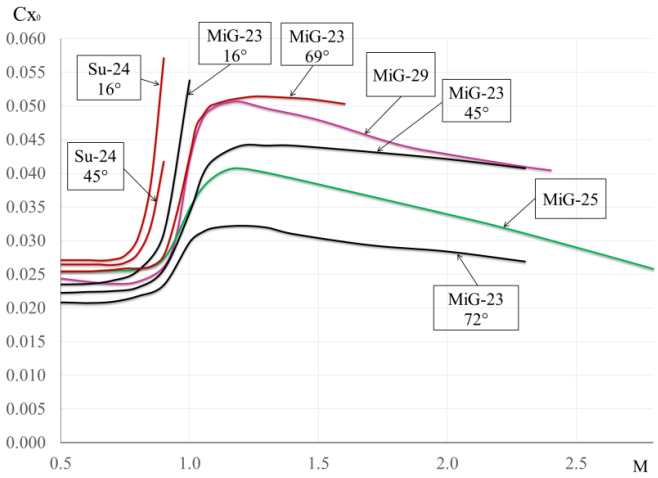

Figure 10: Graphs Cx0 for the studied aircrafts.

Figure 10 shows that in the area of maximum flight speed, the slope of the curves C_{x0} (M) is different for different aircraft.

The power-available curve depends on the engine unit's altitude speed performances, the required one on the drag run, therefore, the IC depends strongly on the specific aircraft (on the flow pattern of Cx_0 and altitude-speed performances), therefore,

linking this coefficient to the aircraft parameters is impractical. However, as the research showed, the IC value for subsonic aircraft is approximately 0.1…0.2 (Table 9), for supersonic: 0.7…0.9.

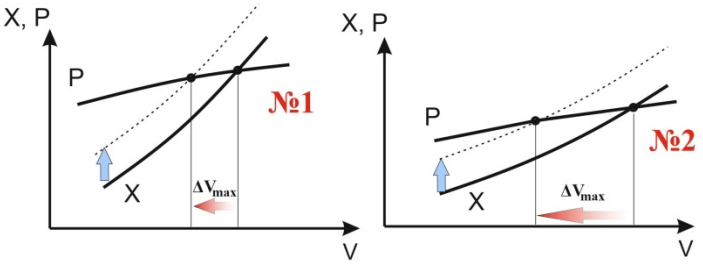

Figure 11. The different nature of Zhukovsky curve crossing. P – engine thrust curve, X – airplane drag curve.

6. Conclusions

The results of this work allow us to estimate the contribution of mass uncertainties and drag coefficient at zero lifting force to the range of variation of the FQP values.

The formulas obtained make it possible to determine the quantitative influence of the parameter on the value of the FQP. Verification of the formulas for some aircraft from the class of operational-tactical aviation showed that the error in determining the spread of flight characteristics according to the formulas obtained is within 10%.

The research showed that the mass influence coefficients Cx_0 on maximum specific excess power, sustained load factor and acceleration time practically do not depend on the parameters of the considered aircrafts of the same class. The IC of mass and Cx_0 on the maximum speed and practical ceiling associated with specific aircraft parameters. The sensitivity of the maximum speed to the zero lift-drag coefficient is determined by the curve crossing nature of the required and available thrust.

The inaccuracy in determining the mass in 1% gives a spread of maximum specific excess power, sustained load factor and acceleration time in about 0.9…1.3%. For the studied aircrafts the inaccuracy in determining the zero lift-drag coefficient of 1% gives a spread in the maximum speed within 0.7 ... 0.9% for supersonic aircraft and 0.1 ... 0.2% for subsonic aircraft.

ABSTRACT

The main advantage of software-defined visible light communication (VLC) systems is that they allow us to reuse modulation, coding, synchronization and medium access techniques used in conventional radio systems. This article focuses on the implementation of an uplink alternative using an infrared (IR) light communication system. For this goal, analog front-ends are designed and implemented. Therefore, they convert a radio frequency signal into an optical signal. In addition, a Universal Software Radio Peripheral (USRP) is used as a software-defined radio platform. The obtained bit error rate is 5.33×10^{-5} *using QPSK modulation with a bit rate of 4 Mbps at a distance of 160 cm between transmitter and receiver.*

1. Introduction

This paper is an extension of work originally presented in *2019 IEEE Colombian Conference on Communications and Computing (COLCOM)* [1]. This article aims to focus into the design process followed to implement analog front ends for the infrared (IR) communication uplink. On the other hand, an explanation is given about the blocks that make up the program to measure the bit error rate (BER) of the IR system. Finally, the signal-to-noise ratio (SNR) measurement is made and compared with the bit error rate (BER) obtained at different distances between transmitter and receiver.

Visible Light Communication (VLC) is currently being developed as a solution that enables the use of standard illumination light-emitting diodes (LEDs) to transmit data wirelessly. This type of communication is an alternative to mitigate the effects of saturation of the radioelectric spectrum in densely populated areas. Furthermore, it is known that the number of wireless devices connected to the internet is growing at an annual rate of 47% until 2021 [2]. This is mainly due to the greater access of terminal devices such as smartphones, tablets, laptops and recently to the deployment of the Internet of Things (IoT). For this reason, VLC is a technology that can serve as a complement of the currently deployed communication systems and provide access to the network. An important feature of VLC is that it can be used as a ubiquitous communication medium because LED lighting lamps are widely used in existing lighting infrastructure. On the other hand, VLC operates in the visible light band, which is not licensed and there is no electromagnetic interference generated by other communication equipment [3].

Information is sent and received through one or more LEDs on the transmitting side and a photodiode on the receiving side using a technique known as intensity modulation and direct detection (IM-DD) [4]. In such a way that the information that is sent produces variations in the level of illumination of the LED stage, these variations are imperceptible to the human eye. After that, the receiving photodiode converts the optical signal into an electrical signal for further processing.

In [5], the authors focused on the design and implementation of Analog Front-Ends, which would allow easy replication of the system through the use of low-cost components. The achieved bit rate was 20 kbps with a BER of 4.89×10^{-10} using OOK modulation and Manchester encoding. In [6], a similar paper was done, but it did not specify the components of the designed interfaces, a BER of 9.77×10^{-5} was measured at a bit rate of 2.5 Mbps and at a distance of 1.6 meters using BPSK modulation technique. In [7], an uplink based on infrared communication is proposed, the simulation result shows a value of 3.57 Gb / s using a transmitter with beam stearing and an angle diversity receiver. However, the experimental implementation stage of the system was not reached. In [8], it was possible to implement an infrared uplink by using an off-the-shelf receiver module (TSOP 1730) and the PPM modulation technique, however, the data transfer rate of

*Corresponding Author: Oswaldo René Banda Sayco, Arequipa, Peru, obanda@unsa.edu.pe

the infrared link reaches up to 1200 bps. In [9], a surveillance camera is used as a receiver for an uplink based on infrared light. In [10], an IR link was implemented using a silicon integrated beam steering device, the achieved bit rate was 12.5 Gb/s and the bit error rate (BER) was less than 10^{-9}.

This article shows the design and implementation process of Analog Front-Ends used on the transmitter and receiver side, achieving a bit rate of 4 Mbps and a BER of 5.33×10^{-5} using QPSK modulation at a distance of 1.6 m. These interfaces have the advantage of being coupled to Software Defined Radio (SDR) systems, in such a way that the modulation, coding and synchronization of the data is carried out within a computer connected to a Universal Software Radio Peripheral (USRP). This allows for rapid prototyping and measurement of the IR communication system.

Section two presents the methodology used to carry out this work, section three delves into the design and implementation of Front-Ends, section 4 shows the results of the BER and SNR. Finally, section 5 shows the conclusions of this research work.

2. Methodology

Figure 1 shows the methodology followed to design and implement the Analog Front-Ends. First, an analysis of the communication system to be implemented is made. This analysis allows us to know all the elements that are required to make the VLC system work correctly. In addition, it is necessary to define the design parameters that allow the development of Analog Front-Ends. After that, the second procedure is Development of the Front-Ends. To carry out this task, it has been divided into two threads: design and implementation.

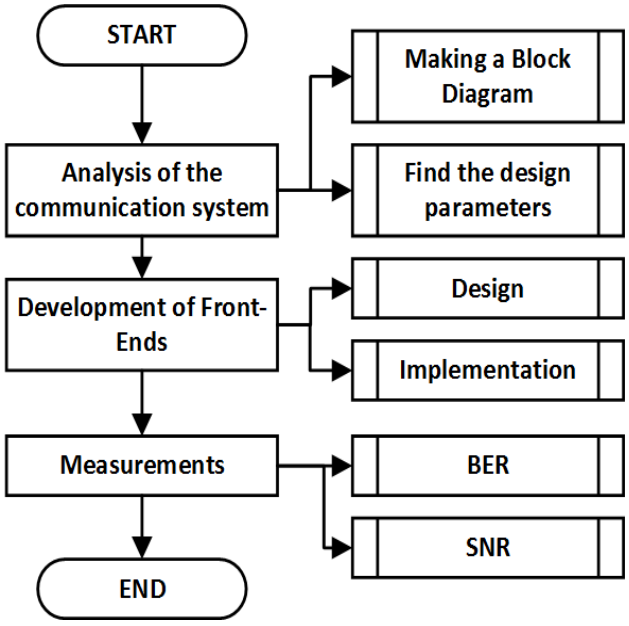

Figure 1: Methodology diagram

Finally, the last step is to carry out the corresponding measurements of the implemented communication system. To do this, a BER measurement is made as a function of the separation distance between transmitter and receiver. On the other hand, the measurement of the signal-to-noise ratio (SNR) is also carried out and a comparison is made with the previously measured BER.

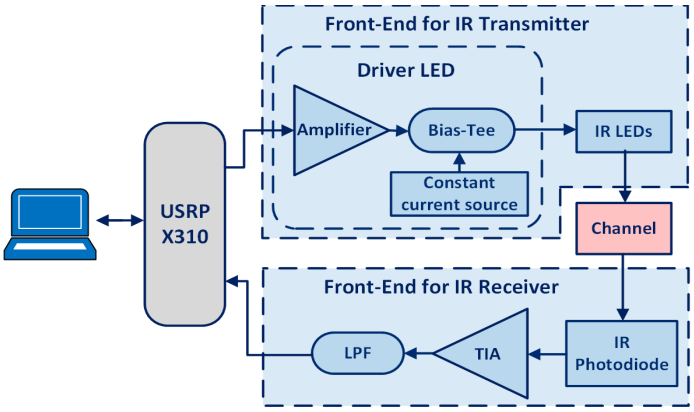

Figure 2: Block diagram of the IR communication system for BER measurement

3. Analysis of the Communication System

3.1. Block Diagram of the System

Figure 2 shows the block diagram of the IR communication system implemented for the purpose of making the BER measurement. This diagram is based on the research article previously made in [1] . It is observed that a laptop has a software stage where the modulation and synchronization of the information is carried out. After that, a USRP X300 is connected, which is a software-defined radio platform that allows to generate a modulated signal in the RF band. In this case, a central frequency of 5MHz has been used to carry out this test. Then, the signal goes to the transmitter front-end. This front-end is composed by an amplifier, a bias-tee, a constant current source and the IR LEDs. After that, the signal travels towards the receiver through the channel. In this case, the channel is the air in the indoor environment. On the other hand, the receiver front-end includes an IR photodiode, a transimpedance amplifier (TIA) and a low pass filter (LPF).

Table 1: Design Parameters for the IR link

Parameter	Description
Application	Indoor
Coverage range	1.6 m
Configuration	Direct LOS link
Bitrate	4 Mbps
Modulation	QPSK / BPSK
Transmitter	LED Specification (each one) - Radiant Intensity: 550 mW/sr - View angle: 10° - Wavelenght: 800 nm – 875 nm
Receiver	Photodiode specifications: - Code: SFH 203 FA - Spectral response: 800 nm – 1100 nm - Sensitive area: 1 mm^2
OP-AMPs	LT6268-10 and LT6268 with dual supply ±2.5 V_{DC}

3.2. Design Parameters

The design parameters of the electronic circuits for the transmitter and receiver analog interfaces are shown in Table 1. It is observed that the configuration used in this paper requires a line of sight (LOS), this is due to the fact that the angle of view of the LEDs arrangement is 10°. Which allows maximum energy transfer in only one direction. In this way, the use of an optical lens that amplifies the optical signal at the receiver is avoided. In addition to this, the other parameters taken into account to implement this communication system can be read.

4. Development of Front-Ends

Front-ends are developed based on the design parameters mentioned in the previous section. First, the design of the front-ends is done. After that, the physical implementation of them is made.

4.1. Transmitter Design

The transmitter front-end is composed by four blocks. The first block is an amplifier that must take the signal from the USRP and feed a LED array. The second block is a bias-tee that superimposes the RF signal coming from the amplifier on a constant current level coming from the third block called "Constant current source". The three previous blocks make up the LED driver. Finally, the last block is an array of LEDs, it is composed of eight high-power LEDs placed in series, which produce an optical signal that will travel through free space until it reaches the receiver front-end.

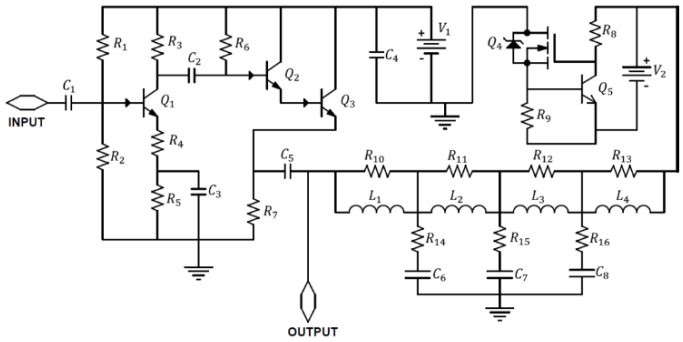

Figure 3: Schematic circuit of the Transmitter Front-end

Figure 3 shows the schematic circuit of the transmitter front-end, it can be seen that it includes a common emitter amplifier, that includes the transistor Q_1. After that, the circuit is followed by a Darlington amplifier, which is made of the transistors Q_2 and Q_3. The common emitter amplifier was designed following the procedure described in [11]. The design equations are as follows:

$$I_b = \frac{I_c}{\beta} \tag{1}$$

$$V_{ce} = \frac{V_1}{3} \tag{2}$$

$$R_3 = R_4 + R_5 \tag{3}$$

$$I_c(R_3 + R_4 + R_5) + V_{ce} = V_1 \tag{4}$$

$$R_3 = R_4 + R_5 = \frac{V_1 - V_{ce}}{2I_c} \tag{5}$$

$$R_{bb} = R_1 // R_2 \tag{6}$$

$$R_{bb} \ll \beta(R_4 + R_5) \tag{7}$$

$$Z_{in} = R_{bb} // \beta(r_e + R_4) \tag{8}$$

$$Z_{out} = R_3 \tag{9}$$

From (1) the base current is obtained from the value of the collector current, which in this case is 10 mA, in addition β has a value of 95. In (2) and (4), V_1 has a value of 12 V. The values of the resistors R_3, R_4 and R_5 are calculated from (4) and (5). On the other hand, (6) and (7) allow the calculation of R_1 and R_2. Next, (8) and (9) allow us to know the input and output impedances. Finally, a Darlington amplifier is inserted to reduce the output impedance and increase the output power.

In Figure 3, Q_4 is a MOSFET that provides a constant current source whose value is defined by (10). In this case, 140 mA was chosen as the I_D value because it allows the LEDs to keep turned on.

$$I_D = \frac{V_{BE}}{R_2} \tag{10}$$

I_D: drain current of MOSFET Q_4

V_{BE}: Base-Emitter Saturation Voltage of Transistor Q_5

LED's must be turned on to modulate their light intensity without turning them off. For this purpose, it is necessary to superimpose the AC signal coming from the amplifier with the DC level coming from the constant current source. The bias-tee is in charge of this task. Finally, this LED driver is connected to an array of eight LEDs in series. In this way, the Front-end transmitter has been designed.

4.2. Receiver Design

Figure 4 shows the schematic circuit of the receiver front-end, which is composed of a photodiode, a transimpedance amplifier and a low-pass filter. The photodiode makes it possible to transform an optical signal into an electrical one. In this project, the SFH 203 FA photodiode is used, which has a switching time of 5 ns, it is inversely polarized with a voltage of 12 V. Furthermore, R_3 and C_5 constitute a low-pass RC filter in order to eliminate noise from source V_1.

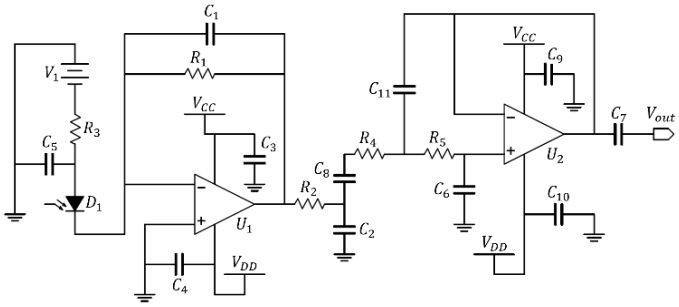

Figure 4: Schematic circuit of the Receiver Front-end

The current at the output of the photodiode enters a transimpedance amplifier. The gain of the transimpedance amplifier is equal to the feedback resistance R_1. After a voltage is obtained at the output of the transimpedance amplifier (TIA), the signal passes through a two-stage low-pass filter. The first stage is

made up of an RC filter composed of R_2 and C_2 and whose cutoff frequency can be calculated using (11). After that, the coupling capacitor C_8 is connected, this capacitor allows only the alternating component of the signal to pass. In this way, the voltage produced by the ambient light is minimized. Finally, a Chebyshev low-pass filter is responsible for eliminating high-frequency noise and adapting the output impedance for connection to the USRP equipment. The design of this filter was done following the procedure described in [12], the calculations were made using (12), (13), (14) and (15).

$$f_{c1} = \frac{1}{2\pi(R_2)(C_2)} \tag{11}$$

$$R_4 = R_5 = \frac{a_1}{2w_c C_6} \tag{12}$$

$$C_{11} = \frac{b_1}{{w_c}^2 R_4 R_5 C_6} \tag{13}$$

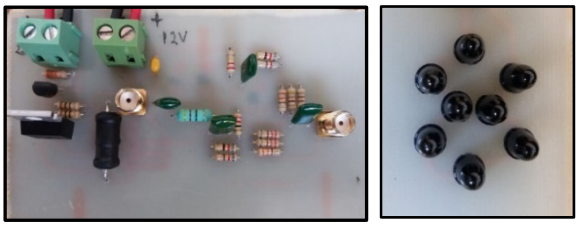
$$a_1 = 1.1813 \tag{14}$$

$$b_1 = 1.7775 \tag{15}$$

4.3. Implementation of Front-ends

The transmitter front-end was implemented as shown in Figure 5. The physical implementation of this circuit can be shown on two single printed circuit boards (PCB). Figure 5.a shows the LED driver. On the other hand, Figure 5.b is the IR-LED array. The reason why the LED array is not included in the same PCB is because it allows to do further tests with different LED configurations. In this way, it is avoided to build new front-ends in order to speed up the tests and improve the transmitting analog interface. Both circuits are connected by a coaxial cable in the experimental setup.

Figure 6 shows the physical circuit of the receiver front-end for the IR uplink. It is observed that the output connection is made through a female SMA connector, to which an RG58 coaxial cable is connected.



a) b)

Figure 5: Physical implementation of the transmitter Front-end.

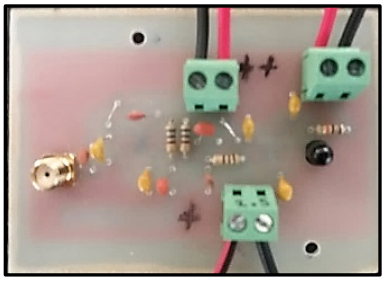


Figure 6: Physical implementation of the receiver Front-end

5. Measurements

Once the Front-ends have been implemented, the Bit Error Rate (BER) measurement is performed. To do this, it is necessary to establish the experimental setup shown in Figure 7. This setup is based on the block diagram described in the third section of this paper. The connection between the laptop and the USRP is made through a gigabit ethernet cable. The connections between the USRP and the front-ends are made through RG58 coaxial cable.

To carry out the BER measurement, the program shown in Figure 8 is used. This program was developed in GNU Radio from the information available in [6], with the difference that now QPSK modulation and the rate are used. sampling rate is changed to 4 MS/s.

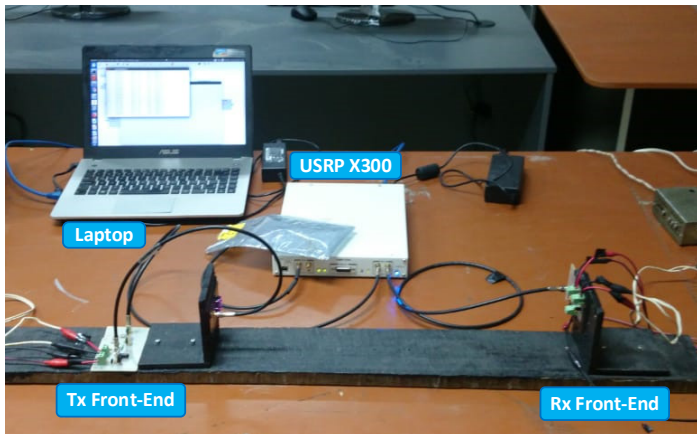

Figure 7: Experimental setup for BER measurement

The explanation of the blocks that make up this program is as follows:

- The "PRBS Source B" block is responsible for generating a random sequence of bits, which is repeated indefinitely.
- “Preamble Insert” is a block that inserts a bit preamble, which is used to indicate the moment at which the BER measurement starts.
- "Root Raiced Cosine Filter" is a block that is used in transmission and reception to minimize intersymbolic interference.
- “Costas Loop” is responsible for the frequency recovery of the carrier signal.
- Subsequently, the "Decode using Preamble Synch" block takes care of the demodulation and detection of the preamble to start the BER measurement.
- The “Binary Slicer” block transforms the demodulated signal into bits. These bits can have two values 0 or 1.
- Finally, the "PRBS Sink B" block is in charge of comparing the received bits with the original sequence and showing the bit error rate (BER).

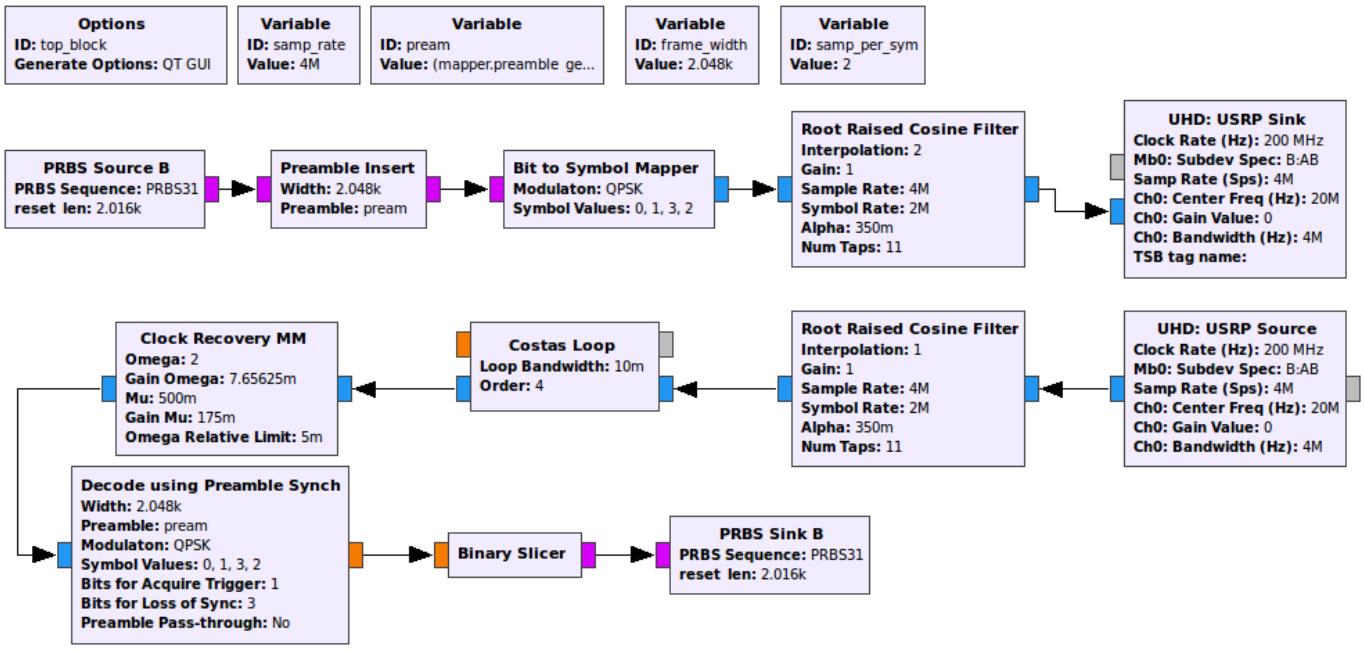

Figure 8: Program in GNU Radio for BER measurement using QPSK modulation

Figure 9 shows the results obtained from the BER measurement as a function of the separation distance between transmitter and receiver. The red graph indicates the BER measured using QPSK modulation at a bit rate of 4 Mbps. A BER of 5.33×10^{-5} was obtained at a distance of 160 cm between transmitter and receiver. The blue graph shows the BER obtained using BPSK modulation, which has a value of 1.35×10^{-5} at a distance of 160 cm and the bit rate is reduced to 2 Mbps.

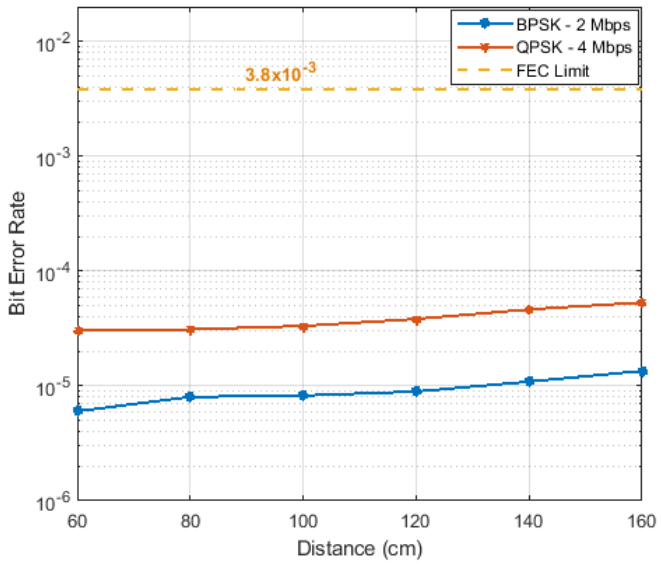

Figure 9: BER with respect to distance

Finally, signal-to-noise ratio (SNR) is measured at different distances between the transmitter and receiver using BPSK modulation. From the obtained data, it has been possible to make the graph of Figure 10, in which the BER is observed as a function of the SNR. With a SNR of 36.2 dB, a BER of 1.35×10^{-5} was measured. In the other hand, with a SNR of 46.4 dB, a BER of 8.032×10^{-6} was obtained. It can be seen that, if the SNR increases, a lower BER is measured. In this way, having an SNR greater than 45 dB, the BER seems to converge, however this is due to the fact that a finite number of packets were sent. Therefore, it is convenient to have the least amount of noise in the system or, failing that, to increase the power of the transmitted signal.

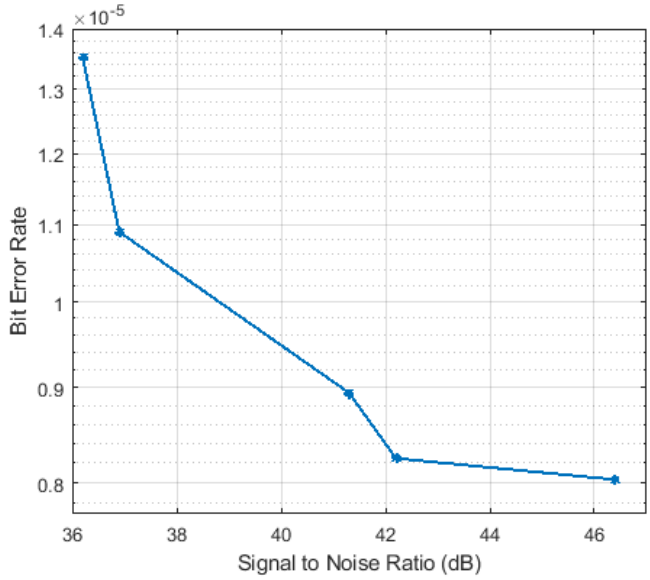

Figure 10: Measured BER vs SNR

6. Conclusions

- A bit error rate of 5.33×10^{-5} has been measured when transmitting at a bit rate of 4 Mbps using QPSK modulation at a distance of 160 cm between transmitter and receiver for an infrared light communication system.

- Signal to noise ratio decreases when the distance between transmitter and receiver is greater. In turn, the bit error rate increases as there is a lower signal-to-noise ratio.
- The transmitter front-end provides a constant current level of 140 mA, this keeps the LED stage turned on, while at the same it is modulated the intensity of the optical signal.
- The receiver front-end is composed by a transimpedance amplifier and a two-stage low-pass filter. The output voltage does not exceed 2 Vpp, which is the input limit for a USRP X300.
- A software program was developed in GNU Radio to measure the bit error rate of the infrared communication link. The used sampling rate is 4 MS/s and the central operating frequency is 5 MHz.
- Front-ends have been designed and implemented for infrared light communication that can be used in Software Defined Radio systems as an alternative for VLC uplink. Taking into account the requirements of this type of links.
- The main advantage of this system is that, as it is based on software defined radio, the modulation, coding and synchronization stages are implemented within a personal computer. Therefore, to implement it, it is necessary to use analog front-ends that allow the conversion of RF signals to optical signals.
- The main disadvantage is that the bit rate is limited by the capacity of the computer processor where the transmission and reception programs are executed, it was necessary to carry out tests with different personal computers and the one with the best performance was chosen.

ABSTRACT

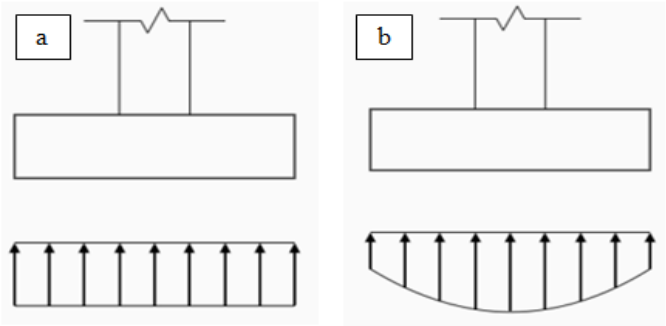
An experimental study regarding structural strengthening of existing reinforced concrete footing was conducted on six full scale reinforced concrete footings, strengthened with concrete jacketing under concentric and eccentric loads. The footings had constant dimensions and flexural steel reinforcement which was designed to prevent brittle failure due to crushing of concrete before steel yielding. Concrete jacketing was installed on all sides and top of existing concrete for footings subjected to concentric loading, while concrete jacketing was installed on three sides and top of existing concrete for footings under eccentric loading. The bonding between the existing and the new concrete was done either by applying epoxy bonding with dowels or by using an epoxy bonding agent on all sides only. This was to investigate the effect of each strengthening technique on the stress distribution beneath reinforced concrete footings rested on cohesionless soil. The dowels were used and designed to prevent any premature shear failure. The experimental results showed that the stress distribution beneath the center of footings subjected to concentric loading was higher than that beneath the control specimen by approximately 10%. The results also showed that the contact stress distribution beneath control and strengthened footings were not consistent with the available theoretical solutions. The effect of using dowels, in connecting old and new concrete, on stress distribution under strengthened footings and load-carrying are presented.

1. Introduction

Strengthening of existing Reinforced Concrete (RC) footings is often conducted when there is a need to increase the load-carrying capacity of such footings. Failure of RC footings is governed by bending, punching shear and one-way shear. The traditional way for strengthening, which is to increase the footing dimensions by adding a new layer of concrete on the top and sides of the existing footing, is an effective method for strengthening. The effect of the bonding technique, between existing and new concrete, on the stress distribution beneath strengthened footing is not known, and it is still based mostly on engineering judgment. This is due to the lack of sufficient research related to estimating stress distribution beneath strengthened footings. Bonding between existing and new concrete is considered as a main factor for load transfer, and for the concrete jacket to act as one part with the old concrete. The contact stress distribution beneath RC Footings resting on soil depends on the type of soil, as well as the stiffness of the footing [1]. Previous research regarding strengthening of existing RC Footing has focused on improving punching and shear behavior [2-5]. In 2017, Gia Toai Truong [2] investigated the effects of inclined shear reinforcement, high-strength concrete, and additional concrete cast with amorphous metallic fibers (AMFs) on the punching capacity of existing footings, the authors stated that the effect of AMFs and high strength concrete on punching resistance was higher than the effect of using inclined shear reinforcement. In 2007, J. Hegger [3] investigated the punching behavior for rigid isolated RC footings resting on sand for different footing depths. The authors also developed a design model for assessing punching strength using the soil-structure interaction, and it was found that the contact stress distribution beneath the rigid footings rested on sand was higher at the center of the footing and lower at edges. In 2013, Bonic and Folic [4] studied the punching behavior on RC footings, subjected to concentric loading, resting on sand. This study showed that the actual punching failure load was higher than the expected failure load, calculated according to the international

[*]Corresponding Author: Mohamed Attia, attia87_2009@hotmail.com

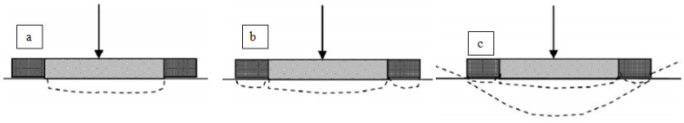
codes [5-7]. The authors stated that the theoretical assumption of uniform distributed stress under footing was conservative. In 2019, Wang-Xi Zhang [8] investigated the punching behavior of RC footings, subjected to eccentric loading, resting on rubber block. The results showed that the stress distribution was linear at low load levels, while it tends to be highly concentrated under the point of load application with load increase. Furthermore, the nonlinearly distributed stress influenced and increased the punching shear strength as well as the punching shear force of the footing. In 1990, Mosley [9] demonstrated the contact stresses distribution beneath a typical rigid footing resting on sand as shown in Figure 1.



In 2015, Todor Vacev [10] investigated the punching behavior of rigid isolated RC column footings, subjected to concentric loading, resting on sandy soil, and found that the stress distribution beneath the footing was different from the theoretical assumption. However, the stresses were concentrated under center of the footing. In 1996, Muller, G. U. [11] analyzed the contact stress distribution under rigid square footings, resting on cohesionless soil, and subjected to eccentric and concentric loading. It was found that the stress distribution was concentrated under center of the footing for eccentric loading, instead of being uniform linear triangular as in the theoretical analysis.

Various codes world-wide [5-7] do not quantify the resistance load of elements repaired with each Strengthened method. Moreover, in all published studies, the variable overloading punching effect is usually examined. Therefore, it is required to measure and examine the influence of the interface surface on the redistribution of the contact stresses.

Dowels and epoxy bonding agent were selected to connect the interface of the jacketed elements based on the outcomes from previous research [12], [13]. In 2013, M.N. EL Siragy [14] assessed the settlement profile, shown in Figure 2, and load-carrying capacity for rigid strip steel footings, resting on sand, after being strengthened with two steel plates from the sides. The authors found that the increase in the footing area led to reduction both the deformation and plastic flow of soil particles under the loaded footing.



2. Research Significance

The current codes and design guidelines [5-7] do not account for the effect of strengthening on the load-carrying capacity and stress distribution beneath strengthened footings, so, in this study, full-scale footings were tested to study the real load-displacement behavior and stress distribution, as the behavior of a small footing will be different than that of a large footing when rested on sand medium under the same gravity load [15]. The current study also investigates the effect of using concrete jacketing for existing RC Footing, using both dowels and epoxy bonding agent or applying epoxy bonding agent only at the interface between the old and new concrete.

3. Experimental Program

3.1. Geometry and detailing of tested samples

Six full scale square reinforced concrete footing specimens were tested under concentric and eccentric static loading till failure. These footings were divided into two groups; each group consists of three footings, a control specimen and two footings strengthened by concrete jackets (with/without) dowels. Table (1) summarizes the test groups dimensions and illustrates the strengthening methodology. Concrete jackets were used to study the effect of dowels and the bonding agent, on the whole bonding strength under eccentric and concentric loads.

Table 1: Test Matrix

Group	Symbols	Dimensions before strengthening (mm)	Dimensions after Strengthening (mm)	Loading Type	Strengthening Methodology
1	C1(control)	1200x1200x400	1200x1200x400	Concentric	---
	G1F1	800x800x250			Concrete jacket with shear dowels on top and sides of existing concrete.
	G1F2	800x800x250			Concrete jacket with shear dowels on top of existing concrete only.
2	C2(control)	1200x1200x400	1200x1200x400	Eccentric (50mm)	---
	G2F1	900x1000x250			Concrete jacket with shear dowels on top and sides of existing concrete.
	G2F2	900x1000x250			Concrete jacket with shear dowels on top of existing concrete only.

All reinforced concrete footings were tested on compacted dense sand inside a square wooden box with side length, and thickness of 2400 and 800 mm respectively. The box was strengthened with steel pipes from all sides. Figure 3-5 show the reinforcement details in all control and strengthened footings, Flexural reinforcement arrangement in the strengthened footings were constant and similar to the control specimens. Figure 6 shows the test setup for all footings. Each tested specimen was subjected to concentrated gravity load induced a vertical hydraulic jack, using load control mode, at which the load was increased by incremental values of 5 kN until failure load level was attained.

3.2. Materials

3.2.1. Properties of Sand

Clean dense sand was used in the laboratory testing. The particle size distribution was determined through sieve analysis (D60=1, D30=0.4 and D10=0.2). The soil can be classified as well graded sand according to the Unified Soil Classification System (USCS) (ASTM Standard D2487, 2011) [16]. The density of the sand placed in the models was 20 kN/m^3, while the friction angle was 43.9°, the friction was relatively high as the roughness coefficient between soil and concrete footing is responsible for increasing the bearing capacity of soil [17]. The soil was prepared and compacted up in layers of 250 mm thickness with vibrator machine as shown in Figure 7, using 10.5% optimum water content.

Figure 7: Compaction process

3.2.2. Concrete

The strengthened footings were cast in two stages. Initially, the concrete ingredients were mixed uniformly with proper proportions of 350 Kg cement, 630 Kg sand, 1260 Kg crushed stone, and 175 Kg water. The platform was cleaned, so that no foreign particle could be mixed with concrete. Precautions were taken during the placing and transportation of concrete so that consistency remained in the mixes, and to prevent segregation. Concrete was thoroughly compacted around reinforcement using electric vibrator. After 40 days, when the initial casting of concrete reached its ultimate strength, the concrete jacket was applied on existing footings using sikadur-32 epoxy bonding agent. During the initial casting and concrete jacketing operations, concrete cylinders and cubes were cast from each type of concrete mix. The actual compressive and tensile strength of concrete of individual footings were determined by testing of the corresponding cylinders and cubes on the day of casting the concrete jackets and on the day of testing. The measured characteristic compressive strengths (f_{cu}) of original concrete, after 28 days, was 24.8 MPa, while it was 33 MPa for the column stub. The compressive strength of the concrete jacketing was 25.2 MPa, with a coefficient of variation (COV of about 8.2%) based on 12 cubes tested according to the British Standards [18].

3.2.3. Reinforcement

10 mm diameter deformed bars were placed at 50 mm cover as main reinforcement for all the footings and 12 mm diameter deformed bars were placed in column stub. The measured yield tensile strength (f_y) of bars was 407 MPa and the corresponding yield strain is 0.00205, while the ultimate tensile strength was 611 MPa based on tensile strength test according to ASTM A615 / A615M [19].

3.3. Surface preparation and installing dowel bars

The preparation of the surface was done when the original concrete footing specimens were 35 days old. The surfaces of the RC footings were roughed by hand-chiseling from all sides and top surface. Dowel bars of 10 mm diameter and 250 mm length rod were installed in original footings between the interfaces of the layered construction. These bars were embedded into the initial cast concrete by drilling after 40 days of casting with 100 mm embedded length and were installed using sikadur-31CF (Thixotropic epoxy resin adhesive). Figure 8 shows surface perpetration process, dowels drilling and placement in original footing and casting concrete jacketing.

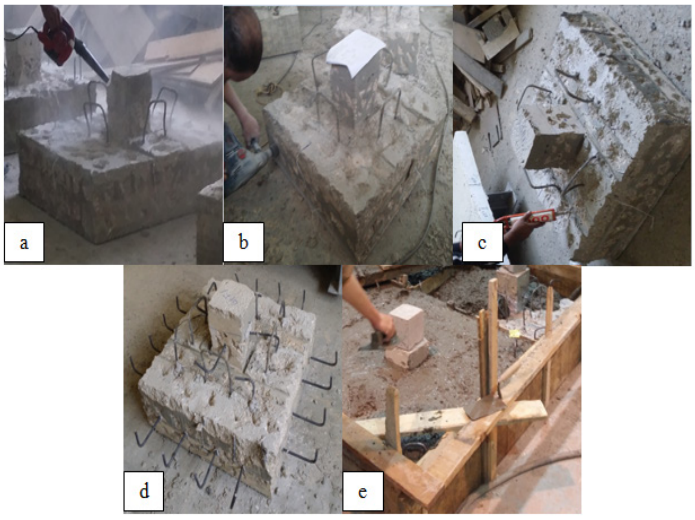

Figure 8: Preparation process (a) Roughening the concrete surface. (b) Drilling. (c) Installing epoxy. (d) Installing and placement dowels. (e) Casting new jacket.

3.4. Instrumentation acquisition system

The data acquisition system included two data acquisition modules for all the strains, displacements, and load cells. Ten

LVDTs were used to record the vertical displacement. Figure 9 shows the distribution of LVDTs on group-1 and group-2 respectively.

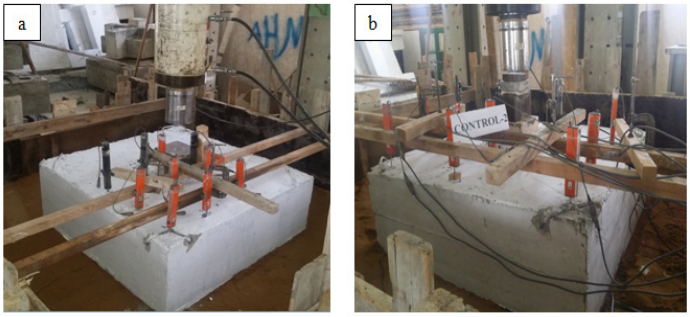

Figure 9: LVDTs distribution for (a) Group-1. (b) Group-2.

Concrete strain gauges were installed on the upper reinforced concrete footing on one direction only for group-1; strains were placed on to orthogonal direction for group-2 as shown in Figure 10).

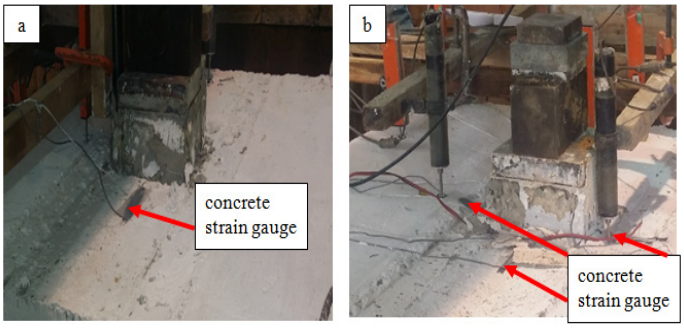

Figure 10: Concrete strain gauge distribution on (a) Group-1. (b) Group-2.

Reinforcement Strain gauges (6mm-length) were attached to steel rebar's in one direction for group-1 and in two orthogonal directions for group-2 as shown in Figures 11 (a and b) respectively. Figures 11 (c and d) show the distribution of additional reinforcement strain on the newly placed steel bars for strengthened footings G1F1, G1F2, G2F1 and G2F2.

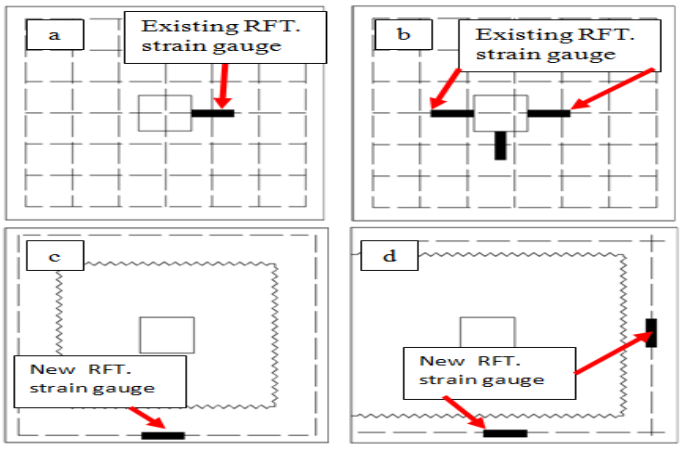

Figure 11: Reinforcement strain gauge distribution (a) Group-1. (b) Group-2. (c) Strengthening footing group-1. (d) Strengthening footing group-2.

Shear dowels, at typical locations, had strain gauges at their mid-length in longitudinal direction in specimen G1F1, while strain gauges were placed on shear dowels in orthogonal directions in specimen G2F1. Figure 12 shows a typical layout for strain gauge placed on shear dowels.

Figure 12: Typical reinforcement strain gauge placed on shear dowels.

Figure 13(a) shows a TY-350 pressure cell placed between the reinforced concrete footing and the soil surface to determine the contact stress distribution below the footing. Thus, it was decided to cover a pressure cell with thin steel plate to protect the pressure cell from damage. Four soil pressure cells were distributed below the reinforced concrete footing for groups (1&2) are shown in Figures (13) (b & c) respectively.

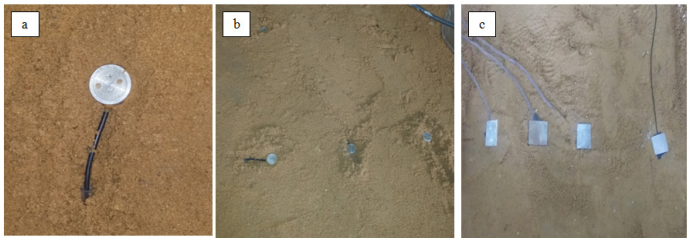

Figure 13: Distribution of load cell pressures beneath concrete footing (a) Typical TY-350 pressure cell. (b) (Group-1). (c) (Group-2).

4. Experimental Results

The application of concrete jacketing increased the ultimate load-carrying capacity of strengthened footings compared with those without strengthening. Moreover, the load-carrying capacity of G1F1 and G2F1 were higher than that of G1F2 and G2F2. However, the difference in the ultimate capacity was not significant. The increases in loading capacity are due to the increase in the concentration of stress at the center of the footing for footings in groups (1&2). The actual moment is calculated using compatibility of ultimate strains, where the location of the neutral axis is determined, and the moment is calculated by multiplying the tension force times the moment arm.

4.1. Failure modes and crack patterns

All footings failed in flexure due to steel reinforcement yielding, no brittle failure and debonding for concrete jacketing was observed. All side cracks were observed during test, while cracking on bottom surface of footings were observed at the end of the tests. The stiffness of the footings decreased with propagation of cracks at increased load levels. Figure 14 shows the typical crack patterns at failure for each footing. The behavior of the strengthened Footings G1F1, G1F2, G2F1, and G2F2 was close to the control specimens in terms of the crack initiation, crack pattern and failure modes whilst having different failure

loads. Increased strains in the flexural reinforcement were measured before failure. Experimental failure loads for different groups are listed in Table (2). Side cracks first appeared at bending moment level of about 50 kN.m in all footings and the corresponding load level were in the range of 700 to 800 kN. The theoretical moment at failure load, using the uniform distribution theory beneath footing rested on soil (Force/Area), was calculated as $WL^2/2$. From Table (2), it is noted that the actual moment at failure is equal to 82% of the theoretical moment which means the stress distribution under concrete footing resting on cohesionless soil was not consistent with the uniform distribution stress theory. Furthermore, the load-carrying capacity for all strengthened footing was higher than control samples, and the stress distributions under strengthened footing were the main reason for increasing the footing capacities.

4.2. Reinforcement and Concrete Strains

For all footings, compressive strains at the top side of the concrete were measured, in addition to the tensile strains of the lower main reinforcement. Figure 15 shows the applied load vs. the compressive strains of the upper side of the footing beside the column stub, showing a similar behavior for all footings under concentric loads. Regarding eccentric footings, the behaviour of the strains in the eccentric direction was different than that in the perpendicular direction, due to the concentration of stresses in eccentricity direction. Concrete crushing did not occur in all specimens and all compression strains did not exceed the plastic limit of 0.003. It was also noticed that the load-strain relationship was almost identical in the linear elastic stage.

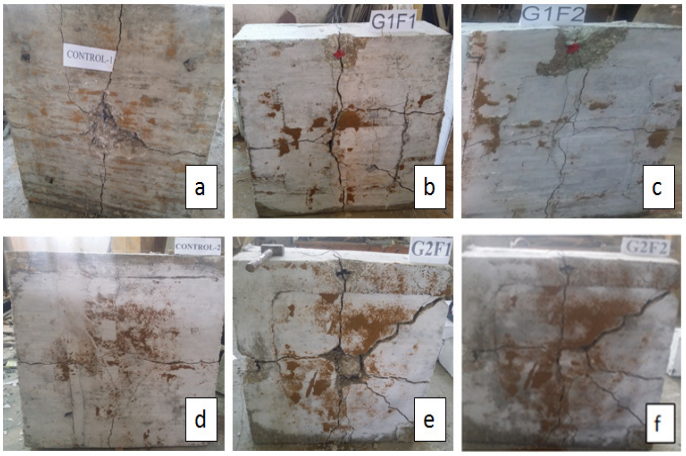

Figure 14: Typical cracking patterns at Failure for footings (a) C1. (b) G1F1. (c) G1F2. (d) C2. (e) G2F1. (f) G2F2.

Figure 16 shows the flexural reinforcement strains measured for concentric and eccentric footing. The strain gauges were installed within the column face region. All maximum measured strain values for existing reinforcements were above the yield limit which indicated that the failure occurred due to flexure, while all recorded strain values for dowels were below the yield strain limit, which indicates that the flexural debonding did not occurred during loading process.

Table 2: Test Results

Group	Label	Failure Load (kN)	% Increase in load-carrying Capacity	Theoretical moment at failure using uniform stress distribution (kN.m)	Actual moment at failure (kN.m)	Max vertical settlement at the center of the footing at control peak load (mm)
1	C1(control)	921	---	79.86	66.13	16.8
	G1F1	994.5	7	79.86	66.51	17.78
	G1F2	980	6	79.86	66.51	18
2	C2(control)	1000	---	79.1	66.5	17.4
	G2F1	1051	5.1	79.1	66.13	17.95
	G2F2	1020	2	79.1	68.24	18.1

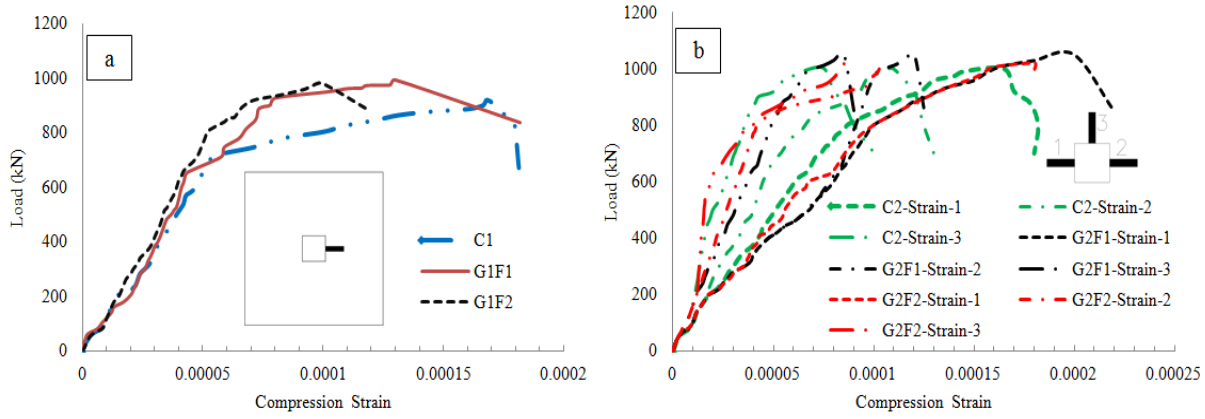

Figure 15: Applied load versus compressive strain (a) Concentric loading (b) Eccentric loading.

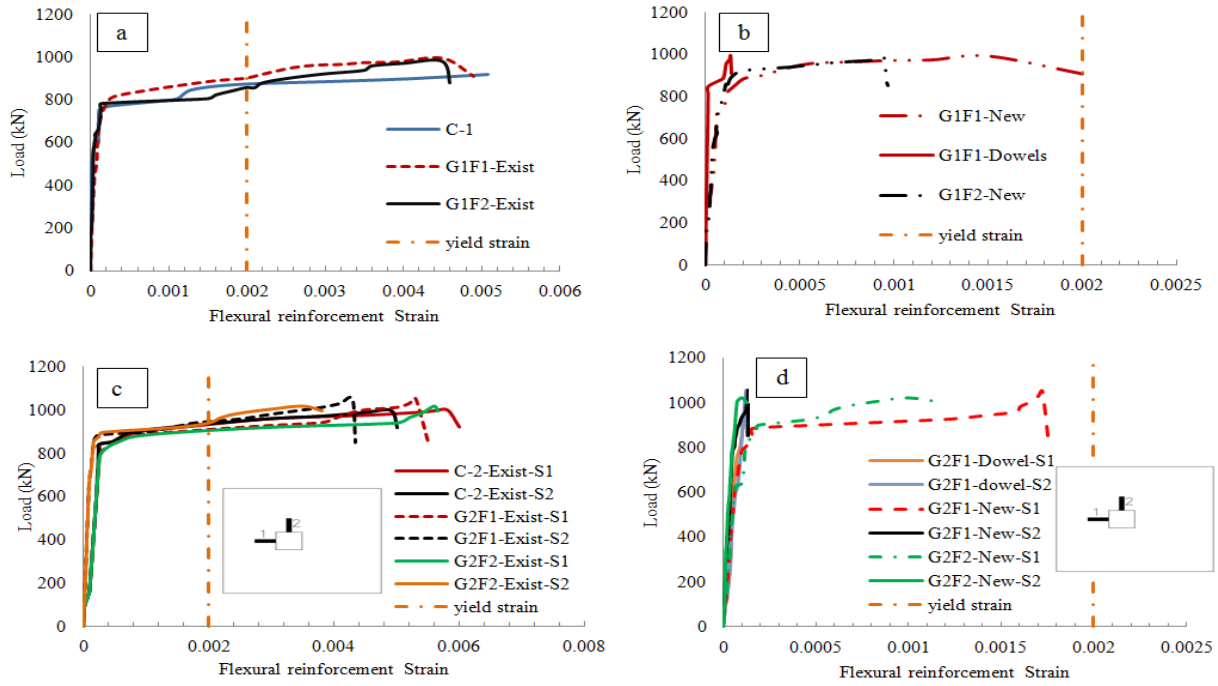

Figure 16: Applied load versus Flexural reinforcement strain (a) Existing reinforcement under concentric loading. (b) New reinforcement under concentric loading. (c) Existing reinforcement under eccentric loading. (d) New reinforcement eccentric loading.

4.3. Settlement under concrete footing

The settlement of the control and strengthened reinforcement concrete footing was determined at the same points along the width of the footing, as indicated in Figures 9 (a& b) for concentric and eccentric footings. The normalized average settlement versus the applied load of the reinforced concrete footing is illustrated in Figure 17. The behaviors of the concentric and eccentric footing were in good agreement until a load level of about 400 kN. After that, due to the eccentricity effect, a clear deviation in measured average settlement between group-1 and group-2 was noticed. Before cracking of the concrete, the settlement of all points along the width of the footing was similar. The rate in increase in average settlement after cracking was higher than that before cracking.

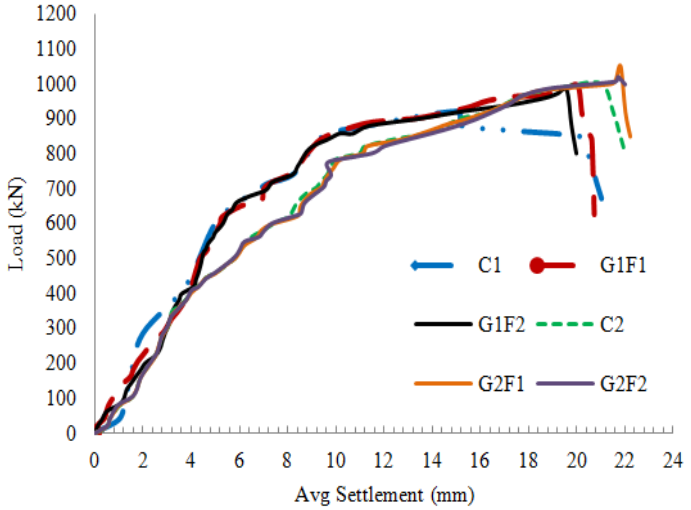

Figure 17: Applied load versus Average Settlement.

For the elastic stage, the behavior of all strengthened and control footings were similar and the elastic stiffness was almost the same according to the linear load-displacement relationship shown in Figure 17. After the concrete cracked, the behavior changed as the stiffness of the reinforced concrete footing decreased and the settlement significantly increased. Average settlements were not affected by using dowels compared with the footings strengthened with epoxy bonding agent only. The maximum settlement at the center of the footings increased with the increase in the contact stresses below the footings as shown in Table 2. The maximum settlement under strengthened footing G1F1, G1F2 were 5% and 7% higher than that of C1 respectively, while the settlement under strengthened footing G2F1, G2F2 were higher than that of C2 by 3% and 4% respectively.

4.4. Contact Pressure Distribution

The contact Stress distribution below control and strengthened concrete footing using concrete jacket with/without dowels were measured using pressure gauges as shown in Figure 13. Figure 18 shows the shape of contact stress distribution at center line of the footing for group-1 at 50% and 100% of the ultimate load of the control specimen C1.

Figure 18 shows the behavior of contact stress pre and post cracking. There was no crack initiation observed at 50% of the failure load of C1. The recorded stress at center line of footing C1 was close to the theoretical uniform stress distribution, but the stress at the edge was less than the theoretical assumption. The stress under center of strengthened footing G1F1 is higher than C1 by 9% and 12% in cases (a) & (b) respectively. Moreover, The stress under edge of strengthened footing G1F1 is lower than C1 by 16% in case (a) and 22% in case of (b) which means the contact surface between existing and new concrete play an important role in stress distribution under strengthened footing.

The stress under center of strengthened footing G1F2 is higher than that of C1 by 18% in case (a) and 13.5% in case (b). While, the stress under edge of strengthened footing G1F2 is lower than that of C1 by 23% and 25% in cases (a) and (b) respectively. The ratio between the center to the edge stress increased with increasing the applied load, which is due to that the effect of cracking. The flexibility of the footing increased with increasing the flexural cracks leading the concentration of the stress to be shifted towards the center of the footing. It is noticed that for the control footings in group-1, the shape of contact stress before cracking was saddle-shaped, but after cracking the shape of contact stress takes place as a parabolic shape for control footing, while the contact stress was a bell shape beneath strengthened footings. Figure 19 shows the shape of contact stress distribution at edge line of the footing for group-1 at 50% of C1 failure load and 100% of C1 failure load.

From Figure 19, it is noticed that the recorded stress at center line of C1 seems close to the theoretical uniform stress distribution assumption. The stress under center of strengthened footing G1F1 is less than that of C1 by 16% in case (a) and 22% in case of (b). Additionally, the stress under edge of strengthened footing G1F1of above figure is lower than that of C1 by 5% in case (a) and 22% in case of (b). The stress under center of strengthened footing G1F2 of the above figure is lower than C1 by 23% in case (a) and 25% in case of (b). Furthermore, the stresses under the edge of strengthened footing G1F2 are lower than that of C1 by 9% and 15% in cases (a) and (b) respectively.

Figure 20 shows the shape of contact stress distribution at the center line of the eccentric footing for group-2 at 50% and 100% of the failure load of the control specimen C2. The stress distribution under eccentric loading is concentrated under the column and completely different than the theoretical assumption (MY/I), these results were in agreement with the experimental results for non strengthened footings by G. U. Muller et al. [11]. The stress concentration under center line of column stub for G2F1 and G2F2 is higher than that of C2 by 1% and 5% respectively for case (a) and 2% and 5.6% respectively for case (b). Moreover, the stress concentration under footing edge at maximum compression zone G2F1 and G2F2 is higher than that of C2 by 1.5% for case (a), while it is lower than that of C2 by 2% and 6% respectively for case (b). The stress concentration under footing edge at minimum compression zone G2F1 and G2F2 is lower than C2 by 16% and 23% respectively for case (a) and lower than C2 by 18% and 25% respectively for case (b).

Figure 21 shows 3-Dimensional Contact stress distribution beneath control footings C1 and C2 at 50% and 100% of their failure loads using Surfer maps version 13.

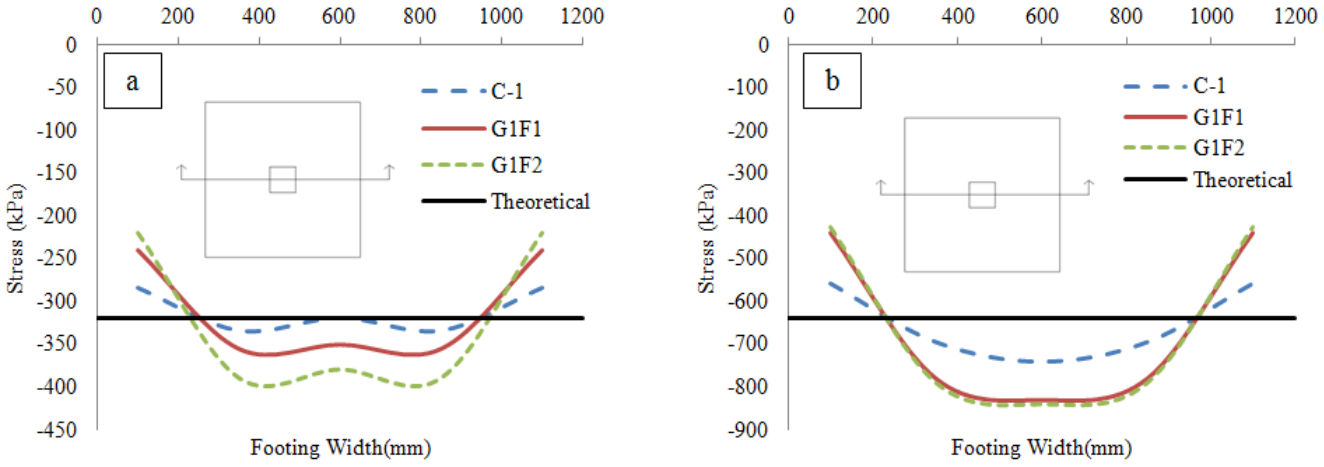

Figure 18: Contact stress distribution beneath footing center line (group-1) at (a) 50% of C1 failure load (b) 100% of C1 failure load.

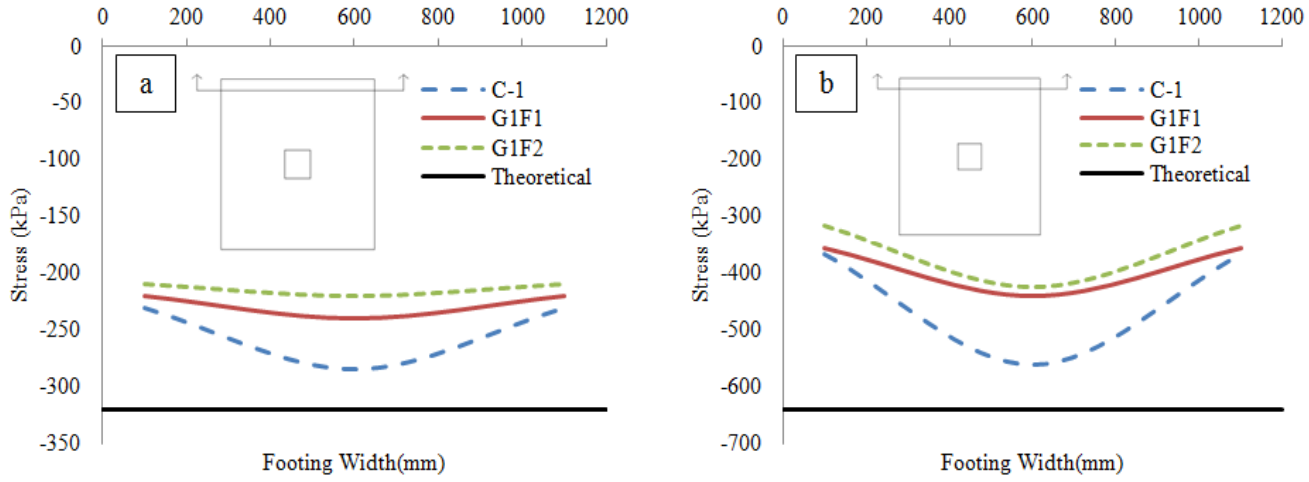

Figure 19: Contact stress distribution beneath footing edge line (group-1) at (a) 50% of C1 failure load (b) 100% of C1 failure load.

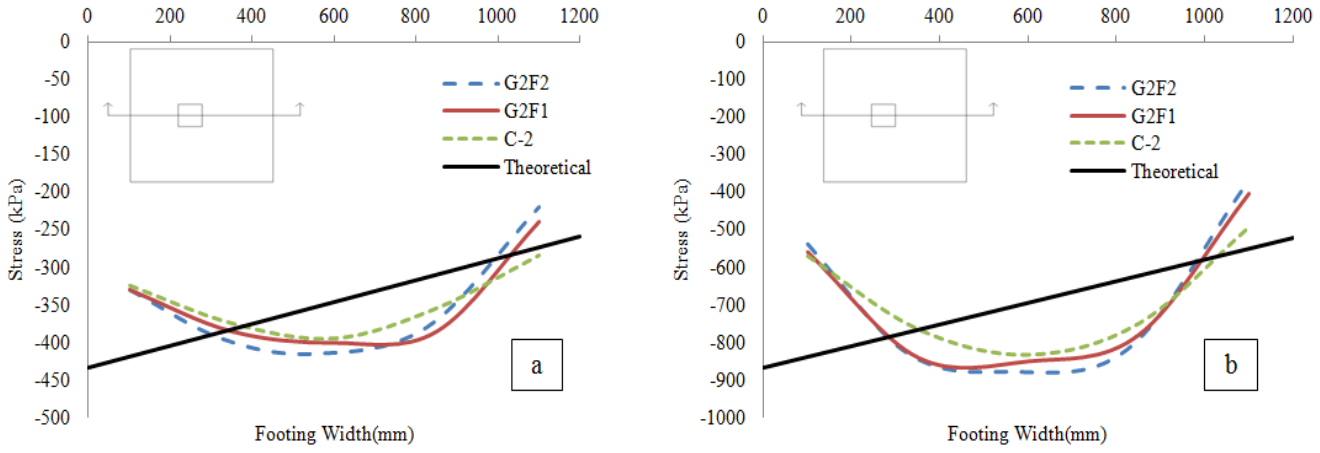

Figure 20: Contact stress distribution beneath footing center line (group-2) at (a) 50% of C2 failure load (b) 100% of C2 failure load.

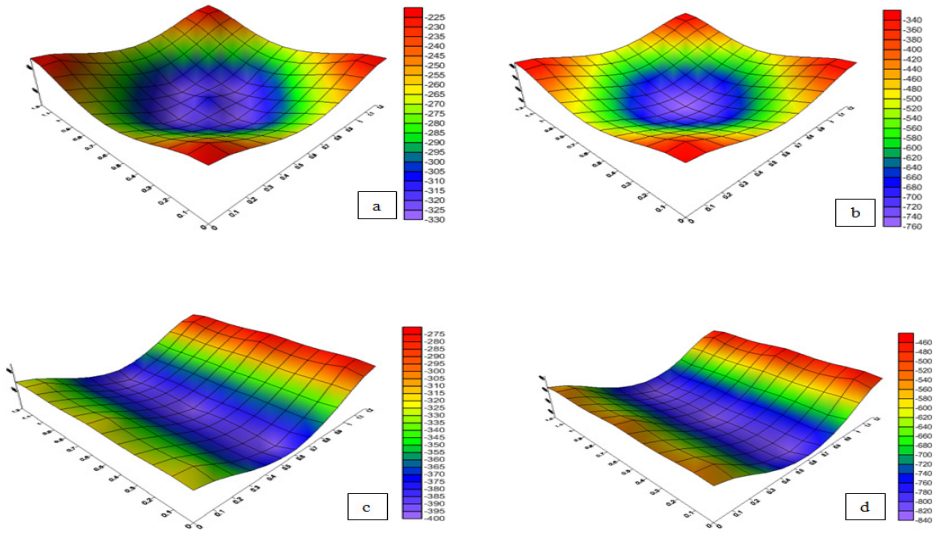

Figure 21: 3-D demonstration the contact stress distribution beneath control footings C1 and C2 (a) 50% of C1 failure load. (b) 100% of C1 failure load (c) 50% of C2 failure load. (d) 100% of C2 failure load.

5. Summary and Conclusions

In the current study, six isolated concrete footing were tested to evaluate the structural performance after strengthening for concentric and eccentric footing. From the test results, the increase in load-carrying capacities was calculated, the stresses and settlement distribution beneath control and strengthened footings were measured and the effect of using dowels in addition to epoxy bonding agent was evaluated an compared to the effect of using epoxy bonding agent only. The following conclusions are summarized:

- In both concentric and eccentric loading, the load-carrying capacities of strengthened footings were close to that of non-strengthened ones with same dimensions.
- Using dowels to connect the existing footing to the concrete jacket did not increase the load-carrying capacity significantly compared to using bonding agent only.
- The contact stress distributions beneath control and strengthened footings were not consistent with the theoretical solutions, the assumption of uniformity solution gives expected higher moment than the actual results and leads to a conservative structural design.
- The stress concentration under column center was increased by average 10% and 15% for concentric and eccentric jacketing respectively compared to the control specimens.
- The increase in settlement after jacketing was approximately 6% and 3.5% for concentric and eccentric jacketing respectively compared to the control specimens.
- The contact stresses seem to be saddle-shaped before cracking and the concentration of stresses tend to be shifted towards the center of footing after cracking during concentric loading.

Piano learning

ABSTRACT

Finger skills are achieved through the training process. This training process will be more straightforward if a training system is used. A novel finger motoric training system is introduced in this paper. This system is to facilitate a beginner piano player to learn the basic piano skill. The system is comprised of a tracking finger sensor, a personal computer, and multimedia feedback. Subjects train with passive and active mode. The passive mode, the subject's fingers are doing nothing when the information is given, whereas the subjects are playing a virtual piano under the sensor. While the information which fingers have to tap are provided by visual, audio, and enhanced with electrical haptic sensation. The experimental results demonstrate that the system equipped with electro-tactile feedback makes the subjects more responsive to both modes. Moreover, this system enabled the user to accelerate learning a new skill.

1. Introduction

Motoric skill learning can be trained with repetition, also utilizing stimulants from the surrounding environment [1]. Such motoric skills, for example, are typing, writing, and playing a musical instrument. To acquire dexterous motoric skills, practice with repetitive movements is needed. Moreover, these practices need persistence from the instructors and the learner. On the other hand, a stimulus can be used to augment the learning process.

Visual and audio information are commonly used as stimulants. Learners are showed how to do the skill accurately. In this process, they are played, or listened to, the appropriate sound. A haptic sensation can be applied to the learner using mechanical interaction. Some researchers utilize these stimuli to enhance the method to train the motoric skills, for example, playing the piano [1, 2], writing Japanese characters [3], writing Arabic and Japanese characters [4], and typing the Braille alphabet [5]. However, these systems are cumbersome, and the user finds it difficult to move their fingers.

To overcome these shortcomings, electrical stimulus is used. This information is given to the skin of the user. The electro-tactile feedback system is proven to become feedback used for controlling mobile [6], arm robot [7] also fingers [8], information for haptic sensors [9], enhanced virtual game [10]. To examine the potential usage of electrical signal, a multimedia learning system for a motoric finger is established. This paper is an extension of work initially presented in the 2019 International Conference on Sustainable Engineering and Creative Computing (ICSECC) [11]

For the experiment, subjects are divided into three groups. They are trained using different methods. Information in the form of audio and visual means are given to the first group to train the finger movements of each subject. In the other groups, the subjects utilized audiovisual means, enhanced with electrical sensations to practice. These groups consist of subjects which do the experiments with active mode and subjects with passive mode. The results show that the group using an electro-tactile feedback system is capable of playing the music appropriately with both active and passive modes. Moreover, they learn more rapidly than the other group. Besides that, the proposed system is simple and easy to use. The haptic sensation also does not cause pain to the subject.

This paper is organized as follows: Section II delivers a brief overview of related works within this field of study. Section III presents the details of system implementation. Section IV describes the experiment, which demonstrates the effectiveness of

[*]Corresponding Author: Daniel S Pamungkas, Politeknik Negeri Batam, daniel@polibatam.ac.id

the system for finger motoric learning. Finally, Section V delivers the concluding remarks.

2. Background

The process or action to achieve an ability to do, or to gain knowledge, is known as a learning process. The actions done in this process require stimulation from the surroundings. Moreover, repetition is needed in the learning process [12]. In this process, one thing can be connected to others, or known as associate learning. Stimulus or information is given repeatedly, resulting in a reaction, until the reaction can be an automatic response and become habitual. This stimulus can be associated with a reaction. Pavlov shows this condition with his experiments, in which the subject dogs have a new behavior. The dogs are able to associate the sound of a metronome with food [13]. Some physical training can be involved in associate learning, such as finger movements.

The skilled fingers motions are involved for a specific action, such as typing a computer keyboard or playing the piano. These finger skills are challenging to learn using only verbal instructions. Such training will be effective and efficient if the learner does a lot of exercises. Some software have been developed to assist people to learn to type in a keyboard or to play the piano. These software are intended to support the user in typing or playing the piano with all fingers. Visual stimulation is used by these software, for example, colors or lights. Other programs utilize audio information, e.g., the sound of the notes. Moreover, some of the applications apply both audio and visual information. However, another sense has excellent potential to transmit data, namely the sense of touch or tactile taste, which uses the skin to deliver stimulation.

Human skin is sensitive to several sensations, for example, vibration, heat, force, and electric signal (voltage or current). The skin has some sensory receptors, namely mechanoreceptors, thermoreceptors, nociceptors, and proprioceptors. These receptors are to accommodate all the sensations. Moreover, these receptors also enable humans to feel texture, paint, etc. [a]. Tactile sense causes humans to have the ability to detect and classify objects through their skin. This sense is sometimes called haptic sensations.

The term *haptic* comes from the word 'hapto' from Greek. This word means ‘to touch and handle objects’ [14]. Several researchers introduce haptic information utilizing vibration [15], heat [16], force [17], and electric sensations [6]. These information aims to enrich the user to interpret or interact with the application more effectively.

Haptic feedback has been used widely in various applications. A simulator to learn how to perform a surgery [17], remotely controlling a robot’s actions [18], a tactile sensor to sense the roughness of a surface [9] and gaming experience using VR [10] are the examples of the application of this feedback. Also, there are applications for training fingers skills using haptic feedback. For instance, haptic feedback is used for learning to play the piano [1,2], and using a Braille keyboard [5]. Moreover, this feedback is combined with other feedback, namely visual and audio, for writing characters [3] [4].

One of the rehabilitation procedures for a person with spinal cord injury (SCI) is to learn how to play the piano. For this training, subjects are equipped with a vibrating glove. This glove is equipped with a vibration motor on every finger. The vibrations help the subject to know which finger has to strike the keys of the piano [1]. The subjects are required to move their fingers while training. Such a method is called an active mode. Markow et al. report that this system enables the subject to play an easy song.

Others report that a passive mode training using vibration cues has positive results. The passive mode method is the method in which the subject trains without actually doing the activity about which they learn. The learning process is given using their senses. In [2] the subjects are trained to play a song with a piano using a vibration glove. The audio and haptic feedbacks are given to the subjects while they are doing the activity. Subjects are listening to the song, while the vibrations in their fingers give information which finger has to move related to the song. These experiments show that this information, including haptic feedback, enables the user to play the piano reflexively.

In [5], active and passive modes are used to train blind subjects to type in a Braille keyboard. This system has a keyboard that has the capability to train the user to use audio and vibration. The vibration information is given to the user's fingers. The subjects are able to use both hands to learn using this system. In these studies, the experiments are done with active and passive modes. The authors argue that both methods using audio and haptic information can be used to learn to type.

Another haptic information is force feedback. One of the devices able to give kinesthetic feedback to the user is called The Phantom. This device is used to train the learner to write Japanese [3] and Arabic [4] characters. This device helps the hand of the user to write the characters correctly. Both studies show that the force feedback is able to assist the subjects in training to write several newly-learned characters efficiently.

Mechanical feedback, such as vibration and force feedback, is able to transmit information for finger skill training. Haptic feedback has a great potential to be a training method, however it is cumbersome and costly. These devices hinder the movement of users in typing on a keyboard or playing the piano.

One type of haptic feedback is electro-tactile feedback. This applies an electric current to forward information to the skin. This feedback gives sensation to the skin and directly to the nerves. Electrotactile feedback system is simple and comfortable to use. Data from electric sensations can be informed through differences in amplitude or frequency. Thus, electrotactile feedback has various ranges of information that can be transmitted to the user [6]. In the next section, detailed methods to demonstrate the potential of electrotactile feedback are presented.

3. System

3.1. Overview

The proposed system for finger training is a computer with a screen and sound system, in addition to a gesture sensor, also with an electro-tactile feedback system. The electro-tactile feedback has different modes to vary the frequency, amplitude and the width of the electrical pulse. These variations have to be adjust to the subjects wearing this device. This system is comfortable to wear and does not hinder the user’s movements [6-11].

The frequency, amplitude and pulse width have a wide range of options, the frequency was varied between 10Hz to 120Hz. For this experiment stimulus pulses are set at 20Hz frequency (Figure 7). The amplitude of the pulses is adjusted by the user between 40-80V to achieve a comfortable condition. The intensity is controlled by the pulse width. The width of signal is varied, particularly between 10 to 100μs.

This system can be seen in Figure 1. Figure 2 shows the diagram block of the system. The screen of the computer displays the character of the note and which finger(s) to bend, while the corresponding frequency of the note is sounded using the computer's sound system. The electrodes in the fingers of the subject are transmitting the electric sensation. These sensations are given to the fingers appropriate to the note. The gesture sensor is used for tracking the fingers of the subjects. This sensor is placed near the top of the screen facing down to detect the movement of the subject fingers.

The learning is done by a passive and active method. The audio, visual, and haptic information are given to the subject while learning in the passive method, whereas the hand tracking device with the feedback is used when active learning is performed. In the test period, only a hand gesture sensor is used with the computer.

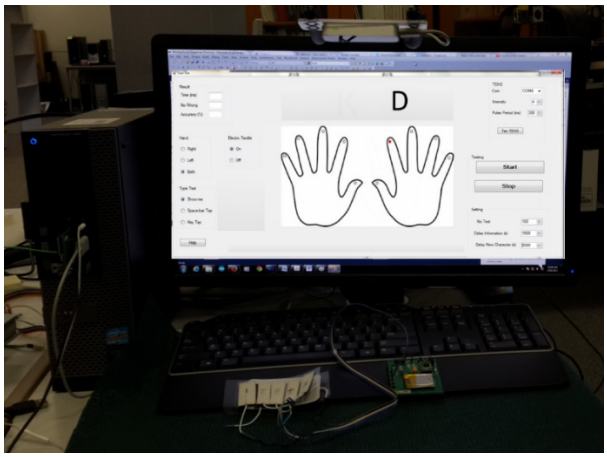

Figure 1: Arrangement of the system

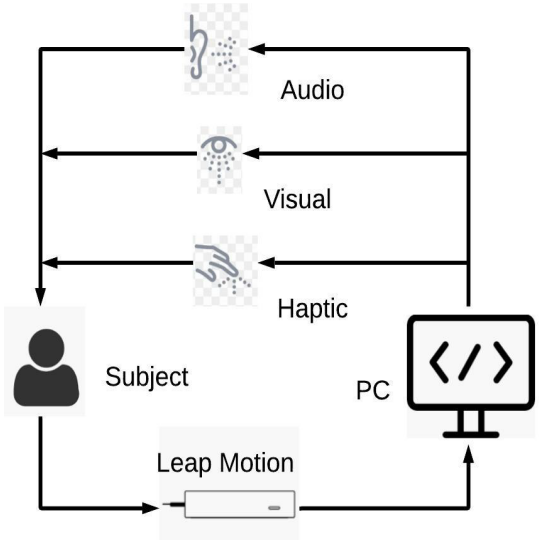

Figure 2: The Diagram block of the system

3.2. Hand tracking and software

One of the main components of the proposed system is the hand and fingers tracking sensor. For these tasks, a leap motion sensor is used. Leap motion is able to detect fingers and hands accurately from around one meter in three dimensions. The accuracy of this sensor is around 0.1 mm. This device is equipped with two infra-red cameras and three infrared LEDs [19]. This sensor has two modes. The first mode faces upward; the hands are above the leap motion sensor, known as a desktop mode. In the second mode, the HMD, the leap motion faces downward. HMD mode is used for this system. A custom bracket is utilized for placing the sensors. In this position, it is possible to have noise from reflective surfaces, so a dark mat is placed to cover the desk. The mat is shown in Figure 1.

The finger training multi senses system has several modes to train the subjects. The first mode is training using three senses; visual, audio, and haptic. The second mode uses visual and audio information, and the third uses audio and haptic information. The first and the second modes will be used to train the subject with the active method, while the third one is used to train with the passive method. The active mode requires subjects to tap the fingers below the gesture sensor.

The software is able to detect the correct or the wrong fingers. The function of this feature is to test the result of the training. The GUI of the system can be seen in figure 3. Moreover, the system is able to train the subject to play piano with only the right hand/notes only, or with both hands (notes and simple chord).

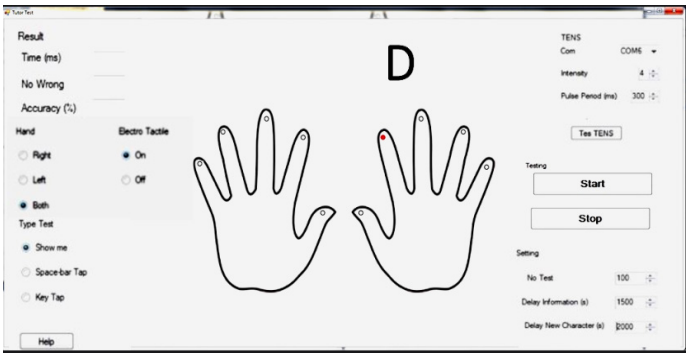

Figure 3: GUI of the system

The software is developed to display the characters of the note. Also, this software shows the appropriate fingers that have to bend. Figure 4 shows the fingers as appropriate to the note in a piano for the left hand (Figure 4.a) and right hand (Figure.4.b). The left-hand fingers of the human are placed in the a lower octave than the right hand. The left hand is trained to press the fundamental note of the chord. For example, if we want to play the C chord (C-E-G) the subjects are trained to press C, and so on such as in Figure 4.a. The left hand and the corresponding notes of the chord are shown in Figure 4.b. The right hand of the subject is trained to play the notes from C to G. Using this arrangement, this software is able to instruct the user to perform simple music. The user can play with only the right hand (melody only) or with both hands (melody with simple chord).

This software also has the capability to produce sound of note. This voice corresponds with the finger as defined in Figure 3. The

output of this information is transmitted to the computer sound system. Moreover, the haptic feedback augments the information for the user. Electric signal is transmitted to the nerve using electrodes patch. Fig 5 shows the illustration of the back of human palms. All the human fingers of both hands are placed the electrode. The software has facility to send electrical sensations appropriate to the visual and audio information. The next section will provide the detailed explanation of the electro-tactile feedback system.

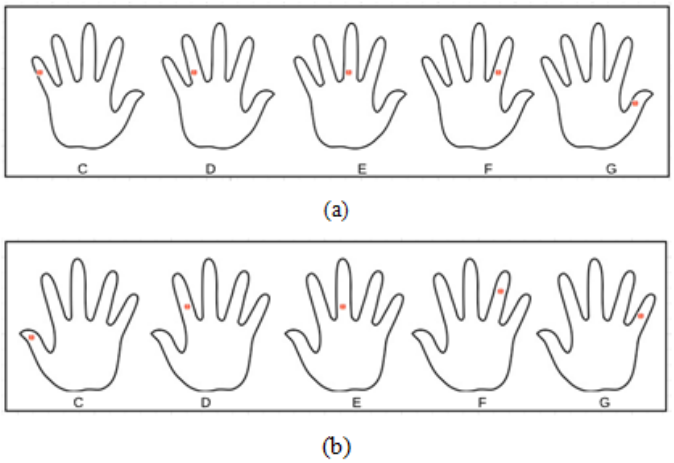

Figure 4: The corresponding fingers with the notes (a) left hand (b) right hand.

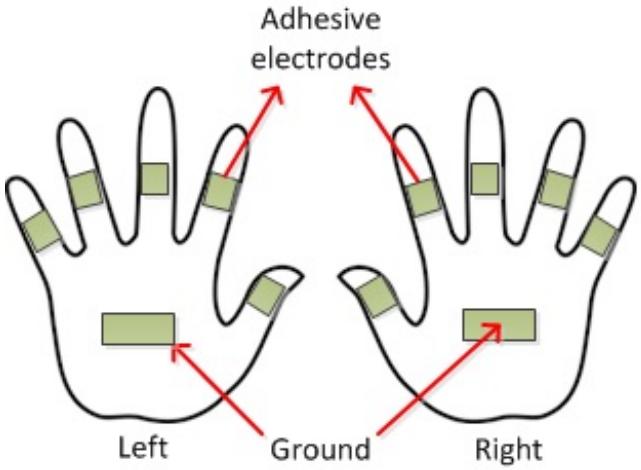

Figure 5: The electrodes in hands of the subject

3.3. Haptic system

The electro-tactile feedback system, which we call TENS (Transcutaneous Electrical Nerve Stimulation) system, comprises of three main components, namely transmitter, receiver and electrodes. The first component is the transmitter; the function of which is to transmit the signal from the computer to the receiver wirelessly. The main element of this component is a Bluetooth transmitter. The receiver receives the information from the transmitter and transformed it into electrical pulses. The five channels receivers with one ground are used. For the experiments, two transmitters are used for both hands. This structure enables the subject to receive ten signal frequencies. The last component is the electrode, placed in the knuckles, and a ground is placed in the middle of each hand. This arrangement allows the nerves of the subjects to obtain the information. The electric signal has frequencies that vary in the range of 10Hz to 120Hz. The width of the pulse varied between 10μs to 100μs. Moreover, the width of the pulse is a factor in controlling the intensity of the signal. The signal has an amplitude range between 40V until 80V. Those features are able to be adjusted. This adjustable function is to attain the subjects' comfort. Every subject has their own preferences. In the following section, the experiment with the results will be shown.

4. Experiment Methods and Results

This learning system is to train the subjects with passive and active mode at improving the basic skills of playing the piano. These trials were directed mainly to confirm the potential of the proposed system using audio and visual information and augmented with electrotactile feedback system. This objective can be done by comparing the experiment with a training system using only audio and visual feedback.

To do the experiment, nine subjects are divided into three groups. All the subjects are never trained to play the piano. They also have never used the electrotactile feedback. The subject's ages vary between 15 until 21 years old. The subjects are comprised of five males and four females. The first group trains using the active mode with audio, visual and haptic information. The second group practices with the active mode, only using audio and visual feedback. The passive mode, with audio and haptic information, is given to the third group. The subjects doing the active mode have to tap their fingers as appropriate as the given information.

Before the trials, all the subjects are given basic music theory, focusing on the use of appropriate fingers and hands for specific note or chords. For the first five minutes, they are trained to use the system. The aim of this training is to enable the subjects play with the virtual piano. Subjects were trained to tap their fingers according to the notes that appear on the screen until they become used to use their fingers under the sensors. This is followed with an initial test. In this state all the subjects tried to play a simple song. The system only shows the letter of the notes that they have to tap, and the errors are counted. Errors include the use of wrong fingers or missed notes.

After the initial test, for the groups where haptic feedback is used, the intensity of the electric signal is adjusted for each subject. This is for the comfort of the subject, also to adapt with the signal. This is then followed with five minutes training of the subjects with the method in their groups. In this time all the subjects are given information about which fingers must be bent in accordance with the letters of the notes shown in the screen. Then, in the last five minutes, all the subjects tried to play music assisted with the feedback and the letters of the notes in the screen. After a short break, the final test is conducted to prove the effectiveness of the haptic feedback. This task is the same with the initial task. The errors are calculated and the percentage of improvement of each subject can be counted.

Based on the experiment, on average, the first group, who learned to bend the fingers utilizing visual and audio information, and enriched with electrical sensation, on average achieved an improvement of around 40%. On the other hand, the second group, who learned through the active method using visual and audio

feedback, but without haptic feedback, achieved 20% improvement. While the last group, which used the passive method, had about 35% improvements. Table 1 shows the number of errors for each subject before and after being trained in the method they use.

Analysis of the outcome of the experiment shows that all the training methods offers positive results. All the methods are able to improve the musical skills of the subjects. However, the methods which employ the haptic feedback show a more significant performance improvement compared to the method not involving haptic feedback. This can be concluded that the systems that involve haptic information are more effective. Moreover, subjects who use electric stimulation feel that the feedback is not painful and easy to use.

Table 1: Error before and after training

Active Electro Tactile Feedback			**Active Without Electro Tactile Feedback**			**Passive With Electrotactile feedback**		
Subject No	**No Errors**		**Subject No**	**No Errors**		**Subject No**	**No Errors**	
	Before	After		Before	After		Before	After
1	25	15	4	28	22	7	30	19
2	27	16	5	27	21	8	23	15
3	22	13	6	26	20	9	24	15

5. Conclusion

This paper introduces a novel system to train fingers to play the piano using multimedia information. The audio, video and haptic feedback is used to teach. A computer's speaker is used to provide audio information. The screen of the computer is used to show visual feedback, while haptic information is transmitted utilizing electrical sensation. This proposed system employs a gesture sensor to become a virtual piano, and a custom software is built to accommodate all the inputs and outputs of the system.

The results of the tests indicate that the system involving electro-tactile feedback using active and passive training methods have positive results. The electro-tactile feedback system enables to train the fingers of the users to move in association with the information reflexively. Moreover, this system augments to train users the new finger skill better than the method only using audio and visual. The improvement of the subjects who use haptic feedback is superior to the subjects who utilize the conventional one. Electro-tactile feedback is inexpensive, convenient to use, simple to wear, and does not hinder the user from moving their fingers.

This system has shown its potential to enhance finger training devices. It is desirable to conduct further research with more subjects, as well as a comparison with existing training systems to measure the performance of this proposed system.

ABSTRACT

A happy employee with high morale is the best asset of an organization. The morale of an individual working in an organization can be impacted by both positive and negative ways by physical environment factors of the workplace. The physical environment of an organization impacts a lot on the work performance of an individual. It becomes more significant in case of aviation maintenance organization formally called Maintenance Repair and Overhaul (MRO) organization as the work performed by an individual requires full accuracy and directly linked with the safety of the aircraft and its occupants. This can only be achieved by providing a safe and positive working atmosphere to individuals working in MROs. Considering the same, this study targets to deliver a brief status report of physical environment factors disturbing work performance in Maintenance Repair Overhaul (MRO) agencies. This study initially explains the impact of different physical environment factors. The study also discusses the impact of unsafe work due to improper working environment in aircraft maintenance organizations. The individual's working in MROs located in the United Arab Emirates were considered for testing the physical environment factors for this case study. This case study aims to provide the status of different physical environment factor of organization causing problems at work for individuals working in aircraft maintenance organizations. The result of the study indicated that MROs in UAE are providing a conducive working atmosphere to employees, however, the lack of workplace is still an area for improvement.

1. Introduction

The human being is manipulating the environment for his survival and comfort contrary to the environment or nature is human's best friend and nearest surrounding. Unsafe and dangerous conditions may arise if we manipulate nature incorrectly and can make the life of human being very difficult. [1].

The efficiency of individuals and the work morale of individual at the workplace might get affected due to the hazardous environment resulting from the poorly administered surrounding. To determine the performance, morale and efficiency of an individual at a workplace, the workplace environment is a key factor. The workplace environment includes the area and condition in which an employee is executing the job however a positive and effective work environment is the condition when the output of the individual working for an organization is same as expected as per job objective [2]. The physical environment where the job is being carried out by an individual significantly affect the performance of an individual.

The bodily atmosphere as a characteristic of the workplace atmosphere has an uninterrupted influence on human intelligence and can slowly variate interpersonal communications and therefore, efficiency. It happens because the features of space/room or an area have significance on the efficiency and happiness of individuals [3]. Several types of research have concluded that the features of a working area affect the satisfaction of the users. These features of a work area are preferred by the user and extremely important to the user for productivity and work satisfaction. These features include proper lighting, good ventilation, soundproofing, temperature and workspace etc. [4].

*Corresponding Author: Kamal Jaiswal, kamaljswl@gmail.com

The factors like proper illumination of the workplace and suitable work resources such as furniture can have an encouraging effect on the health of an individual and subsequently on the efficiency. Other environment elements of a workplace such as controlled temperature, soundproofing, good ventilation etc. play a significant role in the productivity of an organization [5]. These elements ultimately influence the overall working atmosphere and decide the productivity and satisfaction.

The employees who are bodily and mentally motivated to do their job, the performance is expected to be enhanced, and safety is improved. A well-working environment can significantly reduce the absenteeism and conclusively enhance work efficiency [6]. The aircraft maintenance organization work under a complex system and the productivity of the individual decide the success of the organization. The efficiency of individual working in aircraft maintenance organization largely rely on working condition or physical working environment and it is the most important factor for safety as well [7]. The safety management system used in the aviation sector also address this issue and emphasize on providing a good physical environment to the individuals to perform the job safely. However, it is quite challenging for the management to provide a user-friendly environment to an individual in aircraft maintenance organization as the certain task to be performed on aircrafts requires an individual to work under adverse condition [8].

The output of an organization is directly linked with the satisfaction of employees with the physical environment of the workplace. The administration should regularly monitor and ensure that the physical working environment of the organization is conducive to work for the individual performing the job. The commitment of the administration to deal with work environment influences the motivation of the individual to perform properly and it should be assessed regularly and management should make necessary changes whenever required by employees to improve the efficiency and safety [9]. The changes may include, such as a change in the layout of the workplace or the addition of more resources.

Today's administration has to alter the way of working in order to get real modifications in these facets. The organization has to devote more time on governing these issues of the work situations rather than micromanage. This can be accomplished by enlightening on the physical workplace and amenities, assigning tasks, cumulative liability, and inspiring teamwork. This will encourage faith and devotion between the workers and boosts improved cooperation amongst them.

The capability of an employee to successfully perform a job in a tuff work environment is limited. The studies have revealed that a workspace feature changes the approach of employees and intensify their output. It also states that hazardous and insalubrious workplace atmosphere in terms of poor ventilation, incorrect illumination, disproportionate sound etc. disturb employees' efficiency and healthiness

2. Physical Working Environment

Aircraft maintenance engineers work inside a "complex system". There are plentiful characteristics inside this structure that encroach on the aircraft maintenance engineer, outspreading from his knowledge, skills and capabilities, the atmosphere in which he/she works, to the values of the organization for which he/she works. Even beyond the actual company employee works for, the governing requirements laid down for his/her job evidently impact on his/her comportment. All features of this structure may promote headed for inaccuracies that the engineer might make [10].

To well apprehend efficiency on jobs, it is vital to study the relationship between job performance, individuals, and circumstances elements. Job performance is a very substantial factor manipulating the cost-effectiveness of any organization. Performance is a key element for organizations as employees' performance directs to business success. Similarly, performance is vital for individuals, as accomplishing responsibilities can be a basis of happiness [2].

All the activity and behaviours that are executed by an individual, leading to attain the objectives of an organization can be termed as Job performance. The outcome of a task done by an individual or a group of individual in an organization on a specific time directly indicating that how well the individual or a group of the individual did that job while considering the organization's goal can be described as Performance. The physical environment such as operating conditions, procedures, resources and equipment to perform the job can majority impact the job performance of an employee [11].

In aviation, specifically in MROs, the job performance of an individual is very significant as the job performed by them is safety-critical. High level of job performance from an individual is required in the aviation industry to have a safe operation. The physical work environment and its impact have been enormously considered since the conditions can hamper, interfere with, or set restrictions on the variety of work behaviours that are exhibited which, in turn, possibly influences task performance [3].

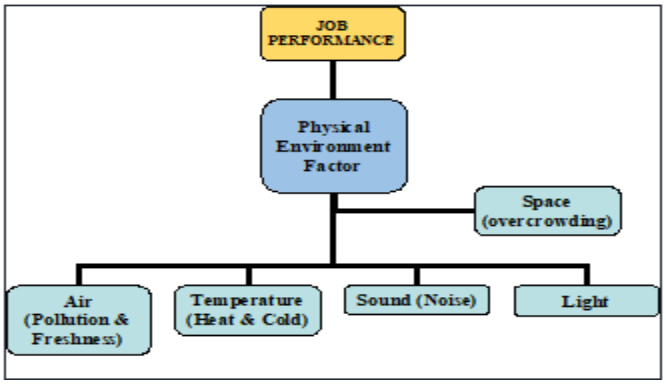

Figure 1: Physical Environment Factor

3. Physical Environment Factor that Influences the Performance

A vigorous interface is discovered between job performance and physical working environment, by the description of what is envisioned by the work environment and literature study findings [12]. The employees' performance, satisfaction, social relations and health is directly linked with physical environment of workplace. Generally, it is presumed that the bodily design of workstations and the ecological condition of workstation are

substantial elements in organizational performance. The study of Badayai (2012) has established earlier studies and categorized five key aspects of an unpleasant working environment as shown in figure 1.

3.1. Air Factor

The behaviour of individuals working in aircraft maintenance organization can significantly alter the job performance due to poor air quality resulting from lack of ventilation or any other factor. The quality of air significantly affect the health of individuals and describe the comfort level of the individual. Sometimes the quality of air can be very poor, specifically individual working with chemicals and in the confined area of aircraft in aircraft maintenance organization [5].

Utmost conceivably unsafe indoor air toxins are radon, asbestos, inorganic material, environmental tobacco smoke, organics, biological and non- ionizing radiation. Supplementary polluting agents such as odours and dust can be the source of serious uneasiness and feelings of reluctance that may lead to a fall in efficiency and job performance. A good ventilation system can overcome this issue and provide a sense of comfort with a combination of controlled temperature. Apart from this, some protective apparatus maybe use to avoid inhalation of pollutants in certain working conditions [10].

3.2. Temperature

The discomfort caused by temperature can be very painful and can significantly reduce job performance. Several types of research have established that the temperature of the workplace has a lot to do with how we interact with others in an organization. The behavior of individuals can significantly change when the temperature of the workplace is not conducive such as too hot or too cold [10]. Working under a condition either hot or cold can cause the lack of attention specifically in those tasks which require a great amount of focus such as crown inspection of rivets on aircraft or Non-destructive testing in workshops.

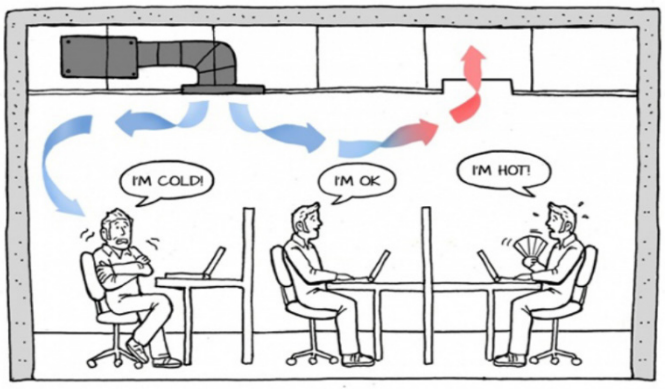

Figure 2: Effect of Temperature

A workplace, which is too hot or too cold, can be the source of stress and can affect the health of individuals. For example, Heat stress can make the body to drop electrolytes and H2O quicker, triggering low psychological act and reduced motor skills. Your musculoskeletal system will be making efforts to save energy, which will absolutely slow your minds, making finishing tasks and escaping errors a hard accomplishment [4].

3.3. Sound (Noise)

Sound is amongst the substantial environmental factors for people's well-being, and it has a vital part in both physical and mental injuries, and it also disturbs individuals' performance and efficiency [6]. The aircraft maintenance engineering is frequently exposed to high noise level such as noise coming from Turbine Engine of the aircraft or from pneumatic equipment used by them. These high level of noise can significantly reduce the ability of an individual to perform efficiently and also have a serious impact on an individual's health both physical and mental [9].

Figure 3: Noise

3.4. Illumination

Poor illumination often gets unnoticed in the workplace, as we talk about mental health and well-being, and the focus is firmly on creating happier and healthier workplaces. But bad lighting is related to a range of ill-health effects, both physical and mental, such as eye strain, headaches, fatigue and also stress and anxiety in more high-pressured work environments [1]. This becomes more significant in terms of aircraft maintenance, as several tasks carried out by aircraft mechanics in aircraft maintenance organization require adequate lighting. The improper lighting can cause serious safety risk as some defects or faults on aircraft may get unnoticed due to lack of lights or bright lights [6].

3.5. Workspace

The individual performing particular task requires an adequate workspace to perform the job properly, however, sometimes it is a bit impossible to have sufficient workspace while performing aircraft maintenance such as C checks performed as a part of major maintenance require several teams of aircraft mechanics to work together [8]. Having a confined space to work, affect the ability of an individual to perform the job and the situation may become worse when it comes with other adverse condition such as noise, time pressure etc.Captions must be written in sentence case (e.g., Macroscopic appearance of the samples.).

Figure 4: Workspace in MRO

4. Research Methodology

The objective of this research paper is to analyze the different physical environment factors disturbing work performance of individuals employed in the Maintenance Repair Overhaul (MRO) organization in the United Arab Emirates (UAE). The profile of intended respondent for this research is individual working in MRO inside the UAE and doing in maintenance activities such as aircraft maintenance technicians, aircraft maintenance engineers and other secondary staff. UAE is a key centre of aviation and patently has the finest airlines in the world. UAE also has the top capability for maintenance of aircraft in the region and unquestionably is the hub of premium MROs in the world. The MROs are functioning under a very multifaceted structure and use innovative technologies for daily operations. The agenda of the research was discussed with the intended audience to have an impartial examination of research elements.

Qualitative and quantitative approaches were engaged in measuring the physical environment factors. The research data was collected through paper-based surveys after a comprehensive conversation with individuals working in aviation MROs. The intended audience considered for this research were the employees of aircraft maintenance organization employed at a diverse level. This research was conducted as a part of the student's project and as project students have to go out and meet industry professionals in different aviation organization. The student involved in the research were studying a four-year Bachelor's Degree program in Aircraft Maintenance Engineering Major.

The structured questionnaire was used and the selection of questions was based on different elements of physical environment factors causing the problem at the workplace. The questionnaire includes the physical environment elements, which can possibly cause problems at the workplace, were related to:

- Inadequate lighting
- Noise
- Excessive Heat
- Excessive Cold
- Overcrowding
- Ventilation
- Fumes
- Maintenance equipment

Cronbach's alpha is used to test the reliability and validity. The Cronbach's alpha value is more than 0.70. The Cronbach's alpha of the questionnaire found to be 0.76. The statistical method used to investigate the data is the frequency and percentage analysis. The data was collected using online survey platform survey monkey. The MS excel software was used to carry out the statistical analysis. The outcomes of the study were arranged after carrying out an in-depth examination of the data collected concerning physical environment elements affecting job performance. Table I shows the statistics of the research survey.

Table 1: Sample Table

STATISTICS OF THE RESEARCH SURVEY		
#	Research Material	
	Type of Material	Quantity
1	Total questions included in questionnaire	22
2	Total questionnaires distributed	200
3	Percentage of responses received	85%

5. Investigation Results

The research outcomes are indicated in the form of the illustration, column and pie tables for the comfort of explanation. The percentage of replies is 85%; it is good and imitates the individual's mindfulness and enthusiasm in relation to the physical environment of the organization.

Figure5 shows that a total of 53% of respondents NEVER had problems due to poor or inadequate lightings at the workplace. Total 38% of respondents choose that SOMETIMES they have problems due to improper lighting. Total 9% respondent OFTEN have problems caused by inadequate lighting at the workplace. In aviation, the adequate lighting is quite critical especially when individuals are working in complex and small aircraft parts during the night and in a dark atmosphere.

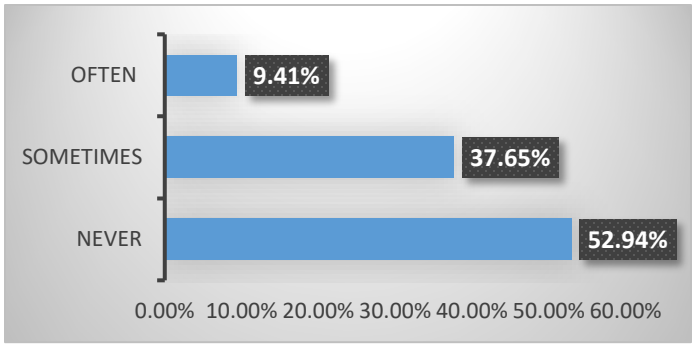

Figure 5: Poor/inadequate Lighting

Figure 6 shows frequency responses to the problem caused by noise at the workplace. As shown, 41% of respondents NEVER have a problem due to noise at the workplace, and 43% of them SOMETIMES have problems due to noise. However, 16% of respondent OFTEN have problems due to noise. Noise can be very annoying and can have a serious impact on health, which can lead to degradation of work performance

Figure 7 shows responses to the effectiveness of individuals exposed to excessive heat. As indicated in the figure, 49%, respondent NEVER have excessive heat working condition, 39% SOMETIMES have excessive heat working condition, and 11%

respondent OFTEN have excessive heat working condition. This is a clear indication that working under excessive heat condition cannot be avoided, but it affects your performance and individuals get less effective when adverse conditions arise.

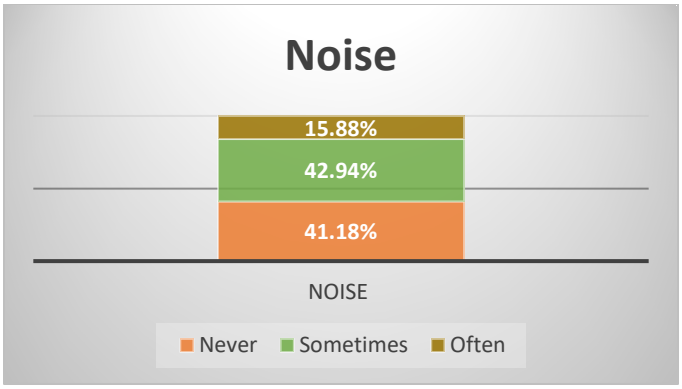

Figure 6: Noise

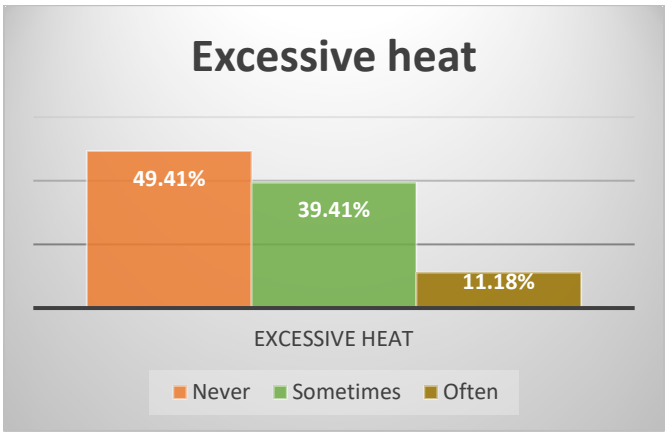

Figure 7: Excessive Heat

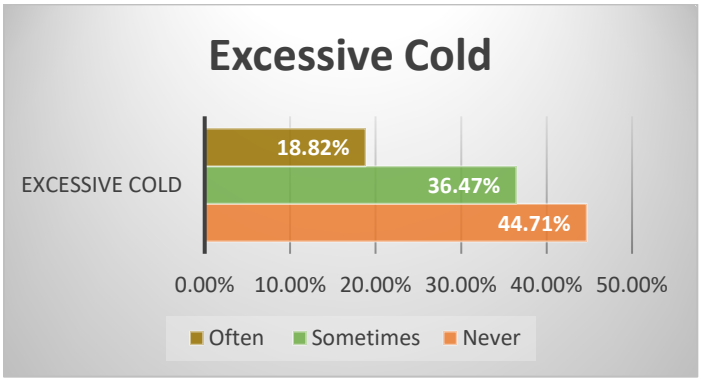

Figure 8: Excessive Cold

Figure 8, shows that 45% of respondents have acknowledged that they NEVER a condition of excessive cold at the workplace while 36% of respondents SOMETIMES have the excessive cold condition at the workplace and almost 19% respondent OFTEN have the excessive cold condition at the workplace. These percentages seem to be quite significant and require action by the organization to control the physical environment condition of the workplace to make it more conducive.

Figure 9 shows responses to the overcrowding of the workplace leading to lack of workspace. About 45%, 40%, and 15% have responded to NEVER, SOMETIMES and OFTEN respectively. This result reflects that the majority of the people have an issue related to overcrowding of the workplace.

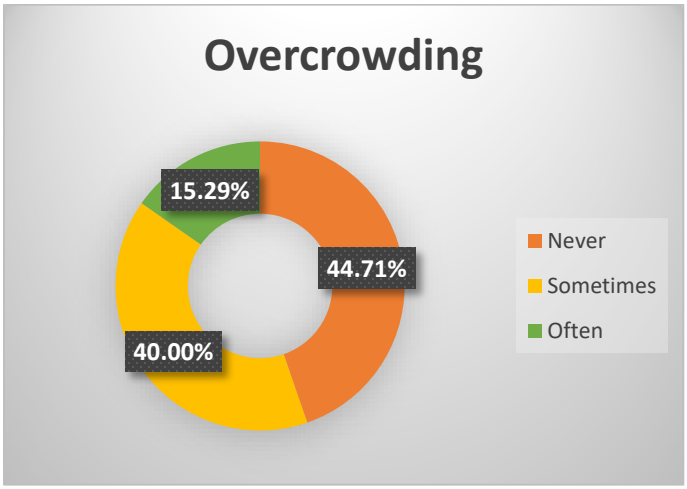

Figure 9: Overcrowding

Figure 10 shows responses to poor ventilation condition at the workplace. About 51%, 38% and 11% have responded to NEVER, SOMETIMES and OFTEN respectively. These results reflect that ventilation condition needs some improvement and it becomes more significant when dealing with hazardous chemicals.

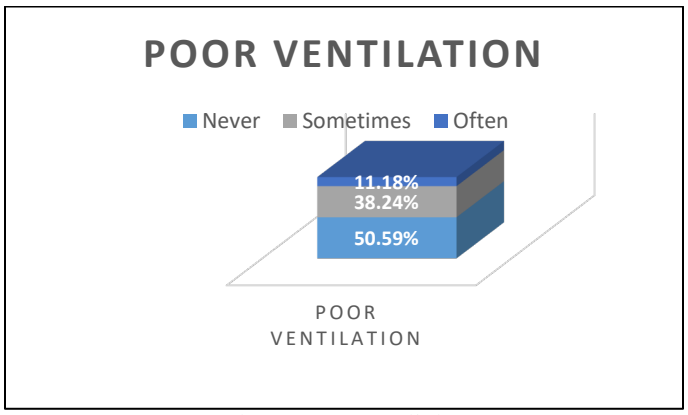

Figure 10: Poor Ventilation

Figure 11, shows responses to the question related to the presence of Dust and Fumes at the workplace. About 54% of respondents NEVER have problems related to dust/fumes, 29% respondent SOMETIMES have problems with dust/fumes and 16% respondents OFTEN have problems with dust/fumes. It indicates that only small no. of the individual having a problem with dust or fumes and thus interfering with their work.

Figure 12, shows the results of poor maintenance condition of equipment used by individuals causing the problem at work. It was found that 52% of respondents NEVER have the problem of poor maintenance of equipment they use, 35% respondent SOMETIMES have the problem of poor maintenance condition of the equipment they use and only 12% respondent OFTEN have the problem of poor maintenance of equipment they use. This

matter is directly related the work performance as equipment used by an individual in the organization provides the basis of good maintenance of aircraft.

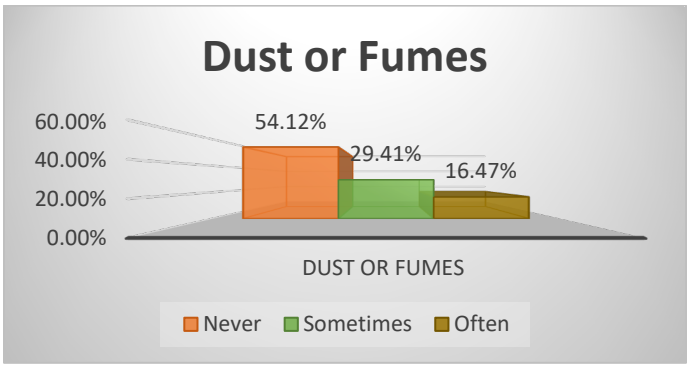

Figure 11: Dust or Fumes

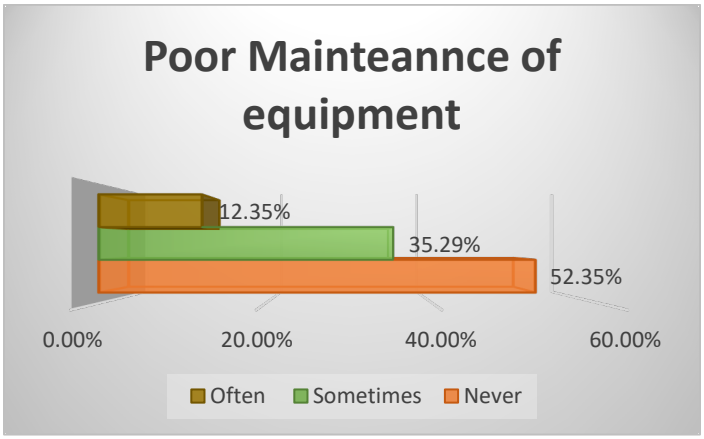

Figure 12: Poor Maintenance of Equipment

6. Discussion and Recommendation

This research specified that (reference to Figure 5) people working in MROs in the UAE typically does not have an issue related to poor illumination, and it does not affect their work. It is a optimistic signal that organizations are aware of this and have the necessary resources in place. However, a substantial number of individuals do have a problem with poor lighting sometimes which further need to be investigated why.

The study presented (a reference to Figure 6) that individuals working in aircraft maintenance organization frequently exposed to Noise, which should be the matter of concern for MROs as noise can seriously degrade the performance of individuals. It is also found (a reference to Figure 9) that a large number of individuals have problems with overcrowding leading to lack of workspace to perform the job specifically for the individuals working in base maintenance.

The analysis from Figure 10, evidently specifies that a great number of persons never have an issue due to poor ventilation which can reduce the air quality of the workplace. However, some respondent reported that they often have an issue with poor ventilation and this need to fix as poor ventilation lead to poor air quality and can result in a poor health condition of individual.

Figure 7 and Figure 8, clearly indicates that the majority the individuals does not have issues related to excessive heat or excessive cold condition. It reflects that temperature control of the workplace is properly maintained to provide a conducive atmosphere to individual working in MRO.

Exploration of figure 12 specifies that the most of the individuals working in MRO's at UAE does not have an issue related to poor maintenance of equipment's they use. However, a significant number of respondents have indicated that they sometimes or often have problems due to poor maintenance of equipment's.

The underneath mention fact specifies the zones of development as per the results of this study, and the succeeding recommendations are identified:

- Increasing attentiveness of the physical work environment and its optimistic effects on the organization and the individuals.
- Management taking proactive action to resolve the problem related to poor working conditions.
- Additional efforts are required to improve working conditions to guarantee enhanced work performance.
- Gathering more often with staff to improve their comfortability to report and to obtain opinion to lift the whole work performance.

Further, a study with hefty no. of the participant and a comprehensive questionnaire is suggested. The study can be very valuable if it is linked to statistics of MRO's worldwide.

7. Discussion and Recommendation

In this exploration, efficiency and significance of physical environment factors affecting work performance in MROs were examined. The MROs in UAE have delivered great backing throughout the course the research and research data was formed with support from MROs. It is concluded that MROs generally have very good physical environment. The MROs are taking all necessary action to provide a conducive atmosphere for employees. However, there are areas for improvement for a better physical environment including the improvement in terms of overcrowding leading to lack of workspace and the introduction of a robust system for proactive actions related to a physical environment.

Acknowledgements

The study was led by endless and unceasing backing from Higher Colleges of Technology (U.A.E.) and different MROs within the United Arab Emirates. The delicate and specialized support by Each Subject Matter Expert has educated me the finest research guidance, and I am appreciative for the generous support delivered by them.

ABSTRACT

This research sought to measure some socio-political indicators using millions of opinionated messages from social network sourced big data. Thus, and using an enhanced mixed method for sentiment analysis and a fusion model algorithm to infer topics from short text, this study attempted to demonstrate the value of computational approaches in measuring some phenomena in the real social world and quantifying public opinion fluctuations in response to certain socio-political issues. The validity of the experimental results was examined by comparing them with data obtained from representative surveys, thus providing a better understanding of the relationships between online and offline opinion dynamics. This contribution is intended to be multidisciplinary, both useful for policymakers and opinion analysts to explore public trends and to inquire into socio-political issues.

1. Introduction

Nowadays, in the communication fields, market research and public opinion analysis, as in many other disciplinary domains, social media are mobilized as new societal trends observatories [1, 2]. The evolution of these networking platforms in the first decade of the 21st century has enabled Internet users without specific technical skills to easily publish and share content on their concerns [3]. The participation architecture on which these services are based has facilitated the information co-production, and has offered spaces for socio-political engagement [4].

In this context, millions of people interact daily on social networks, producing several hundreds of millions of messages of all kinds and of any content. These messages represent valuable clues concerning practices, representations and Internet users' opinions. As such, they form a particularly interesting material to investigate when looking at citizen public behavior studies. Furthermore, due to the development of technical and computational tools that have made it possible to collect, archive and analyze huge data volumes, namely big data, these numerical phenomena can be objectified and quantified, on a large scale, for the investigation's needs. Social media analytics open up a promising way for the quantitative study of certain substantial subjects of declarative surveys, such as quantifying a social object, capturing behavioral representations and uncovering political intentions.

In this work, we seek to exploit data extracted from Facebook and use computational methods to measure some socio-political indicators. This article does not claim to provide affirmative answers about the effective correlations between the phenomena observed on social media and those perceived in the real world. On the contrary, it aims to help support the observation indicating that social networking data constitute a particularly interesting material to investigate when trying to study citizens' behavior, public opinion's fluctuations and social trends, particularly where declarative surveys and others conventional approaches turn out to be often costly, time-consuming and labor-intensive [5].

This paper is an extension of work originally presented in 2019 International Conference on Intelligent Systems and Advanced Computing Sciences (ISACS) [6]. An initial work, which was interested in measuring of notoriety capital on Facebook of a political figure. Here, we will not be limited to measuring political popularity, but we will improve this research to be able to evaluate other socio-political indicators. Likewise, we will not settle for the use and study of messages formulated only in one language, as was the French case in [6], but we will extend the prospecting to include also social networking data expressed in classical Arabic and dialect as well.

*Corresponding Author: Khalid Ait Hadi, khalid.aithadi@gmail.com

Another improvement of the present work is linked this time to the observation relating to the fact that topic models, like Latent Dirichlet Allocation (LDA) and its derivatives, are not efficient in the analysis of short texts due to data sparsity [7]. Alas, it is clear that the overwhelming majority of data extracted from social networks consists of short texts. Here, we will overcome this inconvenience by opting for an improved Biterm Topic Model (BTM) model based on the heat matrix [8].

The rest part of the paper is structured as follows. Section 2 presents an overview of related work. Section 3 is dedicated to the data collection process description and the suggested approach implementation. An experimental evaluation of the method is also presented in the same section. Finally, discussions, conclusions and suggestions for future research openings are made in the last section.

2. Related Work

Studies seeking to examine predictive capacity of social media data and to establish existence of possible correlations between the facts perceived on social media and those observed in the effective world have been subject to a rich and growing literature since the beginning of the 21st century [2].

Many recent studies have used social media data as a new sensor of societal trends and a new predictor of economic or political phenomena, ranging from stock market volatility to box office performance or, in a certain perspective that interests us more directly, public opinion fluctuations and social dynamics [9, 10]. Research in this area has been driven by a positivist approach that is certainly strengthened owing to the unprecedented possibilities offered by these new social platforms, in the sense that they allow unheard-of access to the data shared daily by people as well as to their networks, regardless of any temporal or geographic consideration.

In this context, a review article published in 2014 [11] has listed more than a hundred studies devoted solely to political messages published on the social network Twitter. The penchant of researchers for Twitter can be explained by easier access to data, where, unlike Facebook, the vast majority of accounts are “accessible” and by the brevity of posts on Twitter, limited to 280 characters.

Always on Twitter, a meta-analysis developed by Gayo-Avello [12] examined the predictive usefulness of data published on this social network, leading to the conclusion that such data have relatively predictive power and provide some information referring to electoral consultations results.

It should be noted on the socio-political aspect that the most commonly studied subject is that concerning electoral outcomes prediction using social media data [13]. In the opposite, studies relating to the political popularity evaluation, for example, or to the measurement of social indicators are not numerous, and here too Twitter has often been called upon to make forecasts. In addition, and almost globally, these studies have not examined the validity of the predictions by making comparisons to conventionally more admissible results types, such as those from censuses and surveys [14].

It should also be emphasized, according to the existing scientific literature [1], that most results in the field of forecasting with social media data claim to have produced predictive results to some extent, registering a positive statistical correlation between offline and online data. However, several scientists have criticized these results, which draw up a fundamental limitation to these works that is linked to the lack of sociological representativeness of the populations recorded on social networks [15]. Though, dismissing social media data on this ground would fail to capture the opinion forming dynamics. Some studies have even argued that representativeness search is no longer consubstantial with the need to sample populations in the big data era. The arguments put forward in this wake point to fact that debates led by certain politically active groups prevail over those who develop in society at large [16], and that individuals active on social networks are thought leaders, more politicized than average, influential in their entourage and acquaintances and whose opinions count more than those of "ordinary" individuals. To poll these opinion leaders would indirectly mean polling their entourage and, ultimately, the entire population. In addition, discussions on certain social platforms would above all reflect the concerns and themes put on the agenda by the mainstream media [17]. In many ways, the social network appears to be an echo chamber for the media field, and the associated media agenda would indirectly influence citizens' concerns [18].

Regarding the diversity of methods used in measuring public opinion, whether sentiment-based or social network-based approaches, it should be underlined that there is no unanimity about the most efficient methods in terms of prediction, and several researchers have reported some performance with different approaches and implementations.

Thus, and particularly in the category of sentiment-based studies, where opinions tone is used as a behavior’s indicator, two lines of research stand out in this context, one is based on pre-established lexicas [19], while the other relies on new sentiment models specifically for political messages [20].

Although concerning the dictionary-based sentiment classifiers, some studies have criticized the reliability of these approaches for predictions [21, 22], advancing in this regard some deficiencies such as the incorrect classification of the word in the lexicon, the lack of words disambiguation, and the neglect of contextual inference. Imperfections that are more accentuated in the socio-political context, with the emergence of difficulties especially linked to the lack of subtleties of socio-political language [23].

Through this literature review, it is seen that the majority of research has focused on the electoral and public opinion forecasts, without identifying and analyzing the reasons behind these opinions development, problematic that the present work is concerned with. In addition, there are two more obstacles that we will overcome in this paper, firstly by using a data source other than Twitter, Facebook in this case, and secondly by comparing our results with those of a declarative survey [24].

3. Methodology and Experimental Results

As previously announced, this research aims precisely to support the predictive interest of data extracted from Facebook. This involves, on the one hand, developing algorithm to analyze a very large amount of messages with socio-political connotation in

order to identify their polarity and target and, on the other hand, to compare these information to opinion poll statistics so as to better grasp similarity degrees between online and offline opinion dynamics. For this, we will consider the same period covered by the public opinion survey 'The Arab Barometer' [24] conducted in Morocco from May 7 – June 11, 2016.

Data collection has been made using '*Rfacebook*' (a package that provides a series of functions that allow R users to access Facebook's API to collect public status updates that mention specific tags). Therefore, and in order to cover a very large sample of socio-politically concerned Moroccan Facebook users, the choice has been made so as to extract both messages and comments written in French or Arabic, even dialect. On this register, we admit that debate around socio-politically charged issues is also, if not largely, done in the mother tongue and that disregarded educational level, people remain always sensitive to socio-political themes and use informal language to take part in the debate.

Therefore, and to test our approach, we have looked at two socio-political issues: (I1) 'opinions about politics' and (I2) 'perceptions of freedoms'. For the first theme, we have collected data (posts and comments) corresponding to the following queries: 'politique', 'gouvernement', 'politique gouvernementale', 'سياسة', 'حكومة', and 'السياسة الحكومية'. The second theme was examined using three tags: 'libertés', 'حرية', and 'الحريات'.

3.1. Sentiment analysis

It would be necessary before approaching the opinion mining phase, and in the ultimate objective to recover pure personal opinion, to operate some text preprocessing and cleaning steps: stemming, removal of URLs, punctuations, stopwords, screen names, special caracters and duplicate comments.

For sentiment analysis, two approaches will be used, one reserved for data written in French and the other for those formulated in Arabic or dialect language. For the first category, the choice focused on the use of Carousel greedy algorithm with Cat Swarm Optimization based Functional Link Artificial Neural Networks (CSO-FLANN), a technique for sentiment mining, enhanced in term of accuracy and computational effort [25]. For the other category of data, we used 'SentiArabic', a sentiment lexicon package for standard Arabic [26] coupled with the 'MADAR' corpus, a collection of parallel sentences covering the dialects of 25 cities from the Arab World [27], and for our case we choose the package relating to the Moroccan city 'Fez'. Using these tools, we found 1.15 million positive, 1.48 million negative, and 3.37 million neutral posts and comments for the first issue (I1) 'opinions about politics', and 2.58 million positive, 6.02 million negative, and 4.4 million neutral posts and comments for the second issue (I2) 'perceptions of freedoms'.

3.2. Inferring Topics

Our approach focuses on detecting the main reasons behind a positive or negative impression expressed by Facebook users on a given theme.

Unlike the Latent Dirichlet Allocation (LDA)-based models, which are relatively inefficient in short text processing, where they generate a high dimensional and sparse data problem [7], we opt here for a model called HMBTM (Heat Matrix based Biterm Topic Model), based on Biterm Topic Model (BTM) and improved by introducing the heat matrix. This is also merged with VSM (Vector Space Model) for counting similarities, thus inducing accuracy improvement and dimensionality reduction [8]. Applying an implementation of VSM- HMBTM to reveal the topics from the set of negative posts and comments for the first issue (I1), and from the set of positive posts and comments for the second issue (I2), and using thereafter Maximum Likelihood Estimation (MLE) [28], 906 topics were selected as the optimum number of topics for the first issue (I1), and 798 for the second issue (I2). We admitted here that people express their agreement with positive sentiments as they express their critical positions with negative sentiments.

By examining the most used terms, and despite overlaps and similarities between several themes, we try to assign a unifying label in order to bring together the most relevant subjects. For example, we have assigned for the second issue (I2) 'perceptions of freedoms', the label "freedom of association" to topics containing: joint associations, civil associations, civil organizations… and the label "political participation" to a set including the terms: political parties, free election, partisan activities…

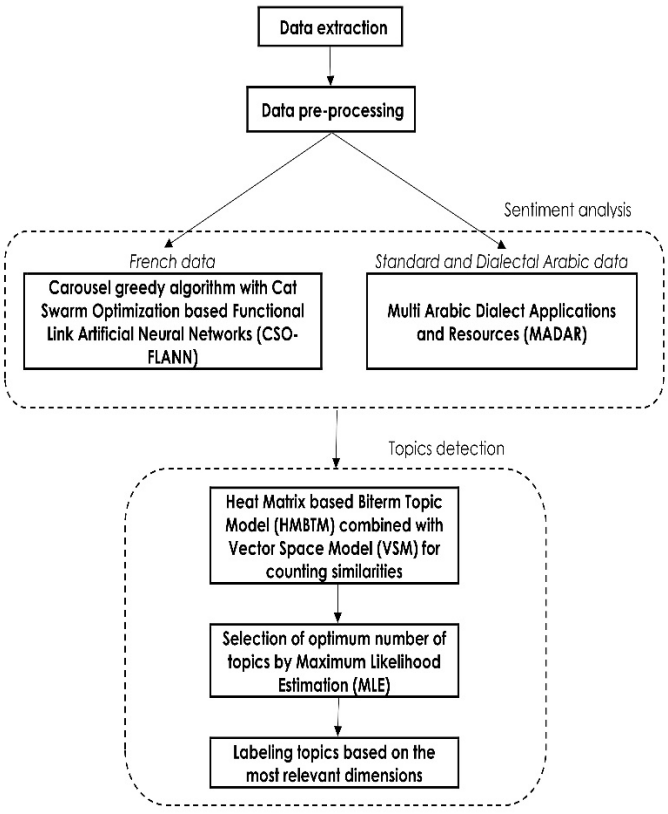

Figure 1: The construction process of our approach

We adopt the same process for the first issue (I1) 'opinions about politics. By examining the main related words such as those in Table 1, we agreed to assign a label based on the most relevant dimensions. For example, we reserved the label "complexity of politics" to topics containing: blurry political landscape, multiplicity of political concepts, number of political parties...

Table 1: A Sample of First Issue's Topics

Complexity of politics	Government not concerned with citizens
multiplicité innombrable ضبابية مبهم	opportunisme détachement لامبالاة ابتعاد
Freedom to criticize the government	Obligation to support the government
reproches critiquable انتقاد خوف	soutien supporter تأييد مساندة

The construction process of our approach is illustrated in Figure 1.

Subsequently, we explore the distribution of labels to get an idea of the topics' distribution and weight for Facebook users. Therefore, Figure 2 represents the rates corresponding to the four relevant subjects that emerge from the analysis, compared to those established by of a declarative survey [24]. Obviously, the values have been scaled given the difference in measurements and scales adopted in each situation.

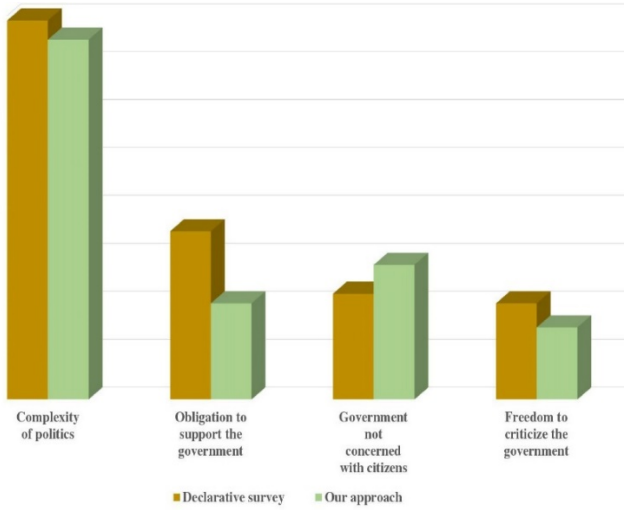

Figure 2: Distribution of First Issue's Topics

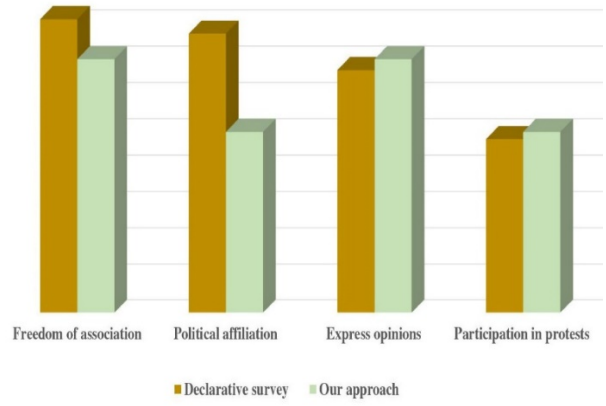

Figure 3: Distribution of Second Issue's Topics

For the second issue (I2) 'perceptions of freedoms', four topics were the most salient: freedom of association, political affiliation, express opinions and participation in protests. Figure 3 compares the weight of these topics to that resulting from the declarative survey [24].

4. Discussion and Conclusions

We have presented a research approach whose objective is to compare the results obtained via two techniques for measuring opinions: the declarative survey, on the one hand, and the analysis of messages published on Facebook, on the other hand. The work sought to situate the data produced by computational methods in relation to the results obtained by surveys. Although the current results do not release certainties, but it appears that, our approach opens up promising horizons, in the sense that it provides very indicative results about the configuration of future declarative surveys results, particularly when the latter are costly in time and even materially. The results presented through this research demonstrate the potential of data extracted from social networks to provide basic and essential information about public opinion dynamics.

However, the results as they stand confirm the observation so much raised by several researchers, indicating that the analysis of social networks would not replace, at least now, public opinion studies based on conventional polls [14]. Nevertheless, it offers indicator data and informative tools to refine our assimilation of public opinion and socio-political behavior. It also opens up perspectives for better capturing indicators relating to engagement and trends measurement, and assessing by the way, the feasibility of many promises in terms of renewing mobilization practices in socio-political field.

One of the possible openings of the present work is to diversify the platforms of data extraction, something that could play, in our point of view, a crucial role to improve the analyses precision. Broadening the base of opinionated data would undoubtedly amount to increasing the representativeness index, so much criticized in this area. One of the concerns that are shaping up recently is the future unavailability of social networks data when the confidentiality of private life is increasingly questioned. End-to-end encrypted messaging applications are attracting new users every day. Social platforms further restrict access to user data to ensure confidentiality of privacy or simply for purely commercial reasons.

One of the possible directions of research is also the one linked to the following question: does not reasoning in terms of positive or negative tones lead to neglecting an essential dimension of the analysis of socio-political messages on social networks, namely the strong majority of messages considered neutral (something that can be seen from the results above)? This leads us to question the silence or neutrality of users and to apprehend its socio-political significance, which would constitute a major issue for future promising research.

Conflict of Interest

The authors declare no conflict of interest.

Robotic Assembly
A Force/Torque Sensor
The Effect of Rotation
Vibrational Device

ABSTRACT

The prospects for the introduction of assembly automation in the industry are largely determined by the reliability of the assembly process. One of the reasons for reducing its reliability is parts jamming. In order to increase the technological reliability of the assembly process, various physical and technical effects are applied. The article presents the results of an experimental study using the rotational movement effect and low-frequency vibrations of the base part in order to reduce assembly efforts and the probability of part jamming.

1. Introduction

Assembly tasks using industrial robots are constantly becoming more complicated over the years. Their main problem is jamming even with slight mismatching. In the case the assembly gap is comparable to the form error, assembly based on rigid basing becomes impossible. The assembly becomes especially problematic when the assembly gap in the joints is comparable to the repeatability of an industrial robot.

The case of the parallel-plane movement of the assembly parts has been considered in known dynamic models of the robotic assembly of cylindrical joints, using passive adaptation [1, 2], as well as control algorithms. In the case of the plane-parallel movement of the installed part, significant sliding friction forces can occur at the contact points of the assembly parts, in which there is a small gap. It leads to jam. Thus, reducing sliding friction forces is one of the ways to increase the reliability of the assembly process. For that purpose, the rotation and the low-frequency vibration can due to provide this effect.

The efficiency of rotational movement for ensuring assembly conditions during the robotic assembly process was considered in works [3-8] and others.

In the work [6] the assembly using the rotational effect with the airflow was experimentally studied. However, an analytical model was not built. In [7, 8], the influence on the assembly process of oscillations along the conjugation axis and along the inclined axis was studied. In work [3], the assembly of parts was studied when the installed part rotates with respect to the non-inertial reference frame and the base part rotates with respect to the inertial reference frame. However, the simultaneous superposition of the effect of rotation and low-frequency vibrations has not previously been considered.

The use of low-frequency vibration remains one of the most promising areas in the field of automatic assembly. This is confirmed by the results of theoretical and experimental works [9-11].

The modern approach to the theory of experiment assumes the need to achieve the required research quality. For this purpose, it is necessary to build a model of the experiment [12].

The effectiveness of technological operation modeling in robotic assembly and the process as a whole based on statistical experimental design allow studying the influence of many process characteristics. It is necessary to establish a connection among the n independent non -random variables $x_1, x_2 \dots x_n$ and the random variable y that depends on them. When processing the results of a multi-factor experiment, the mathematical model of the process, namely the function $\mathrm{M(y)} = f\,(\mathrm{x_1}, \mathrm{x_2} \dots \mathrm{x_n})$ is usually represented as a polynomial of a specific degree. The expression $\mathrm{M(y)} = f\,(\mathrm{x_1}, \mathrm{x_2} \dots \mathrm{x_n})$ is called the regression equation of the mathematical expectation of a random variable y for non- random variables $x_1, x_2 \dots x_n$, and the type of function can be linear or curved [13].

In this article, the authors study the rotation effect and low-frequency vibration to increase reliability in a robotic assembly process. A mathematical dynamics model of the robotic assembly process was presented. A multifactor experiment of this assembly process was carried out, the results and discussion were presented.

2. Mathematical Model

2.1. Choosing a kinematic assembly scheme

The shaft *3* is held by the gripper *2* of the robot *1*. The working movements of the robot manipulator are the progressive movement of the gripper vertically downwards to the specified position. The vibrational device *5* is a three-link manipulator, each of its links is driven by a separate drive. The base bushing *4* is kept in the center of the vibrational disk, attached to the last link of the vibrational device (Figure 1).

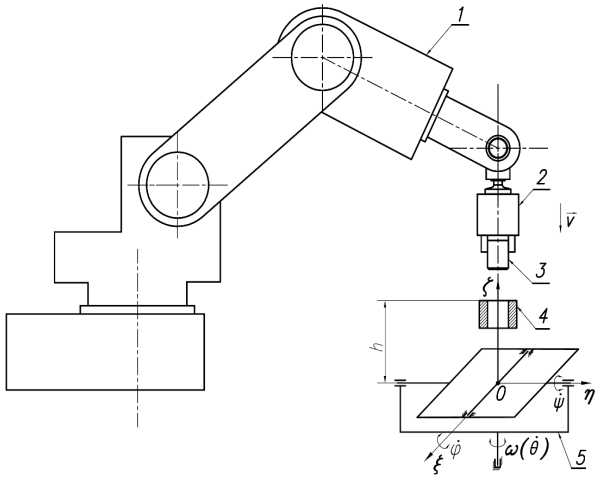

Figure 1: Experimental installation (principle scheme): 1. Industrial robot; 2. The gripper with a force/torque sensor; 3. The shaft, 4. The bushing; 5. The vibrational device;

Four reference frames were defined with a common origin at point O: $Oxyz$ is a fixed reference frame; $Ox_1y_1z_1$ and $Ox_2y_2z_2$ are reference frames, attached to the first and second links of the vibrational device respectively, $O\xi\eta\zeta$ is the reference frame, attached to the third link of the vibrational device. The reference frame $Cx_3y_3z_3$ is attached to the shaft, its origin coincides with the shaft mass center (Figure 2).

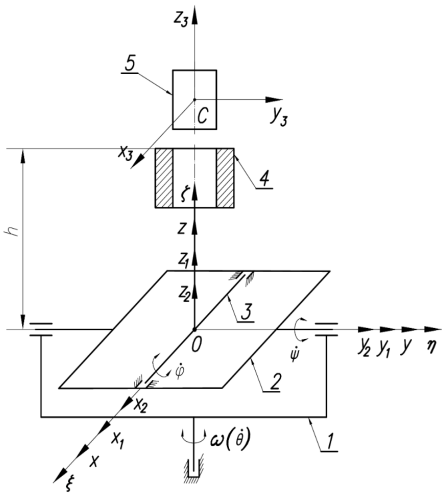

Figure 2: The scheme for determining coordinate systems: 1 - the first link of the vibrational device; 2 - the second link of the vibrational device; 3 - the third link of the vibrational device; 4 - the bushing; 5 - the shaft.

The first link performs rotational motion with a constant angular velocity ω around the fixed axis Oz. In this case, the reference frame $Ox_1y_1z_1$ attached to the first link, at the time t, will rotate with respect to the fixed reference frame $Oxyz$ by an angle θ:

$$\theta = \omega t \tag{1}$$

The second and third links oscillate around mutually perpendicular axes with a phase shift equal to the angle $\pi/2$ as follows:

$$\psi = A\sin kt\,;\, \varphi = A\cos kt \tag{2}$$

where A is the amplitude; k – the angular frequency.

2.2. The mathematical model of the motion dynamics of the shaft mass center with respect to the non-inertial reference frame attached to the base part

Previously, the authors published a mathematical model of the assembly process of a cylindrical joint using rotation and low-frequency vibrations [14]. Therefore, this article presents only a brief mathematical statement.

Formulation of the mathematical model.

On the basis of the theorem on the mass center movement of the system, the movement of the shaft in Figure 3 can be described by a relation of the form:

$$m\vec{\mathbf{a}}_c = m\vec{\mathbf{g}} + \vec{\mathbf{N}} + \vec{\mathbf{F}}_f + \vec{\mathbf{P}} \tag{3}$$

where: m is the mass of the part;

$\vec{\mathbf{a}}_c$ – the absolute acceleration of the cylindrical part mass center;

$\vec{\mathbf{g}}$ – acceleration of gravity;

$\vec{\mathbf{N}}$ – the normal reaction of the vibrational disk plane;

$\vec{\mathbf{F}}_f$ – the sliding friction force;

$\vec{\mathbf{P}}$ – the assembly force.

The relative movement of the mass center of the part with respect to the non-inertial reference frame attached to the bushing can be represented by the equation:

$$m\vec{\mathbf{a}}_{\mathbf{cr}} = m\vec{\mathbf{g}} + \vec{\mathbf{N}} + \vec{\mathbf{F}}_{\mathbf{f}} + \vec{\mathbf{F}}_{\mathbf{ce}}^{\mathbf{fict}} + \vec{\mathbf{F}}_{\mathbf{cC}}^{\mathbf{fict}} + \vec{\mathbf{P}} \tag{4}$$

where $\vec{\mathbf{a}}_{\mathbf{cr}}$ – the relative acceleration of the shaft mass center;

$\vec{\mathbf{F}}_{\mathbf{ce}}^{\mathbf{fict}}$, $\vec{\mathbf{F}}_{\mathbf{cC}}^{\mathbf{fict}}$ – the force of moving space and Coriolis inertial forces of the shaft mass center;

Equation (4) in projections on the axis of the non-inertial reference frame $O\xi\eta\zeta$ has the form:

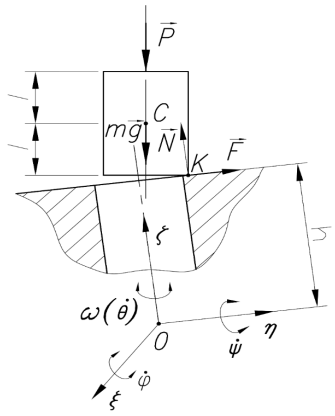

Figure 3: Scheme of forces at single-point contact of the assembled parts

$$\begin{aligned} m\ddot{\xi}_c &= (mg)_\xi + F_{f\xi} + F_{ce\xi}^{fict} + F_{cC\xi}^{fict} + P_\xi, \\ m\ddot{\eta}_c &= (mg)_\eta + F_{f\eta} + F_{ce\eta}^{fict} + F_{cC\eta}^{fict} + P_\eta, \\ m\ddot{\zeta}_c &= (mg)_\zeta + F_{ce\zeta}^{fict} + F_{cC\zeta}^{fict} + N + P_\zeta. \end{aligned} \tag{5}$$

where ξ_c, η_c, ζ_c are the coordinates of shaft mass center (point C) in the reference frame $O\xi\eta\zeta$.

To determine the projections of all forces on the axis of the non-inertial reference frame $O\xi\eta\zeta$, the apparatus of homogeneous coordinate transformation matrices was used [5].

Differential equations of motion of the shaft mass center with respect to the non-inertial reference frame attached to the base part

In [14] the components of (5) were determined, a mathematical model of the dynamics of the relative motion of the shaft mass center in its one-point contact with the plane of the bushing can be as follows:

$$\begin{aligned} m\ddot{\xi}_c &= p\sin\psi - fN\frac{\dot{\xi}_k}{\sqrt{\dot{\xi}_k^2+\dot{\eta}_k^2}} + m(\xi_c\dot{\psi}^2 - \eta_c\ddot{\psi}\sin\varphi \\ &\quad - 2\eta_c\dot{\varphi}\dot{\psi}\cos\varphi - 2\eta_c\omega\dot{\varphi}\sin\varphi - \zeta_c\ddot{\psi}\cos\varphi \\ &\quad + 2\zeta_c\dot{\varphi}\dot{\psi}\sin\varphi - 2\zeta_c\omega\dot{\varphi}\cos\varphi\cos\psi \\ &\quad + \xi_c\omega^2\cos^2\varphi + \eta_c\omega^2\sin\psi\sin\varphi\cos\psi \\ &\quad + \zeta_c\omega^2\sin\psi\cos\varphi\cos\psi) - 2m\dot{\zeta}_c(\dot{\psi}\cos\varphi + \omega\cos\psi\sin\varphi) \\ &\quad + 2m\dot{\eta}_c(-\dot{\psi}\sin\varphi + \omega\cos\psi\cos\varphi); \\ m\ddot{\eta}_c &= -p\cos\psi\sin\varphi - fN\frac{\dot{\eta}_k}{\sqrt{\dot{\xi}_k^2+\dot{\eta}_k^2}} \\ &\quad + m(\xi_c\ddot{\psi}\sin\varphi + \eta_c\dot{\psi}^2\sin^2\varphi + \eta_c\varphi^2 - 2\eta_c\omega\dot{\varphi}\sin\psi \\ &\quad + \zeta_c\dot{\psi}^2\cos\varphi\sin\varphi + \xi_c\omega^2\sin\psi\cos\psi\sin\varphi \\ &\quad + \zeta_c\dot{\varphi} + \eta_c\omega^2\sin^2\dot{\varphi}\sin^2\psi + \zeta_c\omega^2\sin^2\psi\sin\dot{\varphi}\cos\varphi \\ &\quad + 2\xi_c\omega\dot{\psi}\sin\psi\cos\varphi - 2\eta_c\omega\dot{\psi}\cos\psi\sin\varphi\cos\varphi \\ &\quad - 2\zeta_c\omega\dot{\psi}\cos\psi\cos^2\varphi + \eta_c\omega^2\cos^2\varphi - \zeta_c\omega^2\sin\varphi\cos\varphi) \\ &\quad - 2m\dot{\xi}_c(-\dot{\psi}\sin\varphi + \omega\cos\psi\cos\varphi) + 2m\dot{\zeta}_c(\dot{\varphi} - \omega\sin\psi); \end{aligned} \tag{6}$$

$$\begin{aligned} N &= m\ddot{\zeta}_c - m(\xi_c\omega^2\cos\psi\sin\psi\cos\varphi \\ &\quad + \eta_c\omega^2\sin^2\psi\sin\varphi\cos\varphi - \eta_c\omega^2\sin\varphi\cos\varphi \\ &\quad + \zeta_c\omega^2\sin^2\psi\cos^2\varphi + \zeta_c\omega^2\sin^2\varphi - 2\zeta_c\omega\dot{\varphi}\sin\psi \\ &\quad + \xi_c\ddot{\psi}\cos\varphi + \eta_c\dot{\psi}^2\sin\varphi\cos\varphi - \eta_c\ddot{\varphi} + \zeta_c\dot{\psi}^2\cos^2\varphi \\ &\quad + \zeta_c\dot{\varphi}^2 - 2\xi_c\omega\dot{\psi}\sin\psi\sin\varphi + 2\eta_c\omega\dot{\psi}\cos\psi\sin^2\varphi \\ &\quad + 2\zeta_c\omega\dot{\psi}\cos\psi\sin\varphi\cos\varphi) + 2m\dot{\eta}_c(\dot{\varphi} - \omega\sin\psi) \\ &\quad - 2m\dot{\xi}_c(\dot{\psi}\cos\varphi + \omega\cos\psi\sin\varphi) + p\cos\psi\cos\varphi. \end{aligned}$$

where N – the normal reaction of the plane of the bushing. f – the term coefficient of friction; $\dot{\xi}_k$ and $\dot{\eta}_k$ – the projections of the velocity of the contact point $"K"$ on the axis $O\xi, O\eta$ of the reference frame $O\xi\eta\zeta$.

Derivatives $\dot{\xi}_k$ and $\dot{\eta}_k$ are determined as follows [14]:

$$\begin{aligned} \dot{\xi}_k &= r\omega\cos\theta\cos\psi - r\sin\theta\sin\psi\cdot\dot{\psi} \\ &\quad + l\cos\psi\cdot\dot{\psi} + \dot{\xi}_c; \\ \dot{\eta}_k &= r(\omega\cos\theta\sin\psi\sin\varphi + \sin\theta\cos\psi\cdot\dot{\psi}\sin\varphi \\ &\quad + \sin\theta\sin\psi\cos\varphi\cdot\dot{\varphi} - \omega\sin\theta\cos\dot{\varphi} - \cos\theta\sin\varphi\cdot\dot{\varphi}) \\ &\quad - l(-\sin\psi\cdot\dot{\psi}\sin\varphi + \cos\psi\cos\varphi\cdot\dot{\varphi}) + \dot{\eta}_c \end{aligned} \tag{7}$$

and the coordinate ζ_c is determined as follows [14]:

$$\begin{aligned} \zeta_c &= h + r\left(\sin\psi\cos\varphi\sin\theta + \sin\varphi\cos\theta\right) \\ &\quad + l\cos\psi\cos\varphi \end{aligned} \tag{8}$$

The obtained mathematical models (6) and (7), (8) established the relationship between the components of the forces with factors of rotation movement and low-frequency vibrations.

3. Experimental Installation

3.1. Determining the Factors

A multifactor experiment of the process was carried out as follows. Upon reaching the operating mode of vibration, the shaft was fed into the assembly zone in the vertical direction with the contact of the faces of the assembled parts (Figure 1). Under the influence of vibrational and rotational movements of the experimental installation, the shaft was combined with the bushing and the assembly process was carried out. The contact moment of the assembled part faces was taken as the starting point. The completion of the assembly was recorded when the shaft was inserted to a depth of 50 mm. The resulting value of the assembly force was considered as the output optimized parameter (response) of the system when studying the process.

The following parameters were taken as input parameters (factors) in the study of the system: the angular frequency (rad/s); the linear amplitude of the last link of the vibrational device (mm); the linear velocity of the last link of the robot (mm/s); the angular velocity of the first link of the vibrational device (rad/s) and the gap in the joint (mm) (Table 1). All of them meet the appropriate requirements of controllability and integrity used to factors, as well

as the requirements of compatibility and lack of linear correlation applied to a set of factors.

Table 1: Input Factors

Factors	Symbol
The angular frequency of vibrational device (rad/s);	X_1
The linear amplitude of the vibrational device (mm);	X_2
The linear velocity of the last link of the robot (mm/s);	X_3
The angular velocity of the first link of the vibrational device (rad/s)	X_4
The gap in the joint (mm)	X_5

3.2. Selecting the Type of Model

A mathematical description of the assembly force components can be obtained using statistical experimental design [16].

The magnitude of the components of force and torque in the contact zone is measured by a force/torque sensor installed on the last link of the robot. Since the experimental sample was a shaft, then in the experiment 4 components of force and torque were investigated: axial force – F_z, torque around the z-axis – T_z, axial force – F_y and torque around the x-axis – T_x. These force and torque components are dependent on the input process factors. The mathematical model of the research object was understood as the form of the response function connecting the optimization parameter with the process factors. In general, this function can be written as follows:

$$F = f(X_i), \ (i = 1..5) \tag{9}$$

Selecting a type of model means choosing the type of function and its mathematical form. Suppose that the dependencies can be approximated with sufficient accuracy by equations of power type. So, for example, the relationship (9) can be expressed by the equation:

$$F = cX_1^{\alpha} X_2^{\beta} X_3^{\gamma} X_4^{\theta} X_5^{\mu} \tag{10}$$

where $X_i, i = 1..5$, process factors; $c, \alpha, \beta, \gamma, \theta, \mu$ – constant values.

After logarithm, equation (10) is linearized:

$$\ln F = \ln c + \alpha \ln X_1 + \beta \ln X_2 + \gamma \ln X_3 + \theta \ln X_4 + \mu \ln X_5 \tag{11}$$

The possibility of approximating dependences (10) by equations in the form (11) is established by verifying the hypothesis of the linear model adequacy when expressing the results of the experiment with a polynomial in the form:

$$y = b_0 + \sum_{1 \le i \le 5} b_i x_i + \sum_{1 \le i < j \le 5} b_{ij} x_i x_j \tag{12}$$

where $y = ln\, F$, $x_i -$ coded value of X_i.

Coded value x_i of factor i:

$$x_i = \frac{2(\ln X_i - \ln X_{i\max})}{\ln X_{i\max} - \ln X_{i\min}} + 1, \ (i = 1..5) \tag{13}$$

where X_i – natural value of factor i; $X_{i_{max}}$, $X_{i_{min}}$ – natural values of the upper and lower levels, respectively.

3.3. Design of Multifactor Experiments in the Search for Optimal Technological Conditions and Design Parameters of Equipment.

According to the verified experiment results, it is assumed that on the considered small interval, the response function can be described by a polynomial of the first degree. Due to the linearity of the model, the factors varied at two levels. At the same time, the zero levels were taken on the basis of previous studies [2] (Table 2).

Table 2: Levels of Factors and Variable Intervals

Factors	Levels			Range of variation	Dimension
	-1	*0*	*+1*		
X_1	14	16	18	2	rad/s
X_2	1,8	2,0	2,2	0,2	mm
X_3	10	20	30	10	mm/s
X_4	0	0,25	0,5	0,25	rad/s
X_5	0,01	0,03	0,05	0,02	mm

When conducting a full factorial experiment with varying factors at two levels, one replicate of it would involve $2^5 = 32$ experiments. It would make the experiment cumbersome enough if at least three replicates were performed. Therefore, the fractional factorial design of the experiment $N = 2^{5-1}$ was chosen. It reduces the number of experiments of one replicate to 16 due to the system of mixing linear effects of factor x_5 with the least significant interaction effects, but at the same time the number of replicates is increased to three. All experiments, according to the principle of randomization, were carried out in random order. Three replicates for all selected conditions were implemented (Table 3).

Table 3: Experiment Planning Matrix

3.4. Experimental Installation

Experimental Installation has been established (Figure 4). A force-torque sensor *2* (Schunk FT AXIA 80 Ethernet) was installed on the last link of the robot *1*. The base bushing *6* is kept in the vibrational device *7*, described in [6] and [17].

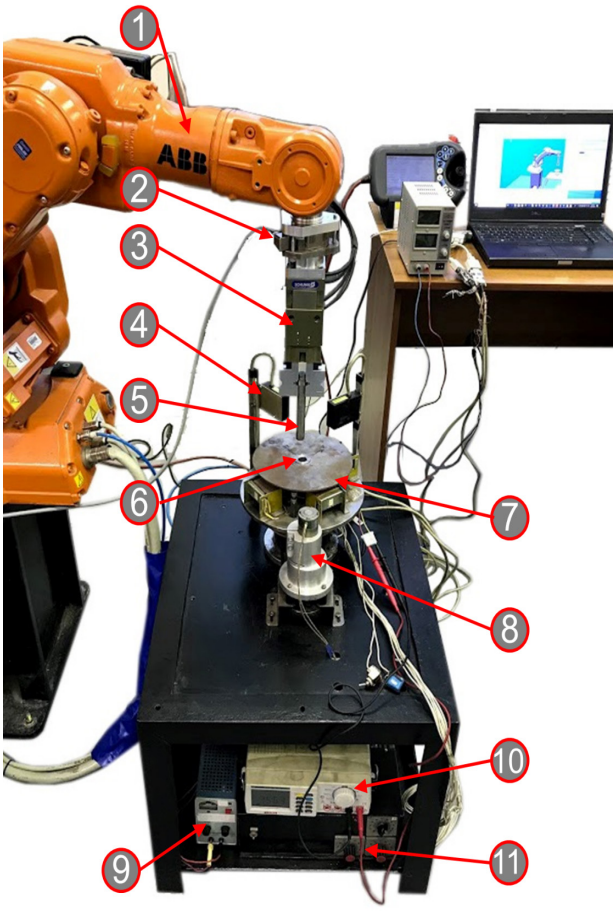

Figure 4: Experimental installation: 1. Industrial robot ABB IRB 140; 2. The force/torque sensor Schunk FT AXIA 80 Ethernet; 3. Gripper; 4. Triangulation Laser Sensors Riftek RF603.2; 5. The shaft; 6. The bushing; 7. The vibrational device; 8. DC motor; 9. Controlled converter; 10. Electronic frequency meter (Mastech M9803R); 11. The generator of low-frequency oscillations.

The experimental procedure was as follows. The shaft *5* was held by gripper *3* of the robot *1*. Vibrations were provided by the original generator of low-frequency oscillations *11*. The generator of low-frequency oscillations was controlled by the electronic frequency meter *10*, and the actual vibration amplitude of the vibrational device was monitored by contactless laser sensors *4*. The first link of the vibrational device performed a rotational motion with a constant angular velocity ω around a vertical fixed axis by a DC motor *8*. The DC motor was controlled by a controlled converter *9*. All sensor signals were collected and processed by the computer. Thus, during the experiments, continuous monitoring of the current values of technological factors was ensured.

The choice of force/torque sensor Schunk FT AXIA 80 Ethernet was determined by the required process sensitivity. The default value of sensitivity is 0.005 (Where: 0 = no damping - robot maintains speed; 1 = full damping - robot decelerates quickly) and its technical data is presented in Table 4.

4. Results and Discussion

4.1. Screening of Coarse Observations in Parallel Experiments

For each row of the experiment planning matrix, according to the results of *n* parallel experiments, $\bar{y}_j$ – arithmetic mean value of optimization parameter was found:

$$\bar{y}_j = \frac{1}{n}\sum_{u=1}^{n} y_{ju} \tag{14}$$

Where u is the number of parallel experiment; y_{ju} is the value of the response in the u parallel experiment of the j row of the experiment planning matrix.

In order to estimate the deviations of the response from its mean value for each row of the experiment planning matrix, the dispersion s_j^2 of the experiment was calculated according to n parallel experiments (Table 5). Statistical dispersion was estimated by an expression of the form:

$$s_j^2 = \frac{1}{n-1}\sum_{u=1}^{n}(y_{ju} - \bar{y}_j)^2 \tag{15}$$

Table 5: Experimental Results and Dispersion of Forces F_y, F_z and Torques T_x, T_z

16	3.543	0.004	2.067	0.009	-0.621	0.00306	4.448	0.001

4.2. Verification of the Uniformity of Dispersions

The dispersion homogeneity was tested by the Fisher F criterion, which is the ratio of the largest to the smallest variance:

$$F = \frac{s_1^2}{s_2^2} \tag{16}$$

where s_1^2 и s_2^2 - respectively, the largest and smallest values of the response variance in different experiments.

If the observed value is $F < F_t$ (F_t is the table value of the criterion F for the corresponding freedom degrees $f_1 = n_{\max} - 1 = 2$, $f_2 = n_{min} - 1 = 2$ and the accepted significance level of 0.05 [16]) then the variances are uniform (Table 6).

Table 6: Testing the Homogeneity of Dispersion by the Fisher Criterion

$F < F_t = 19.2$							
F_y		F_z		T_x		T_z	
14.62876	Yes	13.23305	Yes	18.30958	Yes	12.82161	Yes

With uniform duplication of experiments, the homogeneity of a number of dispersions was checked using the Cochrane G criterion, which is the ratio of the maximum dispersion to the sum of all dispersions:

$$G = \frac{s_{\max}^2}{s_1^2 + s_2^2 + \ldots + s_N^2} = \frac{s_{\max}^2}{\sum_{j=1}^{N} s_j^2} \tag{17}$$

The dispersions are homogeneous if $G < G_t$ (G_t is the table value of the criterion G for the conditions: N is the number of compared variances $N = 16$, and n is the number of parallel experiments $n = 3$ [16]). If $G > G_t$, then the variances are inhomogeneous, and this indicates that the investigated value y does not obey the normal law (Table 7).

Table 7: Testing the Homogeneity of Dispersion by the Cochrane Criterion

$G < G_t = 0.3346$							
F_y		F_z		T_x		T_z	
0.222947	Yes	0.211286	Yes	0.182417	Yes	0.150301	Yes

4.3. Determination of Regression Coefficients

According to the results of the experiment, the coefficients of the model were calculated. The regression coefficients are determined by the formulas:

$$b_0 = \frac{1}{N}\sum_{j=1}^{N} \bar{y}_j; \; b_j = \frac{1}{N}\sum_{j=1}^{N} x_{ij}\bar{y}_j; \qquad b_{jl} = \frac{1}{N}\sum_{j=1}^{N} x_{ij}x_{lj}\bar{y}_j. \tag{18}$$

where i, l – numbers of factors; x_{ij}, x_{lj} – coded values of factors $i$and l in the j-th experiment. These formulas are obtained using the least squares method.

The significance of each coefficient of the regression equation was checked by using Student t-criterion, comparing the obtained values with the table values in the corresponding degrees of freedom and significance level:

$$t_j = \frac{|b_j|}{s_{\{b\}}} \tag{19}$$

where $s_{\{b\}}$ – the dispersion of the regression coefficients, determined by formula:

$$s_{\{b\}}^2 = \frac{s_y^2}{N \cdot n} \tag{20}$$

If the dispersion s_j^2 of the experiments are homogeneous, the dispersion s_y^2 of the reproducibility of the experiment is calculated by the expression:

$$s_y^2 = \frac{1}{N}\sum_{j=1}^{N} s_j^2 \tag{21}$$

Table 8: Significance of each Coefficient of the Regression Equation

b_i	F_y	F_z	T_x	T_z
b_0	2.975	4.297	1.655	-1.071
b_1	–	0.035	–	0.038
b_2	0.163	0.075	0.101	0.12
b_3	0.053	0.045	0.038	-0.031
b_4	0.396	-0.057	0.265	0.382
b_5	0.045	-0.071	–	–
b_{12}	0.057	-0.051	–	–
b_{13}	–	–	–	-0.028
b_{14}	–	–	–	–
b_{15}	–	–	–	–
b_{23}	–	–	–	–
b_{24}	–	–	-0.044	-0.055
b_{25}	–	–	–	-0.034
b_{34}	–	–	–	–
b_{35}	–	–	–	0.038
b_{45}	0.04	–	–	–

Student criterion t is calculated for each regression coefficient. Statistically insignificant coefficients can be excluded from (16). The verification results are summarized in the Table 8. The regression equations for the considered response functions $y_{F_y}, y_{F_z}, y_{T_x}, y_{T_z}$ can be written based on the data given in Table 8.

4.4. Verification of Model Adequacy

After calculating the coefficients of the model and checking their significance, the dispersion of adequacy was determined. The residual dispersion or the adequacy dispersion characterizes the scattering of empirical values of y with respect to the calculated y determined by the found regression equation. The adequacy dispersion was determined by the formula:

$$s_{ad}^2 = \frac{n\sum_{j=1}^{N}(\bar{y}_j - \hat{y}_j)^2}{f} = \frac{n\sum_{j=1}^{N}(\bar{y}_j - \hat{y}_j)^2}{N-(k+1)} \quad (22)$$

where $\bar{y}_j$ – arithmetic mean value of the optimization parameter in the j-th experiment; $\widehat{y}_j$ – value of the optimization parameter calculated by the model for the conditions of the j-th experiment; f – the number of freedom degrees; k – the number of factors.

The final step in processing the experimental results was to verify the hypothesis of the adequacy of the found model. Hypothesis verification was carry out according to the Fisher criterion:

$$F = \frac{s_{ad}^2}{s_y^2} \quad (23)$$

If the value $F < F_t$ (F_t – table value of the criterion, $F_t = 2.1$ for the accepted significance level of 0.05 and the corresponding numbers of freedom degrees $f_1 = N - (k + 1) = 16 - (5 + 1) = 10, f_2 = N(n - 1) = 32$ [16]) then the model is considered adequate. For $F > F_t$, the adequacy of hypothesis is rejected (Table 9).

Table 9: Result of Model Adequacy Checking

	F_y	F_z	T_x	T_z
s_{ad}^2	0.021959	0.003026	0.005974	0.008727
s_y^2	0.017306	0.003367	0.00647	0.005815
F	1.269	0.899	0.923	1.501
$F < F_t$	Yes	Yes	Yes	Yes

In this case, we can conclude that the resulting model satisfies the adequacy condition.

For the transition from the coded values to natural values of the factors in the regression equation, values x_i factors on expressions (12) were substituted by (13) and regression coefficients values b_i were referenced in Table 8, obtained:

$$\begin{aligned}\ln F_y = {} & 11.111 - 3.111\ln X_1 - 10.875\ln X_2 \\ & +0.096\ln X_3 + 0.188\ln X_4 + 0.117\ln X_5 \\ & +4.521\ln X_1 \ln X_2 + 0.016\ln X_4 \ln X_5\end{aligned} \quad (24)$$

$$\begin{aligned}\ln F_z = {} & -5.322 + 3.062\ln X_1 + 11.931\ln X_2 \\ & +0.082\ln X_3 - 0.188\ln X_4 \\ & -0.088\,\mathrm{n}\, X_5 - 4.405\ln X_1 \ln X_2\end{aligned} \quad (25)$$

$$\begin{aligned}\ln T_x = {} & 1.458 + 0.470\ln X_2 + 0.069\ln X_3 \\ & +0.182\ln X_4 - 0.141\ln X_2 \ln X_4\end{aligned} \quad (26)$$

$$\begin{aligned}\ln T_z = {} & -4.670 + 1.459\ln X_1 - 1.075\ln X_2 \\ & +1.392\ln X_3 + 0.244\ln X_4 - 0.406\ln X_1 \ln X_3 \\ & -0.176\ln X_2 \ln X_4 - 0.421\ln X_2 \ln X_5 \\ & +0.045\ln X_5 + 0.086\ln X_3 \ln X_5\end{aligned} \quad (27)$$

Potentiating expressions (24 – 27), the dependence of forces and torques on the studied factors of the robotic assembly process was found:

$$F_y = \frac{66893.374 X_3^{0.096} X_4^{(0.188+0.016\ln X_5)} X_5^{0.117} X_1^{4.521\ln X_2}}{X_1^{3.111} X_2^{10.875}} \quad (28)$$

$$F_z = \frac{0.005 X_1^{(3.062-4.045\ln X_2)} X_2^{11.931} X_3^{0.082}}{X_4^{0.018} X_5^{0.088}} \quad (29)$$

$$T_x = 4.298 X_2^{(0.470-0.141\ln X_4)} X_3^{0.069} X_4^{0.182} \quad (30)$$

$$\begin{aligned}T_z = {} & 0.009 X_1^{(1.459-0.406\ln X_3)} X_2^{(-1.075-0.176\ln X_4-0.421\ln X_5)} \\ & X_3^{(1.392+0.086\ln X_5)} X_4^{0.244} X_5^{0.045}\end{aligned} \quad (31)$$

According to (28 - 31), nomograms can be constructed, which allow, for practical purposes, to determine the components of the force and torque acting on the installed part when determining factors for the robotic assembly process.

A suitable response for the above regression model F_z (29) was constructed and nomograms (Figure 5) were constructed with paired combinations of these factors while the other factors were at the zero level.

Figure 5 illustrates the dependence of the force F_z on variable factors in the assembly process. It is clear that the angular velocity and the gap in the joint are inversely proportional to the force F_z, while the vibration frequency, the vibration amplitude and the linear velocity are proportional to the force F_z. Also, there is an interaction effect of two factors of the angular frequency and the vibration amplitude. The maximum value of the force F_z was 87.17 N (Figure 5.f), the minimum value of F_z was 57.86 N (Figure 5. g).

Force F_z decreases significantly with increasing the angular velocity (Figure 5. c, f, h, j). Force F_z decreases rapidly at the initial stage, and then more slowly decreases in the investigated values range of the angular velocity. The maximum value of the force F_z in the absence of the rotational movement was 87.17 N (Figure 5. f), the minimum value of F_z with the rotational movement was 65 N (Figure 5. h). Also, F_z decreases with an increase in the gap in the joint. With the small gap, the maximum value of the force F_z was 84.7 N (Figure 5. j). With the large gap, the minimum value of the force F_z was 57.86 N (Figure 5. g).

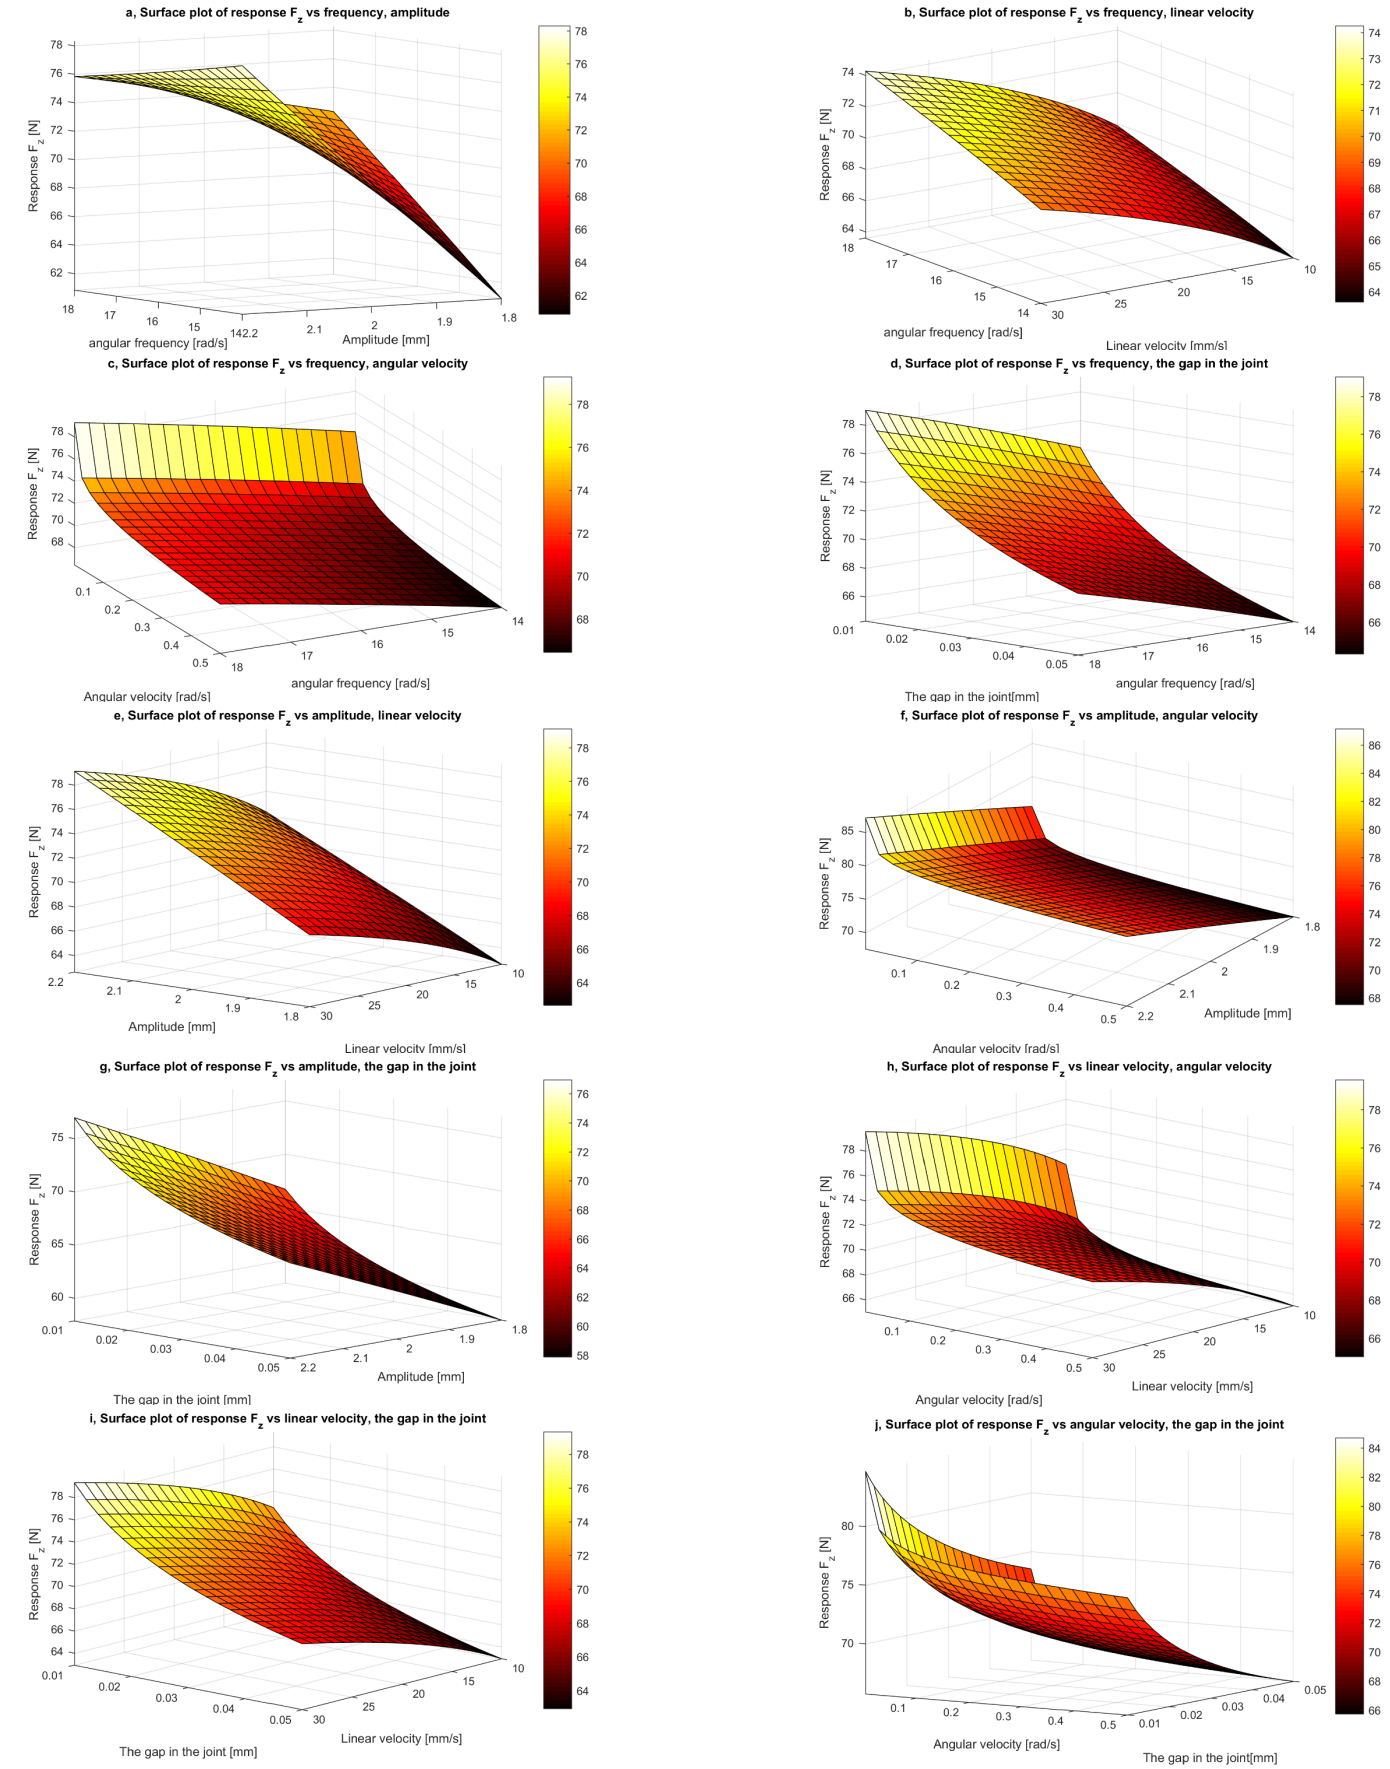

Figure 5: Three-dimensional nomograms showing the behavior of force F_z affected by factors of the robotic assembly process.

The force F_z is proportional to the angular frequency and vibration amplitude. The force F_z decreases with a simultaneous increase or decrease of both these factors (Figure 5. a – Figure 5. g). The angular frequency and vibration amplitude interact with each other, affecting the magnitude of the force F_z. When both factors changed in the investigated values range of them, the change in the value of the force F_z was small (60.8 – 78.3 N) (Figure 5. a). The effect of linear velocity on force F_z is negative (Figure 5.b, e, h, i), however, decreasing the linear velocity the assembly time will increase.

5. Conclusion

The conducted experimental studies revealed the influence of variable factors on the components of the assembly force and torque. Mathematical models that establish the relationship between the components of the friction forces and torques with disturbing factors are formed. The adequacy of the mathematical model of the process is proved. The effects of the interaction of two factors are identified.

The effect of increasing the assembly speed is negative, which correlates with the theory of friction. At the same time, the greatest effect of reducing the assembly force was achieved in the areas corresponding to the lower boundaries of the variation intervals. In various experiments, the decrease in assembly force ranged from 14 to 33%.

The conducted experiments proved the presence of the effect of vibrations and rotation on increasing the technological reliability of the assembly process. Further research will be associated with a change in the zero level of variation of the input factors. It is supposed to check the adequacy of the mathematical model and the results of physical experiments.

ABSTRACT

The Tin Oxide: Vanadium (SnO_2: V) thin films have been deposited on glass substrates with various Vanadium concentration at a substrate temperature;500^{o}C using microprocessor-controlled spray pyrolysis technique. The structural, compositional, morphological and optical analyses of the samples are characterized by XRD, EDAX, SEM and UV-Visible spectroscopy. The XRD analysis shows tetragonal rutile structure formation in lattice configuration of virgin and Vanadium doped SnO_2 thin films. The uniform crystallinity is appeared on the surface of crystal and it is proved by extreme diffraction peak for 3at% Vanadium doped SnO_2 thin films. The optical transmittance increases from virgin to 3at% with increase in doping concentration. The transmittance for 4at% is minimum compared with 3at% of vanadium doping. The FTIR analysis illustrates the bond formation between Sn-O and V-O respectively. This also validates the strong force constant for the consistent crystal structure.

1. Introduction

Thin film technologies paved the way of preparing the most promising material [Transparent conducting oxides] in optical energy controlled electronic devices; solar cells, displays, opto-electronic interfaces devices and electronic-circuitries, owing to its properties such as electrically conductive nature with high transmittance of light [1].The accomplishment of such properties is performed by successive doping with wide-band gap optical semiconductors (E_g > 3.1 eV) and are pivoted to advanced technologies[2-5]. In_2O_3 is considered to be the leading TCO in concerned with their properties as well as its commercial success. However, ITO is playing a major role in electronics market; it is of high cost and limited availability [6-9]. SnO_2 is economically cheap compared to indium oxide. It is an ideal candidate for many applications. Its high chemical stability is considered to be an inherent advantage of SnO_2 [10] and it makes SnO_2 appreciably adoptable for applications in challenging atmosphere, for preparing transparent and strong-conductive electrode on photo enabled electrodes or as a selectively solar energy penetration coating [11, 12]. Its applications include surface coatings, environmental and human health [13] gas sensors [14] organic pollutants and toxic water [15] and heterojunction catalysts [16], Tin dioxide (SnO_2), having lattice parameters a = b = 4.737 Å and c = 3.826 Å with tetragonal Rutile structure is an important n-type semiconductor. Each tin atom at the corners of a regular octahedron is bounded to six oxygen atoms and three tin atoms surround each oxygen atom [17]. High ability to let incoming radiation in the UV region, high reflectance in the IR region, high electrical conductivity, high melting temperature, harmless nature, easy doping and plenty in nature. These are the remarkable characteristics of SnO_2 [18]. For optoelectronic devices and solar cell applications, SnO_2 thin films is a very suitable candidate as it is having a good electrical and optical properties [19].

Many research investigations have been performed on heavily doped and rather doped tin oxide thin films using various available techniques [20-22]. Although there are several techniques for deposition, spray pyrolysis technique is the most preferred technique due to its simplicity, low cost and for large area coating [23]. Doping with certain p block and d block elements augments the light sensitive properties and the ability of transmitting electricity of SnO_2 thin films [24]. As the ionic radius of Vanadium ($V4^+/Sn4^+$ = 0.58/0.71Å) is smaller than the host $Sn4^+$, it can be easily doped into SnO_2 [25]. After screening the literatures, it is revealed that, few researches have analyzed the

properties of Vanadium fused SnO_2 thin films [26-28], it is of particular interest to deposit Vanadium doped SnO_2 thin films by micro controller-assembled spray pyrolysis technique. In the present work, the Vanadium doped SnO_2 thin films have been characterized and they are investigated according to the operated properties. As a first step SnO_2: V thin films are synthesized. Then structural and light sensitive properties of the customized thin-films are keenly observed and the data is validated. This work intends to improve the characteristics of SnO_2 thin films by doping Vanadium at different concentration.

2. Experimental methods

2.1. Synthesis of vanadium doped SnO_2 thin films

In the blended mixture of doubly de-ionized water and intensive solvent; methanol in the ratio 1:1, the precursor material $SnCl_4.5H_2O$ (Tin (IV) Chloride Pentahydrate) (35.06g) is dissolved to obtain 0.1M starting solution and few drops of hydrochloric acid is added to get a clear solution. To the precursor, well grained powder V_2O_5(Vanadium Pentoxide) is added in the ratio of 0,1,2,3&4at% (0g, 0.509g, 1.018g, 1.527g, 2.036g). A reservoir filled with precursor solution is mounted on stand. The area of the substrate is 2.5x7.5cm^2 (optically flat glass slides). Formerly cleaning of the substrates are achieved using hydrochloric acid, non-polar solvent; acetone and sterilized water by suitable ultrasonic cleaner for 35 minutes to terminate organic substance and another contaminant from the surface.

The micro controller-operated spray pyrolysis set up is displayed in Figure1. It consists of a syringe needle having the diameter of 0.6mm connected to the reservoir and its height can be altered to get 0.002mL/Min at the needle tip. Distance of 8cm is kept between the needle and the surface of the substrate. Substrate attracts the precursor solution as high voltage of about (9.65KV) is applied between needle and hot-plate. To optimize the thickness (500nm) different volume of precursor solution is sprayed and the dimensions between the two surfaces of all the sprayed samples are verified using standard method. A timer is connected to high voltage power supply, relay and hot plate. The timer is set in such a way that when hot plate is on, high voltage will be in off condition and vice-versa. The charge presents in substrate holder and syringe needle, substrate temperature, heat inside the chamber are controlled by means of relay, thermocouple arrangement and exhaust fan. The distance of the syringe needle is adjusted up and down to obtain a continuous thin film. In the experiment, five sequential sets of undoped and Vanadium doped SnO_2 thin films are fabricated by controlling the substrate temperature at 500^0C.The optimized time allotment for deposition for each sample is determined as 44minutes by counting the spray intervals of time. The alternating spray process is employed for this study at a spray for 5seconds and an interval of 10seconds for each cycle.

2.2. Characterization Technique

In our present study the surface morphology of the prepared samples is characterized by employing scanning electron microscope (CARLZEISS) shown in Figure 2. The compositional details are analyzed by (EDAX) technique. The lattice parameters are examined by X-ray diffractometer (SHIMADZU-XRD 6000) (Cu–Ka) of wavelength 1.520Å. The profilometer is used to find the dimension between two surfaces of the films by making suitable stylus technique at four different areas on the outside of film and the average dimension is found to be around 500 nm. Weight gain method is also used to find the thickness. The optical absorption and translucence of the films are measured in the wavelength range of 300–1100nm using a Unico 4802 UV–Vis double beam spectrophotometer. FTIR spectra are recorded by means of SHIMADZU1800-UV Fourier transform infrared spectrometer.

3. Results and Discussion

3.1. Structural properties

Figure 3 shows the XRD spectra of virgin and Vanadium doped SnO_2 thin films. The highest diffraction peaks are (110), (101), (200), (211), (220). The coincidence of diffracted peaks with tetragonal structure of SnO_2 (JCPDS card number: 41-1445) is observed for all the recorded peaks of Vanadium doped SnO_2 thin films [29]. No phase consistent to the dopant or other compound is observed. Though the doping level of Vanadium is increased from 1at% to 3at%, Vanadium oxide phases are not

dominated in Vanadium operated SnO_2 films. The intensity of the peak corresponding to the predominant plane (110) in the primary phase is increased on Vanadium doping until 3at% and further addition of 1at% doping concentration, the intensity decreases due to the exchange of $Sn4^+$ ions with Vanadium ions in the lattice of SnO_2 film, whereas the intensity of the plane (211) in the secondary phase rapidly increases with increase in the concentration of Vanadium. This shows better atomic arrangement and lower scattering in these planes. The structural analysis is done for the predominant peak and the results are given in Table 1. The optimized crystallite size of virgin SnO_2 and doped SnO_2 films for all the dopant levels are calculated using Debye-Scherrer formula [30]

$$D= K\lambda/\beta\cos\theta \quad (1)$$

where D is the mean crystallite size, K is a particle size dependent constant whose value is 0.9, λ is the diffraction wavelength of CuKa (λ = 1.5406 Å). β is the full width at half maximum (FWHM) and θ is the diffracted angle. The lattice parameters and crystallite size for the predominant peak (110) of the prepared samples are given in Table1. It is confirmed that the increase in the concentration of Vanadium from 0 to 4at% results in the range of crystallite size from 55.72nm to 41.79nm. The decrease in crystallite size may be due to the density enrichment in the nucleation centers of the doped samples and also may be due to lattice distortion. For further addition of 1at% Vanadium, dopant dominates the crystalline size.

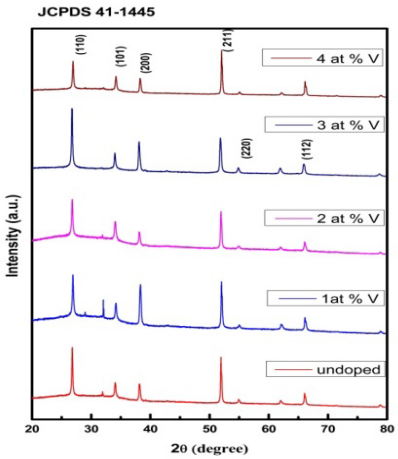

Figure 3: XRD Pattern of undoped and V (1at%, 2at%, 3at%, 4at%) doped SnO_2 thin films.

Table 1: Doping concentration ratio (1at%, 2at%, 3at%, 4at%) for SnO_2 thin films.

Predominant peak	Angle2θ (degree)	d spacing (Å)	FWHM	Crystallite size (nm)
Undoped (110)	26.806	3.3232	0.153	55.72
1at%V (110)	26.908	3.3107	0.180	47.37
2at%V (110)	26.932	3.3079	0.175	48.73
3at%V (110)	26.793	3.3248	0.204	41.79
4at%V (110)	26.748	3.3302	0.172	49.76

3.2. Morphological Analysis

The surface morphology of virgin and Vanadium doped SnO_2 thin films deposited at a temperature of 500°C with different Vanadium content concentration are shown in Figure 4. The SEM image of virgin SnO_2 exhibits smaller grains. It is evident from the images that the surface morphology reveals significant changes on doping [31]. For 1at% of Vanadium doped SnO_2 thin film, molecules of different morphology and sizes are formatted due to inadequate Vanadium doping. Grain size decreases when doping concentration of Vanadium increases [32]. This is observed in the SEM image for 2at% Vanadium doped SnO_2 thin film. A film having superior quality with uniform grains as proved by structural analysis is observed for 3at% Vanadium doped SnO_2 thin film. Above 3at% of the dopant concentration, grains are found to increase in its size and appear with small sized grains in between large sized grains.

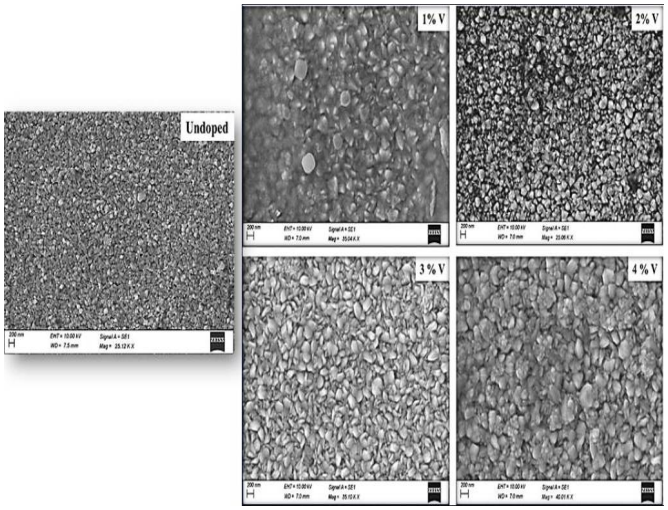

Figure 4: SEM images of undoped and V (1at%, 2at%, 3at%, 4at%) doped SnO_2 thin films.

3.3. Elemental analysis

From the EDAX analysis recorded in Figure 5. The consistent peaks Sn, V and O are observed in the EDAX pattern of all the Vanadium doped samples. For all V-doped SnO_2 samples the existence of Vanadium is also detected. Both vanadium extent and relative intensity are directly proportional to each other.

3.4. Optical properties

Optical transmittance spectra of virgin and Vanadium doped SnO_2 thin films are shown in Figure 6. In the visible region (400–700 nm), the observed translucence is about ~60–80%. For virgin SnO_2 thin film transmittance is minimum compared to the vanadium doped SnO_2 thin film. Transmittance increases with dopant concentration. Increase in transmittance may be due to the

improved crystallinity of the film. In our results, transmittance increases from virgin to 3at% with increase in dopant concentration. Transmittance decreases with further 1at% of Vanadium doping. The decrement of optical transmittance is made due to the increment of particle size and it is evidenced from the SEM image and also may be due to the crystal defects created by doping.

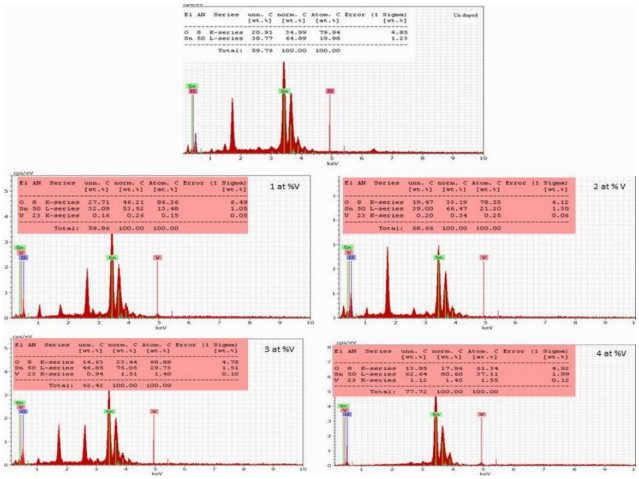

Figure 5: EDAX analysis spectra of undoped and V (1at%, 2at%, 3at%, 4at %) doped SnO_2 thin films.

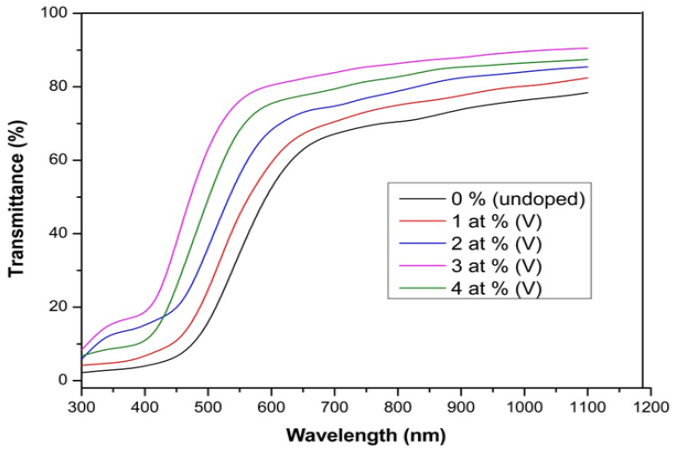

Figure 6: Transmittance spectra of undoped and V (1at%, 2at%, 3at%, 4at %) doped SnO_2 thin films.

The observed absorbance modulated spectra of virgin SnO_2 and Vanadium doped SnO_2 thin films at different concentrations are depicted in Figure 7. Gradually increasing absorption from NIR to the visible region is observed. The absorption edge is prolonged to the visible region due to the fusion of Vanadium ions into SnO_2 ions. A substantial red-shift is absolutely observed on the increment in doping attentiveness of vanadium species [33]. Absorption band edge of the films is observed by the calculated first derivative of the optical transmittance. The band gap is an important property which determines the quality of the deposited thin films. In Figure 8, the curves of dT/dλ vs hν have been drawn and showed the stress of doping on the direct optical band gap (Eg).The band gap values are observed to be ranged from 2.970 eV to 3.130 eV. There is fluctuation in band gap energies with doping concentrations of Vanadium. High value of band gap energy is a result of lower-quality films. In the present case good quality film is obtained in 3at% of Vanadium doping concentration.

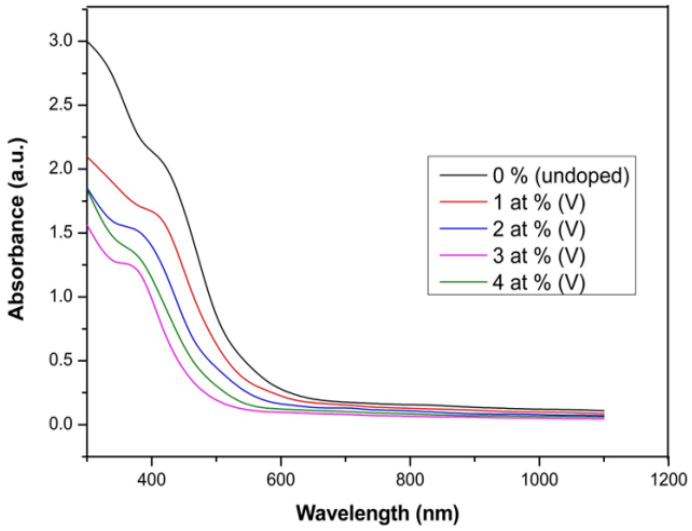

Figure 7: Absorption spectra of undoped and V (1at%, 2at%, 3at%, 4at%) doped SnO_2 thin films.

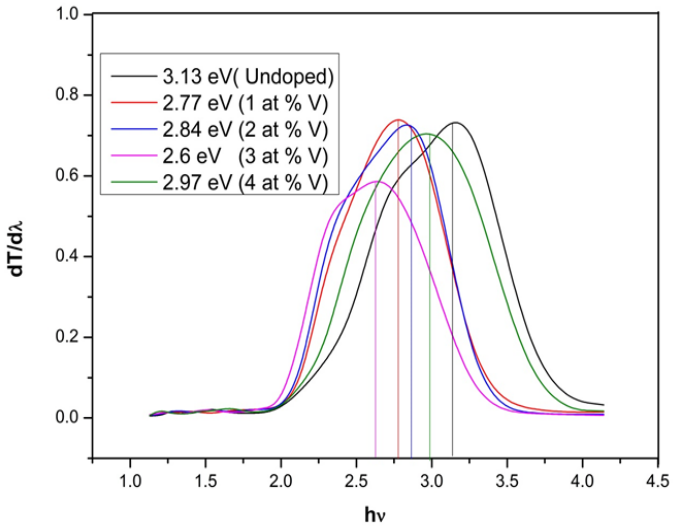

Figure 8: Plot of dT/dλ vs. (hυ) for undoped and V (1at%, 2at%, 3at%, 4at%) doped SnO_2 thin films.

3.5. FTIR analysis

Figure 9 displays the FT-IR spectra of virgin and Vanadium doped SnO_2 thin films fabricated by microprocessor-controlled spray pyrolysis method. As the present case is inorganic compound, all the IR peaks are concentrated in the region of 200-1200cm^{-1}. Particularly, the stretching, in plane and out of plane bending modes for Sn-O bond are observed at 750, 740 and 710cm^{-1}, the in plane bending modes are found at 400, 380 and 360cm^{-1} and the out of plane bending modes are occupied at 280, 260 and 250cm^{-1}. All the observed bands are validated by the literatures [34]. The V-O bond stretching, bending modes are determined at 610, 320 and 210cm^{-1}. All the spectroscopical impressions illustrate the strong coupling of V on SnO_2 configuration.

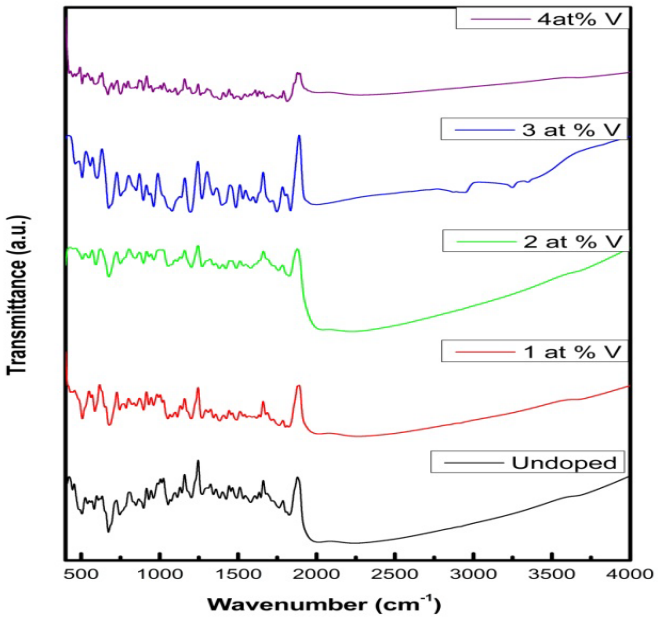

Figure 9: FTIR spectra of undoped and V (1at%, 2at%, 3at%, 4at%) doped SnO_2 thin films.

4. Conclusions

In this work, the popular heavy metal species Vanadium is doped on SnO_2crystal material and it is formed as thin films with the doping concentration of 1at%, 2at%, 3at% and 4at% respectively. The compositional, morphological, structural and optical analysis is made on samples and the results are discussed. From the observed data, the optimized state of doping concentration is found to be 3at%.The vibrational study is confirmed the active presence of strong bonds such as Sn-O and V-O. The presence of Sn-O-V bonds and angles are also validated from the complex form of vibrational bands.The film at doping of 3at % is having superior quality with uniform grains as proved by structural. From the optical studies, it is revealed that, the optical intensive transmittance increases from virgin to doped SnO_2 at 3at% which leads to the decrement of band gap energy. The acquired results from structural, morphological, vibrational and optical studies demonstrated the effectiveness of doped thin film.

ABSTRACT

In the present paper, a universal approach for determining the maximum flow problem in directed graph for solving different problems is applied. It can be considered as a heuristic and it can be used as a denomination for analyzing an arbitrary system with a mathematical description as a directed graph. The physical nature of the flows passing through the arcs of the system considered can be energy, information, transportation, or material. Then the studied system will be power, communication, transport, or manufacturing, respectively. In the present article five types of maximum flow problems are considered. Each of them is solved analytically by the universal heuristic method. The common between these problems is expressed in the fact that its behavior can be presented with the same mathematical model in the form of a directed graph including one initial (pending) vertex and one final (blocked) vertex, respectively. These vertexes are called either real (if they exist) or fictive (if they are introduced additionally) source and receiver depending on the topology of the associated directed graph's model. The final solution obtained with this approach for Problem 1 is compared with the similar one found through Ford-Fulkerson's, Edmonds-Karp's and Dinic's algorithms and it has been shown to be better than those determined by them.

1. Introduction

The maximum flows problem in industrial systems (energy, information or material) can be modeled by graphs' theory which adequately describe the topology of the studied system [1].

Note: For simplicity of the present analysis, it will be used only the term flow, regardless of type of the studied system - power [2, 3], information [4], communication [5, 6] or transportation [7].

Energy flows are optimized in power systems. In this sense, in [8] a review of the stochastic optimization methods, solving the optimal power flow problem. An application of the graphs' theory for the energy flows optimization in electric networks is made in [9]. The transformation of the linear model (e. g. linear goal function and linear constraints as unequations) to the directed graph's model is made there. Thus, the optimization procedure is expressed analyzing the resulting directed graph.

The definition of the flows problem in information systems is made in [10]. In [11] a review of approaches modelling information flow for organizations is presented. A new graph theoretical concept for analyzing the information flows passing through the directed graph's model, using guessing numbers is proposed in [12].

In [13], the problem of optimization the information flows passing through the uncertain networks with a given constrained capacities of the arcs is considered. The solution bases on the two NP-hard subproblems. First, it calculates the expected information flow associated to a source vertex and next it makes an optimal choice of arcs.

The flows optimization passing through the manifacturing systems is widely discussed issue. One possible solution to this problem is given by the graph's theory. For example, in [14] using the shortest path method for flows optimization in cellular manufacturing systems. In [15] an optimization for single-part flow-line configurations of reconfigurable manufacturing systems (RMS) is suggested. In [16] the other optimization approach of the flows in RMS systems is proposed. This approach also uses the graphs' theory for modeling the considered system. In [17] third model for optimizing demand period cost (fixed plus operating) of RMS flow-line configurations, based also on graphs' theory, is suggested.

A wide range of problems arise in real-world networks such as Internet, local information networks, energy systems, etc., which

*Corresponding Author: Simona Kirilova Filipova-Petrakieva, petrakievas-te@tu-sofia.bg

are modeled by directed graphs. In [18] a review of a range of theoretical primitives for generating a simple graph based on the given degree sequence is proposed. This is based on the graphs' theory and the computer networks. Several problems for which efficient algorithms for determining the theoretical solutions are proposed. Since in practice the graphs' models consists of tens of thousands of vertexes, approximation algorithms are particularly important.

The present paper is organized as follows. In a Section 2 the directed graph's model with one source – one recipient is defined, as well as the three necessary and sufficient conditions for performing its topological analysis. Five basic tasks arising in real systems, modeled with directed graphs, are also defined. In Section 3 an universal algorithm for solving all these five problems is briefly described. Solutions of these five type of problems applying the universal algorithm is proposed in Section 4. The applicability of this algorithm is visualized in Section 5 on an illustrative example describing problem 1. In the same section, a comparison is made with the obtained solutions to the same illustrative example using traditional methods based on minimum-cut the theorem, such as: Ford Fulkerson, Edmonds Carp and Dinic algorithms. The paper finishes with the conclusion remarks on the universality and advantages of the suggested algorithm.

The novelty of the proposed method consists in its universal application in determining the maximum flow passed through a arbitrary directed graph, whose model contains one initial and one final nodes. It is applicable to analysis of different systems - information, power, manufacturing, etc. The algorithm can be used for solving the five types of problems, defined in the next section

2. Problem statement

The maximum flow problem passing through the arcs of an directed graph is defined in [1].

In order to refine the considered graph's model, some basic concepts and initial hypotheses will be briefly introduced.

Let's consider a directed graph $G = < V, L >$, with $V = \{V_s\}$, $s = \overline{1,n}$ vertexes and $L = \{L_{ij}\} = \{L^k\}$, $k = \overline{1,m}$ arcs. The latter is associated to the system's channels. Let's $f_{ij} = f(V_i \to V_j) = f(V_i, V_j)$ is the flow passing through the arc L_{ij}. The capacity of this arc is q_{ij} [4].

A necessary and sufficient condition for determining the maximum flows passing through the arcs of the studied directed graph satisfies the following three assumptions.

Assumption 1

Balance condition: The sum of the incoming flows in a vertex V_i is equal to the respective sum of the outgoing ones, i.e.

$$\begin{aligned} &\sum_{V_j} f(V_i, V_j) - \sum_{V_s} f(V_s, V_i) = 0 \\ &V_j \in M^-(V_i);\ V_s \in M^+(V_i) \end{aligned} \quad . \tag{1a}$$

where: V_i is intermediate vertex for the considered directed graph;

$M^+(V_i)$ and $M^-(V_i)$ are the sets of input and output vertexes for the vertex V_i, respectively.

Assumption 2

Sequencing condition: The flow f_{ij} passing through the arc L_{ij} must not exceed its capacity q_{ij}., i.e.

$$f(V_i, V_j) \le q_{ij};\ \forall\ L_{ij} \in L. \tag{1b}$$

Assumption 3

Invariability condition: In absolute value, the flow passing through the directed graph from the source vertex to the recepient vertex must be exactly equal to that in the opposite direction.

$$\begin{aligned} &\sum_{V_j} f(V_{src}, V_j) - \sum_{V_i} f(V_i, V_s) = f_\Sigma \\ &V_j \in M^+(V_{src});\ V_i \in M^-(V_{src}) \\ &\sum_{V_j} f(V_r, V_j) - \sum_{V_i} f(V_i, V_{rec}) = -f_\Sigma \\ &V_j \in M^+(V_{rec});\ V_i \in M^-(V_{rec}) \end{aligned} \quad , \tag{1c}$$

where f_Σ is the flow passing through the directed graph.

$$\begin{aligned} &f_\Sigma = \sum_{V_j} f(V_{src}, V_j) = \sum_{V_i} f(V_i, V_{rec}) = 0 \\ &V_j \in M^+(V_{src});\ V_i \in M^-(V_{rec}) \end{aligned} \quad . \tag{2}$$

The first condition can be violated if part of the flow is dissipated in a vertex of the graph. This can be observed in the energy transfer, when each vertex is a specific physical device that consumes electricity and at the same time can dissipate it in the form of heat.

The second condition cannot be violated, since real systems are considered where it is physically impossible for a flow to pass through an arc that is greater than its capacity.

In real energy systems there are transfer losses, conversion losses, etc. In this case moving in the both directions of the graph (from the source to the recipient and vice versa) these losses cannot be equal, but they are very close.

Note: Without a loss of generality it is assumed, that the directed graph's model of the system has 1 source and 1 recipient vertexes. In general case, it can have multiple sources (N_s) and multiple recipients (N_r). Then the graph is transformed to a directed graph of the first type by adding fictive source V_{src} and recipient V_{rec} vertexes, respectively (Figure 1).

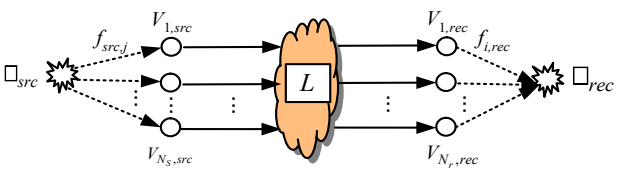

Figure 1: Graph's model with multiple sources (N_s) - multiple recipients (N_r)

In real systems depending on their parameters the following 5 types of maximum flow problems can be arised. In the first four of them the flow through the arcs f_{ij} is constant, and in the last one – it varies.

Problem 1: The arcs' capacities q_{ij} are known and the capacities of all graph's vertexes are infinity, i.e. $P_s \to \infty$.

Problem 2: The arcs' capacities q_{ij} are known and limited in a given range $q_{ij}^{\min} \le q_{ij} \le q_{ij}^{\max}$.

Problem 3: The arcs' capacities q_{ij} and the capacities P_s of the graph's vertexes $V_s \in V$ are known.

The Problems 1, 2 and 3 discuss the directed graph's model with one source and one recipient.

Problem 4: It consideres the directed graph with multiple sources $\{V_{src,l}\}$, $l = \overline{1, N_s}$ and multiple recipients $\{V_{l,rec}\}$, $l = \overline{1, N_r}$ (Figure 1). The arcs' capacities q_{ij} are known.

Problem 5: The arc's capacities q_{ij} of all the graph's arcs $L_{ij} \in L$ are known, but the balance condition (1a) is violated.

$$f_{in}\left(V_i, V_j\right) > f_{out}\left(V_i, V_j\right) \tag{3a}$$

or

$$f_{in}\left(V_i, V_j\right) < f_{out}\left(V_i, V_j\right), \tag{3b}$$

where $f_{in}\left(V_i, V_j\right)$ and $f_{out}\left(V_i, V_j\right)$ are the input and the output flows, associated to the arc $L_{ij} = \left\langle V_i, \quad V_j \right\rangle$, respectively.

For each of the above defined problem it obtains the maximum flow passing through the directed graph from the source to the recipient vertexes.

The basic aim and the contribution of the author of this paper consists of the suggesting the universal general algorithm for obtaining the maximum flow started from the source vertex V_{src} and reached to the final graph's vertex – either real V_{rec} or fictive $\mathbf{V}_{rec}$.

There are always losses when transmitting information or energy through the graph's model from the source to the recipient. They decrease the flow $f_{in}\left(V_i, V_j\right)$, i.e. the condition (3a). The condition (3b) is satisfied in some types of manufacturing systems.

For all 5 maximum flow problems defined above, *the condition* (1b).

The input flow for the system is generated by the source vertex V_{src} and it is named as $f_{src} = f(V_{src})$. The output flow $f_{rec} = f(V_{rec})$ is the flow, consumed by the recipient V_{rec}. It s assumed that the flow passing through the intermediate graph's vertexes is zero.

The different types of flows are defined in [1]. For the future analysis, we will describe them again in briefly.

Definition 1: The **allowed** flow is:

$$f^{allowed} = \sum_{M(V_i)} f_{out}\left(V_i, \quad V_j\right) - \sum_{M(V_j)} f_{in}\left(V_i, \quad V_j\right) = \begin{cases} f(V_{src}), & V_i = V_{src} \\ -f(V_{src}), & V_i = V_{rec} \\ 0, & \forall V \ne V_{src}, V_{rec} \end{cases}. \tag{4}$$

Definition 2: The **maximum flow** is:

$$f^{\max} = \max_{i=1, n_{\max}} \left[f_i^{allowed}\left(V_{src}, \quad V_{rec}\right) \right] \tag{5}$$

where $f_i^{allowed} = \left(V_{src}, \quad V_{rec}\right)$ are all allowed flows with number i passing through the directed graph from the source to the recipient vertexes.

Definition 3: The **conventionally optimal flow** $f^{opt} = \left(f^{opt}\left(V_{src}\right), \quad f^{opt}\left(V_{rec}\right)\right)$ is, if arbitrary allowed flow $f_i^{allowed} = \left(f_{src}, \quad f_{rec}\right)$ satisfies at least one of the conditions (6)

$$\begin{aligned} &f^{+}\left(V_{src}\right) \ge f^{-}\left(V_{src}\right), \ if \ \ f^{+}\left(V_{rec}\right) \ge f^{-}\left(V_{rec}\right) \\ &f^{-}\left(V_{rec}\right) \ge f^{+}\left(V_{rec}\right), \ if \ \ f^{+}\left(V_{src}\right) \ge f^{-}\left(V_{src}\right) \end{aligned}, \tag{6}$$

where: $f^{+}(V_{src})$ - the flow, generated from the vertex V_{src} passing through the graph's model from V_{src} to V_{rec};

$f^{-}(V_{src})$ - the flow, consumed of the vertex V_{src} passing through the graph's model from V_{rec} to V_{src};

$f^{+}(V_{rec})$ - the flow, consumed of the vertex V_{rec} passing through the graph's model from V_{src} to V_{rec};

$f^{-}(V_{rec})$ - the flow, generated from the vertex V_{rec} passing through the graph's model from V_{rec} to V_{src}.

Definition 4: The **maximum allowed flow** is $f^{*} = \left(f^{*}\left(V_{src}\right), \quad f^{*}\left(V_{rec}\right)\right)$, if it satisfies all the conditions (4), (5) and (6) simultaneously.

3. Algorithm of the universal approach for determining the maximum flow problems

Each problem defined in the previous paragraph can be reduced to the optimization maximum flow problem, where the the goal function is:

$$f_{\Sigma}^{\max} = \max \sum_{V_j} f\left(V_k, V_j\right) = \max \sum_{V_i} f\left(V_i, V_r\right) \tag{7}$$

and the constraints:

$$\begin{cases} \sum_{V_j} f(V_i, V_j) - \sum_{V_s} f(V_s, V_i) = 0 \ \ if \ \ V_i \neq V_{src}, \ V_i \neq V_{rec} \\ \sum_{V_j} f(V_i, V_j) - \sum_{V_s} f(V_s, V_i) = f_\Sigma; \ V_i = V_{src} \\ \sum_{V_j} f(V_i, V_j) - \sum_{V_s} f(V_s, V_i) = -f_\Sigma; \ V_i = V_{rec} \end{cases}, \quad (8)$$

where $f_\Sigma^{\max}$ is the maximum flow passing through the minimum intersection $L_{\min}^{C}$ of the considered directed graph.

The basic directed graph, which is divided into two separate ones G^A and G^B this function is:

$$f_\Sigma^{\max} = f_\Sigma^{\max}(L_{\min}^{C}) = \sum_{L_{\min}^{C}} q_{ij}, \quad (9)$$

where: $L_{\min}^{C} = \left[G^A \to G^B \right]$ $\quad V_{src} \in G^A$; $\quad V_{rec} \in G^B$;
$G^A \cap G^B = \varnothing$; $G^A \cup G^B = G$.

The approach, solving the optimization problem (7) with constraints (8) is proposed and described in details in [19]. Each iteration consists of two procedures – vertexes marking and flows correction. The iteration process stops when the minimal intersection $L_{\min}^{C}$ in the directed graph's model is determinated.

Before starting the algorithm, it is necessary to know the structure of the directed graph modeling the considered system as well as the capacities q_{ij} of each graph's arc. It is assumed that the initial values of the flows f_{ij} passing through the graph's arcs $L_{ij} \in L$ are zero.

In **Procedure 1** a vertexes marking is made. Each node is assigned the appropriate pair of marks, moving from source to the recipient vertexes. This marking indicates where the respective flow comes from and its maximum allowable value that can be passed through the respective arc. When all vertexes are marked then the algorithm goes to the **Procedure 2**. This procedure moves from the recipient to the source vertexes correcting the flows passing through each of the arcs in the respective sequences of arcs in the considered directed graph. If all the arcs entering the vertex V_{rec} are saturated, then the maximum flow $f_\Sigma^{\max}$ is determined and the procedure stops. Otherwise it returns to the beginning of Procedure 1.

Note: An arc is saturated if the flow that passes through it f_{ij} is exactly equal to its capacity q_{ij} .

4. Solutions to the defined 5 types of the problems

The maximum flow determination approach, proposed in [19], can be applied to solve each of the typical problems, defined in Section 2.

Problem 1

Before starting the algorithm the directed graph's model is determined. In this model the values of the arcs capacities $\{q_{ij}\}$ and vertexes infinity capacities $P_s \to \infty, \ s = \overline{1,n}$ are known.

To simplify the future exposition and without loss of the generality the maximum flow $(f_\Sigma^{\max})$ is obtained for the intersection of the directed graph's model shown in Figure 2. For simplicity the elements (vertexes and arcs) included in the beginning of the graph are aggregated in the set M^- .

In this problem the condition (1b) is satisfied, i.e. the flow f_{ij} passing through the arc L_{ij} , have to be smaller or equal its capacity q_{ij} .

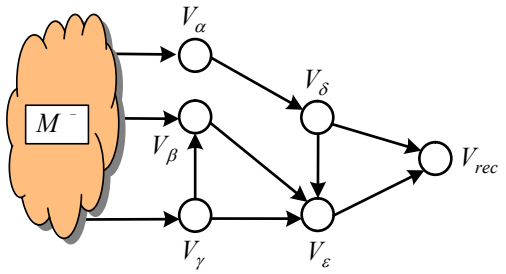

Figure 2: Idealized system described by the graph's model

Based on the minimum intersection $L_{\min}^{C}$ (see Figure 2), which satisfy the condition (4), the respective maximum flows are:

$$\begin{cases} f_{\Sigma_A}^{\max} = q_{\beta\varepsilon} + q_{\gamma\varepsilon} + q_{\delta\varepsilon} \\ f_{\Sigma_B}^{\max} = q_{\delta,rec} \end{cases}. \quad (10)$$

Conclusions:

- The maximum allowed flow $f_{\Sigma_A}^{\max}$ is equal to the sum of the capacities of the arcs $L_{\beta\varepsilon}$, $L_{\gamma\varepsilon}$, $L_{\delta\varepsilon}$, because they beyond to the minimum intersection $L_{\min}^{C}$ and they are saturated (their capacity is exhausted).
- The maximum allowed flow $f_{\Sigma_B}^{\max}$ for the arc $L_{\alpha\delta}$ is equal of the capacity of the arc $L_{\delta\varepsilon}$, because it is assumed that the condition $q_{\delta\varepsilon} < q_{\alpha\delta} + q_{\delta\varepsilon}$ is satisfied. Therefore, the arc $L_{\delta\varepsilon}$ is saturated and it is added to the minimum intersection $L_{\min}^{C}$.
- The final maximum flow, determined by Eq. (4) and Eq. (8) is $f_\Sigma^{\max} = f_\Sigma^{\max}(L_{\min}^{C}) = f_{\Sigma_A}^{\max} + f_{\Sigma_B}^{\max}$.

Problem 2

Before starting the algorithm the directed graph's model is determined. In this model the values of the arcs capacities $\{q_{ij}\}$ are known and each of them must belong to an initially defined range, i.e. $\leq q_{ij} \in \left[q_{ij}^{\min}, \ q_{ij}^{\max} \right]$.

The solution of the Problem 2 requires a transformation the basic directed graph's model to the new one, where:

- Each arc is replaced by two new arcs - L_{rg} and L_{gs}.
- The capacity of each of these new arcs determines as follows:

- about the arc $L_{rg} \to q_{rg} = q_{rs}^{\max} - q_{rs}^{\min}$;
- about the arc $L_{gs} \to q_{gs} = q_{rs}^{\min}$.
- It introduces the fictive arc L_{fict} with infinity capacity, i.e. $q_{fict} \to \infty$.

Then the Problem 2 has a solution only when the condition $f_{\Sigma}^{\max} = \sum_{q_{ij}^{\min} \neq 0} q_{ij}^{\min}$ is satisfied.

The transformed graph's model is the same as in Problem 1. Hence, the maximum flow $f_{\Sigma}^{\max}$ is determined in the same way.

Problem 3

Before starting the algorithm, the directed graph's model is determined. In this model the values of the arcs capacities $\{q_{ij}\}$ and vertexes capacities P_s, $s = \overline{1,n}$ are known.

The specificity of this problem requires that the additional condition (8) to be included:

$$f[L^{\oplus}(V_i)] \le P_s; \ \forall V_s \in V, \tag{11}$$

where: $f[L^{\oplus}(V_i)]$ is the flow entering to the vertex $V_s \in V$;

$L^{\oplus}(V_i)$ is the set of arcs, which are directly connected with the vertex $V_s \in V$ only by one arc.

To get the solution of this problem it is necessary to transform the basic directed graph's model to the new one with $(n+m)$ vertexes where *n* and *m* are the number of vertexes and arcs in the initial directed graph, respectively.

- Each vertex $V_s \in V$ is replaced by two vertexes V_{s_1} and V_{s_s}, which are connected by the arc $L_{s_1 \to s_2} = < V_{s_1}, V_{s_2} >$;
- The capacity of the arc $L_{s_1 \to s_2} = < V_{s_1}, V_{s_2} >$ is obtained as follows:

$$q_{s_1 \to s_2} = P_s; \ \forall V_s \in V. \tag{12}$$

The transformed graph's model is the same as in Problem 1. Hence, the maximum flow $f_{\Sigma}^{\max}$ is determined in the same way.

Problem 4

The initial conditions for this problem are the same as these in Problem 3 with the following additions. Fictive source $\mathbf{V}_{src} = \{V_{l,src}\}$, $l = \overline{1, N_s}$ and receiver $\mathbf{V}_{rec} = \{V_{l,rec}\}$, $l = \overline{1, N_r}$ are introduced, where each of them is associated with more than one real one (Figure 1). It is assumed that the graph's vertexes have infinite capacities, i.e. $q_{ij} \to \infty$.

The graph's model from the Problem 4 has $(n + N_s + N_r)$ vertexes and $(m+2)$ arcs compared to the models in Problems 1, 2 and 3, where *n* and *m* are the number of vertexes and arcs in the initial directed graph from Problem 1, respectively.

The resulting graph's model is the same as in Problem 1. Hence, the maximum flow studied $f_{\Sigma}^{\max}$ is determined in the same way.

Problem 5

Before starting the algorithm the directed graph's model is determined. In this model the values of the arcs capacities $\{q_{ij}\}$ and the values of the coefficients $\{\Psi_{ij}\}$, correcting the flow, passed through all of the graph's arcs are known. The latter are always positive and they reflect to the increasing ($\delta_{ij} > 0$), resp. decreasing ($\delta_{ij} > 0$) of the flow in the arc respective L_{ij}.

The next three steps describe the application of the considered heuristic algorithm [19] for solving Problems 1, 2 and 3, resp. 4 and 5, which are reduced to Problem 1.

1. Flows' ccorrection passing through the graph's arcs

The flows' correction is performed in the following way:

$$\Psi_{ij} . f_{in}(V_i, \ V_j) = f_{out}(V_i, \ V_j). \tag{13}$$

Note: If $\forall \ \Psi_{ij} = 1$ then the condition (1a) is satisfied and the directed graph's model is associated to the Problems 1, 2 or 3.

2. Determining the graph's paths from the source vertex V_{src} to the recipient vertex V_{rec}, where the resulting flow increases

If the conditions

$$\begin{aligned} &f_{in}(V_\alpha, \ V_\omega) < q_{\alpha\omega} \\ &\forall \text{"stright" arc } L_{\alpha\omega} = \langle V_\alpha, \ V_\omega \rangle \end{aligned}; \tag{14a}$$

and

$$\begin{aligned} &f_{in}(V_\alpha, \ V_\omega) > q_{\alpha\omega}, \\ &\forall \text{"opposite" arc } L_{\omega\alpha} = \langle V_\omega, \ V_\alpha \rangle \end{aligned}. \tag{14b}$$

are satisfied, then there is a path from the vertex $V_\alpha \in V$ to the vertex $V_\omega \in V$ in the analyzed directed graph, where the resulting flow increases.

The example of this path including two arcs with straight direction and two ones with opposite direction and their capacities q_{ij} and correcting coefficients Ψ_{ij}, is shown in Figure 3.

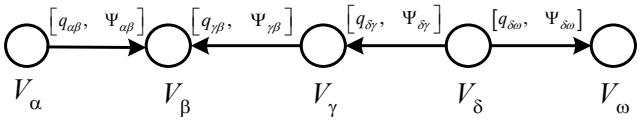

Figure 3: Path with initial vertex V_α and final vertex V_ω, including two straight and two opposite arcs

3. Obtaining the active cycles in directed graph's model

In directed graph's model $G = < V, L >$ there is an active cycle $C(G)$, connected by the recipient vertex V_{rec}, if the following conditions are satisfied:

- The value of the summary correcting cycle's coefficient is bigger than 1, i.e. $\Psi\left[C(G)\right] > 1$.
- The cycle's capacity is not zero, i.e. $q\left[C(G)\right] \neq 0$.
- The cycle includes a vertex V_λ, which is directly connected to the recipient vertex V_{rec}.

The example of this type cycle is shown in Figure 4.

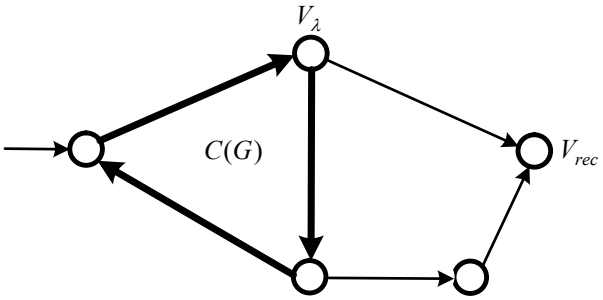

Figure 4: A cycle in directed graph's model

Note: It is allowed in directed graph's model to have cycles, connected to the source vertex V_{src}.

5. Application of the maximum flow suggested approach to an illustrative example about Problem 1

The algorithm for finding the maximum flow [19] will be illustrated for solving the Problem 1. Let's the following example of the directed graph's model is analyzed (Figure 5a). On the directed graph $G = < V, L >$ the following quantities are indicated:

1 The capacities q_{ij} of the respective arc $L_{ij} = \langle V_i, \ V_j \rangle \in L$ are shown below it.

2 The values of the flows $f_{ij} = f(V_i, V_j)$ passing through the arc L_{ij} are underlined and are written above to the arc. It is assumed that the initial values of these flows for all arcs are zeroes.

3 The vertexes marks $\left[M_1(V_i), \ M_2(V_i)\right]$ are noted in the following way:

- $M_1(V_i) = \pm V_j$, with respect to an increasing (+) or decreasing (–) flow passing through the arc L_{ij};
- $M_2(V_i) = f_{add}(V_i)$ - the maximum value of the additional flow $f_{add}(V_i)$ from the source vertex V_{src} to the vertex V_i passing through the sequence of the arcs, where the flow increases. This flow is determined as follows:

$$\begin{aligned} & f_{add}(V_i) = \min\left[f_{add}(V_j), \ q_{ij} - f\left(V_j, \ V_i\right) \right], \\ & \text{if } \ f\left(V_j, \ V_i\right) < q_{ij} \ \wedge \ V_i \in M^{+}(V_j) \\ & f_{add}(V_i) = \min\left[f_{add}(V_j), \ f\left(V_i, \ V_j\right) \right], \\ & \text{if } \ f\left(V_j, \ V_i\right) > 0 \ \wedge \ V_i \in M^{-}(V_j) \end{aligned} \qquad (15)$$

It is assumed that the initial marks of all vertexes are zeroes. And the source vertex V_{src} gets the mark $M(V_{src}) = \left[V_{src}, \ \infty\right]$, i.e. the generated flow from the source vertex is infinite.

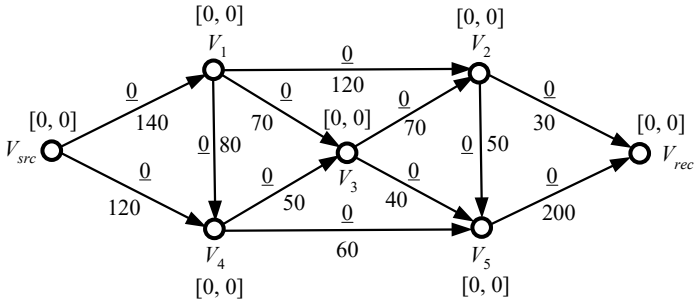

Figure 5a: Illustrative example for solving a maximum flow problem

When applying the heuristic algorithm [19], each iteration consists of 2 steps: first the vertices in the considered directed graph are marked and checked, and second the flows passed through the arcs in the graph's model are corrected. When marking the vertices, the algorithm moves from the beginning to the end of the graph, and when correcting the flows – vice versa, taking into account the capacity of each arc.

The required maximum flow is determined when all incoming arcs in the end graph's vertex are saturated. For the present example, this happens to the third iteration. The iterations are following.

Iteration 1

Vertexes marking (Figure 5b)

The source vertex V_{src} is marked with:

$$M\left(V_{src}\right) = \left[+V_{src}, \ \infty\right].$$

The vertexes V_1 and V_4, that are directly connected with V_{src} get the following marks:

$$\left| \begin{array}{l} M\left(V_1\right) = \left[+V_{src}, \ \ 140\right], \ M_2 = \min\left[\infty, \ 140 - 0\right] = 140 \\ M\left(V_4\right) = \left[+V_{src}, \ \ 120\right], \ M_2 = \min\left[\infty, \ 120 - 0\right] = 120 \end{array} \right. .$$

Therefore, the vertex V_{src} is marked and checked.

Let's move to the next vertex - V_1, which is marked but not checked. The latter is connected to the vertexes V_2 and V_3. So their marks are determined as follows:

$$\left| \begin{array}{l} M\left(V_2\right) = \left[+V_1, \ \ 120\right], \ M_2 = \min\left[140, \ 120 - 0\right] = 120 \\ M\left(V_3\right) = \max\left\{ \begin{array}{l} \left[+V_1, \ \ 70\right], \ M_2 = \min\left[140, \ 70 - 0\right] = 70 \\ \left[+V_4, \ \ 50\right], \ M_2 = \min\left[120, \ 50 - 0\right] = 50 \end{array} \right\} = \left[+V_1, \ \ 70\right] \end{array} \right.$$

Therefore, the vertex V_1 is marked and checked.

The marks of the other vertexes are determined by analogy as follows:

$$\left| \begin{array}{l} M\left(V_5\right) = \max\left\{ \begin{array}{l} \left[+V_2, \ \ 50\right], \ M_2 = \min\left[120, \ 50 - 0\right] = 50 \\ \left[+V_3, \ \ 40\right], \ M_2 = \min\left[70, \ 40 - 0\right] = 40 \\ \left[+V_4, \ \ 60\right], \ M_2 = \min\left[120, \ 60 - 0\right] = 60 \end{array} \right\} = \left[+V_4, \ \ 60\right] \\ M\left(V_{rec}\right) = \left[+V_2, \ \ 120\right], \ M_2 = \min\left[120, \ 30 - 0\right] = 30 \end{array} \right.$$

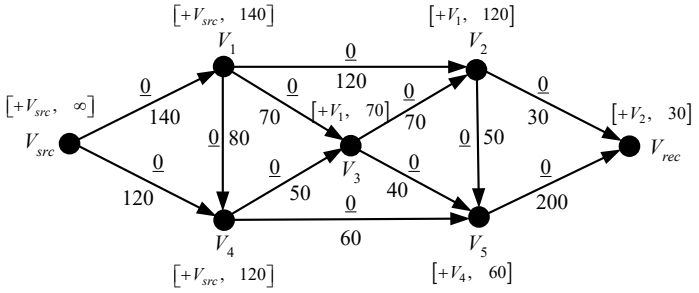

Figure 5b: Results from vertexes marking in an Iteration 1

So, all vertexes in the directed graph are marked and checked.

Flows correction (Figure 5c)

The vertex V_{rec} is chozen as a start vertex and we move from the end V_{rec} to the beginning V_{src} of the directed graph. Using Eq. (11) it determines the flow

$$f_{add}\left(V_{rec}\right) = M_2\left(V_{rec}\right) = 30\,.$$

Thus, the consequence of the arcs

$$\langle V_{rec},\ \ V_2\rangle \rightarrow \langle V_2,\ \ V_1\rangle \rightarrow \langle V_1,\ \ V_{src}\rangle$$

is formed basing on the first mark coefficients $M_1\left(V_i\right)$ of the respective vertexes. Then, using Eq. (12) the corrected values of the flows only in this arcs are calculated as follows:

$$f(V_2,V_{rec}) = f(V_1,V_2) = f(V_{src},V_1) = 0 + f_{add}\left(V_{rec}\right) = 30\,.$$

Then the condition

$$f(V_2,V_{rec}) = q_{2rec} = 30$$

is satisfied for the arc $\langle V_2,\ \ V_{rec}\rangle$. Then the arc is saturated and it is marked with bold.

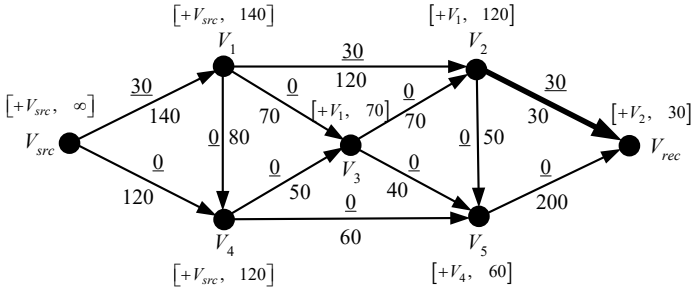

Figure 5c: Results from the flows corrections in the end of an Iteration 1

Since the arcs $\langle V_5,\ \ V_{rec}\rangle, \langle V_2,\ \ V_5\rangle, \langle V_3,\ \ V_5\rangle$ and $\langle V_4,\ \ V_5\rangle$ are not saturated the algorithm passes to next iteration – Iteration 2.

Moving from V_{rec} to the V_{src} as a result of this iteration a flow equal to 30 units is passed through each of the arcs $\langle V_{src},\ \ V_1\rangle, \langle V_1,\ \ V_2\rangle$ and $\langle V_2,\ \ V_{rec}\rangle$.

Iteration 2

Vertexes marking (Figure 5d)

Based on the information from Figure 5c, the new mark of the vertexes is set as follows:

$$\begin{aligned} M\left(V_{src}\right) &= \left[+V_{src},\ \ \infty\right] & M\left(V_2\right) &= \left[+V_1,\ \ 90\right] \\ M\left(V_1\right) &= \left[+V_{src},\ \ 110\right] & M\left(V_3\right) &= \left[+V_1,\ \ 70\right] \\ M\left(V_4\right) &= \left[+V_{src},\ \ 120\right] & M\left(V_5\right) &= \left[+V_4,\ \ 60\right] \\ & & M\left(V_{rec}\right) &= \left[+V_5,\ \ 60\right] \end{aligned}\,.$$

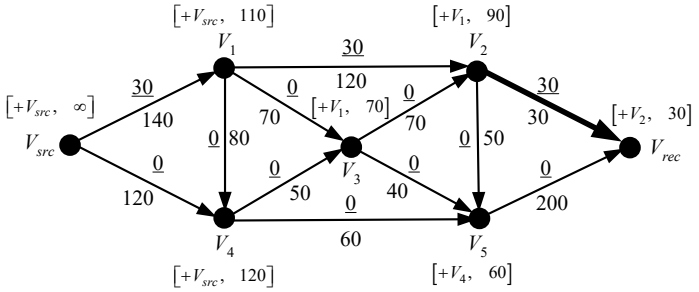

Figure 5d: Results from vertexes marking in an Iteration 2

Flows correction (Figure 5e)

Using Eq. (11) for the arc $\langle V_4,\ \ V_5\rangle$ the additional flow, is determined:

$$f_{add}\left(V_5\right) = M_2\left(V_5\right) = 60\,.$$

Thus, the consequence of the arcs

$$\langle V_{src},\ \ V_4\rangle \rightarrow \langle V_4,\ \ V_5\rangle$$

and

$$\langle V_{src},\ \ V_1\rangle \rightarrow \langle V_1,\ \ V_4\rangle \rightarrow \langle V_4,\ \ V_5\rangle$$

is formed basing on the first mark coefficients $M_1\left(V_i\right)$ of the respective vertexes. Using Eq. (12) the corrected values of the flows only in these arcs are corrected as follows:

$$\begin{aligned} f(V_{src},V_4) &= f(V_4,V_5) = 0 + f_{add}\left(V_5\right) = 60 \\ f(V_1,V_4) &= f(V_4,V_5) = 0 + f_{add}\left(V_5\right) = 60 \\ f(V_{src},V_1) &= 30 + f_{add}\left(V_5\right) = 30 + 60 = 90 \end{aligned}\,.$$

The arc $\langle V_4,\ \ V_5\rangle$ is saturated because the condition

$$f(V_4,V_5) = q_{45} = 60$$

is satisfied. Then the arc is marked bold.

Based on the additional flow $f_{add}\left(V_{rec}\right) = 60$, the corrected flows are:

$$f(V_5,V_{rec}) = f(V_4,V_5) = 0 + f_{add}\left(V_{rec}\right) = 60\,.$$

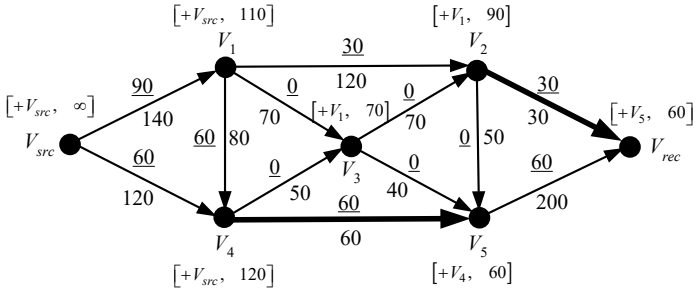

Figure 5e: Results from the flows corrections in the end of the Iteration 2

Since the arcs $\langle V_2, \ V_5 \rangle$ and $\langle V_3, \ V_5 \rangle$ are not saturated the algorithm passes to next iteration – Iteration 3.

Moving from V_{rec} to the V_{src} as a result of this iteration a flow equal to 60 units goes through each of the arcs $\langle V_{src}, \ V_4 \rangle, \langle V_4, \ V_5 \rangle$ and $\langle V_5, \ V_{rec} \rangle$. This additional flow of 60 units is then added to the current flows through the arcs $\langle V_1, \ V_4 \rangle$ and $\langle V_{src}, \ V_1 \rangle$, and finally, the flows of 60 and 90 units pass through the arcs, respectively.

Iteration 3

Vertexes marking (Figure 5f)

Based on the information from Figure 5e, the new mark of the vertex V_4 is set as follows (Figure 5f):

$$M(V_4) = [+V_{src}, \ \ 60].$$

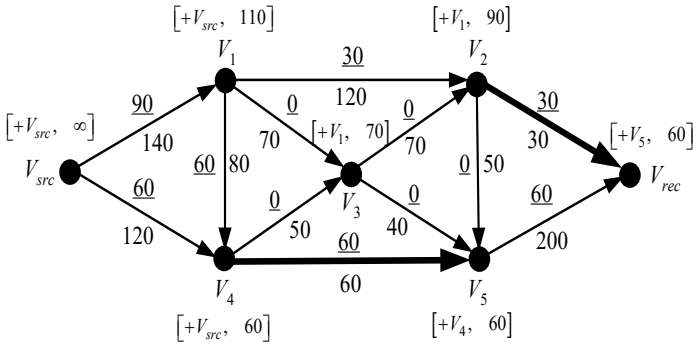

Figure 5f: Results from vertexes marking in an Iteration 3

3.2. Flows' correction (Figure 5g)

Using Eq. (11) the arcs $\langle V_2, \ V_5 \rangle$ and $\langle V_3, \ V_5 \rangle$ the following additional flows, are determined:

$$f_{add}^{V_2}(V_5) = \min\left[q_{25} = 50, \ M_2(V_5)\right] = \min[50, \ 60] = 50$$

and

$$f_{add}^{V_3}(V_5) = \min\left[q_{35} = 50, \ M_2(V_5)\right] = \min[40, \ 60] = 40 .$$

Thus, the other corrected flows are:

$$f(V_2, V_5) = f_{add}^{V_2}(V_5) = 50.$$
$$f(V_3, V_5) = f_{add}^{V_3}(V_5) = 40.$$

here

$$f(V_2, V_5) = 50, \ \text{and} \ \ q_{25} = 50 \Rightarrow \langle V_2, \ V_5 \rangle \ \text{is saturated.}$$
$$f(V_3, V_5) = 40, \ \text{and} \ \ q_{35} = 40 \Rightarrow \langle V_3, \ V_5 \rangle \ \text{is saturated.}$$

Therefore, both arcs $\langle V_2, \ V_5 \rangle$ and $\langle V_3, \ V_5 \rangle$ are marked bold.

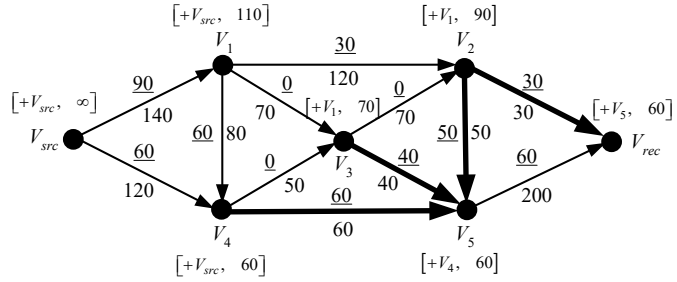

Figure 5g: Results from the flows corrections in the Iteration 3

The solution of the maximum flow problem is shown in Figure 5h, where the final vertexes are marked and flows corrections are made:

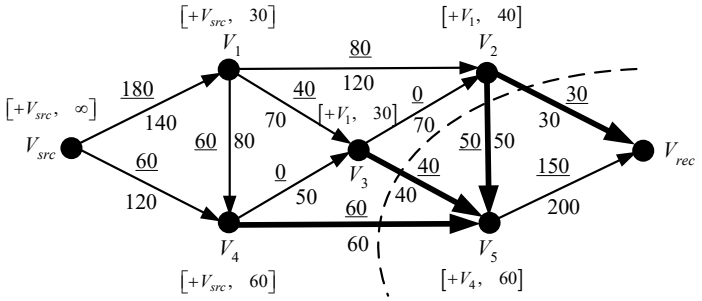

Figure 5h: Final maximum flow

Moving from V_{rec} to the V_{src}, as a result of this iteration, the following will happen. First, a flow equal to 40 units is passed through each of the arcs $\langle V_{src}, \ V_1 \rangle, \langle V_1, \ V_3 \rangle$ and $\langle V_3, \ V_5 \rangle$. This additional flow of 40 units is then added to the current flows through the arcs $\langle V_{src}, \ V_1 \rangle, \langle V_1, \ V_3 \rangle$ and $\langle V_3, \ V_5 \rangle$, and finally flows of 130, 40 and 40 units will pass through the arcs, respectively. Second, a flow equal to 50 units is passed through each of the arcs $\langle V_{src}, \ V_1 \rangle, \langle V_1, \ V_2 \rangle$ and $\langle V_2, \ V_5 \rangle$. This additional flow of 30 units is then added to the current flows through the arcs $\langle V_{src}, \ V_1 \rangle, \langle V_1, \ V_2 \rangle$ and $\langle V_2, \ V_5 \rangle$, and finally flows of 180, 50 and 50 units will pass through the arcs. Thus, the resulting flow through the arc will be 180 units.

After the last iteration, it is seen that all arcs, where a flow passing through, are saturated. Therefore, an end solution is reached and the final maximum flow is:

$$f_{\Sigma}^{\max} = f(V_2, \ V_{rec}) + f(V_2, \ V_5) + f(V_3, \ V_5) + f(V_4, \ V_5) =$$
$$= 30 + 50 + 40 + 60 = 180$$

In the analyzed illustrative example, the final maximum flow has been found after the third iteration, because all arcs of the cross section shown in Fig. 5h passing flow to the end vertex V_{rec} are saturated, i.e. the flow passing through them f_{ij} is exactly equal to the capacity of the corresponding arc q_{ij}.

A comparative study between the discussed heuristic algorithm and a standard min-cut algorithm for solving the maximum flow problem

The obtained solution with a heuristic approach of [19] for an illustrative problem shown in Figure 5a is compared with

analogous ones, determined by traditional methods based on min-cut theorem [20, 21, 22]. The latter is the following: "For any directed weight graph, the maximum flow passed through from the source to the recipient vertex is equal to the capacity of the minimum cut.". Then it is necessary to obtain the set of arcs with minimum weight that after removing from the graph there is no path from the source to the recipient vertexes. The following methods were used: Ford Fulkerson [23], Edmonds Karp [24] and Dinic algorithms [25, 26]. The calculations are made with free software Visualgo. The final the full solution of the considered problem about the maximum flow is obtained.

Note: In contrast to the method applied in this article, in the final solution Visualgo visualizes the flow that passes through each of the arcs and their remaining capacity, depending on the full arc's capacity, as shown in Figures 5a-5h.

The final solution obtained through the used methods are shown in Figures 6a, 6b and 6c.

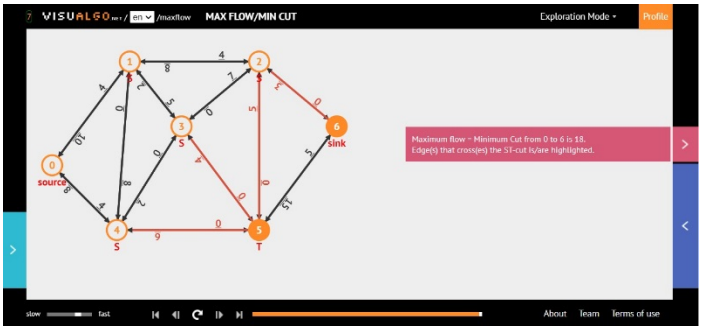

Figure 6a: Final maximum flow obtained by the Ford-Fulkerson's algorithm

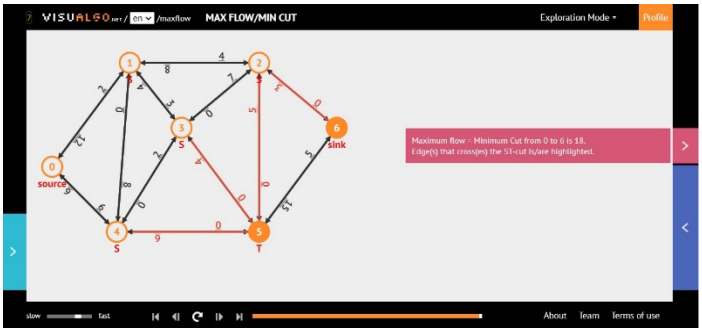

Figure 6b: Final maximum flow obtained by the Edmonds-Karp's algorithm

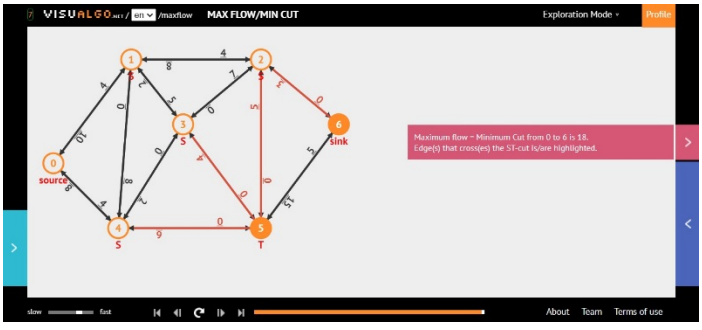

Figure 6c: Final maximum flow problem obtained by the Dinic's algorithm

The final maximum flow, determined by these three methods, based on min-cut theorem (Figures 6a, 6b and 6c), are the same as those of the heuristic approach applied in this article:

$$f_{\Sigma}^{\max} = f(V_2,\ V_{rec}) + f(V_2,\ V_5) + f(V_3,\ V_5) + f(V_4,\ V_5) = .$$
$$= 30 + 50 + 40 + 60 = 180$$

The advantage of the proposed approach is that the final solution is obtained on the 3rd iteration, and each iteration consists of two procedures.

In the method of Ford Fulkerson, the final solution is obtained on the 6th iteration. The Edmonds Karp algorithm consists of two built-in cycles. For the considered example the final solution is obtained on the 4th iteration. As the external cycle is executed 4 times and each time from its execution the internal is executed only once. The Dinic algorithm consists of two build-in cycles. For the considered example the final solution is determined after applying the external cycle 2 times. Initially, the internal cycle is rotated 2 times after that – it rotates 3 times. All this shows the better efficiency of the proposed algorithm

6. Conclusion

Determining the maximum flow and the distribution of the flows in the analyzed directed graph based on the interconnections in its topology is an important prerequisite for the efficient use of resources in the considered system. The solution of this optimization problem depends on the structure of the comsidered graph's model and the capacities of its arcs. The heuristic approach used in this article is universal not only in terms of the physical nature of the studied system, but also in terms of different types of problems considered - the input data of each of analyzed problem are different.

The solutions to the Problems 1, 2, 3 and 4 show that the flows passing through the arcs of the graph's model are constant. The solution to the Problem 5, however, shows that the flow is variable, so one can make a general conclusion when the new approach has been successfully applied in the case of violation of the balance condition.

In the present paper, the results of the solution for Problem 1 with heuristic algorithm are compared with these obtained from other analogous methods: Ford-Fulkerson's, Edmonds-Karp's and Dinic's algorithms. The time complexity of this algorithm is equal to that of the Ford-Fulkerson's and Edmonds-Karp's algorithms - $O\left[|V|.|E|^2\right]$, in contrast to that of the Dinic's algorithm, where it is $O\left[|V|^2.|E|\right]$. The illustrative example shows that it is faster to converge to the final solution comparing to the other considered algorithms.

The used universal algorithm is inapplicable to solving problems in which at least one of the three initial assumptions (defined in Problem statement) is not fulfilled, i.e. Balance condition, second condition for sequencing the flow passing through the arbitrary arc with its capacity and third condition for the invariability of the flow passing through the considered graph moving from the source to the recipient vertexes and vice versa.

One of the possible future development of the work is related to the program realization of the proposed approach for determining the maximum flow passing through a directed graph.

Other trend for the future development of the research on solving this problem is using an algorithm based on determining all possible paths in the considered directed graph, proposed in [27]. It uses two adjacent matrices corresponding to each vertex of the graph - these of the input and output arcs in the vertex, respectively. As a result of the algorithm, one will only be interested in the maximum flow that has passed the shortest path from the start to the end vertex in the directed graph.

Conflict of Interest

The author declares no conflict of interest.

ABSTRACT

Nowadays, smartphones and laptops equipped with cameras have become an integral part of our daily lives. The pervasive use of cameras enables the collection of an enormous amount of data, which can be easily extracted through video images processing. This opens up the possibility of using technologies that until now had been restricted to laboratories, such as eye-tracking and emotion analysis systems, to analyze users' behavior in the wild, during the interaction with websites. In this context, this paper introduces a toolkit that takes advantage of deep learning algorithms to monitor user's behavior and emotions, through the acquisition of facial expression and eye gaze from the video captured by the webcam of the device used to navigate the web, in compliance with the EU General data protection regulation (GDPR). Collected data are potentially useful to support user experience assessment of web-based applications in the wild and to improve the effectiveness of e-commerce recommendation systems.

1. Introduction

This paper is an extension of work originally presented in ISCT [1]. Understanding User eXperience (UX) in the wild is of paramount importance for online business (e.g., e-commerce) to gain information about users' opinion and behavior, in order to increase productivity, customize services and better drive strategic decisions. According to the definition provided by the international standard on ergonomics of human-system interaction, ISO 9241-210, UX is "a person's perceptions and responses resulting from the use or intended use of a product, system or service". It follows that the analysis of the sensations and emotions of the user with the product represents a central topic for UX research [2]. Over the last decade, increasingly accessible social media and tools offered by e-commerce sites themselves (e.g. Amazon.com), which encourages users to share their opinions, have made available a wealth of information potentially useful for understanding UX. Alongside, there has been a growing interest in sentiment analysis based on text analysis and user opinion mining. Several automatic approaches have been proposed to understand user emotion and extract UX information from online user online review [3-5]. However, though these tools are becoming increasingly accurate and effective, it is impossible to rely only on online reviews to understand how customers really feel. As reported by Jakob Nielsen in a study about user behavior in online communities [6], a significant number of customers (90%) are lurkers (i.e., they read and observe, but they do not contribute), while the 9% contribute intermittently within the only community and only the 1% account for most contributions. This phenomenon has been named "the 90-9-1 rule". Consequently, while systems able to get direct feedback from all the users (whether they are someone who will leave on online review or not) are still lacking, companies continue to spend millions of dollars on surveys and analysis of their customers to know what really works and what does not.

Moreover, recent years have shown an increasing interest in enhancing possibilities of human-computer interaction with e-commerce. Recommendation systems have started to attract interest in both business and research [7]. In the last few years there was significant improvement especially over the collaborative filtering approaches thanks to the advance in the field of machine learning and deep learning techniques [8]. However, the effectiveness of such a system remains generally low, as the algorithms used by most of the web e-commerce for providing shopping suggestions to customers use data collected from other customers, so that system difficulty meets the

*Corresponding Author: Andrea Generosi, a.generosi@pm.univpm.it

customer's expectation [7]. In this context, emotion detection represents one of the directions that can be taken to enhance the overall UX with these systems. In fact, it has been proved that recommender systems are more precise in providing relevant suggestions, when emotion variables are considered [9].

Nowadays, a variety of technologies exists to automatically recognize human emotions, spanning across facial expression analysis, acoustic speech processing and biological responses interpretation. The extensive deployment of smart devices equipped with sensors and connected to the Internet today opens the possibility of accessing a huge amount of data that until now would have been very difficult to collect. Smartphones and laptops equipped with cameras became an integral part of our daily lives. The use of cameras is so pervasive that we no longer worry about their presence, and we are not fully aware of how much information can be collected through them. For example, using appropriate systems, it is possible to process video images so that demographic (e.g., gender and age) and behavioral (e.g., emotions, eye movements) information can be easily extracted [10, 11]. This opens up the possibility of using technologies that until now had been restricted to laboratories to analyze UX in the wild.

In this context, this paper aims to extend and integrate the contribution of the work presented in ISCT, which introduced and evaluated a new system of emotion detection for mobile applications, in order to define a toolkit for automated collection of data related to users' emotions and behavior useful to:

- Support the collection of data related to the user behavior during the interaction with desktop and laptop web-based applications in the wild;
- Improve the effectiveness of recommendation systems.

Such a tool will take advantage of the system proposed in [1] to monitor user's emotions, through the acquisition of facial expression and implements new system based on deep learning algorithms to track the eye gazes from the video captured by the webcam of the device used to navigate the web, in compliance with the General data protection regulation (GDPR), the European Union regulation on the processing of personal data and privacy.

The remainder of this paper is organized as follows: Section 2 gives an overview of the state of art in the context of systems for the automatic detection of users' emotions and behavior and in particular of facial expression recognition and gaze tracking systems. Section 3 describes the overall system architecture with the Emotion recognition and Gaze detection modules. In Section 4 performance evaluation results of the proposed are reported. The last section summarizes the main paper contributions and highlights future outlook.

2. Research Background

Over the past years producers and the marketing/branding industry demonstrated an increasing interest in emotional aspects of user behavior, as understanding the emotional state of users is crucial for developing successful products and services [12]. Psychophysiological methods may offer data throughout the process of experience, which unfolds new possibilities for UX evaluation. This motivated the demand for automatic emotion recognition techniques as a tool for getting a larger quantity of more objective data. Several attempts have been made to explore the possibility to use sentiments analysis to extract UX information from online user reviews. However, online reviews have proved to be too generic and lacking contextual references to effectively support UX assessment [13]. Several studies, such as [14] and [15], proposed systems that allow us to correlate data from different typologies of data, e.g. eye-tracking fixations, sentiment analysis, body gestures, or facial expressions. However, these systems are designed to support only formal UX evaluation assessment, while are not suitable for studies in the wild. Based on the best of our knowledge, no studies so far have proposed the integrated use of gaze and emotion recognition systems, based on deep learning algorithms, to support the collection of relevant information useful for UX assessment of laptop and desktop web applications nor to power recommending systems. Only [11] proposed a system to support UX assessment based deep learning, but such a solution works only for mobile applications. While only [7] proposed to process data provided by a common pc webcam to enable users' gaze and emotion detection in order to manage an intelligent e-commerce recommendation system: it proposed respectively to use SVM algorithm to enable emotion recognition and a gradient-based method to perform gaze tracking. These algorithms, compared with most of Deep Learning CNNs, are more efficient for what concerns the computational performance, but less accurate [16].

2.1. Emotion recognition

In recent decades, research in the field of Human-Computer Interaction has shown an increasing interest in topics such as Affective computing, emotion analysis and study of human behaviors.

This has encouraged the development of numerous methods and tools for the recognition of human emotions, characterized by different levels of intrusiveness. Most of them relate to three main research areas: facial expression analysis, speech recognition analysis and biofeedback analysis. Instruments based on biofeedback currently available (e.g., ECG or EEG, biometric sensors) are still difficult to adopt for studies in the wild, although the use of smart watches and bracelets is increasingly widespread [17]. Instead, research efforts in the field of facial expression recognition systems have allowed the development of reliable and non-invasive systems. The theoretical model most widely used in the analysis of facial expressions to develop algorithms for the recognition of emotions is certainly represented by the Face Action Coding System (FACS) [18]. It allows the identification of six universal emotions (i.e., joy, surprise, sadness, anger, fear and disgust) by tracking the movements of the face muscles.

The vast majority of facial expression recognition systems are based on Convolutional Neural Networks (CNN): a particular mathematical model of Deep Learning that, unlike classical neural networks, present some layers, in the first part of the entire network, which apply a convolution instead of a general matrix multiplication to the images in input before passing the result to the next layers [10]. Several tools have been proposed in literature, such as [19-21]. Usually these systems refer to trained models using datasets built in controlled environments, where it

is possible to obtain the best accuracy scores, or, trained with data obtained by crawlers on the web, with low accuracy but mostly reflecting real contexts. To the best of our knowledge, approaches able to ensure a good accuracy using data obtained "in the wild" have not yet been evaluated. To ensure good accuracy in the recognition of human emotions in different contexts of use, the system of recognition of emotions proposed in this study adopts a hybrid approach. The resulting CNN, based on Keras and Tensorflow frameworks, has been trained merging three different public datasets.

2.2. Eye-gaze tracking

Tracking one's eyes movement is challenging yet important in HCI and computer vision fields. When it comes to products (as well as website) design, it is readily understandable how much it means to know where a user is looking at. In recent years research has aimed to achieve increasingly accurate results, using less and less invasive and off-the-shelf systems (especially webcams).

According to the results of a recent survey, gaze tracking techniques can be classified into two main categories: feature-based and appearance-based [22]. The first approaches require the acquisition of high-quality images to determine ocular characteristics, such as infrared corneal reflections [23], pupil center [24] and iris contour [25]. To determine the direction of the gaze independently to the head pose, these features are related to 3D eye models. Although such approaches allow high accuracy to be achieved, the accuracy of the geometric calculation is highly dependent on system calibrations that are often difficult or impossible for ordinary users to perform. In addition, as they need to extract small features of the eye, they require the use of special equipment (e.g. IR light sources, special glasses / contact lenses) to acquire special high-resolution infrared images. Such technologies are not normally available in uncontrolled environments. Conversely, appearance-based approaches do not need particular illumination conditions, so that they work well with natural lighting, and require only a single webcam [26]: they take image contents directly in input and try to implicitly extract some relevant features, thus establishing a mapping to screen coordinates. Applicability of this latter kind of methods is remarkably large, although the potential handling of low-resolution images makes their accuracy generally lower [26].

Recently, deep learning (DL) and convolutional neural networks (CNN) have been gaining interest for gaze estimation, so much so that many datasets [27] and network architectures [26, 28, 29] have been proposed over the last years. The gaze-tracking system described in this paper adopts an architecture similar to the one proposed by Krafka et al. [30], which represents one of the more solid CNN actually proposed for gaze tracking. It is based on the AlexNet model described in [31].

3. System Architecture

For the proposed toolkit a centralized architecture has been designed. This kind of architecture has been inherited from the system described in [11] and adapted to be used in synergy with web platforms instead of mobile applications. In Figure 1 are shown the main components: the Web Plugin and the Deep Learning Platform (DLP), respectively the frontend and the backend sides. The Web Plugin is a Javascript library with different functions usable by the developers (APIs) to get info about user's interactions with the web application, i.e. interactions timestamps, clicks and scroll coordinates and above all the webcam handling, so how and when to enable the webcam activation, shooting frequency etc. This feature is the most important because both the Deep Learning engines that compose the DLP make use of the user's face photos to return the information related to his behavior. Photos taken through the pc webcam are encoded in base64 from the Web Plugin and sent through a HTTPS POST to the REST interface exposed through a specific endpoint from the DLP and developed in Python. The received call is then decoded and parsed to get the original data and store it in the server volatile memory, to ensure the compliance of the system with GDPR about privacy. After that, the encoded photo is stored in three different Redis queues: in this way every DL Tracker module can process every photo asynchronously. These queues are used to store and manage the order of arrival of the data that will be given in input to the Gaze Tracker and Emo Tracker for the prediction, respectively, of the gaze coordinates on the screen and the universal Ekman's emotions. Both trackers are Convolutional Neural Networks (CNN) implemented with the Python frameworks Tensorflow and Keras. Whenever the photo processing is concluded for a CNN, the output is saved in a database.

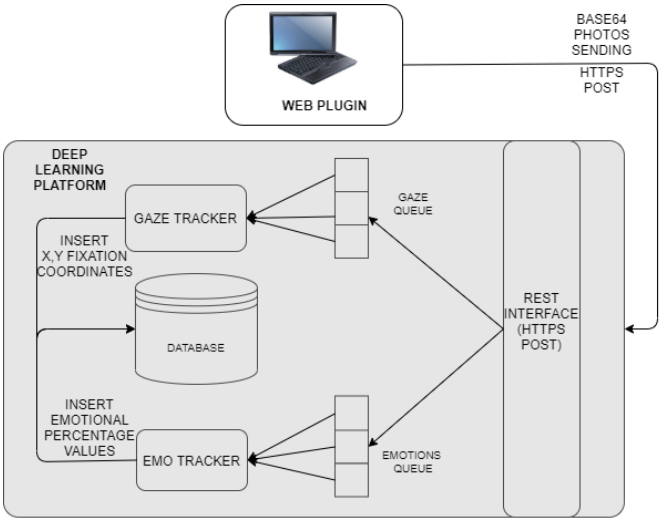

Figure 1: System architecture

3.1. Emo Tracker - the Emotion detection module

Based on [20], a state-of-the-art Deep Learning model that performs well in image recognition should also perform well in a facial expression recognition task: that's because basically the visual discrimination of human emotions is an image classification task. According to different review works, like [19], there exist different DCNNs (Deep Convolutional Neural Networks) that reach various accuracy levels, and those that reach the highest performances are always trained using datasets composed by images retrieved in controlled environments and labeled in labs. Instead, lower accuracy percentages are reached by those datasets with "in the wild" properties, especially retrieved by web crawlers, usually composed by blurred, decentralized or very low-resolution images with misclassified

labels [20]. In return, this kind of datasets are often significantly bigger than the other kind.

To achieve the best emotion recognition accuracy and performances, various tests were conducted. Firstly, by merging the public datasets CK+ (developed in laboratory) [32], FER+ (the FER dataset re-tagged version with crowdsourcing) and AffectNet (manually annotated), a big dataset is constructed. More in detail, FER+ dataset has a label accuracy about 90%, with just 35k photos [20], AffectNet instead has more than 1 million web crawled images, but it also provides more than 400k photos manually labeled by several experts. These datasets have been chosen because they are tagged with almost one of the universal Ekman's emotions labels and because they reach a labeling accuracy relatively high. Moreover, as mentioned, they belong to different dataset categories, so they provide the possibility to improve the resulting model reliability: the assumption is in fact that combining lab generated datasets with those with "in the wild" properties, it is possible to obtain a better accuracy for the in the wild benchmarks. To further improve resulting dataset quality, a Python script to filter all the images with none or more than one face has been developed. The resulting merged dataset at the end counts more than 250k photos, with data distribution shown in Figure 2.

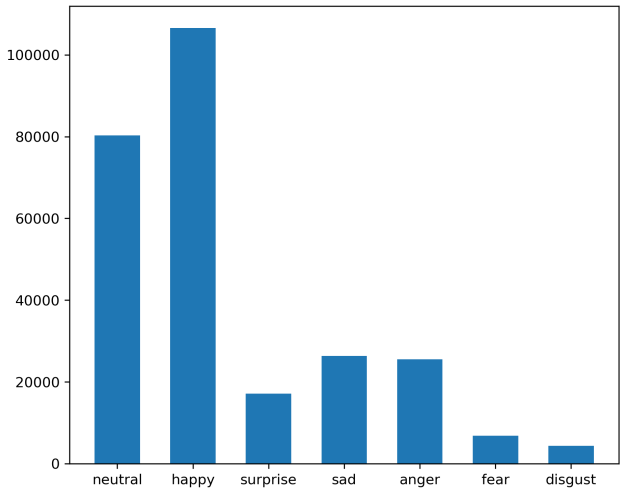

Figure 2: Data distribution

Every single dataset has then splitted into two different parts for training and validation, so to avoid distorting the results during validation phase: for this purpose it was chosen, empirically, to divide each dataset using the ratio 80% for training and 20% for validation, equally for each dataset. After constructing the dataset, preprocessing steps are performed such as facial alignment, centralization of the face respect to the image and face rotation, obtained using Dlib facial landmarks coordinates as reference. All the photos have then been scaled to 64x64 pixels, so to make them homogeneous in size.

For the implementation of the Emo Tracker module, different Python scripts that make use of Dlib, Tensorflow and Keras frameworks have been developed. In particular, Dlib is used to detect one or more human faces in a frame (Face Detection) and provide main face landmarks coordinates, while Keras and Tensorflow provide some of the most used APIs in the Deep Learning field. Trained networks models have been defined to take 64x64 pixels face images in grayscale by the input layer, and to return the Ekman's Emotions (joy, surprise, anger, disgust, sadness, fear and neutral) classification probability by the output layer. Different Keras model architectures such as Inception [33], VGG13, VGG16 and VGG19 [34], were also tested to compare the reached accuracy levels, as listed in Table 1.

Table 1: Performance of different models

Architectures	Accuracy (%)
VGG13	**75.48**
VGG16	74.48
VGG19	73.14
InceptionV2	75.26
InceptionV3	67.20

Network hyperparameters are initialized as it is stated on [20], then the other variations are also experimented such as validation split 0.1, 0.2, number of epochs 30, 50 and 100 and dynamic learning rate defined as

$$lr = lr \times (1 - \frac{epoch}{epoch})$$

Learning rate (lr) is initialized with 0.025 and updated on each epoch accordingly. As shown in table 1, VGG13 model reaches the best accuracy percentage in validation phase, accuracy values over time in relation to the epochs increasing are shown on Figure 3, as a reference of the carried-out experiment. Overfitting occurs during training using other deep neural network architectures, except for the VGG13, when epochs number is bigger than 30.

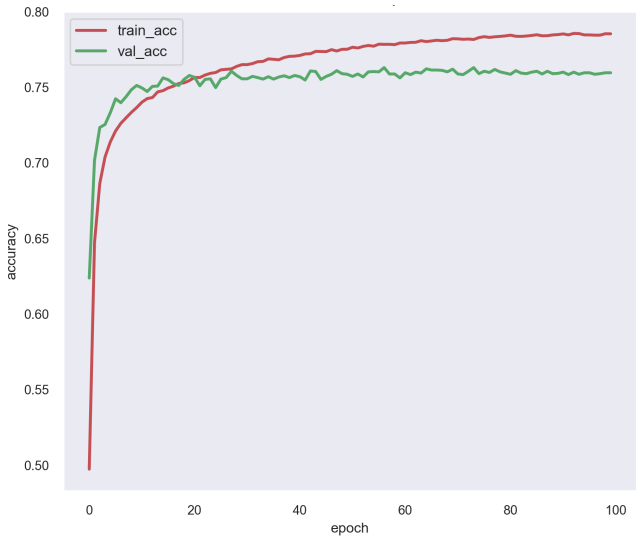

Figure 3: Training and validation accuracy of VGG13

3.2. Gaze Tracker - the Eye-Gaze Detection module

In 2016, Krafka et al. [30] published a paper with a solid CNN proposal for gaze tracking, together with a big dataset of crowdsourcing-collected faces; many researchers are referring to it since then. The Gaze Tracker module's network adopts an architecture similar to the one proposed in [30], which is based on the AlexNet model [31], but respect to that one, a dropout layer

was added to the right after each last convolutional layer. Also in this case, the output is the camera distance, in centimeters. The main challenge using this architecture has been to adapt it to an application context different from the one originally established: iTracker in fact has been trained to work with mobile devices, especially it can reach the best performances on iPhone devices, where it is possible to exactly know, dynamically, the phone camera position. Moreover, practically the whole dataset used to train the model, was built using photos taken by Apple devices. Our purpose, instead, is to propose a gaze detection module optimized to be used on laptop and desktop devices, while it has been decided to not consider a general model that involves also mobile displays in order to not undermine the performance of the model for the specific case taken into consideration by this research.

To achieve this objective, a new training dataset has been built from scratch, collecting pictures from informed volunteers who decided to contribute. For this purpose, a web application has been developed. Each participant was asked to stare at a red dot that was randomly displayed in 30 different screen positions, while the webcam took a picture for each of them; corresponding point coordinates were stored too, to ensure image-screen coordinates association. Concerning screen sizes, this application has been thought to be as general as possible (i.e., capable of dealing with different kinds of displays). However, due to infrastructural reasons, it is not possible to automatically retrieve physical dimensions of a screen from a web page application.

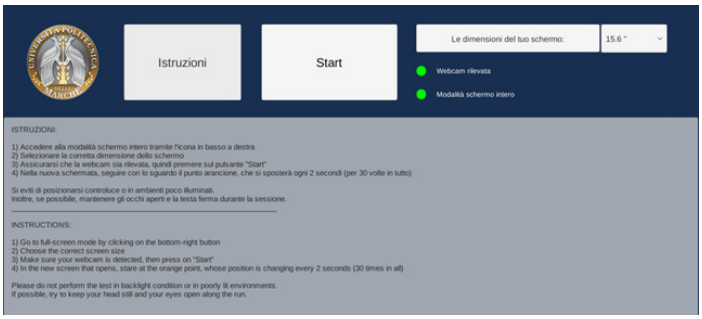

Figure 4: Main screen of the web application for collecting training pictures; by pressing on "Start", a new empty screen appears, in which the dots are shown in succession

For this reason, on the application interface, the user is asked to choose its own screen size, among the ones displayed in a dropdown list, ranging from 13 to 30 inches (i.e., the most common laptop and desktop sizes). By knowing the physical size of the screen and the display resolution (that can be automatically determined instead), it has been possible to express the dots coordinates in cm. At the end, 54 subjects agreed to participate, so the training dataset has been composed of 1620 photos.

The CNN for gaze tracking was implemented and trained using *python* programming language, running *Keras* API upon *TensorFlow* library support and with GPU acceleration.

Inputs of the CNN are the cropped face image (sized 224x224), the two cropped eyes images (sized 224x224) and a 1x4 face grid vector, expressing the portion of the entire image occupied by the face; in order to normalize the dataset, both the face and the eyes images are converted to grayscale, their contrast being increased by means of histogram normalization. The output is a two-dimensional vector containing x and y coordinates of the estimated display point (in centimeters). Faces and eyes are detected and cropped using the dlib [35] frontal face detector and 68 landmarks predictor, respectively. When a face box is found, the screen coordinates of its top left corner and its width and height are stored in the face grid vector; in this way implicit information can be retrieved about the user-screen relative pose. Adadelta [36] has been chosen among the optimizers implemented in *Keras*.

A python script was also realized for visualizing the scan path of the eyes over a displayed image; when launching it, a preset image is shown in full screen, while the webcam repeatedly takes pictures of the user and feeds the network with them. All the coordinates are stored and, when the image is closed, they are automatically processed in a manner that near points are clustered together, thus separating fixations from saccades [37]. Eventually, the colored clusters are depicted over the displayed image, together with straight lines connecting the subsequent ones, to give an idea on the path which the eyes followed overall.

4. Results

The proposed emotion and gaze detection systems were tested separately.

4.1. Evaluation of emotion detection performance

The test accuracy of each emotion category on the confusion matrix plotted as heatmap on Figure 5, shows some interesting results. The images with fear tag misclassified as surprise and disgust tag misclassified as anger has over 20% rate, these are results that are very often found in literature, mostly because these facial expressions are difficult to differentiate even for a human being, so they are often misinterpreted also in the dataset labeling phase. Moreover, as it can be seen, the emotion categories with more training samples resulting in higher accuracy compared to the ones with fewer training samples. Consequently, it is believed that a more evenly distributed dataset may improve the model accuracy further.

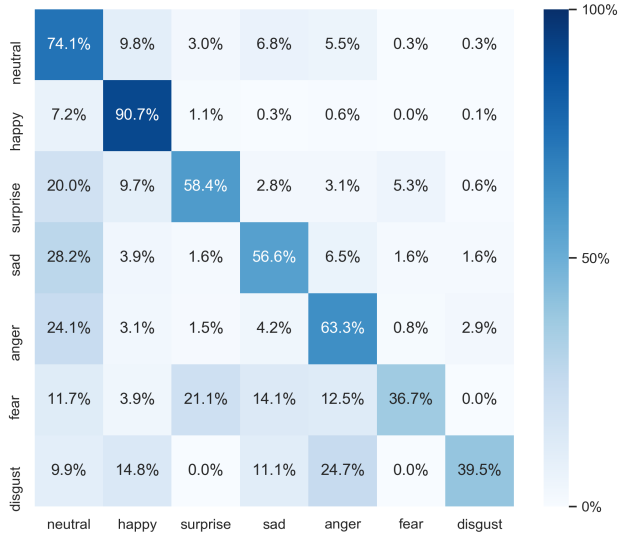

Figure 5: Accuracy of each emotion category

The model VGG13 we trained is also evaluated on EmotioNet [21] 2018 challenge dataset: the Ohio State University, on their website [38], has in fact made available their dataset to give anyone the opportunity to compare their results with those of the challenges of 2017 and 2018. The table shows the evaluation result.

Table 2: Emotionet evaluation results

Categories	Accuracy	F1
happy	**0.9770**	**0.9799**
anger	0.75	0.1198
disgust	0.0128	0.0099
sad	0.5955	0.2888
surprise	0.7059	0.3944

In this case only five emotions have been evaluated: this is because available photos related to Fear emotions were not enough to establish a meaningful comparison. In addition, no photos were made available for the comparison of the Neutral emotion.

4.2. Evaluation of eye-gaze detection performance

To evaluate the performance of the prediction the same software implemented to gather training samples has been used. The human eye detected using dlib [35] landmarks is the input of the python script that crops the region of interests and predicts the coordinates. They are expressed in centimeters and take the top-left screen corner as origin. A total of 20 subjects agreed to take part in the test and for each participant the predictions have been made for 30 different screen positions.

Every time the test is repeated the real and predicted coordinates have been saved in a database. To calculate the error between the predicted point and the real one the following formula has been used:

$$e_m = \frac{\sum_{i=1}^{n} | x_{i\,real} - x_{i\,pred} |}{n}$$

where $x_{i\,real}$ is the real coordinate where the subject *i* is looking at, $x_{i\,pred}$ is the predicted coordinate, *n* represents the total number of participants, and e_m the mean error (in centimeters) that has been calculated for any screen position. The same formula was used to evaluate the error on the y coordinate.

At this stage, 30 values of e_m have been calculated., The mean errors have been aggregated in 12 more meaningful values, as no significant variations have been found in comparison with the high number of screen positions. Each of them represents the error in a specific screen area (see Figure 6 and 7).

Both the heatmaps in Figure 6 and 7 show a higher error value in the top side of the screen (up to 11 cm), but interesting results have been achieved for the other screen positions. In this case the error goes between 0.02cm to 7.2cm. As the heatmap shows, the model still needs some improvement since the accuracy strongly depends on the area the subject stares at, but this experiment proves that it is possible to reach very accurate gaze predictions.

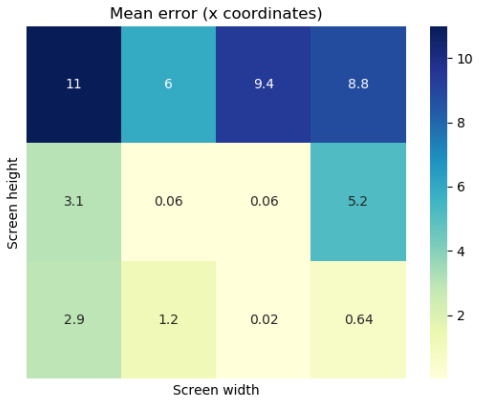

Figure 6: Mean error (cm) for each screen area for the x coordinate.

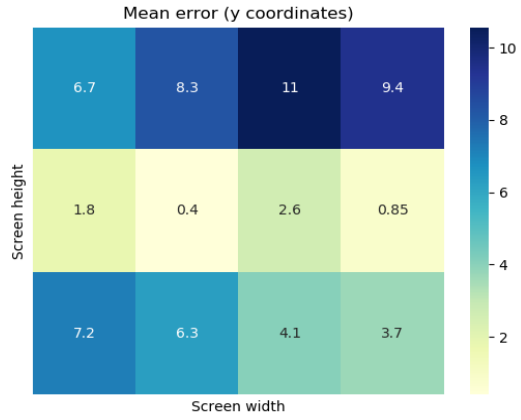

Figure 7: Mean error (cm) for each screen area for y coordinate.

5. Conclusion and discussion

This work proposed a system able to collect, data about user interactions/behavior with web applications potentially useful to support UX analysis. In particular, the proposed toolkit makes use of a deep learning-based platform to allow an "in the wild" data collection during user's interactions with a web application/platform just using a normal webcam. Future studies will be conducted to define an automatic system able to support the analysis of collected data, visualize UX outcomes through the provision of proper KPIs, and suggest useful design guidelines, based on the observed users' behavior, to improve UX design.

Regarding the emotion detection module, experimental results showed that the accuracies of facial expression categories such as fear and disgust are low mainly because of the small dataset of the corresponding category. The other facial expression categories however have reached relatively high classification accuracies. The evaluation results on EmotioNet dataset also supports the results of our experiment. Future work will be focused on the collection of more data on the small dataset categories to improve the classification accuracies of those corresponding categories

and on the exploration of generative adversarial networks to increase recognition accuracy.

About the gaze detection module, has been showed that the average error that can be reached is widely improvable and still does not reach the levels of accuracy of iTracker: this is due both to the small size of the dataset used for training and to the heterogeneity of the environments with which the user may be operating, in particular distance between user and screen, screen size, webcam position, etc. One of the future main works are undoubtedly the expansion of the dataset used to train the gaze network, unfortunately still very limited, adopting crowdsourcing tools.

Finally, data related to users' emotions and behavior, automatically collected through the proposed tool, can be used to improve recommendation systems based on collaborative filtering approaches. Current recommendation systems actually consider only data related to product features, customer preferences, customer demographic data (e.g., age, gender) historical data of purchases, and environmental factors (e.g., time, location). The availability of a huge amount of data related to what users observe the most, and what they feel while browsing e-commerce, opens new possibilities for customization and adaptation of recommendations, based on the real taste and interest of the user. Future studies should go in this direction.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The toolkit is part of the NextPerception project that has received funding from the European Union Horizon 2020, ECSEL-2019-2-RIA Joint Undertaking (Grant Agreement Number 876487). The authors would also thank the research fellow Lorenzo Marchesini for its support in the design and development of the eye gaze detection system.

ABSTRACT

The fast-paced development of smart technologies and the prevalence of vehicles, created an urgent demand to study and improve safety issues related to driving. In order to reduce traffic accidents, driving behavior was found to be very important issues to study and investigate. Recently, the advent and widespread of smartphone platforms with advanced computing competence and embedment of a variety sensing elements have greatly contributed to the development of solutions that can detect, and evaluate driving behavior and skills. In this study the development of a real-time smartphone-based identification and classification system for highway driving maneuvers is presented. The proposed system has been designed to detect ten different maneuvers usually performed by drivers when driving on highways. The methodology is based on separating the identification and the classification processes. The identification process is performed by a hybrid pattern matching scheme that combines Dynamic Time Warping (DTW) and neural networks. While a second neural network has been used to classify maneuvers, severity based statistical and time features. The separation of the identification and classification processes simplifies and accelerates the learning processes of the neural networks and greatly improves both system's reliability and accuracy

1. Introduction

During the last century vehicles have prevailed all over the world and have greatly contributed to the development and prosperity of the world economy. According to [1], the number of registered vehicles in the world has increased from 1.015 billion in 2010 to nearly 1.5 billion in 2020. In spite of all their positive impacts, vehicles have negative consequences on environmental pollution, global warming and greenhouse gas emissions, congested roads and noises, fuel consumption, social impacts, road accidents and many others to list. These negative consequences have stringent the environmental and safety regulations and standards for automotive industry. Therefore, to be in compliance with the regulations and standards, innovative solutions and newly emerging technologies have been adopted and utilized to provide the utmost advanced, efficient, safest and comfortable transportation means. In these days, high-end vehicles are equipped with smart systems such as cruise control, advanced emergency braking, safety warning systems, GPS technology for navigation, fuel efficiency, and automated driving system. Furthermore, in the near future, the automotive industry is expected to evolve even further by the production of autonomous vehicles that operate in a fully connected and digitized environment. Such immense leap in transportation technologies is only made possible by intensive studies in the field of vehicular applications especially the studies of driving behaviors.

Although that advanced technologies such as smart safety systems have been integrated within modern, still fully human driven vehicles is and will continue to dominate traffic safety since almost all of vehicles in use at the present time are of conventional type. Conventional vehicles are those fully driven and controlled by human drivers, and have few or none of the new technologies and accessories. The impediment in utilizing the new technologies is due to prohibitive cost that cannot be afforded by most of vehicles' owners especially in developing countries in addition to insulation difficulties [2]. Based on this argument, safety and road accidents due to human errors are still urgent issues that need to be addressed and solved for the majority of conventional vehicles. Based on the World Health Organization reports, vehicle accidents are considered to be the ninth cause of death in the world in addition they are a leading cause of fatal injuries [3]. Previous road safety studies and statistics have showed that the majority of road accidents are attributed to both physiological and behavioral human factors [4]. Therefore, research in the field of driving behavior monitoring systems has gained great momentum and

*Corresponding Author: Munaf Salim Najim Al-Din, munaf@unizwa.edu.om

several research institutes have developed systems to monitor and analyze the driving patterns and activities. Beside their urgent importance these studies serve the research and developments of different applications such as the design of advanced driver assistance system, intelligent transportation systems, and autonomous vehicles [5-6]. Additionally, they helped logistics companies to reduce their operational costs through tracking and monitoring their vehicles [7], and insurance companies to evaluate the driver performance, usage and can be used to resolve insurance tariffs and disputes [8].

The study and analysis of the concepts related to driving processes and problems involve the utilization of Driving Monitoring and Assistance System (DMAS). DMASs are usually designed to at least provide two main tasks, data acquisition and driving maneuvers analysis. The first unit is responsible for automating the collection of driving data, such as driver's attentiveness, vehicle dynamic state, driver's actions and driving environment or surrounding. The second unit is designed to extract patterns and features from the driving data and then utilizes intelligent computational techniques to identify and classify the driving behavior. In general real-time acquisition of driving patterns and parameters can be achieved through various types of sensors, such as GPS, GNSSs, In-Vehicle sensors such as CAN-BUS signals, costumed designed systems, vision systems and smartphones. Among this range of sensing platforms smartphone-based DMAS have growing so rapidly in number and sophistication, due to the prevalence, continuous improvement of the computing power, advancement of integrated sensors and continuous reduction cost in smartphones. Therefore, smartphones are taking an important role in the field of Intelligent Transport Systems such as vehicle monitoring driver behavior analysis [9].

This paper is an extended version of the work published in [10] and it is intended to presents the development of a real-time smartphone-based highway driving maneuvers identification and classification system. The system consists of three layers namely, data acquisition layer, preprocessing layer and the identification and classification layer. It is well known that the estimation driving parameters with high degree of accurately greatly affects the detection and classification of driving maneuvers. Therefore, in this paper a new approach to estimate the speed of a moving vehicle derived from GPS and the IMUs is developed. The identification and classification layer consists of three main units, a pattern matching units, to identify the patterns of estimated driving parameters. The DTW technique is used to identify the pattern of each driving parameter during maneuver execution. The second unit consists of a single feed-forward neural network that will identify the type of the maneuver based on the combination of the identified patterns from the first unit. Finally the third unit is responsible for the manoeuver classification and it is performed by a second neural network.

2. Literature Review

In the past decade several techniques and methodologies have been proposed and used to recognize and classify driving maneuvers and then infer an evaluation for driving behavior. Up to date there is no agreement on the parameters and techniques that could uniquely be used for this purpose. This section presents a short review of the existing technologies and methodologies used for driving maneuvers identification and classification. The literature review illustrates only two major issues related to this field of research namely, the data collection and identification and classification techniques.

Depending on the purpose and functionalities that is required to be achieved, there are various types of data acquisition systems (DAS) developed in the past ten years. The first category of DAS relies on the in-vehicle sensors which broadcast their data through the CAN-BUS which can be captured through the OBD II port. These systems can only provide information that can be used to monitor vehicle' state such as speed, fuel consumption and engine RPM and some limited information related to the driver actions such as throttle pedals positions [11, 12]. Many research centers have developed customized monitoring systems that combine in-vehicle sensors with GPS unit, inertial measurement units, and video systems of the external road and traffic environment and inside the vehicle itself [13]. In general sensors are configured to perceive external and internal environments to provide contextual details about the driving and drivers states. The drawbacks of the simple plug and play monitoring systems are the limited data that can be extracted with. On the other hand, drawbacks of in-vehicle customized systems are their high cost, installation complexity, compatibility and customer acceptance [5]. The developments of smartphones in terms of computational power and integration of sensing devices such as Inertial Measurement Units (IMUs), GPS and many other sensors combined with their ubiquitous presence have led to wide prevalence of smartphones in vehicular applications. Nevertheless, there are shortcomings when employing smartphones as monitoring systems such noisy measurement, coordinates orientation due smartphone placement, battery life and they cannot access vehicles data by their own. Several techniques, as they will be explained later, have been developed to provide the required remedies to overcome these problems [14]. Smartphones have also been utilizes as an intermediate processing hub with the aid of special applications to collect vehicle's sensors data and perform the necessary computation. In general, these applications enable the smartphone to communicate with the OBD-II port, either through Bluetooth or WiFi, and to collect a number of vehicle's sensors data such as the speed, engine RPM and many other diagnosis parameters. The processing of these in-vehicle sensors' data streams can be combined with smartphone sensors to further enrich the analysis [15].

Based on the collected data or the estimated driving parameters and the maneuvers to be detected, different techniques have been suggested to identify the type of a maneuver and classify it. A straightforward approach used to process the driving data is based on specifying a number of thresholds for each maneuver, that are defined merely based on the range of collected driving data and the experience. Once the sensed signals exceed a predefined threshold for a specified period of time then a maneuver is detected [16-19]. The main disadvantage in using threshold-based approaches is related to the absence of both the sensitivity and specificity that are required to obtain accurate identification and classification since improper definition of thresholds can result in poor performance. In a different approach, researchers considered the vehicle driving as a reasoning process, hence rule-base and fuzzy logic systems have been used to model driving behavior in terms of driving maneuvers classification only, i.e. it is not possible to detect the

type of the maneuver by using fuzzy logic schemas [13,20-24]. The implementation of a classical fuzzy logic classifier depends on the definition and setting of fuzzy input variables, the rule-based inference system and the fuzzification and defuzzification processes. Therefore, fuzzy logic classifiers are not constantly precise, since the both the fuzzy rules and conclusions are based on postulation, so it may not be widely accepted. Furthermore, they don't have the capability of machine learning and the setting of the precise inference rules and, membership functions is a difficult task. To overcome the aforementioned limitations in both threshold-based and fuzzy logic classifiers several adaptive methods have been proposed to automatically generate thresholds and fuzzy rules from numerical data [20-24]. Adaptive systems have showed distinctive superiority over classical fuzzy systems due to their learning capabilities, their ability to be modified and extended and finally the ability to extract newly modified rules and fuzzy variables. As a consequence of this combination between the adaptive learning and human experience adaptive vigorous classification systems can be designed with high degree of reliability and accuracy.

Since the data and information used in the identification and classification of driving behaviors and maneuvers are time varying signals, pattern matching techniques, such as DTW, have been employed. In this approach the maneuvers are identified and classified by comparing the similarity of the collected sensors' signals or estimated driving parameters patterns with predefined templates. If the incoming measured sequence has adequate similarity to one of the standard templates, then the system will indicate that a specific driving maneuver has been executed or detected. The major advantage of pattern matching techniques is that the system can sense maneuvers in spite of any differences, in their amplitudes or durations, with predefined templates. Therefore, it would be possible to develop a single set of standard templates that be used for matching maneuvers for different drivers to the same template set [25-28]. The main drawback of pattern matching approach is excessive computational requirements since the algorithms compute the similarity differences for all elements in two signals. This problem will be more significant when the classification analysis is dependent on multidimensional time series. Furthermore, enormous effort is required to extract and select the reference templates and it is also very hard to gather all types of templates due to the exclusive driving styles and behaviors of drivers.

Very recently, machine learning algorithms have been adopted and implemented to identify and classify driving maneuvers. Machine learning algorithms, when are well trained can generate specific rules that will enable them to identify and classify abrupt irregularity on a large set of data. Different approaches have been suggested and implemented to extract features for training these approaches such as simple threshold-based discriminators, statistical values, time domain parameters, frequency domain parameters, and most importantly rules inferred from clustering algorithms. Machine learning algorithms are generally categorized into three different approaches namely the supervised learning, unsupervised learning and semi-supervised learning. In Supervised learning techniques a dataset is first collected and labeled to certain predefined classes. Then a learning model is chosen and trained with some of the labeled dataset to produce a predicted output in different testing samples. Several algorithms under the supervised learning category have been used in the identification and classification of driving maneuvers and behavior such as K-Nearest Neighbor, Naive Bayes, Decision Trees [29], linear regression [30], Support Vector Machines (SVM) [31-32] and Neural Networks [33]. Unsupervised learning methods are used when there are no pre-knowledge about ground truth labels. Therefore, they are used to classify collected unknown data into groups depending on common trends, attributes, patterns, or relationships. There are different unsupervised approaches such as clustering techniques and self-organizing maps. Each approach uses different algorithm for classifying data into groups, and these algorithms could be simple straightforward that can divide collected data based on the common attributes or similar trends in their features. Nevertheless, when performing a pre-processing step of the data, unsupervised learning techniques are usually used with other techniques to enable specific characteristics of the learning model,. The K-means clustering [34] and Principal Component Analysis algorithms [30] are samples of the approaches used in driving behavior analysis.

2.1. Data Collection

As it has been stated modern smartphones are integrated with sensors that can be utilized to collect vehicle driving data for driving maneuver analysis. Previous work [35, 36] showed that precisely preprocessed and calibrated smartphone sensors are becoming a competitive approach to the high price in-vehicle customized DAS. In this study ten frequent maneuvers usually executed by drivers during highway driving are going to be detected and classified. Four of these maneuvers namely, braking, acceleration and left and right lane changes will be analyzed for both straight and curved road segments, in addition to another two maneuvers which are the merging on or exiting a highway. In the preliminary stages of this study an online vehicle driving data recording system has be developed and installed on three different android-based smartphones. The sensors that have been used are the Accelerometer, Gyroscope and the GPS. The developed App has been test by comparing its performance with well-established available Apps like AndroSensor. The sampling rate for the IMUs is in the range between 50 and 100 Hz, from which the optimal sampling rate then will be obtained.

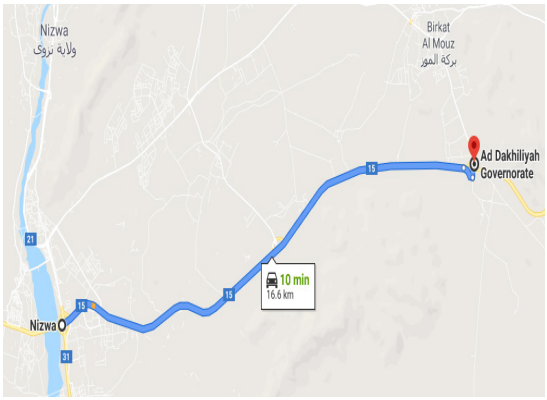

Figure 1: The route used to collected training data

The development of the system proposed in this study passed through two phases, the development and testing phase and the final real-time testing phase. In the first phase adequate data for training and testing the system were first collected. Ten drivers

with different vehicles were enlisted to drive along a highway route of 16km long that covers varying road conditions as shown in Figure 1. In order to have adequate data for training and testing each driver repeat each of the basic divining maneuvers for at least five times with different severity levels from the defensive to the aggressive level. Data collected from inertial sensors in these tests are first pre-processed, then segmented and finally labeled into types and classes.

In addition to the collected data by the smartphone the state of the surrounding vehicles and the state of the driver have been recorded by two video cameras. These two recorded videos are combined with the manually segmented vehicle's driving data to define each recorded maneuver's irregularity levels by three experts. Each expert examined all recorded maneuver and assigned a category or a score for them. Each extracted maneuver will be assigned with an inter-rater agreement score that is calculated from the scores provided by each expert. If the inter-rater agreement score is low then the maneuver is assigned with deviated scores by the experts and there is no agreement on the classification. Therefore, experts are requested to iterate their evaluation to reach a high inter-rater agreement score for most of the extracted maneuvers.

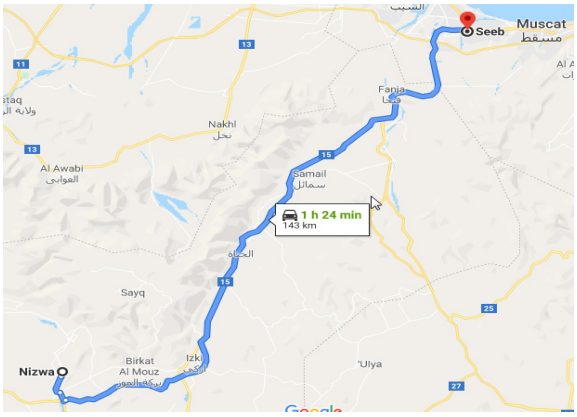

Figure 2: The route used to test data

One of the common problems that obstruct the development of reliable and accurate classification systems is the lack of adequate training and testing data. The lack of sufficient data for any classification problem could results in a noisy and instable class distribution. Therefore, for the sake of improving the system a second dataset was collected by installing a special app, developed by the author, in the smartphones of different 15 drivers, whom they drive on a daily base from the city of Nizwa to the capital Muscat over the route shown in Figure 2. The aim of collecting the second dataset is to enrich the training and testing data by performing a naturalistic driving through a route that is very dynamic and contains almost every different road types.

3. Calibration and Signal Processing

Smartphones' sensors are cheap low-grade sensors that have several deficiencies that may impose restrictions to their use in certain class of applications. In vehicular applications, it is hard to measure and guarantee smartphones accuracy and reliability due to five main prominent problems and limitations namely:

1- Sensor and algorithm complexity

2- Limited battery power.

3- The perturbation of the measurements due to the usage of the device that causes change in its orientation.

4- The low accuracy of smartphone sensors.

3.1. Sensors Calibration

Smartphones' IMUs have poor performance and are prone to error when especially used in measuring dynamic motion applications such as vehicle driving patterns. Therefore, sensors calibrations are used to correct sensors' deterministic errors. The most common types of these sources of errors are biases, scale factors and axes misalignment. In addition to the above mentioned deterministic errors, smartphones' sensors are also exposed to random noise and vibration, non-linearity due to thermal and magnetic effect and many others [37, 38]. To overcome these deficiencies a proper calibration process has been employed to eliminate Smartphones' sensors deterministic errors namely, fixed biases, scale factor errors, and misalignment errors.

The accelerometers are used to measure the instantaneous forces acting on the sensor. The measured acceleration along any axis consists of three components namely; linear acceleration, gravitational acceleration field and noise. On the other hand, the gyroscope measures the rate of change in the device's angular displacement, i.e. angular velocity, along the smartphone's three orthogonal axes. As mentioned errors in an IMU's measurements are contributed to three main categories: biases, scale-factor errors, and misalignment errors. The following equations (1) and (2) are used to model the accelerometer and gyroscope instantaneous measurement:

$$a_m(t) = S_a a_L(t) - g + b_a + n_a \quad (1)$$

$$\omega_m(t) = S_g \omega(t) + b_g + n_g \quad (2)$$

Here a_m, a_L, S_a, g, b_a and n_a represent the instantaneous measured acceleration component, the linear acceleration, scaling factor, gravitational acceleration, bias and noise respectively. While ω_m, ω, S_g, b_g and n_g represent the measured angular velocity along one of the three axes, the true angular velocity, scaling factor, bias and noise respectively. In this paper a new set of calibration procedures were proposed and used to estimate and calibrate smartphone's IMU sensors deterministic errors by considering the effects of vehicle vibration and noise [39-40].

3.2. Filtering

It is well known that data collected using IMU sensors contains substantial noise level, specially the accelerometer and the gyroscope readings. The noise in raw data can be contributed to several sources but mainly it is due to vibration noise and white Gaussian noise. There are different sources of vibration in vehicles such as road roughness, engine induced vibration, whirling of shafts, worn out parts, speed bumps, wheels, etc. In general, the data collected from the sensors contains random white Gaussian noise signals that oscillate with high frequency and typically have zero mean value. A sample for the measured noisy accelerometer and gyroscope signals are shown in Figure 3). In order to attain reliable and accurate recognition, the noise needs to be eliminated as much as possible. There are different approaches to filter

distorted signals; for example statistical filters [41], digital filters [27], Kalman Filter [42] and many others.

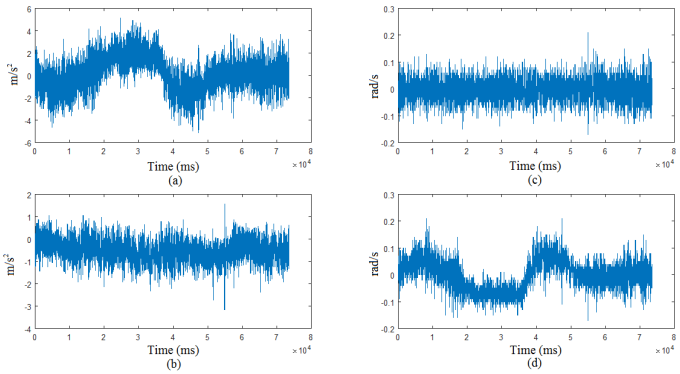

Figure 3: Noisy Smartphone Sensors Signals: (a) Accelerometer Signal x-Direction, (b) Accelerometer Signal y-Direction, (c) Gyroscope Signal x-Direction and (d) Gyroscope Signal z-Direction

In this paper three types of low-pass filters have been investigated namely; one-dimensional Kalman filter, simple moving average filter, and locally weighted running line smoother (LOSS). The performances of the aforementioned filters were compared to select the filter that effectively removes high frequency noise and maintain the real time variation of different driving patterns to the utmost extent.

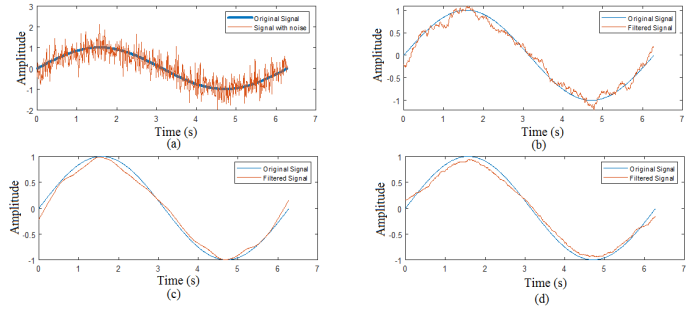

Figure 4: Filtering Results for Test Signal; (a) Original Test Signal; (b) Moving Average Filtering; (c) Kalman Filtering; (d) LOSS Filtering

The simplest filter is the moving average filter which filters the measured sampled signal by replacing each sampled value with the average of the neighboring sampled values defined within a given span or window. Kalman filter is a recursive predictive filter that is based on the use of state space techniques and recursive algorithms. The filter observes over time a series of measured data values, including noise, and then estimates new values that tend to be more accurate than those based on the actual measurement. The LOESS filter estimates the latent function in a point-wise fashion, where for each value of the measured sampled signal a new estimated value is found by using its weighted neighboring sampled (known) values. Detailed theory and implementation of this type of filters is presented in [43]. Due to the random irregular road pavement and vehicle vibration, it is found that the separation between of the real signals through total elimination of noise is not possible. Therefore, a test sinusoidal signal with imposed noise is used to assess the performance of the three filtering approaches. Figure 4 shows the results obtained for the three filters. It is clear that the LOESS technique can achieve very close results to Kalman filter where both effectively remove the nose while preserving the shape of the original signal. Figure 5 shows a sample of the measured accelerometer signals, from which the same conclusion regarding the two filters can be drawn. The LOSS filter has been used in the implementation of noise filtering unit of the complete system because of it is simpler to implement and faster to execute.

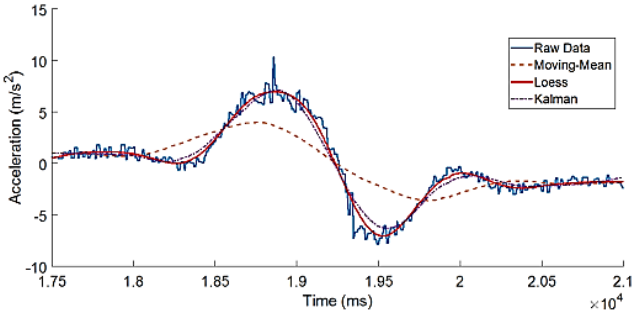

Figure 5: Raw and Filtered Accelerometer Signal

3.3. Smartphone Orientation

When smartphones are used to detect vehicle's driving patterns they could be placed at any location with any arbitrary orientation. Since sensors' measured signals are expressed in a specific frame that is static relative to the device, then one of the most interesting problems of smartphone-based vehicular applications is the separation of the dynamics of the smartphone from the dynamics of the vehicle. In this paper the smartphone is fixed to the windshield by a holder and it could have any orientation. Therefore, a reorientation correction process for the smartphone's coordinate systems is integrated as a pre-processing module to transform the measured sensors data to the vehicle coordinate system. This process is performed by a sequence of geometrical rotations using Euler Angles by assuming that the vehicle is horizontally aligned during the initial calibration period, so that the vehicle roll and pitch angles relative to a tangent frame both are zero. Assuming that the vehicle does not experience any acceleration, the smartphone's roll and pitch angles can be estimated from accelerometer measurements of the gravity vector as shown in Figure 6.

The determination of Euler angles has fully detailed in [44]. Upon the determination of rotational angles, the referenced coordinate system for the smartphone can be transformed to the vehicle-referenced coordinate system by multiplying with the reorientation matrices as follows:

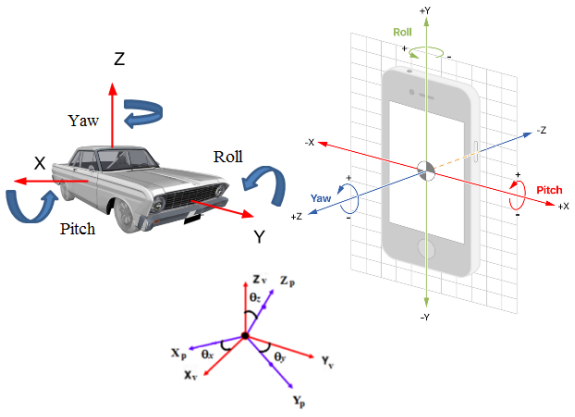

Figure 6: Smartphone and Vehicle Coordinate Systems

$$\begin{bmatrix} f_{xv} \\ f_{yv} \\ f_{zv} \end{bmatrix} = \mathbb{R} * \begin{bmatrix} f_{xp} \\ f_{yp} \\ f_{zp} \end{bmatrix} \quad (3)$$

where f_{iv} is the transformed measured signal to the vehicle reference, f_{ip} the measure signal in the phone reference and R is rotation matrix defined by:

$$\mathbb{R} = R(\theta_x) * R(\theta_y) * R(\theta_z) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos\theta_x & \sin\theta_x \\ 0 & -\sin\theta_x & \cos\theta_x \end{pmatrix} * \begin{pmatrix} \cos\theta_y & 0 & -\sin\theta_y \\ 0 & 1 & 0 \\ \sin\theta_y & 0 & \cos\theta_y \end{pmatrix} * \begin{pmatrix} \cos\theta_z & \sin\theta_z & 0 \\ -\sin\theta_z & \cos\theta_z & 0 \\ 0 & 0 & 1 \end{pmatrix} \quad (4)$$

4. System Overview

The general architecture of the proposed system and its design methodology is shown in Figure 7). The system contains five main modules: raw data acquisition, pre-processing, driving parameters estimation, maneuvers detection unit and maneuvers identification and classification unit. The function of each module is briefly described as follows:

a. Android smartphones were used to capture vehicle's raw data through by using its IMUs, i.e. the accelerometer and gyroscope at a rate of 50 samples/second. Furthermore, smartphone's GPS data are also collected and used to provide vehicle's location and to correct speed estimation.
b. The pre-processing unit is designed to perform four functions namely; signals filtering, sensors error correction, transformation of sensors data to vehicle's coordinate system and finally estimates the driving parameters.
c. The manoeuvre detection unit is designed to detect and slice and executed manoeuvre in real-time by implementing the endpoint detection algorithm that identifies the starting and ending time.
d. The identification and classification unit is responsible to identify manoeuvre's type and its irregularity class. In this study the identification and the classification processes were performed separately by using a hybrid pattern matching and neural networks schemes.

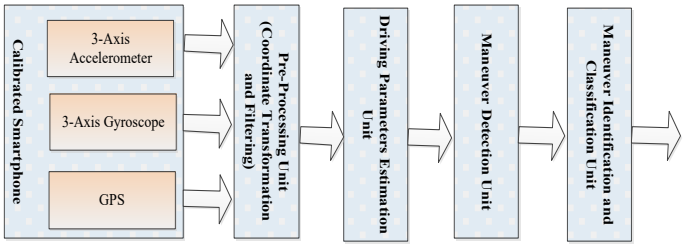

Figure 7: The Proposed System Architecture

5. Driving Parameters Estimation

A successful implementation of a driving maneuvers identification and classification system depends on the set of features and parameters that are used in the this process. In the literature there are two main approaches used to define the set of features and parameters namely, driver actions based approach and vehicle state based approach. In the first approach a number of essential driving signals can be collected from the vehicle's CAN-BUS such as vehicle speed, gas pedal pressure, brake pedal pressure, steering wheel angle, and acceleration. The second approach utilizes different approach by monitoring the vehicle's dynamic state in terms of longitudinal and lateral movements. These longitudinal and lateral movements can be detected and identified by using IMUs, GPS and the fusion of both the IMUs and the GPS. In this study it is believed that the description of vehicle' dynamical state in terms of actual driving parameters is more informative than other approaches and useful for future investigations. Therefore, the vehicle's acceleration, orientation and speed are used and represented as a time-series signals.

5.1. Longitudinal and Lateral Accelerations

The first and the simplest parameters that can be estimated directly are the longitudinal and the lateral acceleration components. The two components can be determined directly by subtracting the gravity the from the filtered accelerometer's Cartesian components, a_{xp}, a_{yp} and a_{zp}. The resulted singles are then transformed from the smartphone's to the vehicle's coordinate system by using Eqn. (4). The two components of the acceleration can be obtained by:

$$a_{lat} = a_{xv}\sin(\gamma) + a_{yv}\sin(\rho) \quad (5\text{-a})$$

$$a_{lon} = a_{xv}\cos(\gamma) + a_{yv}\cos(\rho) \quad (5\text{-b})$$

where, a_{lat} and a_{lon} are the lateral and longitudinal accelerations, a_{xv}, a_{yv} are the x and y components of the acceleration represented in the vehicle coordinate system and the angles γ and ρ are given by:

$$\gamma = \cos^{-1}\frac{a_{xv}}{\sqrt{a_{xv}^2+a_{yv}^2}} \quad \text{and } \rho = \cos^{-1}\frac{a_{yv}}{\sqrt{a_{xv}^2+a_{yv}^2}} \quad (6)$$

5.2. Vehicle's Orientation

The second estimated parameter is vehicle's heading or orientation. The attitude of a vehicle can be described by its angles of rotation along three axes as indicated in Figure 6). The attitude of any object can be modeled by different methods such as Direction Cosine Matrix, Quaternions and Euler angles. The first method has nine parameters to be estimated, hence it is difficult to implement. On the other hand, Quaternions has less parameters and it has advantages over Euler angles since it does not suffer from the gimbal lock problem, but still the Euler angles method is used in this study because it is more comprehensible and easier to decompose the rotations into separate degrees of freedom. Furthermore, since the smartphone is held in a fixed position inside the vehicle then the gimbal lock problem will not appear.

Euler angles can be found directly by using the measured gyroscope's data and integrate them with respect to time [45]. The accelerometer can also be used to estimate Euler angles, where simple trigonometric projections can be utilized to obtain both the Roll and the Pitch angles. Nevertheless, both methods could results in low prediction accuracy due to the stochastic bias variation in gyroscopes and the noisy accelerometer signals that results in an accumulated drift error [45]. To overcome the limitations of the direct approaches, sensor fusion techniques are developed to join all sensors' data to compensate the deficiency of each method. There are two filtering techniques namely; Kalman and complementary filters are widely used for sensor fusion. Because

of its simplicity and reliability, the digital complementary filter is utilized to estimate of the orientation. The filter uses a low-pass filter for the accelerometer's data to remove the high frequency noise and the dynamic bias, and utilizes a high-pass filter to suppress the drift from the gyroscope's data. Figure 8) shows a simple block diagram illustrating the implementation of a digital complementary filter. The filter can determine the angles using the following equation:

$$\theta_i = \alpha\left(\theta_{i-1} + \Delta\theta_{gi}\right) + (1-\alpha)\theta_{a\,i} \quad (7)$$

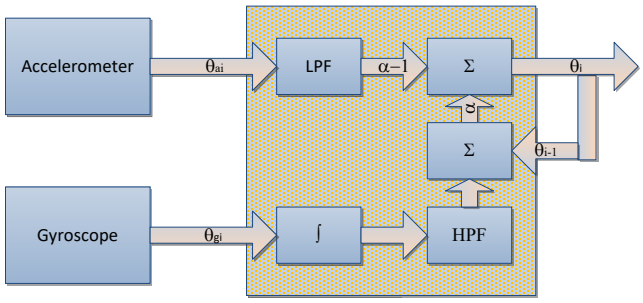

Figure 8: The Implementation of Digital Complementary Filter

In Eqn. (7), θ_i represent any of the estimated angles (Roll, Pitch or Yaw) and θ_{i-1} is the formerly determined angles, while the subscripts *g* and *a* designate the sensor type. The empirical constant α is selected to set the time constant of the error-signal calculations and stabilize the rate-sensor angle calculation.

5.3. Vehicle's Speed

Based on the kinematic equations, vehicle's speed can be found directly from the smartphone accelerometer data by integrating the corresponding acceleration component, longitudinal or lateral, as follows:

$$v_f(t) = v_i(t) + \int_0^t a(t)dt \quad (8)$$

where $v_f(t)$ is final speed, $v_i(t)$ is the initial speed and a(t) is vehicle's acceleration. The system is a discrete one, hence a sequence of the acceleration data is collected and equation (8) can be rewritten as:

$$v_f(n) = v_i(0) + \sum_{i=0}^{nT} \frac{1}{n} a(i) \quad (9)$$

where T is the sampling rate, n is the present nth sample and a(i) is the i^{th} accelerometer value.

As it can be noted the basic idea of estimating the speed is very simple, and it is expected that with rigorous calibration and noise filtering of the raw data will improve the estimation process and a reasonable accuracy would be achieved. Nonetheless, speed estimation by the direct integration of accelerometer data suffer from significant deviations and unrealistic drifts because the accelerometer data is not pure and still contains some noise and other effects. This can be clearly shown in Figure 9), where the variation of the speed obtained from the GPS and those obtained by using the direct integration are shown. The doted green curve shows the estimated speed when the accelerometer data are not calibrated neither filtered while the dashed orange curve shows the trend in the estimated velocity for the preprocessed accelerometer data. As it can be seen, the error is accumulated over time and will obviously cause serious errors in the estimation of the speed. Therefore, a correction method is required to instantaneously correct the speed estimation by eliminating the accumulative error.

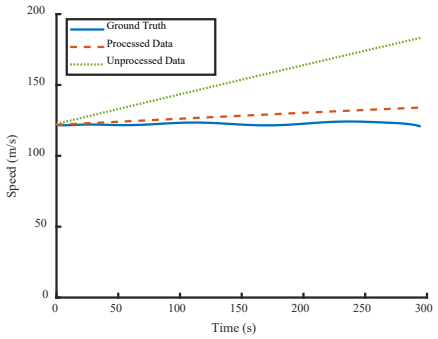

Figure 9: Comparison between Measured and Estimated Speed

In the literature there are mainly three methods that can be used to correct the accumulated error in numerical integration of the accelerometer data namely; high pass correction filter, Kalman filter and sensor fusion techniques. In this study, a simple but effective sensor fusion technique has been adopted and utilized to provide accurate velocity estimation [46].The basic idea of the technique is based on fusing the high frequency estimated speed with a low frequency ground truth speed obtained through the GPS. To illustrate the implementation of the vehicle speed estimator, consider Figure 10) that shows two equally spaced time intervals at which correction process take place at these instants. Suppose that the estimated speed and that measured by the GPS at time instant $t = T_A$ are v_{AE} and v_{AG} respectively, while those at the instant $t = T_B$ are v_{BE} and v_{BG}. The error of the speed at reference points then are given by:

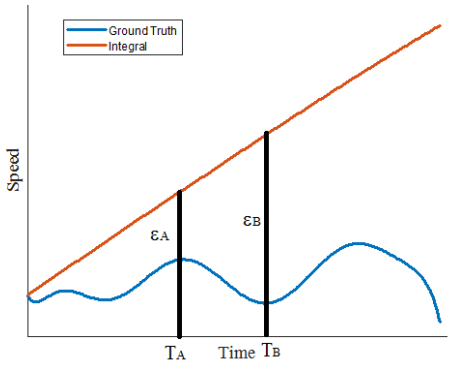

Figure 10: Vehicle Speed Correction Process

$$\varepsilon_A = v_{AG} - v_{AE} \quad \text{and} \quad \varepsilon_B = v_{BG} - v_{BE} \quad (10)$$

If we can consider that the rate of change in the accelerometer error is constant, i.e. that the accelerometer error varies linearly in this short interval, then this rate change can be expressed as follows:

$$\Delta\bar{a} = \frac{\varepsilon_B - \varepsilon_A}{T_B - T_A} \quad (11)$$

From Eqn. (11) the accumulative error at any instant (t) can be given by:

$$\emptyset = \int_{T_A}^{t} \Delta\bar{a}\ dt = \Delta\bar{a}kT_s \quad (12)$$

The constant k is the number of samples passed from the time instant T_A to t, and T_s is the sampling rate of the accelerometer. By knowing the accumulative error at any instant, then the estimated speed at instant (t) can be given by:

$$v_{tE} = v_{AG} + \sum_{i=T_A}^{t} \frac{1}{k} a(i) - \emptyset \quad (13)$$

Further enhancement been has been achieved by using exponential moving average correction to the error rate change as follows:

$$\Delta\bar{a}(i) = \alpha\Delta\bar{a}(i-1) + (1-\alpha)\frac{\varepsilon_B - \varepsilon_A}{T_B - T_A} \quad (14)$$

Figure 11 shows the estimated speed and the speed obtained through the GPS. It can be clearly seen that there is some small error between the estimation and the ground truth, which indicates that the estimator has excellent accuracy.

6. Maneuvers Detection

The main task that is required to be performed by any driving monitoring system is to reveal driving maneuver with reasonable level of reliability and accuracy. Table (1) presents a list of the maneuvers that are detectable by the proposed system. The system should be able to process the measured signals or the estimated parameters and attempts to detect the maneuver. The system detects the variation in the vehicle's longitudinal and lateral states by continuously monitoring the variation in the speed and orientation at a rate of 10Hz. Once a maneuvers is detected, the system can then proceed to recognize and classify it. There are different methods that can be used to detect the starting ending times of a maneuver [47-48]. In this paper the short-term energy endpoint detection algorithm with sliding window has been adopted, where the speed and orientation are continuously separated to event and non-event segments.

Table 1: Maneuvers Classes

1-	Acceleration straight road segment	2-	Acceleration curved road segment
3-	Braking straight road segment	4-	Braking curved road segment
5-	Left lane change straight road segment	6-	Left lane change curved road segment
7-	Right lane change straight road segment	8-	Right lane change curved road segment
9-	Merging into highway	10-	Exit from highway

The detection module consists of three key phases. In the first phase the signal is divided into non-overlapping windows of a 100ms period. The short-term energy is first computed for the data sequence in each window. For an infinite sequence of a discrete signal the energy is defined by:

$$\hat{x}[m] = x[m]\Lambda[n-m], n-N+1 \le m \le n \quad (15)$$

where Λ is a window function given by:

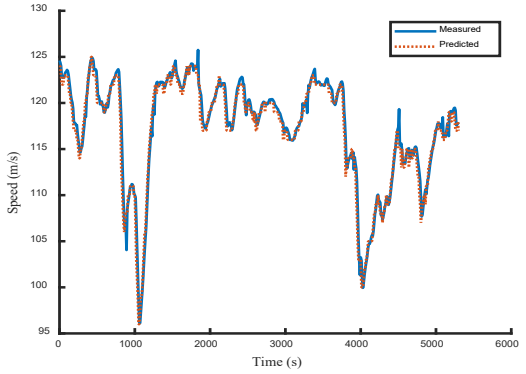
$$\Lambda[n-m] = \begin{cases} 1 & 0 \le n \le N-1 \\ 0 & \text{Otherwise} \end{cases} \quad (16)$$

The energy contained in this short interval then can be computed by:

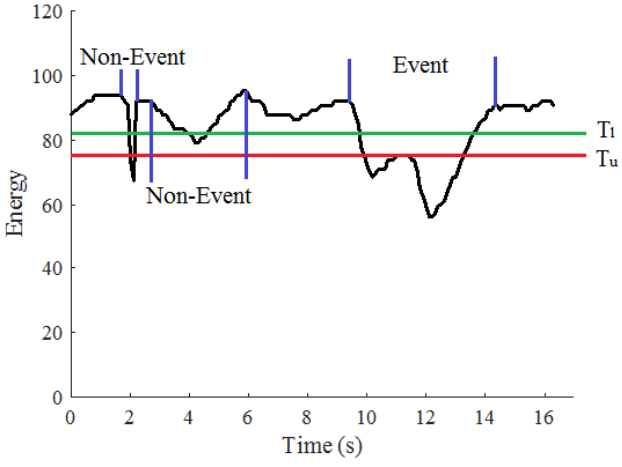
$$E_w = \sum_{m=n-N+1}^{n} (x[m]\Lambda[n-m])^2 \quad (17)$$

The value of the energy computed by Eqn. (17) is then compared to a threshold value, see Figure 12, and if the computed energy is lower than a specific threshold, then this frame is rejected and considered as a non-event segment. Otherwise, if the computed energy is higher than a lower threshold level T_l then the second stage will be executed.

Once the second stage is triggered, the starting time of the detected maneuvers is logged and the short-term energy is computed for a rectangular sliding window function as in Eqn. (17). Depending on the computed short-term energy in the second stage one of the following possibilities could be activated:



(a)



(b)

Figure 11: (a) Estimated and Measured Speed (b) Maneuver Detection using Short-Term Energy

- If the computed short-term energy is maintained to be less than the upper threshold T_u for less than 2 seconds or the energy fall back to a value lower than T_l, then this segment is treated as a non-event segment and the execution will resume from stage 1.

- If the computed short-term energy becomes higher than the upper threshold T_u for more than one second, then this segment will be treated as an event segment. In this case the system will continue computes the energy and compare it with the threshold until it drops back to the lower than T_l again. It is should be noted that if the energy falls down to be lower than T_u before the end of the first second then this segment will be regarded as a non-event segment, and the execution will start again from stage

7. Driving Maneuvers Identification and Classification

The Identification process is used to describe a driving maneuvers by a well-defined unique type. On the other hand the classification process evaluates the driving maneuvers to a certain class according to given criteria. In general there are two main approaches used for maneuver identification and classification, the first is based on the selection of a number of distinctive features and uses a machine learning technique, and the second approach is based on pattern matching algorithms. In this study 60% of the first dataset, described in section three, were used to study the time variation of each estimated driving parameters when a certain maneuvers has been executed. Figure 12) shows a sample of parameters' variations for a brake maneuvers. Intensive off-line observations and investigation were made to study and analyze the behavior of the parameters variation for each maneuvers type and to infer a general trend in their variations. It has been clearly noticed that the variation of the parameters follow common variation patterns and this fact agrees with what been presented in the literature. Figure 13) shows ideal approximated patterns that could be generated during any driving maneuver. As it can be notices that the driving parameters have limited number of patterns, for example the longitudinal acceleration, the lateral acceleration and the speed have three different patterns each, while the heading angle has five different patterns. Based on these facts, the identification and classification processes are performed separately where the identification process is performed by using a hybrid pattern matching neural network unit and the classification processed is performed by using another neural network.

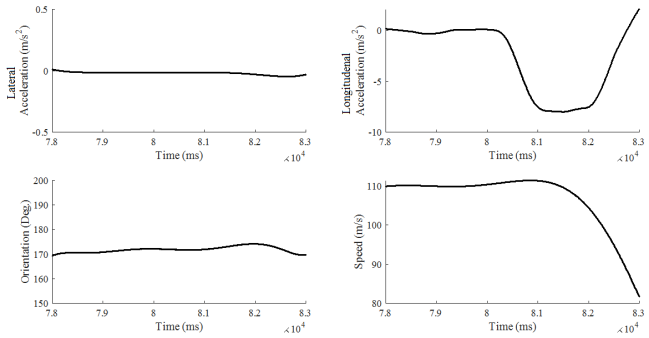


Figure 12: Driving Parameters Variation during a Break Manoeuvre

Figure 14) shows the basic units of the identification and classification module. The module consist of three units, a pattern matching units, to identify the patterns of estimated parameters, the second unit consist of a single feed-forward neural network that will identify the type of the maneuvers based on the combination of the identified patterns. Finally the third unit, which is responsible for the manoeuver classification, is performed by another neural network.

The pattern matching unit utilizes four DTW units, each one is designed to identify the pattern type for one of the parameters. The DTW is a pattern matching technique uses the discrete dynamic programming model to compute the alignment between two discrete time signals or sequences by assessing the similarity between them, regardless of the time/speed synchronization and distortion effects due to dynamic spatiotemporal differences.

Event Type	Longitudinal Acceleration	Lateral Acceleration	Heading Angle	Speed
Acceleration				
Braking				
Left- Lane Change				
Right- Lane Change				
Entry				
Exit				

Figure 13: Driving Parameters Variation for Different Maneuver

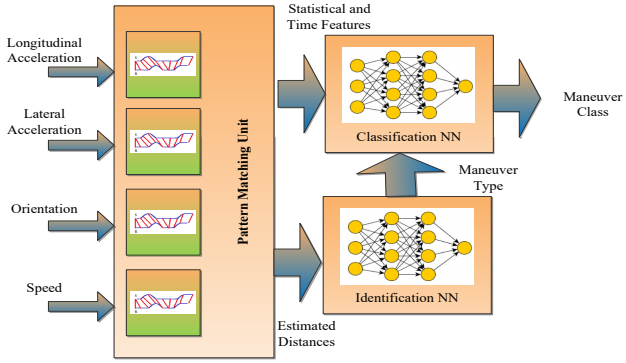

Figure 14: Structure of Identification and Classification Unit

To illustrate how the DTW algorithm works, consider two discrete signals, $R = \{r_1, r_2..., r_m\}$ which is the reference signal and an unknown signal $S = \{s_1, s2..., s_n\}$ that need to be identified, where m and n represent the number of samples in R and S, respectively. In Figure 15) the two time series that are highly similar, are shown. To align these two sequences an $(m \times n)$ local distance matrix is constructed by populating its elements with the Euclidean distances as follows:

$$d(i,j) = (R(i) - S(j))^2 \quad (18)$$

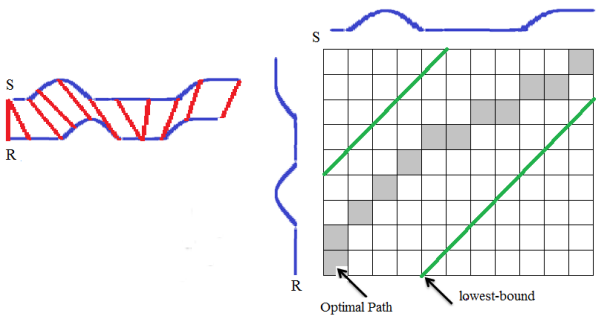

Figure 15: A DWT Matrix with a Warp Path

The correlation between the patterns of these two sequences is expressed by the cumulative distance measured over the optimal path within the distance matrix. For this purpose a warping matrix (D) is constructed and filled by searching for the minimum distance between the two sequences. This minimum distance can be found by computing the total distance D(i, j) for each entry (i, j) as:

$$D(i,j) = \begin{cases} d(1,1), & \text{if } i = j = 1 \\ d(i,j) + \min\{D(i-1,j), D(i,j-1), D(i-1,j-1)\}, & \text{otherwisw} \end{cases} \quad (19)$$

In the final stage the optimal warping path (P), as shown in Figure 15), and the DTW distance are to be computed. The Warping path is a set of adjacent matrix elements that detect the similarity between R and S and it represents the minimum distance between R and S. The matrix (P) contains K elements which range in value as:

$$\max(|R|, |S|) \leq K < (|R|, |S|) \quad (20)$$

Finally the optimal path Po is the one that minimizes the warping cost given by:

$$DTE(R,S) = \min\left\{\frac{1}{K}\sqrt{\sum_{k=1}^{K} P_k}\right. \quad (21)$$

To reduce the complexity of the DTW technique and thus speeding up the execution time, not all the warping paths are evaluated. To reduce the number of paths considered during the matching process four constraints are usually applied namely; monotonicity, continuity, boundary and windowing. To prevent the warping path from rolling back on itself, the monotonicity constrain is imposed to assure that any two adjacent elements, $p_k = (p_i, p_j)$ and $p_{k-1} = (\hat{p}_i, \hat{p}_j)$ will follow the inequalities $(p_i - \hat{p}_i) \geq 0$ and $(p_j - \hat{p}_j) \geq 0$. On the other hand, to guarantee a one-step advancement in the warping path, the continuity constrain is used to restrict the movement of the point (i, j) to the next point must be (i+1, j+1), (i+1, j), or (i, j+1). Finally, to assure that the warping path contains all points of both sequences, the boundary constrain is used to force the warping path to start from the top left corner and ends at the bottom right corner. Finally the windowing will prevent pathological mappings between two sequences by restricting one point in the first sequence to be mapped to a limited number of points in the other sequence; hence the path is likely to be around the diagonal without deviating much from it [49].

In order to identify the types of the maneuver by the DWT technique, a set of templates for each maneuvers are required as reference signals. To find a template signals for different set of sequences, one can consider that template sequence could be the longest common sequence, or the medoid sequence, or the average sequence. The selection of the reference pattern for each specific maneuvers class is not a simple task because the set of sequences collected for each maneuvers class have different time durations and amplitudes. In this study, the sequence with the minimum average distance from all other sequences for a specific class is selected as the reference template. The details of the averaging strategy are given in [50].

When dealing with single 1-D signal identification, the DTW technique will directly identify the test signal. Nevertheless, when it is required to identify a maneuvers or an action by using multiple measured signals, the DTW won't be able to identify its type directly. This is because each signal will need a special DTW unit to identify the pattern of the signal only. In order to predict the type of the maneuvers, the combination of the DTW distances were used as features to train a neural network that will be used for the final identification of the maneuvers.

Statistical and time metrics have been utilized as features to classify maneuvers' irregularities. In general maneuvers are categorized into one of three main types; Hard, Normal and Light. By studying all the possible patterns for all the classes, see Figure 13), it was found that there are seven distinctive patterns as shown in Figure 16). For each pattern time metrics and statistical values such as max, min, mean, standard of deviation and the variance are used as classification features. The segmented maneuvers collected in the first dataset were represented by a vector that contains the statistical and the time metrics for each driving parameter and the classification label. As it has been mentioned the classification labels are obtained from classification made by the experts. It is should be noted that the percentage of the rejected samples was less than 10%.

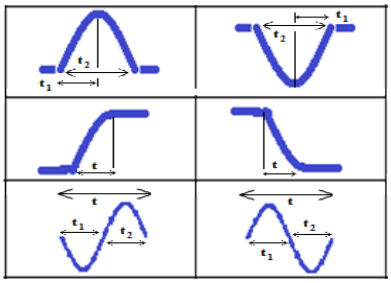

Figure 16: Time features for the common signals

8. System Validation

This section presents an experimental evaluation for the three main components of the proposed system namely, detection, the identification and classification units. To test the performance of the system, two different datasets have been used. In the first phase the first dataset described in section three has been used to train and conduct a preliminary testing of the system. In this phase a single smartphone (Samsung Galaxy S5) have been calibrated and used in all the tests. As been mentioned ten drivers with different car models were asked to conduct each of the basic maneuvers, listed in table (1), at least five times with different severity levels from the Light to the Hard level. From this dataset 1500 maneuvers were collected and segmented then each was combined with two videos, the first used to record the surrounding traffic state and the second used to record the driver's state, i.e. hands and feet. To obtain the ground truth classification of each maneuvers, experts were consulted to evaluate the abnormality level. Each assessor assigned abnormality level scores for the entire recorded maneuvers and the final score for every recorded maneuvers was calculated using the inter-rater reliability method.

For this initial dataset 60% of the collected samples were utilized to extract the information and the features that were used in the training phase. The information and features includes the computation of the DTW reference templates, the DTW's distances and the statistical and time metrics. The DTW reference

templates have been stored and used to measure a vector that includes the distances of the warping for each recorded driving parameter of a specific tested sample. These vectors are used to train the first neural network which is used to identify the type of the maneuvers, while another set of vectors that contain the statistical and time metrics features used to train the classification neural network.

The remaining 40% of the first dataset have been used to validate the performance of the system. Figure 17 shows results obtained when the 40% testing samples fed to the identification module. It can be seen clearly that the identification rate is very high and reached a 100% successful rate for some of the maneuver and the minimum identification rate scored is 85%, and this is obvious since the identification process combines all the similarities for the four parameters. Figure 18, shows the confusion matrix classification for the 40% testing samples. Again it can be noticed that the classification rate is very high nearly 95% for some cases. This high identification and classification rates are expected since the two processes have been separated.

In the second phase of this study, the author developed a complete Android-based APP that detects, identify and classify the highway driving maneuver in real-time. The architecture of the system is described in section five. The first test for the system was to check its ability to detect the starting and end of a driving maneuvers. The complete trips performed by the ten drivers, from which the first dataset was collected, were used just to detect the driving maneuver. Figure 19, shows the detection of maneuvers for a sample trip. It should be noted that the first 1500 maneuver collected in the first data set were used to determine the lower and upper thresholds for short-term energy for both the vehicle's speed and orientation. The results obtained by the system were compared with those already registered manually by the author. The system showed a high detection rate where more than 96% of the manually registered maneuver were detected successfully by the detection unit.

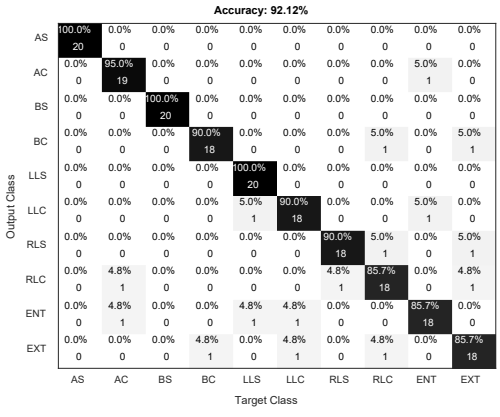

Figure 17: Confusion Matrix for Maneuvers Identification

The developed application allows two types of analysis namely, the real-time analysis and off-line analysis. The graphical interface of the developed application is designed to achieve user friendly interaction with the driver. All the driving maneuver are presented instantly to the driver using both audio and visual indicators. Each maneuvers type is represented by a special icon that it will be lighted up; along with a human voice that utters the name of the maneuvers when it is detected by the application. Furthermore, the icon's color will be changed in accordance to the class of the maneuvers. This attractive and user friendly interface helped in measuring the performance and the reliability of the system in the second stage of the study. As been mentioned in section three a second dataset was collected from a naturalistic driving performed by 15 drivers who are daily travel a distance of 140km back and forth. We have asked driver's companions to check the alerts produced by the application and check them. Data recoded by the companions and those stored in the SD card are then analyzed. Table (2), presents a comparison between the number of maneuver performed by each driver and those detected by the system. Note that the first number in any cell represents the performed maneuver, while the second number represents the detected maneuver. Figure 20 and 21 show the confusion matrix for the maneuvers' identification and classification respectively.

9. Conclusion

This paper proposes a novel real-time smartphone-based highway driving maneuvers identification and classification system. The system collects vehicle's longitudinal and lateral movements using smartphone's IMU sensors and vehicle's location by using the GPS. All the smartphones used in this investigation were calibrated the collected smartphone's raw data were filtered and smoothed by using the statistical LOESS filter. Driving parameters namely vehicle's acceleration, orientation and speed were used in the identification and classification of the driving maneuver. Sensor fusion techniques have been used to estimate vehicle's orientation and speed.

It was noted that driving parameters for each event class have common patterns, thus the DTW technique combined with a feed-forward neural network are used for the identification. In the classification process a second neural network was employed, and it is trained to classify a maneuver classes. Two datasets were collected through a number of experiments conducted on highway routes. Results obtained in this study show an excellent detection, identification and classification rates were achieved.

Customer Loyalty

ABSTRACT

Online transactions make it easy for people to get products or sell the products through online applications. The success and failure of online sales depends on how satisfied and loyal the customer is to the service of the product or business which can certainly influence and increase competition between the online sales industry. Based on that background we want to measure how much influence the quality of services provided by the Online Marketplace to customers has an impact on customer satisfaction and customer loyalty. The measurement method used is to use E-Service Quality, to determine customer satisfaction (Customer Satisfaction) and determine the level of customer loyalty (Customer Loyalty). This research uses a quantitative approach and uses random sampling techniques. Data collection using a questionnaire with data samples totaling 102 respondents. The results of this study indicate that there is a significant relationship between E-Service Quality, Customer Satisfaction and Customer Loyalty to customers that increase customer online shopping transactions so that companies are able to compete with other companies.

1. Introduction

By looking at the growing number of internet users in Indonesia[1], this has an impact on people's behavior in Indonesia towards buying and selling interests [2]. Based on data [3], the number of smartphone users which continues to increase from time to time seems to be in line with the increasing number of online store users from websites and mobile apps. The average amount of Indonesian consumer spending when shopping online from all segments of the shopping category can reach US $ 36 (around Rp. 481 thousand). This value also makes Indonesia occupy the position of second size basketball in Southeast Asia, far behind that of developed countries in Singapore which reached US $ 91 or around Rp1.3 Million [4]. Based on the data and according to experts the development of e-marketplaces in Indonesia is very fast [1], including e-marketplaces owned by XYZ. In 2018 it was stated that five e-marketplace applications that were frequently downloaded consisted of five such marketplaces. Dominating the top ranking is XYZ's e-marketplace. In this study we want increases customer online shopping transactions in the e-marketplaces owned by XYZ by knowing the indicators that influence satisfaction and loyalty can increase competition between the online selling industry so that companies can still compete with other companies.

2. Related Works

Service quality is the key to the success of a business [5], in addition to the quality of service that makes a key factor in the success of a business, loyalty also makes one a key factor in the success of a business [6].

In the previous study conduct by Tianxiang Sheng, the researcher testing e-service quality model from four dimensions, with the customers' satisfaction as the main variable, the study has analyzed the effects of four dimensions of service quality on customers' satisfaction and loyalty where all hypotheses are accepted. Other study by Akroush used SERVQUAL to analyze the effect of service quality on customer satisfaction and loyalty [7]. The result sho positive and significant influence of tangible, assurance, empathy, and reliability on consumer satisfaction, and customer satisfaction has a positive and significant effect on customer loyalty. customer satisfaction is the customer's perspective based on expectations and then the shopping experience thereafter [8], other said customer satisfaction is everyone's awareness that is differents. This feeling is obtained by comparing the expected service and the service obtained [9]. Customer loyalty can also be defined as the relationship that the customer maintains with the seller after making the first transaction [10].

The success and failure of online sales depends on how satisfied the customer[11], the relationship between satisfaction and loyalty is almost as intuitive[12]. In more recent research found satisfaction leads to loyalty[13], then knowing the indicators that influence satisfaction and loyalty can increase competition between the online selling industry[14]. By looking at these developments the author wants to conduct research with the e-service quality scale from Parasuraman's E-S-QUAL[15] scale in terms of the basic service on user satisfaction on XYZ e-marketplace applications that have an impact on customer loyalty [16][17].

3. Research Methods

Research will be conducted by considering the following matters: questionnaire, online searching, and document Study[1]. We used quantitative research for data processing, quantitative research is systematic scientific research on parts and phenomena and their relationships. The purpose of quantitative research is to develop and use mathematical models, theories and hypotheses related to natural phenomena. We have distributing questionnaires that have been filled out by respondents through Google Form which will later be processed and analyzed, we distributed the questionaire with simple random sampling method[1].

This research uses E-SQUAL MODEL[2], where the statement contained in the questionnaire is a description of each variable such as, Efficiency[15], Requirement Fulfillment, Accessibility, Privacy[3] that influence Satisfaction [4] and Loyalty[5]. The following are research models we can use:

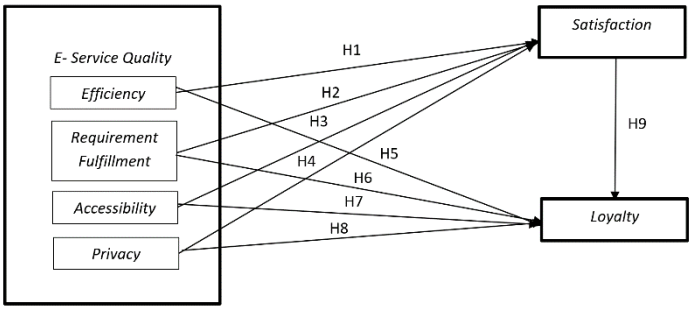

Figure 1: Research Model

3.1. Validity and Reliability Test

By using a valid and reliable instrument, the research results are expected to be valid and reliable as well. If the instrument is not tested for validity and reliability, then the data collected with the instrument is doubtful [19]. A valid instrument means that the instrument can be used to measure what should be measured and can display what must be displayed [19].

Table 2: Validity and Reliability Test Results
Source: Questionnaire Testing Results with SPSS

Variable	Pernyataan	CI-TC	*Cronbach's Alpha*
E-Service Quality	EF1	0.768	0.949
	EF2	0.697	0.950
	EF3	0.558	0.951
	RF1	0.696	0.950
	RF2	0.549	0.951
	RF3	0.557	0.951
	AC1	0.649	0.950
	AC2	0.682	0.950
	P1	0.721	0.949
	P2	0.575	0.951
Customer Loyalty	CL1	0.538	0.951
	CL2	0.372	0.953
	CL3	0.679	0.950
Customer Loyalty	CL4	0.648	0.950
	CL5	0.638	0.950
	CS1	0.760	0.949
	CS2	0.623	0.950
	CS3	0.737	0.949
Customer Satisfaction	CS4	0.584	0.951
	CS5	0.540	0.951
	CS6	0.771	0.949
	CS7	0.645	0.950
	CS8	0.676	0.950
	CS9	0.710	0.950
	CS10	0.676	0.950
	CS11	0.719	0.949
	CS12	0.766	0.949
	CS13	0.790	0.949
	CS14	0.541	0.951
	CS15	0.604	0.951

Based on the results of the validity and reliability test in Table 2, researchers omitted 2 respondents in the validity test using SPSS with 2 respondents coming from the Banten region because the number of respondents in the Banten area was quite large so the sample of respondents the researchers used became 102. Those pieces the statement proposed for this study has an r table of 0.195 with a significant level of 5%, while the CI-TC of all statements are judged to be greater than the r table. The Cronbach's Alpha

value of all statements is above 0.6. It can be concluded that all these statements are valid and reliable as research instruments.

3.2. Convergent Validity Testing

According to [20] convergent validity is the extent to which measures are positively correlated with alternative steps of the same construct. The size loader is said to be high if the value of the collection must be 0.708 or higher.

Table 3: Convergent Validity Testing Result
Source: Questionnaire Testing Results with SPSS

	Accessibility	Efficiency	Loyalty	Privacy	Requirement Fulfillment	Satisfaction
AC1	0.867					
AC2	0.900					
CL1			0.635			
CL2			0.582			
CL3			0.828			
CL4			0.813			
CL5			0.817			
CS1						0.797
CS10						0.696
CS11						0.723
CS12						0.787
CS13						0.814
CS14						0.557
CS15						0.614
CS2						0.709
CS3						0.775
CS4						0.580
CS5						0.538
CS6						0.782
CS7						0.667
CS8						0.683
CS9						0.736
EF1		0.868				
EF2		0.905				
EF3		0.673				
P1				0.942		
P2				0.904		
RF1					0.893	
RF2					0.788	
RF3					0.751	

From Table 2 it can be seen that there are ten indicators that have values less than 0.708, namely indicators CL1 (0.635), CL2 (0.582), CS10 (0.696), CS14 (0.557), CS15 (0.614), CS4 (0.580), CS5 (0.538), CS7 (0.667), CS8 (0.683), and EF3 (0.673).

All indicators above refer to opinions [20], each indicator with a value between 0.40 to 0.70 does not have to be deleted, except when deleted, the indicator can increase the value of composite reliability.

3.3. Testing Discriminant Validity

Discriminant Validity shows the extent to which a construct is completely different from other constructs. Discriminant Validity implies that the construct is unique and can capture events that are not represented by other constructs in the model[21]. Cross Loadings is the first approach to assess the validity of discriminant indicators. Specifically, the external load of the indicators on the related construct must be greater than the other constructs [20].

3.4. Testing the value of AVE (Average Variance Extracted)

The next convergent validity test is to test the average variance extracted (AVE) value of each variable.the value of AVE 0.50 or higher shows that, on average, constructs explain more than half of the indicator variants[20]. Conversely, if AVE is less than 0.50, it shows that, on average, there are variant items that are explained by the construct.

Table 5: Average Variance Extracted
Source: Questionnaire Testing Results with SPSS

Construct	Average Variance Extracted (AVE)
Accessibility	0.781
Efficiency	0.675
Loyalty	0.551
Privacy	0.852
Requirement Fulfillment	0.661
Satisfaction	0.494

It can be seen in Table 5 that there is an average variance extracted (AVE) value on the customer satisfaction variable which

has AVE value of 0.494. The author re-observes in Table 3 to find the outer loading value of customer satisfaction is low. In Table 3 there is a low outer loading value that belongs to customer satisfaction, that is, CS5 with a value of 0.538 and the writer deletes the CS5 indicator to increase the AVE value of customer satisfaction[21].

Table 6: Average Variance Extracted (after)
Source: Questionnaire Testing Results with SPSS

Constructs	Average Variance Extracted (AVE)
Accessibility	0.781
Efficiency	0.675
Loyalty	0.551
Privacy	0.852
Requirement Fulfillment	0.661
Satisfaction	0.510

Table 7: Cronbach's Alpha
Source: Questionnaire Testing Results with SPSS

Constructs	Cronbach's Alpha
Accessibility	0.721
Efficiency	0.756
Loyalty	0.793
Privacy	0.829
Requirement Fulfillment	0.744
Satisfaction	0.924

Table 8: Composite Reliability
Source: Questionnaire Testing Results with SPSS

Constructs	Composite Reliability
Accessibility	0.877
Efficiency	0.860
Loyalty	0.857
Privacy	0.920
Requirement Fulfillment	0.853
Satisfaction	0.935

After the researchers removed the CS5 indicator, it can be seen in Table 6 that AVE value owned by customer satisfaction increased from 0.494 to 0.510.

Table 9: Hypothesis Test Result
Source: Questionnaire Testing Results with SPSS

Hypothesis	Path	Original Sample	T-Statistic	Conclusion
H1	EF→CS	0.385	4.664	Significant
H2	RF→CS	0.193	2.323	Significant
H3	AC→CS	0.046	0.541	Less significant
H4	P→CS	0.444	5.954	Significant
H5	EF→CL	0.245	1.723	Less significant
H6	RF→CL	-0.056	0.446	Less significant
H7	AC→CL	0.091	0.754	Less significant
H8	P→CL	-0.034	0.263	Less significant
H9	CS→CL	0.519	3.029	Significant

After the researchers removed the CS5 indicator, it can be seen in Table 8 that AVE value owned by customer satisfaction increased from 0.494 to 0.510.

The following conclusions are obtained from the results of testing the hypothesis of the research model based on Table 9:

a. Hypothesis 1, Efficiency Factor (EF) has a significant positive effect on Customer Satisfaction (CS). That is because the value of the path coefficient and T-statistics are at a minimum, namely 0.384 and 4.664.
b. Hypothesis 2, Requirement Fulfillment (RF) factors have a significant positive effect on Customer Satisfaction (CS). That is because the value of the path coefficient and T-statistics are at a minimum, namely 0.193 and 2.323.
c. Hypothesis 3, The Accessibility (AC) factor is less influential on Customer Satisfaction (CS). That is because the path coefficient and T-statistics are below the minimum values, namely 0.046 and 0.541.
d. Hypothesis 4, Privacy factor (P) has a significant positive effect on Customer Satisfaction (CS), which is due to the value of the path coefficient and T-statistics are at a minimum value, namely 0.444 and 5.954.
e. Hypothesis 5, Customer Loyalty (CL) Efficiency Factor (EF). That is because the path coefficient and T-statistics are at a minimum value, 1,723.
f. Hypothesis 6, The Requirement Fulfillment (RF) factor is less significant to Customer Loyalty because the value of T-statistics is at a minimal value of 0.446.
g. Hypothesis 7, The Accessibility (AC) factor is less significant to Customer Loyalty (CL) because the value of T-statistics is at a minimum value of 0.754.
h. Hypothesis 8, Privacy Factor (P) Less significant to Customer Loyalty (CL) because the T-statistic value is at a minimum value of 0.263.
i. Hypothesis 9, The Customer Satisfaction (CS) factor is significantly positive towards Customer Loyalty (CL) because the T-statistics value is 3.029.

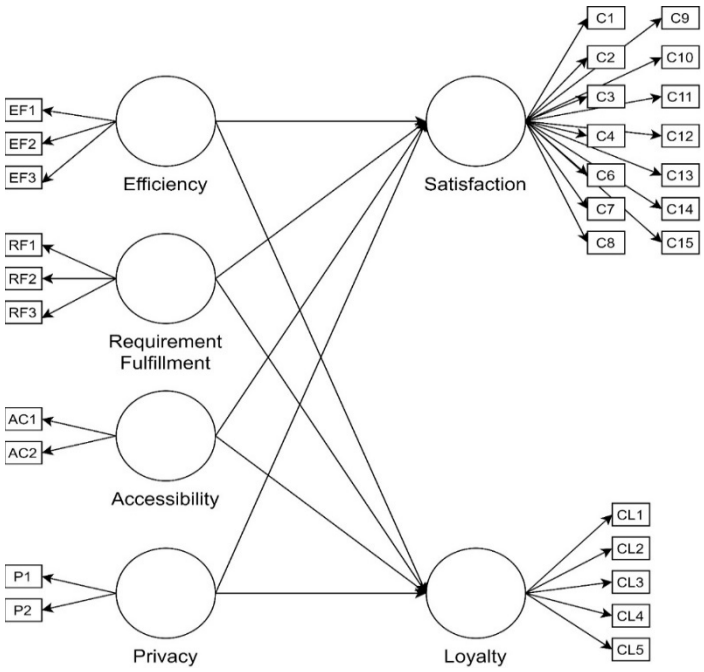

Figure 2: Results of Partial Research Model
Source: (author analysis)

In Figure 2, the relationship between variables based on the hypothesis received and has been proven to have a significant effect. The following discussion of the results of hypothesis testing.

4. Results

Based on the results of data processing related to the influence of e-service quality on customer satisfaction and customer loyalty in the XYZ e-marketplace, it can be concluded as follows:

1. There are 10 indicators namely customer satisfaction (CS4, CS5, CS7, CS8, CS14, CS15), efficiency (EF3), and customer loyalty (CL1, CL2) that do not meet the criteria because the value is less than 0.7 but of the 10 indicators only customer satisfaction (CS5) is omitted due to the low outer loading value that is 0.538 so that the AVE of customer satisfaction shows below 0.5. Therefore, researchers conducted outer loading testing again by removing the indicator on customer satisfaction (CS5) after the researchers re-tested the outer loading, the AVE value indicates that all indicators have reached values above 0.5 and met the required requirements.
2. The factors that influence this research on customer satisfaction are efficiency, privacy, and fulfillment requirements. But other variables such as accessibility have less effect on customer satisfaction. While the factors that influence customer, loyalty are only customer satisfaction. But other variables such as accessibility, efficiency, privacy, and fulfillment requirements have less effect on customer loyalty
3. There is a positive and significant effect on the efficiency, privacy, and customer satisfaction variables on customer loyalty variables with each value above 1.96
4. In measuring the significant level of relationship between variables it can be concluded that the accessibility variable has no significant effect on customer satisfaction. This has been proven by the results of the measurement of accessibility variable has a value of 0.541 <1.96, then so does the variable efficiency, requirements fulfillment, accessibility, and privacy has an insignificant effect on customer loyalty with each value below 1.96, which means not significant.

5. Discussion

E-Service Quality in the XYZ e-marketplace must be re-considered and must be improved again both in terms of the services provided to customers. The results of the study, e-service quality that has been done in the Accessibility section is something that must be considered again because of the low level of customer satisfaction in the given accessibility. On other hand e-service quality does not directly affect customer loyalty due to achieving a customer loyalty, the customer must feel satisfied first so that the customer can be loyal and shop again at the XYZ e-marketplace. The last service quality has a good impact on customer satisfaction, this is because when customers shop using the XYZ e-marketplace application the services provided by XYZ already meet customer needs but there is one indicator that is accessibility that is not achieve customer satisfaction.

6. Future Work

From the results of our research, researchers suggest:

1. In the future work the study should compare to another marketplace.
2. Due to the many insignificant hypotheses (5 of 9) it is recommended that future research use other variables to achieve much better research results.
3. Try to use other models such as UTAUT or TAM to do research about the impact of e-service quality on customer satisfaction and customer loyalty.
4. Adding the number of samples due to the small number of samples then it causes the results of testing the research hypothesis is not satisfactory, so it is advisable to increase the number of samples in future research.

ABSTRACT

Long-range, Low-Power Wide Area Network (LoRaWAN) is a very scalable solution for the Internet of Things (IoT). Due to the air channel environment's complexity, connectivity is a crucial parameter for successfully planning and deploying the IoT networks. Measurements and simulations have been used to evaluate LoRaWAN propagation models in the Urban environment, but it is a challenging task. While practical propagation evaluation has been prohibitively expensive, the theoretical modeling results have been less accurate. This paper uses real-world measurements and a trace-driven simulation technique to evaluate the RF propagation models' prediction performance for LoRaWAN 868 MHz propagation. First, a novel LoRaWAN trace-driven simulation of Glasgow city centre has been performed. Second, LoRaWAN 868 MHz measurements have been used to perform a critical analysis of LoRaWAN trace-driven Radio Frequency (RF) propagation models and validation. The processed trace dataset is composed of GPS coordinates, and the corresponding LoRaWAN received signal strength. The dataset has been extracted from 5017 datasets of LoRaWAN measurements taken from Glasgow city centre. A trace simulation program built-in ICS-Telecom was used to simulate LoRaWAN propagation in the real-world urban environment. Comparison of LoRaWAN simulation traces and the real-world data was performed to evaluate the prediction performance accuracy of Deygout 94, ITU-R 525/526, and COST-Walfish Ikegami (COST-WI) propagation models. All models over-estimated LoRaWAN trace-simulated RSS levels in comparison to collected measurement samples. While Deygout 94 prediction accuracy was higher with mean absolute error (MAE) at 0.83 dBm and standard deviation (SD) at 4.17 dBm, COST-WI performed poorly with MAE and SD at 2.87 dBm and 10.96 dBm respectively.

1 Introduction

This paper is an extension of work originally presented in The International Conference on UK-China Emerging Technologies, Glasgow, UK, August 2019 [1]. The purpose of this work was the application of a trace-based approach to evaluate the prediction capabilities of the conventional propagation models for LoRaWAN networks. As the Internet of Things (IoT) network is steadily growing, an understanding of conventional radio propagation models' prediction accuracy is key to the successful planning and deployment of Long-range, Low-Power Wide Area Network (LoRaWAN).

Unlicensed IoT technologies allow anyone with an idea to create and deploy IoT applications. Authors in [2] have predicted that a global number of IoT connected devices will rise to 75.44 from 15.4 billion in 2025. LoRaWAN [3] is one of the Low Power Wide Area Network (LPWAN) technologies for the interconnection of physical things. It uses Long-Range (LoRa) modulation technology [4] at the physical layer to achieve long-distance connectivity among the connected things. LoRaWAN end-devices connect to LoRa gateway using Radio Frequency (RF) propagation through the air channel and LoRaWAN network and application servers. Due to the complexity of the air channel environment, connectivity is a crucial parameter for the successful deployment of the IoT networks. To understand whether a LoRaWAN network meets the acceptable connectivity performance, a detailed investigation of the network using radio propagation prediction models is requisite to the network's deployment. However, Received Signal Strength (RSS) prediction in LoRaWAN networks has become a complex task due to prediction

*Corresponding Author: Hadi Larijani, Cowcaddens Road, Glasgow, G4 0BA, U.K, (0044)-141-331-3190, H.Larijani@gcu.ac.uk

performance differences in RF propagation models. These models' ability to accurately predict the RSS depends on how correctly they capture factors affecting RF signal propagation in the air channel.

Propagation models rely on natural and environmental factors to calculate signal power attenuation, path loss in the air channel. In the Line-of-Sight (LOS), the signal power attenuators include RF and the distance between end-devices and LoRa gateways. On the other hand, in cities, where Non-Line-of-Sight (NLOS) is dominant, environmental attenuators of signal power include human-made structures such as dense tall and short buildings, cars, and bridges. The path loss incurred by the propagating signal due to these obstructions is a consolidation of LOS and NLOS path loss due to multipath, scattering, diffraction, and reflection losses. To incorporate sufficient natural and environmental factors in the RF propagation models, numerous empirical propagation models [5] and deterministic propagation models [6] have been designed.

Different empirical and deterministic RF propagation modeling techniques highlight contrasts in prediction performance accuracy and application scenario. Empirical models were designed to predict the RSS in the event of insufficient knowledge of terrain profile data. These models were designed based on actual measurements taken from the propagation environment conditions. They are made of simple mathematical formulae with no reliance on the digital terrain data and are less accurate for a distance range of less than 1 *km* [7]. On the other hand, deterministic models largely depend on the digital terrain models to predict the RSS. These models take into consideration the free space and NLOS path loss. Accordingly, detailed knowledge of digital terrain models is a prerequisite for their prediction performance. Further contrasts exist within empirical and deterministic models in terms of parametric design consideration and prediction performance accuracy. Empirically, measurements and simulation methods are accurately used to investigate these models' ability to predict the RSS in radio networks.

Taking measurements from the real-world networks and simulation of the air channel propagation are vital methods used to evaluate the RF models. Studies [5], [6] and [8] have used measurements and simulations to evaluate the performance of various propagation models, but less has been done to validate their applicability on LoRaWAN networks in an urban environment. The studies in [9]–[13] have used only measurements to understand the behavior of air channel propagation on LoRaWAN network operations, but this is an expensive approach as best practices involve taking measurements at the later stages of network optimization. To validate the applicability of empirical propagation models for LoRaWAN in the city environment, our previous work in [14] showed less satisfactory empirical models' prediction performance against measurements. Trace-driven simulation can bridge the gap between measurement and simulation to evaluate RF propagation models' performance for LoRaWAN networks.

In this paper, we use real-world measurements and trace-driven simulation technique to evaluate the RF propagation models' prediction performance for LoRaWAN networks. Trace-driven simulation method can be used to evaluate computer-based models, but it works well if a trace contains the experience required by the trace simulation program [15]. The RF models are implemented in ICS-Telecom [16], and the simulation required a digital terrain model of Glasgow city centre. The simulation that uses a trace that contains the system's experience makes a more realistic simulation performance [17]. The study utilized a digital terrain model at 25 *m* and a dataset from Glasgow city centre. This dataset contained 5017 measurements with GPS coordinates and their corresponding LoRaWAN RSS. Trace-driven simulation results were compared against the real-world measurements to evaluate the prediction accuracy of Deygout 94, ITU-R 525/526, and COST-WI. All models over-estimated LoRaWAN trace-simulated RSS but showed superior prediction performance over empirical models in [14]. The result shows that the LoRaWAN network's trace-driven simulation with these models provides a more realistic RSS prediction than the conventional simulations.

The main contributions of this work are given in the summary below:

- A novel use of measurement and trace-driven simulation of LoRaWAN 868MHz propagation prediction for Glasgow city centre.
- The trace-driven simulation and extraction of LoRaWAN RSS traces spread over the digital terrain model of Glasgow city centre with the minimum, maximum range of trace signal levels, and the total number of trace measurements.
- Critical analysis of LoRaWAN trace-driven RF propagation models and validation with real-world measurements. Deygout 94 prediction accuracy was higher with *MAE* at 0.83 *dBm* and *SD* at 4.17 *dBm*.
- Visual comparative analysis of trace patterns between the LoRaWAN real-world measurement site in Figure 2. and trace-simulated site in Figure 5.
- Shown the functional relationship (Figure 4.) between trace-driven simulation and the data collection, data processing, and input to the prediction models.

This paper is arranged as follows: Section I briefly introduces LoRa technology, LoRaWAN network, conventional RF propagation models, motivation for performance and evaluation of RF models with trace-driven simulation, and the related work. Section II provides details about measurements and simulation. Section III contains the RF models' performance analysis and discussion. Finally, section IV presents the conclusion and prospective future work.

1.1 Overview of LoRaWAN and LoRa

LoRaWAN is one of the media access control protocol for low-power Wide Area Network (WAN). It is a long-range wireless communication technology that enables low-powered IoT devices and applications to communicate over the Internet [18]. LoRaWAN specification V1.0 [3] published in 2015, provides LoRaWAN details to describe the network communication protocol and architecture. The typical LoRaWAN network architecture is a star topology consisting of the end-devices, applications, gateway, and the server. These devices may be connected through the air or cables. LoRaWAN-enabled devices may be categorized as Class A, B, or C, depending

on the capacity for a trade-off between downlink latency and battery-life saving. Figure 1. describes a typical star-topology of LoRaWAN architecture. While LoRaWAN defines the architecture and system communication protocol, LoRa is a modulation technology defined at the physical layer.

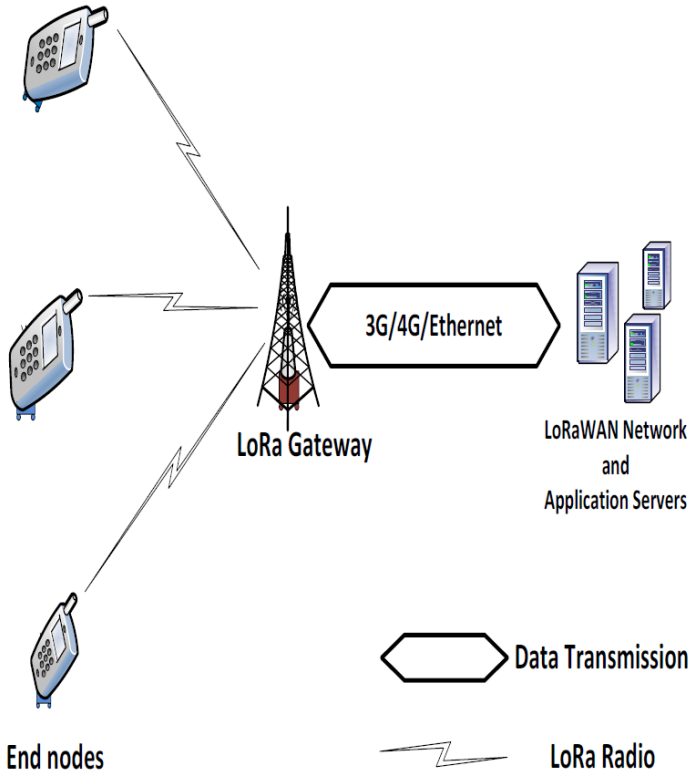

Figure 1: Basic LoRaWAN Network Architecture

LoRa is a spread spectrum technique adapted by Semtech [4] and implemented at the physical layer for digital wireless modulation. It was derived from chirp spread spectrum technology [19] to achieve a long-range radio communication in LoRaWAN networks while retaining the ability to operate at low-power levels. Furthermore, the LoRaWAN network employs different spreading factors (SF), another key technology to allow a trade-off between the coverage and data rates [20]. Higher SF configuration helps the LoRaWAN network to transmit further, but at the cost of low data rates, and vice-versa. Thus, the LoRaWAN network delivers the required connectivity to enable the LoRa end-devices to transmit data over the air channel to the gateway and then to the network and application servers.

1.2 Radio Propagation Models

RF propagation models[21] characterize the propagation of radio waves as function carrier frequency, distance, and other NLOS factors in the air channel environment. These RF models, deterministic, semi-empirical, and empirical, employ several attenuation factors, including LOS, diffraction, multipath, to estimate the RSS. These models perform connectivity analysis in radio networks to fast-track radio coverage information. Radio propagation effects are heavily site-specific and depend on configuration parameters such as terrain cover, operating frequency, distance, transmitter, and receiver antenna height. In this study, commonly used RF models in ICS-Telecom, Deygout 94, ITU-R 525/526, and COST-231 Walfish-Ikegami models are evaluated for RSS prediction accuracy in LoRaWAN network. These models are respectively, deterministic, semi-deterministic, and empirical.

1.3 Deygout 94

Deygout 94 model determines diffraction attenuation for N successive knife-edge or rounded obstacles. The model is based on the idea of the main signal blocking component [22], which exerts considerably high obstruction losses to the link between the transmitting and receiving ends. The overall diffraction loss, L_D, is given as:

$$L_D = \sum_{i=1}^{N} L_1(V_i) \tag{1}$$

where L_1 is the diffraction loss in case of one main obstruction between the transmitter and receiver, and V_i is the diffraction parameter for the i^{th} knife-edge. The total path loss is the sum of Deygout 94 diffraction losses, free space, sub-path attenuation, and 3D losses that are implemented in ICS-Telecom.

1.4 ITU-R 525/526

The ITU-R 525/526 uses ITU-R P 525 [23] to calculate the free space loss and ITU-R P 526 to calculate attenuation due to diffraction [24]. The concept of ITU-R 526 calculation of diffraction losses is similar to Deygout 94. It calculates sub-path and diffraction losses using the Delta Bullington diffraction model [25]. The ITU-R 525 calculates the basic free space transmission loss, P_{A_0} between isotropic antennas, as follows:

$$P_{A_0} = 32.4 + 20log_{10}(d) + 20log_{10}(f) \tag{2}$$

where f is frequency (MHz) and d is the distance (km).

1.5 COST-231 Walfish-Ikegami

COST 231 Walfish-Ikegami (COST-WI) the model [26] is a combination of Walfish and Ikegami models. Unlike the deterministic model that requires digital terrain models, including the buildings layer, COST-WI is an empirical model that requires characteristic values. It improves the path loss prediction by considering more data to characterize medium-sized flat urban environments [27]. Compared to other empirical models, the COST-WI parameters include the heights h_b of the building, the separation between buildings d, the widths of roads w, and the angle θ to the direct radio path. The range of fundamental parameters considered is 800-2000 MHz for frequency, 1-3 m, 4-50 m, 0.02-5 km for distance, and end-device and gateway antenna height, respectively. The model calculates path loss due to the LOS and NLOS. The mathematical formulae for LOS and NLOS are respectively defined in (3) and (4) below.

$$P_{LOS} = 42.64 + 26log_{10}(d) + 20log_{10}(f) \tag{3}$$

If NLOS is the case, then path loss calculation is a combination of attenuation due to free space P_{LOS}, the rooftop to street diffraction, and the scattering L_{rts}, and the multiple screen diffraction loss L_{msd}. The totality of this (NLOS) path loss is described mathematically [27**?**] as follows:

$$P_{NLOS} = P_{LOS} + L_{rts} + L_{msd} \tag{4}$$

The L_{rts}, the diffraction loss from the rooftop to the street is determined as in the following formula:

$$L_{rts} = -16.9 - 10log_{10}(w) + 10log_{10}(f) + 20log_{10}(h_b - h_r) + L_{ori} \tag{5}$$

where, w is width of the roads, h_b and h_m are the height of building and end-device mobile station respectively. The street orientation correction factor, L_{ori}[28] is given as:

$$L_{ori} = \begin{cases} -10 + 0.35\alpha & \text{for } 0° < \alpha < 35° \\ 2.5 + 0.0755(\alpha - 35) & \text{for } 35° < \alpha < 55° \\ 4 - 0.0114(\alpha - 55) & \text{for } 55° < \alpha < 90° \end{cases} \tag{6}$$

where α is the street orientation angle, L_{msd}, the multiscreen loss, represents diffraction loss from multiple obstacles. The following mathematical representation determines it:

$$L_{msd} = L_{bsh} + K_a + K_d log_{10}(d) + K_f log(f) - 9log_{10}(s_b) \tag{7}$$

where the correction factors, L_{bsh} and K_a represent path loss when the gateway is above and below the rooftops, respectively. s_b represents buildings separation. The terms K_d and K_f quantify the diffraction loss as a factor of the distance, d and frequency, f, and are defined in[26] as follows:

$$L_{bsh} = \begin{cases} -181log(1 + h_t - h_b) & h_t > h_b \\ 0 & h_t \leq h_b \end{cases} \tag{8}$$

$$K_a = \begin{cases} 54 & h_t > h_b \\ 54 - 0.8(h_t - h_b) & h_t < h_b \text{ and } d_{km} \geq 0.5km \\ 54 - 1.6(h_t - h_b)d & d_{km} < 0.5km \end{cases} \tag{9}$$

$$K_d = \begin{cases} 18 & h_t > h_b \\ 18 - 15(h_t - h_b)/h_b & h_t \leq h_b \end{cases} \tag{10}$$

$$K_f = -4 + \begin{cases} 0.7(f_{MHz}/925 - 1) & \text{for medium-size city and suburban} \\ 1.5(f_{MHz/925-1}) & \text{for metropolitan centres} \end{cases} \tag{11}$$

1.6 Motivation for Performance and Evaluation of RF Models with Trace-driven Simulation

The evaluation of how the air channel affects the propagation of wireless communication signals is a challenging task. In cities, the physical environment, including buildings, bridges, people's motion, and vehicles, adversely affect propagating RF signals. To accurately evaluate the effects of the physical environment in cities, simulation methods and models have become an integral part of wireless communication systems' planning and deployment. However, it has been challenging to identify which RF propagation models, from their significant number, produce realistic predictions of the RSS. The assumption that simulation models can be applied to modeling propagation effects in different environments, protocols, and applications have often been proved less accurate.

The literature is yet to contain either the RF propagation prediction models or an established understanding of the actual RF propagation prediction models' performance for the LoRaWAN propagation system in cities. Studies that attempted to evaluated LoRAWAN propagation system performance in different urban scenarios used the analysis of the real-world measurements [9]–[13]. However, the use of field measurement to characterize the impact of the air channel on RF propagation is usually costly as it involves real systems. In wireless communication networks, taking real-world measurements is usually the last phase of network planning and deployment, aiming to optimize a wireless network system performance. Instead, the network planning tools use propagation prediction models to estimate path loss due to air channel conditions. In our previous work [14], we evaluated conventional empirical propagation models' performance to determine applicability for predicting LoRaWAN RSS in an urban scenario. Although the study showed that COST-WI had better prediction performance for LoRaWAN RSS than other models considered for the study, this result was over-predicted by 6.48 dBm. Therefore, this indicates that empirical RF models lack accuracy in attempts to capture paths loss over the rooftops, diffraction, and reflections arising from the buildings and streets set up, and these factors are better handled with deterministic models.

In this paper, we intend to evaluate Electromagnetic Wave (EM) based deterministic models to understand the applicability of these models to predict LoRaWAN RSS in urban areas. The EM deterministic models' ability to accurately consider the phenomena of path loss over the rooftops, diffraction, reflections from buildings, dispersion, and wave running are essential features for dense urban outdoor RF propagation [29]. Deterministic models require the use of accurate and high-quality terrain models of the environment. However, in the presence of low-quality terrain models, the use of trace-driven simulation for evaluation of deterministic and semi-deterministic models produced more accurate LoRaWAN RSS prediction than empirical RF models. This study can give insight into the effectiveness of trace-simulation with standard propagation models for evaluation of IoT connectivity with LoRaWAN networks at 868 MHz in the NLOS urban environment.

1.7 Related Work

Trace-driven simulation is a technique that utilizes both measurements and simulation for evaluation and prediction of the performance of the computer-based systems [30]. All the trace-driven studies reviewed in this paper used a software probe to collect measurement trace data except [31], which used device-specific data collection from the testbed. Trace-driven simulation technique has been introduced in [32] as a technique that uses analysis of measurement trace data to redo similar experimental circumstances in the simulations. Trace-driven simulation has been used to perform a realistic simulation.

Trace-driven simulation use analysis of the experimental trace data in an attempt to recreate simulation of the experimental conditions. Authors in [33] stated that sufficient and accurate measurement datasets could directly serve as a basis of propagation performance prediction or fitting the RF models. Trace-driven simulation was used in [34] to model the error behavior of the WaveLAN wireless channel. Chia et al [35] proposed an Automata-Synchronized Replay (EAR) system software to perform trace-based simulation of the measured packets received over the Wireless Local Area Network. The EAR was used to control trace packet, synchronize the environmental effects in trace packet with the packets, and other signals received from the real-world environment. The system implementation results show that the EAR achieved an event reproduction rate of 92.45% under a fading environment. Trace-driven simulation can be used to evaluate wireless link models.

In [36], the authors presented a Wireless Link Simulator (WiLinkSim). This simulator implemented models based on mathematical distribution to correctly represent wireless errors (bit error rate) due to the air channel's effects. WiLinkSim utilizes trace-driven models for realistic simulation of Rayleigh and multipath fading and during the deployment of a real-world network. G. Judd and P. Steenkist [37] indicated that trace-driven simulation is one of the accurate methods to model RF signal propagation. Authors in [38] used measurement error traces to configure stochastic error models to reproduce the signal-to-noise-plus-interference ratio errors of the received wireless signal. The accuracy for Bernoulli, Gilbert-Elliot, and chaotic map error models' ability to reproduce or estimate the measured dataset was performed by comparing the measured traces with models' simulated traces. The results showed that Gilbert-Elliot and chaotic map error models attained enough accurate reproduction of the measured traces.

2 Measurement Setup and Simulation

In the first step, the measurement trace dataset was collected, and then, the RF propagation prediction models were trace simulated using the measurement processed trace data. The measurement trace dataset was collected from an experimental LoRaWAN network installed in Glasgow City using LoRaWAN end-devices and Servers. The processed trace data needed for trace-simulation was selected from the measured data. This trace data served as input data to the trace simulation program. Below is the detailed description of data collection, data processing, and trace-simulation setup.

Table 1: Measurement and Trace-simulation Parameters.

S/N	Parameters	Values
1	Operating frequency Band	868 *MHz*
2	Bandwidth	125 kHz
3	End-device transmit power	14 *dBm*
4	Number of Gateway	3 m
5	Gateway antenna heights	30, 27 and 27 *m*
6	End-device antenna height	1.5 *m*
7	Measurement spreading factor (SF)	7-12
8	Trace-simulation spreading factor (SF)	7, 8 and 12
9	Maximum transmit and receive distance	2275 *m*

2.1 Data Collection Setup

Capturing the field measurements is essential in characterizing air channel impact on LoRaWAN system applications under real-world conditions. We performed an experimental field study to acquire real-world LoRaWAN measurements from Glasgow city, Scotland, the UK. On the map, the city's latitude and longitude are 55.8642° N and 4.2518° W, respectively. The city is built at the bank of River Clyde and constitutes tall and huge buildings and open spaces. Data collection was performed in this city's environment to characterize the effects the NLOS has on the air channel for RF propagation of the LoRaWAN network. The leading equipment used to collect data is the LoRaWAN end-device and three gateways. The former was a Multitech mDot module [39] with LoRa and LoRaWAN protocol, regulated by a single board Raspberry Pi computer, whereas the later constituted Kerlink gateways, enabled with Semtech LoRa SX1301 chip [40]. The Raspberry Pi computer was connected to a 3G/GPS module to keep location records for the received from transmitting end-device operated at 868 *MHz* and 14 *dBm*.

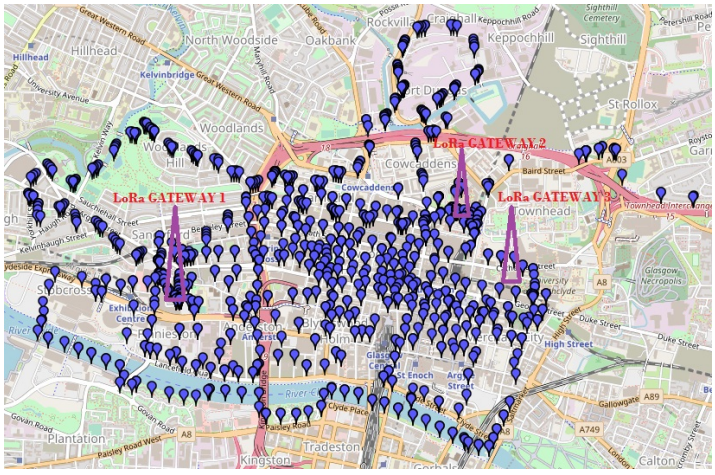

Figure 2: A Google map showing the location of the three LoRa Gateways installed in Glasgow city centre and measurements waypoints. The blue markers on the map represent GPS and their corresponding LoRaWAN RSS waypoints obtained during the measurements

The gateways operated at three locations. The first gateway at Glasgow Caledonian University, 30 *m* on top of George More building. The second gateway at Strathclyde University, 27 *m* on top of James Weir building, and the third gateway placed at 27 *m* on top of

Skypark. The distance between gateway at Skypark and James Weir building is 2005 *m* apart, and both buildings are respectively, 590 *m* and 1900 *m* from George More building. Figure 2. is the display of a 1:300 Google map showing the topography of Glasgow city centre used for the LoRaWAN RSS measurements. It indicates the location of the three LoRa Gateways and measurement waypoints. The three gateways utilize the cable and mobile networks to connect to the network server to record packets received from the transmitting end-device. The mobile end-device transmissions operated the 868 *MHz* and 14 *dBm*. Table 1. shows details of LoRaWAN transmission parameters. The packets were sequentially transmitted, and success or failure to receive an ACK message was recorded. These packets altered between 7-12 the spreading factor. We collected the data in a backpack logger unit at the walking speed in Glasgow city. The data collected in the network server and backpack logger unit were combined and processed in a database. This data shall be known as measurement trace data.

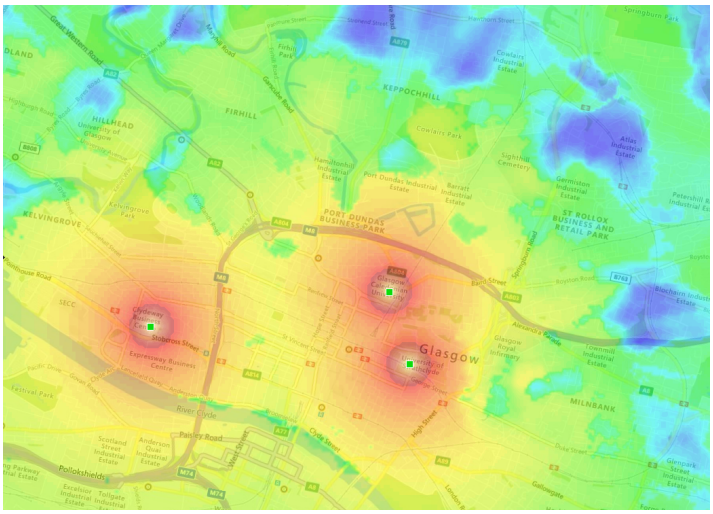

Figure 3: LoRaWAN 868 *MHz* simulation without traces over a Bing digital terrain model of Glasgow city centre. The three green squares in a reddish/brown color represent the simulated LoRa gateways. Colors represent the variation of signal levels, with blue indicating the weakest and reddish the strongest signals.

2.2 Data Processing and Input to Models

To prepare LoRaWAN system measurements for a trace simulation program, we processed measurement trace data. Measurement trace data contained feature data and metadata not required by the trace simulation program. A total of 5008 measurement trace data collected in the backpack logger unit and network server was loaded into the database. We used the command line manipulation commands to pare measurement trace data down to locations coordinates and the RSS suitable trace simulation. Consequently, manipulation of measurement raw data resulted in 5008 datasets for latitude, longitude, and corresponding RSS required for the ICS-Telecom trace simulation function.

The trace simulation program is built from LoRaWAN and RF propagation system models. LoRaWAN system configuration parameters in Table I. and RF propagation models are introduced in section I. The LoRaWAN parameters in this table are based on the LoRaWAN band regulation in the European Union and the physical position of gateway and end-device antenna heights used during the measurements. Similarly, the maximum transmission is the distance between the transmission and reception attained during the measurements. However, due to lack of mobility during the simulation, the SF was heuristically fixed at 7, 8, and 12. The trace simulation program imported the processed trace data through the measurement import function to perform a trace-driven simulation. It executes the LoRaWAN and RF propagation environment using the processed trace data. The trace-driven simulation program's output, which is of interest to this work, was the trace-driven RSS. This output is compared with the RSS in the processed trace data for performance analysis. Figure 4. shows a block diagram of the trace-driven simulation model. This model's main parts are; data collection, data processing, and LoRaWAN and RF propagation conceptual models.

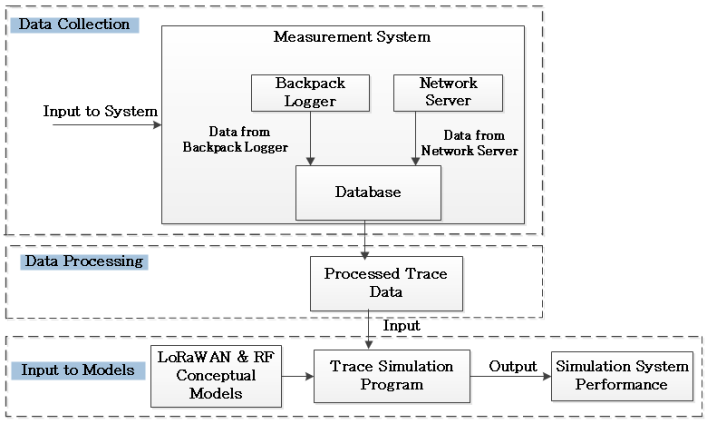

Figure 4: Block Diagram of Trace-driven simulation

2.3 Trace-Driven Simulation

The trace-driven simulation requires a combination of system measurements and simulation [41]. In this paper, trace-simulation set up involved importing processed trace data and configuration of the Glasgow city centre digital terrain model. When the trace simulation program starts, it loads the processed measurement trace data and the LoRaWAN RF propagation system model to reproduce the same experimental conditions in the ICS-Telecom. Authors in [**?**] showed that trace-simulation produces more realistic simulation results than conventional simulation. In [42], the authors provided a detailed account of the advantages of trace-simulation over the conventional simulation. To simulate Glasgow city centre terrain, we imported and configured a 1:300 Bing terrain model of Glasgow city centre at 25 *m* resolution into ICS-Telecom. However, low-resolution terrain maps such as 25 *m* provided a digital elevation model and the city's clutter to the simulator, leaving out the building layer. This input facilitated the simulation of the LoRaWAN system in Glasgow city centre. Over the terrain map, we placed three system gateway models. Each gateway model location configuration on the terrain map matched the latitude and longitude of system gateways used during the LoRaWAN measurements. Like the measurement system, the distance between LoRaWAN gateway models at Strathclyde University and Skypark on the terrain map represents 2005 *m* apart. The respective distance between these

gateway models from Glasgow Caledonian University represents 590 m and 1900 m on the ground. Figure 3. shows the LoRaWAN 868 MHz simulation system set up without traces over a Bing digital terrain model of Glasgow city centre. The next step was to load the processed trace data for trace-driven simulation of the LoRaWAN 868 MHz system.

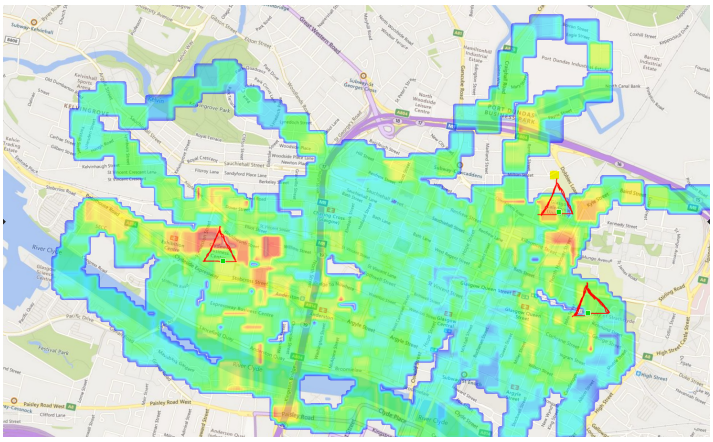

Figure 5: A trace-driven simulation of LoRaWAN 868 MHz over a Bing digital terrain model of Glasgow city centre. The three green squares at the base of red triangles represent the simulated LoRa gateways. Colors represent trace-driven RSS data. The blue color refers to the weakest signals, and reddish/brown refers to the strongest signals. The trace-driven data follows waypoints of the real-world measurements.

Through the measurement import function, the trace simulation program imported the processed trace data. Presented to the digital terrain map are LoRaWAN system measurement locations, a set of latitude and longitude coordinates. Figure 5. shows a trace-driven simulation of LoRaWAN 868 MHz over a 1:300 Bing digital terrain model of Glasgow city centre. It presents the trace-simulated RSS in the previously identified location with the processed trace data, which contains latitude, longitude, and corresponding RSS. At the base of the trace simulation program, there are LoRaWAN and RF propagation system models. These models are the designed base of the trace-driven simulation program. LoRaWAN and RF conceptual system models comprise LoRa modulation, LoRaWAN network, RF propagation models, and the terrain model. The configuration of the LoRaWAN simulation system parameters is similar to LoRaWAN system parameters shown in Table I. On the other hand, the configured RF propagation models are described in Section I. After the trace-simulation, extraction of the predicted trace-driven LoRaWAN RSS followed for each of the RF models.

The extraction of trace-simulated LoRaWAN RSS from the LoRaWAN simulation system provided a trace-simulated dataset required for prediction performance analysis. The minimum trace signal level was set to -140 dBm and the maximum trace signal level set to -61 dBm. The total number of trace data was set to 5008. The trace-simulated LoRaWAN RSS are spread over the digital terrain map of Glasgow city centre in Figure 5. and the color code shows the varying signal strength, which depends on different factors, including clutter obstructions in the environment. The predicted trace-driven dataset for each propagation model was extracted from the LoRaWAN simulation system digital terrain map. Alternatively, the predicted trace-driven dataset can be exported from the simulation system. To validate the obtained trace-simulated dataset, we compared the RF propagation models' trace-simulated LoRaWAN RSS with the LoRaWAN system RSS, measured from Glasgow city centre.

3 Performance Analysis and Discussion

To evaluate models' prediction performance accuracy, we validated LoRaWAN trace-simulation with measurement trace data. Common mathematical error methods measured the prediction accuracy of the models. The error performance metrics used to represent the error between measurement and simulation are the *Mean Square Error (MSE)*, Δ'_{yi}, *Mean Absolute Error (MAE)*, $|\Delta y|$, and *Standard Deviation (SD)*, σ_e. In this paper, N indicates the total number of measured or simulated data samples, whereas Δ_{yi} denotes the difference between predicted and measured datasets. While *MAE* is used as a measure of RF models prediction error, *SD* measures the average distance between measurement and the predicted dataset. C. J. Willmott and K. Matsuura [43] examined the ability of *MAE* and *Root-Mean-Square Error (RMSE)* to represent the average error performance of a model. The authors concluded that *MAE* is a preferred measure of one dimension average error performance compared to *RMSE*, which is suitable for more than one error performance of a model. However, in [44], authors argued that both *MAE* and *RMSE* may be used to evaluate the average error prediction accuracy of the models. In this study, the *MAE* is considered to be an intuitive measure of average error prediction accuracy in RF models.

$$\Delta_{yi} = (RSS_{predicted} - RSS_{measured}) \tag{12}$$

$$\Delta'_{yi} = \frac{1}{N}\sum_{i=1}^{N}(RSS_{predicted} - RSS_{measured})^2 \tag{13}$$

$$|\Delta y| = \frac{1}{N}\sum_{i=1}^{N}|\Delta_{yi}| \tag{14}$$

$$\sigma_e = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(\Delta_{yi} - |\Delta_y|)^2} \tag{15}$$

Table 2: Error Performance Metrics

Parameters	Deygout94	ITU-R525/526	COST-WI
MSE	18.7812	20.978	24.2155
MAE	0.83	1.01	2.87
SD	4.17	5.84	10.96

The comparative analysis of RF models prediction accuracy showed that all the three investigated models over-estimated the RSS measurements. However, Deygout 94 registered higher prediction accuracy with *MAE* at 0.83 dBm. The *MAE* for ITU-R 525/526 and COST-WI was 1.01 dBm and 2.87 dBm, respectively. In terms of prediction error, Deygout 94 prediction had the lowest *Mean Square Error, MSE* at 18.7812 dBm, followed by the ITU-R 525/526 and COST-WI with *MSE* at 20.978 dBm and 24.2155

dBm respectively. Furthermore, Deygout 94 exhibited the lowest *standard deviation,* σ_e at 4.17 *dBm*, followed by the ITU-R 525/526 and COST-WI at 5.84 *dBm* and 10.96 *dBm* respectively. This result implies that Deygout 94, a deterministic model, performs better RSS predictions than the ITU-R 525/526 and COST-WI models. COST-WI poor prediction performance is attributed to its reliance on the buildings' information. Table II. shows models' prediction error performance metrics calculated in equations 12-15 for MSE, MAE and σ_e using measured and trace-driven dataset in the NLOS city environment. Overall, it can be observed that Deygout 94 obtained low prediction error performance.

Density and vertical obstructions presented to the application through a high-resolution DTM is crucial for modeling RF propagation [45]. The DTM at 25*m* resolution that presented the NLOS obstructions over Glasgow city centre terrain landscape into the ICS-Telecom lacked detailed buildings' information. The graphical representation in Figure 6. shows the relationship between the LoRaWAN 868 MHz measurement dataset and models trace-simulation performance in the NLOS conditions in Glasgow city centre. The measurement and trace-driven simulated data are plotted as a RSS function, in *dBm* and distance, d in meters. The visible gap between measurements and trace-driven simulation may be attributed to the low resolution of the DTM, which fails to represent actual NLOS conditions in Glasgow city centre to the Trace Simulation Program. However, trace-driven RSS trend against the distance follows RSS measurements with Walfish-Ikegami keeping more distance and Deygout 94, making a closer drift with measurements. The clustered data visible on the graph indicates many RSS collected at specific locations due to reduced NLOS obstructions. On the other hand, the flattened regions are an indicator of either low variations of LoRaWAN RSS as signal reception reduce or completely blocked due to an increase in density and the height of buildings in the City's air channel.

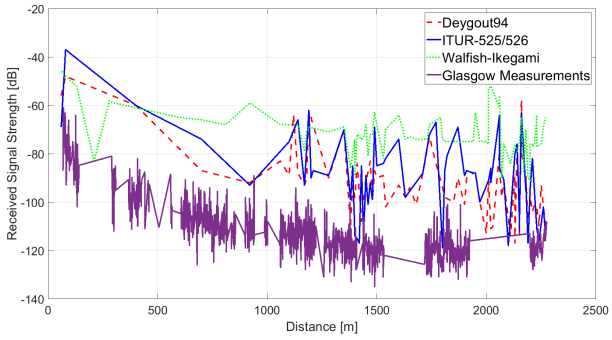

Figure 6: Models trace-simulated performance comparison with LoRaWAN 868 MHz measurements. The vertical axis plots real-world LoRaWAN RSS measurements, *dBm* and models' trace-simulated LoRaWAN RSS data, *dBm*. The horizontal axis represents the distance, d in m.

The trace-driven simulated models improved prediction accuracy performance compared to empirical models in the previous study [14]. Both studies were carried out for LoRaWAN 868 MHz in Glasgow city centre, and the same measurement dataset was used for validation. Table III. shows the comparison of prediction accuracy of empirical models, in cyan color heading and trace-simulated models, in the yellow color heading. The improvement in trace-simulated predictions compared to empirical RF models can be attributed to measurement traces and differences in model design and application. The spreading of LoRaWAN RSS over the Glasgow city centre map shows how trace-driven simulation leads closer to measurements.

Table 3: Comparison of Emprical and Trace-simulated Models Prediction Accuracy

Parameters	*Deygout94*	*ITU-R525/526*	*COST-WI-Traced*	**Okumura-Hata**	**COST231**	**COST-WI**
MSE	18.7812	20.978	24.215	48.84021	57.2056	96.746
MAE	0.83	1.01	2.87	5.564	6.131	7.413
SD	*4.17*	*5.84*	10.96	9.158	11.425	7.454

The analysis of measurements and simulation mapping over Glasgow city centre's map shows significant variation in the RSS spreading. The simulation mapping of RSS in Figure 3. spreads all over the map compared to the mapping of RSS measurement, which follows the data collection path. On the other hand, LoRaWAN trace-driven simulation mapping in Figure 5. attains a close match to the mapping of RSS measurements in Figure 2. when the minimum and maximum trace signal level and the total number of trace dataset is set. The closer pattern between the measured and trace-driven RSS mapping matches the claims that trace-driven simulation performs realistic simulation [32]. This pattern shows that the trace-driven simulation technique can perform a realistic evaluation of RF models for the planning and deployment of LoRaWAN in cities.

4 Conclusion and Future work

We have created a trace-driven simulation of LoRaWAN 868 MHz for Glasgow city centre. Trace-driven simulation techniques using the real-world measurement trace dataset make it possible for RF propagation models to produce realistic RSS predictions of LoRaWAN radio links. This paper has used measurements to perform trace-driven simulation over the DTM of Glasgow city centre. We have used LoRaWAN trace-driven RF propagation models to analyse and evaluate several RF propagation models' prediction performance accuracy for LoRaWAN 868 MHz. The RF models considered in this study are Deygout 94, ITU-R 525/526, and COST-WI. The trace simulation program, built in the ICS-Telecom, imported 5017 processed trace datasets measured from an experimental LoRaWAN 868 MHz network deployed in Glasgow city centre. The processed trace dataset contained the latitude, longitude, and the corresponding measurement RSS. The comparative performance analysis of trace-driven LoRaWAN simulation traces and the real-world measured LoRaWAN processed trace dataset showed that RF propagation models produce realistic LoRaWAN RSS predictions.

All models over-estimated LoRaWAN trace-simulated RSS levels in comparison to real-world collected data samples. However, a comparison of trace-driven simulated models and empirical RF models shows that trace-simulated RF models produce a more accurate prediction. Deygout 94 prediction accuracy was the higher with *MAE* at 0.83 *dBm* and *SD* at 4.17 *dBm*. COST-WI cannot

be used for simulation of LoRaWAN coverage estimation in an urban environment unless high-resolution DTM models are used in ICS-Telecom. Currently, most studies use measurements to evaluate LoRaWAN performance. This approach is expensive, and trace-driven simulation can be a better option. Although it requires DTM, the use of even low-resolution DTM produces results better than conventional models. The random neural network could be used to design a more accurate and inexpensive RF propagation model in the future.

ABSTRACT

The performance of indoor illumination control in many applications, such as in an intelligent building, relies on the quality of the light sensors. In many cases, the light level is not uniform and depends on the direction of the illumination source. It usually requires multiple sensors set up in different directions to gather the overall light level. We propose a system that can provide multi-directional light sensing data by rotating a single sensor. This approach overcomes the problem of static sensors network by dynamically changing the measuring angular of the light sensor. We present a sensor system prototype using the ESP8266 controller board, BH1750 light sensor, stepper motor, and 3D printed rotation base mechanism. The system can calculate the sensing angle and transmit sensing data to the monitoring unit or Internet of Things platforms for visualization and analysis. The testing results in normal workrooms show that the rotating sensor can measure the light level in different directions and detect the direction of the main illumination source. Even blocking some directions, the sensor still is able to accurately measure and provide sensing information on the remaining directions. Our sensor system is useful in both whole lighting and local lighting control applications.

1 Introduction

Light sensing information has a vital role in illumination control applications as in industrial lighting or a sensor-actuator (S-A) building. The characteristics and capability of light sensors highly affect lighting control performance. The indoor illuminance depends on both artificial and natural light. The light measuring is not just based on the photodetector in the sensor, but also other factors like sensor direction and occupant activities. Typically, the S-A system uses multiple light sensors or a network of sensors that are located distributively. As mentioned in [1], there are challenges in the use of a network that contained a large number of sensors such as unreliable sensor nodes (fault tolerance), difficult to add a new sensor or to change sensors direction (scalability), and late respond of light changing events (low latency). For a single sensing node, the sensor could be blocked by unaware objects or illuminated by an offensive light beam (not the lighting source), causing an inaccurate measurement. We proposed in [1] a rotating light sensor system that helps to reduce these issues. This paper presents a new design of the system with more details of the evaluation results.

The system proposed in [1] used a single light sensor rather than multiple sensors, and the sensor can rotate freely to measure the light illuminance from numerous directions. The sensor also recognizes the measuring angle as a part of the sensing data. In [1], we introduced a demonstration version of the sensor system that had a relatively large size. We present here a new version with a reduction in the overall size. For validation purposes, we add a static sensor to the system. The significant advantage of our system is that it is able to provide light sensing data at different angles using just a single sensor compared to a system that uses multiple sensors. The rotating sensor can detect the temporary light changing at a specific angle or determine which measuring direction may have been blocked. These features allow the sensor to accurately tracking the light information in real indoor applications. The system can also work on the Internet of Things (IoT) [2] applications since it can connect and transfer data to the popular IoT platforms.

The paper is organized as follows. The following section provides the related works. The methodology, design, and features of the rotating sensor system are presented in Section 3. The performance analysis and experimental results are provided in Section 4. The last section concludes the paper.

2 Related Work

Light sensing data is used in the illumination control system is often come from either a single sensor or a network of sensors. The use of light sensors networks has become more popular, especially in medium and larger size applications. Using a single sensor may not provide enough sensing information, while a network of sensors has the challenges of fault tolerance [3], scalability [4], and low latency [5]. We have observations about these challenges based on our work in light sensing and lighting control research. Firstly, the fault tolerance feature in the light sensors network requires the system to work correctly when some sensors may have been failed. It is difficult to satisfy this requirement when the light sensors are distributed at a different location. For the scalability, there is a challenge in the application that requires to increase illumination areas such as in the commercial center or industrial working floors. In such a case, the component cost would increase, and the sensor system should be portable enough to adapt to the extensions. Lastly, the static sensor system may have a low latency issue system when it places the sensor in a fixed direction and orientation. The static system may not quickly sense the changing of illumination level in the zones uncovered by the sensor. In [6], the lighting control system used the wireless sensor networks data to control the illumination to reduce the energy costs. A significant deployment and maintenance costs of the sensors was reported. In addition to the components cost, there was another complexity in the controlling system related to the variation of the light level caused by the sunlight [6]. The study in [7] indicated the effect of other natural factors like sun movement, clouds, and shadows on changing the light levels in the testing applications. The effect of distance and direction of the sensors and light sources on the sensing data was studied in [8]. They studied the controlling of both overall and local illumination. The controlling plan uses the local light sensing data to provide illumination upon the user's needs. A limitation is that the system requires a light sensor to be carried with the user to measure the local light level. These local measurement data were used in the illumination controlling plan to meet the user requirement.

For the location-based illumination control, the whole lighting provides background light, and the local lighting provides concentration light [9]. In this system, the control system uses light sensing data to control both background and concentration illumination. The work in [10] had evaluated the effect of the local light sensing on controlling the whole lighting devices. It also requires to determine the location zone of the user to provide the personalized light control [11, 12].

In [13], the author studied the distributed light control system to accommodate both the user occupancy and the natural daylight level. A large number of light sensors were used in their system to examine the relationship between the occupation bases and the relevant light sensors. The testing result also indicates the dependence of the light control performance on the accuracy of the local and whole light sensing information.

We have not seen such a system using a rotating sensor in light sensing applications. In the field of radio tomography, a study presented in [14] introduced a rotating RF sensor system to sense the radio system from multiple directions and improve the accuracy of tomographic imaging. As we stated in [1], since the light ambient is heterogeneous, it is necessary to create a light sensor system that can measure light from different angles and reduce the problem of multiple sensor networks. Such a system is useful to increase the quality of intelligent lighting control applications.

3 Design of the new Sensor System

The rotating sensor motioned in [1] was a demo prototype. We have designed a new version of the sensor system that could be used as a real measurement tool. An image of the new sensor system is presented in Figure 1. The new design took care of the following factors:

- Improving the rotation system.
- Reduce the distance between the sensor and the rotation module.
- Optimizing the overall diameter of the sensing system.
- Adding a static sensor for referencing.

3.1 Multi-Directional Light Measurement Vector

Consider a visible light source s, the Lumens from this source can be calculated based on the I_s intensity [15] as:

$$\Phi_s = 4\pi I_s. \tag{1}$$

For the isotopic light source, where the intensity is the same in all directions, the measurement of the luminous flux on a unit area, also known as or light level in a specific area or illuminance, is the ratio of the Lumens Φ over the area of the measuring surface. However, in the indoor environment where the source is not isotopic, for a flat radiating surface of a sensor, the calculation of the illuminance need to consider cosine the observation angle (θ) with respect to the surface normal as shown in the Equation (2)

$$E = \frac{\Phi_s \cos\theta}{A}. \tag{2}$$

In the lighting control system, the observed ΔE, changing of illuminance on the light sensor surface, are used to control light bulb brightness:

$$\Delta E = \frac{\Delta\Phi_s \cos\theta}{A}. \tag{3}$$

In our proposed system, the light level is measured in multiple directions. Hence, we use a vector of illuminance as:

$$\mathbf{E} = \begin{bmatrix} E_0 \\ E_1 \\ \vdots \\ E_{N-1} \end{bmatrix}, \tag{4}$$

where N is the number of the measuring directions and E_n is the measured illuminance at the direction $n \in [0, N-1]$.

There are two major advantages of the sensing data provided by a rotating light sensor comparing to a static sensor. First, the light intensity measured by a static sensor depends on a single sensing

direction, the angle θ as in Equations (2) and (3), while the rotating sensor provides a combination of illuminances from multiple directions. In the real application, such as lighting control, the measuring direction could be blocked by an object that makes the sensing value of the static sensor inaccurate. The rotating sensor can be able to void this issue as it measures the light from different angles. Second, the rotating sensor uses a vector of illuminance (4) that can indicate the main light source direction. Furthermore, we can apply the gradient calculation (∇) on the vector of illuminance to measure the rate and direction of change in the light intensity.

3.2 *Features of the Rotating Sensor System*

The new sensor system is shown in Figure 1 has an overall diameter of 100 mm. This design is small enough to use in most indoor applications. Table 1 summarizes the features of the sensor system. The system uses one light sensor to dynamically measure multi-directional light intensity. In this system, there is no need to use many sensors as in a sensor network. By rotating the light sensor, our system may avoid the issues when the static measuring angle has been blocked by an object.

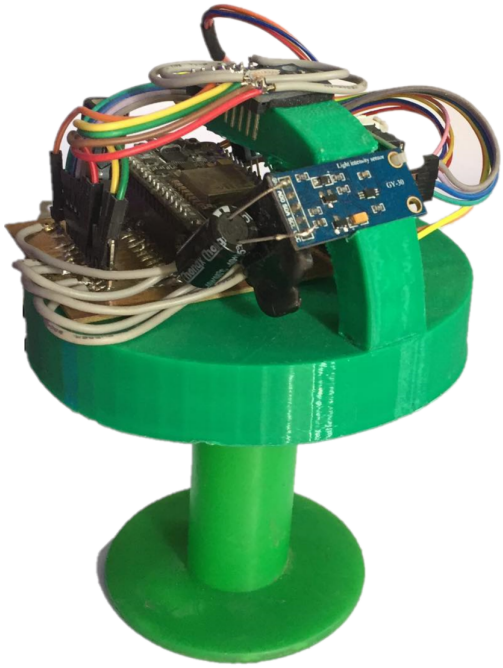

Figure 1: A sample image of the new rotating light sensor system. The light sensor is attached to the side of the curved handle of the rotation base structure.

Table 1: Features of the sensor system

System Features	Value
Light Sensor	BH1750
Stepper Motor	28BYJ-48
Stepper Motor driver board	ULN2003
Microcontroller Module	ESP8266
Overall Dimension (mm)	100
No. of Measuring Directions	8 and 16
Sensor Measuring Resolution (Lux)	1 (high) or 4 (low)

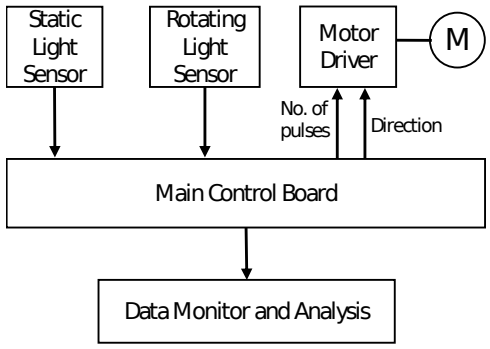

Figure 2: Diagram of the sensor system.

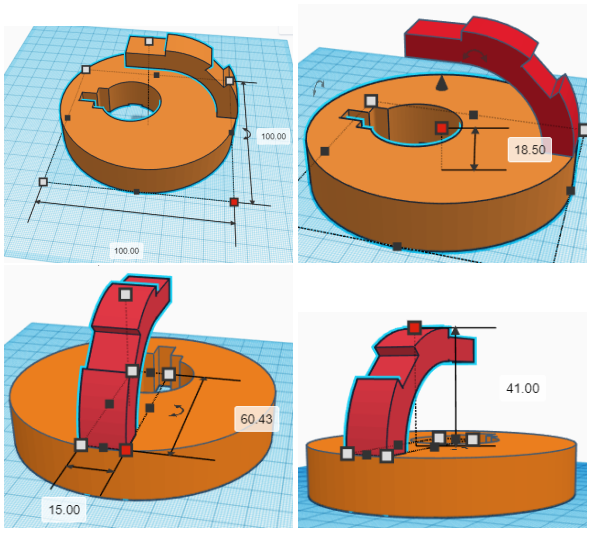

Figure 3: Sample views of the rotation base structure design.

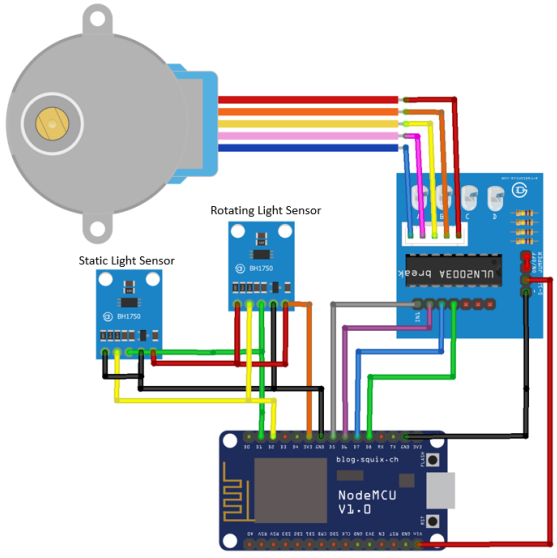

Figure 4: Conceptual logic circuit of the sensor system.

As shown in the system diagram in Figure 2, the major components of the system are the light sensor, stepper motor, motor diver board, and the main control board. The system uses a micro-

controller to control the rotation, sensing the light illuminance, and transfer data to the monitoring platform. In this design, we have improved the rotation system and created a new base structure of the sensor. Figure 3 shows several views our the new base structure. The structure was 3D printed and used in the sensor system.

As a modified version in [1], the new system uses an additional static sensor to provide a reference as requested. In this study, we consider the static sensor is the sensor that has a fixed sensing surface normal vector, thus the observation angle θ for any lighting source stays unchanged (see Equation 2). The rotating sensor is the sensor that its observation angle can be changed. By rotating the sensor in an axis different than the normal vector of its sensing surface, we can change its observation angle.

The logic circuit of the new system is shown in Figure 4. The sensors communicate with the microcontroller using the I^2C protocol. Both static and rotating sensors are the BH1750 [16] digital light intensity measuring module. The sensor module has an internal converter to convert the analog signal to the digital value. The module also contains a preprocessor to process the digital value and return the measuring value in the range of 1 to 65535 Lux.

The circuit uses a ULN2003 stepper motor driver to provide a drive interface between the microcontroller and the stepper motor. The ULN2003 driver pins, IN1, IN2, IN3, and IN4, are connected to the microcontroller digital pins. The power supply pins (VCC and GND) of the ULN2003 driver board are connected to the microcontroller 5V pin and GND pin, respectively. The stepper motor, model 28BYJ-48, runs in 32 steps mode and has a built-in gear with a 64 to 1 reduction ratio to produce 2048 steps per revolution. The step-angle relation is calculated as:

$$\alpha = \frac{i \times 360}{2048}, \tag{5}$$

where α represents the angle, and i is the number of controlling step of the motor. Sample images of the motor and the driver board were presented in [1]. In this new design, the motor is attracted to the center hole of the base structure shown in Figure 3. The motor can rotate the whole structure hence rotate the light sensor. For the microcontroller, we used the ESP8266 [17] board that runs in the Arduino environment. This module has a Wi-Fi microchip with a full TCP/IP stack to transfer the data. We program the system in the Arduino code using the C++ programming language.

Table 2: Relation of the sensing directions, angle interval, and motor steps interval

No. of Sensing Directions	$\Delta\alpha$	Steps Interval
8	45°	256
16	22.5°	128
32	11.25°	64
64	5.625°	32

3.3 Measuring Multi-Directional Light Illuminance

The main procedures of the illuminance measurement are kept similar to in [1] except for the additional signal of gathering the static sensor data. As mention in [1], for the applications that require the data of light intensity in different directions, the users may have to manually set up several sensors at different orientations. We developed an algorithm to automatically rotate the sensors, calculate the angles, and gather the illuminance in multiple directions. Figure 5 presents the major steps of the algorithms. In the beginning, the program set up the initial direction of the sensor. The sensor can rotate in a full 360° revolution, hence any angle can be set as the initial sensing direction. Then the sensor system starts collecting the angle and illuminate data. In each iteration of the major loop shown in Figure 5, the control program rotates the sensor by increasing the motor step, calculates the sensing angle, gets the light level information, and transmits the data to the monitoring software. The counting of the motor steps is used to calculate the angle based on the Equation (5). When the motor reaches a full circle (at 2048 counted steps), the counting is reset to Zero, and the rotating direction is reversed. The sensor system can measure light in any direction or at a group of interval directions. Table 2 summarizes some combinations of the sensing directions, angle interval ($\Delta\alpha$), and the motor steps interval. The visualizations of 8 sensing directions with 45° apart and 16 directions with 22.5° apart are shown in Figure 6.

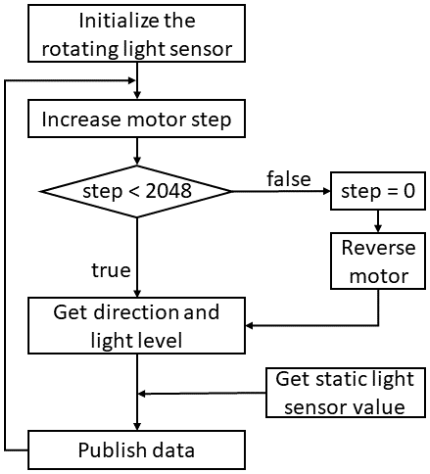

Figure 5: Flowchart of the control algorithm of the light sensor system. The major procedures are to control the rotating light sensor. The command to get static light sensor data is optional.

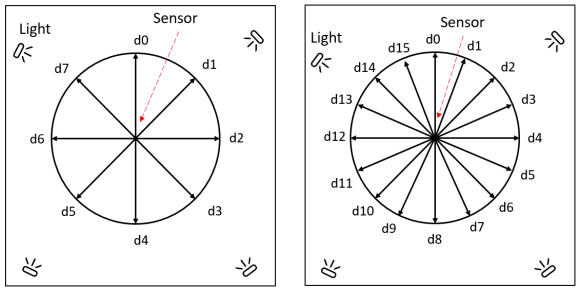

Figure 6: Sample views of the rotating light sensor with different number sensing angles. **Left**: 8 directions from $d0$ to $d7$ with $\Delta\alpha = 45°$. **Right**: 16 directions from $d0$ to $d15$ with $\Delta\alpha = 22.5°$. The lights are for presentation purpose only.

4 Performance Analysis of the Sensor System

Indoor lighting control is the major application of our proposed sensor system. We have tested the system in a workroom with the effect of the popular parameters on the sensor, like the changing of light power and blocking object. We present here the experiments

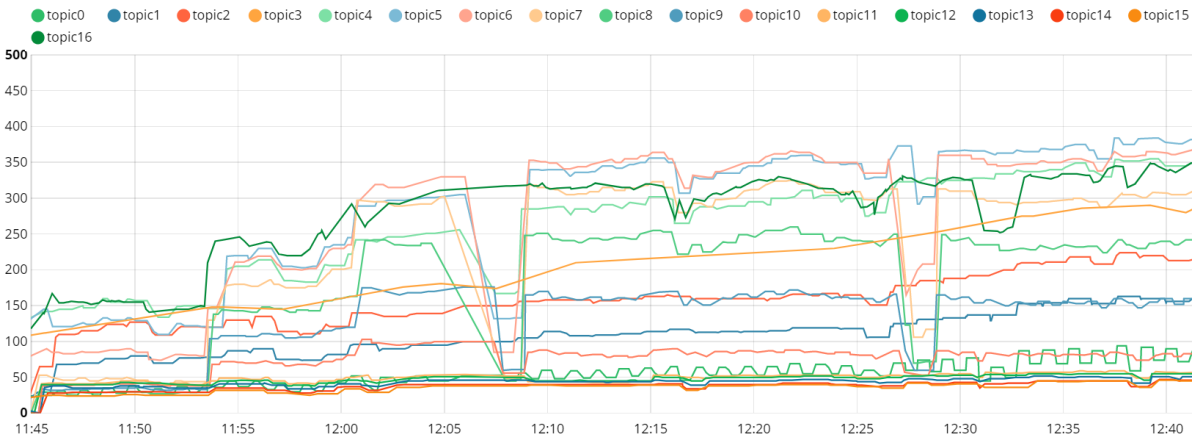

Figure 7: Snapshot of monitoring the light sensing data on the Ubidots website.

and results for testing the ability of the system to detect the main light direction, detect the blocked direction, and accurately measure light intensity.

4.1 Measuring and Transmitting Light Data

In [1], we presented the experiment that showed how the sensor measures the light level from multiple directions. For this new design, in addition to the multi-directional light sensing data, the system also collects the sensing data of a static reference sensor. We tested our device on transferring the data to the Ubidots [18] IoT platform. The data was transferred remotely through the Wifi signal. Figure 7 shows a part of the testing data monitored on the Ubidots website with multiple light sensing signals in one plot. We also have tested our system with the ThingSpeak [19] platform that has integrated MATLAB toolbox for analyzing the data.

For the data presented in Figure 7, the rotating sensor measured the light in 16 directions with $\Delta\alpha = 22.5°$ (Table 2 contains more detail of the measuring angles). It can be seen that our system is able to measure and provide light sensing data from multi-directional. In Figure 7, the rotating sensing data is labeled as a topic channel for each direction from *topic*0 to *topic*15. The static sensor channel is labeled as *topic*16. When monitoring the data, the channel topics (directions), the *Lux* values, and the measuring times can interactively be seen by selecting a data point on the graph. As shown in the figure, different sensing direction has a different value. In the beginning, when all lights were off, all sensing data was low (roughly under 150 *Lux*). Then, after we turned on all the lights (around 11:55 am timestamp, see Figure 7), the system recorded the increase of light levels in all directions. We blocked some directions of the rotating sensor at two later movements. As of the result, there were two failings of the light level at the blocked directions (in the 12:05 - 12:10 pm and the 12:25-12:30 pm periods, see Figure 7). In this experiment, the static sensor (*topic*16) was not blocked at any time, and it was used to provide the reference sensing data.

4.2 Detecting Main Light Direction

The distribution of light sources may generate an unbalance light level in the room. Our sensor can detect the major light direction that information helps to rearrange the illumination sources or indicate the location having the best light level. In this experiment, we place the rotating sensor at the center of a workroom that has several light sources. The light sources were placed around the room at different locations and distances to the sensor. We regularly turn on the lights to test the sensor performance. The sensor was set to measure in 16 directions ($d0 \ldots d15$, with $\Delta\alpha = 22.5°$). Figure 8 displays some radar charts of the measured results. For each chart, the data value as a length on angular spokes represents the magnitude of sensing value in a corresponding direction. The line connects the data values represses one full rotating revolution (360°).

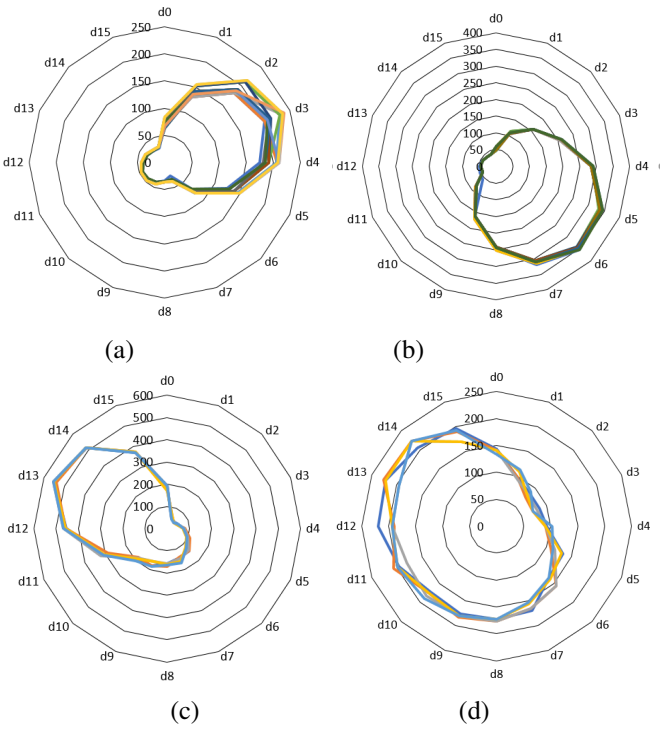

Figure 8: Radar charts of light sensing data on different main illumination directions.

The charts in Figure 8 associate with four scenarios of the lighting in the testing room. For an instant, Figure 8 (a) shows the *Lux* values measured in directions $d2$, $d3$, and $d4$ are much higher than the rest. In that case, only the light source at the direction of $d3$ was on, hence there is a peak sensing data in $d3$ (about 250 *Lux*) and two relevant highs on the adjacent angles $d2$ and $d4$. Figure 8 (b) shows the major level of light in $d5$, $d6$, and $d7$ with the peak value

of 350 *Lux*, and Figure 8 (c) shows the main level in $d12$, $d13$ and $d14$ with above 500 *Lux* peak value. These results plotted in the radar charts admit that the rotating sensor can detect the direction of the main light source. This result also can be observed from our vector of the illuminance shown in Equation 4 since the direction of the vector is influenced by the major scalar member values. Figure 8 (d) presented a test case where the light level is more consistent on the left side of the sensor ($d9$ to $d15$). In the case of a uniform light level, we may obtain consistent light sensing values in all directions.

4.3 Detecting Blocked Directions

We have performed an experiment to show how the rotating sensor can detect the temporary blocking directions with sudden changes in the sensing data. During this test, the rotating sensor was set up to run first, and then some sensing directions were temporarily blocked. Figure 9 plots the testing result. Before the time $T1$, the sensor indicates the major light level in directions $d4$, $d5$, $d6$, $d7$ and $d8$ with the high value above 300 *Lux* ($d6$). In the period of $T1$ and $T2$, when the sensor was blocked from the major light source direction, there was a sudden fall in the sensing value of the relevant angles. As plotted in Figure 9, all sensing values of $d4$ to $d8$ directions have steeply decreased to around 50 *Lux* while other values mostly unchanged. After the $T2$ moment, when the blocking object moved out, the sensing values from the main light directions got back to normal. It can be seen that we can use the directions having a temporary steeply reduction to indicate which sensing angle of the sensor was blocked. In the experiment presented in [1], we reported the result of detecting a sudden change of the natural background light, such as when opening the doors to get more sunlight.

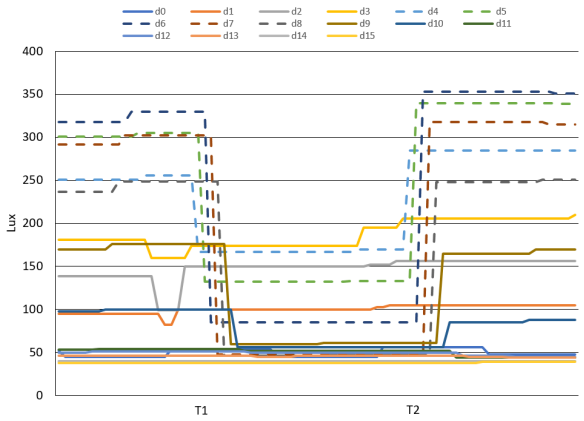

Figure 9: Sensing data of the rotating sensor when blocking some sensing angles.

4.4 Accuracy Analysis

The demand level of illumination to be controlled depends on the change in the sensing value. When using a single sensor or a network of sensors that was set at a static direction, it is possible that an unaware object temporarily blocks the sensor. Such a case makes a temporary change in the measuring data, leading to an inaccurate controlling of the illumination. The rotating sensor provides light sensing values from different directions that can help to avoid this problem.

We performed an experiment that used both static and rotating sensor. The artificial lighting sources were kept unchanged, but the static sensor would be blocked at a certain time during the experiment. Figure 10 shows the *LUX* values of the static sensor at a fixed angle and the rotating sensor rotated in eight directions (from $d0$ to $d7$). In this experiment, the rotating sensor measures light at every 45°. In the beginning, the static sensor data was around 450 *Lux* (±20), while the rotating sensor had different values at different directions with the high value in $d4$ of above 500 *Lux* and $d3$ around 430 *lux*. The directions $d0$, $d5$, and $d7$ had sensing values in between 320 and 350 *Lux*, and the direction $d1$, $d2$, and $d6$ had data in the range of 270 to 300 *Lux*. Then, we blocked the measuring direction of the static sensor. As shown in Figure 10, there is a sharp fall in the value of the static light sensing data down to 100 *Lux* and lower. If an application used just the static sensor to control the lights, it would incorrectly record a reduction in the light level and would control an unnecessarily increase of the illumination power. There was no need to change the illumination since the lights were stable throughout this experiment (except for a small variance in the natural light). For the rotating sensor, the sensing signals in the directions $d0$, $d1$, $d6$, and $d7$ were almost stable (around 300 *Lux* and 350 *Lux*). There was a small reduction in the direction $d2$ and $d5$ and a quire decreasing in the direction $d3$ and $d4$, but these sensing values were still around 250 *Lux*. When we blocked the static sensor, we approached the sensor location through the direction $d3$ and $d4$ that caused the changing of the data in these (and surrounding) directions. If we use the rotating sensing data of multiple directions for the lighting application, the control unit could use the data of the stable directions and decide to keep the illumination level the same. The prevention of an unnecessary increase in illumination power is useful to save energy costs.

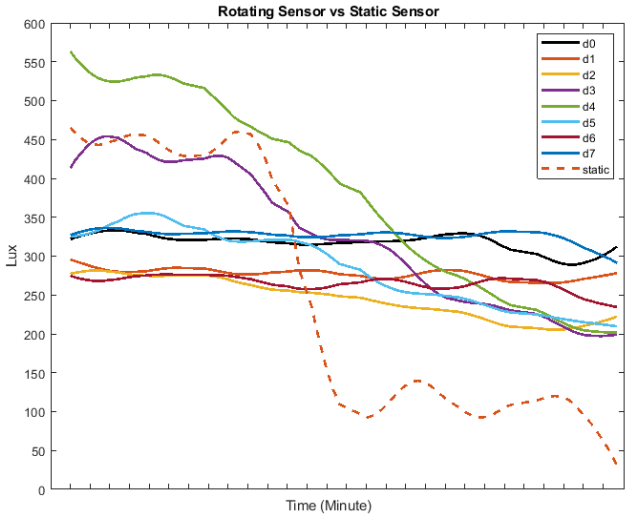

Figure 10: Light sensing values of the static sensor and the rotating sensor. The static sensor was blocked at a certain time, causing a reduction in the sensing value. The time ticks in the horizontal exist are presented at 60 seconds interval.

5 Conclusion

We have presented a rotating light sensor system that can measure light level in multi-direction rather than using server sensors positioning at different orientations. The system uses a stepper motor to rotate the sensor and track the motor steps to calculate the measuring angle. The light level values can be directly transferred to the moni-

toring system for further process. Besides, the sensor can connect with the popular IoT platforms, such as Ubidots and Thingspeak, to remotely visualize and analyze the sensing data. We also presented a new design of the sensor system with an optimal compact structure. The performance of the sensor system has been evaluated through testing experiments. The results show that the proposed sensor system is able to measure light level in different directions, detect the main light source direction, and determine the directions having temporary light changing. Moreover, even some sensing directions may be blocked, the rotating sensor still accurately measures the light level in other directions. In the future, we intend to develop a three-dimensional (3D) rotation light sensor. A motion tracking sensor shall be used to keep track of the 3D orientation. We plan to optimize the rotation system and perform more experiments of using the rotating light sensor in the light control applications.

ABSTRACT

Comparing to other types of vehicle accidents, fatality rate of tipped rollover accidents shows significant number. Thus, tripped rollover prevention systems are important in order to keep driver safe. In other hands, different rollover indices are defined to handle the risk. The variable unknown parameters of each index, for instance, current load of the vehicle or center of gravity, are considered as a difficulty. In this work, the recurrent neural networks, which are designed to work on sequential data in order to provide data estimation without additional estimation algorithm, are investigated in purpose to estimate the tripped and untripped rollover index. The vehicle simulation software with industrial standard CarSim is applied to validate the result. The Tanh recurrent neural network is stated in the result to be the most accurate tripped rollover index estimator for the uncertain parameters, for example, sprung mass and the height of the center of gravity. The suitable input features for tripped and untripped rollover index and neural network structure are verified. To prevent and provide warning of rollover, an advance future prediction can also be designed for the future tripped and untripped rollover prediction.

1. Introduction

This work is an extension based originally on the groundwork presented in the 9th IEEE International Conference on Robotics, Automation and Mechatronics (CIS-RAM 2019) [1]. This paper will focus on development of recurrent neural networks for tripped rollover while Ref. [1] focus on only untripped rollover. The number of rollover accidents has grown continuously according to the change in vehicles' size, which are both weight and dimension, over the last 10 years. The majority type of fatality on the road is pointed to rollover accidents. In 2010, 9.1 million cars, which includes passenger cars, SUVs, pickups and vans, crashed and 2.1% of those crashes were caused by rollovers collected by National Highway Traffic Safety Administration's records (http://www.safercar.gov). From those 2.1% of crashes, there were over 7,600 deaths which was up to 35% of total deaths from vehicle accidents [2]. In addition, 20% of vehicle-crash deaths in Europe are from the rollover [3]. In Germany, 2-5% and 90% of vehicle accidents and deaths from the accidents are caused by vehicle rollover accidents in 2005 respectively [4].

The vehicle rollover accidents are categorized as tripped and untripped rollovers. A rollover accident that have contacted with an external obstacle, such as a pothole or guardrail, is called a tripped rollover. Untripped rollovers are defined the other way

*Corresponding Author: Gridsada Phanomchoeng, Department of Mechanical Engineering, Chulalongkorn University, Bangkok, 10330 Thailand, gridsada.phanomchoeng@gmail.com

round. It happens because of the effect of high lateral acceleration on a dangerous turn, i.e. sharp turn, and it is unrelated to external input [5-6]. Tripped rollovers tend to happen more frequently than untripped rollovers with 95% and 5% of total rollovers according to the statistic provided by NHTSA [2]. From the significant number of deaths from rollovers compared to the total number of high-way traffic deaths, vehicle safety must be improved to prevent the vehicle from rollover accidents.

Hence, several automotive manufacturers, e.g., Ford and Volvo have advanced with active rollover prevention systems which aim to prevent untripped rollover accidents [7]. Analysts and researchers likewise take interest largely in differential braking systems e.g. Anti-lock Braking Systems (ABS), Electronic Braking Systems (EBS) and Electronic Stability Programs (ESP) [3, 7-13]. The baking systems perform vehicle's yaw rate and speed reduction by adjusting each wheel's sequence of brake patterns. Also steer-by-wire technology [13-17] e.g. active front steering (AFS), active rear steering (ARS), or four-wheel steering (4WS) are to be used in case of the balancing of performances among yaw stability, violence, and rollover prevention and an active suspension system [18-20] can be used to avoid rollover when the wheels lifted off the road. Then, an active roll bar stabilization system [20-22] uses an active stabilizer for active torque distribution between front and rear axles of the vehicle. This can reduce the roll motion. In addition, active torque management [23] has the capability to prevent rollover accidents. Many control techniques are developed to enhance these systems.

Precise detection of vehicle rollover is mandatory in order for these active rollover prevention systems to fully function. To the present, there are multiple impending vehicle rollover detections developed with computational rollover index. The rollover indices are developed by various approaches. For example, Static Stability Factor (SSF) was developed to measure the rollover resistance of a given vehicle design configuration [24]; ref. [25] introduced rollover indices that consider kinetic energy, then Rollover Prevention Energy Reserve (RPER) is started off to look into rollover risks by taking energy function as the main account [7]; ref. [26] introduced a dimensionless rollover index that takes roll dynamics into consideration by utilizing phase plane analysis; zero-moment point also is developed to predict the possibility of rollover [9]; lateral Load Transfer Ratio (LTR) is popularly discussed in numerous studies [5, 7, 14-18]; to name a few. It is seen that a lot of rollover indicators are developed based on LTR such as Multiple Rollover Indices (MRIs) for trailer vehicles and Predictive Lateral Transfer Ration (PLTR) [9]. Lateral Load Transfer Ration is actually one of the approaches that take several factors into account, for example, roll angle, roll center and height of center of gravity of a vehicle. Many techniques have been established to estimate these factors. For example, extended Kalman filter technique or nonlinear observer/estimator has been built up to improve the accuracy of the lateral Load Transfer Ratio. Other than that, ref. [27] introduced an algorithm that utilizes the time-to-rollover (TTR) metrics to assess the time until rollover as a warning option. With this approach, an advance real-time prediction of rollover risk can be provided. Moreover, this technique can be used with several other rollover indices simultaneously. Despite a number of rollover detection techniques developed until now, only untripped rollovers are detected.

Ref. [5, 6, 28] has introduced a new rollover index which incorporates external road inputs as a factor to detect not only the untripped but also tripped rollover conditions. The external obstacle road inputs are estimated based on a vehicle dynamic model and nonlinear observer. The simulation and experimental results are presented using a 1/8th scaled vehicle.

Since the indicator to detect rollover risk is very important for improving the rollover prevention systems and rollover warning system [29-31], it is necessary to develop the rollover indicator for detecting both tripped and untripped rollovers. It is shown that the traditional rollover index is not effective enough to identify tripped rollovers and there are only few focused on tripped rollovers that are published. In addition, most accurate rollover indicators relay on dynamic models which require known parameters such as vehicle mass or height of center of gravity of a vehicle. Therefore, here proposed is a neural network indicator developed to identify tripped and untripped rollovers. Neural networks known for adaptable and nonlinear information processing capability perform fittingly in the areas of predication, expert system, and mode identification [32-37]. By taking the approach to be introduced afterward into account, the estimation algorithms to estimate unknown parameters such as roll angle, height of center of gravity of a vehicle, or vehicle mass are not required. These parameters may be changed all the time due to the number of passengers and load. Also, the technique can be applied in many situations. This research is the extended technique in [1, 38] which is focused on untripped rollover to detect tripped rollover.

This research has the following outline: Section 2 will introduce the vehicle rollover and the rollover index for detecting tripped and untripped rollovers. Next, the recurrent neural network technique for detecting tripped and untripped rollover is presented in Section 3, and the methodology to apply the recurrent neural network to the rollover problem is presented in Section 4. The process of evaluation of the suitable neural network, the suitable input features, the suitable neural network structure and the future tripped rollover prediction are included in this section. Then, Section 5 will present the tripped rollover results. Finally, Section 6 will discuss the conclusion to the findings.

2. Vehicle Rollover Index

Traditional rollover index posts as most popular technique to detect vehicle rollover among many techniques [5-7, 14-18, 28-33] used nowadays.

2.1. Traditional Rollover Index

In order to detect lift-off condition of the wheels [6, 7], the rollover index is used as a real-time indicator. Lateral Load Transfer Ratio (LTR) is known as another name of the index. The standard rollover index is designed for predicting incidents that are caused with the lift-off conditions of the wheels for untripped accidents. A number of researches use the basic model to derive their rollover indices. A scaled lateral acceleration, a function of roll angle [12], or a function of lateral acceleration and roll angle [9, 18] is considered as a base argument for these rollover indices.

The rollover index by the conventional definition is portrayed by

$$R = \frac{F_{zr} - F_{zl}}{F_{zr} + F_{zl}}, \quad -1 \le R \le 1 \tag{1}$$

where F_{zr} is right normal tire force and F_{zl} is left normal tire force. $R = 1$ ($F_{zl} = 0$) or $R = -1$ ($F_{zr} = 0$) is the value when a rollover incident is defined. F_{zr} equals to F_{zl} and $R = 0$ is when the vehicle travels straight forward. If $F_{zr} = 0$, then $R = 1$ and this will cause the lift-off occurrence of the left wheel. If $F_{zl} = 0$, then $R = -1$ and this will cause the lift-off occurrence of the right wheel.

Based on the one-degree-of-freedom model, the summation and difference of tire forces $F_{zr} + F_{zl}$ and $F_{zr} - F_{zl}$ can be calculated. An implementable rollover index processed with the one-degree-of-freedom model is demonstrated by [1, 6]

$$R = \frac{F_{zr} - F_{zl}}{F_{zr} + F_{zl}} = \frac{2m_s a_y h_R}{mgl_w} + \frac{2m_s h_R tan\phi}{ml_w} \tag{2}$$

where m_s is Sprung mass, $m = m_s + m_u$, m_u is unsprung mass, a_y is lateral acceleration, h_R is Center of gravity (C.G.) height from roll center, g is acceleration due to gravity, l_w is track width, and ϕ is roll angle.

Lacking influence of the vertical road input and other external inputs limit the rollover index in (2) with only the untripped rollover detection. Lateral acceleration and roll angle influence this rollover index. However, the roll angle, which is complicated to measure, is removed in some published paper's rollover index calculation.

2.2. Rollover Index for Tripped and Untripped Rollover

The influence of road inputs and other external forces are considered in rollover index both for tripped and untripped rollovers in order to indicate the tripped rollovers caused by external input tripping. Figure 1. shows a vehicle rollover model where the influence of right road inputs, z_{rr}, left road input, z_{rl}, and an unknown lateral force input, F_{lat}, at an arbitrary height, h_{lat}, from the roll center are presented. It also demonstrates the normal tires forces, F_{zr} and F_{zl}.

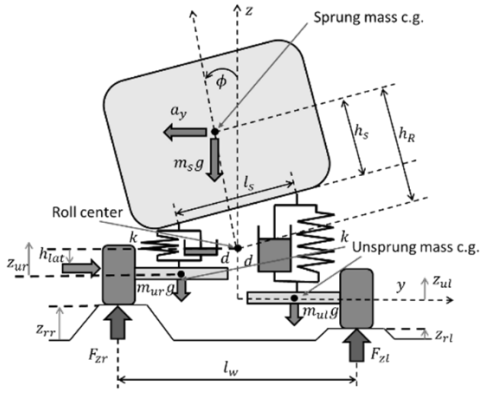

Figure 1: Tripped and Untripped Rollover Model

The four-degree-of-freedom vehicle model provides the derivation of the rollover index in the case of tripped rollover and the derivation is presented in [6]. Equation (3) shows the rollover index for tripped and untripped rollover which is shown in [6].

$$R = \frac{m_u(\ddot{z}_{ur} - \ddot{z}_{ul}) - \frac{2}{l_s^2}(I_{xx} + m_s h_R^2)(a_{zl} - a_{zr})}{m_u(\ddot{z}_{ur} + \ddot{z}_{ul}) + m_s\ddot{z}_s + mg} + \frac{\frac{2}{l_s}m_s a_y h_R cos\phi + \frac{2}{l_s}m_s g h_R sin\phi}{m_u(\ddot{z}_{ur} + \ddot{z}_{ul}) + m_s\ddot{z}_s + mg} \tag{3}$$

where $\ddot{z}_{ur}$ is right unsprung mass acceleration, $\ddot{z}_{ul}$ is left unsprung mass acceleration, $\ddot{z}_s$ is sprung mass acceleration, l_s is length between the left and right suspensions, I_{xx} is roll moment of inertia, a_{zl} is right vertical accelerometer measurement, a_{zr} is left vertical accelerometer measurement, and $m = m_s + 2m_u$.

The second term of (3), the function of lateral acceleration and roll angle, is similar to (2) when comparing the traditional rollover index in (2) and rollover index for tripped and untripped rollovers in (3). To be more clarify, the second term of (3) is the traditional rollover index for detecting untripped rollover, and the first term of (3) is the additional term used for detecting tripped rollover.

There are some difficulties in implementing the (3) to determine tripped rollover due to the parameters and variables that are unable to identify, e.g. the location of roll center, center of gravity (C.G.) height or roll angle. The estimations of these unknowns are required to complete the estimation algorithms. Furthermore, the difference of dynamics between an actual vehicle and the four-degree-of-freedom model might lead to errors. The recurrent neural network is implemented to detect tripped and untripped rollovers in order to optimize the estimation. After training the data, the traditional estimation algorithm to estimate parameters and detect rollover are not required in the model anymore.

3. Recurrent Neural Networks (RNNs)

Recurrent neural network is a popular special type of neural networks. In this paper, sequential data will be sensor data over a period while in other cases it can be, for example frames in video, or words in a text. When a new input is introduced to the sequence, a hidden state vector, h, which is an added memory of the recurrent neural network, is updated. To avoid features losses while training neural networks, the crucial data of the previous sequence is maintained in this hidden state. The recurrent neural network has the ability to work with various lengths of sequence data in addition to the benefit in compression of past information.

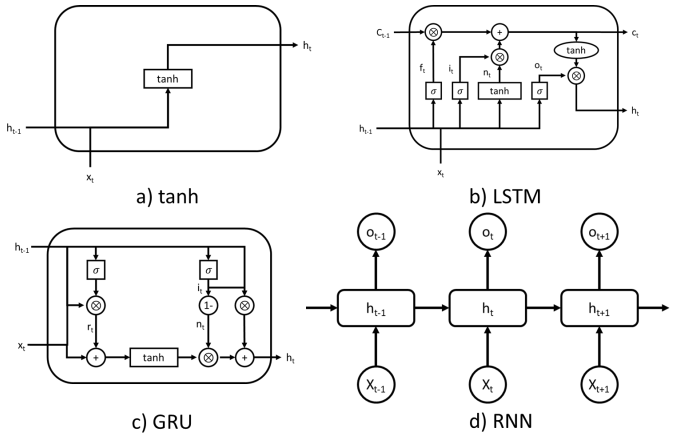

Figure 2: The Structural of Recurrent neural network a) tanh architecture b) LSTM architecture c) GRU architecture d) RNN Connection

There are four types of neural networks used to evaluate and create the neural network models for detecting tripped and untripped rollover. The four types of neural networks are 1) feedforward neural network (FNN), 2) Tanh neural network, 3) long short-term memory (LSTM) neural network [39], and 4) gates recurrent unit (GRU) neural network [40]. The detail of implementing these neural networks can be found in [39-46] and the short introduction of them is shown in [1]. The structural of recurrent neural network is shown on Figure 2.

4. Methodology

The data which is not normally determined in a vehicle such as the wheel's forces exerted on the ground by the vehicle wheels is mandatory to compute the precise rollover index in (1). Moreover, Ref. [6, 28] determine the tripped and untripped rollover index based on half vehicle model (4 Degree of Freedom). The variables, which are used, are right unsprung mass vertical acceleration, $\ddot{z}_{ur}$, left unsprung mass vertical acceleration, $\ddot{z}_{ul}$, right vertical accelerometer measurement, a_{zr}, left vertical accelerometer measurement, a_{zl}, lateral acceleration, a_y, sprung mass acceleration, $\ddot{z}_s$, roll angle, ϕ, roll rate, $\dot{\phi}$, and right suspension compression, $(z_s - z_{ur} + \frac{l_s}{2} sin\phi)$. They also assume that the parameters such as sprung mass, m_s, unsprung mass, m_u, C.G. height from roll center, h_R are constant and not changed.

To detect tripped rollover with various conditions, the good measurement inputs are needed to verify for recurrent neural networks. Also, a feedforward neural network is compared with recurrent neural networks in this case to validate the advantages of employing recurrent neural networks rather than a static neural network. The feedforward neural network uses the same inputs as the recurrent neural networks for processing the data and a comparable number of parameters. Moreover, the structure of neural networks is verified for determining the suitable one.

There is a reconstruction of the relationship between the inputs and the rollover index from a dataset processed in a simulation constraint. The next part is presented with the details on the dataset used for training, also the structure of the neural networks and the training setup will be described

4.1. Dataset generation for tripped and untripped rollover

The software CarSim, a standard industry vehicle simulation software, is used to process all the data concerned. In a first step, 22,000 simulations with non-selectively sampled height of the center of gravity and sprung mass of the car are simulated with a variety of tripped rollover scenarios. The height of the center of gravity is uniformly studied between 0.6 and 1.2 meters, based on [47] as a background which also take an estimate of additional loads into account. The sprung mass is uniformly generated between 2100 to 3000 kg, a mass comparable to loaded SUVs. Next, a trajectory of the scenarios is generated based on Fig 2. The trajectory consists of the 50 meters of straight path and the circular arc path of the random radius in the range from 50 to 200 meters based on highway data of Bangkok, Thailand. Samples 80 to 180 km/h uniform distribution will determine the target velocity of the vehicle. Then, the CarSim is going to control the real velocity over the trajectory in a feedback loop to remain adjacent to the speed that is set goal. Also, the steering angle of the vehicle is close-loop controlled to follow the trajectory.

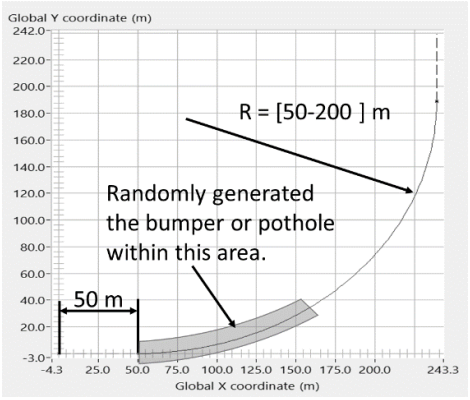

Figure 3: CarSim Trajectory Setup

To create tripped rollover scenarios, the bumper and pothole are randomly generated along the circular arc path of the trajectory as shown in Figure 3. The shape of the bumper and pothole is randomly created from the sine function with the amplitude between -0.15 to 0.15 m and the frequency between 0.625 to 1.25 Hz. Only one bumper or pothole is created for each trajectory. Also, it is created only half lane of the trajectory to make only half side of the vehicle strike the bumper or pothole. For the left turn trajectory, if the bumper is generated, the bumper is created on the left side of the vehicle and if the pothole is generated, the pothole is created on the right side of the vehicle. Then, for the right turn trajectory, if the bumper is generated, the bumper is created on the right side of the vehicle and if the pothole is generated, the pothole is created on the left side of the vehicle. These increase the chance for tripped rollover.

The normal forces on the left and right wheel, F_{zl}, F_{zr}, are provided by a simulation, so each estimation is able to process to determine its rollover index. The rear wheel vertical forces are used to identify the rollover index. However, the front wheels, employing the said methodology together with a small variation from elastic deformations in the wheels and wheel suspensions, can also specify the rollover index as well. The rollover index computed with (1) is the neural networks' training target, calculated according to (1). From there, when two wheels are lifted off road, the sequences stop. That is because the rollover index is defined only for the case of at least one wheel lifting the ground. And it will contribute to a sequence range of length between 0.325 to 19.925 seconds. In every simulation case, there will be a collection of data of the vehicle variables at the sample rate of 40 Hz. However, each simulation dataset also possesses insignificant and irrelevant information of the subject vehicle or those that are unable to be scaled in an actual subject. So, the unnecessary data are needed to be discarded. Then, for the 22,000 files of h5 files (1.64 GB), they are splitted into 3 groups. There are a training set of 16,000 files, a validation set of 4000 files, and

a test set of 2,000 files. The training set is used for training. Other than that, it is mandatory for the validation set to detect possible overfitting of the model while the test set is used to evaluate the error of the neural networks.

4.2. Training of the recurrent neural networks for tripped rollover

There are three major factors of neural networks for detecting tripped and untripped rollover needed to be verified. The first factor is which neural network should be suitable, the second factor is which inputs should be good for neural networks, and the last one is which structure of the neural networks should be implemented. To verify these three factors, three training sets are simulated. Then, future tripped and untripped rollover prediction also is verified with simulation.

4.2.1 Training for determining a suitable neural network type

For this task, four types of neural networks will be compared and given information. Table 1 is presented with the detail of the neural networks which are constructed to take into account approximately the same quantity of parameters. About 5,000 parameters are to be taken to comparison between each neural network. In Table 1, "$N°$ neurons" shows the number of neurons in each layer in the horizontal axis, and also takes into account the input layer (n inputs) and output layer (1 output). The recurrent neural networks, the second entry in "$N°$ neurons" represents the number of hidden states. "$N°$ params" specifies the number of parameters in the neural network. In this column, the added number will be those of all elements in its weight matrices and bias vectors.

Firstly, a feedforward neural network (FNN) will be introduced. FNN is made up of three hidden layers using the $tanh$ activation function and a linear output layer as shown within [1]. Secondly introduced is a neural network (Tanh) which is a recurrent neural network, that employs a $tanh$ recurrent layer. And followed the recurrent layer aforementioned are a $tanh$ hidden layer and an output layer. Thirdly, LSTM neural network which utilizes a long short-term memory layer, again followed by a $tanh$ layer and linear output layer. And for the fourth one, GRU neural network that adopts a static Tanh layer and a linear output layer, works with the gated recurrent unit. Then, the neural networks training diagram is shown on Figure 4.

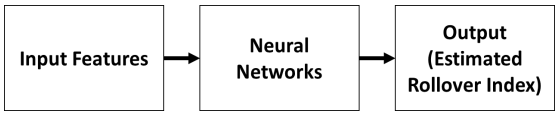

Figure 4: The Neural Networks Training Diagram

A_{xyz}: $[A_x; A_y; A_z]$	Longitude acceleration, A_x, Lateral acceleration, A_y, Vertical acceleration, A_z, (g)
AA_x	Roll Acceleration of sprung mass body (rad/sec^2)
AV_{xyz}: $[AV_x; AV_y; AV_z]$	Roll rate, AV_x, Pitch rate, AV_y, Yaw rate, AV_z, (deg/sec)
$A_{z_{sm}}$	Vertical acceleration of sprung mass C.G. (g)
v_x	Longitude speed (km/h)
$Steer_{DM}$	Steer angle from driver (deg)
$CmpS$: $[CmpS_{L1}; CmpS_{L2}; CmpS_{R1}; CmpS_{R2}]$	Compression of spring each wheel: Left front, $CmpS_{L1}$, Left rear,$CmpS_{L2}$, Right front, $CmpS_{R1}$, Right rear,$CmpS_{R2}$, (mm)

Table 3: Input Combination Training for Determining a Suitable Neural Network Type

No.	Input Features	n	FNN	Tanh	LSTM	GRU
1	$[v_{z_{wc}}; A_{z_{sm}}; A_{xyz}]$	8	4885	4785	5313	5121
2	$[v_{z_{wc}}; A_{z_{sm}}; AA_x]$	6	4789	4693	5073	4929
3	$[v_{z_{wc}}; A_{z_{sm}}; AV_{xyz}]$	8	4885	4785	5313	5121
4	$[v_{z_{wc}}; A_{z_{sm}}; A_{xyz}; AA_x]$	9	4933	4831	5433	5217
5	$[v_{z_{wc}}; A_{z_{sm}}; A_{xyz}; AV_{xyz}]$	11	5029	4923	5673	5409
6	$[v_{z_{wc}}; A_{z_{sm}}; AA_x; AV_{xyz}]$	9	4933	4831	5433	5217
7	$[v_{z_{wc}}; A_{z_{sm}}; A_{xyz}; AV_{xyz}; AA_x]$	12	5077	4969	5793	5505

For the inputs to the neural networks, it is still unclear to select them to predict the tripped rollover. Thus, to initially investigate this task, the inputs are selected based on (3) [6] and the full vehicle suspension model. In addition, the selected inputs can be measured by sensors [6, 28]. The list of the inputs is shown on Table 2. The input combinations are also evaluated in this case. The input combinations for training in this section is shown on Table 3.

Next, the neural networks are trained over 3000 epochs using backpropagation through time. When the process is completed, since the result beyond that came out slower on the validation and training loss. The mean squared error is used as the loss function:

$$L = \frac{1}{N_{traj}} \sum_{i=1}^{N_{traj}} \frac{1}{T_i} \sum_{t=1}^{T_i} \left(R_{ro,i,t} - y_{i,t}\right)^2 \quad (4)$$

with $R_{ro,i,t}$ the rollover index as calculated using the cases data in trajectory i at time step t and $y_{i,t}$ the scalar output of one of the neural networks for the same trajectory and time step.

The leading software that is used for computing the neural networks is the Knet module [49] by the Julia programming language. The program runs on the notebook, Acer Nitro, with CPU i7-7700HQ (2.8 GHz), 8 GB Ram, GeForce GTX1050, and

Window 10 (64 bits). In the meantime, Training is done on a consumer level GPU is used to perform the network training for about 1 hour per model by using average quantity of parameters. This altogether resulted in more than 240 hours of training time. The Ram usage during the training is approximately 6 to 7 GB. And there also implemented the Adam optimizer along with the suggested settings in [50]. Then, the gradient was computed on mini-batches of 2,048 sequences.

4.2.2 Training for determining suitable inputs for the neural network

Since the performance of the neural network is required and the sensor cost is needed to be minimized, the inputs to the neural network need to be optimized. The extra inputs, suspension compressions as using in [28] for each wheel, are included to the list for evaluation. Then, the input combinations are evaluated to determine the suitable inputs for predicting rollover. The input reduction is also included in this test for reducing number of using sensors. The lists of the inputs are shown in Section 5.2 Table 5.

Next, only the best neural network type from the section 4.2.1 are trained. The training process and the loss function are implemented similar to the section 4.2.1.

4.2.3 Training for determining suitable neural network structure

In this task, the neural network improvement is investigated. Eight different structures of the best neural network from the section 4.2.1 are compared. The neural network structure is modified by increasing number of the layers and the neurons. Also, the optimized inputs from the section 4.2.2 are used in this task. Then the neural network structures are also summarized in Table 6. Next, the training process and the loss function are implemented similar to the section 4.2.1.

4.2.4 Training for future tripped and untripped rollover prediction

The future tripped and untripped rollover perdition uses the vehicle parameter measurement to prediction rollover index of a vehicle in the future time based on the training model. It can provide an extra time to prevent or warn the danger of the rollover.

In this case, the output of each data set is shifted by time while the input is reduced to identify with to the length of the output. The shifted time varies from 0.1 second up to 1 second. Then, the best model from Section 4.2.3 are used and, the training process and the loss function are implemented similar to the section 4.2.1

5. Results

The training as descript in Section 4 are applied to the data set. The final losses on the train, validation and test datasets are presented in this section.

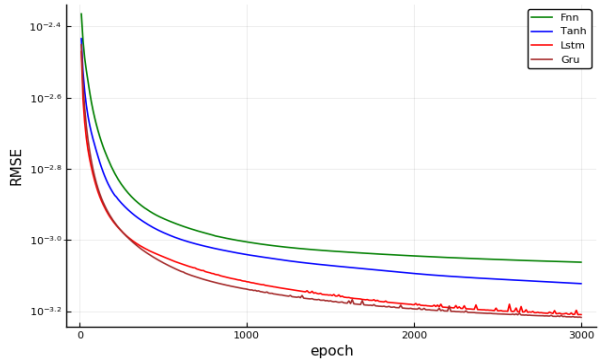
5.1. The suitable neural network type

The test losses in different neural networks on the different input features are shown on Table 4. Also, the example of loss on the train dataset and validation dataset over the epochs are presented in Figures 5a and 5b, subsequently. The training and validation losses of all different neural networks and all input features shows that the overfitting does not occur for all cases because the validation loss decreases as the training loss decreases and the losses from validation dataset are small as the losses from training dataset. Also, the underfitting did not occur for all cases because the neural network models can detect the rollover index as shown in Figures 6 and 7.

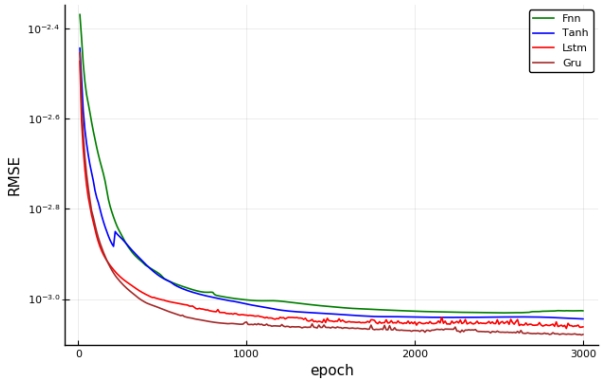
Table 4: Remaining Loss of Different Neural Networks on Test Data Set

No.	Input Features	n	Average RMS error of 2000 Data Set $\times 10^{-4}$			
			FNN	Tanh	LSTM	GRU
1	$[v_{z_{wc}}; A_{z_{sm}}; A_{xyz}]$	8	15.9	10.5	11.3	27.2
2	$[v_{z_{wc}}; A_{z_{sm}}; AA_x]$	6	228	33.3	96.3	156
3	$[v_{z_{wc}}; A_{z_{sm}}; AV_{xyz}]$	8	17.7	13.2	14.4	28.9
4	$[v_{z_{wc}}; A_{z_{sm}}; A_{xyz}; AA_x]$	9	12.5	10.3	11.1	17.4
5	$[v_{z_{wc}}; A_{z_{sm}}; A_{xyz}; AV_{xyz}]$	11	9.82	7.91	9.98	22.8
6	$[v_{z_{wc}}; A_{z_{sm}}; AA_x; AV_{xyz}]$	9	17.1	22.7	13.3	43.0
7	$[v_{z_{wc}}; A_{z_{sm}}; A_{xyz}; AV_{xyz}; AA_x]$	12	9.09	7.54	9.47	21.5

Note: the highlighted cell of the table represents the smallest value of the table.



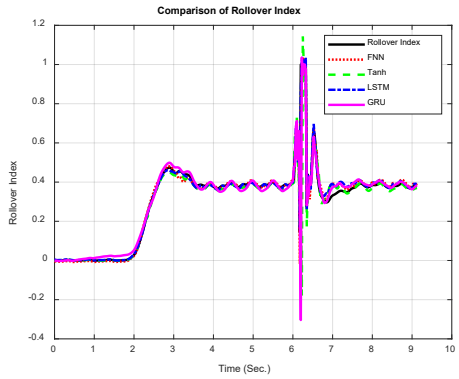
a) Training Loss of No. 7 Table 4



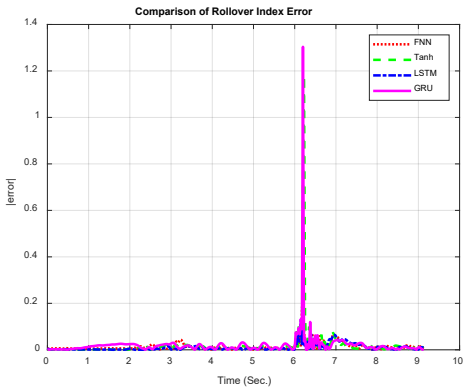
b) Validation of No. 7 Table 4

Figure 5: The Example of Training and Validation Loss

By comparing four types of the neural networks on Table 4, GRU recurrent neural network and FNN seems have the large test losses for all different input features. Since the tripped rollover happen in the very short time So, there is few tripped data occurred. This makes GRU which has a too long-term memory cannot learn the model well. Also, FNN contributes to a large outstanding error because the formula only processes the valuation with the current input x_t.

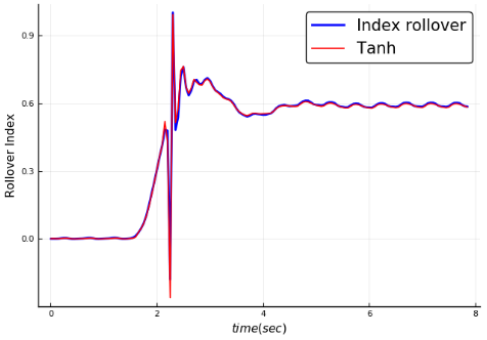


a) Comparison of Rollover Index and Rollover Index from Neural Networks

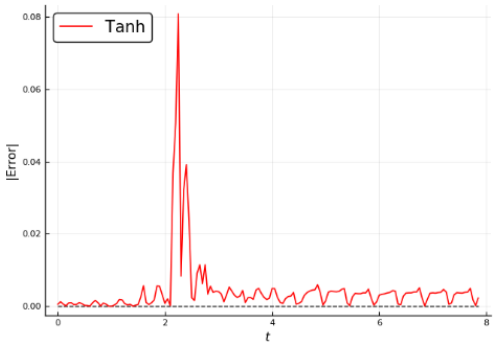


b) Comparison of Rollover Index Error

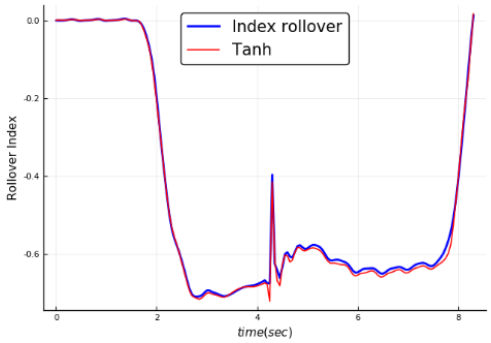
Figure 6: The Example of Rollover Index in the Case of ($m_s = 2722\ kg$, $h_R = 0.847\ m$, $v_x = 82\ km/h$)



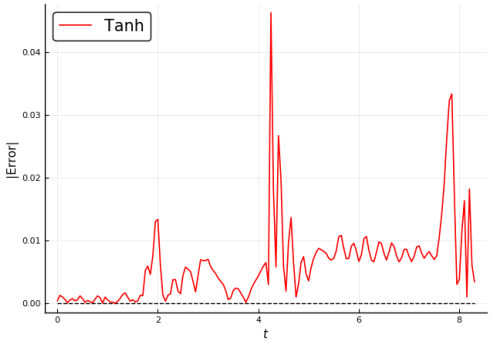
a) Comparison of Rollover Index in the Bumper Case



b) Comparison of Rollover Index Error in the Bumper Case



c) Comparison of Rollover Index in the Pothole Case



d) Comparison of Rollover Index Error in the Pothole Case

Figure 7: The Example of Rollover Index in the Bumper Case ($m_s = 2331\ kg$, $h_R = 0.777\ m$, $v_x = 118\ km/h$) and Pothole Case ($m_s = 2912\ kg$, $h_R = 0.730\ m$, $v_x = 141\ km/h$)

However, Tanh recurrent neural network has the lowest final loss on test loss excepted for No. 6 Table 4 with the input features, $[v_{z_{wc}}; A_{z_{sm}}; AA_x; AV_{xyz}]$ because it has not too long term memory. While the test loss from LSTM recurrent neural network is larger than it from Tanh recurrent neural network except for No. 6 Table 4.

For an empirical comparison, the rollover index (black solid line in Figure 6a) according to (1) and the neural network estimation are shown in Figure 6a for the selected section of the test trajectory. The vehicle takes a cornering at about 2 seconds and during cornering it strikes a bumper at about 6 seconds. This caused a rear wheel to leave the road while its counterpart stayed intact on the ground. The estimated rollover index for the LSTM, Tanh, and FNN are similar and barely distinguishable, whereas the estimation of GRU shows a clear offset and a large error at around 6 seconds. The absolute value of the estimation error is presented subsequently in Figure 6b. As shown, the highest values in the estimation error for the rollover index is seen following the subject vehicle returns from rollover condition back to its normal condition that all of the wheels are on the ground at around 6.1 seconds in the trajectory. However, situational peaks are more prominent, while those of GRU are even more grand.

Figure 7 shows the rollover index and rollover index error of the Tanh recurrent neural network of different vehicle parameters on the bumper and pothole trajectories. The Tanh recurrent neural network can predict the rollover index even though the vehicle parameters are changed because the neural network can handle the vehicle parameter changing. It can learn and adapt the parameters inside the neural network and then predict the rollover index.

Figure 5a shows the case that the vehicle with the parameters, $m_s = 2722\ kg$, $h_R = 0.847\ m$, $v_x = 82\ km/h$, takes a cornering at about 1.8 seconds and during cornering it strikes a bumper at about 2.4 seconds. The maximum error of the estimation happens at about 2.4 seconds. Next, Figure 5b shows the case that the vehicle with the parameters, $m_s = 2912\ kg$, $h_R = 0.730\ m$, $v_x = 141\ km/h$, takes a cornering at about 1.8 seconds and during cornering it strikes a pothole at about 4.4 seconds. Then, the maximum error of the estimation happens at about 4.4 seconds.

In summary, the suitable neural network for tripped rollover is Tanh recurrent neural network since it has ability to retain information of the past and handle the vehicle parameter changing. Also, the lowest test loss happens when using Tanh recurrent neural network with No. 7 Table 4. with the input features, $[v_{z_{wc}}; A_{z_{sm}}; A_{xyz}; AV_{xyz}; AA_x]$.

5.2. The suitable input features for the neural network

Since the error of the Tanh neural network is needed to be improved, the suspension compressions for each wheel, longitude speed, and steering angle are added and evaluated. The test losses of these cases are shown in Table 5. The results show that the suspension compressions for each wheel, longitude speed, and steering angle are significant input features for the neural network. They can reduce the test losses up to 2.93×10^{-4}. Also, once the the suspension compressions for each wheel, longitude speed, and steering angle have been included in the input features, the input, AA_x, seems not effect to the test losses.

In case that the number of suspension compressions is reduced to be only front or rear side, the test losses is increased as shown in No. 3 and 4 Table 5. No. 3 Table 5. has higher the test losses because the actual rollover index is determined from the rear wheel vertical forces.

In summary, the suitable input features for tripped rollover for Tanh neural network is $[v_{z_{wc}}; A_{z_{sm}}; A_{xyz}; AV_{xyz}; v_x; steer_{DM}; CmpS]$ which are agree with [28]. The example of rollover index in this case is shown in Figure 8.

Table 5: Remaining Loss of the Tanh Neural Network on Different Input Feature on Test Data Set

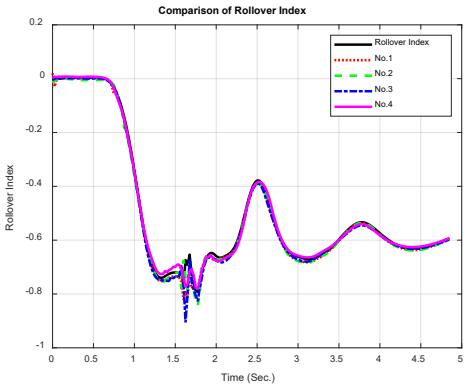
No.	Input Features	n	$N°$ param	Average RMS error of 2000 Data Set $\times 10^{-4}$
1	$[v_{z_{wc}}; [A]; CmpS]$	17	5,199	4.61
2	$[v_{z_{wc}}; [A]; AA_x; CmpS]$	18	5,245	4.82
3	$[v_{z_{wc_{L1}}}; v_{z_{wc_{R1}}}; [A]; CmpS_{L1}; CmpS_{R1}]$	13	5,061	7.41
4	$[v_{z_{wc_{L2}}}; v_{z_{wc_{R2}}}; [A]; CmpS_{L2}; CmpS_{R2}]$	13	5,061	6.58

*$[A] := [A_{z_{sm}}; A_{xyz}; AV_{xyz}; v_x; steer_{DM}]$

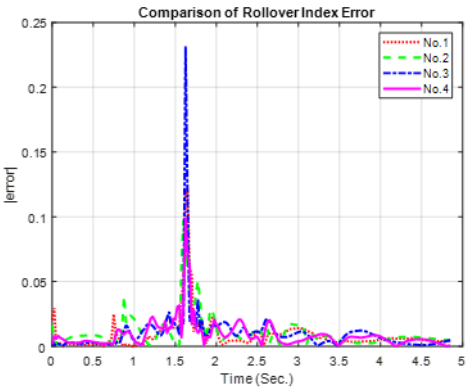
Note: the highlighted cell of the table represents the smallest value of the table.

5.3. The suitable neural network structure

The error of the Tanh neural network is still needed to be improved. The different types of neural network as shown in Table 6. are evaluated with 3 set of input features, case No. 1, 3, and 4 from Section 5.2.



a) Comparison of Rollover Index



b) Comparison of Rollover Index Error

Figure 8: Example of Rollover Index ($m_s = 2583\ kg$, $h_R = 0.829\ m$, $v_x = 101\ km/h$)

The results show that the neural networks in the case no. 7 Table 6 with the input #1 have the lowest test losses of 3.66×10^{-4}. In addition, the neural networks in the case no. 5 Table 6 with the input #3 has the test losses of 4.33×10^{-4} and the neural networks in the case No. 8 Table 6 with the input #2 has the test losses of 7.30×10^{-4}.

In summary, for the lowest test losses, the suitable Tanh neural network structure is the case No. 7 Table 6 which is (n 46 46 50 30 1). Moreover, for the low test losses and low number of input features, the suitable Tanh neural network structure is the case No. 5 Table 6. The test losses in this case is different from the test loss from the best one only 0.67×10^{-4}.

Table 6: Remaining Loss of Different Tanh Neural Network Structure on Test Data Set

No.	Neural Networks' Structure	Average RMS error of 2000 Data Set $\times 10^{-4}$			
		$N°$ param	Inputs #1	Inputs #2	Inputs #3

7	n 46 46 50 30 1	46n+8281	3.66	7.83	5.71
8	n 46 46 50 50 1	46n+9321	4.14	7.30	5.43

* Inputs #1: $[v_{z_{wc}}; [A]; CmpS]$

Inputs #2: $[v_{z_{wc_{L1}}}; v_{z_{wc_{R1}}}; [A]; CmpS_{L1}; CmpS_{R1}]$

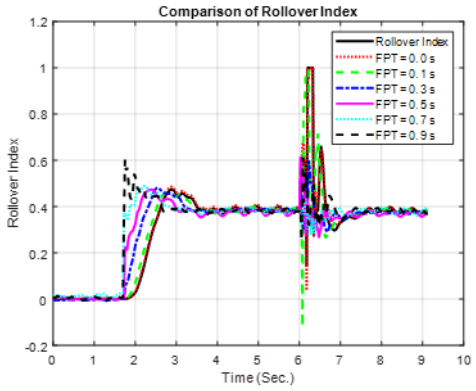
Inputs #3: $[v_{z_{wc_{L2}}}; v_{z_{wc_{R2}}}; [A]; CmpS_{L2}; CmpS_{R2}]$

Note: the highlighted cell of the table represents the smallest value of the table.

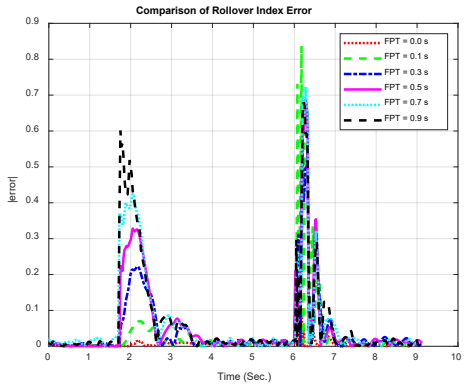
5.4. Future tripped and untrippped rollover prediction

By using the Tanh neural network in No. 7 Table 6, the error of the models shown in Table 7. Also, the example of the rollover index perdition is shown on Figure 9. The results show that once the shift time increases, the error increases. The difference between shift time 0.0 and 0.1 second is approximately 25×10^{-4}. The error seems large. However, if consider the future tripped rollover prediction plot on Figure 9a, the plot shows that they seem correctly predict the trend of rollover index up to 0.5 seconds in future. The prediction lines look like the actual rollover index but it is shelfed by the time.

In summary, this predict is very useful and can provide an extra time prediction for rollover prevention and warning system.



(a) Comparison of Rollover Index



(b) Comparison of Rollover Index

Figure 9. The Example of the Rollover Index in the Case of ($m_s = 2722\ kg$, $h_R = 0.847\ m$, $v_x = 82\ km/h$)

Altogether, the results exhibit that the Tanh recurrent neural network is able to predict the tripped rollover index with a larger preciseness than others once it is considered with the undetermined parameters, for instance, the height of the center of gravity and sprung mass. So, once processing the training data, it is necessary to take the said undetermined values into consideration. The suitable input features for tripped rollover index should be $[v_{z_{wc}}; A_{z_{sm}}; A_{xyz}; AV_{xyz}; v_x; steer_{DM}; CmpS]$ with Tanh neural network structure of (n 17 46 46 50 30 1). Moreover, the future tripped rollover prediction can provide an extra time prediction for rollover prevention and warning system.

Table 7: Remaining Loss of the Tanh Neural Network on Test Data Set

Future Perdition Time (Sec)	Average RMS error of 2000 Data Set $\times 10^{-4}$
0.0	3.66
0.1	29.2
0.2	35.6
0.3	43.4
0.4	55.5
0.5	83.4
0.6	133.4
0.7	214.1
0.8	328.2
0.9	464.5
1.0	616.6

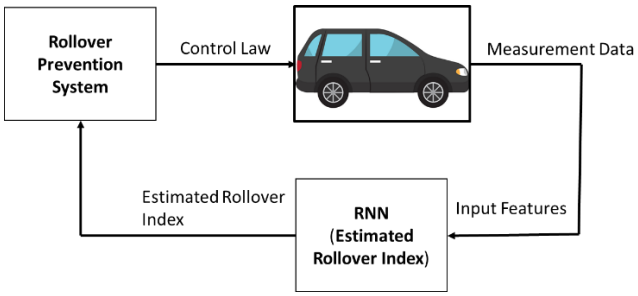


Figure 10: Application Diagram of The Neural Network

The application of the developed neural network is shown on Figure 10. The measurement data from a vehicle is sent to the recurrent neural network which can compute the estimated rollover index within 0.03 ms. Then, the estimated rollover index is sent to rollover prevention/warning system to calculation the control law to make the vehicle action and reduce the roll risk.

6. Conclusions

An essential factor of the carrying out the rollover preventive systems and warning ones is the assessment of the rollover risk. The rollover risk pointer or the rollover index is estimated by employing the feedforward neural network together with three other recurrent neural networks. It is seen that when in occurrence of any uncertain parameters, for instance, undetermined height of the center of gravity of the subject, the Tanh recurrent neural network shows higher performance juxtaposed with others. Calculations of the loss on a test set and an empirical evaluation on test trajectories support in verifying the estimation quality. The outcomes of the test are encouraging for further research, and the performance assessment of the recurrent neural networks in an actual vehicle would be an interesting subject of further research.

The sensory inputs that are chosen play a crucial part in the estimation of the rollover index. The results show that the suitable input features for tripped rollover index should be $[v_{z_{wc}}; A_{z_{sm}}; A_{xyz}; AV_{xyz}; v_x; steer_{DM}; CmpS]$ which are agree

with the previous research. Also, the suitable Tanh neural network structure of is (n 46 46 50 30 1). Moreover, the future tripped rollover prediction can correctly predict the trend of rollover index up to 0.5 seconds in future. This will be useful for rollover prevention and warning system.

Customer Targeting

ABSTRACT

One of the biggest business problems of marketers, is to optimize the return on investments of direct Marketing campaign. This main purpose which can only be ensured by targeting the appropriate customer. The main challenge faced by companies when advertising, is to configure properly a campaign, by choosing the right target, so A high user acceptance rate is ensured to advertisements. However, when dealing with an important size of data, the important specification to consider is the combinatorial aspect of the problem and the limitation of the approach based on mathematical programming methods. In this work, and considering the optimization of targeting offers as an of NP-hard problems, we concluded that the use of a meta heuristic algorithm is more suitable to use a classical (exact) method. We choice to use an improved bat Algorithm hybridized with Genetic Algorithm. The results of computational experiments confirmed that the proposed algorithm gives competitive results.

1. Introduction

There are two axes which characterize research in metaheuristic: exploration and exploitation. Exploration guarantees a diversified search in the space regions; however, the exploitation seeks to ensure the intensification of the search to find a better solution. The goal is to have a balance between these two contradictory objectives [1]. In the literature, many works make a difference between local search methods, instead of single solution-based and population-based methods. In this work, and unlike previous works, we deal with the targeted offers problem in direct marketing campaigns using population-based methods, and we focus on two algorithms; the Genetic Algorithm which can easily escape from the local minimum, and the Bat Algorithm (BA) which has the characteristic to quickly converge towards a local solution. Based on the imitation the concept of natural choice and heredity, the Genetic Algorithm is considered one of the most famous evolutionary search techniques. It was effective in optimizing several types of problem where a deterministic polynomial solution is infeasible. The Bat Algorithm, inspired by the foraging behavior of micro-bats, has been developed by Yang in 2010 [2], and it can be considered as an effort to gather positive side of previous metaheuristic algorithms. Thanks to its simplicity, flexibility, and easy implementation, the Bat Algorithm works well with complicated problems. The main feature of this algorithm is the quick convergence at a very initial stage by keeping a balance when switching from exploration to exploitation. In order to maximize their benefits, firms use "marketing campaigns" as a fundamental tool, along two main axes; by attracting new customers, so-called acquisition or by prospecting additional revenues with their existing customers by proposing new products to them; and this is called retention. Our approach focuses on the second axis (retention). To maximize the marketing profit to determine the combination: which product to offer and for which customer, under a set of constraints by using a new improved Bat Algorithm hybridized with Genetic Algorithm. The final goal is to choose the right product, to offer to the right customer, at the right time to maximize the marketing Return on Investment (ROI). This goal is not easy to implement because of the fact that firms have multiple products to offer under a complex set of business constraints [3]. In this work, and due to the discrete aspect of this kind of problems, the use of a binary version of the Bat Algorithm is essential. The standard BA was originally designed for the optimization of non-discrete problems [4]. The objective is to find a solution with a discrete value. The sought solution is represented by a matrix which contains binary values; 1 if product j is offered to customer i, and 0 otherwise. This paper is organized as follows,

section 2 describes some related works in the same area; works about the targeted marketing problem are mentioned first, followed by works which process the Bat Algorithm's binary aspect in a discrete search space. In section 3, we describe the problem of Market Targeting and the modeling adopted to search a solution for the problem. In section 4, we describe two metaheuristic algorithms; namely the Binary Bat Algorithm (BBA), and the Genetic Algorithm. In this section we present our proposed algorithm: Improved Genetic Binary Bat Algorithm (IGBBA) developed to encounter the shortcomings of the two first algorithms while searching for adapted solutions. Experimental results are presented in section 5 for the three algorithms with a comparison of their performance.

In [3], author presented an optimization problem and replaced the classic database Marketing problem intended to generate the optimal profit under a set of business constraints. Approximately 2.5 million customers, eleven unique offers, and five investments are considered. The solution provided an approximately optimal solution to the ideal capacity assignment problem. The result is a decision describing which customer to target and which product to offer to him. In [5], author presented eight algorithms to solve the problem of maximizing the Return on Investment of targeted marketing. Seven of these algorithms are considered as exact methods and the eighth one is a heuristic method: the Tabu Search (TS). In the results, the TS showed the best performances. In [6], author took up the problem as described by author in [5], focusing on solving the problem by developing an efficient technique. The approach followed by author in [6] consists of hybridizing two metaheuristics: Greedy Randomized Adaptive Search Procedure (GRASP), and General Variable Neighborhood Search (GVNS). Three steps characterize the method followed by in [6]; the first one verified the efficiency of the GRASP algorithm proposed to initialize a good solution. In the second step, author kept the same parameters, but this time, they called the VND procedure for a local search. In the third step the complete proposed algorithm GGVNS was tested and it provided better results. In [7], author proposed a multi-objective DMLS metaheuristic for searching for sets of non-dominated solutions, in order to maximize both the promotion campaign's total profit and the risk-adjusted return. In order to remedy to the concept of volatility, author, in [7] proposed a greedy randomized initial solution builder, able to perform local searches considering different neighborhood exploration techniques, and a genetic method is designed. All the works cited above used metaheuristic based on local search methods to ensure an optimization of the return on investment, while respecting the business constraints. On the other side, the use of a Binary Bat Algorithm will allow us to deal with the target marketing optimization problem by looking for solutions made up of discrete (binary) values instead of looking for continuous solutions. In designing the Bat Algorithm in its binary version, how to update velocity and position must be adapted in order to guarantee the binary aspect of the research. In [8], the goal is to use the concept of velocity and position of bats in real space to move each bat in a discrete space with 0 and 1 values only. The idea was to change the position of micro-bats with the probability of their velocity. To achieve this objective, the technique used is based on a transfer function which allows a transformation of the value of the velocity to a probability, to update the position. this amounts to saying that this transfer function calculates the probability of changing the position from 0 to 1 and vice versa.

2. Problem Description

Direct Marketing is a tool that allows firms to promote their products directly to customers, and measure results quickly. One of the most important benefits of Direct Marketing is "Upgrading firm's loyalty strategies" in order to maximize the companies' Return on Investment. In [5], and In [3] before, authors presented the formulation of the product targeting problem as a mixed-integer programming (MIP) problem including more business constraints, and it can be rewritten as follows:

Given a set of m customers $C = [c_1, c_2 ... c_m]$, and a set of n products' offers $P = [p_1, p_2 \ldots p_n]$, the objective is to maximize the Return on Investment under these business constraints:

- The corporate hurdle rate: each company defines its hurdle rate (HR) to make sure that the Return on Investment is equal, at least, to a value of HR.
- During the campaign, the budget of each product is limited.
- A limitation is imposed on the total number of products offered to each customer.
- And there is also a Minimum Quantity Commitment (MQC), which is the number of units of a product to be offered in order for that product to be part of the campaign. It means that no customer will receive an offer of a product which is not part of the campaign. If the product belongs to the proposed ones then at least $Pj > 0$ customer will receive an offer.

A solution is represented by a binary array $R_{|C|\times|P|}$, where C indicates the set of available costumers, and P represents the possible products to be used in the campaign. If a given cell $s_{i,j}$ |i $\in$ C, j $\in$ P is equal to "1" (true), the product j will be offered to the customer i; otherwise, the value would be "0" (false).
There are two basic parameters of the customer lifetime value's computation; p_{ij} is the probability that customer i responds positively to an offer of product j, and DFV_{ij} is the return to the firm when customer i responds positively to the offer of product j [11, 12]. the problem can be modeled as follows:

$$\sum_{i=1}^{m}\sum_{j=1}^{n}(r_{ij}-c_{ij})x_{ij} - \sum_{j=1}^{m} fc_j y_j \qquad (1)$$

where:

- r_{ij} is the expected revenue of the company from the offer of product "j" to customer "i", and $r_{ij} = p_{ij} DFV_{ij}$
- c_{ij} is the cost generated while offering product "j" to customer "i"
- M_i is the upper limit value of number of different products to offer to a customer "i"
- P_j is the MQC limit associated with product "j"
- B_j is the budget, associated to the product "j" during campaign.
- fc_j is the cost of using product j in the campaign
- O_j is the MQC bound of the product j,
- HR is the hurdle rate specific to each company

The goal is to maximize the fitness function (1), by finding the optimal combination of the two matrices X and Y:

$$X = \begin{pmatrix} x_{11} & \cdots & x_{1n} \\ \vdots & \ddots & \vdots \\ x_{m1} & \cdots & x_{mn} \end{pmatrix} \text{ and } Y = \begin{pmatrix} y_1 \\ \vdots \\ y_m \end{pmatrix}$$

where:

$$x_{ij} = \begin{cases} 1 \text{ If product j is offered to customer i,} \\ 0 \text{ Otherwise} \end{cases}$$

and,

$$y_j = \begin{cases} 1 \text{ If product j is used in the campaign,} \\ 0 \text{ Otherwise} \end{cases}$$

The constraints, to which the problem is subject to, can be modeled as follows:

$$\sum_{i=1}^{m}\sum_{j=1}^{n} r_{ij}x_{ij} \geq (1+HR)\left[\sum_{i=1}^{m}\sum_{j=1}^{n} c_{ij}x_{ij} + \sum_{j=1}^{n} fc_j y_j\right] \quad (2)$$

$$\sum_{i=1}^{m} c_{ij}x_{ij} \leq B_j \quad \text{for each j = 1…, m} \quad (3)$$

$$\sum_{j=1}^{n} x_{ij} \leq M_i \quad \text{for each i = 1…, m} \quad (4)$$

$$\sum_{i=1}^{m} x_{ij} \leq m y_j \quad \text{for each j = 1…, n} \quad (5)$$

$$\sum_{i=1}^{m} x_{ij} \geq P_j y_j \quad \text{for each j = 1…, n} \quad (6)$$

$$x_{ij}, y_{ij} \in \{0,1\} \quad \text{for each i =1…m and j=1 …, n} \quad (7)$$

Figure 1 below, illustrates an example of a problem with an advertising campaign optimization. The matrix represents a solution $S_{|C|x|P|}$ concerning 5 products to offer to 10 customers, so as to optimize the Return on Investment by taking into account business constraints (maximum products to offer for each customer, fixed cost and budget for each product). In summary, this figure represents the offers to be adopted by each customer. The first column on the left, represents the 10 customers who are the subject of the campaign with the maximum product values to offer to each Customer. The first line at the top represents the different product offers with the fixed cost of each product and the budget allocated during the campaign. the values 1 means that product j is offered to customer i during the campaign and 0 if not.

3. Methodology

There are several types of algorithm hybridization; The hybridization used in this paper contains both sequential and parallel hybridization. The sequential one concern using GA in the initialization of a feasible solution. The parallel hybridization is used for perfecting the solution found in each BA iteration by an application of the GA limited in terms of number of iterations.

3.1. Building initial solution using Genetic Algorithm (GA):

One of the very important phases when dealing with the customer targeting problem, is the creation of an initial good quality solution which must be feasible by respecting the business constraints.

$$(P1 - P2 - P3 - P4 - P5)$$

$$\begin{pmatrix} M_1 = 3 \\ M_2 = 3 \\ M_3 = 2 \\ M_4 = 2 \\ M_5 = 2 \\ M_6 = 2 \\ M_7 = 3 \\ M_8 = 2 \\ M_9 = 2 \\ M_{10} = 3 \end{pmatrix} \begin{pmatrix} 1\ 0\ 0\ 1\ 1 \\ 0\ 0\ 1\ 0\ 0 \\ 1\ 1\ 0\ 0\ 1 \\ 1\ 0\ 1\ 0\ 1 \\ 0\ 1\ 0\ 0\ 0 \\ 1\ 0\ 0\ 1\ 0 \\ 0\ 1\ 1\ 0\ 1 \\ 1\ 0\ 1\ 1\ 1 \\ 1\ 0\ 0\ 0\ 1 \\ 1\ 0\ 1\ 0\ 1 \end{pmatrix}$$

Figure 1: A solution example for the optimization problem of customer targeting

The classical initialization of the Bat Algorithm, and which is based on randomization, creates a non-feasible or poor-quality initial solution. To solve this problem, we opted to build the initial solution using GA with a reduced population, and a number of reduced chromosomes. Genetic Algorithms are considered as the most known heuristic technique of search and optimization, and are inspired by natural evolution. They have proven to be effective in several complex problems [3]. GA modeled the decision variable of a search problem by a string composed of alphabets with a certain cardinality. Each chain is considered a candidate solution, and it is called a chromosome, while the alphabets that make up the chromosomes represent the genes. In the problem of marketing campaigns' optimization, a chromosome is considered as a string representation of solutions to the problem. In this kind of problems, the classical GA is imposed and represents the solutions by a bit string. Chromosomes composed of bit strings is a representation formed of genes with binary values allele. These values take 1 if a product is offered to the customer and 0 otherwise. The gene may represent a decision to offer a product j to a specific customer i. The final goal is to optimize the fitness function. It is a calculation which determines to what extent the chromosome can represent a solution to a given problem. GA is also characterized by the notion of population; It treats an artificial population; these are strings in a binary alphabet usually [9]. GA is composed of 6 steps to find an optimal solution for the problem; the objective in targeted offers problem is to maximize the return on investment by finding an optimal solution of equation (1):

1. Initialization

   A randomized procedure is usually used when generating the initial population of the candidate solution. However, if we randomly choose the composition of the chromosomes with a weighting of 50% for each value 0 and 1, we will obtain a non-feasible solution which do not respect the business constraints. For this, we have opted in this paper for a weighting distribution of 80% when a product j is offered to customer i, and 20% when it is not. With this method we have the certainty that our initial solution respects the business constraints but it will not necessarily represent an initial good quality solution.

2. Evaluation

   When the population is initialized first time (population initialized), the fitness values of each candidate solutions are evaluated to determine how fit an individual is.

3. Selection

   The selection is a step that keeps the best solutions by memorizing copies of those solutions with the highest fitness values. This concept imposes the mechanism of maintaining the most suitable among the candidate solutions

4. Crossover

   Crossover is the most impactful phase in GA. It is a phase which consists in combining two or more parent solutions in order to generate a better solution.

5. Mutation

   The GA ensures via this stage a diversity of the population in order to escape a local convergence, by modifying the solution in an arbitrary way while acting locally.

6. Termination

   The algorithm terminates if there is no improvement in the solution quality, when time is reached, or when an acceptable solution is obtained.

The following is a pseudo code of Genetic Algorithm (GA):

Algorithm 1: Genetic Algorithm

```
Randomly create initial population
Calculate the fitness function for all individuals.
while Iteration < MaxGeneration do
        Select the best-fit individuals for reproductions;
        Proceeding to offspring by execution crossover and mutation phases;
        Evaluating the fitness function of new chromosomes;
end while
Return the best solution in the population
```

Figure 2: Pseudo Code of Genetic Algorithm

3.2. Binary version of Bat Algorithm

The Bat Algorithm (BA) is one of the most recent metaheuristic algorithms which uses a technique of imitation of micro-bats behavior to find an optimal solution. Previous work has proven the effectiveness of this algorithm compared to old metaheuristics like Genetic Algorithm (GA) or the Particle Swarm Optimization [8,10]. However, the continuous solutions generated by the BA are not valid for certain types of problem. The objective of our paper is to find a discrete solution (1 when the product "j" is offered to the customer "i" and 0 otherwise). For that reason, in this paper, the use of a binary version of Bat Algorithm is imposed [4]. In order to adapt this algorithm to the context of the Targeted Offers problem in Direct Marketing Campaigns, a binary version of Bat Algorithm will be used and which is proposed by authors [8,10]. This version is called Binary Bat Algorithm (BBA). By modifying the micro-bats positions values from 0 to 1 and vice versa, the BBA moves micro-bats in a binary search space [8, 10]. In [11,2], When designing the BA, author respected the two main techniques used by microbats to find their prey. Micro bats decrease loudness and increase the pulse rate of sound emitted during chase. These characteristics have been modeled as follows [11,2]: Each micro-bat i is characterized by its position pos_i^t, and its velocity vel_i^t at a specific iteration (time). Exploring new solutions is performed by updating positions of micro-bats as following:

$$vel_i^{t+1} = vel_i^t + (x_i^t - Glob^{best})Freq_i \quad (8)$$

$$pos_i^{t+1} = pos_i^t + vel_i^{t+1} \quad (9)$$

$Glob^{bes}$ represents the best solution achieved until this iteration, and $Freq_i$, which represents the frequency of the i-th microbat, is obtained following this equation:

$$Freq_i = Freq_{\min} + (Freq_{\max} - Freq_{\min})\beta \quad (10)$$

where β is randomly generated from a uniform distribution in [0,1]. Thanks to these equations the exploitability aspect is ensured in the Bat Algorithm. However, the exploitation side is guaranteed by a random walk procedure as follows:

$$pos_{new} = pos_{old} + \varepsilon L^t \quad (11)$$

L^t is the loudness of the bats' emitted sound, in order to perform an exploration instead of exploitation. L^t is the average loudness of all the micro-bats at this iteration step: $L^t = \langle L_i^t \rangle$, and ε is a random number in [-1,1] [2,8,9].

To keep balance between exploration aspect and exploitation aspect during the search process, loudness L^t, and pulse emission rate r_i should be updated only if the candidate solution is improved as the iterations proceed. They are updated as following [2,10]:

$$L_i^t = \alpha L_i^t \quad (12)$$

$$r_i^t = r_i^0 \left[1 - \exp^{(-\gamma t)}\right] \quad (13)$$

where α and γ are predefined constants. The search principal in BA, is once a micro-bat has found the prey's location, the loudness will be decreased while the pulse rate will be increased. However, The Bat Algorithm is designed, at the origin, to search in a continuous space of solutions. The algorithm, in its original version is not applicable when the set of solutions is discrete, because during an optimization in a binary search space, by treating only values 0 and 1, the Eq. (9) is no longer valid to update the position of the microbats. To encounter this obstacle, authors in [8, 14] proposed a new solution: the idea is to use a transfer function with the aim of updating the position of micro-bats with the probability of their velocities. In practice the transfer function has the role of mapping velocity values to probability values. In other words, the transfer functions are used to move the microbats in a binary space instead of a discrete space. The most important factor for designing this function is to force micro-bats with high velocities to switch their positions. To do this, a transfer function, called v-shaped function, and position updating rule are proposed in [8,10], and described in Equations (14) and (15) as follows:

$$VEL(vel_i^k(t)) = \left| \frac{2}{\pi} \arctan\left(\frac{\pi}{2} vel_i^k(t) \right) \right| \quad (14)$$

$$pos_i^k(t+1) = \begin{cases} (pos_i^k(t))^{-1} & \text{if rand} < VEL(vel_i^k(t+1)) \\ pos_i^k(t) & \text{if rand} \geq VEL(vel_i^k(t+1)) \end{cases} \quad (15)$$

$pos_i^k(t)$ and $vel_i^k(t)$ are the position and velocity of microbat "i" at the iteration "t", where k is the problem dimension. $(pos_i^k(t))^{-1}$ is the complement of $pos_i^k(t)$. Figure 3 presents the general steps of the Bat Algorithm in its binary version.

3.3. Proposed Hybridized Bat Algorithm

While dealing with the problem of targeted marketing maximization, we note that the Genetic Algorithm takes a considerable time to find a solution but with a minimum chance of blocking in a local minimum, while the Bat Algorithm has the advantage of quickly converging on a solution to the problem. However, BA may easily be trapped in a local minimum. Taking into account the random aspect of the initialization procedures, the two algorithms suffer from the poor quality of the initial solution. To overcome these obstacles, we propose to hybridize the Binary Bat Algorithm, to benefit from convergence in advanced iterations, with the Genetic Algorithm that generates better population from good parents. These results are close to a global optimum.

Algorithm 2: Standard Binary Bat Algorithm

Initializing the population of micro-bats: POS_i(i=1, 2, ..., n)=rand(0 or 1) and VEL_i=0
Define initial pulse frequency value $Freq_i$
while (num_iteration < Max generation iterations) **do**
  Update both frequency and velocities values
  Determining transfer function value by Eq. (14)
  Update micro-bats' positions by executing Eq. (15)
  if (rand > r_i) **then**
    Randomly choice a solution ($Glob^{best}$) among the best solutions.;
    Modifying some of the dimensions of position vector with some of $Glob^{best}$ dimensions;
  end if
  Randomly flying and Generating a new solution
  if (rand < Li and f(posi) > f(Globbest) and Constraint(Globbest)=True) then
  Accept the new solutions;
  end if
  Evaluating the fitness function for all microbats in the population
  Increase r_i and reduce L_i
  Getting $Glob^{best}$ after ranking the micro-bats
end while
Return the best solution.

Figure 3: Pseudo Code of Standard Bat Algorithm

The initial solution in the proposed algorithm is generated by performing the Genetic Algorithm for the first time, with a reduced number of chromosomal parents; this will quickly generate an initial solution of better quality than standard algorithms. The exploration and exploitation are controlled by pulse emission rate, in the case of standard Binary Bat Algorithm [12,13]. By proceeding iterations, this factor takes on larger values, which causes a progressive loss of the exploitation capacity of the algorithm. by introducing linear decreasing inertia weight factor, the exploitation capability of the algorithm is improved while the exploration capability will be improved by the hybridization of both algorithms. Figure 4 presents the steps of the proposed algorithm:

Algorithm 3: Hybridized Binary Bat Algorithm

```
Randomly create GA initial population
Calculate the fitness function for all individuals
while Iteration < MaxGeneration do
      Select the best-fit individuals for reproductions;
      Proceeding to offspring by execution crossover and mutation phases;
      Evaluating the fitness function of new chromosomes;
end while
Return Initial solution to execute Binary Bat Algorithm
Initializing the population of micro-bats: POS_i(i=1, 2, ..., n)=rand(0 or 1) and VEL_i=0
Define initial pulse frequency value Freq_i
while (num_iteration < Max generation iterations) do
   Update both frequency and velocities values
   Determining transfer function value by Eq. (14)
   Update micro-bats' positions by executing Eq. (15)
   if (rand > r_i) then
      Randomly choice a solution (Glob^best) among the best solutions.;
      Modifying some of the dimensions of position vector with some of Glob^best dimensions;
   end if
  Randomly flying and Generating a new solution
  if (rand < Li and  f(posi) > f(Globbest) && Constraint(Globbest)=True) then
  Accept the new solutions;
  end if
  Evaluating the fitness function for all microbats in the population
  Increase r_i and reduce L_i
  Getting Glob^best after ranking the micro-bats
end while
Return the best solution.
```

Figure 4: Pseudo Code of Hybridized Genetic Binary BA (IGBBA)

4. Computational Experiments and Discussion

The proposed algorithm was developed in Matlab 2015on a Lenovo T470s computer Core i7, with 2.6 GHz clock speed and 20 GB RAM. The linear solution was obtained using CPLEX (IBM solution), and the dataset, proposed and generated by author in [5], is used for comparing the three algorithms:

- The cost value c_{ij} may take 1,2 or 3 (Randomly)
- The return of the firm r_{ij} is an integer generated between 0 and 16 randomly.
- The corporate hurdle rate HR can take 5%, 10%, and 15% values.
- In this paper, there are three different values of the number of customers: 100 customers for small category S, 1000 customers for medium category M, and 10,000 customers for large category L.
- For each category of customers, we have two different numbers of product n: 5 and 10 products.
- For each combination (category of customer and number of products), a minimum-quantity commitment bound P_j is randomly generated between $\left[\frac{\sum_i M_i}{n}\right]$ and $\left[2\frac{\sum_i M_i}{n}\right]$.
- The fixed cost fc_j is generated randomly between $\frac{O_j}{2m(1+HR)}\sum_i\left[r_{ij}-(1+HR)c_{ij}\right]$ and $\frac{O_j}{m(1+HR)}\sum_i\left[r_{ij}-(1+HR)c_{ij}\right]$
- For budget B_j, three values are adopted: the two values of $\left[O_j\frac{\sum_i c_{ij}}{m}\right]$ $\left[2\frac{\sum_i M_i}{n}\frac{\sum_i c_{ij}}{m}\right]$ and a random integer between $\left[O_j\frac{\sum_i c_{ij}}{m}\right]$ and $\left[2\frac{\sum_i c_{ij}}{n}\right]$.
- The upper bound M_i is selected between 1 and n/5.

To test the performance of the proposed algorithm, we report the same dataset and conditions from computational experiments in [5] and [6]. The GAP is calculated when a feasible solution is found by the adopted algorithm. By analyzing Table 1, we clearly deduce that the proposed IGBBA algorithm gave better solutions compared to GA and BBA.

The GAPs of IGBBA are significantly lower, and the BBA appears as the second-best algorithm by comparing the GAPs. Figure 5, which is a graphic representation of the fitness function using the three discussed algorithms, shows the fast convergence of the BBA and the IGBBA compared to the Genetic Algorithm. As reported in Table 1, and for the three categories of the S3 format, IGBBA is clearly better than the methods used in the previous works, with a clear difference in performance based on the GAP calculation. However, for the medium and large categories, the IGBBA is considered very competitive and sometimes better than the other algorithms.

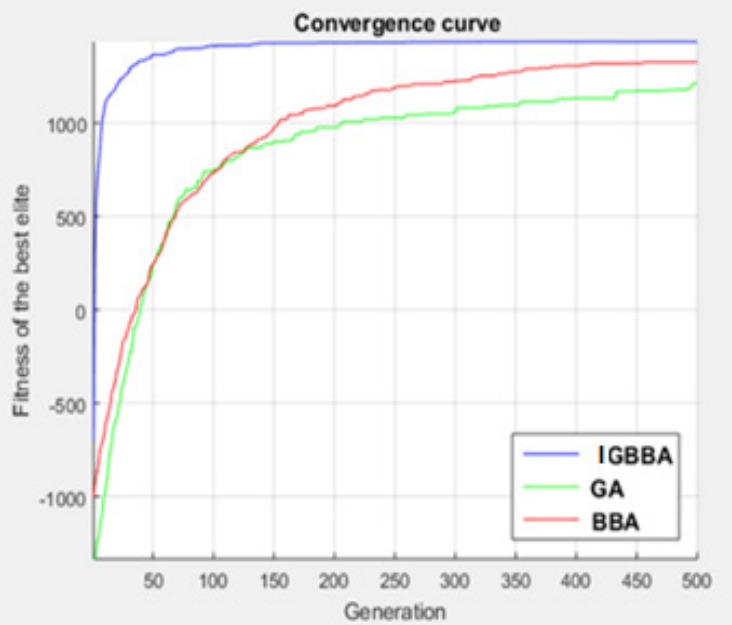

Figure 5: Convergence of fitness function

Table 1: Experiment results

	Small			Medium1			Medium2			Large

5. Conclusion

The BA which is one of the most efficient algorithms was appointed to deal with that type of problem; it was used in binary version given the discrete nature of the solution space. In order to be able to search in a discrete space, a transformation of the positions of the micro-bats, to discrete values, is essential. The hybridization can provide a more efficient behavior and a higher performance when dealing with large-scale problems. This combination carried out in this paper has shown its effectiveness by remedying the disadvantage of the risk of jamming in a minimum local. As extension of our work, new constraints can be proposed, like reducing products costs where customer respond positively to a big number of products or where the number of customers respond positively to a specific product j. On the other hand, an optimization of IGBBA algorithm can be proposed to reduce the execution time. We addressed a very important issue in the marketing strategy of companies in order to optimize their return on investment during advertising campaigns. We have taken up the modeling done by author in [5] with the business constraints that must be respected to maximize the profit of the company. To test its proposal, author, in [5], created a dataset randomly, respecting a certain logic of the upper and lower limits of each parameter; a job that will produce several dataset categories according to different sizes depending on the number of customers, number of products and the value of Hurdle rate. A dataset on which this paper was based to test our proposal and compare it with the results of [5] and the result of other works. Since the problem is considered an NP-hard one, the use of metaheuristics is required; we have treated the problem based on methods based-population differently to the works cited above and which are all based on neighborhood methods.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

This article is a continuation of the work presented in the Third World Conference on Smart Trends in Systems Security and Sustainability (WorldS4). In this version we focus on matching IT and business processes from different management levels by using IT-Governance (ITG) Risk and Compliance frameworks in a smart way. In fact, every information system (IS) has two main interfaces with two key systems: Operating System (OS) and Decision System (DS). Every system has his own frameworks and best practices for efficient management. IT Governance is the ability to control IT strategy implementation by ensuring business and IT alignment for profitable digital services. Also, the variety of IT Governance frameworks for each hierarchical level in the enterprise, should be efficiently deployed together in order to have coherent recommendations for IS, OS and DS users. It is why we use COBIT 5 as a strategic IT Governance framework able to match and integrate other frameworks and best practices dealing with IT services, IT risks and compliance as well. We based the proposed IT GRC smart adviser on artificial intelligence and knowledge management as technical axes. This article presents, IT Governance frameworks, their matching problems and related works. Then it proposes a smart architecture with new functionalities to match COBIT processes with other frameworks in order to cover different management levels. The technical contribution of this article is to propose and implement an IT GRC smart adviser based on many frameworks and best practices to optimize and improve IT Strategies. The simulation was presented, the obtained results were compared to human experts' decisions and big similarities were observed. The aim of this article is to integrate knowledge from many IT GRC frameworks for better IT governance in a smart and easy way.

1. Introduction

Information system Governance is nowadays different from classical management of software and hardware. Many users with different profiles are interacting directly or indirectly with it. They use IS to enrich their data sources through operation systems deployed in different gadgets for simple use. They use it to answer daily questions as well such as production rate, new clients number and providers' expectations. The created data is the most valuable resources ever. It enables CEO and other Business offices to take the right decision. But good IT governance allows to take this decision in the right time through the right IT solution.

The real challenge of top managers is to use digital solution to create value. They should also manage risk, and comply with regulations. The decision is no longer IT responsibility. It achieves business and technical offices as well. The use of one IT governance framework in its document version is no longer enough: It is true that they contain very advanced know-how and feedback, but it requires experts, time and a large budget to take advantage of them. These three elements: time, budget and knowledge are very expensive in the current market due to its severe competition and the law of the most powerful.

As a result, digital tools are mandatory to facilitates the governance of the information system. It is also a need for

*Corresponding Author: Meriyem Chergui, Email: chergui.meriyem@gmail.com

performance management system to ensure the right and efficient use of these frameworks.

Consequently, in this new multi-user, multi-partner environment, the CIO's missions remain information system strategy definition, IT resources management and technical problems resolution as well. Meanwhile, with Big data and cloud computing matters, we notice the emergence of new technical and business risks that should be managed effectively by IT and business together. To perform these tasks, many IT governance frameworks should be deployed in easy to use digital solutions as we did in [1]. But the main problem is how to integrate them in the same personalized repository for every company. How can we design an IT Governance, risk and compliance framework that matches the company's needs with optimal time, minimum budget and good software quality insurance? How can we integrate Data Governance into IT Governance in a fluid and value-creating way by taking in consideration Governance critical success factors [2]?

To answer these question, we propose an intelligent IT Governance model based on COBIT 5 as a business driven repository for corporate and IT governance. In fact, COBIT 5 offers with a common, non-technical and technology-independent language a management framework able to align governance and management standards. By providing a simple architecture to structure guidance documents, Cobit 5 contains knowledge previously distributed in different standards like COBIT 4, Risk IT, Val IT, ITAF and BMIS. It also allows practical matchmaking with different management levels' frameworks like ITIL, CMMI, ISO 27000 family and COSO.

In this article, we propose an update of the smart IT Governance adviser architecture [1] to allow IT services, IT risk management and compliance efficient management, in addition to matching stakeholders' motivations with real business goals [2].

We will add new layers communicating with the semantic model, to link stakeholders and digital solutions via IT Governance ontology designed and created in [3]. We also propose a smart matching between every COBIT process and its correspondence with other frameworks. In IT Governance jargon we call that "Appling a unique and integrated standard principal" for better alignment as presented in [4].

After the introduction in the first section, the second section presents the most pertinent IT Governance Risk and Compliance frameworks and then exposes an overview of their matchings with COBIT 5. The third section gives a brief state of art of Knowledge management as a technical axe. The fourth section analyses briefly related works. The fifth section presents the smart IT Governance adviser updates and the knowledge management system architecture. The fifth section, discusses the new model, its uses and its extensions, the sixth section details the model implementation and results analysis. In the last section, the article is concluded and work perspectives are listed.

2. IT GRC frameworks

In the ITG literature, numerous frameworks are presented, with advantages and limitations of each of them. Thus, each framework offers specific recommendation according to its domain. In practice, ITG should makes these repositories coexist for better results, since they present a necessary complementarily for pertinent decisions. We present some of the main standards in terms of enterprise management, services, projects management and IT security to show how IT governance frameworks drive accountability and process maturity [5]. In what follows, we present the most used frameworks namely ITIL, CMMI, ISO27001 and IT BSC.

2.1. ITIL

IT Infrastructure Library (ITIL), is an approach documentation for IT service management, to support business organizations users. It is created by the British government in 1990 [6]. In 2004, ITIL v2 was created with 9 books, focusing on the link between technology and business, and based on processes to provide the right services to customers. Many companies are using ITIL to improve IT services control and good results are as for processes improvements. ITIL service is a way to deliver value to a customer in an easy way and with low cost and risk. In 2007, ITIL V3 was implemented on five best practice books, offering supplements by sector or by market as well as generic models (process maps). This version is not subject to certification, and it offers continuous improvement of the services offered to IT Department clients. The latest version is ITIL V4. its main advantage is the integration of new agile practices and Devops method. It has developed 34 practices, in 3 themes instead of 26 processes in 5 categories.

- 14 in "General Management practices",
- 17 in "Service management practices"
- 3 in "Technical management practices".

ITIL V4 edition book introduces new like Service Value System (SVS) and the four-dimensional model.

2.2. ISO 27001

ISO 27001 is a framework to implement information security management system (ISMS). Released in November 2005, it also provides a model for operation, monitoring, and review the ISMS. It also enables the creation and implementation of good IT service management, a s presented in [7]. The risk management approach ISO 27001 uses is a top-down and neutral method. It is a planning process with six parts:

- Security policy definition
- WSIS scope definition.
- Risk assessment performance.
- Risk identification.
- Goals and controls implementation
- Applicability declaration.

ISO 27001 deals with responsibility management, internal audit and continuous improvement without specific information security controls. It should be noted that in the accompanying code for each practice, a checklist must be taken into consideration.

The last version is ISO27001 with 2014 and 2015 corrections. It highlights information security management systems requirements with special focus on information technology and security techniques.

2.3. IT Balanced Scorecard

Balanced Scorecard (BSC) [8] is the framework explaining company vision and strategy. It suggests action plans to give internal processes feedback with continues improvement. The BSC, according to its authors Robert Kaplan and David Norton, allows for traditional financial results, but these results highlight the past, which was normal in the industrial era, with long-term investments. There are insufficient customer relationships. These financial elements are insufficient, however, to control companies in the digital age, which should be based on their future value by investing in customers, suppliers, employees, processes, technology and innovation. ". The BSC offers a management tool, organized on four aspects:

- Financial aspect: define the financial benefit provided to shareholders
- Customer aspect: market and customer expectations;
- Internal process aspect: potential improvements to be made to the company's internal processes, which bring value;
- Future construction aspect: mobilization of human resources and infrastructure for improvement and learning.

It is assumed that this approach leads to a good vision of corporate Governance.

2.4. CMMI

The Capability Maturity Model (CMM) [9] is a project management framework developed by the Software Engineering Institute (SEI) of Carnegie Mellon University. It describes software development maturity practices and principals. With an ad hoc path, CMMI proposes to software development organizations a process improvement capability. IT contains a list of models like MM Software, CMM systems engineering and integrated development of CMM products. These models were merged and extended into CMM integration known as "CMMI" with either a stage view or continuous view. As for the staged view, it offers five organizational maturity level (initial, managed, defined, quantitatively managed and optimization). As for the continuous view, it includes six levels of processing capacity (incomplete, executed, managed, defined, quantitatively managed and optimization).

2.5. IT GRC Frameworks matching with COBIT

For better IT Governance, IT department must deal with each task by deploying it in its real context and link it with a project or a process. IT processes are the starting points while governing an information system. For example: deploying an ERP; computer backup organization; servers' security; or new IT supplier integration;

An IT process is defined as a set of activities around a specific event to measure results for customers [10].

While analyzing the IT GRC frameworks before, we remark that process-driven aspect is almost in all them. IT changes approaching components into active components inside the organization. The IT process is measurable in effectiveness and efficiency by defining activities to implement, responsibilities and controls. At this level, each repository focuses on one or more concepts to find more priority and to zoom on either governance risk or compliance.

Meanwhile, process management is highly recommended in the agile environment we are living in. This type of management allows [11]:

- Requirements understanding
- Processes added value;
- Process performance and efficiency measurement;
- Positive communication between stakeholders.
- Top Management easy and measurable decisions.

Technically speaking, IT process is easily designed as a simple or complex function or procedure with inputs and outputs. In this article encapsulate best practices and frameworks processes into computerized executable functions.

a) ITIL –COBIT

COBIT identifies what the CIO should do, ITIL prescribes how it should be done to optimize the use of IT resources. ITIL and COBIT have several common points (for example the BAI10 process in COBIT is equivalent to configuration management process in ITIL).

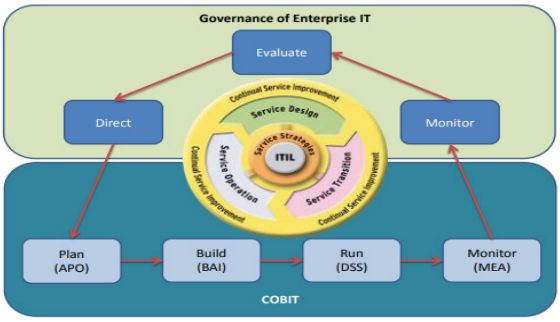

Figure 1: Matching COBIT with ITIL

COBIT 5 proposes the convenient IT investment to link priorities with objectives in both IT and business context (cascade principle). We have already seen it in [1]. The cascade of COBIT 5 objectives makes it possible to align IT objectives and company objectives, which makes it possible to refine and prioritize IT processes. the cascade of COBIT 5 objectives allows stakeholders to answer the following two questions:

- How to prioritize areas of interest when applying ITIL v3 processes?

- How to define the right maturity level and the efficient processes for better business decisions?

One last thing, COBIT 2019 is also correctly matched with ITIL v4 which allow us to upgrade our system regarding future IT GRC Frameworks versions.

b) CMMI –COBIT

Traditional mapping is designed to be used in one direction. Indeed, a user searching for an element in COBIT model finds the element or elements linked to the appropriate CMMI model. Others by the reverse probably exist in several places on the map (several elements of CMMI for a COBIT element) which is not easy to isolate to determine what is linked exactly. These traditional cards are unidirectional and they are valid for the correspondence of all IT GRC repositories. In this perspective, COBIT 5 CMMI Practices Pathway Tool, has emerged as a common Excel tool made by ISACA and CMMI, intended for users who want to navigate freely from COBIT 5 to CMMI and vice versa[12]. The dynamic and permanent correspondence between CMMI and COBIT makes it possible to limit maturity in the different levels of governance, which allows self-assessment and continuous development.

c) ISO27001 -COBIT

There is a mapping between COBIT 5 and ISO 27001 domains: “COBIT 5 for information security” this repository presents a mapping guide aiming at implementing the domain area of COBIT process with ISO27001 controls[13].

3. Knowledge Management

3.1. Definition

Knowledge Management (KM,) is a multidisciplinary research area offering methods, techniques and assistant tools: creation, acquisition, sharing and use of knowledge in an organization, with a view to 'improve individual, collective or organizational learning [14]. Knowledge is defined in a complementary way by raising one of his systemic aspects namely:

- Ontological (what is knowledge),
- Functional (what it does),
- Genetics (genetics here has the meaning of genesis not inheritance)
- Transformational (where it comes from and what it becomes)
- Teleological (why).

In artificial intelligence context, different types of knowledge are identified:

- Procedural knowledge to explain how can we solve a given problem is solved. It indicates how to complete a task;
- Declarative knowledge: it is statements describing objects and concepts and focusing on problem resolution indications.
- Meta Knowledge is specific domain knowledge explanation. For example, what is suitable at a given situation e to solve a given task;
- Heuristic knowledge: also called surface knowledge. It is empirical knowledge acquired by an expert through his past experience, it is used to guide reasoning;
- Structured knowledge: describes a mental model of the expert in the form of a structure (concepts, sub-concepts, objects, etc.).

3.2. Design methods

There are 3 approaches of Knowledge management modeling:

a) Bottom-up modeling approach:

The bottom-up or data-driven approach is based on a step of elicitation of expert knowledge (interviews, document analysis, task analysis, etc.) followed by a conceptualization step. Example: KOD and MIKE [14]. One of the advantages of the bottom-up approach is that it leaves experts free to express their perceptions and their tasks without constraining them. In addition, developed models correspond to existing points of view. However, the high cost in terms of time and expertise in the elicitation process, the difficulty of re-use as well as the complexity of the validation process are major drawbacks of the approach.

b) Top-down modeling approach:

This approach is called Model-Driven Approach. The development of knowledge models in this approach consists of finding pre-existing generic models and adapting them to the field and the application concerned. Two sub-approaches can be distinguished in this family: the select-and-modify approach and the modeling-by-composition approach from library elements. Example: CommonKADS [15], MASK [16]. The main advantages of this approach in addition to providing a support for knowledge acquisition are models generality and reusability. But adapting an existing model to a specific application is a very difficult task. In the literature, we also find mixed approaches which tried to take advantage of the two approaches like [17] and [18].

3.3. COBIT knowledge Base

Applying a single integrated framework is the third principle of COBIT 5 that proposes a knowledge management for COBIT alignment with other standards and frameworks for enterprise complete coverage. As shown in figure 2, Cobit 5 has a knowledge base of current guidance and contents collected from old versions and other standards and frameworks. This knowledge base enriched by enablers such as data, IT processes, resources and ethics allow different stakeholders to find answers to their questions about best practices to deal with different IT Governance situations in different levels (strategy, services providing, risk management…etc.). In fact, simplicity, guidance materials structuring and consistent production are the main advantages of this architecture that integrates different frameworks. knowledge in one shot [19]. IT Governance repositories are a set of knowledge sources capitalized by experts for better Information system management in different types of organizations. In this perspective, we are working on a smart IT Governance Knowledge

Management system that will be interfaced with the adviser in future version.

4. Related works

To assess the state of art of IT GRC platforms, a rigorous evaluation of the fourteen main suppliers [20] is presented in table 1. A comparison of the strengths of each of the solutions was established from the Forrester description, functionalities presented on the official sites and the demos available on the net, as long as the solutions are all proprietary.

Table 1: GRC existing platforms

Vendor	Product	Version	Strong points
ACL	ACL	ACL Analytics 12.5 ACL Analytics 12.5 Exchange 6.5	- Financial control analysis and testing -Audit solution - Community of practitioners -Simple user interface, mobile support and analytical integration.
Enablon	Enablon 8	V8.4	-Operational risks - Legal and regulatory aspect - Environmental, health and safety management - Corporate social responsibility initiatives, litigation, a responsible supply chain, air quality management or public service data.
IBM	IBM Ope,Pages	V7.3	-Financial control management -Operational risk management
LogicManager	LogicManager	V17	-Humain advisors availability
			-Fastest average deployment times
MetricStream	MetricStream M7 GRC PLatform	V7.0	-Energy, health care, insurance, food and beverage and automotive -Good user interface
Nasdaq	BWise	V5	-Middle market and information security organizations
NAVEX Global	PolicyTech NAVE Engage RiskRate EthicsPoint	Sep 1, 2017 July 31, 2017 August 30, 2017 August 15, 2017	-Compliance -Data Management
Riskonnect	Riskonnect Integrated Risk Management	GRC 2017.2	-Support 72 languages -GRC workflow and dashboards -Adapted to Salesforce.com clients
RSA Archer	RSA Archer	V6.2	- IT GRC - Financial risks and regulatory change management
Rsam	Rsam GRC	V9.2	-Data collection from different platforms -Risk analysis and management
SAI Global	Compliance 360	Sept 7, 2017	-Health care and IT GRC
SAP	SAP solutions for GRC	V10.1	- Big data and predictive analytics -Audit tool
ServiceNow	ServiceNow GRC	Jakarta	-IT Services management -IT GRC -Risks to information security and IT operations
Thomson Reuters	Thomson Reuters Connected Risk	Sept 7, 2017	-Risk and Compliance -Financial control management -Managing regulatory changes

The comparative analysis and the measurement of the effectiveness of these solutions in relation to the ITG dependency factors allow us to deduce that:

- In most cases, it is GRC solutions without IT GRC functionalities,
- The majority of these solutions even if they have IT GRC functionalities, it is ERP solution module to be deployed with the rest of the modules.
- The cost of setting up is high (by consulting the list of their references on the market and their targets).

- Need for external advice for better operation (possibly advice from the seller of the solution).
- There is a discrepancy with regard to the ITG implementation in the IS of various companies (size, turnover, type, maturity, location, etc.).
- They do not concern all of Information System stakeholders and all areas of the company at the same time.

5. Proposed model

This project started by EAS team [21] to propose an IT GRC digital solution with five intelligent modules for business and IT alignment by mapping processes. It also manages IT risks and measures business impacts. This was done by choosing for every process the right framework(s). There were many limitations for this architecture namely as far as execution time is concerned and also many communication problems among distributed systems which cause the decrease of IT Governance service's quality. IT is the reason why in[1], we implement the strategic level via a smart advisor to optimize the IT Governance semantic model. This solution main advantage was the "All in one" service and the easy use for final users. The advisor is a simple chatbot to which IT manager, Business Manager, CEO or even a project manager can ask IT Governance questions and he is answered simply and quickly.

In this version, we kept the same semantic engine model that interprets user real time questions using test mining. The same IT Governance ontology [3] to match concepts and relations but we replace our knowledge base by COBIT knowledge base. Cobit knowledge base, as shown before, is fed by Cobit but also the other repositories (ITIL, CMMI and ISO27001 at first) with processes matching.

This change allows the semantic engine not only to answer via Cobit guidelines but also ISO27001 for risk management, ITIL for services Governance and CMMI for IT project management in implicit way. The unique Knowledge base improves the performance of the system and ensures the efficiency of responses by arriving at a more delicate granularity for each process.

Indeed, the smart adviser is mainly made of an expert system applying cascading principles (1st principal of Cobit 5) to unify objective and value creation definition among different stakeholders. By updating the semantic engine, we also unified guidelines in hierarchical way.

Every stakeholder will find deeper guidelines depending on what he is asking for: a top manager will be satisfied by Cobit suggestions but CIO or a business manager will need more details that he will find properly in ISO27001, ITIL or even CMMI. So, by deploying the cascading principle and the single unified principle, the IT GRC smart adviser deep dive enterprise needs to suggest more operational recommendations.

The business driven architecture has a chatbot to ask stakeholder questions about eventual risks, resources management, value creation…etc) according to users' answers the smart advisor cascade his business request into enterprise goals. Then, depending on the questioned profile, the smart advisor asks for more details to match enterprise goals with IT goals.

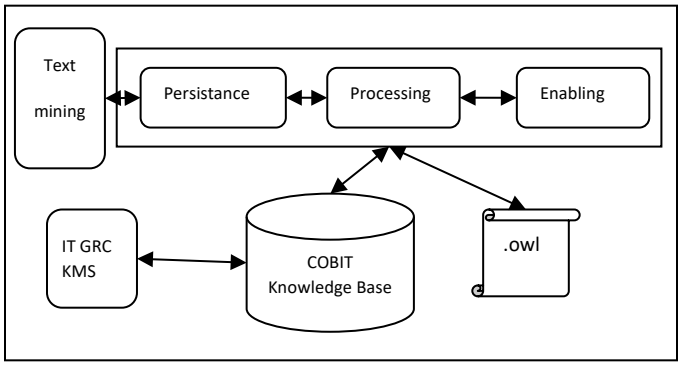

Figure 3: Semantic engine update

Every company description and characteristics should be previously configured in the knowledge base facts to define IT Governance road map. The proposed solution also allows cascading IT decision according to COBIT 5, through the semantic engine as shown in figure 2. After that, IT related goals are matched to enablers in a new abstraction level compared to [13]. The proposed semantic engine is now a five layers' system:

- Text mining layer annotate stakeholder answers.
- Persistence component storages stakeholder needs in the knowledge base
- Processing component compares stakeholder's request to Cobit 5 suggestions from knowledge base.
- Enabling component chooses the best facilitator (s) to implement.
- IT GRC KMS is a knowledge management system to feed Cobit Knowledge base with matched processes and guidelines.

As for Cobit Knowledge base, it is the set of rules and facts related to each COBIT process and domain one by one with: CMMI, ISO27001 and ITIL. In this level we are not updating the ontology since the system will interpret user questions through COBIT cascading.

6. Discussion

In previous work [1], The smart adviser contains a matchmaker agent between the semantic engine described above and IT GRC business driven configuration.

The matchmaker verifies first the company static parameters to initiate the IT GRC road map. It also enables the stakeholder to ask questions and have answers from the semantic engine in Chatbot way. Meanwhile, matchmaking research and priority algorithm detailed in [22] match every request with best guidelines according to a corresponding rate. The indexing algorithm does the following:

- Text indexing according to the words that compose it.
- Similarity test with inverted index.
- Returning similar texts with rank for every user query.
- Knowledge extraction from Cobit Knowledge Base.

Table 3: Proposed solution and state of the art comparison

Solution	Simple user interface	Risks management	- Legal and regulatory aspect	Human adviser	Deployment times	information security	IT GRC	Workflow and dashboards	Data management
ACL	X								
Enablon		X	X						
IBM		X							
LogicManager				X	X				
MetricStream	X								
Nasdaq						X			
Riskonnect	X							X	
RSA Archer		X	X				X		
Rsam		X							X
SAI Global							X		
SAP								X	X
ServiceNow		X	X				X		
Thomson Reuters		X	X						
NAVEX Global			X						X
Proposed solution	X	X	X	X	X	X	X	X	X

The smart advisor update is done in this step: Once similarity ranks are fixed, an inference engine questioned the rules base according to a maximization algorithm. The rules base communicates simultaneously with the fact base and the inference engine to give the convenient answer according to COBIT first and later to ITIL, CMMI and ISO27001 (see figure 3). The answer is returned to the matchmaker agent who sends it to the active adviser. One last thing is that two or three advisors could be handled for the same request successively for IT Governance, risk management or project management as well.

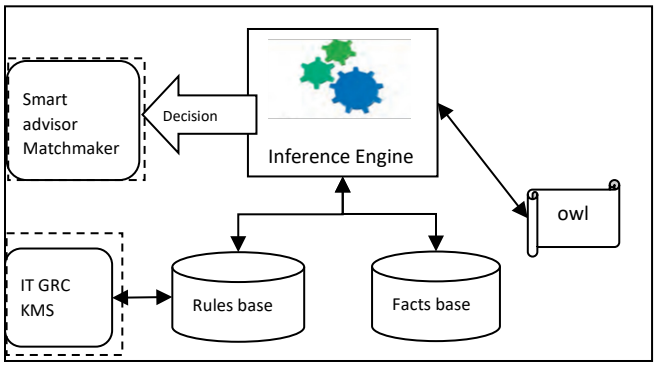

Figure 4: Cobit Knowledge Base architecture

In table 2 we compare the proposed IT GRC smart adviser to solutions presented in table 1:

To summarize, the update of the smart IT Governance adviser understand stakeholders' needs by annotating their questions and finding answers in Cobit 5 cascading model, via a text mining layer. This component is mainly managed by the processing entity connected with the Cobit knowledge base to confront them at this last base of rules to elaborate a roadmap with many granularity levels (IT Governance, risk management, services managements and IT project management. Cobit knowledge base is mainly made of facts bases and rules base linked to IT GRC Knowledge management system (that we will detail in a future work). Rules base is regularly actualized through IT GRC new repositories and expectations. As for Facts base, it is actualized by the organization information system parameters. The inference engine feeds the smart advisor with the appropriate decisions after semantic analysis and primitive matching. In addition, for every level facilitator implementation is also given, with a balanced squared card dimension, the result road map enables a prioritization of processes implementation.

As for the processing and analysis steps compared to [1], we:

- update the semantic engine,
- implement the COBIT knowledge base,
- link the KB with the matchmaker agent,
- implement the chatbot
- annotate answers
- test the adviser
- compare its results with a human expert's decisions
- evaluate the adviser performance

7. Implementation

To validate experimentally the proposed architecture, we implement and improve different versions of the platform. Let's give an overview of the IT Governance platform evolutions:

The first and second versions were java simulators, the third, fourth and fifth version were web application where, in addition to the proposed functionalities, communicate with the global EAS-IT GRC platform[23]. In the first version, we simply validated the communication of different intelligent agents with predefined business goals. In the second version[24], we added to the first version kernel, the knowledge base where we stored the basic information and the different mediation rules and we implemented an agent launch interface to simulate exchanges. We have carried out tests to validate results. In the third version, we have implemented almost all of the features offered with interfaces of potential users;

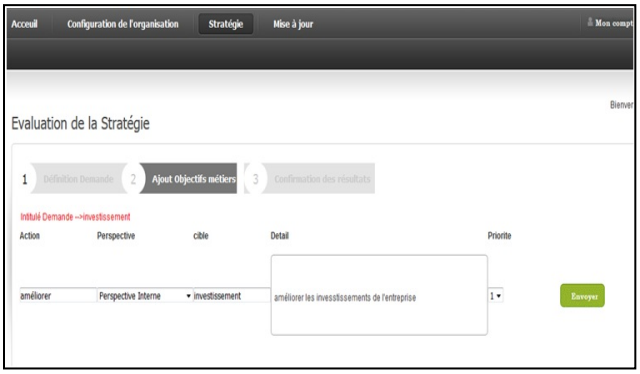
- IT Governance Ontology of information systems governance that we deployed in the mediation layer for the interpretation of offers and requests;
- Global comparison algorithm to improve the expert mediation system;

- Update repository with version 5 of Cobit;
- Request logging and learning to develop the proposed offers.

As for the fourth version presented in [1], we simplify user web interface and encapsulate IS Layer in a configuration agent for better device coordination in multiple access case. We also optimize the semantic engine model, to extract IT Governance knowledge.

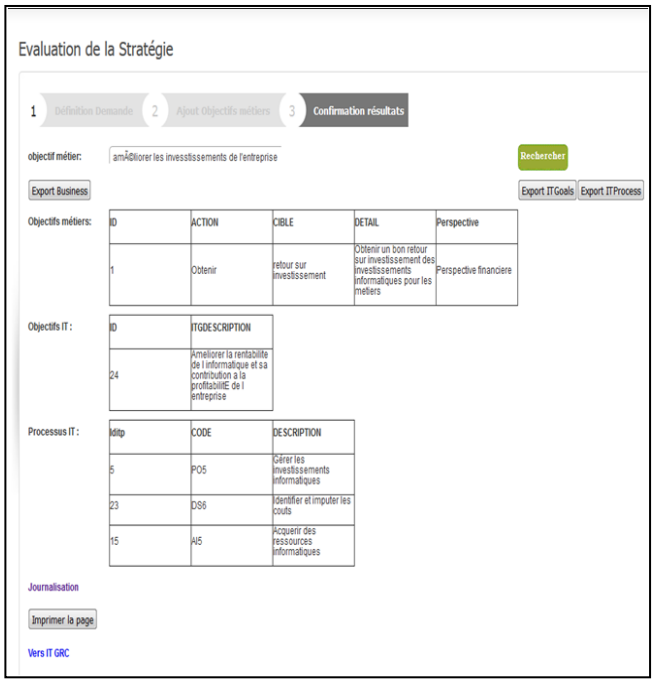
In the fifth version, presented in this paper, we add two main contributions namely the semantic engine knowledge management updater and the knowledge base detailed architecture.

Here is the fifth version IT Governance user query interface:



After a secure authentication and configuration questions interface, figure 5 shows user requests about the IT strategy or business strategy related to digital issues. An order of priority for every request is defined by the user (value from 1 to 5).

Figure 6 shows results as recommended business objectives, IT objectives and IT processes to focus on. A report is generated with other details such as facilitators, controls and metrics, maturity models, key activities and the responsibility matrix.

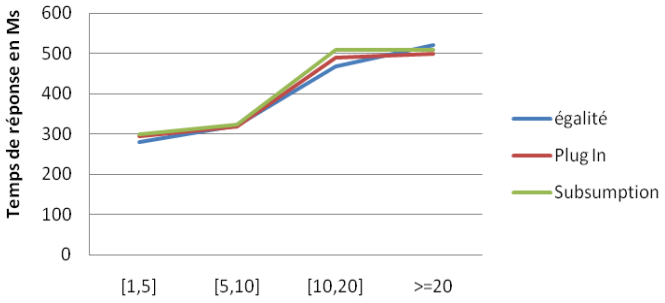


The application presents the detail of the request and the corresponding offers before allowing the user to edit the report, this primary summary allows him to decide whether it is necessary to start detailed ITG processing or obtained results are sufficient.

Many functional tests have been done. The corresponding framework of every objective is calculated via the priority function of the semantic engine. It also depends on the attribute and search criteria in the knowledge base. Let's compare as example the results of the platform with experts' decision about the request: "obtain relevant information and make strategic decisions in relation to risks" (experts proposed framework is ISO27001).

The results of the platform are presented in table 3. The request corresponds to several business objectives (OB). Each OB is detailed on one or more IT objectives and each IT objective is explained with several IT processes. According to results in table 3, we can deduce that the adviser chooses ISO27001 like the expert. IT objectives are recommended with priority gap due to semantic engine priority calculation; an IT Objective could be proposed by the expert but appears in the solution with a lower priority value.

As for evaluating the adviser response time to enhance its performance to give business managers rapid recommendations. It was made on a PC with Windows 10 operating system Intel Core i7 processor, 2.66 GHz and 16 GB of memory. Three comparison matchmaking modes were tested, namely equality, plug-in and Subsumption. We varied the number of requests according to four intervals [1, 5] [5, 10] [10.20] and> 20. The number of results per request were also taken into consideration.



Obtained results are presented in figure 7. The adviser is efficient since obtained results are in milliseconds. Governance advisor [1] is then presented trough a smart semantic model updater with IT Governance knowledge system architecture to deal with frameworks matching problem. These two contributions were added to implement other IT Governance frameworks for a 360° IT Strategy view: strategic alignment, risk and resources management, performance management and compliance. We chose COBIT 5 as IT Governance generic framework and semantic Web, and knowledge management as technical background to implement this solution.

As for limitations, the actual version of IT GRC adviser does not deep dive compliance recommendations. Compliance processes design should be done according to regional regulations. The same remark is available for specific risks namely financial and health risks analysis. As for the state of progress and perspectives of this work, we are working on:

- IT Governance Knowledge management system
- Functional tests and proof of concepts.

These perspectives enable the IT GRC advisor to be more performing so as to achieve industrialization level. The difference is also minimal between the 3 matchmaking mods which means that it is indifferent to requests complexity. The correlation of response time with requests number is linear per part, which means the algorithms complexity is reasonable with the increase of iterations.

8. Conclusion and perspectives

In this article, we raise IT Governance frameworks matching problem. After an introduction, we present IT Governance frameworks and their correspondences with COBIT5 as strategic level repository. We also listed existing IT Governance platforms with their strong and week points analysis. An update of the IT Governance advisor [1] is then presented trough a smart semantic model updater with IT Governance knowledge system architecture to deal with frameworks matching problem. These two contributions were added to implement other IT Governance frameworks for a 360° IT Strategy view: strategic alignment, risk and resources management, performance management and compliance. We chose COBIT 5 as IT Governance generic framework and semantic Web, and knowledge management as technical background to implement this solution.

As for limitations, the actual version of IT GRC adviser does not deep dive compliance recommendations. Compliance processes design should be done according to regional regulations. The same remark is available for specific risks namely financial and health risks analysis. As for the state of progress and perspectives of this work, we are working on:

- IT Governance Knowledge management system
- Functional tests and proof of concepts.

These perspectives enable the IT GRC advisor to be more performing so as to achieve industrialization level.

ABSTRACT

In order to balance the power in intelligent distribution networks (Smart Grid or Microgrid), it is proposed to organize a «multi operated virtual power plant». The resources of active and reactive power for which can be obtained using an AC voltage controller with a phase-angle control for regulation of operating modes of the ohmic load of consumers, for example, distributed systems of electric space heating or electric water heating, etc. A method is proposed and the results of the analysis of the phase-angle control modes by gate turn off (GTO) thyristors of the AC voltage regulator, which provides the generation of virtual reactive power by consumers of active power, are presented. The process equipment of such a virtual power plant is fully suitable both for the dynamic production of a virtual resource of active power to balance, for example, the power of dynamic distributed renewable energy sources (virtual power plant (VPP) mode), and to regulate reactive power to ensure adequate voltage levels and increase stock stability of operation of electric load units (virtual reactive power plant (VRPP) mode). References 24, figures 8.

1. Introduction

This article is an extension and continuation of the work presented in the materials of the IEEE conference [1], which shows the possibility of power electronics to obtain a resource of reactive power from consumers-regulators with an active nature of consumption. Improving the efficiency of power supply, development in the direction of intellectualization according to the concept of Smart Grid is based on modern advances in power electronics [2-4].

In addition to balancing active power with frequency stabilization, an important operational task in Smart Grid systems is to ensure proper voltage levels in power grid units, increase the stability margin of power generation and consumption systems, and optimize operating costs in the transportation and distribution of electricity.

The basis for solving these problems is to ensure the balance of reactive power in the system, the availability of appropriate resources and the ability to quickly involve them at different levels of transmission, conversion and distribution of electricity [5, 6]. In the Smart Grid concept, the problem of reactive power compensation is highlighted as key. Different methods of reactive power compensation are considered in [7, 8].

*Corresponding author: Mykhailo Korchak., misha.korkirov@gmail.com +380981712257

The universal and most efficient centralized source of reactive power at present is the Static Compensator (Statcom) device [9], which is primarily intended for flexible power transmission systems or powerful industrial power supply systems.

Problems of using Statcom in low-voltage networks and their interaction with distributed energy sources are considered in articles [10,11], where special attention is paid to the use of photovoltaic inverters as reactive power sources.

In [12-14], the use of static compensator D-STATCOM for unbalanced radial power distribution systems is investigated in order to ensure voltage stability within acceptable limits. This review of known works addresses issues related to the optimal choice of power, control methods, installation location, etc. of reactive power sources as physical objects installed by the power supplier. However, currently in the Smart Grid an important role is given to virtual energy sources

In the classical sense, a VPP is a distributed power plant that combines the resources of active power generation from distributed energy resources (DER) as a reserve at the disposal of transmission and distribution operators [15]. VPPs in Microgrid are able to increase resource efficiency and maintain the necessary balance of generation and consumption in the power system. Distributed renewables and drives in VPPs are not virtual but real

resources. In fact, virtual (feigned) generation of electricity will be equivalent to refusing or limiting its consumption. For example, by integrating water heating or electric heating systems into a grid and remotely controlling them with electricity consumption, you can align the active power consumption schedule at a particular distribution network node without significant consequences for household or industrial consumers themselves.

Another possibility is the participation of customers in virtual power plants to provide reactive energy. [16-20] discusses the provision of reactive power services from DER using a market mechanism and a plan to convert Microgrid into VPP, which is beneficial for consumers, prosumers and utility operators.

Involving distributed sources to solve the problem of reactive power balancing, by analogy with a virtual power plant, can be combined into virtual reactive power sources. In [21, 22] the problem of reactive power is not allocated separately but included in the list of tasks for the organization of VPP. [23] presents the concept of a dynamic VRPP as an ancillary service to reasonably combine decentralized power distribution sources into a coordinated pool to provide reactive power for the needs of power transmission system operators. Common in the known concepts is the involvement in the VRPP real distributed sources of reactive power.

2. Purpose and task of the research

The aim of the work is to study the problem of balancing active and reactive power in distribution networks with the involvement of consumers' resources in the form of integrated virtual power plant (VPP-VRPP), where reactive power resource is obtained by regulating the receivers used for VPP**.** This is especially true for facility power systems that are not encouraged to install their own sources to compensate for reactive power.

The ranges of complex regulation by means of power electronics of consumers with active character of loading for reception of a virtual resource of active and reactive power by regulation according to needs of operators of power supply systems are substantiated in the work.

3. Finding a solution to the problem

Figure 1 shows the equivalent circuit diagram of one phase VPP-VRPP, which shows the AC voltage regulator, which includes a source of sinusoidal voltage with internal inductance, a block of power dual-operation (GTO) thyristors VS1 and VS2, a limiting diode suppression diode) VD, as well as resistive resistance R of water heater or electric heating.

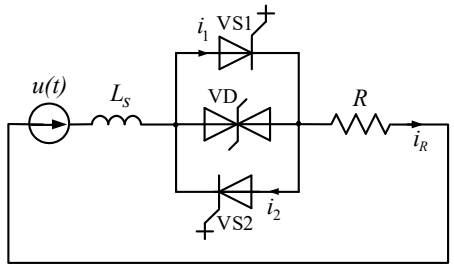

Figure 1: Equivalent power supply circuit of the heater

To protect against the effects of rigid switching of thyristors inductive overvoltage emissions in the interval between the closing of the thyristors, a two-way TVS diode VD is designed.

To obtain the energy characteristics in the steady state VPP-VRPP, we assume that the thyristors VS1, VS2 are ideal switches, not taking into account the diode VD, inductance $L_S = 0$, and voltage of the power supply system is sinusoidal as shown in (1)

$$u(t) = U_m \sin(\omega t + \varphi_u) \quad (1)$$

where U_m is power supply voltage amplitude; φ_u is the initial phase of the supply voltage; ω is angular velocity.

To obtain the power in the circuit of the resistor, controlled by key semiconductor elements, we have to analyze two characteristic modes.

3.1. Mode of consumption of virtual reactive power from the power supply network.

This mode is characteristic for traditional single-operation (semi-controlled) thyristors or SCR (Semiconductor Controlled Rectifier). For its realization thyristors VS1 and VS2 is being opened by the controlling impulses with a delay of an angle α relative to the natural angle of their entry into operation $\alpha_0 = 0 \pm \pi k$, where $k = 0, 1, 2\ldots$, and closing them at the natural time of closing $\beta_0 = \pi + \pi k$ (Fig. 2).

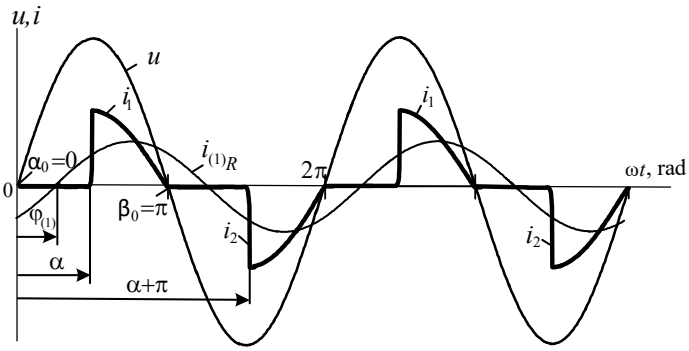

Figure 2: VRPP current and voltage time diagrams in the mode of reactive power consumption

As a result, we obtained the shift of the main harmonic of the source current $i_{(1)R}$ towards the delay relative to the voltage of the grid. It is equivalent to the consumption of virtual reactive power by electrical circuit, in which reactive elements are not presented.

It should be noted that the value of the reference times of the thyristor control angles (natural value of the angles of opening and closing of the thyristors) are characteristic of the purely active nature of the circuits with key elements.

To evaluate the energy effect of the above method of regulating the operation of the electric receiver, we decompose the current i_R in the Fourier series. *n*-harmonic component of the relative current is descripted in expression (2)

$$i_n(\omega t) = I_{nm*} \cdot \sin(n\omega t + \varphi_n) \quad (2)$$

can be obtained as (3)

$$I_{nm*} = \frac{I_{nm}}{I_b} = \sqrt{A_{n*}^2 + B_{n*}^2} \tag{3}$$

where I_b is the current amplitude in the mode of full conductivity of thyristors according to (4)

$$I_b = I_{m,R} = U_m / R \tag{4}$$

A_{n*} and B_{n*} are the coefficients for the decomposing to the Fourier series is written using (5) and (6):

$$\begin{aligned} A_{n*} &= \frac{1}{\pi}\int_{\alpha}^{\pi} i_R(\omega t)\cos n\omega t\, d(\omega t) + \frac{1}{\pi}\int_{\pi+\alpha}^{2\pi} i_R(\omega t)\cos n\omega t\, d(\omega t) \\ &= \frac{1}{2\pi}\left\{\frac{\cos(n\pi)+\cos\left[(1-n)\alpha\right]-\cos(2n\pi)+\cos\left[(1-n)(\pi+\alpha)\right]}{1-n}\right. \\ &\left.+\frac{\cos(n\pi)+\cos\left[(1+n)\alpha\right]-\cos(2n\pi)+\cos\left[(1+n)(\pi+\alpha)\right]}{1+n}\right\} \end{aligned} \tag{5}$$

$$\begin{aligned} B_{n*} &= \frac{1}{\pi}\int_{\alpha}^{\pi} i_R(\omega t)\sin n\omega t\, d(\omega t) + \\ &\frac{1}{\pi}\int_{\pi+\alpha}^{2\pi} i_R(\omega t)\sin n\omega t\, d(\omega t) \\ &= \frac{1}{2\pi}\left\{\frac{-\sin\left[(1-n)\alpha\right]-\sin\left[(1-n)(\pi+\alpha)\right]}{1-n}\right. \\ &\left.+\frac{\sin\left[(1+n)\alpha\right]+\sin\left[(1+n)(\pi+\alpha)\right]}{1+n}\right\} \end{aligned} \tag{6}$$

For the 1st harmonic ($n=1$) obtained equations (7) and (8):

$$A_{1*} = \frac{1}{2\pi}\left[\cos(2\alpha)-1\right] \tag{7}$$

$$B_{1*} = \frac{1}{2\pi}\left[\sin(2\alpha)+2(\pi-\alpha)\right] \tag{8}$$

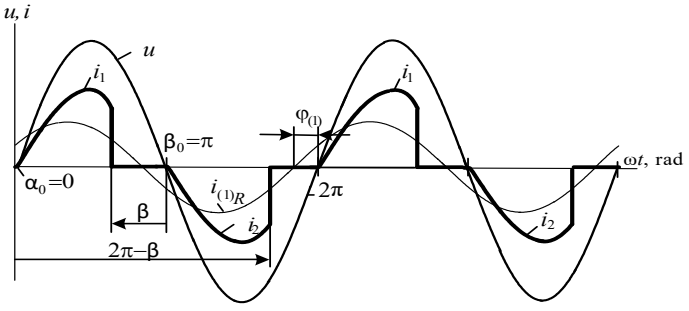

Figure 3: VRPP current and voltage time diagrams in the mode of reactive power generating

3.2. Mode of virtual reactive power generation in the power supply network.

This mode is dual to the previous one. For its realization thyristors VS1 and VS2 is being opened in the natural moments of their entry into operation $\alpha_0 = 0 + \pi k$, where $k = 0,1,2\ldots$, and closing with an advance on the angle β relative to the natural angle β_0 of closure (Fig. 3). As a result, we obtained the shift of the main harmonic of the source current $i_{(1)R}$ in the direction of advance relative to the grid voltage, which is equivalent to generation of reactive power by resistance into the power supply system.

The formulas obtained by the authors for the decomposition coefficients in the Fourier series of the resistor current take the form (9) and (10).

$$\begin{aligned} A_{n*} &= \frac{1}{\pi}\int_{0}^{\pi-\beta} i_R(\omega t)\cos n\omega t\, d(\omega t) \\ &+\frac{1}{\pi}\int_{\pi}^{2\pi-\beta} i_R(\omega t)\cos n\omega t\, d(\omega t) \\ &= \frac{1}{2\pi}\left\{\frac{1-\cos\left[(1-n)(\pi-\beta)\right]-\cos\left[(1-n)(2-\beta)\right]-\cos(n\pi)}{1-n}\right. \\ &\left.+\frac{1-\cos\left[(1+n)(\pi-\beta)\right]-\cos\left[(1+n)(2\pi-\beta)\right]-\cos(n\pi)}{1+n}\right\} \end{aligned} \tag{9}$$

$$\begin{aligned} B_{n*} &= \frac{1}{\pi}\int_{0}^{\pi-\beta} i_R(\omega t)\sin n\omega t\, d(\omega t) \\ &+\frac{1}{\pi}\int_{\pi}^{2\pi-\beta} i_R(\omega t)\sin n\omega t\, d(\omega t) \\ &= \frac{1}{2\pi}\left\{\frac{\sin\left[(1-n)(\pi-\beta)\right]+\sin\left[(1-n)(2\pi-\beta)\right]}{1-n}\right. \\ &\left.-\frac{\sin\left[(1+n)(\pi-\beta)\right]+\sin\left[(1+n)(2\pi+\beta)\right]}{1+n}\right\} \end{aligned} \tag{10}$$

For the 1st harmonic ($n=1$) we obtained equations (11) and (12):

$$A_{1*} = \frac{1}{2\pi}\left[1-\cos(2\beta)\right] \tag{11}$$

$$B_{1*} = \frac{1}{2\pi}\left[2(\pi-\beta)+\sin(2\beta)\right] \tag{12}$$

4. Generalization of the results of the analysis of control regimes

In both of the above modes of thyristor control with a change in the value of the control angles and there is a simultaneous change in both active and reactive power, the value of which can be calculated by expressions (13) and (14).

$$P_{1*} = \sqrt{A_{1*}^2 + B_{1*}^2}\cos(\varphi_{1u} - \varphi_{1i}) = I_{1m*}\cos\varphi_1 \tag{13}$$

$$Q_{1*} = I_{m1}\sin\varphi_1 \tag{14}$$

where, P_{1*}, Q_{1*}

$\sqrt{A_{1*}^2 + B_{1*}^2} = I_{1m*}$ – the amplitude of the fundamental harmonic of the current, $\varphi_1 = \arctan(B_1/A_1)$ – the initial phase of the fundamental harmonic of the current, and $\varphi_{1u} = 0$.

Figure 4 shows the results of the calculation of VPP-VRPP control characteristics by reactive power. The maximum generation of reactive power is $|Q_{1*}| \approx 0,32$ p.u. different signs are reached at the control angles of the boards $\alpha = \beta = \pi/2$. In case of regulating the VPP-VRPP by changing the opening angles $\alpha = \text{var}$ of thyristors and constant closing angles $\beta = \text{const} = 0$ from the mains consumes excess reactive bias power ($Q_1 > 0$), and by constant angles of thyristor opening ($\alpha = \text{const} = 0$) and adjusting the angle $\beta = \text{var}$ change we get the mode of generating reactive bias power to the mains ($Q_1 < 0$).

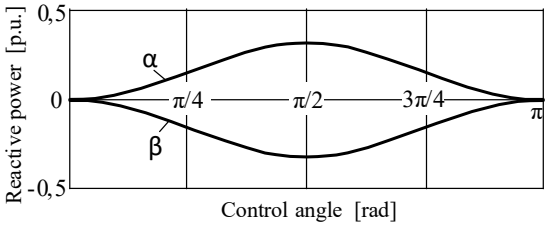

Figure 4: VPP-VRPP control characteristics by reactive power

The obtained characteristics are symmetric with respect to the angle $\alpha = \beta = \pi/2$, but in the mode of reactive power control the preference should be given to the range of angles $\alpha = \beta = 0 \ldots \pi/2$ of regulation of the boards, because in the range of angles $\alpha = \beta = \pi/2 \ldots \pi$ we get a significant harmonic current distortion (Fig. 5)

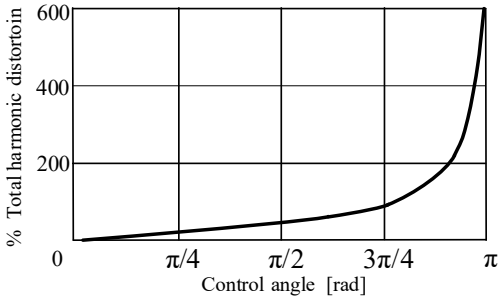

Figure 5: Coefficient of harmonic current distortion

Calculated by expression (15)

$$THD_I(\%) = \frac{I_{dis}}{I_1}100 = \frac{\sqrt{\sum_{n\neq 1} I_n^2}}{I_1}100, \qquad (15)$$

The value of the harmonic distortion coefficients of the current consumed from the mains for the above-recommended range of adjustment of the control angles is $THD_I = (0...36,6)\,\%$. For the mode of full conductivity of thyristors, there is no distortion, and for the modes $\alpha = \beta = \pi/2$ the harmonic distortion of VPP-VRPP current is $THD_I \approx 36,6\,\%$.

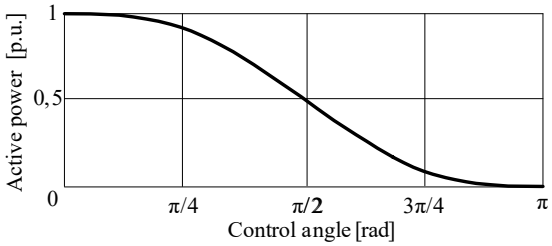

Figure 6: VPP-VRPP control characteristic by active power

The change in the reactive power of the VPP-VRPP in the process of regulation is accompanied by a simultaneous change in the active power consumed by the electric receiver (Fig. 6).

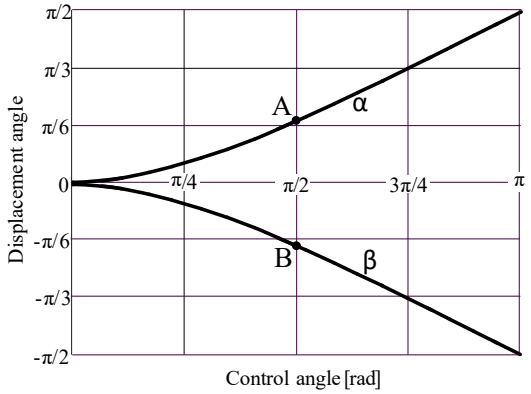

Figure 7: Displacement angle for two ways of regulation (modes) VRPP

As you can see from Fig. 4 and fig. 6, in the process of regulation, with increasing value of reactive power, the value of active power decreases, which generally contributes to the tasks to be solved by virtual power plants, the control effect on the active $dP/d\alpha < 0$, $dP/d\beta < 0$ and reactive $dQ/d\alpha > 0$, $dQ/d\beta > 0$ power of the resistive electrical receiver is different in signs.

We obtained modes in which the generation of reactive power to balance it in the load center is accompanied by a simultaneous decrease in active power consumption, which contributes to both the normalization of the voltage level (VRPP task) and active power balancing (VPP task).

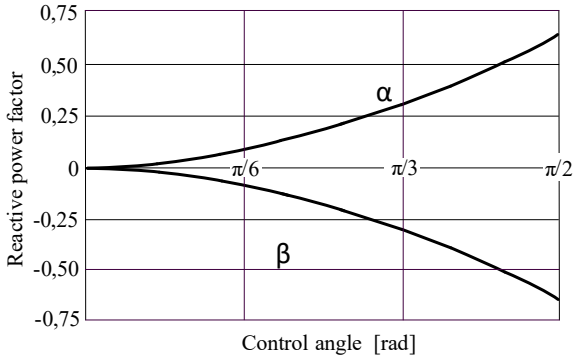

Figure 8: Reactive displacement power factor

In the mode of maximum reactive power $\alpha = \beta = \pi/2$, the value of the displacement angle of the main harmonic of the current is $\varphi_1 \approx \pm 32,5^\circ$ (points A and B on the corresponding characteristics of Fig. 7), and the coefficient of reactive displacement power (Fig. 8) $tg\varphi_1 = \pm 0,64$.

5. Conclusions

The article considers a comprehensive approach to solving the problems of active and reactive power balances in Microgrid networks, using hidden (virtual) resources, which are organized in the form of a virtual active-reactive power plant (VPP-VRPP). Using distributed resources of consumers and their active role in the operation of Microgrid.

Resources of active and reactive power are received from one source - ohmic receivers of consumption with involvement of means of power electronics as regulating elements.

By feeding the ohmic load from voltage regulators with GTO thyristors, the distribution network operator, if necessary, reduces the consumption of active power and adjusts the value and sign (consumption from grid or grid generation) of reactive power.

The range of change of control angles of thyristors of a voltage regulator is chosen for reasons of reduction of negative influence of nonlinear electric loading on quality of the electric power in Microgrid.

The use of integrated multi-controlled VPP-VRPP can be recommended for damping transients and ensuring the stability of Microgrid operation in modes with frequency and voltage value close to critical, to prevent avalanche-like changes.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The authors thank both the authorities of the Lviv Polytechnic National University especially leadership of the Institute of Power Engineering and Control Systems for their support during the preparation of this paper. The authors also thank the anonymous reviewers, whose comments significantly improved the content of the paper.

ABSTRACT

Wind energy is emerged rapidly as the most important and viable sustainable power source due to the mature technology and wide availability. The integration of wind energy sources and utilization of nonlinear loads having different characteristics results in several challenges in a distribution system. One of which is power quality issue .Hence, in this work, the impact of power quality issues in a distribution system integrated with the wind generation system is studied in the uses of a shunt active power filter (SAPF) and presence of non-linear load conditions. The realization of SAPF is carried out using active power component theory (APCT) for reference current extraction, proportional-integral (PI) controller, and fuzzy logic controller (FLC) for dc-link voltage regulation and a basic hysteresis band current controller method for the extraction of switching pulse for operational the inverter. To enhance power quality in the proposed system, a modified fuzzy logic-controlled (MFLC) is developed to improve the transient performance of shunt APF. The proposed model is developed in MATLAB and results are given so as to show the presentation of the performance of this compensation technique in terms of mitigation of system harmonics, reactive power compensation, and enhancing the power factor.

1. Introduction

This Electrical energy has become an integral part of human life and its use is increasing globally by leaps and bounds to improve the living standard. Global concern of utilization of green and clean energy sources for sustainable power systems and shortage of fossil fuel reserves create opportunities for renewable energy sources (RES) of generation. In this manner, the expanding dangers to the earth from the vitality created by the broad utilization of fossil fuels have left us with the thought of renewable energy sources (RES) as the main conceivable arrangement. The demand for sustainable power sources has highly increased due to a lack of fossil fuel, environmental impact and global warming problems of the world. The classification and trends of wind energy chnology has been discussed [1-4] in detail. Wind power is the most developing, promising, and viable sustainable power source that has been dissipated over the word, and utilization of this energy source has been expanding vary large scale. The integration of distributed generation (DG) is directed to increments in vitality productivity and a decrease in emission. The ever-increasing load demand and scarcity of electric power have attracted the attention of power engineers to evolve the new techniques for the effective utilization of electrical energy. Such evolutions have increased the use of power electronics devices and controllers in manifold over the last two decades for more efficient operation of the electrical equipment and to transfer more power through the power networks, but they degrade the power quality in the distribution network connected with wind generation source.

The PQ problem of grid-connected wind energy conversion has been discussed [5-8] by many authors in past years. In [9], the author discussed the power quality issues related to flicker, reactive power, current harmonic distortion, stability of wind generator during the faulty conditions. Further, there are a lot of disturbances that create PQ problems such as harmonics distortion, voltage interruption, transient disturbances, frequency variations, etc. Out of these disturbances the main polluting impact will be created by harmonic distortion but at the same time, it does not mean that power conditioning is only confined to harmonic filtering. In [10], the author introduced the power electronics devices to operate on the sinusoidal voltage but they inject harmonics in the power system networks and increase reactive power demand. The injected harmonics are responsible for the distortion of voltage and current waveshapes. These nonlinear

*Corresponding author: Vikas Kumar Sharma., vikasvs1985@gmail.com

loads are a big reason of harmonics, and extra neutral currents in the power system network. In [11], the author reviewed the different sources of customer- generated harmonics include AC/DC converters adjustable speed drives, switching power supplies, AC phase control circuit, cyclo converters, magnetizing current of transformer, arc furnaces, welding machines, traction systems, switch-mode power supplies (SMPS), computers and programmable logic controllers (PLC's), etc. Moreover, the single-phase loads like personal computers (PCs), fluorescent lights, printers, Xerox machine, television, etc. are also responsible for excessive neutral current distribution system.

The capability and use of SAPF has been investigated in [12-14]. A SAPF could be used as the potential solution to mitigate the utility current disturbances and enhancing power quality in power distribution system integrated with wind generation system. The shunt connected custom power devices are especially useful to maintain power factor, balancing of load, limitation of harmonics and voltage regulation at distribution voltage level, etc. The SAPF operated in the current control mode is capable of injecting negative harmonic current into the grid. Hence, in today's scenario, active power is popular and preferred over the passive filter. Shunt APF has the ability to mitigate the current harmonics from the system but series has sued for voltage harmonics. In [15], the author discussed for fast and precise estimation of reference current, predictive and adaptive controllers based on the neural network have been proposed. The quick estimation of compensating currents a lot of artificial and soft computing techniques was used. Because of the added advantage of ANN to compute the Fourier series coefficient the authors have preferred this over others improved hysteresis current controller technique is overcome wide variation of switching frequency, hence, reduce the switching frequency. In [16], the author implemented a lot of on the hysteresis based current controller in literature like as adaptive frequency domain control of PWM strategy, three-dimensional PWM technique, etc.

In [17], the author developed a standalone wind-diesel hybrid system, in which an active shunt filter is introduced to mitigate the harmonics of load current. In [18-19], they are presented the recent work on the grid integration of renewal energy with SAPF for current harmonic elimination. The dc-link voltage control is achieved by either PI or fuzzy logic technique in SRF based SAPF for proposed system. In [20], the author discussed the purpose of analysis the harmonic reduction and SAPF control technique using harmonic extractor-based method to renewable energy source integrated with grid. In [21**]**, the author proposed the SRF reference current method based shunt active power filter with PI controller to mitigate the current harmonics from the grid connected wind at PCC simultaneously non-linear load conditions. In [22], the author implemented the ICC controller is proposed for shunt active filter for enhance power quality in renewable source interfaced grid system. In [23], the author proposed the system performance parameter like output voltage, frequency and THD level at variable wind speed and nonlinear load conditions. The validity of proposed SAPF is analyzed with fuzzy logic based PWM technique. In [24], the author implemented a technique for reduce of harmonics in hybrid SAPF connected distribution network to enhance the power quality. The optimal controller was made by the improved optimization algorithm.

The recent literatures on the grid integration of wind energy with SAPF mainly focus on the study of current harmonics reduction by the grid current THD analysis. However, a smaller number of publications had been reported for proposing distribution grid level implementation of SAPF for power quality enhancement with the integration of wind energy source. Hence, there is a need to investigate the methods which may be implemented at the grid level to mitigate the power quality problem due to wind energy into the distribution grid. The performance of APC- PI theory with direct and indirect current control methods are compared and found that in both conditions, the neutral current compensation is almost same but the remarkable improvement is observed in power factor, reactive power compensation and load balancing with indirect control method. It is proved through proposed simulation that the indirect current control method performance is better than direct current control for the distribution grid integrated with wind generation system. So, proposed Indirect APC-MFLC methods are suitable to compensate harmonics and reactive power, neutral current during unbalanced loading conditions. The system is capable of maintaining unity power factor as well as sinusoidal source currents. Hence, the power quality of distribution system is improved.

The major contributions of this paper are integration and design of APCT based SAPF in proposed system for enhances the power quality problem. The proposed MFLC controller strategy is validated through APC theory by extensive simulation results for enhancement in overall power quality problem of the proposed system. This paper is classified in five sections, first is the introduction in Section 1. Section 2 mathematical modeling and detail of the proposed model and proposed SAPF control method in Section 3, simulation result and discussion presented in Section 4. The conclusion is shown in Section 5.

2. Proposed Model

A PMSG based wind energy connected through AC-DC-AC converter to distribution grid with a non-linear load connected to load bus shown in Figure 1. A shunt APF connected with the system for enhancement of power quality in non-linear loading conditions and PMSG integrated with the grid. The proposed system is not only capable of transfer the wind energy to the grid, but will also act as a shunt active power filter (SAPF) to mitigate the current harmonics and regulate reactive power feed by the nonlinear loads. Table 1 provides parameter of wind turbine and PMSG.

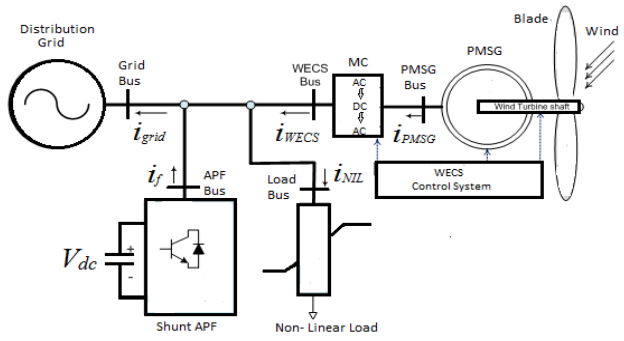

Figure 1: Block Diagram of Distribution Grid- Integrated Wind Generation System with Shunt APF and Non-linear Load.

A. Modeling of Wind Turbine System

The wind speed is sum of these components.

$$V_w(t) = V_B(t) + V_N(t) + V_G(t) + V_R(t) \quad (1)$$

where, V_w is the wind speed, all of them in "meter/ second" and time t is in "second Here this wind speed signal have four component, i.e. the basic speed of wind (V_B), a fluctuating wind (V_N) that describes a steady increase in wind speed, gust component (V_G) and a gradient wind component (V_R). The mechanical energy given wind turbine is determined as follow [3]

$$P_{\text{wind}} = \frac{1}{2} C_p(\lambda, \beta) \pi r^2 \rho_{\text{air}} V_w^2 \quad (2)$$

Power coefficient (C_p) is the ratio of mechanical power generated by the turbine to the power available in the wind. Which λ is the tip speed ratio, C_p is given as [3]

$$C_p = c_1\left(c_2 \frac{1}{\alpha} - c_3\beta - c_4\beta^x - c_5\right) \quad (3)$$

β is a function of the pitch angle of rotor blades, when β is equal to zero.

$$\frac{1}{\alpha} = \frac{1}{\lambda + 0.08\beta} - \frac{0.035}{1+\beta^2} \quad (4)$$

Therefore, the tip speed ratio can be given as [3]

$$\lambda = \omega_a r / V_w \quad (5)$$

The mechanical torque turbine is defined as follow [3]

$$T_{mech} = \frac{0.5 C_p \pi r^2 \rho_{air} V_w^2}{\omega_a} \quad (6)$$

The driven train is treated as one concentrated mass model to time efficiency and precision. It is defined as:

$$\frac{d}{dt}\omega_a = \frac{1}{j}(T_{mech} - T_{elect} - B_x\omega_a) \quad (7)$$

where, B_x is damping coefficient, ω_g is angular speed (rad/sec), T_{elect} is the electromechanical torque (Nm),T_{mech} is the aerodynamic torque and J equivalent rotational inertia of the generator (kg-m^2)

B. Modeling of PMSG

The direct axis and quadrature axis voltage equation of generator is define as

$$V_d \equiv -R_s i_d - L_d \frac{di_d}{dt} + \omega_e L_q i_q \quad (8)$$

$$V_q \equiv -R_s i_q - L_q \frac{di_q}{dt} - \omega_e L_d i_d + \omega_e \mu_g \quad (9)$$

ω_e is the rotor speed in rad/s of the generator, describe by

$$\omega_e = \omega_a P \quad (10)$$

The electromagnetic torque of PMSG is given by

$$T_{elect} = \frac{3}{4} P\left[\mu_g + \left(L_d - L_q\right) i_d\right] i_q \quad (11)$$

Then, the angular speed of generator is defined as [4]:

$$\frac{d}{dt}\omega_a = \frac{1}{j}\left(T_{mech} - T_{elect} - B_x\omega_a\right) \quad (12)$$

Table 1: parameter of wind turbine & generator

Parameter	Value
Generated Power, (P)	2 MW
Stator Resistance (R_s)	0.7305 mΩ
Stator d-axis Inductance (L_d)	1.21 mH
Stator q-axis Inductance (L_q)	2.31 mH
Permanent Magnet Flux (μ_g)	6.61 Wb
Inertia (J_{eq})	10000 kg.m^2
Radius of Blades (r)	38 m
Air Density (ρ)	1.205m^3

3. Proposed Control Method for SAPF

The Voltage Source Inverter has seen widely utilized in shunt APF setup to minimize power quality issues. It is also utilized for energy storage during ideal system conditions, but the charging and discharging of this capacitor controlled utilized a control theory. Hence, only the active filter fit for producing counter harmonic current and feeding the reactive power to point of common coupling (PCC). Figure 2 presents the configuration of the proposed shunt APF with a distribution system integrated into the wind energy conversion system (WECS). The main aim of proposed method is to evaluate the control strategy for current harmonics reduction, compensation of reactive power and balancing of load current at PCC when the supply current is distorted.

3.1. Active Power Component (APC) or Unit Vector Template Theory

Shunt APF can effectively handle the harmonics and reactive power problems simultaneously. Presently shunt APFs are designed to encounter all the harmonics which is generated by nonlinear loads but the distribution system is highly unbalanced, so it is required to mitigate the neutral current burden and make the source current sinusoidal for the calculation of the desired compensation current. The unit vector templates are determined as

$$\begin{aligned} U_a &= \frac{v_{Sa}}{V_{SP}} = sin\theta \\ U_b &= \frac{v_{Sb}}{V_{SP}} = \sin(\theta - 120^0) \\ U_c &= \frac{v_{Sc}}{V_{SP}} = \sin(\theta + 120^0) \end{aligned} \quad (13)$$

In a three-phase system, it is represented as i_a^*, i_b^*, and i_c^*. Neutral current ought to be zero, along these references neutral current taken as zero in a balanced system. Capacitor voltage error goes

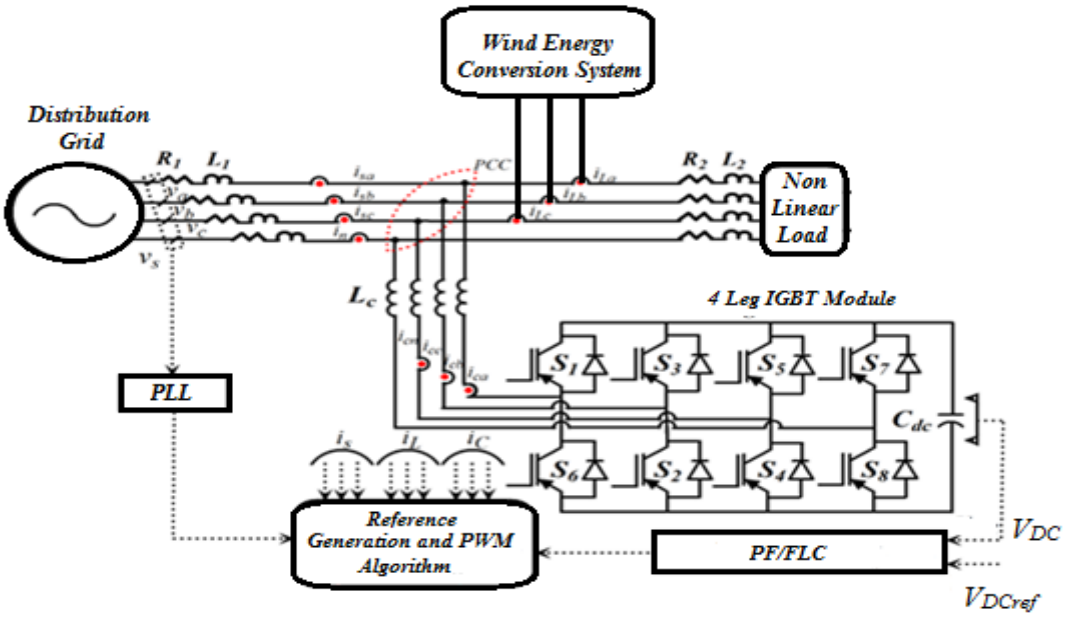

Figure 2: Proposed Shunt APF Configuration with Distribution System

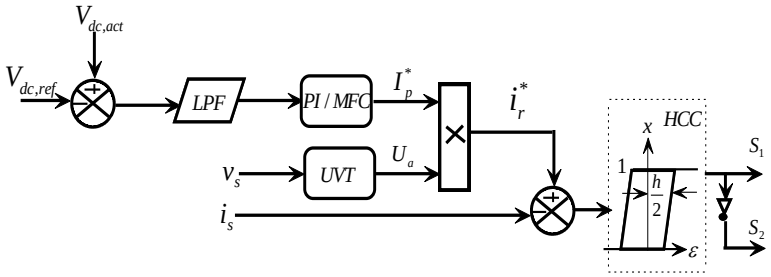

Figure 3: Block Diagram of UVT/APCT Algorithm with Indirect Current Control Method

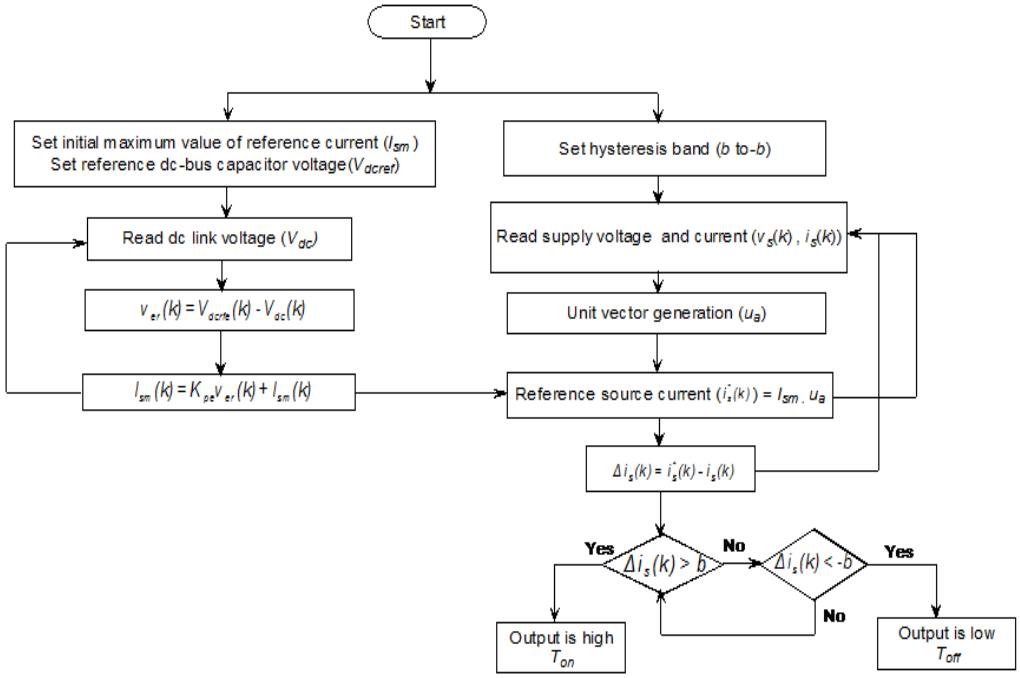

Figure 4: Flowchart of Active Power Component Theory (APCT) Algorithm

through the low power filter. The filtered dc voltage is contrasted with the reference value. Reference current can be composed as

$$i_a^* = I_m U_a,\ \ i_b^* = I_m U_b,\ \ i_c^* = I_m U_c,\ \ i_n^* = I_m U_n \qquad (14)$$

As present in the Figure 3 that capacitor voltage error goes through the LPF, which remove the high-frequency ripple from the voltage. This filtered dc voltage is compared with the reference value. Now error between the reference and grid current is processed by utilizing the following equations

$$\left.\begin{array}{c} i_a^* = I_m U_a \\ i_b^* = I_m U_b \\ i_c^* = I_m U_c \\ and \\ i_n^* = I_m U_n \end{array}\right\} \qquad (15)$$

Figure 4 presents the flowchart of the APCT algorithm with indirect current control method.

3.2. DC voltage Controller

DC voltage controller calculates response of the model and increasing proportional above a value can generate swaying. Integral control expels the error from the output. To actualize the PI controller, the dc link voltage is estimated the reference value. The transfer function of the PI-controller is given from [18] as follows

$$H(s) = (k_i / S) + k_p \qquad (16)$$

For the usage of the fuzzy rule over the PI controller in close loop filter, the dc voltage signal is compared with reference signal and reference error will be produced as follow [18]:

$$e = V_{\text{dc, reference}} - V_{\text{dc, actul}} \qquad (17)$$

The reference for nth sampling time is taken as a change of error in fuzzification process is determining as follows [18]-[19]

$$C_{e(n)} = e(n) - e(n-1) \qquad (18)$$

3.3. Proposed Fuzzy Ligic controller

The proposed modified fuzzy logic controller (MFLC) of the system is used to control the response of the dc voltage. They can be defined, as

$$x = \left(x_i, U_i, \left\{T_{x_i}^1, T_{x_i}^2, \cdots, T_{x_i}^{k_i}\right\}, \left\{\mu_{x_i}^1, \mu_{x_i}^2, \cdots, \mu_{x_i}^{k_i}\right\}\right) \quad \text{for } i = 1, 2, \cdots, n \qquad (19)$$

$$y = \left(y_i, V_i, \left\{T_{y_i}^1, T_{y_i}^2, \cdots, T_{y_i}^{l_i}\right\}, \left\{\mu_{y_i}^1, \mu_{y_i}^2, \cdots, \mu_{y_i}^{l_i}\right\}\right) \quad \text{for } i = 1, 2, \cdots, m \qquad (20)$$

where x & y is the input & output linguistic variable form a fuzzy output space. The size of a term set, $T_{(xi)} = K_i$ is called as the fuzzy partition number of X_i. In the case of a two – input-one-output proposed MFC system, If $T_{(x1)} = 9$ and $T_{(x2)} = 9$, than the number of fuzzy control rules is 9×9. A bell shaped relationship function has been used.

$$\mu_{xi}(x) = \exp\left(-\frac{(x - m_i)^2}{\sigma_l^{\ 2}}\right) \qquad (21)$$

This modified fuzzy controller rules are developed and approved dependent on AND Boolean logic operator. The new rules are characterized by fundamental stability position and moment in time response. To use of fuzzy sets, we restructure operators of the standard set method to fit the particular relationship functions of fuzzy logic for a value between zero & one. Here two variables are utilized as a contribution of MFLC, first is Error E and second change of error C_e. The moment in time response has been divided into four regions A_1, A_2, and A_3, A_4 with two arrangements of point, first is the peak value index (b_1, b_2), and second cross over-index (c_1, c_2). The fuzzy operator AND is formed from a grouping of fuzzy prepositions. Based on the above theory, rules are defined as ZE, PN NB, NS NM, PS, PB, and PB, PM for processing the dc-link response shown in Table 2. Figure 5 shows the moment in time response of a stable closed loop-system.

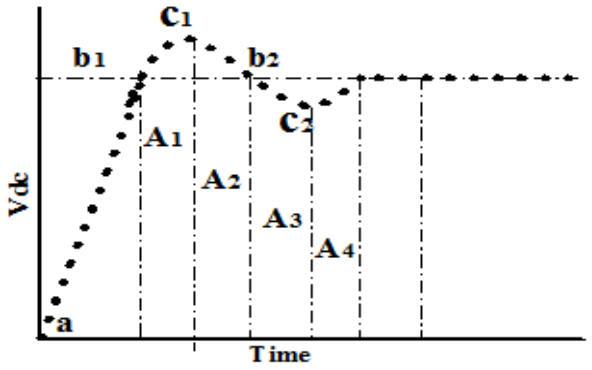

Figure 5: Moment in Time Response of a Stable Closed Loop System.

4. Result and discussion

The performance analysis of the distribution grid integrated with wind generation system is study with proposed SAPF under the use of different controllers for unbalanced loading condition. The impact of PQ issues in a distribution grid integrated with wind generation system is investigated in the presence of SAPF. The effectuation of SAPF is carried out using active power component theory (APCT) for reference current generation with direct and indirect current control method. Proportional integral (PI) controller is proposed with modified fuzzy logic controller (MFLC) for dc link voltage regulation and a basic hysteresis band current controller method. For study state analysis purposes, the load change with an increase at t=1.2 sec, and again it is changed with decreasing at t= 2.3 sec. The RMS load current at t=0.2 sec is in phase "a" 139.2 Amp, phase "b" 103 Amp, and in phase "c" 68.8 Amp. This result presents the unbalanced condition in the distribution system. Without compensation the neutral current flow in 73.3 Amp, the reactive power drawn is 20 kVAR, power factor degradation is below 0.8, and load current THD is 22.50%. A SAPF with a hysteresis-based APC technique is used to enhance the performance of the system according to certain power quality standards. In this technique, the reference signal is compared with actual utility load current.

4.1. Case 1: Direct current control with APCT-PI

In the direct current control method with APCT-PI, the switching pulses are generated through hysteresis controller by comparing the sensed three phase shunt APF current with their computerized generated reference current signal. The performance of the direct current control method with the APCT technique as shown in figure 6. The following observation has been made out after compensation reactive power flow between souse and load is 7 KVAR, natural current is around 7 Amp and system power factor is nearly 0.94.

4.2. Case 2: Indirect current control with APCT-PI

In the indirect current control method, the PWM switching pulses are obtained by comparing the sensed three phase current with their reference current which are generated by the reference current extraction methods. The performance of the in-direct current control method with the APCT technique is shown in figure 7. The following observation is made out after compensation reactive power flow between souse and load is 6 KVAR, natural current is around 6.8 Amp and system power factor is nearly 0.996. Hence the performance of the in-direct current control loop with unit vector template theory is found better than direct control so modified FLC implanted on indirect current method.

4.3. Case 3: Indirect current control with Modified Fuzzy Logic controller with APCT

It provides the batter result in a comparison of harmonics mitigation, reactive power compensation, and power factor improvement. From the figure 8, following observation, has been made out after compensation reactive power flow between souse and load is 3.7 KVAR, natural current is around 4.7 Amp and system power factor is nearly 0.999. Hence the performance of the in-direct current control loop with MFLC based APC theory is found suitable for SAPF. The comparisons of harmonics mitigation are shown in figure 9.

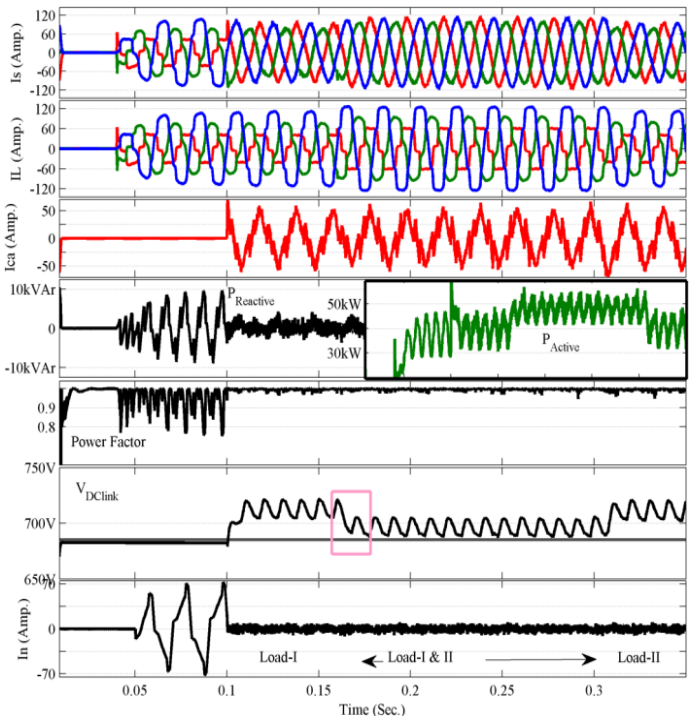

Figure 6: Indirect current control method shown as I_{sourse}, I_{load}, $I_{netural}$, $P_{react.}$, PF, V_{DC} and I_n with APC-MFLC theory.

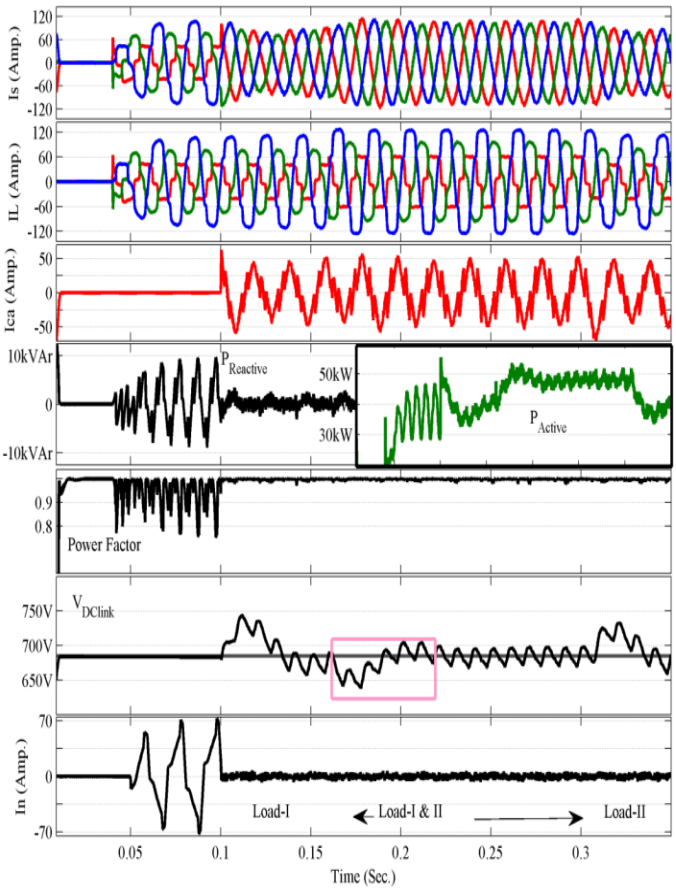

Figure 7: Direct current control method shown as I_{sourse}, I_{load}, $I_{netural}$, $P_{react.}$, PF, V_{DC} and I_n with APC-PI theory.

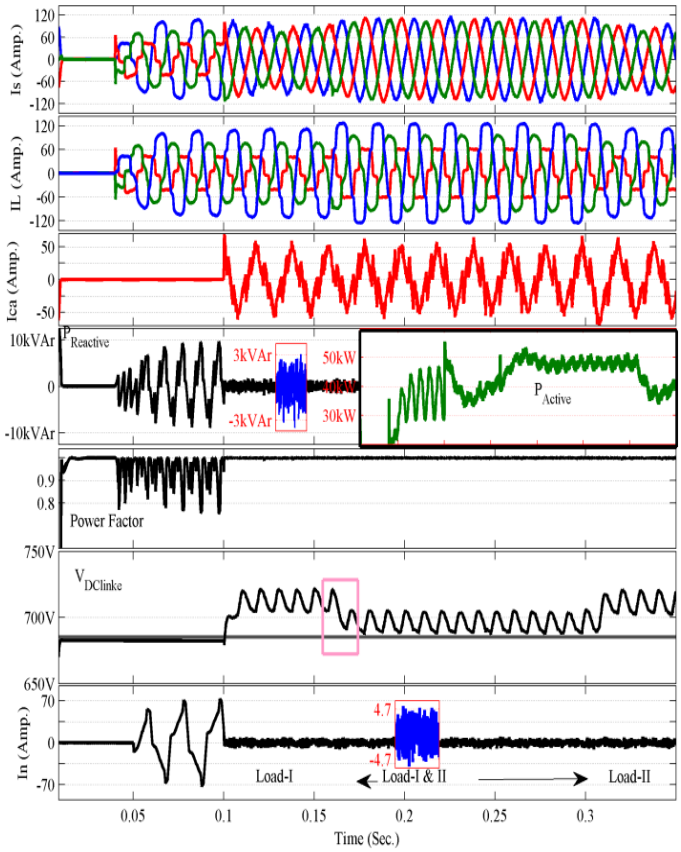

Figure 8: Indirect current control method shown as I_{sourse}, I_{load}, $I_{netural}$, $P_{react.}$, PF, V_{DC} and I_n with APC-MFLC theory.

4.4. Performance comparison of direct APC-PI, Indirect APC-PI and Proposed Indirect APC-MFLC

The comparison of overall performance of proposed system are discussed in Table 3.The performance of APC- PI theory with direct and indirect current control methods are compared and found that in both conditions, the neutral current compensation is almost same but the remarkable improvement is observed in power factor, reactive power compensation and load balancing with indirect control method. It is proved through proposed simulation that the indirect current control method performance is better than direct current control for the distribution grid integrated with wind generation system. So, proposed Indirect APC-MFLC methods are suitable to compensate harmonics and reactive power, neutral current during unbalanced loading conditions. The system is capable of maintaining unity power factor as well as sinusoidal source currents. Hence, the power quality of distribution system is improved.

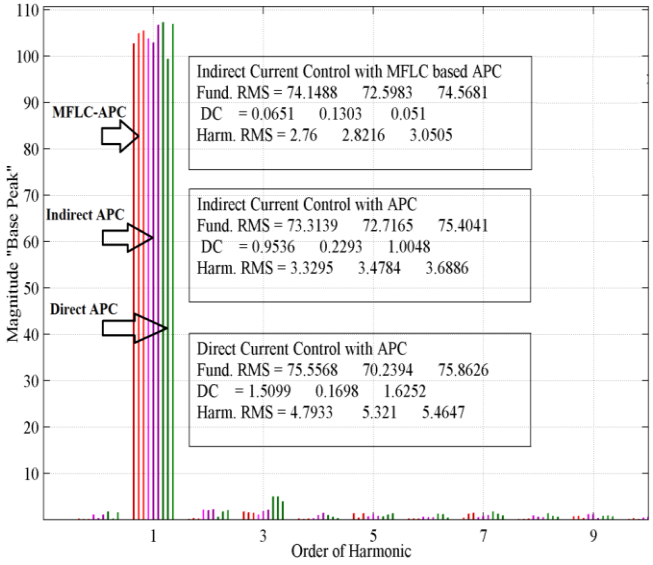

Figure 9: THD with Direct APCT-PI, Indirect APCT-PI & Indirect APCT-MFLC.

5. Conclusion

This paper presents a SAPF based on APC theory for reference current generation and proposed MFLC method for dc-link voltage control to enhance power quality of the distribution grid integrated with wind energy source under non-linear load. The performance of APC theory with direct and indirect current control methods is compared and found that in both conditions, the neutral current compensation is almost the same but the remarkable improvement shown in power factor, reactive power compensation, and load balancing with the indirect current control method.

Table 3: Comparison of direct APCT-PI, Indirec apct-pi and indirect Apct-MFLC

Parameter	**Direct control with APCT**			**Indirect direct control with APCT**			**Indirect direct control with MFLC- APCT**		
	I_{sa}	I_{sb}	I_{sc}	I_{sa}	I_{sb}	I_{sc}	I_{sa}	I_{sb}	I_{sc}
Balancing of source current I_s	108.4	98.06	105.1	103.6	102.8	106.6	110.8	1.8.1	108.1
Harmonic RMS after comp.	4.793	5.321	5.464	3.329	3.478	3.688	2.760	2.821	3.050
Neutral current I_n after amp.	7.0			6.8			4.7		
Reactive power after comp. (kVAr)	7			6			3.7		
Power Factor (PF)	0.94			0.996			0.999		

Hence, it has been proved through a simulation study that the indirect current control loop performance is better than the direct control loop for the unbalanced distribution system. The performance of the proposed method using APC-MFLC based realized SAPF is compared to that of SAPF designed based on reported strategies such as direct APC-PI controller and indirect APC-PI controller. The simulation results show the effectiveness of the proposed control algorithms to mitigate the harmonics, compensate the reactive power, and neutral current and to improve power factor with the balancing of source current using the MATLAB/Simulink.Finally, the proposed algorithms are capable of improving power quality problems in the distribution system with wind energy sources under non-linear load.

ABSTRACT

Learning styles studies have been discussed widely in academic field. It can be considered as a factor that contributes to the achievement of the students in their learning because everyone has a unique learning style when learning. In this paper, we aimed to examine the association of learning styles and attitude towards academic achievement. By identifying the student's learning styles preference, it will offer benefits to the student and instructor by improving learning achievement. Sample data were collected among 328 pre-university science and engineering students using cross-sectional survey. Attitudes Towards Mathematics Inventory (ATMI) and Index of Learning Style© (ILS) were used as the instruments to collect data from the respondents. Data were analysed using Stata statistical tool to examine the result. Result showed that there was no association of learning styles and attitude towards academic achievement in this study.

1. Introduction

Mathematics is one of the subjects in Sijil Pelajaran Malaysia (SPM), a high school national examination taken by secondary school students in Malaysia, as it is one of the subject requirements to continue study in pre-university program. However, the percentage of students who passed with distinction and credit in this subject has not improved from 2017 to 2019. Students who passed with distinction were 31.5% in 2017, 31.2% in 2018 and 31.2% in 2019 while those who passed with credit were 25.2%, 24.9% and 24.1% for 2017, 2018 and 2019 respectively [1, 2]. It is quite worrisome to see these statistics as mathematics does not only exist as individual subject, but it is also used as a tool in other subjects such as physics, chemistry, accountancy and economics to name a few. There are many aspects needed to be studied and improved in order to overcome this problem and the aspects of the students' learning styles and attitudes toward mathematics are among the aspects worth looked into.

In [3], the author mention that the learning style theory was originated from psychology research domain. However, this theory appears to have wide acceptance in many educational researches in exploring the issue of student achievement through learning style. There are several disciplines that have applied this theory in their studies such as nursing, engineering, mathematics [4-6] and online learning mode course [7].

In literatures, some studies on learning styles and academic achievement have been discussed extensively. For example, studies in [8], the studies found that there was no significant difference between learning style and academic achievement among Polytechnic undergraduate business students in Malaysia. The study concluded that by promoting student self-awareness and learning strategies, it will affect their learning style. In [9], the author studied the relationship of learning styles and academic achievement in mathematics among Grade 8 students. The study concluded that learning style is significantly related to academic achievement.

Based on the literature, there is a lack of study that discussed on pre-university students' learning style and attitude towards mathematic achievements. Moreover, the mixed results found in literature have motivated this study to be conducted. In addition, this study is an extension of the original research [10] that examined pre-university student's attitude towards mathematics achievement. Despite the fact that pre-university students from science program have always gained better achievement compared to students from engineering program, the original research showed that mathematical capability of the students was not influenced by the program they enrol in a local public university. Thus, the result showed that there was no significant findings on the attributes associated to academic achievement [10].

Therefore, it is significant to broaden this study on learning styles and attitudes towards mathematics achievement for pre-university students. The objectives of the studies are:

a. To study the student's preference learning style towards mathematics.

*Corresponding author: Nurashikin Abdullah., nurash2856@uitm.edu.my

b. To study the differences of student attitudes towards mathematics.

c. To measure the association of learning style and attitudes towards mathematics achievement.

In the next section, it discusses the related work on learning style. It is followed by research methodology while the final section is result and conclusion.

2. Related Works

What makes individual learning style distinct? Individual learning style is driven by some attributes such as characteristics and behaviour of the learner. According to literature, learning style has three basic elements which are cognitive, motivational and physiological. These elements indicate how the learner perceive, respond, and cooperate with the learning environment [11]. Every student has different level of cognitive, motivation and psychology responsive to the learning atmosphere [12]. Moreover, learning styles give an impact to the academic performance [13].

In an analysis done in [14], result showed there was a positive relationship between students' learning styles and the attitude towards mathematics. Many researches agreed that the effect of learning styles and positive attitude contributed to better achievement in mathematics. In [15], the author suggested that learning environment designed according to learning styles may increase students' success while the researcher in [16] said that individual learning style correlated the highest with mathematics performance. Likewise, studies conducted in [17], the author stated that positive attitudes towards mathematics and science are also associated with higher achievement in each subject.

There are several types of learning model discussed in literature on learning style which includes Kolb's Learning Style instrument (LSI), Learning Style Questionnaire (LSQ), Canfield Learning Style Inventory (CLSI), Cognitive Styles Analysis (CSA), Index of Learning Survey (ILS) and VARK (Visual, Aural, Reading or Write and Kinaesthetic) model [18].

Table 1: ILS dimension

Domains	Description
Sensing vs. Intuiting	Sensing – concrete and practical learner. Prefer facts, sound, sight, data, and physical sensation.
	Intuiting – abstract and theoretical learner. Prefer concept, theories, and insights.
Visual vs. Verbal	Visual – learn from what they have seen.
	Verbal – learning through the words whether from spoken or written.
Active vs. Reflective	Active – learn by performing practical activity and collaboration with others.
	Reflective – learn through thinking or pondering and working alone.
Sequential vs. Global	Sequential – linear thinking process. Prefer to do things step by step.
	Global – holistic thinking process. Prefer to study the whole picture to understand entire subject.

The most common models used in literatures are VARK model and ILS model [5-6],[19]. Different models of learning style have their own strengths and weaknesses. VARK model examines on sensory modality that includes visual, aural, read/write and kinaesthetic of learning styles. This model is used to identify learner preferred learning mode in which the learner may have multimodal learning styles [19]. Another model used among many researchers is Richard M. Felder and Linda K. Silverman's Learning and Teaching Styles based on its instrument of Index of Learning Styles (ILS). Initially, the model consists of five dimensions of Felder and Silverman's Learning Styles; Sensory-Intuitive, Visual-Auditory, Inductive-Deductive, Active-Reflective and Sequential-Global [12] but it has been updated to four dimensions which are Sensing-Intuiting, Visual-Verbal, Active-Reflective and Sequential-Global. In ILS model, information was perceived and processed by four domains [20, 21].

Furthermore, literature on learning style preferences among engineering student showed that students prefer active, sensing and visual learning styles in their problem-based learning (PBL) curriculum course [22]. Moreover, other studies also found that engineering students favoured sensing, visual, active and sequential learning styles [6]. In another perspective, learning styles preferences may differ between genders in which females have reflective, sensing, visual and sequential learning styles while males prefer active, sensing, visual and sequential [23]. In 2015, the author found that there was a significant relationship between learning styles and educational achievement such as in mathematical field [7]. In addition, there is a positive significant relationship between students learning style who used Active-Reflective and Visual-Verbal learning style and their score means.

ILS is more reliable, valid, and suitable for identifying learning styles [20]. It is a well-established tool and widely used to assess learner's learning styles. Moreover, various studies have been done on learning style using ILS [23]. Thus, this study adapted ILS model to fulfil the objectives of the study. Instruments used in this study are Attitudes Towards Mathematics Inventory (ATMI) and Index of Learning Style© (ILS). How does ATMI measure the attitude of the learner in mathematics? In ATMI instrument, it consists of four attributes; i) Self-confidence: learner's confidence and self-concept in comprehend mathematics; ii) Value: belief of usefulness, relevance and worth; iii) Enjoyment: learner has fun working with mathematics; and iv) Motivation: learner's interest and desire to study in mathematics [24].

3. Methodology

This study used cross-sectional survey among students attending pre-university studies in a local university and all students were invited to participate in this survey. A total of 328 students participated in this survey, giving the response rate of 13%.

A set of questionnaire consisted a range of information including socio-demographic as well as questions measuring their attitudes towards mathematics using Attitudes Towards Mathematics Inventory (ATMI) [25] and Index of Learning Style© (ILS) [26] was distributed among the participants. There were four self-reported domains focused in ATMI which included to measure self-confidence, value, enjoyment and motivation. ATMI consisted of 40 items on 5-point Likert scale ranging from strongly disagree to strongly agree. Its Cronbach's alpha indicated good reliability (α= 0.97). To find the result on the attitude of the student, each domain score was summed up. The higher scores showed positive attitudes towards mathematics.

The ILS consisted of 44-items which were divided into four subscales (active/reflective, sensing/intuitive, visual/verbal, and sequential/global). The Cronbach's alpha for ILS was considered

good with 0.74 [21]. The scores in ILS were computed by taking the difference on the number of items selected for each of the two styles in a scale. The total scoring was between -11 to 11. The scoring was categorised as strong (+/- 11-9), moderate (+/--5) and mild (+/-3-1) preferences.

Data analysis was done using Stata statistical software [27]. Prior to analysis, data were cleaned and verified for any errors, outliers or missing values. Continuous data were reported as means and standard deviations while categorical data were reported as frequencies and percentages. Normality test was conducted using Shapiro-Wilk's test. Bartlett's test for equal variances was conducted prior to mean comparisons between groups. P-value of more than 0.05 from Bartlertt's test confirmed the assumption of equality of variance. Bivariate analysis between continuous variables was run using t-test, while ANOVA was used for more than 2 comparison groups. Pairwise correlation was measured using Pearson correlation. The association between mathematics attitude and learning style on mathematics achievement was measured by linear regression. All statistical tests were conducted at 5% significant level.

4. Results

4.1. Participants

Table 2 shows a total of 328 pre-university students who participated in this study. It reflected the same participants who were used in both studies. The respondents were about 53% female and 47% male students. About 60% of the participants were from science program and 40% of the participants were from engineering program. There was a statistically significant difference between program and gender (Chi-square=49.233, p-value <0.001). More than half of the respondents reported that they attended boarding school previously (57%). More than 70% from both male and female students scored A+ in mathematics during their Higher School Certificate (HSC) exam. However, result showed that there was no statistically significant association between school type and gender (Chi-square=0.658, p-value=0.417).

Table 2: Distribution of participants in the survey

	All (N)	Male (n)	Female (n)	Chi-square test	p-value
Program					
Science	195	61	134	49.233	<0.001
Engineering	133	94	39		
Type of school					
Boarding school	187	92	95	0.658	0.417
Non-boarding school	141	63	78		
HSC Mathematics					
A+	235	115	120	0.939	0.333
A	93	40	53		

4.2. Finding from the original research

Result in Table 3 was taken from the original research which was presented in ICEED, 2019. The original research was more focused on the students' attitude towards mathematics final exam achievement for pre-university students. ANOVA test was conducted and the result showed there was no statistical difference between attitude and mathematics achievement (F=074, p-value = 0.658) of the students [10].

Table 3: Attitude and mathematics achievement

Attitude	Sum of squares	Df	Mean square	F	Sig.
Between groups	606.636	8	75.829	0.74	0.658
Within groups	32784.668	319	102.773		
Total	33391.304	327			

4.3. Learning styles preferences

Figure 1 shows the distribution of domain in learning style preferences. Female students were found to score more than 50% in most of the domains. Those who attended boarding school scored higher in all domains compared to non-boarding school attendees. Students who got A+ in their HSC mathematics exam were found to dominate all domains (more than 65%) while those who got between B+ and A for their HSC Additional Mathematics exam were found to score between 20% and 35% in all domains. Majority of the students from science program were found to prefer reflective (65%), sensing (67%), visual (60%) and global (62%) learning styles.

	Learning Style Preferences (Domain)							
	Active	Reflective	Sensing	Intuitive	Visual	Verbal	Sequential	Global
Gender								
Male	(47.1%)	(47.6%)	(40.4%)	(56.4%)	(47.7%)	(41.7%)	(47.2%)	(47.3%)
Female	(52.9%)	(52.4&)	(59.6%)	(43.6%)	(52.3%)	(58.3%)	(52.8%)	(52.7%)
School type								
Boarding	(60.3%)	(51.6%)	(59.0%)	(54.3%)	(57.6%)	(50.0%)	(53.9%)	(57.0%)
Non-boarding	(39.7%)	(48.4%)	(41.0%)	(45.7%)	(42.4%)	(50.0%)	(46.1%)	(43.0%)
HSC Mathematics								
A+	(70.6%)	(73.4%)	(67.6%)	(77.1%)	(72.0%)	(66.7%)	(70.6%)	(73.0%)
A	(29.4%)	(26.6%)	(32.4%)	(22.9%)	(28.0%)	(33.3%)	(29.4%)	(27.0%)
HSC Additional Mathematics

Figure 1: Percentages of Learning Style Preferences (Domain)

Figure 2 shows the distribution of domain in learning style preferences for science and engineering students. Majority of the students from science program were found to prefer reflective (65%), sensing (67%), visual (61%) and global (62%) learning styles.

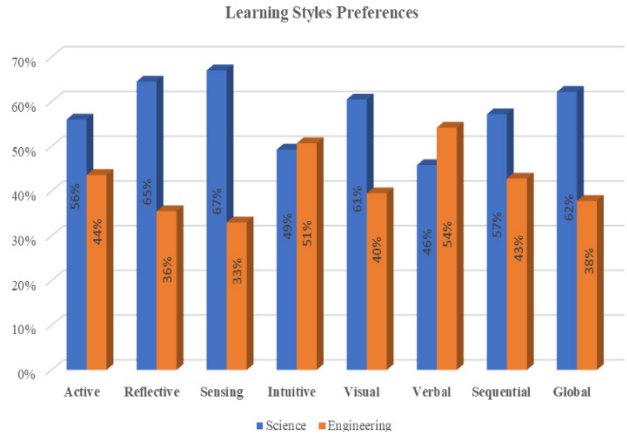

Figure 2: Learning Style Preferences (Domain) by program

4.4. Learning Style Preferences (Domain) during pre-university studies

Students who did very well (grade A) for both pre-university mathematics examinations during their studies had preference in all domains of learning styles. For semester 1 paper, 50.6% of those who scored A grade preferred sequential learning style while for semester 2 paper, students who scored A preferred both verbal (70.8%) and sequential (70%) learning style, respectively. In comparison, students who scored B grades (B- to B+) were found to prefer global learning style for both semester 1 and semester 2 papers as shown in Figure 3.

Learning Style Preferences (Domain)								
Grade	**Active**	**Reflective**	**Sensing**	**Intuitive**	**Visual**	**Verbal**	**Sequential**	**Global**
Semester 1								
A	48.0%	40.3%	44.7%	45.7%	45.1%	45.8%	50.6%	38.5%
A-	22.1	26.6%	22.3%	25.7%	23.0%	33.3%	23.3%	24.3%
B+	12.7%	12.9%	13.8%	11.4%	12.8%	12.5%	14.4%	10.8%
B	7.8%	12.9%	9.0%	10.7%	10.5%	0%	6.7%	13.5%
B-	5.9%	4.0%	6.4%	3.6%	5.3%	4.2%	2.2%	8.8%
C+	2.9%	1.6%	2.7%	2.1%	2.3%	4.2%	1.7%	3.4%
C	0.5%	0. %	1.1%	0%	0.7%	0%	0.6%	0.7%
D	0%	0.8%	0%	0.7%	0.3%	0%	0.6%	0%
Semester 2								
A	67.2%	60.5%	63.3%	66.4%	64.4%	70.8%	70.0%	58.1%
A-	10.3%	12.9%	11.7%	10.7%	10.5%	20.8%	9.4%	13.5%
B+	7.8%	11.3%	8.5%	10.0%	9.5%	4.2%	8.3%	10.1%
B	8.3%	7.3%	8.5%	7.1%	8.5%	0%	7.2%	8.8%
B-	3.4%	2.4%	3.2%	2.9%	3.0%	4.2%	1.1%	5.4%
C+	1.5%	2.4%	2.7%	0.7%	2.0%	0%	2.2%	1.3%

D	0%	0.8%	0%)	0.7%	0.3%	0%	0.6%	0%

Figure 3: Learning Style Preferences (Domain) in pre-university program

4.5. Students' attitude towards mathematics

The summary from ATMI survey that measured the students' attitude towards mathematics is presented in Table 4. The results indicate that male students have more positive attitudes compared to female students. Students from both types of school showed interest or positive attitudes towards mathematics. Those who did very well in both mathematics papers during HSC examinations have much higher positive attitudes compared to others. The same was true for those who were from engineering program. There were variations of attitude scores found across grades in mathematics subjects during pre-university studies. For semester 2 paper, students who scored B- and below were found to have higher positive attitudes' scores compared to the others. However, for semester 1 paper, their attitudes towards mathematics seemed to be equally distributed across all grades.

Table 4: Score on ATMI by gender, school type, HSC Mathematics and HSC Additional Mathematics

Characteristics	**N**	**Mean**	**SD**
Gender			
Male	155	137.941	10.237
Female	173	136.584	9.971
School			
Boarding	187	137.064	10.093
Non-boarding	141	137.410	10.153
HSC Mathematics			
A+	235	137.745	10.334
A	93	135.914	9.429
HSC Additional Mathematics			
A+	13	140.538	9.812
A	101	139.129	8.975
A-	97	137.505	10.586
B+	70	135.514	9.970
B	46	134.283	10.946
B-	1	130.0	0
Program			
Science	195	136.533	10.470
Engineering	133	138.241	9.492
Pre-university Mathematics Semester 1 grade			
A	148	138.412	9.926
A-	78	136.667	9.979
B+	42	134.048	12.791
B	32	137.375	8.454
B-	17	136.353	9.006
C+	8	138.500	6.655
C	2	139.500	2.121
D	1	134.000	0
Pre-university Mathematics Semester 2 grade			
A	212	137.439	10.209
A-	37	136.567	9.907
B+	30	136.867	10.274
B	26	134.154	10.376
B-	10	141.000	9.333
C+	6	138.667	10.875
C	5	140.400	5.771
D+	1	148.000	0
D	1	134.000	0

4.6. Association between learning style and attitudes towards mathematics achievement

Multiple linear analysis was conducted to measure the association between learning style and attitudes towards mathematics on the mathematic score while controlling for the effect of gender, type of school and HSC grade in mathematics. A significant regression model was observed ($F(5,322)=7.44$, Prob>F= <0.001 and Adjusted $R^2=0.089$). In this model, we found that learning style and attitude were not statistically associated with mathematics scores ($B_{learning\ style}=0.446$, $p=0.054$ and $B_{attitude}=0.019$, $p=0.708$, respectively) as presented in Table 5.

Table 5: Association between learning style and attitudes towards mathematics on the mathematics score in pre-university (semester 2 paper)

Predictors	**B**	**t**	**p-value**
Learning style scores	0.446	1.93	0.054
Attitude scores	0.019	0.37	0.708
Female	4.047	3.75	<0.001
Non-boarding school	3.682	3.39	0.001
HSC Mathematics, (A+)	3.221	2.690	<0.001

F (5,322)=7.44, Prob>F= <0.001 and Adjusted R2=0.089

5. Conclusion

This study showed that preference learning style was dominated by the female students from science program who had attended boarding school. Those students who got A+ in HSC mathematics dominated more than 65%. These students' preference learning styles were reflective, sensing, visual and global learning styles. Meanwhile, the result showed that when the students were in pre-university studies, those who scored

grade A during semester 1 preferred sequential learning style while students in semester 2 who scored A preferred verbal and sequential learning styles. Thus, it shows that there is no specific learning style that the students prefer to use because it depends on the environment of the studies. In terms of the student's attitude, we can conclude that there was a variation of attitude score found across grades in mathematics subject during pre-university studies. Those who had positive attitude scored a good grade in mathematics both in HSC and pre-university studies. Besides that, we have studied the factors that contributed towards academic achievement. The result showed no association was found between learning style and attitudes towards mathematics based on the mathematics scores. Thus, this study can help the instructors to plan their teaching through student's learning style to improve student achievement in mathematics. In addition, this study was conducted on pre-university students from science and engineering background which only focused on mathematics academic achievement. Therefore, this research can be expanded by investigating pre-university learning style for all subjects taken by the students and their academic achievement.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Video and its processing are an interesting area as the increase in usage of internet videos, online streaming, CCTV, impact of internet on normal crowd increased. The need to know about video and its processing become an eminent area in research in current era. The paper tries to cover the traditional video processing, the advancement in video codec from the initial year, its origin, features, drawbacks and advancement lead to next stage. It provides an insight to need of video compression, steps involved in it, followed by overall review about video compression in various areas. The detailed explanation with reason of emergence, origin, characteristics are pointed. This information helps to add knowledge about the past and that helps to focus on the advancement and transitions that can be done to the video codecs. It summarizes the advancement in recent video processing using CNN, NN, deep learning too.

1. Introduction

'Video' the meaning has shifted far from a set of moving pictures from a traditional point of view to far extends. But the knowledge of traditional video processing is important to have a clear perspective towards the current video processing era. Video processing have a vast meaning from enhancement of various parameter in video, resolution, restoration of videos, denoising of videos, video compression etc. Each has its own impact and development in each stage of video processing development from video in a digital camera to HDTV to mobile camera to 4K,8K,10K videos. "The development of video compression started from the very started from the very start with a shadow of image compression such as Huffman coding, Golomb coding [1], arithmetic coding [2] etc. Later transform coding was introduced by encoding in spatial frequency including Fourier transform [3], Hadamard transform [4], Discreet Cosine Transform [5] etc followed by JPEG" [6]

The scope of video standardisation focus on video optimisation, allows complexity reduction for implementation and it no guarantee in terms of quality. Only decoder, bit stream and syntax of decoder is standardised. The scope if standardisation lies in the codec part of video processing. The basic knowledge about the fundamental terms in video processing helps to have strong view about any processing or standardisation done in video.

Video processing needs basic overview about the fundamentals like bitrate, display resolution, frame rate, frame type, interlacing, aspect ratio, video quality and compression techniques.

Bit rate is termed as the video data transferred in a frame of time or number of bits in the video transferred in a time durartion.it is related directly to the sharpness of the frame. This is a vital thing when we consider live broadcast into consideration. The term bitrate should be handled intelligently based on the encoder and decoder. Transfer speed also is a matter to be considered here. Display resolution in video is another area to be noted in video processing. Screen resolution /display resolution was not that important part in traditional era of video processing but as time moved and screen came with various sizes colour option, video

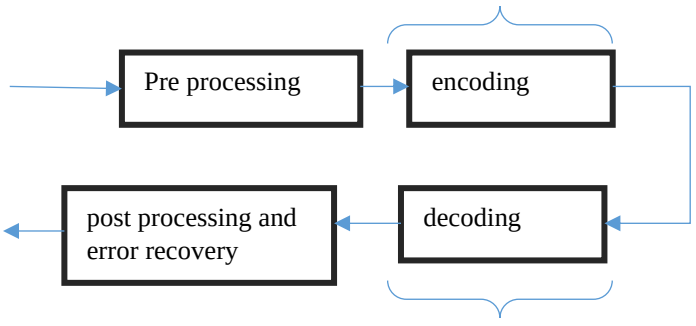

Figure 1: Scope of standardization

*Corresponding author: Helen Kottarathil Joy, helenjoy88@gmail.com

Screen resolution comes with an extension of 'p' and 'i' like 780p,1080p,1080i etc, it represents progressive /interlaced. The CRT monitors and TV followed interlaced scanning were the problem is flickering. Progressive scanning came into market as boom because the recent display screen responds fast. The refresh rate will be 60 normally to have better view effect. There are various frame resolution or frame type as in table

Table 1: Screen resolution Table

Sl.no	Resolution name	Horizontal pixels count	Vertical pixel count	Another Name
1	720p	1280	720	HD
2	1080p	1920	1080	Full HD
3	1440p	2560	1440	Quad HD
4	2160P	3840	2160	4K
5	4320P 8k	7680	4320	8K
6	4320p 10k	10240	4320	10K

Its noted that high resolution video can be viewed in low resolution screen. Video resolution doesn't matter on the screen it watching as it is taken care by the down sampling part in the decoder.

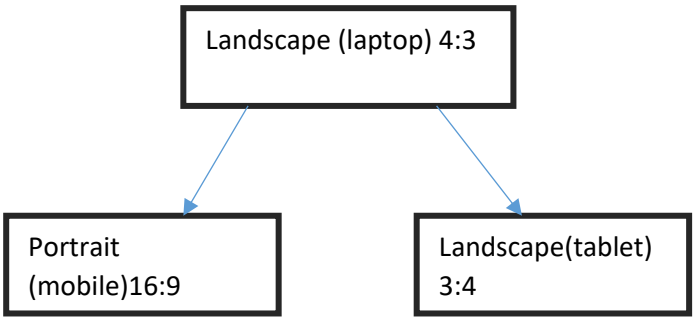

Figure 2: Aspect Ratio ideas

Aspect ratio says how the screen is with respect to the height of the display. In early ages 4:3 was common aspect ratio. In early 2010's by the boom of mobiles 16:9 become so prominent. Display orientation is another thing to be known. Size of the screen resolution should be considered properly for better display.

The paper is divided into three sections. The section 2 give brief idea about the steps in video compression, section 3 give a review of traditional video coding standards its origin, features and developmental stage towards next version. Comparison is done between various compressions followed by a overview about recent video compression with CNN and deep learning [7]. The paper ends with a conclusion with the need of learning traditional video compression for future research.

2. Video compression

2.1. Overview of video compression

Video compression is defined as a data reduction method ie used to encode the video. Video coding process helps that is the reduction of size of video file by making it compatible to store and need only less bandwidth for transfer. Video compression started as a succession of image compression. The compression mainly happens in a better way in video processing as the information carried by the frames are similar in most cases. A better percentage of compression can be achieved by taking this area into consideration. Video compression is essential as storage is taken into consideration. The disk space is important as we can more videos in fact more information can be loaded. Various transforms like DCT, DST etc can also be considered to reduce file size or in other words compression.

2.2. The stages of video compression

The basic steps in video processing are divided into six steps staring with partitioning the picture, predicting the similarity within the frame and between the frame. Majority of compression happens in this stage [8]. The predicted frame and other information's are transformed using DCT and quantized. All these were coded by using entropy coding and send as bit steams with proper bit rate.

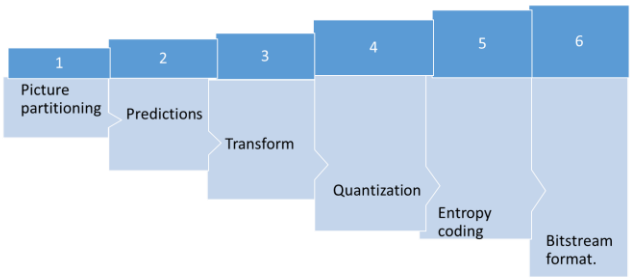

Figure 3: Basic Video Compression Steps

The input frame is transformed using DCT after picture partitioning (Splitting picture into macro blocks as apart of coding tree unit), then quantized. The quantized frame is inversed and compared with the previous frame in motion compensation and estimate is done by subtracting reconstructed frame from input frame and the residual with motion compensation. This is done by intra and inter prediction techniques basically comparing CTU within the frame and between frame to reduce redundancy and to gain maximum compression. The residual frame obtained will be 75 percentage compressed by this stage. The obtained frame 1&2 is transformed and quantized and the reconstructed frame is compared and subtracted. The process repeats and the output is encoded and framed and send in prescribed bit stream format.

3. Traditional video coding standards

Digital video technology covers the area of communication digital video telephony, digital TV, video storage, and a series of applications. This helps in the development of video codec in a faster way. The way of development of video codec are mainly focused on the organization ITU and ISO/IEC, joint venture of IFC and ISO are also available. ITU standards covers video codecs from H.261, H.263, H.263+, and this focus mainly in the video compression in real time communication for example video

conferencing whereas ISO/IEC mainly focus on the internal streaming, video storage etc. The bird view of video compression is shown in figure 4. Based on the purpose and application the compression features vary, upon that the segregation can be as the

one used in web or internet application, in cinemas, and for other medias. The ISO/IEC organization works on MPEG series as ITU/VCEG works on H.26x series. The ancestry of recent video compression followed this way.

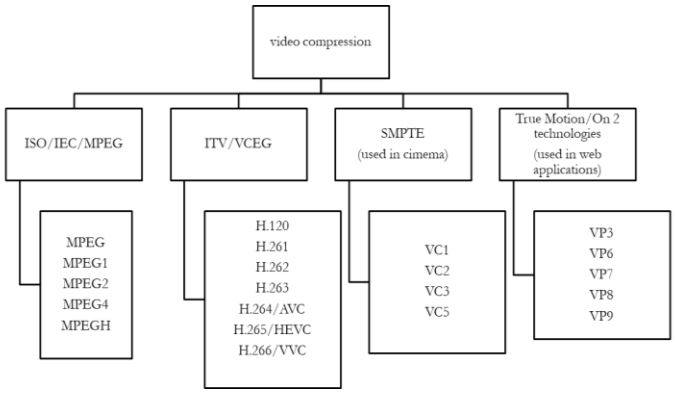

Figure 4: Video Compression Overview

Table 2: Specifications of H.262

1	Bit rate	1.5-2.0 Mbps CBR/VBR constant /variable bit rate
2	Packet/ cell loss rate (CLR)	<1 in 10 (-8)
3	BER	<1 in 10(-10)
4	Packet/ cell delay variation	<500ns

3.1. H.120 Video Compression Standard

The video coding standard starts with H.120 i.e. developed in the year 1984 by CCITT currently known as ITU-T. The primary application was video telephony and teleconferencing over ISDN. The bit rate available was 64kbits /sec.H.120 was not that good enough for real life applications, its spatial domain was good and temporal resolution was poor. The discussion came that encoding should have less than 1 bit as an average in a pixel. This leads to the idea of DCT block-based codec ie H.261.

3.2. H.261 Video Compression Standard

H.261 is the first member in the H.26x family developed in the year 1988-1990 in November by VGCE ie ITU-T9 video coding expert groups. The focus for the development of H.261 was similar to H.120 like video conferencing in ISDN and video telephony as it couldn't satisfy it [9]. The bit rate it was focusing was multiples of 64 kbits /sec. It was used as a backward compatibility mode in H.323 and some video conferencing system still it couldn't be perfect and need refinement that leads to next video codec. But still it remains as a milestone in the history of video codecs.

3.3. H.262/ Moving Picture Expert Group-2

H.262/MPEG-2 was proposed in 1995 by the joint venture of VCEG and MPEG. It is mainly for storage of video like SVCD, digital video, Blue ray, broadcasting, DVD video etc. Its bit rate is suitable for only less than 1Mbps, performs bad for high bit rate. MPEG -2 is a lossy compression method with motion estimation vector, DCT quantization an encoding by Huffman coding, the technique happens in this sequence [10]. The motion vector estimation compares the frame and approximate it into similar set of video frame in a translated form with changes between the frame. This helps to reduce the greater percentage of temporal redundancy in the video frame. This is followed by DCT that helps to convert the spatial information to frequency domain and discard all high frequency information that will not affect the visual experience of human eye. Quantization is applied to the coefficient of DCT. Huffman coding shortens the code and helps in better compression but its lossy with entropy coding.MPEG is good for high quality video with a particular set of transmission limit but not that better for internet transmission as the QoS of MPEG can't be satisfied always with intend.

3.4. H.263 Video Compression Standard

H.263 was designed for low bitrate mainly on video conferencing. This was evolved from the pros and cons of H.261,

MPEG-1, MPEG-2 standard developed in 1996 by ITU -T9. The main application was B-ISDN video on mobile phones (3Gp), video conferencing and video telephony adopted H.324 PSTN. the bit rate followed was 33.6 Kbps. It was developed as their levels that is 1,2,3 as H.263, H.263+, H.263++ with various extra features added on it. H263+ was focusing on improved compression performance and bit stream scalability. H.263++/H.263 2000 namely MPEG 4 part 2, it helps surveillance system its simple profile formal.

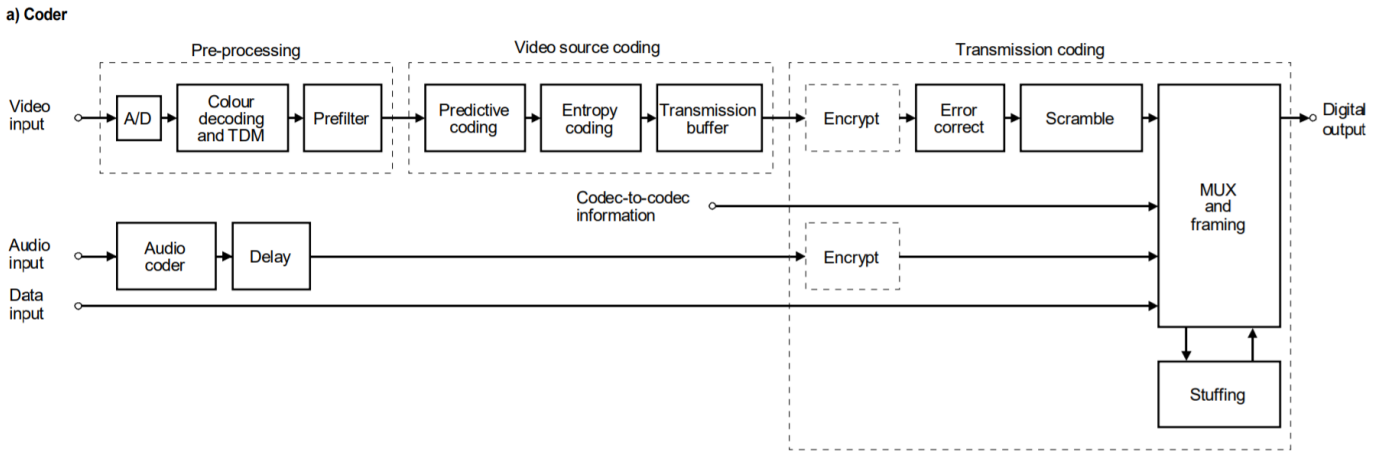

Figure 5: H.261 [7]

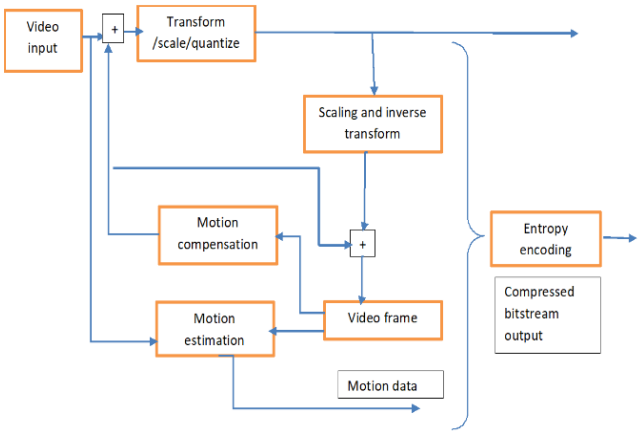

Figure 6: Hybrid video encoder [1]

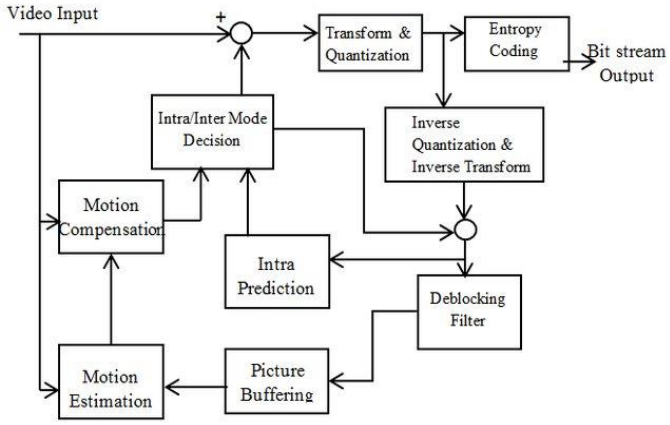

Figure 7: H.264 codec [12]

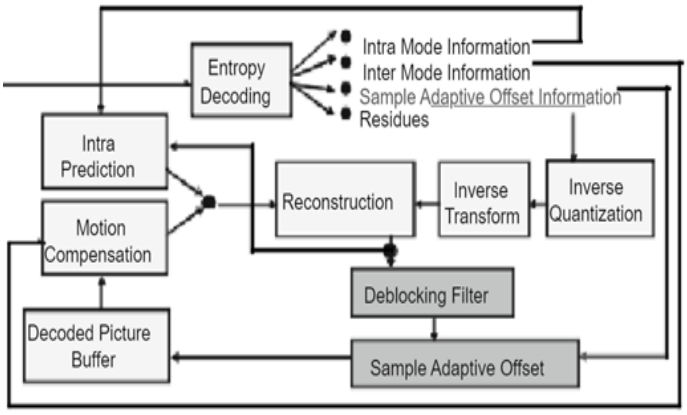

Figure 8: Video Compression with HEVC [14]

3.5. H.264 Video Compression Standard

H. 264/MPEG 4, AVC i.e. [10]an extended version of H.263, MPEG 4 visual released on 30th may 2003 is developed by ISO/IEC and ITU and H .264 and distribution of video content. The resolution it support is 4096X2304 that includes UHD and 4K videos. It uses variable bit rate. Advanced Video Coding /AVC is 25th version of AVC ie MPEG 4 part 10[11]. It is the best-known video coding standard for media storage like Blue ray disc and widely used in streaming in internet source that used variable bit rate. Scaling video coding is a domain feature here added with multi view video coding, 3D-AVC and multi resolution frame compatible (MFC). The application area includes DVBC (digital video broadcast project), HD-DVD, ATSC (advanced television system connector), CCTV (closed circuit TV), DSLR etc.

3.6. H.265 Video Compression Standard

H.265 is devoloped as the successor of AVC with reduced file size, reduced bandwidth[12]. There are CTUs in HEVC than macro blocks in H.264. The HEVC have variable CTU size from 4x4 to 64x64. The main features of HEVC includes flexibility in partitioning size, flexibility in trasform block size and predicting the modes, parallel processing architecture, sophistication for prediction, signalling mode and motion vector[13]. HEVC architecture has encoder and decoder. In encoder picture partioning is done. In the next process is the partioned picture is predicted by intra /inter prediction and the result is subtractred from the original unit[14]. The residue is transformed by DCT and quantised in next step. At the end transformed output, predicted information, mode information, and header are entropy encoded. In decoder the counterpart does the reverse operation to deliver the picture to other end of communication[15].

3.7. Society of Motion Picture and Television Engineers standards

It was introduced in founded in 1916 as the Society of Motion Picture Engineers or SMPE is a global professional association, of engineers, technologists, and executives working in the media and entertainment industry. An internationally recognized standards organization, SMPTE has more than 800 Standards, Recommended Practices, and Engineering Guidelines for broadcast, filmmaking, digital cinema, audio recording, information technology (IT), and medical imaging[16-19]. In addition to development and publication of technical standards documents, SMPTE publishes the SMPTE Motion Imaging Journal, provides networking opportunities for its members, produces academic conferences and exhibitions, and performs other industry-related functions"[20].Compression Systems in SMPTE has standardized five VC standards: VC-1 to VC-5 to provide well-reviewed documentation and enhanced interoperability. The latest of these is the VC-5 standard family that provides documentation and reference software for the video compression used in GoPro systems and workflows. SMPTE also has a new project to document the Apple ProRes codec.

3.8. Video Processing for Internet

On 2 codec designs are popularly known as VP3 then VP7.VP6 was used in flash 8 video codec. It was used in google, skype, YouTube etc. Microsoft and Windows media player version 9 properties similar to Real video, DivX and On 2 tech. AVC improves compression quality, H.264 becomes leading standard and used by many video applications such as in iPod PlayStation Portable, as well as in TV broadcasting standards like DVB-H and DMB[21].AVS audio video standards were initialized by China, the main reason china holds the key factors in development of consumer electronics. Coding efficiency is equivalent to H.264 while computation complexity is less. It was widely used standard [22].

Table 3: Comparison Table of video codecs

Parameter	HEVC	AVC	VP9
Compression Efficiency	Twice compared to AVC	Less than HEVC	Less than HEVC
Resolution &uploading speed	Less compared to AVC	Better compared to both	More
Bandwidth required for broadcast	15mbps	32mbps	More than HEVC
Compatibility	4k TVs, VOD	3Dvideo coding.	Better in chrome, opera Firefox…
Royalty	Not open source	Not open source	Open source
Computation cost	low	high	low
Encoding quality	Good for low bit rate videos	Use lower bit rates better than previous standards	Good for high bit rate videos
FPS	Support up to 300fps	Support up to 59.94fps	Support up to 60fps for video

4. Neural network and Deep learning-based video coding standards.

After the development of H.265/HEVC, the blocks in the codec were explored and improved by adding neural network/ deep learning techniques [22-27] into it. The development of video codec in the following year will be mainly on making a smart video codec by incorporating the deep learning features into it[28-30]. The trial of neural network /deep learning into HEVC standard by the application of trying to make smart modules in HEVC. By using multiple features, the modules are trying to be made smart. The future of codec lies in the hands of deep learning i.e. the future is expecting a smart video codec by absorbing the basic steps in codec and improvising it by adding deep learning techniques into it. Work have been done in HEVC modules intra-prediction, inter-prediction, quantization and encoding and loop filter with neural network methods [31] that can be revised and learned separately.

As an overview the neural network for video coding can be reviewed this way, for intra prediction all the method developed for still image can be used. As we know the applications are many. For neural network based intra-prediction the effective tool considered can be motion, with the better training network it can be effectively done. Some other research happened in this area using CNN are post processing, resolution up conversion sub pixel interpolation, loop filtering, intra-coding, encoding optimization etc.

5. Conclusion

Video and its processing are the area that is focusing on a smart era in the near future with high quality advancement. The paper points the video processing developmental stages from initial days till now. This helps to focus on the recent research in video processing and thus paves way for new research knowing about the origin, features and properties of early codecs, earns us to work on the future of video processing. The early era of video compression started with basic coding like Huffman coding, arithmetic coding etc and transforms like Fourier transform, DCT etc followed by the hybrid video processing era with many compression techniques from Motion JPEG to H 265. The detailed study of this helps to identify that in each stage the was trying to improve the compression ratio, reduce the complexity of circuit, and with high uploading speed. The research and advancement in this area can be done by having a strong base about the existing video processing. The drawbacks of the system can be reviewed and that helps in the research to make it smarter one. The future is focusing on smart video processing and deep learning, NN, CNN are the strong pillars for intelligent video processing.

ABSTRACT

This paper is an extension of work originally presented in PM2.5 Prediction-based Weather Forecast Information and Missingness Challenges: A Case Study Industrial and Metropolis Areas, which focused on imputation algorithm to solve missingness challenge and demonstrated a basic prediction system to prove the proposed algorithm, II-MPA. Distributed and decentralized systems, recently, have been proven for their effectiveness in multiple perspectives. This paper introduces "Overmind", the solution that governs and builds the network of decentralized machine learning as a prediction framework named after its functionality: it aims to discover a set of data and associated attributes for assigning machine learnings in the collaborative decentralized manner. Overmind also empowers feature transfer learning with data preservation. It demonstrates how discovered features are transferred and shared among synergic agents in the network. This model is tested and evaluated the accuracy against the traditional single machine learning prediction model in the original work. The results are satisfactory in both prediction performance and transfer learning.

1. Introduction

This paper is an extension of work in [1]. Traditionally, a single machine learning is built to process upon a dataset; this can be served as a recommendation, prediction, classification, etc. Unfortunately, the drawback of the traditional model is realized where machine learning problems and algorithms are far enough that all scenarios can be resolved using a single model [2]. A traditional approach relies on the training process over a whole dataset; data exploration, perhaps, consumes time and resources. Also, the experience in data analytics does not guarantee the effectiveness of the built machine learning systems to specific business scenarios. Moreover, discovering new attributes in real-world scenarios may require a brand-new dataset and retraining process. As business prefers to preserve data as much as possible, this is supported by system design which deals with a new data pattern and the least trade-off and penalty in performance.

This paper innovates a framework under the "Data Blind" concept – it indicates the knowledge over dataset and scenarios, which are unknown and undiscovered. Hence, the proposed framework performs data analytics for building machine learning models that serve multiple purposes. Overmind, a system conceptual model in distributed artificial intelligence, is named after its theoretical design. Overmind aims for managing dataset, discovering data pattern, and creating collaborative agents, as a complete framework. This paper experiments a demonstration of how it works, and steps, which are taken to gather results and contributions. An interpretation of behaviours and outcomes will be studied and presented in future works.

2. Previous works

The concept of Overmind has been forged base on previous machine learning algorithms and the decentralized systems. We also explore related works on feature transfer and selection. Thus, this section illustrates in two aspects, which are Multi-agent and Decentralized System, and Feature Transfer.

2.1. Multi-Agent and Decentralized System

A term of Distributed Artificial Intelligence (DAI) has been defined based on the concept of distributed intelligent agents. Many projects and methodologies have been reported and summarized into categories proposed in [3] as system conceptual and agent conceptual models. The fine examples of DAI contributions were presented in [4–6] in the area of Intelligent Manufacturing System (IMS) since 1990. Then, a decentralized and distributed machine learning works were published in 1993 [7, 8]. The Cooperative Distributed Problem Solving (CDPS) that involves active agents sharing cooperative behaviours and protocols was invented in 1995 [9]. However, the cooperation is working based on broadcasting negotiation between a system and active agents by receiving the message to perform solving collaboratively.

Undeniably, this paper is highly influenced by the concept proposed in years ago. Although, machine learning has been continuously improved its capability and intelligence to the level that can resolve complex problems in the real-world scenario. Today, a decentralized reinforcement learning [10], which is again inspired by the multiagent system, describes problem statements that require large-scale real-world machine learning whereas the completed work focuses on two dimensions - Networked Evolution Strategies (NES), and Bayesian Optimality in the Wisdom of the Crowd (BOWC). NES describes network structure of communication between parallel-processing agents, that speed up learning process. This network structure of communication inspires Overmind's concept to integrate network analysis components and allow communication among decentralized machine learnings. Lastly, BOWC draws attention to the modelling on how humans learn from the influence of each other; this also inspires the Overmind concept for incorporating the knowledge management framework to mimic the collaboration in humans.

Decentralized Clustering in Large Multi-Agent Systems [11] draws a concept of using multi-agents in decentralized clustering, which is one of the major machine learning objectives. To overcome data clustering real-world problems such as data is widely distributed, data sets are volatile, and data instances also cannot be compactly processed, decentralization of multi-agent has proven its better performance against the traditional k-mean algorithm. This reviewed work hints decentralized clustering of a single dataset, perhaps, gives significant contributions in pre-data processing.

Recently in 2019, Feature Distributed Machine Learning (FDML) is studied collaboratively called FDML: A Collaborative Machine Learning Framework for Distributed Features [12]. This work inspires privacy preservation in feature engineering when one machine learning model can acquire prediction power by using additional features from other machine learning without sharing actual features. This works fully introduces the collaborative machine learning framework with high capability in transfer learning. The experiments are conducted using a different algorithm, and the results yield significance in real-world application development.

Nowadays, a concept of distributed and decentralized artificial intelligence has been widely reported, which shows upcoming era in machine learning integrated fields of research such as artificial intelligence in distributed ledger technology [13], artificial intelligence as IoT [14, 15], distributed security solution [16, 17], etc. Surprisingly, these integrations are all based on a distributed and decentralized concept.

2.2. Transfer Learning

In this sense, transfer learning refers to a process where discovered knowledge is fed to existing machine learning for reinforcement and adaptation over modelling that intents to re-train for better performance. Furthermore, the communication among models in a network is established for transferring particular knowledge from one machine learning to others [18]

Similarly, work in [19] introduces the transferring knowledge over different classes. This work also emphasizes transfer learning in feature selection for machine learning models using a proposed framework. The results of this work influents possibility of transfer learning in real-world dataset across classes and domains.

In sum, this paper draws conceptual designs based on previous works in two dimensions, which are distributed and collaborative systems, and transfer learning. However, the algorithm and process behind our work are different from the origins due to its' concepts and purposes. Ultimate research questions under our contributions are following: (1) how to establish an end-to-end platform for demonstrating collaborative machine learning models in a dynamic network in order to power up the prediction and (2) how to create a flexible system for transfer learning between models in a network that reflects the reinforcement.

3. Methodology

This work follows a quantitative research method. Firstly, the literature review is performed by limiting the scope of previous works and using keyword-searching. The results of the review are compounded into the conceptual design of the proposed framework, Overmind, which will be described in the next section of this paper. The reviewing of the proposed framework is conducted by researchers and authors. Experiment and testing are conducted on our previous work dataset, Thailand Air Quality Index (AQI) and weather forecast information. The result of applying this proposed framework is studied by comparison against the traditional framework on the same dataset, as presented in sections 5 and 6 of this paper.

4. Overmind: A Framework for Decentralized Machine Learnings

Overmind, a collaborative decentralized machine learning framework, is proposed considering dealing with anonymous dataset before building a machine learning model to serve purposes such as prediction, recommendation and classification. Figure 1 shows the main conceptual design of deploying multiple collaborative machine learning models (“agents”) each of which is responsible for a specific cluster of data. Collaboration means the agents can communicate and exchange knowledge, and share the workload for data processing.

This paper proposes Overmind as a collection of functional processes which are:

1. Determine Data Clustering

2. Assign Agent
3. Establish Network
4. Transfer Learning

In the following section, the aforementioned functional processes are explained in the respective order.

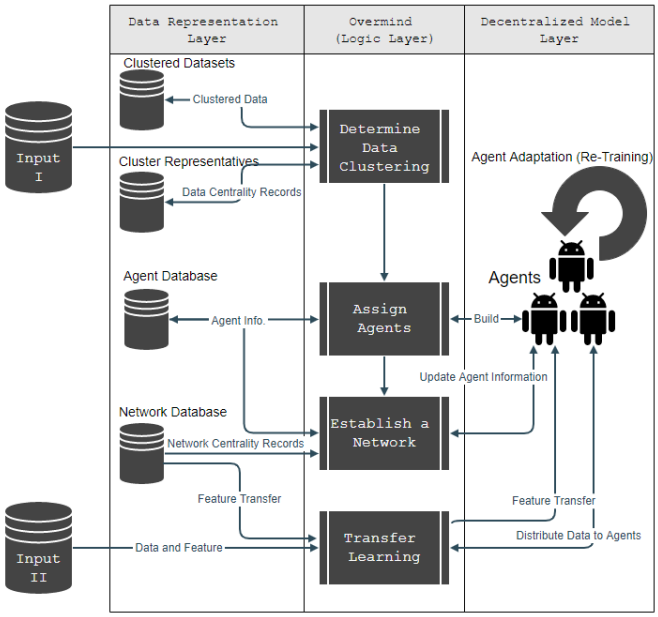

Figure 1: Overmind Architecture

4.1. Determine Data Clustering

Firstly, just the traditional approach, Overmind mimics the data cleansing process by using unsupervised learning algorithms to divide the dataset into clusters. This can be demonstrated as follows:

1. Let D be the training dataset where $D = \{d_1, d_2, d_3, \dots, d_n\}$, given that n is the number of instances.
2. Let F be the feature set, where $F = \{f_1, f_2, f_3, \dots, f_z\}$, given that z is the number of features in D.
3. Overmind deploys unsupervised learning method to divide D into clusters, given C is a set of clusters where $C = \{c_1, c_2, c_3, \dots, c_k\}$ and members in D are allocated and distributed over members of C, and k is the number of clusters.
4. The framework proposes s as centrality node of similarity graph of data under c_i. Hence, each cluster contains centrality node of data which is represented as s_i, where $i \leq k$

Figure 2 illustrates the output of determining data clustering and assigning agent.

4.2. Assign Agent

Agents are the supervised machine learning models trained using data in each cluster. Overmind determines the number of agents and builds a supervised machine learning algorithm to create agents, which can be explained as follows:

1. Let A be a set of agents trained by using C, given that a_i is trained by using data under c_i where $i \leq k$
2. Hence, a_i will be agent based on z features, given each feature contains weight/coefficient for particular a_i. Let W_i be a set of weight/coefficient of features for particular agent a_i

4.3. Establish Network

To build a collaborative framework, there shall be linkages between agents and rules for cooperation. This paper introduces a similarity network of agents based on the graph as below:

1. Let G be a graph of pairs $(V(G), E(G))$ where $V(G) = A$.
2. Similarity of agents in A is measured by W_i of particular a_i, given that y is a pre-determined threshold of similarity.
3. $E(G)$ will be created and linked between agent in $V(G)$ where the similarity measurement of a pair of agents satisfies y. This results in a network of agents.
4. Denote the centrality of G by H_G. If the centrality of G corresponds to multiple agents, Overmind selects one.

Eventually, Overmind creates decentralized machine learning as a collection of nodes in a network by using similarity measurement. Each node represents a supervised machine learning model.

assessed in term of similarity, which can be advanced for future works when one would like to measure affinity among trained models.

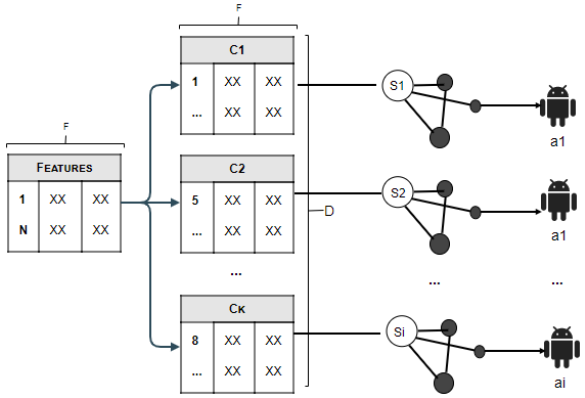

Figure 2: Illustration of Determining Data Clustering and Assigning Agent

4.4. Transfer Learning

This section describes two major transfer learnings of Overmind –data and feature transfers.

4.4.1 Data Transfer

Data transfer is involved when new data arrive for processing. Assumption on testing scenario when d_{n+1} is discovered and fed to framework, Overmind determines a suitable a_i for d_{n+1} by using s_i. This process implies similarity measurement on the centrality of clusters and new data instances. The steps are taken as below:

1. Let D' be a test dataset of this framework. Hence, $\{d'_1, d'_2, d'_3, \dots, d'_q\} = D'$.
2. Overmind determines each d'_x in D' and measures the similarity of d'_x to s_i.
3. Overmind assigns d'_x to a_i which has the highest similarity measured between s_i and d'_x. This step can be considered as

a batch process where D' is divided into subsets for feeding to particular a_i.

4. The accuracy of framework is measured as average accuracy of d'_x or average accuracy of subsets in D'.

4.4.2 Feature Transfer

Features and Feature Transfer are challenging components in designing the machine learning model. A traditional approach may require retraining of model when dealing with newly discovered features. A retaining process takes resources and time consuming for a big dataset. Yet, in the real-world scenario, some business may obtain a set of new information, both data and features, whether it contributes significances or not, but they have no willing to dispose of an existing dataset or pre-trained model.

In this sense, feature transfer refers to the ability that the existing trained model determines and deploy the discovered new features without retraining model; this means the transfer process will occur in every agent in the network. To elaborate flexibility in a dynamic machine learning model which accepts changes in both dataset and features, Overmind is conceptually designed to overcome the aforementioned challenges by described steps below:

1. When f_{z+1} is discovered within a new dataset D_{new}, Overmind predetermines a need of f_{z+1} by mimicking the supervised machine learning model of H_G and process upon D_{new} along with f_{z+1}. However, to avoid data volume bias, Overmind will proportionally random data in each c_i to form a dataset as equal as D_{new}.
2. Let accuracy of forming dataset is denoted by acc_{ext} and accuracy of model upon D_{new} is denoted by acc_{new}.
3. If $acc_{ext} > acc_{new}$, Overmind drops f_{z+1} from D_{new} and takes as data transfer process. This indicates that f_{z+1} cannot improve performance of existing system.
4. If $acc_{ext} \leq acc_{new}$, Overmind considers f_{z+1} as significant feature and process further steps for feature transfer process which is described below:
   4.1. Where the existing dataset lacks of f_{z+1} true values, Overmind creates imputation model by changing target label to f_{z+1} using forming dataset. This imputation model is denoted by a_{imp}.
   4.2. Overmind inserts f_{z+1} for each c_i in C, denoted by c'_i. This may result in extreme missing values in f_{z+1}. Hence, a_{imp} is used for imputation of missingness.
   4.3. Starting from H_G, agent a_i retrains its model along with f_{z+1}, the retrained agents are denoted by a'_i
   4.4. Retrained agents a'_i perform cross-validation and compare a result against a_i. There are two possible outcomes
      - a'_i gives a better performance, then f_{z+1} is accepted. a'_i adjusts W_i, denoted by W'_i, or else
      - a_i gives a better performance, then f_{z+1} is rejected. a'_i flags weight/coefficient of f_{z+1} as zero in W'_i
5. Overmind reshapes a network of agents, this creates $G' = (V(G), E(G'))$. Perhaps, centrality of network may be different from G, Overmind updates the new centrality, denoted by $H_{G'}$

Figure 3 shows the establishing of network of agents and transferring learning that impacts changes over a network.

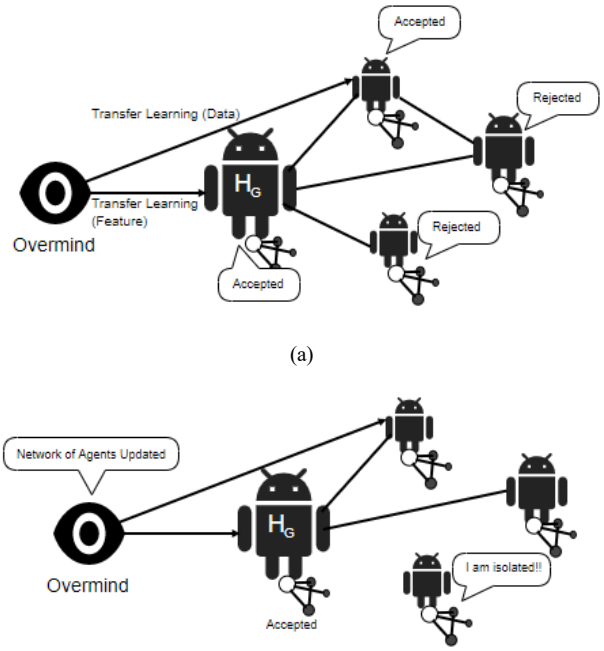

Figure 3: (a) Illustrating an established network with transfer learnings for both data and feature (b) Demonstrating a reshaped network resulted from transfer learning process.

Until now, a proposed framework creates a dynamic network which illustrates the transfer process among decentralized agents. Hence, this is called the collaborative decentralized machine learning framework.

5. Performance evaluation: a case study Thailand PM2.5 and weather forecast information database

To evaluate framework performance, this paper simulates the framework over the testing dataset, which is Thailand PM2.5 and weather forecast dataset presented in [1]. This dataset contains 2,383 instances with 21 features (including target). Overmind's simulation takes place in two functions, Framework Performance and Demonstration on Transfer Learning for Feature Transfer, to predict PM2.5 values from a given set of features.

5.1. Framework Performance

This paper deploys 80% of dataset for training and 20% for testing, for both traditional machining learning model –a single model –and Overmind.

In the training process, five uncorrelated features are removed from the dataset. Two algorithms, Gradient Boosted Trees (GBT) and Neural Net (NN), are used in this paper because the previous work has described Thailand PM.5 prediction using these algorithms. The set of tuning parameters is left by default using RapidMiner 9.6. For GBT, number of trees = 50 with learning rate = 0.01. For NN, training cycle = 200 with learning rate = 0.01. In addition, 10 folds cross-validation with automatic sampling type is used.

Throughout this paper, gradient color codes are used to indicate how good the results are. Green-colored fields indicate the higher accuracy and correlated values and red-colored fields indicate the opposite.

The clustering and agents training results show in Table 1

Table 1: Distributed Agents in Training Process

Agents	Train Dataset (0.8, 1906, F=15)		
	Data Instances (N)	GBT (RMSE)	NN (RMSE)
$D: a_s$	1906	13.50	7.21
$c_0: a_0$	1162	6.56	5.25
$c_1: a_1$	256	17.14	9.62
$c_2: a_2$	488	12.28	7.00
s: single traditional model $C = \{c_0, c_1, c_2\}$ $Distributed\ Agents, A = \{a_0, a_1, a_2\}$			

Table 1 proves a better performance, measured by Root Mean Square Error (RMSE), on agents, a_0 and a_2 than on a traditional single model, a_s, in both algorithms. It may indicate the abnormal data pattern in c_1 which causes variation of performance for a traditional model and assumption of removing these instances are not acceptable by business scenario. In other words, 13.43% of the instances drop performance of agent for from RMSE 6.56 to 13.50, and it seems to be unacceptable tradeoffs.

Establishing a network of agents, we explore the weights of features based on GBT variable importance percentage as shown in Table 2

Table 2: Variable Importance in agents based GBT

Variable Importance	$D: a_s$	$c_0: a_0$	$c_1: a_1$	$c_2: a_2$
AQI	0.762	0.689	0.123	0.282
CO	0.114	0.004	0.683	0.202
PM10	0.075	0.139	0.069	0.112
O3	0.017	0.003	0.041	0.018
PRESSURE	0.009	0.095	0.035	0.002
PRECIP	0.007	0.000	0.013	0.000
HUMIDITY	0.006	0.020	0.019	0.008
CLOUD	0.005	0.018	0.007	0.008
SO2	0.005	0.011	0.000	0.357
NO2	0.000	0.001	0.003	0.004
WIND	0.000	0.011	0.001	0.001
GUST	0.000	0.001	0.001	0.003
TEMP	0.000	0.006	0.005	0.003
TEMP_FEEL	0.000	0.002	0.000	0.000
TIME_POINT	0.000	0.000	0.000	0.000

By examining variable importance in Table 2, both of three highest importance features and lowest importance features were examined giving a clue that the criteria as feature weight on the prediction of PM2.5 differ for each agent. The data in each cluster should require a specifically trained agent.

Recall, an establishing network of agents based GBT algorithm, Overmind determines the similarity measurement of agents using variable importance. A Euclidean Distance Measurement is used to find the distance among agents. In Table 3, the similarity is measured by using the equation:

$$Similarity(s, d) = 1 - Distance(s, d) \quad (1)$$

where s is source node, d is destination node.

Table 3: Agent Similarity Measurement

Source	Destination	Distance	Similarity
$D: a_s$	$c_0: a_0$	0.17	0.83
$D: a_s$	$c_1: a_1$	0.86	0.14
$D: a_s$	$c_2: a_2$	0.60	0.40
$c_0: a_0$	$c_1: a_1$	0.89	0.11
$c_0: a_0$	$c_2: a_2$	0.58	0.42
$c_1: a_1$	$c_2: a_2$	0.62	0.38

Setting a threshold $y = 0.3$ means the edges will be created when the similarity between nodes is higher or equal to 0.3. However, this threshold is an adjustable parameter, the lower the threshold the higher chance for connected agents, the similarity of agents affects and shapes the transfer process. Where connection exists, a pair of the agent can communicate and transfer both data and feature, in another hand, isolated agent requires specially and specifically consideration. In this study, 0.3 is represented for the demonstration that creates linkages between agents unless the transfer process cannot be illustrated. Considering a tradition model, an agent in a network will results in Figure 4, however, this network will be examined again in the feature transfer section.

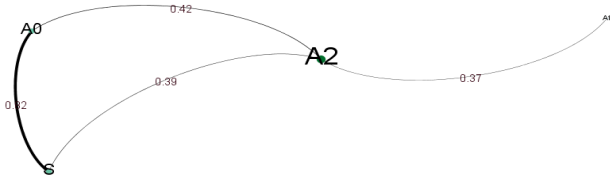

Figure 4: Network of Agents (|F|=15, y =0.3)

In the testing process, 477 instances of the dataset were distributed to specific agents based on the data similarity measurement. Moreover, the prediction assessments on both Gradient Boost Tree (GBT) and Neural Network (NN) were shown in Table 4.

The results show high accuracy when distributed agents perform a prediction over the associated clustered dataset. Undeniably, the traditional model is flexible and stable for input data. Perhaps, it should be considered as a tradeoff. We calculate average performance for distributed agents as:

$$Acc = \frac{\sum_0^i RMSE(a_i, c_i)}{i} \quad (2)$$

where $RMSE(a_i, c_i)$ is an accuracy of prediction by a_i on dataset c_i

Table 4: Test Results

Agent	Trained By	Test Dataset (0.2, n=477)					
		GBT (RMSE)			NN (RMSE)		
		c_0	c_1	c_2	c_0	c_1	c_2
		294	55	128	294	55	128
a_s	477	8.28	22.87	11.25	4.29	8.69	6.99
a_0	294	5.80	36.46	18.51	3.99	22.41	12.34
a_1	55	38.64	17.04	21.40	12.30	7.80	12.04
a_2	128	19.32	22.34	11.00	13.31	15.36	7.23

The GBT has achieved average performance RMSE of 11.28 whereas the traditional model has obtained RMSE of 14.13. On the other hand, the NN achieve the RMSE of 6.34, while the traditional model achieves at 6.65. These performances described in Figure 5.

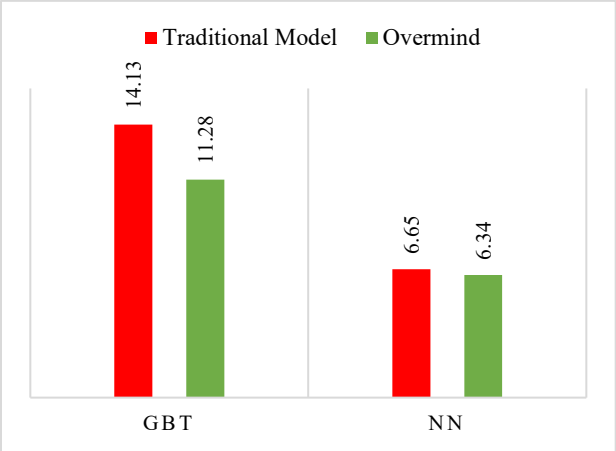

Figure 5: Average Performance, measured in RMSE.

5.2. Demonstration on Transfer Learning for Feature Transfer

In this demonstration, one correlated feature from a training dataset is removed, but a testing dataset remains with full features. Based on variable importance in Table 2, AQI is assumedly removed from the training dataset. The results of newly trained agents are shown in Table 5.

Table 5: Distributed Agents in Training Process, |F|=14

Agents	Train Dataset (0.8, 1906, |F|=14)		
	Data Instances (n)	GBT (RMSE)	NN (RMSE)
D: a_s	1906	14.28	9.97
c_0: a_0	553	15.72	11.96
c_1: a_1	234	16.20	12.45
c_2: a_2	1119	8.17	7.05

The performance of two minor clustered (n =553, and n = 234) significantly drops. However, it is not yet comparable results where |F|=15 because the clustering process may yield a different output. Base on this experiment, a same threshold value, $y = 0.3$ will result isolated a_2 which indicates that the data in c_0 and c_1 should be removed from the demonstration and only one agent required in this scenario, it is a_2; the demonstration will be then bias, hence, we lower a threshold to $y = 0.2$ and the result of networks of agents shows in Figure 6.

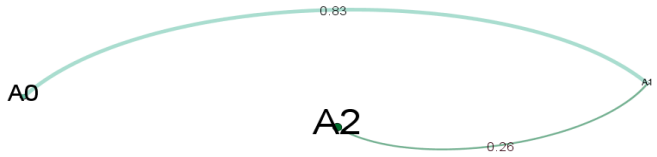

Figure 6: Network of Agents (|F|=14, y =0.2)

Figure 6 shows that a centrality of network is a_1, this means centrality of the network is determined neither by agent performance nor numbers of instances. The centrality of the network is responsible for sharing and transferring the discovered both data and feature.

Demonstration on a discovered new dataset and feature (n=477, |F|=14+1), assumedly, AQI is a new feature. Overmind firstly determines the need for AQI data if it can improve the performance of the overall agent or not. Overmind takes sampling proportional data from clusters in a network, then building a model to evaluate performance against a new dataset.

Table 6: Comparing Results for a Transfer Learning

Agent	No. of instance (n)	No. of feature (|F|)	GBT (RMSE)	NN (RMSE)
Existing Dataset: acc_{ext}	477	14	14.56	10.12
New Dataset: acc_{new}	477	14+1	12.43	7.90

Table 6 shows a better performance with a new feature, hence, a transfer learning should be accepted for the new feature, AQI.

An existing dataset in a network contains no value of AQI, and the business scenario does preserve existing dataset. Hence, an imputation model is built by using a new dataset for training process (n=477, |F|=14+1). Eventually, an existing dataset is imputed for a new feature, AQI; it is deployed to the centrality of the network, all agents accept AQI as a new feature because the comparison identifies AQI can improve performance as shown in Table 7.

Table 7: Distributed Agents in Training Process, |F|=14+1 (imputed AQI)

Agents	Train Dataset (0.8, 2383, |F|=14+1 imputed AQI)		
	No. of instances (n)	GBT (RMSE)	NN (RMSE)
D': a'_s	1906	13.39	6.85
c'_0: a'_0	553	14.19	7.10
c'_1: a'_1	234	14.55	9.55
c'_2: a'_2	1119	7.03	4.71

Overmind update a network of agents based on changing in similarity measurement among agents.

A re-connected nodes between a'_2 and a'_0 is formed, this results in a fully connected network, and the centrality of the network is shifted to a'_2 because it has the highest performance and controlling a majority of data in the network (N=1119). Overmind then continues data transfer process as described in (A). The data prediction results are shown in Figure 7.

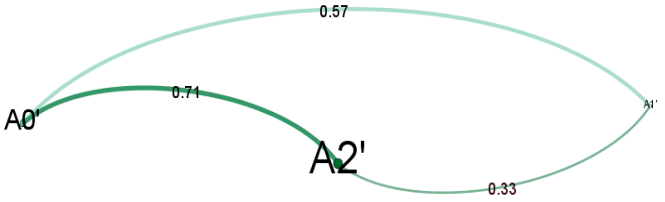

Figure 7: Network of Agents (F=14+1, Y=0.2)

Table 8: Test Result after feature transfer process

Agent	Test Dataset (0.2, 477, |F|=14+1)						
	No. of instance	GBT (RMSE)			NN (RMSE)		
		c_0	c_1	c_2	c_0	c_1	c_2
a'_s	477	14.44	17.02	11.92	7.11	13.11	6.36
a'_0	162	13.25	18.16	17.23	7.07	16.9	11.79
a'_1	37	19.73	13.61	25.73	19.81	10.38	15.64
a'_2	278	18.39	21.18	13.22	11.64	16.21	8.62

The comparison shows average performance in RMSE using GBT with 13.36 in this testing dataset, while a traditional model would give an accuracy, 14.46. For NN, the average performance in RMSE is 8.69, and 8.86 for a traditional model. This comparison is described as shown in Figure 8.

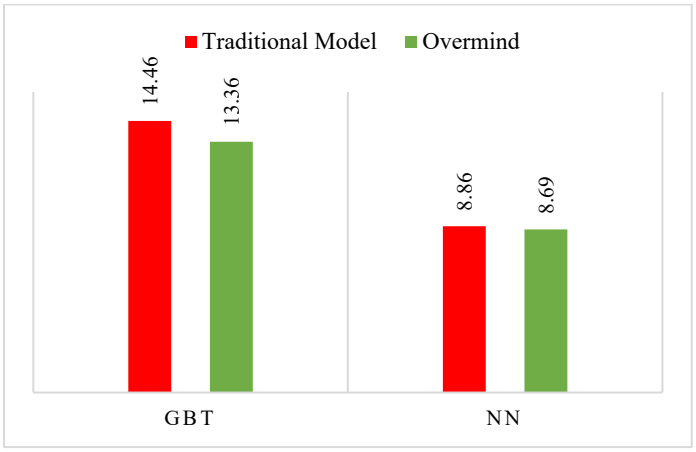

Figure 8: Average Performance, measured in RMSE after feature transfer process

Figure 8 shows penalty in transfer process caused by the imputation model that increases the RMSE after transfer process as shown in Figure 9. However, it should be reminded that demonstrating feature transfer is taken place on the important variable which is the AQI.

To verify the consistency of this approach, the progression of the framework functional processes, Determine Data Clustering, Assign Agent, and Establish Network has been performed. However, in the second round, the dataset is slightly different because (1) 1,906 instances (80%) of training dataset have imputed AQI values, and (2) 477 instances (20%) of the testing dataset have true values of AQI. To avoid confusing, the agents in the second execution is denoted by $a_{x:2}$ where x is a number of clusters produced by this execution.

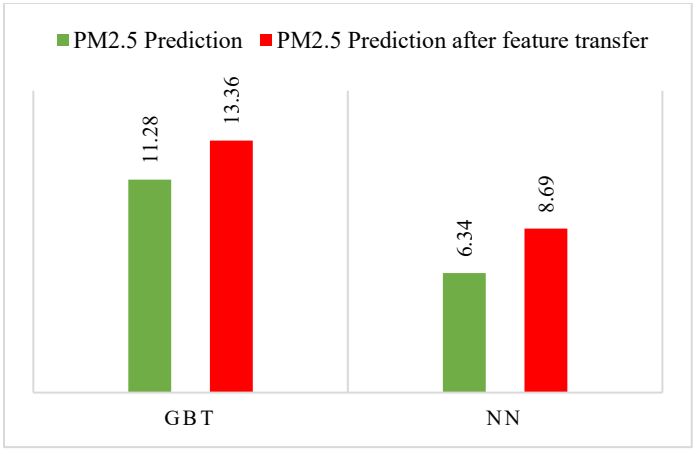

Figure 9: Penalty after feature transfer process

Table 9: Distributed Agents in Training Process by Second Execution

Agents	Train Dataset (1, 2383, |F|=15)		
	No. of instances (n)	GBT (RMSE)	NN (RMSE)
$D: a_{s:2}$	2383	13.05	6.95
$c_0: a_{0:2}$	1458	6.24	4.22
$c_1: a_{1:2}$	316	17.11	11.27
$c_2: a_{2:2}$	609	11.90	6.44
s: single traditional model $C = \{c_0, c_1, c_2\}$ $Distributed\ Agents, A = \{a_{0:2}, a_{1:2}, a_{2:2}\}$			

The result in Table 9 shows consistency over the clustering process which still produce three clusters with similar proportions. Moreover, the overall performance of agents is consistency and even slightly improved. Examining agent similarity using variable importance between the first and second executions are shown in Table 10 and Figure 10. The comparison in Figure 10 shows changes in variable importance, but the agents are keeping their characteristics over the same set of features.

Eventually, a network of agents is re-established as shown in Figure 11; a network of agents also preserves its structure where the centrality of network remains unchanged. However, if the similarity threshold is recalled in the very first demonstration of establishing a network where $y = 0.3$, the isolated agent $(a_{1:2})$ may occur which is assigned to the minority of data (n=316) that contribute poor performance.

Table 10: Variable Importance in agents based GBT by Second Execution

Variable Importance	$D: a_{s:2}$	$c_0: a_{0:2}$	$c_1: a_{1:2}$	$c_2: a_{2:2}$

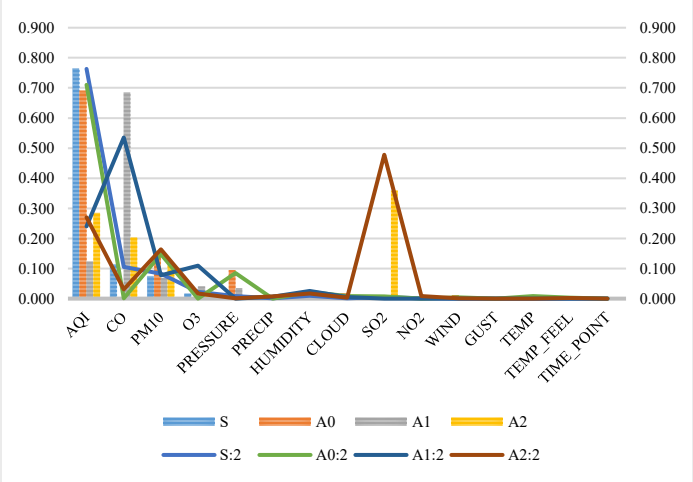

Figure 10: Comparison of Agent Variable Importance based GBT by first and second executions

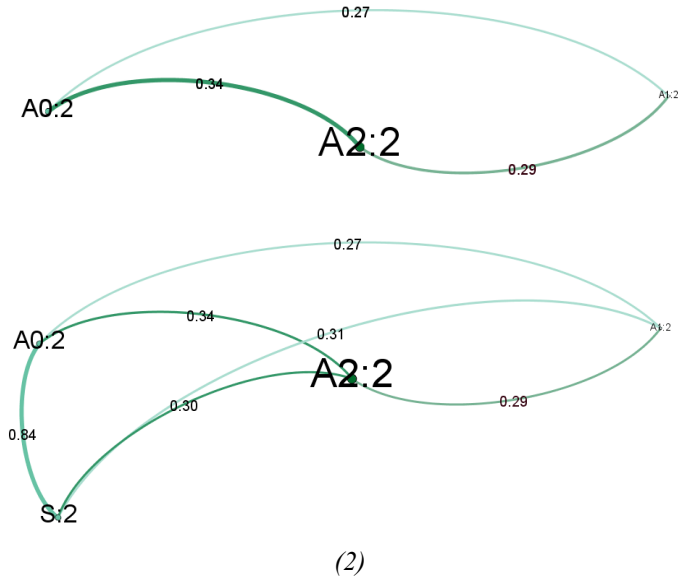
This scenario implies that the business may consider, (1) a separate studying of agents in order to build a specific algorithm for prediction over the associated dataset, (2) removing associated data instances out of dataset in order to reduce inconsistency and improve prediction performance, (3) reducing a threshold (y) in order to keep particular agent connected to a network because this agent can be a specific dataset where a business foresees this data will be increasing over time in soon future.

6. Results and Discussion

Till now, demonstrations of both framework performance, and the transfer process are explained. The summary of the performance of Overmind with four comparing scenarios in cross-validation agents' average performance can be concluded as follows:

1. Scenario I: Overmind assigns distributed agents on a fully completed dataset.
2. Scenario II: Overmind assigns distributed agents on a dataset where importance attributes is removed.
3. Scenario III: Overmind assigns distributed agents to demonstrate a situation where a new feature is discovered and transferred, and
4. Scenario IV: Overmind assigns retrained distributed agents and restates its network



(2)

Figure 11: (1) Network of Agents in Second Execution (F=15, Y=0.2) without Traditional Model, (2) Network of Agents in Second Execution (F=15, Y=0.2) with Traditional Model,

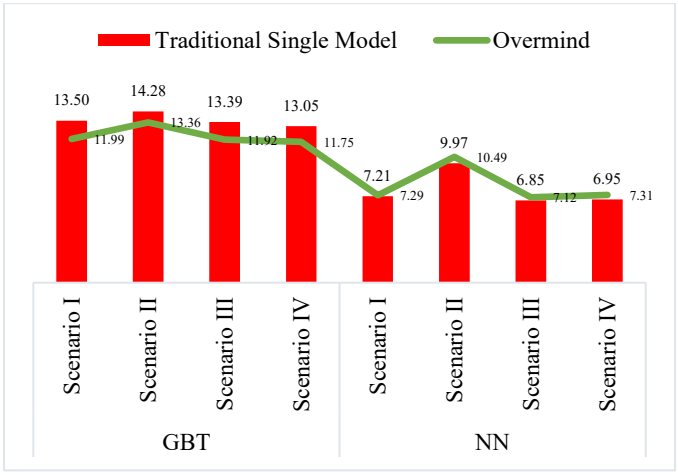


Figure 12: Comparison of Average Performance in Cross-Validation Agent Generated Models measured in RMSE

Figure 12 explains, for all scenarios, the cross-validation performance in Overmind generated models is impressive compared to a traditional single model under GBT algorithm. In the other side, the performance is not satisfied when compared to the traditional model under NN algorithm.

To summarize testing performance in testing data, we divide into two scenarios, (1) Scenario I: Overmind assigns distributed agents on a fully completed dataset, (2) Scenario II: Overmind assigns distributed agents to demonstrate a situation where a new feature is discovered and transferred. The results are shown in Figure 13.

Figure 13 indicates a better testing performance in all scenarios, but the performance is slightly better in the NN algorithm. In sum, Overmind can achieve its primary intended design and concept, this achievement can be demonstrated through our previous dataset for PM2.5 prediction in Thailand.

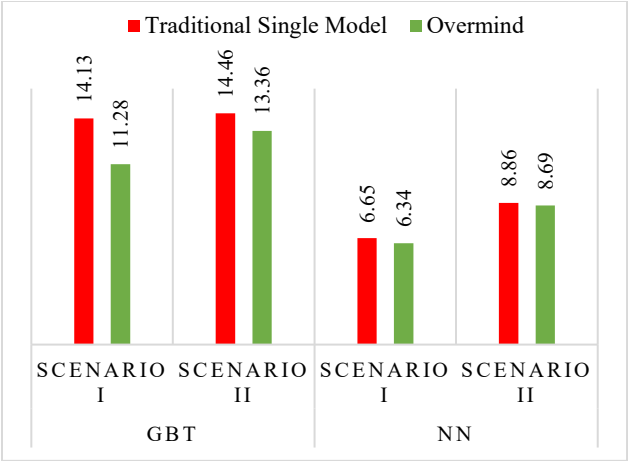

Figure 13: Summary and Comparison on Testing Performance measured in RMSE

7. Conclusion

Overmind is a framework aiming to demonstrate and facilitate a decentralized machine learning-based network analysis. This paper proves the concept and its performance through the mixed dataset between Thailand PM2.5 dataset and weather forecast dataset.

In data prediction, this framework can significantly reduce the data bias scenario, where input data is uncontrollable, variant, and clustered. Moreover, Overmind has proven its performance by comparing an average accuracy measured in RMSE on both traditional models (single machine learning) and distributed agents (multiple machine learning, agents). Overmind performs better performance than the traditional method in selected dataset using the GBT algorithm, reducing the RMSE from 14.13 to 11.28 (20.16% decrease). Furthermore, the RMSE is slightly reduced from 6.65 to 6.34 (4.6% decrease) in the NN algorithm.

A feature transfer process is demonstrated as a conceptual design for data preservation. However, the evaluated performance yields penalty due to imputation method.

In sum, Overmind has successfully formed a collaborative decentralized machine learning framework serving as an alternative in the design of a machine learning system. Possible contributions of Overmind are:

7.1. Higher Performance and Unaffected by Data Bias.

Overmind proves its effectiveness as a prediction system in the selected testing dataset. The design of Overmind is not affected by data bias because distributed agents are designed to function over associated sub-dataset.

7.2. Distributed Resource Utilization

Overmind mimics the concept of a distributed system so that it inherits the advantage where resources are allocated in a decentralized manner. Each agent utilizes computational resources for processing associated input instead of processing the whole dataset. This contribution also involves parallel processing and queue system where particular agents may transfer their queued inputs, as a bottleneck, to similar connected agents in a network for parallel processing where penalty inaccuracy can be traded off. This parallel processing for Overmind is already considered and planned for future work.

7.3. Dynamic Models in Collaborative Manner

Overmind demonstrates dynamic machine learning models for feature discovery and transferring across collaborative network analysis with data preservation. The concept of similarity measurement and network of agents has innovated methods in a dynamic framework. There are still opportunities in exploring the aforementioned methods to study optimization parameters and techniques.

8. Future Work

A study on optimization is recommended on Overmind's parameters. An interpretation over a network of agents formed by Overmind is an interesting topic to be explored and described how it contributes significances to business viewpoints.

In addition, the enterprise system architecture of Overmind can be improved and enhanced for higher performance and resilience such as queueing system and redundancy in agent level For example, when one agent is in abnormal stage, data can be continuously processed by neighbors or connected agents in the network; this will reduce the impact of disruption and error in artificial intelligence system.

Acknowledgment

We would like to thank the members of Faculty of Information Technology and Digital Innovation, King Mongkut's University of Technology North Bangkok, for their guidance and suggestions. Importantly, we would also like to thank Bangkok Air Quality for supporting data.

ABSTRACT

Mobile wallet is an application that allows users to make online payments using their mobile phones. In the context of an outbreak of COVID-19 epidemic in Vietnam and the world, mobile wallets are considered having many opportunities to change people's cash spending habits. The current study assesses the factors impact on the intention to use the mobile wallet, focusing on understanding the relationship of promotion with common factors in technology adoption research such as perceived risk, perceived usefulness, habits, social influences. The research results also show the direct and indirect effects of promotion on intent to use. From this result, 7 of 9 research hypotheses were accepted. Promotion, often overlooked by researchers, has been proven to be a critical factor when researching technology adoption because it significantly improves the level of intentional interpretation of the research model. This study will be the premise for future researches when studying adoption technology, researchers could integrate promotion to the model to achieve a significant improvement in the level of interpretation as showed in this study.

1. Introduction

PricewaterhouseCoopers (PwC) survey in 27 countries recorded Vietnam as the fastest growing mobile payments market in 2018, with the percentage of users increasing from 37% to 61% [1]. Facing increasingly complicated developments of the COVID-19 epidemic, the Vietnam's Government has also recommended people to limit cash payment and increase the use of online payment services to decrease the risk of infection. As a result, cashless payment methods, including mobile wallets, have a great opportunity to become more and more popular. In Vietnam, the ratio of non-cash payments to the total means of payment is only 14%, so the scope for growth of mobile wallets is huge. This context has created many favorable conditions to help mobile wallets develop and increasingly change the cash using habits of most Vietnamese people, actively contributing to bringing Vietnam towards the cashless economy [2].

Mobile payment means all payment services are made through mobile devices such as laptops, tablets or smartphones. Among them, mobile wallets are the latest e-commerce method that helps customers to make payment, shopping online, booking and share services. In terms of technology, a mobile wallet is an application installed in a smartphone or a tablet which allows consumers to input money and make online payments directly with the mobile wallet [3]. Mobile wallets can also be recognized as the revolution derived from e-wallets. Owning a wide ecosystem is a way of integrating into the digital transformation stream of users, especially young people who love technology. Because of the nature of mobile wallets, it is convenient, fast and secure in payment for daily activities, reducing the risks associated with spending and managing cash.

Although the application of technology has received long-standing attention from the government, it has not developed to achieve the desired scale, required for application in the entire systems payments in Vietnam. Vietnamese clients still prefer to use cash, reflected in the fact that there are still nearly 90% of transactions are paid by cash. Until now, almost no scholars doing research on mobile wallet in Vietnam whereas Vietnam is one of fastest growth in Asia area and is considered as a very attractive market for investors in all fields, especially technological payment. This study was carried out to fill the research gap in Vietnam related to mobile wallet.

This research aims to explore the factors affecting the intention to use of mobile wallet in Vietnam. The results are expected to provide the suggestions for mobile wallet suppliers to reach customers more effectively, and policymakers to drive a cashless economy in Viet Nam. In addition, the role of promotion demonstrated in this study will be the premise for future researches

when studying the adoption of technology, researchers could integrate promotion to the model to achieve a significant improvement in the level of interpretation as showed in this study.

We divided the content of this paper into five parts: The first part focuses on statement problem and meaning of this study comparing previous researches. Part two presents theories related study topic and constructing framework model. Besides that, authors have description research method and sampling characteristic in part three. To test the relationship between factors in the proposed model, we have showed analysis and results in part four and the last part is summary research results and implications.

2. Theoretical background and research framework

2.1. Theoretical background

Vietnam belongs to the group of countries with a high percentage of internet users (70.3%), equivalent to 68.5 million Internet users in 2019. With 43.7 million smartphone users (accounting for 45% of the population in 2019), Vietnam are at the regional average, higher than India, the Philippines, Indonesia and Thailand. Many advanced technologies are being applied such as biometric authentication such as fingerprint, face; quick response code (QR Code); Tokenization of information[4].

The development of technology, the popularity of the internet and smartphones has progressively increased the demand for cashless and digital transactions around the world. Customer attitudes and acceptance regarding mobile payments have also experienced a drastic change [5]. Many studies around the world have also confirmed that customers like technologies that can provide fast, useful services on a mobile platform. Mobile payment services, in which mobile wallets are one of the latest advances in the digital economy, have integrated these features [6, 7, 8].

Mobile wallet is one technology that have many growth opportunities in this condition [9]. Mobile wallets could replace physical wallets and even debit or credit cards in online and direct purchases. We see this technology as a major revolution in the digital economy because in the era of technological revolution, the issues of speed, interoperability, security and privacy of mobile technology have been resolved. In our study, we proposed and tested a research framework model which combined constructs in the TAM and UTAUT models, expanding with new variables for a transitional country like Vietnam such as promotion, a construct built from practice.

Promotion

Promotion is considered as a short-term marketing strategy and used to create awareness and interest in products or services. It helps the companies to attain sales and marketing goals [10]. Moreover, promotion could affect to the consumer's mind like a benefit to him/her, then creating the changes in consumer behavior [11]. Many studies have also confirmed the effect of sales promotions on consumer attitudes and consumer behavior [12, 13, 14]. As a result, promotion is a very useful strategic mean to improve profitability. Sellers are using various promotion strategies, for example coupons, product upgrades, price reduction, free samples and free gifts to increase intention to buy of customers. Promotion can be separated into non-financial and financial promotions [15]. The examples of financial promotions are discount of prices, coupons and vouchers while promotions related non-monetary include bonus products and gifts. The value of the promotion is also perceived relatively [16]. Customers could recognize a monetary promotion as a decline in losses because of this kind of promotion brings a reduction in the purchase cost that consumers have to pay. In contrast, promotion of non-monetary sales could be considered as a profit from the deal [17].

Related to the financial and payment sector, [18] showed the influence of sales promotion to persuade customers to open a bank account [18]. The results of this research showed that 50% of the increase accounts of a bank is the result followed a promotional campaign. Other researches showed the efficiency of promotion to influence the computer purchase and confirmed the positive linkages, promoting the behavior of purchase of financial services [19, 20].

Recent research on omnichannel shopping based on IT has included the promotion in the research model but has not found a meaningful impact of the promotion on intention to use [21].

In Vietnam, a recent study on the determinants of the choice of the customer mobile wallet, promotion in second place in the six elements outlined in the survey. As emphasized by several authors, there are academic and managerial deficiencies in the profound understanding of the relationship between promotion and consumer behavior [22, 23]. Especially in technology adoption, sales promotion still receives very little attention from researchers. That is why the construct of promotion is added to this study.

H1: The promotion of mobile wallet will positively affect the customers' perceived usefulness of this technology.

H2: The promotion of mobile wallet will negatively affect the customers' perceived risk of this technology.

H3: The promotion of mobile wallet will positively affect the social influences of this technology.

H4: The promotion of mobile wallet will positively affect the habit of customers for this technology.

Perceived usefulness

Perceived usefulness was mentioned for the first time by Davis in Technology Acceptance Model (TAM). This term refers to the ability of customers to improve performance by fully using the improved system, reflecting users' willingness to accept [24].

In technology adoption research, performance expectancy refers to an individual's perception that using a technology could provide benefits to customers in performing certain activities [25]. Reflecting a range of attributes that a technology could give benefits to clients, performance has been conceptualized by using system features that could enhance speed, productivity, and chances of task accomplishment and perceived usefulness [25, 26]. Unambiguously, in diverse task settings, performance expectancy was affirmed to affect intentions to use technological systems [27]. Consumers' perception that using mobile wallet would support them to achieve benefits in doing payment tasks could influence the behavioral intention of mobile wallet adoption. The following hypothesis was formulated:

H5: Perceived usefulness will positively affect the user's intention to use mobile wallet.

Perceived risk

Perceived risk was a popular construct used in extended models of UTAUT2 by several researchers. Perceived risk is considered negatively affect on intention to use [8]. Featherman and Pavlou also posited that individual's perceived risk of using a technology has negative influence on perceived usefulness (equivalent to performance expectancy) and behavioral intention toward that technology while his or her perceived ease of use (equivalent to effort expectancy) also has an adverse impact on the perceived risk [28]. Since mobile wallet is a new technology and includes complex and sensitive private information, perceived risks could be a difficulty in adopting this technology. Consumers could face monetary loss because of their improper operating system inaccuracy or potential fraud. As a result, their non-refundable paying money would be sent to wrong receivers or scammers or just be disappeared.

Perceived risk diminishes user's readiness and acceptance of new technology to more security dangers of technology like mobile wallets [7]. Perceived risk could make customers underestimate about the perceived usefulness of a technology and deny accepting it [29]. Some researches showed that perceived risk positively affect on user's intention ([30]; [31]). Two studies in 2015 further explored factors such as social influence, perceived risk and stressed their important role in mobile payment adoption [32, 33]. The following hypotheses were developed:

H6: Perceived risk will negatively affect the intention to use mobile wallet.

Social influence

Social influence is defined as the degree to which an individual perceives that essential referents such as family and friends believe he or she should adopt a specific technology [25].

Recently, in mobile payment adoption, many researches integrated social influences into their research frameworks and obtained some empirical support [34, 35, 36]. A study of Chong et al. (2010) showed that a customer considers the thoughts of their friends and their family before choosing a new technology [37]. If views of others are not favourable, they will resist adopting that technology. Social influence is also found as the most dominant on user's behavioural intention in mobile payments [38]. Based on the arguments above, the following hypothesis was developed:

H7: Social influences will positively affect the intention to use mobile wallet.

Habit

Habit is defined as the degree to which an individual performs behaviors automatically because of learning from prior experiences [25, 39]. The effects of habit on both behavioral intention and actual usage behavior have been proposed and validated by researchers [40, 41].

With the current development of mobile commerce, consumers are using mobile devices like smartphones for almost daily tasks such as internet surfing, social connecting, text and voice chatting, video calling, gaming, shopping, bill paying. Therefore, that development could make mobile-related habits relatively more relevant than before toward the influence on both behavioral intention and actual usage behavior of mobile payment. According to Venkatesh et al. (2012) the role of habits in technology use describes the various fundamental processes that affect technology use. In this study, habit is considered being a familiar behavior or an automatic behavior in using mobile wallets. The following proposition was developed:

H8: Habit will positively affect the user's intention to use mobile wallet.

Intention to use

According to Davis, behavioral intention is considered as the degree to which an individual believes that they will implement a particular behavior [42]. In technology adoption theories, the relationship between behavioral intention and usage behavior has been consistently confirmed [25, 26, 27, 43, 44]. In mobile payment context, there is still a gap between intention and actual use toward the technology. Although the development of mobile commerce has led consumers to use mobile devices in various aspects of their daily lives, the actual amount of mobile payment is still small compared to other forms of payment. Under the technological adoption literature, it can be hypothesized that:

H9: Promotion will positively affect the user's intention to use mobile wallet.

2.2. Research framework

Considered the relationships extracted by hypotheses from previous studies, Figure 1 shows the proposed research model. We included perceived usefulness, social norms, habit; integrated them with perceived risk and a novel construct named promotion. Intention to use and frequency of use applied to measure using behavior.

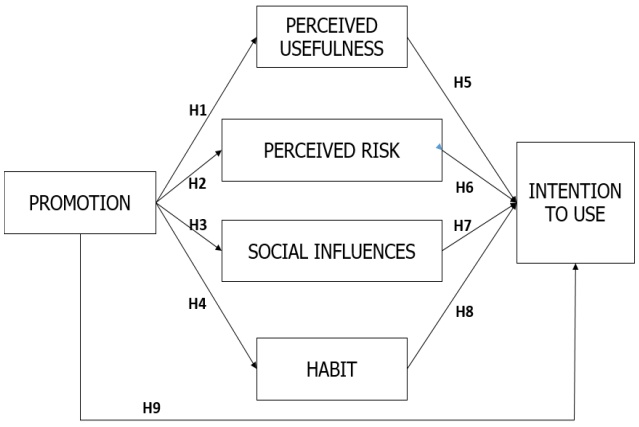

Figure 1: Conceptual framework (Source: own elaboration)

We proposed this research framework because predicting consumer's behavioural adoption and usage should be evaluated from a variety of perspectives. This integrated model can help us have a better recognition of the relationships between these research constructs. These relations are already confirmed in the literature review of previous researches, and the validity of model is confirmed in similar studies except the promotion factor that we added in this study [45, 46, 47]. This proposed model has showed relationship among factors affecting using mobile wallet in Vietnam so that previous studies have not focused on evaluating it.

3. Materials and Methods

Authors have used secondary data from previous studies to construct the proposed research model. We used a survey method with a questionnaire based on the 5-Point Likert Scale to test our research model and developed hypotheses. The potential participants of this research were chosen in convenience sampling method from Da Nang City. 400 young people in Da Nang were contacted by e-mail and social network during the period from January 2020 to April 2020. A link to the survey was included in the messages. 315 valid responses were received. The overall response rate was 78.75%.

3.1. Measurement instrument

The research had seven constructs: perceived risk, social influence, perceived usefulness, habit, promotion, intention to use. Constructs and measurement items in this research were modified from previous works on technology acceptance. Measurement items for constructs of perceived usefulness, social influence, perceived risk, habit were altered from Venkatesh et al. (2012). The scale of intention to use was employed from Davis (1989). All measurement items were measured on a five-point Likert scale, ranging from totally disagree (1) to totally agree (5). The frequency of use measurement was operationalized by one item that measure consumers' actual frequencies of mobile wallet usage.

3.2. Analytical procedures

First, we tested the scales by the Cronbach's alpha, the exploratory factor analysis (EFA) and the confirmatory factor analysis (CFA). In the next stage, we used the Structural Equation Modeling (SEM) method to evaluate the structural relationships between constructs in the theoretical model.

4. Results and Discussion

4.1. Reliability and validity

The reliability and validity of the constructs in the research were evaluated with SPSS 23. We use Cronbach's Alpha reliability test because it is a widely used measure that examines the scale reliability [48]. By measuring the reliability coefficient, the reliability test could assess the consistency of the entire scale. Baron & Kenny (1986) suggested that a scale would be high reliable level if the coefficient alpha is greater than 0.7 while the coefficient alpha is higher than 0.6 means the scale is reliable [49]. Table 2 showed that Cronbach's Alpha of all constructs are above the threshold of 0.7, satisfied internal consistency. All items kept will be included in the analysis Exploratory Factor Analysis (EFA). We used this technique to minimize and summarize data and it is very useful for identifying groups of variables. The relationship of mutually correlated groups of variables consider as several basic factors. Each observed variable will be calculated with a Factor Loading factor, which shows which factor each measurement variable belongs to. The KMO (Kaiser-Meyer-Olkin) coefficient must reach 0.5 or higher, showing that factor analysis is appropriate ($0.5 \leq KMO \leq 1$) [48]. The result of KMO coefficient of the study = 0.889 satisfied the requirements. In addition, Barlett's test is statistically significant (sig = 0.000 < 0.05) proving that the observed variables correlate with each other in the whole [50]. The results of the EFA analysis yielded results consistent with the structure of the six construct. Therefore, all constructs of this model ensure reliability and convergent validity. These constructs would be used in further analysis to test the proposed hypotheses.

In [51], the author recommended that CFA is rigorous to test the overall measurement model and to assess the reliability and validity of the constructs. We measure convergent validity by using composite reliability (CR) and average variance explained (AVE). By the rule of thumb, CR should be above 0.6 and AVE should be above 0.5 for all constructs. As the results shown in Table 1, CRs of all constructs ranges from 0.723 to 0.898 while the AVEs vary from 0.573 to 0.746. These results confirm that our model meets the requirement for convergent validity.

We used the procedure suggested by [52] to check discriminant validity. From this perspective, the AVE for each of the research constructs should be greater than the squared correlation between the construct and other construct. The Table 2 showed the measurement model satisfy the requirement for discriminant validity. The results indicated that the various AVE are lower than the diagonal variables suggesting all the constructs in this study have satisfactory discriminant validity.

Table 3 showed that the CFA model with six concepts also shows a good fit with the data. All the indices satisfied the recommended cut-off point. We conclude that the model fits data well, so this model can be used to test the research hypotheses.

Table 1: Reliability and validity of the tested model

Latent constructs	Cronbach's alpha	CR	AVE	MSV	FL range
SI	0.755	0.723	0.573	0.234	0.503-0.910

PM to PR to IU	.001	-.014	.023	.866	Rejected
PM to HB to IU	.058	.026	.106	.002	Supported

Evaluation of direct effects

After assessing reliability and validity of the measurement constructs, in this section we will test the research hypotheses based on review of literature and the framework of research model. To conclude, the significance of each hypothesis, S.E (standardized estimates) and p-value was assessed using SEM (structural equation modelling). As showed in the Table 4, seven of nine hypotheses were accepted.

The results in Table 5 showed that the direct path from PM to IU was significantly mediated by PU and HB. As discussed above, as PU and HB were found to have significant direct effects on intention to use the mobile wallet, the mediating effects of SI and PR in the relationship between PM and IU were partial in this study.

Evaluation of predictive capability

In the current study, 60% of the variance in intention to use mobile wallet was explained by five factors: PM, PU, SI, PR and HB. The R^2 values of intention to use in this attain a moderate level of predictive accuracy [55]. Hence, the predictive accuracy of the research model was satisfied. Comparing with the model not integrated the construct promotion, we found the R^2 value was only 51%. This result showed that promotion is an important factor when researching technology adoption significantly because it improves the level of intentional interpretation of the research model.

4.2. Discussion

In this study, we integrated and explored the promotional factor on users' intentions of mobile wallet. This is an extra factor and thus we have built 3 items to measure the effect of this factor. We combined with other constructs: social influence, perceived risk, perceived usefulness, habit and promotion to measure consumer's perception. The research model was successfully predicting a large variance in intention to use mobile wallet (60%). These results indicate the effectiveness of various constructs of this research model.

Taken as a whole, results show that promotion may affect intention to use and suitable for the study hypothesis. Seven hypotheses were accepted and two hypotheses were rejected (H2 and H7).

PM impact positively to PU

This is the first study to confirm the direct impact of PM on PU. This result also confirms the separation of PM and PU when in many studies that PU also implies the benefits from service use. Indeed, in the current fierce competition context, the perceived benefits measured by traditional items have become almost inevitable. PU-free technologies from customers will almost certainly be rejected. Therefore, PU is almost a must for all companies who want to enter the market need to prove the advantages of their products. However, in order for customers to choose their products, companies need to have appropriate PM strategies, ensuring long-term maintenance, avoiding batches, and ensuring financial efficiency. Implementing the above will ensure mobile wallet providers a long-term competitive advantage in an extremely fierce market with more than 30 mobile wallet providers like in Vietnam.

PM impact positively to SI

This result is also the first time that PM has been shown to have a direct effect on SI. Indeed, when there are attractive promotions, customers will recommend more mobile wallets to acquaintances because they believe that acquaintances will need to use and will bring similar positive experiences. as they experienced. PM has a strong impact on SI and thus mobile wallet providers can take advantage of this factor to offer promotions that can take advantage of even social influences such as referrals to acquaintances who will receive. attractive promotions, for example vouchers, gifts ... Thus, the effectiveness of the promotions in influencing customer behavior in using the mobile wallet will be improved.

PM impact positively to HB

As expected, more promotions will be an important factor in creating habits among users. Therefore, companies need to offer relevant and lasting promotions, striving to maintain the user's habit as a must-have routine. To do this, providers need to develop and integrate more features into the mobile wallet. Just using the mobile wallet can help users solve many problems in life. All of these will form the usage habits for customers, creating customer loyalty for the mobile wallet. The development of a payment ecosystem to provide a convenient and seamless payment experience for users is seen as a key factor for wallets to retain customers in the long run.

PM don't have a significant effect on PR

Usually, when faced with a decision like whether or not to use a mobile wallet, customers often compare gains and losses, risks and opportunities.

However, this result contradicts the original assumption that PM will negatively affect perceptions of risk. The promotions also do not reduce the risk perception of customers because in recent times in Vietnam, many new technology applications have relied on customers' trust and subjectivity to implement the fraudulent behavior like P2P lending applications. Despite being warned, many customers still have serious problems because of the use of these new technologies [56]. Hence the vigilance and precaution of the customer is very high.

PU have a significant and positive impact on IU.

Perceived usefulness in this research has a positive and significant impact on intention to use mobile wallet ($\beta = 0.274$; p-value < 0.001). This result is similar with many previous studies which found that perceived usefulness was one of the most important factors to determine intention to use [3, 57, 58]. Usefulness of a new technology is essential to increase intention to use. These studies also used UTAUT2 as their basis model and reinforced the impact of perceived usefulness on using behaviour [5, 8]. However, we found others study in which perceived usefulness is insignificant in the prediction of the user's intention of mobile wallet services [32].

PR have significant and negative impact on IU

PR has negative and significant effects on IU. In fact, security is always a major worry for the customer while performing payments via mobile wallet [3]. Public sharing of personal information, private information leaks while doing transactions

with mobile wallet are the most common concerns [59]. In contrast, we have several studies in literature revealed the positive relationship between perceived risk and intention to use [31, 60]. Marketing strategies that reach target customers must show customers that there are no risks involved in using mobile wallet. This would lessen perceived risk of customers and therefore improve their intention to use mobile wallet. A risk-free environment once created would result in a greater intention to use a mobile wallet app.

SI don't have a significant effect on IU

SI in the current research does not show a significant impact on IU. It is contrast with results of previous studies which confirmed that friends, family and relatives significantly influence the user's intention [8, 25, 33].

HB have a significant and positive impact on IU

HB was accepted in this research as a significant factor influencing intention to use mobile wallet. This result supports the perspective of Venkatesh et al (2012) who confirmed HB as a critical predictor of customer intention. Take into consideration, the mobile wallet providers need to make an effort in creating the condition where mobile wallet becomes a habit with consumers. For example, they can integrate the e-commerce ecosystem in using the mobile wallet as a payment method or think about give cashback promotion for payment in the retail market. This effort would generate a habit for the consumer to use a mobile wallet more frequent for daily life.

PM have significant and positive impact on IU

Among the constructs in the model which have a direct relationship with IU, PM was shown to have the strongest impact to IU ($\beta = 0.439$; p-value < 0.001). In a survey conducted in major cities in Vietnam about the key factors influencing consumers' choice of mobile wallets, diverse and regular promotions were assessed as one of the deciding factors to choose a mobile wallet. In fact, many people used a technology for the first time because of attractive promotions. As mentioned in the first part of this paper, this is a factor that has received little attention from academics when studying the consumer adoption of new technology. However, as showed in the results, mobile wallets' suppliers need to have many attractive promotions to gain consumer acceptance. Compared to other platforms, mobile wallets do not have many attractive promotions and that may be the reason that mobile wallets are still not popular in the Vietnamese market.

From practical perspectives, the results of this study provide empirical evidence on critical factors to be considered by not only suppliers but also marketers of the mobile wallet. It reveals that promotion and usefulness of use of mobile wallets are the most important factors in user adoption. These factors will improve intention of use of a mobile wallet. To get users to use a mobile wallet, application developers must emphasize the benefits of usefulness and attractive promotion related with this new financial service.

5. Conclusions and limitations

This study is successful in providing an integrated research model for academics to test the impact of social, psychological, and risk factors on technology adoption. In addition, it also helps companies providing mobile wallet services by identifying key factors that influence users' decisions and helping them to have the most comprehensive view of customers. Using SEM analysis, 7 of 9 hypothesis research were accepted. Results of this research are found significant and coherent with previous works on mobile payment and mobile wallet.

This research model explains 60% of intention to use mobile wallet in Vietnam, whereas the same model but without construct promotion explained only 50% in the variation in intention to use mobile wallet. This result demonstrated that putting the new promotion variable to the research model of the adoption and use of technology is necessary and that makes the theoretical contribution of the current study. This is also the premise for future researches when studying the adoption of technology, researchers could integrate promotion to the model to achieve a significant improvement in the level of interpretation as showed in this study.

Last but not least, in this study, we proposed the scale used to measure promotion based on the literature, expert panel and interviews with focus group. The items in this scale will provide the foundation for further research concerning technology adoption such as mobile wallet.

Beside of our study's major contribution that adds into the existing body of knowledge, we also recognize its limitations, mostly regarding the sampling with typically young, highly educated people as responders. In addition, our results have limitation regarding the specific context of Danang city. Danang is an average city with a relatively limited market as its population is approximately one million people. This sample only covers with young people in this city. In order to further enhance its generality, future research could extend the study to more cities or conduct in more countries in Southeast Asia to improve the generalization of the study. Although this research contributes more empirical results in this area, it also has some limitations and therefore further studies in this area will be needed.

Conflict of Interest

There is no conflict of interest regarding this study.

Acknowledgment

This study involves no supporting grants.

ABSTRACT

Accurate machining control is indispensable for the smart factories of tomorrow. Variations in controller responses may cause unacceptable process deviations during machining leading to productivity losses and possible damage. In the present work, a complex order $PI^{\alpha+j\beta}D^{\gamma+j\theta}$ (COPID) controller was designed to effectively control surface roughness generation while machining CNT Al-Mg hybrid composites. Performance of the designed complex order controller was compared against the conventional PID and fractional order PID (FOPID) controllers for the machined surface roughness system. Output signal responses indicate that the complex order controller attains the desired surface roughness set point with zero percent overshoot in almost same settling time (46 sec) as PID (41 sec) and FOPID (46 sec) controllers. The PID and FOPID output signals registered overshoots of 96.8 % and 36.7 % respectively. Similarly, in case of control signals (feed rate) the COPID controller successfully minimised peak overshoot to 4.6 %; as compared to 64.2 % and 96.5 % in case of the PID and FOPID controllers respectively. The COPID controller was also effective in reducing its peak time response metric (2.001 % for control signal and no peak time for output signal due to zero overshoot). In comparison, the PID and FOPID controllers recorded higher response peak times (7 sec / 26 sec for the PID ouput/control and 5 sec / 7.84 sec for FOPID output/control signal responses). Overshoot elimination in output signal (surface roughness) is crucial for consistency of the machined surface quality. Similarly, overshoot minimisation in control signal (feed rate) is critical because excessive feed rate can damage the cutting tool, work piece, machinery and is a potential safety hazard for the machine operator as well. Hence, the COPID controller can be safely and extensively applied in smart industrial control systems of the future.

1 Introduction

This paper is an extension of the work originally reported in the 2019 IEEE International Conference on Mechatronics, Robotics and Systems Engineering (MoRSE) [1]. In that work, firstly the multi input single output system of surface roughness generation during machining of the CNT Al-Mg composites was identified using the ARX and ARMAX model structures. Thereafter, the fractional order PID (FOPID) controller was designed to control the identified system at the desired set point (surface roughness). The authors reported that the ARMAX model based FOPID control exhibited better time domain characteristics as compared to the ARX model based FOPID controller design. The current work extends this work further to include complex order controller design to improve the time domain performance even more. PID controller has also been implemented for better comparisons. Moreover, the output signal time domain specifications corresponding to the machining variables not discussed in the previous work have also been included in the present study.

Metal matrix composites are new age materials finding new and varied applications due to their superior mechanical properties over conventional alloys [2]. Carbon nanotubes (CNT) in particular have attracted attention of researchers worldwide owing to the superior strengthening characteristics imparted by these nano sized particles to the base metal alloys [3]. Aluminum based alloy systems have almost a universal presence across industry sectors and products [4]. Combination of carbon nantubes and aluminum-magnesium alloys results in composites with superior mechanical characteristics.

Modeling and designing effective controllers is an important step towards automating the machining of these modern materials.

Generally, PID controllers find extensive applications due to their ease of implementation and maintenance in industrial systems. However, specialized machinery may require more sophisticated controllers having better design characteristics. Fractional order controllers offer a better design alternative because they have two more parameters to tune as compared to the traditional PID controllers [5, 6]. These controllers are based on fractional calculus, a branch of integral calculus that enables fractional orders of the model structure parameters. Fractional order PID controllers (FOPID) have been demonstrated to exhibit better performance characteristics in various application areas such as control systems, signal processing, medical research, material science and many more [7]–[10]. FOPID controllers prove to be more robust against system variations against their PID counterparts. Therefore, FOPID controllers are being increasingly preferred in more dynamic systems across industries [11]–[14]. Machining of complex materials like the metal matrix composites is one such example of a dynamic system; wherein the material composition is anisotropic and calls for a more robust controller architecture [6].

Complex order PID (COPID) controllers are the next step in the controller evolution [15]. They are an extension of the FOPID controllers just as the FOPID are extended versions of the PID controllers. The COPID have further two parameters to tune over the FOPID controllers. In the recent years, COPID controllers have been gradually attracting increasing investigations into their design and application aspects [16]–[18]. Khandani et al [19] designed a complex order controller for DC motors. Pinto and Carvalho [20] derived a complex order model for HIV infection drug resistance. Machado [18] optimized complex order controller for linear and non linear systems using genetic algorithm. Ayadi and Amairi [21] applied numerical optimization to tune complex order controller for a second order time delay resonant system. Hanif et al [22] implemented genetic algorithm for tuning of complex order controller design. Silva et al [23] applied complex order structure to model hexapod robot locomotion based on foot-ground transfer function. Jacob et al [15] reviewed frequency domain, time domain and stability aspects in complex order modeling of linear systems. Tare et al [24] compared integral, fractional and complex order controller performances for fractional order systems. Adams et al [25] determined the transfer function solution to the complex order differential equation. Shahiri et al [26] investigated robust control of a non linear fuel cell system using complex order architecture. From the literature review, it appears that the application of COPID controller in machining systems needs attention. The current work aims to bridge this gap.

The CNT Al-Mg composite experimental details may be referred to in the previous part [1] of the current work. It involved variation of the input machining parameters (cutting speed, feed and depth of cut) and data collection of the corresponding values of the machined surface roughness. Machining experiments were performed on a CNC turning center (Simple Turn 5057 Haas Automation) using chemical vapour deposition (CVD) coated tool inserts (Seco CNMG120408). Surface roughness was measured by a Handy Surf E-DTS570 tester. The best performing model structure (ARMAX) describing this machined surface roughness system in the previous work was adopted in the current study for the COPID and PID controller design. The FOPID controller time domain characteristics from the previous work [1] were referred to in the current work for comparisons with the COPID and PID controller responses. In the previous work, high peak overshoots were detected in output / control signal responses of the FOPID controller. The current study aimed to minimise / eliminate peak overshoots by employing COPID controller design. The following section details upon the design methodologies followed for the implementation of the PID, FOPID and COPID controllers in composite material machined surface roughness system.

2 Controller Design Methodology

This section describes the design methodologies of the PID, FOPID and COPID controllers for the machined surface roughness system. All controllers were designed to attain output set point of 1 micron surface roughness. In machining, cutting speed is inversely related to surface roughness whereas depth of cut directly increases machined surface roughness levels. However, feed rate has the most significant effect on surface roughness generation [2]. Therefore, feed rate parameter was selected as the manipulated variable in the current study whereas cutting speed and depth of cut were maintained at their mid levels as per the experimental design [1]. Thus, all controllers were designed to control this multi input (cutting speed, feed, depth of cut) and single output (surface roughness) system as shwon in Figure 1.

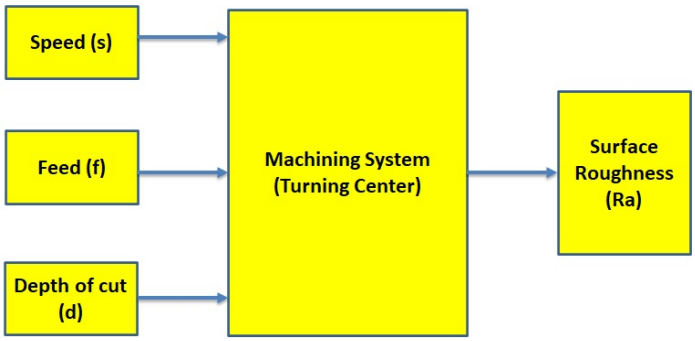

Figure 1: Multi input single output system schematic for the nano composite machined surface roughness system

2.1 PID controller

The PID controller has been widely implemented in industries since many years because of its simple structure and compatibility with the industrial automation software [27]. In the current work, Simulink block was utilised to implement PID controller for the machined surface roughness plant. The PID controller structure is given as follows:

$$C(s) = K_P + K_I\left(\frac{1}{s}\right) + K_D\left(\frac{N}{1 + N\frac{1}{s}}\right) \quad (1)$$

where, K_P is the proportional gain, K_I is the integral gain, K_D is derivative gain and N is the filter coefficient of derivative. The PID block was auto tuned in Simulink using the time domain approach.

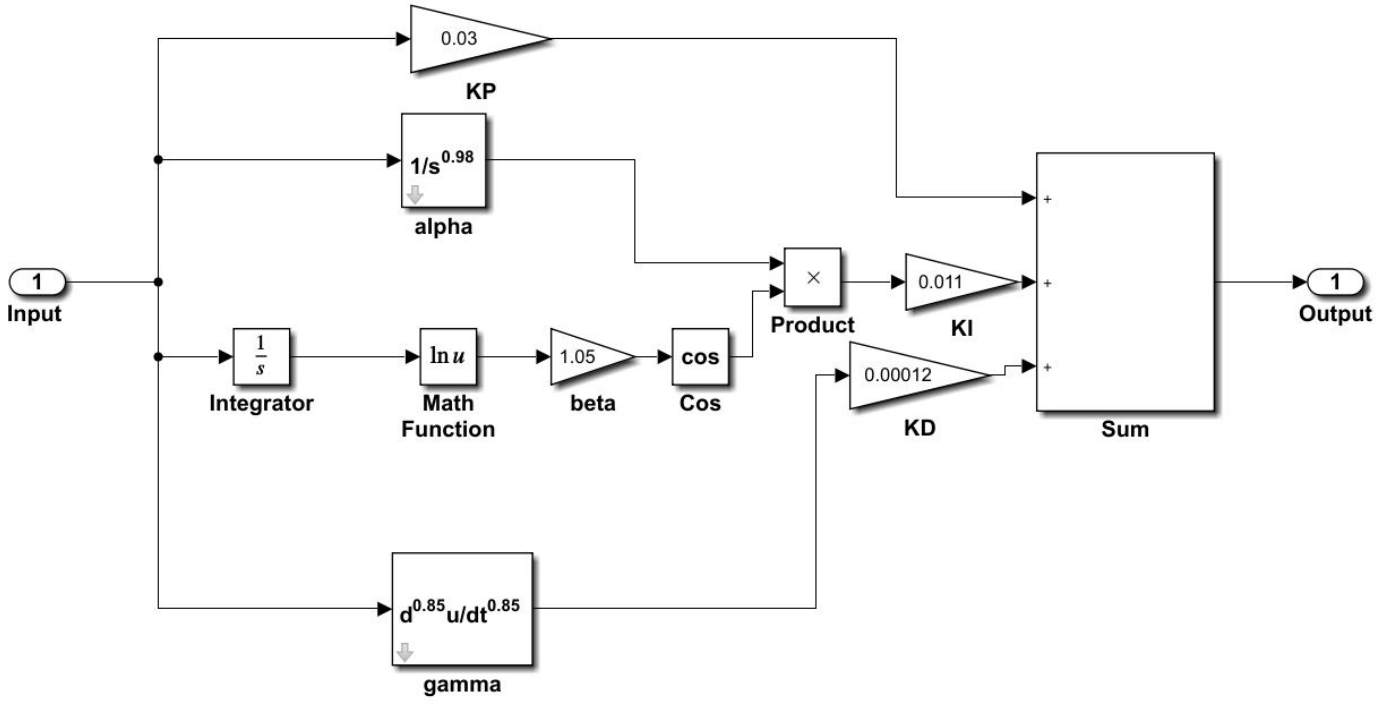

Figure 2: Complex $PI^{\alpha+j\beta}D^{\gamma+j\theta}$ Controller Structure in Simulink

2.2 FOPID controller

Fractional PID (FOPID) controller is an extension of the classical PID controller and is designed based on fractional calculus [28]. In this controller, the orders of integration and derivation are real numbers [29, 14]. The FOPID controller has the following controller structure:

$$C(s) = K_P + K_I\left(\frac{1}{s}\right)^{\lambda} + K_D s^{\mu} \tag{2}$$

where μ is the order of derivative and λ is the order of integration. There are five parameters in the fractional PID controller. This controller has the property of isodamping making it more robust against variations in the system parameters. The values of λ and μ were taken between 0 to 2 for the closed loop system to be stable.

Following equations were employed to synthesise the fractional calculus for the fractional PID controller application:

$$\omega_u = \sqrt{\omega_h \omega_b}$$

$$\omega_0^{'} = \alpha^{-0.5}\omega_u; \omega_0 = \alpha^{0.5}\omega_u;$$

$$\frac{\omega_{k+1}^{'}}{\omega_k^{'}} = \frac{\omega_{k+1}}{\omega_k} = \alpha\eta > 1$$

$$\frac{\omega_{k+1}^{'}}{\omega_k} = \eta > 0; \frac{\omega_k}{\omega_k^{'}} = \alpha > 0$$

$$N = \frac{\log(\omega_N/\omega_0)}{\log(\alpha\eta)}$$

where, N is the order of approximation, ω_h and ω_b are the frequency bounds for approximation.

In the present work, FOMCON toolbox was used for implementation of FOPID and COPID controllers [12]. In this toolbox, Simulink blocks are available for various applications of fractional calculus. It can be used for designing controllers in continuous/discrete time scales, fractional order state space and many more. In FOPID design, the derivative action was considered zero ($K_D = 0$ and $\mu = 0$). The other gain parameters are taken from PID controller settings. Value of λ was selected based on the approach given by Shah and Agashe [29].

2.3 COPID controller

Complex order PID (COPID) controller idea originated from the 3^{rd} generation of CRONE controller [30, 11]. COPID controller is similar to FOPID controller except that the orders of integration and derivation are complex instead of real numbers. The COPID controller has the following structure [16, 26].

$$C(s) = K_P + K_I\left(\frac{1}{s}\right)^{\alpha+j\beta} + K_D\,(s)^{\gamma+j\theta} \tag{3}$$

where, K_P is the proportional gain, K_I is the integral gain, K_D is derivative gain and $\alpha, \beta, \gamma, \theta$ are the orders of the complex order controller.

To implement the above equation, a simplification procedure was carried out in two steps. Firstly, the complex integration was written as:

$$K_I\left(\frac{1}{s}\right)^{\alpha+j\beta} = K_I\left(\frac{1}{s}\right)^{\alpha}\left(\frac{1}{s}\right)^{j\beta}$$
$$K_I\left(\frac{1}{s}\right)^{\alpha+j\beta} = K_I\left(\frac{1}{s}\right)^{\alpha} * e^{\ln\left(\frac{1}{s}\right)^{j\beta}}$$
$$K_I\left(\frac{1}{s}\right)^{\alpha+j\beta} = K_I\left(\frac{1}{s}\right)^{\alpha} * e^{j\beta\ln\left(\frac{1}{s}\right)}$$
$$K_I\left(\frac{1}{s}\right)^{\alpha+j\beta} = K_I\left(\frac{1}{s}\right)^{\alpha} * \left[\cos\left(\beta\ln\left(\frac{1}{s}\right)\right) + j\sin\left(\beta\ln\left(\frac{1}{s}\right)\right)\right]$$

The imaginary part of the above equation cannot be synthesised for time domain implementation of the system. Hence, for implementing the COPID controller in Simulink, imaginary part of the above equation was omitted [16].

$$K_I\left(\frac{1}{s}\right)^{\alpha+j\beta} = K_I\left(\frac{1}{s}\right)^{\alpha} * \left[\cos\left(\beta\ln\left(\frac{1}{s}\right)\right)\right] \quad (4)$$

Similarly, derivative component of the Eq. (3) was simplified for implementation as follows -

$$K_D * s^{\gamma+j\theta} = K_D * s^{\gamma} * s^{j\theta}$$
$$K_D * s^{\gamma+j\theta} = K_D * s^{\gamma} * e^{\ln s^{j\theta}}$$
$$K_D * s^{\gamma+j\theta} = K_D * s^{\gamma} * e^{j\theta\ln s}$$
$$K_D * s^{\gamma+j\theta} = K_D * s^{\gamma} * [\cos(\theta\ln s) + j\sin(\theta\ln s)]$$

The imaginary part of the above equation cannot be synthesised for time domain implementation of the system. Hence, for implementing the COPID controller in Simulink, imaginary part of the above equation was omitted [16].

$$K_D * s^{\gamma+j\theta} = K_D * s^{\gamma} * [\cos(\theta\ln(s))] \quad (5)$$

Combining Eq. (4) and (5), the COPID controller structure may be rewritten as

$$C(s) = K_P + K_I\left(\frac{1}{s}\right)^{\alpha} * \left[\cos\left(\beta\ln\left(\frac{1}{s}\right)\right)\right] + K_D * s^{\gamma} * [\cos(\theta\ln(s))] \quad (6)$$

The COPID controller given in Eq. (6) was initially tuned by incorporating the reference values of FOPID controller and was further fine tuned based on the principles given in literature [31, 29]. The fine tuned COPID controller was implemented in Simulink (Matlab) as shown in figure 2. The initial value of integer order integrator was assumed to be a small number during the controller implementation.

3 Results and Discussions

This section describes the different controller structures, output / control signal responses, time domain characteristics and Bode plot for the COPID controller. The discrete-time ARMAX model (order 3331) with 1 sec sample time from the previous work [1] was obtained as follows:

$$A(z)y(t) = B(z)u(t) + C(z)e(t)$$
$$A(z) = 1 - 0.3675z^{-1} + 0.4876z^{-2} - 0.3772z^{-3}$$
$$B_1(z) = -0.001019z^{-1} - 0.003656z^{-2} + 0.01446z^{-3}$$
$$B_2(z) = 0.6741z^{-1} + 0.2097z^{-2} + 13.82z^{-3}$$
$$B_3(z) = -1.569z^{-1} + 0.4574z^{-2} - 1.532z^{-3}$$
$$C(z) = 1 + 0.4142z^{-1} + 0.554z^{-2} - 0.4004z^{-3}$$

This model depicts the CNT Al-Mg composite machined surface roughness system considered in the current study. The PID controller applied on this model structure has the following structure:

$$C(s) = 0.0407 + 0.0143\frac{1}{s} - 0.0633\frac{0.4367}{1 + 0.4367\frac{1}{s}} \quad (7)$$

The output and control signal responses of this PID controller for a set point of 1 micron surface roughness are shown in Fig. 3 and Fig. 4 respectively.

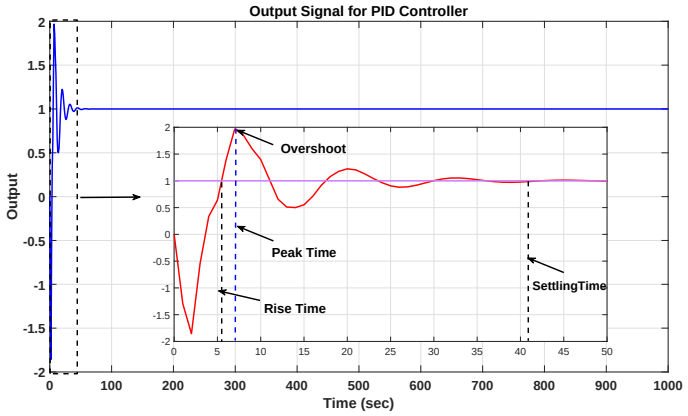

Figure 3: PID controller output (surface roughness, μ) for the machined surface roughness system

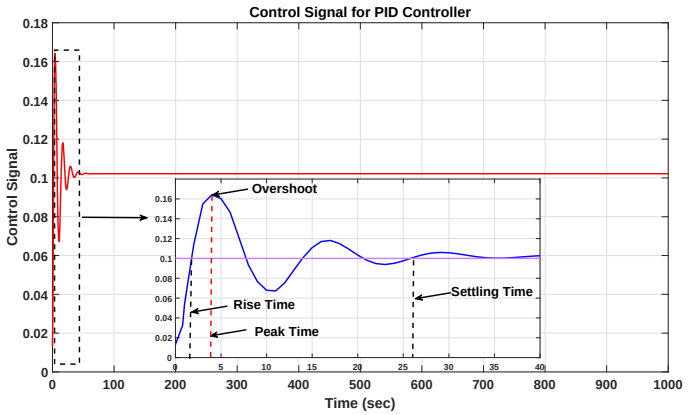

Figure 4: PID control signal (feed rate, mm / rev) for the machined surface roughness system

Following is the structure of the FOPID controller applied to the

composite machined surface roughness system -

$$C(s) = 0.0407 + 0.0143\frac{1}{s^{0.952}} \tag{8}$$

Fig. 5 and Fig. 6 depict the output and control signal plots for the FOPID controller set at 1 micron surface roughness output.

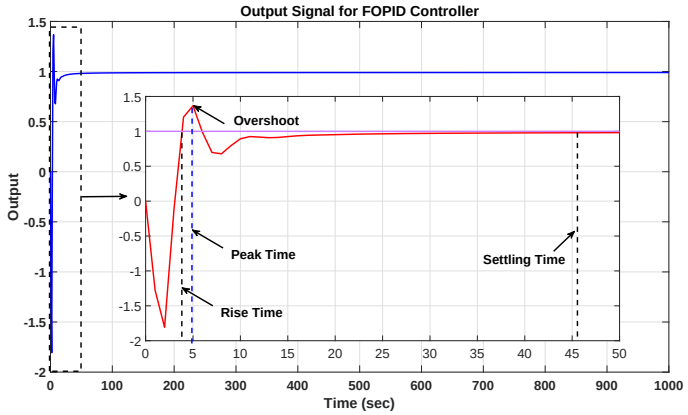

Figure 5: Fractional PID controller output (surface roughness, μ) for the machined surface roughness system

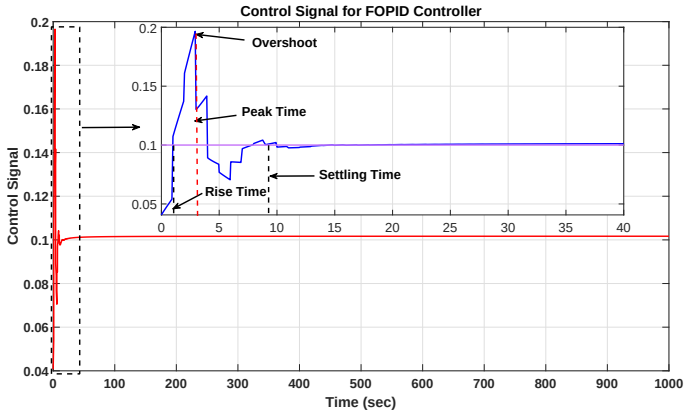

Figure 6: Fractional PID control signal (feed rate, mm / rev) for the machined surface roughness system

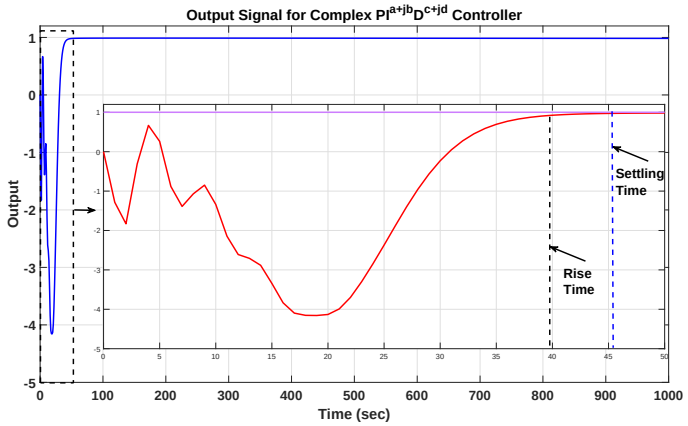

Figure 7: Complex $\mathrm{PI}^{\alpha+j\beta}\mathrm{D}^{\gamma+j\theta}$ controller output (surface roughness, μ) for the machined surface roughness system

The complex order controller structure for the same system is shown below -

$$C(s) = 0.03 + 0.011\frac{1}{s^{0.98+j1.05}} + 0.00012s^{0.85+j0} \tag{9}$$

The output and control signal trends for the COPID controller are shown in Fig. 7 and Fig. 8 respectively.

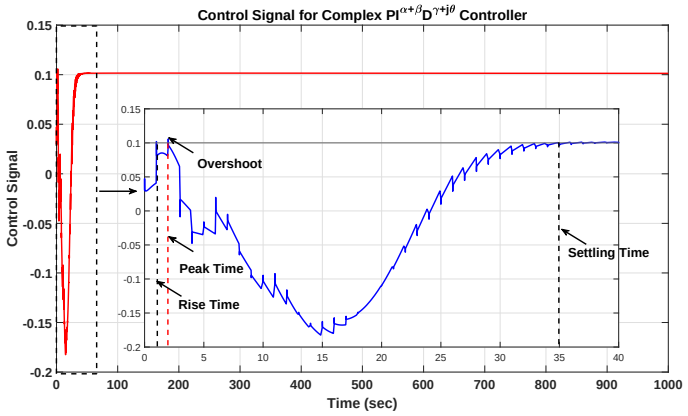

Figure 8: Complex $\mathrm{PI}^{\alpha+j\beta}\mathrm{D}^{\gamma+j\theta}$ control signal (feed rate, mm / rev) for the machined surface roughness system

Table 1: Time domain specifications of output signals

	PID	FOPID	COPID
Rise Time (sec)	5	3.8	39
Peak Time (sec)	7	5	NA
Settling Time (sec)	41	46	46
Overshoot (%)	96.8	36.7	0

Table 2: Time domain specifications of control signals

	PID	FOPID	COPID
Rise Time (sec)	2	1	1
Peak Time (sec)	4	2.924	2.001
Settling Time (sec)	26	7.844	34.38
Overshoot (%)	64.2	96.5	4.6

Table 1 shows the output signal (surface roughness) time domain specifications of the PID, FOPID and COPID controllers for the machined composite surface roughness system. The PID controller scores slightly better than the FOPID and COPID controllers in case of response settling time. PID also scores significantly better than the COPID controller in terms of the rise time. FOPID controller attains the least rise time. However, the COPID controller positively removes peak overshoot from the output signal. The other two controllers have high overshoots in their respective output signal responses. High overshoot in the surface roughness output is undesirable from quality perspective. Generally, critical industrial components require tight dimensional and surface roughness tolerances. Hence, for such cases of precision manufacturing, complex

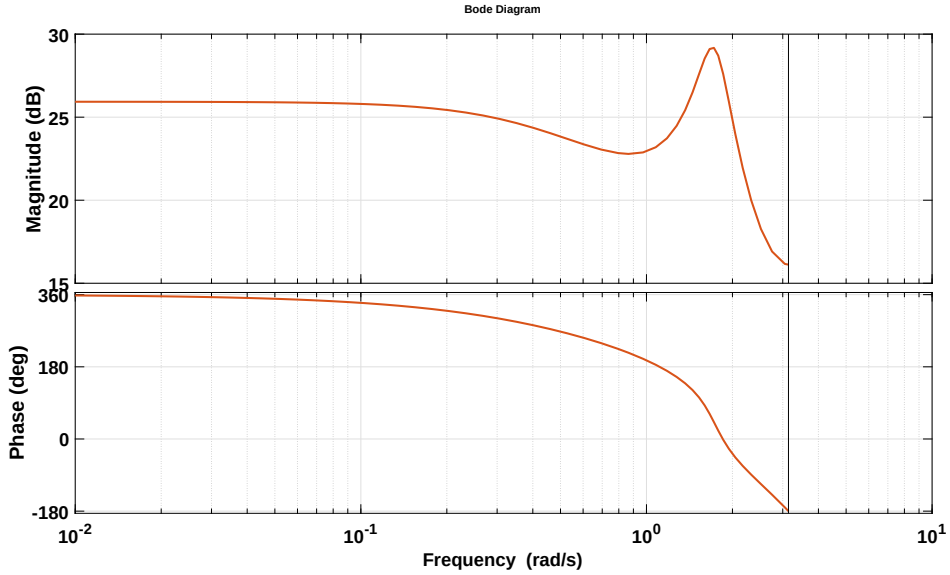

Figure 9: Bode plot for complex order controller

order controller promises to be a better alternative over PID and FOPID controllers.

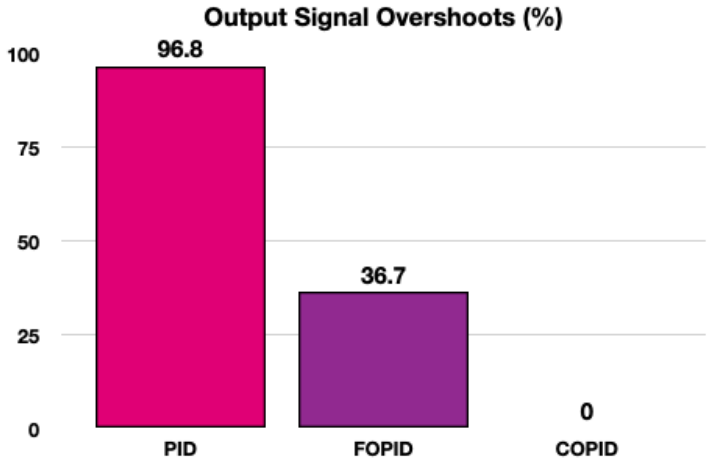

Figure 10: Output Signal Overshoots (%)

Table 2 shows the time domain characteristics of the control signal (feed rate) responses. In this case, the FOPID controller performs well in terms of the rise and settling times. The COPID outperforms the rest for the peak time and overshoot percentages. FOPID has the worst overshoot percentage, whereas the PID controller has the worst peak time characteristic. However, PID controller does perform better than the COPID for settling time. In the current study, control signals correspond to feed rate manipulation in the actual machining systems. High overshoots in feed rate settings may lead to cutting tool damage / breakage, machine tool chatter and possible safety hazard for the machinist. Therefore, minimisation of peak overshoots in feed rate manipulation is a critical machining requirement being fulfilled by the complex order PID controller. Fig. 9 and 10 give visual representations of the relative differences among the output and control signal overshoot percentages attained by the three controllers considered in the current study. Thus, the superiority of the COPID controller over others may be appreciated in light of the importance of the peak overshoot minimisation. Fig. 11 shows the Bode diagram for the complex order controller. This plot indicates that the gain and phase margin for the COPID controller is ∞, implying that the machined composite surface roughness system is robust against variations in the system parameters. This result is crucial from the point of view of the anisoptropic structure of composite materials; that lead to system variations during machining.

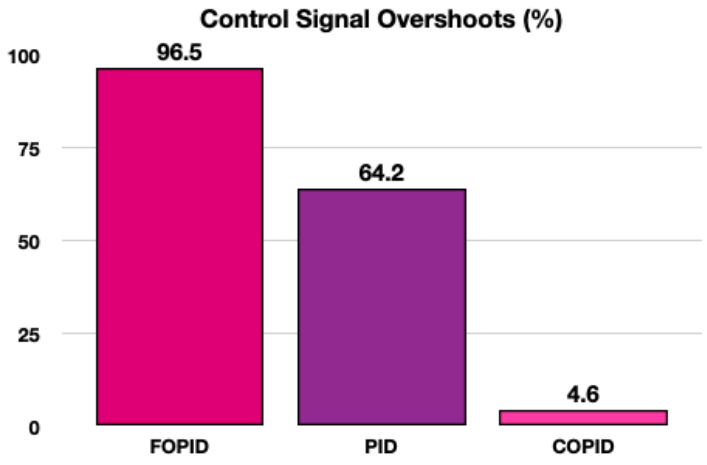

Figure 11: Control Signal Overshoots (%)

4 Conclusions

The current work is an extension of the preliminary study reported in the 2019 IEEE International Conference on Mechatronics, Robotics

and Systems Engineering (MoRSE) [1]. The preliminary study involved system identification and FOPID control of surface roughness evolution in machining of CNT Al-Mg composite materials. The ARMAX model structure controlled by the FOPID controller produced best output signal responses as reported in the maiden paper [1]. The current study expanded that work by including PID and COPID controller designs on the best performing ARMAX model structure determined in the previous work. All three controllers' responses were compared in terms of time domain specifications of the respective output and control signal responses. The current work also included analysis of the output signal trends for the said controllers (which was not considered in the preliminary study). The COPID controller conclusively demonstrated its ability to minimise and eliminate peak overshoot percentages in the control signal (feed rate) and output signal (surface roughness) responses respectively. The other two controllers (PID and FOPID) proved effective in reducing other time domain metrics viz. rise, peak and settling times. However these controllers were unable to stem the peak overshoots to minuscule levels. It is absolutely important to minimise and possibly eliminate the control/output signal overshoots to avoid the adverse affects of such overshoots on the machining process and product quality. This work establishes that the complex order PID controllers can be safely and widely adopted towards effective control of nano composite manufacturing systems for high productivity.

ABSTRACT

The ever-growing technology in mobile smartphones has enabled users to store sensitive and private information; as a result, it required the need for an improved security system. Previous approaches heavily relied on shallow machine learning algorithms that require feature extraction which is time consuming, laborious and can cause, resulting in poor authentication. In this paper, we propose a deep learning - dense neural network to avoid the limitation of the classical algorithms and build a mobile smartphone touch screen authentication scheme based on keystroke dynamics. A deep learning – dense neural network classifier was trained using keystroke dynamics features extracted from users. A comparative analysis was made between our proposed DNN classifier and some selected classical machine learning algorithms on the keystroke dynamics data. The data is split into five different data partition of training and testing. Results clearly indicated that the deep learning – dense neural network has eliminated the feature extraction steps required by the classical algorithms and improved the overall authentication accuracy, as such, improved the security of the smartphone device. In addition, it is found that the propose deep learning – dense neural network authentication scheme is more robust than the classical algorithms and has the potential to be fully implemented on smartphone to improve the security system of the mobile smartphone touch screen devices.

1. Introduction

The rapid advancement of technology in mobile smartphone devices makes them an important part of human life [1–4] . Also, the reduction in cost makes it easier for everyone to possess [5] including Those with disability,[6, 7] and their popularity is increasing [8, 9] They are now equipped with tremendous functionalities and a flexible operating system, providing the opportunity to store sensitive information such as official documents as well as installing official applications to improve the efficiency of office work [10]. Mobile phone users have become addict due to the social media applications and other applications being made available through google play store and apple store, [10] which carry numerous private information. Hence, the security of smartphone devices is becoming sacrosanct [11]. Protecting sensitive information requires a strong security scheme to protect the smartphone from intrusion, many mobile phone authentication schemes have proposed including person number (PIN),password and authentication [2] which are all vulnerable to shoulder surfing [2, 12]and smudge attacks [13, 14].Recently, biometrics have been incorporated into smartphone devices [15] in an effort to improve their security system . These include fingerprint auth entication and facial recognition. Fingerprint authentication is also vulnerable to attacks as a user's fingerprint can be copied from a touched object and used to gain access to the device [16]. Similarly, Facial recognition is also vulnerable to attack as the user's photo or video can be used to gain unauthorized access to the device and this attack is made easier as the pictures of users can be found on social media platforms [17].

The vulnerability to attack of the current security systems of mobile devices has led many researchers to propose different machine learning algorithms to improve their authentication scheme. For example, [18] they used support vector machine (SVM) to build a behavioral authentication scheme to improve the traditional authentication system. The scheme authenticates users

*Corresponding Author: Lubna Abdelkareim Gabralla, Email: lubnagabralla@gmail.com

Based on their behaviors when interacting with social media applications. It is found to perform better than other classical methods. As [19] presented a continuous behavioral authentication model to improve the security of mobile application. In the study, k-nearest neighbor (KNN), random forest (RF) and gradient boosting (GB) were used to build authentication classifiers. In [20], author built an authentication scheme using SVM based on physical activity performed by different mobile phone users. The proposed SVM model showed a promising result when compared with decision tree (DT) and KNN. In [21], the author hybridized SVM and hidden Markova model (HMM) to develop an authentication model using EEG signal while a user is drawing a pattern. The SVM-HMM model provides the best result when compared with naïve Bayes and cosine similarity. In [22], the author trained SVM classifier on facial attributes extracted from real images to build a continuous classification scheme. Results indicated that the proposed scheme shows a significant improvement on the existing continuous facial recognition system. Similarly, in [23] the author used a one-class SVM to build a behavioral biometrics authentication that automatically adapt to human behavior change over time while considering memory constraint. Results show that there is a possibility of using online machine learning to adapt to recent human behavior. In [24], the author trained a two-class SVM classifier using the user's SCG signal which captures heartbeat signal to improve the security scheme of smartphone devices. The heartbeat signal can be used as a unique feature to authenticate smartphone users.

In [25], the author explored four mobile phone non assisted sensors; transmitted data, noise, battery and ambient light to develop a continuous user authentication based on KNN. The KNN classifier achieved a reasonable accuracy. In [26], it exploits user's hand geometry and behavioral biometrics to build a one class classification model based on KNN. The model was compared with SVM and experimental results show that KNN outperforms the SVM in all the different positions. In [27] It creates an authentication scheme using artificial neural network (ANN) based on thumb stroke dynamics. The scheme was evaluated and compared with other .machine learning algorithms and the results of the experiment indicated that the ANN provided the best result. It was found that researchers in this domain heavily relied on SVM [28–33]; [18, 20–23] for mobile smartphone authentication. The previously used algorithms such as SVM, KNN, ANN etc. proved to be good in improving smartphone security especially when the data size is small. However, these algorithms require independent feature extraction before the extracted features are fed to the algorithms [19]. The performance of the algorithms depend on how well the features are extracted before modeling the classifier. Therefore, inefficient feature extraction may lead to poor classification accuracy [34] unlike deep learning which does not require independent feature extraction as it is done automatically and can work on large data size [35, 36]. Finally, a [37] convolutional neural network is applied to create an authentication scheme based on tap sequence and usage behavior of users.

In this paper, we proposed deep learning (dense neural network) based keystroke dynamics authentication for mobile smartphones touch screen device. The closest work to our proposal is [38] the one that employed deep learning technique to build an identification system that identify smartphone users based on keystroke behavior captured via a special keyboard or a web browser. This differs from our work in the sense that it focuses on a user's identification while our proposed model focuses on the user's authorization and authentication. Similarly, it explores gated recurrent unit and bidirectional recurrent neural network (GRU-BRNN) to build the identification model while our work explored the dense neural network. Also, [39] the deep neural network is explored to develop an authentication scheme based on user keystroke dynamics on mobile phone. Furthermore, our work explored supervise learning dense neural network on 71 different features of keystroke dynamics to build an authentication model while [39] applied deep neural network unsupervised learning on timing, tapping and inertial attributes of keystroke dynamics to develop an authentication scheme.

We choose the DNN in view of the fact that the learning features are provided from all the combination of the features in the layers while convolutional layer depends on minor repetitive field with features that are consistent [40].

The rest of the paper is structured as follows: Section 2 describes the concept of deep learning. Section 3 describes the methodology of the study. Section 4 presents the results and discussion before presenting Section five that comprises conclusions and recommendation for future work.

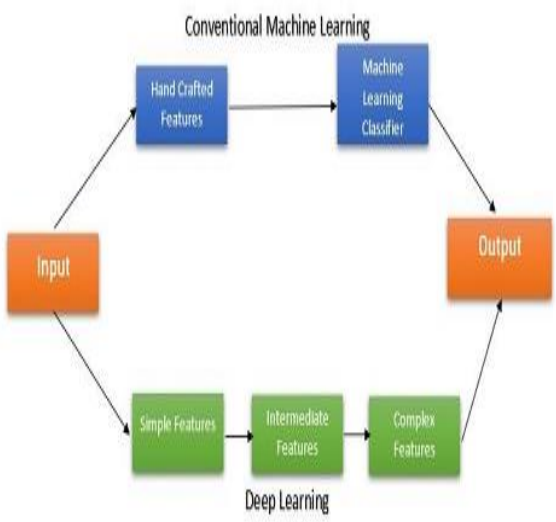

Figure 1: Conventional machine learning VS deep learning

2. Basic Concept of Deep Learning – Dense Neural Network

Deep Learning is an aspect of machine learning which represents multiple hidden layers that can learn on multiple attributes to produce better results [36]. Traditional machine learning algorithms have limitation on processing real data. Building a classification model with conventional machine learning algorithms, requiring reasonable amount of human expertise and efficient feature engineering to transform the raw data to desirable features that can be fed into any learning system or classifier. Deep learning permits inputting raw data into the algorithm without being transformed to feature vector or feature engineering as the features are learnt automatically during training the network [36].

Problems are solved in a hierarchical manner in deep learning, where the lower layers depict the basic representation of the problem and the upper layers are created based on the lower layers to build a more complex model. Deep learning is a hierarchical process as each layer in the deep learning network uses the output of the previous layer and the output of the current layer serves as the input to the successive layer to continuously build a complex concept [36]. The number of layers in a network determines the depth of the network. Cconventional machine learning only focuses on one or two layers, whereas in deep learning, the network contains at least three or more hidden layers. The unique aspect of deep learning is that the feature layers are automatically learned on the raw data not extracted by human expertise unlike the conventional machine learning[36]. The major advantages of deep learning over traditional machine learning are; automatic feature extraction and efficient handling of massive amount of data as a result, it keeps improving as the data gets larger [36]. Based on the concept presented in[36], we created Figure 1 to show deep learning and the conventional machine learning processes.

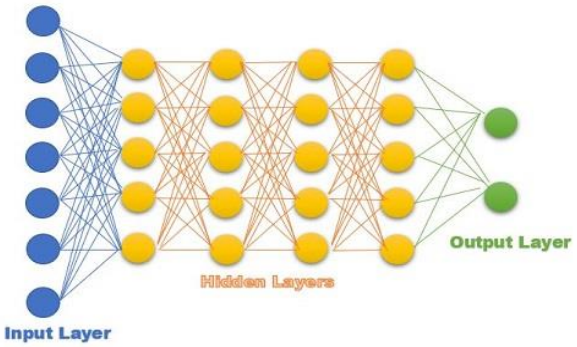

Figure 2: A simple example of dense neural network

In DNN, the layers of the network are fully connected as the name (dense) suggest, each neuron in a layer is connected to all the neurons in the previous layer which means all the nodes are fully connected to the nodes in the next layer. A densely connected layer learns features from all the combined features of the previous layer. The goal of the classifier is to adequately categorize the input data [40]. Figure 2 presents the simple example of DNN.

3. The proposed deep learning - dense neural network authentication model

This section presents the methodology of the study, where the data collection procedure, propose authentication model, propose work flow and performance metrics are outlined. The proposed model authenticates smartphone users is based on user's password typing behavior on a touch screen. The framework consists 4 steps namely; accusation of data, training, user authentication and performance evaluation.

3.1. Dataset

The dataset used for this study contains keystroke dynamics (user typing behavior) data of users collected from nexus 7 touch screen smartphone device when typing the "tie5Roanl" password. The data was collected from 56 subjects and each subject was asked to perform the task 51 times. Therefore, the dataset contains 2856 records. The dataset contains 71 attributes (features), the main features include: hold, up-down, pressure, finger area, average of hold, average pressure and average finger area. Each feature has some feature elements which correspond to the typed characters. The dataset is obtained from the UCI machine learning repository [41]. It was normalized between 0.00 – 1.00, consisting of the user's keystroke dynamics. The data extracted from touch screen smartphone is used to conduct the experiment. The dataset was partitioned several times and the keystroke attributes were used to train the deep learning – DNN classifier model. During the authentication phase, user's tested data for all the 56 subjects. As such, the classes are 56 to authenticate each of the 56 subjects. Each of the 56 subject is authenticated. If the similarities between the two models for each of the 56 users matches, the user is authenticated into the smartphone else the user is rejected. To evaluate the performance of the proposed deep learning model - DNN, the model is compared with previously used machines learning algorithms such as SVM, ANN and KNN. These three algorithms were chosen because the algorithms are found to be highly relied on especially SVM in creating classifiers for improving the security of mobile smartphones device [42].

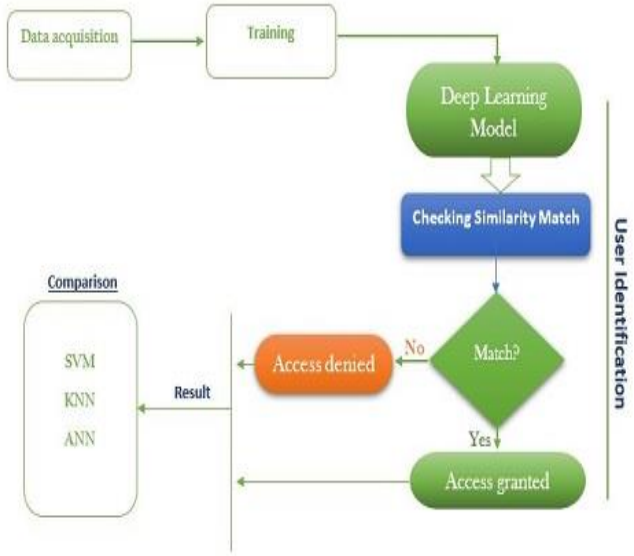

Figure 3: proposed model workflow

The SVM, KNN and ANN were trained to build classifier based on the keystroke dynamics data for the purpose of validation. The performance of the proposed deep learning - DNN classifier is compared with that of the SVM, KNN and ANN. The process involved assessing how well the algorithms perform on the test dataset. The performance of the algorithms on the keystroke dynamic dataset is measured based on performance evaluation metrics. The complete work flow of the methodology is presented in Figure 3.

3.2. Performance Evaluation Metrics

The performance of the proposed touch screen authentication model is evaluated using the true positive (these are instances that are correctly identified), true negative (instances that are correctly rejected), false positive (these are instances that are incorrectly identified) and false negative (these are instances that are incorrectly rejected). The performance metrics were computed

from the results generated from the validation of the models. The performance of the deep learning - DNN algorithm and the classical algorithms are being evaluated using the performance metrics [43].

Table 1: Summary of evaluation metrics

Evaluation metrics	Description
False Positive Rate (FPR) = $\frac{FP}{(FP+TN)}$	Used to determine how many instances are wrongly classified.
F1-Score = $\frac{2TP}{(2TP+FP+FN)}$	Determines the harmonic average between precision and recall.
Recall $(r) = \frac{TP}{(TP+FN)}$	Used to determine how many instances are been classified correctly.
Accuracy (A) = $\frac{TP+TN}{(TP+TN+FP+FN)}$	This is used to measure the accuracy of the technique.

4. Results and Discussion

In this section, the results generated from the experiment were presented including the discussion. The hardware platform, parameter settings of the proposed deep learning - DNN, comparative analysis of the DNN performance compared to the state of the art methods: SVM, ANN, and KNN were presented as well as the implication of the result in theory and practice.

4.1. Parameter Setting

The implementation was conducted on a platform equipped with Microsoft Window 10 with the following specifications:

- System Type: x64-based processor, 64-bit Operating System
- Memory installed on system (RAM): 8.00 GB
- Processor: Intel(R) Core (TM) i3-4000M @ 2.40 GHz 2.40 GHz

The platform for DNN is TensorFlow using Python. a preliminary experiment was conducted to obtain the best parameters of the propose deep learning - DNN. The number of hidden layers and the nodes on each hidden layer are selected after different combination of layers and nodes were run during the preliminary experiment. It was found that the deep learning - DNN setting with the best performance is presented in Table 2. Different learning rates were tested ranging from (0.1 - 0.9), the best value was adopted. Adam optimizer provided the best performance when compared with Gradient Descent Optimization and Adagrad Optimizer. Relu activation function was selected after been compared with other activation functions such as softmax, tanh, etc. The summary of the preliminary experiment result for setting the deep learning – DNN is presented in Table 2.

Table 2: Optimal parameter setting for the proposed DNN

Parameter	Setting
Input layer neuron(s)	71
Hidden layer 1 neuron(s)	20
Hidden layer 2 neuron(s)	20
Hidden layer 3 neuron(s)	20
Hidden layer 3 neuron(s)	20
Output layer neuron(s)	56
Learning rate	0.1
Optimizer	Adam optimizer
DNN structure	71-20-20-20-20-56
Epoch	1000
Activation Function	Relu Activation Function

The deep learning – DNN with the parameter setting in Table 2 is applied to run on keystroke dynamic datasets to authenticate access to mobile smartphone touch screen device. The DNN was run 10 times to ensure consistency of the result produced by the DNN. Data partition ratio affects the performance of the DNN, as such, several partition ratios were used to ascertain the robustness of the DNN and it is performance. An algorithm intend for real world application should be robust in addition to performance. The performance metrics in Table 1 were used to measure the performance of the DNN in user authentication for the mobile touch screen device. To evaluate the performance of the DNN, the classical algorithms SVM, KNN and ANN were also applied on the same dataset to authenticate user access to the touch screen mobile device based on keystroke dynamic authentication. The results of the experiments are presented in Tables 3 – 6 and Figure 4. The first column indicates the different data partition ratio used to evaluate the algorithms. The second column shows the algorithm for the experiment while the third, fourth and fifth columns indicate the mean, best and the worst performance respectively. The bold values in each Table indicates the best result obtained.

Table 3: Performance comparison of the propose DNN with the SVM, KNN and ANN based on Recall

Partition	Algorithms (%)	Mean (%)	Best (%)	Worst (%)
90-10	DNN	89.7	**96.0**	89.0
	SVM	68.7	73.7	51.7
	KNN	44.6	47.7	34.5
	ANN	2.57	3.5	1.8
80-20	DNN	91.2	**94.0**	86.0

	SVM	70.8	72.2	69.7
	KNN	44.6	46.1	43.7
	ANN	2.02	2.3	1.8
70-30	DNN	95.0	**99.0**	92.0
	SVM	71.3	72.7	70.1
	KNN	42.7	45.2	41.2
	ANN	2.1	2.3	1.8
60-40	DNN	93.1	**97.0**	89.0
	SVM	70.4	71.5	68.7
	KNN	41.7	42.4	41.1
	ANN	2.0	2.3	1.7
50-50	DNN	93.0	**98.0**	91.0
	SVM	68.8	69.3	68.2
	KNN	40.4	41.2	40.2
	ANN	1.9	2.2	1.7

The result presented in Table 3 represent the performance of the algorithms based on the Recall for the five different data partitions. It clearly shows that the proposed DNN model produce the best results compared to the classical algorithms. The DNN result indicates that the propose DNN classifier was able to authenticate user access to the mobile touch screen device based on keystroke dynamics with very high level of accuracy. Meaning that the DNN determines the number of instances that were correctly classified as the legitimate user of the mobile phone touch screen device. ANN produced the worst result in all the different data partitions. This is not surprising because the shallow ANN produce poor result as data size increases.

Table 4 clearly indicated that the propose DNN outperforms the classical algorithms in terms of the F1-measure. The performance of the DNN is far more than that of the classical algorithms recording more than 90% in each case. The ANN has maintained consistency in producing the worst performance in all the data partition ratio. This result means that the DNN is a good algorithm with potential to determine the harmonic average between the precision and the recall better than the classical algorithms.

Table 4: Performance comparison of DNN with SVM, KNN and ANN based on F1-Score

Partition	Algorithms (%)	Mean (%)	Best (%)	Worst (%)
90-10	DNN	89.6	**96.0**	84.0
	SVM	69.1	74.5	51.0
	KNN	45.2	48.0	36.0
	ANN	0.1	0.2	0.1
80-20	DNN	91.2	**94.0**	86.0
	SVM	71.1	72.4	69.7
	KNN	45.1	47.0	44.0
	ANN	0.5	0.2	0.1
70-30	DNN	95.0	**99.0**	92.0
	SVM	71.6	73.0	70.3
	KNN	44.0	46.1	42.0
	ANN	0.1	0.2	0.1
60-40	DNN	93.1	**97.0**	89.0
	SVM	70.5	71.8	68.1
	KNN	41.8	42.6	41.3
	ANN	0.1	0.2	0.1
50-50	DNN	93.0	**98.0**	91.0
	SVM	69.1	75.0	53.0
	KNN	40.4	41.2	40.3
	ANN	0.1	0.2	0.1

Table 5: Performance comparison of the propose DNN with SVM, KNN and ANN based on accuracy

Partition	Algorithms (%)	Mean (%)	Best (%)	Worst (%)
90-10	DNN	89.7	**96.0**	89.0
	SVM	84.1	86.6	75.4
	KNN	71.7	73.3	66.2
	ANN	5.0	5.0	5.0
80-20	DNN	91.3	**94.1**	86.2
	SVM	85.1	85.8	84.6
	KNN	72.0	72.6	71.4
	ANN	5.0	5.0	5.0
70-30	DNN	94.8	**98.7**	92.2
	SVM	85.4	86.1	84.8
	KNN	70.8	72.1	70.1
	ANN	5.0	5.0	5.0
60-40	DNN	93.2	**97.0**	89.2
	SVM	84.9	85.5	84.1
	KNN	70.3	70.7	70.1
	ANN	5.0	5.0	5.0
50-50	DNN	92.8	**97.6**	90.6
	SVM	84.1	84.4	83.8
	KNN	69.7	70.1	69.6
	ANN	5.0	5.0	5.0

Table 5 presents the accuracy of the DNN in authenticating the user of a mobile touch screen device in terms of keystroke dynamic. It is clearly indicated that the propose DNN has better accuracy than the compared algorithms.

Table 6: Performances comparison of the DNN with SVM, KNN and ANN based on FPR

Partition	Algorithms (%)	Mean (%)	Best (%)	Worst (%)
90-10	DNN	9.7	3.6	15.8
	SVM	0.5	**0.4**	0.9
	KNN	1.0	1.0	2.0
	ANN	2.5	1.8	3.5
80-20	DNN	8.5	5.8	13.6
	SVM	0.5	**0.5**	0.5
	KNN	1.0	1.0	1.0
	ANN	2.0	1.8.	2.3
70-30	DNN	5.3	1.6	7.6

	SVM	0.5	**0.5**	0.5
	KNN	1.0	1.0	1.0
	ANN	2.0	1.8.	2.3
60-40	DNN	6.7	3.0	10.6
	SVM	0.5	**0.5**	0.6
	KNN	1.0	1.0	1.0
	ANN	1.9	1.7	2.3
50-50	DNN	7.2	2.8	11.0
	SVM	0.6	**0.5**	0.6
	KNN	1.0	1.0	1.0
	ANN	1.8	1.7	2.2

Table 6 clearly indicates that in terms of the FPR, the SVM has the lowest FPR compared to the propose DNN. In this parameter, the DNN fails to outperform the classical algorithms.

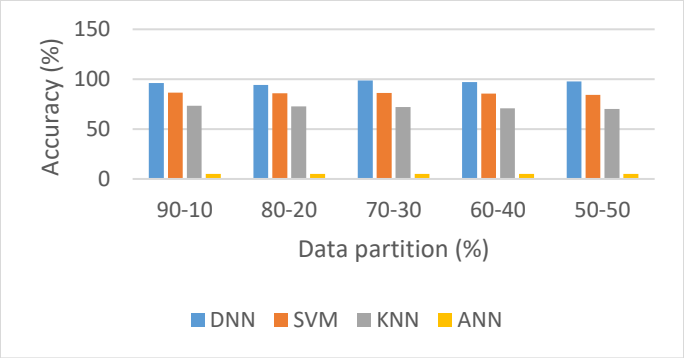

Figure 4: Overall accuracy rate of the proposed deep learning – DNN compared to the SVM, KNN and ANN

Figure 4 indicates that the DNN model has the best classification accuracy than the compared algorithms: SVM, KNN and ANN with ANN producing the worst classification accuracy based on the keystroke dynamics. Our proposed DNN model proves to be the overall best performing algorithm for classification based on the keystroke dynamic data providing the best accuracy rate. It indicates that the DNN model provides a high rate of correctly classified instances and maintaining a low rate of classifying incorrect instances.

Our research work provided a description of the application of DNN in authenticating users of mobile touch screen device based on keystroke dynamics. The authentication security system is to identify authentic users based on keystroke dynamics on mobile touch screen device. As a result, keystroke dynamic features were used for the training of the propose DNN without feature extraction with varying data partition ratios. The DNN authentication based on the keystroke dynamics was applied to classy users based on evaluation measures: f1-measure, recall, accuracy and FPR.

The feature extraction method that the classical algorithms heavily rely on for their performance in the modelling process is a multiple work and human intervention is required significantly. Our propose DNN approach for authentication based on keystroke dynamics is able to eliminate the double work of the feature extraction mostly practiced by researchers in the mobile touch screen device domain.

From the results presented in Tables 3 – 6 and Figure 4. It is clear that the propose DNN can perform better than the classical algorithms in terms of authenticating users of mobile touch screen devices based on keystroke dynamic. The recall and F1-measure values of the propose DNN for authentication based on keystroke dynamics ranges from 94 to 99% while accuracy ranges from 94 – 98.7%. The possible reason why the DNN performs better than the classical algorithms is because of the ability of the DNN to process large size of dataset without requiring feature extraction to discover intricate structures. The propose DNN has proven to provide better authentication of mobile touch screen device based on keystroke dynamic without feature extraction typically required by the classical algorithms. As such, the extra steps of feature extraction that is tedious and incurring extra computational processes can be eliminated with the propose DNN. The DNN has proven that it is a good algorithm with the required robustness to improve the security of the mobile touch screen devices. Therefore, mobile touch screen authentication system can be developed with the propose DNN to improve security of the mobile devices. The experimental result obtained from the study shows that the DNN is a choice algorithm for building classifier for the future research work on keystroke dynamic based user authentication.

The task of authenticating mobile touch screen device considered accuracy, F1-measure and recall as critical measures for evaluating the effectiveness of the authentication systems. The higher the value of these measures the better is the authentication system. The propose DNN authentication based on the keystroke dynamic can be considered to be successful because of its performance on the three performance measures. Though, the propose DNN has inferior performance on FPR compared to the classical algorithms regarding rejections - FPR. This means that the propose DNN can wrongly classify some few instances as the percentage is not much. It is argued that a classification technique is said to be good if the TPR is high while maintaining a low FPR [42]. Therefore, the propose deep learning - DNN is considered the best because the SVM does not maintain high TPR and low FPR like the deep learning – DNN classifier.

5. Conclusions and Future Work

In this paper, we proposed a deep learning approach to build a touch screen mobile phone authentication scheme based on keystroke dynamics. An experiment was carried out and the deep learning model was evaluated by comparing it with conventional machine learning algorithms: the SVM, KNN and ANN. Results of the experiment show that the propose deep learning model outperforms the compared algorithms. The results indicated the feasibility of using deep learning to improve the security system of the mobile smartphone touch screen devices. The deep learning approach has succeeded in eliminating the tedious feature extraction step required by the conventional algorithms: SVM, KNN and ANN. The propose dense DNN low performance on FPR which is considered to be the next future work to improve the value of the FPR. In the future, we plan to use behavioral biometric data extracted from users when drawing a pattern password.

ABSTRACT

Facial emotion recognition is one among many popular and challenging tasks in the field of computer vision. Numerous researches have been conducted on this task and each proposed either standalone- or ensemble-based processing technique. While many researches strive for better accuracy, this research also attempts to increase the processing efficiency of computer correctly classifying human emotions based on human face by utilizing a single standalone-based neural network. This research proposes the use of standalone-based modified Convolutional Neural Network (CNN) based on Visual Geometry Group – 16 (VGG-16) classification model which was pretrained on ImageNet dataset and fine-tuned for emotion classification. The classification is performed on the publicly available FER-2013 dataset of over 35,000 face images with in-the-wild setting for 7 distinct emotions with the provided 80% training, 10% validation, and 10% testing data distributions. The proposed approach outperforms most standalone-based model results with 69.40% accuracy.

1. Introduction

Recognizing facial emotions is a challenging and interesting task, proven with numerous previously held competitions [1–8], available datasets [1, 9–14], and conducted researches on the subject. The progresses made for computer vision in recognizing emotion by face have been described in many publications [15–19]. A notable mention is the extensive paper by Li and Deng [19] which gives explanatory and thorough review about existing and commonly used datasets for facial emotion recognition, along with state-of-the-art (SOTA) approaches and their respective results.

The reviews from [15–19] described many available facial emotion recognition datasets, such as Facial Emotion Recognition 2013 (FER-2013) [1, 9], Static Facial Emotion in the Wild (SFEW) [10], Japanese Association of Female Facial Expression (JAFFE) [11], Cohn-Kanade (CK) [12], Extended Cohn-Kanade (CK+) [13], and Expression in the Wild (ExpW) [14] among many others. These datasets vary in many aspects, commonly described by one or combination of the following: amount of data, number of emotion classes, image- or sequential-based, and in lab-like or in-the-wild condition. The amount of data available in each dataset varies from hundreds to tens of thousands, with some datasets having pre-set training, validation, and/or testing data distribution. These datasets also vary in number of emotion classes, commonly ranging from six to eight emotion classes which include anger, disgust, fear, happiness, sadness, surprise, contempt, and is often appended with neutral emotion as well. Although some datasets do not include neutral and/or contempt expression. Image- or sequential-based (video-based or image-sequence-based) datasets also give variance in the conducted researches, as each dataset type's processing require different approach. Another difference is the condition of the dataset, where lab-like dataset differ from in-the-wild dataset. The former is recorded in an ideal condition (proper lighting, proper face alignment, and/or minimal to no usages of face accessories such as eyeglasses), whereas the latter depicts face expressions captured in a non-ideal condition from real-world scenarios.

These datasets are utilized in many works related to solving facial emotion recognition task, some of which uses conventional methods, deep learning, pretrained model, ensemble neural networks, combination of deep learning with hand-crafted feature selection technique(s), and other related works that will be described in following sections. These approaches achieve various results, which could be summarized in most researches' test accuracy for lab-like datasets often achieving above 90%, while test accuracy for in-the-wild datasets barely surpasses 75% [19].

With such low accuracy result from previous researches for facial emotion recognition with in-the-wild dataset (as compared

*Corresponding Author: Gede Putra Kusuma, inegara@binus.edu

with lab-like datasets), this paper attempts to improve facial emotion recognition accuracy for image-based in-the-wild dataset FER-2013. The proposed model achieved test accuracy of 69.40%, which is better than most existing researches with standalone-based neural network architecture, with the advantage of being simpler in terms of network depth and topology and having the capability of end-to-end training.

Continuing this introduction is a review of core concepts, brief description of FER-2013 as the used dataset in this paper's experiments, existing approaches for facial emotion recognition task using FER-2013 dataset, and the works that inspire and are the base of this paper's model. Afterwards, the proposed model is elaborated in detail. Then, the results from the proposed model are discussed and compared with other related works to understand how well the model performs compared to other taken approaches. Finally, this paper concludes with final thoughts about the proposed model and future works to improve facial emotion recognition task.

2. Literature Review

2.1. Studies and Developments

The study of emotion has gained interest since early 1970s, with one remarkable and frequently used research result being the work of Ekman and Friesen. They introduced six basic emotions: anger, disgust, fear, happiness, sadness, and surprise [20]. Many publications would later improve the known basic emotions, such as the work of Matsumoto which described contempt as another universal basic emotion [21]. Other improvements include the introduction of tools for supporting study of emotion recognition, such as the development of Facial Action Coding System (FACS) [22] with the updated version introduced in 2002 [23].

The interest in emotion study gained attention from computer science researchers as well, resulting in published researches on how to create automated emotion recognition system since the late 1980s. Even a survey on the developments made during those times [24]. These researches were conducted with broad and separate focus, such as establishing dataset [11, 12, 25], mapping features or feature selection process(es) [26, 27], designing architecture [27, 28], and adopting approaches from other fields of study [25, 27]. More recent studies adopted CNN for face emotion recognition, such as the approaches proposed in [29–31]

One, if not the most, attractive feature of emotion recognition is the human face itself. The main reason behind this is because mostly human face expresses emotions one feels [32]. The expression(s) is/are shown due to the work of face muscles' coordination which produces many expression configurations [33]. Note that the human face can express more than one emotion at the same time or at an approximately same time [34].

2.2. Facial Emotion Recognition Dataset (FER-2013)

For such an attractive feature, many datasets have been developed for facial emotion recognition task. As this paper only utilizes one dataset (FER-2013 [1,9]), it is the only dataset discussed in the paper.

Created in 2013, FER-2013 dataset contains 35,887 grayscale 48x48-pixel images, with the images being stored in a spreadsheet where each image's pixel values are stored in cells per row. The images were obtained utilizing Google search and are later grouped per emotion classes, which are anger, disgust, fear, happiness, neutral, sadness, and surprise. As the dataset was built utilizing Google search, the images are in in-the-wild condition, with even very few images being animated characters.

The dataset originally had data distribution of 28,709 images for training and 3,589 images for public test, but after the competition ended, another 3,589 images which were used for private test were added to the dataset. The usages of FER-2013's data distribution vary among published researches, with each using public test images for different purposes, either as part of training set, validation set, or test set. Several images contained in FER-2013 dataset are given in Figure 1.

Figure 1: FER-2013 sample images

2.3. Standalone-Based Neural Network (SBNN)

An architecture was proposed using CNN and batch normalization, in which the batch size was set constant to 256. The training process ran for 8 epochs as higher epochs was reported to result in overfitting [35]. Such architecture resulted in 60.12% test accuracy on FER-2013's private test data.

Other architectures using both CNN and batch normalization, varying in number of filters, were proposed in [36]. The uniqueness of both architectures is that both do not have any fully connected layer and maintain kernel size of 8, and with this design, both architectures achieved test accuracy above 65%.

Global average pooling (GAP) [37] was also used as an addition to both CNN and batch normalization [38]. The architectures vary in terms of depth-wise separable convolution layer, and although both were designed for multi-task purposes (emotion and gender recognition), both architectures achieved 66% accuracy.

Another new architecture inspired by network-in-network architecture and Inception was proposed with addition of utilizing a polynomial-based learning rate decreasing method for faster convergence and better performance [39]. The data used as input were pre-processed first for face feature extraction while still maintaining the image form, which resulted in a maximum of 10% increase in accuracy. With the proposed architecture and data pre-processing, the test result for FER-2013 dataset reached 66.4% after training for 200 epochs with batch size of 250, noting that the test data used is unknown to be either public or private test data.

Two SBNN architectures, one using custom CNN and another using One-vs-All (OVA) Support Vector Machine (SVM) with Histogram of Oriented Gradients (HOG) which resulted in 66.67%

and 45.95% accuracy on test data of FER-2013 dataset respectively were also introduced [40].

A new SBNN architecture based on attentional convolutional neural networks was proposed in [41]. The proposed model was able to focus on only face features that are important to emotion recognition, achieving 70.02% test accuracy on FER-2013's private test data.

The winner of FER-2013 challenge, Yichuan Tang, proposed SBNN architecture with L2-SVMs (DLSVM) as replacement for softmax layer at the end of the neural network architecture. Such modification resulted in the proposed model reaching 71.2% test accuracy on private test dataset [42].

The current SOTA SBNN architecture was proposed in [43], in which they theorized that features at mid-level and high-level of a CNN would have impact on the final prediction. They based their model, termed as Multi-Level Convolutional Neural Network (MLCNN), on VGG architecture with 18 layers and achieved 73.03% test accuracy on FER-2013's private test data.

2.4. Ensemble-Based Neural Network (EBNN)

An EBNN architecture with 3 subnets, containing 3 and increasing convolution layers respectively for each subnet was proposed [44]. With batch size of 100, momentum value of 0.9, learning rate value of 0.01 decreasing to 0.001 by validation error condition, and running from varying epochs of 20 to 100, and 80% and 20% data distribution for training and test set respectively, they reached 65.03% test accuracy.

Referred in their paper as aggregator or hybrid CNN–SIFT aggregator, [45] combined CNN with Scale Invariant Feature Transform (SIFT), specifically Dense SIFT and regular SIFT. The EBNN, constructed and trained from scratch with combining CNN, Dense SIFT, and regular SIFT, resulted in 73.4% test accuracy on FER-2013 private test data.

Another researcher proposed an EBNN coined as hierarchical committee for facial emotion recognition task with 216 retrained deep convolutional neural network (DCN) models using transfer learning and 108 DCN models trained on aligned faces [46]. This method achieved 70.58% test accuracy on FER-2013's private test dataset, with randomly splitting training data for training and validation purposes after removing 11 images from the training data. The work is further developed in [47] which consisted of 9 DCNs, with each having 3 convolution-max pooling stages and ended with 2 fully connected layers. By using both aligned and non-aligned face structure dataset in training each DCN and using Alignment-Mapping Network (AMN) with the ensemble, they achieved 73.73% accuracy on FER-2013 private test data with the same training and validation data distribution as used in [46].

Another proposed EBNN architecture was offered in Pramerdorfer and Kampel's work [48]. The ensemble consisted of 8 DCN models based on VGG, Inception, and ResNet, where each base model underwent convolution and/or pooling layer(s) removal. They managed to achieve 75.2% test accuracy on FER-2013 private test data.

Currently known SOTA EBNN architecture was proposed in [49], which combined 3 VGG models, 2 pre-trained models which were retrained, and 1 model trained from scratch, combined with SIFT and k-means clustering, and flattened extracted feature vector as input to local SVM. This approach achieved 75.42% test accuracy on FER-2013's private test data.

2.5. Other Researches

There are other notable researches that inspire the proposed model which impacts the proposed model's architecture and learning and/or generalization capability. These researches are reviewed in this section in the order of previously stated impact descriptions, with the purpose of giving brief and proper information regarding the researches' results prior to elaborating the proposed model.

The architecture of the model is based on VGG-16 architecture [50], which contains 13 convolution layers with 3 additional fully connected layers at the end of the network. After each convolution layer, ReLU [51] layer is used for non-linearity rectification. Table 1 describes VGG-16 architecture.

However, the existence of fully connected layers in a convolutional neural network architecture may lead to higher overfitting probability [37]. To overcome this, the authors in [37] proposed GAP which works by averaging each of final feature map results and directly using the averaged results for classification. This pooling method regularizes feature maps as confidence map for categories with no parameter requiring optimization, hence avoids overfitting.

Another attempt to reduce overfitting possibility is the use of early stopping [52]. Such implementation affects the training mechanism as the training may stop before fully reaching the specified number of epochs due to no further increase in accuracy or decrease in loss in a specific period. Other than using early stopping to avoid overfitting, a proper optimizer is required for better model learning and/or generalization capability.

One most used and popular optimizer is Stochastic Gradient Descent (SGD) [53, 54], which takes constant parameter learning rate and traverses the gradient by the specified learning rate to find global minima. With SGD, it was reported that the generalization capability of a model improves [55, 56], hence less overfitting probability. Another development for SGD was using momentum as additional parameter which accelerates model learning process, which has been proven in practice in [57]. However, SGD is often slow for learning process since the traversing process is done uniformly by the learning rate value.

An alternative to SGD was proposed in [58] and coined as Adam to overcome SGD's limitation. With Adam, the learning process adapts the learning rate parameter as the learning process continues, resulting in better learning performance compared to SGD. The major drawback of Adam is the generalization capability drops significantly as reported in [56].

In an effort to overcome Adam optimizer's drawback, Keskar and Socher proposed SWATS (Switching from Adam to SGD) [59], which at first uses Adam optimizer to have better initial learning process then switches to SGD on specified trigger condition. They empirically argued that SWATS optimizer gives better performance on most tasks, especially visual- and text-based tasks, by combining both Adam and SGD.

3. Proposed Model

Our proposed model was defined to be based on VGG-16 as the base model and using GAP as final pooling layer prior to VGG-16's classifier. The best model was obtained after experimenting on multiple combinations of SGD/Adam/SWATS as optimizer and inclusion/non-inclusion of early stopping. The researchers made some modifications for VGG-16's classifier due to the use of GAP.

VGG-16 was chosen as the base model for several reasons. The first reason is because VGG-16 uses convolution layer with 3x3 kernel instead of 5x5 or 7x7, hence lesser parameters to train [50]. The second reason is by using two or three stacked convolution layers with 3x3 kernel as an equal for one convolution layer with 5x5 or 7x7 kernel respectively, VGG-16's architecture adds more rectification layers, which results in a decision function that is more discriminative [50]. The third reason is based on empirical findings as the researchers reviewed previous publications, in which the researchers found that several SBNN and EBNN researches used VGG based models and achieved good, with some achieving SOTA, results on FER-2013 dataset among other tested datasets. While VGG-13, VGG-16, and VGG-19, either in its original architecture or modified, are present in the found literature reviews, the researchers decided to go with VGG-16 since it is not too deep and complex as VGG-19, noting that both architecture demonstrated similar results as reported in [50]. The researchers also agreed to not use VGG-13 as Simonyan and Zisserman stated in their paper that increase in depth in networks results in better accuracy [50]. In addition to the architecture selection, the researchers theorized that the use of pretrained model may improve accuracy and reduce training time. The researchers used VGG-16's pretrained model which was trained on ImageNet [60] dataset rather than initializing the network's weights randomly.

The researchers also modified VGG-16's architecture by using GAP as final pooling layer before entering VGG-16's classifier, and therefore the researchers replaced all of VGG-16's classifier layers with a single fully connected layer, taking 512 averaged input neurons and outputting 7 neurons as the equivalent number of FER-2013's emotion classes. Our proposed model's architecture can be seen in Table 2.

With the proposed model's architecture, the researchers experimented on multiple combinations of training mechanism, optimizer choices, data distribution, frozen layers, and batch normalization usage. Our best model was trained using SGD optimizer and used early stopping in its training process. Such combination proved to be superior as compared with the researchers other experiments. The results of the experiments are discussed in the next section.

4. Experiments

4.1. Experimental Design

The researchers experimented on combining VGG-16 with several optimizers and training method. The used optimizers were SGD, Adam, and SWATS, and the training method was customized to use early stopping. The experiment was conducted using PyTorch and ran on Google Colab with GPU acceleration support. Due to the training data's size and Google Colab's lifetime, the researchers had to perform run-and-pause per 10 epochs as part of the training mechanism to prevent sudden disconnect from the machine, since in such an event the training process may stop prematurely. Note that the training and validation were done in one epoch. After each run-and-pause, the test was performed per 10 epochs on the model and the results are recorded.

Initially, the researchers had several options to experiment on. The options include the use/disuse of batch normalization, freezing/not freezing selected layers, imbalanced (original)/balanced training data distribution, use/disuse of GAP, and SGD/Adam/SWATS optimizer selection. All in all, the researchers initially estimated the need to experiment on approximately 12 combinations of VGG-16 model. Due to the

quite large number of possible combinations and since each epoch takes about 7-10 minutes, the researchers had to estimate which combination merits further investigation per specified run epochs. After each combination has passed the specified run epochs, the combination that provided the highest test accuracy was used to undergo further training and/or further combination. At the end of the experiments, the researchers experimented on 23 combinations, with all combinations having equivalent hyperparameter values. The researchers used learning rate value of 0.001, 0.9 for momentum on SGD optimizer, and batch size of 32.

The results of the experiments are given in Table 3. For better readability, the following acronyms are used in Table 3:

- **EG**: Experiment group
  The researchers group the experiments to select the best model in each experiment group, and what the next experiment group's models' possible combinations are.
- **D**: Data distribution
  FER-2013 dataset is very imbalanced, with some classes having more than 5,000 images and some having less than 1,000 images. The researchers tried using both balanced and imbalanced FER-2013 dataset to see which would yield better results. The acronyms for the experiments' FER-2013 data distribution are as follows:
  - *B: Balanced*
  - *I: Imbalanced*
- **BN**: Use batch normalization
  The use of batch normalization should help the model learn in a more stable manner, yet some of the best performing SBNN models do not use batch normalization. To this extent the researchers included the combination of using and discarding batch normalization in the model.
- **GAP**: Use global average pooling (GAP)
  GAP layer helps aggregate feature map information and helps prevent overfitting caused by fully connected layers in the model. For this reason, the researchers tried the combination of using and not using GAP in the experiments. Note that although GAP can be used as the classifying layer, the researchers appended a fully connected layer instead as the classifying layer for GAP's aggregated feature map.
- **LL**: Learning layers
  Finetuning a pretrained model can be done with freezing some layers except for the new classifier layer(s). Our experiments freeze some layers and keep others to be able to learn (learning layers). The following acronyms show possible combinations of learning layers in the experiments:
  - *F447: Fully connected layers with neurons structure 4096-4096-7*
  - *F7: Fully connected layer with 7 neurons*
  - *1C: 1-Last convolution layer and all following fully connected layers*
  - *2C: 2-Last convolution layers and all following fully connected layers*
  - *3C: 3-Last convolution layers and all following fully connected layers*
  - *A: All layers*
- **OPT**: Optimizer
  The researchers selected three optimizers to be used in the experiments, taking into consideration the generalization capability and convergence speed of each optimizer. The three optimizers used in the experiments are:
  - *SGD*
  - *Adam*
  - *SWATS*
- **EP**: Benchmarking epoch
  Measuring the performance of each experiment group must be done using the same settings to have a fair comparison, which in this case being the number of epochs of each model's training.
- **TR**: Test result
  The obtained accuracy in percent on the test set of FER-2013 dataset.
- **M**: Model series number
  To easily refer to a specific model, the researchers number each model. Note that italicized series number means the model is used in multiple experiment groups.

4.2. Experimental Results

EG1 denotes the first experiments. All combinations in EG1 underwent training for 10 epochs due to the large number of combinations. The best result from this experiment turned out to be model with model series number 7 (M7), using balanced training data distribution with no batch normalization, GAP layer, and SGD optimizer with 64.11% test accuracy result.

From the best result of EG1, the researchers decided to perform the next experiment (EG2) on balanced training data with unfreezing 1- and 2-last convolution layer (denoted 1C and 2C in Table 3, respectively) since the researchers hypothesized that with the use of GAP, training the output (fully connected) layer does not do much on improving the model's generalization capability. In addition to the experiment on balanced training data, the researchers tried running an experiment for imbalanced data with only the output layer being unfrozen. The researchers also extended the number of epochs run from 10 to 30 in EG2. The result was out of what the researchers had thought, with the combination utilizing imbalanced training data having the highest test accuracy of 67.26% (M15), and the combination for balanced data and unfrozen 2-last convolution layer (M14) coming in second with 67.20% test accuracy.

The researchers noticed how M14 had a close accuracy gap with M15 (EG2's best model). The researchers then slightly deviated the experiment in EG3 with the thought of using both balanced and imbalanced dataset on no frozen layers. The researchers unfroze all layers in the proposed model and trained the networks for 30 epochs. The results show that using SGD with imbalanced training data and no frozen layer gave the best result of all the experiments, with 69.46% test accuracy, which is M17. The researchers also noted how the combination that uses balanced training data could not compete with the combination utilizing imbalanced training data.

Considering our last observation on EG3, EG4 consisted of experiments on imbalanced dataset with SGD optimizer, and the researchers tried to reduce the number of unfrozen layers by freezing only 3-last convolution layers (3C in Table 3) in hopes of speeding training time by reducing trainable parameter count. Then the researchers compared the combination's result with M15

and M17. Once again, M17 which was built by unfreezing all layers in the network and using imbalanced dataset produced the best accuracy result.

With the best combination now obtained after four experiment groups, EG5 established the comparison for such combination (imbalanced training data, no batch normalization, using GAP, and no frozen layer) but with different optimizers. The researchers also tried to use early stopping in this experiment group, with the early stopping being effective per epoch 30. The researchers set the minimum passing point of the training epoch to be 30 to have the models learn at first and not getting cut out by the early stopping mechanism. The early stopping mechanism was also executed if the validation accuracy does not improve for last 10 epochs since the last best recorded validation accuracy. To this extent, note that benchmarking epoch (EP in Table 3) refers to last epoch for each model after early stopping was effective. What was unique from this experiment group is that M17 had gotten better validation accuracy but lower test accuracy, proven with the decreasing test accuracy in EG5 as compared to EG3 and EG4's results.

After EG5, the researchers attempted to do training without early stopping, to see whether the model may be caught in local minima when early stopping was enabled. The experiments which did not use early stopping are grouped as EG6. EG6 proved our assumption wrong about our model being caught in local minima with the use of early stopping, as all three models in EG6 did not show much improvement after passing 30 epochs, nor after the benchmarking epoch in EG5. The results of EG6 also show the same findings as reported in EG5, in which the model using SGD optimizer with the specified hyperparameters value in Table 3 reigned triumphant compared to other models in EG6.

With the obtained best model from the experiments, the researchers provide their best model's test accuracy comparison with other works' test accuracy on Table 4. Note that the compared models are those from SBNN group as the proposed model is categorized as SBNN model.

Our proposed model outperforms most proposed approaches by a significant margin of 3-24%. The researchers argue that the capability of VGG-16 is adequate as feature extractor for facial emotion recognition and is further enhanced by the addition of GAP layer prior to classifier (fully connected) layer. GAP's addition is observed to greatly increase test accuracy, as the experiments have shown in Table 3 and shown by [38]. Unfreezing all layers in pretrained VGG-16 model also results in the best performance. The researchers believe that the model learns to better extract features as convolutional layers are learning as well during training instead of just letting the fully connected layers learn the preferred mapping. In addition to the proposed model's capability, the use of SGD optimizer benefits the proposed model as reported in [56] where SGD is reported to yield better performance on unseen data. What is unique is the use of Adam and SWATS optimizer without batch normalization leads to worst performances as shown in Table 3, and yet using batch normalization with SGD does not yield the best results.

Our proposed model also achieves similar, albeit lower, test accuracy as compared to the approaches from [40,41] with less model complexity. This would be beneficial since utilizing a simpler model may result in fewer required resources and faster performance in real-life scenarios. Using simpler model would also open further research on the possibilities of using simpler models when pursuing other objectives.

5. Conclusions

In this paper, the researchers report their experiments using FER-2013 dataset as the data source. Several researches using FER-2013 are also reported and they used different kinds of approaches, which the researchers group as standalone-based neural network (SBNN) and ensemble-based neural network (EBNN) approaches. The proposed network is classified as SBNN with VGG-16 as the base model, which was modified into using 13 convolutional layers and GAP as the last pooling layer. The network is then experimented on by varying several variables, such as data distribution, use/disuse of batch normalization, GAP, optimizers choice, and freezing some layers. The researchers experimented on 23 models and found out that using an imbalanced dataset, GAP, non-frozen layer, and SGD optimizer results in the highest accuracy throughout the experiments, which is 69.40%. With this result, the network has surpassed most reported networks defined in Table 4 by quite a large margin. In addition, the model supports end-to-end training and is much simpler as compared to other three best SBNN models [41–43], which in return results in lower time and memory consumption.

Further investigations could be done regarding hyperparameter tuning as the researchers experimented on the variation of data distribution, pooling layer, and optimizer selection only. Other improvement includes using other existing models or developing new architecture with similar topology as the proposed model for better classifying capability. With the proposed model's result, the researchers believe that further modifications may lead to better performance in classifying emotions with in-the-wild settings.

Conflict of Interest

ABSTRACT

Digital twins act through application programming interfaces to their physical counterparts to monitor, model, and control them. Beyond these traditional functions of digital twins, they must also act to secure their physical counterparts. A multi-model scheme is presented to help digital twins towards the task of securing the physical system. Additionally, this work includes an analysis of more than four hundred thousand tweets each relating to digital twin technology and cybersecurity which were collected during June and July in 2020. Of the first corpus of tweets collected by searching for #digitaltwin during the research period, only a small population of 10% reference security concepts. In the second and larger corpus of collected tweets, the top mentioned industries were health, education, and public. A naïve Bayes model reached a 70.3% accuracy at differentiating tweets that were either related to cybersecurity or the internet of things. The study also indicates that cybersecurity tweets are consistently more negative in many areas of sentiment when compared to tweets about the internet of things. The sentiment findings of cybersecurity tweets will reinforce the need to address culture in cybersecurity posture while the security multi-model schema contributes to the state of the art.

1. Introduction

An API development model for digital twins has been proposed recently [1]. This paper augments that work to address the cybersecurity concerns of the digital twin within the context of the various implementations and industries where the twin may be utilized. Furthermore, the adoption of current security models, such as state machine, lattice, non-interference, and information flow models are proposed for digital twins.

In the original paper, a development model for the APIs of the digital twin was created. The model was proposed to establish the context of the environment, the system, relationships between the two, and the functional and non-functional requirements.

This research includes the mining of Twitter tweets using appropriate search criteria for digital twins, the internet of things (IoT), and cybersecurity. The analysis includes mention analysis of industries, exploration of the sentiment, natural language processing (NLP) implementation towards the classification of tweets, and modeling to predict the twitter user behavior.

*Corresponding Author: Jim Scheibmeir, Email: jimscheibmeir@gmail.com

Three sets of tweets were collected for this study with the latter two sets being joined into a combined corpus. Each set was collected through the execution of scripts written in R. The first collection is smaller and has 3,102 tweets about digital twins. The second and third collections are larger. In total, 422,963 industrial internet of things (IIoT) tweets and 497,174 cybersecurity tweets were collected. These larger sets were combined into one corpus for analysis. The search criteria for the tweet collections are listed in Table 1.

Table 1: Tweet collection search criteria

Script Topic	Criteria used in actual R code
Digital Twin	"#digitaltwin"
IIoT	"#industry40 OR #IIOT OR #IOT"
Cybersecurity	"#cybersecurity OR #infosec OR #hacking"

This study is organized as follows. Section 2 reviews the literature and the background information on the subject. Section 3 describes our research method, including the collection of tweets as well as the processing. Sections 4 and 5 present the results from

social media analysis. Section 6 proposes a multi-model security scheme for digital twins. Finally, section 7 presents the conclusion of this study.

2. Background and related work

Digital twins are a logical conduit between physical entities and humans, geared towards monitoring and controlling a system [2]. The design of the interfaces themselves may utilize structured standards such as OpenAPI to list the various objects, paths, and operations [3].

Digital twins can be used during system design for vulnerability detection or during physical system operations to assist with intrusion detection [4]. Digital twins can utilize and manage the Internet of Things (IoT) devices and IoT systems of systems [5]. Wireless Sensor Networks (WSN) and attached IoT sensor components can be energy and cost-effective monitoring approaches [6]. WSNs are also frequently constrained to limited computing and power resources and thus security in WSNs can be challenged [7]. To maintain the integrity of the sensor data and overall system state awareness, secure links with proper authentication must be established [8].

Vulnerable digital twins offer hackers a blueprint of the physical counterpart as well as other backend systems that may be a part of system integration [9]. The digital twin can help secure the physical systems or be yet another vulnerability as IoT growth has created a large cyber-attack surface [10]. IoT has revealed security vulnerability ranging from trust management, authentication, privacy, to access control of embedded systems [11]. While digital twins may present such risk, they are still getting popular. The smart factory market, an economy of integrated automation solutions adopted to streamline manufacturing, is predicted to be worth approximately $205 billion-dollar by 2022 [9]. Hearn and Rix also cite another 2019 study whereof 220 security leaders in industrial and manufacturing who were a part of the research survey, 79% indicated they had experienced an IoT cyberattack within that past year. IoT and digital twins-based systems can be attractive targets for malicious actors.

Hearn and Rix identify advantages, such as the prevention of downtime and monitoring attacks against cyber-physical systems, as potential benefits of digital twins [9]. Risks of digital twins in cyber-physical systems (CPS) include the intellectual property incorporated in the digital twins as well as critical information about the CPS itself. For such reasons, the digital twin itself must go through rigorous software hardening routines, such as fuzz and penetration testing [9]. Security of the digital twin must start from the ground-up, inception to retirement. Security concerns must be incorporated with the organization's culture [9].

IoT systems and CPS are being deployed in the energy industry, and there have been instances of cyber-attacks on them. Some known attacks include the US electrical grid in 2009, Ukraine power outage in 2015, and Stuxnet attacks in 2005 and 2010 [10]. Common problems can facilitate such attacks, such as low power IoT devices have minimal resources and thus they are not resilient to denial of service attacks. A digital twin may create yet another vulnerability of an industrial or energy system.

Atalay & Angin in their 2020 study proposes that the digital twin can help to secure a cyber-physical system by establishing a security framework. The framework should contain an extensible digital twin that represents the smart grid, a cyber-threat database for applicable attack vectors, attack simulation tools, and an analysis and reporting module [10].

The framework suggested by Atalay & Angin starts with the creation of the digital twin through specification and reuse of other models. The framework separates the modeling of the CPSs into two phases, identification of the elements and their relationships, and building the network model using simulation. By creating the digital twin and using models, it is possible to achieve standardization through model reuse, utilization of a central threat intelligence database of smart grid attacks, and to achieve continuity of security evaluation [10].

Digital twins may secure physical systems through rule-based controls as well as intrusion detection as proposed by Eckhart and Ekelhart [4]. They identify a wide range of definitions for digital twins. Some definitions omit simulation and focus on visualization, such as implementing augmented reality (AR). AR applications have their security and quality concerns. Eckhart and Ekelhart also explain how a digital twin be used to implement intrusion detection for an industrial control system (ICS) or CPS. They identify concerns beyond intrusion detection, such as:

- the origin of digital twins was in the simulation of systems, although some authors omit simulation as a benefit of digital twins
- digital twins may have fidelity issues which may limit their use
- digital twins have a lifecycle that follows the lifecycle of their physical counterpart
- proper retirement of a digital twin system is imperative as it may contain private and confidential data
- digital twins may be used for security personnel training or in a cyber range as the attack target
- cost of digital twin creation can still be a prohibitive factor

Eckhart and Ekelhart refer to their 2018 publication, where, it was suggested that previously established specifications of the physical system could be modeled with AutoML, virtualized within Mininet and other tools, which can reduce the cost of creating digital twins [12]. They further proposed that digital twins can assist in intrusion detection by offering a baseline of normal behavior that can be analyzed and compared to the behavior of the physical system to detect outlying and potentially malicious activity [12].

3. Methodology

3.1. Collection

This paper focuses on the analysis of collections of Twitter tweets, as well as academic papers. Scripts have been written in R and executed throughout the research period. More R code has been utilized to clean the collected tweets, transform new classification data fields, and analyze them for n-grams, mention,

and sentiment analysis. The scripts use various libraries, such as the rtweet library as an API to the Twitter social media platform. Figure 1 below omits various keys and passwords yet illustrates the basics of library import and the implementation of a search and data frame store of tweets.

```
library(rtweet)
library(ggplot2)
library(dplyr)
library(tidyr)

c_key <- ''
c_secret<- ''
access_token <- ''
access_secret <- ''
appdt <- ''

twitter_token <- create_token(
  app = appdt,
  consumer_key = c_key,
  consumer_secret = c_secret,
  access_token = access_token,
  access_secret = access_secret)

setup_twitter_oauth(consumer_key, consumer_secret, access_token, access_secret)

digitaltwin_tweets <- search_tweets(q = "#digitaltwin",since = '2020-06-08', n = 50000)
```

Figure 1: Screenshot of example usage of rtweet library within R Studio

Three scripts were written to collect tweets for this research. The first used a single search criterion, "#digitaltwin", which has collected 3,102 tweets within 21 days of June 2020. The second and third scripts ran for the entire month of July 2020. 422,963 industry internet of things (IIoT) tweets and 497,174 cybersecurity tweets were collected. The tweets are stored with metadata made available via the rtweet API, but not all data has been retained. Additional data has been generated and stored such as the industry a tweet may mention and the sentiment score (positive or negative) of the text within the tweet. Table 2 lists the acquired and generated data.

Table 2: Tweet data fields

Field Name	Short Description
created_at	The date the tweet was originally posted to the Twitter platform
text	Character contents of the tweet
favorite_count	An integer representing the number of times a tweet has been marked as a favorite by Twitter users
retweet_count	An integer representing the number of times a tweet has been retweeted by Twitter users
country	Frequently NA within the dataset and sometimes providing the country of origin of the Twitter user posting the tweet
retweet_location	Frequently NA within the dataset and sometimes providing the country of origin of the Twitter user retweeting a tweet
Industry and count	A list of industries and the count of mentions from the gathered tweets
Sentiment	The individual sentiment score of a tweet's text
Retweet	Binomial value indicating if retweet_count > 0
Favorite	Binomial value indicating if favorite_count is > 0

3.2. Data Preparation and Processing

Data preparation activities may account for 80 percent of the time invested in data science effort [13]. In this study, the collection took many days, but the Twitter data was usable practically from the beginning. This is due to the limited search criteria used and the nature of the required data (such as we did not need the country or retweet_location fields for this research, both having many empty or not applicable entries). The longest time in preparation was determining industry mentions and labeling the tweets. Industry and identification keywords for cross-reference and classification efforts were collected from the International Labor Organization's web site [14]. Preprocessing was done cross-referencing the ILO keywords to the tweet's text to determine the tweet's topics. This enabled mention analysis by the labor industry.

In the second corpus of tweets, the labeling of tweets allowed the naïve Bayes models to be trained and then tested. Tweets were labeled based upon the search criteria that was used to collect the tweets. This label would consist of either IoT or cybersecurity. Eighty percent of the data was used to train the models and twenty percent was utilized to test the model accuracy. Various models and parameters were used to predict the correct tweet label. Other preprocessing for the model input parameters included sentiment analysis and word lemmatization. The package textstem was utilized for word lemmatization and the packages tidytext and sentimentr were utilized for the sentiment analysis.

4. Results of First Corpus Analysis

The word cloud illustrated in Figure 2 highlights common bigrams found within the first corpus of collected tweets, those 3,102 found with search criterion #digitaltwin, after removing common stop words. While concerning the word 'security' is not paired with another common word frequently enough to make this bi-gram chart, we do see that conversations on Twitter around defense, risk, and the industrial use of IoT are occurring, each having relevance towards this research.

Figure 2: Word Cloud of Bigrams within the Tweet Collection Text

The word cloud used in figure 2 omits counts of the actual instances of the bigrams. Table 3 outlines a few common security terms and the number of instances they occur within our first

corpus, those 3,102 tweets collected by searching #digitaltwin. Such terms may occur in one tweet multiple times. Overall, terms such as "encrypt", or "vulnerability" have almost no mention in such tweets and do not appear as a part of the social media conversation which is a concerning observation.

Table 3: Common security terms and their occurrence

Terms	Count of occurrences
"security"|"secure"	88
"risk"	212
"defense"|"defensive"	179
"iiot"|"industrial iot"	750
"encrypt"|"decrypt"|"cipher"	1
"vulnerability"|"threat"	1

Looking at this first corpus of tweets, the percentage of tweets containing common security terms make up 10% of the total volume of tweets collected using the #digitaltwin search criteria within the specified time range, as illustrated in Figure 3. We observe a dearth of conversation within the social media analysis towards securing digital twins, which could be used to implement the security models needed.

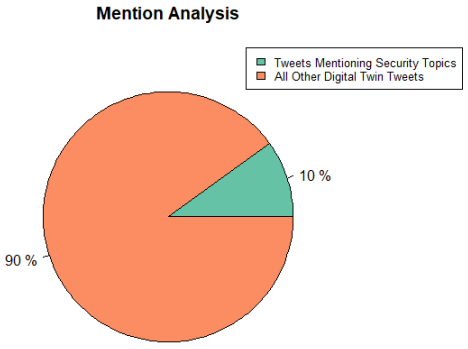

Figure 3: Most IoT tweets do not mention security topics

4.1. Most Favored and Most Retweeted Tweets about Digital Twins

Tweets can be favored as well as re-tweeted. The number of favorites indicates the count of unique user accounts that like or agree with the content of the tweet [15]. In the first corpus, the most favored tweet is also the most retweeted. It will be discussed later in this section. To provide more breadth of the findings, the second most favored tweet is illustrated in Figure 4 [16]. This tweet refers to Intel technology and links to a 2015 white paper where Intel published best practices to help with IoT sensor technology implementation against challenges such as cost of ownership, maintaining security, and designing for scalability [17].

Within the scope of this first corpus, the most retweeted tweet is about the use of digital twin used in contact tracing to help prevent the spread of Covid-19. The digital twin was specifically built and used to help contain the spread of the virus in Dharavi, a location within Mumbai that houses nearly one million residents. Many of these residents rely on daily wages. Living and working conditions may reduce or prevent social distancing. During the time of the tweet creation, epidemiologists had credited the Dharavi community for their efforts towards containment [18]. Figure 5 is a screen capture of this most favorited tweet within the first corpus [19]. While we cannot confirm the accuracy of the tweet, we can recognize from the tweet contents the broad application of digital twin usage to monitor, model, and control a pandemic. The nature of such a system and the associated data also provide support for why such the system requires a mature security posture, to protect individuals and their privacy rights.

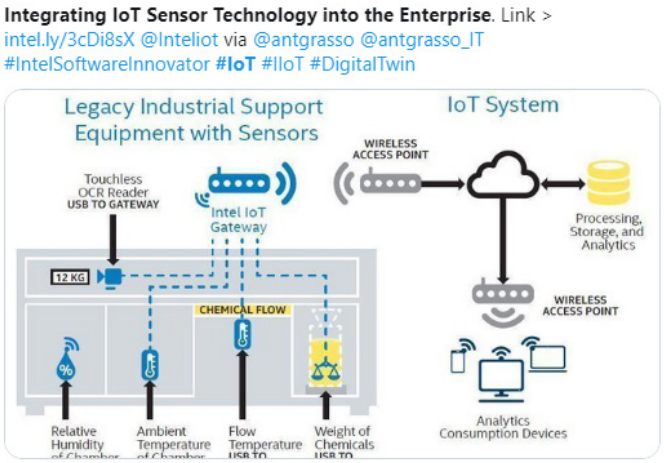

Figure 4: Second Most Favored Tweet within the Scope of this Research

Figure 5: Most retweeted tweet within the research scope

4.2. Mention and Sentiment Analysis

Studies show digital twins being utilized across industries; mention analysis from social media provides an additional perspective. To analyze industry mention among the first tweet collection, we crossed referenced the tweets' text with a list of known industry categories [14]. The simple algorithm reads the tweet texts and counts industry mentions, including when multiple

industries are mentioned within a single tweet's text. Figure 6 illustrates mention analysis results with health, education, and public as the top three topics with most mentions within the tweets' text.

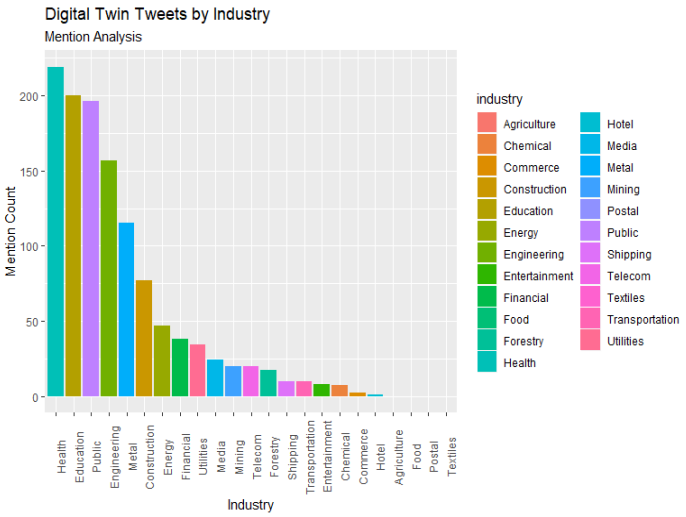

Figure 6: Industry mention analysis: health, education, and public are the top three mentioned industries

Utilizing the sentimentr package, each industry group has the individual tweet text sentiment scores averaged and placed on the chart found in Figure 7. The sentiment scores from the sentimentr package may range from a negative 2.0 to a positive 2.0. While the health and public industries were high in the mention-analysis, the sentiment scores for those industry groups are negative. The three industry groups having the highest average sentiment scores are engineering, commerce, and energy.

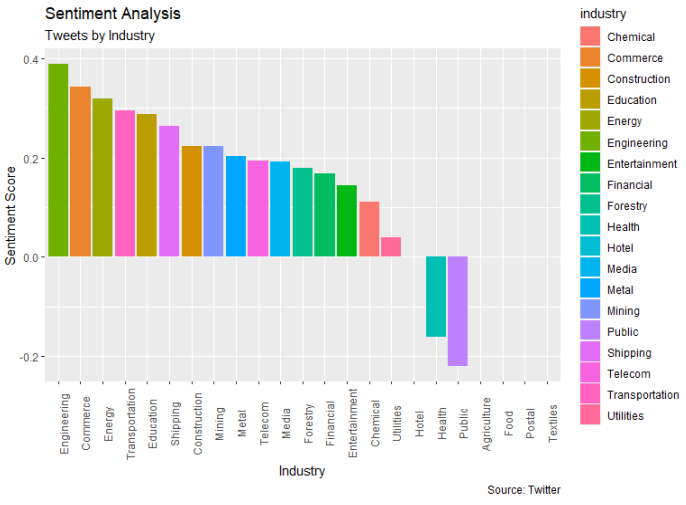

Figure 7: Aggregated sentiment scores grouped by industry

The tweet in the engineering group having the highest sentiment score is given in Figure 8 [20]. This tweet indicates the usage of digital twins to assist in the simulation of electric vehicles for optimal energy management.

Today's electric vehicles market is high stakes. The current pandemic threatens the automotive supply chain [21], a Tesla truck recently marketed towing a competitor's vehicle (F-150) up a hill [22], and Tesla competitor Nikola Motors saw a one-day stock jump of 104% [23]. Security posture is required around the intellectual property in this dynamic and competitive market, and therefore must be applied to such a digital twin.

Figure 8: Tweet having highest sentiment score within the engineering group

5. Results of Social Media Analytics of IIoT and Cybersecurity Tweets

Multiple prediction models were created to further inspect the tweets. This included attempts to predict whether a given tweet was towards the topic of cybersecurity or IIoT. Methods such as word stems, lemmatization, term frequency-inverse document frequency (TFIDF) were utilized in naïve Bayes and general linear models.

A naïve Bayes model that attempted to predict the label, cybersecurity or IIoT, of a given tweet using word lemmatization and sentiment analysis could predict the label correctly with a 70.3% accuracy. While this prediction accuracy is not high, perhaps the sentiment coefficient correlations are more telling. As previously stated, security must start with the organization's culture [9]. An organization's culture consists of the beliefs and values of the employees. Communication incorporating the sentiment of the topic may be more influential towards influencing behavior or belief. The sentiment level of the cybersecurity tweets, when compared to the IIoT tweets, was higher in the areas of anger, disgust, fear, negative, and sadness, whereas the IIoT tweets sentiment level, when compared to cybersecurity tweets, was higher in anticipation, joy, positive, surprise, and trust. Table 4 lists the average sentiment scores for each classification of sentiment by the cybersecurity and IIoT labels.

Given a tweet is about Cybersecurity, there is a 14.5% probability that the tweet is negative, an 11.6% probability that the tweet provokes anticipation, and an 11.3% probability that the tweet has the sentiment of fear. This information may be key for communicating cybersecurity strategies and plans within an organization. We should consider the sentiment of our security posture messaging, and how it fits into the culture, behaviors, and values of the communication's target audience.

The Term Frequency-Inverse Document Frequency (TFIDF) score utilization within a naïve Bayes model had less accuracy,

56.3%, compared with the model using both word lemmatization and sentiment analysis. TFIDF does allow us to see important words in a corpus, we observe that "bugbountytip" had the highest TFIDF score within the cybersecurity corpus at 0.00127.

Table 4: Sentiment coefficient probabilities on tweet labels

Conditional Probabilities of IIoT and Cybersecurity Tweet Sentiment		
Sentiment	Cybersecurity	IIoT
Anger	0.07145	0.03765
Anticipation	0.11663	0.14300
Disgust	0.01868	0.01400
Fear	0.11321	0.06652
Joy	0.05369	0.07048
Negative	0.14541	0.07757
Positive	0.25503	0.35884
Sadness	0.04404	0.02833
Surprise	0.03586	0.03683
Trust	0.14597	0.16677

6. Application of a Digital Twin as a Multi-Model Security Architecture

Digital twins are commonly used to help monitor, model, and control cyber-physical systems. Engineering a digital twin should be done using a systematic approach by performing a needs analysis from the physical device and context of the operating environment [1]. Needs analysis and environmental context must include non-functional requirements, including cybersecurity. Securing information confidentiality of these cyber-physical systems is a growing concern [24]. Beyond the common monitor, model, and control mechanisms, digital twins may also be utilized for incorporating multiple security models.

Several security control models exist. The information flow model is a common mechanism to maintain information confidentiality [25]. We outline in Table 5 how the information flow model may also work to maintain the integrity of a digital twin and its physical counterpart. Multiple models will need to be implemented in the system engineering effort to establish a secure posture. Each model has a strength, such as Bell-LaPadula working towards the confidentiality of information [26]. Furthermore, in Table 5, we indicate how the lattice model, incorporating Biba, can work to ensure information integrity.

The digital twin may also incorporate concepts and techniques such as automated policy exchange (APEX) to prevent data leakage. APEX technology works to keep honest people working within the guidance of security best practices and policies, as large systems and enterprises may have complex policies that not everyone is aware of [27]. Using APEX, the digital twin would monitor labeled files throughout their lifecycle and use control mechanisms, such as deployed agents within the cyber-physical system, to prevent or warn on file activities by users.

Another possible avenue would be for the monitoring portion of the digital twin to utilize a System Call Intercept (SCI) framework. SCI works to reduce data leakage by reviewing policies of subjects and objects, trapping some specific activities before an operating system completing the execution of the activity and perhaps suspending the activity completely [28]. Using the SCI framework, the monitor and modeling functions of the digital twin would use policies to review specific subjects or objects (perhaps all users and system components within a zero-trust approach) and trap some actions for review before the OS or another system component completing the action. An inventory of objects, subjects, and system calls that could be trapped would be required to implement such a framework, which will improve data protection. This inventory could be complemented with behavior analysis by machine learning models to identify malicious activity. Machine learning can be used for countering cybersecurity threats and vulnerability mitigation using regression, prediction, and classification techniques.

Table 5 provides high-level examples of how a digital twin implementation may satisfy or utilize common security models such as State Machine, Lattice, Interference, and Information Flow models.

Table 5: Application examples of a digital twin as a multi-model security schema

Security Model	**Example Digital Twin Application**
State Machine	Digital twin control input is first executed within the model. Validation occurs within the model for an appropriate output state. The input may be rejected before entering the digital twin control mechanism for actual processing on the cyber-physical system.
Non-Interference Model	Monitoring and control mechanisms must obfuscate users reading (monitoring) and writing (controlling) across domains. This reduces the probability of users being influenced by the actions of subjects with greater/lesser clearance. This approach may utilize common discretionary access control (DAC) across file systems, mandatory access control (MAC) through rule-based systems, and role-based control. DAC and MAC limit the availability of information objects to certain subjects to retain the confidentiality of information [29].
Lattice Model	Biba protects integrity by preventing a subject from reading lower integrity or lower-level access data [29]. Using the Biba Model approach, the digital twin modeling process accesses only known secured sensors (having a level of integrity through controls). While we may monitor many sensors, decision dashboards and predictive analytics should utilize only trusted and secured sensors. A matrix of such processes and secure sensors would instruct inputs for such high integrity algorithms.
Information Flow Model	Sensor information flow is one way. The Digital twin may read sensor data for monitoring or modeling purposes. No data is transmitted to a sensor to be later sent back, as sensor-originated data. This prevents levels of spoofing sensor data, by not allowing writes to the sensor memory. Any PUT type of action to sensors APIs would be rejected and logged as malicious intent.

Figure 8 illustrates a situation where a population, Bluetooth sensors from mobile devices, network paths, and system logic are used for the creation of a population's digital twin. In this case, the digital twin of the population would be used by public health officials and the application subscribers for contact tracing. The diagram's purpose is to provide examples illustrating the concepts given in Table 5 applied to a hypothetical contact tracing system.

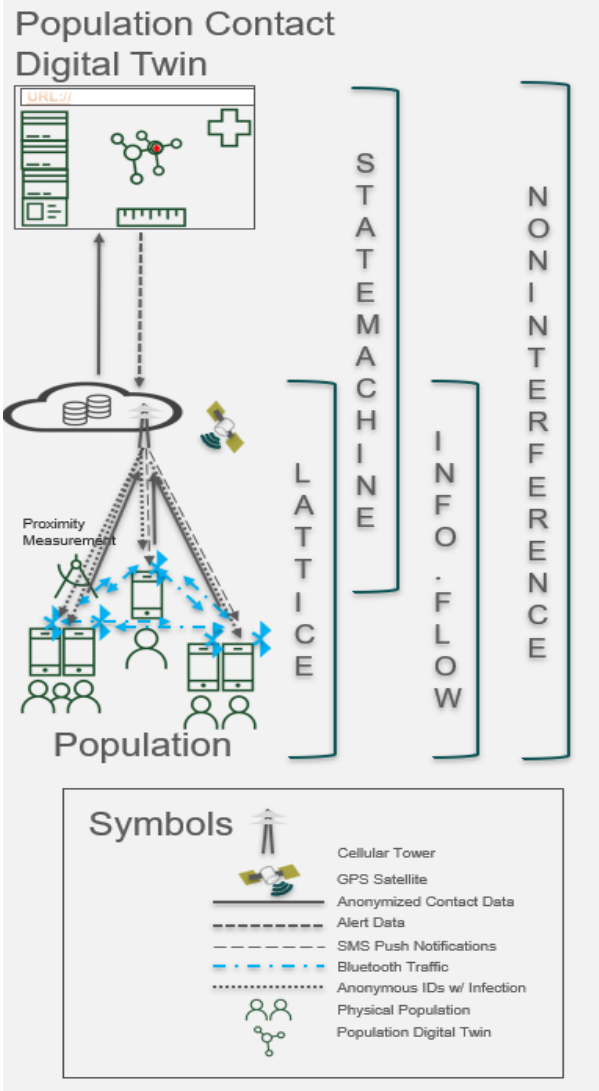

Figure 8: Applying the multi-model in digital twin security

If contact tracing systems were injected with malicious data, it could alter the behaviors of a population. Applying the lattice model helps assure that a system having integrity does not read from a system or sensor with low integrity. The lattice model can prevent a malicious actor's device farm from spoofing the contact system. To validate the integrity of a sensor or mobile device in this case, the system may validate a history of GPS or use human interaction to assure the device is not a simulator or otherwise driven by a malicious bot.

Public health officials may instruct the system to deploy warning notifications to participants who have opted in to use the feature. However, before deploying the notification, the digital twin should utilize the state machine model. Again, a notification could be a malicious message being sent to alarm a population. The logic should first model that notification within the digital twin. The modeling should evaluate the message accuracy and may even predict how the population may behave to help public health officials craft response plans. If the notification messages were not related by a contact tracing scheme, the message may be malicious and should be stopped.

The information flow model is utilized to protect the population and their privacy. The mobile device's application logic allows Bluetooth connections to write to ledgers indicating contacts. This data is anonymized and does not indicate a person's identity. Writing to this ledger is only allowed by the local mobile device which is in the possession of the user. The centralized system does not allow writing to this contact ledger. The mobile device application will pull anonymized alert data from the central system. This data is written to a separate ledger. The only mechanism for the centralized system to send data to the host devices is through the SMS push notification mechanism, which has levels of security such as users being required to opt-in and the state machine model.

Users of the Population Contact Digital Twin dashboard will utilize roles, authentication, and authorization to access the digital twin of the population. Low entitlement users would not have the ability to interfere with the population by spying on them using inference techniques. Entitled users, such as medical doctors, may be granted access to information having more fidelity to help protect the population's health. This protects a population using the non-interference model with access controls.

7. Conclusions and Future Work

7.1. Conclusions

Digital twins operate from and create new cyber-physical system information. A proper design approach for a digital twin should model its cyber-physical system, including its future states. In addition to monitoring, modeling, and controlling the cyber-physical system, a digital twin must also provide security. This fourth element as applied to the prior three digital twin requirements allows for a layered approach to securing cyber-physical systems by implementing multiple security models. While past researchers have focused on intrusion detection, this article proposes that common security control models such as state machine, non-interference, lattice, and information flow models can be utilized in digital twin implementation to secure itself the associated cyber-physical system.

In the first corpus of tweets collected in this study by searching for #digitaltwin, those referencing security concepts represented a small population of 10%. In the second and larger corpus of the collected tweets, the top mentioned industries or business sectors were health, education, and public in that order. The top three industries having the highest tweet sentiment were engineering, commerce, and energy. While naïve Bayes models reached only a 70.3% accuracy at differentiating a tweet that was about cybersecurity versus a tweet about digital twins, the sentiment findings of the messages leaned towards negative messaging from the cybersecurity tweets.

7.2. Future Work

Most of our research utilized social media, which can be time-consuming to prepare such data and has limits in what it can

contribute. Future research should include detailed case studies of direct implementation which would strengthen the approaches proposed in this work. The sentiment findings of cybersecurity tweets deserve further research as other researchers have stated that security must start with an organization's culture. The implication of negative messaging on an organization's cybersecurity posture and culture needs to be studied.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Currently, increasing penetration of the Wind Energy Conversion System (WECs) in Power generation systems has influenced the supply of electrical power reliability for the consumer in comparison with other traditional sources. In this paper, the performance and efficiency of a new optimization approach referred to as the "Differential Evolution Optimization Algorithm" (DEOA) to measure the reliability of power adequacy systems (RPAs). The proposed intelligent algorithm which relies on the Population-based Intelligent Search (PBIs) technique is viewed as a feasible alternative for the Monte Carlo simulation (MCS) method in the assessment of the non-chronological system. The benefit of utilizing this algorithm is apparent in the manner it expedites the calculation and achieves greater precision with less calculation effort. Additionally, there is a deeper understanding of the effect of the increasing levels of wind energy on generation adequacy from the WECs sources to satisfy future power electricity demands. In addition, the effectiveness of the suggested algorithm in assessing the RPAs was compared to the analytical and MCS method.

1. Introduction

The inconsistent nature of wind energy presents challenges to the planners and operation personnel of power plants. Therefore, it is now crucially important to assess the extent that power impacts the dependability and sufficiency of the power being generated by existing plants. In assessing the penetration of the wind power from the WECs based on the nature of the wind can be complicated as it involves a number of critical issues that have to be taken into account when designing the WECs, such as the speed and power of the wind. To design a method for estimating wind production necessitates a massive amount of historical data of wind velocity so that the stochastic nature of the wind at a particular location can be accurately simulated. Another possible option could be to use a dependable stochastic simulation technique for the generation of the time series artificial of the wind speed.

Analyzing how adequate the PS is possible through the identification and evaluation of failure states, which are situations when customer demand for power cannot be met by the power system, hence, making it necessary to practice load shedding to ensure the maintenance of the system integrity. Due to the fact that there are numerous potential failure situations [1], [2], it may not be practicable to directly count and estimate it all even in cases of medium-size power systems.

Currently, RE sources usually combined with the conventional electrical grid for generating less polluting energy; as for example WTGs [3]. As a result, the estimation of the reliability index for unconcentrated resources such as wind energy is complicated [4]. As such, new tools need to be used to assess PS with the wide presence of wind energy sources [5].

Evaluating the dependability of PGS is typically performed by simulation or analysis approaches. The majority of authors in [6] focused on assessing the dependability of PGS in wind farms' basis of analytic approaches. The MCS method offers an accurate estimate of the dependability indices. Therefore, the MCS would be beneficial for such a purpose, but it requires considerable computational work which is time-consuming and should be avoided if convergence efficiency is critical [7]. This research

[*]Corresponding Author: Athraa Ali Kadhem, University Putra Malaysia Email: athraaonoz2007@yahoo.com

offers a replacement for the MCS and PBIs method [8],[9]. This optional approach method is used to identify a num ber of possible failure situations to facilitate the adequacy indices of the system.

Numerous PBIs approaches are possible for intelligent research, epitome for these algorithms like the BPSO, ISSPs, OGA, EC, BPSO, and BCA [10]–[13]. Although some research has been done on the dependability of the generating systems, there is still a need for approaches that are more appropriate and which offer greater computational flexibility and are more realistic in representing the desired PGS adequacy [14]–[17].

Models are needed for the simulation of the stochastic characteristic of PGS behavior, which is not a new issue for population-based intelligent research approaches. However, it has emerged as an important issue when wind sources and the PS are combined and taken into account. This paper suggested a novel algorithm known as "DEOA" to lower the time amount cost of the computation to simulation pattern in the non-SMCS and other Optimization Algorithms by enhancing the checking efficiency in a given area state-space employing a PBIs approach. DEOA is based on the meta- heuristics searching employed in simulating the generating system's operation and taking into account the not expecting failure of current systems and the instability of "WECs" energy. DEOA exhibited benefits in the form of higher computational speed, utilizing a relatively uncomplicated structure, providing ease-of-use, and was shown to be highly robust. Besides, the numerically simulated solution was compared with the MCS-related Work. It also explains the impacts of wind energy capacity from the WECs on power systems to attain at the level of the incremental peak load capability.

Nomenclature

WECs	Wind Energy Conversion System
RPAs	Reliability of Power Adequacy Systems
PBIs	Population-Based Intelligent Search
DEOA	Differential Evolution Optimization Algorithm
MCS	Monte Carlo simulation
SMCS	Sequential Monte Carlo Simulation
PS	Power System
RE	Renewable Energy
WTGs	Wind Turbine Generators
PGS	Power Generation Systems
ISSP	Intelligent State Space Pruning
OGA	Optimization Genetic Algorithm
EC	Evolutionary Computation
PSO	Particle Swarm Optimization
BCA	Bee Colony Algorithm
LOLE	Loss of Load Expectation
LOEE	Loss of Energy Expectation
LOLF	Loss of Load Frequency
LDC	Load Duration Curve
RI	Reliability Indices
LH	load levels
PNS	Power Not Supplied
LOLP	Loss of Load Probability
WDM	Weibull distribution model
WPG	Wind Power Generation
BPSO	Binary Particle Swarm Optimizations
MSGA	Modified Simple Genetic Algorithm
RTS	Reliability Test System

2. Assistant Theoretical Materials

2.1. Assessment of Conventional Generation Systems Adequacy

Analyzing the reliability of electrical energy systems is important to determine PGS adequacy and for possible future increase in the system capacity. This is to ensure adequate availability of power to satisfy consumer requirements for particular installed system capacity. As a result, the could be utilized as an element of the quantitative conditions in a power generation system in planning for the system's risk paradigm. In this study, the essential evaluated were utilized in facilitating the approximation of the PS dependability level of their "Loss of Load Frequency (LOLF)", "Loss of Energy Expectation (LOEE)", and "Loss of Load Expectation (LOLE)".

Load designs system are normally non-sequential or sequential paradigms that can be used with various Optimization Algorithms approaches. The sequential Load Duration Curve scheme (" LDC") can, for epitome, can create values of load demand hourly states, the implication being that around "8736 Hours" separate states can be logged per annum [18]. The annual LDC approach for IEEE-RTS-79 - 96 is presented in Figure 1.

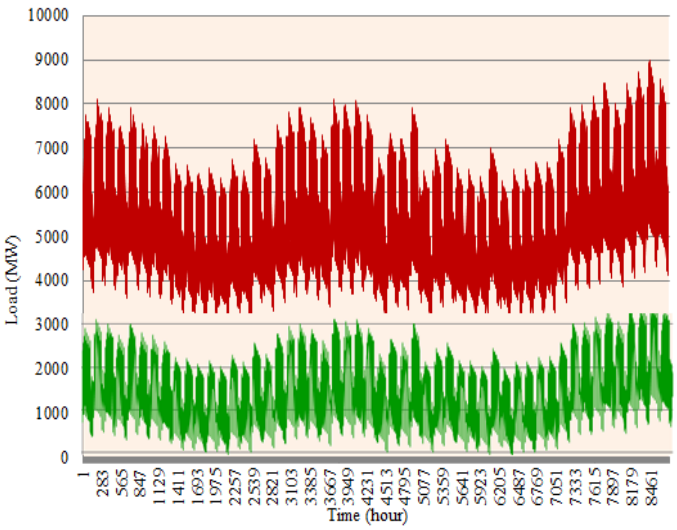

Figure 1: Annual LDC model for the RTS

To attain elevated levels of RPAs and the PGS valuation, the best design of RI has an important role in designing and developing a successful generation system [19]. Estimates of the LOLE, LOEE, and LOLF are made based on the attained capacity states' collections and load characteristics. In this study, denoted the discrete states for the load levels (LH) at a time (t). The "Loss of Load Probability" (LOLP) is estimated as equation (1):

$$LOLP(LH_i) = \sum_{j=1}^{sa} S_j \cdot P_j \cdot Copy_j \quad (1)$$

where:

sa = total number of state arrays, and

Sj = status of the system state.

In a failure state, the status value will=1; while in a successful state, the status will=0, this refers to the status of the load demand satisfaction [20]. equation (2) displayed the values of the LOLE annually:

$$LOLE = \sum_{j=1}^{8736} LOLP(LH_j) \quad (2)$$

Estimated the megawatts of the PNS by used equation (3):

$$PNS(LH_i) = \sum_{j=1}^{sa} S_j \cdot P_j \cdot Copy_j \cdot (LH_i - Cap_j) \quad (3)$$

$$LOEE = \sum_{j=1}^{8736} PNS(LH_j) \quad (4)$$

Equations employed to calculate the components of the LOLF index [19] as:

$$LOLF(LH_i) = \sum_{j=1}^{sa} S_j \cdot FG_j \cdot Copy_j \quad (5)$$

$$FG = \sum_{j=1}^{8736} LOLF(LH_j) \quad (6)$$

$$FL = \sum_{j=1}^{8736} V_j \cdot \left[LOLP(LH_j) - LOLP(LH_{j-1})\right] \quad (7)$$

$$LOLE = [FG_{(LH)}] + [FL_{(LH)}] \quad (8)$$

2.2. Wind Speed Paradigm

Simulating of wind speed/velocity to study WECs performance and dependability was done and reported by [21]. The sequential WECs simulation model involves the generation of hourly wind speed data over a given perio and specified site. The main challenge in maintaining the reliability of PGS is the fluctuation nature of wind power. It is therefore necessary to develop an appropriate wind velocity model before proceeding to analyze the system reliability.

The majority of research recently done dependent on the Weibull distribution model (WDM) to signify the hourly fluctuations in the annual mean wind velocity. The level of wind turbine generated power at a given wind site depends on the mean and standard variation of the wind velocity. Based on the assumption that the WDM is able to change particular variables such as the shape (b) and the scale (a), it is normally used for simulating wind speed fluctuations. Thus, the inverse transform function for the WDM in [22] in equation (9) can be employed to simulate the wind speed s.

$$s = a\left[-Ln(H)^{1/b}\right] \quad (9)$$

where; a and b = two parameters for the WDM;

H = random variable;

s = wind speed.

By applying the wind speed that generated by using the equation (9) to the wind turbine units output model, the turbine units power output is as shown in equation (10).

$$P_{WTG} = \begin{cases} 0 & ws < V_{ci} \\ P_r \times (A + B_x + Cx^2) & V_{ci} \le ws < V_r \\ P_r & V_r \le ws < V_{co} \\ 0 & ws > V_{co} \end{cases} \quad (10)$$

where

ws = wind speed (m/s),

Vci = WTG cut-in speed (m/s),

Vco = WTG cut-out speed (m/s),

Vr = WTG rated speed (m/s),

Pr = WTG rated power output (MW).

The constants A, Bx, and Cx have previously been calculated by [22].

3. Methodology

Two programs based on the simulation method have been developed using MATLAB. The first simulation program was developed to simulate the variations of wind speed using WDM, which was utilized for an estimation of the parameters “a” and “b”, that were deuced form wind speed data. Consequently, during the simulation process, the two parameters (a, b) will generate wind speed variations at any time. Additionally, the program can estimate a wind power result from the wind turbine. Figure 2 shows models for wind speed generation and output power simulation. The second simulation program is based on the DEOA technique to evaluate the dependability of the PGS and, wind power penetration consideration is incorporated in the generating capacity adequacy evaluation. According to the steps taken as stated in reference [22], the RI was calculated utilizing DEOA algorithm as shown in Figure 3.

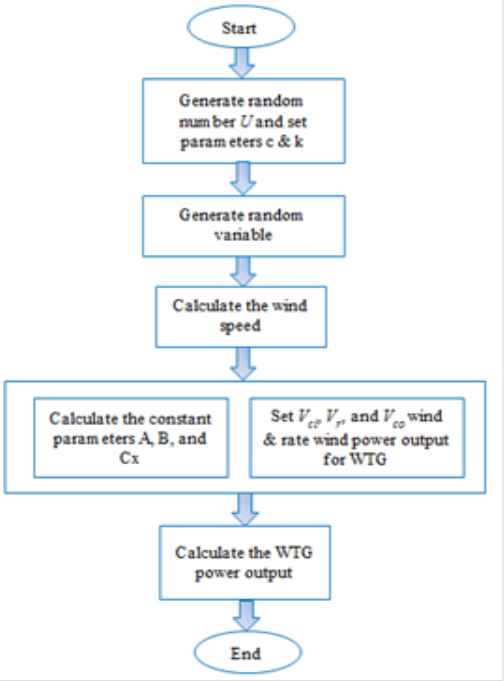

Figure 2: Diagram of speed and wind power for the turbine unit

4. Outcomes Analysis

4.1. Simulation Outcomes of Speed & Power Wind

This study explains the possibility to generate wind energy at different levels which parallel the probability of wind speed fluctuation, therefore, the wind power model can generate wind energy with different abilities states as instant at hourly. One of the features of the wind speed is that the turbine output power is determined subsequently when the hourly wind speed is obtained. The simulation of the profiles of the speed of the wind was employed to simulate ability states from the simulated generation of wind output power.

There is a need to examine the power output from the wind farm, to obtain a better picture of the selected site so that the WDM parameter, a, is set as the mean wind speed and b=2, is the usual wind characteristic [23]. The particular WTG characteristics employed here are the 4, 25, and 19 m/s (cut-in-speed, cut-out-speed, and rate speed) and at a rated power of 2 MW [22]. Figure 4 shows the forecast for hourly wind speed over a year, and also indicates the simulation wind power output for WTG (with 85 WTG) with a power rate of 2 MW for a similar period.

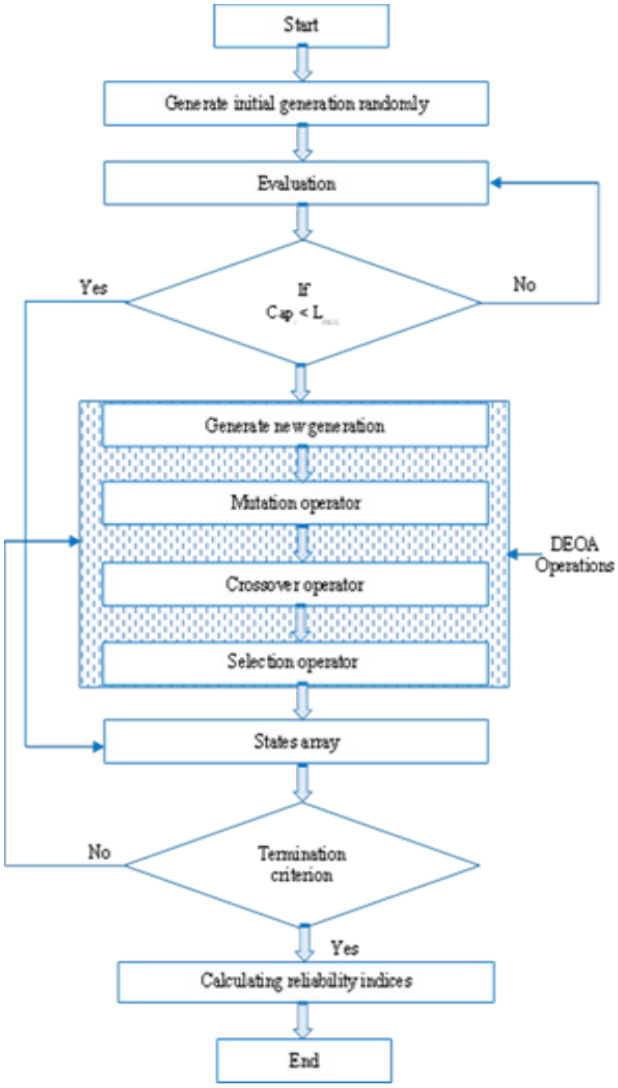

Figure 3: Diagram of reliability indices assessment using DEGA

4.2. Cases Running the Algorithm

This study develops and tests a method for evaluating the reliability of PGS using WECs with two dissimilar test systems ("IEEE-RTS-79" & "IEEE-RTS-96"), to validate how the DEOA performs to assess the dependability and sufficiency of the PGS. Meanwhile, it tests the efficiency of the proposed algorithm to evaluate multiple penetration-levels of wind energy.

The test systems "IEEE-RTS-79 and RTS -96" have 32 and 96 generating units respectively, with the capability to generate power ranging approximately from (12- 400 MW), with a total power supply of 3405 and 10215 MW respectively, at approximately (2850 MW) and (9000 MW) peak load [24], [25]. Figure 5 showing the diagram of the single area of the system RTS-79, and Figure 6 showing the outline of the RTS-96 of three-areas interconnected through merging three single areas from the RTS-79 system.

Run I: *Valuation of Algorithm Performance for the "RTS-79" System*

The designs of the variable control values for the proposed DEOA algorithm was documented as displayed in Table 1 [26], during applied at the "Test System- 79 & 96"

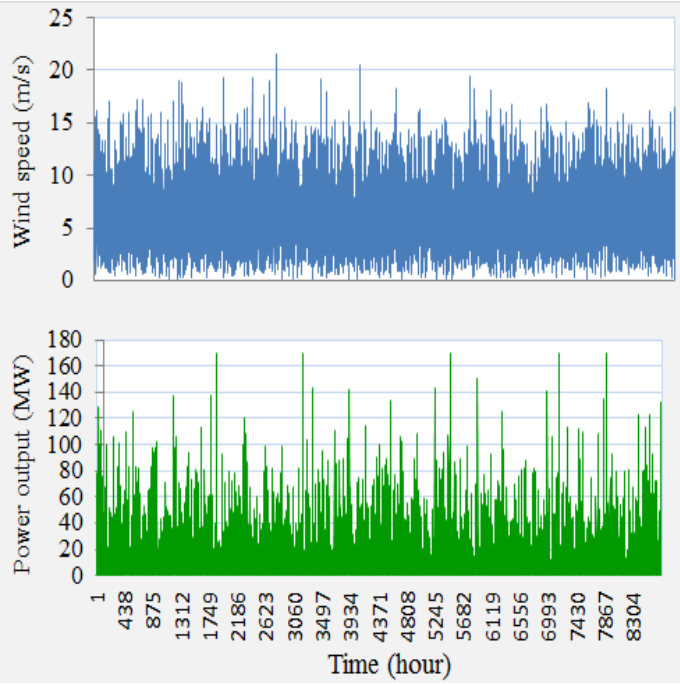

Figure 4: Wind forecasting and simulation of the wind MW generation for one year

The DEOA algorithm was applied for 100 iterations run consecutively in matching conditions as previously stated, to verify the robustness and confidence of this algorithm. The results of the various implementations are presented in Table 2. The results achieved from the DEOA were compared with those of [27]. Figures 7 and 8 show that following runs of 100 iterations, the values were wavering in the region of the real value. Repetitions of the runs of the experiment applying the algorithm displayed that this algorithm was highly accurate when determining the RI.

Table 1: The control values for the proposed algorithm

Parameter	DEOA (RTS-79)	DEOA (RTS-96)
Population size	60	100
Generation limit	100	150
Crossover probability	0.6	0.6
System Capacity (MW)	3405	10215
Mutation probability High	0. 1	0.6
Mutation probability Low	0.6	0.05
Load max	2850 MW	9000 MW
Threshold probability	1e-15	1e-20
Stopping Repetitions	100	150

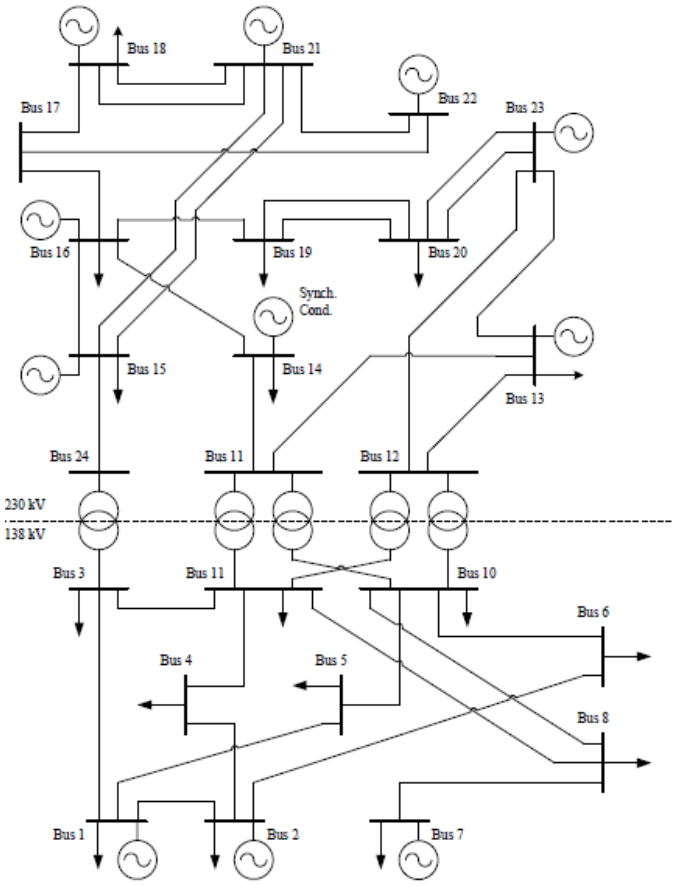

Figure 5: Diagram of single area for the system RTS-79

Table 2: The DEOA algorithm compare with analytical method through runs of the algorithm (100) times

Method	Reliability Indices		Error (%)
	LOLE (hour/year)	LOEE (MWh/year)	
(Accepted value) Analytical method [30]	9.39418	9.3670	0.28
(Experimental value) DEOA method	1176.00	1120.00	4.76

The consequences outcomes of the DEOA algorithm were compared with those of other optimization genetic algorithms earlier mentioned in [28], [29], as shown in Table 3. Comparisons of these outcomes were made. The absolute values utilized for these comparisons were from a single turn one mploying "MSGA", & "DEOA".

The computation effort of the proposed method was also assessed and a comparison was made with those of "MSGA", "MCS", and "DEOA" as shown in Table 4. On the other hand, comparison of the simulated proposed method with MCS was halted when the coefficient of variation level was approximately 5% [29]. This comparison was performed with absolute values obtained from a single turn on of the DEGA and MSGA. Evaluating the computation time of the DEOA, as presented in Table 4 was shorter compared to other methods. Hence, the suggested DEOA exhibits benefits such as enhanced computation speed, by employing a simple structure.

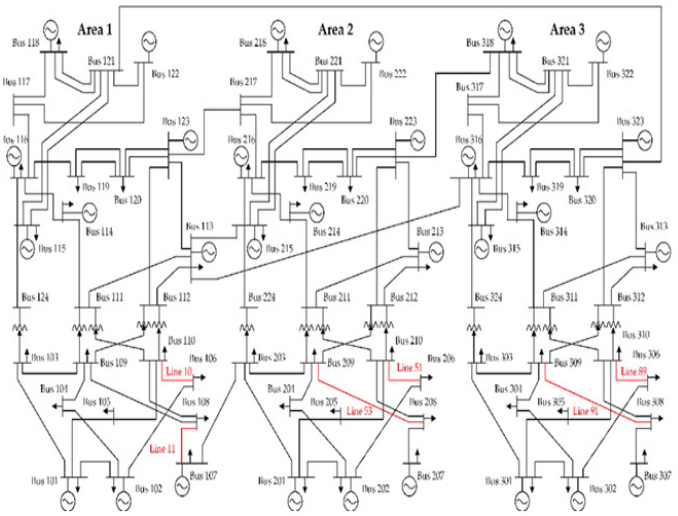

Figure 6: Diagram of three-areas interconnected for the system RTS-96

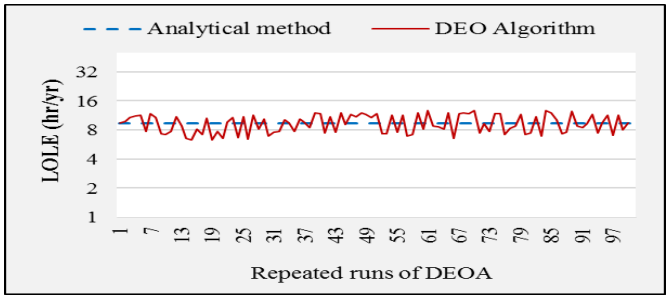

Figure 7: Calculation of estimated LOLE with 100 repeated runs for the RTS-79 System

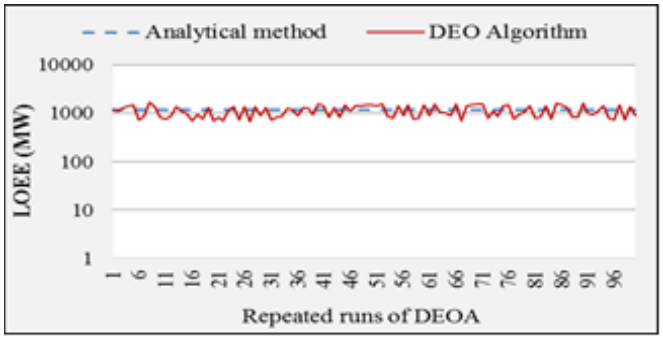

Figure 8: Calculation of estimated LOEE with 100 repeated runs for the system 'RTS-79'

Table 3: Compare the DEOA algorithm RI results for RTS-79 with accepted value

Reliability Indices	Experimental value		
	MCS [26]	MSGA [28]	DEOA
LOLE (hour/year)	9.371	9.324	9.370
Error (%)	0.244	0.745	0.255
LOEE (MWh/year)	1197	1163	1178
Error (%)	-1.785	1.105	-0.170
LOLF (occ/year)	1.9190	2.0030	2.300
Error (%)	0.00	4.37	19.85

Table 4: Comparison of the runs time between MSGA, DEOA, and MCS methods

Techniques	Experimental value		
	MCS	MSGA	DEOA
	Runs= 200	Runs= 750	Runs= 100
LOLE (hour/year)	9.541	9.324	9.37
Time (sec)	372	177	4

Run II: *Valuation of Algorithm Performance for the "RTS-96"*

In this run, the control parameters values had been setting beforehand as shown in Table 1. The tuning for the failures data for Generating stations was in line with previous data provided by [30]. The result of the DEOA was compared to those of Optimization algorithms declared by [31], as shown in Table 5.

In this paper, the percentage of error was considered, where the percentage error for individual values of the proposed DEOA algorithm was compared with individual values of the other techniques, as displayed in Tables 2, 3, and 5. On the other hand, the error percentage shows the effectiveness of the proposed DEOA algorithm in presenting separate values, large positive values of the error indicate a considerable deviation in the predicted value from the real one.

Table 5: Results of the RI for the system RTS-96 utilizing the DEOA method

Techniques	Reliability Indices			
	LOLE (hour/year)	Error (%)	LOEE (MWh/year)	Error (%)
Analytical method	0.1380	-	24.26	-
MCS Algorithm	0.1400	-1.44	23.97	1.195
DEOA Algorithm	0.140	-1.44	26.21	- 8.037

Run III: *Valuation of Performance SMCS with WPG for "RTS-79" System*

In this study, the SMCS method was employed to recompute the RI (for RTS-79 System) for comparison with the DEOA algorithm. From the simulation, Figure 9 shows what the system is capable of based on the conventional and the unconventional units. Figure 10 however presents a whole PGS and what it is capacity of, based on the simulation of the process overlaid together with the sequential load model and Figure 11 shows the LOLE, LOEE, and LOLF for 200 selected SMCS sampling years.

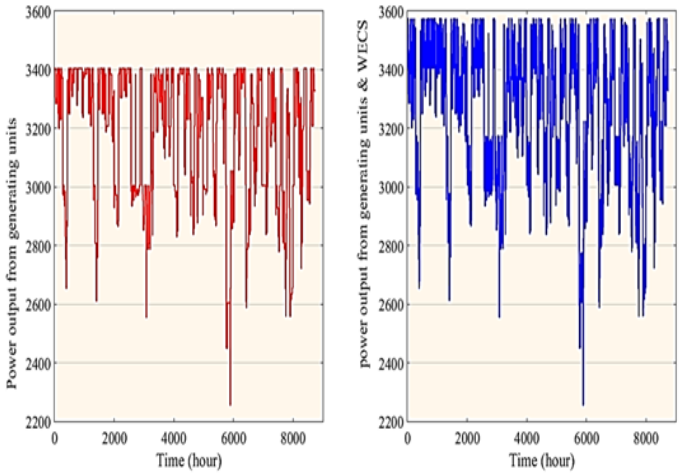

Figure 9: Available capacities obtained from conventional and unconventional units

Some intersections observable in Figure 10, which means that the available electrical power generation from the PGS insufficient for meeting the required load.

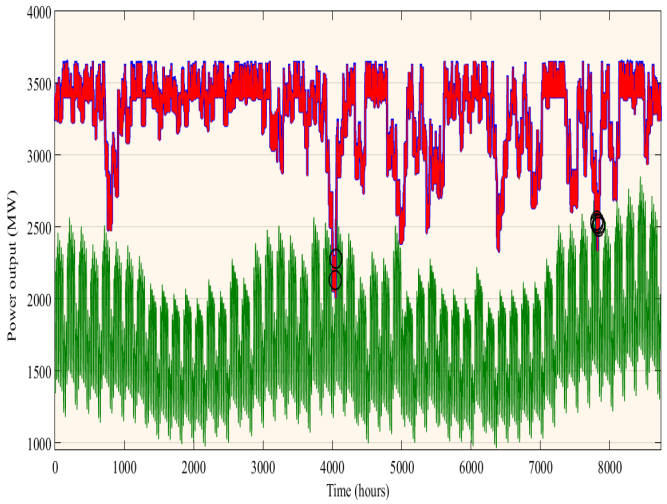

Figure 10: Simulation process shows the available capacities of the system, superimposition with the load paradigm

Run IV: *Valuation of Reliability Indices for DEOA with WPG for "RTS-79" System*

For peak demand load (2850MW) and 170 MW combined with wind energy, the RI the for "RTS-79" derived was from the Optimization Algorithm and the new proposed DEOA approach

as shown in Table 6. The MCS might be utilized for choosing failure states for the systems. However, due to its reliance on proportionate sampling, its effectiveness in the detection of failure states could be diminished. According to the results indicated in Table 6, the SMCS method could lead to extremely poor convergence time. Additionally, the DEOA provides the most efficient computation as well as easy usage in comparison with other algorithms.

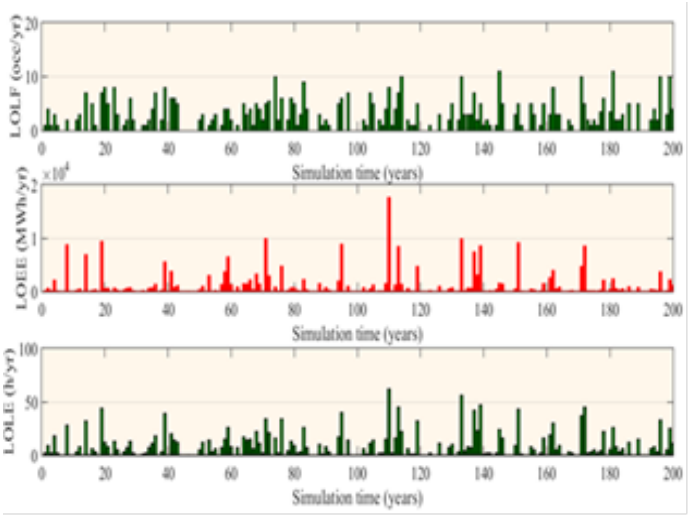

Figure 11: The reliability indices LOLE, LOEE, and LOLF for 200 samplings

Table 7 presents the outcomes of five models previously discussed [32] in comparison with those of DEOA. These techniques, computed the RI employing the MCS approach with variable wind Speed models (the actual wind speed recording data, Markov method, ARMA distribution model, Weibull distribution model, and Normal distribution). It was obvious that the outcomes derived from the use of the DEOA algorithm had values which were about the same as those obtained from using real wind speed data in the MCS approach.

Table 6: Comparison of the runs time between DEOA, BPSO, and SMCS Method

Proposed Methods	LOLE (hour/year)	LOEE (MWh/year)	Time (Sec)
SMCS Algorithm	7.550	941.070	64.641
BPSO Algorithm	7.430	823.780	8.979
DEOA Algorithm	7.450	1318.340	4.00

Table 7: Comparison between suggested methods in literature and proposed DEOA method

Techniques	LOLE (hour/year)	LOEE (MWh/year)
MCS technique with Actual wind data	7.450	908.70
MCS technique with Markov model	7.470	918.10
MCS technique with ARMA method	7.120	884.90
MCS technique with Weibull model	7.780	976.70
MCS technique with Normal model	6.950	858.50
Proposed DEOA with Actual wind data	7.450	1318.34

In real PGSs the LOLE index is used more often for the generation of adequacy analysis to determine sufficiency. On the other hand, the LOEE indicator is used for complex generating/transmitting of the adequacy analysis [33]. This means that outcomes presented in the tables are for assessing the PGS's dependability and sufficiency, which took into account the level of precision of LOLE from the suggested DEOA approach with shorter computation time in comparison with other approaches.

The proposal of an intelligent algorithm to assess the PGS is shown as a feasible replacement for the Non-SMCS in the evaluation of the non-sequential systems. Thus, this algorithm lowered the computation time needed to calculate the Non-MCS approach, which is efficient but does not take into account time-based phenomena, including the frequent computation interruptions of the LOLF and the duration indicatots (LOLD). This means that outcomes in tables that assess the LOLF indicate poor precision from the suggested PBIs approaches with shorter computation time in comparison with other approaches.

Run V: *Valuation of Reliability Indices with Wind Power Penetration for the "RTS-79" System Using DEOA*

In this section, the DEO algorithm is applied to examine the effects of wind power capabilities generated from WTGs on power systems to attain dependability indicators at a similar level to additional peak load capacity. The Weibull distribution approach was employed to simulate hourly repeating wind speed. Figure 12 shows the the simulation results of the forecast forecast for hourly wind speed and wind power output for several installed WTG units with a power rate of 2 MW for a year. The number of additional wind turbines that have been attached to a PGS is commensurate with the proportions of the wind power incorporation. Where the rate of penetration of wind energy ranges from 5% - 30% generates the output of wind energy ranges from 170 - 1020 MW from number WTG units (from 85 – 510).

This paper also examines the choice an appropriate penetration level of wind energy to attain a level similar to that of traditional PGSs. The DEO algorithm was used to analyze the RTS-79 system cases with changes in the number of WTG units, and changes in the penetration level of wind energy.

The effect of the wind energy penetration rate as a result of the number of available WTG units was tested on the values of reliability indicators for generation systems. Table 8 shows the different wind energy penetration levels (%), the number of WTG units and the output power of the WTG units, as well as the values of reliability indicators LOLE, LOEE.

Table 8: The wind power penetration beside on reliability indexes and percentage of installed capacity

Wind Pen. Rate %	No. of WTG	Product Power (MW)	LOLE	LOEE
5%	85	170	7.45	1318
10%	170	340	6.38	1364
15%	255	510	5.44	1214
20%	340	680	4.78	1256
25%	425	850	3.93	1079
30%	510	1020	3.60	1035

It is seen that the values of LOLE and LOEE are decreased for the RTS-79 system with additional WTG units. Figures 13 and 14 show LOLE and LOEE indicayors and the role of some of the WTG units added to RTS-79, where each WTG unit has a rated capacity of 2 MW.

Besides, it is noted that the LOLE value is lowered considerably in the event the wind energy penetration rate ranges from 5% to 20%; after which the rate of decline is relatively insignificant, implying that increasing the wind energy penetration to higher rates will have less effect in reducing the values of reliability indicators.

5. Conclusions

Both MCS and PBIs approaches have been used to assess the reliability of generating system combined with wind energy.

This paper presented a comprehensive performance clarification of the suggested technique for assessing the electric power systems dependability, such as; DEOA. The suggested intelligent algorithm which depends on the PBIs approach is viewed as a feasible alternative for the MCS in the assessment of non- sequential systems.

Furthermore, this study introduced the novel DEOA algorithm with WDM to assess the dependability of the PGSs combined with WTGs. It was shown that with the application of the proposed approach, it was likely that there would be simulation of the wind speed at a given hour for assessing the dependability of the power generation system. The main improvements achieved in this study are as presented below:

- Using the DEOA as an alternative to MCS for guided intelligent searches.
- The repeated runs of the experiment with the algorithm displayed the algorithm's elevated precision level when determining the RI.
- Incorporating WTGs into the power generating system, to revise the dependability evaluation process to adapt to this change.

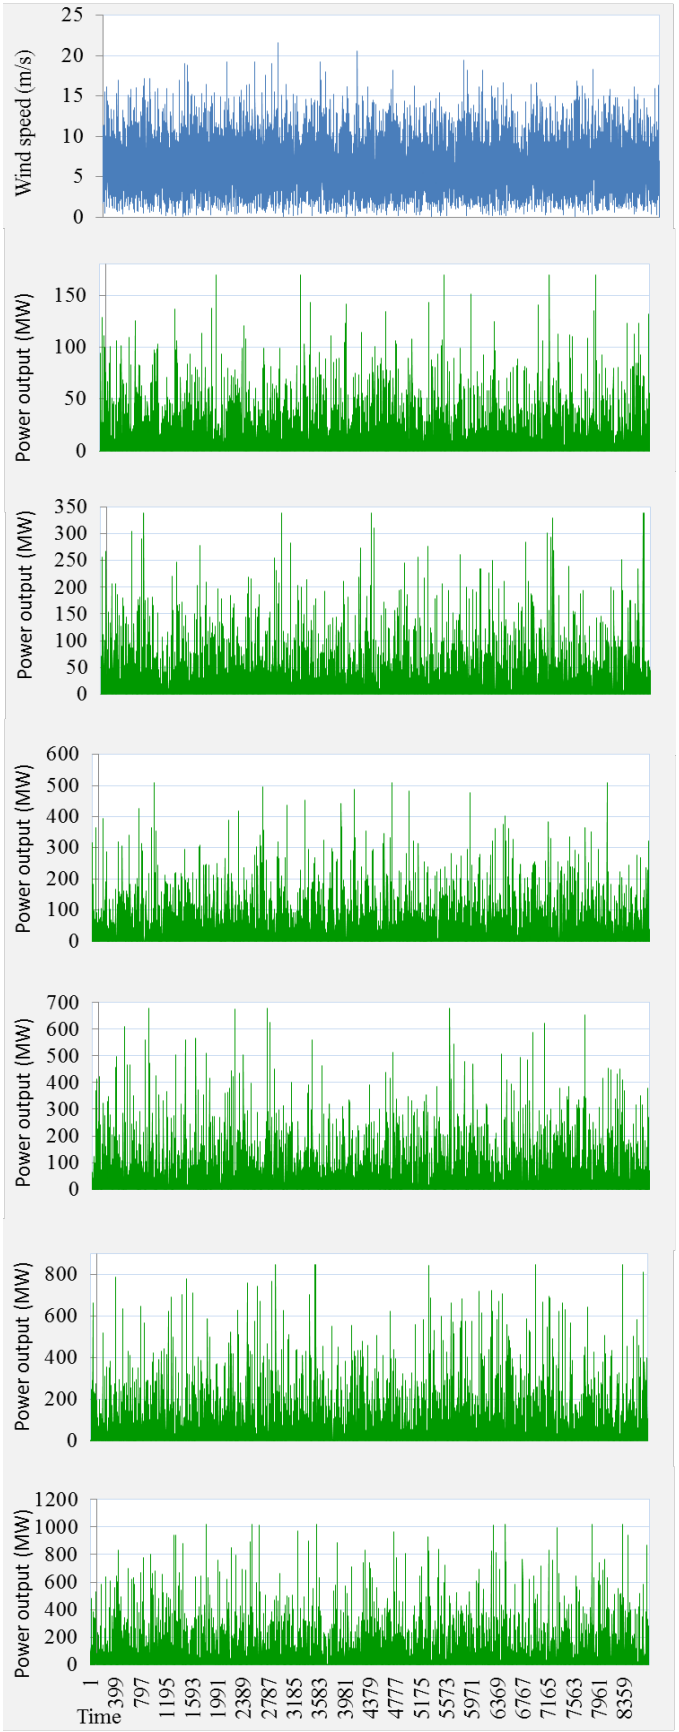

Figure 12: Wind forecasting and simulation of the generated wind energy for a year

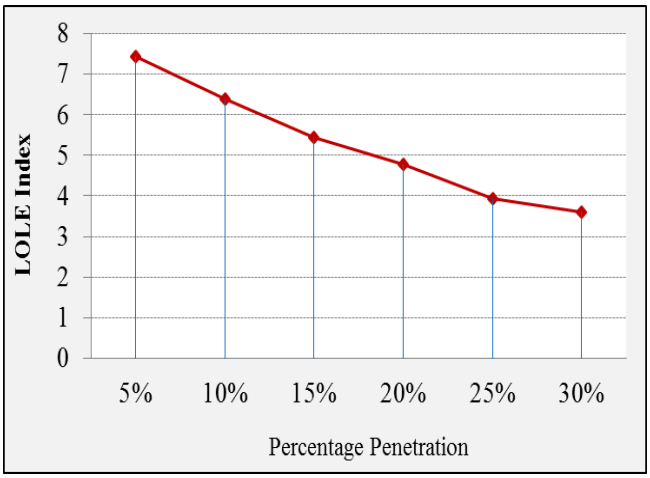

Figure 13: Shows the number of WTG units added to RTS-79 as a function for an estimate of the LOLE indices

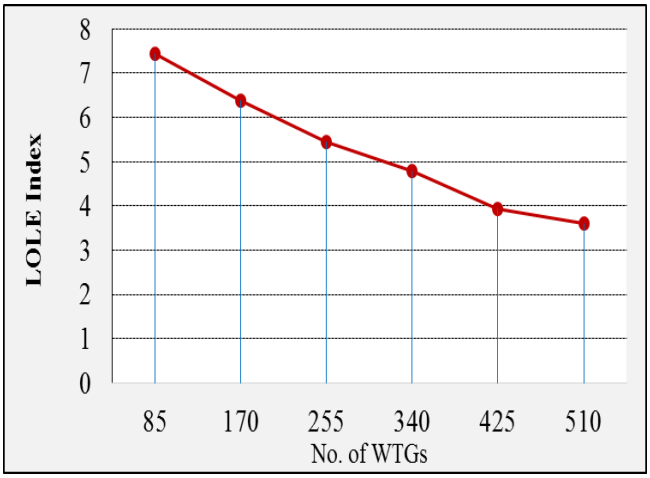

Figure 14: Shows the number of WTG units added to RTS-79 as a function for an estimate of the LOEE indices

On the other hand, RTS test system was used to make a comparison of the achievement of the DEOA with the conventional MCS to indicate the effectiveness of the proposed algorithm.

Besides, selecting an appropriate penetration level of wind power and determining its effect on the PGS and the essential element of investigating the potential of the wind energy source as a replacement for sustainable energy generation. Also, increasing the penetration rates of wind energy to higher rates will have less effect on reducing the values of RI.

ABSTRACT

A grid is a system that can manage and organize services and resources that spread amongst different control domains, employ interfaces and protocols, and offer a high quality of services. The integration of Multi-Agent Systems (MAS) with a grid environment significantly affects grid performance. MAS is considered a suitable solution for open systems that modify frequently. Grid offers a wide range of resources for its users, and some of these resources might not be used or utilized for some time before any new jobs come to the grid for processing. Usually, these resources are accumulated in massive data centers to cater to the grid users' growing demand. This accumulated will lead to consuming a considerable amount of electricity for their operation. The ever-increasing usage of grid computing has led to an increase in electrical energy usage by massive servers in their data centers. In this paper, we have proposed an automated system composed of modern agents that can be used the power wastage resulted from inactive servers inside the data centers for a specific amount of time. The proposed technique depends on switching inactive virtual and physical machines to lower power positions (Sleep/Wakeup or switched off) while still preserving customers' performance requirements. The Automated system has been tested and evaluated using the Jade tools. The results show that the newly proposed method can reduce power wastage for inactive grid resources.

1. Introduction

This paper is an extension of work presented initially in the ITT2019 conference [1]. Grid computing is an improved technology that involves a pool of linked machines that be owned by numerous organizations in diverse locations to construct a distributed system. The grid system can be accustomed to working with complicated scientific and business problems. It is created to assist in the sharing of distributed and diverse resources and to simplify resolving a considerable volume of computing issues [2]. The essential purpose of grid computing is to improve reliability, cut the cost of computing, and enhance flexibility by changing computers from an object that we purchase and operate privately to an object managed by a third organization [3]. However, grid computing is encountering various challenges, such as finding the right resources and decreasing the number of discarded jobs [4], [5]. Figure 1 displays an example of a grid computing environment [6], where the grid may contain different types of resources which need a resource management system in order to coordinates them.

The grid structural design shown in Figure 2 contains the following components [7]: a grid portal, which is also named a grid interface. It is used by the authorized grid clients to access the grid providers (resources). The portal should hide the complexity of the grid from clients by employing an uncomplicated interface. In this manner, it enables the sorting of grid job requisites.

The second element is the grid broker, where this element is described as the core of grid computing. It performs critical jobs in creating an effective grid system by connecting the user demands to the grid providers to fulfill the clients' tasks. The broker is also responsible for reducing transmission delays and increasing the

*Corresponding Author: Tariq Alwada'n, Email: t.alwadan@tees.ac.ae

resource assigning jobs through resources by avoiding the depending on a certain one. The grid broker's primary role is to locate and reserve the most appropriate support for the users' tasks. The broker receives the requests from the clients and sends the job's description files to the clients' requirements is responsible for monitoring the running tasks and hands over the outputs to their related users. To process the grid users' requests, the broker asks the Replica Catalogue Information Service to locate the available resources and data in the grid.

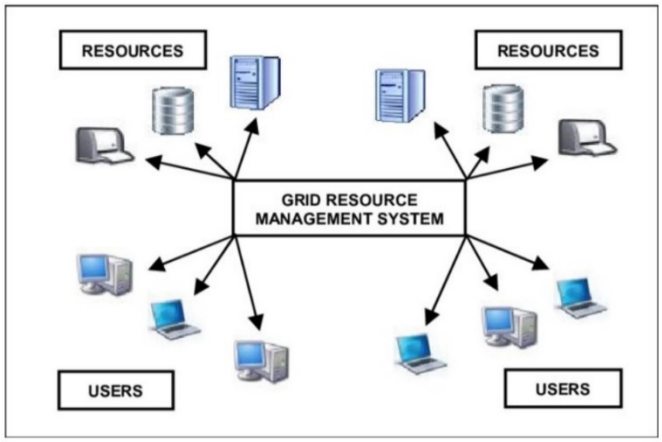

Figure 1: Grid Computing Environment

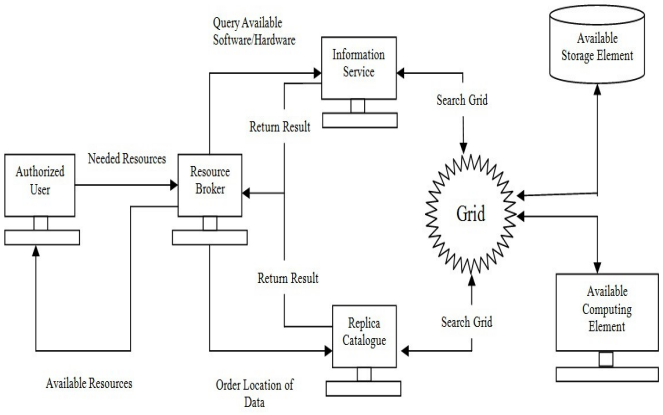

Figure 2: Grid Architecture. [8]

The third element is the Information Service. It is the directory service of the grid, where the grid keeps the information about all grid resources (nodes) and all the running jobs on those nodes. The grid resources have to register and update their information with the Information Services and their available resources. The grid broker retrieves all the information about the available and free resources from the Information Services. The information stored in the Information Services can be dynamic or static. The static information is employed to specify the operating system specifications and hardware requirements. In contrast, the dynamic information is associated with the current job running on the grid resources, the type of software specification, the available time in resources, disk space, and policies.

Replica Catalogue (RC) is the fourth element. RC is the directory that presents information, which helps in locating the saved data in the grid. To simplify employing the grid's data, the grid broker requests the RC for information about locations of the data in the grid and the way to identify the access mechanism needed to utilize this data.

To locate the best resources for the grid clients' requests, the grid broker gets the job specifications from the grid portal and looks for the suitable resources that can fit these specifications. For this purpose, the broker inquires for resources information and the data stored in the grid from the Information Service and the Replica Catalogue. Later it chooses the resource or resources that able to fit the job specifications.

Processing and modeling jobs have grown to be more complicated as the system scopes increased. Accordingly, it is difficult to carry out tasks with such an extensive system using centralized methods. Multi-Agent System (MAS) presents an excellent manner for delivering control. It also can be used to explore and change the local communications amongst entities [9]. Furthermore, artificial intelligence mechanisms can be combined with it. Intelligent agents are incorporated to operate autonomously in a changing environment. The intelligent agent also has the following main features: [10].

- Autonomy: the power to behave dynamically to a particular point in support of the clients and programs and adjust how agents accomplish their jobs.
- Cooperation and Communication: the power to cooperate and communicate with other agents to swap information, receives orders, and respond.
- Learning: the power to enhance the performance steadily while behaving with the external world.
- Re-activity: the ability to react to exterior calls and moderate the agents behave concerning these calls.
- Pro-activity: the ability to create choices as a consequence of internal evaluations.

In this introduction, we have introduced some background about Grid and MAS as a suitable solution for open systems, such as Grid, that modify frequently. This paper is organized as follows. Section 2 introduces related works to this research. Section 3 gives the system model. The experiment and results are presented in Section 4. Lastly, the conclusion of this research is given in Section 5.

2. Related Works

In recent times, combining the MAS with grid computing has taken the interest of lots of researchers. Most topics that have been concerned in the area of grid computing are how to achieve better use of grid data storage, service distribution, infrastructures, cost, and energy efficiency. Nevertheless, the worry in the agent environment's area is on the intelligent side of agents and the procedures that can be exploited to solve complicated problems.

The authors in [11] suggested a multi agent system that can support the growth of the IDAPS micro-grid where this proposed system includes a DER agent, database agent, and control and a user agent. The Agents transmit their requirements using a TCP/IP protocol embedded in the IEEE FIPA standard to assure the system capability. In addition, authors in [12] suggested a model for agent-based grid computing (AGEGC). Based on their model, AGEGC

was created by using the MAGE (Multi-Agent Environment) platform. This research included various levels, such as; information tier, knowledge tier, service-oriented tier, and operating system tier. AGEGC focuses on service-oriented tier provided that current processing system.

In recent times, there are many paradigms concerning the growth of agent systems, such as; MOLE [13], DMARS [14], RETSINA [15]. Lots of companies are contributing to building characteristics for standard agent models; for example, OMG [16] KSE [17] and FIPA [18].

Garimella in [19] employs a new preserve server that works in assistance with the Dynamic Soft Real-Time system [20]. The purpose of the Garimella system is to reserve the resource of the CPU beforehand. By using this system, the user request for some quality of service conditions. E.g. of that the percentage of CPU needed and the beginning time and the duration. Once the request for the preservation is begun, the reserved resources are ready to be reachable for the users. One more proposed model is the Resource Broker (RB) presented in [21] merged with a new preserve server shown in [19]. Both system have continual and quick response times and numerous negotiation probability for the users. Nevertheless, the volume of re-negotiation introduces an extra-large cost to the system, in the event of an unpredicted lack of resources.

The authors in [22] presented several algorithms for keeping an improved preservation approach for supercomputer scheduling systems. Those algorithms improve traditional organizing techniques by combing the reservation demand mechanism with scheduling regular tasks mechanism. Using this way of reservations, let clients ask for more than one resource in parallel from the scheduling systems at the same time. However, the mechanisms used in [22] preserve the whole time slot, which means the resources are not carried on in a distributed way by multiple users for the same amount of time.

3. System Model

Our suggested architecture is adopted from the grid architecture in [23], as shown in Figure 3. It employs Client/Server architecture since it is the most famous architecture in the heterogeneous system [24]. Our proposed architecture uses multi-tier architecture, considering that there is a necessity for the parted database to save the grid resources' location. Our grid architecture includes the following entities; the grid portal, the grid broker, and the grid resource providers.

A grid portal is an interface for an authorized client to send their jobs to the grid. A portal should hide the complexity of the grid from clients by employing an uncomplicated interface. In this manner, it enables the sorting of grid job requisites. The grid broker can connect with agents that operate, control, and support both the grid clients and grid resource providers. The broker is an agent handler who organizes and monitors the running jobs and maintains the grid clients updated with their running jobs.

The grid broker in this paper is moved from operating as a database warehouse that saves the available resources and conditions and matches the clients' jobs with these resources into an agent manager with the ability to control event creations and create and eliminate several agents in the system. The grid broker in our proposed architecture, is a MAS that can interconnect with the grid system on account of grid users to find the information regarding grid resource provider whom they can fit the users' requirements and choose the best one among them. Furthermore, our advanced system can provide and monitor the implementation of the jobs and support the grid users with live feedback concerning the job processes.

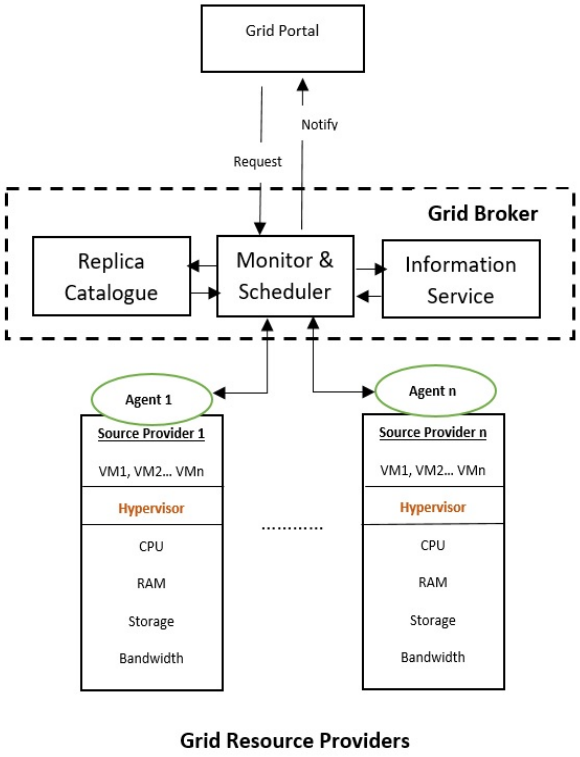

Figure 3: System Architecture

The grid broker is split into three primary entities. The first one is the monitor & scheduler. This entity is in charge of getting the grid clients' tasks and deciding the best available resource providers. The scheduler requests all data about the available resources from the Information Service entity and the data information saved in the Replica Catalogue (RC) entity. The monitor has the authority to monitor and provision the currently running jobs in the grid resource providers. The grid broker might have the improvements and ability to split clients' tasks between multiple resource providers to cut the cost and speed up the operations.

After the Monitor & Scheduler transmit the jobs to the available resource(s) for processing, it receives frequent feedbacks from the agents at the resource providers to verify the standing of the processing jobs and the percentage of the job completed to the grid broker. This point helps the grid broker to provision the running jobs' accomplishment, and by its turn, it will help determine an alternate resource provider(s) in case of failure at any point. The local agent at the resource providers is similarly in charge of updating the grid broker as the job is finished.

The resource provider can include several physicals and virtual machines. The Hypervisor in every machine is in charge of organizing and generating virtual machines on the upper of every physical machine. To react to the fast development of clients'

requests for data processing ability and storage, grid resource providers create a massive amount of data centers throughout the world. The grid datacenters typically include a large number of interconnected resources from physical machines and virtual machines, which will consume a considerable amount of electricity for their operations.

The proposed system depends on switching inactive virtual and physical machines to lower power positions (Sleep/Wakeup or switched off) while still preserving customers' performance requirements. The local agents at the resource providers are responsible for this operation. Each virtual machine (VM) has a local agent that can report the VM utilization to the data center's primary agent. The utilization here means the CPU utilization. Suppose the utilization for a specific VM has a zero amount for 300 seconds. In that case, the data center's primary agent will automatically shut down this VM to reduce the power consumption of the physical machine containing that turned off VM.

4. Implementation and Testing

The Jade platform was chosen to execute our proposed topology. Jade stands for the Java Agent Development framework, developed to help build out and enhance agent software as ruled by the FIPA conditions for smart MAS [25].

We introduced a simulation that deals with 200 physical hosts. The specifications of physical and virtual machines are shown in Table 1 and Table 2, respectively.

Table 1: Specification of Physical Machines

Type	Name	MIPS	RAM (MB)	Bandwidth (Gbps)	Number of Hosts
1	HP ProLiant ML110 G4 servers	2000	4096	2	100
2	HP ProLiant ML110 G5 servers	3000	4096	2	100

Table 2: Specification of Virtual Machines

Type	MIPS	RAM (MB)	Bandwidth (Gbps)	Number of VM
1	2000	1024	100	200
2	1500	2048	100	200
3	500	512	100	200

To create real power-consuming data, we took advantage of the actual data of power consumption offered by the SPECpower benchmark [26] and [27], as shown in Table 3. The power consumption by physical machines can be precisely expressed by a linear relationship between CPU utilization and power consumption. It can be noticed from Table 3 that even at small utilization, the machine exhausts a large volume of power. Therefore it is necessary to shut down such machines or reduce the number of VMs in it when not in use to reduce the power consumption of the physical machine. Figure 4 shows part of our simulation.

Table 3: Power Consumption (Watts per hour) at different load levels.

Machine type	0%	20%	50%	70%	100%
1	86	92.6	102	108	117
2	93.7	101	116	125	135

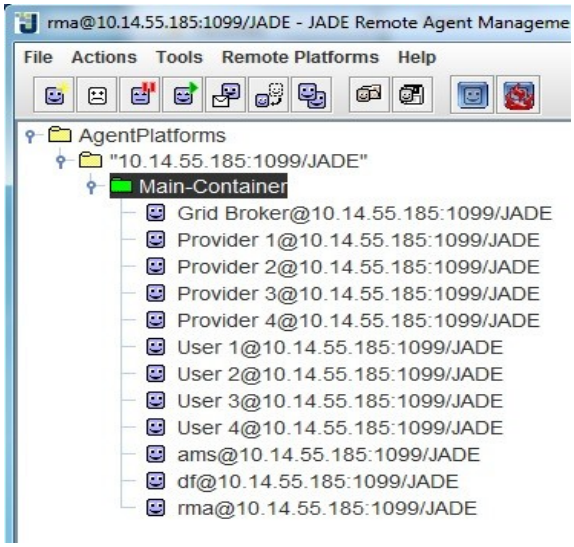

Figure 4: Part of the Summation Stage

The following stages explain the main steps of our simulation:

- Grid users state their tasks by choosing the required hardware and software specification to run their jobs through the grid portal.
- The grid broker receives the grid users' jobs and looks for the best provider(s) for those jobs. This step is done by helping the Information Services and the Replica Catalogue.
- Later, the grid broker sends the jobs to the suitable resource provider(s) and connects to the primary agent attached to that provider.
- The grid broker can divide the job between multiple resource providers to cut down the cost and speed up the operations.
- As the job is running at the resource provider, the provider's agent (primary agent) sends periodic feedbacks about the percentage of completion of the running job to the grid broker. This stage helps the grid broker to supervise the completion of the running job, and that will help find an alternative resource provider in case of failure.
- At the same time, the primary agent at the resource provider periodically checks the CPU utilization of its VMs at the physical machines.
- If the utilization reaches the zero point for 300 seconds, the primary agent will automatically shut down that VM.
- Finally, the grid broker sends the job outputs to grid users.

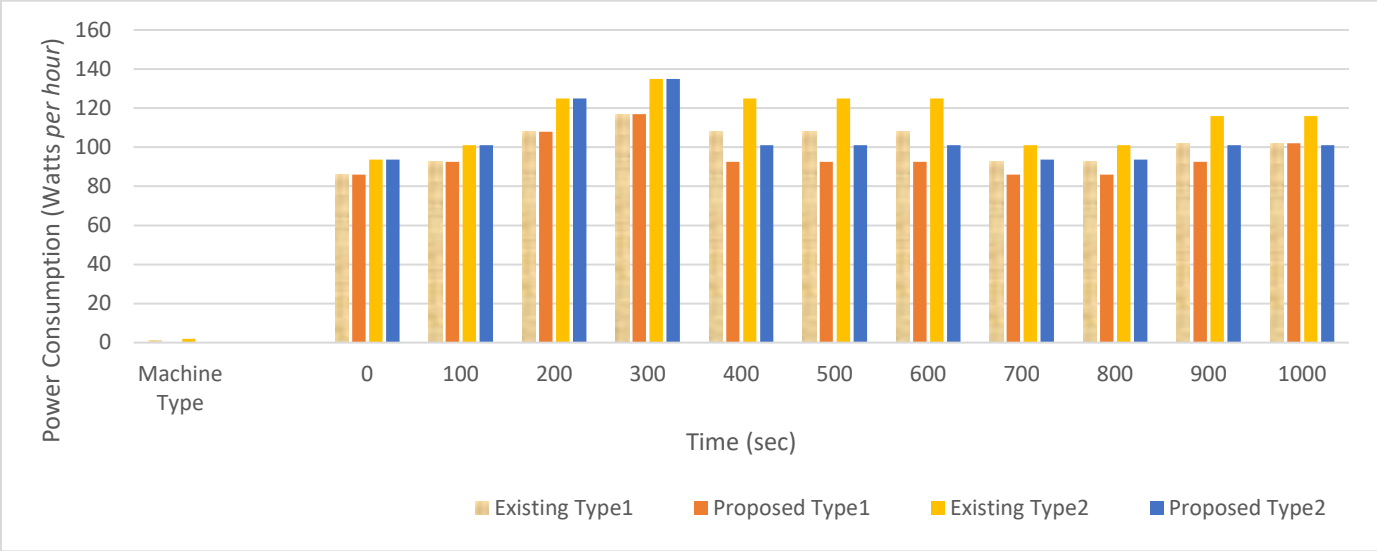

Figure 5: Simulation Results

From the simulation results in Figure 5. It can be seen that by using our proposed system, the power consumption has been slightly reduced for the two types of physical hosts (HP ProLiant ML110 G4 servers and HP ProLiant ML110 G5 servers), especially after the first 300s. This reduction is because the utilization of the physical machines has been reduced as the primary agents in both physical machines automatically shut down that VMs if the its utilization reaches the zero point for 300 seconds. As a result, the power consumption has been reduced in total for machines.

5. Conclusion

The purpose of the grid is to produce a broad scale, and heterogeneous systems intend to solve industrial or scientific problems. The integration of the Multi-Agent Systems (MAS) with the grid environment has a significant impact on grid performance. Grid offers a wide range of resources for its users, and some of these resources might not be used or utilized for some time before any new jobs coming to the grid for processing. As a result, the grid servers will consume a considerable amount of electricity for their operation. The growing usage of grid computing has led to an increase in electrical energy usage by the massive amount of servers in their data centers. In this paper, we have proposed an automated system composed of modern agents that can be used to reduce the power wastage resulted from inactive servers inside the data centers if the utilization of the VM reaches the zero point for 300 seconds, In this case the primary agent in the physical machine will automatically shut down that VM. The Automated system has been tested and evaluated, and the results show that the newly proposed method can reduce the amount of power wastage for the inactive grid resources.

ABSTRACT

Power converters in automotive industries are needed to source electronic devices. DC-DC Buck converter allows to drive loads ensuring their safety operation taking the car battery voltage as an input to generate a sub-voltage or current. By means of a control loop, the system makes sure that the output variable has the desired value in each operation condition. The Peak Current Mode Control (PCMC) is used to control the output current. Whenever the current reaches the reference maximum value (by load specs), the system acts to lower it. Intrinsically over-current protection is guaranteed. The paper presents an improvement of the basic PCMC, where, instead of just controlling the peak value, the loop controls also the average, more delicate feature, resulting in a more reliable driver system. The circuit is able to source 3A average-4.5V from a 13.5V nominal battery voltage, with a peak current of 3.3A and a 0.6A maximum ripple (3±10%A). The concept has been designed and simulated on Simulink and then tested on hardware using dSpace, a Rapid Control Prototyping set-up.

1 Introduction

Electronic devices in Automotive industries need for power converters to be correctly sourced. Indeed, battery voltage could range between 4.5 to > 27V, making it unsuitable for driving any load without provoking damages or malfunctions. DC-DC Converters allow to take as an input the car battery voltage and return as an output a controlled voltage or current required by the load. What is more, the DC-DC protects the load against over-current and over-voltage, ensuring its correct operation. Meanwhile, integrated circuits are required to occupy small space and reduce external components to minimize the associated cost. The core of a Buck DC-DC converter is a switch, or Power-DMOS, which is repeatedly turned on and off, allowing the voltage/current to increase/decrease quickly in the neighborhood of a desired value. The circuit that turns on and off the switch is the control circuit [1]. The control could be either made on the output current or voltage. This paper presents a current control loop able to control all the current features (peak, average and ripple) at once. This paper is an extension of work originally presented in the 26th IEEE International Conference on Electronics Circuits and Systems (ICECS) [2].

The solution arises from the well-known Peak-Current-Mode Control (PCMC), [3] operating in Continuous Conduction Mode (CCM). Instead of having a constant switching period, as it happens in the typical PCMC, the presented control loop has a variable period. In particular, the time in which the power-DMOS stays off, changes accordingly to the calculated current average value, to make it closer to a target desired value. The loop will be now on referred to it as Variable T_{off}. Moreover, the typical PCMC intrinsically suffers of instability issues directly attributable to the fixed switching frequency [4]. Therefore, by making it variable, such issues are consequently solved. The use of stabilization techniques such as Slope Compensation [4] can be avoided, which increase the complexity of the system without improving the control precision (indeed current features will change accordingly to the input voltage). Also protection against over-current is already guaranteed: indeed the maximum current, namely the peak, is fixed. The proposed system operates with 500kHz maximum switching frequency, delivering an average output current of 3 ± 10%A with a load-fixed 4.5V output voltage. The current peak will be limited to 3.3A. The application case could be, for instance, a LED driver, where the LED itself, as soon as the correct current is provided, fixes the output voltage. The circuit has been simulated and then tested in laboratory by using an emulator called dSpace. Instead of a LED, in first place has been used as a load a linear component: a 1.5Ω resistor.

Finally, the current sensing is integrated, with no need for

[*]Corresponding Author: Santa Maria Hoè (LC) Italy, o.gasparri@campus.unimib.it

an external pad to sense the current, resulting in a lighter circuit. Compared to the most common solutions [5], the here used fully-integrated Current Sensing technique requires less external components, with consequent lower cost in terms of BoM and board fabrication.

The paper is organized as follows. The algorithm principle is presented in Section II, together with the formula useful for its implementation, described in Section III. The simulation results are shown in Section IV and the conclusions are drawn in Section V.

2 Variable-T_{off} PCMC Algorithm

A Buck DC-DC converter is a device which in principle allows to convert a given input voltage to a lower output voltage by turning on and off a Power-DMOS, able to withstand to high power. In the application at stake from [4.5, 27]V are obtained 4.5V in output by controlling the current, I_L, flowing into the load. A simple scheme of a Buck converter is given in Figure 1.

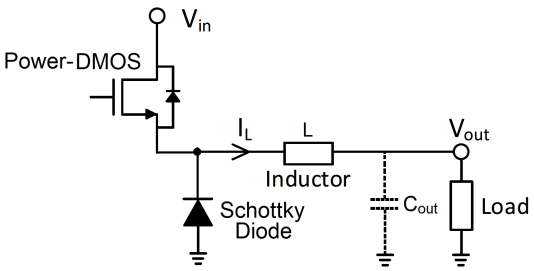

Figure 1: Buck converter scheme

Rather than other diodes, a Schottky diode has been used for its lower threshold (0.5V) and higher speed. The presence of the output capacitor, which minimizes the voltage ripple, can be neglected when controlling the current (and the output voltage is fixed by the load) leading to a lighter circuit. The switching period is divided into two phases: the ON-phase when the Power-DMOS conducts (T_{on}) and the OFF-phase when the diode conducts (T_{off}). Referring to the Duty-Cycle (D):

$$\begin{cases} T_{on} = D * T \\ T_{off} = (1 - D) * T \quad with \quad T = T_{on} + T_{off} \end{cases} \tag{1}$$

The Buck converter should sink an optimum average current I_{avg} to make the load work properly and, to avoid damages, the current must fluctuate limitedly. The current ripple should be indeed limited to the average value±10%, namely 0.3A. Consequently, the maximum current, the peak value, should be 3.15A. The rule of the control loop is to ensure that these specifications are met. The relation between the current features can be expressed as follows:

$$\Delta I_L = 2 * (I_{max} - I_{avg}) \tag{2}$$

In standard PCMC, the period T is fixed. Conversely, in Variable T_{off}, the period is variable. In particular, T_{on} changes automatically according to the input voltage, while T_{off} is forced to vary every cycle by the control loop, based on the vicinity between the calculated output average value of that cycle and the desired value.

The load current during the ON-phase increases with positive slope given by:

$$\left(\frac{dI_L}{dt}\right)_{ON} = \frac{\Delta I_L}{T_{on}} = \frac{V_{in} - V_{out}}{L} \tag{3}$$

Once I_L reaches I_{max}, the power-DMOS turns OFF and the output current decreases with a negative slope:

$$\left(\frac{dI_L}{dt}\right)_{OFF} = \frac{\Delta I_L}{T_{off}} = -\frac{V_{out}}{L} \tag{4}$$

After a time T_{off}, the DMOS is turned ON again and so on. The output current waveform (equal to the inductor current) has the typical triangular CCM shape as in Figure 2.

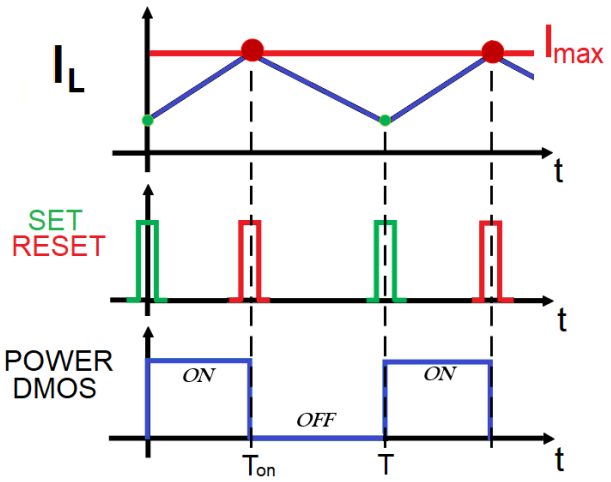

Figure 2: Output current

While I_{max} is fixed, the I_{min} is free to change. The loop, by means of a sensing technique, is able to read I_{min}. Indeed, the current sensing happens during the ON phase to insure the current doesn't grow beyond I_{max}. Therefore, to get I_{min}, it just needed a register to store the first current value when the ON phase begins. Once I_{min} is known, the loop calculates:

$$I_{avg} = \frac{I_{min} + I_{max}}{2} \tag{5}$$

Then, the difference between I_{avg} and $I_{mean,ref}$ = 3A gives an error with sign that, once properly amplified by a factor K, is summed to the previous T_{off} value. The following T_{off} value will be:

$$T_{off,next} = T_{off,prev} + k \cdot (I_{avg} - 3A) \tag{6}$$

In this way, if e.g. I_{avg} is higher than 3A, the T_{off} value will be increased (causing a stretching of the switching period) and allowing the current to decrease more during the OFF phase, reaching a lower I_{min} with the aim of reducing the average value. If otherwise I_{avg} is lower than 3A, the error will be negative, meaning that the T_{off} of the next switching cycle must decrease to make the average value higher and matching with the target. The loop operation is resumed in the flow-chart in Figure 3. The total number of regressions in the algorithm depends on the current rising slope, on the sensing technique sampling frequency and on the counter frequency. Every time a switching cycle ends, the operation restarts from the beginning giving rise to the next switching cycle.

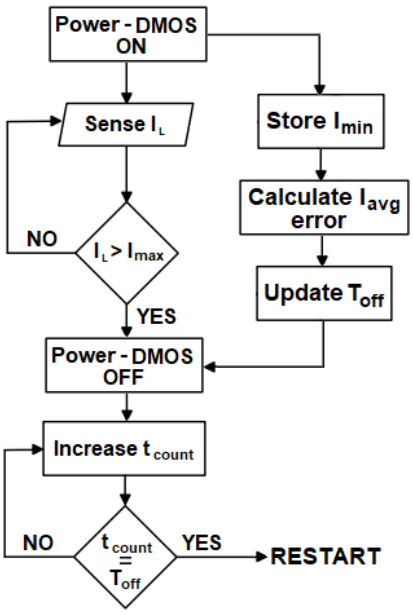

Figure 3: Variable-T_{off} PCMC algorithm flowchart

While T_{off} is decided by the loop, the T_{on}, from (3), changes not only with the the ΔI_L -loop dependent- but also with the battery voltage:

$$T_{on} \propto \frac{1}{(V_{in} - V_{out}) \cdot \Delta I_L} \tag{7}$$

It should be noticed that a first pre-memorized T_{off} value guess must exist (to be later overwritten by the cycle) to avoid malfunction at the cranking of the system during the very first switching cycle. This first guess is based on the application: if for instance the desired average is 3A, the peak is 3.15A, the inductance 30μH and $V_{out} = 4.5V$, it follows that the T_{off} value, from (2) and (4), could be grossly chosen as:

$$T_{off} = \frac{L \cdot \Delta I_L}{V_{out}} = 4\mu \tag{8}$$

Then, given some V_{out} variations due to the load or some uncertainties related to the inductance value, the references etc., the loop will act as described above, varying the T_{off} value to better adapt the system to the load specifications.

Moreover, the T_{off} value has an inferior limit, due to the maximum power-DMOS frequency (f_{max}) allowed. Ideally, the f_{max} can be evaluated for T_{on} tending to zero, namely:

$$f_{max} \simeq \frac{1}{T_{off}} \tag{9}$$

In realty, the minimum T_{on} value won't be zero, but, from (3), for a $V_{in} = 27$V it will be about 0.8μ s.

3 Instability digression

The typical PCMC loop is just able to control the maximum load current, no matter what ripple and average current are. Therefore, such a solution is not suitable in applications where loads require a precise average current with small shifts around its value. However, the biggest issue of the typical PCMC comes from its instability when the duty cycle grows over 50% [6]. Every time $T_{on} > T_{off}$ or, equivalently, $V_{out} > V_{in}/2$, the system would be unstable. In the application case, where $V_{in} = [4.5, 27]$ V and $V_{out} = 4.5$ V, problems would arise when $V_{in} < 9$V. Figure 4 shows what happen when crossing the limit case $D = 0.5$: if the duty cycle is increased the PCMC is no longer helping in controlling the current. The reason behind this issue is that, in typical PCMC, after a fixed period T, the power-DMOS is forced to be turned ON. Instead, in Variable-T_{off}, the power-DMOS turns ON T_{off} seconds after the current has peaked. Contrarily to the typical PCMC, if the input voltage changes, i.e. T_{on} changes, the T_{off} doesn't change (4), the ripple doesn't change and therefore the current features are not impacted. The system stays stable. Techniques as Slope compensation [4] are no longer needed.

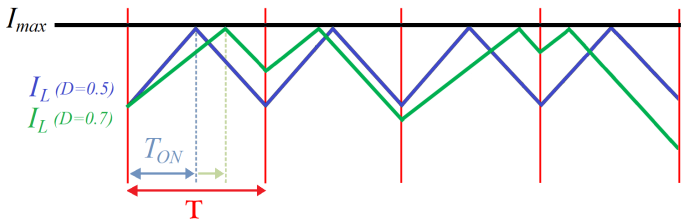

Figure 4: Output current in typical PCMC

4 Constant-T_{off} Algorithm Implementation

The circuit implementation is shown in Figure 5. The only external components are the inductor (L) and the Schottky Diode. As internal components, enclosed in blocks, there are: the Current Sensing, the Control Logic blocks, the Protection, the Internal Reference (including a bandgap voltage reference to generate I_{max} and I_{mean}), the Gate Driver to turn ON and OFF the Power-DMOS [7] and the Power Supply to generate a low voltage domain for the low-side circuit.

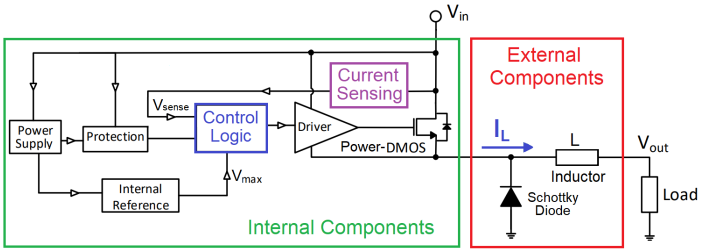

Figure 5: Concept top level

The Current Sensing block is used to read the current flowing I_L. The Power-DMOS current is here mirrored with a factor $N = 1/1000$ and flows through a sensing resistance. Based on the read voltage drop, the system is able to determine the magnitude of the current. Since the proposed technique only operates during the ON-phase (when the Power-DMOS conducts) the power consumption is lower than in the case on which the current is sensed on

the output node, always operating. Furthermore, an internal sensing block also allows to minimize the area occupation on silicon.

4.1 Control Logic block

Figure 6 shows the concept Control Logic block implementation. The result of the comparison between I_{sense} and I_{max} gives the Reset of the SR Latch. When $I_{sense} \geq I_{max}$, the Reset activates and the Power-DMOS turns OFF through the Gate Driver. The Set input is instead connected to a counter consisting of an oscillator and a chain of four D Flip-Flops. As soon as the Power-DMOS turns OFF, the counter starts counting up to T_{off} duration. Afterwards the Set is activated and the Power-DMOS turns ON. The current value at this moment, I_{min}, is stored into a register. The loop then calculates the average error on respect to the desired I_{mean} value. The error, summed to the previous $T_{off,prev}$ value returns the $T_{off,next}$ as in (6).

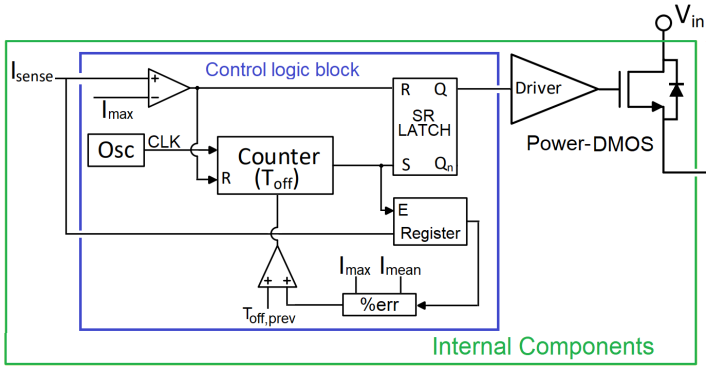

Figure 6: Variable T_{off} Current Control Loop implementation

5 Design example and Simulations results

Table 1 resumes the application specs.

Table 1: Summary of specifications

Technology	0.35 μm
V_{in}	4.5-27 V
V_{out}	4.5 V
f_{max}	500 kHz
Maximum Current Level	3.3 A
Mean Current Level	3 A
Output Current Ripple	0.60 A

By applying the formulas given in Section I, the design parameters are obtained. (9) gives the lower T_{off} limit:

$$T_{off} \simeq \frac{1}{500kHz} = 2\mu s \tag{10}$$

In fact, $1/f_{max} = T_{on,min} + T_{off}$ and (3) becomes:

$$V_{out} \cdot T_{off} = (V_{in,max} - V_{out}) \cdot (1/f_{sw,max} - T_{off}) \tag{11}$$

Therefore a more precise estimation of the minimum T_{off} value is given by:

$$T_{off} = \frac{27V - 4.5V}{27V} \cdot \frac{1}{500kHz} = 1.7\mu s \tag{12}$$

Once the ripple (Table 1) and T_{off} (12) are given, both the peak and the average current are fixed. Furthermore, by using these parameters in (4), the inductance value can be chosen as:

$$L > \frac{V_{out} * T_{off}}{\Delta I_L} = 13\mu H \rightarrow 30\mu H \tag{13}$$

(to stay large, considering also 20% of inductance value uncertainty on the nominal value and considering that actually the typical operation is centered around V_{in} = 16V).

5.1 Simulation results

The concept of Figure 5 has been firstly implemented on Simulink (MATLAB) to ideally simulate the behaviour of the high-level concept design. Simulink works with a block approach system, shown in Figure 7, which follows exactly from Figure 5. Other software are actually exploited in the design phase (such as Virtuoso-cadence). However, there, the circuit must be designed in a deeper transistor-level. Since the design may take large amounts of time, prototyping must be done previously ensuring that the chosen topology is the most suitable one for the application in question and that its worthwhile to proceed with transistor-level design and future fabrication.

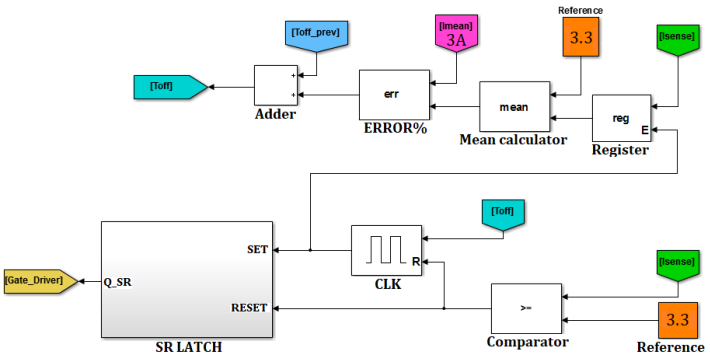

Figure 7: Simulink implementation

The simulations include also worst case scenarios to ensure the correct operation in each condition. To simulate the presence of a load which fixes the 4.5V output voltage with a 3A average current, a 1.5Ω resistor has been used.

Figure 8 (left) shows how the system works with a 7V input voltage and a peak reference reduced from 3.3A to 3.2A, i.e. with a Δ_{I_L} = 0.4A. As expected, the operation is not affected by instability issues which, in a typical PCMC, would surely arise whenever V_{in} < 9V. Later, the input voltage has been abruptly increased to 18V to also prove that a V_{in} change (as could happen during the cranking of the car) has no relevant effect on the operation. The T_{off} remains unchanged (no dependency on the V_{in}) and equal to 2.7μs as expected from (7) (with Δ_{I_L} = 0.4A).

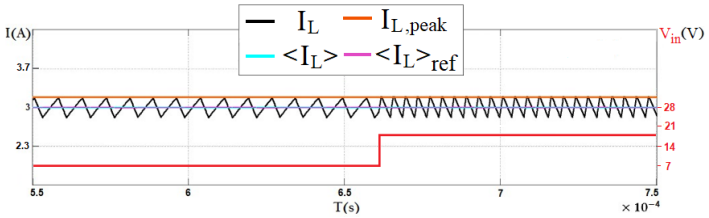

Figure 8: System response changing the input voltage

Figure 9 shows instead the transient simulation plot for V_{in} = 18V with the peak reference at 3.3A as from specification. As expected from (7), the T_{off} = 4μs. To further prove the system robustness, an average reference positive step (from 3A to 3.15A) has been added. In order to achieve the new average current, the loop gradually reduces the T_{off} to make the calculated average equal to the target. Since the peak reference stays equal, according to (8) and (9), the ripple reduces and the switching frequency increases up to 260kHz.

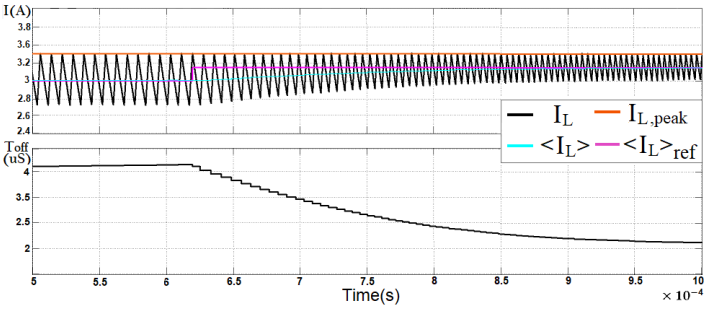

Figure 9: System response changing the average reference

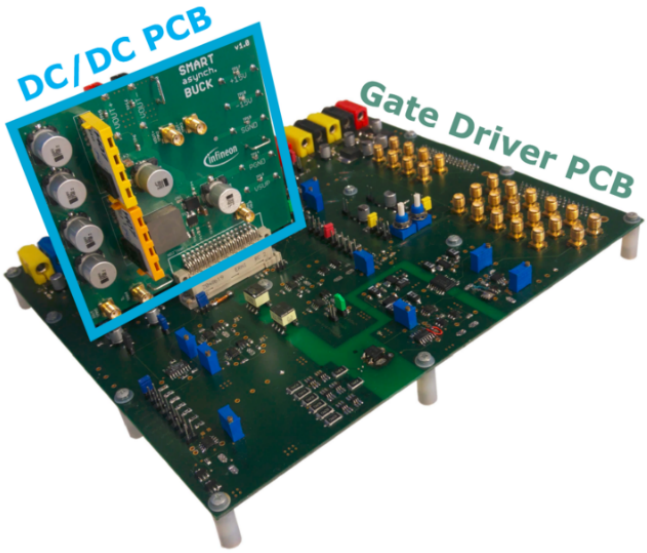

Figure 10: Buck Converter and Gate Driver PCBs

Once proven the concept works as expected, the system can be tested in laboratory by means of a rapid control prototyping called dSpace. Here, the power-DMOS and external components are no longer digital, but located on a DC-DC converter Printed Circuit Board (PCB), which is connected to a Gate driver board (Figure 10), connected in turn to dSpace.

dSpace, through its FPGA, will embody the Simulink bloch approach control logic circuit (uploaded by PC), also providing the current sensing, the internal reference and all the devices to communicate with the hardware (ADCs, DACs). dSpace allows to test whatever control circuit including all the un-idealities of the system, verifying moreover the correct operation of the power-DMOS and that one of a real load. In this way it can be eventully proven that, not only the circuit works as expected, but that is suitable for the application at stake. Through a Graphic User Interface, in Figure 11, the user can monitor the system operation using the PC. Not only to insert the protection to avoid OC and OV, but also to vary the references and other parameters and observe the system response and waveforms in each condition.

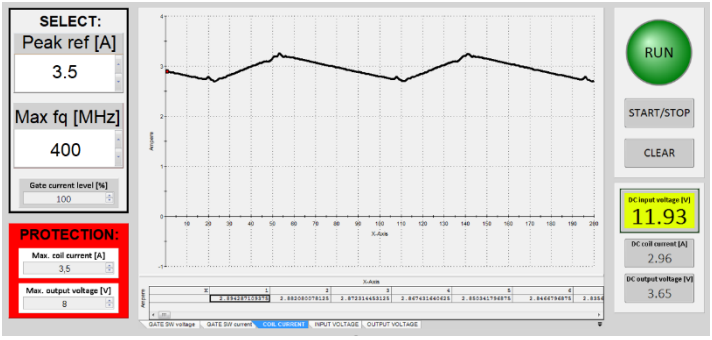

Figure 11: Graphic User Interface

Of course, for having a higher sampling precision, the same waveform can be actually taken from oscilloscope, shown in Figure 12. As expected, the circuit is able to drive the load maintain the desired current features over time and with the same theoretical behaviour of Figure 2.

Figure 12: Output current (violet) and gate driver (green) Waveforms from oscilloscope

6 Conclusions

The presented DC-DC Buck Converter Variable-T_{off} loop allows to precisely and smartly control the current features, returning a reliable car battery sourced driver. Other than the current peak, the

loop is able to control the average current. Moreover, given (2), also the ripple is indirectly controlled. With respect to other solutions, the switching period is variable, intrinsically solving the instability issues. Indeed, the T_{on} changes with the input voltage while T_{off} increases/decreases at each switching cycle accordingly to the comparison between I_{avg} and the target value, making (2) smaller/bigger (i.e. increasing/decreasing I_{avg}).

The system exploits an integrated low-side sensing resistor circuit to minimize the Printed Circuit Board usage space, avoiding extra pads to sense the current. To make the chip lighter and cheaper, the Buck Converter C_{out} has been neglected, as superfluous for the application.

The concept has been simulated with Simulink and then a more rigorous test has been conducted in laboratory with dSpace where worst condition simulations shown an excellent dynamic behaviour. The circuit appears to be robust, proving that sudden perturbations on V_{in}, I_{max} and T_{off} do not upset the operation of the circuit. Compared to [8], the presented solution is lighter and works with an input voltage range of $[4.5, 27]$V, able to drive a 3A LED with 500kHz maximum switching frequency, allowing extremely good average regulation precision and speed. A more detailed comparison of all Buck performances, including efficiency, with the state of the art is provided in [7].

Acknowledgment A part of the work has been performed in the project iDev40. The iDev40 project has received funding from the ECSEL Joint Undertaking (JU) under grant agreement No 783163. The JU receives support from the European Union's Horizon 2020 research and innovation programme. It is co-funded by the consortium members, grants from Austria, Germany, Belgium, Italy, Spain and Romania.The information and results set out in this publication are those of the authors and do not necessarily reflect the opinion of the ECSEL Joint Undertaking.

Global Software Development

ABSTRACT

In recent decades, the challenge of managing the development teams spread across different time zones has become increasingly common, raising the importance of the development of Global Software Development (GSD) techniques, in order to tackle its particular problems. This work discuss these issues in the context of Sidia, an R&D institute which implements technological solutions for global companies. The main partner of Sidia is a mobile multinational company located in overseas. The development team must cooperate with the overseas team, even though there are no overlapping working hours between both teams. Besides, the teams have a different set of skills regarding design, quality assurance, and software engineering. In order to address theses problems, we propose the Blueprint model, a Kanban and Scrum based model that supports the development of GSD systems, the allocation of tasks and teams, and the efficient communication. Finally, we discuss the aspects and lessons learned of development of project and deploy of a new model for systems development on a real-word project.

1 Introduction

Many companies adopt software development methodologies with fixed timebox periods for developing incremental deliveries, which is a strategy aligned with agile-based approaches. In these scenarios, Scrum proved to be the *de facto standard* for the most software-oriented industries, showing improved results over *waterfall* methodologies. Despite this, some groups can face difficulties when dealing with the Scrum's ceremonies in the context of Global Software Development (GSD), e.g., estimating effort during the planning sessions or even conducting daily meetings.

In this current work, we extend the definition of the Blueprint model [1], generalizing it to other scenarios and groups by furthering exploring its technical aspects and presenting add-ons to the original proposal. As described in [1] by the authors, Blueprint Model is a lightweight project management that can encourage and facilitate communication between groups in different sites when matched with the suggested group organization. In this particular work, the authors focus on reporting the main challenges when developing a project in collaboration with an external group that does not use agile methodologies, which resulted in a set of barriers to successful integration. To resolve these issues, the Blueprint Model defines its deadlines oriented by the scope of work, which leads to timeboxes of different sizes that consider the effort needed for each activity. Such an approach is different from Scrum, where *sprint* cycles have fixed size throughout the project lifecycle. In this Model, the scope of work, hereafter called *blueprint*, comprises the individual tasks required to reach the target, the necessary information needed to perform these tasks, and what is needed to integrate the work done by every group member. A blueprint defines different group layers, concerning the nature of the work performed (e.g., design group, quality assurance), and assigns the individual tasks to them. Each group layer can be further split into many other groups or even share group members. In this Model, every group must focus on a specific kind of activity since it leads to facilitated project management.

This research was developed on Sidia, an R&D institute located in Brazil, which produces and validates software for an international mobile device manufacturer. The Institute develops innovative software in a kind of areas such as machine learning, software management, and others related to mobile products. Both local and overseas groups deal with the business model integration problems and manage the Sidia's customer's standards for system and management interactions.

In order to meet its customer's demands, Sidia employs Scrum

*Corresponding author: Paulo Fonseca, Sidia: R & D Institute, Amazonas, Email: paulo.fonseca@sidia.com

in the context of a global software environment to deal with several model integration problems and manage Sidia and its customers for management interactions. In this scenario, both groups found it difficult to follow Scrum's activities and bureaucracies. In fact that the standard daily meeting system becomes arduous to follow, because, unlike Scrum recommends, groups are not multi-functional. Each group has its own set of skills, including software engineering, design, and quality assurance. Another prominent issue is to apply Scrum in large scale projects, becoming impractical with excessive management tasks and many activities to manage under a distributed scenario.

The remainder of this paper is structured as follows: Sections 2 and 3 summarizes other similar methodologies, relating them to our proposal. Section 4 shows the Blueprint approach and its implications. Section 5 shows a set of results obtained when employing our proposal on a real-world project. In Section 6 we present the conclusions and avenues for future work.

2 Background

In this section, we discuss the frameworks and methods used as references for the development of the Blueprint model, which is base on agile methodologies concepts and rules like those influenced by the values of the *agile manifest*, namely: (i) individuals and interactions over processes and tools, (ii) working software over comprehensive documentation, (ii) customer collaboration over contract negotiation, and (iv) responding to change over following a plan. As already stated, the Blueprint model shares similarities with both Scrum and Kanban.

Scrum is a structural framework created to manage work on complex products and consists of Scrum groups associated with rules, events, roles, and artifacts. Each component owned with purpose, and integration success depends on managing the relationships and interaction between them. Scrum was the primary reference when designing Blueprint.

A fundamental difference between Scrum and Blueprint is that, while the former has been used to develop software, hardware, networks of interacting function, autonomous vehicles, schools, government, and managing the operation of organizations, the latter is focused on software development. We stretch this difference in Section 4. The essence of Scrum is a small group of people while remaining highly flexible and adaptive. To achieve that, it prescribes four formal events for inspection and adaptation: (i) Sprint Planning, (ii) Daily Scrum, (iii) Sprint Review, and (iv) Sprint Retrospective. Appointed events are used in Scrum to create frequency and to reduce the meetings not defined in the regular workflow. In contrast, Blueprint is a model that reduces or eliminates the regularity of those ceremonies, once it can negatively impact some scenarios of GSD. We explore these scenarios in Section 4.4.

To task management, Blueprint employs Kanban, once it is focused on managing commitment and balancing workflow to achieve greater agility. Kanban is a method for defining, managing, and improving services that deliver knowledge work, such as professional services, creative endeavors, and the design of both physical and software products. While designing Blueprint, we make sure that it shares Kanban's same values, namely: transparency, balance, collaboration, customer focus, flow, leadership, understanding, agreement, and respect.

In summary, Blueprint deal with two typical GSD challenges:

Communication Barriers Both Scrum and Kanban define meeting and ceremonious as part of project communication, but in a GSD context, they can be challenging to coordinate, once group members and stakeholders are in different timezones.

Scope Management Although Scrum is favorable to accepting a change of scope, the typical framework implementation implies that a group is committed to the sprint scope once it begins. This scenario can cause undesirable overhead once it requires both backlog and sprint replanning.

3 Related Work

In the last two decades, agile methods increased their popularity and were established as the main software development methodologies. A large number of efforts [2–5] were focused on studying their application under different circumstances and evaluate their advantages and shortcomings. In [4] the authors conducted a systematic review of works that used Scrum guidelines in a global software development (GSD) context. The authors identified the challenges of using Scrum in such context and which are the current strategies to deal with them. The main difficulties are related to: synchronous communication, collaboration difficulties, communication bandwidth, tool support, group size and office space.

The lack of synchronized hours between the group hampers the ability of holding long meetings, such sprint planning or retrospective sessions, which can last up to four hours or more. Some groups [6, 7] handle these issues using strategies such as defining strict timeboxes for meetings' duration and executing preparation tasks in order to shorten the meeting. This approach may help teams to face GSD challenges while partially following Scrum guidelines, however, this is not possible between locations where the overlapping hours are scarce, for example, Brazil and Japan have a 12-hour offset.

Additionally, in many cases, the quality of communication is also a problem, given that distributed projects are composed by group members with diverse cultural and linguistic background, which may lead to group members not completely voicing their opinions, due to fear of being misinterpreted. A number of works [8–10] tackles these issues by proposing additional on-site meetings in multiple project phases: before starting a project, in order to reach a common understanding about the project; multiple exchange visits of group members, during the project, in order to reduce the cultural distance. These studies show that such practices are valuable to both teams as they shorten the communication gap, an important challenge in GSD. Nevertheless, these approaches have a high financial and time cost. As a way to address these issues, other approaches [11, 12] focus on enhance documentation practices in order to bridge the communication gap.

Besides these socio-cultural differences, other inherent aspects of GSD projects also cause Scrum projects to heavily rely on a diverse set of tools in order to exchange information, share group's

states and enforce Agile guidelines. In current literature, works as [13–15] used a large number of tools to achieve these goals, including enterprise wikis, shared electronic work space, global issue and bug trackers and backlog management tools, these approaches might be used in order to provide information for distributed teams in a centralized manner. However, these tools might add complexity and bureaucracy to the team operation, negatively affecting its performance.

Another common technique used in large distributed groups is to divide the group into into smaller sub-groups [6, 7, 13], according to different strategies, including: different aspects of the development group(*e.g.* design, back-end, front-end); product features and deliverable; independent modules or subsystems of the main project. This division eases group management due to the smaller gap in communication of a smaller and more focused group. Scrum may also be adapted in different ways to support the groups subdivision: a fully integrated Scrum group, where all members must participate in all meetings, with frequent meeting ensure correct and clear communication between distributed sub-groups; or separated Scrum sub-groups based on location running their own iterations while sharing key points between groups. These subdivisions tackle the management and interdependence problems in GSD because usually team members from the same aspect need to exchange information more frequently than team members from different aspects.

The majority of approaches performs only minor changes in the Scrum framework, by specifying constraints or adding features to original guidelines. Other approaches suggest more fundamental changes to Scrum guidelines or even use other Agile methodologies.

In [16], the authors investigated the impact of using a combination of Scrum and Kanban (Scrumban) on global software development and showed that challenges related to communication, cultural and strategic issues are addressed due to characteristics of Scrumban such as iterative and incremental deliveries, regular feedback ceremonies and limiting the amount of work in progress. However, there are still few challenges related to technical and security issues in GSD that are not addressed or alleviated through the use of Scrumban, which require other methodologies and tools to be mitigated.

In [17], the authors evaluated the use of Kanban on the same environment and found that some Kanban elements, such as the Kanban Board, *Inclusion Criteria*, which guarantees that all items in development deliver value to the customer, and *Reverse Items*, which enables development items to return to a previous state, are valuable to face communication challenges in GSD.

This work proposes a model called Blueprint, which is a lightweight project management that was envisioned specifically aiming global software development scenarios. This combines strengths of Scrum and Kanban, as well as the use additional tools in order to facilitate communication between groups in different sites and provide holistic project view that centralizes information for all team members. In this particular work, the authors focus on reporting the main challenges when developing a project in collaboration with an external group that did not use agile methodologies, which resulted in a set of barriers to successful integration.

4 Blueprint

4.1 Goals

The Blueprint model has been designed to deal with geographically distributed groups, handling timezone issues, which may lead to difficulties in setting up meetings, misunderstanding requirements, delay in receiving or reporting issues. Besides the timezone challenge, this model also focuses on increasing time spent on product development, parallel work, and reduce meetings overhead.

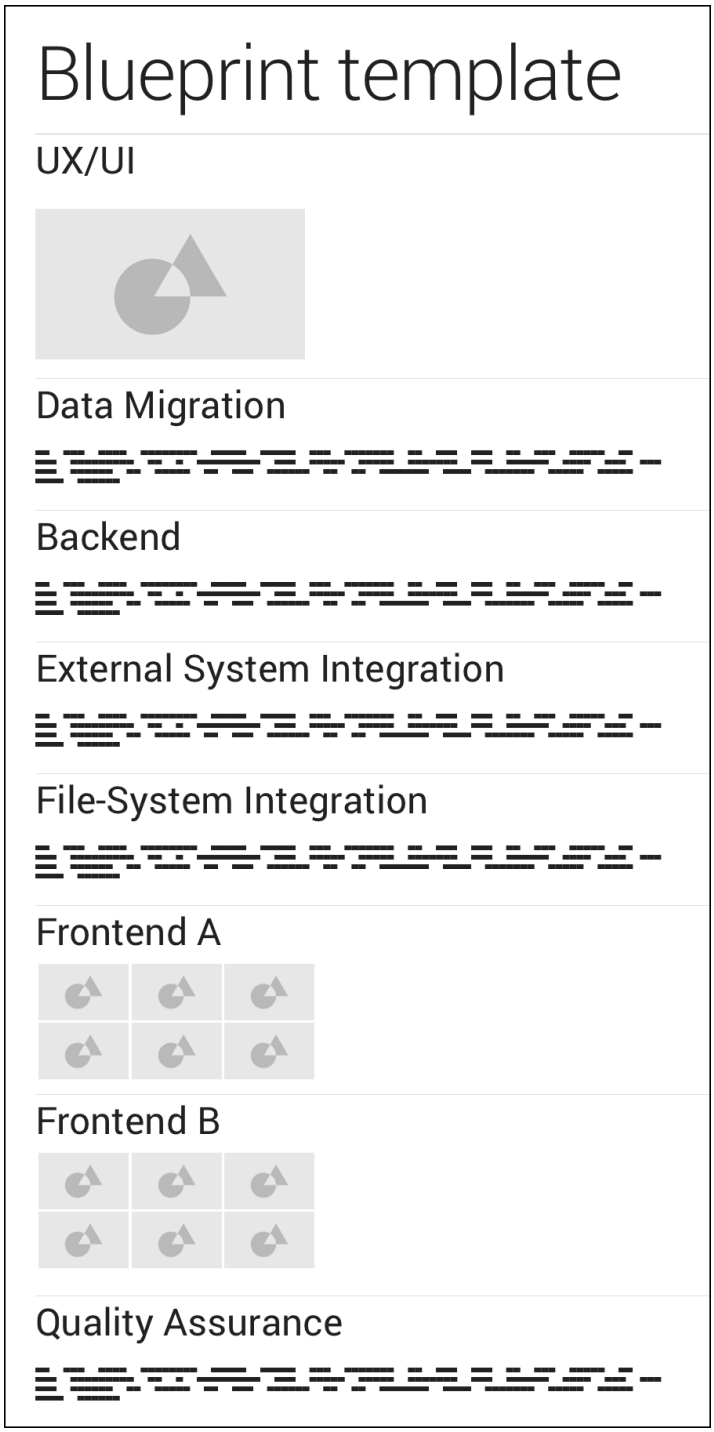

Figure 1: The *Blueprint* Layout, unifying areas *sub-teams* with information on a wiki page.

Therefore, to achieve these objectives, Blueprint seeks to simplify and improve project understanding by using visual-aid tools and helping the group prototype the main project aspects, i.e., UI and technical features. To group communication, these resources are stored in a wiki tool, available to every member so that everyone can be notified of any update.

The Blueprint model employs a hierarchical group organization of sub-groups, once it facilitates the development of unrelated requirements in parallel. Each sub-group is responsible for developing and integrating different aspects of the project into a releasable package. In contrast to other agile methodologies like Scrum, in which groups are considered self-organizing without any prior hierarchical organization [18] other than Testing, Architecture, Operations, and Business Analysis Domains, the Blueprint requires a Leader for each sub-group that is responsible for attending meetings, define requirements, and propose deadlines.

In summary, the primary purpose of Blueprint is to reduce overheads, so the model does not contain predefined which ceremonies must occur neither its regularities, which should be scheduled on demand. Blueprint suggests that each group guides itself by using a set of add-ons, e.g., a wiki tool, improving communication, and information sharing. For the coordinate task, Blueprint suggests Kanban boards, making it easy to share the information across different timezones and provide an accessible project overview.

4.2 Model

In [19], the authors describe an essential aspect of Scrum and Kanban, two popular agile methodologies used in the industry [20], is the constant expansion and improvement of its tools. A Blueprint model is a tool inspired by Scrum and Kanban that manages the project's business entities before it is developed. Blueprint introduces key adaptations to Scrum and Kanban to reduce unwanted bureaucracies and to facilitate global software development. The fundamental concepts of the Blueprint model are:

The Blueprint The concept of a blueprint is very similar to Scrum's story. While both the story and blueprint contain a brief description of the requested features, the latter contains every information needed to design, execute, evaluate, and deliver a set of features, as shown in Figure 3 1. A blueprint should be divided into meaningful sections and contain all related files and discussions to an activity, e.g., the development progress, facilitate the communication between group members and stakeholders, and lower the complexity of both maintenance and monitoring. For efficient scope management, a blueprint can be revised, merged, or divided to reflect the latest requested features and evaluate agreed scope, which should occur at regular intervals. In this document, you can find two very similar terms, the Blueprint Model and the blueprint. The first one, Blueprint Model, is directly related to the model itself. Every time the model is being addressed, it will be called as Blueprint Model, using the first letters for both words in uppercase. The other one is regarding the unity of the work of each blueprint. In this case, the first letter in lowercase refers to every blueprint created for each project, having its characteristics being explained over this document. To implement the blueprint concepts, one could use wiki tools to (i) allow discussions as recorded chats and (ii) keep a history of decisions during development. We further explore the use of wiki tools in Section 4.2.1.

Timebox and Sense of Urgency Timeboxing is a well-known time management technique employed for both project and personal management approaches, once it keeps a constant *workflow* with deliberated deadlines. The use of fixed timeboxes can be challenging, notably in projects with frequent scope changes, since it must be adopted by every group member and stakeholder, imposing difficulties in managing unexpected features requests or modifications. The Blueprint model was designed as a solution for companies and groups struggling to keep with fixed timeboxes, as suggested by agile methodologies like Scrum. In the Blueprint model, every cycle can have an independent deadline determined by the amount of work estimated by the members involved in the development, ranging from days up to weeks. Note that the total time to deliver a set of features is the sum of all activities related to a specific blueprint, similar to a Gantt chart.

Group Organization Contrary to Scrum, in which the group typically uses a flat organization, with members associated with specific roles, the Blueprint model defines a position entitle *group leader*, which is responsible for understanding the solution, define the project schedule, and evaluate deliveries. In the context of a *research and development* project, the Group Leader is also responsible for granting the paper publication. The Blueprint model organizes the group into focused sub-groups, which can be formed by specialists or multidisciplinary members. Sub-groups are advised to define a Sub-Leader to help the group leader in the project management activities, once it eases communication and offers an opportunity for every group member to express its ideas during the discussion of solutions and deadlines. We further explore the Blueprint's group organization in the following sections. Similar to other agile methodologies, the Blueprint model can be adopted by *non-coders*, e.g., testers and designers.

Contrary to the Scrum group division, Blueprint proposes a group hierarchy that can better adapt to software requirements changes during project execution. Blueprint defines its group hierarchy as *sub-groups*. The number of members per *sub-group* is not defined by Blueprint, but as an analogy to Scrum, and as discussed in [19], *sub-groups* should focus on small groups. Also, the number of *sub-groups* may change during the execution of a project.

4.2.1 Add-ons

In the following paragraphs, we present add-ons that can improve Blueprint adoption in different scenarios and groups.

Blueprint Table As explained in Section 4.2, the *blueprint table* is a management tool that should be regularly updated by the group leader to help other members realize the overall status of the project. The *tables* of Blueprint are equivalent to Kanban's boards, but instead of using *status flags* as columns, it uses the concept of *sub-group* ownership. The order of the sub-groups in the table should be defined to reflect the workflow being developed by the group, e.g., design should come first in several common situations, and quality assurance should come last in most of the scenarios.

The list of the condition is used to manage the operation of each stage described in the *blueprint table*, as shown in Table 2.

Contrary to Kanban, in which group members move tasks over the board to indicate the current status of a task, in the blueprint table, the Group Leader is responsible for moving the sub-groups status to consider the *blueprints* in the preferred order of development. The order of development must be arranged between the group, stakeholders, and Group Leader, facilitating project management. The Blueprint model defines the usage of status flags as:

- Every sub-group status should start as PENDING.
- Sub-groups without actions associated with a blueprint, assume the N/A status.
- At the point when the sub-group begins to work in a particular outline, its status should be changed to IN PROGRESS to show that not all conditions and errands are done.
- After a sub-group finishes up all tasks and conditions, the status of the sub-group ought to be set apart as DONE.
- When a sub-group concludes a blueprint, if possible, the sub-group must start working on another blueprint. If not possible, the sub-group must contact the group leader as soon as possible for resource reallocation.
- Status like *SIMILAR* and *BUG FIX* were intended to help general overview.
- SIMILAR ought to be utilized when no effort should be spent by a sub-group due to another outline. At the point when applied accurately, it can diminish modify.

- BUG FIX ought to be utilized to show that a blueprint arrived at its last stage and bugs are being fixed.

Every time a new blueprint is created, abandoned or regrouped, it is advised to replan the blueprint table. The group Leader and the group must be aware of the impacts and dependencies of documentation modification during the entire project lifecycle. The same happens when remodeling sub-groups. If any sub-group is created, ceased, or regrouped, the blueprint table should be planned. In summary, a blueprint table is a tool for sub-group management that can be associated with a collection of Kanban boards for handling tasks administration.

Wiki Tools On the Blueprint model, the usage of Wiki tools is essential to organize and aggregate information on different aspects of the project, facilitating the communication between the group and stakeholders. The main points of integration are:

- The web page format makes it easy to maintain and update.
- Every blueprint should be stored as a unique wiki web page.
- The group Leader should organize all pages and ask for the group to keep every part updated.
- Every sub-group must have its own space following the same order on every blueprint page.
- The storage of technical conversations and discussions in a log format contributes to the project's maintenance.
- All related usage of blueprints in the Wiki tools used the company's infrastructure company's infrastructure and its internal Information Security policy to manage it. This means every group member was under the company's management overview and user access control rules.

Table 2: Status to control activities in the *blueprint table*.

Status	Definition
PENDING	Initial status or *sub-group* activities are on hold. It may have several causes. Descriptions should be at the Blueprint related page.
IN PROGRESS	The activities of this *Blueprint* are on development. It may contain dependencies or impediments but still in progress.
DONE	All activities are finished. Have no dependencies.
SIMILAR	When the activities of this *sub-group* are equals to the activities of the *sub-group* above. This eliminates the effort of the related activities.
BUG FIX	Fixing bugs of the *Blueprint*. The *Blueprint* is in its final status.
N/A	Not applied. It occurs when the *sub-group* have no activities for that Blueprint.

- Replanning should be easy to maintain by employing the wiki's versioning system.
- By leveraging wiki tools, groups that require necessary social distancing, home office, or are facing other adverse situations should communicate effectively by (i) integrating a Kanban board with each blueprint and (ii) using the *export* feature to share relevant information with stakeholders.

4.3 Implementing Blueprint on a Real-World Project

To show Blueprint in detail, we will use a real-world project called *The Project*, which characterized a list of *sub-groups* that can be equivalent to many webs, mobile, or embedded software projects. We first planned *The Project* with a number of *sub-groups*, which was thought to be sufficient, but at the end, the list changed to optimize group allocation, as shown in Figure 2. As showed on the Blueprint model, sub-groups can can aggregate multidisciplinary individuals or authorities with a similar profile, for example analyzers situated in Quality Assurance Sub-gathering, architects in Design Sub-gathering, engineers taking a shot at both or solely on Front end Sub-gathering and additionally Back end Sub-gathering. Note that the sub-bunch rundown can be changed by the necessities of the task to streamline bunch portion or build up another prerequisite. In *The Project*, the accompanying circumstances lead to sub-bunch rearrangement:

- To deliver the back-end features on the schedule, the sub-group was divided to help some members to work on two sets of requests.
- The client requested an alternative and entirely different UI solution from Design Sub-group that was approved to be developed, so it was decided to split the Front End Sub-group into groups *A* and *B* to allow each work on a different release.
- A new mobile solution was requested, but there is no developer with such skills in the group. Therefore, it was decided to hire new members and they will work in the entirely new Mobile Sub-group.
- After a schedule modification, the client suggested for developers to work in a new scope of migration data, and due to this, a new Migration Sub-group is created. The group Leader decided that some back-end developers and testers will work on this group part-time.

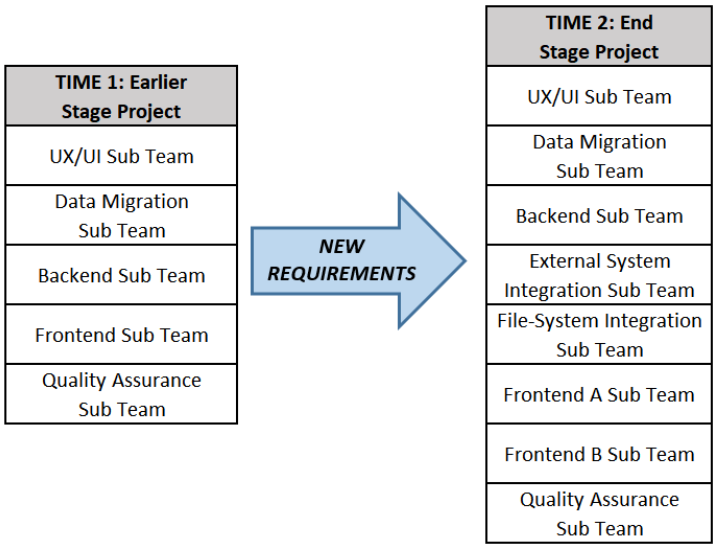

Figure 2: *Sub-groups* preparations during beginning (*time 1*) and ending (*time 2*) of *The Project* execution.

Blueprint consents to the thought that the quantity of individuals doesn't speak to quality or profitability. In the Blueprint model, each *sub-group* has a pioneer characterized as a part of mindfully, and not really work execution. Each *sub-bunch leader* is liable for the exercises and consequences of its gathering. He is additionally answerable for incorporating the errands done by the gathering into the undertaking, planning this cycle with different pioneers. All *sub-bunch leaders* react to the *group leader*, as delineated in Figure 3. This association follows the meaning of how improvement ought to be executed by the Blueprint model to permit and encourage *sub-group* communication.

After the meaning of *sub-bunch leaders*, the following stage is to execute Blueprint select and the board. This stage is a variation and conglomeration of two Scrum the board undertakings and ceremonies, in particular, *Product Backlog* and *User Stories*. All individuals are locked in to effectively take an interest in this stage during venture improvement, as it is the center of the model. As depicted in [12], the duty to characterize and keep up the Scrum's *Sprint Backlog* is in the possession of the job *Product Owner*. It is normal for the *Product Backlog* to require consistent correction and reworking. These assignments may contain business rules in the *User Stories'* depiction. A few organizations have utilized extra documentation to keep engineering definition, model plan, and framework examination refreshed by the *Product Owner*. Uniquely in contrast to Scrum, *blueprints* are business substances that are relied upon to be persistently changed, kept up, and assessed by all individuals from the task. Pioneers must have the duty to change the *blueprints*, however this assignment isn't limited to them.

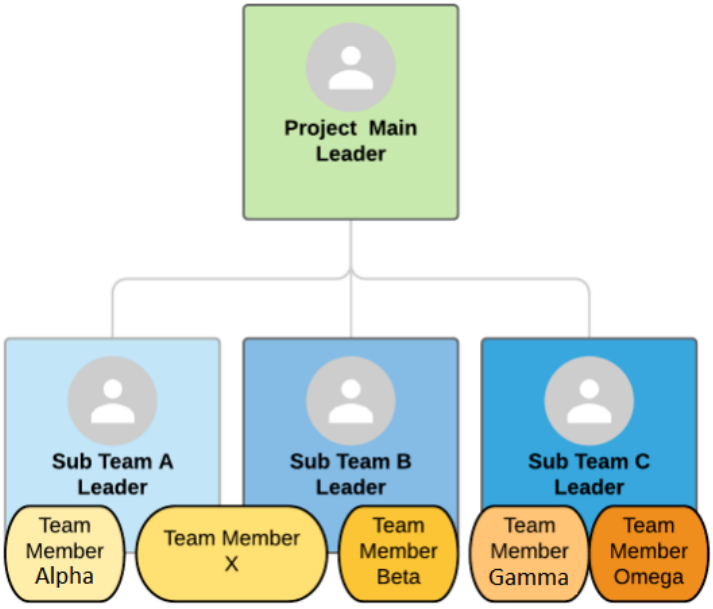

Figure 3: *Sub-group Leaders* and their relationship with the *main group Leader*.

As presented in Section 4.1, the Blueprint model was intended to help bunches in various destinations and to function admirably with distant *sub-groups*. It energizes correspondence among designers and customers by incorporating the conversation in a wiki-based website page. Each *blueprint* ought to be enlisted utilizing a wiki instrument, and its substance development relies upon each *sub-group's* work. At *The Project*, *blueprints* are wiki pages containing

all substance vital for the advancement of a module or an aspect of the undertaking. Table 2 sums up the substance of each *sub-group* obligations that was characterized in *The Project*.

Blueprints must contain all *sub-groups* related materials, as tables, diagrams or file that aggregates information to development. *Blueprints* centralizes information and communication between *sub-groups* as well as with the *group leader* and the client. Wiki tools typically allow for managing discussions between users as a recorded chat. Blueprint takes advantage of this feature to keep the history of decisions made by the group during project execution. Figure 1 illustrates a *blueprint* template that contains fields related to each *sub-group* define in *The Project*.

Blueprint maintenance is done by keeping each blueprint activity from all sub-groups up to date, which helps reflect on the project status. The usage of blueprints encourages deadlines with a focus on the agreement between sub-groups, group leaders, and stakeholders. Each sub-group deadline is a composition of all tasks planned at the blueprint, which can be replanned without impacting other blueprints. Therefore, the Blueprint model enables groups and stakeholders to control and refactor activities by proposing specific deadlines for each sub-group without re-planning activities defined.

The understanding about the hour of every movement is legitimately identified with the development of the gathering and its self-administration. After the meaning of each *blueprint* content and the principle cutoff time of *The Project*, some gathering individuals recognized the requirement for micromanagement exercises. To oblige that request, the underlying adaptation of the *blueprint table* was moved up to characterize reasonable cutoff times for all *sub-groups*. Figure 5 embodies the second form of the *The Project*'s *blueprint table*.

Blueprint encourages deadlines with a focus on *sub-group* assignments that are characterized in in agreement with the *group leader* and the client. Each *sub-group* deadline is a piece of all assignments arranged at the *blueprint*. During the development of *The Project*, bunch individuals started to demand rethinking of certain activities, and it started to impact on previously defined *blueprints*. The Blueprint empowers to gatherings and customers to control and refactor exercises by proposing specific deadlines for each *sub-group* without previously characterized.

The Blueprint model characterizes a*blueprint table* as a administration tool hat ought to be utilized to continually show the general status of an undertaking to all gathering individuals and customers. Figures 4, 5 and 6 show the *blueprint tables* during execution of *The Project*. Toward the start of *The Project*, an underlying form of the *blueprint table* was characterized by the gathering with the assistance of the customer, as observed in Figure 4. This underlying arrangement permitted all partners to concur with the interests of the task and with the substance of each *blueprint*. During the development of *The Project*, members of the *sub-groups* identified that the *SIMILAR* status helped to reduce software rework.

After different steady modifications, *The Project* characterized its last *blueprint table* as appeared in Figure 6. Note that, in examination with Figure 5, new *sub-groups* were made to oblige already impromptu prerequisites of the customer. The creation or evacuation of *sub-groups* can influence different exercises and should be all around oversaw and talked about between *sub-bunch leaders*, however never debilitated. For example, at the underlying rendition of the *blueprint table*, just one front-end gathering, called *Front-end Sub-group* was liable for all front-end exercises. At that point, when an additional necessity rose up out of the customer, another front-end *sub-group* called *Front-end B Sub-group* should have been made to build up an alternate arrangement of arrangements. The underlying front-end *sub-group* was needed to survey its exercises to help the redistribution of errands of the reestablished *blueprint table*. A portion of the gathering individuals need to chip away at bunches *A* and *B* to help extra exercises. *Front-end bunch B Sub-group* was situated at the abroad site and worked distantly with the gathering situated at Sidia. The last rundown of *blueprints* are represented in Table 3.

Table 3: List of Blueprints used in *The Project*

Blueprint Name	Example of work by blueprint
Authentication	Login page. Back-end authentication service. Front-end authentication error page.
CRUD A, B, C and D	Create, Read, Update and Delete business entity A, B, C and D. Back-end service for each. Front-end pages for each.
Extended Specification A and B	New requirement with several business workflow. Requested during the execution of the project. Replan needed.
Report A, B and C	Report generator page. Back-end service for report business model.
External Requests A and B	Unintended external integration. Requested during the execution of the project. Replan needed.
Mobile Integration and Mobile Interface	Unintended mobile version. Requested during the execution of the project. Replan needed.
Customer Service, User Overview and About	Low priority administrator pages. Gained priority due to requested changes.

The Blueprint Model as some other philosophy has its reception challenges, for instance:

- Communication hazards The Blueprint model has a great dependency on documentation process. As proposed, it is very dependent of Wiki documents in order to keep good communication between sites. This dependency combined with possible many changes requests, generates a constant necessity of Wiki documents updates. It can turn out very difficult for the group to keep the good communication under many changes requests.

- Predictability hazards If not applied as its standards by the entire group, the Blueprint model can show up as a harmful tool when it comes to deliveries and projects goals. The presented model requires management skills from each area of the group. Once the required skills are not present in the group members, the entire process can be compromised, which would impact on the completion and good quality of deliveries.

- Performance hazards Concerning software development, all sub-groups that work together have dependency of information from one another. On Blueprint model, as each sub-group is required to maintain its own Wiki page updated, the lack of update of any sub-group can generate delays, compromise

group work and even entirely block group members of working.

4.4 Use Cases

In the following paragraphs, we present some use cases in that the Blueprint model proves successful.

Global Software Development The Blueprint model was designed to support remote groups and sub-groups in different locations, since its hierarchical group organization of a Project Leader and its

Blueprint	Deadline	UI/UX	Backend	Frontend	QA

Figure 6: Last version of the *blueprint table*. New *sub-groups* and *blueprints* are remembered for correlation with past tables.

respective Sub-groups facilitates daily communication, in such a way that this interaction becomes more fluid and objective for adopting a particular scope for each sub-group. In our case, we deal with a customer in a country in which the timezone is at least 13 hours ahead, making real-time communication via call or chat unfeasible. In this scenario, we use the 'wiki' to keep track of what each member of the group is planning for the next few days, what they are doing, and what was done in such a way that everyone has an overview of the project's progress, being able to follow all deadlines and features that have already been developed and those to come.

Remote Work In the face of COVID-19, several development groups and companies in different industries were forced to adopt remote work to continue their work. In this scenario, Blueprint proved to be an adequate strategy to accommodate the remote work regime, regarding the difficulty in communication between groups because from the moment employees are working from home, the practicality and speed of transmitting information are both affected. Consequently, adopting a standard of documenting the information in a centralized form and bringing the division of sub-groups, makes the dissemination of internal information through the wiki page more effective by leveraging a reliable consumption source that is validated by the client.

Scope Change Control The Blueprint also helps to manage frequently *scope changes* since unlike Scrum which suggests another iteration of a set of ceremonies when facing modified requests, such as *Project Vision*, *User Stories*, *Planning*, and others, the Blueprint offers lightweight project management that avoids these ceremonies that can cause rework and further prolong delivery forecasts. To improve on that, Blueprint proposes the idea that both the developer and client will leverage the 'wiki' as a guide for (i) decision making, (ii) discussions about new releases, and (iii) requirements alignment. By documenting information in a centralized repository, the stakeholders are able to easily monitor the requested scope changes, helping to avoid noise or loss of information from typical verbal communication.

5 Implementation Findings

The design of Blueprint was mainly oriented by the GSD challenges faced during the collaboration of remote teams on developing *The Project*, which evolved from 10 members using Scrum to a successful Blueprint case more than 20 members. The increased number of members resulted from the stakeholders' higher engagement and contribution to the process and project. Once the process started running, it allowed the team to accept more work scope, which might be understood as an increase in productivity and led to a natural team increase. Through the advancement of *The Project*, different gradual modifications were made to the Blueprint Model to energize its appropriation. This cycle included both neighborhood and far off groups to facilitate the work process, encourage worldwide programming designing, and improve appropriated correspondence. Following the summarizing of *The Project*, we notice various situations to improve the Blueprint model execution to ensuing tasks.

We found that an essential aspect of a successful Blueprint implementation is to focus on the member's sense of integration and empowerment. Regarding *The Project*, most of the individuals concurred they turned out to be more critical and made more proposals to the undertaking the executives with the appropriation of the Blueprint Model. Every part had the option to share its answers and thoughts to other people, and due to Blueprint central focuses, significant correspondence issues were survived. The primary advantage

of zeroing in on the part's feeling of reconciliation and strengthening is that the group felt inspired for monitoring Blueprint's curios, prompting improved undertaking the executives.

Another significant part of a successful usage was the group's adherence to Blueprint's rehearses. Regularly, less connected with *sub-group leaders* portrayed exercises and progress ineffectively, which can be credited to the difficulties while embracing another administration model. By the by, the individuals saw a connection between (I) the time frame pages changes, (ii) nature of these pages and (iii) commitment of the sub-pioneers. We notice a connection between diminishing the nature of Blueprint pages to diminishing code quality and last on bugs appearing.

The improvement of the communication between team and stakeholders is a crucial objective of the Model, so it is crucial to make more accessible the verification and reporting of information through a *wiki tool*. The successful implementation of the Blueprint Model enables identifying disagreements and conflicts in the Wiki and not necessarily during meetings, which enabled the resolution of these problems in private. Meeting events are not often and gathers a few members, which prevents long discussions of non-related subjects from reducing the execution time and reaching its goal as quickly as possible while the rest of the team keeps working on project tasks. After adopting the BLuePrint Model, the team had performance gains related to the planned x performed activities, related to clear and accurate communication, thus ensuring a clear understanding of the changes. The fact that did not happen using the Scrum model, due to the difficulty of managing constant changes within the sprint and the difficulty of formal meetings due to the time zone. Another improvement that is possible to observe is the quality of deliveries. In the BluePrint model, team members can maintain their specialties without the need to be multidisciplinary, and brings a significant gain in side effects, especially when it came to scope changes. Still linked to the specialty of the team members, it is also possible to see the result in the motivation of the team; it means, to work with the specialty of each one, this brings motivation and engagement in the day-to-day work, and consequently, this is reflected in product quality delivered.

Differently from other agile methodologies like Scrum, the Blueprint Model exempts ceremonies and daily meetings that need the entire team to happen, making the Model more flexible. This characteristic praises the Model because it fits well with the current pandemic scenario where the new common sense of IT company members working remotely and need to keep the flow of work to meet delivery deadlines. Some Blueprint Model positive points:

- No team ceremony: The team adopted the Blueprint Model since the beginning of our development, and we kept it when everyone on the team was doing home office. We managed to keep all deadlines using only the Wiki as a reference for the division of activities.
- Sub team division: This sub-team division was of great value for the atypical home office scenario. The team needed to maintain a very similar communication level as a live-work environment, which made the team feel more comfortable maintaining contact with companions.
- Model suited to a project scope that frequently changes: Scope change is passive to happen very commonly in any software development project. The team validated the model adherence to the common practice since every project was constantly changed. Due to the very centralized information on the Wiki, there were small relevant impacts, all highly negotiable.

6 Conclusion

In this work, we presented the extended definition of the Blueprint model, a management methodology designed to accommodate the best techniques and habits of both Scrum and Kanban to facilitate (i) global software development, (ii) groups and task allocations, and (iii) effective members communication. The straight communication between groups and the high visibility of the overall status of the projects are the main highlights of the methodology, which lead to a better scope change management with low bureaucracy and an accessible understanding of the entire development. To validate the model, we discussed its adoption on a real-world project of a large mobile-related software development company in the context of GSD. The strategic use of Blueprint's add-ons enables us to coordinate, design, develop, and test a complex set of features on a highly unstable scope scenario. Blueprint usage of UI and UX for the documentation of analysis, design, and development phases in conjunction with the lightweight cycle management tool helped to facilitate the project management, once it allows sharing responsibility between the *group Leader*, *Sub-group Leaders*, and other members in documenting and reviewing the progress of the project. More than that, the Blueprint model was improved during the execution of the project through a collaborative effort of groups located in different countries in order to improve its main benefits and to lower any adoption barriers. As future work, we plan to extend the Blueprint's add-ons to integrate other easy-to-use and well-known tools of project and task management, as well as to improve the model's adherence to other types of non-code projects.

Conflict of Interest The authors declare no conflict of interest.

Acknowledgment We thank MSc. Ilsun Hong, Taehee Kim, Rafael S. Zerbini, Marcos R. G. B. Junior and Alison L. Garantizado for their valuable help during the development of this framework. Text Classification

ABSTRACT

Text classification is considered one of the most fundamental and essential problems that deal with automatically classifying textual resources into pre-defined categories. Numerous algorithms, datasets, and evaluation measurements have been proposed to address the task. Within the era of information redundancy, it is challenging and time-consuming to engineering a sizable amount of data in multi-languages manually. However, it is time-consuming to consider all words in a text, but rather several key tokens. In this work, the authors proposed an effective method to classify Vietnamese texts leveraging the TextRank algorithm and Jaccard similarity coefficient. TextRank ranks words and sentences according to their contribution value and extracts the most representative keywords. First, we collected textual sources from a wide range of Vietnamese news websites. We then applied data preprocessing, extracted keywords by TextRank algorithm, measured similarity score by Jaccard distance and predicted categories. The authors have conducted numerous experiments, and the proposed method has achieved an accuracy of 90.07% on real-world datasets. We have proved that it is entirely applicable in practice.

1 Introduction

This paper is an extension of work initially presented in IEEE RIVF 2020 [1] as an invited paper.

Within the era of information redundancy, it is challenging and time-consuming to manually engineer a sizable amount of multilingual data. For example, an electronic library might quickly identify documents for archiving and management. Besides, it is often less accurate and overwhelming if humans are involved in the process. Therefore, apply machine approaches to automate the procedure of text classification is mandatory. It makes the classified results more reliable and less subjective. It helps alleviate human involvement and information overload and enhances knowledge retrieval efficiency. There are many text classification studies such as, e.g. Bayes [2], decision trees [3], K-nearest neighbor [4], and neural network [5]. The literature shows that automated text classification is one mainstream research in natural language processing [6, 7]. Many research papers have been conducted to solve such problems as email-messages filtering [8], topic modeling [9], geo-localization [10], and document categorization [11]. The flowchart of standard text classification is presented in Figure 1.

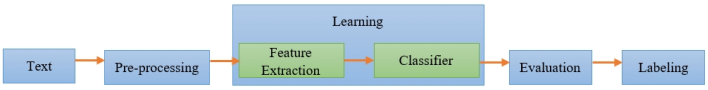

Figure 1: The flowchart of regular text classification where pre-processing and featuring perform an essential role.

The curse of dimensionality affects accuracy and computing time that arise when analyzing and organizing textual data in high-dimensional spaces [9]. However, machine learning models do not need to learn all tokens in the texts to categorize them. Instead, the text's label can be identified through its necessary tokens, which contribute the most to the text's meaning. Consequently, if we can extract the text source's main keywords, we might accurately classify it into an appropriate topic. The TextRank algorithm [12, 13] allows extracting the list of representative keywords of textual contents. On that consideration, the authors propose the method of automatic Vietnamese text classification based on the representative keyword analysis of the text. Textual datasets have been downloaded from several news websites with 15 main topics. Then, keyword sets that represent each topic are built. The system will extract that text's specific keywords when it is necessary to identify the topic

[*]Corresponding Author: Hiep Xuan Huynh, College of Information & Communication Technology, Can Tho University, Can Tho city, 94000, Vietnam, Email: hxhiep@ctu.edu.vn

of a text. The class of the text will be determined by computing the coverage of the representative keywords. It would be the right way for text classification applications in areas such as electronic library management. Although many Vietnamese documents are electronically available, no previous research has applied keywords-based text classification to them.

This work portrays our endeavor to construct a practical framework for addressing Vietnamese texts' classification task on the news. To the best of our knowledge, in this extended article, the authors have made several contributions. First, we discuss the paper [1] in a lot more detail by extending the related works and technical background. Second, we extend the experiments by investigating more scenarios.

2 Related Work

An early effort to address the task of Vietnamese text classification was conducted more than a decade ago [14]. In that paper, the authors solved automatically categorizing the problem, given textual sources into predefined categories. A comparison between statistical N-Gram language modeling and bag of words approaches has been investigated on their collected dataset. Several researchers have applied the idea of spam filtering into Vietnamese text sources [15]. Short messages such as conversational texts have also been exploited by addressing the task of suggestion intents [16]. The authors proposed a user suggestion intent definition in general from conversational texts at a functional segment unit. The task of automatic text categorization has been studied by comparing the performance of several term weighting schemes rather than analyzing the actual classification task [17]. Regarding Vietnamese sources, full-text representation has been exploited by many other research papers [18, 19, 20]. Thoughtfully learning the literature, we could claim that this is the first attempt to featuring Vietnamese texts using the idea of representative keywords.

3 Proposed System

3.1 Design Concept

The Vietnamese text classification system proposed by the authors includes two main components. One is the keyword extraction module, and the other is the comparison with the training set to identify the topic of a new document. We present the overall design of the system in Figure (**??**). The process begins with the text sources featured in the representative keyword vectors. For the training set, the vectors will be marked with the topic label. For the test data, the keyword extraction module is applied to convert the original text data into its keyword-based representation. Next, the system compares it to training data by calculating similarity scores. Finally, the prediction is assigned to the test data.

3.2 Text Pre-processing

Vietnamese is the only language in which every syllable is pronounced separately and is represented by a written word. This feature is evident in all aspects of phonetics, vocabulary and grammar. Data pre-processing is the first important step of any data mining process. It makes data in its original form easier to observe and explore. For the problem of text classification, due to specific characteristics, each language has its own challenges. The preprocessing process will help improve sorting efficiency and reduce the complexity of the training algorithm. Depending on the purpose of the classifier, we will have different preprocessing methods, such as

- Convert text to lowercase and correct spelling errors.
- Remove punctuation marks (if no sentence separation is performed).
- Remove special characters ([], [.], [,], [:], [”], [”], [;], [/], [[]], [$\tilde{]}$, [$\acute{]}$, [!], [@], [#], [$], [%], [$\hat{]}$, [&], [*], [(], [)]).
- Separate tokens by compound words (Vietnamese).
- Remove the stopwords, e.g. the words that appear most in the text that are not meaningful when participating in text classification. We utilize a list of 1942 Vietnamese stopwords[1] in our data processing.
- For the tokenization step, we utilize vnTokenizer [21] in our research. The comparison of tokenization accuracy achievable with different software is beyond the scope of this research paper.

3.3 Vietnamese Text Tokenization

Phonetic characteristics In Vietnamese, there is a special type of unit called ”tieng” or a sound of the thing. Phonetically, each ”tieng” is a syllable. For example, the word ”student” is translated into two syllables ”sinh vien” which are two separate words. As a result, these two words should come together to form a meaning token.

Vocabulary characteristics Each ”tieng”, in general, is a meaningful element. Continuing the previous example, the words ”sinh” and ”vien” have their own meaning when coming alone. But when they come together to form a single word ”sinh vien”, it has the meaning of student as in English. The vocabulary of Vietnamese is based on single words (one syllable) and the countless combination of them. Creating new words is very easy and flexible. If we pronounce a sound, we could write it down as a word.

Grammatical characteristics The Vietnamese words do not change morphology. For example, verbs in Vietnamese do not have -ed, -s, -ing forms. This feature will dominate other grammatical characteristics. When words combine with words into sentences, it is important to know the word order, the word phrase, and keywords for tenses recognition. Sorting words in a certain order is one of the main processes to express syntax relations.

3.4 Keyword Extraction by TextRank

Algorithm TextRank [22] was developed based on the main idea of the PageRank algorithm that Google search engine uses to rank website cite zhou2019chip, langville2008google, berkhout2016google. The bottom line of the TextRank algorithm is to use graphs to represent text and to score important information about the structure in which the text is represented by keywords. In other words, the TextRank algorithm processes a group of keywords representing the entire text. TextRank ranks words by their importance, arranges them in descending order of computed value, and extracts the most important words. The number of important words is a hyperparameter which is determined by the user prior to the TextRank algorithm execution. This algorithm is successfully applied for keyword extraction based on key value from a single text and this is also the advantage of TextRank.

The TextRank algorithm represents the textual source as a graph $G = (V, E)$ where V is the set of vertices and E is the set of edges in the graph. E is derived from a subset of V x V. Each vertex of the graph G corresponds to one word extracted from the text. An edge between any two vertices is created when their words appear in the text at any position between 2 and N. The value for the importance of the vertex V_i is calculated using the following formula:

$$S(V_i) = (1-d) + d * \sum_{j \in \text{In}(V_i)} \frac{1}{|\text{Out}(V_j)|} S(V_j)\,, \tag{1}$$

where $d = [0, 1]$. In our experiments, d is set to 0.85 by default [22]. $\text{In}(V_i)$ is the collection of vertices that point to it, and $\text{Out}(V_i)$ is the collection of vertices that vertex V_i points to it. The TextRank algorithm can be presented in the Algorithm (1).

Algorithm 1 Implementation of TextRank algorithm.

Input: Textual data
Output: Extracted keywords K

1: Build the graph $G = (V, E)$
2: Compute the edges' importance score by Equation (1)
3: Sort the edges by their scores
4: Select top K edges

3.5 Keyword Extraction for Topics

At this stage, we build a sample set of keywords for each topic from a set of keywords extracted from the subject-labeled texts in the training set. The model of building a set of keyword samples for topics can be summarized as Figure (3). The keywords of the topic are calculated by the statistical method of the number of occurrences of each word in the list of keyword sets of training text. Words that are keywords of one topic cannot be keywords of another topic.

3.6 Similarity Measurement by Jaccard Distance

Mathematically, there are many ways to calculate the similarity between any two keyword lists R_i and any R_j, provided they are of the same length. However, in the context of the similarity between two documents, we do not need to include all words in the text but only the representative keywords T. The number of keywords represented will be a lot less than the entire word in the text. Then, a weighted version of the Jaccard [23] distance is determined as follows:

$$\text{Jaccard}(R_i, R_j) = \frac{1}{T} \sum_{d=1}^{T} \frac{\left|R_{i,d} \cap R_{j,d}\right|}{\left|R_{i,d} \cup R_{j,d}\right|}, \tag{2}$$

4 Experiments

4.1 Datasets

Data are collected from highly reputable Vietnamese websites. We used Teleport pro [2] software for automated data collection. The downloaded data is converted to plain text file and saved to the corresponding folders with the folder name as predefined theme name. Specifically, data is downloaded from the website [3] [4] [5] [6] with 15 main topics. These topics are summarized in Table (1). The

[5] http://tuoitre.vn
[6] http://yahoo.com.vn

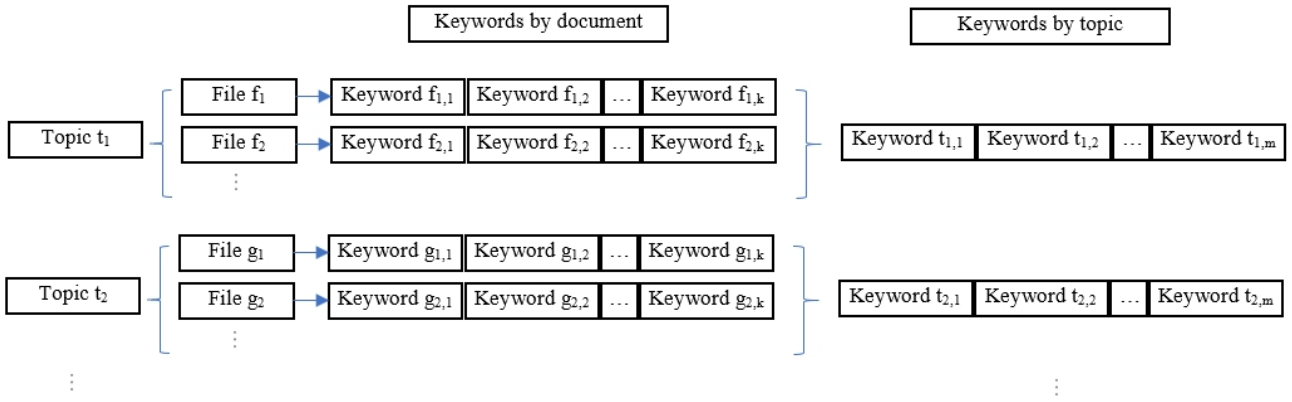

Figure 3: The keyword extraction for topics.

collected data was distributed into 80% training data group and 20% test data group.

Table 1: Summary of 15 topics

#	Topic	Description
1	Music	Singers, songs, musicians, performers, audiences.
2	Cuisine	Food, restaurants, cooks, menus.
3	Movies	Cinemas, genres, actors/actresses.
4	Tourism	tourist destinations, resorts, attractions, hotels.
5	Family	Marriage, family, grandpa, father, mother.
6	Education	Education and training, enrollment, students.
7	Science	Research, inventions, scientific discoveries.
8	Business	market, buying and selling, gold prices, currencies.
9	Beauty	beauty salon, care, therapies.
10	Motorcycle	motorbikes, cars, prices, comparison, repair.
11	Law	Legal, criminal, police events.
12	Health	health information, hospitals.
13	Sports	soccer matches, games, scores, comments.
14	Fashion	Field of fashion, costumes, designers, stylists.
15	Computers	Digital technology, computers, operating systems.

4.2 Evaluation Metric

We define the number of true positive (TP), true negative (TN), false positive (FP), and false negative (FN). We also define m_+ the total of condition positives, m_- the total of condition negatives, $\hat{m}_+$ the total predicted condition positives, $\hat{m}_-$ the total predicted condition negatives, and m the total population. Then, we compute the sensitivity or recall by using:

$$\text{recall} = \frac{\text{TP}}{m_+} . \tag{3}$$

We compute precision as follows:

$$\text{precision} = \frac{\text{TP}}{\hat{m}_+} . \tag{4}$$

Then, we compute F1-score as follows:

$$\text{F1-score} = 2\frac{\text{recall} \cdot \text{precision}}{\text{recall} + \text{precision}} . \tag{5}$$

Table 2: Statistics on all experimental scenarios.

# Keywords	Accuracy (%)	Training time (s)	Test time (s)
10	75.27	2155	1111
15	82.47	2156	1116
20	85.87	2162	1114

all	**95.40**	9279	1362

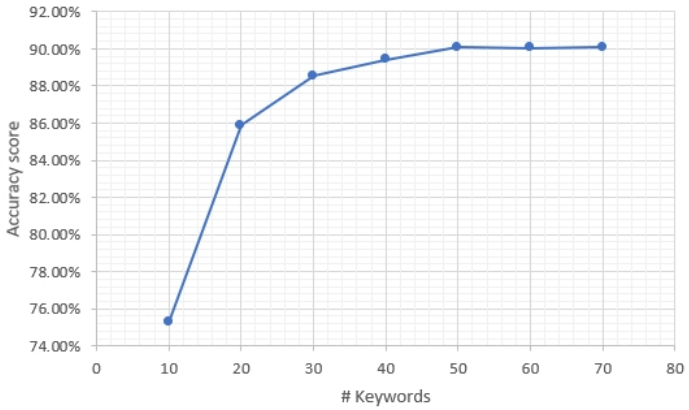

Figure 4: The correlation between the number of keywords and accuracy score.

4.3 Experimental Results

In the experiments, the authors have designed several scenarios where the number of keywords is varied to test the model's performance. The number of keywords $T = \{10, 20, 30, 40, 50, 60, 70\}$ and

in an extreme scenario where all the keywords selected by the TextRank algorithm are used. The experimental results are presented in Table (3), Table (4), Table (5), Table (6), Table (7), Table (8), Table (9), and Table (10) respectively.

15	2	0	2	0	1	0	1	10	3	10	0	0	0	2	**69**	69
Average accuracy																**75**

The authors also make statistics on all experimental scenarios in Table (2). Note that *all* in the Table means all the tokens in a particular text. The texts' length is varied, and the average number of tokens is 500. We plotted the correlation between the number of keywords and accuracy scores in Figure (4). The accuracy of 90% is stable at 50 keywords. In Figure (5), we observe a considerable increase from 60 to 70 keywords. While in Figure (6), the test time grows eventually.

5 Conclusion

In this article, the authors have described a proposed approach that allows text classification based on the solution of extracting specific representative keywords of the text. We discussed the proposed system in detail from the abstract design, text pre-processing, and Vietnamese characteristics. Then we described the TextRank algorithm based on graphs to score important information about the text's structure. Intensive experiments have been conducted to prove the stability and robustness of the proposed system. High accuracy of 90.07% has been achieved. Although many Vietnamese documents are electronically available, this is the first to conduct text classification based on keywords. This research portrays our endeavor to construct a practical framework for addressing Vietnamese texts' classification tasks on news websites.

ABSTRACT

Feature selection method applied on an intrusion dataset is used to classify the intrusion data as normal or intrusive. We have made an attempt to detect and classify the intrusion data using rank-based feature selection classifiers. A set of redundant features having null rank value are eliminated then the performance evaluation using various feature selection algorithms are done to determine the behavior of attributes. We can distinguish the key features which plays an important role for detecting intrusions. There are 41 features in the dataset, out of which some features play significant role in detecting the intrusions and others do not contribute in the detection process. We have applied different feature selection techniques to select the predominant features that are actually effective in detecting intrusions.

1. Introduction

Intrusion Detection System (IDS) works as an application or device which identifies some hostile activities or as policy violations by the intruder in network. IDS is used to analyze the network traffic and detect some possible intrusive activities in the computer network. Mainly misuse detection system and anomaly detection system are the two types of intrusion detection systems. It is capable of detecting probable attacks from the known patterns or signatures, and identify some intrusive activities which deviates from normal behavior in a monitored system, and can detect some unknown attacks [1]. The most popular IDSs are SourceFire, McAfee, and Symantec, which plays an important role for network surveillance and monitoring, and functions like a network security guard. IDS can be categorized as Network based Intrusion Detection System (NIDS) and Host based Intrusion Detection System (HIDS) [2]. In NIDS, the Intrusion Detection System (IDS) is installed before and after the firewall to capture network traffic for the entire network segment, but in HIDS, the Intrusion Detection System (IDS) is applied on a specific host to analyse packets, logs and system calls. As compared to NIDS, HIDS is more suitable for identifying the internal attacks.

We have applied a number of techniques to analyze the intrusion data and build a system that has higher detection rate.

2. Data Mining-based Approach

Data mining is a method of discovering a way of systematic relationship of data and an approach of determining the fundamental information of data. It is broadly divided into two categories such as supervised and unsupervised approach. Classifications and clustering are the best examples of supervised and unsupervised algorithms respectively. In a clustering approach, the group of unique objects are based on the characteristics of such data points [3]. Where these data points in a cluster is similar to other data points in the cluster and is dissimilar to the data points in different cluster. By grouping such similar data points into one cluster which shows the abnormality identification. Hence this approach may be responsible for potentially increase of the false alarm rate. The performance of IDS is highly dependent on the low false alarm rate, which may degrade the performance when it generate high false alarm [4]. Classification is one of the best supervised approach used for classifying the benign or anomalous data, for reducing the false alarm rate. It has the ability to differentiate unusual data pattern, which may be suitable for identifying new attack patterns [5]. Classification is widely used for its strong ability in identifying the normal structure very accurately, which contribute towards its reducing false detection [6]. These ensemble techniques are used to combine several classifiers which obtain better prediction for its accuracy in performance [7].

2.1. Classification

A classification technique (also known as classifier) is a systematic approach to build the classification models from an input dataset. Some of the techniques like Decision Tree based classifiers, Rule based classifiers, Neural Networks, Naïve Bayes classifiers and Support Vector Machines etc., each of the technique employs a learning-based algorithm to identify a model that best suits the relationship between the set of attributes and class label of input data. The generated model by learning algorithm should fit both input data well and also correctly predict class labels of records. The primary objective of the learning based algorithm is to build a model with good generalization and capability; i.e., the models that accurately predict the class labels of previously unknown records. This classification is done using a training set which consists of records whose class labels are known and must be provided. To build a classification model, using this is subsequently applied to the test set, which consists of records with unknown class labels.

The performance of a classification model is evaluated based on the classification of test records correctly and incorrectly predicted by the model. The counts of the predicted values are tabulated in a table known to be confusion matrix. For the learning and classification, we have used various machine learning techniques. There are two major categories of machine learning techniques, namely, Supervised and unsupervised technique, supervised technique requires an initial training phase where the algorithm is trained using existing dataset with appropriate classification. The algorithm then uses this knowledge to perform the real-time classification of test data. Conversely, the unsupervised technique does not require any existing classification method and basically use multiple runs to fine tune the classification patterns.

2.2. Decision Tree

Classifying the test record is a straightforward approach once a decision tree is being constructed. Basically starting from a root node, we go on applying the test condition to the records and follow to the appropriate branches based upon the outcome of the test result. This will lead to us either to the internal node, to which the new test condition is being applied or to the leaf node. This class label which is associated with the leaf node is then assigned to the record.

There are many decision trees, which can be constructed from a given set of attributes, where some of the trees are more accurate than others, and finding a optimal tree is computationally infeasible because of exponential size of the size of the search space. A number of algorithms have been developed to induce, with a reasonably accurate and albeit suboptimal decision tree constructed in a reasonable amount of time. Such algorithms employ a greedy strategy that design a decision tree by taking a series of locally optimum decisions about which, attributes are to be used for partitioning the data. One of such algorithm is Hunt's algorithm, which is the basis of most of the existing decision tree induction algorithms, including, C4.5, Classification and Regression Trees (CART), and Iterative Dichotomiser 3 (ID3). An efficient algorithm to build a decision tree is C4.5, used for classification (also known as statistical classifier), can be described as "a landmark of decision tree program that is probably the machine learning workhorse and most widely used in practice to date".

2.2.1. Random Forest

The most versatile tree-based machine learning algorithm, which is used to build several trees (or decision trees), and then combining each of the output to improve the generalization ability of the building model. This method of combining the trees (i.e combining weak learners (or individual trees) to produce a strong learner (a Forest)) is also known as an ensemble method. Random Forest algorithm can be used to solve the regression problems (where the dependent variables are continuous) and classification problems (where the dependent variables are categorical).

In a given data frame, the tree stratifies or partitions the data, based on rules (such as if-else), then these rules divide the dataset into a number of distinct and non-overlapping regions. Such rules are determined by the use of variable's contribution to the homogeneity or pureness of the respective resultant child nodes. In the regression trees (where the output is predicted by the mean of observations at the terminal nodes), the splitting decision is based on minimizing the RSS. The variable, which leads to the greatest possible reduction in RSS, is chosen in the root node. The tree splitting takes a top-down greedy approach (which is also known as recursive binary splitting) , because the algorithm cares to make the best split, at the current step rather than saving a split for better result on future nodes.

2.3. Feature Selection

Feature selection is a process of selecting a subset of M features from a set of N features, so that the feature space is optimally reduced based on a certain evaluation criteria. The objective of feature subset selection method is to find a optimum set of features such that, the resulting probability distribution of the data classes is as close as possible to the original distribution obtained using all the attributes [8]. Feature selection process used to improve the classification performance by searching for a subset of features, which best classifies the training data. In a high dimensional feature space some of the features may be redundant or irrelevant, which may deteriorate the performance of classifiers [9]. It is very much important to remove these redundant or irrelevant features. It is necessary to find the subset of features involves in the selection process to improve the prediction of accuracy or decrease the size of the features in the dataset without significantly decreasing the prediction accuracy of a classifier which is built using only the selected features.

Feature selection is the foundation of machine learning [10], a process of discovering the most useful and prominent features for the learning-based algorithm. It is very much important to extract the set of redundant or irrelevant features need to prevent the classifiers from being biased and required to minimize the feature selecting error so as to improve the abnormal behavior and detection rate. This is because of the application of appropriate algorithm and its effectiveness highly dependent on the feature selection process. Filters and wrappers [11] are the two generalized methods used in feature selection. Filter-based subset evaluation (FBSE) method is used to remove the redundant features inside the filter ranking [12]. This process examines the complete subset in a multivariate way and select the relevant features and explores the degree of relationship between the features.

Henceforth FBSE is a heuristics approach which involves the probability and statistical measures for searching and evaluation of the usefulness of identified features. The wrapper based subset evaluation (WBSE) method use the classifier for estimating the worth of each feature subset. Basically WBSE methods have greater predictive accuracy as compared to FBSE method, because the selection approach is optimized, when evaluating each of the feature subset using classification algorithm. So more or less the WBSE method use a classification based algorithm for evaluation of each set of features. But WBSE method becomes uncontrollable, at the time of dealing with large databases with many features [13]. Hence, WBSE methods are highly associated with the classifier algorithm which makes it more difficult at the time of shifting from one classifier to another classifier because of the re-initiation of selection process. But the FBSE method uses distance measures and correlation functions for selection criteria of features [14]. Where FBSE method do not need re-execution of different learning based classifiers and hence its execution process is more faster than WBSE. So FBSE is favorable for large databases environment which contains many features.

The statistical based detection approach introduced by [15] based on the collection of data for creating normal behavior profile. Here traffic data over a period of time is collected for utilization of intrusion detection. In Packet Header Anomaly Detection (PHAD), the abnormal patterns are recognized using the packet characteristics and behaviors. The normal profile is constructed using statistical measurement of activity history[16]. A set of traffic can be defined as intrusive, that are deviated from normal profile and behaved abnormally. PHAD uses all of the 33 attributes of a packet header that represents information of data link, network and transport layers of 7 layer OSI model without using IP address and port number, The probability of each packet being benign or tending towards abnormal behavior is measured by the information contain in each attribute. For any such dissimilarity detected at the time of matching against the training data, an anomaly score is given. The anomaly score for each packet is summed-up, and if the score surpasses the preset threshold then it is flagged as anomalous.

Network-based and host-based are two different environments in Protocol based Packet Header Anomaly Detection (PhPHAD) of conventional PHAD system [17]. TCP, UDP and ICMP are the three main protocols used to construct normal profile. The Light weight Network Intrusion Detection System (LNID) has been proposed to identify the malicious packets in Telnet traffic. In LNID, the behavior is extracted from the training data to construct the normal profile which is further used for computing the anomaly score. This anomaly score is used to match between training and testing data. Then surpassed preset threshold score packets are treated as malicious packets. To reduce computational cost the insignificant features from the training data are removed during preprocessing phase.

Rank based feature selection: Feature ranking method calculate the score of each attribute and arrange them in descending order according to their score. The performance of six ranking methods used for feature selection is divided into entropy based attribute evaluator and statistical attribute evaluator technique. Entropy based attribute evaluator technique is used in information theory to characterize the purity of an arbitrary collection of samples. Information Gain (IG), Gain Ratio (GR) and Symmetrical Uncertainty (SU) are the entropy based attribute evaluators used to measure system's unpredictability. Whereas One Rule (One R), Chi Squares and Relief-F Attribute evaluators are statistical attribute evaluator techniques.

3. Rank-based Classification

We have used most of the efficient data mining classification algorithms used for IDS. The Best-First Decision Tree based (BFT) classifier, basically used for binary splitting of both normal and numeric valued attributes, the decision tree learner based on imprecise probabilities and uncertainty measures (CDT), the class implementing decision Forest Algorithm (FPA) using bootstrap samples and penalized attributes [18] , the building of Functional Trees (FT) for classification, more specifically functional trees uses logistic regression based functions at inner nodes and leaves. This algorithm can also deal with the binary as well as multiclass target variables, along with nominal attributes and numeric and with missing values [19]. A Hoeffding Tree (VFDT) is incremental based, anytime decision-tree induction algorithm, which is capable of learning from a massive data stream. Hoeffding trees exploit the fact that, an optimal splitting attribute can often be chosen from a small sample [20], the class for generating a pruned or unpruned C4 (J48) [21] and the class for generating a pruned or unpruned C4.5 Consolidated Tree Construction (CTC) algorithm (J48Consolidated) in which a set of subsamples are used to build a single tree, where the Resampling Method (RM) [22] is built with a few new options added to the J48 class, whereas the class for generating a grafted (pruned or unpruned) C4 (J48graft) [23] and the class for generating a multi-class alternating decision tree using LogitBoost strategy (LADTree) [24]. The classifier for building a Logistic Model Trees (LMT), in which the classification trees are the logistic regression functions of the leaves. This algorithm can also deal with the binary as well as multiclass target variables, along with nominal attributes and numeric and with missing values [25]. The class for generating decision tree with Naïve Bayes classifiers at the leaves (NBTree) [26]. A class for constructing a forest with Random Trees (RF) [27] and the class considers K number of randomly chosen attributes at each level of node (RT) for constructing a tree. The. Fast decision tree learner (REPT) which builds a decision tree or regression tree using the information gain or variance and prunes it using the reduced error pruning method with backfitting, and the Implementation of the decision forest algorithm SysFor (SF) [28].

4. Dataset used

The KDDCUP99 dataset is derived from the DARPA98 network traffic data in 1999, which assembled individual TCP packets into TCP connections. Each of the TCP connection having 41 features along with a label that specifies a specific type of attack or normal as a status of a connection. Dataset consists of 38 numeric features and three symbolic features, which are again classified into following four different categories [29]. First nine (f1-f9) features are used to describe each TCP connection. In this category all the attributes are being extracted from a TCP/IP connection, and these features lead to an implicit-delay in detection. The second thirteen (f10-f22) are domain knowledge related content features used to indicate that suspicious behavior in the network traffic having no sequential patterns. But unlike

Table 1: The Various types of Attacks and their Classifications

Attack Category/ Attack Name		Attack Description
Denial of Service (DoS)		In such attack an attacker tries to make the system's computing/ memory resources too busy or full to handle the legitimate requests, or denies such legitimate users to access a system. The most possible ways to launch the DoS attacks are by abusing the computers for legitimate features, and by targeting the bugs, or by exploiting the system's misconfiguration.
	Back	A DoS attack against the apache web server, in which a client requests URL containing many backslashes, that slows down server response
	Land	A DoS attack where remote host sends a UDP packet with same source and destination, freezes the machine
	Neptune	Syn-flood DoS attack on one port or on more ports
	Ping of Death	DoS ping-of-death
	Smurf	A DoS attack in which a large number of ICMP (Internet Control Message Protocol) packets with its intended victim's spoofed source IP may broadcast to computer network using IP broadcast address. By which the victim's computer may slow down for devices on a network intending to send a reply to the source IP, in a flooded traffic of large no of packets.
	Teardrop	A program, sends IP fragments to a machine which is connected to a network or internet. It is a DoS attack that exploit an overlapping IP fragment bug which is present in Windows 95, Windows NT and Windows 3.1 Operating System Machines. This bug causes TCP/ IP fragmentation reassembly code for improperly handle overlapping IP fragments, which needs a reboot for preferred remedy.
Remote to Local (R2L)		In such attack an attacker without having a registered account in a remote machine, that send packets to machine on a network and exploits the vulnerability for illegally gain local access as a user on that machine.
	Ftp_write	The remote FTP user creates .rhost file in the world writeable anonymous FTP directory that obtains local login which gains user access.
	Guess_passwd	An attacker tries to gain access to the user account, by repeatedly guessing possible passwords.
	Imap	A remote buffer-overflow using Imap port that leads to root shell which gains root access.
	Multihop	Multi-day scenario by which a user first breaks into a machine.
	Phf	The exploitable CGI script that allows a client to execute the arbitrary commands on a machine using misconfigured web server.
	Spy	That sends packets to a machine over a network through it which doesn't have an account in the target machine.
	Warezclient	The user used to download illegal software that was previously posted using anonymous FTP by the warezmaster
	Warezmaster	Exploits a system bug associated with FTP Server.
User to Root (U2R)		Using such attack, an attacker used to access to a normal user account attempts to exploit system vulnerabilities to gain root access to the system. A class of such attacks are the regular buffer overflows, that are caused by the regular programming mistakes and the environmental assumptions.
	Buffer_overflow	Such type of attacks are designed to trigger the arbitrary code execution using a program and by sending it to more than that it supposed to receive.
	Load Module	Non-stealthy load module attack, that resets IFS for the normal user and that creates a root shell.
	Perl	The perl attack sets a user-ID to root in a perl script and it creates a root shell.
	Root kit	A Multi-day scenario where the user installs one or more components of a rootkit.
Probes		In such attack an attacker who scans network of computers to get information or to find known vulnerabilities. An attacker with the information of map of machines and services over a network that can be used to exploit. There are different types of probes, few of them abuse computer's legitimate features or social engineering techniques. These class of attacks are the most commonly heard, which requires little technical knowledge or expertise.
	Satan	A publicly available tool which probes the network for security vulnerabilities and for misconfigurations.
	Ipsweep	The surveillance sweep is performing either a port sweep or ping on multiple host which identifies the active machine.
	Nmap	Network mapping using nmap tool, identifies active ports on a machine.
	Portsweep	The Surveillance sweep is performing either a port sweep or ping on multiple host address.

DOS and Probing attacks, the R2L, and U2R attacks don't contain any intrusion frequent sequential patterns, because DoS and Probing attacks involve many connections to the host(s) in a short period of time, so the R2L and U2R attacks are embedded with the data portions of packets and normally involve a single connection. Hence, we need some features to detect such attacks, which may look in the data portion for the suspicious behavior, (as an example a number of failed login attempts) are called content features. The third nine (f23-f31) time-based traffic features are designed to capture the properties that mature over a two second temporal window, (as an example the number of connections to the same host over a two second interval). Final fourth ten (f32-f41) host-based traffic features basically utilize a historical window, which are estimated over a number of connections instead of time, such features are designed to access attacks, with span intervals are longer than 2 seconds [30]. There are 41 feature attributes for each connection record plus one class label, out of which 38 are numeric and 3 are symbolic. Symbolic attributes are protocol type, service, and flag. Discrete data can be numeric but it can also be categorical, continuous data are always numeric and are not restricted to define separate values and can take any value within a range [31]. The various types of attack with their categories are discussed in the table [32]. The severity of the attack and the classification is discussed.

There are 125973 number of records of the dataset is; out of which 53.48 percent are normal and 46.52 percent of records are of intrusive types. There are 24 different types of attack which can be mainly classified into four categories, such as Danial of Services (DoS), Remote to Local (R2L), User to Root (U2R), and Probing.

Table 2: Different Types of Attack and their Class Occurrences

Class Type		Number of Instances	% of Attack Type	% of Attack Class	% of Total Class Occurences
DoS		45927	-	78.33	36.45
1	neptune	41214	89.74	70.3	32.72
2	teardrop	892	1.94	1.52	0.71
3	smurf	2646	5.76	4.51	2.1
4	pod	201	0.44	0.34	0.16
5	back	956	2.08	1.63	0.76
6	land	18	0.04	0.03	0.01
Probes		11656	-	19.88	9.25
1	ipsweep	3599	30.88	6.14	2.86
2	portsweep	2931	25.15	5	2.33
3	nmap	1493	12.81	2.55	1.19
4	satan	3633	31.17	6.2	2.88
R2L		995	-	1.7	0.78
1	warezclient	890	89.45	1.52	0.71
2	guess_passwd	53	5.33	0.09	0.04
3	ftp_write	8	0.8	0.01	0.01
4	multihop	7	0.7	0.01	0.01
5	imap	11	1.11	0.02	0.01

7	Phf	4	0.4	0.01	0
8	Spy	2	0.2	0	0
U2R		52		0.09	0.04
1	rootkit	10	19.23	0.02	0.01
2	buffer_overflow	30	57.69	0.05	0.02
3	loadmodule	9	17.31	0.02	0.01
4	Perl	3	5.77	0.01	0
Total Attacks		58630	-	-	46.52
Normal		67343	-	-	53.48
Total Instances		125973			100

In the intrusive data set around 36.45 percent data are of DoS type, about 9.25 percent data are of Probes type, 0.78 percent of R2L type and 0.04 percent of U2R type.

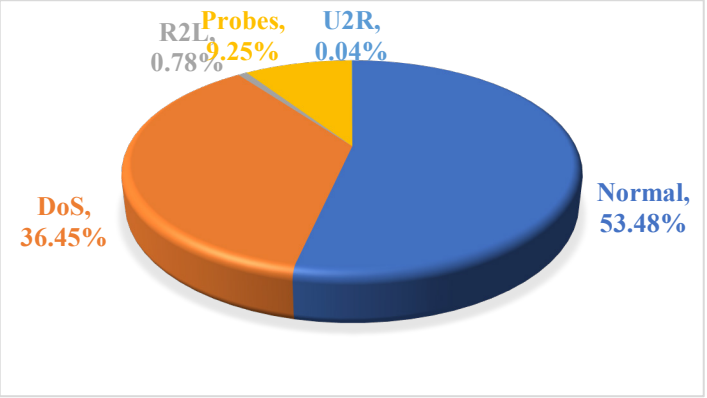

Figure 1: Percentage of Instances of Various Attack Classes

The figure describes various attack categories, around 78.33 percent of data are of DoS type out of which 70.3 percent are of Neptune type, 1.52 percent teardrop, 4.51 percent smurf, 0.34 percent pod, 1.63 percent pod and 0.03 percent of land type attacks. There are 19.88 percent Probes type, where 6.14 percent are ipsweep, 5 percent are portsweep, 2.55 percent are nmap and 6.2 percent are satan type of attack. Nearly 1.7 percent are R2L type of attack, in which 1.52 percent are warezclient, 0.09 percent are guess_passwd, 0.01 percent are ftp_write, 0.01 percent are multihop, 0.02 percent are imap, 0.03 percent are warezmaster, 0.01 percent are phf, and 0.0 percent are spy. In the 0.09 percent of U2R attack, there are 0.02 percent rootkit, 0.05 percent are buffer_overflow 0.05 percent are loadmodule, and there are 0.01 percent perl type of attack.We have applied the rank based feature selection method to compute the rank of the features and the order of the features based on their rank is as follows. The order of the features varies with the different feature selection approach. The rank based feature selection approach applied on the various set of data set of NSL KDD Cup data set is as follows. The rank of the features varies with the

change of rank based feature selection approach applied on various classes of data. The order of the features varies based on their rank values and feature selection mechanism. The rank for different features varies based on their contribution in the selection process is mentioned below. The rank value signify the contribution of the feature to the different class of data.

With the application of rank based feature selection approach, we found the rank value of the features in the above mentioned table is '0' (Null), So these features do not contribute in the process of intrusion classification. The rest of the features mentioned in the below table are responsible in the classification of the Intrusion data.

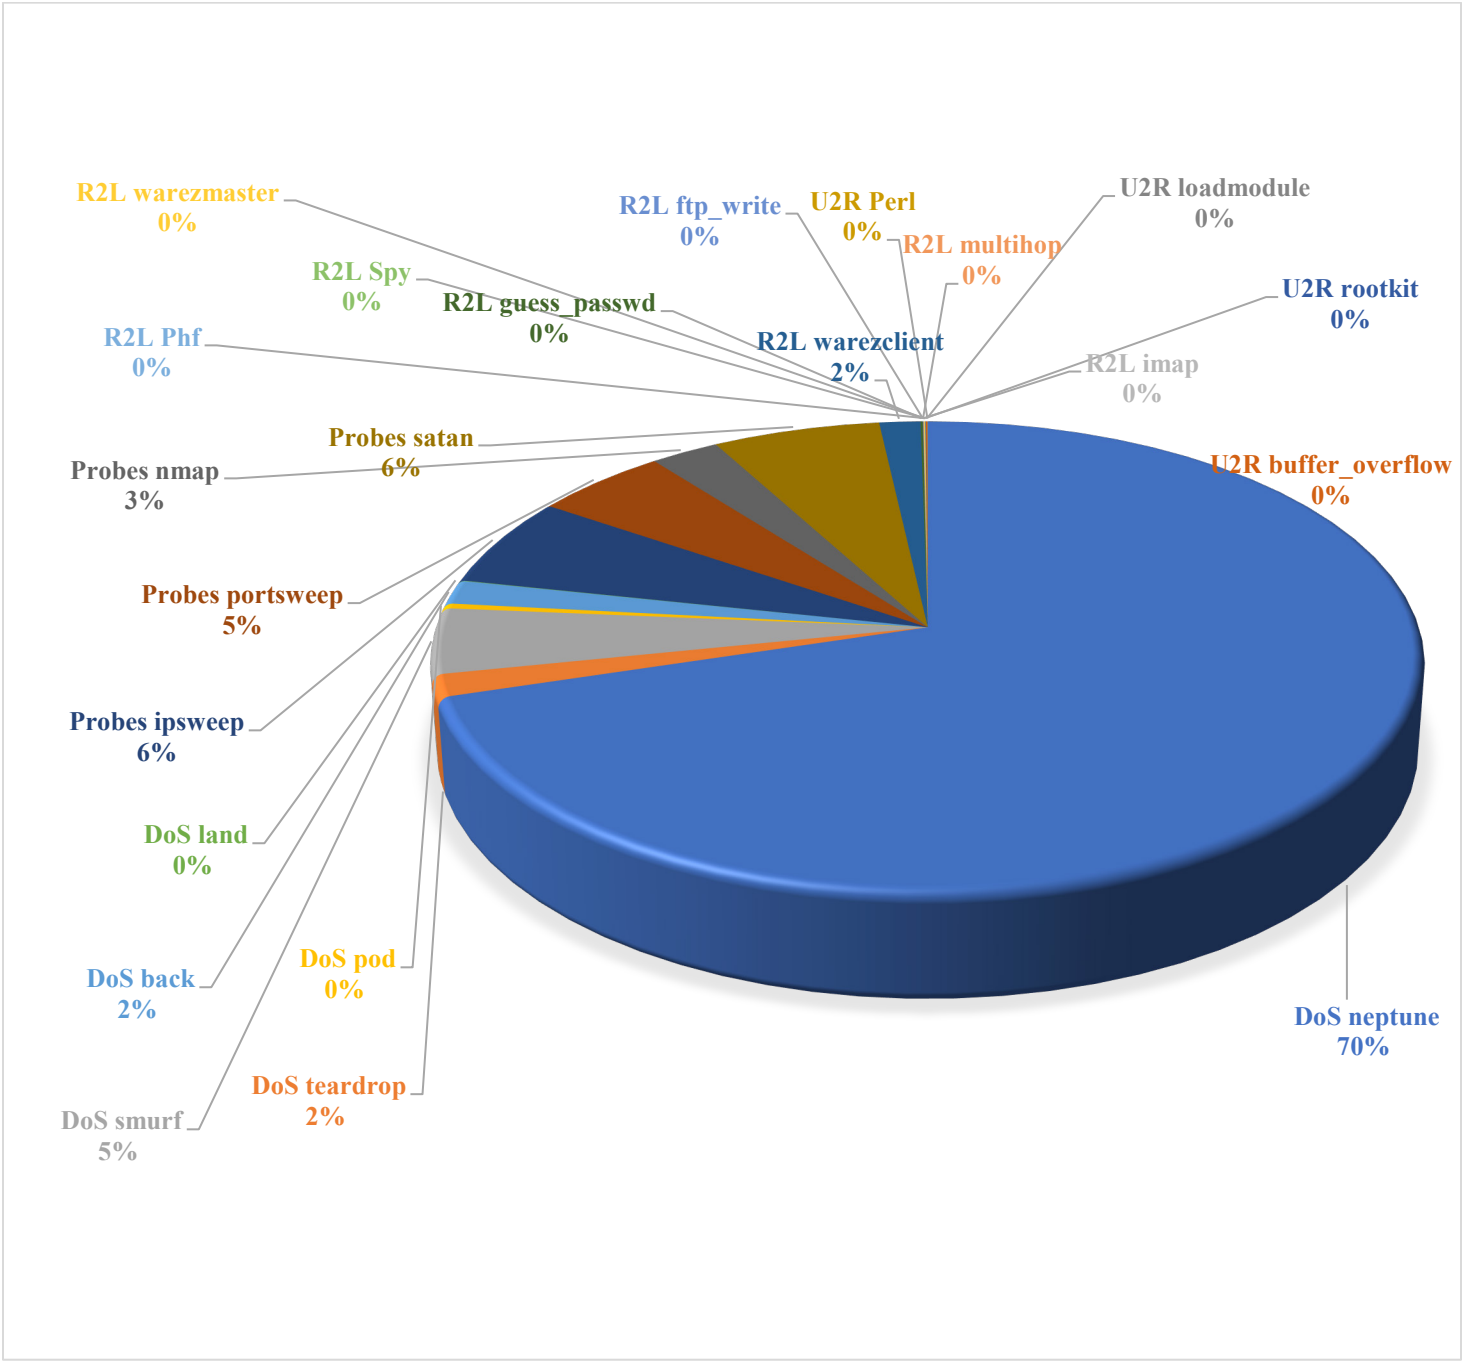

Figure 2: Percentage of Instances of Various Attack Types

Table 3: Number of features do not Contribute in Selection Process

Feature Selection Approach	Number of Features	Feature Selection	Name of Feature	Rank Value
NSL KDD'99 (All)	2	f20, f21	Nu_ob, Is_ho_lg	0
NSL KDD'99 (DOS)	11	f11, f20, f22, f18, f19, f17, f14, f9, f15, f16, f21	N_f_login, Nu_ob, Is_gu_lg, N_shell, Nu_ac_fl, Num_f_cr, R_shell, Urgent, Su_attem, Num_roo, Is_ho_lg	0

5. Experimental Setup

We have tested the various machine learning methods on KDDCUP'99 dataset. In this experiment we have used a computing environment of core i7 processor, 2.6 GHz, 8 GB RAM, 1TB hard disk and windows 10 (64 bit) operating system. The various tree based classifiers have been used to classify different types of DOS, Probes, U2R and R2L attacks.

Table 8: Classification of Various DOS Attacks Using Different Classifiers

Sl. No.	Classifier	Classified Percentage	Unclassified Percentage
1	BFT	99.9935	0.0065
2	CDT	99.9956	0.0044
3	FPA	99.9913	0.0087
4	FT	99.9978	0.0022
5	HT	99.9673	0.0327
6	J48	99.9826	0.0174
7	J48C	99.9935	0.0065
8	J48G	99.9804	0.0196
9	LADT	99.9826	0.0174
10	LMT	99.9978	0.0022
11	NBT	99.9956	0.0044
12	RF	99.9913	0.0087
13	RT	99.9760	0.0240
14	REPT	99.9956	0.0044
15	SF	99.9826	0.0174
16	Min	99.9673	0.0022
17	Max	99.9978	0.0327
18	Avg	99.9882	0.0118

The result shows that FT and LMT has classified about 99.9978 percent. The performance of the tree based classifier has been observed on the KDD CUP'99 DOS attack type dataset. The classified result has been plotted in the below mentioned graph.

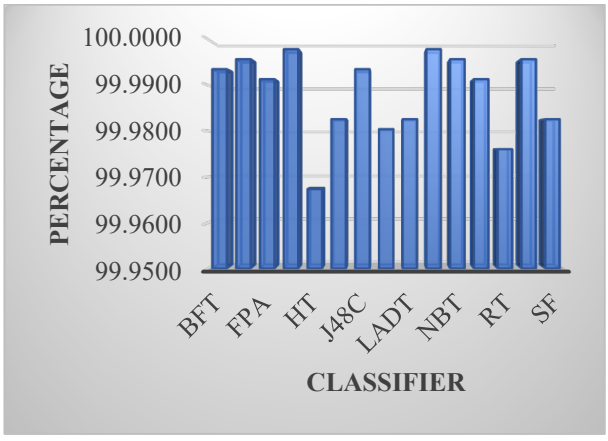

Figure 3: The Classification of Various Attack Type of DOS Attack

We have observed the result of the various classifiers applied on the rank-based feature selection methods. Information Gain (IG), Gain Ratio (GR) and Symmetrical Uncertainty (SU) feature selection methods have been applied to measure the performance and classification of various attack type. The accuracy and classification rate of few tree based classification algorithm is very high. The performance of the various algorithms and the classification percentage is reflected in the plotted graphs.

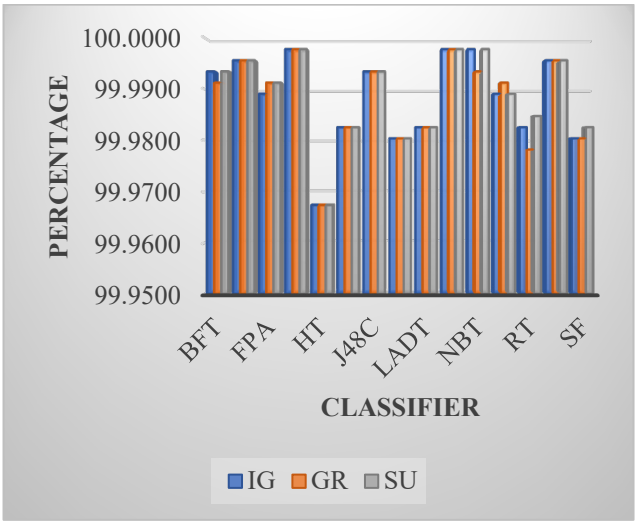

Figure 4: The Classification of Various Attack Type of DOS Attack Using Feature Selection

Further in the rank-based feature selection classification process we have applied a range of features to monitor the change in classification process. We have selected a number of features from the set of 41 features in the dataset and found there are 30 number of features participating or contributing in the classification process. We have applied various tree based classification algorithms to classify the NSL-KDDCUP'99 (DoS) Dataset and found the rank of the features are contributing in the classification process. There are 11 number of features whose rank value is null, which are not participating in the classification process. The performance of the J48 algorithms and the classification percentage is reflected in the plotted graphs.

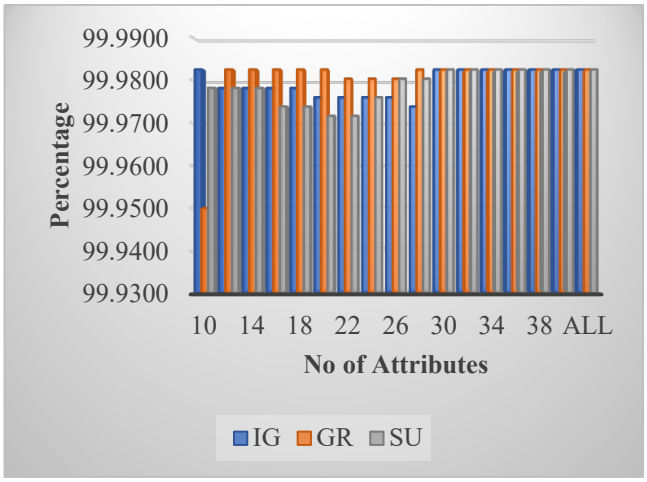

Figure 5: The Classification of Various Attack Type of DOS Attack Using Feature Selection and Attribute Selection

We have applied tree based feature selection classification technique on the NSL KDD'99 data set, The null valued redundant features are eliminated and the classification technique is applied to compute the percentage of accuracy of different attack types.

We have applied the J48, Random Forest and Functional Trees which are one the best decision tree based classification algorithm classifies the optimum accuracy of the different types of attack.

The below mentioned features are eliminated and the other non-null features are used to classify the different classes of intrusive data. The percentage of classification of different classes of attack are mentioned below.

The graph reflects the percentage of classification of different types of DOS attacks. The redundant null valued features are eliminated and the most suited tree-based algorithms are applied to find the optimum classified result.

The graph reflects the percentage of total classification of various DOS attacks. The redundant null valued features are eliminated and the most suited tree based algorithms are applied to find the optimum classified result.

In the classification process there are a number of key features which plays an important role to classify and determine the various attack types in the class of intrusive dataset. We have applied the same algorithms to determine the percentage of classification of various attack types using the key features.

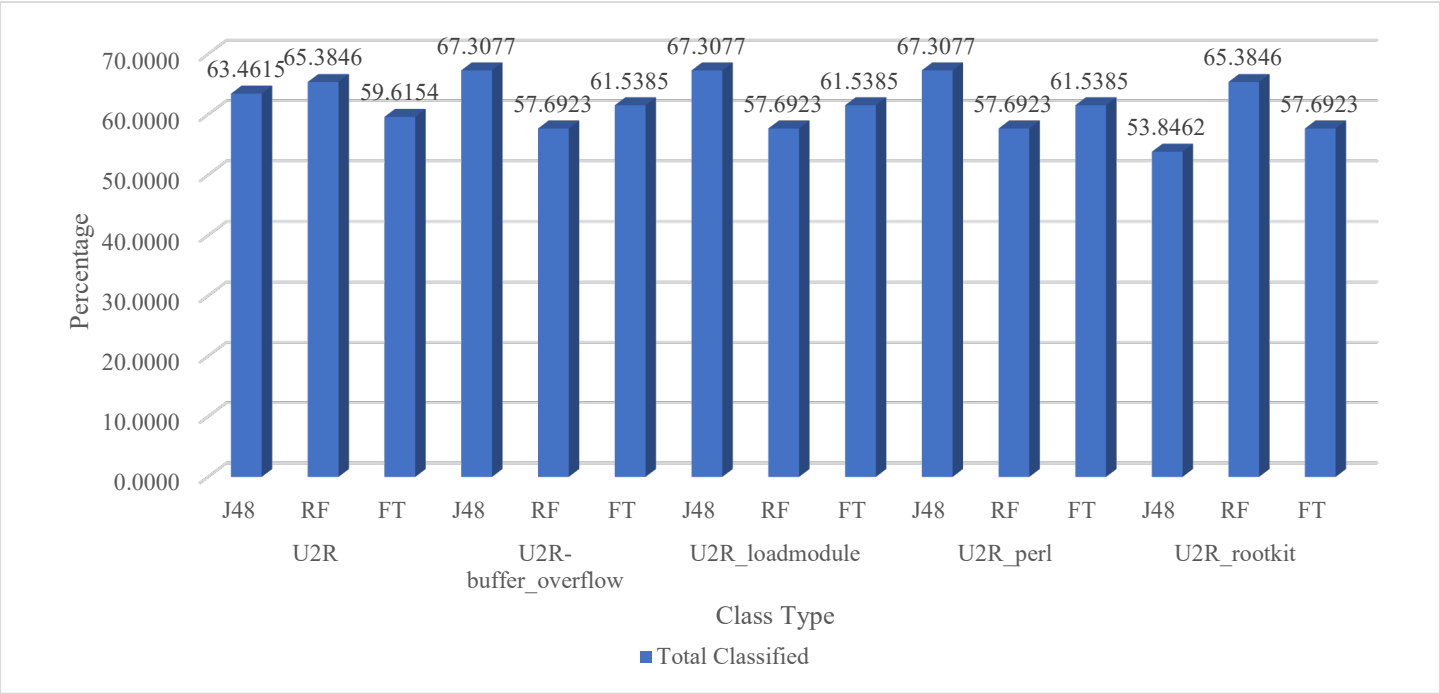

Figure 19: The Total Classification of Various Attack Class Types of U2R Attack by Selecting Key Features

The graph reflects the percentage of total classification of various U2R attacks. The appropriate key features for U2R attack are applied and the redundant null valued features are eliminated then the most suited tree based algorithms are applied to find the optimum classified result.

6. Conclusion

The classification of various attack types is based on the percentage of total classified. The null rank valued features are eliminated and the selected features are applied to find the optimum classification result. The various attack classes are selected and the attack types are classified on the basis of classification result. Various tree-based classification algorithms are used and the results are optimized based on their classification percentage. The optimized result is compared with the result computed by selected key feature. The computed result is merely dependent and influential by the selected key feature. The null valued features are eliminated and the contributing features are selected. Finally, the key feature is selected from the list of contributing features and the result is optimized.

Average Gaze Position
Viewing Position

ABSTRACT

Ultra-high resolution broadcasting such as 4K and 8K are becoming more popular for at-home use. The position of the viewer's mean gaze point when they are looking at a larger display depends on the video clip, viewing position, and viewing distance. The International Telecommunication Union provided the document BT-2022; as the standard viewing conditions for the subjective evaluations of flat-panel TV displays. However, it is rare that a television is viewed at home under standard viewing conditions. In most homes, a TV of any size is watched from the viewer's desired position according to the layout size of the room hosting the TV. No study has been conducted to determine how the movement of a viewer's line of sight changes when a display with different resolution is viewed from a position different from the standard viewing condition. If the gaze position when viewing TV differs due to the difference in resolution, the size of the display, and the difference in observation position, it affects the method of TV production. This would also affect consumers considering the resolution, installation location, and viewing location of a TV. Here, we clarified that the mean gaze position and its standard deviation are almost the same viewing conditions (i.e., resolution, display size, and viewing position) are changed, even when the same contents are viewed. Our findings demonstrate that consumers could buy a display of their preferred resolution and size according to their room layout.

1. Introduction

In Japan, high-definition broadcasting with a resolution of 2K has become widespread, and the public use of ultra-high-definition 4K and 8K broadcasting began on December 1, 2018. In the International Telecommunication Union (ITU-R) document 'BT-2022' ('General viewing conditions for subjective assessment of quality of SDTV and HDTV television pictures on flat panel displays'), the standard viewing distance for a television's display is defined as the maximum distance at which a person with a visual acuity of 1.0 can see the pixel structure [1]. Since the current HDTV broadcasting has approx. 2 million pixels at 1920×1080, the standard viewing distance when watching HDTV images is 3H (H; Display height). In contrast, 4K broadcasting has ~ 8 million pixels at 3840×2160, and that of 8K broadcasting has ~ 33 million pixels at 7680×4320.

It was reported that when the resolution becomes higher, the pixel structure cannot be seen even when one is approaching it, and thus it is possible to view from a closer distance and enjoy a wide-angle image [2]. The ITU-R stipulates that a viewer should watch from the center of the front of the screen even when approaching the screen, but at each home, the viewing position differ depending on the room layout, the number of viewers, the size of the TV purchased, and more. The display is frequently viewed from sites that are not at the center of the screen. According to a survey of TV viewing positions, the positions spread horizontally ±60° and vertically ±30°, and 37% of viewers look at the display from the right side of the TV, only 3% from the center, and 60% from the left side [3]. When watching a movie on a large screen, the impression of the movie varies greatly depending on the position of the viewer's seating, such as the center of the screen, the left and right edges of the front seats, and the rearmost seats. However, no research has examined how the position of the content where a viewer views on a TV display changes depending on the position of the viewer's seating. If the content is viewed differently depending on the seating position, the producers of televised content must consider the effects of the viewing position when producing the content. Consumers seeking a TV to purchase also need to consider where to put the TV and furniture.

*Corresponding Author: Miho Shinohara, 0cjnm010@mail.u-tokai.ac.jp

A study of the differences in the viewing of contents depending on the TV's resolution compared NTSC; analog color system with (525 scanning lines) and high-definition (1,125 scanning lines) [4]. In the low-resolution NTSC, the viewer's gaze points are distributed in the center of the screen because multiple cameras are switched in order to provide the camera shot that the content's director wants to show in the center. In high-definition, the entire screen is displayed, and the viewers' gaze points are spread over the entire screen. Several research groups have verified the differences in viewing distance by using parameters such as screen size, display brightness, resolution, and video content [5-8]. In those studies, the contents were viewed from the center position of the display, and the viewing position was not changed in the horizontal or vertical direction. In addition, an NTSC or phase alternating line (PAL) system was used (not higher-definition 4K), and the results cannot always be applied to a 4K or 8K display. In the present study, using 4K high-definition images that have never been used, we examined the differences in viewers' lines of sight when they were watching television from a distance that is not the standard viewing distance and from various positions (right, center or left). Viewing 4K or 8K ultra-high-definition TV with large-screen images from a wide field of view at a short distance has become established in for home use. As a result, viewers are more likely to see at various viewing positions, not limited to the center of the screen, as seen in movie theaters, but there is no study that examined the effect of viewing position on viewing behavior from eye movements. Therefore, our present findings will provide meaningful data for both viewers and video producers to know whether or not the observation position affects the gaze position.

The purpose of our research is to objectively evaluate the psychological effects of changes in display resolution, size, and viewing position on viewing behavior from eye movements. For that purpose, two kinds of experiments were conducted.

In Experiment 1, we analyzed the influence of the display resolution on the viewing positions of individuals watching three video clips on the display. We showed the subjects a video clip whose resolution was 4K (3840×2160), 2K (1920×1080) or 1K (960×540) at the viewing distance of 0.75H. In Experiment 2, we analyzed the influence of the size of the screen on the viewing position. We showed the subjects a video clip whose screen size was 1/1, 1/2 or 1/4 at 0.75 H as the viewing distance [9].

2. Experimental Method

2.1. Experimental equipment

When viewing a 4K image at the viewing distance of 1.5H, the field of view is 60°. The range that a human being can see by using only saccades, which is a high-speed eye movement, is up to 15° [10]. Head movements are used together with eye movements to exceed the 15° range. It was reported that head movements contributed twice as much as the eye movements when moving the line of sight to fixate at one point [11]. It is also known that in the ratio of head movement to the line of sight, the head share becomes 60%-80% when the line of sight moves outside a 30° range [12, 13]. We thus surmised that in this experiment, it was necessary to detect changes in the line of sight that included the addition of the subjects' head movements to their eye movements. We used the line-of-sight measuring device developed in our laboratory [14]. The accuracy of the horizontal direction was approx. 1.5° to -1.7° at ±30° corresponding to the visual angle of the display edge at 1.5H. The accuracy of the perpendicular direction was approx. 2.6° to -1.4° at ±18°, corresponding to the visual angle of the display edge at 1.5H [4]. We measured eye movements (EMR-8B; Nac Image Technology, Tokyo) and head movements (3DM-GX4; Microstrain, Williston, VT, USA). Data were recorded at 60 Hz. In the experiment, the subjects looked at the display in a free posture without being fixed on the head-chin rest of the experimental set-up.

2.2. Viewing conditions

The viewing distance of the display was fixed at 1.5H, and the subject was allowed to view the display from three positions: the center (display center), the right (1/4 to the right from the display center), and the left (1/4 to the left from the display center) as shown in Figure 1. The standard viewing distance for image-quality evaluations is not 1.5H when the image resolution is 2K or 1K, or when the screen size is 1/2 or 1/4: however, in a most households, the room layout is prioritized, and the viewing distance often does not change even if the screen resolution or size changes. We therefore fixed the viewing distance. Since the subjects' head movements were measured simultaneously with their eye movements, the subject's head movements were not restricted and the subject was instructed to watch the TV in a natural posture. The subjects watch videos with three types of resolution, three screen sizes, and three viewing positions, but each subject was prevented from seeing the same image more than once. This experiment was conducted according to BT-2022 and followed the Ethical Provisions of Tokai University's guidelines for "Research using humans."

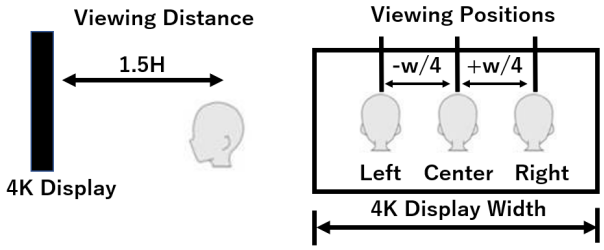

Figure 1: Viewing conditions.

2.3. Laboratory environment

The video clips were presented to a 4K projector (VPL-VW 500ES; Sony, Tokyo) using a personal computer (PC) as the signal source. The height of the screen was 147 cm, the width of the screen was 262 cm, and the screen brightness was 0.04 cd/m^2 at the minimum and 104 cd/m^2 at the maximum. The illuminance in the room was 69.7 Lux. The layout of the laboratory, the procedure of the experiment, and the selection of subjects were based on BT-2022.

2.4. Changes in gaze position due to the difference in resolution (Experiment 1)

The details of the video clips used in Experiment 1 are shown in Table 1 and in Figures 2-4 (scenes used for video clips 1-3). The 4K video clips consisted mainly of natural scenes (mountains, flowers, seas) and were downloaded from a free video clips material website [15]. The 4K video clips were recorded in the

60p/XAVCS format, which is also used for broadcasting, and have low compression. Each video clip length was 40 sec. The series of 4K video clips was edited to a length of approx. 4 min with the use of nonlinear editing software (VegasPro13; Sony). The 2K and 1K video clips were down-converted from 4K video clips using the same nonlinear editing software. A still video showing the fixation point in the center was inserted before and after each video clip presented to the subject, so that it could be recognized even if the calibration of the eye movement was misaligned. The subjects were 25 college students (10 males and 15 females) in their twenties, seven of whom had the visual acuity score of >1.0: the other 18 had the visual acuity score of 0.7 (including corrected vision). We analyzed the data of 21 of the 25 subjects (seven males, and 14 females) because four subjects had a large number of measurement errors during the experiment. No subject viewed the same image more than once. Each subject was randomly determined which image to view at which resolution and viewing position.

Table 1: Video clips used in Experiment 1

Video clip	Time	Resolution
Video clip 1: River, ship or bridge	4 min 14 sec	4K, 2K and 1K
Video clip 2: Cherry blossoms or Mt. Fuji	4 min 2 sec	4K, 2K and 1K
Video clip 3: Town or animal	4 min 9 sec	4K, 2K and 1K

Figure 2: Scenes used for video clip 1.

Figure 3: Scenes used for video clip 2.

Figure 4: Scenes used for video clip 3.

2.5. *Changes in gaze position due to the difference in screen size (Experiment2)*

The details of the video clips used in Experiment 2 are shown in Table 2 and Figures 5-7 (scenes used for video clips 1-3). The video clips were edited as in Experiment 1, and 1/4-size and 1/2-size video clips were generated by reducing the number of pixels from 4K video clips using the nonlinear editing software. The subjects were 24 college students (nine males and 15 females) in their twenties, eight of whom had a visual acuity score of >1.0: the other 16 had a visual acuity score of 0.7 (including corrected vision).

Nineteen of the 24 subjects also participated in Experiment 1. There were no measurement errors in the data of all 24 subjects, and all were used for analysis. No subject viewed the same image more than once. Each subject was randomly determined which image to view at which screen size and viewing position.

Table 2: Table 2. Video clips used in Experiment 2

Video clip	Time	Screen size
Video clip 1: Flowers	4 min 7 sec	1/4, 1/2, 1/1 size of 4K
Video clip 2: Okinawa	4 min 2 sec	1/4, 1/2, 1/1 size of 4K

3. Results

The distribution of the gaze points of each subject was analyzed while the subject viewed the video clips. We used 10 deg/s as the threshold speed for extracting the gaze point from the gaze movement [16]. The horizontal and vertical components of gaze were calculated by the following formulas.

Horizontal components of Gaze = Horizontal components of Eye movement + Horizontal components of Head rotation

Vertical components of Gaze = Vertical components of Eye movement + Vertical components of Head rotation

The mean gaze position and its standard deviation (std. dev.) during viewing have often been used to compare the gaze behaviors of individual watching video clips [4]. We thus calculated the mean gaze position and its std. dev. from the remaining 4 minutes of data excluding the 1 minute immediately after the presentation of the video clips, at which point the data were not stable.

The mean gaze point position and the std. dev. of the mean gaze point distribution showed the same tendencies in all three video clips, and we therefore analyzed the data of the three video clips together. We performed a two-way analysis of variance (ANOVA) to analyze the results. The level of significance was set at 10%.

3.1. Results of Experiment 1: Change in gaze position due to the difference in display resolution (Experiment 1)

During the measurement of a person's gaze, there may be many blinks, or the eye movement sensor may shift, causing an error in eye movement. Of the 21 subjects test in Experiment 1, the seven subjects who had almost no measurement error during the measurements for all the 1K, 2K, and 4K video clips were used for the analysis in order to perform statistical analysis with all the accurate data, because, it is extremely difficult to perform all experiments completely without measurement errors due to the nature of eye movement measurement. Figure 8 shows the averages and standard deviations of the mean gaze point positions of these seven subjects. In the figure, the center of the screen is 0°, and the angles displayed on the horizontal and vertical axes represent the viewing angles used by the subject. Figure 9 shows the mean gaze positions obtained by summarizing the results of the three viewing positions for each resolution.

The mean gaze position at the left and right viewing positions was around the center of the screen, and the average gaze position at the central viewing position was slightly left of the center of the screen regardless of the resolution, as shown in Figure 8. In the summary of the results of the three viewing positions, the mean gaze position is located at the center of the screen regardless of the differences in resolution, as shown in Figure 9. These results suggest that there was a slight difference in the mean gaze position depending on the viewing position, but it was not due to the difference in display's resolution.

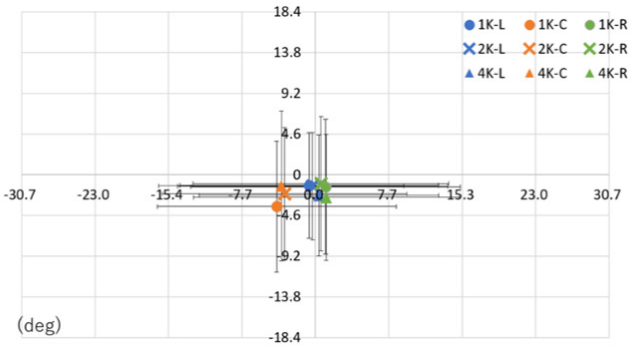

Figure 8: Averages of the mean gaze position and std. dev. (resolution and viewing position)

The results of the two-way ANOVA for mean gaze position with resolution and viewing position as variables are illustrated in Figure 10. No significant differences were observed for resolution, but a multiple comparison analysis revealed a significant difference in viewing position in the right-central and left-central positions. No significant differences were detected in the std. dev. of mean gaze position as shown in Figure 11; however, there was a slight but significant difference in viewing positions at the 10% level of significance.

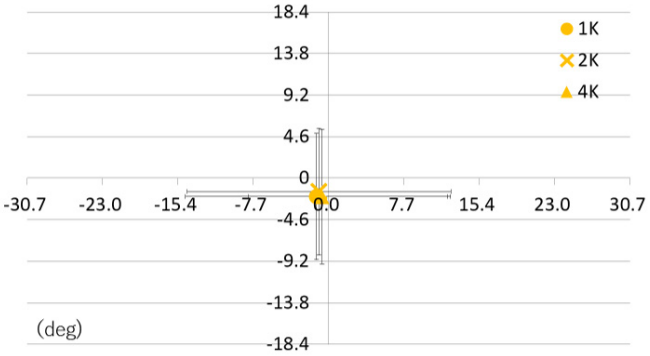

Figure 9: Averages of the mean gaze position and std. dev. (resolution).

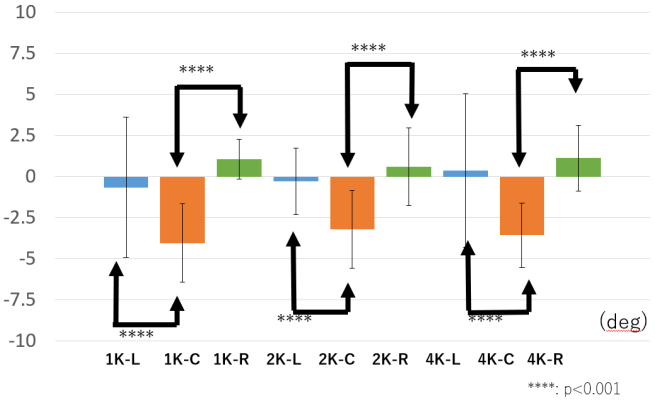

Figure 10: Results of the two-way ANOVA for mean gaze position (resolution).

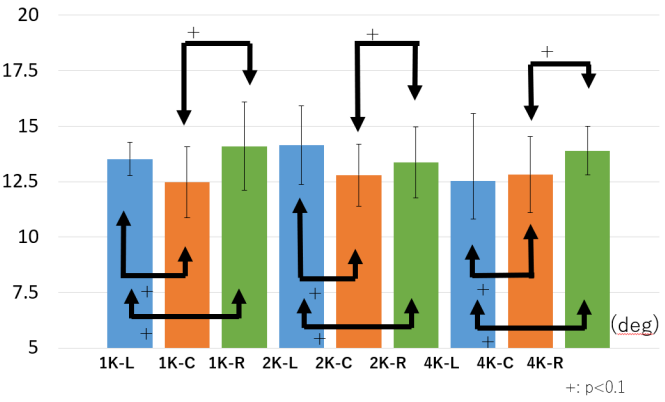

Figure 11: Results of the two-way ANOVA for the std. dev. of mean gaze position (resolution).

3.2. Results of Experiment 2: Change in gaze position due to the difference in screen size (Experiment 2)

In Experiment 2, of the 24 subjects, eight who had almost no measurement error during the measurements for all of the 1K, 2K,

and 4K video clips were used for the analysis to perform the same accurate statistical analysis as in Experiment 1. The average mean gaze position of these eight subjects who viewed 1/4-, 1/2- and 1/1-size video clips at each viewing position is shown in Figure 12. Figure 13 provides the mean gaze positions obtained by summarizing the results of the three viewing positions for each resolution. In this experiment, since only the screen size was changed without changing the viewing distance, the angle of viewing the screen expected from the subjects would be 1/4 and 1/2 for the 1/4 and 1/2 sizes, respectively. Therefore, to examine whether each subject gazed at the same place in the display and had the same gaze range, we normalized these graphs to the 4K 1/1 size.

The results for a 1/4-size image (Fig. 12) indicated that the subjects viewed the area to the right of the center screen from the left and central viewing positions, and they viewed the screen center from the right viewing position. The results for a 1/2-size image (Fig. 12) revealed that the subjects viewed the area to the right of the center screen from the right and central viewing positions, and they viewed the lower right of the screen from the left viewing position. The results for a 1/1-size image (Fig. 12) demonstrated that the subjects viewed the area to the right of the center screen from the right and central viewing positions, and they viewed the screen center from the left viewing position. The results shown in Figure 12 suggest that the mean gaze position depending on the viewing position tended to change slightly when the size of the screen becomes small. According to Figure 13, the average of the results for all subjects and all viewing position regardless of the screen size shows that the mean gaze position falls in the area to the right of the center screen.

The results of the two-way ANOVA for mean gaze position are illustrated in Figure 14, and those of the two-way ANOVA for the standard deviation of the mean gaze position are shown in Figure 15. No significant differences in the size of the screen or in viewing position were revealed by the two-way ANOVA. Although the mean gaze position tended to change slightly depending on the viewing position when the screen size and viewing position changed, the mean gaze position and the standard deviation of the mean gaze position did not show significant differences.

4. Discussion

There were no significant differences in the mean gaze position or the standard deviation of the average gaze position due to differences in resolution, even when the viewing position was changed. Similarly, even when the viewing position was changed, no significant differences were found in the average gaze position or the standard deviation of the mean gaze position due to differences in screen size.

The tendency for the initial gaze position to fall at the center of the image when looking at a still image is called center bias. Photographer bias and viewing strategies have been suggested to be major factors in center bias [7]. Photographer bias is the practice of placing an object or the actor in whom the photographer is most interested near the center of the screen. With respect to viewing

strategies, people usually turn their eyes to the center of the image, having learned through frequent experience with photographer bias that objects that attract attention are generally arranged around the center of the screen. We believe that our present results in which the subjects watched the screen center regardless of differences in resolution and the size of the screen demonstrate a tendency similar to center bias; that is, while center bias is defined as a tendency to look to the center of a still image, our subjects looked to the center of video clips, rather than still images.

5. Conclusion

Broadcasting in 4K and 8K ultra-high-definition video has started, and viewers can enjoy high-definition, wide-angle video near the display. The conditions for subjectively evaluating a display are strictly defined by the ITU-R. Subjective evaluations of displays by broadcasters and manufacturers are performed under these conditions. However, in the home where the display is actually located, the display is viewed at a free position according to the size of the TV, the layout of the room, and structure of the household. For example, when watching a movie in a large-screen movie theater, the viewers experience a different sense of presence and emotion after viewing from the seats at the left and right ends of the front row, the seats at the center of the movie theater, and the seats at the rear. Television broadcasting is also expected to be viewed from various positions in the home by viewing a high-definition, wide-field display. If the impression produced by the image differs depending on the viewing position, it is necessary for the consumers as well as the image producers and the display manufacturers to take this into consideration.

However, the evaluations of displays are performed according to the ITU-R and are rarely performed under the different conditions. Our present experiments show that the mean gaze position during viewing depends on the video clips, the viewing position, and the viewing distance, with the size and resolution of the display fixed and the viewing position as a parameter [17]. This research was conducted with a constant display size and resolution, but in reality, displays with various resolutions and sizes are found in various homes, and it has been necessary to investigate the effects of resolution and size. Therefore, in Experiment 1, we used the resolution and the viewing position as parameters, and in Experiment 2, the screen size and the viewing position were used as parameters, and the mean gaze position and its standard deviation were analyzed. In analyses of the gaze behavior of still images such as photographs, the average gaze position and the variance of gaze points are examined by heat maps and other methods, and there is a photographer bias that places the part that the photographer wants to show to the viewer in the center [18]. It is thus known that there is a center bias in which viewers empirically tend to see the center of the photograph [19].

In addition, regarding evaluations of the viewing of TV images, the mean gaze position and its standard deviation are often used to compare gaze behaviors while subjects watch video clips [4, 17], and we thus applied the mean gaze position and its standard deviation to the analysis of viewing behavior when the resolution, screen size, and viewing position were changed. When 4K-resolution content is viewed from 1.5H, the field of view seen from the eye is 60°. It was reported that the range of visual information that can be captured only by eye movements in daily activities is at most 15° [10]. We therefore, measured the line of sight (head movement + eye movement) with the subjects in a free posture without fixing the head in the device that we developed that can measure head movement and eye movement at the same time [14].

In Experiment 1, the resolution was changed to 1K, 2K, and 4K, and the mean gaze position and its standard deviation were obtained by changing the viewing position using the same-size display. The difference in the mean gaze position was seen by the difference in the viewing position. Notably, the mean gaze position was different between the central viewing position and the left and right viewing positions. There was a slight change in the standard deviation of the mean gaze position due to the difference in the viewing position. However, the changes in the mean gaze position and its standard deviation were slight.

In Experiment 2, the display size was changed to 1/4, 1/2, and 1/1, and the mean gaze position and its standard deviation were obtained by changing the viewing position using the same resolution. The mean gaze position and its standard deviation did not change even when the screen size was changed.

With the introduction of 4K and 8K broadcasting, broadcasting media and video contents have diversified. However, in each home, displays with various resolutions and sizes are being viewed at any viewing position. Our present results demonstrated that when the same content was viewed at different resolutions, screen sizes, and viewing positions, there was almost no change in the mean gaze position, which is one of the viewing behaviors. This means that video producers can engage in program production without needing to being aware of the resolution of the display to be viewed, the screen size, or the viewing position. In addition, consumers can purchase a display according to the size and layout of the room and their preferences, and watch their television from any position.

ABSTRACT

The article describes a way to increase the efficiency of an abrasive tool by its impregnation in an aqueous solution of chromium diiodide. The device scheme for impregnating the instrument is proposed. Research results of durability of tools impregnated with chromium diiodide and structural condition of material of a surface layer of details after processing are resulted. Within of the researches presented in the article the grinding processing a shafts made from various iron-carbon steels with prepared abrasive tools was conducted. As a result of the machining the scattering fields of the batch sizes of the parts within the grinding wheel resistance were determined. This data for processing with standard grinding wheels and impregnated by chromium diiodide were done. Using data from controlled grinding of workpieces, approximate values of the K_{Δ} coefficient were determined depending on the diameter of the workpiece surface, the required size accuracy of part and the method application of the surfactants. It is shown that regardless of the material being processed, the use of a grinding wheel impregnated with chromium diiodide leads to a reduction in the specific value of the accumulated deformation energy E_{spec}. Taking into account these results it is possible to predict up to twofold reduction of the cost of machining with the abrasive tool of grinding parts, which will reduce the cost of their manufacture by 20-25%. The developed process of impregnating grinding wheels with chromium diiodide can be used without large economic costs in many machine-building company also during repair works.

1. Introduction

The problem of increase of efficiency of abrasive processing of surfaces of machine parts remains actual in machine-building manufacture and one of the perspective directions of its decision is impregnation (saturation) of abrasive tools with surfactants.

There are known methods [1] of abrasive instruments [2] impregnation [3,4] with paraffin, ozokerite, phenolformaldehyde resin, sulfur, rosin, cerezin, stearin, potassium ethylxantogenate, sodium silicate solution, aromatic chlorine-containing compounds and other substances [5], compositions of several elements including fillers [6] (graphite, molybdenum disulfide, fluoroplastics, micropowders, etc.). Shortcomings of these compounds are reflected in the limited applicability and the need to select an impregnating compound depending on the material and tool, in some cases, the toxicity to humans and the use of impregnating compounds solely on a water-based, corrosive activity and insufficient retention of chemicals in the pores of the grinding wheel, reducing its hardness, etc, possible increase in quality control points and increase in the prime cost of the final product.

When grinding with impregnated wheels, there are fast processes of destruction and restoration of solid lubricating films in the contact zone between the grinding tool and the workpiece due to high speeds of molecules movement at high temperatures and pressures. The substances located in the pores of the wheel can pass into different aggregate state, and the impregnation efficiency

[*]Corresponding Author: Boris Safoklov, Email: safoklovbb@mai.ru

depends on the products of its decomposition, their penetration ability and the activity of interaction with the processed material [7].

High reactivity at interaction with metals, especially with high adhesion to abrasive material, halogens [8] and among a large number of types of surfactants, as well as methods of their application in the blasting of surfaces of machine parts the most effective is the method of impregnation of grinding wheels in an aqueous solution of chromium diiodide [9, 10], molecular formula CrI_2 [11], we have considered all the various ways to improve the efficiency of an abrasive tool, and developed a new effective method for impregnating grinding wheels.

2. Materials and Methods

To increase the efficiency of the abrasive tool there was developed an effective method of impregnating grinding wheels in the aqueous solution of chromium diiodide [11], the main essence of which is that the abrasive tool on a ceramic bond is placed in a container with aqueous solution of chromium diiodide (20-25 g per liter of water) and within one minute it is informed about the vertical oscillating motion with a certain frequency ν, which provides its complete immersion in the aqueous solution and complete removal from it [12,13]. After impregnation, the impregnated instrument is subjected to convective drying when rotating at a speed of (0.3-0.5) s^{-1} for 1.5-2 hours at a temperature of (40-50) ºC.

Vertical vibrating movements of the impregnated grinding wheel with a given frequency v and amplitude A were carried out using a special installation, shown in Fig. 1 and containing an electric motor 1, gearbox 2, cam 3, pusher 4, rocker arm 5, mobile support 6, rod 7, to which the impregnated abrasive tool 8 is attached, and a container with an aqueous solution of chromium diiodide 9.

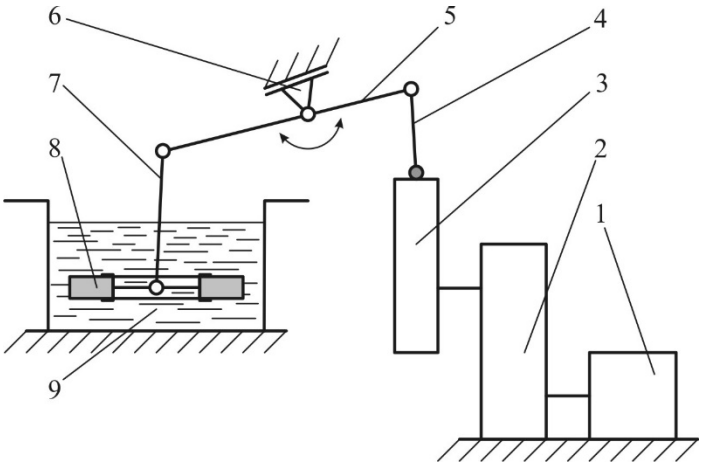

Figure 1: Plant diagram for impregnating grinding wheels

Research of efficiency of application of grinding wheels impregnated with chromium diiodide was carried out by processing of samples from steel 12CrNi3A (Table.1) with diameter 30 mm and length 200 mm after finishing turning (surface roughness before grinding Ra = 8.0-12.5 μm). Grinding of samples was carried out on a circular grinding machine mod. 3U12VF11 PP 400×50×203 14AF60K7V GOST R 5281-2007 with cutting speed V_{gw} = 35 m/s, sample rotation speed V_m = 0.314 m/s, longitudinal feed S_{lon} = 0.02 m/s, cutting feed S_{cut} = 0.01 mm / double stroke, the number of double strokes m = 3. The 5% aqueous solution of emulsion Ukrinol-14 was used as a cooling lubricant [14,15]. The change of firmness of grinding wheels T after their dressing was determined.

Table 1: Steel Type 12CrNi3A, chrome-nickel structural alloy steel products GOST 4543-2016.

C, %	Si, %	Mn, %	P, %	S, %	Cr, %	Ni, %
0.09-0.16	0.17-0.37	0.3-0.6	≤0.025	≤0.025	0.6-0.9	2.75-3.15

With the use of scanning electron microscope "Quanta-200" were carried out spectral studies of the state of the surface layer of samples made of steel 12CrNi3A, subjected to grinding by impregnated chromium diiodide abrasive tool.

In [12,16,17,18] we have shown that the most important characteristic of the operational properties of the surface layer material of processed parts is its energy state, which can be estimated by the specific value of the accumulated energy of deformation E_{spec}. For experimental determination of the value of E_{spec} a special unit was developed, the description of which is given in [17, 19]. One of the most important indicators of the effectiveness of the use of grinding wheels is to ensure the necessary dimensional accuracy of the workpieces during the entire period of tool life. In this regard, a controlled treatment was carried out by grinding shafts of various iron-carbon alloys.

Dispersion fields for batch sizes of parts within the grinding wheel resistance were determined. A large number of shafts with diameters from 20 mm to 40 mm and tolerances of IT6-8 were subjected to controlled machining over a long period of time. Based on the obtained results of controlled machining, the scattering fields of diameters of the parts processed without the use of surfactants ω_1 and with the use of various methods of feeding the impregnative agent – chromium diiodide into the machining zone (impregnation, additive to lubricant-and-cooling technological agent, introduction into the abrasive mass) ω_2 were determined. The scattering fields were determined after processing each batch of 10 pieces. The scattering fields were compared when the first batch ω_1^b, ω_2^b was processed and the last batch ω_1^e, ω_2^e was processed.

3. Results

3.1. The effectiveness of the use of chromium diiodide

The results of research into the effectiveness of the use of chromium diiodide impregnated grinding wheels are presented in the form of histograms in Fig. 2, from the analysis of which it follows that the resistance of chromium diiodide impregnated grinding wheels in the process of dressing decreases: first significantly, then on average by 3-5% after each dressing, and then starts to grow again. This is apparently due to the continuous washing out by the lubricating and cooling fluid of the impregnator chromium diiodide from the intergranular space of the grinding wheel.

3.2. The analysis of spectrograms

The analysis of spectrograms of electronic microscope "Quanta-200" of surfaces of details from a steel 12CrNi3A in an

initial condition and after grinding by impregnated chrome diiodide [17] speaks that in the course of grinding active iodine interacts with juvenile surfaces of details, forming on them the iron iodides having layered structure and possessing low coefficient of a friction [9, 20].

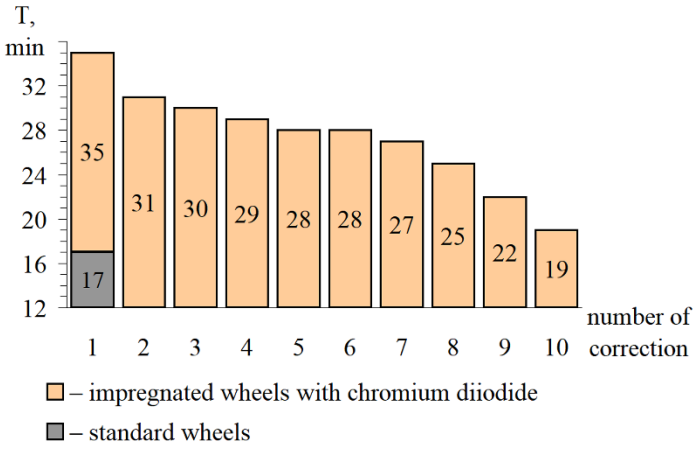

Figure 2: Histograms of changes in resistance of impregnated grinding wheels as they are corrected

3.3. Results of change of scattering fields.

Results of changing scattering fields of sizesits details ω_1 and ω_2 for the period of tool firmness at an admissible range of change of sizes of processed details in the generalized form are presented in fig. 3, which allows to trace the pattern of their change.

It was found that in all cases $\omega^b > \omega^e$, which seems to be associated with a decrease in the number of cutting grains and an increase in smoothing and pressing [21]. This is demonstrated by decreasing in the roughness parameter R_a of the treated surfaces of parts (Fig. 4) and an increasing in the value of technological residual tensile stresses in the material of the surface layer σ_{rem} (Fig. 5) with simultaneous reduction in metal removal.

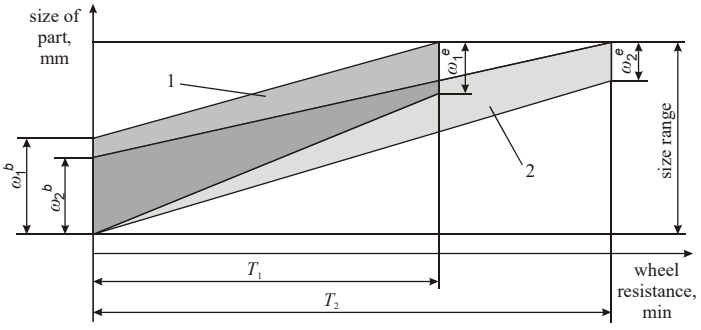

Figure 3: Diagrams of scattering fields for batch sizes of parts within the wheel resistance, processed with standard (1) and impregnated (2) tools.

Analysis of the data shown in Fig. 3, indicates that $\omega_1^b > \omega_2^b$ and $\omega_1^e > \omega_2^e$. If we take $\Delta\omega_1 = \omega_1^b - \omega_2^b$ and $\Delta\omega_2 = \omega_1^e - \omega_2^e$, then $\Delta\omega_1 \geq \Delta\omega_2$.

Using the coefficient $K_\Delta = \Delta\omega_1 / \Delta\omega_2 \geq 1$, then by its value it will be possible to decide on the degree of influence of the adopted type and method of surfactant application on the accuracy of the obtained dimensions of the processed part. Using the data of controlled machining by grinding of workpieces, approximate values of coefficient K_Δ depending on diameter of processed surface, required qualification of size accuracy and application method of impregnator (in this case, chromium diiodide) were determined, which are given in Table 2. These K_Δ values can be used during the selection a surfactant application method.

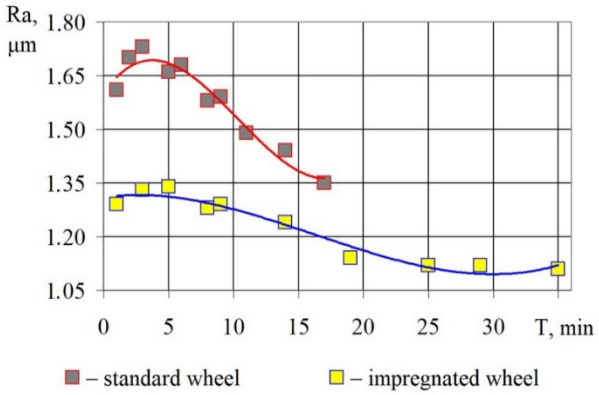

Figure 4: Changing the roughness parameter of the machined surface of the part for the period of the grinding wheel resistance T when using standard and impregnated tools (steel 12CrNi3A)

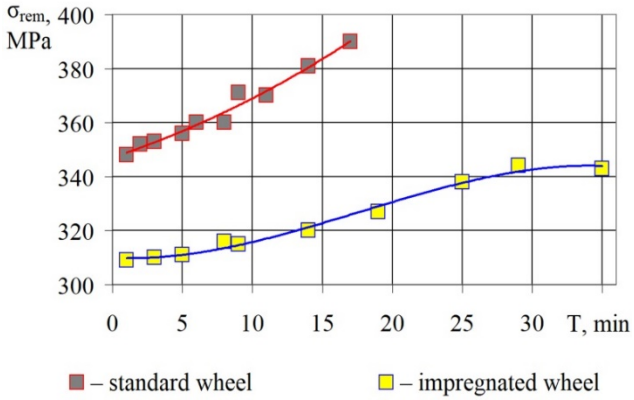

Figure 5: Variation of the value of technological residual stresses in the material of the surface layer of the machines parts for the period of grinding wheel resistance T during the use of standard and impregnated tools (steel 12CrNi3A)

Table 2: Values of coefficient K_Δ by processing parts from iron-carbon alloys with yield point 250-400 MPa

To determine the degree of influence of grinding wheel characteristics, its condition and composition of the used cooling lubricant on the specific accumulated energy of deformation E_{spec}, a significant amount of experimental studies on samples from various iron-carbon alloys, subjected to grinding on the regimes recommended in the reference [22], the results of which are reflected in Table 3. From their analysis it follows that the energy state of the material of the surface layer of the workpiece being grinded depends to a great extent on the state of the abrasive tool used and the composition of the cooling lubricant. Regardless of the material to be treated, using of a grinding wheel impregnated with chromium diiodide leads to a reduction in the specific value of the accumulated deformation energy of E_{spec}. At the same time, the injection of 20 grams per liter of chromium diiodide into the composition of the cooling lubricant also leads to a decrease in the value of E_{spec}.

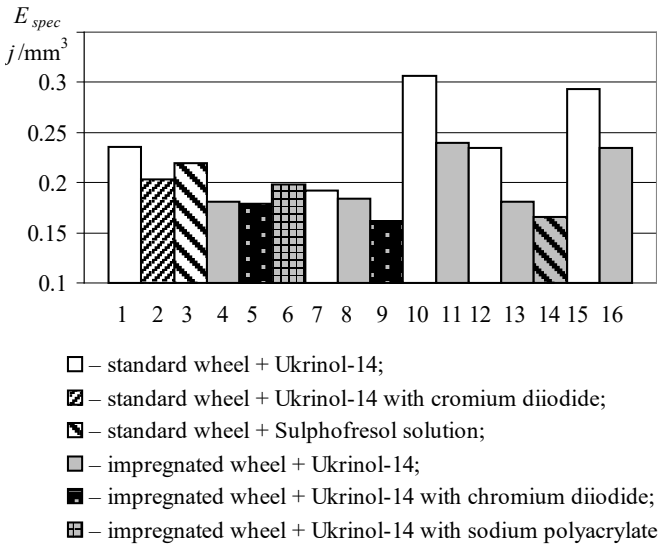

Figure 6: E_{spec} histogram of changes from the state of the grinding wheel and the composition of the used lubricating and cooling process agent

For clarity on the figure 6 is shown a histogram of E_{spec} value changes from the state of the wheel and the composition of the used the cooling lubricant when grinding samples from steel 50 (1-6), steel 12CrNi3A (7-9), alloy 45Cr25Ni20Si2 (10, 11) [23] with a wheel of 14AF60K7V and steel 50 (12-14) and alloy 45Cr25Ni20Si2 (15, 16) when grinding with a wheel of 54AF60 M7V. The histogram shows that the minimum values of E_{spec} can be achieved with the simultaneous use of chromium diiodide impregnated grinding wheel and the cooling lubricant, which consists of 5% aqueous solution of emulsion "Ukrinol-14" with the addition of 20 g/l of chromium diiodide. Apparently in this case, chromium diiodide, which is a part of lubricating and cooling technology, not only reduces the coefficient of friction in the area of contact of the abrasive grain with the processed material, but also contributes to the permanent restoration of chromium diiodide in the impregnated wheel [24-31].

Table 3: Depending of E_{spec} values on the material to be treated, grinding wheel characteristics and the composition of the lubricant and coolant used.

# Ex.	Processed material	Grinding wheel characteristic	Grinding wheel condition	Composition of the lubricant and coolant used	$E_{spec.}$ j / mm^3
1	Steel 50	14AF60K7V	standard	5-% emulsion aqueous solution Ukrinol-14	0.236
2				5-% emulsion aqueous solution Ukrinol-14 + 20 g/l chromium diiodide	0.203
3				5-% sulphofresol solution	0.219
4			impregnated	5-% emulsion aqueous solution Ukrinol-14	0.181
5				5-% emulsion aqueous solution Ukrinol-14 + 20 g/l chromium diiodide	0.179
6				5-% emulsion aqueous solution Ukrinol-14 + 20 g/l sodium polyacrylate	0.198
7	Steel 12CrNi3A		standard	5-% emulsion aqueous solution Ukrinol-14	0.192
8			impregnated	5-% emulsion aqueous solution Ukrinol-14	0.184
9				5-% emulsion aqueous solution Ukrinol-14 + 20 g/l chromium diiodide	0.162
10	Steel		standard	5-% emulsion aqueous solution Ukrinol-14	0.306
11	45Cr25Ni20Si2		impregnated		0.240
12	Steel 50	54AF60M7V	standard		0.235

17	Steel 50	64AF70P10V	standard		0.230
18			impregnated		0.177
19				5-% sulphofresol solution	0.172
20	Steel		standard	5-% emulsion aqueous solution Ukrinol-14	0.298
21	45Cr25Ni20Si2		impregnated		0.234

4. Conclusions

- The energy state of the material of the surface layer of the grinded part depends largely on the condition of the abrasive tool used and the composition of the lubricant coolant. Regardless of the material to be treated, the use of a grinding wheel impregnated with chromium diiodide leads to a reduction in the specific value of the accumulated deformation energy of E_{spec}. The injection of 20 grams per liter of chromium diiodide into the lubricating and cooling process also leads to a decrease in the value of E_{spec}.
- Thus, the processing of parts with impregnated chromium diiodide wheels allows to increase up to two times the resistance of used abrasive tools, it is quite natural to increase the size accuracy of the processed parts, to improve the

quality of the surface layer and to create on the processed surfaces of parts – rotational bodies, such as rollers, axles, fingers, etc., structures with a low coefficient of friction within 0.08-0.12 depending on the operating conditions, which is very important for the parts of tribosystems.

- Taking into account these results it is possible to predict up to twofold natural reduction of the cost of machining with the abrasive tool of grinding parts, which will reduce the cost of their manufacture to 20-25%. The developed process of impregnating grinding wheels with chromium diiodide can be used in any machine-building production, including repair, without large economic costs.

Nomenclature

E_{spec} – specific latent energy of deformation j/mm^3;
K_Δ – coefficient $K_\Delta = \Delta\omega_1 / \Delta\omega_2$;
R_a – arithmetic mean deviation of the profile (μM);
V_{gw} – cutting speed, m/s;
V_m – rotation speed, m/s;
S_{lon} – longitudinal feed, m/s;
S_{cut} – cutting feed, mm / double stroke;
Ukrinol-14 – Cooling and lubricating fluids (oil);
ω_1 – the scattering fields of diameters of the parts processed without the use of surfactants;
ω_2 – the scattering fields of diameters of the parts processed with the use of the impregnation.

14AF60K7V GOST R 5281-2007 – Grinding wheel Russian standard is adopted from the European, code example*:*

14A*F60K7V* (type of abrasive, ***14A*** – normal electro corundum);
*14A****F60****K7V* (***F*** **–** standard FEP (Federation of European Producers of abrasives) and ISO 8486, **F60** average grain size is 0.26 mm);
*14AF60****K****7V* (Hardness, ***K*** – medium soft);
*14AF60K****7****V* (***7*** – structure number indicates how much of the grinding wheel volume is occupied by abrasive grains, **7** – 48...50%);
*14AF60K7****V*** (type of bundle, ***V*** – a ceramic bundle).

Family functionality

ABSTRACT

Family functionality is when the family meets the needs of its members, especially adolescents. Resilience is the adolescent's ability to face situations in which there are difficulties, life problems and thus be able to overcome them. The purpose of the study is to determine the Level of Resilience and Family Functionality in Adolescents of two Educational Institutions of a Vulnerable Area in Lima Province. It is a non-experimental study, descriptive of a quantitative approach, it is a cross-sectional correlational investigation, with a population of 204 adolescents, also demographic data and the resilience scale (CD-RISC) and family APGAR. In the results regarding to the level of resilience and family functionality, adolescents present a mild family dysfunction with a medium level of resilience (58.0%), in comparison of the Educational Institutions, in both cases, the majority of students are located in the medium level of resilience, in the case of students from Honorio Manrique Nicho school 48.5% and in the case of students from the Andrés Avelino Cáceres school 54.2%. It is recommended in these institutions to carry out activities that promote the social formation of the adolescent, since this will allow them to communicate with society and the environment.

1. Introduction

Family plays a fundamental role in the adolescent, since it is an influential factor for the relationship with society [1]. One of the stages where one seeks to find changes in society is adolescence, adolescents try to know each other better and also seek difference from themselves with other family members, this process that the adolescent does is a change abruptly, but it is the way in which they will become autonomous and independent people, this process has passed all the members of the family [2].

Family functionality is understood when the family meets the needs of its members, especially adolescents, since it is a stage where there are differentiated changes with other family members and also adapt to situations of change [3]. So, a family is considered functional when it is able to look for solutions to any problem, so that it does not affect the satisfaction that family members have, including the adolescent [4].

Resilience is understood as the adolescent's ability to face situations in which there are difficulties, life problems and thus be able to overcome them [5]. Resilience is very important for adolescents, because it will allow them to adapt and recover from adversities of the problem so that it continues projecting itself in its future [6].

In [7], the author from Portugal presented that it was evidenced that adolescent males are those who have higher levels of resilience compared to adolescent females; in the self-

*Corresponding Author: Rosa Perez-Siguas, Mrs., +51 1 996826968 & rosa.perez@uma.edu.pe

confidence component, males obtained a score of 35.08% and in the relationship with peers, 26.28%.

In [8], carried out in Taiwan, the author mentioned that in children and adolescents, it was found that there is a risk of family dysfunction where approximately 40% of families have accumulated family risk due to family stress that occurs within their home and also 30% of the mothers have low levels of education or health problems. Lastly, around 7% of the participants, children or adolescents, come from large families that have 4 or more children living in a home.

In [9], carried out in South Korea, the author described that it was found that family dysfunction related to domestic violence and parental addiction was related to smartphone addiction, it was found that the observed association between family dysfunction and Smartphone addiction was not significant in adolescents with self-control or high friendship quality, therefore, adolescents exposed to domestic violence or with addicted parents had a higher probability of smartphone addiction, but had high self-control or friendship quality that could protect them.

The objective of the study is to determine the level of family resilience and functionality in adolescents from two educational institutions of a vulnerable area in Lima Province, in which it will allow to observe what is the level of adolescent resilience and family functionality. This study is important since it will give relevant and real data about family resilience and functionality as adolescents enter a stage of sudden changes where they seek solutions, where they can adapt and manage the situation in the most appropriate way.

In the study, the data collection instrument Connor-Davidson Resilience Scale (CD-RISC) and Gabriel Smilkstein's Family APGAR were applied, which have been useful to assess the level of resilience and family functionality of adolescents from the secondary level of educational institutions. The data collection was processed through the survey of adolescents from educational institutions, the data to be entered was performed in a data matrix that will be designed in the statistical program SPSS (Statistical Package for the Social Sciences) in its version 24.0, in which it will allow a better data processing to make statistical tables so that they can be described and interpreted in results and discussions, respectively.

The research work is structured as follows: In section II, the development of the data collection process of each nursing student will be presented, as well as the guidelines to consider so that they are in the research work. In section III, the results will show the level of resilience and family functionality of adolescents according to the specified dimensions of the instruments in the measurement of the variables. In section IV, we present the discussions and conclusions of the research work.

2. Methods

In this section, the type and design of the research will be developed, as well as the population that will be carried out in the research work, the inclusion and exclusion criteria will be explained in detail, and finally the technique and the instrument for collecting data.

2.1. Research type and design

The present research work is non-experimental, descriptive of a quantitative approach, it is a correlational research [10].

2.2. Population

The population is made up of 204 adolescents from the two educational institutions.

Inclusion criteria:

- Adolescents who normally attend the educational institution.
- Adolescents who have informed consent and assent.
- Adolescents who have the authorization signed by their parents and agree to voluntarily join the study.

Exclusion criteria:

- Adolescents who do not regularly attend to the educational institution.
- Adolescents who do not have the authorization of their parents.

2.3. Technique and Instrument

The technique used is the survey, using the questionnaire or data collection instrument (CD-RISC) and Family APGAR which aims to measure the level of family resilience and functionality in adolescents from two educational institutions of a vulnerable area in Lima Province.

The Connor - Davidson Resilience Scale (CD-RISC) was built by Connor and Davidson in the United States in 2003. Its application is for the adolescent and adult population from 11 to 80 years old, the scale evaluates the following dimensions: Persistence-tenacity-self-efficiency (8 items); Control under pressure (7 items); Adaptability and Ability to Recover (5 items); Control and purpose (3 items) and Spirituality (2 items). It consists of 25 structured items, on a summative Likert scale where 0 "absolutely", 1 "rarely", 2 "sometimes", 3 "often" and 4 "almost always". The scale range goes from 0 to 100, the higher score means more resilience [11].

The family APGAR was designed by Gabriel Smilkstein in 1978 at the University of Washington, it evaluates the following dimensions: adaptation, participation, resources, affectivity and capacity, it consists of 5 items structured on a summative Likert scale where 0 "never", 1 "almost never", 2 "sometimes", 3 "almost always" and 4 "always". The range is from 0 to 20, the higher the score mean greater the family functionality [1].

2.4. Place and Application of the Instrument

The questionnaire was carried out to measure the level of family resilience and functionality in adolescents, it was carried out at the educational institutions Andres Avelino Caceres and Honorio Manrique Nicho.

First, the necessary permissions for research are carried out, coordinated with the directors of both educational institutions to carry out the surveys, then, the permission to each classroom teacher explaining about the survey and why the research work is being carried out to they have knowledge about what is going to be done.

Table 1: Resilience level in adolescent students of both Educational Institutions of Lima Province (N=204)

		Resilience Score				
		Count	%	Mean	Minimum	Maximum
Resilience Dimension (grouped)	Low	46	22,5%	52,28	32,00	60,00
	Medium	105	51,5%	70,28	61,00	79,00
	High	53	26,0%	85,75	80,00	95,00
	Total	204	100,0%	70,24	32,00	95,00

Table 2: Family functionality of adolescent students of both Educational Institutions of a Vulnerable Area in Lima Province (N = 204)

		Family Functionality Score				
		Count	%	Mean	Minimum	Maximum
Family Functionality Dimension (grouped)	Family dysfunction	10	4,9%	7,10	2,00	9,00
	Moderate family dysfunction	29	14,2%	11,90	10,00	13,00
	Mild family dysfunction	100	49,0%	15,59	14,00	17,00
	Good family function	65	31,9%	19,15	18,00	20,00
	Total	204	100,0%	15,78	2,00	20,00

The questionnaire was carried out in consecutive shifts during the morning, at the same time as the adolescents from these institutions, the questionnaire was taken to the adolescents with an approximate time of 25 minutes in each section of secondary level (according to the inclusion and exclusion criteria) in the research work, concluding with good satisfaction when collecting the questionnaires as the adolescents supported our research.

It is important to emphasize the presence of the teacher from each surveyed classroom and the medical staff at the time of filling questionnaire of the adolescent, since most of them showed signs of having a health problem, because both educational institutions are in an area where they are exposed to natural or anthropogenic events where the probability of an event that puts adolescents in educational institutions at risk can happen and also the damage can be considerable.

3. Results and Discussions

The following tables from the surveys carried out following the guidelines corresponding to the research work will be shown in table 1.

In Table 1, the level of resilience in adolescents of both Educational Institutions of a Vulnerable Area in Lima Province, it can be seen that of the 204 adolescents surveyed, 105 (51.5%) of adolescents present a medium level of resilience, followed by 53 (26.0%) of the adolescents present a high level of resilience and lastly 46 (22.5%) of the adolescents present a low level of resilience.

In Table 2, the family functionality of the adolescents of both Educational Institutions of a Vulnerable Area in Lima Province, it can be seen that of the 204 adolescents, 100 (49%) of the adolescents present a mild family dysfunction, followed by 65 (31.9 %) adolescents present a good family function, 29 (14.2%) of the adolescents present a moderate family dysfunction and 10 (4.9%) of the adolescents present a family dysfunction.

Table 3 shows that adolescents with good family function have a high level of resilience (49.22%), adolescents with mild family dysfunction have a medium level of resilience (58.0%), adolescents with a moderate family dysfunction has a medium level of resilience (55.2%) and adolescents with family dysfunction have a low level of resilience (60.0%).

To determine the level of resilience and family functionality, the non-parametric Person's chi-square test was applied, which reported an $X^2 = 44.842$ and a p-value = 0.000 per l indicating that there is a significant relationship between these variables.

In Table 4, both cases, most students are located at the medium level of resilience, in the case of students from Honorio Manrique Nicho, 48.5%, and in the case of students from the Andrés Avelino Cáceres school, 54.2%. So, students with a high level of resilience are located at the Honorio Manrique Nicho school with 30.9% compared to students from Andrés Avelino Cáceres who are only 21.5%.

Both studies with the results of the research work can interpret that the levels of resilience and family functionality in adolescents

are linked to the promotion of mental and family health of adolescents, taking into account that resilience is very relevant because it allows adolescents to have the ability to adapt and also in making decisions about the negative situations that arise. It also focuses on family functionality because in the adolescent, it will allow it to maintain an affective interaction with the members of its family, and also to has the ability to make changes in order to overcome the difficulties that arise in the family. It is vitally important to have a high level of resilience and, have good family functionality since the development of adolescents must be observed, since there is little knowledge about the topics which allows us to obtain a review of the scientific information related to the topic.

In the present study, the issue of level of family resilience and functionality is raised from the point of view of promoting adolescent health, which seeks to contribute to educational institutions as part of adolescent training, which it seeks to include programs that allow adolescents to find ways to enhance their adaptation capacities and make their own decisions, both in society and family, so that they can improve their lives in the future.

In the level of resilience in adolescents from educational institutions, the medium level predominated, followed by the high and low. These results can be based on how adolescents live with their parents sharing their own experiences, in which it is a factor that favors the adolescent since it allows them to easily excel and overcome any anticipated problem. In the study by Sulimani Y. [12], on the results of resilience, he referred to the adolescent's distinction between formal and informal social ties and, also, the ability to seek help and guidance from adult figures, as well as strong relationships and supporting parents and family members is a debatable factor as a major component of resilience for adolescents.

In relation to family functionality in adolescents from Cajatambo educational institutions, mild family dysfunction predominated, this is due to the lack of empathy, understanding and sensitivity towards the adolescent by the family is scarce, where scenes such as intra-family conflicts and parental misbehavior are reflected in the adolescent adapting to such actions, allowing the adolescent to think that this normally happens in all other families. Suarez P. and collaborators [2], argue that the development of values and actions of adolescents will be reflected in the role played by the family in their environment, factors such as care, affectivity and fluid communication are criteria that support the adolescent development.

In relation to the level of resilience and family functionality in adolescents from Cajatambo's educational institutions, mild family dysfunction predominated with a medium level of resilience, it is important to emphasize the intervention of the family in the development of resilience in adolescents, since it is mainly the parents who will help build the adolescent's resilience by providing the necessary support that will allow them to overcome certain obstacles. The family will influence positively or negatively in the construction of the adolescent's own resilience, but some adolescents mostly present a high resilience. Tian L. et al. [13], mention that parental support was more strongly related to adolescent resilience, and that interventions should be made to promote adolescent resilience with greater emphasis on parental support in the future of their children.

In comparison the level of resilience between the two Educational Institutions in Lima Province, it can be seen that in the Honorio Manrique Nicho Educational Institution and in the Andres Avelino Caceres Educational Institute, the middle level predominates more, this is because after the family as Resilience builder is also the school, at school the adolescents experiences certain conditions that make them promote resilience, because the school also has the capacity to build it in the adolescent. The way in which resilience can be built is based on the trust that the adolescent has in front of the parents, teachers or friends that generate security to solve any obstacle without doubts.

It is concluded that the particular way in which adolescent education is carried out, whether in the family or at school, should be taken into account; it could be investigated about resilience and family function through other studies to determine this study in greater depth.

Conflicts of Interest

The authors declare that they have no conflict of interest.
