Tools	Use of ICTs that allows the transformation from closed access to OA in scientific publications [19].
Policies on OA	Regulations and guidelines about initiatives of OA and licenses of use.
Institutions	Aspects related to the changing roles, policies, and practices of the institutions participating in the OA Ecosystem.
Stakeholders	Actors that participate and influence the OA ecosystem.
Impact	Changes produced on the environment, processes, products or in some population groups, due to a certain action [20].

4. Findings

The research questions stated above (see section 3.1). are responded through the analysis performed. For this reason, this section is organized according to each one of these questions. The first issue addressed is the distribution of the publications, then the topics, and, finally, the trends in OA considered by the studies identified in the literature.

4.1. Distribution of publications on OA regarding HEIs

We analyzed 50 studies on OA in HEIs, published between the years 2010 and 2020. We observed that 2019 was the year with the highest number of publications, with 15 works. These results show a growing interest in the subject of OA for the higher education sector. Figure 3 below shows the distribution of documents by year.

Figure 3: Documents analyzed by year

It is also important to note that the result for the year 2020 does not include the whole year, because the search was done on September 15th, 2020.

On the other hand, we analyzed the distribution of the selected works according to the country in which the study was carried out. We noted that 24% of the studies were conducted in the UK, 10% in Austria, 8% in South Africa and India, and 6% in Brazil and Australia. On the other hand, 38% of the remaining works were conducted in Canada, Egypt, Ecuador, France, Germany, Kenya, Mexico, Nigeria, the United Arab Emirates, Slovenia, United States, Zimbabwe, and countries not defined (Table 3). Furthermore, only one study focuses on Latin America and another one in Europe. In the Latin American context, we observed that OA in HEIs has been analyzed in Argentina, Brasil, Costa Rica, Peru, and Mexico. Figure 4 below shows the documents analyzed by the country mentioned in the research.

Table 3: Classification according to country

Country	Documents	Sources
United Kingdom	12	[21–32]

4.2. Topics emerging from the studies

To identify and classify the selected studies according to the authors' contribution. The trends defined in Table 5 were the ones that emerged from the analysis of the selected works. Table 4 presents the results of the classification. The trend with the most associated studies is focusing on the financial aspects (32%), followed by research related to repositories (22%), and education (12%).

Table 4: Classification according to trend

Country	Documents	Sources
Financial Aspects	16	[2,19,21,22,28,30,33–36,38–43,54,67]
Repositories	12	[29,37,41,44,45,51,52,56,58,61,62,64]
Education	6	[47,49,55,65,68,69]
Perceptions	5	[32,39,48,57,59]
Tools	5	[38,40,50,58,66]

Institutions	2	[27,63]
Stakeholders	2	[23,46]
Impact	2	[42,60]
Total	54 ^a	

Note: The results show a higher number of documents because four documents support more than one trend.

4.3. Trends

Below, we present the main trends that emerged from the review process as well as some aspects that stand out in each one.

4.3.1. Financial Aspects

Several authors have focused on different aspects related to the financial difficulties linked to OA. They treat aspects such as the costs of OA for universities [22,28,30,42,54,67], strategies used by some publishers for addressing OA [2], financial challenges for implementing policies for incentivizing OA [19,21,22,33–36,54], and transformative agreements [43].

In [28], the authors investigated the administrative costs incurred by 29 UK universities to publish research results in OA in the "Gold" or "Green" route. The analysis considers the author's time, peer review time, administrative staff time, and academic management time. It identifies that the time and cost invested by universities in the Gold Route is 2.5 times greater than in the Green route, which is faster and less costly. While universities recognize the importance of increasing access to their research results through OA, they are also concerned about the costs involved. On the other hand, [30] determined that the costs of Article Processing Charges (APC) and subscription to journals have increased in HEIs from the UK identifying that the increase in the adoption of OA has created pressures in terms of costs for these institutions. Furthermore, they observed that there is a correlation between the price of APC and the quality of the journals.

For his part, in [67] the author analyzes the impact of indexed Gold OA journals to increase available content, citation frequency, and access to content published by recognized publishers, universities, society, or specific groups. It identifies

the growth of Gold OA journals and their inclusion in indexing and abstract databases. However, this research also highlights the fact that costs of access to academic databases offered to universities have not decreased.

In [54], the author examined the OA Textbooks and Open Educational Resources processes to promote, evaluate, preserve, curate, and facilitate its access as well as the funding required to incorporate them into repositories in the United States. He found that the main role that libraries have is to make this kind of education resources affordable and accessible [54]. Moreover, a study carried out on South African universities, mentioned some challenges associated with the dissemination of knowledge resulting from African research due to the new APC financing model, which implies that institutions must assume this additional cost to traditional research funding, research staff salaries, and journal access licenses available to the educational community. It also highlights risks of low visibility in the absence of resources to assume the costs of the new financing model [42].

On the other hand, in [2] the authors highlight how commercial publishers appropriated academic communication spaces, turning them into an inelastic market that hinders the circulation of knowledge. It finds two sources of financing: either the authors pay APCs; or they find external sponsorships and grants through advertising, donations, and fundraising. These two routes relate to the gold and green access models, respectively.

In [21], the author reported the important steps to the growth of OA in the UK, in 2012. Initially, the Fintech recommendations to the Minister of Universities and Science, followed by the new UK Research Councils policy adopting the Finch Group recommendations. The Fintech report recommended increasing access through three mechanisms – OA journals, extensions to licensing, and repositories. That being said, the Fintech report had some adverse reactions mainly because of the lack of price regulation, and because they estimated some transitions that institutions cannot afford because of the limits of their budgets [21].

Following a survey from 2019 to adopt central funds for the payment of OA in high education institutions, the authors repeated the survey in 2011 finding there were not big advances to encourage the OA publications in 26 UK universities [22]. The possible reasons stated were high APC publication charges, difficulty to associate publishing costs with a related grant, the administrative overhead associated with managing micropayments for APCs, difficulties associated with raising awareness of the fund amongst authors, and perception challenges amongst researchers linking OA with lower quality of the results presented in the investigations which affect current levels of demand [22].

A group of authors focused their attention on the “Austrian Transition to Open Access (AT2OA)”, authorized by the Austrian Federal Ministry of Science, Research and Economy [19,33,35,38–41]. According to [29] in this project, running from 2017 to 2020, “the 21 public universities cooperate to promote OA through concerted measures” [29]. This initiative included four subprojects that focused on: “drafting an expert’s report about the financial impact of a total adjustment to OA on a national and institutional basis, the extension of existing

consortium licenses with an OA component, establishment of an OA publishing fund as well as the promotion of OA monographs and suitable OA infrastructures” [33]. In contrast, in [34] the authors deal with “a number of questions that were discussed in the course of the drafting of a guidance document around funding conditions for publication funds in the project” (p. 1). While in [36] the authors describe “the prerequisites for an equitable and appropriate use of central funds for such transitional business models, and present a case study of a currently running, successful agreement”. Finally, in [35] the author summarizes the methods and findings of the final report of the AT2OA-Transition-Study.

Finally, in [43] the author focuses on transformative agreements as an advance towards “a new global publishing regime where scholarly communication is available and free for all readers with internet access”. According to the author, this change has been primarily caused by “bottom-up pressures from university systems and researchers as producers of knowledge, but it also represents a reflection of many new adventures towards the imagination of the intricate and complex relationships between science and society” [43]. Special attention is paid to the OA2020 project, which “calls on the publishing houses to flip their journals from being ‘pay to read’ to ‘pay to publish’ [43]. Examples of institutions and countries committed to the OA2020 route are the University of California system and China, as well as Sweden, Germany, the Netherlands, and Norway which are putting pressure on Elsevier to “come to the negotiating table to strike up a ‘pay-to-publish’ model rather than the ‘pay-to-read’ one” [43]. Another example of an alternative negotiation model is the SCOAP3 [South African OA publishing] project, coordinated by the European Organization for Nuclear Research (CERN). The project includes a centralized fund. “The project negotiated with the publishers of all the key particle physics journals to enter the kind of agreement captured by OA2020. Each country contributes to the central fund an amount, which is directly proportional to its international share of the publications output, which for South Africa is 0.5% of the global output, and therefore a national contribution of 0.5% of the total central fund. This makes particle physics articles, even in the most high-impact, prestigious journals, openly accessible to all. CERN manages the payment for the publication of the articles. It is an example of diamond OA where there is no APCs or ‘author facing charges’ [43].

4.3.2. Repositories

Works on repositories focus on diagnosing existing repositories [56,70], presenting specific projects or initiatives for putting in place repositories [29,37,41,51,52,56,61], or in studying the challenges faced by researchers and other stakeholders for embracing OA. These challenges could be partly mitigated, if they took advantage of repositories [44,62,64], while others show the challenges for fully taking advantage of repositories [45,58].

In [51], the authors studied the growth of repositories around the world from 2006 to 2012. However, repositories were not well known in that time. That being said, there were universities’ efforts to constitute meta-search engines, catalogs, and directories to make available valid and reliable information. In the Latin-American case, the author presents advances of open repositories in Costa Rica, Peru, Argentina, and Mexico. It also includes the

infrastructure development, its geographic distribution, and some policy initiatives. Then again, in [56] the authors executed a diagnosis and classification of 30 institutional repositories in Ecuador. As a result of the study, they identified that most of the repositories correspond to databases managed by private HEIs, with DSPACE being the most widely used software. However, only 11.37% of IRs use a Creative Commons license, and 7.23% do not indicate the type of license they use.

In the same way, in [52] the authors shown an overview of OA repositories of HEIs in Mexico. They analyzed eleven repositories, which have the highest levels of resources in OpenDOAR. The authors conclude that these repositories are an important alternative for the visibility of resources and keep a growing tendency in the quantity and quality of the resources included in OA repositories. Nevertheless, these authors also noted that there are important challenges shared by the repositories analyzed. It is worth mentioning that according to the authors, there is a Mexican Network of Institutional Repositories (REMEDI by its initials in Spanish), which has defined General Guidelines for OA. REMEDI declares the repository program, aiming at collecting, preserving, and ensuring OA to Scientific, Technological and Innovation Information Resources generated mainly with public resources [52].

At the same time, Singh studies the development of OA repositories in higher education and research institutions in India [37]. The study analyzes the growth, development, geographical distribution, and technical characteristics of the repositories such as software, size, and type of content, OA policy, and protocol for metadata collection. It shows that university libraries have implemented OA IRs to improve service to users and to obtain benefits for both the universities and the academic and research communities in terms of visibility and dissemination of research material to the community.

Researchers from Uganda report an OA project called African Higher Education Research Online (AHERO) to establish a better communication of research among HEIs, making more accessible information resources. This repository is semi-automated and focuses on African education. An online survey to evaluate AHERO was made among 26 countries; and the results showed this repository has been successful especially among Uganda, South Africa, and Kenya users, and could represent the start point to encourage OA among disciplinary communities in Africa [41].

Moreover, McCutcheon and Eadie present the development of IR from the University of Glasgow in the UK as a resource for managing OA [29]. The repository considers the UK's OA policy, the University's OA flow, and the provisions defined by funding funds such as the UK Charities Open Access Fund, the European Union, other funder policies, and internal reporting requirements. Additionally, they considered the national standards for OA Metadata proposed by RCUK (Research Councils UK), REF (Research Excellence Framework), the EU, the CASRAI (Consortia Advancing Standards in Research Administration Information) UK Open Access Working Group, as well as internal requirements.

In 2010, in [61] the author presented that reported to the Kenya Information Preservation Society (KIPS) an initiative to make available bibliographic details and abstracts of electronic theses and dissertations, since 1999. KIPS had a collection of approximately 15,000 citations in the database and 24 organizations contributing records on all disciplines. The author concludes that: "it is asserted that digital theses and dissertations massively increase the impact of institutional research, an essential consideration at a time when evidence of the impact of research is becoming an all-important factor in research evaluation, and therefore in future funding [61].

In [44], the authors focused on OA practices (OAPs) and the challenges faced by African researchers. Among these challenges, there are some for accessing materials, such as the unawareness of "Research4Life availability, inadequate staffing by LIS¹ professionals and infrastructure challenges". They also faced challenges to publish their research papers in OA. According to the authors, these, among other issues, "are the reasons why most African academic institutions are unable to embrace OAPs" [44]. Furthermore, indicated "OAPs can provide a roadmap in research paper publication in academic institutions, which then can be discoverable, implementable and achievable, also demonstrate the value of academic libraries to their institutions and hopefully provide continual sources of funding." [44].

The approach proposed by the authors in [64] analyzes the roles of stakeholders in strengthening the OA initiatives among academic libraries in Zimbabwe. According to the study, "faculty participants confirmed that academic libraries in Zimbabwe could effectively use IRs to generate new e-content and explore opportunities to license their content". They also found that "Academic institutions are also benefiting from OA initiatives as shown by the growing strength of a research culture in all institutions. It is imperative to take into consideration several challenges ranging from costs, an unwillingness by authors to generate content, unclear systems to coordinate and promote the sharing of knowledge, lack of support from institutional management, and copyright issues" [26].

In the same sense, the library's role in encouraging open repositories was studied in Nigeria and its possible contributions to reach Vision 20: 2020 objectives of economic growth. An important conclusion of the study established the lack of dialogue among stakeholders to encourage the accessibility and utilization of research outputs and intellectual products at Nigerian academy institutions. Conclusion: there is a clear need for a National Policy to set up OA repositories. It is necessary to establish national coordination and implementation mechanisms for the policy, as the international and national cooperation among high educational institutions adopt best practices and models to develop open repositories and to contribute effectively into Nigeria's economic objectives [62].

In [58], the authors point out that despite the great benefits that the development of a single OA portal brings to society, this is not always possible as indicated by the Slovenia's case in which a complete unification was impossible due to the differences in the

¹ LIS: Library and Information Sciences
www.astesj.com

control of plagiarism recognition in documents deposited in institutional repositories.

In different circumstances in [45], the authors mentions that one of the greatest challenges for repositories is to insert in the academic culture a favorable environment towards open research data, since collecting, managing, and publishing for future reuse are not phases traditionally carried out. This implies an important change in which, since the commercial publishers are not present because they are not part of their business model, new dialogues between the academic communities are necessary to create stimuli that facilitate their acceptance.

4.3.3. Education

In this category, are the studies that focused on the perception [47,68] and use of OA to support the teaching process in higher education [49,55,69], both classroom-based and distance-learning.

In [47], the authors study OA enabling courses in Australian HEI's² institutions "The study examined the following areas: learning barriers faced by students, student engagement and experience in learning, skills developed, and further skills needed while undertaking OA courses, motivation to complete study, career pathway of students, key reasons for selecting particular pathways" [47].

For their part, in [69] the authors analyze the impact of academic literature OA on the teaching process of the higher education sector in the United Kingdom. Among the perceived benefits is the easy and quick access to content to support teaching without the need to pay additional licensing fees. However, knowledge barriers persist around the location, permanence, legality, and licensing of articles. Thus, they recommend encouraging researchers to license their content to facilitate its reuse [69]. Moreover, [49] conducts a case study at the Federal University of Minas Gerais in Brazil to identify whether the OA to information resources provided by university libraries, contributes to distance learning. Although the libraries indeed offer databases, collections, and digital libraries of Theses and Dissertations, only two resources are from OA, which implies making investments to cover the fees for accessing some databases. In this sense, the potential of OA is evident: institutions can find alternative ways to access content and strengthen the democratization of knowledge and education [49].

Similarly, in [68] the authors conducted a study of the experiences and perceptions of OA held by teachers teaching online in different humanities, social science, and science programs at institutions in the United States, Australia, India, and the United Kingdom. The study showed that participants perceive OA in five different ways, specifically as: 1) a teaching resource, 2) a publishing channel, 3) a social movement, 4) open source; and 5) "free to me" (p. 128). Additionally, each form presented six variations of perception: 1) materials, 2) costs, 3) platforms, 4) benefits, 5) drawbacks, and 6) professional context or purpose. Considering that, there are divergent understandings of OA, publishers, university libraries, and higher education

administrators are encouraged to propose strategies to improve dissemination, communication, and further study of aspects of OA [68].

In [55], the authors established the emergence of open education in 2001 with the MIT OpenCourseWare project; and make a historical and philosophical account, highlighting the most important courses around the World. After presenting a statistical analysis of 14 current journals in curriculum studies, the study concludes that they reflect globalization and economic systems in the educational offer; however, authors question the possibility to create spaces with a different perspective, encouraging knowledge as a social good [55].

In Latin America, Tzoc concludes that universities in the region should work in three scenarios to promote OA: 1) increase of institutional agreements and research projects between universities; 2) increased participation of Latin American teachers in professional networks or foreign projects, and 3) proliferation of open, distance, or virtual education programs [65].

4.3.4. Perceptions

There is an important group of studies that analyze the perception and adoption of OA by the academic community. This group focuses on attitudes towards OA [32,39,48,59], as well as on the use of resources and services available [48,57].

In [39], the authors study how well the teaching community working in HEIs in Tamil Nadu (India) endorse the OA publishing model. The study shows that most of the teaching staff prefer the OA publishing model to the other commercial and hybrid publication models [39].

In contrast, in [32] the author examined the perceptions, development, and conceptions of OA practices in HEIs in the United Kingdom, through an ethnographic study. The results of the study focused on the barriers perceived by the academic community affecting the adoption of OA. The main perceived barriers are operational, technological, political, or legal, and community knowledge and attitudes towards OA. Addressing these barriers will involve developing different strategies that generate cultural acceptance of possible forms of open knowledge dissemination [32].

In [59] the author analyzes the results of the survey conducted by French consortium Couperin (Unified Consortium of Higher Education and Research Organizations for Access to Numerical Publications). The survey aims to understand researchers' practices and opinions regarding OA and the use of social networks. The results show the importance of promoting information related to editorial policies and intellectual property rights. Also, it identifies the opportunity to link the OA and social networks, to promote open science, and increase the visibility of researchers.

For his part, in [57] the author studied the student's adoption of OA online higher education services in Egypt. The study has divided into two phases: 11 deep interviews of information directors of some universities, and senior managers of the

² The search by author, title or year in My Library (2019) OA enabling courses are preparatory [44]

Ministry of Higher Education, and the second phase consisted of student surveys from three universities (public, private, and foreign) [57]. The interviews were structured to test and support the model and the elements that determine the adoption of OA online education. These elements are: a) internal attributes, composed by Facilities and resources, faculty and staff support and quality and risk control b) External, integrated by Socio-economic factors, Market structure, and competition and government support; c) The perception of open innovation attributes has five elements: relative advantage; compatibility; observability; trialability and complexity; d) Faculty innovation adoption and e) Students innovation adoption [57].

Moreover, in [48] the authors presented the results of an OA perception survey of the scientific literature, as well as the use and citation of OA sources. Brazilian researchers responded to the survey. They found that although the researchers know and support the principles of OA, there is low awareness and use of OA repositories. One of the causes identified was the confusion regarding the article's copyright s that could be published in a repository since researchers believe that the papers that should be available are post-prints. Thus, they recommend increasing the awareness of the research community on these issues.

4.3.5. Tools

In this trend, the works related to tools aimed at facilitating the development, use, or access to digital resources are included. A group of works focuses on tools that integrate different resources [38,40,50], while others propose tools to complement the integration efforts [58] and others work on the elements necessary for developing and publishing open academic courses, including the tools that would allow different national standards to be compatible [66].

Swain focuses on Virtual Libraries in Higher Education in modern India and their role in the "formation and dissemination of information and knowledge" [36]. This work focuses on INFLIBNET, which "may be given the status of master repository having linkage with all institutional repositories" [36]. INFLIBNET is the Information and Library Network Centre initiated by the University Grants Commission in 1991³.

In [50], the authors describe the development of a tool that facilitates data integration between the Institutional Repository (IR) of the Federal University of the Amazon, the scientific initiation management system (Lira portal), and the faculty portal. This work contributed to the automation of the flow of deposit and dissemination of scientific initiation projects in the University's IR as a strategy to promote the OA.

In [38], the authors describe the development of a Research Archive Information Retrieval and Visualization System for Indian universities. This system allows access and consultation in the OA of digital resources in the Bengali language. From the prototype created, the aim is, among other results, to promote OA through the dissemination and international visibility of research results.

In [58], the authors point out that before the integration of institutional repositories in a single search engine, it is important

to develop expert plagiarism detection systems based on the design of algorithms that make comparisons between documents. This system was developed in Slovenia, including an exhaustive analysis of documents. This analysis considers linguistic qualities, identification of similarities higher than 60%, and results show. These results show the first five documents that stand out for exceeding the originality threshold. Furthermore, making visible criteria such as visits, downloads, previous readers' ratings, among others.

In [66] the authors reviewed, in Greece, the ASK-CDM-ECTS. This tool facilitates the authoring and publishing of open academic courses using the CDM-ECTS metadata description. Their analysis involves a review of Norway, USA, India, UK, China, and Japan initiatives and the required structure composed of 18 elements to constitute an open course. Another interesting element is the consideration of standards to describe an open course. In this case, a subset in XML format, compatible between two standards was proposed: the CDM standard developed by the University of Oslo for the Norwegian for higher education, and the ECTS standard adopted by high educational institutions in Europe [66].

4.3.6. Policies

The development of the OA has given way to the definition of policies in HEIs. The analyses performed and trends in policy development for OA promotion [45], knowledge communication [31], open courses [25], and commercial exploitation of research results [53].

In [45], the authors show that the OA generated a globalization scenario around education policy thanks to two strategic allies, such as governments and libraries. The first, defined policies with an emphasis on the promotion of OA, compliance frameworks, and infrastructure proposals like the creation of portals of OA; and the second, libraries, with the creation of institutional repositories, and the design of strategies to strengthen the culture of self-archiving in the academic community.

In [31], the authors analyze the use and implementation of the UK Scholarly Communication Licensing policy (UK-SCL) as a strategy that encourages OA and allows control of the content produced in HEIs. The results identify perceived benefits in helping authors gain control of their publications, disseminate publications rapidly and widely, and reduce costs at institutions. On the other hand, the perceived challenges identified are resistance from editors, administrative demands, and confusion among researchers [31]. Also, the factors influencing policy adoption are institutional collaborations, external support, internal communication and engagement, the legal framework, business processes, and the role of the library within the institution [31].

In [53], the author studied the OA advances and situation and proposed an agenda to encourage the legislation to avoid the commercial exploitation of research results and to allow the growth of OA. The proposed agenda encourages higher education researchers and leaders to advance OA by lobbying Congress to pass the FRPAA legislation. The proposed agenda encourages higher education researchers and leaders to advance OA by

³ <https://inflibnet.ac.in/about/index.php> Accessed on September 17th, 2020.
www.astesj.com

lobbying Congress to pass the FRPAA legislation. Furthermore, it works with funding agencies to obtain policies to support OA publication rates; establish institutional funds to support LO publication charges not covered by grants; approve OA mandates on campus and support local IRs in depositing research, and publishers in the formalization of agreements that allow wide and unrestricted distribution of research.

Finally, OA scholarly publishing as mega-journals and academic networking services as in the case of Massive Online Open Courses (MOOCs) currently represent an innovative and disruptive educational form. A study in the UK and USA shows the emergence of policy initiatives to regulate these new forms of academic scope. It is important to notice the economic impact encouraged by this kind of information and educational industry, transforming the traditional academic markets [25].

4.3.7. Institutions

Some authors have focused their attention on the changing roles [27], policies, and practices of the institutions participating in the OA Ecosystem [63].

A case study carried out in the United Kingdom reference how, since 2005, this country has an OA policy [27]. Also, the financing of APC has evolved, since, at first, it was the UK Research Council that was directly in charge of providing the resources individually requested. However, since 2013, these costs are managed and allocated by the research organizations to which the researchers are ascribed. The resources are assigned in a single item, to these organizations. In turn, they oversee transparently managing and allocating them, according to criteria of coverage of disciplines and researchers, at different stages of their career, in compliance with the OA policy.

In [63] the authors study the role of HEIs in the United Arab Emirates (UAE) OA uptake. Their results suggest that although “there seems to be a generally positive perception of OA”, there is also a moderate adoption of OA policies and practices. They also point out the need to create a culture that increases priority for OA adoption, as well as “awareness, policies, best practices, and infrastructure” [63]. They also suggest the need for “nation-wide strategies aligned with international initiatives such as OA2020 and Plan S need to be adopted” if the UAE is to increase its presence in the OA movement [63].

4.3.8. Stakeholders

This trend presents analysis on different stakeholder groups, such as New University Presses [23] and Australian universities [46], presenting the challenges and opportunities these stakeholder groups face.

In [23], the authors studied the University of Huddersfield Press (the Press), one of the 21 New University Presses (NUPs) in the UK, the vast majority of which publish OA journals and monographs. Taylor establishes six key areas on which “the Press has focused on since 2016 to enable a professional, efficient and effective publishing process that suits our journal and monograph portfolio: Commissioning; Review; Production; Discoverability; Marketing; and Analytics. Furthermore, the author emphasizes the importance for OA publications to be transparent, given the rise of predatory OA journals, and to be recognized as academic

publications of high standards and professional quality. According to [23], the Press aims at optimizing the publishing process to achieve a “streamlined workflow, increased discoverability, an improved level of service for authors and editors, an improved reader experience, and ultimately, a steady and measurable increase in downloads and citations” [59, p. 10]. Finally, The Press has proposed a Press Model for university presses.

In [46] the author carried out in a study carried out in Australian universities, points out how the OA scenario is being unduly exploited by agents who develop practices that could be classified as unfair, which generates new actions on the part of the universities who must accompany researchers by providing advice and new tools to identify those journals that meet the desired quality and reputation standards to send their research results.

4.3.9. Impact

In this trend, we find the works that study how OA has altered research [42] and knowledge management activities [60].

In [42], the authors highlight that the dynamics of the research culture have changed from a linear structure- in which the purpose of an investigation is the publication of its results-, to give way to the creation of virtuous circles, around sharing and reusing research data which can be advantageous for developing countries.

A study published in 2010, analyzed the impact of OA on the Socialization, Externalization, Combination, and Internalization (SECI) model from Nonaka applied for higher education institutions. The study concludes that OA is a positive factor for knowledge Management because it makes scientific literature openly accessible for anyone interested in the creation, retrieval, and transfer of scientific knowledge. The OA contributions are resumed as the acceleration of the spiral of knowledge creation; Improvement of transfer into wide dissemination mechanisms; OA also changes the method of storing and retrieving scientific online information; now in repositories; and finally, a potential decrease in the costs of scholarly communication [60].

5. Discussion

This study looks at the current interests of researchers in the OA field in the HEIs sector. As mentioned before, although we had recently studied this subject [1], updating it, showed new trends in OA research in education. We had previously found that researchers were focusing their work mainly on the repositories, journals, tools, and perceptions of the use of OA resources. However, our new study allowed making explicit new emerging trends. Notably, we found that financial issues related to the implementation of OA are now one of the main subjects in which current efforts are focused. Also, the study of policies intended to foster the appropriation of OA at different levels has been the object of attention. In addition, the technological tools that allow OA to work continue to evolve. Furthermore, the changing role of institutions during the implementation of some policies has also been studied, as well as the changes OA has brought to Education. Finally, the impact OA has had on scientific research has also been studied.

Likewise, some previous works have identified research trends in OA. Table 1 presents the main trends identified by [9–11], where some have similarities with the trends identified in this work. Notably, the Finances trend, presents some similarity with what has previously been identified as Business models around OA, although this trend includes many more aspects such as the costs of OA for universities [22, 28, 30, 42, 54, 67], and transformative agreements [43].

Another trend that emerged from this work was the one related to Repositories, which in [10] included in the OA publication channels, together with OA Journals and OA Books, and in [11] appeared in a Sub-category called “Manifestations of OA”, together with OA journals and “Awareness of Open Access Manifestations”. However, in this work, the studies around Repositories appear to be the focus of great interest among researchers.

The Education trend encompasses studies on the perception [47, 68] and use of OA to support teaching processes in higher education [49, 55, 69]. Although previous works mention the participation of Higher Education in OA dynamics [9], they focus on mandates rather than on the teaching processes.

The Perceptions trend was also found as having several works focusing on attitudes towards OA [32, 39, 48, 59], as well as on the use of resources and services available [48,57] by the academic community. Previous studies had identified the Acceptance of OA as well as the Arguments promoting OA [9].

The Tools trend includes works related to the tools aimed at facilitating the development, use, or access to digital resources are included, by integrating different resources [38, 40, 50], complementing the integration efforts [58], presenting the elements necessary for developing and publishing open academic courses, and allowing different national standards to be compatible [66]. Previous works don't seem to address the tools as such but in the relation to the actors that use some OA resources [11] or see them as a part of the technical barriers [11]. On the other hand, we identify in the results associated advances the tools used in repositories of Latin American libraries in developed countries (Argentina, Brazil, Costa Rica, Ecuador, Peru, and Mexico). These advances are associated with the roles, barriers, and benefits presented for developing and transitional countries category [11].

Next, the Policies trend is the one that coincides with previous works that have identified Policies and Mandates [9, 10] as an important research trend.

In terms of institutions and stakeholders, we observed that previous studies have identified actors and their roles [9,11], where Authors and Librarians are included. In addition, in Scholarly Communication, identified by [11] the Commercial publishers are included. Also, the Libraries Sub-category [11] includes the role that Libraries may have as Publishers when they “offer Open Access publishing in Open Access Journals and act as mediators in the depositing of content in Institutional Repositories through Authors Self-archivation” (p. 83). This last aspect shows the changing roles we have identified as being at the essence of the Institutions and Stakeholders trends.

The last trend we identified is the one related to the impact OA has had on research [42] and knowledge management activities [60]. There is a similarity with a previous work [11] that includes Manifestations, Barriers and Benefits of OA as a trend, and mentions “Availability, Usability, and Visibility” of disseminated content (p. 45), which could be seen as an advantage for researchers as it positively impacts the knowledge management cycle. The two impact studies we identified state that OA has accelerated the creation, storing, retrieving, and dissemination processes creating a virtuous circle in benefit of scholarly communication [38]. However, not much work was identified in this trend, which focuses on changes in processes linked to OA scholarly communication, and not to changes in impact factors, where there are many works that have been done [71, 72].

6. Conclusions

The OA is a movement that has grown in recent years. This study focused on the analysis of the research developed on OA in HEIs to identify main research trends. The analysis initial phase was based on the SCOPUS database consultation. The result of this consultation, allowed the identification of nine trends: repositories, financial aspects, education, and perception of the academic community on the use of OA resources, supporting tools, policies on OA, stakeholders, institutions, and impact of publications on OA.

Through this study it is also determined that in addition to technology, the human and financial resources are paramount in the implementation of OA platforms. In this area, it is essential to recognize the central role that HEIs play in the implementation of the OA. Not only because of the institutional efforts concerning platforms, repositories, journals, and the articulation of their internal actors (mainly libraries, academics, and students) but, because of their negotiating power with publishers and their role as public policy actors in the matter. In any case, this work identifies the concern of HEIs about investment in the Gold route and the APC financing model for the dissemination of knowledge.

As we have shown, some works show the academic community and the public sector's acceptance of the orientations that emerged from civil society with the pillar initiatives of the OA, called BBB (Budapest. 2002; Bethesda. 2003; Berlin. 2003). These were nurtured in subsequent years with guidelines that have come from different latitudes, promoting scenarios for their enhanced development, and have therefore, contributed to an important globalization effect in the design of national OA policies and the homologation of standards by educational institutions. In turn, this provides benefits in terms of clarity around the expected contributions of the State and University actors. For example, the State is in charge of approving regulations and financing national OA repositories; while the University is in charge of the construction of institutional repositories thanks to the work of the libraries. In both cases, making strategic contributions to strengthening the OA culture in academic communities.

In the trend of education, we observe that OA is perceived as a resource to support the teaching process. Furthermore, the contents in OA are used both in classroom-based and distance-learning.

It is then not surprising that diverse studies have been made about perceptions. These studies have mainly focus on the opinions of teachers and students, who have expressed their concerns throughout surveys in UK, Egypt, India, Brazil, and France. Universities have led these studies to determine the level of knowledge, attitudes, and perceptions of the academic community towards the services provided by the OA resources, being the institutional repositories, the resources that are mainly analyzed. Although the results of these surveys showed a generalized acceptance of the OA publishing model and its advantages, they also show that there are different ways of perceiving OA, and that some of these perceptions could constitute barriers to its development [9–12] given the operational, technological, political, or legal challenges involved. There is evidence that highlights the academic community's general lack of information and understanding surrounding the appropriate use of publishing licenses and OA repositories, even if it has also been determined that there exists a part of the community that does know and make use of the repositories. In [46], the authors it was noted that there are challenges to improve the visibility of the content that these resources manage, and that it is necessary to improve practices in the use of schemas of indexing descriptors (metadata). Moreover, although progress has indeed been made in the development and use of platforms and software for the management of digital collections, more efforts are necessary on the development and use of interoperability standards that facilitate the integration of OA with existing resources. This will improve visibility and access to content.

In terms of policy development on the OA, efforts led by civil society and the academic community has gotten back some lost domain over their research results. However, it remains a challenge to maintain and fund projects where freedom is not only for society but also for the academic community, releasing it from the responsibility of the APC. Public policies on APC should facilitate the allocation of public resources to finance them. Similarly, it is important to create fiscal policies and incentives to support the private sector.

It is also important to point out that a reorganization of two great forces is taking place: on the one hand, are those publishing companies that have generated an industry from the provision of access services to academic information and therefore, seek to maintain their profitability. On the other hand, HEIs are concerned with a process of advocating and providing information on OA. It is also evident that many of the new forms of OA reported in the reviewed literature, are proposed by the commercial publishers as a response to this global movement, to stay alive in the market in which they are intermediaries. This opens new scenarios on how to connect their research results with society, which shows the rethinking of relationships and discussions about how that knowledge is disseminated and used.

Finally, it has been established the OA has encouraged all steps in the knowledge process, changing the structure of publication and improving the dissemination mechanisms, which are all accelerators of the knowledge spiral and is potentiating scholarly communications.

Conflict of Interest

The authors declare no conflict of interest.

Lossy Inductor

ABSTRACT

The article suggests four circuit topologies for the practical simulation of grounded and floating lossy inductors. All the suggested circuits use commercially available integrated circuit LT1228 chips as active elements, and only two passive elements, namely one resistor and one capacitor. The first two of the proposed circuits employ only a single LT1228 active element and can realize grounded lossy inductors without the need for element-matching conditions. The last two of the proposed circuits can realize synthetic floating lossy inductors with only two LT1228s. The values of simulated equivalent elements can be tuned electronically by simply adjusting the external DC bias current of the LT1228. Non-ideal transfer error effects of the LT1228 on the synthetic inductor performance are inspected. Sensitivity performance concerning transfer errors and active and passive elements is also demonstrated. PSPICE simulation results and experimental measurements of the commercially available integrated circuit, LT1228, are incorporated to corroborate all our theoretical analyses.

1. Introduction

An inductance simulator circuit is an advantageous element in active circuit design and synthesis, especially for analog signal processing solutions and applications such as active filter, analog phase shifter, chaotic oscillator, and parasitic cancellation circuitry. In the past, there are various publications on the implementation of actively simulated lossy inductance simulators based on several active elements [1-34]. The first ones are intended for grounded lossy inductance simulation [1-22], while the others are for floating ones [23, 34]. However, from a careful inspection of the reported circuit topologies in these references, they have one or more of the following disadvantage features:

1. The use of a relatively large number of active and passive electronic components for their constructions [2, 4-6, 20-21, 23-27, 30-32]. Although the circuits of [1, 7-19, 28-29, 33-34] employ only a single active component, they still require at least three passive elements. Owing to the employment of an excessive number of circuit components, these designs are

not suitable for an integrated circuit (IC) implementation point of view.

2. The lack of electronic tuning facility [1-2, 4, 6-18, 20-21, 24-31, 34].
3. The need for strict component-matching conditions or cancellations for the grounded inductance function simulation [1, 6, 9].
4. The use of different types of active electronic devices [20, 23-24, 32], which is inconvenient for further integrated circuit applications.
5. The use of commercially unavailable ICs [1-3, 5-12, 15-17, 19-24, 26, 28-30, 32-34]. Also, the active building blocks used in these publications are complicated active functional blocks. Accordingly, the verification of the proposed realization is mostly performed by only computer simulation results.

Recently, several attempts have been proved that LT1228 IC package has now become a versatile and standard commercial IC in the realization of various types of analog signal processing applications [35-37]. This article reports the four circuit topologies for simulating all grounded/floating lossy inductors employing

This paper is an extended version from the proceedings of 2020 8th International Electrical Engineering Congress (iEECON) [38]

commercially available IC LT1228 chips as essential active components [38-39]. The first two circuit topologies ideally provide grounded lossy series and parallel inductors, while the other two topologies can emulate floating lossy series and parallel inductors. All the realized inductors employ canonical active and passive elements and are made adjustable electronically through the externally supplied current of the LT1228. The tracking error effects of the LT1228 on the circuit performance are investigated, and the active and passive sensitivity analyses are also evaluated. The validity of the synthetic lossy inductors is confirmed by the PSPICE simulation results using the macro-model of the LT1228 by Linear Technology as well as the prototype circuit test results using IC LT1228. Also, the circuit performance is demonstrated on an illustrative example of a voltage-mode second-order bandpass filter. The performance of the proposed practical grounded/floating lossy inductance simulators is compared with the previously presented similar works and also summarized in Table 1.

2. Characteristic of IC LT1228

Figure 1 shows the pin configuration and electrical symbol of the LT1228. It is a commercially available IC package, which is internally a combination of an operational transconductance amplifier (OTA) and a current feedback operational amplifier (CFA). The relationships between the appropriate terminal of LT1228 can be expressed through the following matrix expression given below [39]:

$$\begin{bmatrix} i_p \\ i_n \\ i_z \\ v_o \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ g_m & -g_m & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix} \begin{bmatrix} v_p \\ v_n \\ v_z \\ i_o \end{bmatrix} \quad (1)$$

In matrix (1), g_m is the transconductance gain of the LT1228, which is directly proportional to the external DC supplied current I_B , as defined by the following relation [39]:

$$g_m = 10I_B. \quad (2)$$

3. Actively Realizable Lossy Inductance Simulator Circuits

Fig.2 shows the generic circuit configuration for the simulation of lossy grounded and floating inductors. They consist of IC package LT1228s as active elements. Routine analyses of the

proposed circuits in Figure 2 yield the inductance functions and the finite quality factor (Q) given in Table 2. Inspection of the table, the four different inductance functions realized by the generic circuit topologies can be described in detail below.

- Figure 2(a) can emulate a grounded series RL-type lossy inductor with $R_{eq1} = 1/g_m$ and $L_{eq1} = R_1 C_1 / g_m$.
- Figure 2(b) can emulate a grounded parallel RL-type lossy inductor with $R_{eq2} = R_2$ and $L_{eq2} = R_2 C_2 / g_m$.
- The circuit in Figure 2(c) can emulate a floating series RL-type lossy inductor with $R_{eq3} = 1/g_m$ and $L_{eq3} = R_3 C_3 / g_m$.
- The last circuit in Figure 2(d) can emulate a floating parallel RL-type lossy inductor with $R_{eq4} = 1/g_{m2}$ and $L_{eq4} = C_4 / g_{m1} g_{m2}$.

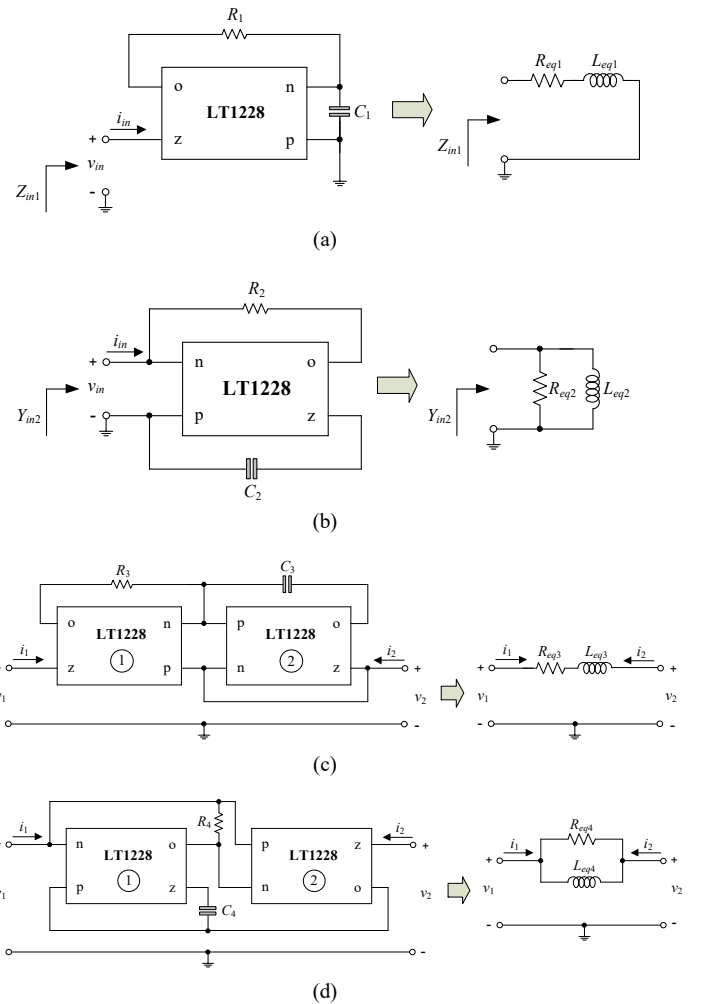

Figure 2: Lossy inductance simulators and equivalent circuits
(a) grounded series RL-type (b) grounded parallel RL-type
(c) floating series RL-type (d) floating parallel RL-type

Note that the proposed grounded lossy inductance sections of Figures 2(a) and 2(b) are no need for critical component-matching conditions. It is known that one can adjust the g_m -parameter by changing the bias current of the LT1228, and then the simulated equivalent elements R_{eq} and L_{eq} of the synthetic lossy inductors are electronically tunable.

Figure 2(c)	$g_m = g_{m1} = g_{m2}$	$Z_{in3} = R_{eq3} + sL_{eq3} = \frac{1}{g_m} + s \left(\frac{R_3 C_3}{g_m} \right)$	$\omega R_3 C_3$
Figure 2(d)	$R_4 = 1/g_{m2}$	$Y_{in4} = \frac{1}{R_{eq4}} + \frac{1}{sL_{eq4}} = g_{m2} + \frac{g_{m1} g_{m2}}{sC_4}$	$\omega C_4 / g_{m1}$

Table 3: Non-ideal parameters of the designed inductors in Figure 2.

Topology	Simulated equivalent elements		Q
Figure 2(a)	$R_{eq1} = 1/\alpha\beta g_m$	$L_{eq1} = R_1 C_1 / \alpha\beta g_m$	$\omega R_1 C_1$
Figure 2(b)	$R_{eq2} = R_2$	$L_{eq2} = R_2 C_2 / \alpha\beta g_m$	$\omega C_2 / \alpha\beta g_m$
Figure 2(c)	$R_{eq3} = 1/\alpha_1\beta_1 g_m$	$L_{eq3} = R_3 C_3 / \alpha_1\beta_1 g_m$	$\omega R_3 C_3$
Figure 2(d)	$R_{eq4} = 1/g_{m2}$	$L_{eq4} = C_4 / \alpha_1\beta_1 g_{m1} g_{m2}$	$\omega C_4 / \alpha_1\beta_1 g_{m1}$

Normalized sensitivities of the simulated equivalent values R_{eq} and L_{eq} with respect to active and passive elements are obtained as:

For Figure 2(a);

$$S_{R_1, C_1}^{R_{eq1}} = 0, S_{R_1, C_1}^{L_{eq1}} = 1, S_{\alpha, \beta, g_m}^{R_{eq1}} = S_{\alpha, \beta, g_m}^{L_{eq1}} = -1 \quad (4)$$

For Figure 2(b);

$$S_{R_2}^{R_{eq2}} = 1, S_{C_2}^{R_{eq2}} = 0, S_{R_2, C_2}^{L_{eq2}} = 1, S_{\alpha, \beta, g_m}^{R_{eq2}} = 0, S_{\alpha, \beta, g_m}^{L_{eq2}} = -1 \quad (5)$$

For Figure 2(c);

$$S_{R_3, C_3}^{R_{eq3}} = 0, S_{R_3, C_3}^{L_{eq3}} = 1, S_{\alpha_1, \beta_1, g_m}^{R_{eq3}} = S_{\alpha_1, \beta_1, g_m}^{L_{eq3}} = -1 \quad (6)$$

For Figure 2(d);

$$S_{C_4}^{L_{eq4}} = 1, S_{\alpha_1, \beta_1, g_{m1}, g_{m2}}^{L_{eq4}} = -1, S_{\alpha_1, \beta_1, g_{m1}}^{R_{eq4}} = 0, S_{g_{m2}}^{R_{eq4}} = -1 \quad (7)$$

From the above, it is clearly seen that the magnitudes of these sensitivity coefficients are less than or equal to unity. Thus, it can be realized that all the proposed inductors exhibit good sensitivity performance.

4. Non-Ideal Consideration and Sensitivity Performance

If the non-ideal transfer errors are considered, the terminal relationships of the LT1228 can be described as follows:

$$\begin{bmatrix} i_p \\ i_n \\ i_z \\ v_o \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ \alpha g_m & -\alpha g_m & 0 & 0 \\ 0 & 0 & \beta & 0 \end{bmatrix} \begin{bmatrix} v_p \\ v_n \\ v_z \\ i_o \end{bmatrix} \quad (3)$$

here, $\alpha = (1 - \varepsilon_{gm})$ and $\beta = (1 - \varepsilon_v)$, where ε_{gm} and ε_v are respectively the transconductance inaccuracy and the voltage transfer error in which $|\varepsilon_{gm}| \ll 1$ and $|\varepsilon_v| \ll 1$. Re-analysis all the topologies in Figure 2 by taking the non-ideal parameters of the LT1228 into account, the various non-ideal characteristic parameters of the synthetic inductors can be evaluated and summarized in Table 3.

5. Simulation Results

The proposed lossy inductance simulators in Figure 2 have been simulated by the PSPICE program using LT1228 standard SPICE macro-model obtained from Linear Technology. The LT1228 was biased with symmetrical supply voltages of $+V = -V = 5$ V. As an example, the proposed floating lossy series inductor of Figure 2(c) has been designed to simulate a floating series RL impedance with $R_{eq3} = 1$ k Ω and $L_{eq3} = 1$ mH. For this purpose, the component values are set as: $I_B = I_{B1} = I_{B2} = 100$ μ A for $g_m = g_{m1} = g_{m2} = 1$ mA/V, $R_3 = 1$ k Ω and $C_3 = 1$ nF. Figure 5 shows the simulated transient responses of the input voltage and current (v_{in} and i_1), where a sinusoidal input voltage of 50 mV (peak) at the frequency of 500 kHz is applied to the simulator. The resulting waveforms show that the current i_1 lags the voltage v_{in} by 70° , whereas the theoretical calculation is equal to $\tan^{-1}(\omega L_{eq3}/R_{eq3}) = \tan^{-1}(2\pi \times 500 \times 10^3 \times 1 \times 10^{-3})/(1 \times 10^3) = 72.34^\circ$. With the same component values, the simulated frequency responses corroborating the ideal responses are also plotted in Figure 6. As can be observed from the results, it behaves serial RL impedance well for the frequencies around 1 kHz to 1 MHz.

Figure 5: Simulated transient responses of the floating lossy series inductor in Figure 2(c)

Figure 6: Ideal and simulated frequency responses of the floating lossy series inductor simulator in Figure 2(c).

To show the electronic tunability of the inductor in Figure 2(c), the detailed analysis of frequency characteristic is provided in Figure 7. In the figure, the magnitude responses of the input impedance Z_{in3} are compared with the ideal series RL impedance by changing the bias current for $I_B = 50$ μ A, 200 μ A and 400 μ A ($g_m = 0.5$ mA/V, 2 mA/V and 4 mA/V).

On the other hand, the simulated transient responses of the proposed floating lossy parallel inductor of Figure 2(d) are given in Figure 8. In this case, the active and passive components are taken as follows: $I_B = 100$ μ A ($g_m = 1$ mA/V), $R_4 = 1$ k Ω and $C_4 = 1$ nF, which yields $R_{eq4} = 1$ k Ω and $L_{eq4} = 1$ mH. In Figure 8,

a sinusoidal input signal was applied to the input of the inductor at a frequency of 200 kHz and signal amplitude of 50 mV peak. The phase difference between v_{in} and i_1 is approximately 36° , which is close to the ideal value ($\tan^{-1}(R_{eq4}/\omega L_{eq4}) = \tan^{-1}(1 \times 10^3)/(2\pi \times 200 \times 10^3 \times 1 \times 10^{-3}) = 38.51^\circ$) with a percentage deviation of 6.52%. The tuning capability of the proposed floating lossy parallel inductor has also been tested for $I_{B1} = 50$ μ A, 200 μ A, and 400 μ A, while keeping I_{B2} constant at 100 μ A. The resulting frequency characteristics showing in Figure 10 prove that the proposed inductor circuit can be conveniently tuned by electronic means.

6. Experimental Results

To further represent the validity of the presented theory, the proposed circuits of Figure 2 were implemented in prototype hardware using IC LT1228 from Linear Technology. The LT1228 is biased with ± 5 V supplies. For the experimental testing of Figure 2(a) and 2(b), the passive components in the schematic diagram are the following values: $R_1 = R_2 = 1$ k Ω and $C_1 = C_2 = 1$ nF. The measured magnitude and phase responses of the proposed grounded series lossy inductor in Figure 2(a) for $I_B = 50$ μ A, 100 μ A, 200 μ A, and 400 μ A are shown in Figures 11 and 12, respectively. The calculated and measurement results for the Z_{in1} frequency responses at a frequency of 100 kHz are summarized in Table 4. According to this table, parasitic gains and signal transfer errors at the corresponding terminals of the LT1228 in conjunction with the tolerances in passive elements used will deviate the impedance frequency responses of the simulated lossy inductor. It should be taken into account the fact that the current and voltage conveying realized by an LT1228 is actually valid under a small-signal operation. However, appropriate adjusting g_m with I_B gives a significant improvement in the magnitude and phase responses.

In the same manner, the measured frequency responses for the input impedance Z_{in2} of the proposed grounded parallel lossy inductor in Figure 2(b) are presented in Figures 13 and 14. Regarding the experimental testing for the actively simulated lossy inductor, the results of the Z_{in2} -frequency response at $f = 100$ kHz is provided in Table 5. Obviously, the practical results are consistent with the theoretical ones. However, the deviation in the magnitude and phase responses is mainly due to the non-ideal parasitic effects and the resistor and capacitor tolerances.

Table 4: Summary of the measured values for the Z_{in1} in Figure 2(a)

I_B (μ A)	g_m (mA/V)	$ Z_{in1} $ (k Ω)		$\angle Z_{in1}$ (degree)

7. Example of Application

To illustrative an application example, the proposed inductor topologies in Figures 2(b) and 2(c) are used for the simulation of serial RL and parallel RL elements of the bandpass filter in Figure 15. The voltage transfer function of Figure 15 is found as:

$$\frac{V_{out}(s)}{V_{in}(s)} = \frac{\left(\frac{R_{eq2}}{L_{eq3}}\right)s}{D(s)}, \quad (8)$$

where the denominator $D(s)$ is equal to

$$D(s) = s^2 + \left(\frac{R_{eq2}}{L_{eq2}} + \frac{R_{eq2}}{L_{eq3}} + \frac{R_{eq3}}{L_{eq2}}\right)s + \left(\frac{R_{eq2}R_{eq3}}{L_{eq2}L_{eq3}}\right). \quad (9)$$

From Equations (8)-(9), the natural angular frequency (ω_o) and the quality factor (Q) of the proposed filter in Figure 15 can be characterized as given respectively by the following equations:

$$\omega_o = 2\pi f_o = \sqrt{\frac{R_{eq2}R_{eq3}}{L_{eq2}L_{eq3}}}, \quad (10)$$

and

$$Q = \frac{\sqrt{R_{eq2}R_{eq3}L_{eq2}L_{eq3}}}{R_{eq2}(L_{eq2} + L_{eq3}) + R_{eq3}L_{eq2}}. \quad (11)$$

In the simulation, the element values for bandpass filter in Figure 15 with $f_o = 159.15$ kHz and $Q = 0.33$ are specified as follows: $g_m = 1$ mA/V ($I_B = 100 \mu A$), $R_2 = R_3 = 1$ k Ω , $C_2 = C_3 = 1$ nF. Figure 16 shows the plots of the theoretical and simulated frequency responses of the filter, in which $R_{eq2} = R_{eq3} = 1$ k Ω and $L_{eq2} = L_{eq3} = 1$ mH. From Figure 16, the simulated f_o is 156.15 kHz, where the relative error is found as 1.88%.

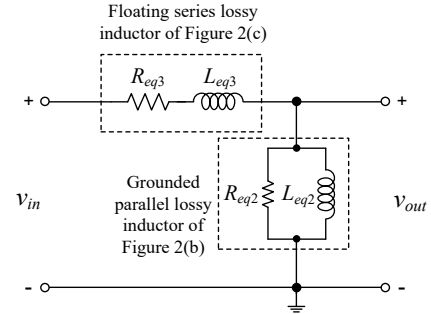

Figure 15: Voltage-mode bandpass filter realization using the proposed actively simulated inductors of Figure 2(b) and 2(c).

8. Conclusions

In this study, the actively simulated grounded/floating lossy inductance simulators using commercially available IC named LT1228 are reported. All of the reported topologies employ a capacitor and a resistor as passive elements and can be tuned electronically through the bias current of the LT1228. The simulation and experimental testing results are achieved to validate their practical performances.

ABSTRACT

Fresh water is already scarce in the world, especially in the Middle East (ME). Desalination industry is the main supplier of the potable water to the municipalities in the ME region. It is well known the high cost of a liter of water produced by the desalination process. Unfortunately, car-washing service consumes substantial amount of this desalinated water. This paper describes a filtration system designed and tested for treatment and reuse of the wastewater generated in car-washing stations. The filtration system assembled from two filters: (1) sand and gravel mix, and (2) activated carbon. The paper is an extension of work originally presented in ASET conference in Dubai. The quality of the effluent (treated wastewater) was investigated and determined in Dubai central laboratories. Wastewater samples were grabbed from different car service stations. Representative samples were prepared and the concentrations of the following parameters were measured in each sample of the effluent: (1) Biological oxygen demand (BOD), (2) Chemical oxygen demand (COD), (3) Total dissolved solids (TDS), (4) Total suspended solids (TSS), and (5) Oil and grease (OG). The results show that the filter system removes the BOD and COD at an efficiency as high as 97.5%, the TSS at 90%, and the TDS and OG at 85.5%. In general, the quality of the effluent was found to fall within the standards set by Dubai regulatory authorities. Further research is recommended to enhance the filtration system performance and make it commercially applicable.

1. Introduction

Water is also termed as white gold in the age of its scarcity and increasing population in the world. The dynamics of geopolitics is changing based on the sharing of this valuable resource among different countries, especially in the Middle East. Desalination industry is the main supplier of the fresh water to the municipalities in the United Arab Emirates (UAE). It is well known the high cost of a liter of water produced by the desalination process (\$ 2.0 / gallon) [1], [2]. Besides, desalination process adversely affects the marine environments. For example, brine as a by-product of the desalination process is usually discharged back into the sea degrading the sea water quality and posing hazards to the marine fauna and flora [3]. This makes the water produced from desalination a precious commodity. Unfortunately, considerable amount of the desalinated water produced, is used for non-potable uses (e.g. car-washing) putting more stress on already stressed fresh water resources. Therefore,

considerable amount of research has been directed towards exploring methods and techniques to recycle and reuse the wastewater to augment the high fresh water consumption especially for non-potable uses [4].

Globally, wastewater recycling/reuse has been practiced for a while for different purposes. Wastewater, is mainly recycled to minimize the disposed amount in order to alleviate the impacts on environment (degradation and pollution). Recently, it has been used as a lower cost alternative for fresh water in non-potable practices. Ground water recharging one of the first applications has been practiced. Other applications include irrigation of green landscape, air cooling (chillers), and recently toilet flushing [5]. In this region (Middle East), wastewater recycling and reuse is widely used to sustain the valuable and expensive water produced from the desalination of sea water [6]. For example, Dubai municipality recycles and reuses the wastewater for irrigation of the green areas in the landscape of the city [7]. Table 1 shows some standards set for the recycled water to be reused for irrigation.

BOD	mg/L	200	200
COD	mg/L	200	200
TDS	mg/L	2000	2000
TSS	mg/L	15	30
pH	mg/L	6 - 8	6 - 8

Source: Dubai municipality

The practice of car-washing is mounting in this region (ME, UAE). The harsh dusty weather necessitates the extension of this practice especially in the UAE. Unfortunately, car-washing service consumes substantial amount of the desalinated water produced in the emirate of Dubai [2]. The car-washing activity is estimated to consume around 30 gallons to wash small size car, and around 60 gallons to wash big size car. A published survey, extracted from 59 car-washing stations, shows that the water consumption reaches 378770 m³ per year [2]. This amount represents around 0.2% of the total annual production.

Currently, the whole amount of water wasted in car-washing facilities, is usually discharged into the city sewer systems after brief in situ pretreatment in holding tanks to facilitate settling of large solid particles. In general, the car-washing facilities pay relatively high cost to dispose their wastewater in the municipal sewer system burdening the car-washing facilities with more operational cost. The estimated costs of water usage and disposal for each car-washing facility are \$37000 and \$4000 respectively [2]. Therefore, considerable amount of research has been directed towards exploring methods and techniques to recycle and reuse the wastewater from car-washing to augment the high consumption of fresh water and reduce the operational cost [8] – [12].

Wide range of technologies, from simple to very complex, are widely used now to treat and recycle the wastewater. For example, the membrane filters (reverse osmosis (RO), micro, ultra, and Nano-filtration) are widely used to remove the dissolved solids (DS) and particulate matter (PM); the membrane bioreactor (MBR) systems are increasingly used now as an efficient technique to reclaim wastewater; the oxidation technique which is advanced to combine ozone, ultraviolet (UV) light, and hydrogen peroxide to create the highly reactive hydroxyl radical (.OH) [4]. The use and level of treatment required, dictates the cost of water recycling [4], [13]-[17].

Almost, all the current treatment methods incur high initial and operational costs. Therefore, this research is a genuine effort to develop and test a system to treat, recycle, and reuse the wastewater generated in car washing facilities in situ. The proposed system incur low initial and operational costs. The proposed system can be well described as a simple filter designed

and assembled from natural materials from local sources. The system is assembled from two filter: (1) sand and gravel mix, and (2) activated carbon. For the purpose of this study, the quality of the effluent (treated wastewater) was investigated and determined in Dubai central laboratories. Wastewater samples were grabbed from different car service stations. Representative samples were prepared and the concentrations of the following parameters were measured in each sample of the effluent: (1) Biological oxygen demand (BOD), (2) Chemical oxygen demand (COD), (3) Total dissolved solids (TDS), (4) Total suspended solids (TSS), and (5) Oil and grease (OG), (6) pH. The results are presented and discussed in section 3 of this paper.

2. Materials and Methods

The test program, in this research, is developed to filter and examine the quality of raw and treated wastewater samples.

2.1. Water Samples

The amount of the wastewater tested in this study was collected from 8 stations of car service around Dubai, UAE. Composite sampling was adopted. Composite sampling is widely used to monitor wastewater discharges [15]. In order to collect representative samples, several samples were grabbed throughout the car's washing process. Figure 1 shows the samples collection process. The samples then were thoroughly mixed together into a composite sample (Figure 2). The characteristics of the composite sample (raw wastewater) are presented in Table 2.

Figure 1: Samples collection process

The samples were screened first to remove the large particles or grit that might damage the filter and then passed through the two stage filter.

Table 2: Raw Wastewater Characteristics

Parameter	mg/L
Biological oxygen demand (BOD)	235
Chemical oxygen demand (COD)	976
Oil and grease	88
PH value at 25°C	7.2
Total dissolved solids (TDS)	1100

Total suspended solids (TSS)	112
Cadmium	0.08
Chromium	0.5
Copper	0.38
Lead	0.53
Nickel	0.2
Zinc	1.98

Figure 2: Sample of raw wastewater

2.2. Filter Fabrication

In order to increase the effectiveness of treatment, two filters were assembled and used. The two filter units were fabricated and assembled at the civil engineering workshop in the Dubai men's campus-higher colleges of technology. The two-stage filter was fabricated using materials available from the local market. These materials include: (1) Coarse Gravel, (2) Fine Gravel, (3) Sand, and (4) Activated Carbon. The schematic and the assembly of the two-stage filter are shown in Figure 3-a and 3-b respectively. For better depiction, the unit of the sand and gravel is magnified in the right part of Figure 3-b.

The schematic diagram shown in Figure 3-a, depicts the filtration process. From the entrance (inlet) the water flows through the first stage filter (dual media of sand and gravel) and then through the second stage filter (activated carbon) towards the exit point (outlet). Throughout the filtration process, samples of treated water were at outflow-1 and outflow-2 (Figure 3-a). Since Dubai regulatory authorities stipulate strict standards for the use of recycled water for different beneficial activities, the quality of the treated water was verified in the laboratories of Dubai municipality.

For better illustration of the effectiveness of the filter and the filtration process, the characteristics of the treated water samples were compared to the characteristics of the raw wastewater (baseline). The effectiveness of the filter is further indicated by the removal efficiency which is estimated by a formula taking the following form:

$$R\% = (C_{in} - C_{out}) / C_{in} \quad (1)$$

where R% is the removal efficiency, C_{in} is the initial concentration of the parameter in the influent (raw water), C_{out} is the final concentration of the parameter in the effluent (treated water).

(a)

(b)

Figure 3: Schematic and assembly of the two-stage filter-workshop-higher colleges of technology-Dubai men's campus

3. Results and Discussion

The results of the lab analysis of the raw and treated water samples are presented in Tables 3. The concentrations of the quality parameters in the treated water are depicted and compared to the levels of the parameters in the raw wastewater (baseline). Then the removal efficiency of the designed filter is estimated.

BOD removal: as shown in the table the BOD, as indicator of the strength of the organic pollution in the water sample, is reduced from 235 to 33.8 mg/L with removal efficiency reaches 86%. The huge reduction in the BOD is mainly attributed to the type of sand used in stage1 filter.

COD removal: the COD, as indicator of the strength of the organic pollution in the water sample, is also experienced huge reduction from 976 to 193 mg/L with removal efficiency reaches 81%.

TDS removal: it is well known that the high level of the total dissolved solids (TDS) can result in many problems such as scale

deposit and precipitates on fixtures; corrosion of fixtures, and reduction or malfunctioning of the filter and associated equipment [18]. Successfully, at this stage the level of reduction of the total dissolved solids (TDS) is fairly good (from 1100 mg/L to 249.6 mg/L) with removal efficiency reaches 78%.

TSS removal: accumulation of TSS in water systems usually causes blockage of the systems and damages the nozzles widely used in car washing facilities. Moreover, by time TSS create a good medium for bacterial growth which pose potential health risks. Unfortunately, the reduction in the total suspended solids (TSS) is of less magnitude of 57 mg/L (from 112 to 55 mg/L) with removal efficiency reaches 51%.

OG removal: To avoid any blockage to the filter/reuse systems oil and grease (OG) was a parameter of great interest in this research. Effectively, the level of the OG was reduced from 88 to 12 mg/L with removal efficiency reaches 86%.

In general, at this stage the performance of the filter, as measured by the removal efficiency, was fairly good. The removal efficiency was as high as 85% for BOD and as low as 50% for TSS, with average overall average removal efficiency of 73.51%.

The following results can be extracted from Table 3 after stage2:

BOD, the removal efficiency of the BOD improved by magnitude of 8% (from 85.6% to 93.32%);
 COD, the removal efficiency of the COD improved by magnitude of 18% (from 80.23% to 98.5%);
 TDS, the removal efficiency of the TDS improved by magnitude of 8% (from 77.31% to 85.31%);
 TSS, the removal efficiency of the TSS improved by magnitude of 39% (from 50.90% to 90.0%);
 OG, the removal efficiency of the OG stayed the same at 86%.

In general, the removal efficiency was as high as 97% for BOD and as low as 85% for TDS, with average overall average removal efficiency of 93%. It is very clear from the results that adding the activated carbon component to the filter assembly enhanced the filter performance a lot. However, within the limits of the parameters (BOD, COD, TDS, TSS, and OG) in the wastewater, it appears that the current levels of TDS had little effect on the removal of parameters examined in this study [18]. However, relative to other studies, the filter system developed, proved to be very effective in producing treated water of high quality and could be reused for car washing safely [8] – [12].

Table 3: Characteristics of raw and treated wastewater

Parameter	Pollution Level			Removal efficiency	
	Original	Stage1	Stage2	Stage1	Stage2
	mg/L	mg/L	mg/L	%	%
BOD	235	33.85	< 7	85.6	97.32
COD	976	193	15	80.23	98.5
OG	88	< 12	< 12	86.36	86.36
TDS	1100	249.6	161.6	77.31	85.31
TSS	112	55	< 11	50.9	90

Figure 4-a, illustrates the high performance of stage 1 of the filter. The color of the sample shown, is greatly diluted from dark black to grey one. This indicates the high removal of the total suspended solid (TSS). Figure 4-b shows from right to left samples of raw wastewater, water after stage 1, and after stage 2.

Figure 5 clearly depicts the removal efficiency of the filter system in magnitude (mg/L) and percentage.

Figure 5: Removal efficiency in magnitude and percentage

4. Summary and Conclusions

This paper describes a filtration system designed and tested for treatment and reuse of the wastewater generated in the car's service stations. The filtration system assembled from two filters: (1) sand and gravel mix, and (2) activated carbon. The system is made of natural materials from local sources. The system is anticipated to incur low initial and operational costs. The quality of the effluent (treated wastewater) was investigated and determined in Dubai central laboratories. Wastewater samples were grabbed from different car service stations. Representative samples were prepared and the concentrations of the following parameters were measured in each sample of the effluent: (1) Biological oxygen demand (BOD), (2) Chemical oxygen demand (COD), (3) Total dissolved solids (TDS), (4) Total suspended solids (TSS), and (5) Oil and grease (OG). The results are presented, discussed, and documented through several figures and table and the following conclusions were drawn:

According to the results, the removal efficiency of the BOD, COD, TDS, TSS, and OG is of magnitudes of 97.32, 98.50, 85.51, 90.0, and 86.36% respectively. The results suggest that, under the range of the current levels of the parameters investigated the performance of the system was good.

Very clear, adding the activated carbon component to the filter assembly led to a great enhancement in the removal efficiency of the filtration process. However, this cannot be said about the TDS removal. The removal efficiency of the TDS, unlike the other parameters, did not change from stage1 to stage2. This result indicates that activated carbon is not that efficient in filtering out the TDS. Alternative material (e.g. silt) must be sought and tested to improve the removal efficiency of the TDS. However, it can be concluded that the results show that the filter system achieved high performance in removing the parameters tested. In general, the quality of the effluent was found to fall within the standards set by Dubai regulatory authorities (Table 1).

Further research is recommended to enhance the filtration system performance and make it commercially applicable. Significant savings can be realized from treating and reusing of the wastewater generated in the car service stations. For example, sustaining (saving) precious resource (desalinated water) for the future and reducing the carbon foot-print on the planet earth.

Lesson summary

ABSTRACT

Automatic Speech Recognition (ASR) technology has the potential to improve the learning experience of students in the classroom. This article addresses some of the key theoretical areas identified in the pursuit of implementing a speech recognition system, capable of lesson summary generation in the educational setting. The article discusses: some of the applications of ASR technology in education; prominent feature extraction and speech enhancement techniques typically applied to digital speech; and established neural network-based machine learning models capable of keyword spotting or continuous speech recognition. Following the theoretical investigation, a model is proposed for the implementation of an automatic speech recognition system in a noisy educational environment to facilitate automated, speech-driven lesson summary generation. A prototype system was developed and improved based on this model, ultimately proving itself capable of generating a lesson summary intended to bolster students' secondary contact with lesson content. This topic-oriented lesson summary provides students with a lesson transcript, but also helps them to monitor educator-defined keyword terms, their prevalence and order as communicated in the lesson, and their associations with educator-defined sections of course content. The prototype was developed using the Python programming language with a modular approach so that its implemented Continuous Speech Recognition system and noise management technique could be chosen at run-time. The prototype contrasts the performance of CMUSphinx and Google Speech Recognition for ASR, both accessed via a cloud-based programming library, and compared the change in accuracy when applying noise injection, noise cancellation or noise reduction to the educator's speech. Proof of concept was established using the Google Speech Recognition System, which prevailed over CMUSphinx and enabled the prototype to achieve 100,00% accuracy in keyword identification and association on noise-free speech, contrasted with a 96,93% accuracy in keyword identification and association on noise-polluted speech using a noise-cancellation technique.

1 Introduction

Student lesson summaries are a valuable resource for allowing students to focus on the key points of a lesson, boosting secondary contact with lesson content. They allow students to realise which aspects of a lesson may be more important and streamline the study process for courses which employ both formative and summative assessments. Formulating a lesson summary from notes and lesson content alone can be challenging to students especially when covering larger segments of course content over a short period of time. Students are also not all equally capable of creating their own lesson summaries and often rely on available course material and notes made during their lessons as study material. These challenges are

also further compounded by a lack of context whenever students attempt to summarise a lesson without integrating with the theoretical focus of the classroom teaching session. Toward providing a solution to these challenges of lesson summary generation; this work is an extension of the paper presented at The 2019 International Multidisciplinary Information Technology and Engineering Conference (IMITEC) wherein a model was proposed for automated lesson summary generation in a noisy educational environment using keywords in the educator's speech as the prompting mechanism for summary of key points [1]. This extension reintroduces the proposed model, along with the theoretical background it is based in, reinforced by a proof of concept prototype system for lesson summary generation which is used to demonstrate the model's application.

Automatic speech recognition (ASR) has been applied in assistive technologies for tasks such as closed captioning, voice search, command detection as well as keyword identification. It therefore stands to reason that these applications of the technology may be applied to the voice of the educator in the educational setting. This work posits that it is possible to generate a lesson summary, by transcribing the voice of the educator during a theory lecture and identifying keywords based on the concepts of the course material being taught. In support of this theory, the objective of this work is to establish an abstract model for the application of ASR technology in the educational setting for generating lesson summaries. Section 2 provides the theoretical base for the model, focusing in three broad areas of theory. First, a number of applications of ASR technologies in education are discussed, particularly as they pertain to disabled learners and distance-based education. Second, recent trends in statistical models used to perform ASR and the underlying machine learning techniques used to design and train these models are addressed. In addition, voice enhancement and noise management strategies are addressed to account for noise pollution in the educational environment known to negatively affect the accuracy of ASR technologies and resulting transcriptions. The model itself is presented in Section 3 and the proof-of-concept prototype is discussed in Section 4. The prototype is evaluated in Section 5, with a discussion of test results in Section 6 and the study's conclusion in Section 7.

2 Background

This section provides an overview of work related to the concepts required to establish and propose the model for lesson summary generation in this work. To that end, Section 2.1 discusses the utility of ASR as applied to an educational context. The topics of feature extraction and noise cancellation are discussed in Section 2.2.2, as these techniques may be used to improve the reliability of speech features in the educator's speech during lesson transcription. Having clearly detectable features is critical in training a machine learning model to recognise, decode and transcribe speech. Neural networks are a widely used technique to train such a machine learning model and Section 2.3 presents a discussion on these techniques, revealing the trends in the improvement of the technology in recent years. The cumulative knowledge addressed in these theory sections provide the theoretical basis for the model and its application.

2.1 Automatic Speech Recognition in Education

ASR is widely known through commercial applications such as Amazon Alexa, Apple Siri, Microsoft Cortana and the Google Assistant [2]. These products enhance the productivity of their users by providing a means of interaction with a variety of applications. The use of ASR is, however, not limited to applications of convenience; it has also found purchase in the domain of education. ASR is one of the key interfaces that humans use to engage with machines in information technology, research in the field has important significance and the interface itself has wide value in application [3, p.84].

A broad overview is provided by 4 of both the underlying literature and experiments conducted with regard to ASR in the field of

education. The technology not only holds the promise of helping students surmount the challenges associated with reading, writing and spelling [4, p. 66], but also provides a facility for teaching staff to improve their pedagogical approach [4, p. 69]. A further application of this technology in the educational space is that it holds the promise of improving the interactions of deaf and second language speakers in the classroom [4, p. 66]. Furthermore, many of the studies included in the work by [4] have found utility as an emancipatory tool for those with physical and/or learning disabilities, as it allows them to write tests and complete projects by means of narration; tasks which would otherwise require the services of a human transcriber. With regard to deaf or hard of hearing students, such an ASR intervention could be invaluable if employed in a classroom environment to provide live captioning or to provide a lesson transcript after the fact. This may also alleviate their dependence on a sign language interpreter, transcriber or hearing aid. It has also been shown that it is possible to integrate an ASR system into the mathematics teaching process at a primary school level [5]. In the work conducted by 5, a voice-activated e-learning prototype was used and it was demonstrated that the use of such a tool could facilitate the learning experience at a primary school level, but also demonstrated feasibility up to a tertiary level; being especially helpful to students who have disabilities, learn on-line or are studying in a second language.

Beyond its utility in helping students with disabilities and in overcoming language barriers, ASR is also being applied to aid in other tasks related to the daily activities of students; including lesson reflection, group discussions and oral presentations [4, p. 66]. ASR can aid these activities by allowing students to have access to a lesson transcript, which facilitates a streamlined approach towards note-taking. It has been shown [6] that ASR technology has definite application in synchronous (real-time) cyber classrooms; an approach that has been pulled into the limelight with the advent of the COVID-19 pandemic [7]. Although such a live approach has been shown to be impeded by issues such as latency and bandwidth, resulting in students missing portions of the lecture [6, p. 367-368], the application of ASR could quite easily alleviate this with the lecturer providing a transcription of the lesson, generated by ASR from a full recording of their speech, after the lesson has been delivered.

ASR systems have also been applied to Elicited Oral Response (EOR) testing. EOR is employed to assess the speaking ability of an examinee by having them listen to a phrase and then restate the phrase to the examiner [8, p. 602]. The application of ASR allows such a test to be conducted automatically, with little to no need for a human examiner. The feasibility of such an ASR-based EOR testing process has been demonstrated [8]. It was found that it is a suitable tool for assessing the validity of content, and is able to do so reliably and in a practical fashion. It represents a means by which to support low-stakes decision making, especially when applied to second language learning. All of these technologies, however, have their downsides. The transcripts generated with an ASR-based tool tend to contain many punctuation errors or to eschew punctuation altogether. It also does not account for any recognition errors which may occur as a result of redundancies in repetitive speech [4, p. 68]. These shortcomings require manual human intervention or a third-party grammar analysis application to correct. Furthermore, a common criticism of using ASR-based technology in a noisy en-

environment such as a classroom, is that the accuracy of the ASR process may be impacted. There are, however, means by which these noise artefacts could be overcome, minimised or filtered out, allowing the required high rate of accuracy to be maintained.

2.2 Feature Extraction and Speech Enhancement Techniques for Robust Speech Recognition

This section focuses on prominent feature extraction and speech enhancement techniques such as noise cancellation and noise reduction; with the noise cancelling techniques serving to augment or complement feature extraction techniques that are not as noise robust.

2.2.1 Feature Extraction Techniques used in ASR systems

Although ASR consists of many steps, one of the most important is undoubtedly that of feature extraction; as this step is used to highlight which components of an input speech signal will serve to support the *recognition* aspect of automated speech recognition. For speech-based audio data to be employed as meaningful data, whether for training purposes or in an active ASR system, it needs to be transformed into a less abstract representation which brings to fore the distinguishable components of speech in the input audio signal. The work done in [9, p. 3] distinguishes between two types of features; temporal features (e.g. short time energy and auto-correlation), which exist within the time domain and spectral features (e.g. fundamental frequency and spectral flux) which exist within the frequency domain of a speech signal. A spectrogram is a time-frequency representation of speech data. It is arguably the fundamental feature extraction method, performed by applying the Fast Fourier Transform (FFT) to the speech signal [10, p. 4525] to transform speech energy through time into frequency estimations through time. As there is a need to highlight the frequency intensity related to speech signals, many feature extraction techniques, related to speech processing, are spectral in nature. The words in most languages are built from smaller components of speech, known as phonemes and the various phonemes consist of distinct formants (fundamental frequencies), evident in their pronunciation. Formants are defined [11, p. 5176] as being created by the resonance of the vocal tract and recognisable as the spectral peaks on the frequency-time spectrum of speech. Therefore, techniques used for spectral feature extraction are highly applicable to ASR systems, allowing them to distinguish between the various formants at their distinct spectral peaks.

Another approach is to apply Linear Predictive Coding (LPC) to create observation vectors, based on the frame-based analysis of speech signals. These vectors may provide an estimation of the poles of the vocal transfer function [12, p. 495]. During the process of performing LPC feature extraction, a signal is run through a pre-emphasis process to reduce the occurrence of audio pop at the beginning and end of each frame and to reduce signal discontinuity between frames. The first of these issues is addressed by the application of frame blocking and windowing. This is then followed by an auto-correlation analysis, applied window-wise, during which the LPC coefficients are derived as the observational vectors [12][p. 495]. To counter the lack of robustness of LPC with regard to noise,

which may cause interference in the calculation of the coefficients, another spectral-based feature extraction technique, Relative Spectral Filtering (RASTA), may be applied to extract features from the spectrogram. The intent of RASTA is to enhance the speech characteristics of the signal by means of the reduction of unwanted and additive noise [12, p. 495]. As part of this technique, a spectral analysis is performed, after which static non-linearities are compressed, a filter is applied based on linear band trajectory in the cepstral or log spectral domain, and then finally, the static non-linearities are decompressed, resulting in the set of RASTA features [12, p. 495]. As stated by [12, p. 496] RASTA-based feature extraction finds purchase where speech recognition needs to be performed in a noisy environment.

Another very widely used feature extraction technique is the Mel-Frequency Cepstral Coefficient (MFCC). This technique focuses on audio frequencies in the range 300Hz to 3400Hz, the critical frequency range of the human vocal tract interpretable by the human ear [12, p. 495; 11, p. 5176]. MFCC is associated with a very efficient method of calculation which follows a similar approach to LPC, in that it involves pre-emphasis of the speech signal, frame blocking and windowing [12, p. 495]. After the windowing process, the FFT is applied and the absolute values it returns are placed in a Mel-filter bank; the log of the filter bank values is calculated and the final MFCC feature vectors are created by applying the discrete cosine transform to each Mel-filter bank. Because it relies on auto-correlation analysis, MFCC shares the trait with LPC that it is not noise robust [13, p. 358]; although there are many MFCC variants, each with their own improvements and compromises [14]. Other feature extraction techniques include Perceptual Linear Predictive Coefficients (PLP), which are often used in conjunction with RASTA for improved performance; Wavelet-based features; and Linear Predictive Cepstral Coefficients (LPCC), an addition to LPC [13–16]. The work performed in [3, p.83] contrasts LPCC and MFCC, demonstrating that LPCC generally results in lower accuracy but has a faster computation rate while MFCC is slower to compute, but often results in improved recognition accuracy.

2.2.2 Speech Enhancement Techniques for improved ASR

The effect of noise has always been a major consideration when implementing ASR system, as a noisy input signal may interfere with the feature extraction process. This may yield unreliable speech features, which in turn leads to a low level of accuracy for the underlying ASR model. There are various major sources of noise, namely background noise from a noisy environment, echoes resulting from recording in confined spaces, feedback resulting from two-way communication when a loudspeaker is too close to the recording device, the background hum caused by an amplifier, quantisation noise resulting from analog to digital conversion, noise resulting from the loss of signal quality when compression is applied, and finally, the distorted signal resulting from reverb, which can also be considered noise pollution [11, p. 5176; 17, p. 318]. Within these various noise sources, noise may be classified according to the following types, which can be mitigated via noise cancellation techniques, namely narrow-band noise, coloured noise, white noise, transient noise pulses and impulse noise [11, p. 5177]. The ultimate goal of a noise cancellation technique is to suppress or de-emphasise

the noise components within an input speech signal [11, p. 5178]. Speech enhancement is the process of enriching the spectral characteristics of a speech signal to make it easier to recognise by machine. This process incorporates noise cancellation techniques, but may also transform the speech signal so that the features within it are more distinguished. 9, p. 2 discuss the principles behind speech enhancement, stating that the performance of such a system is measured based on the quality (detected by human ear) of the enhanced speech and the residual noise level that remains in the speech after enhancement. The main objective of a speech enhancement strategy is to remove any additive noise that exists within a speech signal as a result of the recording being performed in a noisy environment [9, p. 8]. The terms speech enhancement and noise cancellation have become largely synonymous, but 9, p. 9 make the point that feature selection is optimised by "selecting the most uncorrelated features" which often determines the effectiveness of the overall speech enhancement strategy.

Noise cancellation techniques fall under two broad categories, namely linear filtering and adaptive filtering [18; 11; 17]. These noise cancellation techniques may occur in the frequency domain, the time domain or in both [11, p. 5179]. Finite Impulse Response (FIR) and Infinite Impulse Response (IIR) are two types of linear filters [11, p.5178]. The purpose of linear filtering is to remove all frequencies which exist outside of the desired frequency domain by moving linearly along the time domain. In the frequency domain these filtering techniques fall under four categories, namely low-pass, band-pass, band-stop and high-pass filters [11, p.5178]. A combination of these filters may be used to remove all frequencies existing outside of the interpretable range of the human vocal tract. This may be done by applying a high-pass filter to remove frequencies below 300Hz and a low-pass filter to remove frequencies above 3400Hz. This approach, however, will not remove noise within the range of the human vocal tract and may also be problematic in noisy environments because the characteristics of the noise may vary (in intensity) over time and as a result it may not be possible to predict the position in the audio stream at which the noise will occur due to its non-stationary nature [18, p. 336; 11, p. 5178]. Linear filtering has utility in cases where the noise levels are more predictable, such as with amplifier or quantisation noise.

Another form of filtering, the adaptive filter, is based on the mathematical principle of cancellation. This process combines two signals to remove the noise from the original. In such an Adaptive Noise Canceller (ANC), the original signal contains the desired speech to serve as input to an ASR process, but also the noise, which may negatively impact the accuracy of recognition. The second signal serves as a representation of the noise and is adaptively filtered from the original speech signal. This second signal is then subtracted from the original signal [11, p. 5178]. This kind of approach accounts for the dynamic nature of a signal containing speech and other audio. This presents an approach where the parameters and band-pass type are adjusted automatically, depending on the signal, rather than relying on pre-set parameters and a specific band-pass type [11, p. 5180]. This approach is conducted by performing audio framing, after which a unitary transform of the time domain for every frame to the given transform domain is performed. This allows filtering to be applied to individual frames; after which the frames are returned to the time domain by applying the inverse unitary

transform. As a final step, the frames are converted back into a congruent audio file, representing the noise to be subtracted from the original audio [11, p. 5179]. An alternative to focusing on the time domain is to approach the problem from the frequency domain. Examples of adaptive filters are the Weiner and Kalman filters and the Recursive Least Squares (RLS) algorithm [17, p. 318]. A Discrete Fourier Transform (DFT), Discrete Cosine Transform (DCT) or Karhunen-Loève Transform may be used to perform frequency domain transforms [18, p. 336]. Of these approaches, the computational efficiency of DFT makes it the most popular [11, p. 5179]. By applying these techniques to an appropriately selected transform domain, better separation may be achieved between the speech and noise signals. This could result in improved filter estimation which may yield superior speech enhancement performance.

This section has discussed a number of feature extraction techniques and the importance of their appropriate selection, especially in noisy environments. As demonstrated in [19], a feature extraction technique can be chosen to work in conjunction with its underlying ASR model along with a speech enhancement strategy for improved ASR performance.

2.3 Machine Learning Techniques for Automatic Speech Recognition

Hidden Markov Models (HMM) were widely used in the early development of ASR systems. The HMM applies probability theory to track the likelihood of the phonetic state transitions within words based on spectral templates of phonetic units which are decoded from the speech signal to predict voiced utterances. This process was eventually augmented through the addition of a Gaussian Mixture to each state of an HMM to model the short-time phonetic units. This combined process is referred to as a Gaussian Mixture Model Hidden Markov Model (GMMHMM) [20]. The advent of faster computer processors has made it feasible to train Deep Neural Network (DNN) models for speech recognition. DNN-based models deal very well with the high dimensionality of speech data, using fewer parameters to optimise [21] and have been shown to outperform GMMHMMs [22] leading to the widespread adoption of DNN architectures for the purpose of performing machine learning in ASR. There have been many major improvements since the first implementations of DNNs for ASR. Two of these improved architectures, namely Convolutional Neural Networks (CNN) and Recurrent Neural Networks (RNN) are discussed in the following subsections.

2.3.1 Convolutional Neural Networks

A CNN depends on two additional logical layers for performing speech recognition, namely convolutional layers, which act as localised filters, and max pooling layers, which normalise spectral variation[20]. The series of filters in a convolutional layer are applied in an over-lapping fashion across acoustic frames that overlap in time over the entire input space and are often referred to as feature detectors [23, p 1534; 20]. By modelling the associations between the frequency and time domains, and using the local filtering and shared weights of the convolutional layers, a CNN maintains the correlations between these domains and provides a superior result

to the input mapping of DNNs [21]. Varying speaking styles also present a challenge to traditional DNNs as they are not inherently designed to model the translation invariance resulting from formant frequency shifts [21]. Convolutional layers combat this through the use of local filtering and the shared weights. The resulting translation invariance improves the robustness of the model on diverse speech signals by allowing speech features to be detected regardless of their location within local input spaces.

The convolutional layers of a CNN work in conjunction with the max-pooling layers. Max-pooling layers are used to reduce the dimensionality of the resulting convolutions by ensuring maximum filter activation at varying points. This is done to reduce the dimensionality of the convolutions [20]. The performance of the speech recognition task, using CNNs, is also improved by performing pooling in frequency and in time, yielding a robustness towards speaking rate [21]. Convolutional and max-pooling layers may also be applied in alternating pairs to further reduce dimensionality. This improves performance in fully connected hidden layers with fewer trainable parameters. This added robustness towards variations in speech styles, provided by the pairing of convolution and max-pooling layers, allow a CNN to learn the acoustic features for various classes, such as speaker, phoneme and gender [23, p. 1534]. This is another feature which adds to the superiority of CNNs over DNNs for analysing speech signals. Studies have also shown that it is possible to add multiple channels of features, like those from a cochleogram and a spectrogram, as inputs to a CNN. This approach allows the CNN to learn from multiple sets of features simultaneously, providing improved performance over learning from a single channel [10].

2.3.2 Recurrent Neural Networks

RNNs are very useful for language modelling, but are also capable of performing predictions with regard to the likelihood of a feature by making an association based on previously identified spectral speech features. This makes them highly capable of predicting future words or phonetic units based on previously observed words or phonetic states. RNNs make use of Long Short Term Memory (LSTM) cells to keep track of any associations identified in the previous layer with the current layer. RNNs have been employed [24; 25] for creating robust speech recognition models and these approaches have been improved upon [26] by implementing a light gated architecture. It has also been shown [27] that it is feasible to apply convolution and max pooling as inputs of RNN layers to perform local filtering and pooling. The condensed features are then passed to RNN layers, which make use of LSTM cells or Gated Recurrent Units (GRU) to maintain the contextual associations between features through time. HMMs have also been combined with convolution and LSTM to tie phonetic state transitions for speech recognition [28].

3 Model Overview

This section reintroduces the proposed model, which has been updated since its inception, initially published in [1]. This model is theorised through background literature review and exploration; then reinforced by a proof of concept prototype implementation and

the experimentation performed to evaluate it. Figure 1 illustrates the model using a process flow diagram which demonstrates the sequence of processes applied and data flow between them that are applied to generate a topic-oriented lesson summary.

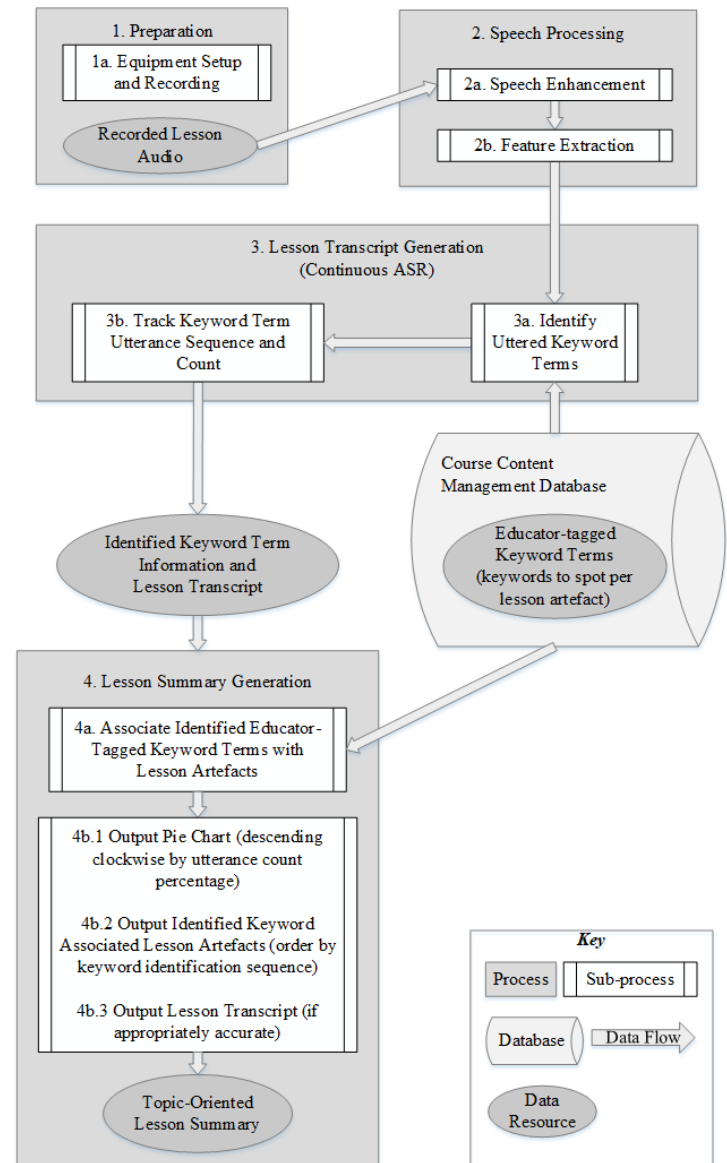

Figure 1: Proposed model for the application of an ASR system used to facilitate topic-oriented lesson summary generation in a noisy educational environment

The subsections that follow discuss the four main processes involved in implementing the proposed model to generate a topic-oriented lesson summary, driven by known keyword terms uttered by the educator during a recorded lesson.

3.1 Preparation

To capture the speech of the educator throughout the lesson, a microphone, connected to a recording device is required. There are a number of microphone options, widely available from commercial retailers. This section discusses two variations of microphone setup for use in conjunction with the proposed model. These are

addressed with regard to ease and suitability of use and constraint on budget, as many of these hardware components are expensive and are not all appropriate for a lesson recording setup. There are a number of microphone products to choose from and their quality and capability of audio capture is what sets them apart. Seemingly, the most professional, and consequently the most expensive, are lapel microphones, often used in stage performances and business presentations. Lapel microphones provide a wireless, high fidelity (16000Hz) audio capture solution for the educator, which promotes freedom of movement. These microphones are typically fixed onto the speaker's collar and plugged into a transmitter usually attached at the waist of the speaker, which transmits the stream of their speech signal to a soundboard of sorts (which could be integrated into a computer or some other audio mixer) for playback and storage. Lapel microphones are intended to capture the primary speaker's voice, with low gain, so as not to capture background noise or over-amplify the speech.

In the medium price range, handheld microphones, with wired and wireless variants, are a more affordable solution for recording the educator's speech during the lesson. Wireless options can still be expensive, but promote freedom of movement compared to their mounted or cabled counterparts. These microphones also transmit the stream of captured speech directly to an audio mixer or computer for storage and playback. Wireless recording solutions provide the most ease of use for the educator or a secondary speaker. The cheapest option for voice capture is the stereo headset, often used for voice communication while gaming or with online voice communication applications like Zoom and Skype. While stereo headsets can be bought cheaply, wireless variants are also more expensive and equally bulky, since the microphone cannot usually be detached from the headset itself and still function. Headsets are also only designed to capture the speech of the primary speaker and cabled variants are more suitable for use while seated, once again limiting the movement of the speaker unless a wireless headset can be used.

Each of these microphone options are also available with hardware-integrated noise cancellation. This additional feature can be costly, but can also remove the need for additional processing for noise management as the lesson is recorded. The choice of which recording devices to use should be made based on budget, fitness of purpose and requirement as well as convenience of use; ideally with a vision of high audio fidelity for a real-world classroom implementation, with the lowest permissible functional costs for testing purposes.

To facilitate voice processing and speech enhancement, discussed in the next section, a combination of microphones can be used. In this case, the primary microphone is used to record the speech of the educator or a student, should they have a question (to be transcribed), in which case they would need to speak into the educator's microphone, with a secondary microphone used to record environmental noise. A mounted wide-band microphone is the cheaper solution to consider for recording environmental noise during the lesson and if appropriately positioned, away from the educator, toward the back of the classroom, will capture noise pollution in the classroom without explicitly recording too much of the educator's speech. These microphones need to record in parallel so that their recordings can be easily aligned and used in

combination with a chosen speech enhancement technique whereby the primary recording of the educator's speech is enhanced using the secondary recording of environmental classroom noise to 'cancel' noise captured in the educator's speech signal by the primary microphone.

3.2 Speech Processing

Once all the speech of the educator has been recorded for analysis after the lesson using the equipment setup and an appropriate recording method mentioned in the previous section, the digital speech must be processed to manage environmental noise. The primary requirement of this recording is that it must be of the waveform file format (file extension .wav); the raw, uncompressed audio format that ASR systems are typically developed and trained to be able to recognise speech from using an appropriate feature extraction technique. The quality of the captured audio must be considered in terms of its cost effectiveness. Improved audio quality results in larger waveform audio files as the range of captured frequencies as well as the bit depth and sampling rate increases. These factors contribute to the file size of the lesson audio, and should be considered carefully, especially if a cloud speech recognition service will be used to transcribe lesson audio, as the file will need to be uploaded for recognition which will take more time if large audio files are uploaded. If a cloud based ASR solution is used to transcribe the recorded lesson, the audio may need to be segmented in overlapping windows of appropriate duration before the ASR system will transcribe the audio due to file size limitations put in place by the ASR service. Resulting segments of lesson transcript will also need to be aligned according to this overlap. In addition, should the audio need to be stored on a web server to be made available to students for review purposes, a large file size will also contribute to storage costs, data usage and buffer time.

Classrooms are notoriously noisy environments owing to the number of students, inevitable chatter, chairs shuffling, corridor activity and a myriad of other possible noise generating events. For this reason, speech enhancement, wherever possible should not be overlooked when implementing speech recognition technology in the educational environment. In the proposed model, speech enhancement is an optional process within the Speech Processing block, and will require the application of a linear or adaptive filter on the recorded lesson audio should this option be taken. This sub-process is optional because if the chosen ASR model uses a noise robust feature extraction technique, applies its own speech enhancement technique or if a noise cancelling microphone is used, then there may not be a need for additional processing for noise management. Over application of speech enhancement can also degrade the educator's speech to a point that it is no longer recognisable by ASR. Speech enhancement should always be considered for classroom applications of ASR technology, but it can be also be accommodated inherently by the feature extraction technique of the ASR system if this technique is noise robust (e.g. RASTA). As stated in the background section, LPC and MFCC are not noise robust feature extraction techniques and will from the application of speech enhancement.

Applying a Speech Enhancement technique will typically require a distinct waveform audio recording of the noise-polluted

speech of the educator during the lesson, recorded by the primary microphone as well as a distinct parallel recording of the noise pollution itself occurring within the classroom, recorded by a secondary microphone. In the ideal recording setup, the noise audio can then be removed from the educator's speech signal almost entirely, resulting in the audible speech of the educator to be analysed by the chosen ASR system, improving its performance and ultimately the accuracy of generated lesson summaries. The chosen speech enhancement technique can be performed during the recording of the lesson, applied to the real-time speech audio stream, using the real-time noise pollution audio stream; or alternatively, the lesson can be recorded in its entirety along with environmental noise and then the speech enhancement technique can be applied to the resulting recording after the lesson once the speech audio and noise audio have been aligned for cancellation. Most importantly, if deemed a necessary intervention, a speech enhancement technique should always be applied prior to ASR.

3.3 Lesson Transcript Generation

The background section covered the capability of ASR systems to transcribe the speech of the educator. Historically, this has been the fundamental reason for implementing speech recognition technology in the educational setting. Lesson transcripts provide many benefits, notably the potential for content reflection and note taking as mentioned in [6, p. 369], as well as improved teaching methods and support of students with disabilities, as described in [4, pp. 65-66], there are clear motivations for lesson transcript generation. In the age of information and with the interruptions in teaching caused by the COVID-19 pandemic, online learning and video conferencing are becoming more prevalent approaches to education. In these learning environments lesson transcripts are an additional resource for students. Cloud-based ASR systems provide an easily accessible ASR service and can allow researchers to access advanced ASR Models like Google Cloud Speech Recognition and CMU Sphinx. An ASR model can be incredibly challenging to develop from scratch even for an educational institution, due to the mathematical complexities involved in training a machine learning model and the tremendous amount of training data required to optimise it, especially for data as diverse as speech. Depending on the available resources and with recent trends making continuous progress on ASR performance, the task of lesson transcript generation itself might be better suited to a well established, cloud-based ASR model.

3.4 Educator Tagged Keywords and Course Content

The proposed model capitalises on the transcript-generation process by analysing the lesson audio to detect, sequence, count and associate known keyword terms with course content items, prompted by the ASR system's detection of a single utterance of each associated keyword. The count of the number of times each keyword term is uttered throughout the lesson audio can also be maintained to show topic prevalence, allowing students to gauge the importance of various keywords used throughout the lesson and prioritise the amount of time they should spend studying associated topics. The identified keyword terms along with their sequence and utterance

counts should only be extracted/calculated based on the new segment of lesson transcript (appended to the overall transcript), after the overlap has been accounted for to avoid duplicate keyword terms being counted.

For the proposed model to be successfully applied, each section within the course content must be tagged with one or more keywords to facilitate the associations between each of the identified keywords in the lesson transcript, with their relevant sections in the course content. This can be achieved by creating meta-tags in a database-bound content management system, storing the relevant keywords for each section of the course. Since the course content is generated from these systems by querying the course content database, the keywords identified through lesson transcription can be queried against the meta-tags within the course content database. Many keywords can be tagged to account for different teaching styles and linguistic preferences. By adding these meta-tags wherever relevant, the identification of a keyword can trickle down through the entirety of the course content and highlight all the sections of the course where the keyword has been tagged. The course content director or the educator should delineate the relevant keywords in each of their associated sections within the course content. The educator must then ensure that they use some of the specific keywords when delivering the lesson so that the model can highlight these associations. The keywords that the educator plans to use are then provided as an input to the transcript generation process to specify which keywords to look for as the speech of the educator is transcribed. This entails sufficient lesson planning and familiarity with subject matter.

3.5 Topic-oriented Lesson Summary Generation

Through the generation of the lesson transcript, the full transcript resulting from segmented ASR performed on the lesson audio, as well as the recorded keyword details were collected. The keyword details include the sequence of its utterance and its utterance count. This information can be summarised and presented to students to help them reflect on what was covered during the lesson, as emphasised in [4, pp. 66-67]. As stated in [4, p. 67] the lesson transcript acts as the primary resource for clarification of what was directly communicated during in the lesson. The additional keyword details captured are supplementary, but allow for the generation of the lesson summary to be structured in accordance with keyword sequence. The identified keyword terms and their utterance counts serve to emphasise the specific topics discussed and their prevalence within the lesson transcript, further bolstering secondary contact with the subject matter.

To finalise the lesson summary and present it to students, one final process must be performed to associate the identified keywords uttered with their relevant sections in the course content. This is achieved by iterating through the list of identified keywords and for each keyword, testing whether it has been tied using meta-tags to a section of the course content, by the educator. If the keyword is assigned then the association is made via the database bound content management system and the section heading along with any additional information stored in the database (such as the page number) is added to the lesson summary. Once all of the keyword information, along with associated course content artefacts have been extracted, the information can be arranged and presented to

students for review. The topic-oriented lesson summary could be structured as follows: first, the details for each keyword term can be stated or plotted on a pie chart (or bar graph) in accordance with their sequence and utterance count to show topic prevalence; second, the sections associated with each keyword can be listed, aligned with the sequence of their related keyword terms; and third, the lesson transcript itself can be added to the lesson summary. It is worth noting that the release of the lesson summary to students could be delayed to allow for the educator to edit the transcript (should it be added to the summary); removing redundancies and adding punctuation where needed to correct mistakes made by the ASR model during transcription.

4 Proof of Concept Prototype Overview

This section discusses the implementation of the prototype based on the proposed model. This prototype was developed in the Python programming language, over versions 3.6 and 3.7, using the Anaconda platform with the Spyder Python editor. Python is a flexible, object-oriented programming language, providing exceptional access to various programming libraries written in Python, C and C++ which are appropriate for handling and manipulating digital speech data. Python was the programming language of choice for the prototype, since it provided access to numerous programming libraries available within the topic area, made available free of charge by its longstanding data science community. The subsections that follow describe the functions of each of the major modules which facilitate the prototype's goal of generating a topical lesson summary. Figure 2 shows the class diagram of the proof of concept prototype developed alongside the model. For simplicity, method input parameters and return types have been omitted.

4.1 Large Vocabulary Continuous Speech Recognition (LVCSR)

The LVCSR Class is responsible for all ASR performed by the prototype. This is achieved through cloud speech recognition services made available by [29], an API which provides access to a number of cloud-based ASR services, some at a cost, and others free for application development, research and testing. The two ASR service providers utilised by the prototype were CMU Sphinx [30] and Google Cloud Speech Recognition [31]. Both of these providers have made their APIs available free of charge for use in the development of speech-driven systems. Regardless of provider, the access methods of this API take as input a single waveform audio file, which the prototype uploads to the given recogniser via the World Wide Web. The chosen recogniser then processes this data on the cloud server and returns the result of transcription of the uploaded audio. Google Cloud Speech Recognition [31] is based in a DNN strategy for ASR and reports to perform speech enhancement technique, while [30] is based in a HMMGMM strategy for ASR and does not perform noise cancellation. Other paid cloud speech recognition solutions made available by the API in [29] include IBM Speech to Text and Microsoft Bing Speech Recognition, among others. What makes this particular ASR service API so useful is that each recognition service is exposed in the same

way, making the implementation cross-compatible, regardless of the recogniser chosen at run-time.

The implemented prototype was adapted to generate a lesson transcript by uploading multiple shorter segments of lesson audio to accommodate cloud-based ASR using Google Cloud Speech Recognition and CMU Sphinx. To achieve this, lesson transcripts were generated by sequencing the overlapping segments of lesson audio from start to finish; then performing ASR on overlapping segments of recorded lesson audio with the transcript accumulating as new audio segments were analysed. The overlap was applied to account for sudden cuts in the audio mid sentence owing to the segmentation and also to ensure continuity between the results of transcribed segments of lesson audio, resulting in a more accurate lesson transcript once the transcript was aligned and textual overlap had been accounted for between segments. Through this process of segmentation analysis, the sequence and a counter of each keyword term uttered by the educator were maintained.

4.2 The Wave Handler Module

The Wave Handler module facilitates all the necessary access, storage and segmentation of Waveform Audio Specification files associated with lesson audio analysis. This is achieved using two methods. The first returns the duration of a WAV file specified by file path. The duration of the specified file is calculated by dividing the number of frames in the file by the frame rate of the file, retrieved from its file header. The result of the division is returned as a floating point number representing the duration, measured in seconds, of the specified file. This method primarily serves to determine the boundaries of a WAV file when accessing or segmenting WAV data, but is also used by the control loop to iterate the analysis window over the entirety of the recorded lesson audio.

The second method is used to segment WAV audio and also takes as input a specified WAV file path as well as a start time and an end time. The start time and end time parameters are used to window the speech audio for segmentation and, ultimately, for analysis by the chosen ASR system. This method also accepts three optional parameters: a possible WAV file path to a noise sample WAV file (defaulted to empty), a noise reduction Boolean (defaulted to false) and a noise cancellation Boolean (defaulted to false) indicating whether the segmented audio should have pseudo-random noise injection, noise reduction and/or noise cancellation applied respectively, using the specified noise sample. This allows for any WAV file to be read and segmented according to appropriate time intervals, as desired. When a noise sample is specified for injection and possibly subsequent noise reduction and/or cancellation, a random interval from within the roughly ten hour noise audio file is chosen to be used for injection each time the speech audio is segmented for analysis.

4.3 Database Design for Lesson Summary Generation

In order to establish associations between known keyword terms and sections of course content, a structure was required to retain these associations. The structure of choice to meet this requirement was a MySQL database. This database has three tables: first, a keywords table, which stores a primary key identity and lower-case

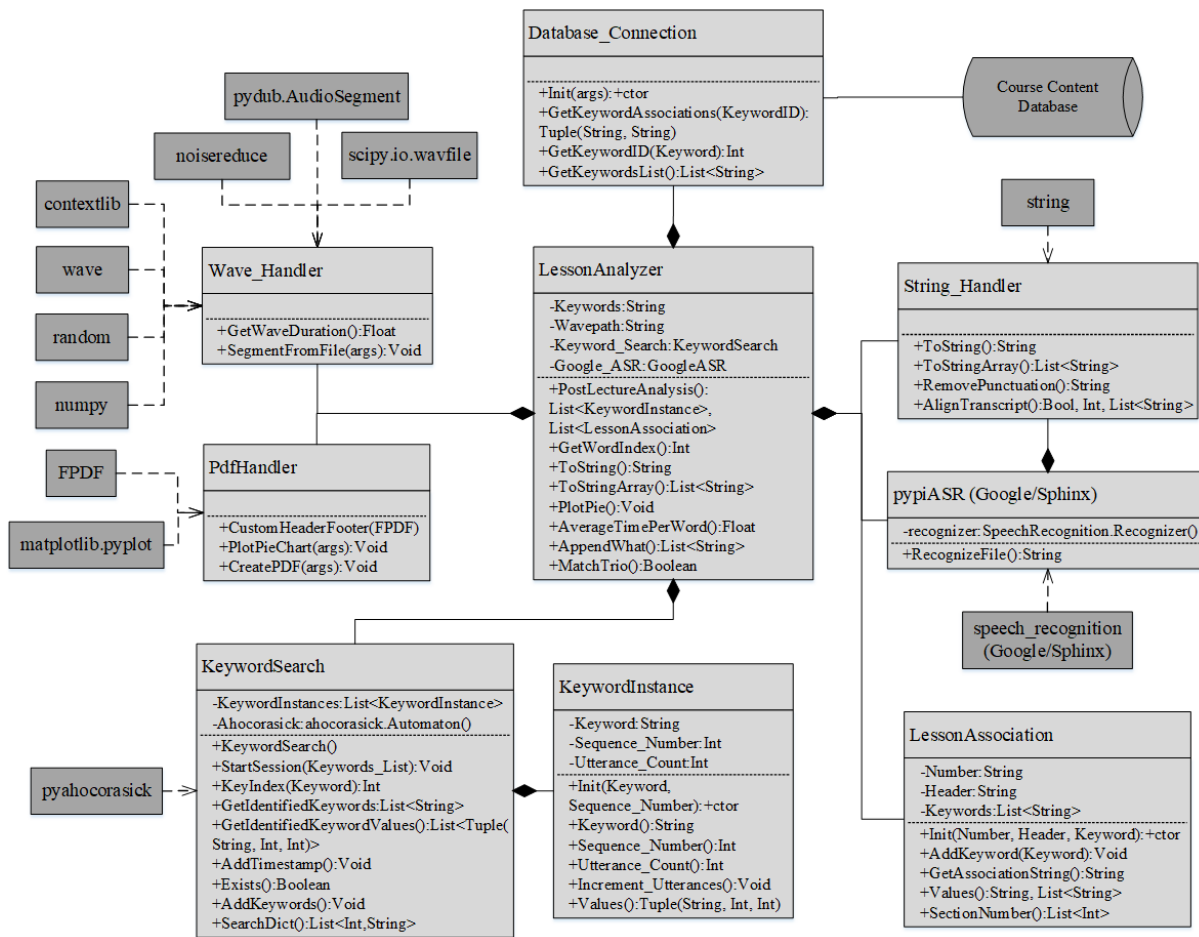

Figure 2: Class diagram of the proof of concept prototype system based on the proposed model

text for each of the known keyword terms the prototype is concerned with; second, a content table, which stores a primary key identity for each course content item, the header text of the course content item, a potential section number as well as a description; and third, a keyword-content relational table that ties each keyword term to one or more course content items. These ties are stored as distinct combinations of keyword term and content item primary key identity pairs which can be queried to yield the course content items associated with any known keyword term that the ASR system has identified.

In the keywords table, spelling is essential and distinctions should be made between standardised (American and British English) spelling. While the associations exist between the identity values of keywords and course content items, the association can only be triggered if the chosen speech recogniser identifies the text of the keyword term while generating the transcript. If the keyword term is misspelled compared to its recognised counterpart, it will not be identified and the association cannot be made. This is also why all string comparisons are performed in lower case since uppercase characters have different values to their lowercase counterparts. The prototype is concerned with seventeen keyword terms in total (four of which are not associated with any course content items), lists fourteen content items (four of which are not associated with a keyword term), and maintains fifteen keyword-content associations,

with some associations existing between one keyword and many course content items.

4.4 The String Handler Module

The String Handler module deals with all text data transferred by prototype operation between processes. This module has five functions, and all string comparisons implemented by these functions are performed in lower case. The first two methods are used to split a sentence (on space characters) into an array of words, and the second recombines this array back into a sentence in the word order of the array indices. These functions are used to analyse and align word sequences during prototype operation. The third function is defined to remove punctuation and accepts any continuous string as input; then returns the equivalent string with commas, apostrophes, full stops, etc removed. This method is also used to facilitate string comparisons and to ensure that grammatical character differences do not prevent word sequence matches.

The last two methods of the String Handler module are used to align transcript segments. The fourth method performs a sequence match using two string arrays, created by the first method, as input. This method iterates through the words in the first array and determines whether the sequence of words in the first array matches the sequence of words in the second input array. If a match is found,

this function returns a Boolean true; and if not, it returns Boolean false. The fifth method in the String Handler module is used to align transcript segments as the audio is windowed, analysed and transcribed by the speech recogniser. This method applies the previous sequence match method to identify the index where two given string arrays align, and then returns the aligned text from the identified index onward. As input, this method takes two string arrays; the current transcript (or an empty array if this does not yet exist) and the most recently transcribed text (converted to an array) as well as an integer to define how many words in sequence are required to match, and a second integer to define how deep through the array the method should search. The last two parameters are dependant on the duration of the overlap of the speech analysis window and the maximum number of words in the longest keyword term. This alignment method also persists with its search once a match is identified to ensure that the last possible matching index is used to return the overlapping text, and not simply the first identified match. This is to prevent transcribed utterances that are repeated from being matched prematurely, which would result in repeating segments of the transcript. This alignment is performed with each iteration of the prototype over the lesson audio, prior to any keyword term identification and possible association.

4.5 The Aho-Corasick Keyword Search

To identify keyword terms uttered by the educator, an Aho-Corasick keyword search was implemented. This search algorithm, made available by [32] was chosen because it is fast and reliable, and would not result in significant delays when searching for keyword terms between overlapping windows. Technically, any string-search algorithm would suffice here, but the Aho-Corasick search was deemed most appropriate to meet the requirements of the prototype. This search algorithm is implemented as an automaton whereby each keyword term that the prototype is concerned with is added to the watch list of the automaton at run-time. Any known keyword term can be identified in any potential search string. The Aho-Corasick automaton searches for keyword terms in parallel, meaning that the prototype does not need to iterate through each known keyword term and search for it; instead, the automaton has its bound keyword terms set at run-time and will search for any of these terms simultaneously. This behaviour facilitated the identification and accumulation of keyword term utterances stored by a customised Keyword Instance class.

4.6 The Lesson Analyser Program

The Lesson Analyser class combines the logic of each of the modules discussed in the previous subsections to form the execution algorithm of the prototype for lesson summary generation. The prototype is configured at run-time and requires the path to the recorded lesson audio; a directory into which to output the lesson summary; a duration for the analysis window (defaulted to ninety seconds); a duration for the overlap between analysis windows (defaulted to fifteen seconds); a string to specify the speech recogniser to use; an overlap comparison length used by the transcript alignment method (defaulted to twenty five words); and an overlap comparison match count (defaulted to four words). In addition, the algorithm accepts a

possible noise audio path to use for noise injection, a noise reduction Boolean and a noise cancellation Boolean to specify which noise management technique(s) to apply.

The prototype's algorithm iterates over the lesson audio in ninety second windows of data with fifteen seconds of overlap in the data between them. If a path to a noise file has been specified, the prototype samples a random ninety second window of data from the noise audio and injects it over the current segment of lesson speech audio. The windowed audio is then written to a temporary directory, where it is uploaded via the World Wide Web to the specified speech recogniser. Once the upload completes, the lesson audio is transcribed and the text result is returned to the prototype. The returned transcript text is then analysed for overlap with the existing transcript text and the new text is appended to the transcript. The newly appended section of the transcript is then analysed for known keyword terms and, upon identification, a database lookup executes to identify the lesson content item(s) that the educator has associated with the keyword term. In addition, the utterance counts for each known keyword are maintained or updated. Identified keyword terms and their associations are then stored in memory and the loop iterates over the next 75 seconds (analysis window minus the overlap window) of lesson audio. This process continues until all the lesson audio has been processed, transcribed and analysed for keyword terms and associations. Once the process completes, the information acquired during analysis is handed off to be ordered and written to a PDF document to be presented to students. This PDF lesson summary document has three sections: first, a pie chart demonstrating the keyword terms uttered during the lesson, the sequence of their utterance and the number of times each was uttered; second, the list of associated course content items for students to review; and third, the lesson transcript. The lesson summary generated by the prototype is then provided to students, either via email or in print to support them in their secondary contact with the lesson material and to point them toward the course content that the lesson was based on.

5 Evaluation of the Prototype

To test the robustness of the prototype for ASR, keyword term identification and subsequent association to lesson content, a series of evaluation metrics were considered and a series of test case scenarios were established to provide quantitative evidence of the prototype's performance. The subsection that follows provides contextual definitions of the chosen recorded (base-line) performance metrics, and the chosen comparative (derived) performance metrics used for statistical evaluation of the prototype. After this, the next subsection defines each of the five established evaluation test scenarios. These scenarios are established to contrast the potential for acceptable lesson summary generation of Google versus CMU Sphinx cloud-based ASR systems against the combined effects of noise injection, noise reduction and noise cancellation.

5.1 Chosen Prototype Performance Metrics

Since the prototype system is driven by the speech of the educator, the lesson summary generation process is dependent on the ASR

system for keyword term identification. Consequently, the accumulation of keyword-term utterances and the association of keyword-terms to lesson content is also dependant on the implemented ASR system. If the prototype fails to identify a keyword-term which is tied (via database relationship) to a lesson association, the association will not be made. In this sense, the proposed model is dependent on the speech recogniser. However, at a functional level, this dependence is binary in terms of the prototype's ability to associate any correctly uttered keyword term with its database-bound relationship to course content, defined by the educator. Established binary predictive machine learning models use base-line metrics known as True Positives, True Negatives, False Positives and False Negatives to measure binary predictive performance.

The four base-line performance metrics are defined in [33] and [34] where the outcomes of the predictive model result in a confusion matrix that describes its positive and negative behaviours. While the prototype system and reflective proposed model presented herein isolate the associations between keyword terms and course content as a database relationship, the ASR component of the prototype system either identifies a known keyword term - resulting in association, or it does not. An example is provided [35] where a binary classifier for diabetes detection is laid out. Contrasted with this example, one can think of each keyword identification as an independent classification resulting in the detection of known lesson content association. The descriptions of base-line performance metrics in the context of the prototype system presented in this work are described in Table 1.

Table 1: List of recorded performance metrics considered to evaluate the prototype

Recorded Metric	Known Keyword Term Recognition	Educator Defined Association
True Positives	Prediction is +ve	Keyword Term has +ve Association(s)
False Negatives	Prediction is -ve	Keyword Term has +ve Association(s)
False Positives	Prediction is +ve	Keyword Term has -ve Association(s)
True Negatives	Prediction is -ve	Keyword Term has -ve Association(s)

Table 1 defines the measurements recorded by the prototype during lesson analysis. A true positive occurs when the prototype identifies a known keyword term uttered by the educator and associates this keyword term to the correct course content item(s). Conversely, false negative occurs when the prototype identifies a known keyword term, but cannot associate the keyword because there is no required database constraint. A false positive occurs when the prototype identifies an unknown, spoken keyword term and associates it with unintended course content item(s). On a functional level, the prototype should not measure any false positives given that the relational database constrains the associations between keyword terms and lesson content. A true negative occurs when the prototype identifies a known, spoken keyword term, but there is no association between the keyword term and course content item(s). Due to the database constraints, true negatives can be eliminated by ensuring that only keyword terms with existing

associations can be identified by the prototype.

The number of utterances of the keyword term gives the ASR component multiple attempts at keyword-term identification; however, if the particular term (e.g. the word "Euclidian") is not in the ASR system's lexicon, then the likelihood of detection falls to zero and the association cannot be made until further training of the ASR component. This constraint or dependency of the prototype on its ASR component is a trade-off between the number of times a keyword term is uttered and the reliability of the speech recogniser in identifying the keyword term.

Using the baseline performance metrics described allows for the measurement of derived performance metrics that can be calculated to provide a better indication of the prototype system's performance. Table 2 defines the formulas according to [33] and [34], which are used to calculate each of these comparative performance metrics using the values captured by the baseline performance metrics.

Table 2: List of comparative performance metrics considered to evaluate the prototype

Performance Metric	Measurement Formula
Accuracy	$\frac{TP + TN}{TP + FP + FN + TN} \quad (1)$
Precision	$\frac{TP}{TP + FP} \quad (2)$
Recall (Sensitivity)	$\frac{TP}{TP + FN} \quad (3)$
Specificity	$\frac{TN}{TN + FP} \quad (4)$
F1-Score	$2 \times \frac{Recall \times Precision}{Recall + Precision} \quad (5)$

As previously addressed, the prototype's design constraints and dependencies, in theory, prevent it from capturing false positives and can prevent it from capturing true negatives with optimal configuration of the prototype's database component. Although these are both measured for, when their values equal zero, they become trivial to some of the comparative metrics that use them in associated formulae. In addition to this factor, the third-party nature of using a cloud-based ASR component abstracts the prototype (as the user) from the base-line metrics measured by the ASR model itself when decoding (transcribing) the educator's speech. Thus, we cannot measure the ASR model's performance directly using these comparative metrics.

Table 3: List of considered comparative performance metrics to use in evaluating the prototype system

Performance Metric	Metric Formula
Average Accuracy (AA)	$\frac{\sum_{n=1}^n Accuracy_n}{N} \quad (6)$ <p>where n is the test case number and N is the total number of tests conducted for the test case</p>
Average True Accuracy (ATA)	$\frac{\sum_{n=1}^n TAccuracy_n}{N} \quad (7)$ <p>where FP = 0, TN = 0, n is the test case number and N is the total number of tests conducted for the test case</p>
Global Average Accuracy	$\frac{\sum_{n=1}^n AA_n}{N} \quad (8)$ <p>where n is the test case number and N is the total number of tests conducted for the test case</p>
Global Average True Accuracy	$\frac{\sum_{n=1}^n ATA_n}{N} \quad (9)$ <p>where FP = 0, TN = 0, n is the test case number and N is the total number of tests conducted for the test case</p>

The database constraints on the prototype system coupled with the lack of base-line recognition metrics of the underlying ASR model, mean that some of the comparative metrics from Table 2 do not truly reflect the intention of the metric in the context of the prototype system. Because the count of false positives measured by the prototype will always be zero, precision and specificity were deemed inappropriate metrics for prototype evaluation from the outset. This consequently eliminated F1-Score as a potential measure for contrasting the performance of cloud-based Google and Sphinx recognition services. If we cater for FP = 0 and TN = 0, our

measure for sensitivity results in the same value for Accuracy. By this deduction, accuracy was deemed the most appropriate metric to measure prototype performance. Table 3 provides formulae for the types of accuracy, measured for the evaluation of the prototype.

The accuracy metrics in Table 3 will provide a measure of accuracy for the prototype over the series of tests conducted across test cases. To cater for the potential of true negative values being measured as zero, the Average Accuracy (AA), which includes the number of true negatives measured, is contrasted with the Average True Accuracy (ATA) where the number of true negatives measured is assumed to be zero. These accuracy metrics are reported for each test case and the Global Average Accuracy and Global Average True Accuracy is reported across all the test cases to provide a final measure of prototype performance using the given speech recogniser.

5.2 Specification of Test Samples

To test the ASR prototype system, two audio readings of the article ‘Speech Recognition for Learning’ [36] were recorded using a stereo headset. The participants, one male and one female, were encouraged to enunciate their speech as well as possible and to read at a comfortable pace in their natural voices. In addition to these two audio recordings, a total of twelve hours of captured classroom background noise was acquired to use as sample audio for noise injection. These three audio test samples were all recorded at 16000Hz with a 256kbps bitrate as signed 16-bit PCM encoded single channel (mono) waveform audio (.wav).

5.3 Prototype Test Cases

A series of test cases were established to test the prototype system’s performance using the test samples and performance metrics discussed. These test cases simulate alternative classroom equipment setups and environmental noise constraints on the prototype. Table 4 indicates whether the input data had noise injection (NI), noise reduction (NR) and/or noise cancellation (NC) applied for each of the test case scenarios, as well as the recogniser used to identify keyword terms.

Test Case T is established to provide an indicator of the functional performance of the prototype system assuming that the underlying ASR system is completely accurate. Rather than performing speech recognition on the speech audio, this test case instead has the algorithm operate on the raw text of the document which was read aloud. This allows for the algorithm to be tested and modified until it was proven to be working ideally on a functional level, with its dependency on ASR accuracy removed. Test case A, on the other hand, is used to measure the prototype’s performance working with the ASR system to provide a measure of the prototype system’s accuracy with its ASR dependency, but without any environmental noise. Test case B introduces this environmental noise by isolating a random sample within the specified classroom noise sample audio and overlaying this randomly chosen sample on the speech audio prior to ASR analysis. This pseudo-random noise injection is applied at each overlapping window of lesson audio analysis. Test case B is designed to simulate spontaneous noise that may occur in the educational environment and be recorded by the educator’s

microphone as they deliver their lesson. Test cases A and B simulate a single microphone setup to capture the educator's voice.

Table 4: Test case scenario specifications used in evaluating the prototypes' performance with different audio pre-processing techniques

Test Case	NI	NR	NC	ASR System
T	FALSE	FALSE	FALSE	Aho-Corasick Search
A	FALSE	FALSE	FALSE	Google, Sphinx
B	TRUE	FALSE	FALSE	
C	TRUE	TRUE	FALSE	
D	TRUE	FALSE	TRUE	
E	TRUE	TRUE	TRUE	

Table 5: Sphinx Average Accuracy and Average True Accuracy per Test Case

Test Case	Average Accuracy	Average True Accuracy
A	0,6333	0,7000
B	0,3907	0,4730
C	0,1660	0,2350
D	0,5300	0,6170
E	0,4600	0,5490
Global Average	0,4360	0,5148

Test cases C, D and E are concerned with noise management interventions and are intended to simulate a dual-microphone equipment setup where one microphone records the educator's voice and the other records environmental classroom noise. These recordings are then aligned, and the recorded environmental noise is used as input to reduce or cancel environmental noise recorded by the educator's microphone. Note that the prototype would be drastically less effective if the microphone recording the environmental noise were also to record the educator's voice, as the noisy sample would include the speech, which would then be cancelled or reduced. Thus, this prototype is not appropriate for a situation where the educator's voice is being amplified by a loud speaker. The educator's microphone in this case is intended only to record their speech and inherently, any environmental noise generated in the classroom which is also captured.

5.4 Prototype Test Results

The prototype was tested one hundred times for each of the test cases defined in Table 4 using Google Cloud Speech Recognition and then using CMUSphinx ASR. Test case T was performed without a recogniser and instead used the Aho-Corasick search to identify keyword

terms. The prototype was debugged and tested in a cyclical manner until the results of test case T showed an accuracy of 100% and it had been demonstrated that the logic used to measure each base-line performance metric was accurate. Ultimately, the prototype was able to demonstrate 100% accuracy on test case T and any doubt of inaccuracy of base-line metric measurement was resolved. This prompted the next phase of testing of the prototype using a speech recogniser to transcribe the educator's speech and then to generate a lesson summary. Table 5 shows the performance of the prototype when generating lesson summaries using CMUSphinx cloud-based ASR.

Table 6 shows the performance of the prototype when generating lesson summaries using Google Cloud Speech Speech Recognition.

Table 6: Google Average Accuracy and Average True Accuracy per Test Case

Test Case	Average Accuracy	Average True Accuracy
A	1,0000	1,0000
B	0,8927	0,9390
C	0,4387	0,5360
D	0,9693	0,9900
E	0,8860	0,9400
Global Average	0,8373	0,8810

6 Discussion of Prototype Performance

The discussion of test results will centre around the reported Average True Accuracy across test cases for each recogniser. The results of the prototype testing reported in Table 5 and Table 6 for test case A demonstrate a difference in accuracy of 30% for lesson summary generation between Google Cloud Speech Recognition (CSR) and CMUSphinx ASR. This can be attributed to the design difference of these machine learning models. It has been shown that DNN-based approaches to ASR outperform traditional HMM-based models as they provide more modelling complexity. When noise is injected into the educator's speech in test case B, the performance of both models declines, but Google CSR is reportedly noise robust so the drop in accuracy is far less significant than that of CMUSphinx, where Google had a 6.01% reduction in accuracy, contrasted with a drop in accuracy of 22.7% for CMUSphinx. Both recognisers saw a significant reduction in accuracy with noise injection and then with noise reduction applied in test case C. From a qualitative perspective, the noise reduction algorithm had the effect of dampening the speech and was likely de-emphasising spectral formants, leaving the speech sounding hollow and making it difficult to distinguish utterances by ear. By contrast, when noise cancellation was applied instead in test case D, both speech recognisers saw an improvement in performance; with Google improving in accuracy by 5.1% compared with a greater increase in accuracy for CMUSphinx of 14.4%. This demonstrates that noise cancellation was the ideal noise management technique applied by the prototype, most notably with Google CSR which lost only 1% accuracy of lesson summary

generation when comparing performance without noise injection as opposed to noise injection with noise cancellation applied. The results of test case E are the most surprising where noise reduction and noise injection was applied, a balance in accuracy between noise reduction and noise cancellation was achieved, seemingly diminishing the negative effects of the noise reduction technique, while still removing background noise and retaining the integrity of the speech signal. Nevertheless, the prototype showed satisfactory performance using either recogniser under no noise injection, or while only applying noise cancellation to the noisy speech data. Overall, using Google Cloud Speech Recognition in combination with noise cancellation demonstrated the best performance of the prototype for speech-driven lesson summary generation in a noisy environment.

7 Conclusion and Future Work

This paper has discussed some of the key topic areas involved in incorporating ASR systems for use in educational settings. A model was proposed for the application of an ASR system in a noisy educational environment to automatically generate a lesson summary, driven by the speech of the educator. A prototype system was then developed based on the proposed model and improved and adapted alongside it. The prototype goes beyond the baseline utility of transcribing the speech of the educator with additional analysis on the transcribed text used to identify and associate keyword terms to course content artefacts, summarising this information by monitoring the number of times each keyword is mentioned, providing a reference point for keyword terms and directing students to the underlying course content from which they originate via database bound associations. These relatively simple additions, along with the lesson transcript can allow for the educator to speak at length about the given topics, cross-referencing to related course content artefacts and potentially helping to guide the flow of their lesson, with the peace of mind that relevant sections are made known to the students. Additionally, secondary contact with the lesson transcript after it has been taught helps students with making notes and the additional reference points could help in prioritising certain topics and reaffirming/reinforcing what was communicated during the lesson.

To further the proposed model, future work involves the development, testing and classroom implementation of a more advanced system based on the proposed model and the proof of concept prototype presented and argued herein. The classroom prototype would need to be evaluated using both qualitative and quantitative research methods. For qualitative evaluation, a survey could be designed to gauge both student and educator perspectives on the system's utility, potential for improvement and the overall sentiment of the system implemented in the classroom. Quantitative evaluation could be incorporated into the survey whereby aspects of the prototype's utility could be rated on a Likert scale or Linear Numeric scale to indicate positive or negative sentiment towards particular aspects of the system and the lesson summaries produced. The prototype's database components could also be expanded to cater for multiple lessons across multiple courses and the performance evaluation conducted in this work could then be applied at various levels to measure prototype performance on a lesson and course level and also per-

formance contrasted between courses with varying subject matter. The model could also be improved by automating the definition of keyword terms and their association with course content items so that the educator would no longer need to. This could be done using unsupervised machine learning whereby a machine learning model would have access to course content and automatically extract and assign keyword terms to course content artefacts.

ABSTRACT

Industry 4.0 implementation stipulates effective actuator control. In the present work, a complex order $PI^{a+jb}D^{c+jd}$ (COPID) controller was designed for a fractional order model of a direct current (DC) motor system. For comparisons, the DC motor system model was also controlled using the conventional proportional integral (PI), proportional integral derivative (PID), proportional resonant (PR) and fractional order PID controllers (FOPID). Time domain results indicated that the PR controller performed exceedingly well for output signal responses, but fared poorly in case of control signal specifications. The PI controller responses suffered from high time domain characteristics for both control and output signals. The PID controller performed moderately in terms of time domain and peak overshoot metrics. The FOPID controller attained the best time domain characteristics, but was unable to effectively limit the control and output signal peak overshoots. It was only the COPID controller, that successfully minimised / eliminated peak overshoots in control and output signals (0.1 % and 0.0 % respectively). Moreover, the COPID controller was also successful in limiting the rise, peak and settling times. In addition, Bode diagram, root locus plot were obtained and system gain parameters were varied to confirm the robustness of the proposed COPID controller. Thus, COPID controller promises to be an effective solution towards accurate and robust actuator control in modern manufacturing.

1 Introduction

This paper is an extension of the paper presented at the IEEE International Conference on Mechatronics, Robotics and Systems Engineering, MoRSE 2019 [1]. Therein, a direct current (DC) motor system was successfully modeled by the application of fractional calculus to closed loop system identification approach. Of the four identified fractional order models, the best performing model comprised of three parameters and attained R-squared 0.9942, root mean square error (RMSE) 0.0084 and sum of squared estimate of errors (SSE) 0.0711. In the current work, that fractional order model has been utilised to implement PI, PR, PID, fractional order PID (FOPID) and complex order $PI^{a+jb}D^{c+jd}$ (COPID) controller designs with an aim to achieve stable and robust control of the DC motor system with minimum time domain characteristics.

The proportional, integral and derivative (PID) controllers have been implemented in industrial control systems on a large scale owing to their simplicity of design and maintenance [2]. Recently, fractional calculus has been employed to solve various complex

problems in engineering and science [3]–[7]. One of these applications is designing controllers using fractional calculus. The fractional order controllers have been shown to exhibit superior control characteristics in numerous applications including the non-minimum phase systems [8]–[12]. This is due to the additional two parameters available for control in the fractional model structure. The complex order $PI^{a+jb}D^{c+jd}$ controller is a logical extension of the fractional calculus based control as it includes two more parameters for control as compared to the FOPID controller [13]–[16].

In [17], the authors implemented a complex order structure to identify hexapod robot movement on the basis of a transfer function for the foot-ground system. In [18], the authors obtained a transfer function to solve a complex order differential equation. In [19], the author employed genetic algorithm to optimize complex order controllers for non linear and linear systems. In [20], the authors investigated robust control of a non linear fuel cell system using complex order architecture. In [21], the authors modeled HIV infection drug resistance using a complex order model. In [16], the authors reviewed time domain, stability and frequency domain in

^{*}Corresponding Author: Pritesh Shah, Symbiosis Institute of Technology, Pune, India Contact No. +91 20 28116400 & Email pritesh.ic@gmail.com

complex order modeling of various systems. In [22], the authors tuned complex order controller by numerical optimization for a time delay resonant plant. In [23], the authors tuned complex order controller using genetic algorithm. In [13], the authors compared complex controller performances to integral and fractional order controllers for fractional order systems. They reported superior time domain characteristics attained by the complex order controllers. However, they did not apply complex order controllers to a DC motor system. A complex order controller was designed for DC motors [24]. However, the designed controller in this work [24] was unable to minimise the overshoot in the step response. minimizing peak overshoot in the output signal response is critical to prevent any undesired process variation which may damage the actuated machinery in the long run. Similarly, minimizing control signal overshoots is critical to prevent damage against voltage spikes and enhance the service life of DC motors in industry [25, 26].

The main contribution of the current work lies in the identification of the most suitable DC motor controller design based on minimal output/control signal peak overshoots and settling times among the various controllers considered in the scope of the current study. The following section (2) details upon the controller design methodology adopted in the current work pertaining to the PI, PID, PR, FOPID and COPID controllers. Time and frequency domain results of the investigated controllers are compared and discussed in section 3. Finally, conclusions of the present work are presented in the section 4.

2 Controller Design Methodology

The current work addresses the constant torque region for DC motor modeling and control. The field weakening region (figure 1) is not considered in the present work.

Figure 1: Field weakening region [27]

Following sub-sections describe the PI, PID, PR, COPID and FOPID controllers for the DC motor system considered in the current study.

2.1 PI and PID controller

The PID controller is popular in industry because of its compatibility with the PLCs and its simple structure[2, 28]. The following PID

controller structure was used for the DC motor system [29].

$$C(s) = K_P + K_I \left(\frac{1}{s} \right) + K_D \left(\frac{N}{1 + N \frac{1}{s}} \right) \quad (1)$$

where, N is the bandwidth of the low pass filter on the derivative, K_P is proportional gain, K_I is integral gain and K_D is derivative gain. This controller was tuned by the auto tuning capability available in the Matlab Simulink block. Auto-tuning can be done via time and frequency based methods. In this work, frequency based auto tuning method was implemented. In the case of PI controller, K_D is zero and there is no need of derivative filter. It's structure is given as follows.

$$C(s) = K_P + K_I \left(\frac{1}{s} \right) \quad (2)$$

2.2 PR Controller

The PI controller yields infinite gain at $s = 0$ and generally responds in a slow mode to step inputs without any steady state error. Moreover, it is unable to trace sinusoidal reference input. The PR controller yields infinite gain at zero phase shift and resonant frequency. Its form is given as follows [30]–[32].

$$C(s) = K_P + \frac{K_I * s}{s^2 + \omega^2} \quad (3)$$

2.3 FOPID controller

FOPID controllers are based on fractional calculus wherein the orders of derivation and integration are real numbers [9, 33]. Fractional calculus has been defined in many ways. The following definitions are generally applied in control system applications [34].

2.3.1 Grunwald-Letnikov definition

The GL (Grunwald-Letnikov) definition is very effective for obtaining numerical solutions of the fractional differential equations [35]. This definition is expressed as follows

$${}_a D_t^\alpha = \lim_{h \rightarrow 0} \frac{1}{h^\alpha} \sum_{r=0}^{\left[\frac{t-a}{h} \right]} (-1)^r \binom{n}{r} f(t - rh) \quad (4)$$

where, the integer part is represented by $\left[\frac{t-a}{h} \right]$; t and a are the limits of operator; n is an integer subjected to $n - 1 < \alpha < n$. The binomial coefficient is expanded as follows -

$$\binom{n}{r} = \frac{\Gamma(n+1)}{\Gamma(r+1)\Gamma(n-r+1)} \quad (5)$$

Similarly, the Gamma function in the above equation can also be defined as -

$$\Gamma(x) = \int_0^\infty t^{x-1} e^{-t} dt, \Re(Z) > 0 \quad (6)$$

2.3.2 Riemann-Liouville definition

The Riemann-Liouville definition is appropriate for the determination of analytical solutions of simple functions like $e^t, t^b, \cos(t)$ [36]. Riemann and Liouville applied fractional operators to derive formulae for the integration of arbitrary numbers and for solving differential equations respectively. The Riemann-Liouville definition combines the distinct approaches followed by Riemann and Liouville in a composite formula expressed as follows -

$${}_a D_t^\alpha = D^n J^{n-\alpha} f(t) = \frac{1}{\Gamma(n-\alpha)} \left(\frac{d}{dt} \right)^n \int_a^t \frac{f(\tau)}{(t-\tau)^{\alpha-n+1}} d\tau \quad (7)$$

where, J is the integral operator, α is a real number, n is an integer subjected to $n-1 < \alpha < n$ and t, a are the limits of integration. For example, if α is 1.8, n will be two because $1 < 1.8 < 2$.

2.3.3 M. Caputo definition

The M. Caputo definition is very popular among engineers because it directly relates the type of fractional derivative to the corresponding type of initial conditions [37]. In this definition, initial conditions like $y(0)$ and $y'(0)$ are allowed; unlike $y^{0.5}(0)$ (fractional conditions) [8]. The Caputo definition of fractional calculus is given as follows -

$${}_a D_t^\alpha = \frac{1}{\Gamma(n-\alpha)} \int_a^t \frac{f^n(\tau)}{(t-\tau)^{\alpha-n+1}} d\tau \quad (8)$$

where, α is a real number, n is an integer subjected to $n-1 < \alpha < n$ and t, a are the limits of integration. As stated before, fractional calculus is a branch of mathematics wherein the orders of integration and derivation are real numbers [9, 33, 38]. This real number feature has a significant impact towards improvement of the controller performance [39]–[41]. The classical PID Controllers are particular cases of fractional controllers where λ and μ are equal to one (figure 2). With reference to the PID plane, this implies that instead of moving between four fixed points it is possible for λ and μ to move across the entire plane [42].

Figure 2: FOPID region in $\lambda - \mu$ plane [9]

The fractional PID controller structure implemented in the current work (figure 3) is given as follows.

Figure 3: Fractional PID controller structure [43]

$$C(s) = K_P + K_I \left(\frac{1}{s} \right)^\lambda + K_D s^\mu \quad (9)$$

where λ is the order of integration and μ is the order of derivative. In FOPID, there are two more parameters in the controller structure as compared to PID controller. Because of this, two more specifications can be achieved using the FOPID controller. The parameter range of orders is generally accepted 0 to 2 for the stability of the closed loop system because the locations of closed-loop poles lie mostly in the first sheet of Riemann [44] in this order range. The same approach has been followed in the current study as well. The fractional differentiator can be synthesised for FOPID controller application using Oustaloup's recursive approximation method as follows -

$$s^v \approx K \prod_{k=-N}^N \frac{1 + s/\omega_k}{1 + s/\omega'_k} \quad (10)$$

$$\omega_u = \sqrt{\omega_h \omega_b} \quad (11)$$

$$\omega'_0 = \alpha^{-0.5} \omega_u; \omega_0 = \alpha^{0.5} \omega_u; \quad (12)$$

$$\frac{\omega'_{k+1}}{\omega'_k} = \frac{\omega_{k+1}}{\omega_k} = \alpha \eta > 1 \quad (13)$$

$$\frac{\omega'_{k+1}}{\omega_k} = \eta > 0; \frac{\omega_k}{\omega'_k} = \alpha > 0 \quad (14)$$

$$N = \frac{\log(\omega_N/\omega_0)}{\log(\alpha\eta)} \quad (15)$$

where ω_h, ω_b are the approximation frequency bounds, v is the order of the fractional differentiator, N is the order of fractional differentiator approximation and K is a constant. In the present work, the fractional order controller was implemented using FOMCON toolbox for fractional calculus [45, 46]. In this toolbox, fractional calculus can be approximated using the refined Oustaloup approximation method by varying the order and frequency ranges. This toolbox can be used for time domain, frequency domain and many more analyses for fractional calculus. The fractional order parameters in the current study were tuned based on the approach given in related literature [39].

2.4 COPID controller

Just as the FOPID controller is an extension of the classical PID controller, similarly the COPID controller is an extension of the FOPID controller. In complex order PID controller, integration and

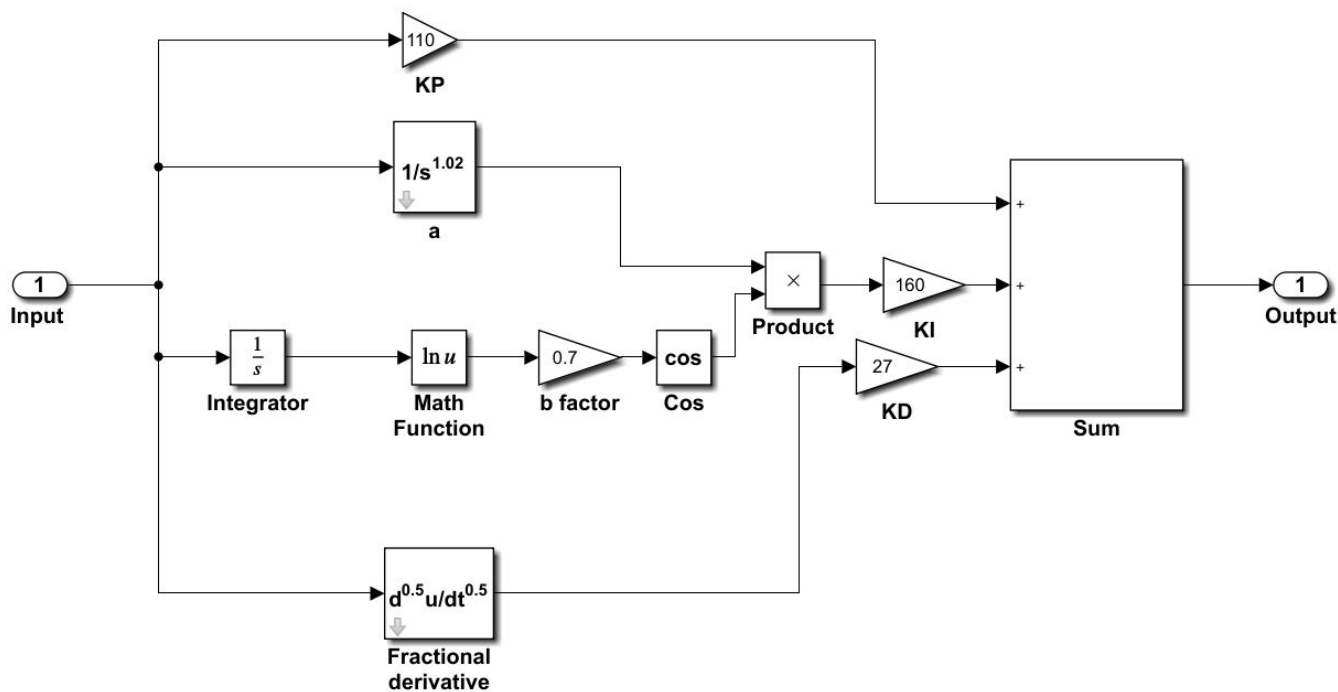

Figure 4: Complex $PI^{a+jb}D^{c+jd}$ controller structure

derivative orders are expressed in the form of a complex number $(x+jy)$. The genesis of COPID controller is related to the CRONE controller (third generation) [47, 48]. The complex order PID controller structure for the DC motor fractional order model in the current study is given as follows [14, 20, 49].

$$C(s) = K_P + K_I \left(\frac{1}{s} \right)^{a+jb} + K_D (s)^{c+jd} \quad (16)$$

where, a, b, c, d are the complex order controller orders. The integral gain component of this equation is simplified as follows -

$$K_I \left(\frac{1}{s} \right)^{a+jb} = K_I \left(\frac{1}{s} \right)^a \left(\frac{1}{s} \right)^{jb} \quad (17)$$

$$K_I \left(\frac{1}{s} \right)^{a+jb} = K_I \left(\frac{1}{s} \right)^a * e^{\ln \left(\frac{1}{s} \right)^{jb}} \quad (18)$$

$$K_I \left(\frac{1}{s} \right)^{a+jb} = K_I \left(\frac{1}{s} \right)^a * e^{jb \ln \left(\frac{1}{s} \right)} \quad (19)$$

$$K_I \left(\frac{1}{s} \right)^{a+jb} = K_I \left(\frac{1}{s} \right)^a * \left[\cos \left(b \ln \left(\frac{1}{s} \right) \right) + j \sin \left(b \ln \left(\frac{1}{s} \right) \right) \right] \quad (20)$$

It is necessary to omit the imaginary part of the above equation because it cannot be synthesized for time domain implementation of the closed loop system with COPID controller in Simulink [14].

$$K_I \left(\frac{1}{s} \right)^{a+jb} = K_I \left(\frac{1}{s} \right)^a * \left[\cos \left(b \ln \left(\frac{1}{s} \right) \right) \right] \quad (21)$$

Similarly, the derivative part of Eq. (16) is simplified as follows -

$$K_D * s^{c+jd} = K_D * s^c * s^{jd} \quad (22)$$

$$K_D * s^{c+jd} = K_D * s^c * e^{\ln s^{jd}} \quad (23)$$

$$K_D * s^{c+jd} = K_D * s^c * e^{jd \ln s} \quad (24)$$

$$K_D * s^{c+jd} = K_D * s^c * [\cos (d \ln s) + j \sin (d \ln s)] \quad (25)$$

As followed in case of the integral gain component, it is necessary to omit the imaginary part of the derivative equation as well because it cannot be synthesized for time domain implementation of the closed loop system with COPID controller in Simulink [14].

$$K_D * s^{c+jd} = K_D * s^c * [\cos (d \ln (s))] \quad (26)$$

Thus, Eq.(16) may be rewritten for tuning as follows.

$$C(s) = K_P + K_I \left(\frac{1}{s} \right)^a * \left[\cos \left(b \ln \left(\frac{1}{s} \right) \right) \right] + K_D * s^c * [\cos (d \ln (s))] \quad (27)$$

The tuning of complex order controller is more challenging than FOPID and classical PID controller as there are seven parameters in the complex order controller. In this work, Eq. (27) was utilised for the implementation of complex order controller. This controller was tuned based on the tuning principles provided in literature [39, 50]. Figure 4 shows the structure of the COPID controller implemented in Simulink (Matlab). The initial value of the integer order integration was assumed to be a small number for this implementation. For all controllers, high control signal overshoots were limited by adding saturation block in the closed loop system models.

Figure 5: Pole zero map for fractional order DC motor plant model

3 Results and Discussions

The fractional order DC motor system model derived in the work reported in the 2019 IEEE International Conference on Mechatronics, Robotics and Systems Engineering (MoRSE) [1] is given below.

$$G(s) = \frac{0.7992}{s^{1.9018} + 80.0440} \quad (28)$$

It may be noted that this model has a low DC gain. Low DC gains in second / higher integer order system models are expected to cause the system responses to become sluggish due to the presence of the non-dominant pole(s) in the pole zero map. Similar effect is observed in the pole zero map (figure 5) of the fractional order system model considered in the current study as well. However, the presence of a large number of dominant poles keep the system response fast; overcoming the adverse impact of low DC gain. This model consisting three parameters was employed for designing the PI, PR, PID, FOPID and COPID controllers in the current work. The PI controller design for the DC motor system was obtained as follows -

$$C(s) = 10 + 92.6736 \frac{1}{s} \quad (29)$$

Figure 6: PI controller output for fractional order DC motor plant model

Figure 7: Control signal for PI controller output for fractional order DC motor plant model

Figures 6 and 7 show the output and control signal plots for the PI controller respectively.

Similarly, the following PR controller structure for the DC motor system was generated -

$$C(s) = 1.0469E05 + \frac{-8.2380E08 * s}{s^2 + 10000} \quad (30)$$

The output and control signal responses for the PR controller are depicted in figures 8 and 9 .

Figure 8: PR controller output for fractional order DC motor plant model

Figure 9: Control signal for PR controller output for fractional order DC motor plant model

The auto tuned PID controller architecture for the fractional order DC motor plant model considered in the current study was obtained as follows -

$$C(s) = 0.00001 + 92.5368 \frac{1}{s} + 0.001 \frac{100}{1 + 100 \frac{1}{s}} \quad (31)$$

Figure 10 shows the output response of the PID controller output, whereas figure 11 shows the control signal plot for the same.

Figure 10: PID controller output for fractional order DC motor plant model

Figure 11: Control signal for PID controller output for fractional order DC motor plant model

The fractional order PID controller structure was obtained as follows -

$$C(s) = 125 + 1125 \frac{1}{s^{0.95}} + 51s^{0.77} \quad (32)$$

Figures 12 and 13 depict the output and control signal responses for this FOPID controller, respectively.

Figure 12: Fractional PID controller output for fractional order DC motor plant model

Figure 13: Control signal for Fractional PID controller output for fractional order DC motor plant model

The complex order PID controller structure was obtained as follows -

$$C(s) = 11 + 125 \frac{1}{s^{0.99+j0.7}} + 27s^{0.5+j0} \quad (33)$$

Figures 14 and 15 show the output response and the control signal of the complex controller designed for the DC motor system.

Figure 14: Complex $PI^{a+jb}D^{c+jd}$ controller output for fractional order DC motor plant model

Figure 15: Control signal for complex $PI^{a+jb}D^{c+jd}$ controller output for fractional order DC motor plant model

Table 1 gives the output signal rise and peak time domain specifications of all controllers explored for the DC motor system consid-

ered in the current study. The PR controller is successful in attaining the least rise time and peak time among all controllers. The FOPID controller attains the second best peak and rise time characteristics. The COPID controller registers higher rise and peak times as compared to FOPID output signals. The PI and PID controller output signals consume relatively higher rise and peak times. Figures 16 and 17 showcase graphical presentations of output signal overshoots and settling times.

Figure 16: Output signal overshoots (%)

Figure 17: Output signal settling time (sec)

The FOPID controller achieves the least settling time, whereas the COPID controller minimizes peak overshoot percentage to zero. In contrast, the PR, PI, PID and FOPID output signals record overshoots of 1.3 %, 1.0 %, 1.4 % and 2.2 % respectively. This result proves the efficacy of the complex order controller in limiting the output signal overshoot for the DC motor system. The DC motor system output is the output shaft revolutions per minute. In indus-

Table 1: Time domain specifications of output signals

	PI	PR	PID	FOPID	COPID
Rise Time (sec)	3.9	0.0003	2.2473	0.1946	1.7366
Peak Time (sec)	5.7	0.0005	5.4711	0.5011	5.0000

Table 2: Time domain specifications of control signals

	PI	PR	PID	FOPID	COPID
Rise Time (sec)	2.47	-	2.5285	0.0001	1.7365
Peak Time (sec)	9.75	-	6.6835	0.0184	4.7587

trial systems, DC motor outputs actuate machinery for achieving the stipulated processing control. Eliminating peak overshoots in the DC motor output signals is important to avoid undesirable process variations which may be detrimental and even hazardous in some cases.

Table 2 shows the control signal time domain characteristics for the five controllers under the scope of the current study. In this case, the PR controller performed very poorly and registered extremely high overshoot (of the order of 10E6); rise, peak and settling times. The FOPID control signals attained minimum rise and peak times, followed by COPID and PID control signals. The PI control signals achieved much higher rise and peak time metrics. Figures 18 and 19 showcase graphical presentations of control signal overshoots and settling times. The PI controller also under performed with respect to the settling time metric. However, it performed much better in case of control signal peak overshoots. Similarly, the PID controller attained very low peak overshoot but suffered from higher settling time. The FOPID controller attained minimum settling time, but was unable to keep the control signal overshoot in check. Thus, it was only the COPID which consistently outperformed all other controllers with minimum peak overshoot and second best settling time characteristics. For DC motor systems, the control signal corresponds to the voltage input. Excessive voltage spikes (as evident in FOPID control signal response) may prove detrimental to the motor's active service life and might even result in premature damage. It is important for the controller design to ensure protection to the DC motor against high voltage shocks. Moreover, faster settling of the input voltage corresponding to the desired output set point is desirable for a highly responsive system. The COPID controller exhibited reliable performances in both aspects.

Figures 20 and 21 show the Bode plot and root locus diagram for the closed loop system with COPID controller. The Bode plot indicates that the gain and phase margin for the closed loop system with COPID controller is ∞ . This implies that the system is robust against variations in the system parameters. Similarly, the location of closed loop poles to the left side of the s-plane in root locus diagram also proves that the DC motor system performance is stable and robust under complex order controller. Figure 22 depicts the robustness of the COPID controller against variations in the gain of the DC motor system. The system gain was varied with values of 0.5, 0.8, 2, 5, 10 and 20. The gain variations do not have any significant impact on the settling trends of the COPID controller responses, which is a positive indication.

4 Conclusions

The current work is an extension of the one reported in the 2019 IEEE International Conference on Mechatronics, Robotics and Systems Engineering (MoRSE). Building upon the fractional order

Figure 18: Control signal overshoots (%)

Figure 19: Control signal settling time (sec)

Figure 20: Bode plot for complex order controller for fractional order DC motor plant model

Figure 21: Root locus for complex order controller for fractional order DC motor plant model

model of the DC motor system identified in the previous work; the current work involved design of PI, PR, PID, FOPID and COPID controllers for the same. Primary results indicate that the PR controller performed very well in output signal responses; but fared very poorly in control signal time specifications. The PI controller also performed poorly in terms of output and control signal rise, peak and settling times. However, it performed comparatively better in terms of peak output and control signal overshoots. The PID con-

troller's performance was mediocre in terms of control and output signal peak, rise and settling times. Its performance was also not very impressive with regards to the output signal peak overshoots, but it did much better in minimizing the control signal overshoot percentage. The FOPID controller attained very low rise, peak and settling times for its output signals. However, it suffered from the highest peak overshoots for both output and control signal responses. The COPID controller exhibited excellent performance with regards

Figure 22: Responses of complex order controller for various values of K

to minimizing / eliminating the peak overshoots in the control (0.1 %) and output signal (0.0 %) responses. COPID controller also attained the second best low range rise, peak and settling time values. Minimisation and possible elimination of the peak overshoots in the control and output signals is vital for ensuring the safety of the controlled process machinery as well as for the long service life of the DC motor based industrial actuators. The COPID controller fulfills this requirement without sacrificing the settling time much. In addition, the Bode plot, root locus diagram and stable controller responses under varying system gain parameter confirm the stability and robustness of the designed complex order controller for the fractional order DC motor plant model considered in the current study. Thus, complex order controllers can be extensively and safely applied towards industry 4.0 oriented implementation of advanced industrial control systems such as smart actuators and collaborative robots.

ABSTRACT

In this article supervised classification methods for the analysis of local Panamanian rice crops using Near-Infrared (NIR) spectral signatures are assessed. Neural network (Multilayer Perceptron-MLP) and Tree based (Decision Trees-DT and Random Forest-RF) algorithms are used as regression and supervised classification of the spectral signatures by rice varieties, against other crops and by plant phenology (days after planting). Also, satellite derived spectral signature is validated with a field collected spectral model. Results suggest that MLP networks, either for regression or classification, were more efficient (RMSE of 8.78 and 0.068, respectively) than either tree based methods to regress/classify the rice spectral signature (RMSE of 19.37, 19.09 and 0.979, respectively). The validation made using satellite derived spectral signatures resulted in MLP models with RMSE of 0.216 and 7.318, respectively, leaving room for further improvement of the models. This work aimed to present a practical example of the employment of recent supervised classification algorithms for the determination of regression and classification models from reflectance spectral signatures in local rice varieties.

1 Introduction

The electromagnetic spectrum interacts with matter in a balanced relationship that indicates that the light reaching a body will be proportional to the light that is transmitted (measured through transmittance), absorbed (measured through absorbance) and reflected (measured through reflectance) in the body per in a unit of time. These measurements provide a signal that can be plotted, thus visually showing the relationship between the incident and reflected radiation flux.

These measurements are generally called spectral fingerprints or spectral signatures. Their measurement in agricultural crops is of special interest in precision agriculture, since they can provide a look into the crop health and phenological state. This information

allows to determine how acceptable are the growth and development of the crop at a given planting stage.

This paper is an extension of the work originally presented in the 2019 XLV Latin American Computing Conference (CLEI) [1]. It will address other ML methods to achieve supervised classification of rice spectral signatures in Panama.

Supervised classification Machine Learning (ML) methods, such as Artificial Neural Networks (ANN), are commonly used for the analysis of Near-Infrared (NIR) spectral signatures [2]–[3]. ANN allow a way to identify relevant characteristics from a set of inputs (in this case spectral signal) and map them to corresponding output targets (physical or logical values associated with the object of under study). The model is learned through weight adjustments between connected units, called neurons, which are arranged in different

*Jose R. Fabrega; jose.fabrega@utp.ac.pa

layers. ANN are well regarded method. Especially in agriculture to determine quality parameters [4]–[5]. Deep neural networks (DNNs), on the other hand a widely used in NIR spectral analysis [6]–[7]. DNNs are basically ANN with a vast number of hidden layers, which allow them to learn complex mapping relationships between inputs and outputs [8, 9].

Other ML methods rely on tree structures that partitions sample groups and the data set of features in order understand the relationship between labelled samples. Among these methods the most notable are: Decision Trees (DT) [10, 11] and Classification and Regression Trees (CART) and Random Forest (RF) [12]. The latter being of special interest since it is suited to understand massive data sets, by aggregating/averaging decision trees [13]. As ANNs and DNNs, tree based methods have been used to understand the relationships between sets of NIR spectra [14]–[15].

The objectives of this study are twofold: 1) Explore methods for the classification of spectral signatures of rice varieties, using networks and tree based algorithms; 2) Be able to train/test/validate a model that relates to field acquired spectral signatures with satellite signatures. The rest of this article is structured as follows: Section 2, presents the spectral database and the algorithms used for the classification. Section 3, shows the results obtained and discusses the implications to the model characterization. Section 4, provides overall conclusions of the article and focuses on suggesting future work that could be used as starting point for upcoming analysis.

2 Materials and Methods

2.1 Spectral Database

As described in [1], the spectral signatures were collected on-site from 3 different plots locations using a portable Spectroradiometer. The raw measurements were organized into a database consisting of signatures in the 350 nm to 1050 nm wavelength range (447 wavelengths points per signature). For each one of these 1453 signatures the database also contained information about the plot management, including crop variety, and more importantly *days after planting* (DAP), at which the spectral signature was collected.

The most prominent crop in the database is rice with 1348 signatures, with onion and pimento having less than 60 signatures, and other crops such as tomato, and maize having less than 15 signatures in total. Three local varieties of rice were more prominent in the plots: IDIAP-38, IDIAP 52-05 and FL137-11, the first two being experimental varieties from the Instituto de Investigaciones Agroindustriales de Panama (IDIAP), while the latter being a commercial variety.

Spectral signatures were normalized using unit variance scaling. Later, the total number of wavelengths (spectral features), was reduced from the original 447 dimensions by using Principal Components Analysis (PCA). Only the first 100 components were kept for each signature.

2.2 Satellite Derived Spectral Signature Database

This study made use of satellite images from *PlanetScope*, as a source of external signatures and among other reasons for models

validation. The exact polygons, where field spectral signatures were acquired, were treated as a source for spectral signatures.

A successful comparison between the spectral signatures and their satellite derived counterpart was made by normalizing matching dates (or closest days available) in which there were also field measurements and by integrating (summarize) the reflectance values obtained in the field into the satellite 4 band format, as follows: blue (455 - 515 nm), green (500 - 590 nm), red (590 - 670 nm), and infrared (780 - 860 nm). Finally, all the satellite derived spectral signatures were organized into a database for later use.

2.3 Regression and Supervised Classification of Spectral Signatures

Since one of the goals of this study was to find a model capable of predicting the days after planting (DAP), just by using the spectral signatures two families of models were selected. The first being a (continuous) regression models family in which the targets were numerical values representing the DAP. The second being a (discrete) binary classification model family, which makes possible to make rice predictions from non-rice related signatures, coded as 0 and 1,

Three regression models were tested to predict the DAP of the signatures:

1. Multilayer Perceptron Regressor (MLPR)
2. Decision Tree Regression (DTR)
3. Random Forest Regression (RFR)

Two classification models were test to predict the rice and non-rice:

1. Multilayer Perceptron Classification (MLPC)
2. Random Forest Classification (RFC).

In all models, spectral signatures were divided as 70% and 30% for training and testing purposes, respectively.

2.4 Cost functions and Evaluation Metrics

Two cost functions were compared for all models, the Mean Square Error - MSE (1), and the Mean Absolute Error - MAE (2). Two measures were used to evaluate the performance of all models, the Root Mean Square Error - RMSE (3), and the coefficient of determination, also known as: R-squared - R^2 (4).

$$MSE = \frac{1}{n} \sum_{i=1}^n (y_i - \hat{y}_i)^2 \quad (1)$$

$$MAE = \frac{\sum_{i=1}^n |y_i - \hat{y}_i|}{n} \quad (2)$$

$$RMSE = \sqrt{\frac{\sum_{i=1}^n (\hat{y}_i - y_i)^2}{n}} \quad (3)$$

$$R^2 = 1 - \frac{\sum_{i=1}^n (\hat{y}_i - y_i)^2}{\sum_{i=1}^n (\bar{y} - y_i)^2} \quad (4)$$

For binary classification models, evaluation of their performance was made via a different set of metrics. Generally, the performance

of these models are tied to the model capacity to provide true predictions: true positive (TP) and true negative (TN), but also, prediction errors or false prediction is accounted via: false positive (FP) and false negative (FN). These counts are organized into a confusion matrix, shown in Table 1.

Table 1: Theoretical confusion matrix between actual and predicted classes.

Prediction	Actual		
		Positive	Negative
	Positive	TP	FP
	Negative	FN	TN

Using the confusion matrix, metrics that use the true predictions and prediction errors can be determined, among them:

- Accuracy: a measure of the number of true predictions made by the model. That can be calculated with the following formula: $\frac{\#TP + \#TN}{\#TP + \#TN + \#FP + \#FN}$.
- Precision: a measure that can be used to evaluate the proportion of positive predictions that were correctly classified. It can be calculated using the formula: $\frac{\#TP}{\#TP + \#FP}$.
- Sensitivity (Recall): a measure that can be used to evaluate the proportion of the actual positive predictions (observations) that were correctly classified. It can be calculated with the formula: $\frac{\#TP}{\#TP + \#FN}$.
- F1 Score: a measure of the model accuracy, but considering both the precision and recall. In general, a model can have a bad F1 Score (closer to 0) or a good one (closer to 1). It can be calculated employing the formula: $2 * \frac{\text{Precision} * \text{Recall}}{\text{Precision} + \text{Recall}}$.

2.5 Software Implementation

All plots were made using matplotlib. Database normalization, dimensionality reduction, regressions and classification methods and their errors were implemented using the Scikit-Learn library in Python [16]. The trees structures generated by Decision Tree and Random Forest algorithms were plotted using *graphviz* (<https://graphviz.readthedocs.io/>).

3 Results and Discussion

3.1 Characteristics of the Spectral Signatures

Figure 1 shows the complete set of reflectance spectral signatures present in the database. Figure 2 shows the reflectance spectral response of the local varieties for the Juan Hombron plot.

Figure 2A, shows the spectral signal variation of the FL137-11 material, from 48 to 116 DAP. Figure 2B, shows the variation of the IDIAP-38 material in 13 and 19 DAP, and also the variation of the IDIAP 52-05 material from 13 to 116 DAP. In all cases, the spectral signature has less variation in the visible range (400-700 nm) and more activity in the near-infrared part of the spectrum (700-1000 nm) as the DAP increases.

Figure 1: Rice Spectral Signatures in the Database

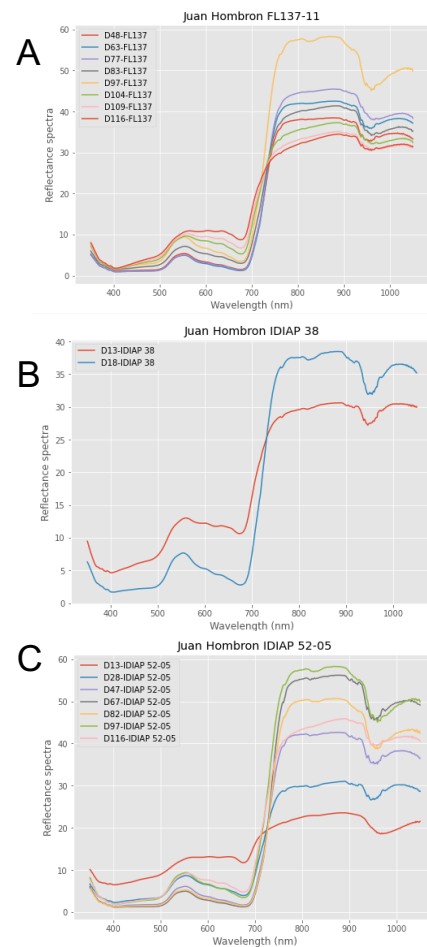

Figure 2: Spectral signatures of Rice varieties in Juan Hombron. A) FL137-11, B) IDIAP 38 and C) IDIAP 52-05.

Figure 3 shows the average spectra of rice (red) as compared against other crops in the database. It is notable that rice and onion have similar spectral signatures, with lower reflectance values in the NIR region. While tomato, maize and onion have a similar signature with higher reflectance values in the same range.

Figure 3: Comparison between Spectral Signatures of Crops in the Database

3.2 Regression Models applied to Rice Spectral Signatures

The Multilayer Perceptron Regressor network was set up to have 500 neurons in the hidden layer, tolerance of $1e^{-4}$ and using as ADAM as optimizer. For the Decision Tree Regressor, MSE was set to be the criterion, and the default settings were followed. The Random Forest Regressor was set up to build 50 trees (estimators), as in the Decision tree, the default settings were followed. Error metrics for the three algorithms are shown in Table 2.

Table 2: Resulting Errors for Regression Models

Metrics	MLPR	DTR	RFR
R^2	0.92	0.56	0.57
MAE	6.148	10.807	13.783
MSE	77.095	375.400	364.779
RMSE	8.780	19.375	19.099

The MLPR model achieved the higher R^2 with 0.92 and the lower RMSE values with 8.78. The two tree based regression models showed to behave similarly with R^2 of 0.56 and 0.57, respectively. Also, having RMSE values of around 19, in both cases. Figure 4 shows the loss curve per iterations for the MLPR model, with a final loss of 0.08. The network training was stopped after 1492 iterations and resulted in an overall MLP training score of 0.99.

Figure 4: Loss Curves for MLPR Model

3.3 Classification Models applied to Rice Spectral Signatures

The Multilayer Perceptron Classifier network was set up to have 200 neurons in the hidden layer, tolerance of $1e^{-4}$ and using ReLU as an activation function. As for the Random Forest Classifier was set up to build 50 trees (estimators), here also, the default settings were followed. Error metrics for the two algorithms are shown in Table 3.

Table 3: Resulting Errors for Classification Models

Metrics	MLP Classifier	RFC
R^2	0.94	0.47
MAE	0.005	0.039
MSE	0.005	0.039
RMSE	0.068	0.197
Acc.	0.995	0.961
F1 Score	0.998	0.979

The MLPC model achieved a better R^2 than the RFC, with a value of 0.94 and the lower RMSE of the two with a value of 0.006. The two algorithms perform in the 90% having accuracy values of 0.99 and 0.96, respectively. Also having high F1 scores, with values of 0.99 and 0.97, respectively. Figure 5 shows the loss curve per iterations for the MLPC model, with a final loss of 0.006, after 166 iterations.

Figure 5: Loss Curve for MLPC Model

Figure 6 shows the final tree structure of the RFC. In warmer colors it shows the statistically significant decision nodes. In general, the RFC models were not as accurate as MLPC models, but they help us determine the most relevant wavelengths for classification, Table 4 provides a list of the Top-5 wavelengths that could be used as to classify the signatures. Interestingly, all these wavelengths are in the visible range between 400 and 600 nm.

A partial conclusions that can be addressed is that when predicting the DAP from the spectral signatures, it is very important to reduce the parameters to increase the precision of the model. It is important to notice that also, that when classifying crops (rice or other), there was no need to apply PCA since the model is quite accurate and has fewer losses. It even starts at a loss value of 0.4, close enough to 0, in the first iterations, as shown in Figure 5.

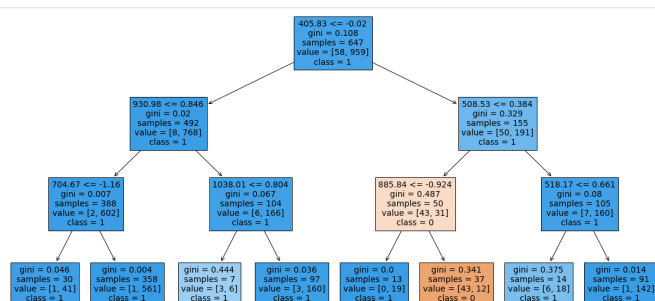

Figure 6: Resulting Tree and Rules learned by the Random Forest Classifier

Table 4: Summary of Top-5 Predictors from RFC model

ID	Wavelength	Importance (P-value)
111	534	0.031
95	508	0.028
118	545	0.023
34	409	0.023
139	579	0.028

3.4 Regression and Classification of Satellite Derived Signatures

The database for this experiment was comprised of the satellite spectral signatures and also the field (on site) spectral signals. The satellite spectral signatures are the ones compared using the Spectral Angle Mapper (SAM) method, as described in [1]. As for the (on site) spectral signals they had to be integrated to four wavelength bands that are used to represent satellite images. Table 5, shows the distribution of the spectral signature in the expanded database, with both spectral signatures collected on site and from the satellite image.

Table 5: Distribution of Spectral Signatures

Signature Type	Quantity
Rice spectral signatures (on site)	459
Rice spectral signatures (from satellite)	1303
Forest & road spectral signatures (from satellite)	337

A neural network model capable of distinguishing between the rice, and not-rice (namely, forest and road satellite signatures) was trained using a Multilayer Perceptron Classifier. The network was set up to have 600 neurons in the hidden layer, tolerance of $1e^{-4}$ and using ReLU as an activation function. Figure 7A shows the loss curve for the MLPC model, having a final loss value of 0.11 after 733 iterations.

Subsequently, a model was trained with the field spectral signatures reduced to 4 bands and the satellite spectral signatures. The field collected spectral signatures were used for training and testing (calibration), while the satellite spectral signatures were used for validation of the model. A Multilayer Perceptron Regressor was used. The network was set up to have 1000 neurons in the hidden layer, tolerance of $1e^{-4}$ and using as ADAM as optimizer.

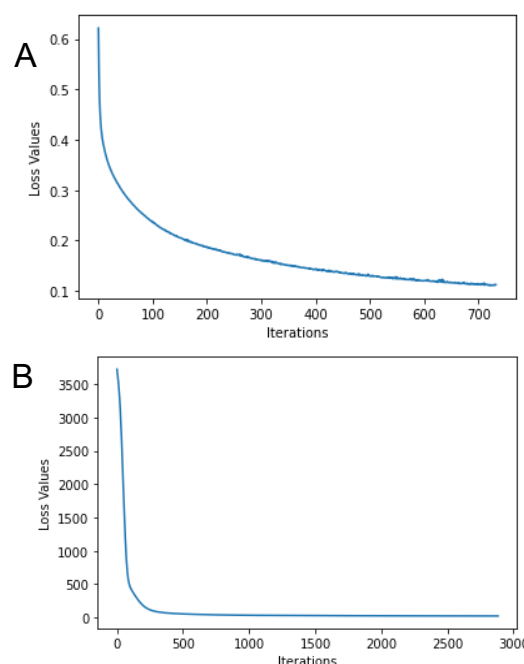

Figure 7: Model Loss Curve for the MLPC (A) and MLPR (B) methods

Figure 7A shows the loss curve for the MLPC model, having a final loss value of 0.11 after 733 iterations. Figure 7B shows the loss curve of the MLPR model, it had final loss value of 23.74 after 2884 iterations.

As it is shown in Table 6, the MLPR model achieved the highest R^2 with 0.88 and an overall score of 0.90. However, the MLPC model had a lower RMSE value with 0.216.

Table 6: Resulting Errors for Satellite Derived Models

Metrics	MLPC	MLPR
R^2	0.711	0.886
MAE	0.046	53.564
MSE	0.046	5.101
RMSE	0.216	7.318

The validation of the model, using satellite spectral signatures resulted in having a R^2 of 0.54, a MAE of 14.998, MSE of 413.237 and RMSE of 20.3282.

A result from this subsection is that when validating the model to predict days after planting, the error is still quite large. It might be possible to make it lower by having a larger amount of field spectral signatures, since this would give more information to the model longer learning time.

4 Conclusions

The aim of this work was to be able to train supervised classification Machine Learning models in order to further understand rice reflectance signatures. A database of spectral signatures collected using a portable spectroradiometer and a set of satellite image derived signatures were employed as input for these models. As output or targets for the training of these models, few variables were

used, among them: days after planting (DAP), and the possibility of distinguishing rice from other crops or from other geographical features.

In order to develop these regression and classification models, neural network based algorithms (Multilayer Perceptrons) and tree based algorithms (decision trees and random forest), were used.

For both cases, regression and classification of rice spectral signatures, the use of Multilayer Perceptron models are recommended. Our results suggest that MLPR is the best method to make a model able to regress on the DAP just from the spectral signatures. For the classification of rice and non-rice signatures MLPC was one again the best resulting method. The tree based models, although providing less useful models, were able to suggest a list of most relevant predictors and a visualization of their results. It seems that the most useful wavelengths to build this models are found mostly in the 500-600 nm wavelength range, which corresponds to the green and yellow colors of the visible spectrum. These wavelengths are in line to changes in the panicle, as described by [17].

For the work on satellite derived signatures both MLPC and MLPR show interesting results over 0.7 and 0.88, respectively. However, the error metrics on the MLPR model are quite large. A large error that can be attributed to normalization effect between satellite and on site measurements, and total reflectance correction that exist between both spectral signatures. Suggesting that more samples should be added to the model to produce a more robust model.

One of the limitations of this study was the relatively small size of the database of spectral signatures employed. It is known that Machine Learning algorithms need more samples in order to have robust results. The need of more spectral signatures is evident by the poor generalization obtained, especially for the validation of satellite derived spectral signals.

For future work, few changes to the approach employed should be done. For instance, having different percentages in the training and testing splits. This work shows results only with 70%/30% split. It could be beneficial to test the limit of prediction by changing the percentages and/or using cross-validation techniques. Second, a class imbalance is evident in the spectral database, due to the focus on rice signatures by the original objective, leaving other crops or other spectral signatures astray. In order to make this database more balanced pseudo replicates need to be made from the non-rice signatures. In [18], the author presents an interesting approach for feature selection and replication using Variational Auto-Encoder (VAE) type of network, that could be pursued. Also in this line, the author presents a complete framework for Data Augmentation (DA) approach for convolutional neural network (CNN) based deep learning chemometrics [19], that seems worth exploring for this application. Third, recent literature shows a shift from deriving spectral signals from satellite images, to working directly over the Hyperspectral images (HSI) [20]. Even using deep learning frameworks for identifying soil characteristics [21], rice varieties [22], rice phenology [23], and even focusing on data imbalance in the image of domain [24].

The value of this work rest about on the fact that it presents a practical example of using supervised classification algorithms for the determination of regression and classification models from reflectance spectral signatures of a local crop. This study provides

a basis for future works in deep learning based on chemometrics, and in particular the possibility of predicting crop conditions and characteristics from spectral signatures or satellite images.

Conflict of Interest The authors declare no conflict of interest.

ABSTRACT

A significant problem of routing protocols in the Flying Ad Hoc Networks (FANET) is a significant overhead cost due to the high mobility of networking nodes. The problem is caused by a need to send information messages about locations of unmanned aerial vehicles (UAVs). In order to reduce the amount of service information, the following trajectory approximation algorithms have been investigated: an algorithm for conjugating courses and an algorithm based on continuous piecewise-linear functions (CPLF). Four modifications of the CPLF-based algorithm are considered, which differ in the type of piecewise linear function used: basic CPLF, generalized CPLF, generalized CPLF with a compact notation form, and adaptive CPLF. The disadvantages of each algorithm are analyzed. The CPLF approximation of a fragment of an aircraft trajectory consisting of two straight sections and a curved section with variable steepness between them is performed. It is established that adaptive CPLF with variable step reduces the error of trajectory approximation due to the location of most points on the curved sections of the aircraft maneuvering. The modified version of ADV routing protocol has shown a lower overhead value (the gain for small pause time values reaches 23 %). Thus, the effectiveness of the proposed approximation-based routing in FANET is shown.

1. Introduction

This paper is an extension of work originally presented in the 7th International Conference on Control, Decision and Information Technologies (CoDIT' 20) [1].

Networks built on the basis of unmanned aerial vehicles (UAVs) (Flying Ad Hoc Network, FANET) [2] are characterized by an unstable network topology due to the movement of network nodes. This aspect should be taken into account when developing and applying routing algorithms. The well-known network layer protocols do not fully meet the requirements of the FANET, so the development of new routing protocols for flying networks remains relevant.

Proactive protocols calculate routes between all network nodes beforehand and maintain a relevant routing table at each node [3]. An integral part of such routing protocols is a connection management mechanism that establishes logical connections between network nodes that are within earshot of each other, and also closes logical connections. All stations distribute information

about the established logical connections over the network. Thus, each of the stations decentralizes the logical topology of the network and fills in its own routing table. In addition, proactive routing protocols provide minimal delay in the delivery of data packets, and when the network topology changes, broadcast messages about these changes are initiated [4].

The author proposed a reactive protocol Dynamic Source Routing (DSR) [5]. In reactive routing protocols, routes exist only when they are needed, that is, when data is being transmitted over them. When the route is initially determined, packets are sent in all possible directions, and information about the passed node is added to the header. As a result, when the goal is reached, the packet header contains a fully formed route between the specified nodes. In the event of loops, i.e. re-reception of the first packet, the node destroys this packet. The high mobility of FANET nodes when using proactive protocols requires frequent updates of the routing table, which is their disadvantage.

Hybrid routing protocols combine the advantages of reactive and proactive routing protocols, but require a relatively complex implementation. Their use is associated with the need to divide the

<https://dx.doi.org/10.25046/aj060263>

network structure into segments, which reduces the efficiency of routing (for example, HWMP-Hybrid Wireless Mesh Protocol).).

Geographic routing protocols use the spatial coordinates of network nodes and are more efficient for FANET, especially when the network is large. An example is the Greedy Perimeter Stateless Routing protocol (GPSR) [6]. Directional antennas-based protocols reduce the number of transit nodes and, as a result, lower the delay time (DOLSR-Directional Optimized Link State Routing Protocol [7]).

A significant problem of routing protocols in the Flying Ad Hoc Networks (FANET) is a significant overhead cost due to the high mobility of networking nodes. The problem is caused by a need to send information messages between nodes about locations of separate unmanned aerial vehicles (UAVs) [8]. Also the use of directional antennas on board the UAV [9-11] necessitates additional transmission of the angular coordinates of each node, since when the airplane turns, the receiving antenna may deviate from the maximum of the radiation pattern, which will reduce the useful signal.

In [1] the application of UAV trajectory approximation for adaptive routing in FANET networks is justified. However, the expressions are given in a fairly brief form. In addition, the approximation example of a trajectory fragment in the form of a sinusoidal function does not allow us to fully evaluate the advantages of the proposed approach, for which it is necessary to model a trajectory consisting of a set of straight sections and curved sections with variable steepness.

2. The algorithm for conjugated courses

Approximation of the UAV trajectory will reduce the overhead caused by the transmission of additional information about the position of network nodes. The use of trajectory approximation algorithms will allow the vehicle coordinates to be transmitted only at the beginning or end of each maneuver. With this approach, it is not necessary to transmit data about intermediate points of the trajectory between maneuvers, which reduces overhead costs.

The creation of the trajectory of an flying vehicle consists of several stages [12]. The first is to set the motion kinematics, which determines the spatial position of the object at an arbitrary time t . For this purpose, the object is assigned a trajectory that can be set by a set of reference vertices with a velocity vector defined at each vertex. Next, the trajectory of the air object is plotted along the reference vertices. The main disadvantage of the method of conjugating courses is a rather large amount of calculations and, accordingly, a decrease in the speed of the algorithm.

The course matching algorithm is based on dividing the trajectory into segments, and each segment is described as a mathematical expression [13]. The input data of the algorithm are the coordinates of the node points of the trajectory. The rectilinear motion of the aircraft is described by parametric equations:

$$x = x_0 + g_{0x}t + \frac{a_x t^2}{2}, y = y_0 + g_{0y}t + \frac{a_y t^2}{2}, \quad (1)$$

where x and y are current spacial coordinates, x_0 and y_0 are initial values of spacial coordinates, $g_{0x,y}$ are projections of velocity on x

and y axis, a_x and a_y are projections of acceleration on x and y axis, accordingly.

When calculating straight segments of the trajectory, the minimum trajectory curvature radius with a nominal (acceptable) level of overload, it is necessary to calculate the coefficient $K(\varphi_n)$

$$K(\varphi_n) = \begin{cases} \frac{1,017456}{\sqrt{\lg \frac{\varphi_n}{2}}} \cdot \left(1 + \frac{1}{3 \cdot \lg^2 \frac{\varphi_n}{2}} \right) & \text{at } \varphi_n \geq \frac{\pi}{2} \\ 0,272166 + \frac{1,014303}{\lg \frac{\varphi_n}{2}} & \text{at } \varphi_n < \frac{\pi}{2} \end{cases} \quad (2)$$

where φ_n is course at the segment n of a trajectory.

For circular segments of the trajectory, when calculating speed, one might need to calculate the sine, cosine:

$$g(t) = \frac{(\varepsilon \cdot (t - t_0) + \omega_0)^2}{\sqrt{x^2 + y^2 + z^2}} \cdot \begin{bmatrix} \cos(\psi(t)) \cdot (x \cdot A_x + y \cdot A_y + z \cdot A_z) \\ -\sin(\psi(t)) \cdot (x \cdot B_x + y \cdot B_y + z \cdot B_z) \end{bmatrix} \quad (3)$$

where $g(t)$ is current radial velocity of an aircraft, ε is circular acceleration, t and t_0 is current and initial time, ω_0 is initial circular velocity, x , y , and z are spatial coordinates, ψ is current current maneuvering angle, $A_{x,y,z}$ and $B_{x,y,z}$ are coefficients of the movement.

For parabolic segments when calculating the maximum move in a parabola, there is a need also calculate the arc sine:

$$\psi_n = 2 \arcsin \left[3 \lg \frac{\varphi_n}{2} \sqrt{\frac{\lg^2 \frac{\varphi_n}{2} + \frac{1}{9}}{\left(\lg^2 \frac{\varphi_n}{2} - \frac{7}{72} \right)^2 + 36 \lg^2 \frac{\varphi_n}{2} \cdot \left(\lg^2 \frac{\varphi_n}{2} + \frac{31}{144} \right)^2}} \right], \quad (4)$$

where ψ_n and φ_n are current maneuvering angle and course at the segment n of a trajectory.

Expressions (1-4) describe a smooth trajectory with high accuracy, which is necessary in automatic control systems [14] and simulation systems of full-scale modeling of aircraft [12, 15]. However, routing algorithms do not require such high accuracy in describing the path. The main requirement for the routing algorithm is the choice of optimal transit nodes for a specific network topology, which can be successfully performed with small errors in the representation of the trajectory. Thus, for routing algorithms the very detailed trajectory model is redundant, computationaly complex and not required.

3. Algorithms based on continuous piecewise linear functions

Studies have shown that continuous piecewise linear functions (CPLF) based on the modulus of a linear function are effective for approximating nonlinear characteristics, trajectories [16-18]. Calculating the approximation coefficients and the function itself

requires less computational resources compared to the course conjugation algorithm.

A smaller value of the error is achieved at the expense of equality of error in every area of approximation. The use of this approach when approximating straight lines leads to a decrease in the error, since the approximating function "adjusts" (adapts) to the change in the nature of the nonlinearity of the original characteristic.

The approximation of the trajectory using the adaptive CPLF is schematically shown in Figure 1. The function section is divided into segments. The approximation nodes are calculated as follows: a fixed error value is set, then the number of segments (approximation nodes) is determined by the algorithm. The length of segment xi varies depending on the value of approximation error ε .

Figure 1: The principle of trajectory approximation using CPLF

The CPLF approximation assumes the replacement of the object's trajectory along an arc with the trajectory of movement along a straight line. The time and velocity modules are selected according to the reference algorithm [12]. As a result, in both cases (trajectories $f(x)$ and F_i) start and end speed is the same and time spent is also the same. This means that each point of the reference segment is projected onto the corresponding point of the CPLF segment. For example, consider a section of the trajectory of Figure 1 in the interval $[x_0, x_1]$. It is shown in Figure 2. It can be seen that the error in determining the position of the object on the segment is equal to the maximum length of the projection line. In the adaptive CPLF, the errors ε_i are aligned with each other. The geometric meaning is shown in Figure 3.

Figure 2: Fragment of the trajectory

The actual error is the distance between the position of the object on the reference curve and its position on the approximating curve. Figure 3 shows the discrepancy between the actual error and the approximation error. Knowing that $\varepsilon_1 = \varepsilon_2 = \dots = \varepsilon_n = \dots = \varepsilon_{N-1}$ we estimate the range of changes in the error value δ_i . From the right triangle ABC in Figure 4, we obtain $\sin(\pi/2 - \alpha_i) = \delta_i / \varepsilon_i$,

where α_i is the angle between the CPLF and the reference trajectory. Thus

$$\delta_i = \varepsilon_i \sin\left(\frac{\pi}{2} - \alpha_i\right). \quad (5)$$

Figure 3: Determination of the approximation error

To estimate the error δ_i we need to know the error α_i . The minimum value $\alpha_0 = 0^\circ$ (at the origin in Figure 4), $\delta_{i\min} = \varepsilon_i \sin\left(\frac{\pi}{2}\right)$. The maximum value $\alpha_i = \frac{\pi}{2} - \frac{\varphi}{2}$ and $\delta_i = \varepsilon_i \sin(\varphi/2)$, therefore the actual error δ_i is determined by the inequalities $\delta_{i\min} < \delta_i < \delta_{i\max}$ and $\sin \frac{\pi}{2} < \delta_i < \varepsilon_i \sin\left(\frac{\varphi}{2}\right)$. It follows from the inequality that the greater the value of φ , the smaller the error δ_i , and δ_i (the side of the triangle ABC) does not exceed ε_i . This means that ε_i is the maximum error of the approximation of the reference trajectory using the CPLF.

Figure 4: Determination of the linear and angular approximation error

3.1. Basic CPLF

It has a compact form and contains only one approximation coefficient. The basic CPLF is convenient for representing functions and nonlinear characteristics approximated with a fixed argument step, with a small number of approximation nodes. The base CPLF has the form:

$$f_M(t) = b_M |t - t_0 - \Delta t \cdot M|, \quad (6)$$

where t_0 is an initial shift of the CPLF relative to the origin;

Δt is a shift of the modules relatively to each other;

$M=0,1,2,3$ is a count of the number of modules;

b_M is approximation coefficient.

Summing up the four functions shifted relative to each other by a fixed value, we get the basic CPLF (Figure 5):

$$b_0 \cdot |t - t_0| + b_1 \cdot |t - t_0 - \Delta t| + b_2 \cdot |t - t_0 - 2 \cdot \Delta t| + b_3 \cdot |t - t_0 - 3 \cdot \Delta t| = f(t) \quad (7)$$

We determine the coefficients b_M . To do this, using the four points $(t_0; 0)$; $(t_0 + \Delta t; y_1)$; $(t_0 + 2 \cdot \Delta t; y_2)$; $(t_0 + 3 \cdot \Delta t; 0)$ shown in the figure, we make a system of four equations:

$$\begin{cases} b_0 \cdot |0| + b_1 \cdot |-\Delta t| + b_2 \cdot |-\Delta t| + b_3 \cdot |-\Delta t| = 0 \\ b_0 \cdot |\Delta t| + b_1 \cdot |0| + b_2 \cdot |-\Delta t| + b_3 \cdot |-\Delta t| = y_1 \\ b_0 \cdot |2\Delta t| + b_1 \cdot |\Delta t| + b_2 \cdot |0| + b_3 \cdot |-\Delta t| = y_2 \\ b_0 \cdot |3\Delta t| + b_1 \cdot |2\Delta t| + b_2 \cdot |\Delta t| + b_3 \cdot |0| = 0 \end{cases} \quad (8)$$

After the transformations, the system takes the form:

$$\begin{cases} 0 + \Delta t \cdot b_1 + 2 \cdot \Delta t \cdot b_2 + 3 \cdot \Delta t \cdot b_3 = 0 \\ \Delta t \cdot b_0 + 0 + \Delta t \cdot b_2 + 2 \cdot \Delta t \cdot b_3 = y_1 \\ 2 \cdot \Delta t \cdot b_0 + \Delta t \cdot b_1 + 0 + \Delta t \cdot b_3 = y_2 \\ 3 \cdot \Delta t \cdot b_1 + 2 \cdot \Delta t \cdot b_2 + \Delta t \cdot b_3 = 0 \end{cases} \quad (9)$$

Solving system (9) by the Gauss method [20], we obtain:

$$b_0 = \frac{y_1}{2 \cdot \Delta t}; \quad b_1 = \frac{y_2 - 2 \cdot y_1}{2 \cdot \Delta t}; \quad b_2 = \frac{y_1 - 2 \cdot y_2}{2 \cdot \Delta t}; \quad b_3 = \frac{y_2}{2 \cdot \Delta t}, \quad (10)$$

where y_1, y_2 are the function values in the approximation nodes.

Figure 5: Basic CPLF

In order not to use separate expressions for each coefficient b_0, b_1, b_2, b_3 , we present them as a single coefficient B_M :

$$\begin{aligned} B_M = & \frac{(M-1)(M-2)(M-3)}{-3} \cdot \frac{y_1}{2 \cdot \Delta t} + \\ & + \frac{M(M-2)(M-3)}{1} \cdot \left(\frac{y_2 - 2 \cdot y_1}{2 \cdot \Delta t} \right) + \\ & + \frac{M(M-1)(M-3)}{-1} \cdot \left(\frac{y_1 - 2 \cdot y_2}{2 \cdot \Delta t} \right) + \\ & + \frac{M(M-1)(M-2)}{3} \cdot \frac{y_2}{2 \cdot \Delta t}. \end{aligned} \quad (11)$$

We transform equation (11):

$$B_M = y_2 \frac{5M^3 - 21M^2 + 19M}{6 \cdot \Delta t} - y_1 \frac{5M^3 - 24M^2 + 28M - 3}{6 \cdot \Delta t}. \quad (12)$$

Substituting the coefficient B_M , we finally get:

$$f(t) = \sum_{M=0}^3 B_M |t - t_0 - \Delta t \cdot M|. \quad (13)$$

The disadvantages of the basic CPLF include a cumbersome expression for determining the approximation coefficients B_M . In addition, to approximate functions over a large number of points (more than three), it is necessary to add up individual base CPLFS shifted between each other.

3.2. Generalized CPLF

The generalized CPLF reduces the computational cost of approximation using the basic CPLF. This function is the sum of a few basic CPLF. Using the generalized CPLF, we can approximate functions of any kind based on a single expression for the approximating function, rather than a large number of expressions:

$$F(t) = \sum_{n=1}^N \sum_{M=0}^3 B_{M,n} |t - [t_0 + 2 \cdot \Delta t(n-1)] - \Delta t \cdot M|, \quad (14)$$

where

$$B_{M,n} = y_{n2} \frac{5M^3 - 21M^2 + 19M}{6 \cdot \Delta t} - y_{n1} \frac{5M^3 - 24M^2 + 28M - 3}{6 \cdot \Delta t}$$

is the approximation coefficient, n is the number of basic CPLF for the approximation; $t_0 + 2 \cdot \Delta t$ is the initial offset of the second approximating function; $y_{n1} = y(t_0 + \Delta t \cdot (2n-1))$ are values of the initial characteristic in odd approximation nodes;

$y_{n2} = y(t_0 + \Delta t \cdot 2n)$ are values of the initial characteristic in even approximation nodes.

The disadvantages of the generalized CPLF include additional terms under the module and two sum counters, which complicates the computational process. A generalized CPLF can have a compact notation form and include only one sign of the sum.

3.3. Generalized CPLF with compact notation

We design a function that has a compact expression and allows us to perform an approximation with an arbitrary step. It is the sum of the modules of linear functions with different coefficients in front of them. Expressions under modules represent shifts of linear functions in the time domain. These shifts determine the approximation step. Thus, shifting the individual linear functions by a different value t_n we get the CPLF:

$$F(t) = \sum_{n=1}^N K_n \cdot |t - t_n|, \quad (15)$$

where n is the sum counter; t_n is the approximation step; K_n is the approximation coefficient.

We define an expression for finding the coefficient K_n . To do this, we approximate the function $y = f(t)$ $n = N$ points. Let the first approximation node correspond to the value $t = t_1$,

and the value of the approximated function $y_1 = f(t_1)$. The expression for the CPLF at this point:

$$F(t_1) = \sum_{n=1}^N K_n \cdot |t_1 - t_n| \quad (16)$$

or

$$\sum_{n=1}^N K_n \cdot |t_1 - t_n| = y_1. \quad (17)$$

The law of motion along each straight segment can be given by a function of the parameter t :

$$x(t) = v_{0x}t + \frac{a_x t^2}{2}, \quad y(t) = v_{0y}t + \frac{a_y t^2}{2}, \quad z(t) = v_{0z}t + \frac{a_z t^2}{2}. \quad (18)$$

By decomposing the expression for the CPLF into separate modules we get:

$$K_1 \cdot |t_1 - t_1| + K_2 \cdot |t_1 - t_2| + \dots + K_{N-1} \cdot |t_1 - t_{N-1}| + K_N \cdot |t_1 - t_N| = y_1. \quad (19)$$

We perform a similar operation for the second node $t = t_2$, which corresponds to the value of the approximated function $y_2 = f(t_2)$ and the expression for the adaptive CPLF at this node:

$$F(t_2) = \sum_{n=1}^N K_n \cdot |t_2 - t_n| \quad (20)$$

or

$$\sum_{n=1}^N K_n \cdot |t_2 - t_n| = y_2. \quad (21)$$

As a result, for N approximation nodes we obtain a system of N equations:

$$\begin{cases} K_1 |t_1 - t_1| + K_2 |t_1 - t_2| + \dots + K_{N-1} |t_1 - t_{N-1}| + K_N |t_1 - t_N| = y_1 \\ K_1 |t_2 - t_1| + K_2 |t_2 - t_2| + \dots + K_{N-1} |t_2 - t_{N-1}| + K_N |t_2 - t_N| = y_2 \\ \vdots \\ K_1 |t_{N-1} - t_1| + K_2 |t_{N-1} - t_2| + \dots + K_{N-1} |t_{N-1} - t_{N-1}| + K_N |t_{N-1} - t_N| = y_{N-1} \\ K_1 |t_N - t_1| + K_2 |t_N - t_2| + \dots + K_{N-1} |t_N - t_{N-1}| + K_N |t_N - t_N| = y_N. \end{cases} \quad (22)$$

We find the values of the coefficients $K_1 - K_N$ by the inverse matrix method. In matrix form, the system will take the form:

$$[K] \cdot [T] = [y]. \quad (23)$$

Hence, the desired coefficients $K_1 - K_N$ have the form:

$$[K] = [y] \cdot [T]^{-1}. \quad (24)$$

3.4. Adaptive CPLF

Approximating trajectories with a fixed step is impractical if the trajectories contain long straight sections. To represent each linear fragment, two approximation points are sufficient, and it is advisable to place most of the approximation points on curved sections. Thus, it is promising to apply an adaptive CPLF with a variable approximation step.

As a criterion for the quality of the approximation, we use the minimum mean square error (MSE) criterion. The expression for the approximation MSE in the range (t_0, t_N) has the form

$$\sigma^2 = \int_{t_0}^{t_N} [y(t) - F(t)]^2 dt. \quad (25)$$

The approximation is carried out based on finding the vector $\mathbf{T} = (t_1 \dots t_{N-1})^T$ which fits to the condition of the minimum MSE value:

$$\sigma^2(\mathbf{T}) \rightarrow \min. \quad (26)$$

Adaptive CPLF allows to approximate nonlinear characteristics and functions with a lower error than CPLF with a fixed approximation step. This is achieved by obtaining an equal error in each approximation section. The use of this approach when approximating with lines leads to a decrease in the error, since the approximating function "adjusts" (adapts) to the change in the nature of the nonlinearity of the original characteristic.

Equal approximation error in each section will reduce the total error. To obtain an equal approximation error in each section, the following condition must be met:

$$\delta_1 = \delta_2 = \dots = \delta_n. \quad (27)$$

Based on the MSE expressed by Equation (25), we write:

$$\int_{t_0}^{t_1} [y(t) - F(t)]^2 dt = \int_{t_1}^{t_2} [y(t) - F(t)]^2 dt = \dots = \int_{t_{N-1}}^{t_N} [y(t) - F(t)]^2 dt. \quad (28)$$

Let's represent the integrand expressed in Equation (28) as follows:

$$g(t) = [y(t) - F(t)]^2. \quad (29)$$

$$\delta = \int_{t_l}^{t_k} g(t) dt = G \Big|_{t_l}^{t_k} = G(t_k) - G(t_l), \quad (30)$$

where G is antiderivative of the function $g(t)$.

We find the points for the approximation of an arbitrary function based on the adaptive CPLF with a lower error. To find these points, we define a system of equations:

$$\begin{cases} G(t_1) - G(t_0) = G(t_2) - G(t_1) \\ G(t_1) - G(t_0) = G(t_3) - G(t_2) \\ \vdots \\ G(t_1) - G(t_0) = G(t_N) - G(t_{N-1}). \end{cases} \quad (31)$$

From the system of equations (31), the values of t_n are determined, which approximate the studied characteristic with an equal error in each section. The values of the function $y(t_n)$ at the points t_n are determined from the known expression for the original function $y(t)$.

4. Approximation of the trajectory fragment of the aircraft based on the CPLF

The solution of the minimization problem (26) was performed on the basis of the nonlinear conjugate gradient method [19,20],

the value of convergence tolerance parameter of 10^{-6} was accepted. Evaluation of the approximation MSE based on Equation (25) is shown in Fig. 3.

The approximation result of the aircraft trajectory fragment $\tilde{F}_{1,2}(t)$ by $N=16$ nodes and the absolute approximation error $\Delta_{F1,2}(t)$ are shown in Figures 6 and 7. Here, the lower index 1 corresponds to the uniform law for the approximation nodes, and the index 2 corresponds to the optimal law. The dots in the figures show the approximation nodes. The values of the source function and the approximating function at the nodes are equal, so the error at these points is zero. The MSE values are $\sigma_{F1}^2=1,187 \cdot 10^{-3}$; $\sigma_{F2}^2=1,982 \cdot 10^{-5}$. With the optimal nodes, most of them are located on a curved section, where the trajectory changes most quickly, which gives a significant decrease of MSE (by 59.9 times).

Figure 7: Approximation error of the aircraft trajectory fragment based on the CPLF: a) with a uniform step; b) with an adaptive step

5. Modeling of approximation-based routing in FANET

A comparative simulation of the UAV network with two routing protocols was performed: the standard ad-hoc on-demand vector (AODV) and the modified one. In the modified version of the protocol, Route Request packets were not transmitted at a fixed time interval, as in the standard version, but only when the course changed by more than 200. Otherwise, Route Request packets were not transmitted, and the coordinates of the nodes obtained from the past coordinate values by the piecewise linear approximation were used to update the route table. Changes in the course of individual nodes were taken into account in the node mobility model (the OPNET modeler 14.5 simulator was used). Thus, the modified routing protocol is a hybrid of the standard AODV protocol and geographic-based routing. When modeling the network, the following parameters were obtained:

- the number of network nodes - 20;
- channel bandwidth - 2 Mbit/s;
- the power of the UAV receiving and transmitting device is 10 mW;
- threshold receiving power-minus 90 dB;
- the maximum data packet size is 1024 bytes;
- MAC layer protocol - CSMA/CA (carrier sense multiple access with collision avoidance)
- network size 10x10 km;
- average speed of mobile nodes is 10 m/s.

Mobility model - Random-Waypoint [21]

During the simulation, the Pause time parameter of a mobility model (time between changes in direction and/or speed) was varied and the routing overhead in percent was determined for the standard and modified AODV. The simulation results are shown in Figure 8. The overhead value of the standard AODV is in good agreement with the results in [22]. The modified version of AODV routing protocol shows a lower overhead value (the gain for small pause time values reaches 23 %). Thus, the effectiveness of the proposed approximation-based routing in FANET is shown.

Figure 8: Routing overhead vs Pause time for a standard and modified AODV

6. Conclusion

A serious problem of routing protocols in FANET is the significant overhead caused by the high mobility of network nodes. The problem is caused by a need to send information messages about locations of unmanned aerial vehicles (UAVs). The perspective of algorithms for constructing the UAV trajectory to reduce the amount of service information about the UAV position transmitted via the FANET routing protocols is substantiated. When using such algorithms, information about the coordinates of the nodes is directly transmitted only in the areas of maneuvering of the aircraft, and in the areas of rectilinear motion is calculated based on the algorithms for approximating the trajectory. In order to reduce the amount of service information, the following trajectory approximation algorithms have been investigated: an algorithm for conjugating courses and an algorithm based on continuous piecewise-linear functions (CPLF). Four modifications of the CPLF algorithm are considered which differ in the type of function used: basic CPLF, generalized CPLF, generalized CPLF with a compact notation form, and adaptive CPLF. The advantages and disadvantages of each algorithm are analyzed. Adaptive CPLF with variable approximation step allows lower computational resources compared to the rate-matching algorithm, as well as more accurate compared to the CPLF with a fixed step.

An approximation of a trajectory fragment consisting of two straight sections and a curved section with a variable steepness between them (approximately described by the arctangensoidal function) was performed. The computational experiment has shown the effectiveness of the direct approach: in the considered example with long straight sections, the approximation MSE by the adaptive CPLF is 59.9 times less compared to the fixed step CPLF. The modified version of ADV routing protocol shows a lower overhead value (the gain for small pause time values reaches 23 %). Thus, the effectiveness of the proposed approximation-based routing in FANET is shown.

Anopheles Gambiae

Cytochrome P450 Family

Pyrethroid Resistance

Model Structure

ABSTRACT

The *Anopheles gambiae*'s CYP6Z3 protein belongs to the Cytochrome P450 family and functions in oxidation-reduction processes, many studies including our previous work on elucidating insecticide resistance genes of the *Anopheles* also implicated her in pyrethroid insecticide resistance. Model prediction, functional analysis, and enrichment of the target gene with triplex binding sites may become a useful diagnostic biomarker for the disease subtype, but wrong classification of the model by various existing alignment algorithms is a daunting issue that complicates and misleads in decision making during pathway and functional analysis. The aim of this study is to predict five in-silico model of CYP6Z3 *Anopheles* protein by homology modeling, evaluate and classify them to elucidate the performance of the sequence alignment algorithm deployed, then characterize the top model that is correctly classified. Template selection from three alignment algorithms with sequence of the target-protein, (*Anopheles*-CYP6Z3) obtained from UNIPROT served as input, Clustal omega and Clustalw2 algorithms was used to generate alignment files for homologous template search to the target-protein. Best template was sought, and the 3D model built in an-automated-mode. PROCHECK was used to evaluate the best-of-the-five-obtained models. Estimating the quality of all models, the prime model emerged from ClustalW2 alignment algorithm, but was wrongly classified as a homo-tetramer-state. These provided a misleading-information which was revealed during model evaluation and interpretation, that resulted to an inappropriate pathway and functional-analysis, false positive model was then isolated, and the current best model emerged from clustalo alignment algorithm having 87.7% amino residues in the most favorable regions, 0.7% in the disallowed regions at monomer oligo state. Functional analysis of the best *Anopheles* CYP6Z3 secondary structure showed characteristics that explain the different degrees of genetic regulation translating to resistance mechanism in the malaria vector.

1. Introduction

The *Anopheles gambiae* CYP6Z3 protein is a member of Cytochrome P450 protein family functioning in oxidation-reduction processes. It has the VECTORBASE Annotation ID AGAP008217, primary (citable) accession number Q86LT6 and entry name Q86LT6_ANOGA. It has a sequence length of 492AA and is located on Chromosome 3R: 6,971,669-6,973,290. It has a mass of 56,490(Da) [1], [2]. It has been implicated in pyrethroid resistance [3].

The CYP6Z3 protein is expressed during the mosquito's larval stages [4], this protein belongs to the Cytochrome P450 family and functions in oxidation-reduction processes. The P450 is a large family that plays critical role in xenobiotics detoxification or

activation. Instances are insecticide detoxification in the West African *Anopheles gambiae* [5].

Over 30 species of *Anopheles* transmit malaria (<http://www.cdc.gov/malaria/about/biology/mosquitoes/>), hence identification of resistance mechanisms in other species is a focus of many researches. *Anopheles funestus* is the next as a major malaria vector in Sub-Saharan Africa. When quantitative trait loci (QTL) are considered, several genes are strongly associated with pyrethroid resistance in *A. funestus*, this include our target protein CYP6Z3 [6]. In a recent study, genes transcripts from the four known detoxification genes family, (cytochrome P450s, glutathione transferases, carboxylesterases and UDP glucosyltransferases were reported to be generally enriched in the midgut and malpighian tubules of *A. gambiae*. Recently,

*Corresponding Author: Marion Olubunmi Adebisi, Email: mariona@dut.ac.za

www.astesj.com

<https://dx.doi.org/10.25046/aj060266>

Cytochrome P450 proteins were reported to have developed different levels of resistance to multiple insecticides [7]. Specifically, the CYP6Z3 family was found to be highly enriched in the malpighian tubules consistently with its role in detoxification [8].

The malpighian tubules therefore display roles similar to liver of vertebrates, kidney and their immune system. Despite the wide distribution of detoxifying enzymes in insects, baseline mechanisms protecting vectors against insecticides is resident mainly in the excretory canal (system) of the insect's, which corresponds to less than 0.1% of its total mass [9].

1.1. Theoretical framework

Homology modelling, also called comparative modelling is the central concept of relative and trans-mutative biology. It is the existence of morphological structures and features in various species or organisms linked by sharing common ancestor. Homology was invented in the nineteenth century and found to be phylogenetic in nature and well rooted in comparative practice even before the invention of evolution theory [10]. It is believed that various developmental mechanisms are responsible for formation of homologous structure, however, varying specie may have anatomical structures with same or different characters, featuring similar shape, internal structure, and function, but may only be closely related species by taxonomic link in different mammals. The idea of homology originated with the recognition that the same structures exist in less closely related species (mammals and birds, or even mammals and fish) and that the sameness of morphological (body) units is independent of their function and form [10], [11]. Figure 1 depicts the flow diagram of the conceptual framework of this research.

Figure 1: Conceptual framework of homology modelling [12]

The theoretical model is a molecular model premised on the notion that if two proteins possess a high sequence similarity, they will most likely have highly similar three-dimensional structures. To select the best template, a search for homologous Protein that has experimental structure by empirical methods by X-ray

crystallography, nuclear magnetic resonance (NMR), or cryo-electron microscopy, existing on Protein Data Bank (PDB) [13].

2. Experimental

The method deployed was adopted from [14]. The FASTA format sequence of the target protein CYP6Z3 of the *Anopheles* was retrieved from UNIPROT database, (UniProt entry Q86LT6).

2.1. Template Selection

BLAST Program [15], blastp variant was used to the search for homologous sequences within Protein Data Bank (PDB) database [16]. The BLAST search returned many sequences that were homologous with the target sequence but only one was selected as the template.

2.2. Selection Criteria

Sequence identity of 30% or more was considered. Generally, the homologous sequences returned had low sequence identity between 19%-33%. E-value less than 0.001 and query cover above 50% were also considered. Potential templates were filtered based on these criteria and the atomic resolution of their experimentally derived 3D structures as viewed from PDB. Structures that failed to meet one or more of these criteria were excluded and the protein with accession 1TQN_A was selected as the template, with query cover 96%, E-value $2e-68$ and sequence identity 31%. It has a medium atomic resolution of 2.05Å and was determined by X-ray crystallography. The 1TQN_A protein is a crystal structure of the human microsomal P450 3a4. It has a sequence length of 486AA. It is also a Cytochrome P450 enzyme functioning in oxidation-reduction processes. The sequence for the template was downloaded directly from the BLAST webpage in the fasta format.

2.3. Sequence Alignment

In [17], [18], the authors were used to perform sequence alignments for the target sequence and template sequence using the default settings. The resulting .clustalw2 and .clustalo files were downloaded to serve as an input files for the next step.

2.4. Building the Model

Swiss Model Server in [19], was deployed for building the 3D structure of the target protein.

3. Results

This study modelled five (3D) secondary structure of the *Anopheles* protein, CYP6Z3 by homology modeling, evaluated, classified, and compared their classified features to gauge how the sequence alignment algorithms rates the features of each of the model. The purpose of comparison was to reveal the best of the five models and elucidate possible errors in the features of their secondary structure, the evaluation result detected a wrong classification error in the supposed best structure, while other features are correctly classified. If the structure with error is the only one modelled and validated, performing further analysis such as functional characterization and pathway analysis based on the result built with error may result in misleading result hypothesis and fatal conclusion.

Clustal omega and Clustalw2 algorithms was used to generate alignment files for homologous template search to the

target-protein. The final correctly classified result of the best CYP6Z3 *Anopheles gambiae* secondary structure was functionally analysed, the result revealed the different degrees of genetic regulation translating to resistance mechanism deployed to pyrethroid class of insecticide by the malaria vector, *Anopheles*.

3.1. Using .clustlaw Alignment File

The “Alignment Mode” was used where the target-template alignment from Clustalw2 was submitted to the server. The server generated a model built with template 1tqn.2.A (Table 1).

Table 1: Features of model from template 1TQN.2.A with Clustal W2 alignment file

Templat e	Seq ID	Oligo- state	Metho d	Seq similarit y	Coverag e
1tqn.2.A	30.30 %	Homo- tetrame r	X-ray, 2.05Å	0.36	0.96

3.2. Using .clustalo Alignment File

First, the “Alignment Mode” was used where the target-template alignment from Clustal Omega was submitted to the server (TABLE 2). Next, the “Automated Mode” was used where another entry was submitted into the server with only the target protein as input data, allowing Swiss Model Server to search through databases for its template(s) of choice (TABLE 3).

3.3. Alignment mode

Table 2: Features of model from template 1TQN.1.A with Clustalo alignment file

Template	Seq ID	Oligo- state	Method	Seq similarity	Coverage
1tqn.1.A	30.85%	Monomer	X-ray, 2.05Å	0.36	0.96

3.4. Automated mode

The server found 50 templates and built 3 models

Table 3: Features of the three models from automated mode

Built	Templat e	Seq ID	Oligo- state	Metho d	Seq similarit y	Covera ge
Mod el 1	1tqn.1. A	30.85 %	Monom er	X-ray, 2.05Å	0.36	0.96
Mod el 2	4k9w.4. A	30.19 %	Monom er	X-ray, 2.4Å	0.36	0.95
Mod el 3	3ua1.1. A	30.19 %	Monom er	X-ray, 2.15Å	0.36	0.95

From the models generated, it was observed that using Clustalw2 for sequence alignment, the model was predicted to be a homo-tetramer while for Clustal Omega, all models were predicted to be monomers. Also, both alignment modes (i.e from .clustalw and .clustalo files) generated structures for 1TQN_A proteins (1tqn.2.A and 1tqn.1.A respectively). It was hypothesized that these two proteins were more closely related based on their coverage of 0.96 although they differed in sequence identity compared with a similarly named model (1tqn.1.A) built via automated mode which had a coverage of 0.95.

3.5. Model evaluation

PROCHECK [20], [21] generated the Ramachandran plot, this plot was used to validate the built models (Figures 2, 3, 4, 5, 6).

Table 4: Ramachandran plot interpretation for the modelled structures (result validity table)

Source	Alignment mode	PDB SUM	Most favoured regions	Disallowed regions
Cluster W2 Alignment	1tqn.2.A	d839 (Figure 2)	87.9%	1.2%
Cluster O Alignment	1tqn.1.A	d860 (Figure 3)	87.7%	0.7%
Automated mode	1tqn.1.A	d861 (Figure 4)	80.9%	1.4%
Automated mode	4k9w.4.A	d862 (Figure 5)	83.2%	1.7%

4. Discussion

From the above tables, as hypothesized, the structures derived from Clustalw2 and Clustal Omega sequence alignments were similar, having the highest percentage of residues in the most favored regions than every other model generated via the automated mode (TABLE 4). All the structures built represented the same protein, but clustalw2 ‘misinterpreted’ it to be a homo-tetramer protein. Clustalw2 model would have been the best with 87.9% amino acid residue highly deposited in the most acceptable region and 1.2% deposit in the disallowed region, but since it could not classify the protein appropriately into a monomer oligo state, where the protein family belongs, the result was disregarded and could not be considered for further functional analysis and quality scrutiny.

This shows that the quality of the choice of template sequence used as input data into any modelling server, Swiss model in this case, is very important. For the automated mode, the 3ua1.1.A model was the best with the highest percentage of residues in the most favored/ acceptable regions. Comparing this with those obtained via alignment mode, the model 1tqn.1.A generated from .clustalo (Figure 8) alignment file with Ramachandran plot (Figure 3) respectively was the overall best structure having 87.7% amino residues in the most favorable regions and 0.7% residue deposits in the disallowed regions. All model proteins derived from both alignment and automated modes are in Figures (7, 8, 9, 10, 11).

Figure 2: Ramachandran plot of Figure 7

Figure 3: Ramachandran plot of Figure 8

Figure 4: Ramachandran plot of Figure 9

Figure 5: Ramachandran plot of Figure 10

Figure 6: Ramachandran plot of Figure 11

4.1. Alignment mode

In [22], the author used to summarize the statistical details of the prime model (1tqn.1.A from alignment mode), while SaliLab Model Evaluation Server (ModEval) was also used to estimate the quality of the best model. The model from ClustalW2 alignment algorithm came up as the best model, but the alignment algorithm wrongly classified the model to be at homo-tetramer-state. These provided a misleading information which sufficed during result interpretation and model evaluation, these resulted to inappropriate pathway and functional characterization, until model with false positive classification was isolated and the real true positive model emerged the best model and was characterized.

Figure 7: 1tqn.2. A

Figure 8: 1tqn.1. A (Best of all Models)

Figure 9: 1tqn.2. A

Figure 10: 4k9w.4. A

Figure 11: 3ua1.1.A

5. Conclusion

In this work, the best model was obtained by comparing the modeled structures produced by clustalo and .clustalw alignment files, meaning that the 3D-models produced by the two alignment-modes were very-similar, having a high-amino-residue-percentage deposited most favored-regions on the Ramachandran-plot than the model by the SWISS-automated-mode. Meticulousness and carefulness in the selection of procedure for analysis and choice of criteria for template protein selection from the avalanche of selectable criteria is an explorable virtue that can be deployed to avoid performing further analysis on true negative errors and interpreting false positive results. Our result showed that the quality of structure predicted by in-silico modeling cannot be over emphasized. Results showed that the 3D-model generated from template-protein-(1tqn.2.A), by Clustalw2-alignment and 3D-model generated from template-protein (1tqn.1.A) by Clustal Omega alignment were similar, having a high amino residue percentage deposited at regions that are most favored on the Ramachandran plot than the rest of the models generated via the automated mode. MolProbity for statistical analytics-summary and SaliLab-Model-Evaluator (ModEval) estimated the quality of the prime/leading model and evaluated the model from ClustalW2 as the best model, but wrongly classified the protein into a homo-

tetramer state. These provided a misleading information which suffice during results interpretation, hypothesis generation and may result to inappropriate pathway and functional analysis. This matter in decision making during interpretation of result. it goes a longer way to determine not just the quality of the outputted target or modelled structure, but also considered aptly in taking decision to elicit the quality of the predicted functions of the target proteins, even in taking hypothesis while interpreting the output model as result, researcher may be misguided if an appropriate criterion was not considered during template selection on BLAST search. The role of CYP6Z3 in physiological processes including hormone and pheromone metabolism as well as insecticide detoxification, especially of pyrethroid, in *Anopheles gambiae* was also deduced.

Conflict of Interest

The authors declare that they have no conflict of interest.

MPPT

ABSTRACT

In grid connected wind turbine (WT) systems, the maximum power point tracking (MPPT) approach has a crucial role in optimizing the wind energy efficiency. To search for the maximum power value of the wind turbine, this contribution proposes a new Maximum Power Point Tracking System (MPPT) for wind turbine related to a permanent magnet synchronous generator (PMSG)). The new proposed MPPT combines two techniques: Artificial Neural Network (ANN) and Fuzzy Logic (FL). The ANN is employed to estimate the maximum voltage of the WT, for various values of wind speed, while the control of DC-DC boost converter operation is executed by applying Fuzzy Logic technique. The comparison of our proposed algorithm to P&O technique has shown that it ensures more efficiency, and we used for that a simulation under Matlab/Simulink.

1. Introduction

Nowadays, motivated by the environmental issues caused by the outrageous use of traditional energy resources such as oil, natural gas or coal, many countries in the world tend to an ecological transition. They also pay more attention to the ecological effects generated by this ruinous exploitation such as: global warming, air pollution, etc.

Due to their adaptability and ease of use, renewable energies are currently a crucial form of energy used in different fields. Thus, we are going to concentrate in this contribution on the case of wind turbine as a mechanism of generating renewable energy.

Wind turbine is an unflagging source of renewable energy that is able to produce electricity, using the power of the wind. It is also worth to mention that the wind power plants can be established either on earth or in oceans. [1]

The WT is an instrument that converts the dynamic wind energy into electrical energy, which will be sent to the power grid.

In the grid connected systems of wind turbines (WT), the maximum power point tracking algorithm (MPPT) is a pivotal criteria to improve the wind energy productivity.

In last few years, diverse MPPT techniques have been applied, the major controllers that are used extensively are Climb Search (HCS) or Power Signal Feedback (PSF), Perturbation and Observation (P&O), Optimal Torque Control (OTC), Top Speed Ratio (TSR) and methods of soft computing such as Fuzzy Logic Control (FLC) and Artificial Neural Network (ANN).

The Perturb and observe (P&O) or HCS (Hill climb search) control methods are applied when the system's optimal relation is determined. The P&O approach is used to follow the MPP, by changing the maximization factor and measuring the obtained power.

The MPPT controller based on the Fuzzy Logic Controller (FLC) and the (ANN) are designed to overcoming the limitation of all methods listed above. They have a more rapid response, in the case of fast varying wind speeds.

This article exhibits a new *approach* for Maximum Power Point Tracking for Wind Energy Conversion System.

*Corresponding Author: Hayat EL AISSAOUI, Team SEERIA, ENSAO School, Electronics and Systems Laboratory, Faculty of Science, Mohammed First University, Oujda, Morocco, Email: hayatel89@gmail.com

In fact, we propose a new MPPT based mainly on fuzzy logic (FL) and Artificial Neural Networks (ANN) and by doing so we will be able to take out maximum power of the wind turbine. The idea is to use the ANN to estimate the maximum voltage of the WT using different values of wind speed, while a fuzzy controller will be responsible of controlling the DC-DC boost converter.

Our system involves wind turbine related to a permanent magnet synchronous generator (PMSG), a rectifier and a DC-DC converter with MPPT control.

Our results have shown that the proposed system guarantee more efficiency in terms of tracking the MPPT and extracting the maximum power of a WT.

The proposed model is presented in figure 1 below:

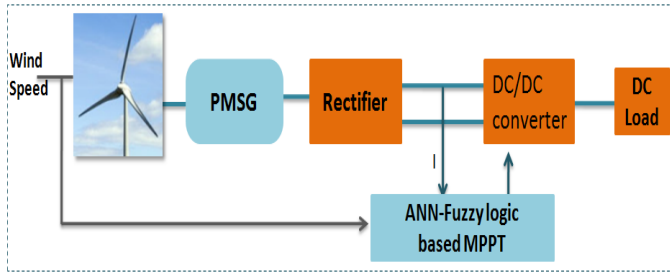

Figure 1: Overall schematic of PMSG based ANN and Fuzzy logic

The manuscript is structured as listed below:

Section 2 describes the designing of a WT wind turbine. The section 3 presents the modeling of the used converter. Section 4 explains the different types of MPPT controllers used in this article: ANN and FLC and later P&O. Section 5 gives the results obtained from the simulation realized in this work with a discussion of the performances of the proposed algorithm.

2. Modeling of A WT

The mathematical expression of the mechanical power generated by the WT is presented by the following equation presents: [2]

$$P_{\text{Par}} = C_p(\lambda, \beta) \frac{\rho A V_w^3}{2} \quad (1)$$

P_{Par} is the output mechanical power of the turbine (w), ρ is the air density (kg/m^3), $C_p(\lambda, \beta)$ is the performance coefficient of the turbine, A is the turbine swept area (m^2), V_w is the wind speed (m/s), λ is the tip speed ratio, and β is the blade pitch angle (deg).

$$\lambda = \frac{R \omega}{V_w} \quad (2)$$

R means the turbine ratio (m), ω is the turbine angular velocity (rad/s).

The power coefficient is in accordance with β and λ . The coefficient of performance is shown as below:

$$C_p(\lambda, \beta) = 0.22 \left(\frac{116}{\lambda i} - 0.4\beta - 5 \right) e^{-\frac{21}{\lambda i}} \quad (3)$$

$$\frac{1}{\lambda i} = \frac{1}{\lambda + 0.08\beta} - \frac{0.035}{\beta^3 + 1} \quad (4)$$

The aerodynamic torque is presented as follows:

$$T = \frac{P_{\text{Par}}}{\omega} = \frac{1}{2\lambda} \rho \pi R^3 V_w^2 C_p(\lambda, \beta) \quad (5)$$

Based on equation 1, we can say that the most significant factor to achieve the maximum power produced by a wind turbine is the curve of C_p ; in fact, When the C_p is at maximum, it means that the power produced by the wind turbine has reached its maximum. For this work, β is equal to zero.

Every different value of λ we obtain a constant β and an optimum C_p . For every wind speed value, we can define a unique rotor speed that allows achieving a maximal power. Thereby, considering the wind speed constant invariable, the optimum C_p value will be bound only on the wind turbine rotor speed [3].

Figure 2: Characteristics of power coefficient

Figure 3: Power graphs under various wind speeds ($\beta=0$)

The parameters of the Turbine Generator are detailed as follows:

Table 1: WT generator system characteristics

Characteristics	Values
Rated Voltage	90 V
Rated Power	1000W
Synchronous inductance	1mH
Rated Current	4.8A
Number of poles	8

Characteristics	Values
Synchronous resistance	1.13Ω
Friction coefficient	0.006N.m.s/rad
Magnetic flux	0.16Wb
Moment of inertia	0.005N.m
Blade length	1.2m
Air density	1.2 kg/ m ³

3. Converter Modelling

The boost converter is basically a voltage step-up power converter which accepts a low-voltage input and delivers an output at a much higher voltage. The DC/DC boost converter topology is the most commonly used topology. [4]

The electrical circuit of DC/DC boost converter used in this contribution is shown in the figure below:

Figure 4: Configuration of Boost converter

The Boost Converter is the conventional basic DC/DC converter, which runs with a single switch.

The boost converter contains a capacitor, a switch, a diode for its operation, and an inductor, as illustrated in Figure 4. [5]

Once the switch is activated, the diode is reverse-biased, the current begins to increase by charging the inductor; and a capacitor holds the charge.

The model of the boost converter is as described below:

$$V_0 = \frac{1}{1-D} V \quad (6)$$

The V_0 , V are the output and the input voltage respectively.

The mathematical expression of the parallel chopper is:

In the case of $t \in [0, DT]$:

$$\frac{di}{dt} = \frac{V}{L_f} ; \quad \frac{dV_0}{dt} = \frac{V_0}{RC} \quad (7)$$

In the case of $t \in [DT, T]$:

$$\frac{di}{dt} = \frac{V-V_0}{L} ; \quad \frac{dV_0}{dt} = \frac{i}{C} - \frac{V_0}{RC} \quad (8)$$

The inductor of the boost converter and capacitor are determined by:

$$L = \frac{V.D}{\Delta I_L . f} \quad (9)$$

$$C = \frac{I_0 . D}{\Delta V_0 . f} \quad (10)$$

where ΔI_L and f are the approximate inductor ripple current and the corresponding switching frequency, respectively. ΔV_0 the estimated output ripples voltage.

4. The proposed MPPT method for the Wind Turbine

To search the maximum power produced by the wind turbine, we propose a new power tracking approach based mainly on fuzzy logic (FL) and Artificial Neural Network (ANN), as shown in Figure 5.

Figure 5: Block diagram developed MPPT

In this paper, two steps are applied to keep track the PPM of the WT.

In the first step, the ANN is used to obtain an Estimated Optimal Voltage Value (V_{MPP}) for each wind speed value.

ANN estimates the maximum value of voltage of the wind turbine associated to each given wind speed. It predicts the value of V_{MPP} based on the training of a database that combines each wind speed with the associated V_{out} voltage.

During the second step, the Fuzzy Logic method is implemented to give the value of the Duty cycle.

From the maximum voltage (V_{MPP}) and the value of the current I_{WT} , the derivatives ΔP and ΔV are calculated, which will then be the Fuzzy block inputs. The fuzzy logic controller is implemented to indicate the value of Duty cycle based on the inputs ΔP (power) and ΔV (voltage).

4.1. ANN Based MPPT Algorithm

The design of artificial neural networks is based on the biological neuron structure of the human brain. Artificial neural networks can be described as systems composed of at least two layers of neurons, an input layer and an output layer and usually including hidden layers. If the problem is complex, the artificial neural network must have more layers. Each layer contains a large number of specialized artificial neurons.[6]

Figure 6: ANN Diagram

Neurons are linked and interchange with each other. Every neuron node has data as an increment and it is able to execute trivial operations on it.

Afterward, the outcome of these actions is delivered to other neurons. The result of each neuron node is called the nodes activation or node value.

Figure 7: V_{MPP} prediction using ANN

where X_1 represents the wind speed value, it is the input of the ANN, Y_1 represents the output V_{MPP} (optimal voltage).

The artificial neural network is created from a program under Matlab, based on the training of a given database (wind speed, V).

In our case, in the first layer, the optimized number of neurons is forty neurons, the second layer has one purelin neuron, one neuron in the input layer and also one in the output layer is constructed. The model of network is as below:

Figure 8: Neural Network Model

4.2. FLC For Wind Turbine

The strong point of the fuzzy logic controller is that it deals with the unspecific inputs and nonlinearity and brisk changes.

FLC is mainly The FLC is mainly structured in three phases that represent the fuzzification, the fuzzy inference engine (rule base table determined by previous instructions) and defuzzification.

Fuzzification: Transform numeric input values to linguistic values using a membership function. [7]

Rules base: Fuzzy rules have been used to characterize the connection that exists between the output and input of the fuzzy control. The number of fuzzy rules depends, among other things, on the partition of the speech universes of the input and output parameters. [8]

Defuzzification: This step consists of converting a linguistic value into a numerical value.

In this method, the fuzzy logic controller is used to indicate the value of D based on the inputs delta P (power) and delta V (voltage).

The process of FLC for the WT subsystem is shown in Figure 10.

Figure 9: Structure of a fuzzy controller

Delta P and Delta V are shown by the equations below:

$$\text{Delta}P(k) = P(k) - P(k-1) \quad (11)$$

$$\text{Delta}V(k) = V(k) - V(k-1) \quad (12)$$

The membership functions of Delta P , Delta V and D are respectively shown in Figure 10(a), Figure 10(b) and Figure 10(c).

(a)

(b)

(c)

Figure 10: Membership functions related to (a) Delta P , (b) Delta V , (c) D .

The table 2 shows the inference rules for the various combinations of the variables DeltaP, DeltaV with output D. [9]

Table 2: Inference Rules related to Fuzzy Logic WT

Delta V \ Delta P	NG	NM	NP	Z	PP	PM	PG
NG	NG	NG	NG	NM	NM	NP	Z
NM	NG	NG	NM	NM	NP	Z	PP
NP	NG	NM	NM	NP	Z	PP	PM
Z	NM	Z	NP	Z	PP	PM	PM
PP	NM	NP	Z	PP	PM	PM	PG
PM	NP	Z	PP	PM	PM	PG	PG
PG	Z	PP	PM	PM	PG	PG	PG

4.3. Perturb and Observe Based MPPT Algorithm for wind turbine

The Perturb and observe (P&O) method is the most widely employed because of its simple implementation. The concept of this algorithm is illustrated in Figure 11.

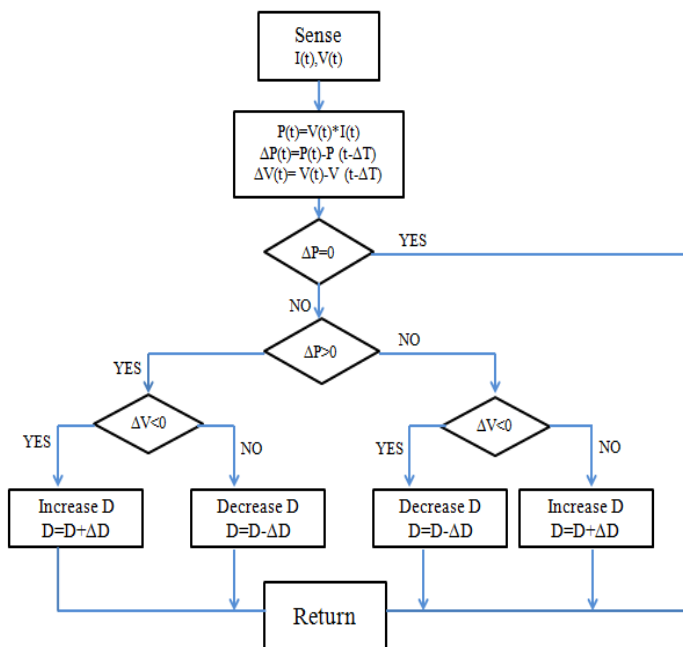

Figure 11. Perturb and Observe Approach (P&O)

5. Results and Discussion

The proposed algorithm is verified with MATLAB SIMULINK, as illustrated in Figure 12:

To implement the new MPPT algorithm and to verify its efficiency, MATLAB / SIMULINK is used as shown in Figure 12.

The system includes the following elements: a wind turbine, a permanent magnet synchronous generator (PMSG), a rectifier, a boost converter, an ANN block and a fuzzy logic block.

Figure 13 shows that the wind speed varied in three stages, it passes from 8.4 m / s to 8.5m / s, then to 9.1 m / s.

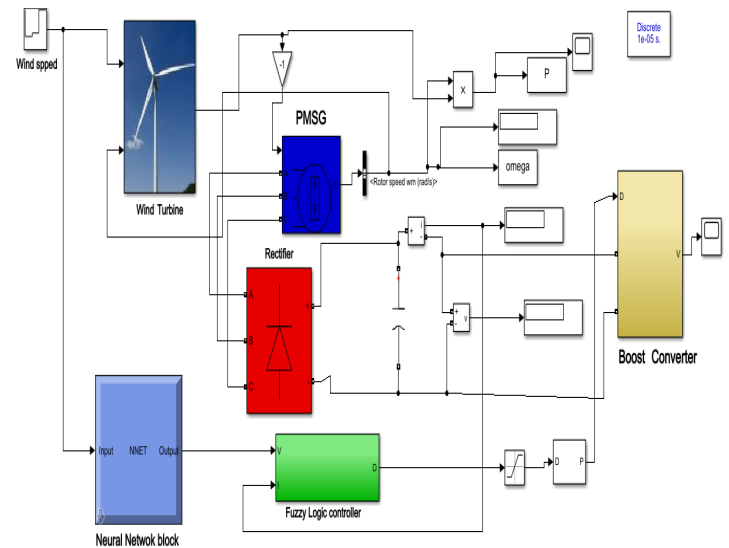

Figure 12: ANN-Fuzzy based MPPT algorithm deployment on Simulink

Figure 13: Varying wind speed

Figure 14 shows, the variation of the performance coefficient, for the wind speed which varies between 8.4m/s, 8.5m/s, and 9.1m/s.

Figure 14: power coefficient for different wind speed.(maximum value is 0.48) using ANN-Fuzzy algorithm

Our results seem to confirm that our system is able to keep track of its MPP ($C_p=0.48$) considering various wind speed values.

Figure 15: Tip speed ratio curve under a varying wind speed using ANN-Fuzzy logic algorithm

According to the simulation results the power coefficient and tip speed ratio are set at the maximum values.

Figure 16 shows the torque evolution curve related to the proposed approach based on ANN and Fuzzy logic.

Figure 17 shows the WT's mechanical output power, using the new ANN-FL MPPT approach, for the wind speed which varies between 8.4m/s, 8.5m/s, and 9.1m/s.

Figure 17: The output mechanical power under different wind speed using ANN-Fuzzy algorithm

By comparing the evolution of the power delivered by WT (figure17), with the results of figure3, under different wind speeds,

we can deduce that our system is able to keep track of the maximum mechanical power through new MPPT method based on ANN and Fuzzy logic.

Figure 18 shows the WT's mechanical output power, using the P&O algorithm, for wind speed which varies between 8.4m/s, 8.5m/s, and 9.1m/s.

Figure 18: The output mechanical power under different wind speed using P&O algorithm

By comparing the evolution of the power delivered by WT (figure18), with the results of figure3, under different wind speeds, we can deduce that the system can't reach the maximum mechanical power through MPPT based on P&O.

By comparing the power curves provided by WT using the ANN and Fuzzy Logic algorithm and the one using P&O, it seems that the ANN technique reaches the maximum power with more stability than the P&O technique.

The P&O technique is not able to achieve MPP, because the power delivered using P&O is not maximum and it represents a significant oscillation, as shown in the power curve.

6. Conclusion

As a way to improving the power produced by the wind turbine it is necessary to track and extract the maximum power point.

This work presents a new MPPT method based on the ANN and fuzzy logic method. The idea is to combine these two methods, to provide an efficient system that outstrip the P&O based one in terms of MPPT and extracting maximum power from the WT. In the proposed approach, the ANN estimates the value of V_{MPP} for various wind speed values while Fuzzy logic controller gives the value of Duty cycle D for controlling the DC-DC boost converter.

In order to show the efficiency of the proposed new approach based on ANN and fuzzy logic, it has been compared with the famous P&O algorithm.

The simulation realized in this work demonstrates that the maximum power point tracking based on the ANN and FLC algorithm can track and maintain the maximum power delivered by the wind energy production for every wind speed value. According to these results, it is undeniable that the new MPPT

based on ANN and fuzzy logic is more efficient than the P&O method.

Based on the results of the simulation, it appears that the validity of the proposed MPPT controller has been confirmed for wind speed variations, using MATLAB /SIMULINK.

ABSTRACT

The Public Administration is forced to transform itself by taking advantage of the contribution of ICT to in the process of reducing bureaucracy and increase transparency, promoting the dematerialization of processes, increasing the quality of online services, allowing greater ubiquity of access, reducing response times, in the search for improvement of the quality of life of its citizens. Decision-making should consider objectives not only technical but also financial, environmental, and social objectives, ideally aligning with Green IT. The objective of the paper is to present a framework, supported by international standards and frameworks, that allows measuring and guiding the alignment of ICT with Green IT for the optimization of practices instituted in organizations, namely in Local Government. This framework includes a qualitative component with several phases and quantitative component with a metric that allows the evaluation of alternative strategies for a given goal. The phases considered are Problem Identification; Problem assessment; Study and planning; Project; Telecommunications and Printing; Information Security; Innovation; Improvement of Citizen Service; Evaluation / opinion. The complete metric includes four valences: IT, financial, environmental, and social. The IT valence, its indicators and corresponding weights are illustrated in a practical example. The proposed framework is an innovative contribution to the area, clearly integrating the support of the perspective of Green IT and thus actively contributing to the implementation of sustainability policies and alignment with Green IT best practices in Local Government, as well as presenting with greater level of detail the components of the structure that emphasize Green IT concerns. The main expected results of the application of the framework are contributing to the implementation, in local government, of sustainable policies and good practices aligned with Green IT, whilst targeting cost reduction and optimization, ubiquity of access, increased productivity and ensuring safety standards.

1. Introduction

This paper is an extended version of the article originally presented in 2020 at the 15th Iberian Conference on Information Systems and Technologies (CISTI), where the themes address the alignment of public administration (PA) good practices, namely the alignment with Green IT of local administration (LA) practices [1].

The pervasive way in which Information and Communication Technologies (ICT) are currently part of our daily lives, associated with environmental concerns, motivated this work of integrating environmental sustainability aspects into information technology

(IT) governance. Environmental sustainability should be translated to strategic thinking within organizations and is based on three objectives, pollution prevention, product management and the use of clean technologies; these objectives incorporate underlying concerns such as carbon footprint, global warming, fossil fuels, volume of material recycling and economic sustainability [2]. The three objectives can be applied at three different levels: individual, organizational, and social. Its combination can be used to identify IS or IT deployment opportunities to improve sustainability [3].

The objective of this communication is reporting a framework that includes ICT best practices in technology governance, aligned with Green IT, where the focus is on the phases that are more

*Corresponding Author: Manuel Landum, Email: A55265@ualg.pt

aligned. The design of this framework was supported by international standards and frameworks, and aims at optimizing governance in organizations, namely in LA. The framework incorporates PA specific constraints into implementing best practices and how these best practices can be defined. The main contributions of this framework are based on the metrics presented, sustainability and the improvement of the ICT ecosystem.

This article is organized into four sections: firstly, in this introduction, the contextualization of the problem and the objective of the article are presented; in the second section, the literature review is presented, which includes the theoretical foundations of the supporting thematic; following, in section three, the framework that includes ICT best practices, aligned with Green IT and supported by international standards and frameworks in order to optimize practices instituted in organizations, mainly in the LA under study, is presented; finally, in the fourth section, some conclusions highlighting the consequences from the use of the framework and its contributions to the community are presented.

2. Literature review

The literature review, based on the collection of articles on the subject, was supported by references and citations of papers, together with keywords directed to the theme, as well as in the analysis of sustainability and the pursuit of good practices in alignment with Green IT.

1.1. Digital Transformation

The process of digital transformation arises in the daily life of organizations, particularly in PA and more specifically in LA, driven by the need felt to modernize internally, externalizing more and better services for their customers, in a ubiquitous way, allowing for greater mobility and freedom in the way these customers relate to the organization. And ubiquity is a good practice, aligned with Green IT.

It should be noted that "computer technology and the increasing availability of digital data are radically changing forms of research and production of knowledge" [4] in our areas. Customers seek solutions that lead to a streamlining of processes, where requests and deliveries of services are made remotely, so that they can avoid face-to-face calls, that would otherwise cause loss of time and costs. With this demand, customers press services to ensure that processes suffer digital transformation, conducting to prompt, fast and click-away responses.

The process of "digital transformation is not just about computerizing a productive system. It involves exploring these systems to develop, maintain or improve skills that a company needs or dominates. Having this idea in mind is important when a company thinks about taking the step towards digital transformation" [5]. From this, it can be inferred that digital transformation is not just about digitization of processes, and it is much more than that. From the perspective of [4], digital copies of printed theories do not transform these theories into digital theories, just as literature is much more than a mere transliteration of oral discourse.

Moreover [6], the digital transformation of society does not follow directly from digital technology. The latter is a necessary

condition, but not enough. For digital transformation to take root, digital technologies must be imbued with social significance. Digital transformation implies process reengineering, creation, and optimization of flows, incorporating the acquisition of new skills and business practices. Organizations are thus driven to adhere to digital transformation and automation, maintaining or strengthening their competitive position, further enhancing the human-machine relationship, and increasing the degree of automation of processes.

1.2. Virtualization

Virtualization will be a way to implement the digital transformation process more quickly, being an important technique for the increasingly digital world of our daily life. One of the achievements of this technique is the creation of several servers or virtual desktops, from one or more physical machines; this allows, among other factors, to reduce the number of physical machines, leading to the reduction simultaneously of the amount of power supplies, the reduction of the time until readiness by facilitating the management of virtual machines, the reduction of energy consumption and environmental improvement and consequently leads to a decrease in the need to purchase new equipment. Virtualized data centers are designed to provide better management flexibility, lower cost, scalability, better resource utilization and energy efficiency, and thus, consequently, reducing costs with installation, maintenance, cooling, and physical space, thus contributing for an alignment with Green IT [7].

Cloud computing, or cloud computing, turns out to be one of the factors responsible for boosting virtualization, given the fact that it is defined as a shared set of virtualized resources, where in fact users access cloud resources using a unit, independent, called Virtual Machine (VM) [8]. These VMs are housed on physical servers, within large infrastructures, of data centers. Commercial offers facilitate the access to these virtualized pools of resources, providing users with nearly infinite computing resources in the form of processing power, memory, and disk space. Thus, and according to [9], the concept of virtualization is applied in cloud computing systems to help both users and owners get better use and efficient management of the cloud at the lowest cost.

Generically, virtualization is a technique that allows the reduction of resource use and contributes to environmental improvement, fostering the alignment with Green IT.

1.3. Green IT

Based on the alignment mentioned above, a definition was sought and a set of good practices that demonstrate it. If there is no single definition of what Green IT is, it is then considered a set of good practices about the use of computers and IT resources, in a sustainable, more efficient, and responsible way with the environment.

Green IT, as a concept, surfaces as a worldwide movement from the concern of organizations and/or individuals in preserving the environment, seeking the promotion of social and environmental responsibility, in this technological world. This movement focuses its ideals on "preserving the environment, in the search for the reduction of environmental impacts, based on sustainable practices and, in this particular case, interconnected

with ICT" [10]. Currently, the theme is of particular interest given the problems of climate change and sustainability, considering the daily reality, where these issues need to be included in the decision-making process to contribute in a timely manner to the environmental non-aggravation.

It should be seen that as the population increases, developing or underdeveloped economies end up committing to the rapid growth of infrastructure, leading to a great pressure from the consumption of natural resources. The realization that natural resources are not inexhaustible and that it is not possible to continue with economic growth without considering the variable environment and society, opens the way to the search for new alternative solutions for the productive system, such as the concept of Sustainable Development, which aims to maintain the balance between economic growth, social equity, and the natural environment [11].

Currently, with growing concern about the impacts of environmental strategies at local and global level, there is a need to achieve development in a more environmentally responsible manner, by balancing the choices between the environmental, economic, and social aspects of sustainability [12]. It is therefore necessary for organizations, particularly those responsible for hardware development, to look at the concept of Green IT and develop policies of social and environmental responsibility. Some organizations, in response to customer pressure, already exhibit an awareness and an effort to reduce operational and technological costs, through energy efficiency, in alignment with the good practices of Green IT.

The concerns regarding ICT consider the negative impact on the environment, not only by the electricity consumed, but also by the materials used in the manufacture of hardware, such as lead, arsenic, antimony trioxide, selenium, cadmium, chromium, cobalt, and mercury. This problem of society, in particular ICT, "includes electronic waste, municipal waste, the toxicity and hazard stemming from this equipment and whose solution is to comply with the directives on electronic waste, not allowing it to be deposited in bins, but rather collected by suppliers, treated and recycled, where even some restrictions are placed on manufacturing materials and legislation to control the transfer of electronic waste between borders" [10].

It is generally accepted that in organizations the use of some resources in some processes is conducive to waste, such as energy waste, paper waste, or of other materials, time, and financial resources. In view of this fact, Green IT practices can generate financial returns, sustainability, and environmental improvement. It is necessary to raise awareness among organizations and the PA, to consider the environment, but effectively, not only with good intentions. In [13], the author defends that the perspectives of sustainability transitions emphasize the need of the public sector to adapt policies towards technological innovation, and to be institutionally redesigned. Ecological concerns that allow environmental sustainability, such as reducing the carbon footprint or reducing the use of fossil fuels, are effective if actions involving e-waste management and waste management are considered, adopting an ecological stance in the life cycle of products that allows the reduction of the quantities of equipment and materials to be recycled and the costs inherent. In this way, Haley considers

the urgent need to make the transition to a low-carbon economy and has reintroduced the importance of technology-specific policy approaches [13].

In view of this scenario, more efficient resource use practices should also be considered and allow for the reduction of energy consumption, which leads to a reduction in CO₂ emissions and reduction of energy costs in the case of virtualization. Actions that lead to paper reduction, such as dematerialization and digital transformation, are also important.

It should be noted that the implementation of sustainability policies and practices in public administration has been adopted at different paces, depending on the country, the level of administration (e.g., local versus national or central) or the activities and objectives of each organization [14]. All this depends on the organizations being willing to adopt a posture of social and environmental responsibility. The adoption of environmental practices and tools in general management is a growing reality in local public organizations as these institutions are shifting their management to sustainability, although local governments move faster than other levels of the public sector in terms of integrating environmental and sustainability aspects into operations and strategies [15]. It should also be considered that in the 2030 Sustainable Development Goals Agenda, in addition to the limited obligations of governments, there is an emphasis on impact, and the means for implementing the targets should be significantly updated [16]. Therefore, "local governments are faced with the need to be part of the change from the perspective of sustainability and integrate good practices to improve their own performance" [15].

Faced with this reality and considering the need for organizations, particularly in LA, to find sustainable ICT good practice models that require less of the environment, aligning them with Green IT, a framework is presented.

3. The framework

This framework for the alignment of ICT with Green IT encompasses two complementary approaches: a qualitative methodology, supported by international standards and frameworks, to provide the optimization of practices in organizations, namely in LA; a quantitative methodology for the assessment of strategies. Given the approach developed, and which can be implemented in other municipalities of the country, it is considered that the results can constitute an added value. Generally, considering the set of skills of the organization, the Chief Information Officer (CIO) should validate the suitability and the weighting factors used in the assessment of alternative strategies.

In Sections 3.1 and 3.2 an overview of the qualitative and quantitative components of the framework are presented and, where appropriate, illustrated with small instances from the use in a real case scenario.

1.4. Qualitative components of the framework

This component includes practices, deemed good, which are added value because they contribute simultaneously to increased productivity, increased information security, and management optimization. Different contributions towards the definition of

these good practices were taken into consideration. Considered relevant were all those practices that contribute to economic and environmental sustainability, process optimization through dematerialization and digital transformation, combat waste, reduce materials to be recycled, reduce costs, reduce CO2 emissions, fostering greater alignment with Green IT. These good practices were formalized into the model. This component also incorporates sustainability factors, aligning with Green IT and includes the generality of the objectives and constraints, identified in the municipality under study, at the level of ICT.

Figure 1 represents the phases of the model, starting in phase zero, with the Identification of the Problem, followed by eight more phases, in a governance model that allows identifying good practices that align with the objective of the activity.

- Phase 0, Problem Identification.
- Phase 1, Evaluation and Continuous Improvement.
- Phase 2, Study and Planning.
- Phase 3, Project.
- Phase 4, Telecommunications and Printing.
- Phase 5, Information Security.
- Phase 6, Innovation.
- Phase 7, Improvement of Citizen Services.
- Phase 8, Evaluation/Opinion.

The model will be iterative from phase 2 to phase 6, going through all phases up to phase 8, where, based on the collected elements, evaluation and opinion, there may be a need to go through the entire cycle again, optimizing processes, alluding to the Plan, Do, Check and Act (PDCA) cycle, but this with more phases. It should be noted that when applying the model, choices are made and, in the corresponding qualitative component, greater weights are given to greater sustainability.

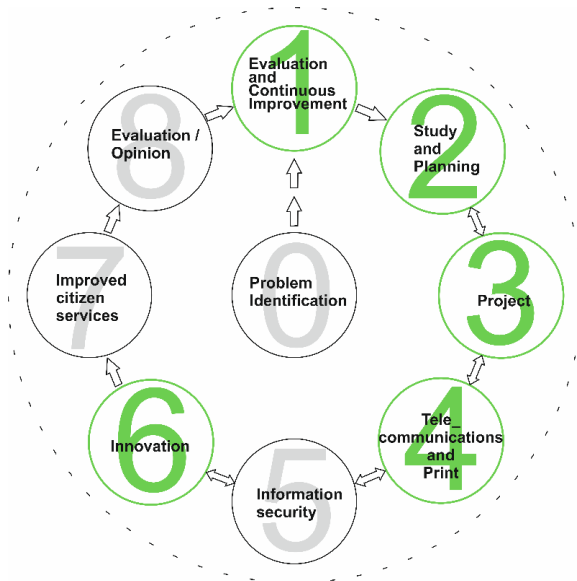

Figure 1 - The Framework

Complementing the context of the main objective of this article, it is intended to deepen the phases where the alignment of good practices with Green IT; consequently, the phases 1, 2, 3, 4 and 6, marked in green color, are more focused.

Figure 2 - Phase 1, Evaluation and Continuous Improvement

In Phase 1, as illustrated in Figure 2, the goal is to study the possibility of moving from a traditional model to a virtualized infrastructure model, including telecommunications. This virtualized model can be a way to reduce costs with maintenance contracts, enhance increased information security and internal know-how in the maintenance and configuration tasks of the virtual plant. In the context of this evaluation phase, it is also intended to ensure the ubiquity of access, between the various buildings, decentralized throughout the county, providing the data on impressions to ensure greater mobility of people and autonomy daily [17]. Particularly relevant are the two final tasks in this Phase 1: the evaluation of ease of management and environmental improvement, always present throughout this project the environmental preservation and the use of technologies that allow this preservation, in alignment with Green IT; and the containment equation or whenever possible, cost reduction without compromising the project [17].

Figure 3 - Phase 2, Study and Planning

Phase 2, as summarized in Figure 3, begins with the Study and Planning, having been concluded the assessment of the constraints encountered, the needs for improvement, and upgrade of the solution.

This phase should be considered as one of the most relevant and decisive in the conduct of the whole approach, although we are facing an iterating process between this phase and phase 6, as it will be based on the results of the study and planning carried out, that all subsequent phases will be supported, and where the need to change the areas outlined may bring unexpected costs to the organization or unforeseen results [17]. Thus, it is intended to study an approach that allows the involvement of all variables described in the previous phase, and that simultaneously includes the possibility of environmental improvement, encompassing both the internal environment and the external environment., aligning with Green IT. Consequently, there is the intention of planning a solution that can be compatible and retro compatible with the existing one, used, at the level of ICT, both hardware and software, also minimizing the costs of the final solution.

After the completion of the Study and Planning, Phase 3 begins (see Figure 4) where the architecture will be developed in design.

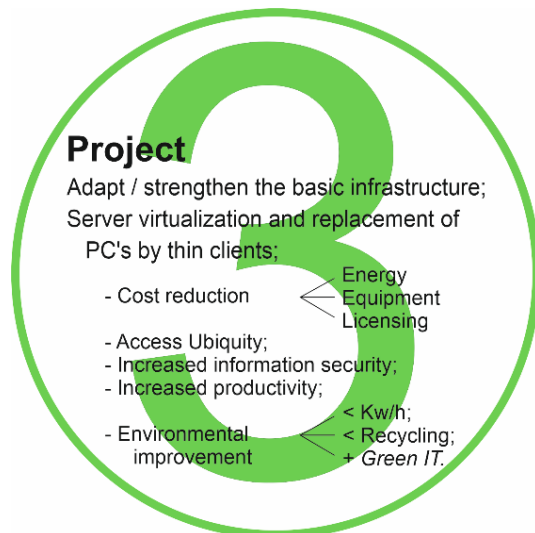

Figure 4 - Phase 3, Project

The input of this phase will be based on the output of the previous phases, where it is intended to adapt and strengthen the basic infrastructure as fundamental support of the project.

The aim is to build a data center internal to the municipality, which can serve to housing the active and passive equipment necessary for the interconnection of all buildings of the municipality, through routing and switching, internet connection and data storage, to allow ubiquity of access to data and printing, increasing productivity increase and without compromising information security, preferably aligned with Green IT. This infrastructure should be in a virtualized environment, as described in phase 1 and all equipment must be supported and connected to a UPS capable of maintaining the infrastructure for some time in the event of a power outage. In addition to server virtualization, with the creation of several VMs, in a distributed environment, the replacement of most PC's, in the end of life, by thin clients that will connect to the servers, that after the cost/benefit assessment and

considering the requirements, one can opt for connections by Remote Desktop Protocol (RDP), or connections to Virtual Desktop Infrastructure (VDI). Costs must be evaluated together with the benefits of the adopted solution [17]. Also, in the field of virtualization, it is noted that the replacement of end-of-life PC's by thin clients is conducting to reduction of costs, particularly energy as will be proven later, not undermining the alignment with Green IT.

Figure 5 – Phase 4, Telecommunications and Print

In phase 4, one targets the solutions that allow the reformulation of telecommunications and printing, as can be seen in Figure 5 to optimize these two areas of resource expenditure and equate how contributions to environmental improvement and containment or cost reduction can be achieved. Although distinct, it is considered that they should be treated in an integrated way per se, because they group a set of features and valences related to digital transformation and that allow, in this context, the clear expression of added value for the organization.

Specifically, in telecommunications, it was identified a critical situation with the continued use of physical telephone centers in old, deteriorated buildings, where humidity prevails, implying constant breakdowns and obviously the breakdown of telecommunications between buildings and the exterior, with the consequent constraints and intrinsic costs. Another problem is the difficulty of daily management of IT technicians, hindered by the need to go to the different locations and locally deal with issues; an integrative solution should be achieved in the future and one that allows facilitated management, without increased costs [17]. Even if the option is virtual telephone centers, we will also be contributing to environmental improvement, with the reduction of the number of materials to be recycled and, after checking the numbers, one may state that a reduction in energy consumption occurred, as less movement will translate to a reduction of CO2 emissions to the atmosphere, which will help in reducing the ozone hole, clearly in alignment with Green IT.

Regarding printing, one of the concerns of the municipality, or of any municipality or organization, is the high costs, of the equipment and space occupied, of the printing itself, in terms of paper and ink or tonner, as well as of keeping stock of printing consumables, worsened by the proliferation of various models,

requiring the increase of stocks, contributing all this to the increase of costs. It should be noted that there is also the stock management process: adding to the need of a large investment due to the number of different models, it may happen that cartridge stocks are renewed by the terminus of their shelf life, even if the corresponding printers have already been disposed of and information not propagated [17].

Thus, solutions should be sought to reduce the number of equipment and achieve homogeneity of models, contributing to scale savings, simultaneously aiming to reduce or end stocks, and so contributing to process optimization, faster response and containment or cost reduction. The ubiquity of access, in a safe way, to printed documents is a target allowing better productivity and improvement of processes in everyday life, to those who use it in the different buildings. As far as printing is concerned, the decision to be taken should also be aligned with environmental improvement, where the acquisition of new equipment, and therefore, the amount and type of materials to be recycled in the future, is also in alignment with Green IT is to be reduced.

Figure 6 - Innovation

Phase 6 will address the innovative aspects that the PA, in this case and more properly LA, can and should provide its citizens, customers of its organization, with more and better services preferably innovative and strategic, at the distance of a click, thus saving travel costs and loss of time. To this effect, the LA must take the path of digital transformation, adopting the digitization of processes based on a document management system, unique and transversal to the whole organization, that allows integration with online services, providing added value services to citizens.

Referring to innovation, it was stated [18] that the word innovate is widely used when we approach transformation and strategy. This is the path that has been outlined for the municipality under study. Realistic and well-founded transformation should be seen as a future perspective and seen as digital transformation; as such it will be necessary that on the part of organizations and the PA, there is a concerted strategy so that a new, faster, collaborative mode of action among several actors can implement responses to the needs and perspectives of citizens and citizens in general [17]. There is an increasing interest in the form of stimulating innovation in the public sector, being noted the mention [19] of recent research

points of collaboration between actors as a factor of superior innovation. In this sense, the public sector or other non-governmental organization consider in their daily agenda the incentive to innovation, by political, economic weight and quality of services. Similarly, there is some agreement [20] with the previous statement and the recognition that the economic weight of these entities leads to the growing political interest in stimulating innovation in PA, which may culminate in a marked improvement and increased efficiency in the use of resources, adding quality of public services and preparing to face the most varied social challenges.

Innovation can be another catalyst for improving services, increasing productivity, and, containing or reducing costs, aligned with Green IT good practices, can bring benefits at various levels.

1.5. Quantitative component of the framework

The qualitative component of the framework aims at evaluating different alternatives. It was understood that alignment with Green IT can be measured through four dimensions [21]:

IT valences: Hardware, software, information systems, security, governance.

Financial valences: Direct and/or indirect costs of IT.

Environmental valences: Environmental impact including CO₂ emissions, use of natural resources, contribution to global warming, recycling.

Social valences: satisfaction of the citizen, speed of response, number of trips, time on the move, image of the municipality.

Thus, the Green IT alignment (1) metric includes the IT, financial (Fin), environmental (Env), and social (Soc) dimensions.

$$\text{Green IT alignment} = 0.3 \text{ IT} + 0.2 \text{ Fin} + 0.3 \text{ Env} + 0.2 \text{ Soc} \quad (1)$$

In each dimension, the evaluation is achieved by a set of weighted indicators. The indicators correspond to the valences identified. The direction - positive (+) or negative (-) value - of the indicators will convey if it furthers or hinders the green alignment, respectively. The relative relevance of an indicator is conveyed by a weight (in %).

Greater sustainability, in one case, may be obtained by the virtualization of the infrastructure in the data center of the municipality, which will favor the exchange of end-of-life computers by thin clients. As an example of this component of the framework we will consider two strategies: maintain PCs or replace them by thin clients. It must be noted that some indicators are not applicable to the current case study and are presented but not included in the comparison; a one-year timeframe was considered; costs and prices refer to the time of writing; to illustrate the application, we will instantiate the financial dimension.

Table 1 lists some of the IT indicators that shape operational objectives, especially those aimed at optimizing reliability, service availability, management times, productivity, breakdown reduction, access ubiquity and information security; in short, the relevant IT indicators when in the search for sustainability.

Table 1: IT indicators

Indicators	Direction	Weight factor
reliability	+	20 %
management times	-	5 %
service availability	+	10 %
productivity	+	15 %
quality management	+	5 %
number of malfunctions	-	10 %
information security	+	20 %
ubiquity of access	+	10 %
reduction of file space on digital support	+	5 %

The PA should pay particular attention to its cost management, as on the one hand it strives to remain competitive about the technology at its disposal, on the other hand it should be moderate and contain the costs to keep the budget balanced. Nowadays the IT sector is a strategic asset within each organization and digital transformation assumes significant role in an organization although the study and adoption of technological solutions may raise costs in the annual budget, informed choices reflect good strategic planning preferably aligning with Green IT.

Table 2 illustrates the measurement of some financial indicators demonstrating infrastructure and energy costs, energy consumption and equipment lifetime in the municipality.

Table 2: Financial indicators and instantiated values

Indicators	Direction	PC	Thin client	Weight factor
cost of infrastructure	-	€ 650	€ 250	45 %
equipment lifetime	+	4 Years	7 Years	25 %
energy consumption	-	377 Wh	5 Wh	30 %

After normalizing the financial indicators, one would reach the values -0,61 and + 0,08, for PC and thin client, respectively, indicating that the latter will better approach Green IT.

Society today is already governed by the maximum environmental improvement or preservation of nature, as such, organizations should also be aware that it needs to be properly aligned with the business, but not to be able to improve a good alignment of IT with Green IT, as it will certainly become more expensive to remedy than to prevent environmental problems.

Table 3 presents some environmental indicators which involve CO2 emissions, care for nature preservation, sustainability and recycling, and concerns about global warming. These indicators also demonstrate the existing concern with environmental quality, also aligned with the financial indicators contained in Table 2.

Table 3: Environmental indicators

Indicators	Direction	Weight factor
CO2 emissions	-	50 %
preservation of natural resources	+	20 %
suitability for recycling	+	10 %
global warming	-	20 %

Achieving excellence in the valences of IT, Financial and Environmental, implies, achieving the satisfaction of citizens, improving the image of the municipality, the well-being of employees, increasing the speed of response to processes, avoiding travel to the service services, which contributes to the reduction of costs to the citizens themselves, therefore, a social improvement that should not be bleached. Reducing calls to care also contributes to reducing CO2 emissions, once again in alignment with Green IT and environmental improvement.

The mirrored indicators in Table 4 corroborate the opinion already demonstrated by the authors and are proof of the above, and should be taken into account, as an example of social responsibility in PA, which can also be understood as environmental social responsibility, in a clear allusion to the respect shown by people and human values and simultaneously by environmental causes [21].

Table 4: Social indicators

Indicators	Direction	Weight factor
satisfaction of the citizen	+	10 %
image of the municipality	+	10 %
well-being of employees	-	10 %
time in the circulation of information	-	15 %
speed in the response to the citizen	+	10 %
number of trips to the service	-	10 %
loss of time on travel	-	10 %
travel costs to citizens	-	15 %
service times	-	10 %

Finally, the evaluation of a new process or the global activity be qualitatively resumed as presented in Table 5.

Table 5: Green IT Alignment

Nominal score	Qualitative score
$\leq 20 \%$	Very little aligned
$>20\% \wedge \leq 45\%$	Little lined up
$>45\% \wedge \leq 75\%$	Aligned
$>75\% \wedge \leq 90\%$	Very aligned
$>90\% \wedge 100\%$	Strongly aligned

This model can be used to support strategic decisions and informed choice on changes such as substituting desktop computers by thin clients or making services available online can be facilitated.

4. PC vs Thin Client in detail

The reasoning between the implementation of PCs or Thin Clients regarding consumption, costs, and quantity of materials to be recycled, is shown in Table 6. The implementation of thin clients allows the reduction of energy consumption, contributing to the reduction of the carbon footprint and environmental improvement. As they are small equipment, they also allow the reduction of the number of materials to be recycled. They simultaneously allow the reduction of management times, which means increased productivity, and licensing costs are also lower, not in any way decorating the quality of service and information security.

Table 6: Comparison PC - Thin Client

	PC	Thin Client
Power supply	600 W	30 W
Average consumption	377 Wh	5 Wh
Weight	7,900 kg	0,240 kg

In the calculation of annual consumption, it was considered that the equipment of individual use is connected 7 hours a day, 5 days a week for 48 weeks. Whereas a PC consumes 377 Wh [22], if connected 7 hours a day you will have an annual consumption of about 633.40 kWh. Likewise, considering that a thin client consumes 5 Wh [23], if you are connected the same 7 hours a day, you will have an annual consumption of about 8.40 kWh. Comparing the values of the two equipment, there is a reduction in energy consumption in the order of 625kWh year. If we use 400 thin clients then we will have a reduction in annual energy consumption of 262 MWh, which at an average cost of € 0.165 per kWh, translates into a cost reduction of around € 41,250.00 per year.

Regarding the number of materials to recycle, it is noted that a PC has about 7,900 kg of material and the thin client has only 0.240 kg, and there is a gain in the reduction of materials to be recycled in the exchange of the PC for thin client. It should also be noted that the lack of treatment of these wastes, through the recycling of equipment, may lead to contamination of soil, water, and air, considering heavy metals and toxic substances, existing in computer components, such as cadmium, lead, bromine, copper, and nickel present in small quantities in equipment and devices, especially boards and that affect both people and animals and plants.

5. Conclusions

It has been assumed that the implementation of ICT measures, which address sustainability concerns, is crucial. Thus, it was possible to identify and quantify options to optimize established practices, thus contributing assertively to sustainability. About the Green IT, this article has several contributions, namely on the presentation of indicators for the reduction of energy consumption, contributing to the reduction of costs and the carbon footprint and

consequent environmental improvement. Another aspect of Green IT focuses on reducing the volume of materials to be recycled and its pollutants, considering the replacement of computers by thin clients. In addition to the IT aspect, the financial aspect has also been exemplified, where it has been shown that the alignment of IT with Green IT can also be a boost in reducing costs, both in equipment costs, in increasing the life of the same, by reducing consumption and the number of materials for recycling, obviously aligning with Green IT.

Environmental indicators have shown that it is possible in the PA to contribute to an improvement in environmental quality, without increasing costs and technological developments, in reducing the carbon footprint. Finally, the four strands presented here, it was also possible to demonstrate that the social aspect is no less important and that it is possible in the PA, in this case in LA, to contribute to the satisfaction of citizens, by increasing the speed in response, by reducing the number of visits to services, which in itself end up contributing to the reduction of time losses and the reduction of travel costs, which eventually contribute to the improvement of environmental quality, increased confidence in THE and the improvement of the image of the municipality, still allied to the improvement of workers' working conditions, all aligned with Green IT.

The main contribution of this work is the example of a model to focus efforts to optimize ICT management practices that integrate environmental improvement and quality in a sustained manner. The main conclusions of the exercise presented here illustrate how the model increases productivity by reducing management times and containing or reducing costs in ICT. Based on the proposed framework and as a possible line of research to be developed, it is considered that the inclusion of weights in the various stages of the cycle allows their use in various real environments, such as local authorities. An aggregating instrument of all the information inherent in the framework may be another line of future research and may culminate in its development and improvement.

Conflict of Interest

The authors declare no conflict of interest.

BBS algorithm

ABSTRACT

With the rising number of web services created to build complex business processes, selecting the appropriate web service from a large number of web services respond to the same client request with the same functionality are developed independently but with different quality of service (QoS) attributes. From this point, there are many approaches to web service selection. Nevertheless, this is still deficient due to a considerable number of discovered web services. The prefiltering is a solution to reduce the number of web services candidates. In this paper, the K-means clustering is applied to determine similar services based on QoS information. The results of this prefiltering are considered at the selection task using the Branch and Bound Skyline (BBS) algorithm. The experimental evaluation performed on real Dataset proves that our approach presents efficient results for web service selection.

1. Introduction

This paper is an extension of [1], where an advanced mechanism of prefiltering and selection of web services based on QoS is proposed.

Over the past decade, many researchers have developed a strong interest in web services, an important standard of Service Oriented Architecture (SOA). It is a novel paradigm to build the large-scale of distributed applications. Web service is defined as a software-system and identified using an URI, where its public interface and binding description use the XML language, can be discovered and invoked by other web services. This invocation requires a prescribed of resources using XML messages via such protocols of the Internet.

WSDL, SOAP, and UDDI are the series of technology criteria for web services [2], on which other technologies closer to the application problem can be specified and implemented. It presents standard web service protocols to implement /develop the interaction between applications (services) among diverse platforms. The web service architectures are based on the following three entities; (i) service provider, (ii) service registry, and (iii) service customer. The service provider corresponds to the proprietor of the service. It is required to depict the web service and publish it in the service registry (a central entity). The service registry possesses the technical details of web service and the service provider information to facilitate and find services for

customers. The customer is the application that is going to search for and invoke a service. The client application can itself be a web service.

Figure 1: Web Service Model

The increased web applications usage for different fields, making service providers to respond to customers by releasing an enormous number of web services ; the customer finds a problem in choosing the web service that meets his request with this large number of published web services. QoS appears as a solution to help customers select an adequate web service that meets the

*Corresponding Author: Mourad Fariss, m.fariss@ump.ac.ma

www.astesj.com

<https://dx.doi.org/10.25046/aj060270>

customers' requirements. These requirements seek to benefit from more web service performances as cost, response-time, and other QoS properties [3].

One of the immense challenges of SOA is to attribute QoS to the description of web services to facilitate the choice for customers according to their requirements as well as to dynamically select the most efficient web services for each customer according to the criteria of the requirements given by the client or just the best web service among the web services found in the web services registry that have similar functionalities.

The rest of the paper is presented as follows: Section 2 gives the related works. Section 3 explains the background used in this paper as the QoS in web service, the K-Means clustering and the BBS algorithm. Section 4 contains our proposed approach. Section 5 discusses the experimental results. The final section concludes the paper.

2. Related works and motivation

The selection of web service is a hard process because various web services offer similar features. Applications in their consumption of services struggle to employ the optimal QoS; however, the selection phase faces many hardships since the QoS is at the same time influenced by several inconsistent QoS features. Present solutions have a shortage in performance for the reason that they take in consideration the potential web services to find QoS features. In case, customer needs are taking place in the selection process. We can use this bit of information in order to distinguish between web services that possess similar QoS as end-user QoS features. For the sake of gathering similar web services together, it is useful to use cluster technology with reference to QoS properties. The selection considers only web services, which is abided by the customer's QoS requirements.

Recently, to solve the selection web service problem, the skyline algorithms have been introduced by selecting service as the optimal candidate services [4–9]. The BBS approach is the most famous skyline algorithm suggested by [10]. As far as the large data spaces are concerned, it is the most efficacious algorithm.

The authors of [11] compared two algorithms: the BBS and the SFS algorithms on the service web selection. The service selection system was performed efficaciously and reliably by the BBS algorithm as the experimental outcomes show.

Authors in [12] were the first to propose the filtering of web services system named "*F-WebS system*". The system builds the performance on the description and discovery area of web services [11,13–15] as semantics-based web service filtering and utilizes a variety of matching algorithms such as those in the discovery task.

In [7], the authors proposed a framework named "*KRSWS*" to reduce the web services candidates based on QoS attributes and the customer requirements, the proposed method use the Fuzzy AHP method and a new version of Promethee [16].

The clustering mechanism for generating services clusters according to the same QoS is useful for determining the relevant web service [17]. Nonetheless, to cluster the generic type of QoS properties in one group can negatively effect the efficiency of the selection of web service [18].

The authors of [19] proposed a cluster and filtering system architecture model, and have demonstrated that the use of the clustering technique does not effect on the system's accuracy and pertinence, yet it increases the speed of the process of simple service processing.

The proposed method for selecting web services uses a cluster approach based on QoS parameters to pre-filter web services, once we filter the web services with a pre-filter based on K-Means clustering, we obtain a decreased set that contains the web services filtered, after that we select the dominate web service with the skyline technique. The proposed solution presents a significant precision and performance of selecting web services regarding other approaches cited in the literature.

3. Preliminaries

3.1. QoS in Web Service

Several works that have been conducted in web service discovery focus only on the functional features (content requirements) of a web service, but this phase remains insufficient to meet the customer's requirements because of the many similar web services that offer the same functionalities for the customer. However, the web service selection phase introduces the notion of non-functional features (context requirements), namely QoS, to determine the most efficient web service that meets customer requirements.

QoS is a set of features and characteristics of an entity or a service that gives it the ability to meet stated or implicit needs. The needs can be linked to parameters such as accessibility, availability, response time, reliability, cost, etc. The parameters can help to select from the candidate web services and reduce the consumed time.

We can distinguish between customer-independent QoS attributes such as (cost, reputation, accuracy) and customer-dependent QoS attributes such as (throughput, scalability, availability) [2], [3].

QoS has the capacity to satisfy its significance by:

- Defining the operational measurements for the web service.
- Distinguishing between providers and services.
- Filtering and ranking the web services.
- Selecting the efficient and appropriate service that achieves the whole customer needs.

Those QoS attributes can be classified into six categories as shown in Table 1.

Table 1: QoS Categories and Attributes [20].

QoS categories and attributes	1. Service Provider	Service provider reputation, Accountability, Throughput, Scalability, Availability.
	2. Service Customer	Response time, Reliability,

		Usability, Cost, Discoverability.
	3. Service Developer	Maintainability, Interoperability, Composability, Reusability, Stability, Traceability, Testability.

3.2. K-Means Clustering

The clustering algorithms are classified into hierarchical clustering, exclusive clustering, probabilistic clustering, and superimposed clustering [21]. The K-Means clustering can be considered the most known to resolve many clustering problems. Our use for this algorithm is to rank web service applications according to the QoS attributes.

The advantages of the K-Means clustering are as follows [22]:

- The larger number of the variables are, the smaller the number of the clusters, and the smaller the speed of calculation than the hierarchical clustering algorithms.
- If the clusters are globular, K-Means will produce tighter clusters, which will be tighter than hierarchical clusters.

Despite all of these advantages, K-Means has also some limitations, but these later ones do not influence our approach to study the QoS between queries and published web services.

The goal of applying the K-Means clustering algorithm is to classify the database of QoS attributes offered by the list of discovered web services. This is done in multiple steps. The first is to randomly initialize the number K of centroids. The centroids represent the centers of the clusters. The following process takes place in two stages called expectation and maximization; these two stages involve assigning each data element to its nearest centroid. Next, the algorithm calculates the new centroid of all the points of

each cluster and define the new centroid. The following algorithm describes the K-Means algorithm's steps:

Algorithm 1: K-Means algorithm

```

1: Define  $K$  // The number of clusters
2: Initialize  $K$  centroids (Randomly)
3: repeat
4:   expectation: Assign the points to their closest centroid
5:   maximization: Calculate the new centroid of clusters
6: until: The position of centroid does not change

```

3.3. Branch and Bound Skyline Algorithm

The BBS algorithm is considered as an enhancement of the K-Nearest Neighbors (KNN) algorithm with a difference that the BBS algorithm crosses the R-tree only once. The algorithm uses a priority queue, where data points are organized according to their minimum distances (*mindist*) or minimum bounding rectangles (*MBR*) from an origin point. A minimal bounding rectangle is used to evaluate a complex shape. It is a rectangle with parallel sides to the x and y-axis and minimally surrounds the utmost complex shape [23].

The algorithm chooses at each step, among all the unvisited points, the closest tree points to the origin. In addition, it keeps these discovered points in a set S for the validation step of dominance.

The description of the BBS algorithm is given as follows:

Algorithm 2: BBS Algorithm

```

01:  $P = \emptyset$  //  $P$  is a set of dominant points
02: fill the root  $R$  by all entries in the heap
03: while  $R$  not empty yet do
04:    $c$  is removed //  $c$  is the top entry from  $R$ 
05:   if  $c$  is dominated by other points in  $P$  remove  $c$ 
06:   else
07:     if  $c$  is an intermediate entry
08:       for each child  $c_i$  of  $c$ 
09:         if  $c_i$  is not dominated by some point in  $P$ 
10:           insert  $c_i$  into heap
11:         else //  $c$  is a data point
12:           insert  $c_i$  into  $P$ 
13:       end
14:     end
15:   end
16: end

```

Figure 2: Example of BBS Algorithm

The BBS algorithm performs better than other skyline algorithms, ensuring a minimum cost of input/output, and the number of R-tree node access, and processing time. However, since the number of attributes is increased, the number of points in the skyline is increased substantially [24]. Hence, the idea of using a filter is to decrease the number of candidate points.

Figure 2 provides an example of domination point using two attributes of QoS.

4. Proposed Approach

The QoS-based selection consists to choose the best web service from the candidate (discovered) web services to satisfy the customer's non-functional requirements as QoS needs. This selection depends on the specification adopted when defining the QoS criteria and the QoS profile of the web service.

For solving this problem, we propose to add a filter with K-Means clustering as a first step to generate the clusters of web services based on the QoS properties assigned to each discovered web service. This technique determines the number K of classes as an input and generates the K clusters. When the process starts, it chooses centers randomly. Then at each step, it recalculates the new cluster centers as the mean of the QoS for this cluster. The criterion function used in this step is expressed in equation (1) [25] below:

$$E = \sum_{i=1}^k \sum_{ws \in C_i} |ws - Mi|^2 \quad (1)$$

where E is the error value between the consumer 'constraints and the candidate web services, ws refers to the candidate web service, and Mi is the mean of the cluster C_i which contains ws . Each cluster created by the K-Means algorithm contains web services with similar QoS attributes. The algorithm serves as a pre-filter for the discovered web services. The cluster obtained from this phase has the most efficient centroid to meet customer requirements while all web services in this cluster can also meet these requirements, and they are affected to step two.

The second step is to exploit the filter results and apply the BBS algorithm on the filtered cluster web services. The objective of this step is to determine the dominant web services among the obtained cluster web services using their QoS properties. Eliminating inappropriate web services in the pre-filter phase with K-Means clustering makes it easier for the BBS algorithm to find the most appropriate web service and meets customer requirements.

Figure 3 summarizes the model of our proposed approach. The customer submits a request for a service that meets their needs and requirements. In the discovery stage, the web service registry determines a set of candidate web services that can meet customer needs. In the web service selection stage, we propose to add a pre-filter using K-Means algorithm which minimizes the candidate web services. This step takes place by creating clusters that contain web services including similar QoS properties and determining which cluster meets the customer requirements, thereby the BBS algorithm is applied to find the appropriate web service for customer needs and requirements.

Figure 3: Web Service Selection Model

5. Experimental Results

The evaluation of the proposed approach aims to show the interest of adding a pre-filter to a web service selection system. The pre-filter proposed in our approach is based on K-Means clustering.

A real-world dataset of QoS attributes named QWSDataset [26] is used for experimentation. The dataset contains 9 QoS attributes per service, downloaded by a web service Crawler Engine [27]. The used version contains 2507 web services. This dataset contains 11 segments representing 9 QoS attributes, the URL of WSDL file and the service name. The database is used in experiments to prove the efficiency and performance of our proposed approach. Table 2 represents some values of QWSDataset used in the experimentation.

To reduce the search domain, we apply the K-Means algorithm to determine the web services that have similar QoS parameters. The selection process is conducted using the BBS algorithm. The performance and efficiency of our proposed approach are verified using the evaluation metrics: Success rate and execution time for a selection process with different approaches.

5.1. Success Rate

The success rate (SR) of all selected web services is the proportion of customers' QoS requirements (C_i) to the QoS values

Table 2: QoS Values of QWSDataset.

Service Name	Response Time	Availability	Throughput	Successability	Reliability	Compliance	Best Practices	Latency	Documentatio
MAPPMatching	302.75	89	7.1	90	73	78	80	187.75	32
Compound2	482	85	16	95	73	100	84	1	2
USDADData	3321.4	89	1.4	96	73	78	80	2.6	96
GBNIRHoliday Dates	126.17	98	12	100	67	78	82	22.77	89
CasUsers	107	87	1.9	95	73	89	62	58.33	93

of these web services ($\bar{U}_i(S)$). The success rate of a web service (SRn) equals 1 if its value is greater than a threshold value (ts).

$$SR = \frac{SRn}{n} \times 100\% \quad (2)$$

and

$$SRn = \sum_{i=1}^n \begin{cases} 1, \cap_{i=1}^n \frac{c_i}{\bar{U}_i(S)} \geq ts \\ 0, otherwise \end{cases} \quad (3)$$

where SRn is the success rate for n web services. Based on [11], the values of parameters used in the experimentation are $ts=0.86$ and $n=200$.

Figure 4 presents the success rate of our approach compared to other approaches depending on the number of candidate web services. The success rate is increased for our approach compared to other approaches. Furthermore, the more the number of candidate web services is increased, the more the success rate of our approach is increased, which means that the proposed approach is scalable for the large dataset of web services. However, the other approaches have a stable success rate or a decreased success rate when the number of candidate web services is increased.

Figure 4: Success Rate Comparison with QWSDataset.

5.2. Computation Time

To evaluate the efficiency of our approach in comparison with other ones, the execution time is computed as shown in Figure 5. The execution time for our approach is minimized than other approaches depending on the number of web services. As a consequence, our approach has a high performance considering the execution time even we deal with a large dataset.

Figure 5: Time Execution Comparison.

After that, we have calculated the execution time by modifying the number of QoS attributes from 3 to 9. This modification is performed to examine the impact of QoS attributes' number to select the adequate web service. Moreover, the comparison between the proposed approach with other approaches is performed in terms of the execution time. As illustrated in Table 3, the execution time for the compared approaches shows a high performance of our approach, which uses the K-Means clustering as a pre-filter. The effectiveness of our approach is proved by increasing the number of QoS attributes.

Table 3: Execution time according to QoS attributes.

Number of QoS attributes	Execution Time (ms)			
	BBS Algorithm	F-WebS system	KRSWS	Proposed Approach
3	5	7	6	4
4	7	7	8	6
5	12	10	11	10
6	15	16	17	13
7	17	19	17	15
8	34	30	32	28
9	60	55	53	43

Adding a pre-filter to the web service selection process has allowed us to improve the success rate up to 97% and minimize the execution time of web service selection compared to other approaches. This is due to the elimination of the inappropriate

web services using a new pre-filer mechanism that is based on the K-Means clustering.

6. Conclusion

The selection web service problem consists to find the most adequate web service from a large dataset with a short period of time based on the QoS proprieties. To resolve this problem, we proposed a new mechanism using the K-Means clustering as a pre-filter to eliminate the inappropriate web services, which leads to minimizing the search space. Then the BBS algorithm is applied to select the dominant web service for increasing the precision rate. The experimentation results show a high performance of our approach compared to other ones in terms of the scalability, the execution time, and the precision rate.

The current work will provide many benefits and advantages to end-users, practitioners, and researchers who deal with a large data set of web services. It allows to prefilter an enormous number of web services that are generated from different systems such as smart health, smart agriculture, smart city, etc.

In the future, we can use this approach to resolve the web service composition problems and minimized the composition time, and we try to integrate uncertain QoS parameters in our approach.

ABSTRACT

Internet of Things provides the support for devices, people and things to collaborate in collecting, analyzing and sharing sensitive information from one device onto the other through the internet. The internet of things is thriving largely due to access, connectivity, artificial intelligence and machine learning approaches that it supports. The stability and enhanced speed of the internet is also attributable to the huge adoption rate that IoT continues to enjoy from Governments, industry and academia in recent times. The increased incidences of cyber-attacks on connected systems in recent times, has inspired the heightened efforts from Governments, industry practitioners and the research world towards improving existing approaches and the engineering of new innovative schemes of securing devices, the software or the platforms for the deployment of IoT. Security solution for Internet of things includes the use of secure ciphers and key exchange algorithms that ensures the provisioning of a security layer for the: devices or hardware, communication channels, cloud, and the life cycle management constituting the Internet of things. The use of key exchange algorithms in resilient cryptographic solution that have less computational requirements without compromising the security efficiency in the encryption of messages for IoT continues to be the preferred approach in securing messages in a node-node exchange of data. This paper aims at providing a cryptographic solution that uses a key exchange cryptographic primitive and a strong cipher in encrypting messages for exchange between nodes in an IoT. Towards achieving this goal, the Diffie-Hellman key exchange (DHE) protocol was used to provide a secure key exchange between the communicating nodes, while the Twofish block cipher was used in the encryption and decryption of messages, assuring the security, privacy and integrity of messages in a node-node IoT data exchange. The cryptographic solution has a high throughput.

1. Introduction

The use of sensors, actuators, radars and other diodes in the collection, intelligent analysis and communication of sensitive data in connected systems have driven the user specific needs for homes, businesses, public, private institutions as well as security agencies in expanding access to support the scaling of network resources to drive new value propositions. From surveillance to the aggregation of sensitive information such as humidity, pressure, temperature and in some case depth measurement in restricted environments like mining, construction and naval systems, IoT has been the preferred solution in achieving these desired goals.

This paper is an extension of work originally presented in the International Conference on Communications, Signal Processing and Networks/International Conference on Cyber Security and Internet-of-Things ICCSPN/ICSIoT. The relatively complex key schedule that Twofish cryptographic primitive supported together with the DHE provided an efficient and tamper-resistant security scheme for data exchange between nodes in IoT [1].

The security of communication in connected devices has understandably been of great concern to both governments, industry and academia due to the rather recent increase in the number of high profile cybersecurity attacks on these networks where several accounts with sensitive information have been tempered with and in some cases, holders of these accounts have lost huge sums of monies. The cases of cyber-attacks in the past

*Corresponding Author: Bismark Tei Asare, Ghana Communication Technology University, Ghana, +33638556158, btasare@gctu.edu.gh

five years have motivated several public and private organisations to increase their budgetary allocations and investments into providing a stronger security infrastructure to secure their networks [2]. The devices serving as the main actors for the internet-of-things could introduce additional sources and points for attacks that hackers could use in exploiting the vulnerabilities in IoT because most of these devices are not secure by design and hence lack the appropriate robust security configuration to ensure secure communication of sensitive data, yet these devices end up forming essential components for systems that aggregate sensitive data for communication across several devices through the internet. These devices are mostly susceptible to several cybersecurity challenges including the backdoor vulnerability where hackers could easily exploit to successfully manipulate these IoT systems to their skewed benefits [3]-[6].

There exist various techniques for supporting secure node-to-node authentication that assure integrity and availability of sensitive data. Most of these techniques demand higher resource requirements for effective and efficient implementation. In the particular context of IoT devices, due to the resource constraint nature with regards to computational power, storage and power consumption, these encryption techniques and approaches are not adoptable for them, in most of the cases. In addition, since IoT devices automate their processes by eliminating human intervention in their operations, the use of some of the off the shelves solutions that exists are not practicably suited for them. Symmetric encryption involves the use of a shared key between two participating nodes in a communication. It allows these participating nodes to generate key pairs - a private key and a corresponding public key using a key generator - a trustee component in a key exchange protocol application that allows two nodes that have no prior knowledge of each other to jointly share secret for encryption and decryption of message. The public keys are common keys that are known by the participating nodes before any communication is even established. The public key is also known as a shared key. Both private (secret) key and public (shared or symmetric) keys are used in encrypting and decrypting data in a communication session between two participating nodes or parties. There are several key exchange protocols. The Diffie-Hellman key exchange (DHE) protocol allows two nodes to securely exchange session key (the public or shared key) prior to communicating messages between them [7]. The Diffie-Hellman key exchange protocol ensures the creation of a new session key for each message to be communicated, this provides another layer of security. Session keys are generated using random number generator schemes or algorithms. The key exchange protocol only supports secure sharing of session key and does not provide authentication of the source node for creating the message. Replay attacks, Man-in-the-middle attacks, Dictionary attacks, Key compromise impersonation attacks and ephemeral key compromise attacks are some of the vulnerabilities that DHE protocol suffers [1]. Cryptographic algorithms provide mechanisms for authentication using various approaches like digital signature schemes and public-key certificates.

The scalable nature of IoT and its ability to support the rapid generation volumes of traffic and their associated processing and temporary storage, places additional overload on the edge nodes used in the network. The nodes are originally constrained by design as well as operational capabilities particularly for large

computational activities. Hence, complex security infractions and exploitations are constantly deployed on these IoT nodes using modern and sophisticated tools by hackers [8]-[11].

A key exchange algorithm like the DHE by itself is limited in use alone unless, it is fed into another protocol for undertaking encryption and decryption of messages. The use of the DHE in the Twofish encryption algorithm increases the confusing of the encryption key to enhance the diffusion of the distribution of the ciphertext to avoid redundancy. This improves the level of security in the cipher. The use of DHE within the Twofish cryptographic symmetric key block cipher for message encryption assured privacy and confidentiality of IoT node data.

The rest of the paper is structured into five sections. Section 2 presents key concepts needed for a better understanding of the article and related works. Section 3 is dedicated to the proposed methodology. Section 4 discusses results and Section 5 concludes the paper.

2. Background and Related Works

2.1. Background

A description of key notations and terminologies used in the paper is outlined as follows:

- **Key** – Is any random number as an output from a random number generator. It is used in encryption or decryption of messages. It is mainly referred to as a cryptography key.
- **Public Key** – It is also known as a shared or symmetric key. This key is a common key shared by two participating nodes prior to initiating a session for message communication. Two keys are generated for every participating node the public key and its corresponding private key.
- **Private Key** – The private key is a unique key for each participating node. The private key is used in combination with the public key of the sender for encryption of messages. During decryption of messages also, the private key of the receiver is used.
- **Encryption** – It is the process of encoding or hiding the content or message details by changing them from plaintext to a ciphertext using cryptographic keys. In a symmetric encryption, the private key is used to encrypt and decrypt messages.
- **Decryption** – It involves the use of cryptographic keys and approaches in changing ciphertexts to their original plain texts. In symmetric encryption algorithms, the private key of the destination node is used together with the public key of the source node for the decryption.
- **Plaintext** – It describes an unencrypted message in which the original message format and content are maintained.
- **Ciphertext** – It is a description for an encrypted message. Thus, the output or transformed text for any plaintext message on an encryption algorithm.
- **Cipher** – It is a cryptographic algorithm for transforming plaintext to ciphertext. It is used for encryption and decryption of messages.

- Algorithm – It involves a standard outline of sequential procedure or steps for undertaking encryption or decryption of messages.

The next section presents related works.

2.2. Related Work

2.2.1. Secure Cloud Communication

In our previous conference paper, we pointed out the security weakness of the DHE protocol in the provision of security solution against threats such as man-in-the-middle attacks due to vulnerabilities in the protocol to authenticate participating nodes using their unique identifying features in block stream cipher [1].

Cloud computing infrastructure services where enterprises manage and share resources between the local devices that are stationed in their premises and remote servers offer some convenience but have security challenges including data loss and tampering [12].

The absence of a trusted and robust security framework in the cloud to protect against security threats including access control management, authentication challenges, integrity of stored information that cloud services suffer is a concern that attracts equal attention from industry and academia to explore approaches to address the security vulnerabilities in these services to improve the security of the cloud to support secure remote processing and storage of information [13]-[16].

2.2.2. Internet-of-Things Security

In [17] an extensive survey on the security, privacy and authentication challenges in internet of things confirmed the fact that although there have been improvement in the design and development of cryptographic solutions tailored for the individual elements within IoT, there is equally an increase in the number of exploitation of attacks in recent times. Therefore, authentication, confidentiality, and data integrity challenges exist in IoT domain making it demand a cryptographic solution that adopts an algorithm that provides efficient privacy and security.

In [18], the authors delved into the material agents used in the design and development of smart objects and internet of things systems. Majority of the devices used in an IoT system have sensing capabilities to independently collect data from its environment for transport to other devices within the network. A defective device by design is a threat by itself and introduces a weak link for attack exploitation to a system that has such a device as component. Compatibility challenges in intelligence sensing, interoperability, distributed intelligence and flexibility to adapt to a universal authentication solution for an IoT ecosystem have become fundamental in implementing IoT security solution.

An efficient encryption scheme that involves less computational overheads and runs on adequate power for constrained devices without compromising on the security, privacy and integrity of data in IoT is needed in modern IoT security architectures [19]. The algorithm developed in [20] combined machine learning approaches to detect and control network congestion in IoT using the fitness function that is based on the grey wolf optimization algorithm (GWO), since network

congestion could increase the execution overheads for cryptographic algorithms to run efficiently.

The intensity and size for IoT investments by enterprises keep increasing to improve the security of their network, as the number and the scale in the incidences of security attack on IoT keep rising [21], [22]. Modern and more sophisticated malware that targets IoT devices and the various components of IoT systems to exploit the security vulnerabilities in these devices to the skewed benefits of those attackers is on the increase [8].

2.2.3. Twofish

The authors in [23] adopted the Twofish encryption algorithm in securing data and maintaining confidentiality of the communication network and implemented the solution using the chilkat encryption activeX. Figure 1[24] illustrates the working of the Twofish encryption algorithm. The encryption involved splitting the input data into four halves of 128 bits, where the XOR operations were conducted on the bits input with a key. The key whitening and the XOR operation provided the needed security to the data to assure privacy of the data in the communication network.

The Twofish encryption algorithm was used in addition to other cryptographic primitives to enhance the security in Bluetooth encryption. The combined encryption approach supported the protection of data in Bluetooth transmission. The use of the Twofish cryptographic algorithm improved the security and efficiency of the encryption scheme in the Bluetooth communication [25].

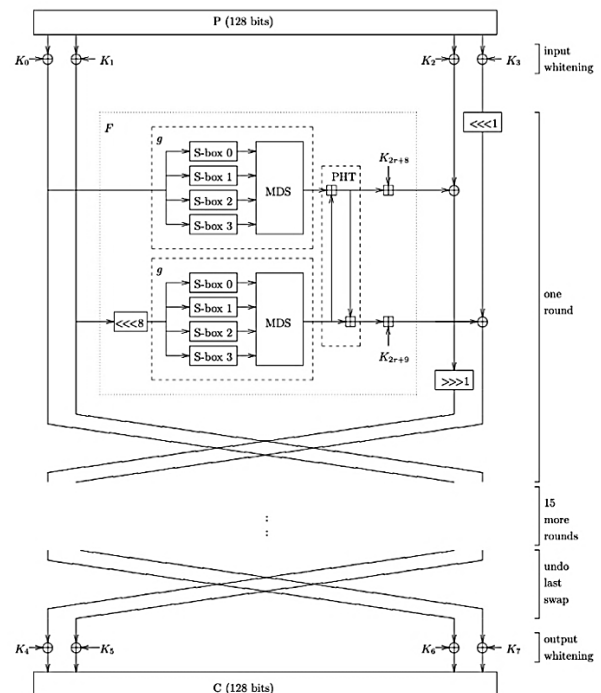

Figure 1: Twofish [24]

The Twofish cryptographic algorithm provided an enhanced security for a software to support secure communication of information over the internet. In their paper, the Twofish algorithm with 192-bits key space was implemented in encrypting messages.

The algorithm provided efficient and secure encryption of data for communication [26], [27].

In [28], a variant of the Twofish algorithm with an increased complexity for multi-level keys adoptable for dynamic bit size inputs to improve its cryptographic strength that made it resistant against the differential attacks was adopted for encrypting images.

The standard Feistel encryption algorithm involving several rounds of encryption with key whitening techniques to improve the security of the encryption is what the Twofish encryption algorithm offers. The input and output data are XOR-ed with eight sub-keys. The encryption in the Twofish encryption algorithm involves encrypting a message over 16-rounds in a Feistel network that uses a bijective function comprising four-byte wide pre-computed key dependent substitution (S) boxes; a matrix; a key schedule, and a Pseudo Hadamard Transform of bitwise rotation. After each round of encryption, the ciphertext generated is swapped and fed as input into the next round such that the left encrypted text is interchanged with the right counterpart and vice versa. The final round of encryption produces a ciphertext in two halves-the right and left halves of cipher texts. The resultant ciphertext for the Twofish encryption is achieved by interchanging the positions of the ciphertexts and combining both as the ciphertext for the message [23], [24]

2.2.4 Diffie-Hellman Key Exchange (DHE)

The communicating nodes through a key generator acquire two sets of key pairs (a private key and a public key) to enable them authenticate for communicating data. The DHE is susceptible to several attacks including key compromise impersonation attacks [23], [29].

The authors in [30] adopted an algorithm that is based on the Linear Feedback Shift Register (LFSR)-dependent correlation technique to supplement the Diffie-Hellman key exchange protocol to maintain the privacy of message communication between the cloud and the local device. The LFSR correlation algorithm detected and verified digital signatures from a digital signature pool between the devices and the cloud by using the correctional framework for digital signature analysis through the calculation of linear complexities between the cloud and the local devices. This technique helped with the detection of errors with digital signatures of messages thereby maintaining the privacy of the information shared between the cloud and the local devices, eliminating the possibility of key compromise or impersonation and the related attacks.

In [31], cryptographic-based public key infrastructure approaches provided at the device levels were adopted to support secure communication of message in an end-to-end encryption that ensured privacy, confidentiality and device integrity. The Elliptic Curve Diffie-Hellman key exchange (ECDH) guaranteed a secure key sharing between communicating devices on a chat application that operated on the android environment. The RC4 encryption scheme was used to encrypt the multimedia messages for communication between the devices used on the chatting application.

The use of authentication scheme based on the Diffie-Hellman model supported the efficient key exchange and management for communication devices with more than one identity. The authors

in [32] used a key agreement and management protocol adaptable for IoT communicating devices with more than one identity. The key agreement and management protocol supported the efficient selection and initialization of session key pairs from devices with multiple identities and helped authenticate the communicating devices in the IoT system.

The next section deals with the proposed methodology.

3. Methodology

The proposed methodology is a combined cryptographic primitive consisting of a key exchange protocol or key agreement protocol such as the Diffie-Hellman Key Exchange (DHE) protocol illustrated in figure 2, and a cryptographic cipher for encryption and decryption such as the Twofish cryptographic algorithm illustrated in figure 1.

Figure 2: Diffie-Hellman Key Exchange between Node A and Node B.

The Diffie-Hellman Key Exchange (DHE) protocol is a public-key cryptographic primitive with an implementation involving two unknown nodes or devices to securely establish communication by generating and exchanging shared secrets between them. The securely shared secret is used in performing a symmetric key encryption and decryption. The DHE is structured on the discrete logarithm problem which is based on a one-way function; finding the factorization of the product of two prime numbers p and g .

Such that p is a prime number and g is a primitive root mod (p) .

where: p and g (generator) are two large integer number.

$$1 < n \leq (p-1); \text{ where } n = g^k \text{ mod } p$$

Thus, for every number n between 1 and $p-1$ inclusive, there is a power k of g such that $n = g^k \text{ mod } p$.

Publicly available numbers of p and g are to be used by any two untrusting and unknown devices or nodes to generate their key pairs: namely the public key (P_u) and private key (P_v).

Figure 3: The generator for the shared key in DHE

As shown in Figure 3, the notations for Pv_1, Pu_1 and Pv_2, Pu_2 represent the Private key and shared key for the source node and the receiver node respectively. The DHE protocol used four numbers in all. The first two numbers are to generate the shared key (of same value) $Pu_1 = Pu_2$. Thus, both sender and receiver have the same value for the shared key Pu_1 .

The DHE and Twofish Algorithm:

Figure 4: Twofish Encryption Algorithm based on the DHE Protocol

As shown in Figure 4, (k_1, y_1) represents the private key and public key respectively for the source node.

(e) , represents the Twofish cryptographic function.

(x_1, y_2) represents the private and shared keys respectively for the receiver node.

The shared key for the communicating nodes is $(y) = y_1 = y_2$.

Plaintext of arbitrary size data up to 128 bits. The input bits are grouped into four sections, thus four parts of each constituting a 32-bit part. The four sections are divided into halves. The first two sections of 32 bits each forms the right component of the input bits and the other two sections of two 32 bits, form the left component [23].

The four keys for whitening the encryption are applied on the Bit-XOR input.

$$R_{0,i} = P \oplus K_i ; i = 0, \dots, 3$$

Where:

R denotes the rounds of encryption in the Feistel network.

K denotes the key (K_i) where i represents the sub-key for whitening. There are four sub-keys. 0, 1, 2, 3.

$$\text{Encryption: } e_k, k_1, y_1(M) = e_k(M \oplus k_1) \oplus y_1 = C_T$$

$$\text{Decryption: } e_k^{-1}, x_1, y_2(C_T) = e_k^{-1}(C_T \oplus x_1) \oplus y_2 = M$$

where:

M represents the plaintext.

C_T denotes the ciphertext or encrypted message.

e_k represents the Twofish encryption function.

e_k^{-1} represents the Twofish decryption function.

k_1 denotes the private key for the source node.

x_1 represents the private key for the receiver node.

y_1 denotes the public key of the source node.

y_2 denotes the public key of the receiver node.

$y_1 = y_2 = y$, denotes the shared secret for encryption and decryption of the DHE-Twofish cryptographic solution.

Encryption at the source node is implemented using the shared key with the Twofish algorithm encryption function.

Algorithm 1: Secure Node-Node Data Exchange -
Encryption - Twofish (M, S_k)

Input : M, S_k

Output: C_T

Begin

Split M into four 32-bit parts $M_{i=0,1,2,3}$

Split S_k into four 32-bit partial keys key $K_{i=0,1,2,3}$

For $i=0..1$ **loop**

$R_{i,0} = M \text{ XOR } K_{2*i}$

$L_{i,0} = M \text{ XOR } K_{2*i+1}$

For $j=1..3$ **loop**

$L_{i,j} = R_{i,j-1}$

$R_{i,j} = L_{i,j-1} \text{ XOR } (((2 R_{i,j-1} * K_j)^x) \% (2^{32}-1))$

End loop

End loop

Combine L_{13}, R_{13}, L_{03} and R_{03} into C_T

Return C_T

End

Algorithm 2: Secure Node-Node Data Exchange -
Decryption - Twofish (C_T, S_k)

Input : C_T, S_k

Output: M

Begin

Split C_T into four 32-bit parts $C_{T i=0,1,2,3}$

Split S_k into four 32-bit partial keys key $K_{i=0,1,2,3}$

For $i=0..1$ **loop**

$R_{i,3} = C_T \text{ XOR } K_{2*i}$

$L_{i,3} = C_T \text{ XOR } K_{2*i+1}$

For $j=2..0$ **loop**

$R_{i,j} = L_{i,j+1}$

$L_{i,j} = R_{i,j+1} \text{ XOR } (((2 L_{i,j+1} * K_j)^x) \% (2^{32}-1))$

End loop

End loop

Combine L_{10}, R_{10}, L_{00} and R_{00} into M

Return M

End

The Algorithm 1 above is the encryption procedure for the Twofish cipher at the source node.

The Algorithm 2 above is used for the decryption of the ciphertext at the receiving node using the Twofish cipher.

In Algorithms 1 and 2:

M represents the plaintext.

S_k shared key, represents the Key K

C_T represents the ciphertext.

K_i represents the partial key or the subkeys where i represents the indexes from (0,1,2,3)

Li and Ri are Left and Right partitioned 64-bits block size
 f represents the Twofish cipher.

$\%$ represents the Modulo operator.

Li represents the Leftmost partitioned part of the Feistel structure
 Ri represents the Rightmost partitioned part of the Feistel structure
 x represents the total number of rounds, which is 16 in this case.

4. Results and Discussion

At the source node, using the DHE through a handshake request with the destination node established a shared key for encryption and decryption.

The Twofish encryption uses the data, and the shared key to produce the ciphertext. Decryption of ciphertext at the destination node is also implemented using the Twofish on the shared key and ciphertext.

Table 1: Displayed results

ID	SK	Data	Ciphertext	Recovered
1	262262262	2345	OXEVxUcVBXZk lzbF0F1D+A==	2345
2	232232232	1291	7efDjnVQrVwEV qBD3rguLA==	1291
3	452452452	4672	+gJXYsjBJP/Y/UE djUMIWQ==	4672
4	232232232	1456	RXec4NLFwt1nmX eWqQkm3g==	1456
5	232232232	2121	IeTtTlkRgQuvjD0h AFQFIg==	2121

The ID denotes the unique node identity number which represented the order of arriving data for the encryption. The 1st, 2nd, 3rd, 4th, 5th showed the first data, second data, third data, fourth data, and fifth data to arrive in that order.

The SK represents the shared key by the DHE for message encryption.

Data denotes the plaintext.

Ciphertext represents the output of the plaintext with the Twofish cryptographic algorithm.

Recovered Data represents the decrypted data.

The Diffie Hellman key exchange protocol that took the unique ID of the communicating devices for establishing the shared key using the key generator helped for encryption of node data.

Table 2: Average Encryption Throughput (MiB) in the ARMv7-a of Samsung and Xiaomi Devices [33]

Algorithm/ Pack Size	1 MiB	5 MiB	10 MiB
AES	77.539	78.058	77.586
RC6	51.84	53.556	53.1065
Twofish	47.7135	48.6145	47.1835

As presented in Table 2 [33], the average encryption throughput for data packet sizes 1MiB, 5MiB and 10 MiB shows an improved throughput for Twofish algorithm. The management information base (MiB) values catalogued the properties and data objects from the encryption of implementation of AES, RC6 and Twofish respectively for the block ciphers. Across all the pack sizes of the MiB values, the encryption throughput for Twofish was higher than the AES and the RC6.

Table 3: Average Decryption Throughput (MiB) in the ARMv7-a of Samsung and Xiaomi Devices [33]

Algorithm/ Pack Size	1 MiB	5 MiB	10 MiB
AES	66.671	68.541	69.026
RC6	52.0065	53.3635	52.877
Twofish	47.785	48.6215	47.0225

As seen in Table 3 [33], the average decryption throughput for data packet sizes of 1MiB, 5MiB and 10 MiB shows an improved throughput for Twofish algorithm. The management information base (MiB) values catalogued the properties and data objects from the encryption of implementation of AES, RC6 and Twofish respectively for the block ciphers. Across all the pack sizes of the MiB values, the encryption throughput for Twofish was higher than the AES and the RC6.

Table 4: Speed of AES Candidates for different Key Lengths [34]

Algorithm Name	Key Setup	Encryption
MARS [BCD+98]	Constant	Constant
RC6 [BCD+98]	Constant	Constant
Rijndael [DR98]	Increasing	128: 10 rounds 192: 20% slower 256: 40% slower
SERPENT [ABK98]	Constant	Constant
Twofish [SKW+98, SKW+99a]	Increasing	Constant

As shown in Table 4 [34], the speed of the AES candidates for different key lengths for encryption is presented. The Twofish algorithm adopts an increasing key setup but encrypts and decrypts at a speed independent of the length. The performance and security of an encryption is as a function of the key space or key length.

5. Conclusion

The combined cryptographic scheme consisted of the DHE, an algorithm based on mathematical approaches for exchanging a shared secret between the communicating nodes and the Twofish. The Twofish encryption algorithm provided a relatively better encryption time than the AES and RC6. The use of the DHE increased the confusion and diffusion of the key for the encryption algorithm to improve the strength of the cryptographic algorithm of Twofish in eliminating the possibilities of relative key attacks that could result in man-in-the-middle and its associated attacks.

The Twofish cryptographic algorithm complemented by the pre-shared secret key protocol in the DHE key exchange provided authentication for the nodes as well as the creation of a secure channel between the communicating nodes to guarantee a secure

node-to-node exchange of IoT messages. It helped in assuring the integrity of the content of messages between the communicating nodes since the DHE, in generating the shared key, only included and engaged the intended receiver node prior to the actual message communication. The complex key exchange logic provided in DHE algorithm improved the key diffusion in the Twofish cryptographic symmetric key cipher assuring an improved security with a relatively high throughput for end-to-end encryption for secure communication within IoT systems. As presented in Tables 2, 3 and 4 [33], [34], the Twofish encryption algorithm produced an encryption and decryption with a high throughput [32], [33], [35].

An analysis on the throughput, battery drain, key space and its impact on the security of related symmetric key ciphers for IoT constrained devices would be explored for future works.

Conflict of Interest

The authors declare no conflict of interest.

Perturb-observe 'P&O'

MPPT

Boost Buck SEPIC CUK

ABSTRACT

This article aims at comparing two controls to follow the maximum power point, making use of DC-DC converters for PV uses. All transformers operate continuously. To fulfil maximum power, we will exploit two MPPT controls: a traditional perturb – observe 'P&O' and a smart one – the fuzzy logic 'FL'. The goal of this article is two-fold: to scrutinize the efficiency of DC-DC transformers (Boost, Buck, Cuk and SEPIC), and to assess the outcomes of the simulation. For the construction of models and simulations, the Matlab / Simulink environment is employed.

1. Introduction

There has been recently a crucial advancement in renewable energies. With its permanent potential and without adverse effect on the external environment, new energies are an adequate and affordable technique for development. The main lines of research concerning the conversion of new energies are as follows: recovery of basic energy, mechanical transformation, electrical transformation, electricity production, conversion, and injection into the network. The main axis is to determine the quality of "green" energy generation [1, 2].

Transformers DC-DC are an essential constituent in power generation. These converters are chiefly used in connection with batteries, wind turbines, hybrid systems, solar panel. Transformers DC-DC are to match the tension between the input stage and the output stage of a system. In this work we will make a comparison between different converters: Boost, Buck, Sepic and Cuk for two commands perturb – observe 'P&O' and fuzzy logic 'FL', in order to obtain the maximum power of a solar panel source for meteorological variations conditions [3, 4].

2. Modeling of Photovoltaic System

The fundamental element of the solar panel is the semiconductor, consisting of many cells mounted in shunt or

mounted in cascade. The photovoltaic cell is schematized by a circuit: a parallel resistance, a series resistance, and a single diode, represented in figure 1 [5].

Figure 1: Circuit of solar panel cell.

The relationship of the electrical intensity current I_{ph} :

$$I_{ph} = [I_{sc} + K_I(T_c - T_{ref})] \frac{G}{G_{ref}} \quad (1)$$

whereby K_I is the temperature coefficient [%/K]; I_{sc} is the short intensity current [A]; T_c is the module temperature [K], G is the sunlight solar effect [W/m^2]; $T_{ref} = 298$ K and $G_{ref} = 1000$ W/m^2 . [6, 7]

www.astesj.com

<https://dx.doi.org/10.25046/aj060272>

The formula giving the electrical intensity I is:

$$I = I_{ph} - I_d - I_{sh} \quad (2)$$

whence

$$I = [I_{sc} + K_f(T_c - T_{ref})] \frac{G}{G_{ref}} - I_s \left[\exp\left(\frac{q(V + R_s I)}{N.K.T}\right) - 1 \right] - \frac{(V + R_s I)}{R_{sh}} \quad (3)$$

where

I_{ph} the short electrical intensity,

I_s the electrical intensity saturation of the diode;

q the elementary charge of the electron ($1.60 \cdot 10^{-19}$ C);

V the diode tension (V);

K the Boltzmann's universal constant ($1.38 \cdot 10^{-23}$ J/K);

T the temperature,

N Ideality factor of the diode,

R_s the cascade resistance,

R_{sh} is the parallel resistance,

3. Prepare Transformers DC-DC analysis

The transformers DC-DC is a very important element in power generation of a solar panel. It is a block between the load and the photovoltaic panel that allows to extract the maximum power for the panel.

The transformers DC-DC consists of a capacitor, a diode, an inductor, command switch (controlled by PWM signal) and uncontrolled switch.

3.1. Buk Transformer

The buck transformer makes it possible to reduce the input tension [8].

Figure 2: Buck transformer.

The relationship between input tension and output tension is:

$$V_o = DV \quad (4)$$

where D represents the duty cycle.

3.2. Boost transformer

The boost transformer allows to increase the input tension [9, 10].

Figure 3: Boost transformer.

The relationship between input tension and output tension is:

$$V_o = \frac{1}{1-D} V \quad (5)$$

3.3. Cuk transformer

Cuk transformer converts the input tension into a tension of the opposite sign. [11, 12].

Figure 4: Cuk transformer.

The relationship between input tension and output tension is:

$$V_o = -\frac{D}{1-D} V \quad (6)$$

3.4. SEPIC transformer

The SEPIC transformer is drawn from of the Cuk which gives a positive output tension [13].

Figure 5: Sepic transformer

The relationship between input tension and output tension is:

$$V_o = \frac{D}{1-D} V \quad (7)$$

4. MPPT techniques

The aim of the maximum power point tracking technique is to determine the maximum power operating point by changing the duty – cycle ratio of the DC-DC transformer, and then moving to the relevant point.

In this article two MPPT techniques are used: Perturb – Observe and fuzzy – logic 'FL'.

4.1. Technique P and O

The perturb and observe P&O command is ranked among the most used techniques. As its name suggests, this technique involves disturbing the V_{PV} voltage of a low amplitude around its initial value, and examining the impact on the power at the output of the Solar panel.

Figure 6 shows the structure of the Perturb – Observe command [14,15].

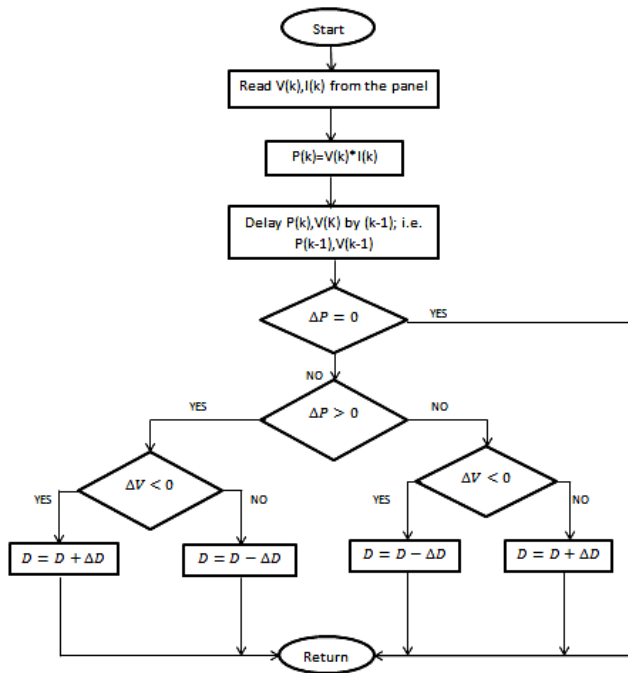

Figure 6: Organization chart P&O

4.2 Fuzzy – Logic ‘F-L’

The ‘F-L’ technique is used in a point tracking system maximum MPPT power, this technique offers the importance of being a powerful technique and relatively simple to develop and it does not require exact specification of the model to be regulated. The ‘F-L’ technique is more suitable for non-linear systems than photovoltaic systems. The process of this technique is executed in three blocks: Fuzzification, defuzzification and inference. This figure supplies the clue 7 [16].

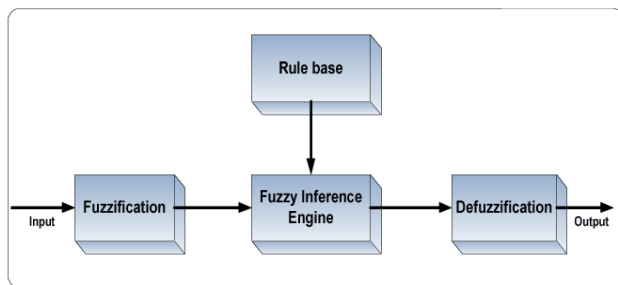

Figure 7: ‘F-L’ diagram

The ‘F-L’ diagram input parameters are: the variation of the error CE and the error E giving by the formula:

$$E = \frac{P(k) - P(k-1)}{V(k) - V(k-1)} \quad (8)$$

$$CE = E(k) - E(k-1) \quad (9)$$

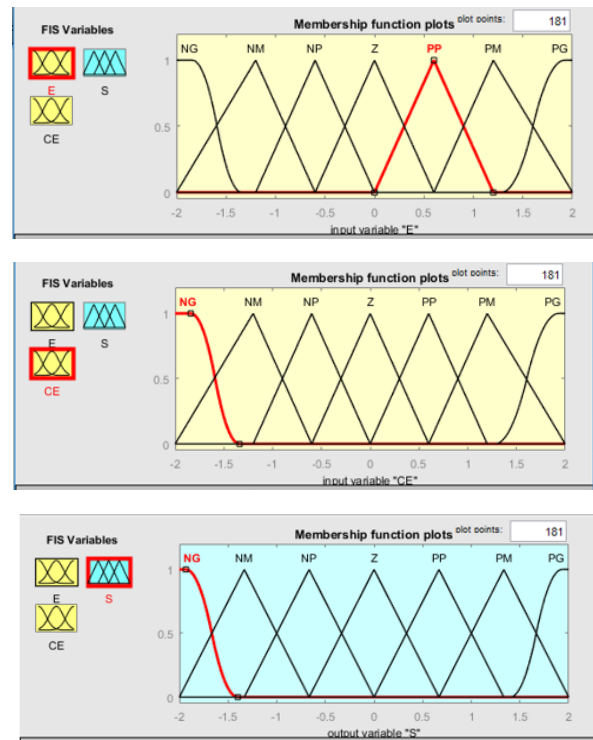

Figure 8: Output and inputs parameter

Table I below shows the different combination inference rules that link the linguistic parameters E (Error), CE (Variation of error) and output S (Output Variable).

Table 1: ‘F- L’ INFERENCE

E \ CE	NG	NM	NP	Z	PP	PM	PG
NG	NG	NG	NG	NM	NM	NP	Z
NM	NG	NG	NM	NP	NP	Z	PP
NP	NG	NM	NM	NP	Z	PP	PM

5. Simulation and Results

Under Matlab Simulink environment the PV system is modeled. In this block we find mainly: the equivalent diagram of the converter, the command used and a PV system predefined in Matlab simulink.

Figure 9: Diagram Block of the Perturb—Observe and fuzzy—Logic commands for the different transformers processed

Figure 9 presents an overview of all blocks: photovoltaic panel, DC-DC converter, MPPT commands, irradiation data and temperature data.

The Solar panel used in the simulations is P20-36-TDC-36-20W.

Table 2: P20-TDC-36-20W

No-Load tension V_{oc} (V)	21,20
Tension at maximum power V_{mp} (V)	17,20
Short-intensity current I_{sc} (A)	1,280
Current at maximum power I_{mp} (A)	1,170
Puissance maximum (W)	20,0
The Coefficient of temperature of V_{oc} (%/deg.C)	0.360990
Coefficient of temperature of I_{sc} (%/deg.C)	0.0650

Figures 10 and 11 depicts the change of the real solar radiation the and temperature data over a day.

Figure 10: The change of temperature

Figure 11: The change of solar radiation

Figure 12: Power with Perturb-observe technique for the Boost transformer

Figures 12,13,14 and 15 enumerates the outcomes of the different transformers: Boost, Buck, CUK and SEPIC, using as a technique the Perturb and Observe.

Figure 13: Power with Perturb-observe technique for the Buk transformer

Figure 14: Power with Perturb-observe technique for the Sepic transformer

Figure 15: Power with Perturb-observe technique for the Cuk transformer

For the second simulation figures 16,17,18 and 19 the fuzzy logic command was used.

Figure 16: Power with 'F-L' technique for the Boost transformer

Figure 17: Power with 'F-L' technique for the Buck transformer

Figure 18: Power with 'F-L' technique for the Sepic transformer

Figure 19: Power with 'F-L' technique for the Cuk transformer

Figure 20: Evolution of power for the four transformer with Perturb-Observe

Figure 21: Evolution of power for the four transformer with 'F-L'

Figure 22: The best power produced with Perturb-Observe and fuzzy-logic

In the Perturb-Observe technique simulation context, the power of photovoltaic panel in the Sepic transformer – is maximal with regard to other transformers, but it is more stable in the boost transformer.

In the 'F-L' technique, the power photovoltaic panel in the Buck transformer generate more power compared to other transformers; it is also more stable, but in Boost transformer context.

6. Conclusion

This article studied two maximum power point tracking techniques – a traditional Perturb-Observe and a smart one: 'F-L' control to obtain the maximum power of the panel photovoltaic.

In this work, four DC-DC transformers are used to improve the quality of the MPP tracking by analyzing the power produced and the stability of each converter.

Simulation results gives an overview of the power evolution for a temperature and solar effect irradiation data for a day.

ABSTRACT

Induction motors (IM) are used widely in high energy applications where high torque is required such as ships/ aircrafts manufacturing industry. Those motor drivers are populated in many advantages especially their wide control strategies. However, new technology is invented for enhancing efficiency and smoothing the torque curve by increasing number of phases in the motor drive. Speed control can be achieved by changing the pole numbers between any two different phases using pole-phase modulation (PPM). The problem is raised when a large number of phases are used to enhance the voltage profile. This problem is manifested in the complexity of control and complexity of hardware (more devices need to be involved) which increases the cost and degrades the performance. This paper argues using a multilevel inverter to produce an enhanced voltage profile and motor speed control without needing to increase the number of devices. The performance of the proposed model is compared with conventional models in terms of efficiency, power factor, speed, torque ripple, and ripple frequency. Results obtained using multilevel inverter based induction motors are found optimum.

1. Introduction

Induction motors (IM) are widely used in high power applications more likely in aircraft engines, ships tractions, and other heavy industrial applications [1]. The main requirement of heavy industrial applications is a motor with high fault tolerance. The fulfillment of fault tolerance requirement is ensured using polyphase (multiphase) induction motors [2]. However, in contrast with high energy applications, multiphase induction motors drives are the state of the art. Performance of such drivers witnesses good improvement after applying two levels of inverter. Hence, experiments are continued to examine multilevel inverter impact on (multiphase) induction motors drives performance. These motors are inherited the same performance of three-phase induction motors such as high efficiency and low ripple of torque [3]. A mains-fed three-phase cage induction motor still dominates in industrial applications worldwide more than a century after its invention.

As the induction motor is a significant consumer of electrical energy globally, more stringent criteria are regularly imposed on its manufacturers, primarily in terms of the efficiency but also in terms of NVH (noise, vibration, harshness) requirements, [4]. Pole changing techniques are inbuilt prosperities of induction motors

give it a flexible speed control capability. Pole changing technique is performed in either of pole phase modulation or pole amplitude modulation. The control strategy of three-phase IM is achieved using v/f control vector, the same can be extended for multiphase motors controlling. The two-level excitation of voltage in multiphase IM is realized improved due to enhanced efficiency of such machines that lie on their smooth torque curve and minimized losses [5]. High starting torque can be achieved even with IM of a smaller number of phases by increasing the poles number using the pole phase modulation technique. A higher number of poles might worsen the case more likely degrades in performance might be happening due to high pole number. The performance degradation can be observed by realizing the torque curve ripple, ripple is likely raising due to high number of poles. One of the feasible solutions for tackling this degradation in three-phase IM is proposed by employing multilevel inverters. Multilevel inverters show good performance in reducing torque level and improving machine efficiency. The technique of multilevel inverter already exists on three-phase machines for performance-related support; furthermore, multilevel inverter is used in multiphase machines as well [6]. The complexity of control strategy and a large number of devices in multiphase machines have triggered another sort of performance degradation. In this paper, we utilized the fact that phase effective voltage is represented by total profile coins voltages [7]. This can be further utilized to create multilevel

voltage in the phase without needing to increase the pole number by using a two-level inverter. The strength of this approach is smoothening the torque curve by improving machine efficiency and tackling the computational complexity of the control strategy. Calculations of control vectors in this case can be tackled using data processors such as FPGA chips. Pole phase modulation is further used along with the mentioned approach for applying more consistency on the system without involving a large poles number.

2. PPM Technology

PPM is one of the leading methods to provide motor speed control by changing the excitation voltage phase, this change is impacting the pole pitch and hence continuously reforming the speed ratio. The same concept can be derived using K slotted squirrel cage multiphase induction motor. Assuming an induction motor with two phases (P1 and P2) and two poles (b1 and b2); those stand for two possibilities of phase and pole combination which is used to control speed of IM. So-to-say, the number of slots can be given as below:

$$K = P_1 \times m_1 \times \frac{Q_1}{(2)^{-1}} \quad (1)$$

Hence, the slot can be represented by the second pole and second phase terms as following:

$$K = P_2 \times m_2 \times \frac{Q_2}{(2)^{-1}} \quad (2)$$

Where Q_n is speed ratio, $n=1,2, \dots$, i.e. Q_1, Q_2

$$K = P_1 \times m_1 \times \frac{Q_1}{(2)^{-1}} = P_2 \times m_2 \times \frac{Q_2}{(2)^{-1}} \quad (3)$$

Let pole ration to be:

$$S = \frac{Q_2 \times m_2}{Q_1 \times m_1} = \left(\frac{\text{pole2}}{\text{pole1}} \right) \quad (4)$$

If pole 2 > pole 1 then the term S will either equal to 1 or greater than 1. Let the design of pole-phase modulation to be as in table 1. K is obtained according to the above formula.

Table 1: Pole-phase modulation proposed designs

Possibilities	M1	P1	Q1	M2	P2	Q2	K
PPM 1	4	3	1	6	2	1	12
PPM 2	5	4	2	2	10	2	20

According to table 1, two designs are proposed namely: PPM1 and PPM 2. However, in first design, the pole is changing between three and two with applicable pole phase modulation between four phases to six phases. Whereas, at design 2, the pole is changing between four to ten with pole phase modulation between five phases and two phases. The same is demonstrated in Figure 1.

Looking on the pole-phase combination at both designs, the combination is led to different pole width generation and that must be avoided. The same can be prevented the pole ration i.e. $P2/P1$ must yield an odd positive integer number. In order to do so, the ratio S must equal the following term. Where $x \in [0,1,2,3,4]$, however, may allow the feasibility of odd speed ratios to be obtained using pole-phase modulation [8].

$$S \geq 2x + 1 \quad (5)$$

Figure 1: Pole pitch changes as per the procedure in Table 1

3. MIM PPM design

A nine phase induction motor which made by pole phase modulation concept as a full pitch, single-layer winding. In table 2, the slot numbers of both rotor and stator are chosen carefully to prevent none desired effects [9], [10]. More likely, crawling, cogging and cups synchronizing are none desired circumstances in machine functionality. The proposed design is depicted in figure 2.

Figure 2: Two slots, four poles IM design (a single-phase connection sample)

The design is made to preserve one slot for each pole in each phase i.e. $Q=1$. Figure 3 demonstrates the pole-phase feasible combination of pole-phase modulation of nine phase motor along with excitation of each phase and polarity of the conductor. Arrows in figure 3 illustrate the conduction direction (polarity) inside the slot. Experiments showed that changing the number of phase angle of slots more likely for 40-degree phase angle of nine phases will yield a speed of 1500 rpm to the four poles combination. On the other hand, same four poles combined with nine phases of 120-degree will yield 500 rpm speed. Figure 3 demonstrates three-pole phase combinations of the machine; however, third part of the figure illustrates an alternative way of multiphase motor designing using a lesser number of inverter legs. However, this kind of design is having no roles in torque improvement or efficiency enhancement as well as speed control. In multiphase inverter speed control, inverter legs number (number of transistors in the inverter) need not change for performing speed control. Usually, angles of transistor firing which are generated using pulse width modulation are changed for fixing the pole pitch. Table 2 shows a parameters details with inverter integration of nine phases single layer induction motor.

Triggering method	PPW

4. Inverter design

The five-level multilevel inverter is obtained by cascading three full-bridge inverter circuits. The three full-bridge inverters are connected in series and a single-phase output is taken. Each full-bridge is fed from a separate DC source. The number of output levels m in each phase is related to the number of full-bridge inverter units n by, $m/2n+1$. Here number of levels is five, hence number of inverter circuits connected in series is two. Where figure 4 shows general demonstration of PWM signals and reference signals. The single-phase five-level topology of cascaded H bridge multilevel inverter is shown in Figure 5. Each H-bridge is fed with the same value of DC voltage hence it can be called a symmetrical cascaded multilevel inverter. Each full-bridge inverter can generate three different voltage outputs: $+V_{dc}$, 0, and $-V_{dc}$. The output voltage is synthesized by the sum of two inverter outputs are at two angles. These two angles are used for giving pulses to eight switches.

Figure 4: General demonstration of PWM signals and reference signals

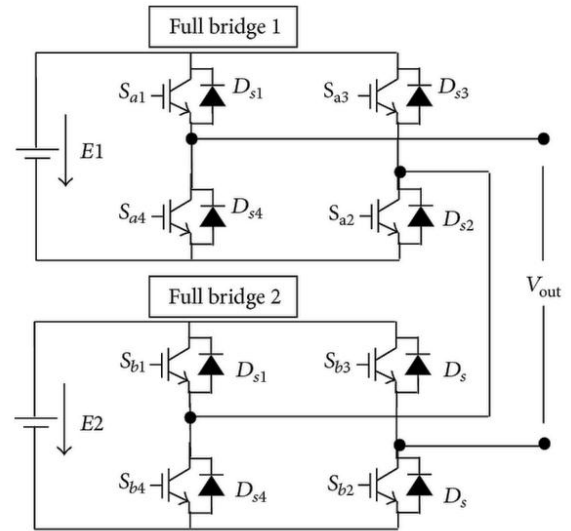

Figure 5: Circuit diagram of two levels DC-AC converter (inverter)

5. Design of high levels voltage generator

The observations made on four-pole, nine phases with two-level voltage exciters on each phase have shown the good performance of the induction machine. With nine phases, good performance is achieved while in the case of three phases-twelve poles, performance is noticeably reduced for the same level of phase voltage excitation. These observations are motivated thinking of another method to enhance the voltage through the phases (windings in each phase). The operations of three-phase twelve poles induction motors are similar to the same of nine phases and higher pole number induction motors. The equivalent voltage profile coins of twelve poles, three-phase induction motor are formulated by participation of four pole-nine phases windings (winding per phase) [10]. The real-life voltage profile coins are interconnected serially across each phase. The fact is changed while using a multilevel inverter, each voltage profile coin is supplied with voltage from an inverter leg. In another world, no actual voltage profile coins have existed unless the voltage is divided into several levels in each phase which gives the same impression of using a series winding as a voltage profile. So to say, the voltage effective during the phase is equal to the summation of each voltage across the voltage profile coin. This fact paved the way for increasing the voltage of each phase by providing more

levels on member voltages without needing to device count increment, this might use the same control strategy of a standard phase setup before voltage levels uplifting. According to the chart in Figure 3, the effective phase voltage can be obtained as follows:

- For phase R, the voltage effective at the phase is a summation of voltages across phases a, d, and g. where the phase angle is zero.
- For phase Y, the voltage effective at the phase is a summation of voltages across phases b, e, and h. where the phase angle is 120 degree.
- For phase B, the voltage effective at the phase is a summation of voltages across phases c, f, and i. where the phase angle is 240 degree.

Each sub-phase i.e. (small lettered labeled phases such as a, b, g, etc.) represents a voltage profile coin and can be used to produce a voltage with multilevel by deploying techniques such as pulse width modulator. So-to-say, three phases displaced at a 60-degree phase difference can be used along with a pulse width modulator to generate a multilevel voltage. Those three voltages with 60-degree phases are known as reference voltages whereas the pulse width modulation signals are known as carrier signals. However, the output of the carrier and reference voltage combination will produce the waveform as in figure 4 shown above.

Multilevel inverter is basically working to convert a direct current voltage into an alternate current voltage by using multiple switching process. Figure 5 demonstrates the inverter prototype. Four switches are terms to four levels inverter. Switches are commonly made using a transistor such as IGBT, this type of transistor are performing switching operations by referring a firing signals generated from a pulse generator. Pulse width modulator is commonly used as pulse generator in multilevel inverter [11].

6. Outcomes

Performance of multilevel inverter combination with pole-phase modulation induction motor is investigated in three cases more likely: four pole-nine phase machines with two levels voltage (model 1), twelve pole-three phase machines with two levels voltage (model 2) and finally twelve pole-three phase machines with multilevel voltage (model 3). So figure 6 (a,b,c) shows comparison of torque performance and phase voltage obtained from each case by examination (model 1), (model 2), (model 3). The performance is studied in each case by examination of torque, torque ripple, torque ripple frequency, speed of the rotor, and power factor, As shown in the following figures (7,8,9,10,11) However, Table 3 demonstrates the performance according to the mentioned metrics.

Table 3: Results of the empirical models with different performance metrics

Metric of performance	Model 1	Model 2	Model 3
Output power	3212 W	3212 W	3212 W
Torque ripple	15 %	31 %	13 %
Frequency of torque level	4.34 kHz	1.89 kHz	2.5 kHz
Speed	1450 r.p.m	470 r.p.m	471 r.p.m

7. Conclusion

Induction motors are powerful drivers in large power industries which had significant importance in research sectors. This paper is illustrating an approach to enhance the efficiency of

those machines by increasing the device count. Mainly, parameters such as voltage profile per phase and complexity of control strategy are interested to be examined. However, speed control is executed by changing the device count more specifically by changing the number of poles between different phase numbers. In this paper, three models are made namely: four pole-nine phase machines with two levels voltage (model 1), twelve pole three-phase machines with two levels voltage (model 2), and finally twelve pole three-phase machines with multilevel voltage (model 3). The performance of each model is tested using metrics such as efficiency, power factor, speed, torque ripple, and ripple frequency. Model 1 and model 2 are made using the conventional voltage profile enhancing method e.g. changing the device count in several iterations until reaching the required performance. However, this technique may face drawbacks like control complexity and device count increment which degrade the overall performance. Multilevel inverter is used to provide the required enhancement on the voltage profile and hence increase the efficiency and power factor on the machine without needing to increase the hardware complexity. Model 3 is outperformed over the other models as given in table 3.

Human-Computer Interface

ABSTRACT

A Japanese method in teaching at classroom show good result by implementing Kamishibai. On the other hand, technology is inseparable from daily life. Computer-based learning media innovations are fast and diverse, ranging from 2D animation to 3D environments. The hologram is one example of 3D object visualization to deliver the learning material. Based on Kamishibai's opportunity and hologram multimedia utilization to enhance the environmental education teaching activity, research about the adaptation of 3D pyramid hologram for teaching environmental education in elementary school is proposed. Firstly, the kamishibai model for teaching environmental education from Japan is explored and modified to fit Indonesia's condition. The kamishibai and hologram multimedia utilization in teaching environmental education has been experimented with in class. The results of learning kamishibai and multimedia holograms show that students will improve their abilities in environmental problems. The students lead the literacy and caring attitudes were following their level of knowledge and skills as well as their attitudes about caring about disposing of garbage in its place, learning to clean sewerage at school, learning to farm in the yard of schools, and understand how plants exist in school gardens.

1. Introduction

Our earth's condition is continuously degrading. Many environmental-related problems start with pollution, waste, climate change, global warming, and civilization. Those problems are not only faced by Indonesia but all of the countries in the world. Environmental education for a sustainable living must be applied to start from an early age. Every school must invite and introduce students to understand the natural conditions and natural problems at this time.

Environmental education plays an essential role in preserving and improving the world's environment in realizing a sustainable life. A necessary goal of environmental education is to make individuals and communities understand the complex nature of nature and the built environment resulting from the interaction of their biological, physical, social, economic, and cultural aspects, and acquire the knowledge, values, attitudes, and practical skills to participate in a way that is responsible and effective in

anticipating and solving environmental problems, and in managing environmental quality. To increase students' awareness to be more sensitive to current natural conditions for a sustainable society, environmental education should include the affective aspects of behavior, values, and commitment. Therefore, in the learning process, the teacher needs to have methods to clarify and internalize values.

Japan is one of the best examples in the world to learn about environmental education. There was a city named Kitakyushu that once was severely polluted, as in the 1960's air pollution in the Kitakyushu area was the nation's worst and had a sea contaminated with industrial waste. The municipal government worked very hard together with businesses and citizens to solve the problems. To create a low-carbon society, the city was selected in July 2008 to be an Eco-Model City. One of the steps to make it an Eco-Model City is hidden behind how environmental education is done there.

^{*}Corresponding Author: Asep Herry Hernawan. Email: asepherry@upi.edu

Learning from Japan's school curriculum on environmental education has a similar concept to the Indonesian curriculum. Environmental education is also integrated with other subjects, but they have a different method to teach. Nagoya, a historical city in the development of knowledge, has an experiment about *Kamishibai* in teaching environmental education and shows an excellent result at the effectiveness [1]. The same excellent product comes from Miyagi University in collaboration with JICA and Japanese Overseas Cooperation Volunteers (JOCV), while they used *kamishibai* as a learning medium in developing countries.

Kamishibai is a traditional form of Japanese storytelling that uses large color pictures to accompany a dramatic narration [2]. *Kamishibai* consists of stories in images with multiple uses. It is arranged based on a plot and designed to enhance imagination by enriching developed words and ideas. The pictures can be either selected from readily available stocks or self-drawn. *Kamishibai* has enjoyed a renaissance because teachers and librarians have revived this Japanese art of illustration telling for their children's benefit [3]. Based on previous research, *Kamishibai* can motivate the student, create a joyful environment, improve student ability, and be involved in the context quickly [4]. It opens opportunities for teachers to make critical choices across various possibilities that range from extreme top-down control [5]. Therefore, the potential of *kamishibai* usage for teaching environmental education in Indonesia should be explored.

On the other hand, technology is inseparable from daily life. Essentially technological advances will go according to scientific progress. Besides, technology can also make it easier for students to understand the learning material delivered and bring benefits to the advancement of the human race civilization [6]. Computer-based learning media innovations are fast and diverse, ranging from 2-dimensional (2D) animation to using Augmented Reality (AR) or Virtual Reality (VR) technology in 3-dimensional (3D) environments. With 3D object visualization, learning material becomes easier to understand and intuitive [7]. The hologram is one example of 3D object visualization to deliver the learning material. Many methods can be used to create holographic objects. One of the most frequently used is the pepper ghost method [8]. Using the pepper ghost hologram method, 3D virtual objects can be displayed directly in the real world without the need to use unique cameras or glasses such as VR or AR. Unlike AR or VR that limit the user from seeing the 3D object image and isolates them from their environment, hologram technology can be used by more than one people at the same time and enable its user to do the social interaction. Based on the opportunity of *Kamishibai* and hologram utilization as a media to enhance the environmental education teaching activity, a research about the adaptation of *kamishibai* and 3D pyramid hologram for teaching environmental education in elementary school is proposed.

Firstly, the *kamishibai* model for teaching environmental education from Japan is explored and modified to fit Indonesia's condition. The content of hologram multimedia is also designed to meet the needs of teaching environmental education. Then, the *kamishibai* and hologram multimedia utilization in teaching ecological knowledge have experimented in class. The experiment learns about the effectiveness of *kamishibai*, hologram multimedia, and the combination of both. The data is

collected from questionnaires, interviews, post-tests, and pre-tests gathered during the class experiment. The research purpose: (a) Explore hologram multimedia's potential as an innovative approach to teach environmental education along with *Kamishibai* card' (b) Design and build the *kamishibai* card and hologram multimedia for teaching Environmental Education in Indonesia.

2. Literature Review

2.1. Kamishibai

Kamishibai is a method of storytelling using images. Images that represent the story are painted on pieces of paper. Both sides of the report are used in such a way as to help facilitate the delivery of the information. [9] suggested that the article's front side was painted with colored pictures to show the audience. Simultaneously, the article's backside is written with words to make it easy for the singer to tell the story.

Figure 1: A *kamishibai* performer at Shimonoseki, Japan
(Source: <https://www.shimonoseki.travel/news/?newsid=434&cate=3>)

According to [10], *Kamishibai* is almost the same as a presentation, but a presentation usually uses power points as supporting media. The *Kamishibai* method has several advantages, which can help students increase self-confidence when appearing in front of people and as a learning medium for writing. Besides being able to train students' cognitive skills, the *kamishibai* method can also make students think creatively.

In [11], there is a publishing company that publishes *Kamishibai* teaching materials used by teachers in schools. Using this *kamishibai* teaching material, the teacher can explain the material to be taught in a fun way by telling stories. Therefore, researchers researched the effectiveness of the *Kamishibai* method in environmental education learning.

In some studies, the *kamishibai* method is suitable for adaptation in learning. Because this *Kamishibai* method does not only offer verbal potential. However, many other possibilities can be extracted from the *Kamishibai* method, such as writing and drawing. This can have a significant impact on learning.

In [12], the author said *kamishibai* could also help students find symptoms and causes of environmental problems by emphasizing environmental problems' complexity, thereby encouraging critical thinking and problem-solving skills. Students can also utilize a variety of learning environments and approaches

in learning environments with an emphasis on changing students' mindsets.

2.2. Hologram for Educational Multimedia

Research on the methods of displaying 3D objects has been carried out in recent years. There are two techniques for displaying 3D objects, namely stereoscopic and autostereoscopic. Autostereoscopic 3D Display methods use projection techniques such as a volumetric display [13] or by using 3D architecture and artificially generated displays [14], [15] for displaying 3D objects. Volumetric displays of strings and projectors that project objects on artificially generated displays such as fog displays and water droplet displays were also developed. At least one projector is needed to project a 3D floating object and the observer cannot reach their hands to the 3D object because there is an artificial screen around the object and the object will disappear when the hands interact with it.

Another more straightforward method for displaying 3D objects without glasses is the concept of pepper ghost using an oblique plane reflector made of acrylic, as shown in Figure X, developed by the previous team [16]. Four symmetrical variations of opposite objects on the LCD screen are projected on the pyramid's four faces, and we adopted from [17]. Through this projection, each side of the object falls in the middle of the pyramid. Figure 2 shows the design of the holographic reflector system on one side.

Figure 2: The concept of hologram reflection[16]

Four symmetrical variations of opposite objects on the LCD screen are projected on the pyramid's four faces. Through this projection, each side of the item falls in the middle of the pyramid. Figure 3 shows the design of a pyramid holographic reflector system.

Figure 3: Build a 3D image object from 4 2D images[16]

2.3. Environmental Education in Indonesia

Environmental Education is one of the efforts in instilling an attitude of environmental love. In UU no. 32 Year, 2009 Republik Indonesia concerning environmental protection and management, it has been stated that the environment is defined as a unitary space that includes all objects, power, and living conditions, including humans and their behavior that affect the environment, the sustainability of life, and the welfare of humans and other

creatures. Environmental education certainly has a particular vision, namely the realization of Indonesian people who have the knowledge, awareness, and skills to play an active role in preserving and improving the environment's quality; this vision was conducted with [18]. Based on this vision, of course, environmental education is taught as early as possible to children, including children aged 7-12 years in elementary school [19].

According to development and basic concepts of environmental education[20], the implementation of environmental education learning in schools has several obstacles, including the methods and materials used which are not yet sufficient so that students' understanding is incomplete [21]. Therefore, in the delivery and learning process, there need to be exciting innovations. Of course, it is connected with daily life so that the learning process becomes more meaningful while answering existing environmental problems.

At the Elementary School level of education, the environmental education material already in the Environmental Education subject has been integrated with other topics such as Indonesian Language and Natural Sciences. This is done because integrated learning can foster students' thinking skills. Following the child's needs, learning becomes more meaningful so that learning outcomes will last longer than learning separately.

One of the environmental education materials in grade 5 Elementary School in theme 2, Clean Air for Health in sub-theme 3, discusses maintaining human respiratory organs. This material was chosen because from 2018 to the present, upper respiratory tract disease occupies the first position in the condition most experienced by Bandung residents. The material teaches children how to prevent respiratory illness through clean and healthy living habits and maintain human respiratory organs.

3. Research Method

The research method is used as a plan for how a study is carried out. To answer all the research problem formulations, a Research & Development (R&D) research or research methodology is often called. Research and development methods are research methods used to produce specific products and test their effectiveness [22]. The research will be carried out for 12 working months, from the preparation stage to the reporting stage. The research will be conducted in two countries, Indonesia and Japan. The data from Japan will be the basis of the development while it is modified to Indonesian's curriculum. The designing stage of *kamishibai* and hologram content firstly will be taken place in Japan. Further development site is carried out at UPI Bumi Siliwangi and UPI Cibiru Campus. The experimentation research on *kamishibai* and hologram usage will take place in two elementary schools in Bandung.

This research will be done with an R&D procedure; however, some addition and grouping make it as seen in the figure below.

- Analysis and data collection
The research started by study the Indonesian curriculum on environmental education. The context is enlisted and explored. The most suitable topic will be selected as an example of the content of *Kamishibai* and hologram multimedia. The system requirement analysis is also done in this step to prepare the development of hologram multimedia.

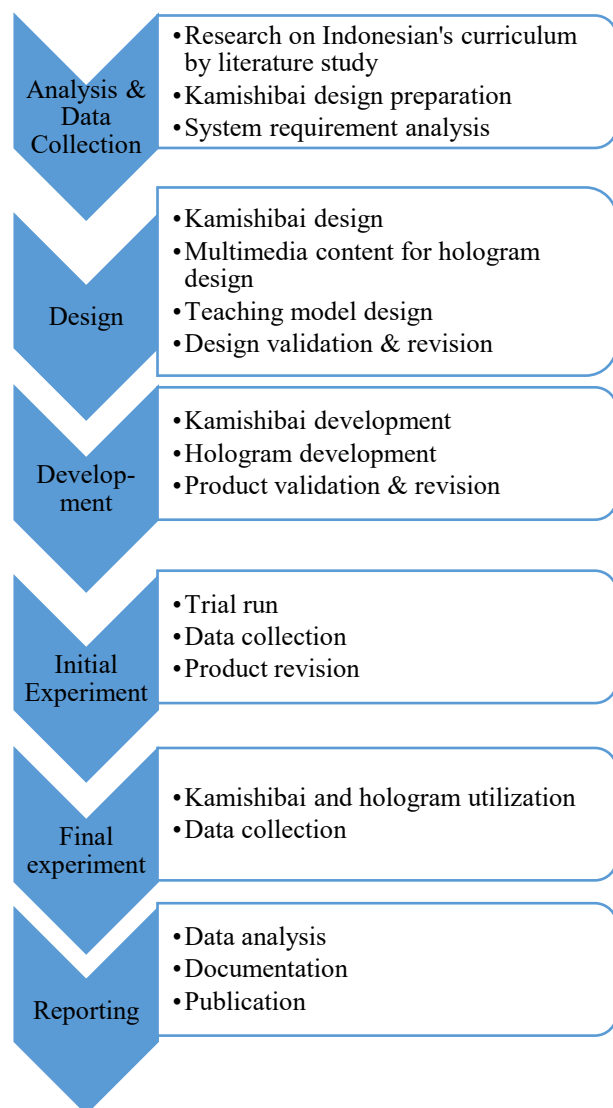

Figure 4: Research Design

- **Design**
The *kamishibai* card and the hologram multimedia should have a meaningful story that is explained through some pictures. Based on the analysis and data collection from the previous step, the content and storyboard are designed. Along with *kamishibai* and hologram multimedia, the teaching model was also developed in this step. Finally, the result of this step should be validated by the expert.
- **Development**
At this step, all of the teaching media is created. Kamishibai's prototype should be printed, and the hologram with its content should be finished to develop at this step. Those products then should be validated by the expert again. After the validation and revision, the production of the *kamishibai* card then should be finished.
- **Initial experiment**
The first trial run is done at a smaller sample of research. At this point, the sample might is not the elementary school student but the student at university. After the trial run, the

product revision will be done according to the trial run's foundation and data collection.

- **Final experiment**
The final trial run is taken place at the elementary school. The real sample is observed, and the research data is also collected in this step
- **Reporting**
The last step of this research is reporting. The research data is analyzed and documented. Finally, the result should be published.

The research instrument in the form of a questionnaire and test are used in this study. This questionnaire aims to get feedback and opinions from the research subject and the expert in terms of user satisfaction and multimedia learning effectiveness. Pre-test and post-test also are delivered in this research to analyze the student's ability improvement.

The study was conducted with research subjects divided into two groups, namely students and expert teams. The expert team is an expert in the field of multimedia and education. In this study, the expert is some selected lecturer from the University of Kitakyushu and UPI. The subjects of the study are elementary school students. For sample selection done randomly or by random area sampling. In [23], the author suggests that in quasi-experimental research, researchers can use existing classes and make one class as an experimental class and another class as a control class. The selection of regions for the sample and control of each of the three schools in the different areas. And each student for the control class and model has equal abilities so that they meet the matching element requirements according to the method approach used.

4. Result and Discussion

4.1. Explore the potential of hologram multimedia as an innovative approach to teach environmental education along with the Kamishibai card

The development of multimedia holograms has been carried out in stages by paying attention to the advantages and conveniences for students who use them. Of course, the same is true for the teachers, where they have to be ready and master what and how this multimedia hologram is, considering that teachers must first master the characteristics of this multimedia hologram which is at the same time how to package environmental education content that they will present to their students. As the research team described in the literary study, visually, this multimedia hologram's design can be seen in the image below.

The kamishibai Hologram product model has been developed from this research, starting from the product engineering development stage, as shown in the picture below.

From the Multimedia Hologram, there are stages of prototype development that must be considered by both the developer and the teacher who will be the user. For example, this prototype's use must be avoided from the instability of the electric current, considering that if it is unstable, it will cause the effect of the holographic object that appears to be weak [24]. This fig. 6 construction will produce a light replicator effect that will display three-dimensional objects [25] as objects presented and seen on

the television screen in front of them. This process allows this hologram-shaped object to attract users who observe it.

4.2. Design and build the hologram multimedia and kamishibai card for teaching Environmental Education in Indonesia

Kamishibai card design and development are integrated and presented through the effect of a hologram containing environmental education material. The theme of environmental education is made in pictorial stories whose content is related to students' world at the age of elementary education, which was conducted from [26]. The results of the developments that have been carried out can be seen in the following.

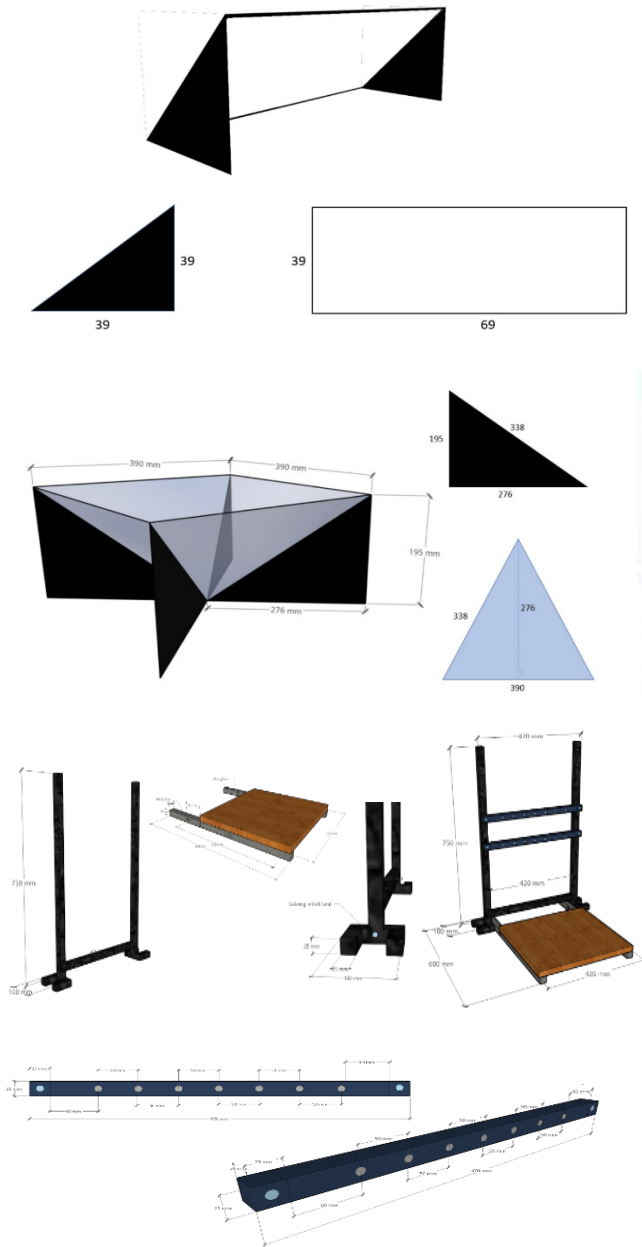

Figure 5: Multimedia Hologram Production Equipment and Materials

Figure 6: Final Product of Hologram Multimedia Kamishibai

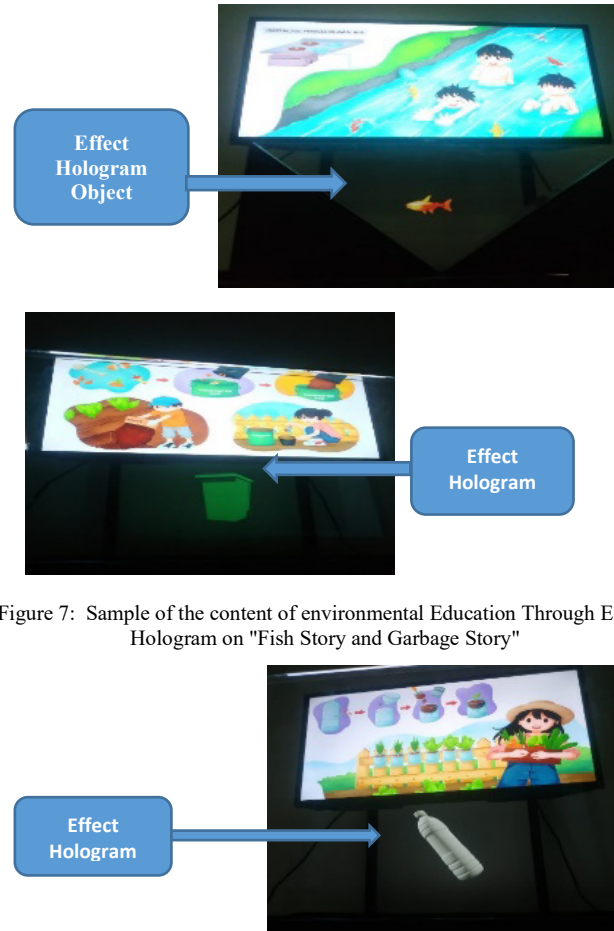

Figure 7: Sample of the content of environmental Education Through Effect Hologram on "Fish Story and Garbage Story"

Figure 8: Sample of the content of environmental Education Through Effect Hologram on "Utilization of Plastic Bottle Garbage"

From the analysis of environmental education content and policies, various points of view can be described to strengthen the development efforts that can be equated through the Kamishibai and Hologram models as formulated in this study[27]. The study of the environment is a spatial unity with all objects, forces, conditions, and living things, including humans and their behavior, which affect nature itself, the continuity of life, and humans and other living creatures' welfare. That is the definition of the environment as in Law No. 32 of 2009 concerning Protection and Management of the Environment. Final Garbage Disposal Place, or TPA,[28]. Garbage is a place to quarantine garbage or pile up garbage transported from a waste source to disturb the environment. This must be the primary target of students' knowledge and attitudes towards environmental learning

materials. The research shows that students' attitudes change after taking lessons with the kamishibai and hologram models they see.

In the notebook, in 1986, environmental and population education was included informal education with the formation of the subject? Population and environmental education (PKLH) ?. The Ministry of Education and Culture felt the need to start integrating PKLH into all subjects at the primary and secondary education levels (general and vocational secondary), the delivery of topics on population and environmental issues in an integrated manner as outlined in the 1984 curriculum system by incorporating population and ecological problems lives into almost any subject. Since 1989/1990 until now, various training pieces on the environment have been introduced by the Ministry of National Education for elementary, junior high, and high school teachers, including vocational schools.

A joint memorandum was issued between the Ministry of Education and Culture and the Office of the State Minister for the Environment No. 0142 / U / 1996 and Kep No: 89 / MENLH / 5/1996 concerning Guidance and Development of Environmental Education, dated 21 May 1996,[29]. In line with that, the Directorate General of Primary and Secondary Education, Ministry of Education and Culture, also encourages the development and consolidation of implementation. Environmental education in schools, among others, through teacher upgrading, encouraging environmental service months, preparation of Population and Environmental Education Implementation Guidelines (PEEIG) for elementary, junior high, high school, vocational school teachers, and beautiful school programs, and others. Meanwhile, NGOs and higher education institutions develop environmental education through seminars, workshops, teacher upgrading, educational facilities such as the preparation of integration modules, reading books, etc.

On 5 July 2005, the Minister of Environment and the Minister of National Education issued joint decree number: Kep No 07 / MenLH / 06/2005 No 05 / VI / KB / 2005, [30] for the guidance and development of environmental education. This joint decision strongly emphasizes that ecological knowledge is carried out in an integrated manner with existing subjects. Environmental Education (EE) is a process to build a human population in the world who is aware of and cares about the total environment (as a whole) and all the problems associated with it, and people who have knowledge, skills, attitudes, and behavior, motivation and commitment to work together, both individually and collectively, to be able to solve various current environmental problems, and prevent new problems from arising[31].

In the context of this research, the meaning of EE or the environment, as described above, basically wants to be seen from the aspect of its sustainability. So that in this context, the understanding of Environmental Sustainability Education according to [32] is explained as: " sustainable development is about integration: developing in a way that benefits the most comprehensive possible range of sectors, across borders and even between generations. In other order words, our decisions should take into consideration potential impact on society, the environment, and the economy, while keeping in mind that: our actions will have implications elsewhere and our efforts will affect the future."

Environmental issues are systemic, complex, and have a broad scope. Therefore, the material or issues raised in the implementation of environmental education activities are also very diverse. Following the national agreement on Sustainable Development stipulated in the Indonesian Summit on Sustainable Development (ISSD) in Yogyakarta on 21 January 2004, 3 (three) pillars of sustainable development have been established: economic, social, and environmental.

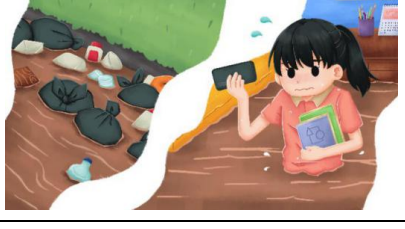

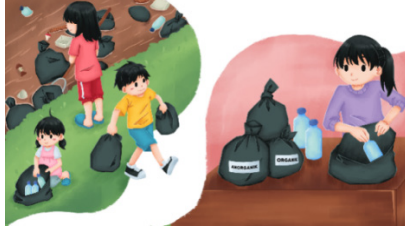

The three pillars form a unity that is interdependent and mutually reinforcing. The core of each post is:

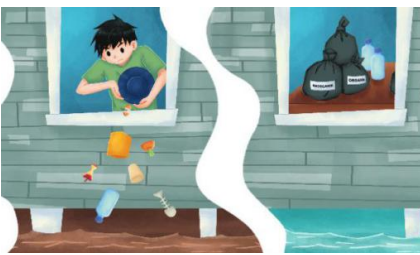

- a) Economic Pillar emphasizes changes in the economic system to make it more environmentally friendly following sustainable development principles. Related issues or materials are: consumption and production patterns, clean technology, funding/financing, business partnerships, agriculture, forestry, fisheries, mining, industry, and trade
- b) Social Pillar emphasizes community empowerment efforts in environmental conservation efforts. Related issues or materials are Poverty, Health, Education, local wisdom/culture, rural communities, urban communities, isolated / remote communities, good governance/institutions, and law and supervision.
- c) The environmental pillar emphasizes the sustainable management of natural resources and the environment. Related issues or materials are water resources management, land resources management, control of air resources, management of marine and coastal resources, energy and mineral resources, conservation of rare animals/plants, biodiversity, and spatial planning.

The team has developed environmental education content used as learning material with the Conventional Kamshibai Models, which will then be projected from the research results. Furthermore, the content development of Kamishibai Hologram Multimedia is carried out; as previously explained, Kamiholo content consists of assets, including kamishibai scenes in the form of 2D images and background sounds. The storyline and content series displayed on the Kamishibai Hologram Multimedia system is as follows.

From the results of the development of the Kamishibai Hologram Multimedia model, several indicators have been found to strengthen the learning of PLH at the elementary school level. A number of these reinforcers include (1) Learning Process; (2) student motivation; (3) PLH Material Content; (4) Multimedia Aspects; and (5) Usage Constraints; and (6) Technology. As for the design results of the development of the Conventional Kamishibai (Cards) model in the form of Cards (Kamishibai Cards), it can be found several influences on the learning process of Environmental Education in Elementary Schools. A number of these indicators include (1) Learning Process; (2) student motivation; (3) PLH Material Content; (4) Media Aspects; and (5) Usage Constraints. The findings of each of these indicators are an explanation of the opinion of the previous research results on environmental learning research, including according to[12], [17], [31], [33].

Table 1: Develop Content of Kamishibai Hologram Multimedia

No. Scene	Kamishibai Image	3D image	Back sound	Story
1		N/A	Music with a cheerful tone.	In the opening scene, the teacher provides an initial description of the material to be delivered.
2		Animated Fish	The sound of water gurgling	Near my house, there is a prominent river. Lots of fish and plants. I love to play by the river. The air is fresh, too; I love the sound of the river water splashing. The teacher interacts with students about the types of fish displayed or fish that have been seen in the river.
3		Garbage bags	Staccato music with a sneaky impression	However, some people throw their garbage into the river so that the river becomes dirty, and a lot of waste piles up in the river body
4		Paper Garbage	The sound of water and panic music	The river became dirty. Lots of trash on the riverbank. Lots of plastic waste on the riverbank. The river water becomes contaminated and cloudy. When it rains, the water overflows, and there is a flood.
5		Types of Garbage: - Paper - Plastic bottle - Cans	Upbeat music	Fortunately, some children are already learning about environmental education. They clean the river. They pick up trash. Invite parents, neighbors, and friends to throw garbage into the river and make the environment clean and healthy. These children already understand the importance of environmental cleanliness. Teachers can deliver material about organic and inorganic waste.
6		Examples of trash: Cardboard Leftovers Glass bottle The plastic toy is broken	Music with an uplifting tone.	They sort trash. Organic waste is used as organic fertilizer. Inorganic waste is taken to the garbage bank. So that their home environment looks clean and the air becomes fresh. The teacher reconfirms the material presented on the previous slide with a 3D image stimulus.
7		Vegetable waste and bone waste	Music with an uplifting tone	Garbage that comes from A home kitchen can be used as organic compost to fertilize plants in your home to make it healthier.

8		PET bottles	Music with inspirational tones	We can grow crops, with healthy vegetables or flowers. We are planting vegetables in bottled pet media. We can use plastic bottles as a medium. Do you have plastic bottles in your house?
9		Wastewater	Music with inspirational tones	Likewise with dirty water from home. Used bathroom water, Water from washing dishes, water from washing clothes. These are referred to as household wastewater. Let's filter it out in the water management plant And throw it into the river.
10		N/A	Music with impressions provokes thought.	Then, what do you think? If all the people in your city keep the river clean, Do not throw garbage into river bodies, and do not dispose of wastewater into rivers. What do you think? The teacher concludes the material that has been delivered.
11		N/A	Music with inspirational tones.	What can we do? So that our rivers will be clean? The teacher opens discussions and reflects on the material with students.

5. Conclusion and Recommendation

Exploring the potential of multimedia holograms as an innovative approach to teaching environmental education and Kamishibai cards has been systematically formulated in this study. The multimedia development approach is directed at supporting multimedia resources. Students are more attracted when they know the various types of waste in the environment that can be used or recycled. Of course, through the multimedia hologram found in this study, students have determined the garbage classification only for recycling. Likewise, with the trash around the river, with this multimedia hologram media design, students have been able to identify it too because they have clearly shown the effect of an authentic hologram.

Designing and building kamishibai cards and multimedia holograms for learning Environmental Education in Indonesia have been shown from the research results in the form of a series of storyboards in pairs between descriptions and serial picture cards as kamishibai cards. These findings have been formulated in lesson plans regarding a series of explanations about students' care and ability to demonstrate literacy, knowledge, attitudes, and psychomotor, which are facilitated when making decisions about caring for the surrounding environment. Through this research,

students are aware that they will maintain the balance of nature and the environment's cleanliness, which they show through their real knowledge, attitudes, and activities. Thus, this change has been demonstrated to show the multimedia hologram prototype's strength, providing concrete messages about all environmental education content at the basic education level.

Pandemic

Covid-19

ABSTRACT

This article aims to determine to what extent the self-perception of acquiring professional skills has been affected, by the context of the Covid-19 pandemic in University Students of Business Administration; For which, the results obtained in two satisfaction survey processes, carried out in academic semesters 2019-B and 2020-A, have been compared, marking a before and after in relation to the declaration of a state of emergency in Peru. Initially, it was determined that the indicators "To solve specialty cases" and "To assume self-education" are the most affected in this dimension, with a percentage of decrease in satisfaction of 3.42% and 3.82%, respectively. Then it was determined through the use of the statistical analysis of crossed tables, that the percentage of totally dissatisfied students, in the self-perception of having acquired the competences referred to the two indicators with the greatest negative impact, has remained invariant, almost constant, around of 44%. With this, it can be concluded that the self-perception of acquiring professional skills has been affected, by the context of the Covid-19 pandemic, decreasing by 3.1%, student satisfaction, as observed in the two indicators with the greatest impact negative "To assume self-education", and "To solve specialty cases". These results will allow the Public University of Peru to establish improvement plans, in order to advance towards the development of the teaching-learning model in a virtual way in higher education.

1. Introduction

Society has seen the need to adapt in multiple areas to an unexpected enemy; In the study of [1], it is pointed out that this unexpected enemy has affected the way in which living beings coexist in a society, and within this is the University community and its learning. Likewise, in the research of [2] it states that more than 1,500 million university students, from 165 countries, were unable to attend learning centers, due to the Covid-19 pandemic.

In the study of [3], it is specified that the context of Covid-19, from one day to the next, led the university student to be forced to change the classrooms for rooms in their houses, replacing the learning contents, tasks and activities face-to-face through content based on virtual environments.

Given this [4], he points out that for the university student the circumstances generated by the Covid-19 pandemic imply changes that require capacities that, in many cases, may be underdeveloped to adapt to the type of virtual educational modalities.

In the research of [5], it is pointed out that many universities worldwide in the context of Covid-19, have seen the teaching-

^{*}Corresponding Author: Nestor Alvarado-Bravo, Mz. K Lote 22, Urb. La Estancia de Carabayllo, Distrito de Carabayllo, 951201999, nmalvaradob@unac.edu.pe

learning process affected, even more so in pedagogical aspects on the side of the teacher and the acquisition of competences by the student's side.

In the study of [6], a professional competence is defined as the ability of an individual to interact effectively with their environment, as long as it is learned, as part of a stepped process; competition is closely related to motivation or satisfaction.

In turn, the study of [7] affirms that in the face-to-face system the perception of satisfaction in relation to the acquisition of professional competences was influenced by learning based on direct social interactions, however, in the virtual system it is Perception can be further influenced by the lack of a fluid and direct dialogue.

In the research of [8], it is pointed out that, in the context of the pandemic, it is evident that many universities to adapt to this scenario have not carefully innovated the teaching-learning design, but rather in the process of developing the classes they have been adapted according to the circumstances, leaving aside the development of the student's competencies.

In the study of [9], the author agrees with what was said in the previous paragraph, in which he points out that we must be aware that in order to plan virtual courses, the ideal is to start preparing them much earlier (months in advance), in such a way that a learning process was designed that guarantees that students reach the competences of each subject; but this has not happened when the pandemic occurred.

In the same line of thought as the previous author, in the study of [10], it is pointed out that the context of the pandemic has not only made the existing deficiencies and major inequities more noticeable, which already made it difficult to achieve the achievement of competencies in the university students in the face-to-face context, has also brought to light the deficiencies of acquiring these skills through virtual environments.

In Peru, and through the Ministry of Education, Vice-Ministerial Resolution No. 085-2020-MINEDU was promulgated, in which guidelines are given for the continuity of the university higher education service, in the framework of the health emergency caused by the covid- 19; However, in the study of [11], it is pointed out that in Peru, it had to face the crisis in an abrupt and unexpected way.

However, even before the presence of the pandemic, there was the problem of the acquisition of skills by university students; In the study of [12], it is pointed out that university education currently poses significant challenges in the search for an education that contributes to the realization of a relevant society, responding to the needs of the labor and business system.

In this regard, in the study of [13], it is pointed out that the professional competences acquired by the students of the professional career of Business Administration turn out to be necessary for a correct development in the field of human talent management in organizations, the orientation of seeking that workers have key competencies so that companies are competitive is assumed.

Based on the above, the purpose of this article is to determine to what extent the self-perception of acquiring professional skills

has been affected by the context of the Covid-19 pandemic; For which, the results obtained in two satisfaction survey processes, carried out in academic semesters 2019-B and 2020-A, will be compared, marking a before and after in relation to the declaration of a state of emergency in Peru. It will be sought to highlight which indicators of this dimension called self-perception of competences are the most affected, and whether there is coherence between the decrease or increase of these indicators, through the use of the statistical analysis of crossed tables, for qualitative data of nominal.

2. Investigation methodology

2.1. Research design

The research design is non-experimental, of a longitudinal trend type, because no alteration or modification of the variable was made, in order to see any effect on the sample under analysis; in non-experimental investigations the data is analyzed in its natural state.

In addition, it is of the longitudinal type of trend since the data to be collected were carried out in two different academic semesters (Before the declaration of pandemic- 2019-B, and after the declaration of pandemic- 2020-A).

The research level is descriptive, because the variables are not altered, and what is intended to highlight are the aspects related to the variation of the Self-perception of university students of Business Administration with respect to Professional Competences, which are established in the satisfaction survey of the Public University of Peru.

2.2. Population and Sample

The population will be made up of university students from the seventh to the tenth cycle of the professional school of Business Administration, enrolled in the academic semester 2019-B and 2020-A. Regarding what has been described [14], it indicates that students who are in the last four cycles of study are more aware of the perceptions in relation to the satisfaction of professional skills.

On the other hand, the sample under study will be made up of the entire population, since it was possible to apply the data collection instrument to the entire student population, without any distinction, this with the purpose or purpose of achieving better precision in obtaining results.

It should be noted that the data collection period is carried out at different times, and at different samples, because the number of students surveyed is not the same in the 2019-B semester, as in the 2020-A semester.

Table 1: Research population and sample

Population	Sample
University students enrolled, from the seventh to the tenth cycle - Business Administration 2019-B	135
University students enrolled, from the seventh to the tenth cycle - Business Administration 2020-A	155

Table 1 shows precisely that the sample will be made up of 135 students from the 2019-B semester and 155 students from the 2020-A semester.

2.3. Data Collection Technique and Instrument

The technique used in the present investigation is the document analysis technique, and the instrument is a data record sheet. This is because the source I will turn to extract the data are reports from the student satisfaction survey reports for the academic semesters 2019-B and 2020-A, approved by the office of academic and prospective management, of a university state in Peru.

It is important to note that the record sheet used as a data collection instrument takes as a variable to analyze the self-perception of professional competences, which in turn consists of ten indicators, the same ones shown in Table 2.

Table 2: Indicators of self-perception of professional skills

Nº	Indicators of self-perception of skills
1	To work as a team
2	To solve problems and cases of the specialty
3	To act with autonomy and initiative
4	To confront your own ideas with others
5	To speak in public with appropriate language
6	To have a positive attitude towards change
7	Assume a self-study
8	To master practical professional skills
9	To work under pressure
10	To have investigative powers

Likewise, the data collected was processed and transformed, initially using the scale of attitudes and opinions, known as the Likert scale; Since the questionnaire has two self-perception options to choose from, being dissatisfied and satisfied, each one was valued with the numeral 1 and 2, respectively.

It should be taken into account that for the statistical analysis of crossed tables, the Chi-Square test will be carried out, in order to validate the hypothesis, which indicates the association between the variables under study. It should be noted that usually, H0 indicates that both variables are independent, while H1 indicates that the variables have some degree of association.

Described in the previous paragraph, we proceed to establish the null hypothesis (Ho) and alternative (Ha) that will be used in the investigation.

Ho: The self-perception of acquiring professional skills has not been affected, by the context of the Covid-19 pandemic.

Ha: The self-perception of acquiring professional skills has been affected, by the context of the Covid-19 pandemic

3. Research Results

The data collected were subjected to a validity analysis through Cronbach's alpha. It should be noted that since two different scenarios were worked, that is, one scenario is in the context of face-to-face classes, that is, before the declaration of the state of

health emergency by Covid-19 (Semester 2019-B) and the other scenario It is the context of virtual classes (Semester 2020-A). Table 3 shows the results of Cronbach's alpha.

Table 3: Validation of collected data - Cronbach's Alpha

Validation of collected data Cronbach's alpha	Cronbach's Alpha
Self-perception of professional competences 2019-B	0.938
Self-perception of professional competences 2020-A	0.908

3.1. Comparative analysis of the Indicators of the self-perception of professional competences

In the comparative analysis of the percentage of satisfaction of the indicators of self-perception of professional competence before (semester 2019-B) and after (semester 2020-A) of the declaration of a state of health emergency due to the pandemic, it can be seen in the Figure 1, that the indicators that show a greater negative impact or decrease in satisfaction as an effect of carrying out the teaching-learning process in a virtual way, are the indicator "To solve cases of the specialty", with a percentage of decrease in satisfaction of 3.42%, while the other indicator is "To assume a self-education", with a percentage of decrease in satisfaction of 3.82%; The analysis will basically focus on these two indicators, since in the other cases it is observed that the level of negative impact with respect to the level of satisfaction is below 2.5%, that is, it is relatively lower in relation to the high levels shown Most of the indicators that make up the self-perception variable, whose satisfaction level before the pandemic was in the range of 80.74% and 89.63%, while after the declaration of the pandemic it is in the range of 79.35% and 87.10% ; As i emphasize again, these values are above the average for student satisfaction in general, which is 63%.

Figure 1: Comparison of the percentage of satisfaction of the indicators of self-perception before and after the declaration of the COVID-19 pandemic

Next, we will proceed to verify if there is an association between these two indicators, through the statistical analysis by cross table. This analysis will be carried out by academic semester, that is, before and after the declaration of the state of health emergency.

3.2. Level of association of indicators with the greatest negative impact on self-perception

The results of the chi square test are shown below, to determine the association between the variables.

Table 4: Chi-square test

	Value	gl	Continuity correction
Pearson's Chi-square	32,023	1	,000
Continuity correction	28,952	1	,000

As can be seen in Table 4, the value of the Chi-square statistic is 32.023 and the continuity correction is 28.952; Regarding these indicators, it has been established according to different authors that they are valid when the value of an expected frequency is greater than 5, for significance levels greater than 0.05; as described and as shown in the table above, for both cases, the test results comply with what is established.

On the other hand, the significance (bilateral) of the Chi-square is 0.000; This value is less than the level of significance, $\alpha = 0.05$, according to different authors, if the observed results are greater than $\alpha = 0.05$, that is, they differ from what is theoretically established, it is possible to reject H_0 and affirm that H_a is true, concluding that the variables are associated. On the contrary, if the observed results do not differ significantly, that is, the bilateral significance is less than and equal to alpha, the veracity of H_0 is confirmed and it is affirmed that the variables are independent.

With what was obtained, it would be validating that the self-perception of acquiring professional skills has been affected, by the context of the Covid-19 pandemic. Once this association has been verified, the level of association of the indicators with the greatest negative impact on self-perception will be determined, which were identified in the previous point 3.1.

Using the statistical software SPSS v25, the results obtained from the descriptive analysis are shown below through cross tables; This is due to the fact that the indicators represent qualitative data related to student satisfaction and dissatisfaction, corresponding to the indicators with the greatest negative impact or decrease with respect to the self-perception of professional skills, identified in the previous section.

Table 5: Cross table - to assume a self-education and to solve problems and cases of the specialty-2019 B

		To solve problems and cases of the specialty, 2019-B		Total
		Dissatisfied	Satisfied	
To assume a self-education, 2019-B	Dissatisfied	44.0%	2.7%	10.4%
	Satisfied	56.0%	97.3%	89.6%
Total		100.0%	100.0%	100.0%

From Table 5, it can be seen that before the declaration of the state of health emergency due to the pandemic (academic semester 2019-B), 44% of students from the professional school of Business Administration were dissatisfied with the self-perception of having acquired professional competences referred to "To assume a self-education", as well as "To solve cases of the specialty"; While 97.3% of students from the professional school in question, were satisfied with respect to the self-perception of having acquired professional competencies referred to "To assume a self-education", as well as "To solve cases of the specialty".

As can be seen in Table 5, it shows us the results as a percentage, while the following table 6 shows the count of satisfaction and dissatisfaction, of the 135 students of the semester 2019-B, who have the same relationship between their perception and the self-perception of having acquired skills. professionals referred to "To assume a self-education", as well as "To solve cases of the specialty"

Table 6: Cross counting table - to assume a self-education and to solve problems and cases of the specialty-2019 B

		To solve problems and cases of the specialty, 2019-B		Total
		Dissatisfied	Satisfied	
To assume a self-education, 2019-B	Dissatisfied	11	14	25
	Satisfied	3	107	110
Total		14	121	135

Figure 2 shows the representation of the results obtained.

Figure 2: Indicator association count to assume a self-education and to solve problems and cases of the specialty-2019 B

As can be seen in Figure 2, and according to the count of the total of 135 business administration students, 11 students were dissatisfied with the self-perception of having acquired professional competences referred to "To assume a self-education", as well as "To resolve specialty cases" and 107 students were satisfied with these two indicators.

From table 7, it is observed that after the declaration of the state of health emergency due to the pandemic (academic semester 2020-A), 44.1% of students of the professional school of Business Administration were dissatisfied with the self-perception of having

acquired professional skills referred to "To assume a self-education", as well as "To solve cases of the specialty"; While 94.2% of students from the professional school in question were satisfied with respect to the self-perception of having acquired professional competencies referred to "To assume a self-education", as well as "To solve cases of the specialty".

Table 7: Cross table - to assume a self-education and to solve problems and cases of the specialty, 2020-I

		To solve problems and cases of the specialty, 2020-A		Total
		Dissatisfied	Satisfied	
To assume a self-education, 2020-A	Dissatisfied	44.10%	5.8%	10.4%
	Satisfied	55.90%	94.2%	89.6%
Total		100.0%	100.0%	100.0%

As can be seen in Table 7, it shows us the results as a percentage, while the following table 8 shows the count of satisfaction and dissatisfaction, of the 155 students of the semester 2020-A, who have the same relationship between their perception and the self-perception of having acquired skills. professionals referred to "To assume a self-education", as well as "To solve cases of the specialty". In the figure 3 shows the representation of the results obtained.

Table 6: Cross counting table - to assume a self-education and to solve problems and cases of the specialty-2020 A

		To solve problems and cases of the specialty, 2020-A		Total
		Dissatisfied	Satisfied	
To assume a self-education, 2020-A	Dissatisfied	11	14	25
	Satisfied	3	107	110
Total		14	121	135

Figure 3: Indicator association count to assume a self-education and to solve problems and cases of the specialty-2020 A

As can be seen in the figure 3 and according to the count of the total of 155 business administration students, 15 students were dissatisfied with the self-perception of having acquired

professional competences referred to "To assume a self-education", as well as "To resolve specialty cases" and 114 students were satisfied with these two indicators.

Thus, it can also be observed that the percentage of students from the professional school of Business Administration, who were previously fully satisfied in the self-perception of having acquired professional skills referred to "To assume a self-education", as well as "To solve cases of the specialty", Has had a negative impact, as an effect of the teaching of classes through virtual platforms, since it has decreased by 3.1%, while the percentage of totally dissatisfied students, in the self-perception of having acquired the aforementioned competences, has been kept invariant, almost constant, at around 44%.

4. Discussion of results

In relation to the discussion of the results, the following can be specified:

- The results show that the indicators that show a greater negative impact or decrease in satisfaction as an effect of carrying out the teaching-learning process in a virtual way, are the indicator "To solve cases of the specialty", and the indicator "To be assumed a self-education". Regarding this, in the study of [15] it is indicated that, in the career of business administration, professional competences are used as an organizing principle, and they serve to face the types of situations that students have to be capable of. solve effectively in the workplace; Therefore, the great importance of teamwork, as an organizational set, will have a positive impact on the internal logic of the business world.
- Regarding the result, where it is indicated that the percentage of students of the professional school of Business Administration, who before were totally satisfied in the self-perception of having acquired professional skills referred to "To assume a self-education", as well as "To solve cases of the specialty", has had a negative impact, as an effect of the teaching of classes through virtual platforms, decreasing by 3.1%. Given this, it can be argued that these two indicators are affected, with respect to student satisfaction, because, in virtual classes, they are not getting to work, an essential factor, such as the development of skills and competencies, which through face-to-face learning, was obtained through teamwork, which allowed students to communicate effectively, function, transmit new ideas, show their creativity; which leads to generating in each one their leadership style and their positive influence on others. As indicated in the study of [16], administration professionals define that teamwork is highly valued in today's companies, and that it is necessary for the collaborator to contribute intellectual capital to the company and to the development of the human team that make up.
- Regarding the result that shows us that the percentage of totally dissatisfied students, in the self-perception of having acquired the skills referred to "To assume a self-education", as well as "To solve cases of the specialty", through the teaching of classes through of virtual platforms has remained invariant, almost constant, at around 44%. It can be indicated that students perceive these extremely important

competencies, and in both teaching-learning scenarios, there have not been updated information and communication technology tools, used in administrative management, marketing planning and strategic planning, tactical and operational. Regarding this, in the study of [7], it is indicated that the administrative technological tools have the objective of guiding the methodological and didactic actions, which allow not only to improve the cognitive system, but also the qualities and principles of the student. of administration.

- Given the results obtained, it can be said that they resemble the study carried out by [16] where it is stated that there is a (bilateral) significance lower than $\alpha = 0.05$, therefore it can be statistically supported that there is a significant association between the Analyzed indicators, Since, when the student feels with the ability to master practical professional skills, it becomes much easier for him to solve problems and cases of the specialty, thus being able to present himself in front of the labor market.

5. Conclusions

In relation to the conclusions, the following is specified:

- The self-perception of acquiring professional skills has been affected, by the context of the Covid-19 pandemic, decreasing by 3.1%, student satisfaction, as observed in the two indicators with the greatest negative impact "To assume a self-education", and "To solve specialty cases".
- The indicators that show a greater negative impact or decrease in satisfaction as an effect of carrying out the teaching-learning process in a virtual way, are the indicator "To solve cases of the specialty", with a percentage of decrease in satisfaction of 3.42%, while the other indicator is "To assume a self-education", with a percentage decrease in satisfaction of 3.82%.
- The statistical analysis of crossed tables shows us that the percentage of totally dissatisfied students, in the self-perception of having acquired the skills referred to "To assume a self-education", as well as "To solve cases of the specialty", through the dictation of classes through virtual platforms has remained invariant, almost constant, at around 44%.

Conflict of Interest

The authors declare no conflict of interest.

Lake Victoria basin

Conservation planning

ABSTRACT

The ecosystems and landscape patterns in Lake Victoria basin are increasingly being modified by changes in land use/land cover. Understanding dynamics of these changes is essential for appropriate planning. This study evaluated changes in landscape environment, of the lakeside counties of the Kenyan Lake Victoria basin, which have occurred over a forty-year period (1978-2018) and their potential impacts on the lake using remote sensing and GIS techniques. Landsat imageries of 1978, 1988, 1998, 2008 and 2018 were analyzed for each county to develop land use and land cover maps and to detect and quantify changes using the Maximum Likelihood algorithm. Supervised classification was utilized. The study showed that the six land use/land cover classes, identified in the counties, have undergone drastic modifications in a span of four decades. Over the years, built-up areas steadily increased in all the counties, forested and vegetated areas steadily declined in all the counties, areas under water bodies remained relatively constant in all counties, while the rest of the land use and land cover types experienced periodic rise and falls in areal coverage. Generally, the major gains in coverage by the various land use and land cover types occurred between 2008 and 2018 while major losses occurred between 1978 and 1988. The study suggests that future regional conservation measures should take cognisance of the general ecological and socio-political processes in the entire Lake Victoria basin for integrated watershed conservation.

1. Introduction

Land use and land cover are often used together to describe the terrestrial settings relative to both anthropogenic and natural processes [1-3]. Land use and land cover change has increased on local and global scales over the past few years [4-6]. This is driven by a synergistic effect from biophysical, political and socio-economic factors [7, 8]. Studies have shown that, it is the complex interactions of these factors, coupled with population pressure and technological advancements, which results in land use and land cover change [1, 6, 9]. This implies that interactions between

human and natural factors are the root causes of land use and land cover changes on the earth's surface.

Land use and land cover has been transforming from the time humankind started manipulating their surroundings [10]. The changes in land use and land cover impact both the biotic and abiotic components of the ecosystems of the earth [11]. The patterns of natural catastrophes, climate and socio-economic livelihoods are negatively impacted by land use and land cover modifications at both local and global levels [12]. Moreover, studies have indicated changes in land use and land cover to be the major cause of widespread species extinction, replacements as well as biotic differentiation or homogenization [13, 14]. There is a growing interest, since the last decade, on the effects of land use

*Corresponding Author: Dancan Otieno Onyango, dancanthomas@gmail.com

and land cover change globally [15]. Traditionally, land use and land cover has been a critical research area locally and globally [16, 17]. This is driven by the need to understand landscape patterns and how they are influenced by interactions with natural processes and anthropogenic activities. Such understanding is necessary for improvement of decision-making and management of land [18].

Remote sensing has been a major source of data for the historical land use and land cover conversion. It utilizes various techniques and datasets to produce land cover change analysis, an evaluation of the various classes and their accompanying changes over time [19]. Remote sensing is capable of revealing the nature, magnitude and spatial trends of land use and land cover changes, which is vital for monitoring urban development and natural resources for their effective management [1]. A large volume of literature suggests that remote sensing using Landsat imageries have greatly aided the large-scale classification of various landscape components in screening for land use land cover problems [20].

Land use problems are widespread in both developing and developed world [21]. In the developed world, Mediterranean biodiversity loss from land-use/land-cover change, associated with increased cultivated areas, has been reported in Italy [22] while forest drying is reportedly common in Ukraine and Latvia countries [23]. In Southern and South East Asia, widespread air quality issues due to rapid industrialization, urbanization and increased energy demand has been reported [24]. It is also worth noting that substantial quantities of greenhouse gas emissions, due to intensification of agricultural activities, has been recorded in Eastern European nations including Slovakia [21]. In US cities, increased non-point-source pollution from various degrees of urbanization has been reported [25]. In the developing world, dwindling biological resources diversity in rural areas of Ethiopia and Eritrea, which are experiencing overgrazing and encroachment by farms has been mapped [26]; widespread desertification and land degradation has been reported in Benin [27] while major changes in land use and cover have caused environmental problems in catchment areas in Tanzania, including drying of streams and rivers [28].

Kenya, like many African countries whose economy is heavily dependent on agricultural production and exploitation of natural resources such as forests, is facing land use and land cover change challenge [29]. The lake region of Kenya encompasses five counties of Migori, Busia, Homabay, Kisumu and Siaya. This region has the Lake Victoria watershed which contains numerous wetland resources that sustain the livelihoods for the surrounding communities [30]. Wetlands of Lake Victoria account for 37% of total land surface in Kenya [31]. Studies have shown that the hydrology of Lake Victoria itself and the numerous wetlands within its basin, including rivers, have been altered by the changes in land use and land cover within the lake region [32,33]. With the current trends in climate change, the impacts of land use and land cover change are poised to put more strain not only on the ecological resources found in the basin but also the socio-economic conditions of the riparian communities. The quantity and dynamics of these land use and land cover changes within the whole Lake Victoria basin area are still currently not well understood because none of the limited studies that exists has valued the entire lakeside region. Mapping and quantifying the

land use land cover changes and assessing its effects in the whole lakeside region will make great contribution in providing information for effective policy and regulatory changes in land use and environment planning and management.

This study mapped the changes in land use and land cover that have occurred in the five counties of the lake region overtime. These counties were chosen because of their proximity to the Kenyan portion of Lake Victoria and changes in the environment within these counties will not only have an effect on the riparian communities, but also on the lake itself. The Lake is the greatest natural resource in East Africa supporting millions of people [30]. The adoption of the devolved system in Kenya through the new constitutional dispensation promulgated in 2010, has resulted in rapid population growth, urbanization and socio-economic activities in the five Kenyan lake-side counties over the years. This has brought about changes in the land use and land cover in this important region. The main objective of the present study is to evaluate changes in the landscape environment of the riparian counties that have occurred over forty-year period (1978-2018) and their potential impacts on the Lake Victoria basin environment using remote sensing and GIS techniques.

2. Materials and Methods

2.1. Study Area Description

Occurring along the equatorial region, Lake Victoria is situated between latitudes 0°20'N–3°S and longitudes 31°39'E–34°53'W [34], at an elevation of 1134m above sea level [30]. The lake surface (water) spans an area of 68,000 Km² which is shared among three countries of East Africa – Tanzania (49%), Uganda (45%) and Kenya (6%). Lake Victoria is the most critical natural resource in the region, supporting about 30 million livelihoods within its basin [29]. The basin is a unique resource to the East African Community because it provides water, fisheries, wildlife, natural forests as well as tourism and transport services [35]. Moreover, holding an estimated water volume of 2750 Km³, the lake is the second largest freshwater lake in the entire world [30]. Lake Victoria has both inlets in form of major rivers such as Sondu Miriu, Yala, Awach and Nzoia, among others, and outlet in the form of the White Nile River, which outflows northwards from Uganda to Egypt. The region experiences a mean annual rainfall of between 900 mm and 2600 mm, making precipitation the main source of water for the Lake Victoria.

The Kenyan region of Lake Victoria basin, which is the subject of this study, covers about 22% of the 195,000 Km² total basin area. This lies in the western parts of Kenya – Nyanza and parts of Rift Valley and Western Province. In the immediate border of the lake are five administrative counties namely, Homabay, Migori, Kisumu, Siaya and Busia (Figure 1). The counties are new regional units of administration, experiencing different levels of population growth, urbanization and socio-economic activities as more development resources are devolved to them. This is likely to exacerbate land use and land cover changes with negative environmental implications. This study is based on comparing the possible land use and land cover changes among the lakeside counties (hereafter referred to as Kenyan Lake Victoria Basin, KLVB) and their implications on the basin environment.

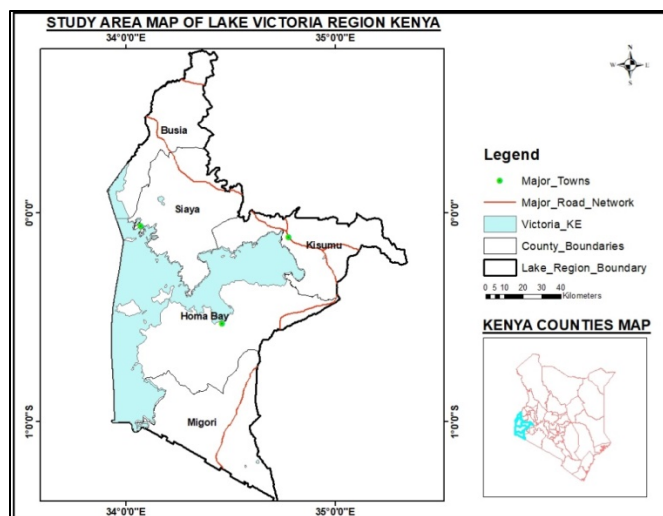

Figure 1: The Kenyan Lake Victoria Basin (KLVB)

2.2. Methodology

Data Sources and Data Acquisition Methods

A combination of remote sensing and GIS techniques were employed in analyzing and comparing LULC changes during the 1978–2018 periods. The study used data sets obtained from Landsat images acquired for the dry month (January) for the years 1978 (Landsat 3 Multispectral Scanner); 1988 (Landsat 4, 5 Thematic Mapper, TM); 1998 (Landsat 4, 5 Thematic Mapper, TM); 2008 (Landsat 4, 5 Thematic Mapper, TM) and 2018 (Operational Land Satellite – Thematic Infrared Sensor) from the United States Geological Survey (USGS) website www.earthexplorer.usgs.gov. The properties of these imageries are presented in Table 1. All the imageries were acquired for the dry month of January because the absence of both cloud cover and moisture content are necessary for minimal reflectance.

Data Pre-processing

To enhance visualization and interpretability, the acquired Landsat imageries were systematically pre-processing through ERDAS Imagine 2015 Version. The images were extracted in compressed formats to obtain separate bands. The first step involved compositing images for each county to bring out the true colour image of the scene. Pan sharpening was then carried out and this involved using panchromatic bands to enhance the spatial resolution of panchromatic images from 30m to 15m. In order to reduce the effects of haze captured on the Landsat images, haze reduction was carried out as the major radiometric correction. Mosaicking was necessarily required because of the large study areas and therefore three separate images were utilized (Kisumu, Migori and Homa Bay counties occupied two images while Busia and Siaya counties occupied one single image). These three separate images were mosaicked into one single image covering the whole area for the ease of processing. Finally, sub-setting process was done using the shapefiles of the counties Kisumu, Siaya, Busia, Homa Bay and Migori. The shapefiles were used to

subset from the main image the images of interest for respective counties.

Data Processing and Analysis

The 2015 version of ERDAS Imagine and ArcGIS 10.5 software were used in the data processing. ERDAS Imagine was employed in carrying out supervised classification through the Maximum Likelihood algorithm [36] to obtain the land use and land cover classes. The supervised classification process through the Maximum Likelihood algorithm is essentially controlled by the analyst who specifically selects the pixels that are representative of the desired LULC classes. In the classification process for this study, the LULC classes of interest were defined as water bodies, forest cover, grasslands & vegetation, agricultural land and built-up areas. Six (6) ground-truth polygons, each representing the six LULC classes, were then randomly selected and digitized based on aerial photographs and visual analysis of geographical locations on Google Earth maps. Each training sample polygon used in classification process contained 17 pixels, bringing the total training sample to 100 pixels. The training sample polygons which were found with unwanted pixels were thrown out and replaced with the new ones with wanted spectral signatures. After training the image using signature editor, the Maximum Likelihood algorithm was run a couple of times to obtain the defined classes in the image. Since the images were of medium resolution, Pixel based classification was employed. The final Land use and Land cover maps with appropriate cartographic properties for the years 1978, 1988, 1998, 2008 and 2018 were produced using the ArcGIS software for the respective counties. This entire process led to the identification of six land use and land cover categories.

Post-processing

Accuracy assessment is a post processing procedure of remote sensing which compares the information from the classified land use and land cover maps with the information from ground reference points. This process is essential for assessing the quality of data acquired from Landsat imagery [37]. Based on this premise, accuracy confusion matrixes were computed for the classified images having the different land use and land cover classes. A confusion matrix is appropriate for authenticating classified satellite imageries [38]. The confusion matrix, also known as error matrix, analyzes the statistical components of producer's accuracy, user's accuracy, overall accuracy, kappa statistics and overall kappa co-efficient [39]. These statistical elements were produced for all the LULC images of respective riparian counties. This study utilized 100 random reference points which were subsequently ground truth to validate the actual land use/land cover type. The location of the ground random reference points were identified on the medium-resolution images and their class values specified to ascertain the accuracy of a pixel. Using the recommended formulas [40], the accuracy reports were calculated for each of the LULC classes in each of the images, containing the values for producer accuracy, user accuracy,

overall accuracy and Kappa coefficient. Finally, a confusion (error) matrix report was computed for all of the LULC maps used.

Change detection analysis was subsequently used to evaluate the areal coverage of the different LULC classes for each map. This was done by considering the pixel count against the total area of the basin. The information obtained was expressed in percentage coverage and square kilometres for each of study years (1978, 1988, 1998, 2008 and 2018) for the five riparian counties. Net changes in areal coverage were then analysed for respective LULC classes in order to unravel specific changes of the landscape environment. A comparison was then made on the degree of LULC changes among the five lakeside counties of the Lake Victoria basin and their implications for the larger basin environment analyzed.

3. Results and Discussion

3.1. Distribution Pattern and Trends of LULC Categories

The study identified six LULC classes in the riparian counties Busia (Figure 2), Siaya (Figure 3), Migori (Figure 3), Homabay (5a & 5b) and Kisumu (6a & 6b). All the counties were found to be characterized by agricultural land (includes surface areas dedicated to the cultivation of crops, vegetables and fruits); water bodies (includes areas under rivers, lakes, swamps and wetlands); grasslands & vegetation (includes areas covered by grasses, shrubs and bushes); bare land (includes exposed rocky or soil surfaces lacking any vegetation cover); forests (includes areas under naturally occurring or planted indigenous and exotic trees) and built-up areas (includes areas under residential, commercial, industrial and infrastructural establishments). The results confirmed findings from previous study which had shown similar land use land cover categories on the Ugandan basin of Lake Victoria [41]. The spatial-temporal coverages of these LULC

classes are presented in Tables 2-6. From the tables, the results indicate that in terms of total surface area, Homabay County is the largest with 4759.57 km², followed by Siaya County (3706.88 km²), Migori County (3166.12 km²), Kisumu County (2680.32 km²) and finally Busia County (1819.40 km²).

3.2. Relative Spatial-Temporal Change in LULC

Agricultural Land

In 1978, agricultural land coverage (2850.68 km²) in Homabay County was higher than in Migori, Siaya, Kisumu and Busia. Similar trend in agricultural land coverage was observed in 2018. Generally, all counties recorded slight net losses in agricultural land coverage from 1978 to 2018 (Figure 7). However, decade-by-decade analysis shows that both positive and negative growth patterns were realized in the coverage of agricultural land during the period between 1978 and 2018 (Figure 7). From 1978–1988, agricultural land decreased in the counties of Busia, Migori, Kisumu and Siaya by 10.71%, 6.62%, 1.14% and 1.03% respectively, while it increased in Homabay County by 1.25% (Figure 7). Between 1988 and 1998, agricultural land expanded in Busia, Migori, Homabay and Siaya by 25.64%, 3.71%, 1.99% and 1.83% respectively, with only Kisumu County declining by 2.48% (Figure 7). The next decade (1998–2008) was characterized by net losses in agricultural land in the counties of Busia (9.49%) and Homabay (9.90%) while the other counties of Kisumu, Migori and Siaya recorded net gains of 3.10%, 2.68% and 2.16%, respectively. For the last decade (2008–2018), agricultural land portrayed a similar trend to the period of 1978–1998 when it decreased in the counties of Busia (-2.56%), Migori (-4.28%), Kisumu (-6.09%) and Siaya (-10.05%), and increased only in Homabay county (4.65%) (Figure 7).

Table 1: Properties of Landsat imageries used

YEAR	Sensor	Path / Row	Acquisition Date	Resolution (m)	Cloud cover (%)	Season	Source
1978	Land sat 3 MSS	170/60	Jan, 1978	30	0	Dry	USGS

Communities on the lakeside counties depend majorly on fishing in Lake Victoria and farming within the basin for their livelihoods [42]. The poverty level of the riparian communities has been estimated at about 66% [43]. The variations in agricultural land uses could be attributed to the problems of land degradation which could sometimes make the farmers abandon some agricultural farms which had become infertile over time due to intense cultivation [44]. Erosion caused by heavy surface run-off most especially in agricultural land is responsible for rampant soil infertility in cultivated areas [44]. The decreasing agricultural land coverage could also be attributed to the gradual shifting of households from farming to fishing and fishing related activities most especially when the rain-fed agricultural production becomes

marginal and unpredictable [45,46]. In the 1980s, the riparian communities of Lake Victoria would pay greater attention to fishing during the Nile perch “boom” hence neglecting farming altogether [45]. Further, the inverse relationship between farming and fishing in Lake Victoria basin had been established whereby an increase of one result into a decrease in the other [45]. The abandoned farmlands would be later converted to built-up areas (when structures are constructed on them), bare land (when they are used for grazing purposes) or grasslands (when they are left fallow for a long time). These incidences have been widespread because according to [45], the then Nyanza province has never been a particularly agricultural productive region.

Figure 9: Net changes in agricultural land coverages for the period of 1978 – 2018

Water Bodies

The coverage of water bodies in 1978 and 2018 was highest in Homabay County than in other counties. Generally, water bodies' coverage remained relatively constant in all the counties from 1978 through 2018 (Figure 8). Conversely, decade-by-decade analysis shows that both positive and negative growth patterns were observed in the coverage of water bodies among the counties between 1978 and 2018 (Figure 8). From 1978–1988, the coverage of water bodies increased in Migori County by 14.84% and decreased in Busia County by 1.67%, while the remaining part of the counties remained constant (Figure 8). In the subsequent decade (1988–1998), all the counties recorded net losses in coverage of water bodies with the exception of Busia County with a slight net gain (Figure 8). In the decade of 1998–2008, slight positive increment in the coverage of water bodies was observed in Busia, Kisumu and Homabay counties, while slight negative growth was observed in Migori and Siaya (Figure 8). In the last decade (2008–2018), the coverage of water bodies tended to remain fairly constant in all the counties, with negligible fluctuations (Figure 8).

Marginal losses or gains were realized in total land area for water bodies, an implication that the immediate land areas bordering the waters of the Lake Victoria have been marginally affected during these periods. The coverage of water bodies has tended to remain constant in Lake Victoria basin except for occasional fluctuations during the flood season. The water levels in the lake have been known to occasionally experience relative rise and falls [47]. These fluctuations could be attributed to prolonged dry seasons with high evaporation rates, and widespread massive flooding during periods of intense rainfall, especially around the plains [48,49]. The heavy rains also fill up the rivers extending their banks and causes scattered marsh pools in the basin [49]. There is also the possibility that the slight reductions in areas

under water could be due to the draining and conversion of wetlands to built-up areas and agricultural farms [50]. About 62% of wetland areas around the Lake Victoria have been converted to agricultural land between 2002 and 2014 [51].

Grasslands and Vegetation

Grasslands and vegetation cover were more dominant in Migori County than in Homabay, Siaya, Kisumu and Busia counties in 1978. But by 2018, Migori had more areal coverage of grasslands and vegetation followed by Busia, Homabay, Kisumu and then Siaya. Generally, all counties recorded net gains in the grasslands and vegetation coverage from 1978 to 2018 with exception of Siaya County which recorded an overall net loss in the period between 1978 and 2018 (Figure 9). However, decade-by-decade analysis of net changes shows that both positive and negative growth patterns were noticeable in the grasslands and vegetation coverage among the counties between 1978 and 2018 (Figure 9).

Between 1978 and 1988, a noticeable increase in the areal coverage of grasslands and vegetation were observed in Busia, Kisumu and Homabay counties, while Siaya and Migori counties recorded slight losses (Figure 9). The next decade (1988–1998) there were net losses in grasslands and vegetation in the counties of Busia (39.61%), Siaya (24.08%) and Homabay (27.49%), while net gains were recorded in the counties of Migori (159.60%) and Kisumu (24.51%). Between 1998 and 2008, grasslands and vegetation grew almost three-fold in Homabay County (Figure 9). During the same period, Busia County also recorded a 75% increase in grasslands and vegetation while the counties of Siaya, Migori and Kisumu registered substantial net losses in grasslands and vegetation coverage (Figure 9). In the last decade (2008–2018), grasslands and vegetation recorded positive growth rates in all counties except Homabay County (Figure 9).

Figure 10: Net changes in water bodies' coverages for the period of 1978 – 2018

Figure 11: Net changes in grassland & vegetation coverages for the period of 1978 – 2018

Although varied changes in grasslands and vegetation coverages were observed among the counties, generally most areas of grasslands and vegetation were actively undergoing conversion to other land uses. Some areas of grasslands and vegetation probably became bare ground because of desertification problems, construction and bush burning activities [42,47]. Grasslands and vegetation occurring in wetland areas might have been lost when the water in these areas get drained or dry out due to prolonged drought conditions observed around the Lake Victoria in the 1970s and 1980s [52]. Grasslands and vegetation cover occurring near Lake Victoria might have declined during the incidences of the lake water retreating, like the drastic fall in water level observed in 2005 [53]. Other areas of grasslands and vegetation might have been cleared for residential and agricultural expansion to cater for the expanding population growth. However, gains in grasslands and vegetation occurred in some areas where several flood pools sprung like in Nyando of Kisumu County [33]. Also, forest plantations were established by the government for water catchment conservation (such as Gwasssi and Wire Hills forest reserves) [54], and bare lands slowly grew grass, shrubs and bushes with time.

Bare Land

Bare land coverage followed a descending order of Siaya County has the largest area of bare land compared to other counties in 1978, however, by 2018; Busia had the largest area of bare ground compared to other counties. Generally, three counties of Busia, Migori and Kisumu recorded high net gains in bare land coverage while two counties of Siaya and Migori recorded overall net losses from 1978 to 2018 (Figure 10). Moreover, decade-by-decade analysis of net changes shows that both positive and negative growth patterns were recorded in the bare land between 1978 and 2018 period (Figure 10).

Between 1978 and 1988, bare land increased by 341% in Migori Counties while the rest of counties experienced net losses in bare land coverage (Figure 10). The following decade (1988-1998) saw this pattern change with Busia, Siaya and Migori recording negative increase in bare land (-26.43%, -43.01% and -78.98%, respectively) while Homabay and Kisumu experienced substantial positive net gains (59.31% and 174.22%, respectively) (Figure 10). Between 1998 and 2008, although at different levels, the same trend observed during the previous decade (1988-1998) replicated itself, whereby Busia, Siaya and Migori experienced net losses in bare land coverage while Homabay and Kisumu experienced net gains in coverage (Figure 10). Finally, between 2008 and 2018, all the counties experienced growth in bare land with Migori County leading with a net gain 645.05%, followed by Busia (255.88%), Siaya (62.06%), Homabay (22.50%) and Kisumu (7.51%) (Figure 10).

The loss in bare land could be due to their utilization for agricultural and settlement purposes. Others have been colonized by vegetation over time once bare/barren land receives precipitation [55]. For the counties with large increase in bare land, the dry climatic conditions might have caused widespread desertification which effectively made some land areas covered by grasslands and vegetation and agricultural lands to become bare over time. Widespread desertification and flooding in the Lake Victoria riparian counties are consequences of climate change effects in the region [56]. Also, mining and quarrying activities (for example gold mining in Migori County) in the riparian counties could have contributed to bare land by outstripping vegetated areas and turning them into waste bare lands. Most mining operations in Kenya involve open cast and underground mining methods which leaves large areas with rocky pits and trenches [57]. Plant growth in these wastelands is often hindered by the acid drainage conditions, therefore wastelands from mined areas can lay bare for several years [57].

Figure 12: Net changes in bare land coverages for the period of 1978 – 2018

Forests

In 1978, Siaya County has the largest forest coverage among the counties, while in 2018, Busia County had the second highest forest cover compared with its position in 1978. Generally, Busia, Migori and Homabay recorded net losses in forest cover while Siaya and Kisumu had overall net gains from 1978 to 2018 (Figure 11). Moreover, decade-by-decade analysis of net changes shows that both positive and negative growth patterns were observed in forest cover among the counties between 1978 and 2018 (Figure 11).

From 1978 to 1988, forest cover substantially declined in Busia, Migori and Homabay by 51.10%, 21.07% and 56.48%, respectively. On the other hand, Siaya and Kisumu experienced growth in forest cover by 22.21% and 37.61%, respectively (Figure 11). In sharp contrast, during the following decade of 1988 to 1998, Busia, Migori and Homabay, which had recorded net losses in forest cover, recorded net gains in forest cover while Siaya and Kisumu, which had net gains in forest cover, recorded net losses (Figure 11). In 1998-2008, substantial net losses were observed in all the counties with exception of Busia County which remained unchanged (Figure 11). The last period (2008-2018) experienced massive net gains in forest cover in Kisumu (165.14%), Migori (103.92%) and Siaya (25.36%) counties, and net losses in Busia (55.01%) and Homabay (1.06%) counties (Figure 11).

Losses in forest cover could be a consequence of clearing forested areas to provide land for other competing uses. The regions around Lake Victoria suffer widespread deforestation due to increased land demand for grazing, agricultural and settlement purposes [58]. An estimated 80% of deforested areas are used for agricultural purposes in developing countries [59]. The problem of deforestation was so widespread around the country in the mid-1990s that it forced the government to institute a permanent ban on tree harvesting from designated forested areas [60]. The high

deforestation around the basin could also be attributed to increased demand for wood fuel and forest products for settlement and infrastructural related developments for the increasing population [61]. This region experiences widespread usage of wood for household fuel due to the pervasive high poverty levels [62].

The overall increased forest cover in Kisumu and Busia counties could be due to their practice of agroforestry cultivation. These counties have a long history of agroforestry practices since 1980s [59]. The overall decrease in forest cover of Migori, Homabay and Busia could be attributed to the clearing of woody trees in farmlands and forested areas for the lucrative charcoal business, which thrive among Lake Victoria shore dwellers [60,63]. The massive gains in forest cover over the last decade in the three counties could be attributed to the Vision 2030 program which empowered the Ministry of Youth Affairs and Sports to utilize the youths in ambitious tree planting programmes in deforestation hotspots around the county with the aim of creating employment opportunities for them while driving forest conservation goal of achieving the 10% forest cover in the country [60]. Also, the compliance with the Agriculture Act (CAP 318) on Farm Forestry Rules enacted in 2009 requiring at least 10% forest cover in every private farm might have contributed to the gains in forest cover in these counties and around the country [60]. The most recent 2015 forestry statistics indicate that the lowest forest covers nationally are found in counties within the Lake Victoria basin [64], an indication of pressure on the region's forest ecosystems. Based on the latest statistics [65], the forest cover of the riparian counties in the Lake Victoria basin is distributed as follows; Homabay (2.59%), Busia (1.01%), Migori (0.64%), Kisumu (0.44%) and Siaya (0.42%). The results of this study show that forest covers among these riparian counties in 2018 ranged between 0.53% and 4.29%, an indication of a general increment. However, with the national forest cover at 6.99%, the whole country is generally still struggling to attain the constitutionally mandated forest cover of 10% [64].

Figure 13: Net changes in forests cover for the period of 1978 – 2018

Figure 14: Net changes in built-up areas coverages for the period of 1978 – 2018

Built-up Areas

The coverage of built-up areas among the counties was in the descending order of Siaya, Kisumu, Homabay, Migori and Busia in 1978 but by 2018, the order had changed to Homabay, Siaya, Kisumu, Migori and Busia counties. Generally, all counties registered huge overall net gains in built-up areas from 1978 to 2018 (Figure 12). Moreover, decade-by-decade analysis of net changes shows that only positive growth patterns were recorded of

built-up areas among the counties during the period between 1978 and 2018 (Figure 12).

In the first decade (1978-1988), built-up areas increased in all the counties as seen in the net gains of 138.94%, 133.52%, 35.41%, 20.83% and 4.98% for Homabay, Migori, Kisumu, Siaya and Busia counties, respectively. A similar trend was observed for the period of 1988 to 1998, though with reduced percentage gains as follows: Homabay (28.34%), Migori (3.77%), Kisumu (41.58%),

Siaya (10.27%) and Busia (22.05%) (Figure 12). Between 1998 and 2008, all the counties recorded positive growth patterns in built-up areas but with even higher net gains from the previous ones (Figure 12). The last decade of 2008 and 2018 also saw positive growth patterns for all counties in built-up areas, with higher percentage gains compared to the previous decade (Figure 12). The built-up areas generally experienced net gains throughout the entire period under study.

From the foregoing, built-up areas continued to increase exponentially among all the counties from 1978 to 2018. Over the years, several scattered land areas under agriculture, grasslands and vegetation, forests and bare lands were indiscriminately utilized for constructing human structures for the ever burgeoning population. The Lake Victoria region has seen rapid population increase over the last three decades, which means more demand for built-up areas for settlement [36]. As the country's economy grew after independence, so was the population and infrastructural developments in Lake Victoria region which therefore cut into the

land areas originally under vegetation of some sort or farms [66]. The increasing built-up areas around Lake Victoria could be attributed to the well documented rapid growth in population and urbanization in the region [43,67]. Population growth and urbanization caused urban sprawl in several rural areas around the country which became administrative and shopping centres [68]. This trend has increased over the years in the whole country with the dawn of devolved governance in Kenya in 2010 which made counties the basis for development [68].

3.3. Accuracy Measurement of the LULC Classification

The summarized report of the confusion (error) matrices is presented in Table 7. It shows the overall accuracies and the overall Kappa co-efficient values. The overall values of accuracy and Kappa co-efficient characterize a combination of the classification aspects and therefore are the most important statistical elements for accuracy measurements reports [40].

Table 7: Summarized confusion (error) matrix report for the counties classification maps for the years 1978, 1988 and 1998.

County	1978		1988		1998		2008		2018	
	Overall Accuracy	Overall Kappa Statistics	Overall Accuracy	Overall Kappa Statistics	Overall Accuracy	Overall Kappa Statistics	Overall Accuracy	Overall Kappa Statistics	Overall Accuracy	Overall Kappa Statistics
Busia	0.88	0.75	0.86	0.70	0.90	0.79	0.92	0.78	0.90	0.72
Homabay	0.89	0.77	0.91	0.82	0.89	0.80	0.84	0.67	0.89	0.80
Kisumu	0.81	0.65	0.84	0.62	0.89	0.78	0.84	0.68	0.87	0.73
Migori	0.91	0.78	0.92	0.84	0.91	0.80	0.93	0.86	0.96	0.91
Siaya	0.92	0.83	0.92	0.85	0.92	0.85	0.90	0.83	0.91	0.82

The results in Table 7 indicate that for Busia County, the land use/land cover classification for the years 1978, 1988, 1998, 2008 and 2018 recorded overall accuracies in the range of 0.86 – 0.92 and overall Kappa co-efficient values in the range of 0.70 – 0.79. For Homabay county, overall accuracies were in the range of 0.84 – 0.91 while the overall Kappa co-efficient values fell within the range of 0.67 – 0.82. The overall accuracies and overall Kappa co-efficient values for Kisumu County were in the ranges of 0.81 – 0.89 and 0.62 – 0.78, respectively. Migori County's overall accuracies was in the range of 0.91 – 0.96 and overall Kappa co-efficient values in the range of 0.78 – 0.91. Finally, for Siaya County, recorded overall accuracies in the range of 0.90 – 0.92 and overall Kappa co-efficient values in the range of 0.82 – 0.85.

Generally, all the imageries used for LULC classification registered overall accuracies above 80%, which is considered acceptable [69]. This means all the imageries were highly reliable and the LULC classification acceptable. On the other hand, all the imageries used for LULC classification registered overall Kappa co-efficient of above 0.62, which when compared to the rating criteria for Kappa co-efficient statistics [70] shows that the LULC

classification had a strong to moderate agreement with the ground reference data hence high reliability. Kappa co-efficient basically assesses how much the data acquired from the classified imageries agrees with the ones acquired from the ground reference points [71].

4. Conclusion

This study illustrates the effectiveness of using data obtained from multi-temporal satellite imageries for comprehensive monitoring of land use and land cover changes over a given area. The counties experienced varied changes in LULC from 1978 to 2018. Generally, major gains in coverage by the various land use and land cover types occurred in the period between 2008 and 2018 while major losses occurred between 1978 and 1988. These changes were driven by a combination of natural climatic and human-induced factors. Rapid population and economic growth in the region are responsible for the conversion of large natural land areas to other uses. Therefore, it can be concluded that these regions within the Kenyan Lake Victoria basin may remain susceptible to degradation from rapidly increasing urbanization

and population pressure effects unless urgent remedial measures are undertaken.

In this regard, the study recommends that respective county authorities responsible for land use and urban planning should periodically monitor and regulate the development patterns in their communities to ensure that they protect livelihoods, economic interests and ecosystems. There should also be aggressive public awareness creation among the respective county government officials and residents so that proper land use management becomes a stakeholder's affair for better results. Finally, urgent conservation efforts are needed to recover lost vegetated land areas such as forests, grasslands and vegetation. This study provides important information on the land use and land cover dynamics of respective counties which could inform conservation planning of degradation hotspots within the respective counties of Lake Victoria basin. Future conservation measures should take into consideration, the general ecological and socio-political processes in the entire Lake Victoria basin for integrated watershed conservation.

Optimization

ABSTRACT

Protecting the rights and interests of shareholders is the important research topic. This study takes "Tatung Operation Rights Competition" as an example to execute case study. Game tools are applied to analyze which corporate supervision strategies should be used by government. The research and analysis results show that both the corporate group and the market group are suitable for using mixed strategies to compete for management rights in the operation rights competition case. However, doing something is the best regulatory strategy for government regulators to protect shareholders. In addition, this study suggests that government should assist enterprise with long-term business failures in their industrial upgrading and transformation in peacetime.

1. Introduction

In today's world, investment is very important issue especially in Taiwan because Taiwan citizen's per capita GDP has been reached US\$25,000 and Taiwan's nominal national savings rate is closed to 40% [1-2]. The volume of investor has been increasing in recent year (Refer to Figure 1). Among them, many Taiwanese citizens invest their funds in high-risk stock markets. The government should ensure that Taiwan investors are not cheated by major shareholders [3]. In order to ensure that Taiwan's stock market is fair, government should prevent insider trading. Therefore, Taiwan government is strengthening enterprise supervision for preventing companies to use various tools to harm shareholders in order to get benefit for themselves.

Figure 1: Account opening status of Taiwan stocks in the past 6 years

Yu-Chun Huang, yutsun314@stu.edu.tw

Due to limited government resources, it is impossible for government to inspect each company one by one in the face of all listed companies. This will cause market inefficiency and consume too much resources to visit companies with good credit. Therefore, Taiwan government mostly inspects and supervises a few companies that may have problems. The purpose of this research is to use game theory tool to analyze and evaluate the effectiveness of corporate supervision system and to provide some reasonable suggestions to government and enterprises.

This study is divided into five parts. In the beginning, research background, research motivation will be discussed. And then, the related literatures about enterprise supervision and game theory will be collected and arranged. Game evaluation model will be construct in next section. A case will be described and game analysis will be executed. Conclusion of this work and suggestions to the government and enterprises will be taken over as ending.

2. Literature Review

2.1. Enterprise Supervision Research

In [4], author explored the importance of the information transparency system based on the Asian financial crisis and used it to improve Taiwan's corporate supervision system. In [5], author designed questionnaires to investigate the issues of company supervision such as the company's board of directors and supervisory system. The research results show that the government should provide appropriate incentives to increase the importance

of corporate directors and supervisors for executing corporate supervision. Shareholders should strengthen their concern for corporate supervision. The participation and the number of supervisors should be based on the scale of the company. In [6], author analyzed the lack of supervision mechanism of Taiwan enterprises based on the procomp informatics example and seek improvement direction. In [7], author analyzes the lack of corporate governance and financial supervision in the Liba case and compares it with past malpractice cases to sort out improvement measures.

In [8], author designed dynamic game models to evaluate the supervision performance of government supervision mechanism. Research result shows that the supervision mechanism was not feasible if enterprises may neglect product quality for short-term interests. This research suggests that punishment degree to violating enterprise should be increased and the regulation of secure food enterprises must be enhanced. In [9], author built supervision game model between manufacturing enterprises and government department in order to execute enterprise quality management. In this model, the mixed strategy for enterprises and government were decided based on Nash equilibrium mechanism. In [10], author thought that learning theory and information processing theory can be applied to enhance the supervision degree of enterprise. In [11], author designed the supervision game model between the online shopping platform and the governmental quality supervision department based on complete information. Research result shows that costs of governmental supervision will influence supervision effectiveness of government. In [12], author analyzed and discussed the enterprise supervision system based on the government's policies. Enterprise supervision system were used to effectively enhance the competitiveness of enterprises. In [13], author used evolutionary game to regulation mode for analyzing long-term evolutionary trend between dairy enterprise and government supervision. They applied Python matplotlib to simulate research results. Research results shows that the standard recall system of defect and dairy products can reduce government supervision cost.

2.2. Information Asymmetry Theory

Information Asymmetry refers to the fact that transaction information possesses by seller or buyer can affect the transaction price. This information usually causes the buyer's economic loss. If causes that buyer only wants to purchase low-priced product (adverse selection). It leads to the phenomenon about "Bad money drives out good money" [14-15].

In the stock market, the phenomenon of information asymmetry is even more serious. For their own benefit, large shareholders and high-level managers in companies will buy (sell) stocks in advance and release news that is beneficial (not conducive) to the company afterwards. Increasing (decreasing) the stock price to gain self-interest, this kind of insider trading behavior often occurs. the corporate supervision system is mainly to prevent this behavior and the fundamental reason for the existence of the corporate supervision system is also the persistent information asymmetry in the society.

In the stock market, information asymmetry causes "peacock behavior". Companies like peacocks and enterprise will take effort to generate good data in financial statements in order to let listed

companies to sell company products to their subsidiaries. The quarterly profitable financial statements make market retail investors and fund managers mistakenly believe that the company's profit growth is profitable after the stock price rises. This is also the supervision focus of the corporate supervision system [16].

2.3. Game Theory Research

The relevant research on the use of game technology for corporate analysis is as follows:

In [17], author used game theory to analyze the financial decision-making of corporate capital. The research results show that the establishment and implementation of corporate governance by the government can reduce incentives for entrepreneurs and accountants to collude and reduce corporate speculation risks. In [18], author used static game model of multinational corporation's parent and subsidiary companies to analyzes the repeat game process of the parent-subsidiary structure of multinational corporations. The research results show that the comprehensive governance of multinational corporations' subsidiaries can help to achieve the goal of "win-win" between the parent company and its subsidiaries. It solves the corporate governance issues of the subsidiaries of multinational companies. In [19], author collected literatures about applying game theory for handling individual and organizational decision-making problem. In [20], author constructed the "Multi-agent game model for governments, consumers and enterprises" in order to analyze which factors can effectively affect the development of green economy by enterprises. The research results show that consumers have a positive attitude towards "green products" and "pseudo-green products". In order to avoid inverse selection behavior, government must conduct subsidy language certification for green products in order to increase the willingness of enterprises to develop green products.

In [21], author uses game theory as a research tool to explore the price of multinational companies and competitors under the four dimensions. The dimensions include "cost structure", "market price", "channel management" and "government's exchange rate policy trend". This model can execute strategy Analysis to select the most suitable price strategy for multinational companies under the condition of exchange rate uncertainty. In [22], author employed Entropy method and analytic network process (ANP) to acquire subjective and objective weight of criteria. Game theory and decision-making trial and evaluation laboratory (DEMATEL) were adopted to adjust weight among subjective criteria and objective criteria and made the analysis result reasonable in supplier selection problem. In [23], author established innovative game model by applying asymmetric normal Z-value (ANZ) to collect relative information. In this model, concordance/discordance index and outranking relation of strategies for different players under multiple criteria were provided according to classic outranking rules. In [24], author handled noncooperative multi-criteria Nash game by using fuzzy robust weighted method (FRWM). In this game, every decision maker can possess his/her several competing objectives. The uncertainty of performance will be evaluated by FRWM. Every player should minimize his/her maximum weighted sum objectives. Fuzzy robust weighted Nash equilibrium (FRWNE)

will be designed for acquiring weight of each objective. FRWNE can be transferred as mathematical programming problem which can be solved by software. In [25], author used utility function and integrated non-cooperative game and social identity model to evaluate performance of each strategy for self-interested players.

3. Game Theory Model

3.1. Notation Discussion

Players, Players' Strategies, and Players' Strategies Payoffs are the three basic components of the game. Relative notation is explained as follows:

(1) Players

A group of players can form as player set

$P = \{p_1, p_2, \dots, p_v\}$, v means the volume of player.

(2) Players' Strategies

Every player has his/her strategies. $s^1 = \{s_1^1, s_2^1, \dots, s_{m_1}^1\}$, $s^2 = \{s_1^2, s_2^2, \dots, s_{m_2}^2\}, \dots, s^v = \{s_1^v, s_2^v, \dots, s_{m_v}^v\}$. s^1, s^2, \dots, s^v are strategies for player 1 to player v . Where s_j^i is j -th strategy for player i . m_k is the volume of strategy for player k .

(3) Players' Strategies Payoffs

Each player's strategy can combine as the strategy combinations $[s_{x_1}^1, s_{x_2}^2, \dots, s_{x_v}^v]$. $R_{a, [s_{x_1}^1, s_{x_2}^2, \dots, s_{x_v}^v]}$ is the profit of player a under strategy combination $[s_{x_1}^1, s_{x_2}^2, \dots, s_{x_v}^v]$

(4) Selection Probability of Players' Strategies

Single strategy of each player has a certain probability to be selected to be executed by player. $\tau^1 = \{\tau_1^1, \tau_2^1, \dots, \tau_{m_1}^1\}$, $\tau^2 = \{\tau_1^2, \tau_2^2, \dots, \tau_{m_2}^2\}, \dots, \tau^v = \{\tau_1^v, \tau_2^v, \dots, \tau_{m_v}^v\}$. τ_j^i is the probability about i -th player select j -th strategy to execute.

3.2. Evaluation Model

There are various general types of games, which can be divided into (1) cooperative games and non-cooperative games, (2) static games and dynamic games, (3) complete information games and incomplete information games. Those game models are explained below [26].

(1) Cooperative and non-cooperative games

"Non-cooperative game" refers to whether there is a binding agreement between the parties interacting with each other. On the contrary, it is a "cooperative game". Cooperative games will produce collusion. The case in this study is a non-cooperative game.

(2) Static and dynamic games

"Static game" means that the participating players choose strategies at the same time in the game. "Dynamic game" means that the actions of the participating players have a sequence in the game and players who act later can observe the first action chosen by the action player. The case of this study is a static game.

(3) Complete information game and incomplete information game

"Complete information game" means that each participating player has accurate information about the characteristics, strategy space, and profit function of other participating players during the game. Conversely, it is "Incomplete information game" when the

participating players cannot grasp complete information. The case of this study is a complete information game.

The complete information non-cooperative static game can be obtained using the following formula:

$$\max v^1 \quad (1)$$

$$\begin{aligned} \text{Subject to} \quad & \sum_{i=1}^{m_1} R_{1, [s_1^1, s_2^2, s_3^3]} * \tau_i^1 \geq v^1 \\ & \sum_{i=1}^{m_1} R_{1, [s_1^1, s_2^2, s_3^3]} * \tau_i^1 \geq v^1 \\ & \dots \\ & \sum_{i=1}^{m_1} R_{1, [s_{m_1}^1, s_{m_2}^2, s_{m_3}^3]} * \tau_i^1 \geq v^1 \\ & \sum_{i=1}^{m_1} \tau_i^1 = 1 \\ & \tau_i^1 \geq 0 \quad i=1, 2, \dots, m_1 \end{aligned}$$

$$\max v^2 \quad (2)$$

$$\begin{aligned} \text{Subject to} \quad & \sum_{i=1}^{m_2} R_{2, [s_1^1, s_2^2, s_3^3]} * \tau_i^2 \geq v^2 \\ & \sum_{i=1}^{m_2} R_{2, [s_1^1, s_2^2, s_3^3]} * \tau_i^2 \geq v^2 \\ & \dots \\ & \sum_{i=1}^{m_2} R_{2, [s_{m_1}^1, s_{m_2}^2, s_{m_3}^3]} * \tau_i^2 \geq v^2 \\ & \sum_{i=1}^{m_2} \tau_i^2 = 1 \\ & \tau_i^2 \geq 0 \quad i=1, 2, \dots, m_2 \end{aligned}$$

$$\max v^3 \quad (3)$$

$$\begin{aligned} \text{Subject to} \quad & \sum_{i=1}^{m_3} R_{3, [s_1^1, s_2^2, s_3^3]} * \tau_i^3 \geq v^3 \\ & \sum_{i=1}^{m_3} R_{3, [s_1^1, s_2^2, s_3^3]} * \tau_i^3 \geq v^3 \\ & \dots \\ & \sum_{i=1}^{m_3} R_{3, [s_{m_1}^1, s_{m_2}^2, s_{m_3}^3]} * \tau_i^3 \geq v^3 \\ & \sum_{i=1}^{m_3} \tau_i^3 = 1 \\ & \tau_i^3 \geq 0 \quad i=1, 2, \dots, m_3 \end{aligned}$$

4. Case Study

4.1. Case Introduction

This research uses Tatung as a case study. First, this research explains the current situation of Tatung. Tatung Company is a comprehensive enterprise with the electronics industry as its core technology business. It was founded in 1918. Tatung Company is the first batch of listed companies in Taiwan in the fields of electrical appliance manufacturing, distribution, trade, and construction. It is divided into three major business groups - power, systems, and consumption.

Tatung's main business has performed poorly in recent years. However, its Tatung enterprises have a lot of high-value land. It

led to marketers wanting to come in and fight for dominance in Tatung company. This is the current situation of Tatung company.

4.2. Case Analysis

In this case, it is a three-player game. The players are Tatung company faction (p_1), Tatung market faction (p_2) and Government Supervisor (p_3). The related strategies are summarized in Table 1:

Table 1: The strategies for each player

Player	Strategy of each player
Tatung company faction p_1	Strategy (1) Find an external merge object (White Horse Knight) s_1^1 Strategy (2) Swallowing poison pills s_2^1 Strategy (3) Mass acquisition of equity s_3^1 Strategy (4) Sued Tatung Market for illegal Chinese investments s_4^1
Tatung market faction p_2	Strategy (1) Mass acquisition of equity s_1^2 Strategy (2) Convene a temporary stock meeting s_2^2
Government Supervisor p_3	Strategy (1) Announcing full delivery in Tatung Stock s_1^3 Strategy (2) Do nothings s_2^3

Tatung company faction has 4 strategies, Tatung market faction has 2 strategies, and Government Supervisor have 2 strategies. The total of strategy combinations is $4 \times 2 \times 2 = 16$.

In this study, 10 experts were invited to evaluate the effectiveness of the above strategies on the Tatung company faction (p_1), Tatung market faction (p_2) and Government Supervisor (p_3) by using 1 to 10 points (1 for the lowest benefit and 10 for the highest benefit) based on the above strategy combination. Experts express their opinion about the effectiveness of each strategy for Tatung company faction (p_1), Tatung market faction (p_2) and Government Supervisor (p_3) under special of strategy combination by taking a value from 1 to 10. All of experts' opinion (evaluation value) will be add to represent the performance of each strategy. The evaluation results can refer to Table 2 to Table 4.

Table 2: The benefits of Tatung company faction under different strategic combinations

		s_1^1	s_2^1	s_3^1	s_4^1
s_1^3	s_1^2	32	31	23	41
	s_2^2	27	34	25	28
s_2^3	s_1^2	74	71	63	63
	s_2^2	84	83	76	72

Table 3: The benefits of Tatung market faction under different strategy combinations

		s_1^1	s_2^1	s_3^1	s_4^1
s_1^3	s_1^2	44	34	43	32
	s_2^2	47	29	41	53
s_2^3	s_1^2	64	52	56	71
	s_2^2	61	47	52	60

Table 4: Benefits of government supervisor units under different strategic combinations

		s_1^1	s_2^1	s_3^1	s_4^1
s_1^3	s_1^2	58	64	62	71
	s_2^2	54	58	60	73
s_2^3	s_1^2	34	27	42	29
	s_2^2	29	24	37	23

The relative formula can refer as follows

$$\max v^1 \quad (4)$$

$$\begin{aligned} \text{Subject} \quad & 32\tau_1^1 + 31\tau_2^1 + 23\tau_3^1 + 41\tau_4^1 \geq v^1 \\ \text{to} \quad & 27\tau_1^1 + 34\tau_2^1 + 25\tau_3^1 + 28\tau_4^1 \geq v^1 \\ & 74\tau_1^1 + 71\tau_2^1 + 63\tau_3^1 + 63\tau_4^1 \geq v^1 \\ & 84\tau_1^1 + 83\tau_2^1 + 76\tau_3^1 + 72\tau_4^1 \geq v^1 \\ & \sum_{i=1}^4 \tau_i^1 = 1 \\ & \tau_i^1 \geq 0 \quad i=1,2,\dots,4 \end{aligned}$$

$$\max v^2 \quad (5)$$

$$\begin{aligned} \text{Subject} \quad & 44\tau_1^2 + 47\tau_2^2 \geq v^2 \\ \text{to} \quad & 34\tau_1^2 + 29\tau_2^2 \geq v^2 \\ & 43\tau_1^2 + 41\tau_2^2 \geq v^2 \\ & 32\tau_1^2 + 53\tau_2^2 \geq v^2 \\ & 64\tau_1^2 + 61\tau_2^2 \geq v^2 \\ & 52\tau_1^2 + 47\tau_2^2 \geq v^2 \\ & 56\tau_1^2 + 52\tau_2^2 \geq v^2 \\ & 71\tau_1^2 + 60\tau_2^2 \geq v^2 \\ & \sum_{i=1}^2 \tau_i^2 = 1 \\ & \tau_i^2 \geq 0 \quad i=1,2. \end{aligned}$$

$$\max v^3 \quad (6)$$

$$\begin{aligned} \text{Subject} \quad & 58\tau_1^3 + 34\tau_2^3 \geq v^3 \\ \text{to} \quad & 64\tau_1^3 + 27\tau_2^3 \geq v^3 \\ & 62\tau_1^3 + 42\tau_2^3 \geq v^3 \\ & 71\tau_1^3 + 29\tau_2^3 \geq v^3 \\ & 54\tau_1^3 + 29\tau_2^3 \geq v^3 \\ & 58\tau_1^3 + 24\tau_2^3 \geq v^3 \\ & 60\tau_1^3 + 37\tau_2^3 \geq v^3 \\ & 73\tau_1^3 + 23\tau_2^3 \geq v^3 \\ & \sum_{i=1}^2 \tau_i^3 = 1 \\ & \tau_i^3 \geq 0 \quad i=1,2. \end{aligned}$$

According to formula 1 to formula 3, the strategy selection probability of Tatung company faction (p_1), Tatung market faction (p_2) and government supervisor (p_3) is as follows. Tatung company faction should randomly adopt a mixed strategy of "swallowing poison pills" or "sue Tatung Market Group as illegal Chinese capital". Tatung market faction should randomly adopt a mixed strategy of "massive acquisition of equity" or "convening temporary stock meetings". The best strategy for government supervisor is to "declare full delivery of Tatung stocks".

Table 5: Probability of different players' strategy choices

	s_1^1	s_2^1	s_3^1	s_4^1
Probability	0%	35.84%	0%	64.16%
	s_1^2	s_2^2		
Probability	54.18%	46.82%		
	s_1^3	s_2^3		
Probability	100%	0%		

5. Conclusion and Future Research

This research uses Tatung companies as the research target. The game analysis tools are used to explore the best strategies of Tatung company faction, Tatung market faction and government supervisor. The research and analysis results show that government supervisor's best strategy is to take action to deliver the shares of Tatung stocks in full while the Tatung company faction and Tatung market faction are suitable to adopt a mixed

strategy to gain equity. This result shows that government's best plan is doing something. The two parties who compete for the right to operate are better to adopt a mixed strategy.

This study believes that Tatung company faction's best strategy is to perfect its business operations. This behavior can naturally gain the support of the small investor in the market and there is no motivation for investor to fight for management rights. In addition, selling corporate bonds without voting rights are also a good fund-raising tool to assist companies in obtaining operating resources and preventing market usurpation. Cross-shareholding by companies is also a good way to preserve operating rights. This study suggests that the government should assist companies with long-term business failures in their industrial upgrading and transformation in peacetime. It can be known that company may do some damage to shareholders if there is the competition for management rights according to the analysis results of this research. The behavior should be severely punished by taking drastic measures for the efficiency of government supervision. The contribution of this research is to design the framework which can be used to evaluate performance of relative enterprise supervision activity. Based on this framework, we can know which strategy is suitable for government and enterprise. This study uses a static game method to analysis. In the future, relevant scholars may consider to use repeating game to analyze this problem because the battle for management rights in Tatung may continue for many years in the real world.

Conflict of Interest

The authors declare no conflict of interest.

Ridge Regression

Food Prediction Model

ABSTRACT

Forecasting food prices play an important role in livestock and agriculture to maximize profits and minimizing risks. An accurate food price prediction model can help the government which leads to optimization of resource allocation. This paper uses ridge regression as an approach for forecasting with many predictors that are related to the target variable. Ridge regression is an expansion of linear regression. It's fundamentally a regularization of the linear regression model. Ridge regression uses the damping factor (λ) as a scalar that should be learned, normally it will utilize a method called cross-validation to find the value. But in this research, we will calculate the damping factor/ridge regression in the ridge regression (RR) model firsthand to minimize the running time used when using cross-validation. The RR model will be used to forecast the food price time-series data. The proposed method shows that calculating the damping factor/regression estimator first results in a faster computation time compared to the regular RR model and also ANFIS.

1. Introduction

The global food demand in the first half of this century is expected to grow 70 percent, and if we don't do anything there would be a major problem with food security by 2050 [1]. One of the reasons why there has been a massive demand for food is the growing population. Increased population means increased demands on food produce. Right now, there is a 7.8 billion population, and the number continues to rise. High food price was one of the reasons listed why there is a high amount of malnutrition in the world.

The three common sources of carbohydrate are rice, wheat, and corn. Countries in Asia and most of Africa and South America, eat rice as the main staple food. Based on the data by BPS in Indonesia, it shows that in 2018 the average per capita consumption of rice per week was 1.551 kg [2]. Forecasting commodity prices play an important role in the livestock or agriculture industry because it is useful for maximizing profits and minimizing risks [3]. Accurate food price prediction can lead to optimization of resource allocation, increased efficiency, and increased income for the food industry [4]. The increase in food prices can become a burden, especially for the middle to the lower-income community.

Several studies have been done using the regression model, whether it being the classic linear regression or ridge regression. A study by [5] in stock market prediction uses linear regression to forecast the daily behavior of the stock market. The results show a high confidence value in linear regression compared to the other regression methods. In another study on the prediction of wheat prices in China [6], prices are predicted using a combination of linear models. Though there are downsides that could be found in a linear model, one of them being a multicollinearity problem.

In a linear regression model, multicollinearity happens when independent factors in a relapse model are associated. This relationship is an issue since independent factors should be free. If the level of connection between factors is sufficiently high, it can cause issues when you fit the model and decipher the outcomes. Multicollinearity diminishes the accuracy of the estimated coefficients, which debilitates the statistical power of the regression model. Multicollinearity also enables the coefficient estimates to swing fiercely dependent on which other independent factors are in the model. The coefficients become delicate to little changes in the model.

To deal with multicollinearity, in [7] the author proposed a Bayesian ridge regression method and treating the bias constant. They use a conjugate and non-conjugate model while diagnosing and treating the collinearity simultaneously. They mention that

*Corresponding Author: Antoni Wibowo, Bina Nusantara University - Jl. Kebon Jeruk Raya No. 27 Jakarta Barat, Indonesia 11530, +62 21 5345830 & anwibowo@binus.edu

www.astesj.com

<https://dx.doi.org/10.25046/aj060280>

the practice of dropping variables from the data is not a good practice to correct the results of the regression model. Their study suggests dealing with multicollinearity by finding the k value. Kernel ridge regression and proper damping factor values are believed to be able to overcome multicollinearity which causes a weak testing hypothesis [8,9], and also with a less complex structure. Especially if the best damping factor can be determined earlier, it can reduce the time required for computation to find the value of the damping factor (λ) by cross-validation. The ridge regression method with the best damping factor is believed to produce good predictive results with a shorter computation time in the learning process.

2. Related Works

In some previous work, several methods of food prediction can be found. A study by [6], in Thailand Rice Export, uses the Autoregressive Integrated Moving Average (ARIMA) and Artificial Neural Network (ANN) model. Another study in wheat price in China [7] uses ARIMA, ANN, as well as a combination of linear models.

A study done by [10] on real-time wave height forecasting uses an MLR-CWLS hybridized model. The model uses Multiple Linear Regression (MLR) and then considered the influence of the variables which then is optimized by Covariance-weighted least squares (CWLS) algorithm. They compare the proposed model with several past models, them being MARS, M5tree, and the regular MLR. The result MLR-CWLS shows the best performance, followed closely by MLR.

Linear regression has been used in several studies in time-series data, one of them being a study by [5] in stock market prediction. They use linear regression to forecast the daily behavior of the stock market. The results show a high confidence value in linear regression compared to the other regression methods. The linear regression method shows a confidence value of 0.97, while polynomial and RBF's confidence values are 0.468 and 0.562 respectively.

The problem of multicollinearity was addressed by the author in [11] referring to it as the goldilocks dilemma. They mention three possible solutions to address the problem from the perspective of multiple applications by using simple regression, multiple regression, and from the perspective of order variable research.

A method was proposed by [12] explains how to select the optimal k value for ridge regression and minimizing the mean square error of estimation. The author uses a two-step procedure to demonstrate the existence of an MSE error point of the ridge estimator along the scale, k , and then present an iteration where we can obtain the optimum value in the scale k while minimizing the mean square estimator in any correlated data set.

In research on ridge regression for grain yields prediction [13], identify the potential and limitations for the use of the factors derived and ridge regression to predict the performance. Results have shown that prediction accuracies depend on the variables, and there are statistical models (in this case ridge regression) suitable for predicting performance in the areas and highlights limitations associated with the crop and environmental data in the model.

To face the problem of multicollinearity, the author in [7] proposed a Bayesian ridge regression and treating the bias constant. They use a conjugate and non-conjugate model, they diagnosed and treating the collinearity simultaneously. They mention that the practice of dropping variables from the data is not a good practice to correct the results of the regression model. Dealing it by finding the k value will provide a more robust finding.

Based on the previous works that we reviewed, the use of the ridge regression method with the best damping factor for the time-series prediction model is relevant to research. The ridge regression technique can be used to predict time-series. Ridge regression (RR) can also solve the multicollinearity problem that exists in linear regression. In this study, the authors will also look for the best damping factor/ridge estimator beforehand for the prediction of food prices from the existing damping factor formula. Through this, the writer also reduces the computation time when using cross-validation in learning time. Finally, the author will also compare the prediction model using the best damping factor with the predictive model that already exists. Evaluation is done by comparing the RMSE value, MAPE value, and computational time.

3. Proposed Method

We use linear ridge regression for our model, and to optimize the design of a regression predictor for food price prediction, we propose a model with the optimal/best damping factor. This is done by calculating the damping factor / ridge estimator value (λ) according to the dataset used. This results in a model that can do a good prediction with a faster computation time.

3.1. Classic Linear Regression

Regression analysis is one of the most utilized methods to investigate multifaceted information [14]. In an exemplary classic linear regression model, they give a straight fair assessor of the normal estimation of the relapse y given regressor X , it can likewise give the straight fair-minded forecast of an individual drawing of y given X . A regression equation of the structure [15] :

$$y_t = x_{t1}\beta_1 + x_{t1}\beta_1 + \dots + x_{tk}\beta_k + \varepsilon_t \quad (1)$$

explains the value of dependent variable y_t in a set of k observable variables in x_t and an unobservable random variable ε_t . The vector β contains parameters of a linear combination of the variables in x_t . A set of T realizations of the regression relationship, indexed by $t = 1, 2, \dots, T$, can be compiled into a formula

$$y = X\beta + \varepsilon \quad (2)$$

Using least squares, the estimate of the parameter β is derived as:

$$\hat{\beta} = (X'X)^{-1}X'Y \quad (3)$$

The predicted model becomes:

$$\hat{Y} = X\hat{\beta} \quad (4)$$

3.2. Ridge Regression

Ridge Regression is one of the reliably alluring shrinkage techniques to diminish the impacts of multicollinearity for both linear and nonlinear regression models. Multicollinearity is the presence of close to-solid or solid direct relationships among the indicator factors [16].

In a test originally done by [17] [18], they notice that to control the inflation and instability related to the least square method, one can utilize

$$\hat{\beta}^* = [X'X + kI]^{-1}X'Y; k \geq 0 \quad (5)$$

The group of assessments given by $k > 0$ has numerous numerical similitudes with the depiction of quadratic response functions [19]. Consequently, assessment and examination worked around (5) have been named "ridge regression." The relationship of a ridge estimate to an ordinary estimate is given by the elective structure

$$\hat{\beta}^* = [I_p + k(X'X)^{-1}]^{-1}\hat{\beta} \quad (6)$$

$$= Z\hat{\beta} \quad (7)$$

By characterizing the ridge trace it very well may be indicated that the ideal qualities for the k_i will be $k_i = \frac{\sigma^2}{\alpha_i^2}$ there is no graphical comparable to the ridge trace but an iterative procedure initiated at $\hat{k}_i = \frac{\hat{\sigma}^2}{\hat{\alpha}_i^2}$ can be used [20]. In another study. about ridge regression, the author of [21] characterized the harmonic-mean version of the biasing parameter for the ridge regression estimator as follows:

$$k_{HM} = \frac{p\hat{\sigma}^2}{\sum_{i=1}^p \alpha_i^2} \quad (8)$$

where $\hat{\sigma}^2 = (Y'Y - \beta'X'Y)/(n - p)$ is the estimated mean squared error (MSE) using equation (2), and α_i is the i -th coefficient of $\alpha = Q'\beta$. Q is an orthogonal matrix such that $Q' \wedge Q = X'X$, and $\wedge = (\delta_{ii}\lambda_i)$ and is the matrix of eigenvalues.

3.3. Mean Absolute Percentage Error (MAPE)

In statistics, MAPE is a measure of prediction accuracy of a forecasting system, for example in trend estimation, often used as a loss function for machine learning regression problems. Typically, accuracy is expressed as a ratio specified by the formula:

$$MAPE = \frac{1}{N} \sum_{t=1}^N \left| \frac{A_t - F_t}{A_t} \right| \quad (9)$$

where A_t is the actual value and F_t is the forecast value.

3.4. Variance Inflation Factor

Variance Inflation Factor is an indicator to measure the seriousness of multicollinearity in an ordinary least square's regression analysis. It gives a list that estimates how much the fluctuation (the square of the estimate's standard deviation) of an expected regression coefficient is expanded due to collinearity. For a multiple regression model with p predictors X_i $i = 1 \dots p$, VIFs are the diagonal elements r^{ii} of the inverse of the correlation

matrix $R_{p \times p}$ of the p predictors [22][23]. The VIF for the i^{th} predictor can be defined by :

$$VIF_i = r^{ii} = \frac{1}{1 - R_i^2}, i = 1, \dots, p \quad (10)$$

where R_i^2 is the multiple correlation coefficient of the regression between X_i and the remaining $p-1$ predictor. Although there is no clear way to distinguish between a 'high' and 'low' VIF [23]. Several studies have suggested the cutoff values for "large" VIFs which is greater than 5 or 10 based on the R^2 [24][25].

3.5. Root Mean Square Error (RMSE)

The standard deviation of the residuals is defined as the Root Mean Square Error (RMSE) or otherwise known as prediction errors. Residuals are a measure of how far away the data points are from the regression line; RMSE is a measure of how spread out these residuals are. In other words, it indicates how concentrated the data is near the line of best fit. The root mean square error is a term that is frequently used in climatology, forecasting, and regression analysis.

$$RMSE = \sqrt{\frac{\sum_{i=1}^n (\hat{y}_i - y_i)^2}{n}} \quad (11)$$

4. Results and Discussion

The data we are using is secondary data obtained from hargapangan.id, id.investing.com, and Bank Indonesia website, the data are from August 2017 until March 2020. We are going to use two data sets, rice price data set and egg price data set. Each of the datasets contains the national and regional (DKI Jakarta) food commodity price (e.g.: rice price and egg price), USD buying price against IDR, and Gold price. In this research, all independent variables are used in predicting the food commodity price in DKI Jakarta. The independent variables are dependent on time.

$$X_1(t-1), X_2(t-1), X_3(t-1), X_1(t), X_2(t), X_3(t)$$

The variables above are the national food price, USD buying price against IDR, and gold price, which is represented by x_1 , x_2 , x_3 , and time represented by t .

The data analyzed has different units, so it is necessary to have a data center and scale for standardization of each variable. The standardization is done using Z-Score normalization.

Table 1: Normalized Rice Price Data Set

No	X ₁ (t-1)	X ₂ (t-1)	X ₃ (t-1)	X ₁ (t)	X ₂ (t)	X ₃ (t)	Y(t)

Table 2: Normalized Egg Price Data Set

No	$X_1(t-1)$	$X_2(t-1)$	$X_3(t-1)$	$X_1(t)$	$X_2(t)$	$X_3(t)$	$Y(t)$
1	-	-	-	-	-	-	-
	2.524	1.473	0.630	2.535	1.468	0.639	2.388
2	-	-	-	-	-	-	-
	2.524	1.475	0.638	2.535	1.480	0.679	2.388
3	-	-	-	-	-	-	-
	2.524	1.487	0.678	2.535	1.480	0.779	2.388
...
970	0.458	4.225	2.447	0.226	4.388	2.382	0.886

We first calculated the VIF score for each independent variable, in a linear regression model, the result can be found in table 3.

Table 3: VIF linear regression model using rice data set

Independent Variables	VIF
$X_1(t-1)$	4.4681
$X_2(t-1)$	108.432
$X_3(t-1)$	39.536
$X_1(t)$	4.4394
$X_2(t)$	113.610
$X_3(t)$	40.553

From table 3 we could see that there is high multicollinearity in a few variables mainly X_2 and X_3 which are the USD buying value against IDR and gold price.

Table 4: VIF ridge regression model using rice data set

Independent Variables	VIF
$X_1(t-1)$	0.329
$X_2(t-1)$	0.156
$X_3(t-1)$	0.198
$X_1(t)$	0.329
$X_2(t)$	0.157
$X_3(t)$	0.195

After applying the data into a ridge regression model, the VIF value decreases significantly ($VIF < 5$). This proves that ridge regression can deal with multicollinearity problems found in linear regression. Using the proposed method for multiple linear regression and ridge regression in section 3 for our model, we get the prediction results in figure 1 and figure 2.

Figure 1: Linear Regression and Ridge Regression with the best damping factor prediction using Rice Price data set

Figure 2: Linear Regression and Ridge Regression with the best damping factor prediction using Egg Price data set

Based on figure 1, we could see that the prediction using ridge regression is closer to the actual line. In table 5 and table 6 we compare the performance of each model.

Table 5: Performance Overview using Rice Price Dataset

	RMSE	MAPE	Computational Time
Linear Regression (cross-validation)	0.7461	-0.0157	1.558560s
Ridge Regression (cross-validation)	0.6062	-0.2568	0.938901s
ANFIS Model	56.3763	0.0019672	52 s
Linear Regression (with the best damping factor)	0.04510	0.0421578	0.162167s
Ridge Regression (with the best damping factor)	0.04510	0.0421577	0.228641s

Table 6: Performance Overview using Egg Price Dataset

	RMSE	MAPE	Computational Time
Linear Regression (cross-validation)	0.5557	0.0471	1.680529 s
Ridge Regression (cross-validation)	0.5329	0.1062	0.936147 s

ANFIS Model	474.4033	0.0063840	58s
Linear Regression (with the best damping factor)	0.03622	0.03548663	0.231017 s
Ridge Regression (with the best damping factor)	0.03622	0.03548587	0.175020 s

From the performance in Table 5 and 6, in rice dataset the proposed RR model performs good with 4,2% MAPE evaluation, but it is still higher compared the ANFIS model which shows 0,19 % of MAPE evaluation. While the MAPE value in LR and RR model using CV turns out to be negative in value. This might be caused by the particular small actual values that could bias the MAPE, and how in some cases the MAPE implies only which forecast is proportionally better. In the egg data set where the proposed RR model performs in average 3,5% MAPE, better than the one using Cross Validation, but it is still higher compared to ANFIS which have an MAPE score of 0,63%. If we compared the computational time, the regression model performs in a much faster speed compared to the cross-validation model and the ANFIS model where the proposed RR model in average could compute in less than a second while ANFIS model took almost a minute to generate the results. This is because the training time that are usually used to find the optimal results could be reduced by finding the damping factor firsthand.

5. Tables and Figures

This study demonstrated how a ridge regression model can be used as an effective way to forecast the food price prediction in DKI Jakarta. These models acquired accuracy in food prediction, on the model where we had to calculate the ridge parameter/damping factor beforehand also shows a faster computation time compared to the one where we used cross-validation.

The proposed model uses a linear ridge regression equation by [20], a future study using a different equation should be done to improve the overall performance. Since the dataset we are using is fairly small (970 (t) observation), using a bigger data set may show a more significant computational time difference. Further study by using a nonlinear forecasting model or implementing the kernel method should be to enhance the current model so it could produce better results.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

The article substantiates the relevance of conducting research on the structural characteristics of a company's employee knowledge, which is the result of his mental activity and his practical experience. The conditions under which information becomes a source of employee knowledge are determined. An abstract analysis of the process of transforming knowledge into an intellectual product – the competence of company employees is presented. In the process of the comparative analysis of the concept of «competence» its dual content is substantiated. Taking into account the recommendations of the scientific and methodological approach to building the model «Effective Consultant», its practical implementation was carried out on the example of the activities of consultants of a consulting company, taking into account the levels of their development and their performance of professional tasks. The article clarifies the essence of the concepts «consultant-manager» and «consultant-expert», describes the main stages of implementation of the model «Effective consultant» of the company. Calculations were carried out to assess competencies, which were previously divided according to group characteristics (superficial general and special, behavioral, adaptive and personal). Based on the results of the assessment, a set of key competencies of consultants was formed in the form of a package «Intellectual resource». Based on the results of the study of the dependence of the knowledge structure of the company's employees on their competencies, the practical rationality of the application of the scientific and methodological approach to the formation of the «Effective Consultant» model has been brought. The practical significance of the calculations performed using the method of expert assessments - hierarchy and priorities has been established. It has been substantiated that such an approach will allow companies to effectively use the intellectual knowledge of employees as a stable competitive advantage, and in the shortest possible time to achieve a high economic effect.

1. Introduction

The main characteristic of modernity is the rapid development of the processes functioning in it, which requires the employees of the enterprise to quickly adapt to the environment. The changes that occur in connection with the integration of capitals affect the transformation of relationships both within the enterprise and outside it. Updated technologies or made new products innovation (services) provide an enterprise with only short-term advantages, since competitors quickly adopt innovations, which allows them to occupy a leading position in the market.

The knowledge and skills of employees who are able to effectively use the limited resources of business entities form a special influence on the processes of maintaining competitive advantages. An employee of any company, who has a high level of general education, scientific and professional training, is capable not only of reproducing the acquired knowledge, but also of generalizing, analyzing and generating new knowledge in accordance with the needs of the labor market and operating conditions.

An important role in these processes is assigned to information resources, which, along with labor, capital and natural resources,

www.astesj.com

<https://dx.doi.org/10.25046/aj060281>

determine the efficiency of production and the logic of macroeconomic dynamics. And, unlike the recent past, when the statement of the English banker, businessman, financier Nothan Rothschild was relevant that who owns information, he owns the world for the present, it is important, if not the generation of information, then at least the ability to quickly analyze and transform it into intelligent products. In these conditions, there is a process of formation of special professional characteristics of employees – competencies, which eventually determine the competitive advantages of the enterprise.

2. Literature Review

Well-known foreign and domestic scientists made a great contribution to the formulation and theoretical development of issues that illuminate the content of the concept of “competence” and the conditions for the formation of a set of competencies for employees of enterprises, depending on the knowledge gained on the basis of the resource concept.

In the course of their research, in [1], the famous Ukrainian scientists emphasized knowledge, which is becoming a major factor in the post-industrial economy, and efficiency, which is not being paid enough attention to. They support the research of Swiss scientists, where only 20% of the knowledge possessed by the company's employees finds real application, despite the fact that 42% of corporate knowledge is the intelligence of the personnel, which is not recorded in any way on physical media.

Most often, knowledge is associated with such a concept as competence. For the first time the concept of “competence” was proposed by the American psychologist D. McClelland, who in 1973 in his article “Measuring competence instead of measuring intelligence” noted that competence is necessary to predict the level of performance of efficiency. According to his interpretation, competence is a circle of problems or a field of activity in which a person has knowledge and experience. In his theoretical study, [2] author described enterprise competence as a set of personnel competencies. The studies that conducted showed that traditional academic tests of aptitude and knowledge, as well as the availability of any diplomas from potential job performers, do not provide them with the effectiveness of performance of work duties and success in professional activities. Such conclusions led to the search for “competencies” as characteristics that distinguish and predict the level of performance of efficiency in specific performers.

In [3], the authors are considered directly the developers of the competence-based approach, according to which competence is the basic quality of an individual, which has a causal relationship to effective performance in work or other situations. Basic quality means that competence is a permanent (persistent) part of the personality that can determine a person's behavior in a large number of situations and work tasks.

In [4], well-known scientists proposed the concept of key competencies, they became the founders of the work «Key competencies of corporations» (1990), which continued the development of the competence approach. These scholars define core competencies as the skills and abilities that enable a company to deliver fundamental benefits to consumers. Proposing their concept, in [5], the authors argue that the term “core competence”

is used to characterize a set of skills and technologies, a set of unsystematically accumulated knowledge and experience by a company, which become the basis of successful competition.

In [6], the authors note that almost every company has at least one type of activity in which it has succeeded enough to consider the knowledge gained there as key competencies, that is, one that provides a competitive advantage. They argue that key competencies do not have a direct impact on the success or failure of a brand, since they are not directly focused on the needs of consumers and therefore cannot contribute to consolidating the brand's position. Excellence in the marketplace can be achieved not simply through unique enterprise resources and capabilities, but through their proper application.

A number of scientists distinguish between “knowledge” and “value” components in the competence. Thus, European scientists in the TUNING project note that the concept of competence includes knowledge as understanding (theoretical knowledge of the academic field, the ability to know and understand), knowledge of how to act (practical and operational application of knowledge to specific situations), knowledge of how to be (values as inherent part of the way of perception and life with others in a social context) [7]. In [8], the authors explain that competence is a general ability based on knowledge, experience, values, inclinations that are acquired through training. In [9], the author described the term “competence” as the ability to solve problems, provided not only by the possession of ready-made information, but also by the intensive participation of the mind, experience, and creative abilities of students.

In [10], according to the views scientists competence is considered as an open system of procedural, value-semantic and declarative knowledge, taking into account the interacting components (associated with cognition, personal, social), which are activated and enriched in activity as real vital problems arise that the bearer of competence faces. In this sense, in [11], the author notes that competence is a set of interrelated personality traits (knowledge, abilities, skills, means of activity), which are set relative to a certain range of objects and processes, as well as necessary for effective productive activity.

However, the development of a rational and effective set of competencies for employees of the enterprise in accordance with the structure of knowledge that they received during their professional activities based on the model of an “effective consultant” of the company remains outside the field of vision of most scientists on personnel management..

3. Methodology

3.1. Studies of the structural characteristics of knowledge as an economic category

All the arguments that are accepted and form the human worldview are not uniquely determined by the data of experience, but depend on the choice of the conceptual apparatus with which they can be interpreted. At the same time, choosing one or another conceptual apparatus, one can change the entire worldview. The main thesis of traditional conventionalism, of which, for example, A. Poincaré is a representative, is that there are problems that cannot be solved based on experience until some conventions

(concepts) are introduced, and only then these conventions together with experience data allow you to solve the problem. Therefore, before proceeding to highlight the objectives of the article, it is appropriate to provide an understanding of the basic concepts.

In the scientific literature, you can find many approaches to the problem of the relationship between the concepts of “information” and “knowledge”. Some scientists identify these concepts, consider them interchangeable. So, for example, the concept of “information” [12] as a set of knowledge, images, feelings available in the mind of a person or artificial intelligence, coming through various transmission channels, are processed and used in the process of human life and the operation of automatic computer systems, and the concept of “knowledge” [13]: information available in the mind of a person serves to solve intellectual and speech problems, is used in everyday cognitive and speech activities, predetermines human behavior.

In [14], scientists notes that knowledge today is information that has practical value: arise from the need to achieve effectiveness. If knowledge isn’t challenged to grow, it disappears fast.

In [15], the authors call knowledge the information contained in the human mind and is used to make decisions in a situation of uncertainty. In the sense of this study, as in cognitive psychology, the concepts of “information” and “knowledge” are clearly differentiated: knowledge is formed from information by means of its transformation and transformation, knowledge is an ordered accumulation of information. Based on this, objectivity is inherent in information, and knowledge is influenced by individual or social subjectivity.

In [16], the author described that sensory knowledge (information) is somewhat changeable, single, and knowledge is constant, stable, general, knowledge is nothing without understanding. The conditional structure of human knowledge can be depicted as a chain (fig. 1).

Figure 1: Conditional structure of knowledge

Data is a collection of facts, numbers (for example, measurements), in general, it is raw information. After processing the content data, information is obtained through analysis. As a result, of the synthesis of information, more complex structures are formed based on models describing an object or process, and knowledge arises. People, groups of people collect, process information and form knowledge. Knowledge is the result of a person's mental activity, his professional experience gained as a result of practical activity, or, in other words, information becomes knowledge when it is realized by a person, becomes part of her surrounding world, affects her opinion and actions. So, a specialist in a certain field is someone who is able to carry out the process of transforming data information knowledge.

Regarding the concept of “knowledge”, there are many theories about their classification, but the most common is the division into “explicit” (objective, with a clearly expressed

content, which can be written down, saved, transmitted, disseminated) and “hidden” (abstract, non-formalized, most often, subjective sensory knowledge, which is based on individual experience, represent beliefs, ideas). In the scientific literature, you can find similar names: “wandering” and “attached”, formalized and non-formalized, “hard” and «soft” and others.

Based on this distribution, in [17], the author described the theory of knowledge creation (“SECI model”). He believes that the creation of knowledge is an abstract spiral process of interaction between explicit and hidden knowledge, which leads to the emergence of new knowledge. This knowledge transformation process is shown in Figure 2. The transformation of knowledge, which is carried out by a successive transition through four processes, forms a spiral, so that it increases with each new turn of the spiral both in the vertical and in the horizontal plane, embracing the new knowledge of people. Space in which the spiral located, I. Nonaka called “Wa” (from Japanese philosophy - the space in which the created knowledge is located), and the knowledge that accumulates as a result of the model's action is “activated” knowledge. “Wa” is divided into four types depending on sequential processes: postal (environment for socialization), conversational (for externalization), simple systemic (for combination), research (for internationalization). These types correspond to different levels of knowledge.

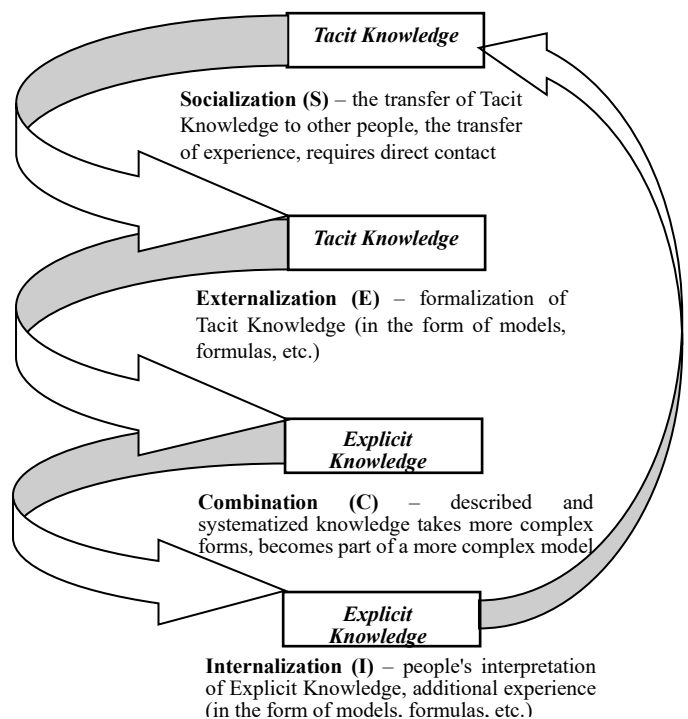

Figure 2: The SECI model

It should be noted that according to I. Nonaka's theory of knowledge creation, knowledge cannot be created from nothing. To create them, you need resources - “assets” of knowledge, which are the source for creating knowledge. “Assets” are divided, according to the previously considered processes (fig. 2) and types of “Wa”, into: empirical (transmitted exclusively through the exchange of experience), conceptual (transmitted through images, symbols, language), template (laid down in practical activity based

on internal rules and operating conditions of the enterprise) and systemic (formalized knowledge such as patents, copyright certificates, regulatory documents, etc.). Such distribution, according to I. Nonaka, will allow the company to take into account the “assets” of knowledge more effectively.

Nowadays, knowledge of the company (practical knowledge, experience of employees, patents, etc.) is an important and rather valuable resource or “intangible asset”. Usually, the process of preserving knowledge, one way or another, is implemented in each company, since reports, instructions, notes and other documents are created. Over the years, the number of documents only grows, then no one at all remembers about some of them and does not use them. This leads to ineffective use of the “assets” of knowledge of the enterprise [18]. In such circumstances, the company's employees become the main resource that is able to rationally use their knowledge and apply it effectively, depending on tactical and strategic situations in the process of the company's functioning.

3.2. Analysis of the process of transforming knowledge into an intellectual product - competence

In [19] and [20], prominent scientists noted that the employee, as human capital, was defined as the main resource that, depending on the circumstances, uses a set of his knowledge, skills and abilities to effectively manage the resources of the enterprise, and forms the competitive advantages of the company, characteristic and significant features of its products and market behavior, its know-how, image and brand. From the standpoint of the competence-based approach proposed, the employee's set of knowledge should be considered as the competitive advantages of human capital in accordance with the formed set of key competencies.

Studies prove that in the scientific world there is no clear opinion on the concepts of “competence”. So, according to the personal approach (American School), competence is the highest level of achievement of knowledge, which is considered as a quality (characteristics, ability) of a person, ensuring success in work. Supporters of the functional approach (British School) prove, competencies are the structural components of general competence, which are understood as the characteristics of work tasks and expected results of work. Most scientists perceive the personal aspect of the American School in addition to the functional aspect of the British School, since it provides criteria for the level of development of workers, studies positions, performance standards, professional requirements, while the American aspect studies the employee, his abilities and qualities [21]. The results of research by scientists confirm the fact that competence is the ability of a person to effectively perform a certain (in particular professional) activity, and competencies (plural of “competence”) are personal characteristics of a person that determine his behavior and affect the level of performance of a certain (in particular professional) activities.

Composite analysis of the essence of the concept of “competence” has revealed the dual nature of its substantive characteristics. In this regard, it is proposed to take the definition as the basis for the concept of “competence”, where competence is considered as an open system of knowledge, abilities and personality traits, in the process of creating company values, it provides effective productive activity, which is regulated by the

professional requirements of the position and quality standards [21]. The complex of competencies of the company's employees creates its intellectual capital, the set of qualities of which is proposed to be divided into [22]:

- -hereditary (features of the nervous system that determine the nature, inclinations of work, thinking, speech, mental inclinations and abilities);
- physical (endurance; agility);
- intellectual;
- convergent abilities (efficiency of the information processing process, first of all, the correctness and speed of finding the only possible (normative) solution in accordance with the requirements of a given situation);
- divergent abilities (creativity - originality, sensitivity to unusual details and metaphorical thinking) ability to learn; cognitive style).

The qualities of human capital are determined, they are individual and specific for each individual employee of the company, they are formed and implemented in the production process through a set of key competencies that the employee improves over time. In these conditions, employees become a strategic resource of the company, and the process of generating and transforming their knowledge will be provided with a set of key competencies in accordance with the standards, norms and rules that are formed in the company.

Using the example of a consulting company in accordance with the existing competence-based approach and taking into account the methodological foundations of the “Effective Consultant” model, the process of formation of knowledge and key competencies of consultants in the mechanism of consulting interaction is first schematically presented (fig. 3) [21].

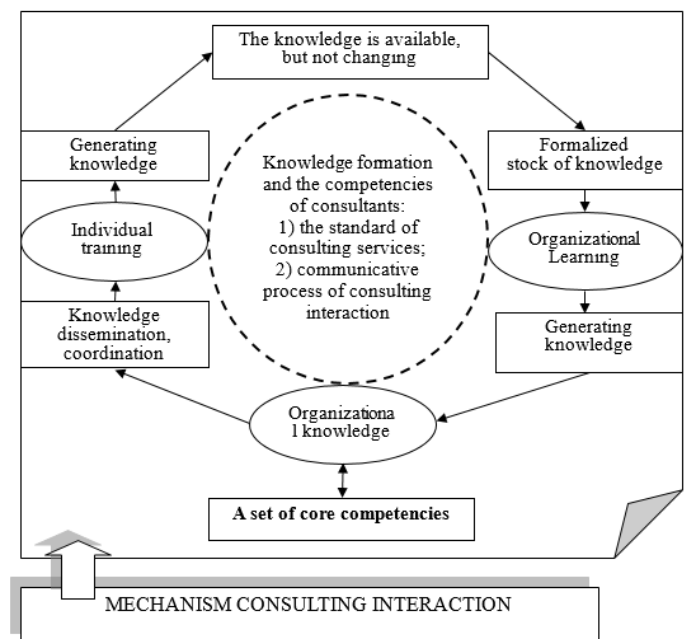

Figure 3: The process forming the knowledge and key competencies of consultants in the mechanism of consulting interaction

At the beginning we will rank the main features of the concepts “consultant-manager”, and “consultant-expert”, then will describe the main stages of the implementation of the algorithm of the model “effective consultant” of a consulting company, based on which it is proposed to conduct a practical assessment of the proposed competencies by the levels of performance of their professional tasks.

A consulting company, like any company, has a large intellectual capital (potential) to create its value, the basis of which is the concept of knowledge (value) and information management, which makes it possible to introduce intellectual products into the activities of customer enterprises and give recommendations on their development in a constant competitive struggle and self-organization of their human capital. In their activities, competence is defined as an open system of knowledge, abilities and personality traits; in the process of creating company values, it

ensures effective productive activity, which is regulated by the professional requirements of the position and quality standards. The complex of competencies of the company's employees creates its intellectual capital or potential during the communication process in the mechanism of consulting interaction [23].

In the course of the study, the main representatives of the consulting company identified the following groups of consultants as managers and experts. In terms of content, a “consultant-manager” is a specialist who is endowed with the functions of a leader in managing a business and its individual business processes based on a goal-setting system in a strategic perspective, and a “consultant-expert” is a professional in a separate business process who is endowed with qualities of synthesis and analysis, rational assessment of the situation, aimed at achieving the goals set by the manager. The consultant-specialist is the direct executor of the tasks provided by the consultant-manager [21].

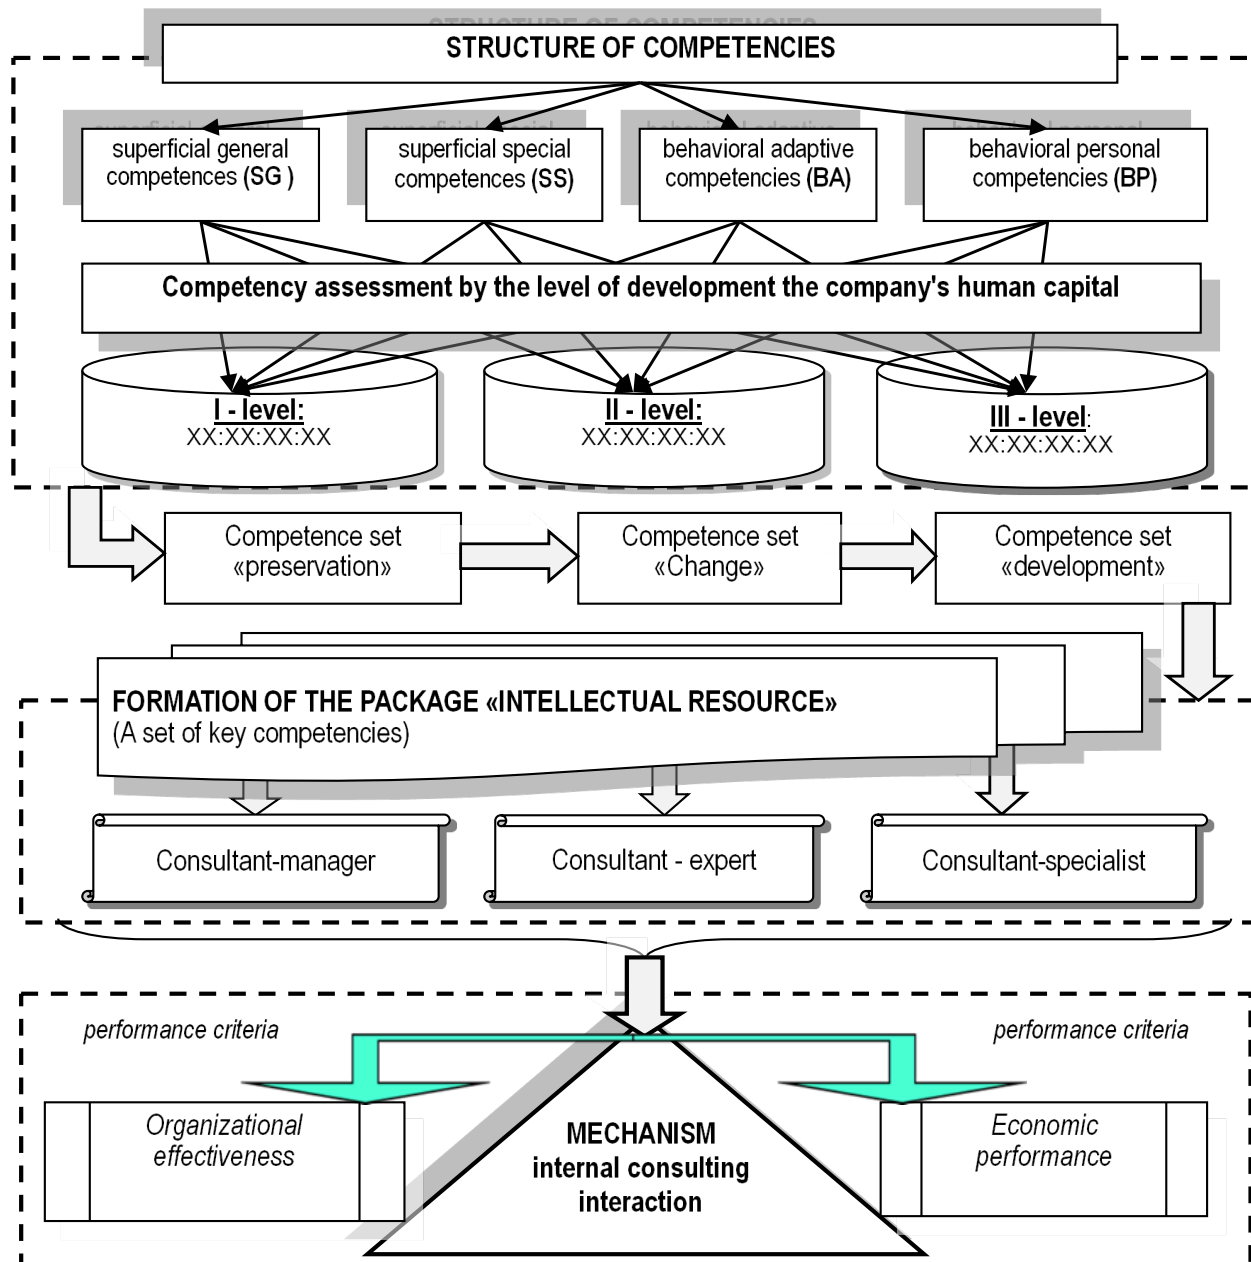

Figure 4: Model "Effective Consultant" of a consulting company as a component of the mechanism of internal consulting interaction

In the course of its activity, the efficiency of the consulting company is associated with the accurate fulfillment of tasks, in the future, they will affect the quality, content and terms of work performed. The solution of these tasks is proposed to be carried out using methodological tools, which are implemented in the “Effective Consultant” model of a consulting company based on a competency-based approach (fig. 4) [21].

The scientific and methodological approach to the construction the model “Effective Consultant” a consulting company is presented by the author in [21], consists of the following stages:

Stage 1 - the formation of a set of competencies for the company's consultants by levels of human capital development.

At the first stage of the “Effective Consultant” model, we form a set of competencies according to the levels of human capital development (fig. 5), according to which competencies will be considered as an integral indicator, presented in the form of functional dependence:

$$K = F(SG1, SS2, BA3, BP4), \quad (1)$$

where: SG – superficial general competences,
 SS – superficial special competences,
 BA – behavioral adaptive competencies,
 BP – behavioral personal competencies.

The levels of human capital development of the consulting company are given in (fig. 5) [21].

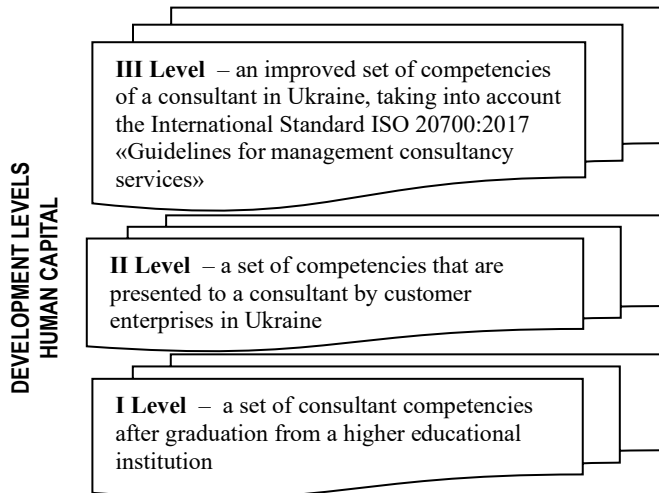

Figure 5: The level of human capital development of a consulting company

Note that the basic set of competencies of a consultant, according to the first level of human capital development, which he receives after graduating from a higher educational institution, are those that are formed in accordance with the guidelines for the development of educational programs [24].

Stage 2. At the second stage of building the “Effective Consultant” model of a consulting company, a set of competencies is assessed by levels of development in accordance with their weight. To determine the degree of production and consumer novelty, the Analytic Hierarchy Process method (AHP) [17] is used. The weight of the factors according to all experts is calculated by the formula:

$$W_j = \frac{\sum_{i=1}^m w_{ij}}{\sum_{i=1}^m \sum_{j=1}^n w_{ij}}, \quad (2)$$

where: W_{ij} – weight assessment i-th competence given by the j-th expert, score;

m – number of experts;

n – number of competencies in the group.

Stage 3. At the third stage, a package of intellectual resource “Effective Consultant” of a consulting company for consultants (managers, experts and specialists) is formed, in which key competencies are selected in accordance with modern requirements.

4. Empirical findings

Using the example of a consulting company in Ukraine, we carried out the practical implementation of the stages of building the “Effective Consultant” model.

According to the results of data processing carried out in the process of analyzing the set of matrices for comparison of the I-level of human capital development of the consulting company “Competence of a consultant upon graduation from a higher educational institution”, the most significant competencies were identified in the groups «Superficial general competences» (0,644) and “superficial special competences (0,229). The key competencies are those that affect after receiving a diploma in the relevant specialty: skills in the use of information and communication technologies; expert knowledge in a certain area (economics, finance, accounting, reengineering, psychology, etc., the ability to generate new ideas, skills to establish interaction with partners (Table 1) [21].

Table 1: The results of the assessment of competencies for the I-level of development - “Competence upon graduation from a higher educational institution”

Competency structure	Weight	General Competence (factors)	Weight by individual factor
Superficial general competences (SG)	0,644	Basic general knowledge (higher education for I, II and III levels) (SG ₁)	0,41
		Skills in the use of information and communication technologies (SG ₃)	0,127
		Ability to communicate in the state and foreign languages (BP ₆)	0,112
		Ability to work with the regulatory framework (SG ₇)	0,139
Superficial special competences	0,229	Expert knowledge in a specific area (economics, finance, accounting, reengineering, psychology, etc.) (SS ₁)	0,325
		Partnership Skills (SS ₅)	0,151

		Ability to conclude deals, establish contacts, negotiate (SS ₇)	0,108
Behavioral adaptive competencies	0,083	Research Skills and Abilities (BA ₁)	0,365
		Ability to generate new ideas (creativity) (BA ₄)	0,184
		Ability to work independently (BA ₅)	0,222
Behavioral personal competencies (BP)	0,044	Initiative (BP ₉)	0,105
		Ability for criticism and self-criticism (BP ₁₀)	0,143
		Self-confidence (BP ₁₁)	0,108
		Desire to achieve success and provide inspiration to the team (BP ₉)	0,184

- ability to observe ethical behavior;
- ability to define success criteria to ensure the required quality of results;
- knowledge of marketing technologies;
- ability to solve problem situations and create innovative solutions for customers;
- skills to form expert opinions;
- to ensure the quality of work performed (projects) and decisions, taking into account the rules and regulations of corporate culture;
- be able to effectively manage their own time to complete tasks on time;
- ability to deepen knowledge and improve skills, based on the experience of their own and other past project tasks;
- skills to analyze the market of consulting services, its competitors and identify the capabilities of a consulting company.

Table 2: The results of the assessment of competencies for the II-level of development – “Competencies that are presented to the consultant by employers in Ukraine”

Competency structure	Weight	General Competence (factors)	Weight by individual factor
Behavioral adaptive competencies (BA)	0,598	Knowledge of marketing technologies (customer orientation) (BA ₂)	0,164
		Ability to adapt and act in a new situation (BA ₃)	0,168
		Knowledge of change planning and development of new projects (BA ₆)	0,272
		Ability to evaluate and ensure the quality of work performed and decisions (BA ₈)	0,172
Behavioral personal competencies (BP)	0,259	Interaction risk management skills (BP ₄)	0,203
		Conflict management skills (BP ₇)	0,231
		The desire to succeed and inspire the team (BP ₁₃)	0,114
Superficial special competencies (SS)	0,099	Ability to plan and control business processes (SS ₃)	0,238
		Ability to work in an international context (SS ₈)	0,117
		Ability to motivate people (SS ₁₀)	0,163
		Knowledge of corporate culture (SS ₁₁)	0,167
Superficial general	0,044	Knowledge of analysis and synthesis (SG ₂)	0,185
		Reasonable decision making skills (SG ₅)	0,131

According to the results of processing by experts of the data carried out in the process of analyzing the set of comparison matrices of the II-level of human capital development of the consulting company «Competences that are presented to the consultant by employers in Ukraine», the most significant competencies are determined by groups «Behavioral adaptive competencies» (0,598) and «Behavioral personality competencies» (0,259). Significant are those competencies that are defined as key from the point of view of employers: knowledge of marketing technologies (customer orientation); knowledge of planning changes and developing new projects; interaction risk and conflict management skills; ability to plan and control business processes; skills of making informed decisions (tab. 2) [21].

Also, by rejecting practical tips, which are valued by employer, from theoretical and scientific knowledge, as it is hoped for the completion of study at universities, to form the protagonist of a consulting company as which is becoming a human capital of Ukrainian company.

If we add to the proposed II-level human capital development “Competences that are presented to a consultant by employers in Ukraine” the competence of the International Standard “Guidelines for management consultancy services” in accordance with the International Framework of Competence developed under the leadership of the International Council of Management Consulting Institutions, then we get an improved III-level of development of the company's human capital with “A set of consultant competencies in Ukraine, taking into account the International Standard ISO 20700: 2017”.

In the process of improving the set of key competencies at the III-level of human capital development, it was proved that the main ones in the structure of competencies are “Behavioral personal competencies” (0,658) and “Superficial special competencies” (0,215). Significant are the competencies that are separated by key ones taking into account the International Standard ISO 20700:2017:

- skills of risk management of interaction, including risk identification and the ability to work to minimize it;

	Ability to communicate in state and foreign languages (SG ₆)	0,152
	Ability for continuous learning and self-development (SG ₈)	0,257

However, it is desirable to confirm the above key competencies with a certificate of at least one year of counseling experience. The results of the expert assessment on the third level of human capital development of the company “Improved set of competencies of a consultant in Ukraine, taking into account the International Standard ISO 20700:2017” Guidelines for management consulting services” in their importance are presented in Table 3 [21].

Table 3: The results of the assessment of competencies for III-level “An improved set of competencies for a consultant in Ukraine, taking into account the International Standard ISO 20700:2017”

Competency structure	Weight	General Competence (factors)	Weight by individual factor
Behavioral personal competencies (BP)	0,658	Interaction risk management skills, including. risk identification and ability to assess it (BP ₅)	0,185
		Conflict management skills (BP ₆)	0,107
		Ability to adhere to ethical conduct and the Code of Professional Conduct and Ethics established at the national or international level (BP ₁₁)	0,182
		Ability to define success criteria to ensure the required quality of results (BP ₁₂)	0,288
Superficial special competencies (SS)	0,215	Certificate confirming at least one year of consulting management experience (SS ₂)	0,199
		Knowledge of marketing technologies (customer orientation) (SS ₆)	0,032
		Ability to solve problem situations (SS ₇)	0,063
		Ability to form expert assessments and conclusions (SS ₈)	0,122
		Knowledge of corporate culture (SS ₁₂)	0,187
		Ability to evaluate and ensure the quality of work performed (projects) and decisions (SS ₁₃)	0,168
Behavioral adaptive competencies (BA)	0,096	Purposefulness in achieving results in professional development (BA ₁)	0,035
		Ability to adapt to a new situation (BA ₂)	0,033
		Ability to successfully complete customer tasks, ensuring goals, deadlines and budgets are agreed and delivered on time (BA ₅)	0,266
		Knowledge of change planning and development of new projects (BA ₆)	0,286
		Creating innovative solutions for customers (BA ₇)	0,103
		Ability to effectively manage their own time to complete tasks on time (BA ₈)	0,049
Superficial general	0,031	Basic general knowledge (higher education at I, II and III levels) (SG ₁)	0,152
		Knowledge of analysis and synthesis (SG ₂)	0,05
		Applying knowledge and tools to create value for the client (SG ₃)	0,037

	Skills in the use of presentation tools and other research methods (SG ₄)	0,371
	Ability to work with the regulatory framework (SG ₆)	0,071
	Ability to deepen knowledge and improve skills based on experience of own and other past project tasks (SG ₇)	0,270

The calculations carried out by a group of experts in the second stage to assess the set of competencies of the company's consultants by levels of development according to their importance allow ranking the competencies of human consulting company, which form the basis for building the package (Table 4) [20].

Table 4: Ranking of competencies by groups and levels of development human capital consulting company

Competencies by group and level	I - level a set of competencies of a consultant after graduation from a higher educational institution		II - level a set of competencies that are exposed to a consultant by customer enterprises in Ukraine		III - level an improved set of competencies of a consultant in Ukraine, taking into account the International Standard ISO 20700:2017 «Guidelines for management consultancy services»	
	Weight	Rank	Weight	Rank	Weight	Rank
Superficial general competencies (SG)	0,644	1	0,044	4	0,031	4
Superficial special competencies (SS)	0,229	2	0,099	3	0,215	2
Behavioral adaptive competencies (BA)	0,083	3	0,598	1	0,096	3
Behavioral personal competencies (BP)	0,044	4	0,259	2	0,658	1

Based on the results of the assessment of competencies, it was found that the competencies defined by employers, combined with theoretical and scientific knowledge, which are provided after completion of training at the university, form an employee of a consulting company, who has already become the company's human capital.

If we add to this level some competencies of the International Standard ISO 20700: 2017 «Guidelines for management consultancy services» according to the International Framework of Competence, developed under the leadership of the International Council of Management Consulting Institutions, we get an improved set of competencies for consultants of a consulting company.

According to the results of the competence assessment, high importance is given to “Behavioral personal competencies” (0,658), which the consultant develops in the process of accumulation of professional skills and self-development on the basis of “Superficial special competencies” (0,215) and “Superficial general competencies” (0,031). In modern conditions, the Behavioral adaptive competencies group does not significantly influence the development of the company's consultants, modern gadgets and information platforms help them to adapt, etc.

Nevertheless, the main asset of the “Effective Consultant” model is the construction of the “Effective Consultant” intellectual resource package based on the results of the competence assessment for each individual group of consultants according to their key features (Table 5) [21].

The joint competencies of the consultants of the consulting company are as follows [20]:

- basic general knowledge (higher education for I-, II- and III-levels) (BP1);
- certificate confirming less than one year of experience in consulting management (SS2);
- knowledge of analysis and synthesis (SG2);
- application of knowledge and tools to create value for the client (SG3);
- ability to work with the regulatory framework (BP6);
- ability to deepen knowledge and improve skills based on the experience of one's own and other past tasks (SG7);
- knowledge of corporate culture (SS12).

The proposed model “Effective Consultant” regulates the process of forming a universal set of key competencies according to the levels of human capital development for a consultant-manager, consultant-expert and consultant-specialist in accordance with the demand by external or internal circumstances. The process of assessing competencies at structural levels has an innovative content that will certainly affect the quality of the company's consulting services. Under such conditions, the formation in the process of consulting interaction will ensure a balance between the performance and organizational efficiency of resources. Formed package of intellectual resource “effective consultant” is not universal. Over time, knowledge and information change, providing for a revision of the company's

potential management system and its human capital management system. A decrease in the growth rate of labor productivity of employees of a consulting company at all levels of management will certainly affect the rate of profit growth. It is advisable to annually conduct expert research to revise the package of intellectual resource “Effective Consultant” and form such a set of key competencies, which is in demand by the time, existing and potential clients [20].

Table 5: A set of key competencies for the skin group and consultants at the border of the package “Intellectual resource”

Species sign	Characteristics
Consultant-manager	<ul style="list-style-type: none"> – ability to comply with ethical conduct and the Code of Professional Conduct and Ethics established at the national or international level (BP11) – ability to define success criteria to ensure the required quality of results, and their application in professional activities (BP12) – knowledge of planning changes and developing new projects (BA6) – creation of innovative solutions for clients (BA7) – ability to assess and ensure the quality of work (projects) and solutions (SS13) – skills of risk management, including risk identification (prevention, mitigation, transmission, reception, contingencies) and the ability to assess it (BP5) – knowledge about the characteristics of the market for consulting services, competitors and its opportunities (SS4).
Consultant - expert	<ul style="list-style-type: none"> – ability to solve problem situations (SS7); – ability to form expert assessments and conclusions (SS8); – ability to assess and ensure the quality of work (projects) and solutions (SS13); – ability to adapt to a new situation (BA2); – conflict management skills (BP6); – commitment to achieving professional development results (BA1); – ability to successfully solve client problems, ensuring goals, timelines and budgets are agreed and delivered on time (BA5); – ability to effectively manage your own time to complete tasks on time (BA8).
Consultant-specialist	<ul style="list-style-type: none"> – commitment to achieving professional development results (BA1); – knowledge of marketing technologies (customer focus) (SS6); – ability to successfully solve client problems, ensuring goals, timelines and budgets are agreed and delivered on time (BA5); – conflict management skills (BP6); – ability to effectively manage your own time to complete tasks on time (BA8).

To continuously improve their existing competencies and acquire new knowledge, consultants must distribute their stock, generate new knowledge, take courses to improve professional skills and engage in their own training during the implementation of consulting projects. Moreover, the knowledge transfer process, taking into account the key competencies of consultants, will take place in accordance with the consulting service standard created

by the owners of the consulting company itself or proposed for use at the level of a regulatory and legislative act.

5. Conclusions

Based on the consideration of the above, we can conclude that the personnel management of the company today is expanding its economic content and acquires a new meaning as capital. The modern process of human capital management is aimed at its effective use and development. In these circumstances, the owner has the opportunity to maximize the return on the skills, knowledge of the worker, and the worker - to receive the maximum level of material and psychological satisfaction from his work. Then the goal of management acquires strategic development in two directions.

The first should provide for a high degree of competitiveness of the enterprise, flexibility of forms and methods of human capital management, intensification of labor of highly qualified workers and participation of workers in the distribution of profits. The second direction should include ensuring responsibility for the creation of competitive advantages of the enterprise by the employees themselves, and their participation in the affairs of the enterprise is achieved through such factors as effective organizational communication, high motivation and flexible leadership. However, in both the first and second directions, the role of human capital in the process of consulting interaction, accompanied by the value chain, is endless. The human capital of a consulting company is not just its main intellectual resource, its potential, in contrast to other resources, is formed through the renewal of intellectual knowledge and information. In these conditions, human capital becomes the source of the company's values, which over time are recognized as competitive advantages for a reasonable desire to transform resources into capital.

The article presents a scientific and methodological approach to building the model "Effective Consultant". The methodological basis for assessing competencies according to the "Effective Consultant" model has an innovative content. The proposed model regulates the process of forming a universal set of key competencies according to the levels of human capital development for a consultant-manager, consultant-expert and consultant-specialist. The Effective Consultant model takes into account a set of competencies in accordance with the demand from external or internal factors. In the course of the research, it was found that the weighty groups defined "Behavioral personal competencies" and "Superficial special competencies".

The "Effective Consultant" model has been tested and implemented in the activities of consulting companies in Ukraine, which allows to be recommended for widespread use by any consulting company in the world. Human resources and academic departments of the company can use the "Effective Consultant" profile of consultants as a tool for managing business processes. Consultants can use the recommendations as part of a scientific and methodological approach to building the model "Effective Consultant" as a source of personal growth. It is proposed to evaluate consultants periodically so that the dynamics of the development of their competencies can be tracked.

Image Processing

ABSTRACT

Waste is currently a serious problem often found in rural areas, rural areas, and even industrial areas. Waste is a side effect of activities carried out by humans to meet social or industrial needs. Increasing human productivity will also increase the amount of waste produced. To overcome this, a sorting management system is needed. Good waste is seen from the processing method to the recycling process. The waste management problem still relies on the old system transporting and disposing of waste to the final disposal site (TPA). The TPA itself sometimes piles up in one place so that the waste process becomes uneven and the sorting process is not good, causing type waste. This accumulates and mixes with other hazardous waste. In today's modern era, the management and sorting system is the same. Object detection and waste classification are carried out in the Sensor system to introduce the previously prepared model. The prototype article recognition model is prepared with waste images to produce a freeze forecast graph used for object discovery which is carried out via the camera associated with the Arduino Uno as the basic unit handling. Ultrasonic sensors are inserted into each garbage compartment to filter out the refill filling rate. The sorting system itself can use computer-based image processing methods. Image Processing is used to process data in real-time and fill the trash level. The sensor module that is implanted to detect waste management personnel, the results of this study prove that image management can accommodate waste particles and tested in the BlackBox method produces results following the required quantitative with the accuracy in both the camera, sensor, and image process used can detect an average of 70%.

1. Introduction

Currently, waste can be referred to as the effect of activities carried out by urban or rural communities. Waste is a waste product or a used product that is not produced. This residual product has less benefit compared to the product used, so the residual effect is discarded or not reused. Various types of waste are called Solid Waste. Garbage is divided into two types, namely organic waste and non-organic waste. Organic waste is waste that can be broken down, such as food scraps. Leaves, and wood, while non-organic, are waste that cannot be decomposed but can be recycled, such as plastic, glass, paper, and metal waste. This waste will be a disaster for human life and the environment if it is not appropriately managed so that a sorting system and good processing to reduce the effects and side effects for the environment are needed [1, 2].

While human waste (human waste) is commonly utilized for stomach-related items, the human can be a genuine wellbeing danger since it can be used as a vector (implies of advancement) for infections caused by infections and microbes. One of the advances in diminishing infection transmission through human squanders with a clean and sterile way of life. A sound sanitation system cannot be separated from the regulation. Some examples of waste generated in households include waste from batteries, electric lights, electronics, pesticide packaging, clothes bleach, floor cleaners, paint, pressure cans (aerosol), fuel packaging, leftover medicines (pharmaceuticals), mercury thermometer, and syringes. The ingredients contained therein have characteristics that can cause harm to human safety and health and environmental pollution [3, 4].

Waste management is an excessive activity as it takes up a lot of assets and work. The specialists have endeavored to improve the board frameworks by setting up the recyclable canister and

*Corresponding Author: Mochammad Haldi Widiyanto, Kecamatan Buah Batu, Bandung, Indonesia, mochamad.widiyanto@binus.ac.id

dispatching the 3Rs lobby (recycle, reuse and reduce). At the same time, the problem currently faced is waste disposed of either by home or industry. It is still mixed and has not been correctly sorted. For example, the household waste itself has dangerous substances such as high-pressure aerosol cans, waste liquid, and pharmaceutical drug remnants, this type of waste will become toxic. Some of the items can be flammable, which is dangerous for cleaners and the surrounding environment. Current waste sorting system technology has offered various solutions, including the use of technology-based electronic sensors [5].

Information is a component of the IoT needed in communicating because several main elements must be known in communicating on IoT devices, namely the communicator, listener, and information message. Further processing of data that already has added value or, in other words, information is data that has been classified or processed or interpreted for use in the decision-making process. The communication system used can be a GSM module to transmit data from sensors to the clouds in the form of a web-based [6, 7].

There was no tool for sorting waste into certain parts in previous research due to inadequate waste processing factors. This study focuses on processing waste sorting by utilizing computer vision [8,9] and sorting management where data processing is accurate and very suitable for placing on other large machines. It is hoped that this tool can help several dumpsites [10, 11].

2. Related Work

With the uneven development of Internet of Things (IoT) arrangements comes the more major worry over security issues related to most gadgets. It is extended that the product on the Internet of things related gadgets will surpass 20 Billion devices by 2020 [12, 13]. A considerable lot of these arrangements will use and using cell association availability to interconnect. An inadequately architected cell network can open the answer for potential security issues. A profoundly gotten compositional understanding requires a multilayered security approach enveloping the by and large building plan for the web, traversing from the edge gadget as far as possible up to the objective host for preparing, stockpiling, and further use.[14–16].

For an IoT-based answer to being actualized, it ought to be energy effective, ready to impart and share data across broadened inclusion. An IoT-based installed framework is proposed in [17]. GSM correspondence innovation is utilized as the stage to perform information transmission to the worker. In [18], a keen container framework dependent on AI, picture handling, and IoT is proposed. This framework utilizes a convolutional neural organization (CNN) to distinguish and isolate squander into various classes, like metal, glass, paper, and plastic. A sum of 400 to 500 pictures containing the four unique types is utilized to prepare the organization [19].

The IoT device has a central control system or what is called a microcontroller [20,21]. A microcontroller is a computer system built on a single chip and a processor used for control purposes. Even though it has a much smaller form than a personal computer and the mainframe computer, the microcontroller is built from the same essential elements. One of the microcontrollers often used is the Arduino Uno [22,23]. The system utilizes Raspberry Pi 3

and Xilinx PYNQ-Z1 FPGA board and pre-trained ResNet-34, a convolution neural organization containing 34 pre-trained layers to perform gathering. The data accumulated from the canister is sent utilizing a LoRa correspondence arrange from a sensor center to the section.

Arduino is a microcontroller development board based on Arduino using the Atmega2560 chip. This board is total, has everything required for a microcontroller. With primary usage, the researcher has to connect the control from USB to PC or via a connector. The following is a table of specifications from the Arduino Mega [24, 25]. Another sensor that is used to monitor the volume of the trash can is ultrasonic. The working principle of the HCSR04 Ultrasonic Sensor is a transmitter that sends an ultrasonic wave which is then measured by the time it takes until the reflection of the object arrives. The length of time is proportional to twice the distance between the sensor and the object [26–28]. because there are many types of microcontrollers, the image below is the result of how the microcontroller diagram works.

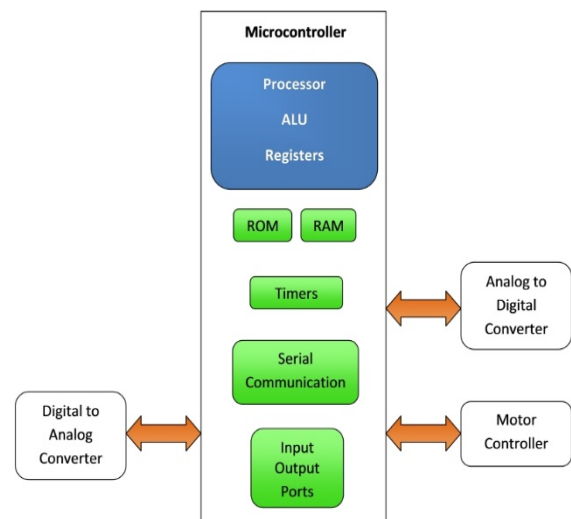

Figure 1: Microcontroller Diagram

In a waste bin, waste is divided into two parts, namely solid and liquid waste. Liquid waste is a type of waste that is dangerous because it can seep into the ground and will affect air quality, so detection is necessary for the trash. This liquid waste uses a pH Meter sensor. The sensor will deal with the edge of waste and go into protected or dangerous conditions. Next, the pH meter comprises an anode (estimating test) conveyed to an electronic gadget that measures and shows the pH esteem.

The main working principle of a pH meter lies on the sensor probe in the form of a glass electrode by measuring the number of H_3O^+ ions in a solution. The tip of the glass electrode is 0.1 mm thick round glass. By using a layer (bulb), this tool is paired with an elongated non-conducting glass or plastic cylinder, which is then filled with HCl. In the HCl solution, a long silver electrode wire is immersed on the surface that compounds the AgCl balance.

The constant amount of HCl solution in this system makes the Ag / AgCl electrode has a stable potential value. The pH sensor core is on the surface of a glass ball which can exchange positive

ions (H+) with a measured solution. The things above that can help in the sorting process into the TPA (final disposal site). With the help of existing sensors. It is also our contribution because, in previous studies, there has not been any research until the landfill [29, 30].

Figure 2: Methods used in image processing

3. Research Methodology

Based on several literature studies, a sorting system can be combined with a hardware device or device, these devices include infrared sensors and metal detection sensors which are commonly used, identification of the types of metal and non-metal waste itself functions to facilitate the sorting process as well as the plastic and paper waste separation system and another method is the use of image processing, this system is beneficial when sorting in visual form, an application that has a reliable level of intelligence is needed in sorting waste types so that the sorting method with image processing techniques and IOT combinations becomes a solution and help choose the type of waste and its characteristics [31,32].

Before creating a sorting system, a grouping of the kinds of waste is needed. It is necessary because the type of waste itself has different effects and characters. It is based on the type and area of waste found. In contrast, the most recent waste is toxic waste and is very dangerous to human health and the environment. Based on this problem, a reliable sorting system is needed. This research has reviewed IoT-based waste processing technology. It can be

combined with the sensor to detect the presence or absence of a toxic substance. Toxic substances in the waste are carried out by a sensor sorting the use of image processing technology to detect the categorization of types of waste [33, 34].

Figure 2 analyzes the waste image images and sorts them by several stages. First, data collection is carried out. The researcher in this section looks for the pictures needed as a database. Second and third image processing is done into RGB and Grayscale to assist in the image processing process. Fourth, image processing is carried out by looking for patterns from the image. Fifth, the result of the pattern obtained is the recognition of the shape of the image, which will be used for classification at a later stage. The last is to determine the classification to determine whether the image is as desired and looking at the resulting accuracy, the resulting accuracy will explain in the last section. [35].

Figure 3: Our Research Methodology

Figure 3 is our sequences of this research as explained below:

- **Taking Picture**
In this process, taking pictures can be using a mobile device or a camera mounted on a conveyor machine. The camera is endeavored to have a high image capture capability so that the accuracy of the object taken has a high reading data precision.
- **Sharping Picture**
In this process, image sharpening reduces accuracy if the object is taken in a low light condition. The image processing algorithm has a high reading accuracy and can sharpen the item to be processed.
- **Removing Noise**
Removing vandalism or distracting light objects can result in decreased accuracy of per-item readings. In this process, the worrying process will be eliminated by the system.
- **Image Processing**
the object reading process is performed by distinguishing the objects read by the system. It can be determining the color of the texture, the shape of the item, the data of each object will be converted into binary numbers. After That stored in the database as training data, the amount of training data using plastic, metal waste samples, cans, and organic.
- **Result**
In this process, the system will display and classify several types of waste into metal and non-metal waste and classify it into organic and non-organic waste[36, 37].

In this method, a sorting system is performed using image processing techniques. This method has reliability in recognizing an object and has been implemented in various fields. This system also has a level of accuracy and can be used to sort waste by type and size. In general, the current sorting system using a conveyor machine is used to sort metal and non-metal waste, which in turn serves to facilitate the process of smelting and recycling. This conveyor system works by reading sensors installed on the sorting machine. Sensors that are often used are usually humidity sensors, heavy sensors, and solenoids to detect metals. This system can detect and classify types of waste but still has the disadvantage of distinguishing types of waste based on the form of waste and the presence or absence of hazardous chemicals in the waste. This must be overcome so that a manual sensor is needed that is combined with imaging techniques and is equipped with image processing. So it can endanger hazardous chemicals in treated waste. Another thing that causes the spread of toxic substances in a waste to be detected. The space of chemicals can be very dangerous and visible, especially in waste-making materials that contain metals.

Sampling data for training is more than 5000 garbage data collected. The amount of data is a data collection standard used to identify types of organic and non-organic waste. The garbage data is then converted into a binary number which represents an assessment of the type and color of the object. After that, it will then be seen visually by the system.

Figure 4: Pseudocode RGB & Color conversation

Figure 4 above is the process of image conversion using python and the NumPy library. The script above shows that the captured image will be converted to RGB format for each picture frame. The image is then converted to 100x100 pixels, which is the size set for

255 as the largest size. This method serves to calibrate the image size and the selected object to be determined.

In this study, researchers used a BlackBox to measure the success of the prototype quantitatively. By understanding the black box, the resercher can interpret the model, know the role of each layer, as well understand the stupid side of the model made.

4. Result

The following is a display of the results of the UI / UX program from the IoT application program for the efficiency of trash cans and the results of implementing an image-based process.

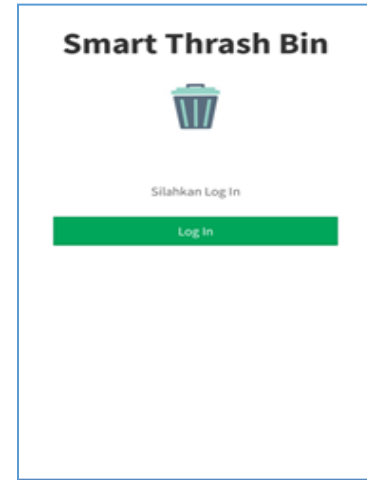

Figure 5: Trash bin login system

Figure 5 above is a place sorting system that is integrated with mobile devices. In this application, there are additional security features that are used for login validation. It uses an email data recognition system and can manage more than one trash can area.

Figure 6: Trash bin login system

Figure 6 above shows how the gas sensor works, which will forward the data taken from the sensor installed on the smart trash bin. The sensor sends data via clouds and is displayed from the mobile device in a website application. The sensor data will automatically be monitored by the system and displayed changes every time depending on the amount of waste available.

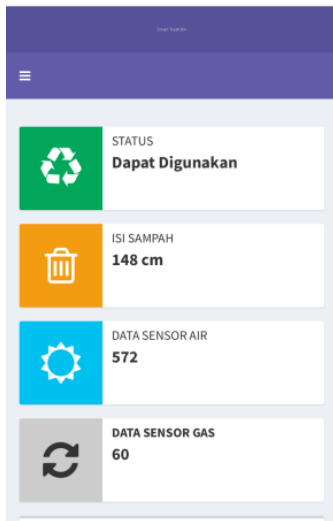

Figure 7: Overall monitoring system

Figure 7 is the overall data monitoring system. Four components are monitored, namely;

- **Trash bin status**
The same place has two monitoring conditions that can be used and are not ready to be used. If it is full, then the trash cannot be used and is in a full state until it exceeds the trash bin's capacity limit.
- **The number of contents in the trash bin**
The second component is measuring trash bins based on the number of bins with a capacity of up to 180 cm high and then filled with 148 cm. Based on this data, the trash cans are still in use.
- **Liquid sensor data**
This type of detectable waste has two types of solid and liquid. Waste in liquid form has high toxicity and can damage other waste. This sensor will detect a lot of waste in liquid form, and the system will provide information if the pH meter of liquid waste exceeds normal limits.
- **Gas sensor data**
The last sensor is a gas sensor. This sensor will detect the presence of waste and hazardous chemicals in the trash. Hazardous chemicals can cause poisoning to fires that can endanger the surrounding environment. The smart trash bin has menu information that can see the condition of the trash that is full. After that, toxic gas is also measured. This sensor is located on the lid of the trash because harmful gases are lighter and more comfortable to detect.

The waste sorting system has a function to process images to select two types of waste, organic and non-organic. This system uses a computer vision method where waste data will be recognized and identified according to the type of waste. Make this system, and waste type data must be collected first by dividing the research data into two, namely in the training data mode and data testing.

Figure 8: Process of Taking Pictures of Plastic Waste

Figure 8 is an image-based sorting system used as a processing material for the sorting system, as training data for the author to take image data from various sources on the Internet. Direct image taking requires additional lighting and tools because the image processing system itself depends on the camera's reliability.

Data reading and accuracy on the amount of training data and testing data used. The type of algorithm selection is very influential on the pattern recognition method. This method dramatically determines the speed and accuracy of data reading.

Figure 9: Greyscale Image Change Process

Figure 9 is a method for changing the color from the original RGB image to greyscale. This process is needed to identify plastic bottles and glass bottles because the white color in an image processing will be converted to zero (0) and black with a value of one (1). , so that one of the plastic bottle sorting systems apart from the color will also be read. From its shape by using the edge detection method, in this section, the data information from the glass plastic bottle will be taken through the level of additional lighting so that the nuances of the resulting data color become gray or also called by the achromatic method.

Figure 10: process of detecting patterns, shapes, edges, and colors

Figure 10 is an essential step because an object, in this case, a plastic bottle and glass bottle, will be processed and recognized again by detecting its shape, then clicking the edges to see the type of characteristics of the bottle.

Figure 11: The final result of the plastic waste identification

Figure 11 is the final result of the plastic waste detection system. That image the system visually provides information on the type of plastic waste. This case is divided into various kinds of plastic bottle waste and glass bottle waste. The sorting procedure is carried out quickly by the system using image processing algorithms.

To see the results based on the Blackbox, here is a quantitative measurement of the results of this study.

Table 1: Arduino camera functions based on the distance of the trash

No	Distance	Detected / Undetected
1	0 cm	Detected
2	4 cm	Detected
3	5 cm	Detected
4	5.5cm	Detected
5	6 cm	Detected
6	10cm	Detected
7	40 cm	UnDetected

Table 2: Ultrasonic functions based on the distance of the trash

No	Distance	Detected / Undetected
1	0 cm	Detected
2	4 cm	Detected
3	5 cm	Detected
4	5.5cm	Detected
5	6 cm	Detected
6	10cm	UnDetected
7	40cm	UnDetected

Table 3: Accuracy Testing Results

No	Image Name	Accuracy
1	Image1	70%
2	Image2	68%
3	Image3	73%
4	Image4	75%
5	Image5	79%

The results according to table 1-3 show that the functionality of the prototype is fairly good because the accuracy in both the camera, sensor, and image process used can detect an average of 70%.

5. Conclusion

In the experiment, the waste processing process using several technologies by using IoT (Internet of Things) using image processing methods. IoT systems are very suitable for use outdoors and mounted on a sensor. This sensor is straightforward to configure and integrate with the system. Website application, the IoT sensor has the advantage of being able to detect the type of waste in the form of liquids and gases, which functions to detect waste and hazardous substances. In contrast, the image processing method has reliability. Can detect types of waste by recognizing types of waste. Image processing techniques can run in various programming languages and types of platforms. Image processing is fully available in the form of platform libraries in all programming languages. Also, the output system can assign classes to objects, and to use the image processing method can be used to detect the type of metal or non-metallic waste according to the dataset used as needed. The results also show, from the side of the tool, it can detect waste. While the image imaging process where the prototype is capable of with an average accuracy of 70%. For further investigations, it is hoped that it can be checked not only in the form of a prototype but also in the form of a device with a detection result above 90%.

Recurrent Neural Network

ABSTRACT

Music Emotion Recognition (MER) is a study to recognize emotion in a music or song. MER is still challenging in the music world since recognizing emotion in music is affected by several features; audio is one of them. This paper uses a deep learning approach for MER, specifically Convolutional Neural Network (CNN) and Convolutional Recurrent Neural Network (CRNN) with 361 Indonesian songs as the dataset. The music is classified into three main emotion groups: positive, neutral, and negative. This paper demonstrates that the best model for MER on Indonesian music is CRNN with the accuracy of 58.33%, outperforming that achieved by CNN.

1. Introduction

Music is one language to express your emotion. By knowing emotion from music, listeners can enjoy music based on their emotional condition. Recognizing emotion from music is also useful for supporting a smart system in the future. One example is for supporting smart cars to help stabilize the driver's emotions while driving. The driver's driving condition will be affected by their emotional condition. Positive or negative emotion will affect the risk level, reaction to a particular condition, their action, and driving awareness level [1].

Based on the study in [2], there are 28 emotion variations to indicate human emotion from valence and arousal level. This research focuses on classifying music into three main emotion groups: positive, neutral, and negative. Music Emotion Recognition (MER) has become a new challenging thing in the music world because emotion on a particular song will be conducted by tone, tempo, and lyrics of the song. Deep learning is used to find the best solution for MER. Convolutional Neural Network (CNN) has a great occupation for analyzing audio in MER than using machine learning [3], as well as Convolutional Recurrent Neural Network (CRNN), where it has a great occupation for analyzing audio in MER to classify music into two main emotion groups: positive and negative [4].

A study in [5] found that by using RNN encoding, algorithm can be very intelligent in predicting the emotion inside a music, and even though it cannot explicitly predict the emotion in music, it is useful for selecting music with strong emotion and gives user recommendations. Another experiment conducted by [6] shows that CNN has an advantage on extracting useful features from raw data which would help in emotion recognition. Study conducted by [3] also mentions that CNN is an effective method to predict the emotion of songs using spectrogram. However, there are still things that could be done to improve the model precision. Based on those statements, it was decided to conduct a research in Music Emotion Recognition using CNN and CRNN. Through this research we also found the best parameters to be applied on the CNN and CRNN models that we proposed. We decided to do the experiment specifically on Indonesian music because of a study conducted by [7] found that using data sets from a specific country gives a better performance. It can also help shows the genre trends in that country.

2. Literature Review

This section shows basic knowledge applied to our research, such as emotion model, Music Emotion Recognition (MER) and related works.

2.1. Valence-Arousal Emotion Model

The Valence-Arousal model (V-A model) proposed in this study [2] is mostly used by researchers as an emotion model.

*Corresponding Author: Inten Yasmina, Bina Nusantara University, Jakarta, Indonesia 11530. Email: inten.yasmina@binus.ac.id

Emotion variety introduced in [2] is shown in Figure 1.

Figure 1: 2D Valence-Arousal Emotion Space [2]

Figure 1 explains two-dimensional space which consists of a horizontal line as a valence and a vertical line as arousal. Valence is the affective quality referring to the intrinsic attractiveness/goodness (positive valence) or awareness/badness (negative valence). Arousal is a state of emotional condition that makes us feel motivated or feel the same as our emotional condition.

2.2. Music Emotion Recognition (MER)

In this digital era, music becomes one of the important things in human life. Following music growth in the digital era, MER becomes interesting in the past few years because music is highly related to mood or someone's emotion.

There is some multimedia system to recognize or obtain emotional information from music as being developed by Moodtrack, MusicSense, Mood Cloud, Moody, and I.MTV [8]. In the study [8], the authors claimed that a machine or computer that can recognize emotion from music can improve the interaction between computer and human being. With this consideration, developing MER is required so that the computer can automatically recognize or classify music based on emotion in that music. Developing MER has become challenging because MER has a variety of emotion conception and emotion association, thus there is a debate in emotion's concept category in MER. Table 1 shows multidisciplinary from developing MER.

Table 1: Comparison of Existing Work on MER [7]

Categorical MER	Categorical	Predict the <i>discrete emotion labels</i>
Dimensional MER	Dimensional	Predict the <i>numerical emotion values</i>
Music Emotion Variation Detection (MEVD)	Dimensional	Predict the <i>continuous emotion variation</i>

The categorical MER approach categorizes emotion into several classes and applies to machine learning to train a classifier. Dimensional MER approach defines emotions as numerical values from a particular dimension like valence and arousal [2]. MEVD aims to produce music's prediction for every short-time segment of songs, and it helps to predict more complex emotions.

2.3. Related Works

This paper refers to several studies in MER using machine learning and deep learning with audio features. One study used Million Song Dataset (MSD) [9] that consists of a timbre segment along with audio features[10]. This research focuses on classifying data using 5-fold cross-validation. Support Vector Machine (SVM), Random Forest (RF), k-Nearest Neighbor (k-NN), Multilayer Perceptron (MLP), Logistic Regression (LR), and Naïve Bayes (NB) are used in [10] and it claimed that LR achieved the highest accuracy of 57.93%. The authors in this study [3] claimed that using Convolutional Neural Network (CNN) achieved better accuracy than machine learning. It contains 30,498 spectrograms from 744 songs. Every song supplied 45-second clips and every single clip was transformed into spectrograms. The study shows us that CNN is a better model than machine learning with 72% accuracy [3]. Another study conducted by the authors in [4] used CNN, RNN, and CRNN to solve the MER problem. 48,476 songs from MSD [9] were used as dataset and every song was transformed into Mel-spectrogram. This research focuses on classifying data into two classes: positive and negative. The study shows that using CRNN is better than CNN and RNN with 66% accuracy, where CNN and RNN achieved the accuracy of 64% and 63%, respectively [4].

The study conducted by [5] uses a fusion of antonyms to describe emotions in the context of MER. It was mentioned that tempo and energy were useful features. By using RNN encoding, the algorithm can be very intelligent in predicting the emotion inside a music, and even though it cannot explicitly predict the emotion in music, it is useful for selecting music with strong emotion and gives user recommendations. The study conducted by [6] proposes a novel method that combines original music spectrogram with CNN to predict the emotion tag. They reported that CNN has an advantage on extracting useful features from raw data which would help in emotion recognition but there should be more research conducted on the meaning of CNN outputs. Another study conducted by [3] proposes a method to classify features extracted from the music's spectrograms using CNN. The study states that CNN is an effective method to predict the emotion of songs using spectrogram. However, there are still things that could be done to improve the model precision. From the studies aforementioned, the research presented in this paper focuses on using CNN and CRNN for classifying our dataset into three main groups.

3. Proposed Method

This section discusses how data is collected and pre-processed and showcases our proposed method in this research. The illustration of flow diagram on the research methodology could be found in Figure 2.

Figure 2: Flow Chart of Research Methodology

3.1. Data Collection & Pre-processing Data

There are 614 non-vocal audios collected from YouTube. The data is Indonesian music covering various genres; the majority of them is pop music. The decision to use music from a certain country is based on the hypothesis that every country has unique style of music. A research in MER conducted using specifically Korean music as experiment's dataset is able to achieve good accuracy [7]. After collecting the audio, several questions in the form of a questionnaire were distributed to respondents to help label the data into three labels/emotion groups, i.e., positive, neutral, and negative. Positive is the emotion when the music consists of positive energy, like excited, happy, and pleased. Neutral is that when the music consists of neutral energy, like relaxed, calm, and bored. Finally, negative is that when the music consists of negative energy, like sad, frustrated, and angry emotion. For the labelling process, we conducted a survey where we assign five people to assess/label each data sample; this was to ensure that we obtained an objective assessment. After we collected all the responses from the respondents, we validated our data with agreement percentage. We will only be using data that have above 50% of agreement score. For that reason, in our final data set, we will be using 536 non-vocal audios where 180 songs are positive, 226 songs are neutral, and 130 songs are negative.

After validating the data from the questionnaire, the data is split into two groups: full-songs and 45-second-clip songs. Full-song means one complete song whereas 45-second-clip song means that the complete song is divided into 45-second clips. After that, the data is converted into spectrograms. A spectrogram is a visual representation of the spectrum of frequencies of various times. By using a spectrogram, the machine can learn a variety of emotions from the song's spectrum. There are several types of spectrograms; one of them is Mel-spectrogram. Mel-spectrogram is selected because it has been one of the most widespread features from audio analysis tasks like music auto-tagging and latent feature learning. Mel-scale is supported by domain knowledge of the human auditory system [9] and has been empirically proven

by impressive performance gains in various tasks [10]. Our program could only process .wav as the input type for the mel-spectrograms converter. Therefore, before we converted our data into Mel-spectrograms, we need to convert songs from .mp3 into .wav. The following parameters are used to build the Mel-spectrograms: 4096 number of samples per time-step in the spectrogram/hop_length, 128 number of bins in the spectrogram/n_mels (height of the image) and 256 number of time-steps/time_steps (width of the image). These Mel-spectrograms are converted into a 128x256 image with grayscale color. This Mel-spectrogram image is then used as the input data to the CNN and CRNN model.

The final dataset used in this experiment is spectrograms from 361 songs where there are 86 negative, 156 neutral, and 119 positive labels. This final data was obtained after removing problematic songs, which are those with ambiguous labels or those generating spectrograms with missing data. Aside from using the full song in the first experiment, the 45-second clips were used in the second one, which made the latter spectrogram dataset became 3095 songs (767 negative, 1308 neutral, and 1020 positive labels).

3.2. Proposed Framework for MER

This research aims to build and evaluate the system of emotion recognition or classification for Indonesian music. CNN and RNN were used to implement the objective. CNN is one of the Feed Forward Neural Network classes inspired by the brain's visual cortex. CNN is specifically designed to process grid structure data. CNN based architecture is shown in Figure 3.

Figure 3: Convolutional Neural Network Architecture

CNN is useful for analyzing image data [11]. Convolutional-2D and Rectified Linear Unit (ReLU) were used as activation functions.

RNN is one of the neural networks that processes the input data for several times. Generally, RNN is used for analyzing sequential data such as Natural Language Processing (NLP) [12], voice recognizing/analyzing [13], etc. Another research claimed that RNN is useful to recognize or predict emotion in music [14]. An RNN-based architecture is shown in Figure 4.

Figure 4: Recurrent Neural Network Architecture

These two deep-learning methods were combined to solve the MER problem described earlier. Convolution-LSTM layer was used as the RNN. CNN-LSTM is a type of recurrent neural network that has a convolutional structure in both the input-to-state and state-to-state transition. Several models were built for comparison purposes, which can be seen in Table 2 and 3.

Table 2: Proposed Model using CNN

Input (126x258x1)	
Convolutional	16 filters
Convolutional	32 filters
Convolutional	64 filters
Convolutional	112 filters
Max-Pooling	2,2 pool size
Flatten	
Dense	128 filters
Dense	128 filters
Dense	3 filters

A 3x3x3 kernel was used for the CNN layers in the first model. Four layers of CNN and three layers of Fully Connected layer were used in this model, then Re-Lu was applied to the CNN and the dense layers activation. The output layer used SoftMax activation. Adam and Categorical Cross Entropy were used as the optimizer and the entropy for the loss function in this model, respectively. For comparison purposes, CRNN model was also built (Table 3).

Table 3: Proposed Model using CRNN

Input (126x258x1)	
Convolutional	16 filters
Convolutional-LSTM	30 filters
Convolutional	36 filters
Convolutional-LSTM	50 filters
Flatten	
Dense	128 filters
Dense	128 filters
Dense	3 filters

A 2x3 kernel was used for the CNN and CNN-LSTM layers in this model. Re-Lu was also applied to the CNN, the CNN-LSTM and the dense layers activation. This model used SoftMax as output layer activation. Adam optimizer and Categorical Cross entropy loss function were also used in this model.

4. Result and Discussion

As described earlier, there are 361 songs consisting of 86 negative, 156 neutral, and 119 positive labels as the input dataset to the proposed methods. From 361 spectrogram's images, 80% was used as the training dataset, 10% as the validation dataset, and 10% as the test dataset. We split the data using the algorithm provided by ImageDataGenerator that is available on Keras, a function named validation split. Before we apply the function, we first calculate the weight of each data manually, comparing the labels on each data sets. Then we combine the training and validation dataset into one folder to be split using the function mentioned. The testing dataset are saved in a separate folder. The experiment was split into two datasets: full-song dataset

containing 361 spectrograms and 45-second-clip dataset containing 3095 spectrograms.

4.1. Full-songs Experiment

In this section, the complete version of the music was used, which was the full track. The testing performance of MER using the two proposed models, CNN and CRNN, are presented in Table 4.

Table 4: Summary of Test Result Using Full-Songs Dataset

Model	Training Accuracy	Validity Accuracy	Test Accuracy
CNN	55.33%	44.12%	41.66%
CRNN	75.95%	52.94%	58.33%

From the performance summary shown in Table 4, it can be concluded that the CRNN model outperforms the CNN one for all the training, validity, and test accuracies.

4.2. 45-second-clip Experiment

45-second clip songs were also used in the experiment because 45 seconds are considerably long enough for humans to recognize what emotion appears in a song [3]. Similar to the full-song experiment, CNN and CRNN were also developed to investigate the MER performances. The results are shown in Table 5.

Table 5: Summary of Test Results Using 45-Second-Clip Songs Dataset

Model	Training Accuracy	Validity Accuracy	Test Accuracy
CNN	43.14%	43.18%	38%
CRNN	52.46%	47.73%	38%

4.3. Discussion

We process our data by using the algorithm stated in Algorithm 1.

Algorithm 1: Audio time-series/y parameters

Result: Audio time-series/y parameters

for data in datas

```

    Load audio from audio's path;
    Define y using librosa library
    (librosa.load(audio path));
    Define start_sample with
    zero/0;
    Define length-sample with
    time_steps*hop_length;
    Define array of window;
    for start_sample in
    start_sample + length_sample
        Add window with
        y[start_sample];
        start_sample + 1
    End

```

End

return array of window

In Algorithm 1 we capture the array from each song. The more data we capture, the more feature that could be extracted from the audio. This is the results of the multiplication of time_steps and hop_length. The higher the number, the more features that it could cover. With that logic intact we may assume by using a 45-second clip, which is shorter, it could generate better results, because it will cover the whole feature by the spectrogram. With more results obtained by using Algorithm 1, the more sensitive the spectrogram becomes in capturing the feature in the audio that we use. In other words, using the optimal time_step and hop_length could result in a more complete data, and a quick pre-processing time.

However, the results obtained indicate that the full song model performs better than the shorter clip one. We found that the reason is because our assumption for the shorter clip may only work if we wanted to focus on a specific point of the song, where in this case we wanted to know the overall emotion or as we may say the full audio. When using the 45-second clip, the machine could not capture the whole essence of the song, only focusing on that specific part instead. In this case the machine faced the case of ambiguity because within one song there may be a part where it shows a positive emotion but followed with neutral or even negative emotion. If we wanted to use the 45-second model, we might have to add a more complex algorithm to the machine to determine the song emotion. In this case, we could say that it is better to use the full song clip for music emotion recognition where the model would see the major points instead of only a specific point.

While conducting our experiment we also found that when we are using a lot of convolutional layers, the machine tends to generalize most clips with a neutral label and stop learning, also known as overfitting. When we use more than five convolutional layers, a large filter, or less than five layers but with an even greater filter, feature machine tend to decline and stop learning. In this case, we must create a balanced architecture using Table 2. This is not limited to a convolutional layer model, but also in convolutional recurrent neural network that is greater than 3 recurrent layers and 2 convolutional layers. Overfitting will be more likely to happen when there are too many convolutional recurrent layers. This results in the case where the machine tends to generalize the audio with a neutral label. We have tried using dropout layer to overcome overfitting, but the use of dropout layer does not give a significant difference. The difference in kernel size and amount of parameter filter are the one that helps overcome overfitting. Another reason that we found could be because neutral-emotion audios were the dominant label in this experiment. The machine absorbs more information from neutral-emotion datasets. Neutral emotion, in a way, is a bridge between the positive and negative emotion datasets.

5. Conclusion and Future Works

In this work, music emotion recognition using spectrograms with Convolutional Neural Network (CNN) and Convolutional Recurrent Neural Network (CRNN) has been proposed. The data that we use are songs from Indonesia. The spectrograms used 256 time_steps, 128 n-mels, and 4096 hop_length parameters. Two types of experiments have been conducted: one using full-songs and one using 45-second-clip songs. From those experiments,

CNN achieved the test accuracy of 41.66% and 38% using full-songs and 45-second-clip songs dataset, respectively; while CRNN achieved the test accuracy of 58.33% and 38% using the same two types of datasets, respectively.

From this experiment, it can be concluded that using a full-song dataset achieves better MER accuracy than using 45-second-clip dataset. However, more experiments need to be conducted to confirm such a finding, such as adding a more complex algorithm to support the 45-second dataset thus the machine could become more precise in predicting the emotion while still maintaining the objectivity of the whole audio instead of only focusing on one part. More data also need to be collected for future works to achieve higher accuracy and use more labelled category or classification. We guess that it is probably due to the ambiguity in one label or ambiguity from this experiment. Thus, we think it will be more accurate if we use more labels for our future works. To fix overfitting we plan to use an ensemble method in our future research. Moreover, it would be interesting to include the songs' lyrics as additional features to develop a multimodal music emotion recognition system.

Conflicts of Interest

The authors declare no conflict of interest.

Acknowledgement

The author would like to thank everyone who helped with this research, and Bina Nusantara University for supporting the author in completing this paper.

Internet Protocol Version 6

Neighbor Discovery Protocol

Neighbor Cache Entry poison

ABSTRACT

Neighbor Discovery Protocol (NDP) is used to discover the MAC address of the connected hosts in Internet Protocol Version 6 (IPv6) in a networked environment. Neighbor Cache Entry (NCE) table holds the association between a host's IP address and MAC address. However, according to the protocol, the MAC address could be overwritten by sending a single fake packet to its victim. This is a serious security loophole as traffic can easily be sniffed by the attacker. In this paper, we present a scheme to address this problem. Our proposal suggests that when Neighbor Solicitation (NS) and Neighbor Advertisement (NA) process completes, a randomly generated key can be exchanged between them so that, in case of an attack, that key can be used to verify the request. We implemented the proposed scheme in NS3 and simulation results show that our proposed scheme can perform effectively while circumventing the attack that uses override flag of IPv6.

1 Introduction

Internet Protocol Version 6 (IPv6) is the latest technology in addressing networked devices. Similar to Internet Protocol Version 4 (IPv4), IPv6 is an addressing mechanism that provides network identification to a device at the network layer of Open Systems Interconnection (OSI). Its predecessor IPv4 had an address space limitation which has been mitigated using the technologies like Network Address Translation (NAT) [1]. But, such measures were only temporary and could not provide a permanent solution. Which is why IPv6 was developed with a large address space with 128-bit address, compared to 32-bit address space of IPv4. Additionally, some methods were used to reduce the complexity of the addressing scheme. Many other advantages from IPv4 was also baked inside IPv6 for better adaptation such as reduce dependency on NAT, and gain connectivity using automatic address allocation [2].

However, some of the common security vulnerabilities are observed in the IPv6 and attack like man-in-the-middle is still possible [3], [4]. Like existing TCP/IP stack, to successfully send a packet from one device to another, data link layer address, also known as Media Access Control (MAC) Address, is required in IPv6. As pre-populating the MAC address table for each of the connected devices is not practical, IPv4 used a mechanism called Address Resolution Protocol (ARP) [5]. The purpose of ARP is to send out a broadcast asking for destination device to reply with its own MAC address, given that the assigned IP on the destination device matches with the IP address in the broadcasted packet. In

an ideal scenario, only the device with matched IPv4 holder will reply with its own MAC address so that link layer communication can be established. Once MAC address and IP address are resolved, the source device adds the MAC address in ARP cache for future use as both of them will possibly have to communicate between themselves for a certain period. ARP cache reduces repeated ARP resolution calls.

Unfortunately, in IPv4, the ARP cache in a device can easily be poisoned; an attacker can easily send fake ARP messages and those fake requests will be accepted and processed by the device as per the protocol. This creates a significant security risk as all the traffic can be diverted to the attacker host [6]. Such mechanism paves the way for sophisticated attacks including stealing username and password, obtaining users session ID, redirecting users to fake sites, etc. The attack becomes extremely effective if the client and server communication is not protected by any encryption mechanism [7]. Even a novice attackers can use tools like dsniff [8], cane and able [9], ettercap [10], etc. to launch such attacks.

Although IPv6 does not use ARP to resolve MAC address, it employs a similar protocol called Neighbor Discovery Protocol (NDP) [11]. Using NDP, nodes in the same link advertise their existence as well as learn about the other nodes. Similar to ARP cache, NDP maintains Neighbor Cache Entry (NCE) table to reduce repeated NDP resolution. In NDP, Neighbor Advertisement (NA) and Neighbor Solicitation (NS) packets are used to resolve MAC addresses of the connected hosts. Although unsolicited NS messages are ignored in IPv6, MAC spoofing attack is still possible [12]. The

author showed that the *override* flag in the NS packet could be used to distort the NCE table and perform hijacking of traffic [13]. The primary objective of *override* flag is to announce the changes in the data link layer. For example, hot-swappable Network Interface Cards (NIC), which are usually used by high end routers or switches, can be replaced without powering down the device; in such case, the NIC would send out a NS with *override* flag set to announce its new MAC address [14].

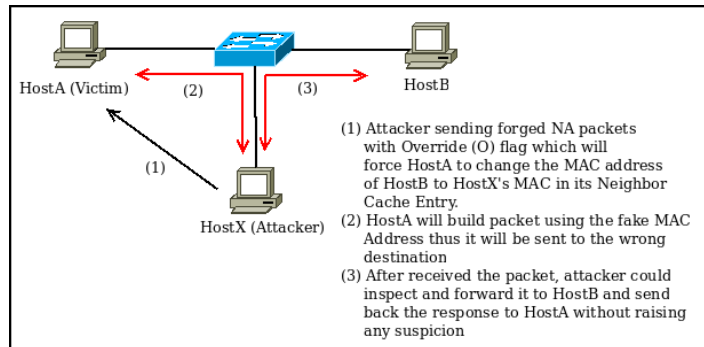

Figure 1: How an attack can be initiated in IPv6

Unfortunately, this override mechanism in IPv6 can be easily exploited by an attacker unless specific countermeasures are taken. The overall attack mechanism is illustrated in Figure 1 where *HostX* is the attacker and *HostA* is the victim. Here, we assume that *HostA* already has MAC address of *HostB* in its NCE table. At first, the attacker *HostX* sends a forged NA packet with *override* (O) flag set, claiming to be *HostB*; this will force *HostA* to change MAC address for *HostB* in its NCE table with the MAC address of *HostX*. Subsequently, all packets for *HostB* from *HostA* will be delivered to *HostX*. Thus, *HostX* can intercept, and inspect the packets and can also act as middle-man between *HostA* and *HostB*. Each and every node in local area network is in risk of such attack irrespective of the number of the nodes in the network. For prevention, we could use mechanisms like SEND or IPsec but they have their own limitations like complex configuration, overhead and difficulty of use.

In this paper, we propose a scheme where the a randomly generated key will be transported when two hosts initiate communication between themselves. This key will provide a layer of protection against unsolicited *override* requests by providing a challenge to the sender. As this protection mechanism will be baked inside the protocol, it will be seamless to the end users as well as to the network administrators; thus it should obtain wide adaptation. We implemented the proposed scheme in NS3 and experimental results show that our proposed scheme can effectively handle this attack without introducing any major performance impact.

The rest of the paper is organized as follows. In Section 2, we will look into the ICMPv6 and will discuss NDP and try to illustrate the exact problem we are trying to address. Then, in Section 3, we will explore current solutions available and what is preventing them from adaptation. We will then discuss proposed solution in Section 4 with some details. In Section 5, we will discuss simulation of the current implementation and show how an attack can be lunched against a host. Section 6 will demonstrate and prove the proposed scheme using simulation. Approximate requirement for storing key will be shown followed by performance comparison in

Section 7; memory requirement and shortcomings will be discussed in Section 8. We conclude the paper in Section 9.

2 Background

Previously, ARP was managed as a simple messaging and was not a part of any other protocol[5]. However, in the IPv6, this mechanism of resolving from IP address to MAC address and other functionalities have been confined within Internet Control Message Protocol version 6 (ICMPv6) [15]. The structure of ICMPv6 packet has been given in Figure 2.

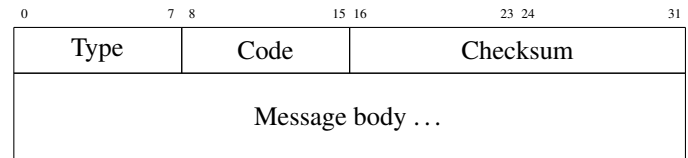

Figure 2: ICMPv6 packet details

In the following, we will give an overview of neighbor discovery protocol protocols to provide a better understanding of the proposed scheme.

2.1 Neighbor Discovery Protocol (NDP)

Neighbor Discovery Protocol (NDP) is used to send and receive message from other connected hosts. There are five different ICMPv6 message types and some conceptual demonstration are provided below:

2.1.1 Router Solicitation (Type 133)

When a node becomes active, in most of the cases, it needs to locate the gateway on that network because it will be able to communicate with the internet by reaching the gateway. This type of message is being used to request the routers to respond with their gateway address so that the device can communicate with necessary servers immediately.

2.1.2 Router Advertisement (Type 134)

In many cases, finding out the gateway for the node is not considered as high priority. Because reaching other networks is not required immediately and the node can wait for a certain period. The router will send out periodical updates to all the hosts in the network with the updated gateway address. This system makes maintaining a complex network easy because in the production environment, changing the gateway can cause downtime. By using this method, such downtime can be reduced and the nodes will be able to maintain connectivity with the gateway.

2.1.3 Neighbor Solicitation (Type 135)

To determine the MAC address, this type of packet is used by the hosts. NS packets are responsible for requesting MAC address from a specific target. The detailed description of the packet is given in Figure 3. This packet is sent out to all the hosts in that broadcast

domain; thus, all the hosts will receive this packet when transmitted by a host.

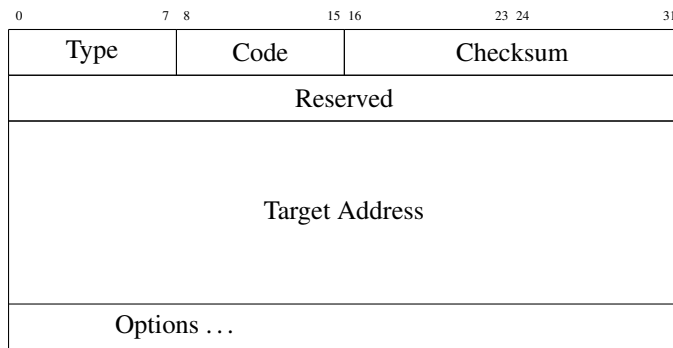

Figure 3: NS packet description

This packet is quite simple and it does not have any specific bits or flags to convey additional information. The value of type field will be 135 as per specification and the target address will contain the IP address of that device with which the initiator wants to communicate with.

2.1.4 Neighbor Advertisement (Type 136)

In response to a received NS packets, NA packets are used. The NA packet structure is shown in Figure 4

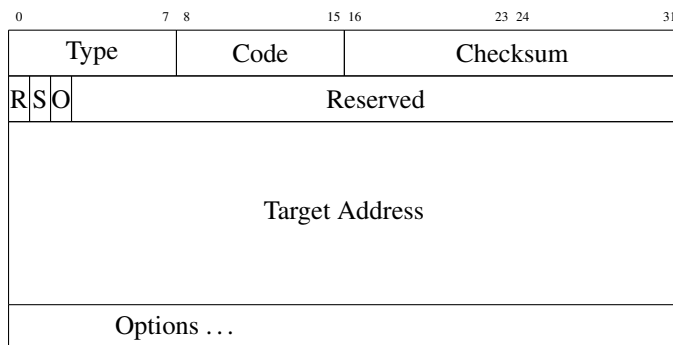

Figure 4: NA packet description

This packet is comparatively complex than the NS packet and have three fields which we will discuss below:

- **Router flag (R):** Router flag is used to indicate that the device sending this packet is a router.
- **Solicited flag (S):** When the packet is sent in response to a NA, this flag is set.
- **Override flag (O):** Override flag is used to overwrite cache entry in the NCE table and update the MAC address.

NA packets can be solicited as well as unsolicited, meaning, a host can receive and process an NA packet even if it did not send out any NS request. Moreover, NA packet has an *override* flag which is sent out if any host has changed its MAC address. This is substantially effective and fast considering how easily a device can announce its new MAC address when it is changed. However,

such packets can easily be forged and poison one or more hosts. We are going to focus on this field as exploiting this flag can cause man-in-the-middle attack.

2.1.5 Redirect (Type 137)

Redirect type is used only by routers because in many cases better route to a network has to be advertised to the hosts and by using this type of packet, such objective can be achieved.

3 Related Works

To address the attack for NDP in IPv6, protective measures are required to make the NDP messages secure. SEcure Neighbor Discovery (SEND) was proposed with protection for NDP. It uses Cryptographically Generated Address (CGA) to provide security to the NDP packets. However, lack of solid guideline and procedures make this protocol difficult to implement. Other obstructions include a valid Certification Path and performance impact [16]. There are also lack of tools which can be used in production environment making this system almost impossible to implement [17]. Moreover, it is also known to be resource hungry as well. If such protective measures are to be implemented, it will certainly require advanced knowledge as well as complicated configurations in all of the networked devices in the environment. Such implementations are difficult to adopt and thus, acceptance is low which ultimately leads towards insecure network.

IPSec was proposed to secure the NDP from the possible problems which are caused by the unaddressed complications of the protocol. Unfortunately, the problem with IPSec is multifold. Firstly, the concept of IPSec requires a time to grasp because of its complexities. For example, there are many ways by which it can be configured and being a security feature, any misconfiguration will result in the interoperability. This complex configurations can lead towards frustration and avoid this protocol for something less secure. Moreover, in IPSec, shared key based authentication can be configured. If the administrator wants to distribute the keys manually, then he or she has to perform a complex task of maintaining keys for every host. If the automatic method is preferred over shared key, it would introduce further complex configuration in the host devices. On top of this, not all devices support same IPSec configuration; thus each type of operating system requires its own separate configuration. It appears that IPSec creates more problem then it promises to solve [18], [19].

In [20], the author proposed a scheme that uses Dynamic Host Configuration Protocol Version 6 (DHCPv6); it suggests that a DHCPv6 server should be used to provide IP address to the end hosts based on Stateful Address Autoconfiguration (SAA). But, there are many situations where DHCPv6 server is not practical. Small or medium offices, where technical expert might not be available; thus configuring and managing a DHCP server might seem complex for them. Additionally, it may become a single point of failure for the whole network.

To reduce the difficulties suggested by these mechanisms, certificate authority based system is intentionally avoided so that our proposed scheme can be widely adopted and incorporated. As PSK does not depend on any other hardware, configuration or incur any

additional cost, it is expected that it will be used by many and provide a more secure networking environment.

4 Proposed Pre-Shared Key (PSK) Based Scheme

In this section, we present our proposed PSK based scheme. In our scheme, each pair of hosts in the network will have its own secret key. The proposed length of this key is 16 bytes (128 bits) long. This PSK is communicated to other hosts using a new packet type. In the following, we discuss the details of the scheme.

4.1 New Packet Header and Description

Our proposed header is compliant to RFC 4861 and is shown in Figure 5. Now, we will briefly discuss the header.

0				7 8				15 16				23 24				31							
Type (200)								Code								Checksum							
V				R				K				A				Reserved							
Target Address																							
Pre Shared Key (PSK)																							

Figure 5: Proposed PSK header

- **Type:** This header is responsible for describing what kind of packet it is and how the node will process it. We propose to use the next available sequence; however, in this paper, we will be using Private Experimentation type which is denoted by 200.
- **Verification (V) flag:** This flag will indicate that the packet is to be sent out using multicast so that all the hosts in the network receive it. This packet is an instruction that the IPv6 address holder should return its key using unicast to the initiator. This flag will be mostly used in situation where there is a conflict or the node which requested the *override* does not have any associated key to present to the recipient; thus the scheme will force the receiver to check the network whether such association is still present in the network.
- **Response (R) flag:** The purpose of R flag is to perform key verification. It is being used to respond to a verification multicast packet which has been received by the node. This flag will be used when responding to the verification packet flag.

- **Key (K) Flag:** When the host is responding to a PSK NS, this flag will be set so that the initiator can understand that the packet contains the key for a particular request.
- **Acknowledge (A) flag:** After the key has been sent to the destination host, by using the K flag, it will reply using this flag enabled so that the initiator can understand that a key has already been sent and subsequent response has been received.
- **Target Address:** This field will hold the target IP address of the host.
- **Pre Shared Key (PSK):** This field is 16 bytes, i.e., 128 bits and will be used to share the key between two hosts.

4.2 Key Cache Entry (KCE)

This is a table which will be stored in the slower part of the operating system's memory and will hold all the exchanged keys between hosts in a network. The reason for suggesting to store them in the slower part is because this key is not required in per packet operation. This set of data only required to be accessed when there is an *override* request and when new entries are added or removed from this list.

4.3 Key Generation

The key generation process will be done by the operating system during the initial communication phase. The key shall consist of capital letter, small letter, numerical as well as symbols to ensure it cannot be brute-forced in any practical manner. As the networking systems improve, the chances of brute forcing a key also increases. To ensure that this scheme is protected against such attack, 128 bit long key has been chosen. As previously stated, all of the ASCII characters will be used, thus even with a million attempts per second; it will take over billion years to brute force this key thus making it practically impossible to crack [21].

4.4 Key Sharing Phase

When two hosts, e.g., *HostA* and *HostB*, in the network want to communicate, they must have each others MAC address. Below, we discuss the full process for NS, corresponding NA and our proposed shared key mechanism, i.e., *Key Sharing Phase*. The process is shown in Figure 6.

1. By sending an NS message, *HostA* initiates the connection process.
2. *HostB* responds with NA packet containing the link layer address of its own.
3. Both the devices now have MAC address of each other.
4. Now, *HostA* starts the PSK process by generating a key and crafting a packet with type 200 (experimental) with the Key (K) flag set.
5. *HostB* receives packet and saves the key in its memory and responds by returning a key-acknowledge (A) packet back to the *HostA*.

6. *HostA* receives the packet and saves the key sent previously into it's own NCE table.

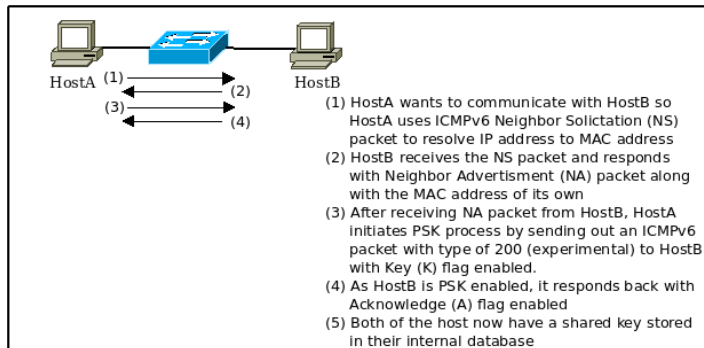

Figure 6: The process of shared key exchange

The full process on how the attack prevention system will work is depicted in Figure 7.

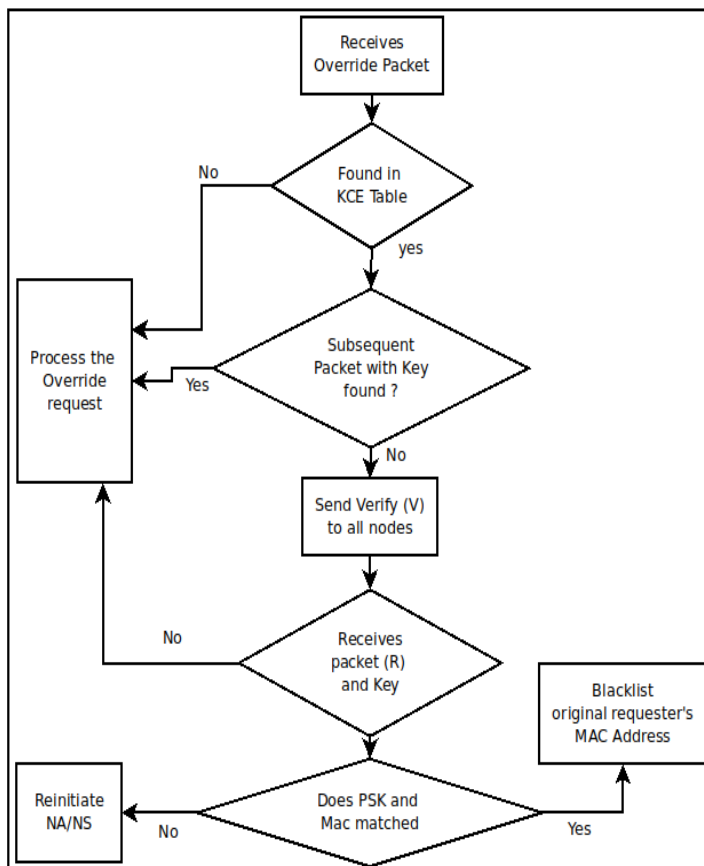

Figure 7: Overview on how the prevention mechanism works.

Now, we will discuss two scenarios where one of these devices are not PSK compliant or does not have our proposed feature enabled.

4.4.1 Source does not have PSK but destination have it enabled

As described in Figure 6, after step number two, the process will not continue and the source which is denoted by *HostA* will not send an PSK packet. As no instruction is being sent by the initiator, the destination will also comply and avoid sending any key-acknowledge packet. The communication between these two hosts will continue as usual.

4.4.2 Source have PSK enabled but the destination does not

In this situation, the source will send a packet with the Key (K) flag enabled but as per the specification of ICMPv6, that packet will not be recognized by the destination and will be dropped. Because no subsequent packet will be received by the source, it will decide that PSK mechanism is not enabled and will safely remove any generated key allocated for destination. Thus, communication between these two host will remain uninterrupted.

4.5 Affects of PSK in Normal Scenario

When a legitimate host, e.g., *HostB*, needs to update its own MAC address, and inform other connected nodes, it will send a separate NA packet to each host with *override* flag set and its own PSK from the KCE table for the target host using Key flag set. Upon receiving the key exchange packet, the host, e.g., *HostA*, will match the PSK in its KCE table and update the corresponding KCE. Thus, a legitimate host will be able to update its MAC address without any security risk.

4.6 Affects of PSK in Attack Scenario

We illustrate the attack scenario in Figure 8. Here, *HostA*, and *HostB* are legitimate hosts and *HostX* is the attacker. To initiate an attack, *HostX* sends out an NA packet with the *override* flag set announcing his own MAC address as the new MAC address to reach *HostB*. Since the hosts are using PSK mechanism, the victim host, *HostA*, will request for the PSK from *HostX*. As the attacker does not have the PSK of *HostB* for *HostA*, it may respond with a random PSK or may not reply at all. In case of random PSK, the probability that the PSK matches is $\frac{1}{2^{128}}$ since the PSK is 128-bit long; so, the attack is highly unlikely to be successful. When *HostA* does not receive a valid response, it will multicast, also known as broadcast, a verification packet which will contain the original MAC address. In reply, *HostB* will reply with its PSK using unicast raising the V flag and by sharing its key; thus, the authenticity of the *HostB* will be confirmed. So, the attack will fail and the override packet sent by the attacker will be ignored.

The verification packet will be dropped by other hosts in the network as the target address will not match. Only the holder of the target address will respond with Response (R) flag set.

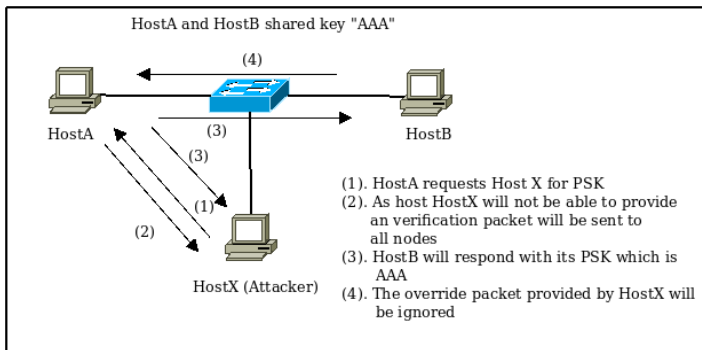

Figure 8: Overview on how the prevention mechanism works.

Figure 9: Overview of the network

4.7 Handling Different Scenarios

There might be a situation where a host has lost the PSK key among a pair. If this pair tries to initiate connection, there could be a case where one host will have a key but other host will have no knowledge of previous communication, e.g., sudden power loss. In such case, they will have to re-agree upon a new key as one of the host will have to re-initiate NA and process subsequent NS. After which PSK processes will be initiated and eventually both of the hosts will have a shared key like before.

Now, let us consider an extreme case where the MAC address of a host, HostS, has been hot-swapped. In such case, that device should store the existing PSK(s). After the address has been changed, the device will send out a multicast using the *override* flag. At the same time, an attacker, HostX, who was waiting for such an event, may send out another fake packet with *override* flag. As per proposal, all the nodes in the network will check PSK and only HostS which will be successful as the PSK will be available to HostS; thus, the fake messages will not be processed as it will be canceled out by the verification mechanism.

One of the primary focus of this work is to ensure that a non-PSK and a PSK-aware system can coexist. All the keys are being transferred using the proposed packets for a minimum impact. Only a verification packet has been proposed, which will be ignored if received by a non PSK enabled system.

5 Simulation without PSK

We have implemented the proposed scheme and showed how it can prevent an attack in Network Simulator (NS3) [22]. NS3 is a discreet event simulator capable of producing results by simulating the source code of IPv6 protocol. In our simulation, we modified the ICMPv6 layer code of NS3 in order to achieve result.

In this simulation, we are trying to show the scenario that has been graphically described in Figure 9. In our simulation, the IP address and MAC address described in the figure will be used. In the simulation, we will first test the original attack scenario and then, gradually move into modifying the logics of ICMPv6. We will also analyze the part of the code which is responsible for updating the MAC address when a *override* packet arrives and then, we will show two situation where the key is matched against the cache of the host and in another, there is a mismatch.

5.1 Attacker Host

In this section, we discuss an attacker host which we developed for simulation. This host will be responsible for sending out fake packet with malicious intent. This host has been denoted as *HostX* in Figure 9

In the code, a separate AttackApp has been used which inherits from Application class in NS3. This application has two primary features which are discussed below:

- The application will have high packet sending rate as the objective of the attacker app is to flood *HostA* with fake packets. Although such flooding of packets is not necessary, but it is better to keep on sending them so that even if *HostA* recovers from the attack for any reason, the attacker will keep on overriding the actual entry with a fake one.
- As the attacker will send forged NA packets, it will utilize the SendNA method found inside the ICMPv6 implementation in NS3. Using this method, we will be able to send fake NA packets.

The portion of code which is responsible for sending out fake NA packets is given below:

```
void AttackApp::SendPacket(void)
{
    m_attacker->SendNA(m_fakeAddr, m_vAddr←
        , &m_vMac, 1);
    ScheduleTx();
}
```

5.2 Traffic Generator

We have selected ping, also known as Echo, as the traffic generator as it is simple to trace, and implement and it is understood by many. We will run the simulation for ten (10) seconds; during that time, the ping application will send multiple ping requests from *HostA* to *HostB* and if the packet is received by *HostB*, it will send back a response. It should also be noted that if the attack is successful, *HostA* will send packets with *HostX*'s MAC address and that ping request will not receive any response because the attacker host is not configured with ping application.

file are coded in this file and all the logic is implemented. In this file, we will locate the possible problem and will try to solve this issue using PSK mechanism.

Below, we will discuss some basic modifications which are required:

6.1.1 KCE Initialization

As already discussed, we will require a list to store MAC addresses and its associated keys. Following line was included in the header so that we can achieve our goal.

```
std::map<std::string, int> k_token;
```

Here, map is a standard C++ declaration where a key value pair is declared. The string will store the MAC address for the remote host and the int variable is programmed to store the corresponding key value for that host. Here, to make our proposal more reader-friendly, we have used integer variable so the concept remains clear without altering our ultimate goal.

This segment of the code will be executed when the ICMPv6 layer of IPv6 initializes.

6.1.2 Key-cache Value Initialization

For simplicity we will insert values into the key cache table and will eventually check against this list when the host receives an *override* request from another host.

In the CreateCache method of the initialization for ICMPv6, we have added against two hosts:

```
k_token.insert(std::make_pair(
    ("00:00:00:00:00:01", 1122));
k_token.insert(std::make_pair(
    ("00:00:00:00:00:03", 1122));
```

As we can see, these are the MAC addresses for *HostA* and *HostB* and corresponding shared keys. The *HostX* will be the attacker which will flood *HostA* with fake NA packets having their *override* flag set and will try to divert the traffic from *HostA* to *HostX* rather than to *HostB*.

6.1.3 Vulnerable Code

In NS3, upon receiving *override* flag, the change in the code is done by the line:

```
entry->SetMacAddress (lla.GetAddress ())←
;
```

Here, the *entry* is the variable which holds the a specific entry from the Neighbor Discovery Cache and this line of code is used to update the value of the MAC address and eventually propagate the changes into the KCE table.

We will eventually change this part of the code where it will only execute when key matches from the key-cache table.

6.2 Key Mismatches Situation

In this section, we will discuss the scenario where an attacker is trying to send fake NA packets to *override* the MAC address for a particular IP address. Now, we will have to extract the values from the incoming *override* packet and they are being done by modifying the a section of the logic and extracting information from the packet and the code for which is given below:

```
io<<entry->GetMacAddress();
std::string mac = io.str().substr(6,23);
```

After we gather information from the received packet, we now look into the key-cache table.

```
bool isFound = false;
bool isTokenMatched = false;

std::map<std::string, int>::iterator it ←
    = k_token.begin();
while(it != k_token.end())
{
    if(mac.compare(it->first) == 0)
    {/// a match found
        isFound = true;
        if(it->second == receivedToken )
        { isTokenMatched = true; }
    }
    it++;
}
```

As shown in the code above, we iterate over all the entries inside the list and look for a matching MAC address. And if such MAC address is found, we will then again check it against the *isTokenMatched* variable which is in this scenario empty. As the attacker has no knowledge of the key which has been exchanged.

And finally if both the *isTokenMatched* and *isFound* is found, KCE is updated using the following code.

```
if(isTokenMatched == true && isFound == ←
    true)
{
    entry->SetMacAddress (lla.GetAddress ←
    ());
}
```

As we can see, this code is now protected with a key and it cannot be updated by any host without knowing the key first.

If we check captured files generated by the NS3 system, we will see that like in the unmodified version of the code, same NA packets are being sent to *HostA* (Figure 14). In this packet, we can see that it has the *override* flag set and it is being sent from *HostX* to *HostA* in order to perform man-in-the-middle attacks. We also see that even though an *override* packet was sent to *HostA* requesting it to update the MAC address, the request was not honored. In the 69th packet (Figure 15), the response to the request was received successfully from *HostB*; thus making it impossible for the attacker to alter the KCE table and perform any man-in-the-middle attack.

6.3 Key Matching Scenario

Now, we will discuss the scenario where *HostX* is the legitimate owner of a IP Address and the MAC address behind that IP Address has changed; so, it is required to propagate this change to another host.

To do this, we will set the value to the equal to the value found in the key-cache table. All other aspects of this code will remain same.

```

7 Comparison

As already stated, to counter this type of attack, SEND protocol is suggested. Unfortunately, as this protocol uses CGA, such generation and verification have resource overheads. Even though various algorithms have been proposed to improve the response time and General-Purpose computing on Graphical Processing Units (GPGPU) has been suggested to improve generation time, the overhead is significant for devices with low computing resource or limited power source as every packet must follow some cryptographic process. It has been widely accepted that introducing cryptographic elements in each packet will undoubtedly introduce some delay. Such delay may not become apparent to high end computing devices, but devices with fewer resources will have to face performance issues [24].

IPSec also has some adverse impact on the throughput of the associated devices. As various cryptography tasks have to be performed, it will incur various complex calculations for not only data but also for the header of the packet. The impact of such complex calculations does not seem to affect high end computational hardware but the impact on the devices with lower specifications is obvious. To compensate lack of resource, the traffic rate will have to be sacrificed [25].

Compared to above methods, our proposed scheme has no processing per packet basis which makes it faster and “CPU friendly” as it will not introduce any additional burden on its computing unit.

7.1 Qualitative Analysis

In this section, we will discuss some aspects of PSK based system and non-PSK based system in order to understand more about the benefit of our proposed model.

- Our suggested method have performance benefit as there is no per-packet based processing. For example, in case of both

IPSec and SEND, some additional calculations are required in order to either validate the content of the packet or to perform cryptographic transformations. However, our proposal has purposefully avoided any cryptographical calculations so that performance related impact is avoided.

- Simplicity is also another feature of our proposed mechanism. This protocol should be easy to implement and was designed in such a way that both end users and administrators face no difficulties while implementing it.
- This mechanism is also applicable for the public network like the free WiFi we find in the public areas. As other suggested protocols require some sort of authentication in order to connect to the network, it becomes almost impossible for such protocols to be implemented in a public networks. However, as PSK based model does not require any authentication with any one else, a new node can easily join the network.
- Even though at initial stage, installation based modules might be necessary in order to use PSK based model but originally it is designed primarily considering that the proposed mechanism will be baked inside IPv6 protocol. Thus, the proposed scheme is independent from other system. As of now, all other suggested systems require separate installation and configurations for them to work.
- Undoubtedly, cost is a serious concern when deploying security mechanism. Other available systems will incur cost in either certificate purchasing or developing infrastructure whereas our proposed system requires none.

7.2 Quantitative Analysis

In this section, we will compare packet size to show that the proposed scheme requires either less handshaking packet or reduces size for every packet.

7.2.1 Comparison With IPSec

IPSec has several phases which need to be established prior to any communication can take place. It uses two encrypted tunnels between nodes and each tunnel establishment requires additional communication. The first tunnel requires six packets and second tunnel requires three packets in order to establish initial communication. However, in case of our proposed mechanism, only two packets are required.

Additionally, the size of initial handshake packets are much larger in IPSec which requires approximately 1000 bits of packet size. The packet size for our proposed scheme is only 40 bits.

7.2.2 Comparison With SEND

SEND can be configured with minimum configuration for initial handshake. If trust anchor is used which is the most practical solution, it requires additional three packets in order to verify that the certificate chain is valid. On the other hand, our proposed scheme requires only two packets.

Additionally, in case of SEND, we see a significant increase in every packet size where a simple ping can jump up to approximately 450 bytes as SEND need to add various segments like Timestamp, Nonce and most importantly RSA Signature. As our proposed mechanism does not include any per packet based data, the size will not change.

8 Discussion

8.1 Memory Requirement

Regarding storage requirement of storing the keys, the storage for link layer address is 6 byte (48 bit) and the proposed key is 16 byte (128 bit). Thus the overall storage required for this method will be 22 bytes.

It should also be noted that because the PSK key will not be required for every packet transmission, keys does not have to be directly stored in active memory segment. They can be pushed to swap area of the memory if it is available. When it is required, the data can be fetched from the slower area for further processing.

8.2 Shortcomings

We noted that the proposed scheme is designed for an environment where all of the Layer 2 networking components are switches. As switches operate in Layer 2 of OSI layer, it is aware that in which port a specific host is located; thus traffic from one host to another is considered safe. However, if we consider a networking environment where some of the devices are hubs, this proposed PSK mechanism will not work as all of the packets will be sent to all of the nodes connected to the hub. As this mechanism works by transmitting a key between two nodes, using hubs will certainly have adverse consequence as the key will not be able to move from one node to another without leaking it to other parties.

However, nowadays devices like hubs are now non-existent in networking environment as prices for devices like switches have reduced drastically. Hubs does not provide any security features as all the packets received by the Hub are forwarded to all the connected nodes. As none of the packets are filtered in any way, malicious observer can gain full visibility on what is going on the network. Moreover, in addition to security related constraints, higher transfer rate is not possible in a hub based system. Because in hub based network only one node can send traffic at a time, all other nodes will remain inactive when one node is sending information to another. So, such obsolete technology is almost non-existent in recent times. So, our proposed scheme should work in most of the networking environment.

9 Conclusion

IPv6 is the future of network addressing; so, the security of this protocol should be embedded into it. Unfortunately, as of now, a simple forged NA packet can cause significant damage. The protection measures currently available are complex and also introduces other side effects. We propose to rectify this problem at the protocol level. In this paper, we proposed a scheme that can solve MAC address

override attack in IPv6 with minimal overhead. As the proposed scheme is baked in IPv6, it would work out-of-the-box without additional configurations. Experimental results from NS3 implementation show that the proposed scheme can effectively identify fake NA packet and thus, foil the attack.

The primary concern of this mechanism is key transportation and verification; we plan to design cryptographic procedure for secure sharing of PSK. This can be done by using various hashing methods where subsequent keys could be hashed. Thus, it will be quite difficult for the attacker to obtain information on the key even if there is a verification request. Additionally, since it is extremely difficult to track all the changes in the protocol level, further studies should be conducted to ensure the all other functionalities in NDP can be made secure using a pre-shared key mechanism. As a key has been already shared in this scheme, further trust relationship can be built on top of that which may lead towards trusting gateway and verifying other nodes in the network as well.

ABSTRACT

This work is concerned with the detection and classification of birds that have applications like monitoring extinct and migrated birds. Recent computer vision algorithms can precise this kind of task but still there are some dominant issues like low light, very little differences between subspecies of birds, etc are to be studied. As Convolution Neural Network is a state-of-the-art method with respect to the accuracy of various computer vision related work like object detection, image classification, and segmentation, so CNN based architecture has been proposed to do the experiment for this work. Besides we applied Gaussian and Gabor filters for noise reduction and texture analysis respectively. Histogram of Oriented Gradient (HOG) has been utilized for feature extraction as it is a widely accepted method and it can extract features from all portions of the image. LeNet and ResNet are two good architectures of CNN. In our work, we used the HOG extracted features as input to implement LeNet and ResNet. A standard dataset is used for the experiment and we found that LeNet based CNN gives better results than other methods like ResNet based CNN, SVM, AdaBoost, Random Forest, (we used for the experiment) and other existing state-of-the-art proposed work as well. The experimental results using LeNet based CNN gives 99.6% accuracy with 99.2% F-score, and 96.01% accuracy with 94.14% F-score in detection and classification of birds respectively.

1 Introduction

Object detection is a work of identifying an object instance of a particular class within an image that deals with detecting the objects such as human, building, car, cat, bird, etc. Typically a few instances of the object remain in the image, however, a large number of possible locations and scales where they can present and that require to anyhow be explored. Any detection can be reported with some forms of pose information. The pose information contains the parameters of a linear or non-linear transformation. Object detection techniques are in two major categories, generative [1], [2] and discriminative [3], [4]. The first type is a probability method for the pose variability of the objects together with an appearance model. The parameters can be determined from training data and the decisions can be made based on ratios of posterior probabilities. The second type usually builds a classifier that can differentiate between images (or sub-images) with the object and those are without the object. The parameters of the classifier are considered to minimize errors in the training data. Object detection techniques have applications in different areas including robotics, medical image analysis, surveillance, and human-computer interaction.

Object recognition refers to a collection of related tasks for iden-

tifying objects in digital images. It is a technology in the field of image processing and computer vision for finding and identifying objects in an image or video sequence. It is one of the most important applications of machine learning and deep learning. The goal of this area is to teach machines to learn (understand) the content of an image like a human. Humans recognize a multitude of objects in images with little effort, although the image of the objects may vary somewhat in various viewpoints, in many different sizes and scales, or even when they are translated or rotated. This is a challenging task for computer vision systems. To perform this task many approaches have been proposed over the decades. Machine learning and deep learning are state-of-the-art methods used to detect and recognize the objects in the images.

In recent years, a huge improvement has been made by deep neural networks in detecting and recognizing images [5]. Although face recognition is the most common application area of deep neural network other objects like birds, retinal images are the candidates of the application of deep neural networks for recognition and detection. This is now rapidly used to cope up with various issues and some ecological problems too, our main interest is to recognize and detect birds. In the recognition task, we have tried to recognize crows and hawks.

*Corresponding Author: Susanto Kumar Ghosh, Email: susanto_bag@yahoo.com

From the last few years model of fine-grained recognition gained a lot of success in the purposes to solve the bird classification and detection problems [6], [7]. Birds are not a good object for detection as they have different flying positions as well as still positions. This is the most difficult task to differentiate birds and other flying objects and it is the dominant cause of accidents in the sky. To rescue from this type of difficult situation the name of the fine-grained model is come first. Except for this image discovery using a camera is an excellent way of preclusion[8], [9]. The drawback of this system is to collect a great number of optical information and a system with high authorization. In this circumstance, for few decades Machine learning algorithms including deep learning algorithms are becoming quite famous and effective for recognition and it is also gaining great performance. Such algorithms are recurrent neural network(RNN), deep neural network, convolutional neural network (CNN), etc. In the contrast, shape, size, color, HOG, Haar-like, discriminative, texture-based features are very popular to gain better results [7], [10]–[12]. Improving results is shown by these deep learning algorithms in various types of competitions for struggle discovering and identify objects as shown in Figure 1.

However, the performance of the deep neural network in different aspects of computer vision problems including detection and classification are very impressive, but in real-world experience bird detection and classification are not easy tasks. In recent time some works considering detection and recognition of birds are done. Some related works are the experiments in [13]–[17]. Akito et.al. raised a model so that it can solve the problem of bird detection in the case of enlarged landscape images for applications in the wind energy industry [13]. Besides, Fagerlund and Seppo tried to build a system with automation for bird classification according to species considering their sound produced in the field [14]. To build architecture for visual categorization Branson, the author proposed a model that takes refuse in human accuracy. Their main concern is to differentiate among bird species [15]. A full model of bird species identification was proposed that would help inexperienced bird watchers. The model works by capturing images [16]. These works are not recent, the accuracy is not that satisfactory and the precession rate is not stable. In the case of low-resolution images of birds, the models are not certain.

Figure 1: The images of birds taken around a wind farm (upper) [10] are significantly different from the generic image recognition datasets (lower) [7].

A dataset from the neighboring area of a wind farm has been used as a benchmark dataset to find the actual accuracy as well

as detection rate in case of low-resolution images of the birds in this work]. In this proposed method, as we know the Gabor filter and HOG features are promising we used these two in this experiment. A convolutional neural network (CNN) has been applied as a classifier. As bird detection is a very useful and important topic, many researchers were done for improving detection accuracy. Widely used methods are Support Vector Machine (SVM), AdaBoost, Decision Tree, Random Forest, Neural Network, and many other established machine learning approaches to detect a Bird. For feature extraction Histogram of Oriented Gradient (HOG), Gabor filter, etc. Using SVM and HOG good accuracy was obtained. From all the mentioned methods, Convolutional Neural Network(CNN), a deep learning approach is gaining much popularity in recent years. Moreover, the Deep learning method is best for its detection accuracy. Convolutional Neural Network is specially designed for the Computer Vision field. It works better on image data. HOG is a widely used feature extraction technique and along with the Gabor filter is used for feature extraction. We have used the Gaussian filter for removing noise and Gabor and HOG for extracting features. The convolutional neural network has worked tremendously well with these two feature extractors.

1.1 Motivation

We proposed the HOG feature based LeNet and ResNet models for the detection and classification task. LeNet and ResNet are two different architectures of Convolutional neural network and these are widely used too. The author used LeNet for road sign image detection and classification and they achieved an accuracy of 96.85% in the detection part and 96.23% in the classification [18]. The author used LeNet for detection and classification tasks and obtained 96.37% of accuracy in detection and 87.00% of accuracy for classification [10]. ResNet is also a promising and well-known CNN architecture. The author used a hybrid classifier called SE-ResNet for breast cancer histopathological image classification. They obtained accuracy between 98.87% and 99.34% for the binary classification and achieve accuracy between 90.66% and 93.81% for the multi-class classification [19]. Another work done in white blood cell classification automatically They used ResNet architecture and got a real promising result [20]. From the above discussion, it is a fact that both LeNet and ResNet had a great ability in detection and classification tasks. This is the reason behind choosing LeNet and ResNet for bird detection and classification.

The rest of this paper has been discussed as the following organization. Section 2 briefly discusses similar work for bird detection and classification. Section 3 is a description of our proposed methodology. Section 4 has been written as a description of experimental results that includes experimental setup, implementation details, performance measures, and results. Finally, this work has been concluded in Section 5.

2 Related Works

Bird detection and classification are very important issues in the area of computer vision. Object detection specifically bird detection has received great attention during recent years. Some research

papers related to this field are described below.

2.1 Detection of small bird's semantic segmentation

A model was developed by Akito et.al. for solving the bird detection problem by using enlarged landscape images to apply in the wind energy industry [13]. In this experiment, the CNN model was trained for detection purposes and a method called super pixel-based semantic segmentation was used. To detect small birds they used a successor of CNNs. For better and concurrent detection and recognition of the background, the Super Parsing method was used. A fully FCNs was used for larger areas of images. Then, a combination of all of the detection results is made by a linear SVM. The results of the three methods are merged by using SVM to get high detection performance. The experimental results on an image dataset of birds showed significant high precision and efficiency of the proposed methodology [13]. Their proposed model achieved 87.2% accuracy.

2.2 Bird species recognition using support vector machines

Fagerlund and Seppo tried to build a system with automation for bird classification according to species considering their sound produced in the field condition [14]. In the first step based on the signal level, they classified the birds' sounds into two specific parameters. Here for the automated recognition of birds, the SVM classification methods were used. A decision tree is another machine learning algorithm for classification and detection tasks that used along with the SVM. The task of classification between two species of birds is performed by the classifying methods. Then the performance of the models is tested according to the previously tested two sets of bird species. The previous test was done with a range of alternative methods. Compare to other existing systems this work suggests identical better or equal performance.

2.3 Bird species categorization using pose normalized deep convolutional nets

The author proposed a model that takes refuse in human accuracy. Their main concern is to differentiate among bird species [15]. They collect the local images of birds and find out features in the first step. A deep convolutional network is used to compute the extracted features to multiple image patches. The pose of the object in an image is described by these features. For learning a compact pose normalization space a graph-based clustering algorithm is presented. The performance of their model was increased for the use of CNN features which are modified by the CUB-200-2011 dataset for each region. They also used different CNN layers for different alignment levels. A similarity-based warping function was used in their method. More numbers of detected key points from the image are used to calculate features. At last, to learn a set of pose regions they introduced an approach. This system explicitly minimizes pixel alignment error and also beneficial for complex pose warping functions [15]. They achieved 75% accuracy on the CUB-200-2011 dataset.

2.4 Bird species identification from an image

A full model of bird species identification was proposed by Aditya, Ameya, and Rohit that would help inexperienced bird watchers. The model works by capturing images [16]. The main concern of this experiment was to identify the qualitative elaboration of various bird species by utilizing different machine learning methods. Actually for solving this problem, three key features were used. Color, pattern and shape features of a particular part of the images were used. For detecting birds in the images two machine learning algorithms (the KNN and the NaiveBayes classifier) were used. To see the improvement of the Accuracy different feature selection and feature reducing approaches were utilized. Firstly, They used various changing kernels for SVM - Linear and Radial Basis Functions. Then, they applied PCA (reduces feature) and SVM, Logistic Regression, and LDA. After applying feature reduction methods these were applied. After that to remove low variance features and select tree-based univariate feature L1 based method was used. Then to get new feature data by feature selection PCA was used. LDA, Logistic Regression, and SVM were implemented with this data from the previous feature reduction method. They claimed that this technique helped them to increase accuracy [16]. Their proposed model achieved 75.7% accuracy.

2.5 Crow birds detection using HOG and CS-LBP

KidaneMihreteab and Masahiro Iwahashi(2012) Proposed a detector based on features for birds [17]. Using feature extraction methods for crow bird detection is the main target of this research. Here, by combining Histogram of Oriented Gradients(HOG) and Center-Symmetric Local Binary Pattern (CS-LBP) features, the discriminative descriptor feature is produced and applied to the model. The authors used SVM as a machine learning algorithm. Here, they compared the HOG CS-LBP feature and HOG-LBP combination feature and finally, HOG CS-LBP based combination performs better[17]. This proposed model achieved 87% accuracy.

2.6 Detection and species classification of bird with time-lapse image around a wind farm

The author was proposed a model for the detection of the bird. They used time-lapse images around a wind farm for this experiment [10]. Here, two approaches were compared, in their first approach they make a combination of AdaBoost(A machine learning algorithm) and Haar-like or HOG(feature extracting algorithms) and in other methods is made based on Convolutional neural networks (CNN). At last, they compared the accuracy and other performance measures between these two methods [10]. There proposed model achieved 99.2% on bird detection and 87% on bird classification. They experienced that their proposed method will continue to improve bird detection and classification in terms of both accuracy and speed in using for real-time applications.

2.7 Application of Deep-Learning Methods to Bird Detection Using Unmanned Aerial Vehicle Imagery

The author built a bird detection model by using aerial vehicle images [1]. Region-based Convolutional Neural Network (R-CNN), Region-based Fully Convolutional Network (R-FCN), Single Shot Multi-Box Detector (SSD), Retinanet, and You Only Look Once (YOLO) are used as deep learning algorithms in this experiment. Migratory birds monitoring, counting, and detection of wild birds are mentioned as their experiment's application. Here 95.44% of accuracy is achieved by the experiment.

2.8 Bird Image Retrieval and Recognition Using a Deep Learning Platform

The endemic bird classifier proposed and achieved 99.00% of accuracy [2]. They used CNN as a classifier algorithm and random flipping, rotation, and shifting are used as preprocessing methods. Skip layer connection can enhance feature quality. The authors proposed to skip layer connections for improving feature extraction.

3 Proposed Methodology

To detect birds from images, we perform the preprocessing steps and extraction of feature vectors from the image. Then the image passes through the classifier where the pre-trained model and weights come from the database. Then the model predicts the result if the image contained any bird. Different combinations of classifier model techniques are investigated to achieve a better result.

3.1 Training Phase

At first in this phase, we took a different number of samples where positive and negative samples are indicating images with birds and non-birds respectively. These positive and negative samples are passed through different phases. Both the training and validation sets are gone through pre-processing and feature extraction processes. The purpose of the training phase is to train the classifier and the validation set is responsible for checking the classifier's performance. Mainly the purpose of the validation set is to increase accuracy. After that, the classifier has been fed with both training and validation sets.

3.1.1 Preprocessing

In preprocessing steps we have performed the following tasks.

Image Resizing We resized the images to 28×28 and then sent it for further processing.

Filtering [21] Images contain noise and for reducing the noises from images we used Gaussian filter. The benefit of this filter is it can preserve every useful detail when cleaning noise and it also helps to develop a fine-grained detection [21]. The following equation of 1 illustrates the equation of the Gaussian filter.

$$G(x, y) = \frac{1}{2\pi\sigma^2} e^{-\frac{x^2+y^2}{2\sigma^2}} \quad (1)$$

Here, intensities are represented by x and y of the input image, the standard deviation of Gaussian distribution is denoted by σ .

3.1.2 Feature Extraction

Suitable shape information which represents a pattern is found from feature extraction. These features are helped to make classifying tasks simple by a formal procedure. Machines and human eyes can respond differently about these features as features are the machine-understandable codes. Every feature represents characteristics in an image like shape, position, the existence of a specific object. A normal image cannot be good enough for feature extraction so before feature extraction different preprocessing methods are applied to the raw images. Figure 2 is a flow of feature extraction in our experiment.

Gabor Filter A grayscale image is found from a pre-processed color image by applying the Gabor filter. After applying the Gabor filter the image is sent for HOG feature extraction.

Histogram of Oriented Gradients(HOG) HOG (Histogram of Oriented Gradients) is a feature extraction method that can extract features from every position of the image by constructing a local histogram of the image. In this technique, cells (small connected regions) construct the image. Within each cell, a HOG direction is composed of the pixels. First, the gradient of the input image of size 28×28 is found by utilizing a 16×16 filter. To provide a compact representation the filter describes a patch of an image. Magnitude and direction are two such values that are contained by the gradient of the patch. The overall lighting is a sensitive thing for gradients.

By dividing all pixel values by two we have made the image darker make our descriptor to be neutral to lighting diversity. As a variation of lighting is a barrier we must normalize the histogram in a way that this variation of lighting cannot be affected. By sliding 16×16 cells through all areas of image we can finally find HOG extracted image.

3.2 Classifier

A classifier is defined as a supervised function where the learned attribute is categorical. It is used after the learning procedure to classify new data by giving them the best target attribute. In our methodology, we have worked with CNN.

3.2.1 Convolutional Neural Network(CNN)

In the proposed methodology, CNN has been used. Image classification, digit recognition, Indic handwritten script identification, object detection, and face recognition are the application area of CNN where already CNN has performed very well [22]–[26]. Although image detection and classification are not a very easy task for computer vision algorithms as well as machine learning algorithms CNN is very promising according to accuracy [10]. Moreover, CNN has an automatic learning ability and the ability to learn complex models. It works at pixel-level content. CNN works with some simple operation sequences like filtering, local contrast normalization, non-linear activation, local pooling. A dataset with a lot of data and a technique of training called backpropagation are key factors of the performance of CNN. The number of both the Convolutional

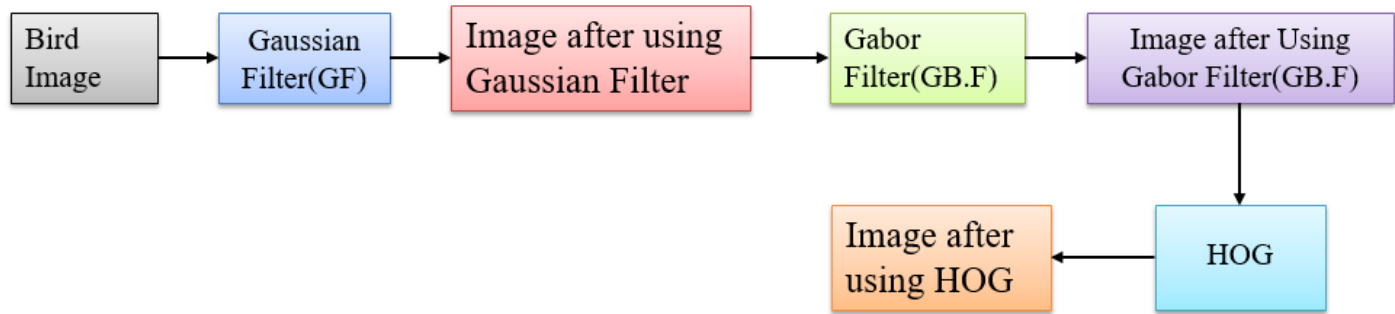

Figure 2: The feature extraction process.

layer and hidden layer are three in our proposed architecture of CNN. 28×28 sized images are fed into the convolutional layer. The convolutional layer has 3×3 sized 32 filters. Rectified Linear Unit (ReLU) is used as an activation function that is the non-negative part of its all arguments. Only zero or positive values can be passed. Here is the function of ReLU in equation 2:

$$f(x) = \max(0, x) \quad (2)$$

Two convolutional layers with 64 and 128 filters respectively are used after that. The filter size is 3×3 . After a journey through the convolutional layer, A flattened array is produced from the feature map. Convolution layers and flattening are followed by a fully connected hidden layer. The flattened array is passed through this hidden layer. With activation function ReLU we used 128 neurons in all three hidden layers. The only exception is in the output layer, the sigmoid function is used in the output layer contains. The previously hidden layer is fully connected with this output layer. The sigmoid function exists the value in a range of 0 and 1 that is why the output layer consists of a sigmoid function. Our proposed model has just binary output so the sigmoid function is useful here. Expression of sigmoid function:

$$s(x) = \frac{1}{1 + e^{-x}} \quad (3)$$

‘No bird’ in the image will be the result for 0 as the output of the output layer and ‘one or more birds’ in the image will be the result for 1 as the output of the output layer. The overview of the proposed CNN model is in Figure 3.

Figure 3: Block diagram of CNN architecture.

In the convolution layer, two sets of information are merged by a mathematical operation and this is called convolution. A feature map is produced by a convolution filter. In our case, $32 \times (26 \times 26)$ filter is used as a convolution filter on (28×28) sized image like Figure 4.

The convolution operation is performed by sliding the filter over the input image. Element-wise matrix multiplication occurred and the results are summed. The summed results are put at every location of the feature map. Every convolution layer is followed by a pooling layer Figure 4. Among all pooling methods, max pooling is the most common. In our experiment $32 \times (13 \times 13)$ filters are used after conv1. Pooling is used to dimensionality reduction and max-pooling does this job by taking the maximum value. By sliding over the output from the convolution layer this filter takes maximum value to fill up every location. The input image goes through several convolutions and the pooling layer before feeding it to the flatten layer.

After Convolutional and pooling a fully connected hidden layer is added to wrap the CNN architecture as shown in Figure 5. Before passing through this layer output from pooling is flattening. Flattening is just arranging three-dimensional volumes of numbers into a linear vector. The fully connected hidden layer tasks the output from the flattening layer. In our experiment, 128 nodes are used in every layer of the hidden layer. An activation function is utilized in every layer as well as in the output layer. The hidden layer produces the input for the output layer. The whole model of CNN consisting of Input, Convolutional, Flatten, Fully connected hidden and Output layer is shown in Figure 6.

Figure 5: Hidden Layer of CNN.

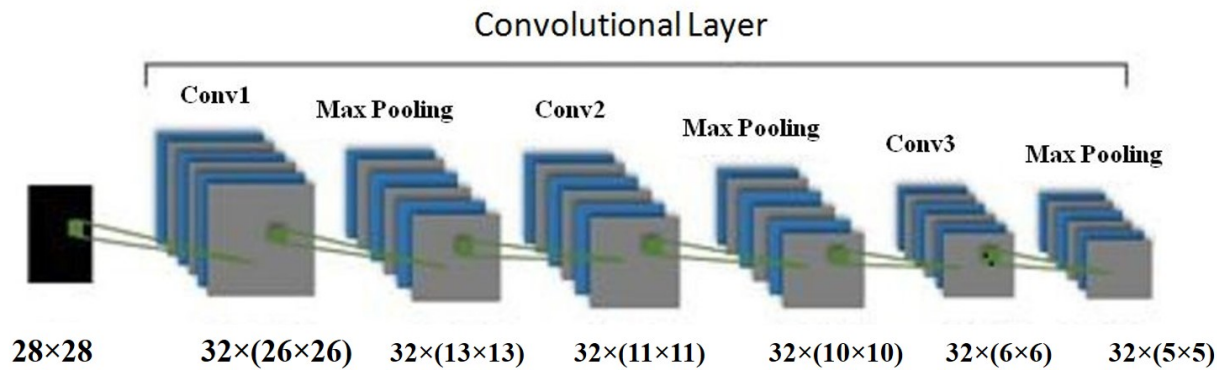

Figure 4: Convolution Layer of CNN.

Figure 6: Full Model of CNN.

3.3 Model Parameter and Weights

After doing preprocessing and feature extraction the samples were divided into a training set and validation set where the training set was used for training the classifier and validation set was used for checking the classifier accuracy during training. By checking accuracy the validation set is improving the classifier. Then both sets are fed into the classifier. After finishing the training the model parameters such as 0, 1 and weights are stored in the database. When we predict the result in the testing phase, the pre-trained model parameter and weights are sent to the classifier.

3.4 Testing Phase

we took a different number of positive and negative samples, where positive and negative samples are indicating images with birds and non-birds respectively. Like the training phase, the pre-processing and the feature extraction methods are the same. Then the classifier predicted the result from the extracted features. 'No bird in the image' will be the result for 0 as the output of the output layer and 'one or more birds in the image' will be the result for 1. Figure 7 illustrates the full workflow of the system architecture. The proposed architecture is similar to the architecture used in our conference paper [27]. However, we have done an extensive experiment using

different methods and compared the results.

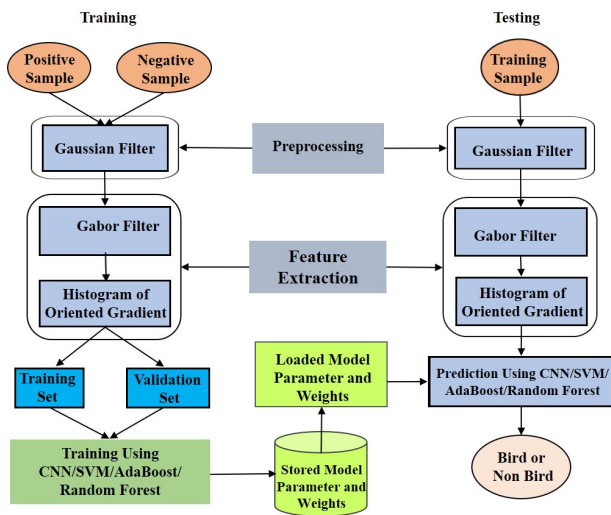

Figure 7: System architecture.

Figure 8: Sample images of the dataset [10].

Table 1: Categories of Images in Dataset [10]

S/L	Name of class	Number of Images	Total
1	Birds	5000	29000
2	Non-birds	20000	
3	Crows	1000	
4	Hawks	3000	

4 Experimental Results

We performed the experiment using dataset taken from link <http://bird.nae-lab.org/dataset>, which was also used for the experiment in the approach proposed in [10]. Two types of experiments such as bird recognition and classification of species were done here. Detection is treated as classification of birds and non-birds and the classification means differentiation between hawks and crows. The hawks and crows are the available classes of objects that were included in the dataset, where there is a sufficient amount of information for doing an experiment. The authors of the paper [10] took their images at the wind farm.

4.1 Experimental setup

In the experiment, positive and negative samples were used for training as it is required for the machine learning technique. As in the paper [10], we performed the experiment using both positive and negative samples. For a fair comparison, the 6000 positive samples and 20000 negative samples were used for the experiment. Examples of birds and non-birds are shown in Figure 8. The 5-fold cross-validation process was used to perform the experiment proficiently. In the detection experiment, birds labeled in the dataset were positive samples and non-birds were negative samples [<http://bird.naelab.org/-dataset>]. In the detection experiment, birds labeled in the dataset were positive samples and non-birds were negative samples. In the classification experiment, hawks labeled in the dataset were positive samples, and crows were negative samples. Figure 8. We conducted holdout validation using 600 hawks and 200 crows for the training data and the rest of each group for the test data.

In the classification experiment, hawks labeled in the dataset were positive samples, and crows were negative samples. Classification is a more difficult task than detection on this dataset; thus, to evaluate the behavior of each method in detail, we investigated the effect of image resolution by dividing the positive and negative images into groups based on resolution. Figure 8. We conducted holdout validation using 600 hawks and 200 crows for the training data and the rest of each group for the test data.

In SVM we had to vary parameters called C (regulation parameter) and gamma (kernel co-efficient). We used RBF (radial basis function) as a kernel. We used 5 numbers between 0.25 and 128 as C and 5 numbers between 0.08 and 4 as gamma. In detection at C = 0.1 and gamma = 0.8 SVM performed best and in classification task SVM performed best at C=64.125 and gamma = 0.02. For the AdaBoost algorithm, 100 weak classifiers worked better than 50 weak classifiers in both detection and classification. The different learning rates are used in this case. Detection worked best at the learning rate of 0.3 and classification worked best at the learning rate of 0.01.

Random Forest 500 weak classifiers performed better than 250 weak classifiers in both detection and classification. Among different maximum depth of trees in Random Forest, the detection task worked better at the maximum depth of 4 and the classification task worked better at the depth of 7.

For CNN we used 128 output filters and 3×3 kernel size. We used three convolution layers and three max-pooling layers to construct the network. Here, we used ReLU as the activation function. This method performed best among the methods described above.

In the experiment, we evaluated the four best methods in the detection (bird-vs-non-bird) and classification (hawk-vs-crow) ex-

periment, namely CNN, Ada-Boost, Random Forest, and SVM. We quantified the detection and classification performance by using two measures, true positive rate (TPR) and false-positive rate (FPR). TPR is the ratio of the number of true positives and the number of all positives in the test data. FPR is the ratio of the number of false positives and the total number of negatives in the test data. Because there is an equipoise between TPR and FPR, the total performance of an algorithm is represented by the receiver operating characteristic curve (ROC), a curve of TPR versus FPR. A curve that goes near the upper left-hand corner means better performance.

4.2 Implementation details

In this work, we used four different methods for detection between birds and non-birds and classification between crows and hawks. The methods are SVM, AdaBoost, Random Forest and CNN (LeNet, ResNet).

In our proposed LeNet(CNN) architecture we used $128 \times 3 \times 3$ convolution layers. The input shape of the images is 28×28 . Then Batch Normalization is done and we used Leaky Relu as an activation function. The same layer of previous has been repeated. Then the pooling operation applied with the pool size of 2×2 . Another two-layer like before applied after this with $256 \times 3 \times 3$ convolution layers. Here the pool size is 2×2 . Then the output is flattened and the flattened output is feed to the fully connected neural network. This network consists of three layers with a dense of 512, 256, and 128. Every layer is activated by LeakyRelu and we used sigmoid as the activation function for binary classification. Figure 9 illustrates the architecture.

ResNet is several leveled or staged architecture. In Figure 10 architecture of ResNet has been shown. In our proposed architecture applied a $64 \times 7 \times 7$ convolution layer to the 64×64 image. Then batch normalization and activation are done. We applied max pooling with the 3×3 filter. Let, this is called convolution block. Another block we called ResNet which contains three convolution layers. Firstly pre-processed imaged feed to two consecutive convolutional layers. After that, the output is stored and feed to two consecutive ResNet blocks like Figure 9. Previous results from two convolutional layers and current output from these ResNet blocks are added and feed to another convolution layer. Then the output from this layer and output by feeding another three ResNet blocks is added and feed to the output feed to another ResNet block. Like previous, the result from another five ResNet blocks and the convolutional layer is added and feed to another convolution layer. The result from this layer and result from another 2 consecutive ResNet block is added and average pooling applied. Then the result is flattened and feed to the fully connected layer. The process is shown in Figure 10.

In SVM we had to vary parameters called C (regulation parameter) and gamma (kernel co-efficient). We used RBF (radial basis function) as a kernel. We used 5 numbers between 0.25 and 128 as C and 5 numbers between 0.08 and 4 as gamma. In detection at $C = 0.1$ and $\gamma = 0.8$ SVM performed best and in classification task SVM performed best at $C=64.125$ and $\gamma = 0.02$.

For the AdaBoost algorithm, 100 weak classifiers worked better than 50 weak classifiers in both detection and classification. We used different learning rates in this case. Detection worked best at the learning rate 0.3 and classification worked best at the learning

rate of 0.01.

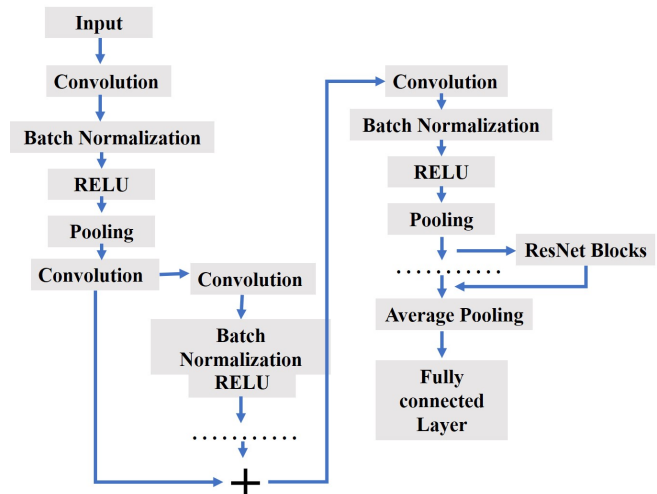

Figure 10: Proposed ResNet(CNN) architecture.

Random Forest 500 weak classifiers performed better than 250 weak classifiers in both detection and classification. Among different maximum depth of trees in Random Forest, the detection task worked better at the maximum depth of 4 and the classification task worked better at the depth of 7.

4.3 Performance Measures

For calculating the accuracy, precision, and recall first we have taken the true positive, true negative, false positive, and false negative from the confusion matrix. Then we have calculated accuracy, precision, recall using the confusion matrix. For the dataset, we have got a confusion matrix.

Accuracy means the number of appropriate results from the whole dataset divided by all samples. The accuracy is calculated by the following equation.

$$Accuracy = \frac{TP + TN}{TP + FP + FN + TN} \quad (4)$$

Error rate means the number of wrong results from the whole dataset divided by all samples.

$$ErrorRate = \frac{FP + FN}{TP + FN + FP + TN} \quad (5)$$

Precision means the number of accurate results (or true positives, a bird that is detected as a bird) divided by the number of all positive results (that is, the sum of birds and non-birds detected as birds). Precision shows the probability that a retrieved object was a bird [28].

$$Precision = \frac{TP}{TP + FP} \quad (6)$$

Recall means the number of appropriate results divided by the sum of birds detected as birds, and birds not detected as a bird. Recall shows the probability that a bird was retrieved [28].

$$recall = \frac{TP}{TP + FN} \quad (7)$$

Figure 9: Proposed LeNet(CNN) Architecture.

The F-score measures the accuracy of a test by dealing with both the Precision and the Recall. F-score is very effective to avoid unbalanced systems [28].

$$recall = \frac{2 \times Precision \times Recall}{Precision + Recall} \quad (8)$$

In this research area, our proposed methodology performs very well as the accuracy of detection is 99.60% and classification is 96.01%.

We have run the CNN model several times with changes of a convolutional layer, convolutional layer feature map size, hidden layer, input shape, number of neurons and we have got the best result according to the dataset. After testing with the dataset we have got a confusion matrix for bird detection shown in Figure 11. and a confusion matrix for bird classification given in Figure 12.

Figure 11: Confusion matrix for bird detection(LeNet).

Figure 12: Confusion matrix for bird classification(LeNet).

4.4 Results

The detection results are shown in Figure 13. In this figure, we introduced a visual plotting called ROC (receiver operating characteristic) curve. Here, we see that the blue curve (curve for CNN) more prone to the upper left corner. The other curves red, yellow and green are for AdaBoost, Random forest, and SVM respectively. These three curves are less prone to the upper left corner than the curve of CNN. That is why we can say that CNN performed best. In the figure, FPR means the rate of misrecognizing backgrounds as birds, and TPR means the rate of correctly recognizing birds. Even at the FPR of 0.09, CNN detected over 0.97 of the birds. Flying objects are more difficult than negatives due to their visual similarity to birds. Note that the number of false detections depends on the number of negative samples in the data. More negative samples mean more false detections with the same FPR. Thus, the actual number of false detections may change depending on the test environment.

The results of the classification (hawk vs crow) are shown in Figure 14. In this figure, It can be seen that the blue curve for CNN is more prone to the upper left corner. The other curves red, yellow and green are for AdaBoost, Random forest, and SVM respectively as detection. These three curves are less prone to the upper left corner than the curve of CNN. In this case, again the ROC curve shows us that CNN performed best. Here, FPR is the rate of misrecognizing crows as hawks, and TPR is the rate of correctly recognizing hawks. This curve shows the overall performance in the resolution

groups. Because of visual similarity, the species classification is more difficult than the birds-versus-others classification; thus, its performance is lower. However, among the methods, the deep learning methods showed relatively promising results for classification. For example, at the FPR of 0.1, CNN detected 0.90 of the hawks. By contrast, when we set the TPR at as high as 0.9, CNN misclassified 0.3 of the crows as hawks.

Figure 13: Result of detection (birds vs. non-birds). Curves that go closer to the upper left-hand corner have better performance .

Figure 14: Result of classification (crows vs. hawks). Curves that go closer to the upper left-hand corner have better performance .

Sometimes, visually similar images are correctly classified, sometimes not. The CNNs do not have explicit misclassification trends because of their black-box training process.

4.5 Comparison

The objectives of HOG-CNN techniques are used to improve detection and classification accuracies and compare them with the results

of existing techniques. In this experiment, we have worked with the dataset [10] using the Gabor filter, HOG, and CNN. CNN has been run several times and the best result is taken. In this experiment Intel(R) Core(TM) i5-4200M CPU with 2.50 GHz and 4GB RAM have been used. Python is used as a programming language. For this purpose, we have used OpenCV for preprocessing and feature extraction and Keras and tensor flow for training and testing the model. The results are collected and compared with different methods. Comparison is shown in tables 2 and 3.

Table 2: Experimental results of bird Detection

Methods	Accuracy	Precision	Recall	F-score
CNN(LeNet)	99.60%	99.52%	98.89%	99.2%
CNN(ResNet)	96.37%	95.24%	84.50%	89.55%
R.Yoshihashi et. al.	99.20%	90.16%	75.13%	81.96%
SVM	92.22%	97.53%	92.65%	95.03%
Ada Boost	94.34%	96.64%	83.36%	89.51%
Random Forest	94.42%	94.32%	85.00%	89.41%

Table 3: Experimental results of bird Classification

Methods	Accuracy	Precision	Recall	F-score
CNN(LeNet)	96.01%	96.61%	91.79%	94.14%
CNN(ResNet)	78.54%	76.40%	65.20%	70.36%
R.Yoshihashi et. al.	87.00%	88.99%	92.08%	69.13%
SVM	75.25%	74.43%	60.37%	66.88%
Ada Boost	79.12%	77.44%	65.81%	71.15%
Random Forest	80.83%	81.2%	67.71%	73.84%

Figure 15: Accuracy comparison of bird detection (birds vs non-birds).

Figure 18: Precision comparison of bird classification (hawks vs crows).

Figure 21: F-score comparison of bird detection (birds vs non-birds).

Figure 22: F-score comparison of bird classification (hawks vs crows).

Furthermore, the author achieved an average of 95.37% for bird recognition [2], the author got 88.00% of accuracy for bird detection using Siamese neural network [3], and attain an average of 93.19% of accuracy on bird species identification [4]. In the bird detection case, we got the highest 99.60% of accuracy by using LeNet (CNN) architecture and in the bird classification case, 96.01% accuracy has been achieved by LeNet (CNN). In both of the cases, our LeNet (CNN) architecture shows higher accuracy.

Tables 2 shows the results of accuracies with F-scores of all compared methods in detection of birds. On the other hand Table 3 gives the results of accuracies with F-scores of all compared method in classification of bird. In Figures 15 and 16 we depict the results of accuracy in detection and classification of bird. Figures 17 and 18 are for comparisons of precisions of all methods in detection and classification respectively. Comparisons of recalls of all methods are shown in Figures 19 and 20. Finally, Figures 21 and 22 shows the comparisons of all methods in case of F-score.

4.6 Discussion

Birds are really important for ecological balance. Bird detection and classification have some applications. Monitoring extinct birds is one of them. By monitoring the extinct birds, it could be understood how and why they are on the verge of extinction. Another application of this experiment is monitoring the migrated birds. Migrated birds can carry different types of germs that can spread diseases in the area around them. If these birds could be observed, it is possible to keep them detached from human residences. Furthermore, new bird watchers couldn't recognize different species. So a tool is being provided for helping them.

In the detection experiment, we obtained the best results using CNN. The existing features are designed for detecting objects such as faces and pedestrians, which are not often at low resolution. Thus, these features are not necessarily effective in our bird detection because of the limited object resolution. For example, HOG represents details of images by gradients and is preferred in tasks like pedestrian detection and generic object detection. However, it is less robust for low-resolution bird detection. The parameters and optimization play an important role in the performance of CNN [10].

In the classification experiment, CNN outperformed the other

methods in all groups with different resolutions, and Random Forest performed the second best. The hand-crafted features may be less effective in classification because of the subtle differences between the classes. Conversely, the learned features of the CNNs succeeded in adapting to the classification task through training. The size of the training data may have been the reason. The classification experiments were conducted with less training data than in detection, and this put deeper networks, which are more difficult to train, at a disadvantage.

The results of the filtering experiment suggest that classifiers work well even when unspecifiable birds exist in the environment. This means that our classifiers can extract a single species from all the data, and this is useful for investigation purposes. Each method performs 10% to 20% better in filtering than in classification. This seems to be because of unspecifiable birds have distinguishable characteristics in themselves from specifiable hawks, and this makes filtering easier than classification.

In Our proposed methodology we used resized images. Images are then filtered by Gaussian filter to reduce noises and Gabor filter to make the grayscale of the image. Then we used the HOG feature as an input of LeNet and ResNet architecture of CNN. For evaluating results we also applied other machine learning algorithms like SVM, AdaBoost, and Random Forrest.

The author's work is based on Haar-like and HOG features using LeNet Architecture for the detection of birds and classification of bird species[10].

The author proposed a method for wild bird detection [1]. They used five different deep-learning-based object-detection methods for the experiment, i.e., Faster R-CNN, R-FCN, SSD, Retinanet, and YOLO, to create bird detection models using aerial photographs captured by UAV. For deep neural networks, they cropped the images in the size of 600×600. Then they were divided into sub-images and flipped horizontally and vertically.

The author proposed a model for bird image retrieval [2]. They develop the Internet of Birds (IoB) mobile app for bird image retrieval, applied the softmax distribution to function to obtain a probability distribution of bird features, use a convolutional neural network (CNN) and SVM. So, It is clear that we have introduced a new methodology.

5 Conclusions

We used a bird-image dataset and evaluated typical image recognition methods for the purpose of developing an automatic bird detection and classification system for wind farms. By using a dataset from a realistic environment and representative methods in computer vision, we provided practical results and analyses of recognition performance. The experiments were executed using our CNN based architecture and we found that LeNet based CNN gives the best results than other approaches like ResNet based CNN, SVM, Adaboost, Random forest, existing state of the art method in recognition and classification of birds. The LeNet based CNN shows 99.6% accuracy and 99.2% F-score in case of detection of bird. On the other hand it shows 96.01% accuracy and 94.14% F-score in case of classification of bird. Hence we can conclude that LeNet based CNN gives highest results both in accuracy and

F-score. In this work, we use binary species classification but the work with multiple bird species classification can be done in the future.

Conflict of Interest The authors have no conflict of interest.

ABSTRACT

Information and Communications Technologies are developing faster today than ever before, giving an important contribution to the global economy. Organizations in developed and developing economies explore new technologies to gain advantage and add value. That evolution also brings an increasing complexity to the organizations' management. The alignment of organizational practices with international standards and best practices worldwide accepted in this domain is a relevant topic. To identify gaps in Information and Communications Technologies management area, a brief analysis of international standards will be considered in the state-of-the-art. Considering that Information Technology Infrastructure Library and Control Objectives for Information and related Technology are the most used in the literature review, this paper will propose an Information and Communications Technologies management framework based on those two standards. The approach pretends to solve some gaps found in process alignment, continuing improvement of Information and Communications Technologies services in the context of the organization, driving stakeholder satisfaction and cost optimization. Concluding, the final goal of this paper is to present the framework features analysed, to allow an integrative and multidisciplinary vision, leading to cost optimization, increasing communication, and stakeholder satisfaction.

1. Introduction

This work is an extended version of the paper [1] originally presented in 2020 at the 15th Iberian Conference on Information Systems and Technologies (CISTI).

Information and Communications Technologies (ICT) is one of the main motors of economic development in the XXI century and a success factor of strategic business evolution. In this context, the theme of ICT management and governance processes in organizations is considered relevant, especially on the alignment of organizational objectives and ICT operational efficiency and management of services based on stakeholders needs. A company must implement information technology that is oriented to customers and stakeholders to be competitive [2]. Applications have become an integral part of business strategies while creating new opportunities for alliances and collaborations [3]. Core assets of organizations, business processes shape the functioning and efficiency of organizations [4]. Process modelling guidelines are a valuable instrument for increasing the quality of process models

[5], and the human factor is of great importance in Business Process Management (BPM) implementation [6]. Early involvement of stakeholders from top management to the operational level is essential for successful implementation of BPM [7]. The way processes are designed and performed affects both the quality of service that customers perceive and the efficiency with which services are delivered [8].

Managing and using IT services is considered very important for modern businesses to improve their performance [9]. The management of IT services is increasingly driven by the necessity of cost reduction and quality improvement. As a result, new organizational models have been created and implemented aiming at achieving economies of scale, while improving customer satisfaction and experience has been one of the main focuses of recent research in Service Science [10]. Information Technology (IT) grows very rapidly and affects the success of the business lifecycle of an organization [11]. The constant evolution and diversity of technologies and components used in hardware, software and communications networks [12], results on complex management and governance processes in ICT departments

*Corresponding Author: Joaquina Marchão, Email: jamarchao@gmail.com

involving different knowledge and different teams. ICT services are always changing, seeking to respond to business' demands. The growing complexity of customer needs is one of the prevailing problems faced by IT enterprises at present. At the same time, quick response to unexpected problems and externally imposed requirements are testing the IT change management [13]. Additionally, the high availability of information technology (IT) applications and infrastructure components is a significant factor for the success of organizations because more and more business processes depend entirely on IT services [14].

The alignment of organizational practices with international standards and best practices worldwide accepted on this matter is a relevant topic. Among other frameworks and international standards, it was selected the Information Technology Infrastructure Library (ITIL) [15] and Control Objectives for Information and related Technology (COBIT) [16]. Based on those best practices, some models or frameworks are used to manage the complexity of organizations [17]. IT service delivery should be done in a cost-efficient manner. Combining ITIL and COBIT can be valuable for organizational goals. ITIL should be used to define strategies, plans, and processes, on the other hand, COBIT will be used for metrics, benchmarks, and audits [18].

ICT management and governance thematic involve multidisciplinary knowledge. This work is based on a real context analysis of stakeholders from IT support area, and related operational processes and flows. The proposed framework pretends to solve some gap alignment between ITIL and COBIT. The main goal of this paper is to identify the framework features to allow the alignment between several process areas. Operational efficiency and optimization of ITC cost of service, and to stakeholder's satisfaction are other benefits.

The paper presents 5 sections. The first section is a brief introduction to the problem under study. Section 2 presents the state-of-the-art related to this theme. Section 3 shows an overview of the initial processes. In section 4 the framework features are identified based on the processes under analysis and respective interactions. Section 5 includes conclusions and perspectives for future work.

2. State-of-the-Art

ITIL and COBIT are the international most implemented IT frameworks in organizations around the world. ITIL has a focus on IT departments and management services, and COBIT has a focus on organizations' objectives and business control. It was considered to analyse both ITIL and COBIT because these are the most used international best practices. It is expected the framework under construction could solve gaps found in the alignment processes of ICT services for continuous improvement, leading to stakeholders' satisfaction and cost optimization. A brief description of the international standards considered relevant to the framework is presented below.

2.1. ITIL

ITIL's best practices are oriented towards ICT Service Management through the stages defined in ITILv3, the life cycle management of ICT services are Strategy, Design, Transition, Operation, and Continual Service Improvement. Figure 1 shows the stages of ITIL related to the scope.

Figure 1: ITIL v3, stages selected within the scope of this paper, adapted from [15]

Stages of Service Operation (components: incident management, request management, and problem management) and Service Transition (components: change management and service asset and configuration management) are used by ICT service support. Stakeholders perceive the service value in the Service Operations stage. Data collection and analysis began with reported incidents and requests for new service: which services were more affected by incidents and why. Consequently, the analysis covered the processes, technology, and people involved. After reflecting, we concluded that the scope should not only be based on this stage but also include others, such as the Service Transition stage, to understand the changes that occur in the production environment and manage the impact in related service assets and configurations, on a day-to-day work basis with stakeholders. ITIL presents good practice guidelines for ICT service management, with scope in the life cycle of services. The implementation of this framework is complex because the literature provides only some general guidance [19]. Implementing ITIL is usually long, expensive, and risky [20], and should require an organizational change affecting procedures, functions, and common attitudes within the organization [21]. The alignment between IT business processes and business objectives is important to achieve stakeholder's satisfaction.

2.2. COBIT

COBIT [16] is a reference model of Governance and Management Objectives, allowing the alignment of ICT management with organizational and business objectives. COBIT defines the components underlying the decisions to be made, how and by whom. This model does not guide what strategies to follow, what technologies to adopt, or what the best architecture to choose. It can address results in three different roles: managers, users, and auditors. Managers seek risk assessment and control of investments; users seek the quality of services; and auditors seek to assess ICT management work. COBIT defines factors and components that should be considered by the organization to build and maintain an appropriate governance system: processes, organizational structures, policies and procedures, information flows, culture, ethics and behaviour, competencies and capabilities, services, applications and infrastructure of the organization, and not just ICT. This framework treats information and related technologies as assets, which must be managed. It presupposes a mental change in the organization, both at the level of ICT managers and business managers, and the latter is responsible for ICT related assets.

Figure 2 shows the COBIT objectives related to the scope.

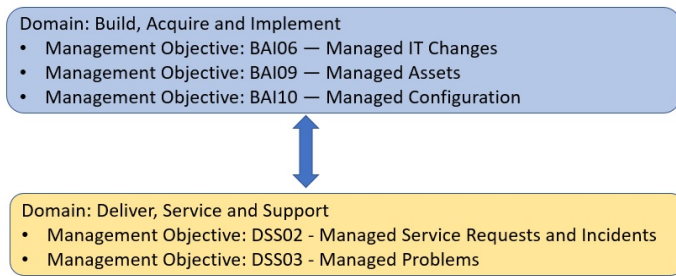

Figure 2: COBIT, Objectives selected within the scope of this paper, adapted from [16]

COBIT presents numerous objectives towards the alignment between the organization and IT. It has a transversal vision for the organization. The interceptions between ICT management objectives and organizational objectives allow the definition of metrics to achieve strategic objectives with standards. For its implementation, it requires cooperation between the different responsibility levels. This framework allows you to define a strategy to generate maximum value creation through IT investments. One of the basic elements in management is the creation of value added [22].

2.3. ITIL vs COBIT

ITIL is the framework most used for IT service management in IT departments. COBIT is the framework most used for governance and management concerning organizations' objectives. It was designed to support the audit and evaluation of IT activities. The sponsorship of the board of directors is important. IT governance has become critical to successful business operations. Many organizations implement IT governance to ensure that they align their IT strategy with the overall business goal [23]. Both can be used by different organizations' types and dimensions, and organizations usually begin implementing ITIL before implementing COBIT. ITIL and COBIT can be applied to improve the quality of service [24]. By planning a mature IT governance implementation of IT services is expected to do well and the embodiment of good IT Governance [25]. Table 1 presents ITIL and COBIT analysis.

Table 1: ITIL and COBIT analysis

Parameter	ITILv3	COBIT19
Scope	Best practices for IT service management, implemented by any organization providing internal and external IT services. Focus on the service lifecycle, value, and customers.	Best practices for strategic teams and people responsible for audit and compliance. Focus on governance and management objectives, enterprise goals and stakeholders' needs.
Advantages	Improve management and utilization of IT resources.	Integration with the ITIL framework and other models.
	Increase efficiency by eliminating redundant tasks and standardizing concepts.	Alignment between governance and management business objectives with IT

		governance and management
	Alignment of services with business needs.	
	Optimize IT costs.	
	Improve the quality of service delivery.	
	Increase stakeholder confidence.	
Gaps	Does not contain detailed process maps.	Does not guide how to assess processes.
	Does not define measures for process improvement.	Does not provide a "road map" for continuous improvement.
	Difficult implementation.	Difficult implementation.
	Does not provide working instructions.	
	Does not align IT processes and business objectives.	

The objective of the work is to develop a framework to solve organizational problems, and gaps identified on ITIL and COBIT, in particular: describing some process maps, how to assess them and how to align IT with business objectives.

Table 2 presents the alignment between ITIL processes and COBIT objectives, for the scope of this paper.

Table 2 : Alignment between ITIL and COBIT

ITIL v3	COBIT19
Incident and Request Management	DSS02 – Managed Service Requests and Incidents
Problem Management	DSS03 – Managed Problems
Change management	BAI06 – Managed IT Changes
Service Asset and Configuration Management	BAI09 – Managed Assets BAI10 – Managed Configuration

Table 2 shows that only Service Asset and Configuration process of ITIL has two different objectives in COBIT, the other processes have one corresponding in COBIT objectives.

The analysed related work has focus on: tool implementation and assignment of responsibilities [26]; tool implementation, indicators, and management metrics [27]; business process integration, patterns [28]; business process integration, an approach quality-oriented [29]; and a survey presenting the state-of-the-art about business process integration and exploring its trends [4]. The paper with the survey demonstrated that most integrated stakeholders' views are obtain by a notation. In conclusion, it can be argued that there are no business process approaches integrating the stakeholders' perspective. The proposed framework presented in this paper is oriented on the

alignment of business process definition and modelling, with continuous improvement.

3. Initial Processes

Figure 3 presents the original processes and flows. Incident and request management process; change management process and service asset and configuration process.

Figure 3: Original processes and flows

Incident/request management process and the service asset and configuration management process are integrated but change management process is managed in a different technological platform. The change management process is oriented to software development and managed in the enterprise project management and planning system. Without technological integration, other mechanisms were applied between the change management process and the incident/request management process, and the change management process and the service asset/ configuration management process to allow the information flow.

4. Identifying framework features

The objective of improving stakeholder satisfaction and optimizing costs for frontend area of service support was the basis to start the research of operational and standard literature. A project was developed to structure the information, organize resources, and control the achievement of the goals. The final phase will propose a framework for alignment and continuous management improvement within the context of ICT departments, to be validated by other organizations. In fact, knowing international best practices is not a guarantee of success because these models present what should be implemented, but not how to do it. The implementation exercise is a challenge in which many organizations fail [30].

The proposed approach is based on ITIL and COBIT frameworks yet adjusted to organizational specificities, considering literature review, and based on professional experience in the area.

The basic artifacts were directly observed for the collection of data. Third-party contracts for service support were analysed in detail, identifying resources used to perform the support function, skills and technical competencies, time-schedule allocation; technical system implemented and functionalities used to support the frontend area, number of incidents, problems and request services recorded per period, time used to solve a ticket and other data recorded that can be used to resource management; service catalogue and services available or under support; normative literature available in the organization and customers relationship;

procedures and technical documentation used by technicians, and knowledge used to share relevant information.

Daily activity monitoring allows verifying procedural compliance, including attendance skills, technical knowledge, and efficiency in support; receipt of requests and records in the support system; workflow and work organization; priority management; relationships between teams of different levels of support and knowledge management. Customer complaints analysis provides an external perspective and perception of the service provided.

Literature review related with business processes management and best practices models ITIL and COBIT was carried out, informal interviews with key users, technicians, and external specialists in IT management area. Bottom-up analysis was important to find out what could be done best, which processes could be reviewed, and at what point. With the analysis of frequent points of failure, related services and the associated responsibilities matrix, adjustments could be defined and planned in the internal organizational work model. The software system used in support activities, with workflow associated with resolution of each category, the procedures in use to solve the issues and the human resources involved, were analysed to contribute to processes' review and to improve alignment for efficiency.

The "adopt and adapt" procedure is widely accepted as the best approach to ITIL [21]. With focus in the service operation' stage after analysis and validation, the operational support processes were redefined, such as incident and request management, and problem management, considering these are the support function's main processes.

As the support function is based on assets and configurations underlying the supported services, effective service management is considered essential, knowing changes are being implemented and anticipating impacts in the production environment - where the end-user support function is developed. Asset configurations and change management processes were also redefined. These are associated with the service transition stage in the ITIL framework. The approach proposes an integrative and multidisciplinary vision to standardize concepts, alignment and process improvement, procedures, operational relationships, and other communications difficulties between department areas and stakeholders.

Figure 4 presents the features defined in this paper. It was identified with three main operational areas and four main processes and related flows.

The ICT Infrastructure Management area has, among others, the responsibility of specialized support of second intervention level – expert team, which includes maintenance and technological evolution of ICT communications' infrastructures - voice and data, monitoring and administration of servers that support corporate systems, implementation and management mechanisms to control infrastructures' security - logical and physical including data centres and maintenance of ICT recovery plan in case of disaster.

Application and Systems Management area is responsible for corrective maintenance and evolution of production systems or new solutions development that respond to business or regulatory needs, managing the impact of the changes in the existing systems architecture and related interfaces.

The responsibilities of ICT Support Management area focus on the Helpdesk function, frontend team, basic resolution support the first intervention level in data network access, roll-out of workstations, and support for peripherals, software configurations, installations, and upgrades.

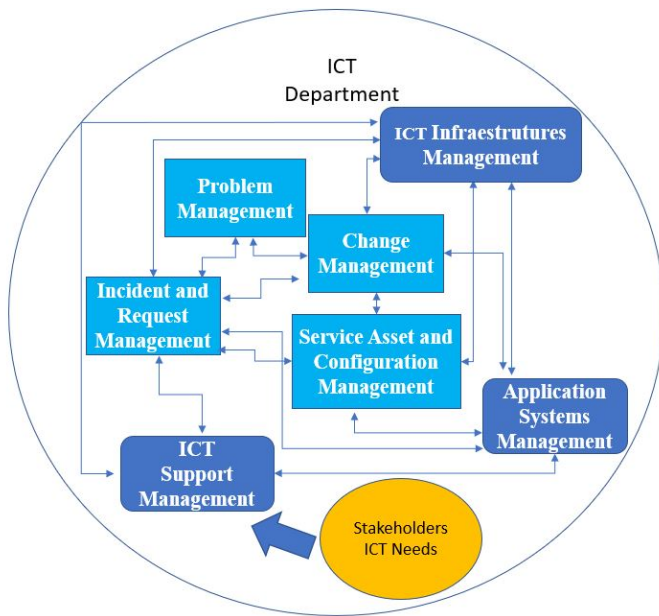

Figure 4 - Operational areas and related processes

Should be noted in Figure 4 that infrastructure management and application management share processes of change, asset and configuration management, and both interact with support management through the incident and request management process.

Problem management is a distinct process, which aims to solve complex situations. The concept is to activate and manage the problem as a project, bringing together the necessary technical teams with the appropriate skills and expertise, to find a satisfactory answer or resolution. From experience, it is expected that it will be impossible to solve all the problems, sometimes it could end up unsolved, with a temporary resolution or a workaround solution.

The bidirectional flow presented in Figure 4 is based on the necessary and constant feedback to optimize and adjust the processes, in a continual improvement cycle.

4.1. ICT Support Management

ICT Support Management starts on helpdesk, the frontend area of the IT department. ICT service requests and incident management require hard work for the team in terms of human relationship and flexibility in new situations adjustment. This support can be done on-site or remotely. The performance of the team is closely related to the level of technical knowledge but also the experience in the existing technology platforms in the organization. As support begins in the service, it is relevant to sensitize these resources to the theme of customer relationships, by the potential impact on the image of the department and the organization. The incident and request management process is what best translates daily operations of supporting areas. Reported incidents are classified by priority levels according to the impact

and urgency of each situation. The resolution underlies the procedures and responsibilities at the different levels of intervention.

Repeated errors or incidents for which there is no known solution are managed in the problem management process lack detailed investigation and analysis, and technical experts with different skills can intervene. Control of the infrastructure components and systems that make up ICT services and their relationships is carried out in the service asset and configuration management process. In this process, changes to configurations and assets installed in production environments are managed, following solutions found for problems or newly installed assets.

Evolutionary or corrective maintenance interventions, which lead to the implementation of changes in the production environments that support the services provided, should be managed in the change management process, with the inherently associated risk management, by the disruptive impact they can cause on the services and consequent operation of the organizations.

4.2. ICT Technological Management of Infrastructures and Systems

Technological Management of Infrastructures and Systems plays a central role in the continuity of the organization itself. These teams ensure the availability of the most appropriate technological resources at every moment, helping the development and speeding up business processes.

The approach presented, having a multidisciplinary vision, powers the aggregation of several areas of knowledge, namely in ICT infrastructure management, application management, and support management areas. Security management is also incorporated, given its cross-cutting nature across all areas, and is increasingly relevant. In this context, it is considered essential an integrative approach to support the organization's business strategy, providing integrity, availability, confidentiality, and ubiquity to one of the organization's most valuable assets – information.

For the approach design, the ITIL and COBIT standards were analysed. The contribution of ITIL to the design of the approach will enhance the introduction of good practice in the operational management of ICT services when ITIL is well implemented, and ITIL enables organizations to provide services with great efficiency, quality, and cost reduction [31]. Framework COBIT contributes to the organization's good practices in governance, information management, and ICT management.

4.3. Improved processes

Business Process Management (BPM) is the art and science of overseeing how work is performed in an organization and it is not about improving the way individual activities are performed but about managing entire chains of events, activities, and decisions that ultimately add value to the organization, and its customers. These chains of events, activities, and decisions are called processes [8].

Processes underlying this approach aim to represent the various iterations in the context of ICT assistance. It should be

noted that the processes interact with each other, depending on the situation under analysis.

The following processes were analysed: Incident and Request Management, Problem Management, Change Management, and Service Asset and Configuration Management, as shown in Figure 5. It presents the flows between the different processes involved in the operational management of IT services support. The communications between the processes are bidirectional to allow a continuous improvement.

Figure 5 shows the processes within the scope of this paper.

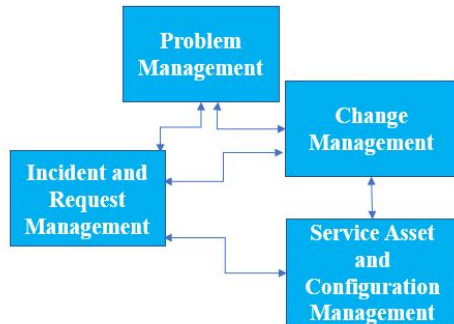

Figure 5: Processes and related flows

Incident and Request Management

The Incident and Request Management Process could be the first process to be implemented [32]. This process can begin with inputs from monitoring tools or stakeholders contacted through self-service portals, emails, or phone calls. Frontend teams are working to resolve anomalies and restore the normal function of services as quickly as they can. This is the main process for IT frontend support, with direct contact with stakeholders, asking for assistance or asking for a new service. This process allows, e.g., assistance optimization and time resolution control. Through this process, the stakeholders interact with the technical team and form their opinion on the IT services performance in general [33]. Incident and request management interacts with the change management process to send feedback when some changes are needed. Incident and request management process also communicates with problem management process whenever a resolution is unknown or cannot be processed by frontend team.

Figure 6 presents the primary process in the frontend support area, incident, and request management process.

Using a prioritization matrix, some incidents can be classified with high urgency and severe impact on business processes. These cases were treated as major incidents and a specific sub-process was defined.

Major Incident Management

Major Incident Management process, presented in Figure 7, is a sub-process of Incident and Request Management process, specifically defined to manage incidents with highest priority. A major incident demands a quick response from the technical team. A senior supervisor could lead the situation, control the status of resolution and be aware of risks and challenges the situation

demands, managing the communication plan to the board of managers and sometimes also the communication outside of the organization. After the conscient decision, decide if or when to apply the disaster recovery plan to restore the services and put the company working again with basic resources.

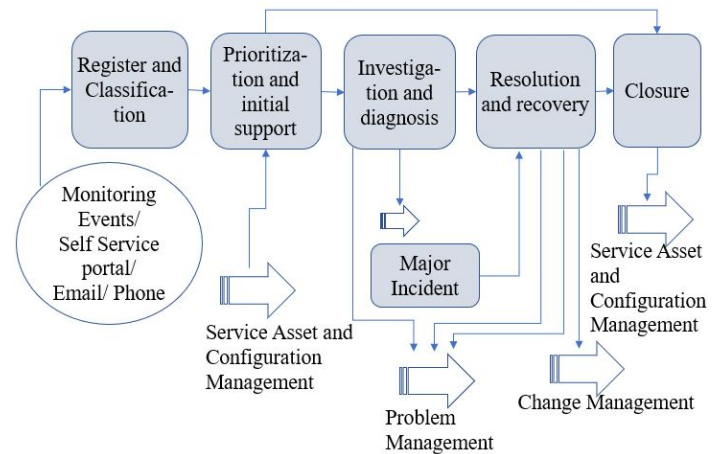

Figure 6: Incident and Request Management Process

Figure 7 shows major incident management process.

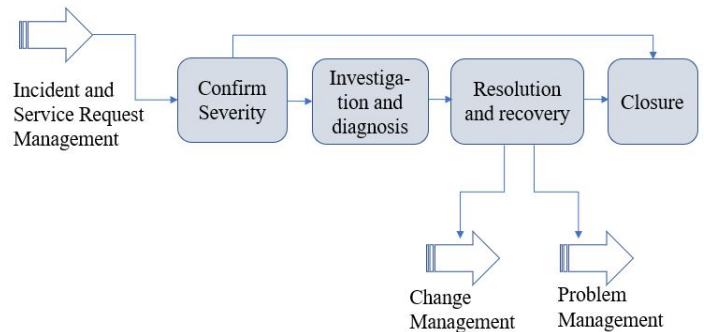

Figure 7: Major Incident Management Process

The major incident process interacts with the change management process to send feedback after resolution, to avoid similar incidents in the future. The major incident process interacts with the problem management when the resolution needs deeper analysis and resolution with expert teams.

Problem Management

Through the problem management process an expert team with different skills analyse and solve complex incidents. This process interacts with incident and request management, when the frontend team cannot resolve an incident based on existing procedures or known errors, the issue is transferred to an expert team. Some inputs from the change management process can be useful to solve problems and after conclusions some data could be sent to the change management process, e.g., to document and correct errors. Every problem analysed is managed as a project, with specific tasks and schedules for each expert team. Periodic meetings are planned to discuss solutions and to align following strategies. The maturity of the teams and their knowledge of IT architecture implemented are important factors for the success of the operationalization on this process.

Figure 8 presents the scheme of the problem management process.

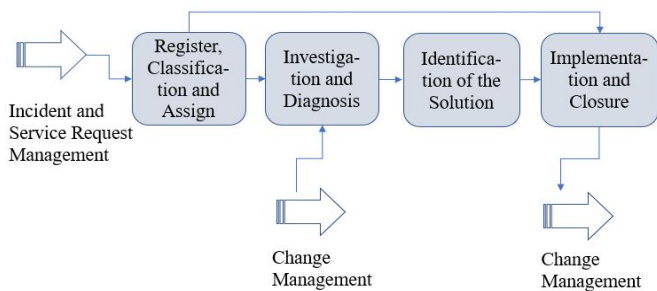

Figure 8: Problem Management Process

Change Management

The change management process ensures documentation and control of changes in software development and systems implemented in the production environment. This includes changes in software applications and other ITC configuration items such as network infrastructure and hardware that supports the systems used.

Figure 9 presents the scheme for the change management process.

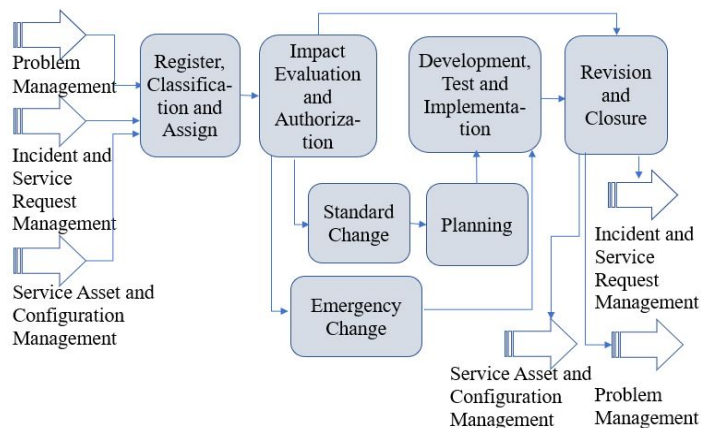

Figure 9: Change Management Process

The change management process can be triggered by the problem management process, incident and service request management process, and service assets and configurations management process.

Service Asset and Configuration Management

Service asset and configuration management is a process to manage changes of infrastructure assets and other controlled assets in production environment. Multiple data are structured in a database of configuration items and the information is used to support other processes. Figure 10 presents the scheme of the Service Asset and Configuration Management process.

The service asset and configuration management process communicate with incident and request management process, when the technical support team needs to check some data to make a diagnosis e.g., equipment characteristics or software versions. Communicates with the change management process

when the team update the database configuration items, e.g., manage software licenses, upgrade software versions, or manage equipment lifecycles in the production environment.

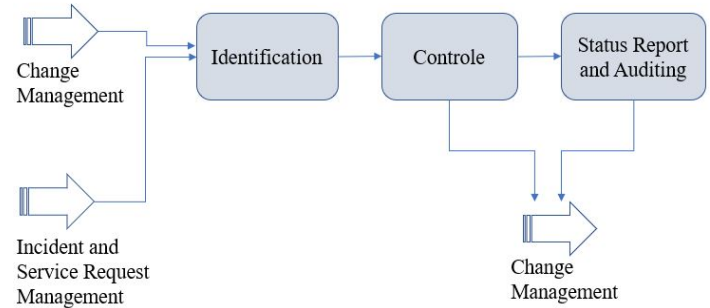

Figure 10: Service Asset and Configuration Management Process

4.4. Framework features

Table 3 summarizes the framework's steps developed.

Table 3: Phases and steps included in framework

Phase	Steps
Initiation	Identify the problem
	Communication with stakeholders (managers)
	Research resources (AS IS processes analysis)
	Problem description, detailed (involve strategic business objectives and alignment metrics)
	Preparation of processes proposal TO BE, applying ITIL and aligning with business objectives (strategy) through COBIT
Planning	Communication with stakeholders (key-users) to detail functional needs
	Communication with operational teams (technicians) to identify specific needs and constraints regarding technology
	Business processes definition TO BE
	Business processes validation (key-users)
	Alignment validation between business processes defined with strategy (managers)
	Define alignment metrics and indicators between strategy and processes

The framework is under development. Table 3 presents the main steps of the initiation and planning phases. The execution, monitoring and closure phases will complete the framework.

At this moment the project lifecycle is not concluded, nevertheless it is important to refer that in the following phases, not detailed in this proposal, it could be necessary adjust the plan to reach stakeholders objectives.

5. Conclusions and Future Work perspectives

Currently, ICT governance and management are inseparable from Corporate Governance. Constant alignment and focus on stakeholders' needs constitutes the basis for organizations' optimization costs. ICT departments can provide solutions that enhance the business or create new business opportunities.

Based on the analysis of international best practices ITIL and COBIT we intend to contribute to aligning IT goals with business goals, a departmental but also organizational view. The framework under construction will present the mechanisms to solve some GAPS found in ITIL and COBIT, in particular: describing some process maps, how to assess them and how to align some business processes. Using ITIL to organize work and manage IT services will improve operational efficiency. Using COBIT from its top-down perspective, the alignment of business goals to IT goals can be achieved and controlled evidencing in that way IT value to business, thus enabling a multidisciplinary and integrative strategic vision.

In future work we will carry out a systematic review of the literature that analyses other approaches. Based on the contributions of this paper and the future Systematic Literature Review, it is intended to present the final proposal of framework implementation and validate it in an organizational context to achieve stakeholder satisfaction and cost optimization.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Brain-computer interface (BCI) has extensively been used for rehabilitation purposes. Being in the research phase, the brainwave-based wheelchair controlled systems suffer from several limitations, e.g., lack of focus on mental activity, complexity in neural behavior in different conditions, and lower accuracy. Being sensitive to the color stimuli, the EEG signal changes promises a better detection. Utilizing the Electroencephalogram (EEG) changes due to different color stimuli, a methodology of wheelchair controlled by brainwaves has been presented in this study. Red, Green, Blue (primary colors) and Yellow (secondary color) were chosen as the color stimuli and utilized in a 2×2 color window for four-direction command, namely left and right, forward and stop. Alpha, beta, delta and theta EEG rhythms were analyzed, time and frequency domain features were extracted to find the most influential rhythm and accurate classification model. Four classifiers, namely, K- Nearest Neighbor (KNN), Support Vector Machine (SVM), Random Forest Classifier (RFC) and Artificial Neural Networks (ANN) were trained and tested for assessing the performance of each of the EEG rhythm, with a five-fold cross-validation. Four different performance measures, i.e. sensitivity, specificity, accuracy and area under the receiver operating characteristic curve were utilized to examine the wholesale performance. The results suggested that Beta EEG rhythm performs the best apart from all the rhythms for the color stimuli based wheelchair control. While comparing the performance of the classifiers, ANN-based classifier shows the best accuracy of 82.5%, which is higher than the performance of the three other classifiers.

1. Introduction

This paper is an extension of work originally presented in 1st International Conference on Advances in Science, Engineering and Robotics Technology 2019 [1]. The presented paper [1] utilized electroencephalogram (EEG) for wheelchair control using color stimuli where the current article is expanded further to validate the EEG based wheelchair control system using multiple machine learning models. Also, this paper examines the utility of the different color stimulus on the EEG based wheelchair control system.

EEG is a reflection of our neurons activity which is associated with all kind of human behaviours- thoughts, emotional state, eye vision etc. Due to its nature, EEG changes its value of features with respect to different influencer like eye vision. The EEG rhythms are defined by their frequency range, named delta, theta, alpha, beta and gamma corresponds to 1-4 Hz, 4-8 Hz, 8-13 Hz, 13-30 Hz and 36-44 Hz respectively.

To make life easier of the person with quadriplegia and paralyzed patients, many initiatives have been taken, but most of the latest works are eye blink based control systems [2]. But eye blink can not be a good command due to its uneasiness to control. In [2], a system is introduced by means of a different range of attention level and double eye blink (both identified by EEG) to

*Corresponding Author: Md Mahmudul Hasan, 2 Rochester Terrace, Brisbane, QLD 4059, Australia; Email: mahmudul.hasan.eee.kuet@gmail.com

make a brain-controlled wheelchair. Four range of attention level as four direction command and double eye blink as on/off command were used at the preliminary level. Nonetheless, retain the attention level at an indefinite range requires sophisticated long term training, thus making these alike systems less feasible in real-world application. By using an indefinite number of eye blink as logic and cognitive level, a brain-computer interface (BCI) was developed with the wireless operation and interfaced with RS-232C in another study [3]. In order to make more advanced EEG based wheelchair, it was tried to be wireless. Depending on modification and attention; eye blinking signal the system was tried to be constructed in the study.

In some cases, steady-state visually evoked potentials (SSVEP) showed promising results [4]. There are some eye blink pattern-based works, which are also providing very optimistic results [5,6]. Neurosky mindwave headset was utilized in [6], which detected the eye blinks, counted and rendered to Arduino UNO by Bluetooth to control a DC motor and thus the wheelchair. In [6], EEG signal was extracted by MindWave mobile application and sent to the Raspberry pi microprocessor. The output of Raspberry pi and joystick are taken as input for Arduino Mega to control the DC motor through the motor driver. They introduced a virtual map by analyzing familiar wheelchair routes as well. In advance, eye blinking with glancing a model has been proposed in few studies [7,8]. Specifically in [7] autoregressive neural network was built to classify EEG eye signals such as eye blinking, eye glancing in left and right. In [8] Steady-State Visual Evoked Potential (SSVEP) based work and implementation of artificial neural network and support vector machine is introduced to classify flickering frequency lights. Here multiclass support vector machine worked better than ANN while input features was obtained from Fast Fourier Transform.

Most of the previous research on wheelchair control have worked with the eye blink, SSVEP or Internet of Things (IoT). But still there are very few works on the EEG based wheelchair control. The use of Brain-computer interface (BCI) is currently in the research phase. The existing systems suffer from several limitations, e.g., lack of focus on mental activity, complexity in neural behaviour in different conditions, and lower accuracy. Being sensitive to the color stimuli, the EEG signal changes promises a better detection. A previous study worked with EEG signal for wheelchair control, where time-frequency domain features were extracted from the signals and used for the wheelchair control with a color stimuli pattern. By applying artificial neural network, the study found the beta EEG band as the most influential frequency band where alpha as the least influential band [1]. This study showed promising results but utilized only one classifier (ANN without hyperparameter tuning) for the classification approach and only one performance measure (mean square error) for the assessment of the system [1]. However, considering the sensitivity and specificity metrics are most important for an EEG based control system. As higher sensitivity with lower specificity leads to the higher false decision and the opposite trend causes the missing of a lot of negative states, a compromise between the two metrics is crucial.

The proposed study examines the EEG based wheelchair control using a 2×2 matrix shape color screen with the combination of four different colors, being Red, Green, Blue and

Yellow. These four different colors have been proven to be sensitive to the EEG signal changes [1], which were designed to indicate the left/right/forward/stop functioning, and were assigned as four numerical values (0,1,2,3) to be considered as ground truth. The principal component analysis (PCA) was conducted to separate the background effect of color stimuli on the EEG signal. After the rhythm separation from EEG, the data analysis and classification was done. The data was recorded using the BIOPAC® data acquisition unit, and the pre-processing and feature extraction was done using the Acqknowledge-4.1® software [9,10].

So far, there is no specified classification model to be used for a specific dataset. Considering the computational complexity and the learning mechanisms, four supervised classification models, namely, K- Nearest Neighbor (KNN), Support Vector Machine (SVM), Random Forest Classifier (RFC) and Artificial Neural Networks (ANN) were trained, tested, and compared for evaluating the performance of each of the EEG rhythm. Being a smaller dataset with respect to the number of features, five-fold cross-validation was used to validate the performance of the classifiers. Four different performance measures (sensitivity, specificity, accuracy, and area under the receiver operating characteristic curve) were utilized to examine the system performance.

The following part of this paper is organized as follows- a brief methodology, including experimental design and tools, then the result section with the findings. Last, the paper was concluded followed by a short discussion on the outcomes.

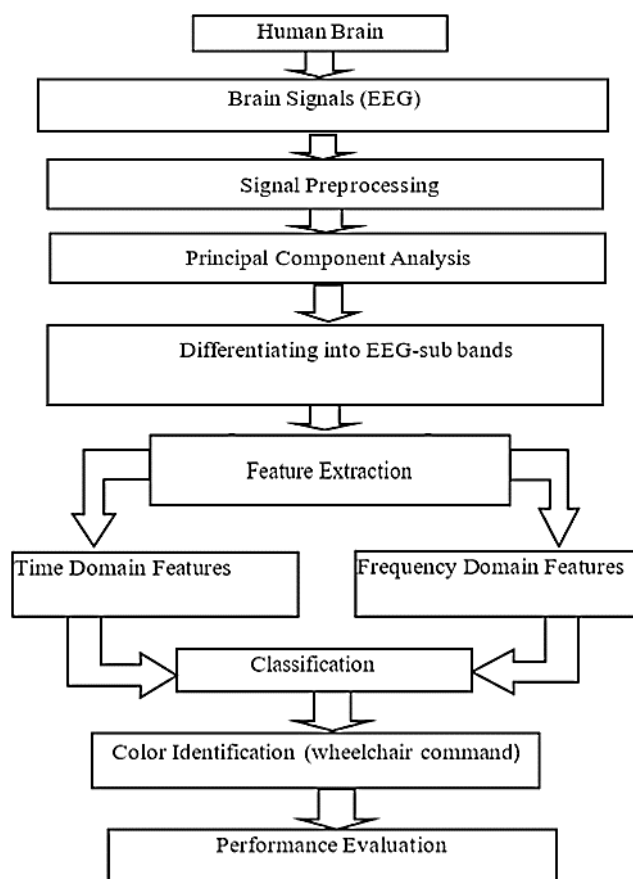

Figure 1: Block diagram for the proposed EEG based wheelchair control system

2. Methodology

2.1. Experimental Design

The roadmap for building an electroencephalogram based wheelchair by color stimuli is shown in figure 1. From the selected three participants, EEG were obtained by the BIOPAC® signal acquisition system. The eye blink artefacts were removed using the EOG blink removal techniques, with the help of Acqknowledge 4.1® software. Then FIR bandpass filter was used to separate bands while PCA for demolishing background effect. Afterwards, total twenty features were extracted for each of the EEG band, which are sensitive to color stimuli and the selected features were supplied towards the machine learning tools as the independent variable. The four different colors were coded to 0-3 as the dependent variable and were labeled for four different color detection. Four different classification models, namely K-nearest neighbours (KNN), support vector machines (SVM), artificial neural network (ANN) and random forest classifier (RFC) classifier models were developed in python 3.6.9 platform in Google Colab platform. Best classifier and rhythm were evaluated by their performance.

2.2. Experimental Equipment

2.2.1. Hardware tool

In this experimentation, BIOPAC MP 36 was used at Biomedical Engineering (BME) lab, KUET, which is shown in figure 2 [1].

2.2.2. Pre-processing and feature extraction software tool

BIOPAC® student Lab Pro and Acqknowledge 4.1® software was used for PCA and feature extraction. Machine learning based classification models were used in the python 3.6.9 version in Google Colab platform.

2.3. Participants

In this experiment, three subjects participated who were male, healthy and not suffering from any color blindness or psychological illness. and they were The color blindness was tested using the Ishihara 38 Plates CVD Test [11,12], to check their vision and to ensure they are not suffering from difficulties in choosing colors, especially the deuteranopic vision (red-green color blindness). Then, the Color stimulus matrix was shown in a computer monitor (21.5" with a 1920 × 1080 resolution). The color stimuli was consisting of Red, Green, Blue (primary colors) and yellow (one of the secondary colors), which were utilized in a 2 × 2 dimension color window for four-direction command, namely left and right, forward and stop. The participants were instructed to focus on each of the color for 15 seconds long, with their normal blinking. It took 60 seconds (1 minute) in total to complete a full visualization of the four colors. The color matrix sub windows for the specific color were programmed to give a pulse after every 15 seconds, such that the participants can automatically focus on the specified sub-window. In total, 20 trials of 20 minutes were taken for visualization of the four colors sequentially, i.e., red, green, yellow and blue. The electrodes were placed on the right central (C4), and the right occipital (O2) position, with a reference electrode in A2 position.

2.4. Experimental Procedure

2.4.1. Signal Preprocessing

Because of muscle movement, eye blinking, hand movement and the background effect behind the colour stimulus, the primarily obtained EEG signals could have contained noise. Along with line frequency was 50 Hz. To pre-process raw EEG was gone through bandpass finite impulse response (FIR) filter with a range of 0.5 to 44 Hz, as it removes the non-linear trends of the signals. Later the signal was further smoothed, taking a moving average over a small period of the signal. Figure 3 shows the EEG signal representation with in Acqknowledge software.

Figure 3. EEG signal representation in Acqknowledge-4.1® software

2.4.2. Principal Component Analysis

As a data reduction tool PCA decomposes input signal to a new signal, removing the components which are not significant. After the signal pre-processing and feature extraction, the PCA was used to select the most significant features, which included standard deviation (STDDEV), skew (sk), kurtosis (k), power spectrum density (PSD) mean, PSD max, PSD skew, Fast Fourier Transform (FFT) mean, FFT max, FFT skew. Total of nine features were chosen out of 20 features based on the PCA analysis. The features were selected based on the threshold that was put on 'k' principal components. It is worth noting that most of the selected features were frequency domain features.

2.4.3. Separation of the frequency sub-bands

The build-in bandpass filter was used in Acknowledge 4.1® software to find alpha, beta, delta and theta rhythm. The frequency ranges used for delta, theta, alpha and beta EEG bands are 1-4 Hz, 4-8 Hz, 8-13 Hz, 13-30 Hz, respectively.

2.4.4. Feature Extraction

Total twenty features were extracted in time and frequency domain, including maximum value (E_{max}), standard deviation (STDDEV), skew (sk), kurtosis (k), moment of order from one to five, Lyapunov exponent, mutual information (m), correlation coefficient (c), power spectrum density (PSD) mean, PSD max, PSD skew, Fast Fourier Transform (FFT) mean, FFT max, FFT skew were extracted for each subject, color, rhythm using the Acknowledge 4.1® software. An epoch size of 1 second was utilized to extract all the EEG features.

2.4.5. Feature Scaling

The features extracted from time and frequency domains have a different range in their magnitude. Different machine learning models work with various features putting them in the same matrix; it is necessary to put all the features in a same range, which is referred to as feature scaling. There are two common types of feature scaling that is done in preliminary data: standardization and normalization [13].

As a part of the normalization process, MinMaxScaling was done in this study in python platform using the MinMaxScaler() function from sklearn library. Here the data is shrunk within a range between [-1,1].

$$x_{new} = \frac{x - x_{min}}{x_{max} - x_{min}} \quad (1)$$

The min-max scaling can be defined by the equation (1), where, x_{new} is the normalized value of a feature point x , within a range x_{min} and x_{max} [13].

2.5. Classification

To control a wheelchair on the decision of the appropriate movement, classification is the final step which is done with the help of machine learning models. Machine learning is the application of artificial intelligence, which provides a system capable of learning nature from a given data. There are three categories of Machine Learning models and applications, supervised learning, unsupervised learning and reinforcement learning [14]. Supervised learning is extensively used for the classification and regression problem [14]. Previous studies worked with EEG have used supervised learnings, especially K-Nearest Neighbour [15], Support Vector Machine [16], Random Forest Classifier [17] and Artificial Neural Network [18]. Based on the previous studies, these four classifiers were chosen for the data classification in this research.

2.5.1. K-nearest neighbours (KNN)

KNN is a simple supervised learning algorithm which is very popular and widely used for classification and regression problems. At the very starting point, KNN read the value of K, type of distance D and test data; then it finds the K nearest neighbours D to the test data and thus sets the maximum label class of K to test data. The same process is gone through as an iterative process named looping. In details, it's algorithm initializes the value of K from 1 (setting as initial iteration value). After loading data, iteration from initial K =1 (generally) to total number of training data point. Then, distances specifically Euclidean distance between test data and each row of training data is measured and sorted in ascending order to get topmost k rows from the sorted array and the most frequent class is returned as the predicted class [19]. The value of K was tuned, and the K for best efficiency was chosen in the classifier model in this research to reduce overfitting.

2.5.2. Support Vector Machines (SVM)

SVM aims to obtain a hyperplane which classifies the data point (data points can be at any side of hyperplane) in feature dimensional space while depending on both linear and non-linear regression. Data points distance across to hyperplane are called support vector whose detection can exchange hyper plane's location [19]. The model used a Gaussian kernel for SVM classifier in this research due to the non-linear trend of the dataset. Two parameters- 'C' and 'gamma' was adjusted within a set of values using the grid search algorithm to reduce overfitting.

2.5.3. Random Forest Classifier (RFC)

Random forests are made of individual decision trees with a logic of group of weak learners to finally make a strong learner

while the decision trees operate as divided or conquer. A class is predicted from every decision tree and a final class is predicted by model depending on their vote [19]. Two parameters were tuned in the RFC models, namely, 'n_estimate', which implies the number of trees in the forest and 'max-depth' which signifies the depth of each tree.

2.5.4. Artificial Neural Network (ANN)

An ANN consists of neurons which assess the weighted sum of the inputs contemplating that there is a bias and passes the sum applying activation function such as sigmoid, RBF etc. The research used a feed-forward neural network model (with backpropagation algorithm) which relates input with appropriate output to obtain low squared error (output v/s expected output) by applying gradient descent. The number of hidden layers and the number of neurons in each hidden layer was tuned here in the ANN model. Regularisation was done using the dropout layer with a dropout rate of 0.5 to reduce overfitting.

2.6. Performance Measures

2.6.1. Sensitivity or True Positive Rate (TPR)

Sensitivity is the proportion of the true positives (desired factor), which is correctly identified from the given test set [20]. The definition of sensitivity can be provided by equation (2), where, TP = True Positive and FN = False Negative.

$$\text{Sensitivity} = \frac{TP}{TP + FN} \quad (2)$$

2.6.2. Specificity or True Negative Rate (TNR)

Specificity is the proportion of true negative (undesired factor) in which was correctly excluded from the given test sets [20]. The definition of specificity can be provided by equation (3), where TN = True Negative and FP = False Positive.

$$\text{Specificity} = \frac{TN}{TN + FP} \quad (3)$$

2.6.3. Accuracy

Accuracy is defined as the proportion of true results (either true positive or true negative) in an experiment [21,22]. The definition of accuracy can be provided by equation (3), given that TP = True positive, TN= True Negative, FP= False Positive and FN = False Negative

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \quad (4)$$

2.6.4. Area under the receiver operating characteristic (ROC) curve (AUC)

To find out the best compromise between sensitivity and specificity, ROC is plotted. It is a plot of the sensitivity (true positive rate) against the (1- specificity) or false positive rate, where all the possible combination of TPR and FPR are plotted, showing the trade-off between them [16,20,23]. As sensitivity and specificity are two major parameters of performance measures, AUC under ROC always provide a compromise between them.

Five-fold cross-validation was done while evaluating the performance measures. For each of the validation, the dataset was divided in a ratio of 4:1 for training and test data, respectively. The

mean value and the standard deviation (SD) were noted, considering the five experimental validations. As the classification is a four-class problem, one versus all method was used in all the classification approach, splitting the four-class problem in binary class. Thus, the mean sensitivity, specificity and AUC was calculated from the obtained confusion matrix.

3. Results

3.1. Data Visualization

The data points found from the selected features were plotted in violin plots to observe the range of each of the features. The following Figure 4 shows that the time and frequency domain features are having a versatile variation in the range in the horizontal box plot. The plots were done for the observation of the entire feature sets. The Maximum value/magnitude (of EEG signal) and the power spectral density maximum value show a greater range than the other features while the PSD mean and FFT (max) are showing the lowest range. Range of the difference features varies among themselves either in the time domain or in the frequency domain. Thus, feature scaling was done on the given dataset.

Figure 4: Box plot of part of the EEG beta rhythm features showing the varying magnitude of different features

3.2. Classification Performance

After necessary feature extraction and scaling, all the features were scaled and were supplied towards the machine learning models with necessary parameter tuning. Four different performance measures were evaluated, namely, sensitivity or true positive rate (TPR), specificity or true negative rate (TNR), accuracy and area under the receiver operating characteristic curve (AUC). The obtained results are listed below in Table 1.

3.2.1. Scenario 1: Delta Rhythm

The plots of the performance measures (mean \pm SD) obtained from the classification of colours using the delta rhythm features from four different classifiers, KNN, SVM, RFC and ANN, are shown in the following Figure 5. The plots show that the gap between sensitivity and specificity is higher in KNN (gap = 15.3%) and RFC (gap = 7.9%). The gap is less in SVM (2.2%) and ANN (0.3%). Overall, ANN gives an accuracy of 62.8%, which performs the best.

Table 1: Performance measures (mean value) for EEG based wheelchair control using four different classifiers, with a five-fold cross-validation

EEG Rhythm	Performance Metrics	KNN	SVM	RFC	ANN
Delta	Sensitivity	60.8	55.4	55.1	63.3
	Specificity	45.5	57.6	47.2	63
	Accuracy	53.5	56.2	54.6	62.8
	AUC	53.9	56.7	57	69.6
Theta	Sensitivity	63.6	66	60.2	80.8
	Specificity	55.6	62.8	60.6	62.1
	Accuracy	59.6	63.9	60	71.5
	AUC	59	64.5	70.6	73.2
Alpha	Sensitivity	92.3	82.1	55.7	62.1
	Specificity	25	62.5	60.7	52.9
	Accuracy	59.2	72	58.2	72
	AUC	55.1	71.8	68.1	63.4
Beta	Sensitivity	82.7	78.2	79	88.5
	Specificity	68.4	67.2	77.5	75.3
	Accuracy	75.4	72.7	77.5	82.5
	AUC	75	76.9	88.3	89.1

Figure 6: performance measurement of theta rhythm

3.2.2. Scenario 2: Theta Rhythm

The plots of the performance measures (mean \pm SD) obtained from the classification of colours using the Theta rhythm features are shown in the following Figure 6. The plots show that the gap between sensitivity and specificity is higher in ANN (18.8%), KNN (8.05%), and SVM (3.16%). Less gap is observed in the case of RFC (0.4%). Overall, ANN gives an accuracy of 71.5%, which performs the best.

Figure 5: Performance measurement of delta rhythm

3.2.3. Scenario 3: Alpha Rhythm

The plots of the performance measures (mean \pm SD) obtained from the classification of colours using the Alpha rhythm features are shown in the following Figure 7. The plots show that the gap between sensitivity and specificity is higher in KNN (67.3%), SVM (19.7%) and ANN (9.19%). The gap is less in RFC (5%). Overall, ANN gives an accuracy of 72%, which performs the best.

Figure 7: performance measurement of alpha rhythm

3.2.4. Scenario 4: Beta Rhythm

The plots of the performance measures (mean \pm SD) obtained from the classification of colours using the Beta rhythm features are shown in the following Figure 8. The plots show that the gap between sensitivity and specificity is higher in KNN (14.3%), ANN (13.2%), and SVM (11%). The gap is less in RFC (1.45%) and Overall, ANN gives an accuracy of 82.5%, which performs the best.

Figure 8: performance measurement of beta rhythm

Figure 9: Comparison of accuracy matrices for four different classifiers

3.3. Choosing the best EEG Rhythm

To choose the best EEG frequency band, the overall accuracy measure was considered as the reference metrics as it is difficult to compare different classifiers using several factors. The plots of the

accuracy for four different classifiers corresponding to the four different frequency band are shown in Figure 9. From the given figure, it is evident that the accuracy for beta rhythm is better than any other frequency bands for all the four classifiers. So, in the rest of the paper, the Beta EEG rhythm will be considered for further analysis.

3.4. Choosing the best classifier

The plots for the area under the ROC curve for the classifiers built using the Beta EEG features are shown in Figure 10 below. The figure illustrates that the ANN classifiers show the best compromise between sensitivity and specificity, with covering the highest area under the ROC curve (AUC = 0.89). Thus, the next part of the paper will compare the performance of the frequency bands considering ANN classifier.

Figure 10: Comparison of AUC for four different classifiers built using the Beta EEG Features.

The plot of the area under the AUC curve for 5 different experiments in 5-fold cross-validation with the Beta rhythm using ANN classifier (see Figure 11). The AUC for beta rhythm-based models ranged from (0.75-0.92), with a mean of 0.89 and standard deviation of 0.07. This signifies that, the beta rhythm shows an excellent performance than the other frequency bands of EEG signal in EEG based wheelchair control using the color stimulus.

Figure 11: ROC Plots for Beta rhythm-based ANN model with 5-fold CV

4. Discussion

This study used four different classifiers for assessing the performance of the EEG rhythms for EEG based wheelchair

control using colour stimuli. The results revealed that Beta rhythm performs the best among the other rhythms while the Alpha rhythm performs the worst. The delta and theta rhythm showed an average performance. The reason behind the better performance of the beta rhythm could be it is more prominent in the concentration while the theta and alpha are responsible for drowsiness and relaxation, respectively. It also revealed that the maximum performance was obtained using the ANN Classifier, with a sensitivity, specificity and accuracy of 88.5%, 75.3% and 82.5%. Moreover, ANN based model with beta EEG based dataset shows promising AUC (0.89), which is a good compromise between sensitivity and specificity. The finding of this study is consistent with the previous study [1], where the authors found the Beta band as the best performing rhythm, though they have used only one classifier (ANN), and one performance metrics (Accuracy). The possible reason behind the best performance of ANN could be the backpropagation algorithms, which is strong enough to learn the inherent features and complex structure of the data. This is likely due to the simultaneous update of the weights while running every iteration for each forward pass and backward pass. The study [1] also achieved a higher accuracy than the current study, which is probably due to not using the cross-validation techniques. Rather, a hold-out validation was used in the previous study [1], which most probably created overfitting problem. The given problems were overcome in the current study.

On the other hand, the Delta rhythm performs the worst (ANN accuracy = 62.8%). However, some difference is found in the obtained results due to different parameter setting in the neural network (such as hidden layers, and the number of neurons). For future implications, three major issues are recommended. First, using the four-colour stimuli that we have used and validated using EEG sub-bands. Second, using the Beta EEG-band power while utilizing the brain-computer interface system for wheelchair control, as it shows comparatively higher performance in identification of the different color stimuli. Third, it is recommended to use the color codes in a small monitor attached with the wheelchair handle, which would help the user to focus on the screen and thus enhance the detection accuracy of the control system. However, the scope of the paper is not out of limitations. The correlation of the EEG signal with different color stimuli was out of the scope of the study; however it could be considered for future research. The study consisted of only three healthy subjects, who are not paralysed. The lower sample size may lack the generalization for proper implication; however future research could be done on large number of sample and involving peoples suffered by paralysis. The background effect is one of the main challenges while using the color stimulus. Inter-individual difference among participants is another factor, which is needed to be considered. As the paper represented a novel methodology of EEG based wheelchair control using four different colours (for left-right/ forward/backward action), research is required to find out the feasibility in real-world condition as well.

5. Conclusion

In order to develop EEG controlled user-friendly wheelchair, using this proposed model, an analysis was done in this study to find out the feasibility of the time and frequency domain features. Here the designed system was obtained after applying several steps- feature scaling, tuning of classifiers and finally with five-

fold cross-validation of the developed models. The analysis from the results of the study shows that beta rhythm shows the best accuracy with KNN (75.4%), SVM (72.7%), RFC (77.5%) and ANN (82.5 %). On the other hand, the Beta EEG rhythm offers the lowest accuracy with all classifiers. However, the experiment could be done on a greater number of participants to validate the model based on leave one participant out approach. Also, efficiency will increase with the addition of more EEG channels which can be considered for future work.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The authors want to acknowledgment the staffs of the Biomedical Engineering Laboratory, KUET, for providing with the signal recording facilities.

Timing speculation

ABSTRACT

In the Internet of Things era it is expected that low-end processor domination of the embedded market will be further reaffirmed. Then, a question will arise, on whether it is possible to enhance performance of such processors without the cost of high-end architectures. In this work we propose a better-than-worst-case (BTWC) methodology which enables the processor pipeline to operate at higher clock frequencies compared to the worst-case design approach. We employ a novel timing analysis technique, which calculates the timing requirements of individual processor instructions statically, while also considering the dynamic instruction flow in the processor pipeline. Therefore, using an appropriate circuit that we designed within this work, we are able to selectively increase clock frequency, according to the timing needs of the instructions currently occupying the processor pipeline. In this way, the error-free instruction execution is preserved without requiring any error-correction hardware. We evaluate the proposed methodology on two different RiscV Rocket core implementations. Results with the SPEC 2017 CPU benchmark suite demonstrate a 12% to 76% increase on the BTWC design performance compared to the baseline architectures, depending on the appearance rate of instructions with strict timing requirements. We also observe a 4% to 37% increase on power consumption due to the operation of the pipeline at higher clock frequencies. Nevertheless, the performance increase is up to nine times larger than the power consumption increase for each case.

1 Introduction

Traditional microprocessor design ensures an error free instruction execution on general purpose processors. According to the established model, the designer designates the clock frequency and the voltage values of the processor, so that no timing violation of the critical path occurs. Thus, the design revolves around the timing analysis of the worst-case scenario, and the critical path acts as a strict timing threshold, constraining the processor performance.

In contrast to the traditional model, the better-than-worse-case (BTWC) paradigm attempts to relax any critical path restrictions through timing speculation (TS), by scaling up and down the processor voltage or clock frequency, allowing timing errors to occur. The resulting errors can then be resolved by an integrated rollback error correction mechanism. Such a paradigm presents many design opportunities for performance enhancement and power reduction.

This paper is an extension of work originally presented in MO-

CAST conference in [1] and is loosely based on the BTWC design paradigm, primarily focusing on the performance increase of the processor pipeline for low-cost processors. In this work, we present instruction-based clock-scaling, a methodology that improves performance by executing instructions in varying clock frequencies, according to the opcode of the executing instructions. A proposed timing analysis methodology detects instruction opcodes that may run at high speed, as well as instruction opcodes that must run at low speed. The instruction pipeline is then fed with multiple clock signals, multiplexed in a way that when a critical instruction is decoded, a slower clock is selected for the cycle that exhibits the maximum timing delay, reverting to the previous clock in the following cycle. Thus, the typical clock selected can be faster than the one designated via traditional timing analysis.

Such an approach diverges from classic BTWC design techniques, in that we utilize the knowledge about each individual instruction timing requirements, obtained from our timing anal-

^{*}Corresponding Author: Athanasios Tziouvaras, attziouv@inf.uth.gr

ysis methodology. With that knowledge, our model foresees any upcoming timing errors and corrects them a priori. In this way, we eliminate any execution error probability, thus no error recovery mechanism is deployed, as each instruction is certain to meet its timing requirements. Since performance penalty induced by error correction is non-trivial, our more deterministic error detection mechanism avoids the performance implications of traditional BTWC techniques. Furthermore, the developed methodology is architecture independent making it applicable to any given single-issue in-order-execute design, without requiring intrusive changes to its microarchitecture.

The above technique has been implemented and tested on two different post-layout RiscV Verilog processor implementations, using the SPEC 2017 CPU benchmark suite. The same tests have been applied on the implementations without clock-scaling, and the results obtained show a clear improvement in processor performance, between 12% and 76%, and an average 3.7-fold improvement in performance-to-power ratio, despite the expected increase in power consumption due to high frequency operation. Further comparison with state of the art TS methodologies highlights the effectiveness of our technique when considering throughput improvement.

The rest of this paper is organized as follows. Section 2 contains a research review on the topics of our research, whereas Section 3 discusses the proposed processor timing analysis technique. Our opcode-based clock-scaling technique is presented in detail in Section 4. The processor model used and the experiments conducted are described in Section 5. Finally, Section 6 gives the conclusion of our work.

2 Previous research

Following decades of standard worst-case processor design methodologies, a considerable amount of research is being conducted in BTWC designs in the last years. The BTWC is a paradigm that encompasses various techniques which approach the critical path timing requirements more flexibly than traditional designs [2]. In particular TS, which is a type of BTWC design, violates critical path restrictions, allowing and then correcting any resulting execution errors. Such technique enables researchers to experiment with energy-performance tradeoffs and manages to increase the performance and lower the power consumption of the circuit [3].

The application of TS on processor designs has led to the development of Razor [4], [5]. Razor employs TS to improve the performance-to-power ratio of the design, and utilizes “shadow latches”, which identify and correct the timing errors made by the alteration of the voltage. This correction mechanism operates in real time and ensures the error free instruction execution. Another research work focuses on the dynamic frequency scaling of a superscalar processor, supported by error recovery mechanisms to compensate for resulting timing errors [6]. In that work, researchers deploy both local and global error correction mechanisms, which ensure a correct instruction execution when the processor is over-clocked at higher frequencies.

BTWC design methodologies have also proven able to address the ever increasing process variation effects or the uncertainty caused by the environment and the fabrication process of the in-

tegrated circuits [7]. As a result, a significant amount of research compensates for process, voltage and temperature (PVT) variation, while exploring possible TS benefits [8]. In such cases, probabilistic methods can be deployed to model the PVT fluctuations [9], while guardbanding has been proposed in one work to safeguard the circuit against timing violations [10]. Another work shows that process variation effects result in pipeline imbalances as long as timing delay is concerned [11]. In order to overcome such problem, a framework has been developed to tighten the timing of the circuit using a time stealing technique that equalizes the timing delays of each pipeline stage. A third work exhibits that the mitigation of PVT effects may be achieved by a properly developed framework [12]. In that work, the researchers manage to model the PVT effects and create a framework that enables error-power and error-frequency tradeoffs. Finally, another work demonstrates novel techniques which may be used to design PVT resilient microprocessors [13]. Such techniques include the monitoring of critical paths by sequential circuits that detect timing errors, or the monitoring of each pipeline stage for worst-case delays. In both cases, the designers also propose error recovery mechanisms and exhibit a significant performance increase by utilizing clock frequency scaling.

Previous work has also shown that designers may obtain efficient energy-performance tradeoffs at a higher architecture level [14] when applying BTWC paradigms. A marginal cost analysis demonstrates the potential of circuit voltage scaling on architectural level, highlighting the optimal operational point of a target processor. Furthermore, the design process of a microprocessor could also be aligned to facilitate TS friendly microarchitecture adjustments. Specifically the optimization of the most frequently exercised critical paths may result in clock frequency scaling and lower power dissipation on existing TS architectures [15]. Along the same lines, the slack redistribution of the most frequently occurring timing paths of a processor may lead to architectures with lower power consumption and minimum error rate [16]. Another work in [17] proposes a TS cache design which manages to lower the energy consumption of the system while maintaining high cache hit ratios within various cache organizations.

As the TS paradigm revolves around scaling the clock frequency in real time, research is also focused on clock adaptation techniques. Specifically, previous work in [18] manages to adapt the clock frequency of a POWER 7 processor core by adjusting the voltage level in firmware level. Combined with a critical path monitoring mechanism, researchers achieve voltage scaling when the critical path is not excited while using the available timing margin as a guardband mechanism. Another work utilizes a unary coding scheme to enable the PLL to quickly adapt to the required clock changes in real time [19]. This approach can be applied on a single core clock to enable its dynamic frequency change without imposing significant delays. A research that also underlines the importance of a robust real time clock adaptation scheme is [20]. In this work, researchers manage to deploy a clock adaptation scheme which can reduce the clock frequency in an AMD 28nm microprocessor core improving the power efficiency of the system. This approach utilizes a phase generator which can modify the clock's phase in order to stretch its period. Similarly, in [21] authors employ a dynamic clock adjustment technique on a simple processor pipeline to adjust the clock frequency according to the application type that is being executed

on the processor pipeline.

TS designs are often prone to exhibit metastable behavior, resulting in non-deterministic timing phenomena which should be taken into account when designing a TS processor [5], [22]. This issue usually appears when the input data arrives close to a rising clock edge, resulting in the possibility of undetected errors. In the course of minimizing the metastable behavior of timing speculative circuits, design methods have been proposed, utilizing a time borrowing technique alongside of a careful examination of the data path timing, which simplifies the issue of metastability by moving such behavior to the circuit error path only [23]. Despite the progress being made on this issue, a more recent work claims that circuit metastable behavior in TS designs is not yet efficiently addressed [22]. In this regard the mean time between failures of such designs discourages any possible industrial applications.

Another thought provoking aspect in BTWC techniques is the error recovery mechanism and the performance penalty it imposes on the design [24]. Due to that penalty significant effort has been made on the improvement of the deployed error prediction mechanisms [25]. While some designs employ statistical methods to successfully detect specific instruction sequences which have pre-analyzed timing requirements [10], others tend to focus on monitoring the critical path excitation by individual instructions [26], [27]. Another approach revolves around the identification of timing critical instructions during runtime, using that knowledge to improve the energy-efficiency ratio of the processor [28]. Finally a study on the cmos recovery mechanism reveals the impact of the technology on such techniques, as researchers develop a hardware model sufficient to simulate timing speculation designs [29]. The same research also underlines the importance of a fine-grained error recovery mechanism in BTWC designs. Although the penalty imposed by the execution or by the unsuccessful prediction of a critical instruction is relatively low, results indicate that the performance loss due to error recovery is non-trivial. Moreover, in some extreme cases the design's performance deteriorates to the point that the TS design displays lower throughput than the baseline processor [10].

From all the above reviewed work we have concentrated our interest on the issues of error recovery in the TS design paradigm, as well as on the issues of metastability observed in that paradigm. Our motivation has been to study such issues and come out with a novel technique that exploits TS in a way that any possible speculation errors are detected dynamically and recovered before they appear, thus avoiding the costly error recovery mechanisms, and at the same time eliminating metastability phenomena altogether. In the following sections we introduce our opcode-based timing analysis and clock scaling technique for error-free timing speculation in pipelined microprocessors.

3 Timing Analysis in Processor Datapaths

3.1 Static and Dynamic Timing Analysis

Timing analysis is a technique traditionally used in order to analyze the timing requirements and timing delays of a digital circuit. By employing the traditional timing analysis approach, designers designate the optimal clock frequency for a design which is usually derived by the timing requirements of the critical path.

Standard static timing analysis (STA) is performed either at flop to flop or at input to output basis. STA is used to calculate the worst-case delay of the circuit and to detect any timing violations that may occur under certain design constraints. STA can be used to identify the critical path of the circuit, which is a major factor for the clock period selection of the design. However, STA is overly pessimistic, as it calculates the worst-case slack for timing paths and thus, it is considered inefficient for the BTWC paradigm.

On the contrary, dynamic timing analysis (DTA) is used to extract more accurate timing information from a digital circuit. DTA utilizes a large set of vectors which are used as circuit inputs that excite the circuit paths for various input combinations. An exhaustive DTA will calculate every possible timing path for a given circuit, at a very high time cost though. DTA eliminates the path pessimism as it analyzes the timing requirements of every possible input of the circuit. Although DTA would be more appropriate for BTWC design timing analysis, its time cost renders its usage impossible on large designs, as it trades accuracy for completion time.

3.2 The Pseudo Dynamic Timing Analysis Concept

The technique proposed in this work revolves around the BTWC design paradigm. In this sense, we develop a timing analysis methodology that extracts timing information from a circuit to enable us to take advantage of the timing differences of the circuit paths. To this end, we analyze each individual instruction supported by the processor, with respect to the unique timing requirements it presents. In order to analyze each instruction independently, we isolate from the circuit all the possible paths an instruction may take, while declaring the rest of the paths as false. We iterate this process until we exhaust all the available supported instructions. In the sequel, we perform STA on each separate path group related to each individual instruction. As a result, the timing results we obtain depict the worst-case delay of each instruction, instead of depicting the worst-case delay of the processor critical path.

In order to present our technique, we refer to a standard timing analysis tool, with which we conduct timing analysis on the post-layout netlist of a recent open-source 64-bit six-stage pipelined processor implementation of the Risc-V ISA. Figure 1 depicts our initial approach to the problem. First, we pick an instruction supported by the processor. Then, we examine the processor ISA to identify the instruction opcode, while ignoring any register or data fields facilitated within the instruction word. For that opcode we commence a "case analysis" operation, in which the designer may set any of the circuit inputs to constants, and let the tool being utilized perform a flop to flop timing analysis given the fact that some of the circuit inputs are set to a fixed value. In our case these values represent the current instruction opcode field. The tool propagates any generated signals through the processor pipeline to analyze the timing of each pipeline stage separately while performing STA. As a result we calculate the timing requirements for each pipeline stage separately with respect to the fixed instruction opcode and thus, for the corresponding instruction. That report gives the worst-case scenario of the analyzed instruction with respect to timing.

```

1  Start
2  instruction_number = number_of_supported_instructions
3  While (instruction_number > 0)
4    instruction = next_instruction
5    opcode = instruction [opcode]
6    set_case_analysis [opcode]
7    stage_delays = STA_timing_report [netlist, opcode]
8    worst_case[instruction_number] = max[stage_delays]
9    instruction_number --
10 End

```

Figure 1: The proposed timing analysis methodology which studies each instruction as an individual entity.

In the sequel, we keep record of the slowest pipeline stage timing, before moving on to the next instruction. Finally we pick another instruction and reiterate this process, until all the available instructions are exhausted.

It becomes clear that the proposed timing analysis methodology is a hybrid between STA and DTA. In this sense, it performs STA for each instruction of the processor ISA, but it further analyzes all possible instructions, giving a DTA flavor to the result. However, it is not a full DTA, since it only varies the opcode field of the instruction word, thus not considering input values neither for any other field of the instruction word nor for any other part of the circuit. In particular, the implementation of the architecture we work on supports 215 instructions, which means that we only need 215 analyses in our method, instead of 264 which would be needed for a full DTA on the variations of the instruction word alone, or many more if we were to consider other circuit inputs as well. On the other hand, our approach is not as pessimistic as classic STA, and with only little higher complexity it can produce designs that exhibit significantly better performance than designs produced by STA. Our second approach presented next can produce even more efficient designs.

3.3 Dynamic Opcode Value Changes

Using the proposed technique we manage to analyze the timing requirements of each processor instruction individually. To this end, we are iteratively affixing certain circuit inputs at constant voltage values. Specifically, we are bounding the opcode field bits to static binary values in order to analyze each instruction behavior.

In real time digital circuits, inputs change in a dynamic way as new values are stored into the pipeline registers at the rising edge of the clock signal, immediately before they are needed and used. As a result, new instructions are fetched for execution on each clock cycle and thus, inputs representing the opcode bits of each instruction are not constrained to fixed voltage values; instead they dynamically change, resulting in an unpredictable transient timing behavior in every pipeline stage after the fetch stage. Such behavior appears at the decode stage due to the opcode bits per se, as well as at all subsequent stages due to the control bits produced by the opcode bits and is propagated to such stages. For this reason, the discrepancy between our initial concept and a real time system behavior in timing deviations should be addressed.

```

1  Start
2  instruction_number = number_of_supported_instructions
3  While (instruction_number > 0)
4    instruction = next_instruction
5    for (all possible opcode transitions)
6      opcode = instruction [opcode]
7      set_case_analysis [opcode, opcode_transition]
8      stage_delays = STA_timing_report
        [netlist, opcode, opcode_transition]
9      worst_case[instruction_number] = max[stage_delays]
10   instruction_number --
11 End

```

Figure 2: The timing analysis methodology which compensates for the dynamic voltage change of the opcode field.

In order to compensate for the dynamic voltage change in the processor pipeline inputs, we employ a modification of the aforementioned timing analysis methodology. Since our focus is now around the timing variance created by the dynamic behavior of the instruction opcode field, we consider the opcode as a bit sequence whose length is defined by the ISA. Consequently we have to take into account every possible value transition which leads to the currently analyzed bit sequence. Normally the amount of all possible combinations grows exponentially with the length of the sequence. We consider this approach unsuitable for our needs as its high time cost makes it impossible for practical application. Furthermore, we aim at the development of a methodology, which can be employed to analyze any ISA, without depending on the instruction opcode length of the design.

The solution we propose to resolve this is based on the observation that in processor architectures not all possible bit transitions lead to valid bit sequences of the opcode field. More specifically, as the instructions succeed one another during the instruction fetch stage, the number of valid opcode bit combinations is constrained by the number of the instructions supported by the ISA. So instead of analyzing the timing delay of each possible opcode bit sequence transition, we focus on the analysis of each possible instruction succession.

Figure 2 depicts the proposed solution, which relies on the initial concept as described earlier, augmented with the dynamic value change compensation approach we discussed. In this solution, we analyze each instruction's timing requirements individually as before, but instead of using fixed voltage values to describe the currently examined instruction, we analyze each possible opcode transition that could lead to the opcode bits of the current instruction. Such transitions represent any rising and falling voltage values that could result in that particular bit sequence. The timing analysis of such cases is studied individually, while the timing analysis tool propagates all generated signals through the processor pipeline. We still use the "case.analysis" function, as it can be expanded to include rising and falling voltage change. When we complete the timing analysis of an instruction, we save the worst-case delay. Afterwards we proceed with the analysis of the next instruction, until all supported instructions are exhausted.

The method we proposed in this section uses STA to find the worst-case delay path of each individual instruction. But in order to achieve an accurate timing result we utilize an exhaustive iterative analysis resembling more now that of a DTA method. However,

even if we restrict value variations within the instruction opcode, with an opcode field of x bits, a standard DTA approach would require 2^x iterative timing analyses to effectively analyze the timing of the opcode length, as each possible x -bit combination may lead to the required sequence. Instead, using our methodology, the number of iterations needed for each opcode analysis is only equal to the total number of supported instructions, in our case 215 iterations.

The proposed timing analysis technique lies somewhere between STA and DTA, closer to STA with respect to complexity, but closer to DTA with respect to output quality. We call this technique Pseudo Dynamic Timing Analysis (PDTA). In the following section we discuss the application of PDTA to adaptively scale the clock frequency of the core pipeline of a processor.

4 Clock scaling using opcode-based pseudo dynamic timing analysis

4.1 Adaptive clock scaling in pipelined processors

Adaptive clock scaling is often used for power control in modern high-performance processor architectures. Processor cores can be slowed down when not in full use, in an attempt to reduce power consumption and avoid overheating. In some cases, cores can be sped up for a limited time, in order to boost performance for cycle-hungry applications. On the other hand, low-cost processors that are preferred for embedded and low-performance systems can also use clock scaling in order to increase performance, especially if this is achieved in a fairly cheap manner.

Another way to effectively scale up the clock frequency is to deepen the processor pipeline. In this way each stage's latency is reduced and the system may operate lower clock periods. Previous works in [30] and [31] demonstrate that deepening the processor pipeline results in an increase in circuit area and power consumption due to the implementation of additional pipeline registers. Furthermore, deep pipelined processors require more complicated forwarding, control and stalling mechanisms thus, further impairing the design's area and power requirements. As a result, authors in [30] and [31] conclude that the increase of the pipeline stage amount does not necessarily result in performance increase as the costs of wrong branch predictions and pipeline flushing become greater.

Our work focuses on low-cost IoT processors which present significantly low area and power requirements as stated in [32], [33]. Under this premise we do not opt in deepening the pipeline width or enhancing the complexity of the system, instead we focus on increasing the processor throughput while preserving the system microarchitecture as it is. In this section we will present how PDTA can be employed for such a purpose.

4.2 Scaling clock by opcodes

PDTA can be used to acquire timing information for each instruction separately and thus, we aim to use such information for adaptive clock scaling based on the instruction opcode. In order to validate our clock-scaling technique, we will continue using the same 64-bit six-stage pipelined processor that we referred to in Section 3, which is a single-issue in-order-execute RISC-V processor implementation.

We will refer to this implementation as “baseline processor”. In order to tighten the timing of the processor's functional units we also deploy a second implementation that utilizes pipelined functional units. As a result time consuming operations require more clock cycle to complete but they display lower latency. We will refer to this implementation as “pipelined execution”. We classify the obtained results into 11 instruction classes as shown in Table 1. Each instruction class contains a group of individual instructions with similar timing requirements. We also pinpoint the slowest pipeline stage in terms of delay, for every class and we refer to such stage as “critical stage”. Finally, we assign a “worst-case delay” value to each class, which is the highest instruction delay in the corresponding group. The classes go as follows:

- The *Logical* instruction class which includes logical operations such as *and*, *ori* and *xor*.
- The *Shift* instruction class which includes shift operations such as *shift left logical* or *shift arithmetic*.
- The *Comparison* instruction class which includes *bit comparison* operations.
- The *Jump* instruction class which includes jump operations such as *jump and link*, *jump register* or *jump*.
- The *Multiplication* instruction class which includes integer *multiplication* operations.
- The *Division* instruction class which includes any *integer division* operations.
- The *Other arithmetic* instruction class which includes all other *integer arithmetic* operations except for multiplication and division, such as addition or subtraction.
- The *Memory access* instruction class which includes any *memory access* operation such as *load word* or *store byte*.
- The *FP Multiplication* instruction class which includes *floating point multiplication* operations.
- The *FP Division* instruction class which includes *floating point division* operations.
- The *Other FP arithmetic* instruction class which includes all other *floating point arithmetic* operations except for FP multiplication and division, such as FP addition or subtraction.

Table 1: Analysis of the instruction classes of the RiscV Rocket core architecture.

Instruction class	Slowest pipeline stage (critical stage)	Baseline worst case delay	Pipelined execution worst case delay
Logical	Execute stage	1.2 ns	1.2 ns
Shift	Execute stage	1.5 ns	1.5 ns
Comparison	Execute stage	1.5 ns	1.5 ns
Jump	Execute stage	1.1 ns	1.1 ns
Multiplication	Execute stage	2.9 ns	1.5 ns
Division	Execute stage	3.3 ns	1.1 ns
Other arithmetic	Execute stage	1.9 ns	1 ns
Memory access	Memory stage	3.9 ns	1.3 ns
FP Division	Execute stage	3.7 ns	1.3 ns
FP multiplication	Execute stage	3.2 ns	1.1 ns
Other FP arithmetic	Execute stage	3.0 ns	1 ns

After studying the aforementioned instruction classes we observe the following:

- Each pipeline stage presents unique timing requirements depending on the instruction being executed.
- Some pipeline stages may produce error free results while utilizing higher clock frequencies than the others.
- The error free instruction execution is preserved if we satisfy the timing requirements of each individual pipeline stage for the executing instruction.

We deduce that we can dynamically adapt the clock period of the processor during the run time in order to achieve higher throughput, while also guarantying the error free instruction execution. To this end, we isolate the critical instructions, i.e. the instructions that constrain the clock frequency and we display the results we obtained for each implementation in Table 2. We track down all critical instruction classes for our architecture and we assign a minimum operational clock period to each one of them. Due to the prior timing analysis, we are guaranteed that each critical instruction will execute without errors at the designated clock period. We also consider a typical clock period for each design which is suitable for the error free execution of non-critical instructions.

Our design focuses on letting the pipeline operate at high clock frequencies when critical instructions are absent. When a critical instruction is detected, we downscale the clock frequency, as soon as the critical instruction enters the pipeline stage which would otherwise cause a timing error. We refer to such stage as critical stage. Figure 3 shows an execution instance of a small instruction sequence on the Rocket core Baseline implementation. We track the minimum clock period with respect to the pipeline stages involved and we mark the critical stages that contribute to frequency downscaling. Under this premise, the critical stage is the slowest pipeline stage in which the clock frequency needs to be adjusted so that no timing errors occur. In this example, the pipeline under examination may operate at higher clock frequencies during the 1st to 5th and 8th to 10th clock cycle, while the clock frequency must be lower at the 6th and 7th cycle.

Figure 3: An instruction execution instance of the Rocket core implementation displaying the minimum operational clock period during each stage.

Table 2: The clock periods for critical instructions along with the typical clock period for the Rocket core implementation.

Critical instruction class	RiscV baseline	RiscV pipelined execution
	Multiplication, Division, Memory access, FP division, FP multiplication	Shift, Comparison, Multiplication
Critical instruction clock	4 ns	1.5ns
Typical clock	2 ns	1.3 ns

4.3 Dynamic clock scaling mechanism

We will now present in detail the circuit we designed to enforce the adaptive selection of the clock frequency. The circuit uses the information extracted from the timing analysis proposed in Section 3, to designate whether the clock frequency should be adapted. As the decision making will be occurring in real time, our design needs to employ reliability and speed. Figure 4 displays the designed clock control unit, which is charged with such task, and is implemented on the Rocket core implementation. It consists of an instruction snooping module and a clock selection module. In order to make the design nonintrusive for the processor architecture, we attach the two-module circuit at the side of the fetch and the decode stages of the processor pipeline.

Instruction snooping module: To be able to change the clock frequency dynamically, we need information about the class of the instructions that are headed for execution. To this end, we implement an instruction snooping circuit that receives a copy of the instruction word coming out of the instruction cache. This circuit monitors the instructions fetched and tracks down their progress in the pipeline. Moreover, it utilizes lookup tables which contain both the critical instruction opcodes and the critical pipeline stage for each corresponding instruction as calculated in Section 4.2. Using this information, the circuit produces a logical output on whether the clock frequency must be changed, driving with that output the clock selection module. **Clock selection module:** This module propagates the appropriate clock pulse selected by the frequency selector mechanism of the instruction snooping module. The clock selection module inputs are the frequency selection signal generated by the instruction snooping module and two PLL signals, one of high and one of low frequency. The frequency selection signal determines which pulse will be selected for the pipeline clock, when the instruction arrives at the critical stage. If frequency is indeed switched to low, the module must revert to the high frequency in the following cycle. The selection circuit is a simple multiplexor with insignificant contribution to the total delay of the module.

In the implementation of the second module, we observed that reverting to the original frequency may result in an unstable pipeline clock behavior, as shown in Figure 5. Such a phenomenon exists due to the frequency difference between the clocks and may prove catastrophic for the instruction execution. We address this problem in the way shown in Figure 6, by generating another low frequency pulse signal with a 180 degrees phase shift of the original. We also design a phase selector circuit which is responsible for selecting the appropriate phase when necessary. The phase selector is signaled by the frequency selector when a frequency scaling event is about to happen. It then designates the selected PLL phase so that no unstable behavior is exhibited. The complexity of the phase selection mechanism depends on the number of PLLs required.

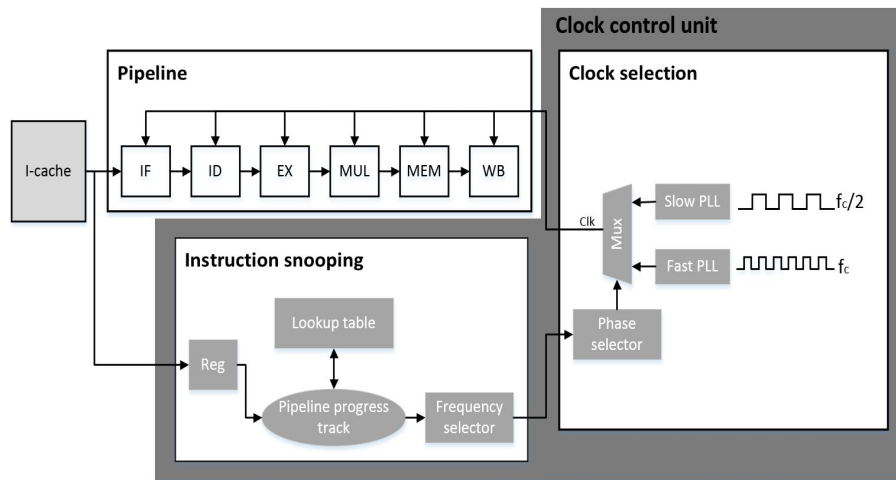

Figure 4: The clock control unit integrated in the rocket core.

Figure 5: Unstable clock behavior due to subsequent clock selections.

Figure 6: The clock instability compensation technique.

In the case of the implemented Baseline RiscV pipeline, where one period is an integer multiple of the other (2ns and 4ns), the generation of one additional shifted PLL resolves the problem. In other processor implementations though, additional PLLs may be needed, each with a specific phase shift, in order to enable the phase selector to compensate for all possible unstable behaviors of the pipeline clock. We adopt this approach as we acknowledge the need for a robust real time clock scaling mechanism. In contrast with [19] and [20] which manage to change the clock frequency for up to 7.5% of the core clock speed, we require much higher adaptation values. For that reason we do not change the clock frequency directly, instead

we pre-generate the number of PLLs required and we proceed in selecting the appropriate candidate each time.

In general, when we have two clocks with a period ratio $m:n$, m and n being mutually primes, we need m PLLs for the phase shifts of the first and n PLLs for the phase shifts of the second clock, giving a total of $m+n$ PLLs. Such a solution to the possible instability problem serves as the most efficient in terms of performance. As we saw earlier, clock frequencies used are the highest possible, with longer clock periods just enough to cover the critical pipeline stage delay. But this choice may result in a large number of PLLs. A cheaper solution would be to always use a slow clock period that is a multiple of the typical period. In this way we would not need that many PLLs, sacrificing performance for simpler implementation. In some cases, like the one examined above, it occurs that the optimal performance solution coincides with the cheapest solution, but this is definitely not the general case though.

4.4 Clock tree synthesis and distribution network

The proposed methodology requires the adoption of multiple PLLs to formulate the processor core clock frequency. The processor clock is dynamically selected according to the information obtained by the clock control unit and any change should be enforced within a very limited amount of time. Previous works in [21] and [15] have shown that cycle-to-cycle clock selection is possible and thus, the feasibility of the proposed methodology is ensured. To this end we opt to synthesize a single clock tree that reaches every register of the design, as we consider the propagation of all the available PLLs very costly. Under this premise, we perform the clock tree synthesis operation as if the design was operating under a single core clock with a constant clock frequency. The resulting clock distribution network is implemented by using timing constraints for the lower possible period that is obtainable by the clock in our designs, i.e. 2 ns and 1.3 ns for the corresponding “baseline” and “pipelined execution” implementations.

The clock control logic is implemented in a global level; on the clock tree root where the available PLLs are driven in order to select the most appropriate to propagate through the constructed clock tree.

In this way we avoid the expensive area, routing and energy costs of multiple PLL distribution, but we impose timing skew in the clock tree network. Also local, cell level clock gating for heavily gated clock networks such as ours results comes with various challenges, as a previous works in [34] and [35] suggest, that are not within the scope of this work.

In order to compensate for such a delay we design the clock selection unit to generate the outputs that control the clock selection process within the available timing margins. In this sense, we implement a low complexity and low latency control circuit capable of generating outputs with low delay, before the imminent clock pulse. As a result each decision on the dynamic clock frequency change is made within the timing margin available in order to properly distribute the clock pulse throughout the clock network in time. Also, the clock tree synthesis process we employ does not require the routing of all the PLLs of the design; instead it manages to propagate the dynamically selected PLL through a single synthesized clock tree.

5 Evaluation

In this section we discuss the evaluation process we employ in order to evaluate the PDTA methodology. To this end, we elaborate on the CAD toolflow and simulation environment we utilize and we present the results we obtain in terms of speedup, power consumption and overhead of the PDTA.

5.1 CAD toolflow and simulation

After rigorous consideration of many open-source simple processor cores that have been used in architecture-oriented research in the last decade, we have opted for the RiscV Rocket Core [36] processor implemented in Verilog for evaluating our methodology. We have implemented two processor versions as mentioned in Section 4, both of which include our clock control design; we then compiled and tested the circuits using a number of benchmarks, and produced a final evaluation of our ideas. For the front-end design flow we used the Synopsys Design Compiler [37] in conjunction with the NanGate 45nm Open Cell Library [38], whereas for the back-end place and route process we used the Synopsys IC Compiler [39]. Afterwards, we used Synopsys PrimeTime [40] to apply the PDTA methodology we described in Section 3 on the generated post-placement netlists. We subsequently performed post-layout simulations, back annotating the design with Mentor Graphics Modelsim [41]. In order to analyze the performance and power consumption of the system, we selected the SPEC CPU2017 benchmark suite and we utilized the RiscV toolchain to compile each benchmark to generate the required binaries in accordance with the RiscV architecture. Finally, we employed Synopsys Power Compiler [42] to generate power reports for each benchmark. The parameters of both the baseline processor and the pipelined execution implementations are displayed in Figure 7. The processor supports in-order instruction issue and execution with 64-bit instruction length. It also employs a BTB of 512 entries using the g-share prediction mechanism. We have also incorporated an L1 cache to the processor; in particular a 4-way associative 16KB i-cache and a 4-way set associative 16KB

Processor Parameters shared on both implementations	
ISA : Risc V Implementation : Rocket core Instruction width : 64 bits Instruction issue : In order, single issue Pipeline depth : 6 stages	
I-cache	BTB
Associativity : 4-way Size : 16 KB Round trip : 1 cycle TLB size : 512 entries	Prediction mechanism : gshare History length : 9 bits Prediction levels : 2 Table entries : 512 entries
Baseline Processor Parameters	Pipelined Execution Processor Parameters
D-cache Associativity : 4-way Size : 16 KB Round trip : 4 cycles TLB size : 512 entries Execute stage: All operations : 1 cycle Worst-case clock period : 4ns PDTA PLL count: #4	D-cache Associativity : 4-way Size : 16 KB Round trip : 7 cycles TLB size : 512 entries Execute stage: Multiplication : 2 cycles Division : 3 cycles Other arithmetic : 2 cycles FP Division : 3 cycles FP multiplication : 3 cycles Other FP arithmetic : 3 cycles Worst-case clock period : 1.5 ns PDTA PLL count: #18

Figure 7: The configuration parameters of both processor implementations.

d-cache with LRU replacement policy. The access time of the data cache is 4 and 7 clock cycles for the baseline and the pipelined execution implementations correspondingly, while the access time for the instruction cache is 1 clock cycle. The clock period for each implementation is defined by the slowest pipeline stage as described in section 4. Finally, the amount of PLLs required for the implementation of the PDTA methodology is 4 for the baseline and 18 for the pipelined execution RiscV implementations.

5.2 Speedup

We have run the Spec2017 CPU benchmarks on the baseline processor implementation, on the pipelined execution implementation and on their corresponding BTWC versions. We present the normalized instruction throughput improvements we obtained according to our experiments in Figure 8 where results indicate an average performance increase in instruction throughput of 1.6 and 1.3 correspondingly. In the same figure we also present the appearance rate of critical instructions for each processor implementation. Further result analysis discloses the following information:

Firstly, designs with relaxed timing constraints benefit more from the PDTA methodology when compared with designs that display tighter timing requirements. This behavior is expected as the PDTA methodology exploits timing differences between individual processor operations. As a result, the more relaxed the system timing, the higher performance increase is achieved. Secondly, frequent appearance of critical instructions throttles the system's performance as the design is forced to operate under the worst-case clock period. As a result benchmarks that display low critical instruction appearance rates, also display higher throughput increase.

In order to further assess the effectiveness of PDTA methodology we compare the obtained throughput results with other state of the art timing speculation techniques. Tables 3 and 4 below demonstrate

Figure 8: Normalized throughput improvement and critical instruction appearance rate of the proposed design methodology compared to the corresponding baseline processors.

the outcomes of such comparison. Table 3 depicts the normalized throughput improvement of the application-adaptive guardbanding technique proposed by A. Rahimi et. Al. in [10]. We compare the PDTA methodology of both RiscV implementations with the best and worst performance-wise design corners explored by [10]. The application-adaptive guardbanding technique outperforms our methodology when it comes to the best-case design corners, but PDTA proves to be more efficient in terms of performance in worst-case design corners. Table 4 below displays the PDTA results in conjunction with Blueshift optimization as described in [15]. In this work the proposed TS methodology is applied on both Razor [4] and OpenSPARC T1 processors displaying significant performance improvements. According to table 4 PDTA design approach achieves better throughput improvements if compared with Razor or OpenSPARC T1 processor when the baseline RiscV is considered. In contrast, the pipelined execution RiscV design is slightly behind the Razor processor in terms of performance, while it still surpasses the OpenSPARC T1 with the Blueshift design paradigm. PDTA comparison with state of the art TS methodologies highlights the competitive edge of our methodology as its performance is measured on average the same level if not above, compared to other TS approaches.

Table 3: Throughput improvement comparison between Application-adaptive guardbanding and PDTA.

Benchmark	Adaptive Guardbanding Best/Worst design corner [10]	PDTA Baseline /PDTA Pipelined
dijkstra	1.87 / 1.36	1.61 / 1.28
patricia	1.89 / 1.38	1.8 / 1.26
susan	1.81 / 1.58	1.4 / 1.25
blowfish	1.84 / 1.35	1.6 / 1.25
Average	1.88 / 1.25	1.6 / 1.26

Table 4: Throughput improvement comparison between Blueshift OpenSPARC, Razor and PDTA methodology.

Benchmark	Blueshift OpenSPARC [15]	Blueshift Razor [4]	PDTA Baseline /PDTA Pipelined
b2zip	1.18	1.37	1.8 / 1.28
gcc	1.25	1.39	1.42 / 1.29
mcf	1.04	1.05	1.7 / 1.25
Average	1.15	1.27	1.64 / 1.273

5.3 Power consumption compared to the baseline processor

Due to clock frequency scaling, our design often tends to operate at higher frequencies. As higher frequencies are more power hungry, we expect a higher power usage compared to the baseline processor. To verify that assumption, we measure the power consumption of the BTWC design and we compare it to its relevant baseline processors in Figure 9. Results show that the power consumption increase is higher for the benchmarks that present more opportunities for aggressive frequency scaling. Specifically, an increase of 4% to 36% in power consumption is observed, depending on each benchmark's capacity for frequency scaling. Nevertheless, by dividing the performance improvement over the power increase for each benchmark, we get an average of 3.7 improvement rate for the performance-to-power ratio, which is a quite significant overall improvement that we observe with our technique.

5.4 Overhead of the PDTA methodology

In order to properly evaluate the overhead of the PDTA methodology we measure both the PDTA design costs in terms of area and power complexity and the PDTA analysis cost in terms of time requirements.

Regarding the design costs of the PDTA, we quantify the overhead in power and area of the post-layout implementation of the

Figure 9: Normalized power consumption increase of the proposed methodology compared to the baseline processors.

clock control circuit and instruction snooping modules. Such modules are the essential components of the PDTA design and are used as described in section 4. Table 5 lists the power and area requirements of the aforementioned modules, along with the power and area requirements of the baseline processors. We observe that the power overhead of the control unit is less than 2% of the total average power consumption of the baseline pipelines, while the area overhead almost 0.001%. Further, Table 6 depicts the area overhead comparison between the state of the art methodologies and the PDTA approach which is proposed in this work. We observe that the PDTA methodology achieves the least area overhead compared with the rest and thus, we conclude that the PDTA is well suited for low-end, low power pipelined processors.

Regarding the time requirements of the PDTA, we measure the amount of iterations and the amount of time required for the PDTA analysis to complete. The results we obtain are depicted in Table 7 in comparison with the standard STA and DTA methodologies. We define the iteration count as the amount of times the corresponding timing methodology is invoked in order to sufficiently cover the timing paths of the pipeline under examination. To this end, the DTA methodology examines every possible bit-transition and thus, it requires $2^{\text{instruction.Length}}$ iterations (2^{64} for the 64-bit RiscV Rocket core implementations). On the other hand, the STA methodology examines the worst case scenario only, for each instruction path and thus, the required timing iterations are analogous to the complexity of the design. The PDTA methodology resides in between the DTA and STA approaches as the amount of the required iterations is depended on the bit length of the opcode field of the ISA, as discussed in section 3. As a result, the PDTA requires 2^7 iterations in order to properly analyze the timing paths of the RiscV Rocket core pipeline, as the opcode field of the rocket core ISA is 7 bits. In order to evaluate the time requirements of each methodology, we run the DTA, STA and PDTA approaches on the same RiscV rocket core pipeline using an Intel i7 coffee lake processor with 6 cores and 16 GB of DDR4 DRAM. Results indicate that the STA analysis

finishes in a 20 second period of time while the PDTA methodology requires 5 minutes. In contrast, the DTA requires over 100 hours to finish and thus, it is considered time costly for timing analysis in processor pipelines. We conclude that the PDTA methodology manages to efficiently manage the tradeoffs between STA and DTA as it provides detailed timing reports for each ISA-supported instruction while also requiring a reasonable time to finish.

Table 5: The power and area overhead of the clock control and instruction snooping circuits in comparison to RiscV .

Implementation	Average power	Area
RiscV Baseline	65.67mW	0.24mm ²
RiscV Pipelined execution	149.04mW	0.55mm ²
Clock control and instruction snooping	98.21uW	321um ²

Table 6: Area overhead comparison between PDTA methodology and the state of the art.

Benchmark	Area overhead
iRazor [5]	13.6%
Application-adaptive guardbanding [10]	0.022%
TS Cache [17]	1.8%
Active management [18]	0.12%
DynOR [21]	5 – 13%
Optimal In Situ Monitoring [26]	3.15%
Razor-Lite [43]	4.42%
Bubble Razor [44]	21%
PDTA (this work)	0.001%

Table 7: Time requirements of DTA, STA and PDTA to complete the timing analysis of RiscV pipeline.

Implementation	Iterations Theoretical	Iterations (RiscV)	Time (RiscV)
DTA	$2^{instruction_length}$	2^{64}	Over 100 hours
STA	Supported instructions	215	20 seconds
PDTA (this work)	2^{opcode_length}	2^7	5 minutes

5.5 PVT tolerance considerations

In order to evaluate our design we utilize a single design corner that operates in 0° and 0.72 V. We select the aforementioned corner as the 0.72 V is considered low power pipeline operation and thus, it stays within the scope of this work. We also set a clock uncertainty of 10% to compensate for the process variation effect which may induce clock jitter and uncertainty to the integrated circuit. Evaluating the proposed methodology with a full range of dynamic variations as well as static process parameters variations is possible but the PDTA analysis should be conducted independently for each individual design corner. A higher voltage than 0.72 volts would result in shorter delay instruction paths, while lower operating temperatures would lead to higher delays in the low-voltage region of 0.72 volts as previous work in [45] demonstrates. To this end, the PDTA analysis should be conducted for each design corner in order to extract the exact timing information for the corresponding operating Voltage and Temperature values. On the other hand, the process variation effect can be emulated by setting clock jitter and clock delay values, similarly to our approach. The methodology of the PDTA does not require any modifications in order to function properly within different PVT effects and thus, it can produce accurate timing results given the exact operating condition of the integrated circuit.

6 Conclusion

The BTWC design paradigm promises to alleviate critical path constraints which have negative effects on processor timing. In this paper we present PDTA, a timing analysis methodology, which shifts the focus from a general critical path analysis to the less constrained analysis of paths that are actually followed by individual instructions. To this end we design and implement a circuit capable of identifying the timing requirements of any incoming instruction and selecting the appropriate pipeline clock out of a number of deployed PLLs. Thus we are able to scale up the clock frequency beyond its worst-case operational limit. We evaluate our methodology using a RiscV processor architecture which presents differences in pipeline stage timing. Results demonstrate an average performance increase of 1.62x, as well as a 3 to 4-fold improvement in performance-to-power ratio, compared to the baseline processor. The main contributions of this work to the current state of the art include:

- We propose a novel methodology implemented on the circuit level which considers instruction opcodes for performance increase. Previous consideration of opcodes for performance increase has been compiler-only consideration, i.e. instructions with expensive opcodes are identified at compile time and avoided in code generation.

- The timing analysis we present is focused on individual instructions rather than on whole instruction sequences. In this way we collect information that is more applicable in real systems, as certain instruction sequences do not appear in a steady and predictable rate.
- Our methodology identifies the timing requirements of individual incoming instructions. Since we are a priori aware of such constraints, we do not deploy any error detection or error correction mechanism, while also avoiding any metastable behavior which commonly manifests in such cases.
- We explore an architecture-oriented approach for the BTWC design paradigm. Our work studies the processor architecture to extract timing information based on the ISA of the processor. As a result, we consider this approach to have greater applicability as it can be used on any processor architecture without requiring any further adjustments.
- The proposed methodology does not make any intrusive changes on the processor architecture. This means that it can be applied without any additional design costs, and it maintains the original pipeline intact.

Overall, the BTWC approach presents many opportunities for designers to experiment with novel methodologies and innovative techniques. We believe that research will produce various studies related to this field in the future, as it promises to redefine the design paradigm of modern integrated circuits. Finally, given the dominance of low-cost processors in embedded and many domain-specific designs, ideas that boost performance of processors within those fields in a simple and cheap way will appear, some of which successfully establishing new directions in microprocessor design.

Conflict of Interest The authors declare no conflict of interest.

Dynamic Point Selection

Traffic Load Aware

ABSTRACT

Coordinated MultiPoint (CoMP) has been introduced for LTE-Advanced system to overcome the inter-cell interference problems and enhance the signal quality of cell-edge UEs (User Equipments). With such concept, the overall system performance should be improved considerably to support the significantly increasing amount of demand on data transmission via mobile communication that happens nowadays. Dynamic Point Selection (DPS) is one of the major CoMP techniques offering benefit through its practicality and low complexity. This work proposes the actual traffic-based load-aware DPS for LTE-Advanced system. The key important cell selection criterion employed in this work is based on the actual traffic load of the calls along with the UEs received signal indicator. The adapted Vienna downlink system level simulator has been used for the system evaluation. The video streaming traffic model was employed with the data rate of 512 kbps for the realistic use cases and four simulation scenarios including the uniformly distributed UEs case and different patterns of hotspots distribution use cases were deployed. The system performance evaluation includes the system throughput performance, the number of UEs achieving expected data rate, and eNBs' traffic load. The results show that our proposed method offers a substantial improvement over the traditional system as well as the system embedded with the existing DPS mechanisms when the traffic loads are imbalanced such as in certain hotspot cases.

1. Introduction

Mobile communication has entered the fifth generation (5G) with the expectation to support a dynamically increasing number of mobile users as well as the devices supporting IoT services such as e-health, smart metering, and Car2X communication. These mobile services are growing at a compound annual growth rate of 47% as shown in the cisco report [1]. To support such high demand on data transmission with the available radio resource, the Heterogeneous Networks (HetNets) has been deployed. The approach maintains the intended coverage and optimizes the overall system capacity, especially at high traffic demand. In HetNets, the service coverage area is located with cells of different sizes (with different maximum transmit power), referred to as macrocell, microcell, picocell, and possibly femtocells, forming different network tiers. Although, the 5G LTE-Advanced system can gain benefit from an implementation of HetNets, a mixture of cell sizes leads to the complexity in network planning. The Inter-Cell Interference (ICI) caused by the transmission of different base

stations in the collocating area will occur especially at the cell edge. Many works have investigated interference management technologies to improve cell-edge throughput. Inter-Cell Interference Coordination (ICIC) has been introduced in LTE Release 8 providing the coordination of neighboring cells in order to mitigate inter-cell interference for UEs at the cell edge. The Enhance ICIC or eICIC was launched in LTE Release 10. The two major techniques under eICIC include the Almost Blank Subframes (ABS) and the Cell Range Expansion (CRE) technique. Using CER, macrocell traffic can be offloaded to the small cells in the same area. The use of Almost Blank Subframes (ABS) results in the key contribution, which is the addition of time domain to ICIC. The signal will be transmitted from the macro-eNB in accordance with a semi-static pattern when eICIC is applied. In these blank subframes, UEs are able to receive the DL information (both for control data and user data) since they are at the cell edge that is normally in the CRE region of the small cells. The performance evaluation of the system embedded with CRE and ABS mechanism with diverse CRE and ABS configurations are investigated in [2].

The transmission of Coordinated MultiPoint (CoMP) was first mentioned in 3GPP Release 11 [3]. Its main concept is to reduce the inter-cell interference and improve the quality of signal of cell-edge UEs by implementing multi-cell cooperation. The new framework based on the multi-cell Channel State Information (CSI) feedback from the set of cells in a CoMP cluster was introduced. Many mechanisms have been proposed under the umbrella of CoMP. In [4], the integration between Joint Transmission (JT) CoMP and the Non-Orthogonal Multiple Access (NOMA) in the downlink HetNet was investigated. The JT CoMP scheme with the anisotropic path loss model was satisfied for the requirement of the fifth generation (5G) of mobile communication by the author of [5]. In [6], coordinated scheduling CoMP was analyzed in terms of the throughput with different cells. However, the Dynamic Point Selection (DPS) CoMP is the research gap of such work

In this work, the actual traffic load-aware Dynamic Point Selection (DPS) is proposed. The major benefit of the DPS mechanism in general is that it is a simpler approach in terms of practicality since UEs are being served by only one serving cell at a time. Several DPS mechanisms have been proposed previously in [7] and [8] without considering the traffic load condition of the cells. In [9]-[11], DPS mechanisms with cell load consideration were presented. However, the call load was estimated by the average value of the PF (Proportional Fairness) metrics and the current number of active UEs. Unlike the previous papers, this work proposes the actual traffic based load-aware DPS, in which the current traffic load of the cells is considered. The obtained results ascertain that overall system performance can be enhanced as well as the service quality especially in the cases of load imbalanced in the CoMP clusters.

This paper is organized as follows. Section 2 gives a review on CoMP techniques in LTE-Advanced system. This section presents previously proposed DPS approaches along with the traffic model used in the studies. In section 3, the algorithm design of our proposed actual traffic load-aware DPS is described. The simulation model and simulation scenario are defined in section 4. The simulation results are given along with the discussion in section 5. Finally, conclusions are given in section 6.

2. Coordinated MultiPoint in LTE-Advanced System

2.1. The Coordinated MultiPoint (CoMP)

According to [12][13][14], the basic principle of CoMP is to improve the spectrum efficiency by making use of the multiple transmitting and receiving antennas from multiple site locations though they may or may not belong to the same physical cell. Also, by taking the advantage of the co-channel interferences, the enhancement of effective coverage area can be achieved. Although CoMP is mainly used to enhance the cell-edge UE experience, it can be applied to improve the service quality of UEs experiencing intense signal from different eBSs/cells. CoMP can be divided into two terms which are inter-site CoMP and intra-site CoMP depending on the coordinating Transmission Point (TPs). If the coordination is executed between eNBs located at the separate geographical areas, it is the inter-site CoMP. If the coordination is executed among multiple antenna units between sectors of the same BS, it is the intra-site CoMP. Refer to the previously

proposed mechanisms, CoMP can be categorized into two types which are; a) Coordinated Scheduling/Beamforming (CoMP-CS/CB) and b) Joint Processing (CoMP-JP).

• Coordinated Scheduling/Beamforming (CS/CB)

In CS/CB CoMP, the data packet requiring to be sent to a UE terminal are ready for transmitting from only one BS in the CoMP cooperating set [15], whereas the user scheduling and beamforming decision are dynamically obtained after the coordination among all TPs in the cooperating set is completed. By applying the semi-static point selection, the transmission decision is made. Although fast and strict coordination can be obtained from CS/CB, the selection of the users' best serving set for transmitter's beams construction is still based upon their geographical position. This is because the beamforming in a coordinated manner of CS/CB relies on the capabilities of the MIMO antenna. Focusing on the behavior of the beam to resources selection, as shown in Figure 1(a), the coordinated generation of beams manages not only to obtain the interference reduction among other neighboring users, but also the enhancement of signal strength of the targeted users.

• Joint Processing (JP)

The most advanced CoMP scheme that has been commonly applied to achieve spectral efficiency improvement, especially for the cell-edge user, is the JP scheme. In this case, considering the same time-frequency resource, the UE's data is available at more than one TP in the CoMP set. In terms of cooperation mechanisms, there are two main categories of CoMP-JP including Joint Transmission CoMP (JT-CoMP) and Dynamic Point Selection CoMP (DPS-CoMP).

Joint Transmission CoMP (JT): In the JT-CoMP scheme, UE data is processed and transmitted from the multiple cooperating BSs at the same time. Even in the heterogeneous scenario and dense small cell network with low power nodes, the essential signal strength delivered from the multiple BSs can be simultaneously sensed by the UEs. Although the JT-CoMP is the most powerful and attractive approach applied to enhance the efficiency of the spectrum and the average throughput, it requires high system demand in terms of computational power and signaling overhead as presented in Figure 1(b).

Dynamic Point Selection CoMP (DPS): In the traditional DPS-CoMP scheme, UEs can reselect the serving BS by considering the highest received SINR and the minimum path loss. However, the DPS-CoMP is different from the CS CoMP in that all cooperating BSs contain the UE's data in DPS. The UE performs the selection of the best serving BS for its next frame dynamically and then notifies all cooperating BSs of the CoMP set. As shown in Figure 1(c), after the newly serving BS is chosen, it informs the others to refrain from transmission via the X2 interface. This action is done to support the resources that this UE is about to employ. Therefore, the transmission of data is taken place only by one BS at a time.

In the baseline scheme of the DPS, the transmission switching metric can be defined as.

$$S_k^{s,t} = \frac{r_k^t}{r_k^s} \quad (1)$$

where the term r_k^t is the instantaneous throughputs of user k when being served by the TP t and r_k^s is the instantaneous throughput of user k when being served by TP s . In this basic DPS mechanism, the cell load of the eNB is not taken into account for DPS switching metric.

In [10], an instantaneous load-base DPS scheme was proposed. UE's channel and cell load of the serving cell are used to achieve the transmission switching metric. In this case, the transmission switching metric can be derived from eq. (1) by including the cell load representing the eNB load state. As a result, the transmission switching metric of the load-base DPS scheme can be defined as:

$$S_k^{s,t} = \frac{\left(\frac{r_k^t}{\rho_t}\right)}{\left(\frac{r_k^s}{\rho_s}\right)} \quad (2)$$

where the terms ρ_t and ρ_c are the cell load of the transmission point t and s , respectively.

Figure 1: Downlink CoMP transmission [16]

2.2. Traffic Model Studied in DPS

The performance of DPS for LTE-Advanced system has been investigated in several works. The authors of [7] and [9] have analyzed the DPS mechanism in the homogenous networks with the full buffer traffic model. The HetNet case has been implemented in [8]. The authors of [10] and [11] have compared the performance of DPS under bursty traffic model in comparison with the full buffer traffic model. In [17], the DPS mechanism in the HetNet scenario with the FTP traffic model was implemented. Nonetheless, in such a proposed algorithm design, the bursty traffic model and the full buffer traffic modal may not be the best

type of traffic to be used. This is because when all UEs use a bursty traffic model or a full buffer traffic model, the cell is more or less need to offer full capacity, which leads to the cell load of around 100% most of the time. With that, the traffic offloading effect is hard to be monitored.

In this work, the video streaming traffic model is therefore focused, which is more or less the most used kind of services in the real world these days. The configurable video traffic model has been developed here and used to analyze the system performance embedded with our DPS with the load-aware mechanism. Table 1 presents the configurable parameters of the video streaming traffic model used in this work.

Table 1: Parameter of the video streaming traffic model

Parameters	Value
Slice size	400 bytes
Slice interarrival time (encoder delay)	6 ms
Number of slice per frame	16 slice
Data rate constraint	512 kbps
Arrival time for all slices	100 ms

3. Algorithm Design of the Proposed Actual Traffic based Load-aware DPS

3.1. Cell Load Estimation

In [7] and [8], the performance of DPS in both homogenous networks and HetNet has been analyzed. Load-aware with DPS was implemented with different mechanisms from our proposed method here. As for the cell load estimation, the authors of [9] define traffic load as the summation of the data traffic from all UEs attached with the cell. There are two approaches for cell load estimated by the author of [10] and [11]. In [10], the cell load is estimated by the average of the Proportional Fairness (PF) metrics of the UEs currently served by that cell.

$$\rho_c = \frac{\sum_{i \in \mathcal{A}_c} \frac{r_i}{x_i}}{N_c} \quad (3)$$

where ρ_c is the traffic cell load of the TP_c , \mathcal{A}_c is the set of active UEs currently served by TP_c , and $\frac{r_i}{x_i}$ is the ratio of the PF metric of UE_i . In [11], the cell load is estimated by using the current number of active UEs served by that current cell. However, in reality, traffic load of a cell cannot be estimated by the number of UEs. This is because the traffic demand of each UE is not always the same.

In this work, the actual traffic load of a cell is used for analysis in our proposed system. The actual traffic load estimation used in this work can be defined as:

$$\rho_c = \frac{\sum_{u|X(u)=c} \frac{D_u}{R(SINR_u)}}{N_{tot}} \quad (4)$$

where D_u is the constant data rate requirement of each UEs, $R(SINR_u)$ is the data rate per PRB by user u , and N_{tot} is the total number of resources [18]-[20].

3.2. Algorithm Design

The actual traffic-based load-aware DPS is proposed in this work. The algorithm to reselect the serving cell proposed here is based on the criteria including CQI as well as the cell load condition of the potential TP(s). In the first step, each cell in the simulation scenario is calculated for the actual traffic load by using the equation (4). If the actual traffic load of each cell in eNBs is more than 80%, the targeted number of offloading UEs will be increased, otherwise decreasing the targeted number of offloading UEs. For those congested cells (set here with >80% cell load), UEs with low link quality are considered for changing of a serving cell. The new serving cell that provides the best connection can be chosen from the selection of cells within the CoMP cluster. The offloaded UEs' serving cells will be reselected in case of the offloaded cell has turned congested and the UE receives low link quality. The threshold for maximum cell load has also been set to make sure that offloaded cells have enough capacity to admit additional connections without affecting the currently attached UEs. The algorithm design of the proposed actual traffic base load-aware DPS is shown below.

Algorithm: Actual Traffic base Load-aware Dynamic Point Selection

```
//Initialization
j: Cell
J: Number of Cell
N: Number of offload UEs
M: Number of offloaded UEs

//Calculate actual traffic cell load
for j = 1 to J
    | Cellulate actual traffic cell load(j) by eq. (4)
end

//Calculate the number of offload UEs in each cell
Set N to zero
for j = 1 to J
    | if actual traffic cell load(j) > 80%
    | | Increase N(j)
    | else
    | | Decrease N(j)
    | end
end

//offload UEs
for j = 1 to J
    | if N(j) > 0
    | | Sorting cell-edge UEs
    | | Set M to zero
    | | while N < M
    | | | //offload cell edge UEs
    | | | Offload cell-edge UE (reselect cell eq. (2))
    | | | Increase M
    | | end
    | end
```

```
else
    | continue
end
end
```

4. Simulation Model and Simulation Scenarios

4.1. Simulation Model

The downlink system level simulation has been used in this work to observe the system performance of the LTE-Advanced system embedded with our proposed DPS mechanism, the actual traffic-based load-aware dynamic point selection. The simulator used here was adapted based on the Vienna LTE system level simulator [21]. The adapted model is used to evaluate the system performance under four different test scenarios. Table 2 presents the simulation parameters used in this work.

Table 2: Simulation parameters

Parameters	Value
Bandwidth	15 MHz
Carrie frequency	2.1 GHz
CoMP cluster	3-cell intra-site CoMP
UE speed	3.6 km/h
Antenna configuration	2x2, single pair of cross-pole antennas both at Tx and Rx
Propagation scenario	3GPP Macro Case1, 500 m inter-site distance
Traffic	Video streaming, Data rate 512 kbps
Scheduler	Proportional Fair (PF)
Handover interval	50 ms
Simulation Time	3,000 ms
Number of UEs	Normal load - uniformly distributed with 10 UEs/cell, Hotspot load - 50 UEs/cell

4.2. Simulation Scenarios

The 3-cell intra-site CoMP cluster as defined by 3GPP [3] has been used to define the coordinating area as a UE CoMP set, also known as the co-operating cluster. Figure 2 depicts the 3-cell intra-site CoMP cluster. In this work, this CoMP cluster is used as the COMP clustering pattern in the LTE-Advanced system studied here.

Figure 2: The 3-cell intra-site cluster

Four simulation scenarios have been implemented. Figure 3 shows the plot of UEs distribution within the Region of Interest (RoI) with regards to each simulation scenario. Base on the 3-cell intrasite CoMP cluster, as shown in Figure 2, the test scenarios

were designed in such a way that the system performance under heavy traffic as well as the hotspot type of traffic distribution can be observed. The four simulation scenarios implemented here consists of the randomly and uniformly distributed UEs (with normal traffic load) in scenario 1 and the hotspot scenarios with different hotspots' locations (high load in certain areas) in scenario 2 - 4. There are 19 eNBs or 57 cell sites in the simulation scenario. The red dots in Figure 6 represent the eNB and the blue crosses represent the position of the UEs.

In the first simulation scenario, 10 UEs are uniformly distributed within each cell to mimic the system under normal traffic load as illustrates in Figure 3(a). In the second scenario, one cell in each CoMP cluster (under the coverage of each eNBs) has 50 UEs located in to form a hotspot and 10 UEs on the other cells in the same cluster, as shown in Figure 3(b). There are three scattered hotspots implemented in simulation scenario 3 and 4. In scenario 3, the hotspot cells generated with 50 UEs are in the exact location of the three cells of one eNB. In other words, 150 UEs were located in those eNBs for high traffic demand areas, as illustrated in Figure 3(c). The last simulation scenario is similar to that presented in scenario 3. However, each three 3-cell coverage hotspot was located across three different clusters as can be seen in the Figure 3(d).

Figure 3: The plot of UEs distribution in the different scenario

5. Simulation Results

In this section, the simulation results obtained from the adapted system level simulator discussed in section 4 are presented. For the comparative studies, different mechanisms have been configured to observe the system performance including the non-DPS system (traditional LTE Advanced system), DPS (with received signal strength-based), and our proposed DPS with load-aware using actual eNBs' real-time traffic situation. The observed results for system performance evaluation include 1) the throughput performance i.e. the peak

throughput, the average throughput, and the cell-edge throughput 2) The number of UEs achieving the expected data rate and 3) eNBs' traffic load.

5.1. Peak, Mean, Edge Throughput Performance

Figure 4 – 7 illustrate the simulation results of the test scenario 1 – 4, respectively. The x-axis identifies different types of throughput observed from the simulation including the peak throughput, the mean throughput, and the cell-edge throughput. The y-axis represents the throughput level in Mbps. Different colored bars represent the throughput performance obtained from a non-DPS system (in blue), a system embedded with a traditional DPS mechanism (in orange), and a system embedded with our proposed DPS mechanism (in gray).

The simulation results for test scenario 1 are given in Figure 4. It can be seen that when the system operated under normal traffic load, the system performance in terms of peak throughput, average throughput, and cell-edge throughput provided by implementing the three mechanisms i.e. non-DPS, DPS, and DPS with actual traffic load-aware are the same. This is because with a low number of UEs, traffic demand from the generated UEs is low. Hence, the system is not saturated and has no problem providing good Quality of Service (QoS). As a result, the system embedded with three different mechanisms offer similar performance.

Figure 4: Simulation results from scenario 1

Figure 5 shows the simulation results obtained via test scenario 2. It can be seen that in the case of non-DPS and typical DPS mechanisms, the system performance is similar though slightly higher peak, mean and edge through are offered by the DPS mechanisms. When comparing DPS with load-aware DPS, it is obvious that the throughput performance offered by our load-aware DPS is the highest for peak, mean, and edge. Since in scenario 2, the hotspot is located in one of the three cells in each cluster. In other words, there is a load imbalance among the cells in the same cluster. As a result, traffic can be offloaded from the congested cell to the neighbor(s) (within the same cluster) who handle a small number of UEs. With the load-aware mechanism, the overall system can then be highly improved.

Figure 6 and Figure 7 present the simulated results of the test scenario 3 and 4, respectively. The hotspot cells were allocated with the same number of UEs. However, the positions of hotspot cells are at different locations. In test scenario 3, it can be seen

from the simulation results that system performance obtained using the three mechanisms provides similar results. As in this scenario, although there are hotspot areas with highly generated traffic demand, the high traffic load covers the entire CoMP clusters, which makes it rather impossible to transfer the heavy load to the cell(s) with lower traffic. This is due to the property of the fixed clustering mechanism.

Figure 5: Simulation results from scenario 2

Figure 6: Simulation results from scenario 3

Figure 7: Simulation results from scenario 4

Simulation scenario 4 observes the case when the hotspots' coverages are across the fixed CoMP clusters. From the simulation results, shown in Figure 7, it can be seen that although it has the same number of UEs as in scenario 3, the DPS mechanism offers slightly better throughput performance in general. But When the actual traffic load of eNBs is considered as

the main part of the offloading condition, our DPS with a load-aware mechanism provides much better results, especially for the cell edge throughput. It can also be seen that the results from scenario 2 and 4 are very similar, which is due to the ability of the proposed load-aware DPS mechanism in such a way that higher loaded cell can offload some UEs to those with available resources, thereby allowing better overall system performance and capacity.

5.2. The Number of UEs Achieving Expected Data Rate

In this section, the results are presented in the view of users' experience. Note that the video streaming traffic model has been implemented here to mimic the realistic use cases. Figure 8 shows the results for the number of UEs (as in percentage) that achieve the expected data rate (512 kbps) for all test scenarios. The results provide a comparison for the system embedded with non-DPS, DPS, and our DPS with actual traffic load-aware, represented by the blue bars, the orange bars, and the gray bars, consequently.

In simulation scenario 1, all UEs achieve the expected data rate (100%) for all three mechanisms. With low traffic demand, all three systems can maintain system performance. In scenario 2, it can be seen that in the case of the non-DPS mechanism, only 50.3% of UEs can achieve the expected data rate, while the DPS mechanism offers 3.4% higher. Using DPS with load-aware mechanism, the number of UEs achieving expected data rate increases by 16.3% to 66.9% satisfying users. Note that, in this scenario, one-third of the entire simulation plane has high traffic demand. In scenario 3, the number of UEs that can gain the expected data rate is approximately 63% for all DPS mechanisms. It can be concluded that in the event of a hotspot occurring in all cells of the CoMP cluster, no matter what DPS mechanism is used, the system performance cannot be further enhanced as the hotspot cells have entered the saturated stage.

The different situation can be seen from the results of simulation scenario 4. DPS mechanism provides the number of UEs achieving expected data rate at approximately 61%, which is rather close to that of the non-DPS mechanism. On the other hand, when the proposed DPS with actual traffic load-aware is used, the number of UEs achieving the expected data rate increases by approximately 9% to the 70.4% of all users. This is due to the real-time awareness of actual traffic, which each cell is handling, by using our proposed mechanism. As a result, unsatisfying UEs, who are most likely located at the cell edge of the hotspot cells (saturated cell) can be offloaded to the cell in the same CoMP cluster with more available resources (lower traffic).

Coined from the comparison, in the event that the number of UEs in each cell is small, the system is not saturated, thus all UEs can achieve expected data rate. In the case that the number of UEs in some cells of the CoMP cluster is high (saturated traffic), when using the proposed DPS mechanism with load-aware, traffic load can be transferred to other cells in the same CoMP cluster with more availability to handle the new connections, thus increasing the number of UEs achieving the expected data rate. On the other

hand, in case of all cells in a CoMP cluster becoming hotspot or has a high number of UEs, the use of DPS and DPS with load-aware mechanisms only cannot increase the number of users achieving the expected data rate. This leads to the plan for our future work to consider also the clustering mechanism in combination with our proposed DPS mechanism to further enhance the system performance through best resource utilization.

Figure 8: Number of UEs achieving expected data rate

5.3. Offered Traffic Load

Figure 9 - 11 illustrate the traffic load of each cell (sector) in a CoMP cluster obtained from the scenario 2. Refer to Figure 3(b), each CoMP cluster is generated with one hotspot cell and the other two normal-traffic cells, known as intra-site CoMP cluster. It can be seen that cells with a large number of UEs or hotspot cells are handling a lot of traffic, no matter what mechanism is being used, since the system has been saturated, as shown in the plot of offered traffic in Figure 9.

Figure 9: Traffic load of cell 1 in eNB 1 (hotspot cell), scenario 2

Figure 10 and 11 show the traffic loads of cell 2 and 3 in the same CoMP cluster as cell 1. In the case of the non-DPS mechanism, these cells with a low number of generated UEs has offered traffic at approximately 20%, but when using the DPS mechanism, traffic load are slightly higher. In the case of the DPS with a load-aware mechanism, traffic load increases to around 35% and 50% in cell 2 and cell 3, respectively. This set of results confirm that our DPS with load-aware mechanism checks the actual traffic load of every cell in the CoMP cluster and uses that as one major criterion for dynamically selecting the transmission point at each decision-making interval. Hence, when one cell is

saturated, the load will be transferred to the other cell(s) in the same CoMP cluster. As seen in the results, the traffic load of cell 1 is offloaded to cell 2 and cell 3. The amount of offloading traffic is not necessarily the same for each cell. It depends on how close the UEs to the cell-edge and the level of traffic loads of the offloading and offloaded cells. Hence, the traffic load results of DPS with the load-aware mechanism shown in Figure 10 and 11 are not the same.

Figure 10: Traffic load of cell 2 in eNB 1, scenario 2

Figure 11: Traffic load of cell 3 in eNB 1, scenario 2

6. Conclusion

In this paper, the actual traffic load-aware DPS has been proposed. The system performance of the traditional LTE-Advanced system, the system embedded with baseline DPS mechanism, and the system embedded with our proposed DPS with actual traffic based load-aware mechanism are investigated. The adapted Vienna downlink system level simulator has been used for the system evaluation. The video streaming traffic model adapted here has been deployed with a data rate of 512 kbps for realistic use cases. The system performance is observed in different dimensions including the throughput performance (peak throughput, mean throughput, and cell-edge throughput), the number of UEs achieving expected data rate, and the traffic load illustrated for each cell in the imbalanced offered traffic scenarios, i.e. simulation scenario 2 implemented here. The four different scenarios have been investigated covering uniformly distributed traffic over the simulation terrain as well as different patterns of hotspot cases. While in the non-saturated traffic case and congestion covering the entire cluster case, all mechanisms perform similarly, our proposed mechanism offers a significant system performance improvement over the other DPS mechanism and traditional system for cases with irregular or imbalanced traffic within a CoMP cluster. As for our future work, a more

flexible clustering mechanism will be studied to further enhance our mechanism.

Finite element method

ABSTRACT

Within the results of scientific research, vibrations and their reduction have been described for the brushless direct current motor with permanent magnets (BLDC motor). In this paper, calculations (the finite element method using commercial Finite Element Software Ansys) and measurements were performed to identifying the sources of vibrations in BLDC motor. The article presents numerical and experimental research on the resonant frequencies of the stator and the rotor; transient vibrations of the stator due to Maxwell forces in the motor have been analysed. It was shown that the natural frequencies were the main source of vibrations. The vibration sources identification made possible formulation of better principles of choice of constructional motor parameters with the aim of attaining minimalization of vibrations.

1. Introduction

Due to the high efficiency, electrical BLDC motors are becoming more widely used within the framework of practical applications. In this field, development of new permanent magnets with the very big energy density is additionally of great importance [1]. The large and impressive technical progress within rotating electrical machines is connected with dynamical extension of power electronics converters. For motors there is possible the modern speed control on a large range. Present-day instantaneous torque/flux control makes possible considerable improving the electrical machines operation. For practical applications, disadvantage of PWM inverters consists in enlargement of the overall motor noise. Here it can be noticed that the special variant is substantial when the phenomenon of resonance appears within the framework of supply harmonics and resonant frequencies of machine's parts. Designers of electric motors ought to undertake an obligation to create less noisy devices [2].

Magnetic sources of vibrations in BLDC motor are caused by Maxwell forces, cogging torque ripple and torque ripple [3, 4]. If the natural frequencies of the stator or the rotor coincide with frequencies of magnetic forces or torque ripple resonance may occur. Also, as a result of imperfections of construction or assembly, rotor eccentricity can occur and distortion of the magnetic field may appear. Owing to this disadvantageous situation, the magnetic force distribution changes and the unbalanced magnetic force exists [5]. Vibrations can also be due to friction of different parts of machine, e.g. bearings.

Aerodynamic noise is generated by the circulation of the cooling medium of the machine.

In literature analytical methods have been also used to describe mathematically Maxwell magnetic forces harmonics taking into consideration both the spatial and time frequency order [3]. For correct designing, the best numbers of slots were found and given in order to attain avoidance of low harmonic radial forces and considerable reduction of vibrations.

The numerical investigation to predict vibrations are based on creation of magnetical and mechanical finite element models [6]. According to the general strategy within the scientific methodology, authenticity of research work may be realized by comparing numerical results with experimental ones. In the magnetic motor model the flux distribution in air-gap and the cogging torque—obtained by calculations - are compared with measurements. In the case of the mechanical model natural vibrations frequencies are compared for theoretical and practical activities. Among other things the accuracy of calculated results depends on proper modeling of magnetic, mechanical and acoustic parameters of the motor structure and the quality of the model of the numerical mesh. The magnetic forces can be minimized by optimizing changes within the geometric parameters of the magnetic circuit.

In literature concerning modern power electronics it was shown that the selecting appropriate strategies of Pulse Width Modulation (PWM) could ensure avoidance of the mechanical resonance [2]. For the other example it was illustrated that geometrical modification of the rotor was the effective method to

*Corresponding Author: Jerzy Podhajecki, Email: jerzypodh@o2.pl

increase natural frequencies and by this constructional way the phenomenon of resonance has been eliminated [7].

2. BLDC motor and magnetic calculations

2.1. The BLDC motor

Taken to theoretical and practical investigations electronically controlled BLDC motor, with the stator having concentrated windings and with the interior rotor possessing permanent magnets, has been presented as three separate parts in Figure 1. The specification of characteristic parameters and different data of the motor are presented in paper [8].

Figure 1: The analysed BLDC motor (stator, rotor) with PWM converter for power supply

Within the fundamental governing equations there is the Maxwell's equation [9]:

$$\text{rot } H = J \quad (1)$$

where H is the magnetic intensity, J – the current density.

In accordance with Gauss's Law, taking into account divergence theorem we have for the magnetic flux density B the following relation:

$$\text{div } B = 0 \quad (2)$$

The relationship between inducing field strength and magnetization intensity is given by:

$$B = \mu H \quad (3)$$

where μ is the magnetic permeability.

The current density distribution of the coil is here described as follows:

$$J = I \cdot J_z \quad (4)$$

Numerical solution of 2-D magnetostatic problem is based on the equation:

$$\Delta^2 A_z = \mu J_z \quad (5)$$

The outer boundary of the stator yoke has been applied for all outer nodes of the stator yoke:

$$A_z(x, y) = A_{z1}(x, y) = 0 \quad (6)$$

The stress tensor method is used for calculation of the magnetic force.

2.2. Magnetic field results

Within the framework of computations concerning the finite element methodics, several assumptions are here taken into consideration. The magnetic field reckoning is performed using the principles connected with the magnetostatic analysis.

For the 2-D FEM model, the BLDC motor is fed with rectangular wave current. The rotor is rotating at one mechanical degree of freedom.

The two-dimensional model for magnetic field calculations is shown in Figure 2 (so-called geometrical model) and in Figure 3 (here it is the numerical mesh – the quarter of the model).

Figure 2: Geometrical model of BLDC 6/8 motor (6 - stator teeth, windings and rotor with 8 - magnets applied)

Figure 4 presents the distribution of the tangential and radial flux densities in motor air-gap. By other means and for the selected rotor position, Figure 5 illustrates the calculated magnetic flux distribution.

Figure 3: Numerical mesh of the magnetic model: stator (the part of stator iron, windings) and rotor with magnets (1/4 of the BLDC motor model)

Figure 4: Radial (rad) and tangential (st) flux densities distribution in the middle of the air-gap in BLDC motor

The Maxwell forces variations identify the mode orders in the electrical machine. The dominant mode shapes are associated with Maxwell force distribution in the air-gap shown in Figure 6. On the ground of detailed analysis of diagrammatic presentation in Figure 6, it can be noticed that the general pattern is repeated twice; here the lowest order of radial force and dominant mode order are equal two [10]. It means that the most important circumferential modes of vibrations of the stator are the second and fourth mode of natural frequencies.

Figure 5: Magnetic flux distribution in BLDC motor

Figure 6: The magnetic forces radial and tangential distribution acting on stator poles in the air-gap in BLDC model

3. Modal analysis

3.1. Modal analysis of stator

Two important reasons: determination of the natural frequency and recognition of the mode shape of structure are the sought purpose of modal analysis. We are interested in characteristics of a structure's dynamics connected with varying loads.

The equation for the free vibrations of the undamped system can be expressed in matrix notation as follows [11]:

$$\{[K] - \omega^2 [M]\} \{u\} = 0 \quad (7)$$

where: $[K]$ - stiffness matrix, $[M]$ - mass matrix, ω - angular frequency, u - displacement matrix. Frequencies: $f = \omega / 2\pi$ and displacement matrix: u are the solutions of the equation (7).

The natural frequencies of vibrations can be excited by radial Maxwell forces acting on the stator poles. The maximum amplitude of vibrations occurs for resonance when the excitation frequency matches with the natural frequency of the motor and the spatial distribution of Maxwell force is similar to one of the mode of the natural frequencies of the stator.

The numerical calculations using Lanchos algorithm of the natural frequencies were performed for two various stator's models: only alone core in the first variant and the core with the

winding in the second case. Within such methodics the stator core is modeled as steel. However in literature it was shown that the influence of windings on vibrations could be also important [12]. Because of the complex structure, windings can be taken into account in simplifying manner by adding mass or by increasing density of stator teeth [13].

To realize calculations with the using finite element method (FEM) and allowing for windings, density of stator teeth has been increased by such manner to accomplish finally the smallest possible error for the dominant second and fourth mode. The compromise value of the density was determined as the following value: $\rho = 1000 \text{ kg} / \text{m}^3$. The selected result is given in Figure 7.

Here it ought to be underlined that – despite of efforts – taking windings in a simplified way in the physical model into consideration causes some errors for other modes of natural frequencies of stator (Table 1). Experimental studies using hammer impact method were conducted to verify the results of the numerical calculations and the radial vibrations were recorded using accelerometers Brüel & Kjær. The results have been given in Figure 8. The comparison between numerical results and outcomes of measurements can be realized on the ground of data given in Table 1.

Figure 7: Modal analysis results of the for stator core with windings modelled by increasing stator density ($r=2$, $f=2400\text{Hz}$)

Figure 8: The natural frequencies of the stator - radial acceleration A_r [m / s²] of stator structure obtained by hammer impact method

Table 1: Natural frequencies of the stator [Hz]

Mode order	FEM - stator yoke	FEM - stator yoke with windings	Measurements (stator yoke with windings)
1	3026	2400	2400
2	4024	5366	4320
3	6753	7101	8120
4	12600	10223	9880

3.2. Modal analysis of rotor

The numerical calculations of the natural frequencies using Lanchos algorithm were performed for two cases: the first variant of the separate rotor and the second case of the rotor with bearings modeled as spring elastic - damping element. The selected result is given in Figure 9.

The shaft is made of steel and ferrite magnets. Calculations were performed for different stiffness to elastic - damping element to fit the measurements best of all [7]. Experimental studies using shaker method were conducted to verify the results of the numerical results and the radial vibrations were recorded using accelerometers Brüel & Kjær by [11]. The obtained exemplary results of calculations and measurements using shaker methods are presented in Table 2.

Figure 9: Modal analysis of rotor model without bearings – numerical results bending mode, $f = 9766$ Hz

Table 2: Calculation bending natural frequencies of the rotor [Hz] for different stiffness of bearings and measurements

Mode of deformation	FEM - 10^6 [N/m]	FEM - 10^7 [N/m]	Measurements
first bending mode	4019	4136	3950
second bending mode	9770	9797	10550

4. Magnetic forces and transient analysis

The magnetic forces depend on the number of teeth, the number of poles and the speed of rotation. The frequencies of magnetic forces in 3-phase BLDC motor can be calculated as follows [4]:

$$f_{lf} = n \cdot p \cdot \frac{N}{60} \quad (8)$$

$$f_{tr} = 6n \cdot \frac{p}{2} \cdot \frac{N}{60} \quad (9)$$

$$f_{ct} = n \cdot l_{cm} \cdot \frac{N}{60} \quad (10)$$

where: n - arbitrary integer, p - number of pairs of poles, l_{cm} - number of stator slots, N - rotor velocity [rpm]. The rotation speed was chosen to be 4000 rpm. The first frequencies of Maxwell forces, torque ripple and cogging torque are equal: $f_{lf} = 533$ Hz, $f_{tr} = 800$ Hz, $f_{ct} = 711$ Hz.

The transient analysis is governed by the following equation [9]:

$$[M][\ddot{u}] + [C][\dot{u}] + [K][u] = F(t) \quad (11)$$

where: $[M]$ - mass matrix, $[K]$ - stiffness matrix, u - vector of displacement; $[C]$ - damping matrix. Newmark method has been employed for differential equation solution. The calculations were carried out for the rotor velocity $N = 4000$ rpm. Magnetic forces calculated in magnetic analysis are loads in the mechanical analysis. In keeping with the energy absorbing in the constructional structure of the BLDC motor, mainly due to the windings, structural damping has been presented [9]. However due to lack of the experimental data damping are assumed to zero. The maximum amplitude of vibration occurs near the resonant frequencies the second and fourth natural frequency of the stator. The results are given in Figure 10 and Figure 11. The stator deformation due to magnetic forces during no-load for selected time-steps are presented (Figure 12 and Figure 13).

Figure 10: Numerical transient analysis of stator vibrations due to magnetic forces - velocity versus time V [m/s] - radial (blue) and tangential velocity (green) for selected outer node

Figure 11: Numerical transient analysis - Fourier analysis of radial velocity for selected outer stator node of stator V [m/s] - radial (blue) and tangential velocity (green)

Figure 12: Numerical transient analysis - the stator deformation and displacement U [m] for selected time-step

Figure 13: Numerical transient analysis of stator deformation and Von Mises stress σ_{eqv} [Pa] for selected time-step

5. Measurements of BLDC in no-load mode

Experimental studies were conducted to verify the numerical results. The rotation speed in no-load mode was equal 4000 rpm. The maximum oscillation amplitude occurs near the natural frequencies of the stator (second mode vibration: $f = 2960$ Hz and fourth mode vibration: $f = 10020$ Hz) and rotor (second bending mode of rotor: $f = 10550$ Hz measured for the rotor placed within the motor structure by shaker method) – Figure 14. Here it is advisable to make a note of additional information that the investigated motor was suspended by elastic springs. The current was recorded in no-load mode and its Fourier transformation is presented in Figure 15. It can be noticed that the vibrations spectrum was similar for different values of velocity of the rotor. The main sources of vibrations are resonant frequencies excited by magnetic forces and in keeping with different electric machine imperfections creating harmonic forces exciting the bending mode of the rotor [3]. It may be concluded from comparison of Fourier analyses (FFT). In Figure 14 this analysis is realized within the radial velocity of vibrations however in Figure 15 the current of the motor stator can be investigated.

Figure 14: Measurement of stator vibrations - Fourier analysis of radial velocity V_r [mm/s] for selected point

Figure 15: Measurement of current supply I [A] of BLDC motor during no-load mode - Fourier analysis

6. Conclusions

Due to the high efficiency, electrical BLDC motors are becoming more widely used as torque motors in control systems and instrumentation. One of the disadvantages of BLDC motor is the increase in noise due to the use of PWM converters, so the study of the possibilities of reducing motor noise is an important problem. The article investigated the natural frequencies of the stator and the rotor, as well as the possibility of resonance due to coincidence of the frequency of magnetic forces and the pulsation of the motor torque with natural vibrations of the stator or rotor.

The study of the magnetic forces in the air gap using the finite element method allowed us to determine the main modes of the magnetic forces, the influence of which can lead to the occurrence of resonance and an increase in motor noise. The analysis of the natural frequencies of the stator was carried out on the basis of the equation of free oscillations without taking into account damping. The influence of the windings was taken into account in a simplified way, by adding mass to the stator by increasing density of stator teeth, which led to a small error for most important circumferential modes of vibration of the stator (the second and fourth mode natural frequencies) and significant error in comparison with the experimental results for the other natural frequencies.

The natural frequencies of the rotor were also determined by comparing experimental and numerical results calculated for different stiffness values of the bearings implemented as spring elastic - damping elements.

Transient stator vibrations due to magnetic forces were depending on the number of teeth, the number of poles, and the speed of rotation. The rotation speed was equal 4000 rpm. Experimental studies were conducted to verify the results. The maximum oscillation amplitude occurs near the natural frequencies of the stator and rotor. Hence, it is concluded that the main sources of vibration are the natural frequencies of the motor.

During motor operation and rotation of the rotor, the form of the stator vibrations may change the dominant order of mode. These scientific results should be taken into account when designing the BLDC motor.

ABSTRACT

Haze removal is an extremely challenging task, and object detection in the hazy environment has recently gained much attention due to the popularity of autonomous driving and traffic surveillance. In this work, the authors propose a multiple linear regression haze removal model based on a widely adopted dehazing algorithm named Dark Channel Prior. Training this model with a synthetic hazy dataset, the proposed model can reduce the unanticipated deviations generated from the rough estimations of transmission map and atmospheric light in Dark Channel Prior. To increase object detection accuracy in the hazy environment, the authors further present an algorithm to build a synthetic hazy COCO training dataset by generating the artificial haze to the MS COCO training dataset. The experimental results demonstrate that the proposed model obtains higher image quality and shares more similarity with ground truth images than most conventional pixel-based dehazing algorithms and neural network based haze-removal models. The authors also evaluate the mean average precision of Mask R-CNN when training the network with synthetic hazy COCO training dataset and preprocessing test hazy dataset by removing the haze with the proposed dehazing model. It turns out that both approaches can increase the object detection accuracy significantly and outperform most existing object detection models over hazy images.

1 Introduction

This paper is an extension of work initially presented in conference name [1]. Computer vision has recently played a major role in broad applications on urban traffic, such as autonomous and assisted driving, traffic surveillance, and security maintenance. However, the existence of haze, mist, dust, and fumes can severely degrade the visibility of images captured outside. Haze generates reduced contrasts, faded surfaces, and color distortion to outdoor scenes, which will inevitably complicate many advanced computer vision tasks, including object classification and segmentation. Since the depth information of haze is non-linear and dependent over a global scene, haze removal becomes a challenging task. Most computer vision algorithms are designed based upon haze-free input images. They benefit a lot from haze removal, making it a highly desired task in computational photography and computer vision applications.

Many algorithms have been proposed to restore clear images from hazy images. Polarization-based methods presented in [2]–[3] analyze the polarization effects of atmospheric scattering and re-

move haze through as few as two images with different degrees of polarization. Depth-based approaches introduced in [4], [5] evaluate depth information upon some assumptions or priors, then estimate transmission map $t(x)$ and atmospheric light A from it. Some recent CNN-based haze-removal models proposed in [6]–[7] are built upon various powerful CNNs to self-learn transmission map $t(x)$ directly from large-scale image datasets. Among effective conventional dehazing algorithms, Dark Channel Prior (DCP) [8] is generally accepted due to its novel prior and outstanding performance. In most non-sky patches of the haze-free image, at least one color channel contains dark pixels with extremely low intensity, which is primarily generated by the air light. However, the estimation on the medium transmission $t(x)$ and atmospheric light A is not precise, especially when the scene object is inherently similar to the air light over a large local region and no shadow is cast on it. And the restored image looks unnaturally dark when there is a sky region with sunlight.

In this paper, the authors propose a novel Multiple Linear Regression Dark Channel Prior based model (MLDCP). Trained with

the training dataset in REalistic Single Image DEhazing (RESIDE) [9], the MLDCP model can optimize the rough estimation of transmission map $t(x)$ and atmospheric light A by self-learning. The authors show experimentally on RESIDE test dataset that their model achieves the highest SSIM and PSNR values (two important full-reference metrics) compared with DCP and some other well-known state-of-the-art dehazing algorithms and CNN-based architectures. The authors further evaluate the effect on object detection in the hazy environment when dehazing the test images by their MLDCP model. Besides, the experimental results demonstrate that MLDCP not only enhances the performance of object detection in the hazy environment but also outperforms most dehazing algorithms on this task with higher detection accuracy.

The authors also present a straightforward and flexible algorithm to generate synthetic haze to any existing image datasets, inspired by a reversed MLDCP model. The authors aim to enhance object detection performance in the hazy environment by utilizing synthetic hazy images as training datasets. In the experiment, this algorithm is applied to MS COCO training dataset [10] by adding synthetic haze to the images and build a new Hazy-COCO training dataset. The authors evaluate the mean average precision (mAP) of Mask R-CNN [11], a widely adopted object detection and segmentation model, by training the network with the Hazy-COCO training dataset. The experimental results indicate that it leads to an impressive improvement when preprocessing training datasets with the inverse MLDCP algorithm.

2 Related Work

2.1 Overview of Dehazing Algorithms

2.1.1 Background Knowledge

In computer vision, the widely used atmospheric scattering model to describe the generation of a hazy image is as follows:

$$I(x) = J(x)t(x) + A(1 - t(x)) \quad (1)$$

where $I(x)$ is the observed intensity (hazy image), $J(x)$ is the scene radiance (haze-free image), $t(x)$ is the medium transmission map, and A is the atmospheric light. The first term $J(x)t(x)$ is called attenuation and the second term $A(1 - t(x))$ is called airlight [12].

The medium transmission map $t(x)$ describes the portion of the light that is not scattered and reaches the camera [8]. When the atmosphere is homogeneous, the transmission matrix $t(x)$ can be defined as:

$$t(x) = e^{-\beta d(x)} \quad (2)$$

where β is the scattering coefficient of the atmosphere, and $d(x)$ is the scene depth representing the distance between the object and camera.

Most state-of-the-art single image dehazing algorithms exploit the atmospheric scattering model (1) and estimate the transmission matrix $t(x)$ and the atmospheric light A in either physically grounded or data-driven ways. Then the haze-free images $J(x)$ can be recovered by computing the reformulation of (1):

$$J(x) = \frac{1}{t(x)}I(x) - A \frac{1}{t(x)} + A \quad (3)$$

2.1.2 Conventional Single Image Dehazing Algorithms

Haze removal is a challenging task due to the non-linear and dependent depth maps over a global scene in hazy images. Many efforts have been made to tackle this challenge by exploiting natural images priors and depth statistics. Most conventional dehazing algorithms focus on predicting two critical parameters, medium transmission matrix $t(x)$ and global atmospheric light A , which are necessary to recover haze-free images via computing (3). In [12], an automated method is proposed based on the observation that the contrast of a haze-free image is higher than that of a hazy image. Furthermore, a Markov Random Fields (MRFs) framework is implemented to estimate the atmospheric light A by maximizing the local contrast of a hazy image. The output results are visually impressive but may not be physically valid. Assuming that the transmission and surface shading is uncorrelated in local areas, the authors eliminate the scattered light by locally estimating the optical transmission map of the scene with constant constraints in [13]. Despite its compelling results, it may fail in the cases with heavy haze and lead to the inaccurate estimation of color and depth maps.

A widely recognized single image dehazing algorithm called Dark Channel Prior (DCP) is proposed in [8], which can estimate the transmission map $t(x)$ more reliably. A regular pattern is found that in most non-sky patches of haze-free images, at least one color channel (dark channel) has some pixels whose intensity is very low and even close to zero. Then this pixel-based observation can be formally described by defining the dark channel J^{dark} as:

$$J^{dark}(x) = \min_{y \in \Omega(x)} (\min_c J^c(y)) \approx 0 \quad (4)$$

where c indicates RGB color channels and y refers to the pixel in a local patch $\Omega(x)$ centered at x . Adding minimum operators to both sides of the transformation of (1):

$$\min_{y \in \Omega(x)} (\min_c \frac{I^c(y)}{A^c}) = \tilde{t} \min_{y \in \Omega(x)} (\min_c \frac{J^c(y)}{A^c}) + 1 - \tilde{t} \quad (5)$$

Transmission map \tilde{t} can be put outside of the minimum operators based on the fact that \tilde{t} is a constant in the patch.

Since the dark channel of a haze-free image can be approximately taken as 0, the multiplicative term in (5) can be eliminated by adding (4). Then transmission map \tilde{t} can be predicted by:

$$\tilde{t} = 1 - \omega \min_{y \in \Omega(x)} (\min_c \frac{I^c(y)}{A^c}) \quad (6)$$

The additional parameter ω is a constant parameter that optionally controls the degree of haze removal. Even in a haze-free image, the haze still exists among distant objects. A small amount of haze will keep the vision perceptual natural with the sense of depth. The dehazing parameter determines how much haze will be removed.

In case that the recovered scene radiance $J(x)$ is prone to noise when transmission map $t(x)$ is extremely low, DCP restricts $t(x)$ by a lower bound t_0 , which is set to 0.1 in [8]:

$$\tilde{t} = \max(t(x), t_0) \quad (7)$$

As for the estimation of atmospheric light A , it is defined as the color of the most haze-opaque regions in [12], which refers to the brightest pixels in a hazy image. However, this assumption only

applies when there is no sunlight in local regions. This limitation is optimized in [8] by considering the sunlight and adopting the dark channel to detect the most haze-opaque. DCP picks the top 0.1 percent brightest pixels in the dark channel, among which the pixels with the highest intensity in an input image are selected as the atmospheric light.

2.1.3 Limitations of DCP

DCP has some limitations that it may fail to accurately estimate transmission map $t(x)$ and atmospheric light A , when object surfaces are essentially analogous to the air light over a local scene without any projected shadows. Although DCP in [8] takes sunlight into consideration, the influence of sunlight is still tremendous when there is strong sunlight in the sky region. It will underestimate the transmission map of these objects and overestimate the haze layer. Thus the brightness of the restored image is darker than the real-world haze-free image. The authors compare a group of hazy images and recovered images from DCP, the color distortion in the sky region can be observed obviously in Figure 1:

Figure 1: Limitations of DCP

Additionally, the constant parameter ω in (6) is fixed to 0.95 in [8] without any changes corresponding to different haze distributions. Excessive haze removal will create color distortion, and images with insufficient haze removal will remain blurred. In order to solve this problem, the authors propose a dehazing parameter adaptive method in [14] based on DCP that estimates dehazing parameter ω locally instead of globally. It can automatically adjust the value of ω according to the distribution of haze. DCP in [8] implements soft matting to optimize the estimation of transmission map $t(x)$, which is further enhanced to be more accurate and ef-

ficient by utilizing an explicit image filter called *guided filter* in [15]. In [16], the authors point out that traditional DCP has not fully exploited its potential and will generate undesirable artifacts due to inappropriate assumptions or operations. Then it introduces a novel method that estimates transmission map $t(x)$ by energy minimization. The energy function combines DCP with piecewise smoothness and obtains an outstanding performance compared to conventional pixel-based dehazing algorithms. Several attempts have been made in [17], [18] to process the color distortion and optimize the restoration in some bright regions, such as the sky and reflective surfaces.

2.1.4 Overview of CNN-based Dehazing Algorithms

In recent years, neural network has made significant progress in numerous computer vision tasks [19], [20] and natural language processing tasks [21], [22]. Various Convolutional Neural Networks (CNNs) are designed to obtain a more accurate estimation of transmission matrix $t(x)$ by self-learning the mapping between hazy images and corresponding transmission maps, which outperform most conventional dehazing algorithms. DehazeNet in [23] is an end-to-end system built upon a deep convolutional neural network whose layers are specially designed to embody established priors in haze removal. Furthermore, a novel non-linear activation function is executed to improve the quality of output recovered images. A multi-scale deep neural network is proposed in [7] to dehaze a single image, which consists of a coarse-scale stage that roughly predicts the transmission matrix $t(x)$ over a global view, and a fine-scale stage that refines the rough estimation locally. In [24], the DCP energy function is defined as the loss function in a fully-convolutional dilated residual network. Feeding the network with real-world outdoor images, it minimizes the loss function completely unsupervised during the training process. A light-weight CNN model called All-in-One Dehazing Network (AOD-Net) in [6] is designed based on a reformulated atmospheric scattering model. It generates the recovered images directly and can be widely embedded into other deep CNN models to enhance the performances of some high-level tasks over hazy images.

2.1.5 Dehazing Benchmark Datasets and Metrics

Traditional haze-removal algorithms used to evaluate and compare dehazing performances by merely presenting a group of hazy images and dehazed images restored from various dehazing algorithms. The enhancement of dehazing performance is expected to be observed from the visual comparison of images. However, it is not convincing to prove that a new dehazing algorithm outperforms other algorithms only from human eyes perception. Two widely adopted image metrics to evaluate and compare single image dehazing algorithms are PSNR and SSIM [25]. PSNR refers to the peak-signal-to-noise ratio, which is generally applied to evaluate the image quality. SSIM refers to the structural similarity index measure, a well-known metric to measure the similarity between two images. Since it is generally impossible to capture the same visual scene with and without haze, while all other environmental conditions stay identical, it is incredibly challenging to measure the SSIM value between a hazy image and its haze-free ground truth

image. Therefore, recent efforts have been made to create synthetic hazy images from haze-free images based on the depth information.

In [26], the authors build two sets of images without haze and with synthetic haze from both real-world camera captured scenes and synthetic scenes to evaluate the performance of the proposed visibility enhancement algorithm. They utilize the software to generate 66 synthetic images built upon a physically-based road environment. By obtaining the depth information, four different fog types are added to 10 camera images and finally create a dataset with over 400 synthetic images in total. A fog simulation is proposed in [27] by simulating the underlying mechanism of hazy image formation (1) and utilizing the standard optical model for daytime haze. The fog simulation pipeline is leveraged to add synthetic fog to urban scenes images in Cityscapes dataset [28] and generate a Foggy Cityscapes dataset. Foggy Cityscapes dataset consists of 550 refined high-quality synthetic foggy images with detailed semantic annotations and additional 20000 synthetic foggy images without sufficient annotations.

The REAListic Single Image DEhazing (RESIDE) dataset [9] is the first large-scale dataset for benchmarking single image dehazing algorithms, and it includes both indoor and outdoor hazy images. RESIDE dataset also contains a large-scale synthetic training set and two sets designed respectively for objective and subjective quality evaluations. Moreover, in the supplementary RESIDE- β set, they add annotations and object bounding boxes to an evaluation set consisting of 4322 real-world hazy images, which can be utilized to test the performance of object detection in the hazy environment. A rich variety of criteria beyond PSNR and SSIM is also provided in [9] to evaluate the performance of dehazing algorithms, including full-reference metrics, no-reference metrics, subjective evaluation, and task-driven evaluation. However, the criteria are only practically applicable to the global performance of haze-removal. It cannot embody the difference locally between two images, failing to judge if our MLDCP model outperforms traditional DCP specifically in the bright region. Therefore, the authors compare dehazing performances experimentally with both recovered images' visual quality and two pivotal metrics PSNR and SSIM.

2.2 Overview of Object Detection Models

Object detection is the combination of object classification and localization, which can both recognize and localize all object instances of specific categories in an image. Due to its close relationship with image and video analysis, object detection has been widely applied in various computer vision tasks, especially in autonomous driving, traffic surveillance, and some other smart city fields.

Fast R-CNN refers to Fast Region-based Convolutional Network [29]. The network is fed with an image and a set of object proposals and outputs a convolutional feature map. A region of interest (RoI) pooling layer is proposed to extract a fixed-length feature vector and feed it into a sequence of fully connected layers. The output layers contain a softmax layer that estimates the softmax probability over K object classes plus a background class, and another layer with offset values that refine the bounding box positions of an object. Fast R-CNN overcomes the disadvantages of R-CNN and SPPnet [30] with a higher detection accuracy as well as faster training and test speed. Later in [31], a Region Proposal Network

(RPN) is added into Fast R-CNN generating a Faster R-CNN. The RPN aims to simultaneously propose candidate object bounding boxes and corresponding scores at each position. It then implements RoIPool in Fast R-CNN to extract features from each candidate box and perform classification as well as bounding-box regression. Both RPN and Fast R-CNN are trained independently but share the same convolutional layers. While achieving state-of-the-art object detection accuracy, the unified network can further increase the speed significantly.

Mask R-CNN [11] extends the Faster R-CNN by an output branch with a binary mask for each RoI, in parallel to a branch for bounding-box recognition and classification. However, the quantization of RoIPool in Faster R-CNN has a negative effect on predicting binary masks. To remove this harsh quantization, Mask R-CNN replaces RoIPool with a RoIAlign layer that aligns the extracted features with the input properly. It can efficiently detect object instances in an image and simultaneously generate a pixel-accurate segmentation mask for each instance. Due to its compelling performance and influential architecture, Mask R-CNN is widely used as a solid baseline to exploit more object detection tasks.

2.3 Domain Adaption Methods

Domain adaptation is a novel strategy that can be utilized to advance object detection models [32]–[33]. And it has been proved effective, especially in some extreme weather [34], [35], such as hazy, rainy, and snowy. A Domain Adaptive Faster R-CNN is proposed in [34] to enhance the cross-domain robustness of object detection. Based on H-divergence theory, two domain adaptation components on image level and instance level are integrated into Faster R-CNN architecture, aiming to reduce the domain discrepancy at both levels. Training data with images and full supervision is used as the source domain, and only unlabeled images in test data are available for the target domain. For both components, it adapts the classifier trained on a source domain and implements the adversarial training strategy to learn domain-invariant features. The method further incorporates a consistency regularization into the Faster R-CNN model to obtain a domain-invariant region proposal network (RPN).

Inspired by Domain Adaptive Faster R-CNN in [34], the authors in [36] adopt a similar idea and designs a Domain-Adaptive Mask-RCNN (DMask-RCNN). The source domain takes the clean images in the MS COCO dataset, and the target domain takes unannotated real-world hazy images in RESIDE dataset [9], and their dehazed output images by MSCNN [7] respectively. And DMask-RCNN adds a domain-adaptive branch after the base feature extraction layers in Mask R-CNN architecture, aiming to mask the generated features to be domain-invariant between the source domain and target domain. The experimental results in [34], [36] demonstrate that the domain adaptation method can enhance the performance of both Faster R-CNN and Mask R-CNN models when tackling the object detection task in the hazy environment. Moreover, this enhancement can be more effective when feeding the target domain with images restored by a robust dehazing algorithm.

2.4 Object Detection Datasets

Object recognition is a core task to understand a visual scene in computer vision, which involves several sub-tasks, including image classification, object detection, and semantic segmentation. All three tasks have high demands for image datasets. Object classification requires each image to be labeled with a sequence of binary numbers, which indicate if object instances exist in the image or not. Object detection is more challenging, which combines object classification and localization. It not only identifies which specific class an object belongs to but also locates it in an image. The object localization requires collecting bounding boxes that locate one or more objects in an image, which is a considerable workload in a large-scale image dataset. The PASCAL VOC challenge [37] is a widely recognized benchmark in visual object recognition and detection. The VOC2007 dataset contains 20 object categories spread over 11000 images. The annotation procedure is designed to be consistent, accurate, and exhaustive, and annotations are made available for training, validation, and test data. The ImageNet dataset [38] involves millions of cleanly labeled and full-resolution images in the hierarchical structure of WordNet [39]. The dataset provides an average of 500-1000 images to illustrate each synset in a majority of 80000 synsets of WordNet. Many object recognition algorithms have made a significant breakthrough by using the training resource of the ImageNet dataset. This benchmark dataset also plays an essential role in advancing object recognition tasks.

Semantic segmentation requires labeling each pixel in an image to a category, and it is an extremely time-consuming task to build a large-scale dataset with detailed semantic scene labeling. The Microsoft COCO dataset [10] consists of about 3.3 million images, and over 2 million of them are labeled. It collects 91 common object categories, which are fewer than the ImageNet dataset. However, in contrast to both the VOC2007 dataset and ImageNet dataset, MS COCO dataset contains significantly more instances per category and considerably more object instances per image. And every instance of each object category is fully labeled and segmented by a novel instance-level segmentation mask. MS COCO dataset has been widely utilized for training some more complex CNN architectures that aim to make further progress on object recognition as well as semantic segmentation tasks.

3 Proposed Methods

3.1 Multiple Linear Regression DCP Model

DCP estimates transmission map $t(x)$ from (6) and selects the pixels in the dark channel with the highest intensity among the top 0.1 percent brightest pixels as the atmospheric light A . Then hazy images can be recovered from (3) motivated by the estimations of $t(x)$ and A . However, the rough estimations in DCP introduced in Section 2.1.3 can generate some unpredicted deviations, which are theoretically impossible to be eliminated during the estimation process. Now the authors implement a multiple linear regression model to optimize the haze-removal algorithm in DCP.

Multiple linear regression is a statistical technique using several explanatory variables to predict the output response variable. As a predictive analysis, multiple linear regression aims to model the

linear relationship between two or more independent variables and a continuous dependent variable. The authors still adopt the rough estimations on transmission map $t(x)$ and atmospheric light A in DCP. Three components $\frac{I(x)}{t(x)}$, $\frac{A}{t(x)}$ and A in (3) can be regarded as explanatory variables, since $I(x)$ refers to the pixel of input hazy image while $t(x)$ and A can be estimated from DCP. The scene radiance $J(x)$, which refers to the pixel of output recovered image, can be regarded as the response variable. The authors add regression coefficient weights to each explanatory variable and a constant term (bias) to the atmospheric scattering model. Then (3) can be reformulated as a multiple linear regression model (8), which describes how the mean response $J(x)$ changes with explanatory variables:

$$J(x) = \omega_0 \frac{I(x)}{t(x)} + \omega_1 \frac{A}{t(x)} + \omega_2 A + b \quad (8)$$

As the authors introduced, DCP is already an effective dehazing algorithm even with the rough estimations on $t(x)$ and A . The authors implement a multiple linear regression model to optimize DCP by learning the relationships between hazy images with haze-free images, which is extremely challenging to find out in traditional pixel-based dehazing algorithms. Since both $J(x)$ and A are defined and estimated on RGB color channels, the dimensions of three weights and a bias should be (3,1), intending to refine the parameters at all three color channels. The Outdoor Training Set (OTS) in RESIDE dataset [9] provides 8970 outdoor haze-free images, each of which also contains 30 synthetic hazy images with haze intensity ranging from low to high. During the training process, the network learns the relationships between output recovered images and their relevant haze-free ground truth images. However, it is theoretically impossible to obtain the ground truth image of a real-world hazy image. The most efficient approach is referring to a real-world haze-free image as ground truth image and its synthetic hazy image as input image respectively. The various intensity of synthetic haze guarantees that the MLDCP model can be applied to more than a fixed haze intensity in real-world scenes.

When MLDCP model is trained on OTS dataset, the authors refer to haze-free images as target ground truth images J , refer to synthetic hazy images as input images I , and refer to the recovered images as output images J_ω . In order to simplify the formula (8) during the training process, the authors assign $x_0 = \frac{I(x)}{t(x)}$, $x_1 = \frac{A}{t(x)}$ and $x_2 = A$. Then (8) can be reformulated as:

$$J_\omega(x) = \omega_0 x_0 + \omega_1 x_1 + \omega_2 x_2 + b \quad (9)$$

The deviations between the output images J_ω and the target ground truth images J are estimated by mean-squared error (MSE):

$$MSE = (J - J_\omega)^2 \quad (10)$$

MSE measures the average squared difference between an observation's actual and predicted values, which is commonly adopted in linear regression models. The loss function of MLDCP is evaluated based upon MSE:

$$L(\omega) = \frac{1}{2n} \sum_{i=1}^n (J^{(i)} - J_\omega^{(i)})^2 \quad (11)$$

During the training process, the authors calculate the gradient of loss function by Stochastic Gradient Descent (SGD), a widespread

and effective technique to address optimization tasks. Then the optimal weights and bias can be obtained by minimizing MSE through the following steps:

- Implement SGD to compute the derivative of loss function to find the gradient of the error generated from current weights and bias, and adjusts the weights by moving in the direction opposite of the gradient to decrease MSE. Then authors iteratively update three weights via:

$$\omega_k = \omega_k - \alpha \frac{\partial}{\partial \omega} L(\omega) \quad (12)$$

where α is the learning rate, and $k \in (0, 1, 2)$.

- Expand the derivative of loss function (11), then (12) can be reformulated as:

$$\omega_k = \omega_k - \alpha \frac{1}{n} \sum_{i=1}^n (\mathbf{J}^{(i)} - \mathbf{J}_\omega^{(i)}) x_k \quad (13)$$

- Update the bias with the same process repeatedly by training each image in OTS dataset via:

$$b = b - \alpha \frac{1}{n} \sum_{i=1}^n (\mathbf{J}^{(i)} - \mathbf{J}_\omega^{(i)}) \quad (14)$$

When the optimal weights and bias are obtained from the training process, they can be added to the haze-removal model (8) directly, and real-world hazy images can be dehazed in the same way as that in conventional DCP. The improved performance is determined by the quality of synthetic hazy images. If the synthetic haze is more close to the real-world haze, the MLDCP model can learn more realistic haze information during the training process, and the dehazing performance can be further enhanced.

3.2 Synthetic Haze Generated Model

There have been some large-scale image datasets released for the object detection task. However, few image datasets are built just for object detection in extreme weather like hazy and rainy. The Real-world Task-driven Testing Set (RTTS) in RESIDE [9] contains 4322 real-world hazy images annotated with both object categories and bounding boxes, which is an essential contribution taken as a test dataset for object detection task in the hazy environment. However, even with data augmentation techniques, its amount of training images is far less efficient in training an object detection model in comparison with the larger scale of the MS COCO training dataset [10]. It means a considerable workload to build a large-scale image dataset with detailed annotations and segmentation instances like MS COCO or PASCAL VOC. And the rarity of real-world hazy images, especially in urban cities, makes it more challenging to collect the same amount of high-quality hazy images as those in the MS COCO training dataset.

The authors propose an algorithm that generates synthetic haze to any existing large-scale haze-free image datasets without much computation. Inspired by the multiple linear regression haze-removal model, the authors propose a new algorithm that implements a similar inverse MLDCP model to add synthetic haze to an

image. If an object detection model is trained on the synthetic hazy dataset generated by this algorithm, its performance of detecting an object in hazy weather can be significantly enhanced.

Since DCP is an effective dehazing algorithm, and the multiple linear regression model can further exploit its potential, the authors suppose that similar ideas can also be applied to synthesize higher quality hazy images based on the regular dark channel pattern. Co-efficient weights and bias are added to (1), which is expected to maximally restore the deviations between haze-free images and their relevant synthetic hazy images. Then the reformulated atmospheric scattering model is obtained as follows:

$$\mathbf{I}(x) = \beta_0 \mathbf{J}(x)t(x) + \beta_1 A t(x) + \beta_2 A + b \quad (15)$$

The synthetic haze generated model is still trained on OTS in RESIDE dataset [9]. In contrast to MLDCP model, the authors refer to haze-free images as input images \mathbf{J} and refer to synthetic hazy images in OTS as target images \mathbf{I} . And the output synthetic hazy images are taken as \mathbf{I}_β . The cost function is defined based on MSE that evaluates the deviations between the output images \mathbf{I}_β and target images \mathbf{I} :

$$L(\beta) = \frac{1}{2n} \sum_{i=1}^n (\mathbf{I}^{(i)} - \mathbf{I}_\beta^{(i)})^2 \quad (16)$$

The authors implement SGD during the training process to travel down the slope of cost function until it reaches the bottom lowest value, and three weights and a bias are updated iteratively by calculating the derivative of cost function as follows:

$$\beta_k = \beta_k - \alpha \frac{1}{n} \sum_{i=1}^n (\mathbf{I}^{(i)} - \mathbf{I}_\beta^{(i)}) x_k \quad (17)$$

$$b = b - \alpha \frac{1}{n} \sum_{i=1}^n (\mathbf{I}^{(i)} - \mathbf{I}_\beta^{(i)}) \quad (18)$$

where $k \in (0, 1, 2)$ and x_k equals to $\mathbf{J}(\mathbf{x})t(x)$, $A t(x)$, and A in (15) respectively.

In fact, traditional DCP does not support the inverse functionality of generating synthetic haze to a haze-free image. Self-learning the haze information from input synthetic hazy images, the MLDCP model fully utilizes the superiority of DCP to generate a much higher quality synthetic haze with a more similar visual and inherent effect to real-world haze. Additionally, the inverse MLDCP model can add various intensities of haze to an image dataset, making it possible to train an object detection model on training datasets with different synthetic haze intensities corresponding to the density of real-world haze in test images. Since the method focuses on the enhancement by preprocessing the training dataset, it can be applied simultaneously with any improvements on the object detection models or preprocessing images in test datasets with more effective dehazing algorithms.

4 Experiment Results and Analysis

4.1 MLDCP Dehazing Performance

4.1.1 Experiment Setup

In the experiment, both training and test datasets are obtained from RESIDE dataset [9]. In the training process, 8970 haze-free images

and their corresponding synthetic hazy images in the OTS dataset are utilized for training the MLDCP model. In the test phase, the Synthesis Object Testing Set (SOTS) is used to test the dehazing performance. Since MLDCP focuses on recovering outdoor hazy scenes, the authors do not evaluate its dehazing performance over the 500 synthetic indoor images in SOTS. The dehazing performance of MLDCP is compared with conventional DCP on both SSIM and PSNR metrics over 500 outdoor synthetic hazy images and their haze-free ground truth images.

4.1.2 Dehazing Performance on SOTS Dataset

In Figure 2, the authors present the comparison of recovered images by conventional DCP and our MLDCP model. It is obviously observed that the recovered image by DCP (c) suffers from the color distortion in the sky region. In contrast, the recovered image by MLDCP (d) performs competently even in the sky region with strong sunlight. And the non-sky region in (c) is much darker than that in (d), and it looks unreal. In comparison with the input synthetic hazy image (a), MLDCP almost removes the haze completely. Besides, its recovered image (d) looks natural and shares a high similarity with the ground truth haze-free image (b).

Figure 2: Comparison on synthetic hazy image. (a) is a synthetic hazy image in SOTS, (b) is the haze-free ground truth image, (c) is recovered by conventional DCP algorithm, (d) is recovered by our MLDCP model.

The authors compare the dehazing performance of MLDCP with several conventional dehazing algorithms as well as some CNN-based haze removal models over two major image benchmark metrics PSNR and SSIM. PSNR evaluates the quality of recovered images, while SSIM measures the similarity between recovered images and haze-free ground truth images. In Table 1, MLDCP model increases PSNR and SSIM by 5.3 and 0.23 respectively in comparison with the conventional DCP. Compared with the performances of other widely adopted dehazing algorithms obtained from [9], the proposed MLDCP model achieves a reasonably acceptable PSNR value and the highest SSIM value. Considering that SSIM

is essentially more dominant than PSNR when indicating the pixel-wise effect of haze removal, MLDCP outperforms all other dehazing algorithms in Table 1.

Table 1: Average SSIM and PSNR comparison among different dehazing algorithms over 500 outdoor synthetic hazy images in SOTS.

500 outdoor images		
Dehazing method name	PSNR	SSIM
Improved DCP model	23.84	0.9411
DCP	18.54	0.7100
FVR	16.61	0.7236
CAP	23.95	0.8692
NLD	19.52	0.7328
BCCR	17.71	0.7409
GRM	20.77	0.7617
DehazeNet	26.84	0.8264
MSCNN	21.73	0.8313
AOD-Net	24.08	0.8726

4.1.3 Real-world Hazy Images Dehazing

Even though synthetic benchmark datasets and metrics have achieved great success in comparing dehazing performances, the visual effect of synthetic haze is still different from the real-world haze. In Figure 3, the authors also present the recovered images by conventional DCP and MLDCP from real-world nature hazy scenes (first three rows) and hazy scenes in urban cities (last three rows). It is obviously observed that the MLDCP model performs better than conventional DCP in both sky and non-sky regions. The output images restored by MLDCP prevent the color distortion in sky regions, and the brightness over a global view seems more natural and closer to realistic haze-free scenes.

4.2 Object Detection with Pre-dehazed Test Dataset

4.2.1 Experiment Setup

Some object detection tasks on RESIDE RTTS dataset have been tested in [6], [9], [36]. The Domain-Adaptive Mask R-CNN model proposed in [36] achieves the highest detection accuracy on RTTS test dataset among several well-known object detection models including Faster R-CNN [31], Mask R-CNN [11], SSD [40] and RetinaNet [41]. A concatenation of dehazing algorithm and object detection modules is proposed in [6] to detect objects in the hazy environment. In [36], the authors further try more combinations of effective dehazing algorithms and object detectors in the cascade and evaluate their performances on the mean average precision (mAP) values. MLDCP model is utilized to dehaze the RTTS test dataset, and Mask R-CNN and DMask-RCNN modules are fed with the recovered images. Then the authors compare the detection accuracy with the results of dehazing-detection cascades in [36].

In Table 2, the proposed cascade of MLDCP dehazing model and Mask R-CNN or Mask R-CNN increases the detection accuracy by about 2% or 1.7% respectively, which is the highest in comparison with other dehazing approaches, including AOD-Net [6], MSCNN [7] and conventional DCP [8]. And pre-dehazing RTTS dataset with MSCNN and DCP can both enhance the performance of object

detection in the hazy environment. In [6], AOD-Net outperforms several dehazing algorithms on PSNR and SSIM values. However, it decreases the mAP result of DMask R-CNN from 61.72% to 60.47%, which means that a better dehazing performance on PSNR and SSIM values does not align with a higher accuracy on object detection in the hazy environment.

Figure 3: Visual comparison between real-world hazy images (first column), recovered images from DCP (second column) and recovered images from MLDCP (third column).

Table 2: Object detection accuracy (mAP) comparison among different dehazing-detection cascades

Framework	mAP(%)
Mask R-CNN	61.01
DMask R-CNN2	61.72
MLDCP + Mask R-CNN	63.06
AOD-Net + DMask R-CNN2	60.47
MSCNN + DMask R-CNN2	63.36
DCP + DMask R-CNN2	62.78
MLDCP + DMask R-CNN2	63.42

4.3 Object Detection with Hazy-COCO Dataset

4.3.1 Experiment Setup

The authors train Mask R-CNN on the new Hazy-COCO training dataset and evaluate its performance in comparison with the original Mask R-CNN trained on the MS COCO training dataset. During the training process, the backbone network is set as resnet101, and the training starts with the pre-trained COCO weights. The authors also tried various combinations of training stages to check the effect on its detection performance. It turns out that when training the head layers by ten epochs with a learning rate of 0.001 and fine-tuned layers from Resnet stage 4 and up by 60 epochs with a learning rate of 0.0001, the authors obtained the weights and bias with the highest detection accuracy on both RTTS and UG2 test datasets.

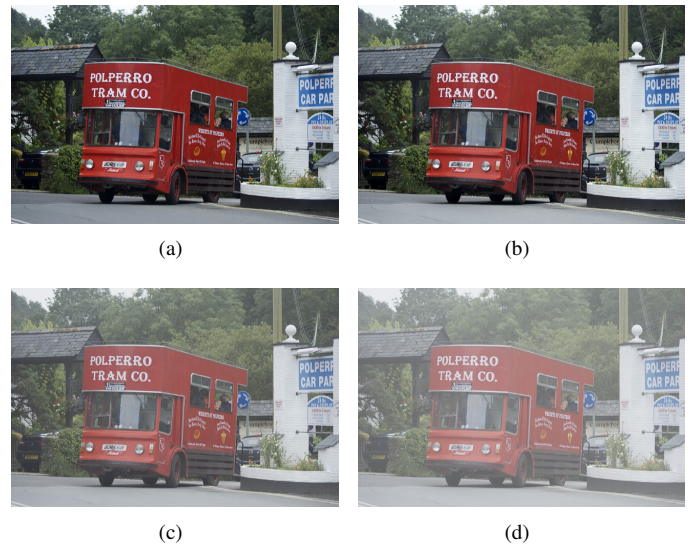

Figure 4: Comparison on synthetic hazy image. (a) is a haze-free image in MS COCO, (b) is the synthetic hazy image generated by inverse DCP, (c) is the synthetic hazy image with 0.1 haze density generated by our algorithm, (d) is the synthetic hazy image with 0.2 haze density generated by our algorithm.

Table 3: Object detection accuracy (mAP) comparison between MS COCO and Hazy-COCO training datasets

Test Dataset	Training Dataset	mAP(%)
RTTS	COCO	61.01
	Hazy COCO	66.08
RTTS+MLDCP	COCO	63.06
	Hazy COCO	66.15
UG2	COCO	32.07
	Hazy COCO	38.53

4.3.2 Experiment Results with Hazy-COCO Training Dataset

In Table.3, the authors evaluate the difference in detection performances when Mask R-CNN is pre-trained on MS COCO and Hazy-COCO datasets. The mAP results increase significantly by about 5% and 6% on RTTS and UG2 test datasets respectively, which presents how effective the Hazy-COCO training dataset is. Additionally, when training Mask R-CNN on the Hazy-COCO dataset, dehazing

Figure 5: Visual comparison between haze-free outdoor images from MS COCO dataset (left column) and the synthetic hazy images with 0.2 haze density generated by our algorithm (right column).

the RTTS test dataset by the MLDCP model can simultaneously increase the mAP result by 0.07%. However, this increment is much lower than the increment 2% when we preprocess the RTTS dataset individually. This is caused by the overlaps of enhancement effects between MLDCP and the advanced inverse DCP since they share some similarities over the dark channel regular pattern and multiple linear regression model.

4.3.3 Visual Effect of Synthetic Haze

Generally, traditional DCP does not support generating synthetic haze to a haze-free image by simply implementing the dark channel

regular pattern inversely. This limitation becomes possible after the authors apply the multiple linear regression techniques to the atmospheric scattering model.

In Figure 4, the effect of haze generated by the inverse DCP algorithm can be barely observed in (b), in comparison with the haze-free image (a). Synthetic hazy images created by our advanced inverse DCP algorithm with haze density 0.1 and 0.2 are presented as (c) and (d) respectively. Both of the two synthetic hazy images are covered with seemingly realistic haze. And it is obviously observed that the synthetic haze in (d) is denser than the haze in (c). The authors also present four more groups of haze-free images from the

MS COCO dataset and their corresponding synthetic hazy images in Figure 5 to demonstrate the effectiveness of our algorithm.

5 Conclusion

As autonomous driving and traffic surveillance become widespread in smart cities, object detection in extreme environments like hazy has been paid special attention to. This paper proposed the approaches that increase the detection accuracy in the hazy environment from both dehazing test dataset and preprocessing training dataset.

First, an advanced Multiple Linear Regression Haze-removal Model was proposed, aiming to overcome the deficiencies of Dark Channel Prior. The authors implemented Stochastic Gradient Descent to update and find the optimal weights and bias to refine the rough estimation of two essential parameters transmission matrix $t(x)$ and atmospheric light A . The experimental results showed that MLDCP not only achieved higher PSNR and SSIM values than other state-of-the-art dehazing algorithms and CNN-based dehazing models, but also increased the detection precision by a higher rate when concatenated with object detection models. It demonstrated that sometimes exploiting practical conventional dehazing algorithms by machine learning techniques was superior to building more complicated neural networks.

Second, the authors proposed an inverse DCP algorithm formulated on the multiple linear regression model that could generate synthetic haze to any existing image datasets. The authors expected this technique to prevent from spending excessive time and workload on building a large-scale image dataset with synthetic or real-world haze, as well as detailed annotations for object detection and segmentation. Synthetic haze was added to the MS COCO dataset and trained Mask R-CNN on this Hazy-COCO training set. The experimental results presented a significant increase in detection accuracy in the hazy environment. However, this approach could only generate the average synthetic haze with the same density over all pixels in an image. On the contrary, real-world haze density normally varies from pixel to pixel. In future work, it is expected to optimize this limitation and generate more realistic synthetic haze.

CNN

Dilated Convolutions

ABSTRACT

Depth prediction plays a key role in understanding a 3D scene. Several techniques have been developed throughout the years, among which Convolutional Neural Network has recently achieved state-of-the-art performance on estimating depth from a single image. However, traditional CNNs suffer from the lower resolution and information loss caused by the pooling layers. And oversized parameters generated from fully connected layers often lead to a exploded memory usage problem. In this paper, we present an advanced Dilated Fully Convolutional Neural Network to address the deficiencies. Taking advantages of the exponential expansion of the receptive field in dilated convolutions, our model can minimize the loss of resolution. It also reduces the amount of parameters significantly by replacing the fully connected layers with the fully convolutional layers. We show experimentally on NYU Depth V2 datasets that the depth prediction obtained from our model is considerably closer to ground truth than that from traditional CNNs techniques.

1 Introduction

This paper is an extension of work originally presented in conference name [1]. Depth prediction has always been a core task to understand the geometric relations within a 3D scene. It provides rich information about the distance of the objects in the image from the viewpoint of camera. This technique is necessary for many applications in computer vision including smoothing blurred parts of an image [2], [3], rendering of 3D scenes [4], virtual reality, self-driving cars [5], grasping in robotics [6] and autopilot [7]. However, predicting depth from images is a quite complex and challenging task. In absence of the environmental assumptions, the inherent ambiguity of mapping an intensity or color measurement into a depth value makes depth prediction an ill-posed problem. Many unique techniques have been proposed to tackle this problem, such as superpixels based algorithms [8], Structure-from-Motion (SfM) [9], data-driven methods [10] and CNN based approaches [11].

Neural Network has been widely applied on computer vision tasks and natural language processing tasks [12]–[14]. And Convolutional Neural Network (CNN) has achieved a great success on outperforming many state-of-the-art algorithms over object classifi-

cation and detection [15], semantic segmentation [16], scene reconstruction, and face recognition [17]. Recently, depth prediction can also be addressed by CNNs due to the power that the ambiguous mapping between a single image and depth maps can be modeled via learning in the neural network. [11] increases the output resolution by efficiently learning the feature map up-sampling within the fully convolutional residual networks. The Multiple-Scale Deep Neural Network in [18] improves the depth prediction by estimating the global scene structure and refining it using local information. Three different computer vision tasks including depth prediction are addressed in [19] with a single multi-scale convolutional network architecture. [20] proposes a novel training loss in the CNN architecture, which enforces consistency between left and right depth maps, to perform end-to-end unsupervised single image depth estimation.

Despite Convolutional Neural Networks performs well on depth estimation, there are still some deficiencies remained to be improved. Some depth predicting CNN models still use pooling layers to extend receptive field. Pooling layers provide an effective approach to reduce the dimensionality of the network by summarizing the presence of features in patches of the feature map. However, they inevitably lose a lot of valuable information during the down sam-

pling process. In contrast, fully connected layers will obtain the global relationship between pixels and image, and inherit all the combinations of the features from the previous layer. This will generate too many parameters, making fully connected layers incredibly computationally expensive.

Dilated convolutional neural network has been proved to be more effective than traditional CNNs in [16], [21]. The feature of dilated convolutions is illustrated in Figure 1. Instead of contiguous pooling filters in traditional CNNs, dilation imposes filters that have spaces between each node. The dilated convolutions support exponential expansion of the receptive field without loss of resolution or coverage, which reduces the computation and memory costs. While preserving the dimensions of data at the output layer, dilated convolutions also maintain the ordering of data.

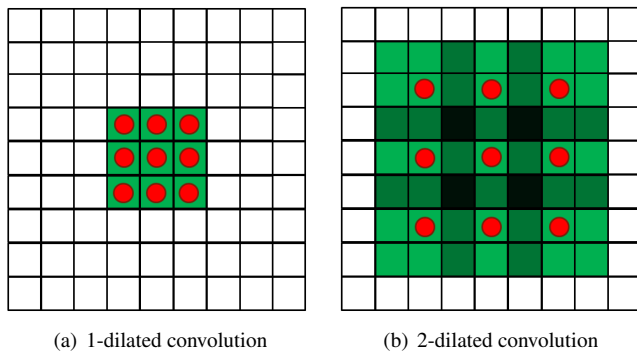

Figure 1: Examples of dilated convolutions with receptive field. (a) refers to an 1-dilated convolution with a kernel of a 3x3 receptive field, which is inherently a standard convolution. (b) refers to a 2-dilated convolutions with a kernel of a 7x7 receptive field. The amount of parameters corresponding to each layer stays identical.

In this paper, a fully dilated convolutional neural network is proposed to enhance the performance of depth prediction. Our model is designed based on the framework in [18]. It contains two components: the global coarse-scale network, which estimates the coarse depth, and the local fine-scale network, which refines the coarse depth estimation combined with local information. In the coarse-scale network, the convolutional layers are replaced with the dilated convolutional layers and the fully connected layers are replaced with the convolutional layers. We train and evaluate our network on NYU Depth V2 datasets and make comparison on the depth predicting performances between our model with traditional VGG-16 model. The experiment results demonstrate that our model reduces the computational and memory costs, and achieves state-of-the-art performance on benchmarks.

2 Related Work

2.1 Depth Estimation

Depth estimation refers to a set of techniques and algorithms aiming to obtain the spatial information from a scene, which has been an essential computer vision task with a long history. Normally a 2D image taking from the camera is not able to represent the local spatial relations of a 3D scene. Since only one point of each pixel is projected in the real scene, its depth information is mathematically

eliminated when projected into plane in a image. Depth information is a key prerequisite to perform multiple computer vision tasks. With the depth information, we are able to back project images captured from multiple views and the 3D scenes can be perfectly restructured by matching all the points. In order to accurately move the actuators in robotics, the depth estimation is required to multiple tasks such as perception, navigation, and planning. In the single image dehazing task, scene depth is a key parameter that supports to remove the haze locally instead of globally.

Depth estimation is an inherently ambiguous and complex task. Geometrically, infinite points in the scene are not projected, thus the depth information may be generated from considerable possible world scenes. For some specific computer vision tasks benefited from depth prediction, it will face more challenges. In the application of autonomous driving in particular, depth estimation will be degraded by occlusion, dynamic object in the scene and imperfect stereo correspondence. Despite the loss of depth information in the 3D dimension, depth map prediction has been investigated inspired by the analogy to how human eyes perceive depth information from depth cues.

2.2 State-of-the-art Algorithms

Humans estimate depth by comparing the images obtained from left and right eyes. Our eyes perceive and recognize the depth cues of the scene, then our brains will subconsciously analyze and recover the depth information easily. There are basically 4 categories of depth cues: Static monocular, depth from motion, binocular and physiological cues [22], making it possible to construct the spatial arrangement of objects in the scene. In computer vision, depth information is extracted mainly from monocular images and stereo images by exploiting epipolar geometry. And many efforts have been made to tackle the challenge of predicting depth from stereo vision depth estimation and monocular depth estimation.

Stereo vision is inspired by how human eyes calculate the approximate depth map from the minor difference between both viewpoints. It compares two differing views on a scene and predicts the relative depth information from the displacement in horizontal coordinates of corresponding image points. The local disparity can be obtained effortlessly using local appearance features. By contrast, estimating depth information from a single image requires a global view of the scene, which is one of the reasons why the monocular depth estimation has not been solved to the same degree as the stereo vision approach [18]. In [23], Scharstein summarizes a taxonomy and evaluation of existing dense two-frame stereo correspondence algorithms, including some earliest stereo vision based depth estimation algorithms [24], [25] with impressive performances. [26] proposes a probabilistic deep learning approach to model disparity and generate binocular training data to estimate model parameters, which outperforms state-of-the-art algorithms with fewer requirements for global detailed information of the scene.

Structure-from-Motion (SfM) is one of the most successful state-of-the-art techniques of depth estimation [27]. SfM estimates the camera motion from the relative pairwise camera positions of the extracted features. Then it predicts the depth information via triangulation from pairs of consecutive views, and recovers the 3D structure through the spatial and geometric relationship of objects in

the scene [9]. Despite its advantages over the lower cost and the less restricted environment, SfM has not been widely adopted in commercial applications due to its complex theories and the difficulty to further enhance the accuracy and speed.

Several techniques address the depth estimation task based on superpixels. In [28], the author proposes an algorithm to find an oversegmentation of the image that breaks up the planar surfaces into many small patches, which are named as superpixels. For each homogeneous superpixel in the image. In [4], the author uses a Markov Random Field (MRF) to infer depth information through a set of plane coefficients, which extract both the 3D location and orientation in the image. The MRF is trained via supervised learning to learn how different depth cues are associated with different depths. In [4], the author further extends the model by combining triangulation cues and monocular images cues, which supports to restructure a full and photorealistic 3D model of a larger scene. There are also some superpixels based algorithms deploying the Conditional Random Fields (CRFs) for the regularization of depth information. Deriving from the CRFs in [8], the author formulates monocular depth estimation as a discrete-continuous optimization problem. The continuous variables encode the depth of the superpixels in the input image, and the discrete variables represent the relationships between neighboring superpixels. In [29], the author extracts multi-scale image patches around the superpixel center and learn to encode the correlations between input patches and corresponding depths regressively with a deep CNN. Then it refines the depth estimation from the superpixel level to pixel level by using CRFs.

2.3 CNN Based Algorithms

A CNN-based depth estimation from a single image is a challenging task if without the local correspondences. A CNN model needs to self-learn the pixel-wise local details as well as the correlations between a pixel and the global scene during the training process.

In [18], the author presents a novel network to regress dense depth maps by implementing a deep network with two stages: global coarse-scale network and local fine-scale network. The coarse-scale network is initialized based on AlexNet [30] with five feature extraction layers, including convolution layers and max-pooling layers, and two fully connected layers followed. The network is able to integrate the understanding of a global view by making effective use of depth cues to predict the coarse depth information. The fine-scale network consists of convolutional layers and one pooling stage for the first layer edge features. Aligning with local details in the scene, the fine network fine-tune the coarse prediction by concatenating an additional low-level feature map.

Building upon the two-scale CNN architecture in [18], [19] authors a paper about predicting depth, surface normals and semantic labels with an improved multi-scale convolutional network. It replaces the Alexnet network with a deeper VGG-16 network [31]. Generating pixel-maps directly from an input image, this network can also align to many image details by using a sequence of convolutional network stacks applied at increasing resolution, without the need for low-level superpixels or contours.

A novel fully convolutional network incorporated with efficient residual up-sampling blocks is proposed in [11] to model the am-

biguous mapping between monocular images and depth maps. It can output the depth maps with higher resolution, at the same time reduce the amount of parameters and train on one order of magnitude fewer data. This paper further proposes a scheme for up-convolutions and combine it with the concept of residual learning to create up-projection blocks for the effective up-sampling of feature maps, which has been proved to be more applicable when addressing high-dimensional regression tasks.

Fully connected layers in some CNN architectures will generate considerable parameters, causing several problems like slower training time, much memory consumption, and chances of overfitting. Some networks in [32], [33] replace fully connected layers with convolutional layers, which can decrease the image matrix to a lower dimension and reduce the amount of parameters. However, convolutional layers are not capable to encode the position and orientation of objects and lack the ability to be spatially invariant to the input data. Thus the output accuracy is much lower than that of fully connected layers. Some further improvements have been proposed to compensate the loss like the convolutional residual networks [11] we introduced above and the dilated convolution we will discuss in next section.

2.4 Dilated Convolution

The dilated convolution is a type of convolution that expands the kernel by inserting holes between the kernel elements. The standard convolution operator is defined in [21] as:

$$(F * k)(\mathbf{p}) = \sum_{\mathbf{s}+\mathbf{t}=\mathbf{p}} F(\mathbf{s})k(\mathbf{t}) \quad (1)$$

The dilated convolution operator has been referred to as convolution with a dilated filter. We refer to l as a dilation factor and the l -dilated convolution operator $*_l$ can be defined as:

$$(F *_l k)(\mathbf{p}) = \sum_{\mathbf{s}+\mathbf{t}=\mathbf{p}} F(\mathbf{s})k(\mathbf{t}) \quad (2)$$

When $l = 1$, the discrete convolution is simply the 1-dilated convolution. The dilation factor l should be increased exponentially at each layer when building a network with multiple dilated convolution layers. At the same time, the number of parameters associated with each dilated convolution layer is identical. That's the reason why dilated convolution can significantly reduce the amount of parameters.

Dilated convolution is widely adopted to enhance the performance in computer vision tasks. The multi-scale context architecture with dilated convolutions presented in [21] has increased the precision of the advanced semantic segmentation models effectively. In [16], the author adopts dilated convolution in deep convolutional neural networks, which increases the dense computation of neural net responses and achieves a higher accuracy than state-of-the-art algorithms at semantic segmentation task. A network for congested scene recognition (CSRNet) in [34] is easily trained by replacing pooling layers with dilated kernels. And the results demonstrate that CSRNet improves the output performance significantly with lower mean absolute error (MAE) than state-of-the-art algorithms.

The Alexnet and VGG-16 models apply the pooling layers to downsample the input images and simultaneously extend the receptive field. However, this process generally results in a loss of pixel-wise details. Dilated convolutions can avoid the similar resolution degradation issue but obtain the same computation as pooling layers in Alexnet and VGG-16 networks. Derived from the application of dilated convolutions on semantic segmentation, a similar technique is implemented to tackle the depth estimation task. Dilated convolutions hold the superiority with exponentially expanding of the receptive fields, which supports obtaining the global relationships among pixels in an image without the resolution reduction when decreasing the amount of parameters.

3 Dilated Fully CNN Architecture

3.1 Overview of the Method

Our dilated fully CNN architecture designed for depth estimation is presented in Fig. 2. It is built upon the multi-scale deep network in [18], which incorporates two stages: the global coarse-scale network and local fine-scale network.

The upper component (Stack 1) is the global coarse-scale network, which is similar to the VGG-16 network and designed to predict the coarse depth information. The convolutional layers and the fully connected layers in VGG-16 are replaced with the dilated convolutions and convolutional layers respectively. The coarse stage contains dilation layers and fully connected layers (FCN). The dilation layers apply 3x3 convolutions with different dilation factors. The dilations are 1, 2, 3, 2, 3 and 4. Rather than reducing the feature map sizes by convolutional layers and implementing fully connected layers to learn details over the local scene, our network can remain the same feature map sizes with much fewer parameters and simultaneously obtain an overall view of the scene from fully connected layers without the resolution loss.

The bottom component (Stack 2) is taken as the local fine-scale network. While the coarse stage captures the global scene, we also need to obtain local information in the refined stage. The inputs images will pass a 9x9 convolutional layer with pooling. Then its output and the low-level feature maps output from coarse stage will be concatenated.

Figure 2: The architecture of two-stages dilated fully convolutional network

The architecture of the proposed dilated fully CNN with structural parameters is demonstrated in Table 1. In the coarse stage of VGG-16 network, the original frames of size 160x120 pixels are down-sampled by each convolutional layer. The front-end module

that provides the input to the coarse stage of our network produces feature maps at 80x60 resolution. Our architecture remains the same resolution in the whole framework by replacing the convolutional layers with dilation convolutions. Table 1 demonstrates that the dilated convolution layers are particularly suited to coarse prediction due to its advantage of expanding the receptive field without the resolution reduction.

Table 1: Module architecture with the image size (size), the convolutional layer number (conv), the channel number (chan), the kernel size, and the dilation layer number in each layer.

3.2 Training Loss

Due to the ambiguity of the scale over a global scene in depth estimation, majority of the error is generated when obtaining the average scale of a scene. In order to compensate this training loss, we adopt the scale-invariant mean squared error in [18] as our loss function. Regardless of the absolute global scale, the scale-invariant error is applied to measure correlation among local pixels in the scene, which is defined in as:

$$D = \frac{1}{2n} \sum_{i=1}^n (\log y_i - \log y_i^* + \alpha(y, y^*))^2 \quad (3)$$

where y and y^* represent the estimated depth map and the ground truth respectively. Each of them contains n pixels that are indexed by i . And $\alpha(y, y^*)$ aims to minimize the error between given y and y^* , which is defined as:

$$\alpha(y, y^*) = \frac{1}{n} \sum_i (\log y_i^* - \log y_i) \quad (4)$$

For any predicted depth map y , e^α is the scale that best aligns it to the ground truth y^* . The scale-invariant means that the error won't change with any scalar multiples of y .

We refer to this scale-invariant error as our training loss function that is formulated as:

$$L = \frac{1}{2n^2} \sum_{i,j} ((\log y_i - \log y_j) - (\log y_i^* - \log y_j^*))^2 \quad (5)$$

where $i, j \in \{1, 2, \dots, n-1\}$.

The difference between the estimated depth map y and the ground truth y^* at pixel i is defined as:

$$d_i = \log y_i - \log y_i^* \quad (6)$$

Then (5) can be re-formulated as:

$$L = \frac{1}{n} \sum_i d_i^2 - \frac{1}{n^2} \sum_{i,j} d_i d_j \quad (7)$$

(7) measures the error from the relationships between the output pixel i and pixel j . And each pair of predicted pixels and its corresponding ground truth pixels should share a similar amount of the difference between pixels, which can further reduce the errors.

4 Experiment Setup

4.1 Datasets and Implementation

We setup the experiment based upon NYU Depth V2 datasets [35], which is one of the largest RGB-D image datasets for indoor scene reconstruction. The raw dataset consists of 1449 RGB images with detailed object labels and annotations with physical relations. Comprising 464 different indoor scenes and classified by 26 scene classes, those images are captured from a variety of buildings in modern cities. NYU Depth V2 dataset is significantly larger and more diverse than another similar Kinect scene dataset - NYU indoor scene dataset, which has limited diversity with only 67 scenes. In order to reduce the chances of overfitting, we shuffle the entire dataset. During the training process, only 800 images of the raw distribution are required. Then we take 200 images to execute the validation test and test our network with 449 images.

4.2 Training Procedure

In our network, we are committed to the universality of the structure. Since the image dataset will not generate any additional processing, our proposed network can be simply applied on other datasets.

Our network is implemented on Keras library running on top of Tensorflow. We train the network in two phases and use the GPU acceleration to speed up the training. First, dilated convolution layers and fully connected layers in the coarse-scale network are pretrained on the NYU Depth V2 training dataset. During this process, the parameters stay identical. Second, the coarse stage outputs concatenated with the edge features of input images are referred as the input images of the fine-scale stage. The convolutional layers in the fine-scale network refine the coarse prediction by aligning it with the detailed information in a local scene.

To make a fair comparison with the performance of traditional VGG-16 framework, two frameworks are both trained on NYU Depth V2 dataset. And they generate output images with the same size, 80x60 for each. The size of input image in VGG-16 framework is 320x240 and the size of input image in our proposed dilated fully convolutional network is 80x60. We refer to stochastic gradient descent (SGD) as the optimizer with the mini-batch size of 16 in the experiment. And we set the learning rate as 0.1 and the momentum as 0.9 for both global coarse-scale stage and local fine-scale stage.

5 Experiment Results and Analysis

5.1 Parameters Comparison

Fig. 3 demonstrates the effectiveness of dilated convolutions on decreasing the amount of parameters. "Total params" in (a) and (c) represents the amount of total parameters of the coarse-scale stage based on VGG-16 network and our proposed network respectively.

(a) and (d) present the total parameters in the whole framework of VGG-16 network and our proposed architecture. Since the coarse-scale network is more complex with more layers than the fine-scale network, majority of parameters are generated from the coarse-scale stage, which can be observed from the comparison between total parameters in (a) and (c).

(d)	

Figure 3: Comparison on the scale of parameters generated in CNN. (a) and (c) present the number of total parameters in the coarse-scale stage (Stack 1) and the whole framework based on VGG-16 network, (b) and (d) present the number of total parameters in the coarse-scale stage (Stack 1) and the whole framework based on our proposed network.

The experimental results demonstrate that our proposed network achieves over seven times reduction of the parameters amount both in the coarse-scale stage and the whole framework compared with the conventional VGG-16 network. Thus our proposed network can liberate considerable computation resources during the training process, which benefits from the significant parameters reduction. Besides, the limited scale of parameters makes the proposed network a viable candidate to be applied to other embedded architectures.

5.2 Depth Estimation Results

We propose a dilated fully convolutional neural network which is designed upon the architecture in [18], and evaluate its depth estimation performance compared with the conventional VGG-16 network. The experimental results are presented in Fig. 4.

Figure 4: Example depth estimations. (a) and (b) represent the input images and the ground truth images respectively, (c) refers to the output depth estimation from VGG-16 network, (d) refers to the output depth estimation from our proposed network

The comparison between output images and ground truth images demonstrates that the dilated convolutions in our architecture can still obtain the related details between local pixels in a patch and the

global view of a scene even without the fully connected layers.

Since fully connected layers learn all combinations of the features of the previous layers, the VGG-16 module achieves a good performance in some local spatial details. Comparing the predicted depth information based on VGG-16 module and our network, it is observed that our architecture can't perform as good as VGG-16 module when predicting depth maps around the object contours. The ambiguous pixels are generated during the training process, where majority of the output depth information will be blurred by the missing pixels around objects boundaries and reflective surfaces. Several techniques have been proposed to predict the boundary type of the superpixel edges, such as the discrete-continuous depth estimation approach in [8]. However, our model focuses on the enhancement over a global view of the scene and ignores the boundary performance. It's obviously observed that our network outperforms traditional VGG-16 network a lot globally, with much higher resolutions and more realistic representation of the relationships between objects and the environment.

6 Conclusion

In this paper, we proposed a dilated fully convolutional neural network to predict the depth information from a single image. The network is designed based on the multi-scale deep network in [18], which contains two stages: the coarse-scale network and the fine-scale network. The coarse stage predicts the global depth information, which is refined locally in the fine-tune stage. We replace the convolutional layers and fully connected layers in the coarse stage with dilated convolutions and convolutional layers respectively. By implementing the dilated convolutions, the network can reduce the amount of parameters significantly without the resolution reduction, which benefits from the exponential expansion of receptive fields in dilated convolutions. And the experiment results demonstrate that our proposed network achieves the state-of-the-art performance on depth estimation for NYU Depth V2 datasets. The output depth information outperforms VGG-16 network with higher resolutions and more realistic representation of the relationships between objects and the environment, while generating much fewer parameters and releasing more memory resources.

Predicting the depth information around the objects boundaries is a weak point of our proposed network. In future work, we will incorporate specific techniques into our network and effectively enhance the depth prediction performance around objects boundaries. Besides, our network only evaluates the visual performance on a single dataset, which is insufficient to demonstrate all the superiority. We plan to further evaluate the predicted depth information on several effective image criteria, which can represent the strong points that are not presented visually. And we will apply the dilated convolutions to more advanced CNNs to further improve the depth prediction performance.

ABSTRACT

In this paper, second order generalized integrator (SOGI) is discretized to design the control algorithm of unified power quality conditioner (UPQC). A UPQC is combination two voltage source converter (VSC) and VSC are connected with back to back DC link. The first one VSC is in series to maintain the desire voltage at point of common coupling (PCC) and second is connected with shunt VSC to share the reactive power demand of load. Moreover, it protects the AC mains from pollution of the load. A phase lock loop (PLL) based SOGI model is implemented to design an algorithm for UPQC under light polluted load. Whereas under highly polluted load the Laplace Transformation based PLL-SOGI model is fail to eliminate harmonics of current and voltage at PCC. Thus, a discretization of PLL-SOGI is needed to meet disadvantage. In this paper, reference current is generated under polluted load using discretization of PLL-SOGI model and compared it with actual current to pulse the gate of shunt VSC. Moreover, a feedback unit (m) is proposed to pulse the gate of series VSC under voltage sag/swell condition. A hardware setup is performed in the lab to verify the proposed algorithm under highly polluted load.

1. Introduction

This paper is extension of original work, existing in **2020 IEEE 9th Power India International Conference (PIICON)** [1]. In this paper, recent demand of electrical energy consumers and services are satisfied with international standard like Institute of Electrical and Electronics Engineers (IEEE) and International Electrotechnical Commission (IEC). It is done by using custom power devices (CPDs). The various kinds of CPDs are available in the present market while authors have chosen Unified Power Quality Conditioner (UPQC). This is unified controller to suppress the burden like current harmonics at source side and voltage harmonics at point of common coupling (PCC) of electrical distribution system [2]. Moreover, it suppresses the voltage related problems like voltage sag and swell at PCC [3]. A UPQC consist two voltage source converters (VSCs), associated back to back DC link. One VSC is connected in series with whereas second one is coupled in parallel to the load [4, 5]. The VSC is nothing without control algorithms which generates pulse. Thus, shunt and series

part of VSCs require good control algorithms to improve the multiple power quality of the 3-phase AC primary distribution system [6-8]. The second order generalized integrator (SOGI) is the simple control approach which gives the information like time, magnitude and phase angle of the signals [9]. The SOGI have phase lock loop (PLL) combination and frequency locked loop (FLL) combination [10, 11]. The PLL based configuration of SOGI is discretization in the proposed work. The literature survey indicates many resemble works are reported in grid synchronization using SOGI [12, 13] to extract harmonics. In [14], SOGI based control approach to reduces sensors whereas power quality enhancement is reported in [15, 16]. A SOGI-PLL is presented in [17] to extract active and reactive power. A PLL based second and third order mixed generalized integrated is implemented in grid connected inverter [18]. As the order of equation is increased the further calculation require which again burden for programming to design a controller. Generally, PLL-SOGI and other modified SOGI are applicable to synchronize the voltages/currents signals [19, 20]. The phase of two periodic waves are minimized by PLL. Thus, two phases are synchronized exactly

*Corresponding Author: Mashhood Hasan, Email: mhasan@jazanu.edu.sa

in the proposed algorithms whereas back to back DC level voltage is increased to proper synchronization of two phases. The proposed configuration of SOGI is able to create two output signals. These output signals provide active and reactive components in the direct axis (α -axis) and quadrature axis (β -axis) respectively. Under polluted loads the point of common coupling (PCC) and AC mains get effected which produces harmonics. Thus, input currents/voltages signals of PLL-SOGI contains harmonics while output active components is passed through bandpass filter which reduces the harmonics components of current (i_a) and voltage (v_a) at certain level. Moreover, reactive component is passed through low pass filter at 90° degree of input signal. It gives reactive component (β) of current (i_b) and voltage (v_b). These voltages and currents signals are helpful to calculate real time active power ($p_L(t)$) and reactive power $q_L(t)$. While, researchers have found many ways to calculate real time $p_L(t)$ and $q_L(t)$ power [21-23]. Moreover, way of extraction of instantaneous power search accuracy of active and reactive component. Thus, in this work, PLL-SOGI is discretized using trapezoidal method. The trapezoidal methods measures accurate 90° degree lagging with respect to input signal under heavy polluted loads [24]. It helps to measure accurate instantaneous power of $p_L(t)$ and $q_L(t)$. The authors have following contributions in the present work which are given as follows,

- PLL-SOGI is discretized to design the control algorithm of UPQC which pulses the shunt part of VSC and series part of the VSC
- The reference signals of the AC mains currents are generated using simple mathematical calculation.
- A feedback unit 'm' is proposed to mitigate the voltage sag and swell at PCC.

Furthermore, in section 2, a brief information of model configuration is presented whereas section 3, control algorithm of UPQC is given. Results and discussion are shown in section 4 and in the last section 5 conclusion is presented.

2. Model Configuration

In Figure 1, a model arrangement of 3-phase, AC mains is connected with UPQC to mitigate the voltage sag, swell, reactive power and eliminate harmonics. The series part VSC of the UPQC is connected left from the PCC whereas shunt part VSC of UPQC connected at PCC. The back to back DC link voltage is maintained 180V for proper and fast working of the proposed algorithms. The DC link capacitor value is estimated nearly 3.3 mF. The AC mains supplies line voltage 110V at 50Hz to polluted load current with 20% THD and its apparent power is 819VA. The switching harmonics of series and shunt VSC are eliminated by R-C filters. The value of R and C are 10Ω and $10\mu F$ respectively. The series VSC is interfaced by series transformer whereas shunt VSC is interfaced by inductors value 8 mH. The control algorithm of series and shunt part are separately developed. In the control algorithm block, authors have contributed to develop an idea of algorithm for series VSC and shunt VSC.

3. Control Algorithms of UPQC

Two mathematical model descriptions are presented to design a control algorithm of UPQC. A UPQC has two VSC, thus it requires two separate algorithms.

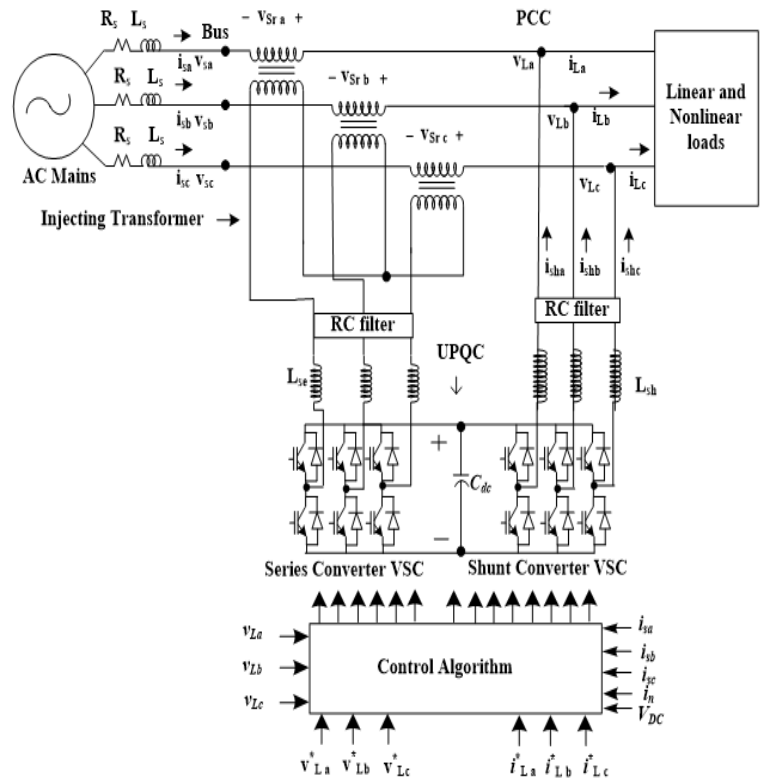

Figure 1: Schematic diagram of 3- Phase 3 Wire AC distribution system connected with UPQC

3.1. Design an Algorithm for Shunt VSC

The discretization of the input signals of SOGI is done to get the exact 90° degree phase shift of input signals. A trapezoidal method is suitable to design the algorithm. The $H(z)$ is the discrete function of Laplace Function (LF) $H(s)$, if it is satisfied by given rule.

$$H(s) = H(z) \bigg|_{\frac{1}{s} = \frac{T_s}{2} \left(\frac{1+z^{-1}}{1-z^{-1}} \right)} \quad (1)$$

where z is z -transformation and T_s is the sampling frequency.

The simplest form of discrete form of SOGI structure [1] is given as,

$$v_\alpha(z) = \left(\frac{a_0(1+Z^{-2})}{1-(a_1)Z^{-1}+(a_2)Z^{-2}} \right) v(z) \quad (2)$$

The quadrature axis voltage (v_β) of general configuration of single phase PLL is estimated as follows,

$$v_\beta(z) = v_\alpha(z) * \frac{2}{T_s} \frac{1-z^{-1}}{1+z^{-1}} \quad (3)$$

$$\text{where } a_0 = \frac{2k\omega T_s}{2k\omega T_s + (\omega T_s)^2 + 4}, a_1 = \frac{2(4 - (\omega T_s)^2)}{2k\omega T_s + (\omega T_s)^2 + 4}$$

$$\text{and } a_2 = \frac{(2k\omega T_s - (\omega T_s)^2 - 4)}{2k\omega T_s + (\omega T_s)^2 + 4}$$

The equation (2) and (3) are used to extract the discrete value of active part of voltage (v_a) and reactive part of voltage (v_b). These discrete values are helpful to get real time active power ($p_L(t)$) and reactive power ($q_L(t)$). The $p_L(t)$ and $q_L(t)$ are estimated as follows,

$$\begin{bmatrix} p_{La} \\ q_{La} \end{bmatrix} = \begin{bmatrix} v_{La,\alpha} & v_{La,\beta} \\ -v_{La,\beta} & v_{La,\alpha} \end{bmatrix} \begin{bmatrix} i_{La,\alpha} \\ i_{La,\beta} \end{bmatrix} \quad (4)$$

where p_{La} and q_{La} are real time active and reactive powers of phase 'a'. While, i_a active part and i_b are a reactive part of input AC current. The AC mains is designed for active power only thus, reactive part in equation (4) is taken as zero. Next stage, AC mains is delivered balanced power which is given as follows

$$p_s^* = \frac{p_{Ltotal}}{3} = \frac{(p_{La} + p_{Lb} + p_{Lc})}{3} \quad (5)$$

The equation (5) gives load demand of active power per phase. The reference of actual active and reactive part of reference current can find as

$$\begin{bmatrix} i_{sa,\alpha}^* \\ i_{sa,\beta}^* \end{bmatrix} = \begin{bmatrix} v_{La,\alpha} & v_{La,\beta} \\ -v_{La,\beta} & v_{La,\alpha} \end{bmatrix}^{-1} \begin{bmatrix} p_s^* \\ 0 \end{bmatrix} \quad (6)$$

$$\begin{bmatrix} i_{sa,\alpha}^* \\ i_{sa,\beta}^* \end{bmatrix} = \begin{bmatrix} v_{La,\alpha} & v_{La,\beta} \\ -v_{La,\beta} & v_{La,\alpha} \end{bmatrix}^{-1} \begin{bmatrix} p_s^* + p_{DC} \\ 0 \end{bmatrix} \quad (7)$$

The DC link of UPQC is controlled by a simple Proportional Integral (PI) controller. The input of PI is an error signal ($\varepsilon(n)$) of DC link voltage. And $\varepsilon(n)$ can be extracted by the difference of the reference voltage (v_{DC}^*) and actual sensed voltage ($v_{DC}(n)$). The power loss at nth sampling time is estimated using equation (8).

$$p_{DC}(n) = p_{DC}(n-1) + k_p \{ \varepsilon(n) - \varepsilon(n-1) \} + k_i \varepsilon(n) \quad (8)$$

where k_p and k_i are gain constants of PI controller. While $\varepsilon(n)$ and $\varepsilon(n-1)$ sampling time.

Finally, using equation (7) reference currents (i_{sa}^* , i_{sb}^* , i_{sc}^*) can be evaluated as follows,

$$\begin{aligned} i_{sa}^* &= \frac{v_{La,\alpha}(n)}{v_{La,\alpha}^2 + v_{La,\beta}^2} \{ p_s^* + p_{DC} \} \\ i_{sb}^* &= \frac{v_{Lb,\alpha}(n)}{v_{Lb,\alpha}^2 + v_{Lb,\beta}^2} \{ p_s^* + p_{DC} \} \\ i_{sc}^* &= \frac{v_{Lc,\alpha}(n)}{v_{Lc,\alpha}^2 + v_{Lc,\beta}^2} \{ p_s^* + p_{DC} \} \end{aligned} \quad (9)$$

However, the pulses of shunt VSC are generated by comparing the equation (9) signals and the signals of 3-phase AC mains currents (i_{sa} , i_{sb} , i_{sc}).

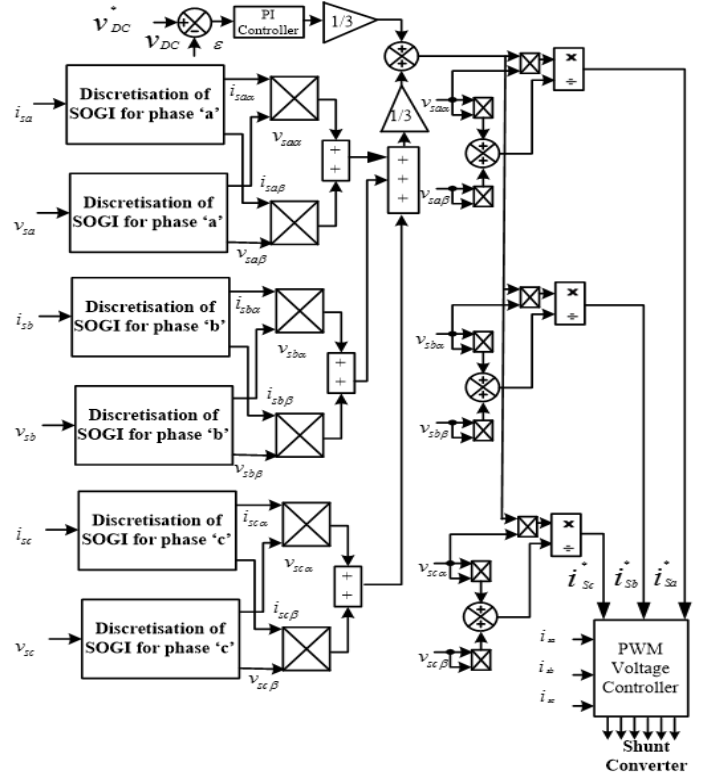

Figure 2: (a) Modified control Algorithm for shunt VSC

Figure 2: (b) Control Algorithm for series VSC

3.2. Design an Algorithm for series VSC

In Figure 2b, a feedback unit 'm' is played a role to design an algorithm of series VSC. Where m gives the proper feedback voltage under sag/swell condition of AC mains voltage. It maintains the desire PCC voltage. The actual PCC voltages are

extracted by a simple calculation which is square root sum of direct axis voltage ($v_{a,\alpha}$) and quadrature axis voltage ($v_{a,\beta}$). These values are further multiplying by 0.5 to get root mean square (rms) value. Moreover, a reference load voltage (V_L^*) is divided by the actual rms load voltage to obtain the m . Mathematically, m can be obtained as,

$$m = \frac{V_L^*}{v_{a,rms}} = \frac{V_L^*}{0.5 * \sqrt{v_{a,\alpha}^2 + v_{a,\beta}^2}} = \frac{V_L^*}{v_{La}} \quad (10)$$

Thus, under normal condition m predict a value equal to one to get desire voltage at PCC. This controller is an adaptive in nature. Similarly, m can predict a different correct value under abnormal condition of the AC mains. It is given as follows.

3.2.1 Voltage Sag Condition

In this case, assume, AC mains voltage of phase 'a' is running with voltage sag by factor x . Consequently, at PCC the voltage is reduced by factor x . The feedback unit is predicted $m1$ under voltage sag and it is calculated as follows,

$$m1 = \frac{V_L^*}{x * v_{a,rms}} = \frac{V_L^*}{0.5 * x * \sqrt{v_{a,\alpha}^2 + v_{a,\beta}^2}} = \frac{V_L^*}{x * v_{La}} = \frac{m}{x} \quad (11)$$

If factor x become one, the $m1$ is equal to m , hence it is proved by equation (11) that the proposed control algorithm is an adaptive in nature under voltage sag condition. Moreover, the generated reference voltage (v_{La}^*) is equal to multiple of direct axis voltage ($v_{La,\alpha}$) and feedback unit ($m1 * x$) under voltage sag condition. Now, v_{La}^* can find as,

$$v_{La}^* = m1 * x * v_{La,\alpha} = m * v_{La,\alpha} \quad (12)$$

3.2.2 Under Voltage Swell

In this case, assume, AC mains voltage of phase 'a' is running with voltage swell by factor y . Consequently, at PCC the voltage is reduced by factor y . The feedback unit is predicted $m2$ under voltage swell and it is calculated as follows,

$$m2 = \frac{V_L^*}{y * v_{a,rms}} = \frac{V_L^*}{0.5 * y * \sqrt{v_{a,\alpha}^2 + v_{a,\beta}^2}} = \frac{V_L^*}{y * v_{La}} = \frac{m}{y} \quad (13)$$

If factor y become one, the $m2$ is equal to m , hence it is proved by equation (13) that the proposed control algorithm is an adaptive in nature under voltage swell condition. Moreover, the generated reference voltage (v_{La}^*) is equal to multiple of direct axis voltage ($v_{La,\alpha}$) and feedback unit ($m2 * y$) under voltage swell condition. Now, v_{La}^* can find as,

$$v_{La}^* = m2 * y * v_{La,\alpha} = m * v_{La,\alpha} \quad (14)$$

In the same way, the above equation can extract for phase 'b' and phase 'c' of primary AC distribution system. The proposed control algorithm can work under abnormal condition of AC mains and it is good to opt for the UPQC.

4. Experimental Results

A 3-phase, 3-wire AC system is integrated with UPQC in the lab which is shown in Figure 3. It consists D-Space software to

link with hardware and PC for evaluation the performance of the modified algorithm under polluted loads. In Table 1, model parameters are given. Whereas in Table 2 shows the THD and power factor under various load conditions. The hardware results are shown in Figures 5 and Figures 6&7 under steady state conditions and under dynamic condition respectively. Moreover, a comparative Matlab result is shown in Figure 4 to understand the value of modified algorithm.

Figure 3: A lab model of 3-phase 3-wire AC system integrated with UPQC

Figure 4 a comparatives results under quasi square wave demand of load current, (a) polluted load current waveform ($i_L(A)$), (b) AC mains current waveform under SOGI ($i_{c,L}(A)$) and AC mains current under modified SOGI ($i_{c,B}(A)$).

Table 1: Practical Parameters

Quantities	Value
PCC line voltage	110V

(a) The line to line voltage and Phase currents abc at AC mains under normal condition

(b) The line to line voltage and Phase currents abc at PCC under normal condition

Figure 5: The AC mains voltage, currents, load voltage and load currents under normal condition.

4.1. Performance Under Normal Condition

The power analyzer 3-phase 4 channel is used to show the results of modified algorithm. The line to line voltage v_{sab} and 3-phase AC mains current are indicated as i_{sa} , i_{sb} , and i_{sc} respectively. It is shown in Figure 5(a) whereas in Figure 5(b), the line to line load voltage v_{Lab} and single phase load current are indicated as i_{La} , i_{Lb} , and i_{Lc} . It is observed from the results that source AC mains are free from harmonics while load is under heavy polluted thus, shunt algorithm works properly. Whereas, series algorithm maintain desired voltage at PCC properly under steady state condition.

4.2. Performance Shunt VSC Under Dynamic Condition

In Figure 6(a), performance of modified control algorithm for shunt VSC is presented under dynamic load condition. In this case, phase 'c' of load is abruptly off. Thus, load current i_{Lc} is zero and at the same time shunt VSC become active and inject shunt current i_{shc} in phase 'c' to stable the AC mains source current i_{sc} . Whereas, in Figure 6(b), when load demands current in phase 'c' active, the shunt VSC injects harmonics to make supply pure sinusoidal AC mains current. It is seen that the modified control algorithm works properly to maintain AC mains source as an international standard and balanced. Moreover, the DC link voltage (V_{DC}) is unchanged under dynamics condition of load.

(a) Performance of shunt converter under zero load

(b) Performance of shunt converter under dynamic load

Figure 6: Current waveform of AC main current, shunt current and load current under dynamic condition

4.3. Performance Series VSC Under Dynamic Condition

The performance of series VSC is shown in Figures 7(a)-(b) and Figures 7(c)-(d) under voltage sag and swell conditions. In Figure 7(a), AC mains line to line voltage v_{sab} is running under voltage sag while at PCC line to line voltage v_{Lab} is regulated to maintain the desire voltage of the load. The series voltage v_{srab} is added in series with the AC mains to regulate load voltage at 110V using series VSC.

In Figure 7(b), AC mains 3-phase voltages are regulated by series VSC. The line to line voltage v_{sab} and v_{sbc} are running under voltage sag condition whereas line to line load voltage v_{Lab} and v_{Lbc} are regulated at desire voltage 110V. Thus, the waveform of three phase voltage shows that the performance of feedback unit 'm' works satisfactory and series VSC works at desire level to mitigate voltage sag.

Moreover, the feedback factor 'm' is tested under voltage swell condition. In this case, series VSC injects voltage in feeder of AC mains to opposite phase of AC mains voltage. It suppresses the AC mains voltage and consequently load voltage is maintain at desire level 110V. In Figure 7(c), AC mains v_{sab} is running under voltage swell while at PCC v_{Lab} is regulated to maintain the desire voltage of the load. The series voltage v_{srab} is subtract in series with the AC mains to regulate load voltage at 110V using series VSC. While, AC mains current i_{sa} reduces under voltage swell condition to balance the power of the AC mains.

(a) Performance of series converter under voltage sag

(b) Regulated voltage of three phase load under voltage sag

(c) Performance of series converter under voltage swell

(d) Regulated voltage of three phase load under voltage swell condition

Figure 7: Voltage waveforms of AC mains voltage, load voltage and series converter voltage under dynamic condition

In Figure 7(d), AC mains 3-phase voltages are regulated by series VSC. The v_{sab} and v_{sbc} are running under voltage swell condition whereas v_{Lab} and v_{Lbc} are regulated at desire voltage 110V. Thus, the waveform of three phase voltage shows that the performance of feedback unit 'm' works satisfactory and series VSC works at desire level to mitigate voltage swell.

5. Conclusion

The discrete value of second order generalized integrator (SOGI) has realized to design control approach of UPQC which performance have been verified under heavy polluted load and under various conditions of load. Under normal condition, series VSC is inactive while shunt VSC eliminate the harmonics of the load and injects reactive power demand to the 3-phase load. And under dynamic condition, the shunt VSC shows the excellent performance whereas the series VSC works under voltage sag and swell conditions. The voltage sag from 110V to 99V while voltage swell from 110V to 121V are generated at AC mains while at load side (PCC) the voltage is regulated at 110V. The performance of proposed feedback unit 'm' for series part of UPQC has unique to suppress the sag and swell voltage of PCC and modified algorithm of shunt part of UPQC eliminates the harmonics of load and enhance the performance of AC mains. Thus, it has been seen that proposed algorithm of UPQC improve the multiple power quality of the 3-phase primary distribution feeder line of power system.

Table 2: THD and Power Factor Under Various Load Conditions

Parameters	Nominal	Sag	Swell
Load Current THD	20%	20.14%	19.80%
PCC Current THD	3.77%	2.88%	4.65%
Load Voltage THD	3.58	3.50%	3.55%
PCC Voltage THD	1.92	1.96%	1.9%
Power factor at grid	0.99	0.99

Research Article

Usage of Additive Manufacturing and Topology Optimization Process for Weight Reduction Studies in the Aviation Industry

Tamer Saraçyakupoğlu*

Department of Aeronautical Engineering, Istanbul Gelisim University, Istanbul, 34315, Turkey

ARTICLE INFO*Article history:**Received: 25 December, 2020**Accepted: 24 March, 2021**Online: 31 March, 2021**Keywords:**Aircraft**Additive Manufacturing**Engine Mount**Topology Optimization**Weight Reduction***ABSTRACT**

The Additive Manufacturing (AM) technology is a disruptive and novel technique that changes the paradigm of manufacturing methodology. It is based on the principle of having 3D parts by adding simple 2D layers on and on. Before AM was implemented, the conventional subtractive and chip-away techniques such as milling and turning processes had been used widely in the aviation industry. The mentioned conventional methods are still in use. However, it is observed that AM replacing legacy methods, especially for the complex and relatively heavy parts. Thanks to mutual-usage of the Topology Optimization (TO) techniques and AM, many weight reduction studies have been done successfully. The weight reduction studies have an impact on the Direct Operational Cost (DOC) of the aircraft. With the benefit of weight reduction studies, many airliner companies have the opportunity for carrying more payloads with the same type of commercial-passenger aircraft. Also, the TO and weight reduction studies are beneficial for lowering the carbon footprint. Obviously, the weight reduction, the DOC, and the carbon emission are interrelated with each other. In this paper, a research was carried out for a generic engine mount that is specifically used by famous aircraft types. Eventually, it was found that, with the help of AM, TO and material optimization studies it is possible to save weight on the engine mount.

1. Introduction

The aviation industry is a pioneer of the integration of novel manufacturing technologies because it requires high technologies. International Civil Aviation Organization (ICAO), stated in its 2016–2030 Capacity and Efficiency Report that, since 1977 the global air passenger volume has been expanding two-fold once every 15 years and will continue to do so [1]. The International Air Transport Association (IATA) is an important association, declared that almost 8,2 billion people will be flying in 2037 [2]. These two reports from two strong organizations are complementing to each other. The reason for this increasing trend in aviation traffic is because of the more frequent mobilization demand.

On the other hand, the aircraft companies are seeking the implementation of novel technologies such as AM into the aviation industry in terms of having lighter airplanes. Because lighter aircraft means having more passengers, bigger payloads, reaching

longer ranges, higher maneuver capacities, more comfortable services, and easier maintenance abilities, etc.

Like all other novel technologies that are implemented in the aviation industry, the AM has vital importance because it is a pillar of industry 4.0 [3]. For example, the aviation industry was the earliest adopter of carbon fiber materials, and it was the first to integrate CAD/CAM into its design process [4]. The use of AM technologies has become increasingly widespread for three decades, starting with rapid prototyping studies [5]. The implementation of AM has been the fastest one, particularly in the aviation industry because of its unbeatable advantages. While reducing the weight of a part, maintaining the same mechanical features as its traditionally produced predecessors is vital.

There are some constraints in the aviation industry. The implementer always has to follow the airworthiness regulations. As an airworthiness authority, the ICAO took attention to the implementation of the new technologies that may have a negative impact the aviation safety [6]. There are many successful samples for additively manufactured airborne parts. For example, General

<https://dx.doi.org/10.25046/aj060294>

Electric's (GE) fuel nozzle is an iconic part that has been manufactured with AM technologies. For the Leading Edge Aviation Propulsion (LEAP) engines. GE has combined 20 parts into 1 part, produced in a single machine, and decreased the weight up to 25% less than the conventionally manufactured predecessors [7]. Federal Aviation Administration (FAA) announced that more than 40.000 nozzles will be manufactured by the end of 2020 [8]. The mentioned nozzle also contributes to clean fuel burn and helps to reduce the carbon deposits [9].

In the open literature, there are studies regarding manufacturing the engine mount by Additive Manufacturing methods. In [10], made an investigation for the engine mount of a truck that works under low and high cyclic loads similar to an aircraft engine mount. In this study, it was found that producing the engine mount using Additive Manufacturing is possible. In another study [11], the author investigated the usage of topology optimization and additive manufacturing for weight optimization of an engine subframe mount used. In this study, it was underlined that 20% of weight reduction is possible of the mentioned mount.

In the mentioned papers, the studies were mainly focused on the automotive related parts. However, in this study, a general aviation engine mount was examined.

2. The Relation Between the Weight of the Aircraft and the Impact of Forces

For weight reduction studies, sorts of weight should be clarified. The impacts of the main four forces affect the design of an airplane.

2.1. Four Main Forces

As it is depicted in Figure 1, four major forces shape the flight. Roughly these forces are categorized as,

- **Thrust:** The force which is generated by the engines and moves the aircraft in the air.
- **Drag:** The aerodynamic force is generated by the surface of the aircraft and opposes an aircraft's move through the air. It is a result of air-friction.
- **Lift:** The force which has an upward direction and it is mainly generated by the wings. The lift enables the aircraft to stay airborne.
- **Weight:** Weight is the force that is generated by the gravity on the aircraft. It is depended on the mass of the body.

In a level and straight flight, an aircraft is in equilibrium since these four forces are well balanced and their moments are zero. The lift should balance the weight and the thrust should balance the drag. In conclusion, the four forces must be in equilibrium during flight [12]. The rate of climb is an indicator of the stability of the airplane. Increasing weight is an undesirable situation [13]. The equilibriums that are basically given in (2-1) and (2-2) are the vertical and horizontal loads of an aircraft.

$$\text{Thrust} - \text{Drag} - (\text{Weight} \times \sin\alpha) = 0 \quad (1)$$

$$\text{Lift} - (\text{Weight} \times \cos\alpha) = 0 \quad (2)$$

As it is demonstrated in Figure 2, the rate of climb is directly related to the weight of the airplane.

Figure 1: The Four Main Forces that Affect the Flight [12]

Figure 2: Rate of Climb [14]

As it can be seen for having a better climb performance, the increased thrust, the lowered drag, and the weight are crucial. Through the next paragraph, sorts of weight will be described shortly.

2.2. The General Weight and Loads

There are many weight types regarding the aircraft's configuration. In pursuit of weight reduction, some important weight definitions are given below;

- **Maximum Zero Fuel Weight (W_{MZF})** is the maximum weight that an aircraft can carry with no fuel.
- **Design Gross Weight (W_0)** is the weight of the aircraft as it initiates the mission for the design purpose.
- **Empty Weight (W_e , W_{empty})** is the weight of an airplane without useful fluids like oil, hydraulic fluids, and trapped (unusable) fuel. It should be emphasized that W_e include airframe, landing gears, structural parts, empennage, engines, avionics, and all other equipment.
- **Crew Weight (W_c , W_{crew})** is the weight of the cockpit crew that is required for flying the aircraft.

- Fuel Weight (W_f , W_{fuel}) is the weight of the fuel which is necessary for the accomplishment of the design mission.
- Weight of Payload (W_p , $W_{payload}$) is the parameter of cargo and/or passenger.
- Weight of Useful Load (W_u) is the weight of all other things the aircraft has the capability of carrying besides her own weight [14].

The difference between W_u and W_p has crucial importance for an airliner since the lesser fuel means more freight and more passengers.

2.3. Weight Relations

There's a correlation amongst the sort of weights. The primary equations and ratios are provided as follows:

Design gross weight:

$$W_0 = W_u + W_e \quad (3)$$

Useful load:

$$W_u = W_c + W_p + W_f \quad (4)$$

Design gross weight then becomes:

$$W_0 = W_c + W_p + W_f + W_e \quad (5)$$

Empty weight ratio (EWR) is found to be:

$$\frac{W_e}{W_0} \quad (6)$$

Fuel weight ratio (FWR) is found to be:

$$\frac{W_f}{W_0} \quad (7)$$

Equation (2-3) becomes:

$$W_0 = W_c + W_p + \left(\frac{W_f}{W_0}\right) W_0 + \left(\frac{W_e}{W_0}\right) W_0 \quad (8)$$

W_0 is calculated by:

$$W_0 - \left(\frac{W_f}{W_0}\right) W_0 - \left(\frac{W_e}{W_0}\right) W_0 = W_c + W_p \quad (9)$$

W_0 can be written in the form:

$$W_0 = \frac{W_c + W_p}{1 - \left(\frac{W_f}{W_0}\right) - \left(\frac{W_e}{W_0}\right)} \quad (10)$$

W_0 is a key driver of design features and flight safety of the operations as well. Different types of aircraft demonstrate varying characteristics depending on the Empty Weight Ratio [15]. Conclusionally, AM techniques are used for reducing the W_0 .

2.4. Categorization of AM and the Materials

American Society for Testing and Materials (ASTM) released a standard for categorizing the AM techniques which are called "Standard Terminology for Additive Manufacturing Technologies, Designation: F2792 – 12a" [16]. This standard mainly classifies AM techniques into seven categories. These are:

- Binder jetting,

- Directed energy deposition,
- Material extrusion,
- Material jetting,
- Powder bed fusion,
- Sheet lamination,
- Vat photopolymerization.

The material selection is based on the customer requirements and there are some hybrid methods as well. In every AM process, the processing material differs from one to another. For example, wax-like materials can be processed with material jetting and binder jetting. Metals such as nickel-based alloys and aluminum can be processed with directed energy deposition. Thermoplastic filaments can be processed with Material Extrusion. With powder bed fusion the materials such as nickel-based superalloys, Inconel 625, Inconel 718, polymers, maraging steel, stainless steel 316 L, 15-5PH, 17-4PH, Hastelloy X, titanium TA6V, and chrome-cobalt can be processed. Adhesive coated papers, metal tapes, and foils, the plastic sheet material can be processed with sheet lamination, and light-curable resin and photopolymers can be processed with Vat Photopolymerization.

2.5. W_0 Reduction and Topology Optimization Relationship

An aircraft is not permitted to fly unless it is made of airworthy parts airworthy part certification is given and validated by airworthiness authorities only. Because of the design freedom available with AM techniques, topology optimization (TO) of the airworthy parts which are used on the airplanes are perfect applications [17]. For example, GE's engine nozzle that was mentioned in the introduction paragraph is lighter 25% after AM application. In another study, thanks to AM and TO studies, European Aeronautic Defense and Space Company (EADS) redesigned the nacelle hinge brackets of Airbus A320 as depicted in Figure 3. The brackets' weight saved up to 64% while keeping the mechanical features satisfactory [18].

Figure 3: TO and AM Application of Airbus A320 Nacelle Hinge Bracket [18]

The result of TO studies always benefited the buy-to-fly-ratio. Buy-to-fly-ratio is formulated as follow;

$$\frac{\text{The weight of the component itself}}{\text{The raw material used for a component}} \quad (11)$$

With AM technologies, the buy-to-fly ratio can be minimized to 1:1 [19]. It is a very critical benefit since aviation materials are expensive in the market as mentioned before. Besides buy-to-fly-ratio, with the usage of AM technologies there are some other benefits such as given below;

- The cost of the parts may be reduced to almost half,

- Part weight can be reduced to 64%
- Scrap reduction can be as low as 10%,
- Time-to-market can be reduced to 64% [20].

As it was mentioned previously, weight reduction studies generally conclude with the lower fuel consumption and increased load capacity of aircraft [21]. For example, the Boeing company stated that Boeing 777-300 has improved its fuel economy against Boeing 767-300 and succeed to take up to 368 passengers compared to 269 passengers in Boeing 767-300ER thanks to the weight reduction studies [22]. In another study, from the Airbus project called the SAVING, by redesigning the seat buckles of Airbus 380, 55% of weight has been saved over seat buckles. With the help of the TO and AM studies, in a regular configuration, for the Airbus 380 which has 853 seats the saving would be a total of 72,5 kg of weight [23]. With project SAVING, a total of 3,3 million liters of fuel savings is targeted to gain over the service life of the aircraft Airbus A380 [24]. In addition to the commercial aviation industry on the military side, there are some studies such as Lockheed Martin's Joint Strike Fighter (JSF)'s engine Bleed Air Leak Detector (BALD) bracket. For the mentioned bracket the buy-to-fly ratio is reduced to 1:1, as compared with the 33:1 ratio possible by conventional methods with the advantage of 50% in total cost [25]. In accordance with the cost studies, the fuel and oil consumption in airliner operational cost is the top driver with a percentage of 33,4%. The Aircraft Ownership as the second item with 10,6 percentage is far below Fuel & Oil [26]. It is known that for an airliner company that owes more than 600 aircraft, such as American Airlines, reducing even one pound of weight from each aircraft saves approximately 11,000 gallons of fuel annually. On the other hand, a lesser carbon footprint can be gained by the reduction of the W_0 of the airplanes. For example, For the Boeing 747-400, which has 396,890 kg of W_0 , and Airbus A330-300, which has 242,000 kg of W_0 with the weight reduction of one kg built-in aircraft it, is possible to reduce carbon emissions up to 0.94 kg and 0.475 kg respectively [27].

3. Materials and Method

In general, before presenting further information regarding W_0 and TO correlation the relation between design and TO should be provided.

3.1. Design and Topology Optimization Relation

For W_0 and TO studies the mechanism of the design process should be described. As it is presented in Figure 4, design can be described as a feature of an object, which is initiated by an agent, for handling the goals, in a framed environment, using a set of fundamental components to satisfy a set of requirements in a designated environment [28].

The conceptual design method provided in Figure 4. covers the general approaches in terms of designing. This concept can be adapted to legacy and novel technologies such as Additive Manufacturing. The relation between design and manufacturing is a crucial indicator of the success of fields such as material development, thermodynamics, aerodynamics, structural integration, heat transfer, and machining as well [29]. While using AM techniques, the core of the whole process is creating a CAD model. In other words, a CAD model initiates the AM process [30].

In Figure 5, the CAD model and the following steps of the AM process are shown in consecutive steps.

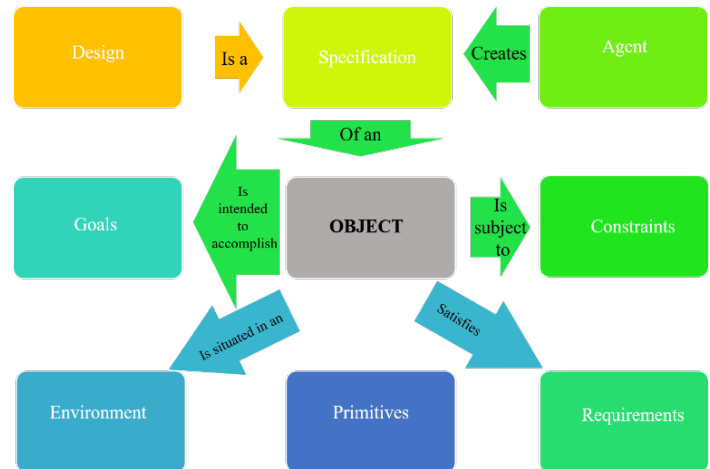

Figure 4: Conceptual Model of Design [28]

Figure 5: The steps of AM [22]

3.2. Steps of Topology Optimization

As it is shown in Figure 6, the preparation of data is the first step and includes important issues such as material definition and CAD model preparation. The second step is topology optimization which includes the steps of creating a finite element model and finite element analysis. The third step is the TO result from adaptation. And finally, the fourth step is creating a final finite element model and CAM model.

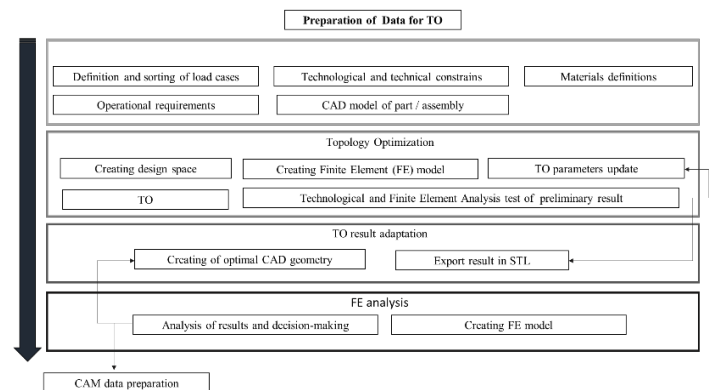

Figure 6: The Steps of Topology Optimization [31]

4. Results and Discussion

There are many investigations and research studies on the application of TO in the aviation industry [32;33;34]. In this study an engine mount which is shown in Figure 7. is selected. It is a generic engine mount that is used for the Ultra-Light (U/L)

airplanes in the market which have retractable landing gears and 250 km/h of cruise speed. The basic equations are given in section 2.3. are valid for the U/L aircraft types. These U/L aircrafts are famously known as low-speed general aircrafts [35] with the Design Gross Weight up to 472,5 kg.

Figure 7. A Common Engine Mount for the U/L Airplanes
(Image Courtesy of the Correspondent Author)

The engine mount is a vital part that is attached to the airframe of the airplane. It holds the engine while dampening the effect of vibrations and transmitting forces between the engine and the airplane body structure. As it is shown in Figure 8, the engine mount is installed in front of the firewall in the engine bay. It is located between the firewall and the engine. Generally, 4130 steel is preferred for producing engine mounts because of reliable heat-treating practices and processing techniques [14]. The weight of the engine mount is 10,4 kg as its twin which is used in black-shape aircraft [36].

As it is shown in Figure 8-a, a CAD model of the mentioned engine mount is shown while the STL model is provided in Figure 8-b.

Figure 8: (a) The 3D Solid-form of Engine Mount, (b) The STL-form of Engine Mount (Generated by authors using Catia V5 R21)

During the AM process, Carbon Fiber Reinforced Polymer (CFRP) is selected in terms of reducing the weight and while maintaining the same or exceeds mechanical properties. The weight of the engine mount which is manufactured by using CFRP is about 2 kg. In Table 1, the density comparison between before and after materials is provided.

Table 1. The Density Comparison Between Engine Mount Materials [37]

S.No	Material Type	Density (gr/cm ³)
1	4130 Steel	7,8
2	Aluminum 7075	2,7
3	Carbon Fiber Reinforced Polymer (CFRP)	1,6

With this study, it is shown that almost 8 kg of saving can be achieved by using AM technology instead of legacy methods. The 8 kg of weight saving is a significant amount when it is compared with the Gross Design Weight of general aviation U/L category air vehicles.

5. Conclusion

This study presents the importance of W_0 reduction studies in the aviation industry. It highlights the previous W_0 reduction studies while submitting information about AM and TO studies. In many cases, it is observed that the weight of the original part reduces after AM and TO application. An engine mount was provided as a sample of the TO model. Based on the experimental study the followings are noteworthy conclusions;

- Based on the experimental study it can be claimed that with the usage of AM technologies, the weight of the generic engine mount can be reduced with the same or exceeded mechanical features and functionality.
- The vertical and horizontal vector stability is a crucial issue for aircraft mass and balance. In this manner, any study for weight reduction should be subjected to further investigations in terms of mass and balance studies.
- Decreasing the weight of the engine mount has a direct effect on the fuel-saving in short term, however has a beneficial effect on less carbon emission in long term.
- With the topology optimization studies based on the investigation of the researched engine mount, the weight reduction studies can be done and implement in general aviation projects.
- It is recommended to make further studies with Ti6AL4V alloy that has a wide potential in the aviation industry.

Weight reduction studies in the aviation industry will gain more importance in the future. Conclusionally, the TO and AM studies will have gain more importance as they are beneficial for both decreasing the operational cost and carbon emissions.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The author's AM studies such as weight reduction etudes and a patent are encouraged by Artuk Aviation Ltd. Company which is located in Afyonkarahisar/Turkey. The author is immensely grateful to Artuk Aviation Ltd. for supporting his engineering studies.

ABSTRACT

Formal methods are one of the efficient tools to verify and validate designs for different kinds of systems. Smart systems are attracting researchers' attention due to the rapid spread of new technologies all over the world. Modeling a smart system requires connecting heterogeneous subsystems together to build it. Our contribution to this work is in focusing on using formal methods to prove that a design model meets its specifications. We have chosen to design a smart school building system due to the lack of research in this particular area, and to prove that formal methods are appropriate for different systems applications. In this paper, we have used UML diagrams and the formal specification language TLA+ to design a smart school building system. We validate our design using the TLC model checker. The smart school system has many subsystems connected together including a secure access system, lighting control system, climate control system, and smoke detection system. Safety is a very important attribute in this system. Our goal is to have a smart system that satisfies its functional requirements as well as any non-functional requirements like safety. The system provides safety for employees and students in the smart school.

1. Introduction

Smart systems that have been designed and modeled by researchers include a smart school [1], smart library [2], a smart office [3], a smart home [4], and a smart campus [5]. The main focus of these systems was on safety and the ability to achieve specific goals. This paper is an extension of work originally presented at the 2020 IEEE 3rd International Conference on Information and Computer Technologies (ICICT), San Jose, CA, USA. [1]. In this paper, we modify the old smart school system in [1] using TLA+ tools to make it a more secure and safe system. To prove the design correctness, we validate our design using the TLC model checker.

We used both informal modeling methods like the Unified Modeling Language (UML) [6] and formal methods [7] to define system entities, system behavior, and sequence of actions. UML provides different kinds of modeling diagrams such as state diagrams, sequence diagrams, and object interaction diagrams. As well as diagrams, UML has notations and presentation conventions that have become common in the object-oriented domain and structured methods. UML can be defined as a set of graphical models which represents several properties of an object-oriented

design [6]. The structural and behavioral models are UML's two most important model types. In this paper we choose to use behavioral models to represent the behavior of the smart school system.

To model a complete smart system, we need to integrate different subsystems together, which makes verification and validation of the whole system harder to accomplish. Formal methods are one approach that can provide verification and validation [7]. Formal methods are valuable due to their ability and effectiveness in designing systems which are close to bug-free. Many reputable companies have begun welcoming and using formal methods in the last decade [8, 9]. Furthermore, many researchers used formal methods to validate their design systems. Examples include the work done in [3, 10, 11, 12].

Formal methods support development, specification tools, and verification in both hardware and software systems [7]. Formal methods are techniques that are mathematically based and are used to prove that the system's specifications meet its implementation. Formal methods provide simplicity and remove complexity, which is an important factor in system development, as well as verifying different system attributes such as reliability, accuracy, correctness, security, and safety [7]. A formal verification scheme is used in formal methods to ensure the system will be correct

<https://dx.doi.org/10.25046/aj060295>

before accepting the design. All these characteristics of formal methods make them highly trusted compared to other verification methods [7]. Formal methods have been used for different systems applications to guarantee safety and correctness and have been extensively verified for many of these systems. The strength of formal methods lies in catching systems bugs and errors which cannot be caught by other verification methods. This makes them popular with big industrial companies seeking to verify and validate their complex systems. Modeling the system using an abstract mathematical model is the first step in applying formal methods. This first step describes the system's requirements using a formal specification language. In this work, we focus in ensuring both safety and security for our smart system since having a secure login system will enhance the overall system's safety as a result. We also add in additional safety features such as fire or smoke detection.

Formal methods use formal specification languages in the process of system analysis, requirements analysis, and system design [13]. Describing a system using a specification language is different from writing executable code using a programming language. Specification languages do not describe the "how?", they describe the "what?". Verifying the program correctness by creating proofs is one of the important features of specification languages. We can use formal system syntax, proof rules, and semantics rules when applying a specification language [13]. The language can be determined by the syntax and semantics, and the proof system is the result of the proof rules. Specification languages use expressions to represent specifications. These specification languages are used to stipulate design of hardware/software systems, describe a domain formally, or to give requirements recommendations to the system [13].

In this paper we will use the TLA+ specification language. TLA stands for "Temporal Logic of Actions". TLA+ is a high level mathematically based formal modeling language. It is used to model distributed and concurrent systems. It is also used to find design errors which are hard to find in the code level and hard to correct. The designer of TLA+ is Lamport, who wanted to describe distributed algorithms formally. He published his book *Specifying Systems* [13] in 2002. He describes TLA+ in this book, along with how to use TLA+, and how to use its efficient tools. TLA+ has modules that include specifications and can be reused independently. Most mathematicians consider TLA+ to be a standard basis to formalize specifications [13]. In TLA+, both properties and specifications of a system are written as logical formulas. Actions like hiding of the internal state, refinement, and composition of the system are performed using logical connectives of quantification, implication, and conjunction. In order to help a designer in the formal development process, TLA+ has supporting tools such as theorem provers and its powerful model checker TLC, which we used in this work to validate our model [13].

In this work, we will use the TLA+ formal specification language to model the smart school system. We describe the system's abstract model using UML. Extending work in [1], we improve the TLA+ model, and we use the powerful TLC model checker to verify and validate our system. Our modified smart school building system has various subsystems. Students, employees, and visitors must enter using a secure login sub-system to ensure security and safety. Each person must enter a correct

username and password to enter the school building using the main door. Once the first allowed person enters the school, the lighting sub-system will work automatically, and so will the HVAC sub-system, which uses temperature sensors to sense the temperature and adjust it inside the building. The smoke detection sub-system will work all the time to sense any smoke and guarantee safety in the building and open all exit doors in case of fire.

In this paper, the related work is described in section 2, the UML models are described in section 3, the TLA+ formal specifications using TLA+ are described in section 4, the TLC verification model which represents the final result will be described in section 5, and finally the conclusion and future work will be described in section 6.

2. Related Work

Because of the massive technology evolution going on, smart systems implementation has become an attractive research area for researchers [14]. Many smart systems have been modeled by many researchers. For example, in [4], the author modeled a smart home system that uses a wifi network based on the AllJoyn framework. It uses asymmetric elliptic curve cryptography to apply authentications during system operation. The authentication process of this system allows the user to interact with the system and control it using an application program based on Android. Utilizing a mobile social network, a smart campus was proposed in [5]. The author set up a collaboration between a flexible system architecture and social interactions in the campus. His model addresses the server side represented by social connections and services and the client side represented by the mobile users. In [15], the author presented a prototype for a smart office system which was one of the pilot applications in the FP7 EU project ELLIOT (Experiential Living Lab for the Internet of Things). He used the LinkSmart semantic middleware for the solution he described. In [16], the author proposed a smart parking system. It uses parking destination and parking cost to reserves a parking spot. His smart system lowers the average parking time and cost to reserve a parking spot. For each decision, mixed-integer linear programming (MILP) was used. As a sub-system for a smart city, in [10], the author proposed a smart sewage system. He used UML, Nondeterministic Finite Automata (NFA), and TLA+ to model his smart sewage system. In [17], the author presented a survey of the enabling architecture, technologies, and protocols for an urban Internet of Things (IoT). He discussed best-practice technical solutions and guidelines for the Padova Smart City project in Italy [17].

Several researchers worked on modeling a smart campus system [18-20], focusing on a mobile-learning domain, cloud learning, E-learning, and an environmentally aware campus. As for modeling smart school buildings, a few researchers worked on modeling with focusing on power consumption and power management [21-24]. Our smart school building model is different because it has advanced features, including security and safety, compared to what was modeled so far in the same research area.

In smart systems, a main concept is having sub-systems which are connected together and work efficiently as one controllable system. Safety is one of the most important properties in any system, especially in a smart school system since it is dealing with human lives (students, teachers, and school employees). Security

also is an important property to have in a smart school system. It will enhance the overall system's safety. Most researchers modeled their systems focusing on either safety or security, but our model achieves a system which is both safe and secure.

Formal methods had been used to verify and validate many smart systems. Researchers used different formal specification languages to model their systems including TLA+ [13], VDM [25], Z [26], and Alloy [27]. In [11], the author modeled and verified a smart parking system using TLA+. In [3], the author designed and verified a smart office system using the VDM-SL toolbox. And in [28], the author used Alloy to validate his smart home system. In this work, we decided to use TLA+ to model and verify our smart school building system. We choose TLA+ over other specification languages for many reasons, which we list here.

In comparison to Alloy in modeling nested structures, TLA+ doesn't need too many layers of identification, which makes it simpler and more direct. TLA+ is also more expressive than Alloy. Although Alloy has its efficient Alloy Analyzer model checker that is faster than the TLC model checker and able to handle important large analyses that TLC currently is not able to handle, Alloy Analyzer crashes or hangs in some cases that are needed for larger systems. Also, using TLA+ allows users to trace every single state and get results for each one using its Trace Explore feature, which makes tracing bugs, finding bugs, and fixing them much simpler and easier. Alloy has the same advantage, but the results for systems with more than a few variables or a few time-steps are not clear-cut. Some other features make TLA+ a better choice than Alloy and other specification languages including VCC and Z. TLA+ is flexible when there is a need to support high-level functions and edit details to the specifications, unlike VCC that would require us to write "ghost code" which is a superset of the C programming language and Alloy that does not support high-level functions like recursive functions. One important feature in TLA+ is its powerful TLC model checker that can operate over massive state-spaces with reasonable throughput. The TLC model checker is also fast because of its ability to use multi-cores efficiently, unlike B, VCC, and Event-B model checkers, which are not able to use more than one core. TLA+ is also a very expressive language, and it supports the liveness property better than any other formal specification language [9].

In the following section, we will illustrate how to use UML as a first step to model our smart school building system.

3. UML Modeling for Smart School Building System

Unified Modeling Language (UML) is one of the most common languages used to represent the informal abstract model of a system. UML captures system properties and provides graphical notations. Smart school system outputs and inputs are shown in Figure 1 [1]. As shown in Figure 1, the smart school inputs are taken from a user or different kinds of sensors and reactions to these inputs appear as outputs from the system. The login input is handled by entering a valid username and password by the user, who can be a student, an employee, or a visitor and it may or may not open the main door based on the validation of the username and the password. The smoke sensor senses any smoke in the building and gives an alarm as an output, and in this work, we added a new output that in case of smoke all exit doors will be opened to increase the safety of our system. The temperature

sensor senses the building's temperature and turns the heat or the AC on or keeps them off. The light sensor senses the natural light inside the building and adjusts the lights based on it. The system may have multiple sensors depending on the size, orientation, and architecture of the building. The outputs of the system depend on the inputs. For example, if the username and password were entered correctly as an input, the main door will automatically open to allow entrance to the school building as an output. If the HVAC sub-system receives an input from the temperature sensor that is the temperature is too low (e.g., 60 F), the output will be to automatically turn on the heat in the building. If the smoke detection sub-system receives an input from the smoke sensor that there is smoke in the building, the output will be to turn on the smoke alarm and open the exit doors to let everyone leave the school building immediately.

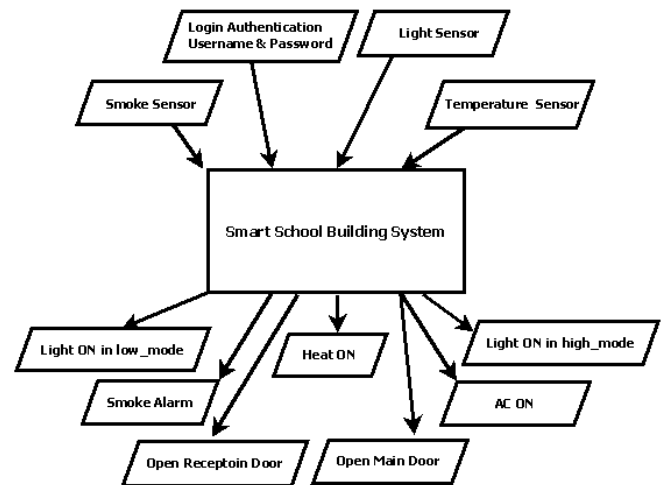

Figure 1: Inputs and Outputs of the Smart School Building System [1]

Figure 2 shows the UML use case diagram of the system. This diagram shows when the actors (student, employee, and visitor) login to the system by entering the username and password correctly, the main door will open, and they will have access to the sub-systems in the building.

Figure 3 [1] shows the UML activity diagram of the smart school building. The activity diagram will help in better understanding how the system works.

Figure 4 provides a UML sequence diagram of the smart school building system. It illustrates the sequence of all actions that happen in the system. As an extension of work in [1] and in order to increase system's security and eventually safety, the new smart school model requires that each person entering the school has to have a unique username and password. These usernames and passwords will be given by school or school district to each person. Visitors must request a username and password from the school before their visit, i.e., visitors to the school building must have a valid login username and password to be allowed to enter the building.

If the username and password are correct, the main door will automatically be opened. Once the first person enters the building, all systems, including the lighting sub-system and the HVAC sub-

system, will automatically start working. The smoke detection system will work all the time, even after school hours, to guarantee safety in the building in case of fire.

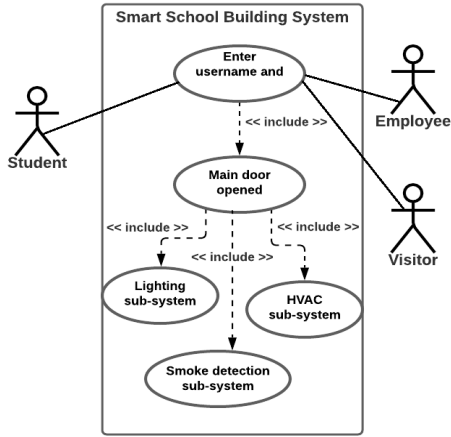

Figure 2: UML Use Case Diagram of the Smart School System

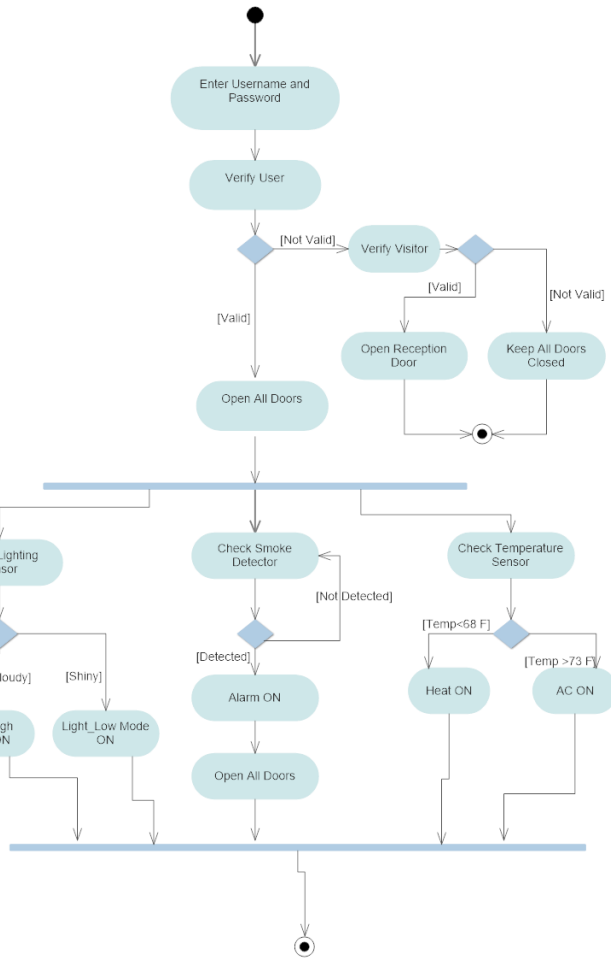

Figure 3: UML Activity Diagram of the Smart School Building System [1]

4. Formal Specification Using TLA+

This section illustrates the formal specification of our extended smart school system model. We use the TLA+ toolbox to

write the system's specifications and the TLC model checker to validate our system. We represent all of the system's operations using TLA+.

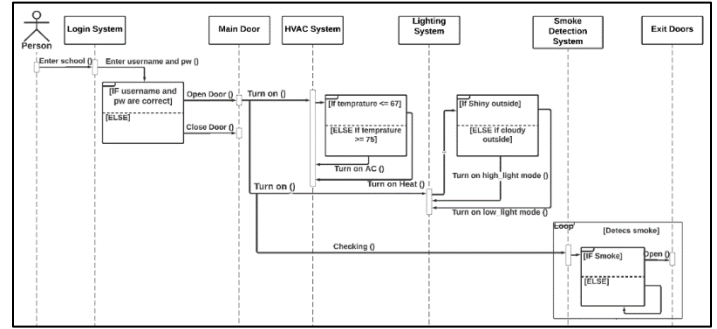

Figure 4: Sequence Diagram for the Smart School Building System

In TLA+, the system's specifications are called spec, and they are written in a module which we have called in our case *smartSchoolSystem*. In the module, we include the system's variables that we will use inside the module as shown in Figure 5.

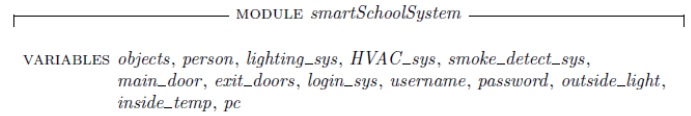

Figure 5: smartSchoolSystem Module Variables

The top module of the smart school system is represented by *smartSchoolSystem*. The module has the set of variables shown in Figure 5. For example, *person* variable represents anyone who is allowed to enter the building (employee, visitor, or student). The *main_door* variable represents the main door for people to enter the school building, and *exit_doors* represents the doors which will be opened in case of fire/smoke. The *username* and *password* variables represent the values of the person's username and password, and these values must be unique for each individual person.

In any TLA+ module, declaring the *Init* function, invariants, and *Next* function is a must. The *Init* function represents the initial values of the system's variables, the invariants represent the limitations and conditions in the system, and the *Next* function represents the next-state action.

In the *smartSchoolSystem* module, we declared the *Init* function with the range of all possible values of each variable in the module as shown in Figure 6. For example, *main_door* variable may take on either open or closed values only. Similarly, *person* variable may take either student, employee, or visitor values in this spec. The *pc* variable represents the current state, and *pc'* represents the next state as we will see later in the spec.

To ensure that the school building in our system is always safe in case of fire, we designed our system to have a smoke detection sub-system working all the time in and out of school hours. To apply this safety functionality in our system, we added a system invariant and called it *safe* as shown in Figure 7. This invariant

guarantees that the smoke detection system will be working all the time.

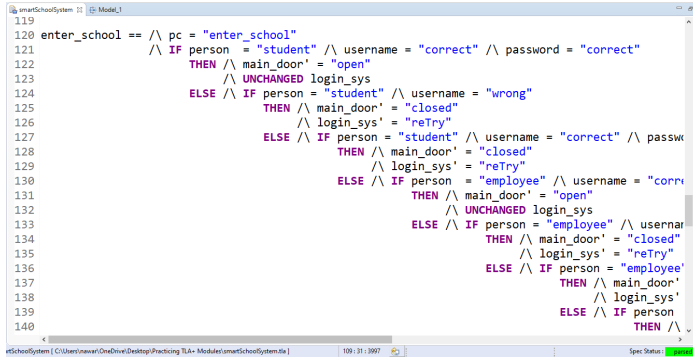

```
Init  $\triangleq$  Global variables
 $\wedge$  objects = { "person", "lighting_sys",
               "main_door", "HVAC_sys", "smoke_detect_sys", "exit_doors",
               "login_sys", "username", "password", "outside_light", "inside_temp" }
 $\wedge$  person  $\in$  { "student", "employee", "visitor" }
 $\wedge$  lighting_sys  $\in$  { "low_mode", "high_mode", "off", "on" }
 $\wedge$  HVAC_sys  $\in$  { "heat_on", "AC_on", "off", "on" }
 $\wedge$  smoke_detect_sys  $\in$  { "on" }
 $\wedge$  main_door  $\in$  { "open", "closed" }
 $\wedge$  exit_doors  $\in$  { "open", "closed" }
 $\wedge$  login_sys  $\in$  { "ready", "reTry" }
 $\wedge$  username  $\in$  { "correct", "wrong" }
 $\wedge$  password  $\in$  { "correct", "wrong" }
 $\wedge$  outside_light  $\in$  { "clear", "cloudy" }
 $\wedge$  inside_temp = defaultInitValue
 $\wedge$  pc = "enter_school"
```

Figure 6: Init Function

$safe \triangleq smoke_detect_sys = "on"$

Figure 7: System Invariant

The function *enter_school* is the function that represents any of the employees, students, and visitors entering the school. This function requires the person desiring entry to enter a valid username and password as input in order to open the main door for entrance as an output. If the username and/or the password is wrong, the main door will not open, and the system will ask the person to retry to enter valid values. Figure 8 shows the *enter_school* function.

```
119 enter_school ==  $\wedge$  pc = "enter_school"
120  $\wedge$  IF person = "student"  $\wedge$  username = "correct"  $\wedge$  password = "correct"
121 THEN  $\wedge$  main_door = "open"
122  $\wedge$  UNCHANGED login_sys
123 ELSE  $\wedge$  IF person = "student"  $\wedge$  username = "wrong"
124 THEN  $\wedge$  main_door = "closed"
125  $\wedge$  login_sys = "reTry"
126 ELSE  $\wedge$  IF person = "student"  $\wedge$  username = "correct"  $\wedge$  password = "wrong"
127 THEN  $\wedge$  main_door = "closed"
128  $\wedge$  login_sys = "reTry"
129 ELSE  $\wedge$  IF person = "employee"  $\wedge$  username = "correct"  $\wedge$  password = "correct"
130 THEN  $\wedge$  main_door = "open"
131  $\wedge$  UNCHANGED login_sys
132 ELSE  $\wedge$  IF person = "employee"  $\wedge$  username = "wrong"
133 THEN  $\wedge$  main_door = "closed"
134  $\wedge$  login_sys = "reTry"
135 ELSE  $\wedge$  IF person = "employee"  $\wedge$  username = "correct"  $\wedge$  password = "wrong"
136 THEN  $\wedge$  main_door = "closed"
137  $\wedge$  login_sys = "reTry"
138 ELSE  $\wedge$  IF person = "employee"  $\wedge$  username = "correct"  $\wedge$  password = "correct"
139 THEN  $\wedge$  main_door = "open"
140  $\wedge$  UNCHANGED login_sys
```

Figure 8: enter_school Function

$Smoke \triangleq \wedge pc = "Smoke"$
 \wedge IF main_door = "open"
 THEN \wedge IF smoke_detect_sys = "smoke"
 THEN \wedge exit_doors = "open"
 ELSE \wedge TRUE
 \wedge UNCHANGED exit_doors
 \wedge pc = "Smoke"
 ELSE \wedge pc = "Light"
 \wedge UNCHANGED exit_doors
 \wedge UNCHANGED {objects, person, lighting_sys, HVAC_sys, smoke_detect_sys, main_door, login_sys, username, password, outside_light, inside_temp}

Figure 9: Smoke Function

We set *smoke_detect_sys* to be *on* all the time as an invariant in our system as mentioned before. If there is smoke detected from

the smoke detection sub-system, in this case *smoke* function will be *on* and all exit doors will open automatically to allow all people inside the school to leave immediately for their safety. Of course, the smoke detection sub-system will have a built-in alarm in case smoke is detected. Figure 9 shows the *Smoke* function.

Once the first person enters the school, the lighting and HVAC sub-systems will automatically start working. In the light function, the light sensor will start sensing the natural *outside_light* brightness to control the light inside the building. The *outside_light* could have two values, clear or cloudy. If it is clear outside, the lights inside the building will be turned on by the system in a *low_mode*. If it is cloudy outside, the lights inside the building will be turned on by the system in a *high_mode*. This lighting sub-system will help in managing and controlling power consumption in the system. Figure 10 shows the *Light* function. In practice there will be multiple light sensors for multiple sides of the building.

$Light \triangleq \wedge pc = "Light"$
 \wedge IF main_door = "open" \wedge outside_light = "clear"
 THEN \wedge lighting_sys = "low_mode"
 ELSE \wedge IF main_door = "open" \wedge outside_light = "cloudy"
 THEN \wedge lighting_sys = "high_mode"
 ELSE \wedge TRUE
 \wedge UNCHANGED lighting_sys
 \wedge pc = "HVAC"
 \wedge UNCHANGED {objects, person, HVAC_sys, smoke_detect_sys, main_door, exit_doors, login_sys, username, password, outside_light, inside_temp}

Figure 10: Light Function

The HVAC sub-system helps in controlling the temperature inside the school building. In the HVAC function, the temperature inside the building has been sensed by the temperature sensor and the HVAC sub-system acts based on that. If the *inside_temp* is more than 74 F, the HVAC sub-system will turn on the AC in the building. If the *inside_temp* is less than 69 F, the HVAC sub-system will turn on the Heat in the building. If the *inside_temp* is more than 69 F and less than 74 F, the HVAC sub-system will be turned off. Figure 11 shows the HVAC function.

$HVAC \triangleq \wedge pc = "HVAC"$
 \wedge IF main_door = "open" \wedge inside_temp ≥ 74
 THEN \wedge HVAC_sys = "AC_on"
 ELSE \wedge IF main_door = "open" \wedge inside_temp ≤ 69
 THEN \wedge HVAC_sys = "Heat_on"
 ELSE \wedge IF main_door = "open" \wedge inside_temp $> 69 \wedge$ inside_temp < 74
 THEN \wedge HVAC_sys = "off"
 ELSE \wedge TRUE
 \wedge UNCHANGED HVAC_sys
 \wedge pc = "Done"
 \wedge UNCHANGED {objects, person, lighting_sys, smoke_detect_sys, main_door, exit_doors, login_sys, username, password, outside_light, inside_temp}

Figure 11: HVAC Function

Figure 12 includes housekeeping functions which are essential for writing good specifications for a system. Some of these functions must be in any TLA+ spec, e.g., the *Next* function. The *Next* function enables collection and execution of all functions in the spec and moving to the next state in the system after initialization. The Termination function guarantees the

termination when pc reaches *Done* state. In TLA+, the Spec function is the main function that is responsible to run all system specifications in the main execution of the system.

$$Terminating \triangleq pc = \text{"Done"} \wedge \text{UNCHANGED vars}$$

$$Next \triangleq enter_school \vee Smoke \vee Light \vee HVAC \\ \vee Terminating$$

$$Spec \triangleq Init \wedge \Box[Next]_{vars}$$

$$Termination \triangleq \Diamond(pc = \text{"Done"})$$

Figure 12: Terminating, Next, and Spec functions

In order to verify that the module is correct and there are no syntax errors in our system, we have used the TLA+ toolbox to write these specifications and save the module. Figure 13 shows the parsed model. As shown in the figure, the green box on the bottom right corner of the screen proves that this model is correctly parsed via the TLA+ toolbox. The next section will describe the system that will be verified through the TLC model checker.

```

155 Smoke == /\ pc = "Smoke"
156           /\ IF main_door = "open"
157              THEN /\ IF smoke_detect_sys = "smoke"
158                 THEN /\ exit_doors = "open"
159                 ELSE /\ TRUE
160                 /\ UNCHANGED exit_doors
161                 /\ pc' = "Smoke"
162             ELSE /\ pc' = "Light"
163             /\ UNCHANGED exit_doors
164             /\ UNCHANGED pc
165 /\ UNCHANGED << objects, person, lighting_sys, HVAC_sys,
166 smoke_detect_sys, main_door, login_sys, username,
167 password, outside_light, inside_temp >>
168
169 Light == /\ pc = "Light"
170           /\ IF main_door = "open" /\ outside_light = "clear"
171              THEN /\ lighting_sys = "low_mode"
172              ELSE /\ IF main_door = "open" /\ outside_light = "cloudy"
173                 THEN /\ lighting_sys = "high_mode"
174                 ELSE /\ TRUE
175                 /\ UNCHANGED lighting_sys
176           /\ pc' = "HVAC"

```

Figure 13: TLA+ Parsed Model for Smart School System

5. Formal Verification Using TLC

In the previous section, we illustrated the smart school system specifications, and we parsed the module correctly using the TLA+ toolbox. We did this in order to verify the model is correct and to validate our work. We used the powerful TLC model checker to debug a TLA+ specification. It checks the specification's invariance properties of its finite state model [13]. TLC checks for deadlock and the system invariants. In our TLC model, we set the safety invariant to keep the smoke detection sub-system working all the time, as shown in Figure 14. This means that this invariant will guarantee that the smoke detector will work all the time, whether there is someone in the school or not, day and night, to enhance the safety in the school building. As shown in Figure 14 as well, the TLC model checker has a feature to check for a deadlock in the design. It's an optional feature. In this model, we choose to check for deadlock and it returns that there is no deadlock.

After setting-up the TLC model checker, we ran it to verify our *smartSchoolSystem* module. Figure 15 shows the TLC model checker while running.

www.astesj.com

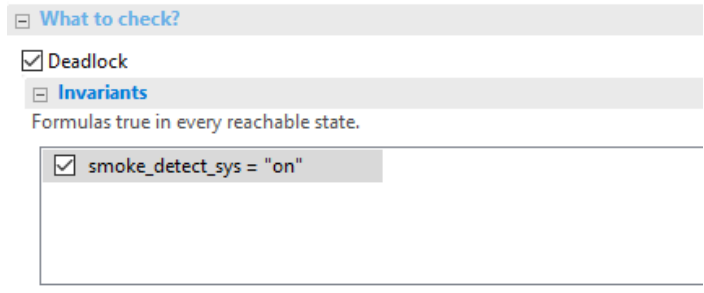

Figure 14: Safety Invariants Setup in TLC

Figure 15: TLC Model Checker While Running

Figure 16 shows the final result for the *smartSchoolSystem* model. In order to validate a system using the TLC model checker, the model must be parsed, and the model checker should run to completion, and no errors should be detected. Our smart school system was verified and validated correctly using the TLC model checker since, as shown in Figure 16, the TLC model is parsed correctly with no errors, which proves our system's validation.

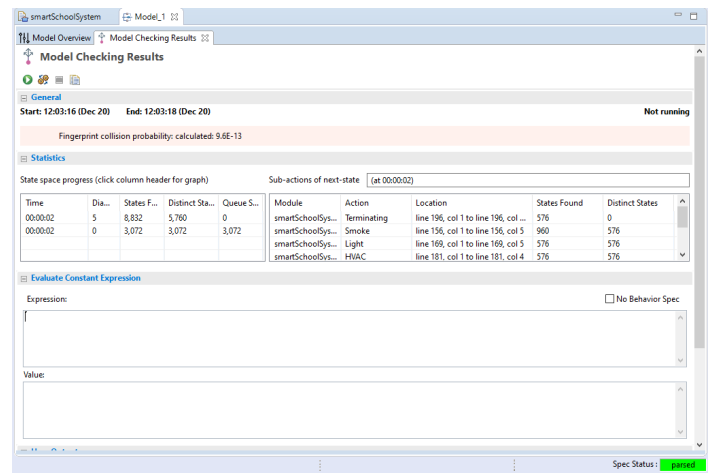

Figure 16: TLC Verification Model

6. Conclusion

This work is an extension of the work in [1]. We have modeled a smart school building system using UML and TLA+.

We used UML to define the system's components and to illustrate the sequence of actions in the system. TLA+ defines the system's specifications and the system's behavior. The TLA+ toolbox was used to capture the system's behavior and to parse the model. The final result was to verify the model using the TLC model checker. The model was successfully verified and validated with the TLC model checker. We used formal methods to validate our design and to make sure there are no errors in the design. In this design a failure may still happen. For example, if we simulated the design and built the school from this model, we could have a failure in the lighting system because in practice we will need a light sensor in each room. But our design assumes that the light will be the same in the whole building. This design is an initial and general design to show and explain our methodology, details such as the more complex lighting system would be needed in the final design.

To enhance security and safety in the system, the system requires each person who enters the building to login by entering a valid username and password. To enhance the safety as well, the smoke detection sub-system is working all the time. To control the power in the system, the lighting sub-system will use natural light when possible to reduce the power consumption in the building.

In future, we will work on improving the system by adding more sub-systems to it to enhance system security and safety.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

Figure 2 and Figure 4 were made using chart-making tools at www.lucidchart.com and the authors would like to thank the website. Figures 5,6,7,9,10,11,12 were taken from the TLA+ tool that uses LaTeX translator to generate pretty-printed specs. Figures 8,13,14,15,16 were taken from the TLA+ toolbox. The authors would like to thank Mr. Leslie Lamport for the TLA+ tool which is essential in this work. The authors would also like to thank the University of Cincinnati for its support.

Wearable locket and bracelet

Bluetooth

ABSTRACT

Harassment and violence against women have become one of the social security problems in Bangladesh. In this paper, we aim to develop safety devices for women named BOHNNI and BADHON which resemble legitimate jewelry. We used a microcontroller for the hardware device to make it most decisive and less immoderate. BOHNNI, a locating device, is the imitator of a locket including a voice recognizer, Bluetooth, Arduino, GPS, and GSM module. BADHON which imitates a bracelet is a rescue device for the victim whenever she thinks of herself being in a very deliberate situation. Both devices are activated by the user's voice commands and also by a manual switch. The devices are aesthetically designed which will make the users enthusiastic to wear them. The device will generate messages to the predefined relative's numbers with the victim's location and relevant surrounding information. The device can also be used as a self-defending weapon as it can produce a shock up to 10 mA with an interval of two seconds which can temporarily paralyze or freeze a person. After calculating, we have obtained the lowest response time of BOHNNI and BADHON which is 1.95s, and the highest accuracy level of 91.67% in different situations that ensure the superlative performance level of our devices. We found our device as an all-in-one device that combines all the features in it regarding safety.

1. Introduction

Bangladesh has met the eligibility requirements for shifting from 'Least Developed Country' to 'Developing Country' status, the UN says [1]. Women's empowerment is also on the rise, but incidents of various forms of violence against women, including dowry torture, sexual assault, abduction, and rape continue to take place extensively in Bangladesh. The "State of Rights Implementation of Women Ready Made Garment Workers" study, conducted by Karmojibi Nari and Care Bangladesh, shows that about 12.7% of workers face sexual harassment in their workplaces [2]. Around 94% of women face harassment in public transport [3]. Bangladesh Mahila Parishad (October 2019) statistics indicated that in the last year at least 3,918 women have been victims of various forms of violence across the country [4]. Surviving in these situations becomes a great challenge for women. By adopting modern technology and devices to protect

them from their oppressors, the defense strategy used by women needs to be revolutionized [5]. This current situation has encouraged us to come up with a solution to harassment and violence against women. This work has been done to ensure safety for women moving alone. It is not the only solution to a problem but also comes with wearable safety products. These are very handy safety devices that can be used by any woman. GPS and GSM modules are used to give alert calls and messages to the victim's previously established numbers and nearest police station numbers including the instant location and that location can be tracked immediately or later using our device "BOHNNI" and "BADHON". The devices that we have built can be activated by using vocalized passwords which ensures the surety of access to the devices in any critical situation. It is very easy to operate and anyone can operate it as it can be used manually or by using voice commands. This product is multi-functional. It makes it easier and faster to catch the criminals as the lowest response time of BOHNNI and BADHON is 1.95s and also works as a self-defender. The highest accuracy level of 91.67% was obtained in a

*Corresponding Author: Md. Ashrafuzzaman, Email: ashezaman@gmail.com

different situation that ensures the performance level of our devices. It is intelligent enough because it can understand the user's voice command and can be used by people of any age. Materials used there are recyclable. We have maintained the safety of the user while designing the device with polymer plastic material to protect the user from accidental shock. The notable accomplishment of our design is the shocking module which can give a shock to the harasser up to 10 mA with an interval of 2 seconds which help the victim to escape from the location. We believe that this device can bring a huge change in violence and harassment against women. It can be a blessing for women and also develop their social norms in our country.

2. Related Works

The project described in [6] developed a wearable device for the protection of women by analyzing physiological signals in association with body position. Galvanic skin resistance and body temperature are analyzed as the physiological signals. Real-time monitoring of data is obtained by wirelessly sending data to an open-source Cloud Platform. In critical situations, this device sends notifications to designated individuals. A proposal is available in [7] anticipated "FEMME" as a safety device specifically designed for women in situations of threat. Using Bluetooth, both the device and the smartphone are synced. With instant location information, it can record audio, give an alert call and message to the pre-set contacts. A hidden camera detector is a visible feature here as well. A smart Intelligent Security System was proposed in [8]. The system features a band on the wrist associated with a pressure switch. The screaming alarm and tear gas mechanisms are appointed for self-defending purposes. This system also sends the appropriate locations and messages to the emergency contacts and uses live streaming video to figure out the assaulter [8]. It was aimed to create a common system that incorporates a wearable computer and acts as a safeguard for women facing any danger in [9]. Body area sensors, Bluetooth communication, GPS, SMS and MMS, Internet connection, and a mobile database system are used for the composition of this system. Another proposal named "Suraksha" is developed in [10] to flash a warning to provide the police with an immediate location of the distressed victim so that the incident could be prevented easily. A smart intelligent device is proposed in [11] where a wearable smart band and a secret webcam linked via Bluetooth are integrated into the device. Women's information such as call log, messages, motion, pulse measurement, blood oxygen levels, heartbeat rating can be tracked by the application. It automatically generates signals to the predefined smartphones and the nearest police stations when the SOS present in the smart band is pressed continuously. A smart women's security system using Radio Frequency Identification (RFID) and Global Positioning System (GPS) was established in [12]. In scanning the information, the RFID reader is used and assigns that information to the microcontroller. In [13], the team developed a device that can use GPS to track the location of women and send emergency messages using GSM. The pulse sensor checks the victim's pulse and the device also sends the current GPS location to the ambulance every 10 seconds in the form of SMSs in abnormal health situations. The authors in [14] developed a device that will be clipped to the user's footwear and can be carefully triggered four times by tapping one foot behind the other. A device is

developed in [15] that reads and creates patterns such as body temperature and pulse rate automatically during running, including temperature and pulse sensors. If the readings are higher than normal readings, more than one person will automatically get a call and message. In non-dangerous conditions, data is first collected by sensors to train the algorithm. A passive continuous monitoring system is proposed in [16] using both survivor-attached biosensors and machine learning techniques. According to the current status of wearable and biomedical device technology, the monitoring structure of the system supervises a lot of bio-signals. In [17] a system is designed to detect location with GPS and GSM mechanisms to pass the current location to any of the trusted contacts as a Google map link and services are provided from that moment on to track the locations to save the individual. A wearable system was designed in [18] that resembles a normal watch with a button that can be pressed in an unpleasant situation to activate the system. Using a Global Positioning System (GPS) sensor, the system monitors the victim's location. The system also includes a screaming alarm using a real-time clock. A smart band is developed in [19] that gets activated to send the GPS location to the ICE contacts and police control rooms by tapping on the screen twice. A micro USB charge is supported by the device and two metal points generate the shock on the top of the band screen. A project 'watch me' is developed in [20] for a purpose whenever a woman or child wearing a smartwatch called 'watch me' is exposed to sexual or vulnerable assault, the device works. It will automatically make a call to the registered contacts of the victim and will also detect the nearby police station via GPS / GSM to make a ring there so that police can arrive at the spot soon by tracking the GPS. The developers in [21] developed a female safety jacket that flashes a warning giving the police an instant location of the distressed victim so that the incident can be avoided and the culprit captured. An efficient woman's security recognition system has been introduced in [22] consisting of an ARDUINO NANO Controller, a Bluetooth module, a Taser, and a versatile Android. It monitors the victim's location using GPS and sends emergency messages via GSM. An electronic device including biometric touch sensors has been developed in [23] that generates extremely high voltage pulses at around 3 KV range. The high voltage causes body pain, numbness, and balance loss. From its use, no permanent injury is noticed. For women, a self-defense system using Raspberry-pi 0 controller and GSM, GPS, Temperature sensor, Heartbeat Sensor has been developed by [24]. The location of a place via GPS is indicated by a single click on this device and a message consisting of the location URL is sent to the registered contacts to assist them in dangerous situations. In terms of latitude and longitude, a rapid response mechanism was developed by [25] that helps women when they press the button attached to the device and the location information is sent as an SMS alert to a few predefined emergency contacts. A smart security wearable device for women was implemented by [26] in the form of a smart ring (SMARISA) comprising Raspberry Pi Zero, camera, buzzer, and button. The victim can activate the device by clicking on a button that fetches her current location and also captures the attacker's image.

For all sections of women in Bangladesh, a user-friendly mobile-based approach 'BONITAA' was developed by [27] with several unique features, primarily aimed at supporting victims of rape by facilitating their ways to obtain justice with legal solutions,

physical and mental support, etc. Another mobile app ‘SafetiPin’ was introduced by [28] where the device can gather crowd-source data and information on insecurity in cities using several features such as GPS navigation, digital camera, high-speed internet connectivity, and many more. The team in [29] created a women's security Android application. Using the Wikitude SDK, the women's safety app can be integrated with augmented reality that helps to place articles and reviews related to the current location. A smartphone application prototype was introduced in [30], which is primarily a safety decision aid designed to help women estimate the risk in their abusive relationships, set safety priorities, and develop a personalized safety plan. A “Virtual Friendly” device was created by [31], consisting mainly of GPS, GSM modem, microcontroller, RF transceiver, temperature sensor, voice recognizer to provide trouble-safety. The GPS receiver obtains location information in the form of latitude and longitude from satellites. The temperature sensor senses the temperature of the body and sends an SMS alert in the event of a low temperature. A portable device was developed by [32] incorporating a pressure switch that gets activated by compressing it. The pressure sensor senses the pressure instantly and a conventional SMS, with the location of the victim being sent to phone numbers stored in the device followed by a call to their parents/guardians [32]. A smart device is developed by [33] that can be clipped to a woman's footwear and can be discreetly triggered within 5 seconds by tapping her feet 10 or more times. It will also sense the unnatural rise or fall of her heartbeat and the values will be displayed on the smartphone of the victim.

GSM, Bluetooth, Arduino, voice recognition module, and camera module. The primary components of the circuits are the voice recognition module which is used to capture the user's voice & turning on the operation of the device, Arduino to send messages & location to the programmed numbers, GSM Module which is used to send messages & location to the programmed numbers, Bluetooth Module to send & receive a signal during the operation of the device and lastly the Camera Module to save pictures during the operation of the device.

3.2. Design

The circuit is designed in Proteus software. The microcontroller is the processing unit that processes all data from the sensor and voice recognition module. It also sends the necessary command to GPS and GSM units.

We have designed the initial outer designs of the device BOHNNI in SolidWorks that is represented below in Figure 2:

Figure 2: 3D Design of BOHNNI & BADHON

3.3. Fabrication of Prototype

‘BOHNNI’ and ‘BADHON’ are fabricated initially on bread-board connecting all parts including Arduino, LED, voice recognition module, Bluetooth module, GSM, and a GPS module. ‘BADHON’ consists of a shocking module, Arduino, a Bluetooth device, a video camera, and a buzzer. Initially, the video camera was not used in the prototype. During mass production or making a real-time product, the video camera will be included. A visual representation of our prototype ‘BOHNNI’ and ‘BADHON’ are given below in Figure 3 and Figure 4:

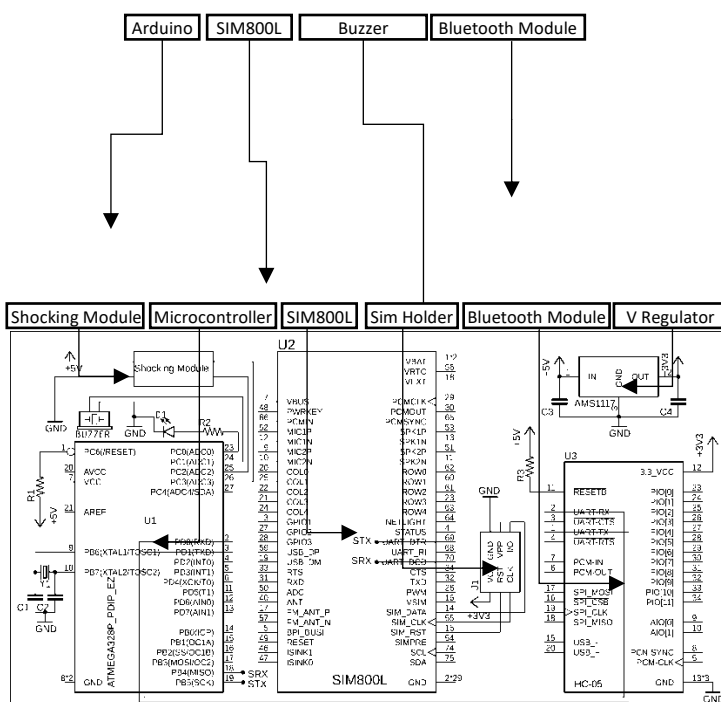

Figure 1: Circuit Diagram of BOHNNI and BADHON

3. Materials & Methods

3.1. Hardware Components

Materials that have been used to produce these devices are non-toxic, heat & current resistant. The core of the device is embedded with the PCB circuit board consisting of the circuit of

Figure 3: Prototype of BOHNNI

Figure 4: Prototype of BADHON

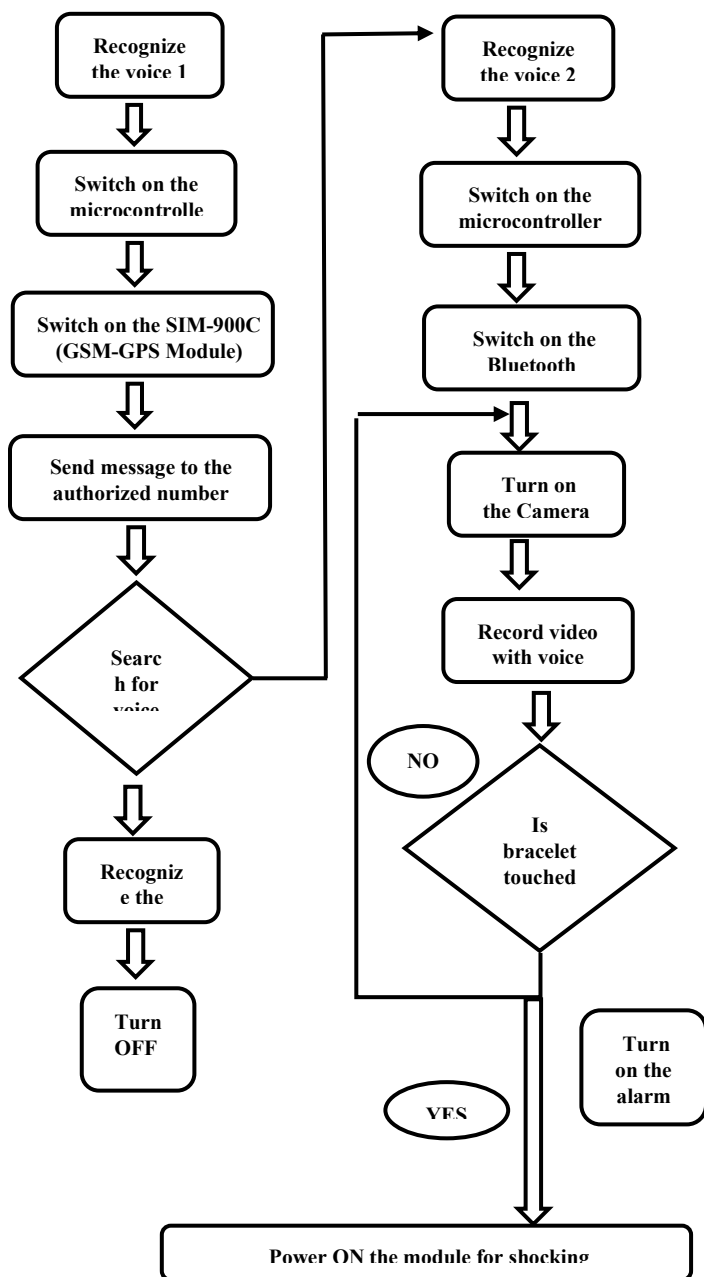

Figure 5: Flow chart of the operating process of BOHNNI and BADHON

3.4. Working Procedure

For WOMEN we are introducing a system that resembles some normal jewelry like locket (BOHNNI) and bracelet

(BADHON). BOHNNI is a locating device including a voice recognizer, Bluetooth, Arduino, GPS, and GSM module. The device will be activated using the voice password set by the user. As it activates it will send messages to the user's family member's numbers which were previously set by her and the nearest police stations with the link of her location. This will provide vital protection to the victim. BADHON which reassembles a bracelet activates another voice password set by the user. It is a rescue device for the victim if she is in a very critical situation. This device includes a shocking module, Arduino, Bluetooth device, video camera, and a buzzer. Using another voice code in BOHNNI will activate the device BADHON. After it activates, the video camera will capture video of the victim's surroundings as it can be used as evidence in the future. The shocking system will be activated which can give a shock to the harasser up to 10mA (10 mA) with an interval of 2 sec which can make him paralyze or freeze his muscle for few minutes and help the victim to escape from the location. As the device will be made of polymer plastic the user will not be affected by the shock. It also has a buzzer that activates when it is touched. Then the buzzer will buzz 120 decibel sound to attract people from further. This device can also be used for children when aesthetically designed which will make the children enthusiastic to wear them. In this way, the guardian can always be aware of their child when they are not with them.

4. Results & Discussion

4.1. Design of Experiments

The design of the experiment runs by putting BOHNNI and BADHON together in different combinations. In table 1, for the first five rows, BADHON was placed on the right arm where BOHNNI was placed on the left arm, right wrist, left wrist, neck, and chest respectively. For the next four rows, BADHON was placed on the left arm where BOHNNI was placed on the right wrist, left wrist, neck, and chest respectively. Again, for the next three rows, BADHON was placed in the right wrist and BOHNNI was placed on the left wrist, neck, and chest respectively. For the last two rows, BADHON was placed in the left wrist and BOHNNI was placed in the neck and chest respectively. In this total of 14 rows, BOHNNI and BADHON were subjected to different combinations to check the response time of each for every possible combination. The experimental design has been formatted in Table 1 below.

Table 1: Different combinations and placements of BOHNNI and BADHON

Right Arm	Left Arm	Right Wrist	Left Wrist	Neck	Chest
BADHON	BOHNNI	--	--	--	--
BADHON	--	BOHNNI	--	--	--
BADHON	--	--	BOHNNI	--	--
BADHON	--	--	--	BOHNNI	--
BADHON	--	--	--	--	BOHNNI
--	BADHON	BOHNNI	--	--	--
--	BADHON	--	BOHNNI	--	--
--	BADHON	--	--	BOHNNI	--

--	BADHON	--	--	--	BOHNNI
--	--	BADHON	BOHNNI	--	--
--	--	BADHON	--	BOHNNI	--
--	--	BADHON	--	--	BOHNNI
--	--	--	BADHON	BOHNNI	--
--	--	--	BADHON	--	BOHNNI

Response times have been calculated by following the combinations of BOHNNI & BADHON's placement & placed in Table 2.

Table 2: Response time for different placement combinations of BOHNNI and BADHON

Right Arm	Left Arm	Right Wrist	Left Wrist	Neck	Chest	Total Response Time (s)
0.55	1.45	0	0	0	0	2
0.56	0	1.85	0	0	0	2.41
0.58	0	0	1.85	0	0	2.43
0.57	0	0	0	1.4	0	1.97
0.56	0	0	0	0	1.4	1.96
0	0.58	1.85	0	0	0	2.43
0	0.56	0	1.85	0	0	2.41
0	0.57	0	0	1.4	0	1.97
0	0.55	0	0	0	1.4	1.95
0	0	0.59	1.85	0	0	2.44
0	0	0.57	0	1.4	0	1.97
0	0	0.55	0	0	1.4	1.95
0	0	0	0.57	1.4	0	1.97
0	0	0	0.55	0	1.4	1.95

The total response time for BOHNNI and BADHON was obtained by adding the response time of BOHNNI and BADHON for each combination. From table 2, we have obtained the lowest response time that is 1.95s.

Findings from this data are the precise locations to place the device in the body. We found three locations with the minimum response time. Those combinations are-

- Right Wrist (BADHON) & Chest (BOHNNI)
- Left Wrist (BADHON) & Chest (BOHNNI)
- Left Arm (BADHON) & Chest (BOHNNI)

From these findings, we have designed our devices so that they can be worn on the wrist & chest to obtain the least response time.

Figure 6: Main effect plots for Total Response Time

Table 3: The response of the device in different situations

Ser No	Different Situation	Tested Times	True (+)ve	False (-)ve	Sensitivity	% of Error
1.	Inside a room	12	11	1	0.92	8.33%
2.	Inside a bus	12	8	4	0.67	33.33%
3.	Inside a CNG	12	9	3	0.75	25.00%
4.	Inside a car	12	11	1	0.92	8.33%

7.	Walking on the street during night	12	10	2	0.83	16.67%
8.	Walking on the street during midnight	12	11	1	0.92	8.33%

$$\% \text{ of Error} = (1 - \text{Sensitivity}) \times 100 \%$$

4.2. Accuracy calculation

Sensitivity analysis is the study of how to divide and allocate the uncertainty in the output of a mathematical model or system (numerical or otherwise) into its inputs to different sources of uncertainty. Uncertainty analysis, which focuses more on quantifying uncertainty and propagating uncertainty, is a related practice; ideally, uncertainty and sensitivity analysis should be performed in tandem. We have checked the sensitivity and percentage of error in various situations. The formula of Sensitivity (S_n) [34] is given below,

$$S_n = \frac{\text{True positive}}{\text{True positive} + \text{False negative}}$$

The obtained results using the Sensitivity formula are given in Table 3.

We have also obtained a bar diagram regarding the results. Here we have shown the percentage of error and accuracy in different situations.

Figure 7: Bar chart of percentage & accuracy

From the chart, we found out 91.67% accuracy occurred during three situations. Those are: -

- Inside a room
- Inside a car
- Walking on the street during mid-night

Other situation's accuracy is higher than the error percentage which indicates the feasibility of the device.

4.3. Comparative Analysis

We have made a comparative analysis with two of the existing works "Suraksha" [10] and "Watch Me" [20]. The major achievements of our design that distinguish itself from others are the shocking system which can give a shock to the harasser up to 10 mA with an interval of 2 sec which can make him paralyze or freeze his muscle for few minutes and help the victim to escape from the location and also the fact that we have taken the safety of the user under account while designing the device with polymer plastic material to protect the user from the shock.

Table 4: Comparative analysis with existing works

Device	Suraksha	Watch Me	BOHNNI and BADHON
Country	India	India	Bangladesh
Features	Voice recognition, GSM/GPS module, Switch, force sensor.	Pulse rate sensor, motion sensor, GSM/GPS module, alarm.	Voice recognizer, GPS, GSM, buzzer, video camera, shocking system.
Product Components	Miniature device which can be embedded in jewelry or mobile phone etc.	Smartwatch	Wearable Locket, a bracelet made of polymer plastic.
Application	The device will activate by voice command or switch or if thrown by	The sensor of the device will activate when the targeted heart rate for the targeted time is	The device will activate using the voice password set by the user. After activation, it will send messages to

	force then it will send an alert message to the police and registered number.	achieved, then will produce an alarm sound and send a notification to the cops and registered numbers.	the user's emergency numbers and nearest police stations with the link of her location.
Limitations	There is no such feature to attack the attacker and also the device needs to be set with accessories.	The device is physically dependent.	Physical modifications can be done to ensure durability and the size of the locket can be reduced to some extent.

4.4. Mass Production Plan

Mass production plan for BOHNNI & BADHON starts with internal components placement. In BOHNNI, five components are needed to place into the inner circuit. From Fig 8 below, we can see the total weight of the components of BOHNNI is 26.1 gm & the outer portion of BOHNNI is made of a polymer of rubber and plastic for anti-shocking weighing 7.25 gm. The total weight of BOHNNI including all of its components is 33.35 gm which is much lower than the necklace that women usually wear.

From Fig 8, we can find the area of every component which defines the feasibility of mass production of this device. The device BADHON's weight & size is quite similar to the regular smartwatch and so we have not designed the positions of placement of its components but it will be made of polymer plastic to protect the user from getting sudden shocks.

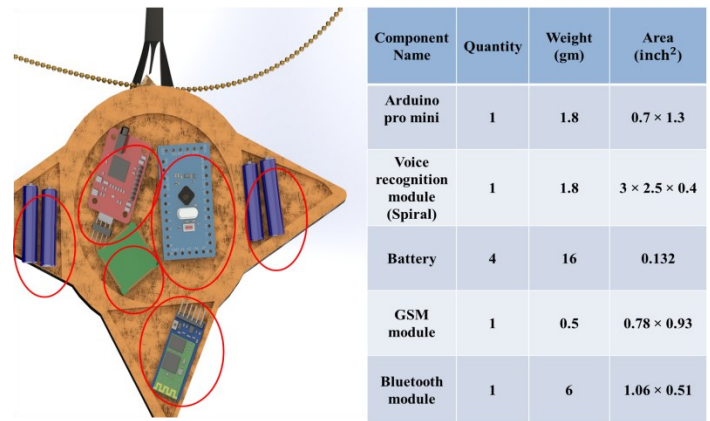

Figure 8: Inner components of BOHNNI including weight and size

5. Conclusions

In this twenty-first century, our country is experiencing a notable change in society because of women's empowerment. But the bitter truth is that these women are continuously being harassed every day and everywhere. So, women's safety issue has become a matter of great concern nowadays. For women, there are several safety devices available, but affordability for all has yet to be achieved. Keeping that in mind, we have designed our "BOHNNI" & "BADHON" to prevent harassment in our country. This device is simple structured, inexpensive, and feasible as well. This safety device is much more user-friendly & accurate during critical situations than other existing devices. It is very lightweight

and as it resembles jewelry, it can easily remain hidden from the attacker. We built the prototype & tested it during several situations. Our findings are the accuracy of the device which indicates the feasibility of using it. Our products- “BOHNNI” & “BADHON”, will ensure a safe environment for women and children in all situations by providing the hidden camera, GPS and GSM module, shocking device, and voice recognizer. In our paper, we presented only the proto-type of a wearable safety locket and bracelet. Various health and activity monitoring sensor belts are already available on the market, but the design of an integrated safety device is completely different as very accurate calculations and designs are mandatory. Therefore, future work will aim to present both physical and appropriate modifications of the devices to improve their durability and prevent any damage to the hardware. With additional study and innovation, our project can be sufficiently competent to reduce the rate of crime against women and children.

Cycle efficiency

ABSTRACT

Fossil fuel can no longer supply the constantly spiking demands of energy around the world, hence the increasing research on renewable energies as an alternative. The Stirling Engine is an external combustion engine, giving us a wide range of heat sources: solar, nuclear. The Stirling engine makes best of use of solar sources in an environmentally friendly way. It has no emissions and live longer as compared to Photovoltaic cells. The Stirling engine can operate at Low Temperature difference, which makes it prominent. In order to study the efficiency of a conversion from thermal energy to work, we need to take into account the energy efficiency, which is a key parameter in Low Temperature Difference Stirling Engine, even if its efficiency is lower than those of high temperature Stirling engine. In this article, we are studying the efficiency of the Stirling engine as a first step using a parabolic mirror to focus the sun's radiation onto the engine. In this article, we are studying the efficiency of the Stirling engine as a first step, by making isothermal and adiabatic analysis of the engine to detail the operation throughout its process, and be able to act on the various input parameters that impact the value of the final yield, and in a second step, using a parabolic mirror to focus the sun's radiation onto the engine.

1. Introduction

Solar energy is an energy that falls into the category of renewable energies, because it is considered inexhaustible. Technologically, two ways are practiced in the use of direct solar energy; solar thermal energy and Photovoltaics. Regarding the solar thermal, it's a system that uses solar energy to produce heat by heating a fluid at more or less high temperature. We can therefore produce energy, like the case of classical thermal power stations. In this case, we are talking about thermodynamical central power plants. As to the Photovoltaics, it is a system which is composed of photovoltaic cells. It directly converts a part of solar rays to electricity with photovoltaic effect. A solar powered Stirling engine is a type of external combustion engine, which uses the energy from the solar radiation to convert solar energy to mechanical energy. The resulting mechanical power is then used to run a generator or alternator to produce electricity. Initially, Stirling engine was invented by Robert Stirling in the year 1816 [1].

Solar power generation could be accomplished using various methods, such as linear Fresnel systems, Parabolic through Solar tower systems, and most importantly Solar dish systems (Figure 2), which happen to be one of the most intuitive and efficient ways of concentrating solar heat on the receiver that drives the Stirling engine-generator unit. It is applied in several situations. Due to the available sizes of Stirling engines, this method is most useful in small capacity cases that do not exceed tens of kW.

Furthermore, we are studying the efficiency of the Stirling engine and comparing it with existent internal combustion engines to see if it is worth using it as an alternative. Furthermore, we are going to study the possibility to combine the Stirling engine with solar energy for a more environmental-friendly solution.

Figure 2: Design of the EURODISH System. [2]

2. Engine operation

A Stirling engine is a piston engine operating on the general principle of the Stirling cycle. The Stirling cycle and engine were defined in 1989 by the international scientific community as [3]:

“A Stirling cycle is defined as a process that occurs in any closed space containing a working fluid in which changes in volume induce cyclical changes in pressure of the fluid and its displacement in the closed space induce changes in cyclic temperatures in the fluid.”

The Stirling engine offers the possibility of having one of the best efficiencies with less emissions unlike internal combustion engines. Its older models are less efficient and huge, but the current models are more developed, which improves efficiency, as well as the use of any external heat source for very high temperatures [4].

Figure 3: Stirling engine cycle. [1]

The theoretical Stirling cycle is similar to the Carnot cycle, except that the in th Stirling cycle the isochoric processes replace the adiabatic heating and cooling processes of the Carnot cycle. The Stirling cycle then involves four successive evolutions of an

ideal gas between two heat sources that has constant temperatures T_c and T_e , which in turn are separated by a perfect exchanger which has an isochoric process. When applying the first principle of thermodynamics, we get the same efficiency as the Carnot cycle [4].

The thermodynamic cycle can be plotted on a PV diagram that represents the variation of the pressure versus the volume. (Figure 3).

In a theoretical case, this thermodynamic cycle can be split into four reversible processes (Figure 3).

2→3: (heat transfer from an external source to the working fluid). The cold cylinder piston (the working piston) is at the top of its downstroke, while the hot cylinder piston (the expansion piston) is in the middle of its upstroke; the expansion piston moves down, while the working piston remains stationary. This is the engine time; the hot source supplies the gas with thermal energy, and the descent of the expansion piston drives the crankshaft. On the theoretical indicator diagram, this cycle time corresponds to curve 2-3. As the volume of the gas increases and its temperature is constant, the pressure of the gas in the hot cylinder decreases.

3→4: (heat transfer from the working fluid to the regenerator). The last stroke being completed, the cycle is returned to its initial state, the mechanical coupling between the two pistons is such that the working piston begins to rise, while the expansion piston goes down; during this double movement, the gas being hot, it gives up its heat to the regenerator and the gas cools as it passes from one cylinder to another. As its volume remains constant, its pressure decreases; which is represented by segment 4-3 of the theoretical diagram. The engine has returned to the starting point, the regenerator is ready to absorb heat again, and a new cycle can begin again.

4→1: (heat transfer from the working fluid to the cold source). the ingenious coupling between the pistons allows the expansion piston to be stationary while the working piston descends. The gas is compressed, but its temperature does not increase, because the compression takes place in the cylinder connected to the cold source. Energy is rejected to the cold source and the compression is isothermal; this time is represented by curve 4-1 on the theoretical indicator diagram.

1→2: (heat transfer from regenerator to working fluid) The expansion piston goes up and the working piston goes down, which allows the movement of the gas from the hot side, without changing the volume; segment 1-2 of the theoretical diagram is therefore vertical. Passing through the regenerator, the gas recovers the heat that was stored there and, at the same time, returns this element to its initial temperature. [1]

During this cycle, the system releases an amount of energy, which is needed later to heat the fluid, and restart the cycle as a loop.

Robert had the idea to use a regenerator to recover the transferred energy and then use it for heating. Ideally, the curve is elliptic, hence all amounts of energy are recovered (Figure 4).

We mostly find Stirling Engines in one of the three common configurations which are α , β and γ .

Figure 4: Stirling cycle curve. [1]

2.1. Alpha-type Stirling Engine

The α -type engine is composed of two separated cylinders (Figure 5). The two cylinders are exposed, respectively, to a hot and a cold temperature source. And to each cylinder, is sealed a "hot" piston and a "cold" piston. contains two separate power pistons in separate cylinders, a "hot" piston and a "cold" piston. It also has a pipe that connects the two cylinders. This pipe is usually filled by a regenerative material in order to enhance the thermal efficiency.

Figure 5: Alpha-type Stirling engine. [5]

Figure 6: Beta-type Stirling engine. [5]

2.2. Beta-type Stirling Engine

In contrast with the α -type, β -type engine is composed of one unique cylinder with one piston sealed to it, and a displacer as shown in Figure 6. At the top of the cylinder, is placed a heat source, and a cold source at the bottom. The gas flow through the

small clearance between the cylinder wall and the displacer; when it flows towards the hot end of the cylinder, then the expansion process occurs, and when it flows towards the cold end, then the compression process occurs. It is the displacer that allows the gas to move between the cold zone and the hot zone. The system is linked to a flywheel.

2.3. Gamma-type Stirling Engine

The γ -type engine is similar to a β -type engine, the main difference is that the cooling chamber is mounted in a separate cylinder as demonstrated in Figure 7, but it is still connected to the same flywheel.

Figure 7: Gamma-type Stirling engine. [5]

2.4. Comparison between the three types

To make a comparison between the 3 types of architectures, the compression rate must be defined: The compression rate r_v is defined here as the ratio of the maximum volume V_M by the minimum volume V_m that it will occupy during this same cycle:

$$r_v = \frac{V_3}{V_2} = \frac{V_4}{V_1} \quad (1)$$

For given hot and cold source temperatures, and for identical displacements, Alpha engines have higher compression ratios than those of type Beta, which in turn are slightly higher than those of Gamma engines. This has the consequence of being able to extract more power from an Alpha engine because it will run more quickly. The downside is that they require more design and manufacturing rigor.

3. Advantages and disadvantages

3.1. Advantages

- **Quiet operation:** In contrast with internal combustion engines, there is no relaxation in the atmosphere. With that absence of gas that will eventually escape, plus the absence of the open-close valves, this engine is quiet and has a reduced mechanical stress.
- **High efficiency:** Stirling engines have the best efficiency compared to an internal combustion engine, and it could even exceed 40 % as efficiency.
- **The multitude of possible "hot springs" and ecological aptitude:** Due to its heat supply method this engine can operate from any heat source.

- **Reliability and easy maintenance:** The technological simplicity of this engine allows engines to be very reliable and require little maintenance.
- **The long service life:** Due to its simplicity, the life of this engine is, in theory, longer than that of conventional engines. Indeed, it requires less maintenance and its replacement is much faster and less dangerous.
- **Reversible operation:** The Stirling cycle is reversible, when a Stirling engine is driven by another engine; it becomes a heat pump capable of working in cooling and heating mode.

3.2. Disadvantages

- **The price:** The main drawback of this engine is its manufacturing cost, which is about twice that of a diesel engine. Stirling engines require inlet and outlet heat exchangers, which contain the high temperature working fluid, and must withstand the corrosive effects of the heat source and the atmosphere.
- **Lack of flexibility:** Quick and efficient variations in power are difficult to achieve with a Stirling engine. This is more suitable for running at constant nominal power. This point is a big handicap for the automotive industry.
- **Height and weight:** External combustion, which requires heat exchangers at both hot and cold spots, makes the Stirling engine generally bigger in size and heavier than a generic internal combustion engine with the same power output.

3.3. Advantages of Stirling engine compared to an internal combustion engine

In comparison with a combustion engine, Stirling engine overtakes it on many levels, for example we can look at fuel flexibility; A Stirling engine does not require a highly refined liquid to operate, it can use a variety of liquid and gases, which makes it more flexible than a Diesel engine that required refined Diesel fuel. And because of the external-combustion process of the Stirling engine, it also burns any given fuel cleaner than an internal-combustion engine. In addition, Stirling engines can be balanced mechanically, making them less noisy by eliminating the mechanical vibration problems. On the other hand, internal-combustion engines have severe noise because of the periodic nature of their combustion and mechanical motion processes. We can enhance them to be more silent, by using mechanical isolation and acoustic design, but this would increase the cost of the engine, and would make it impractical in some situations. [6].

3.4. Applications of the Stirling engine

Besides the academical use of the Stirling Engine, we can find this technology in various daily useful applications. The American Stirling Company offers one of these applications which is the wood stove Stirling fan (Figure 8): A silent fan that does not need electricity to move the heat from a wood stove, and have more heated area in the house instead of having only a restricted heated area near to the wood stove.

Another interesting application of the Stirling engine is the Combined Heat and Power systems (CHP) that can be very useful in businesses such as a commercial laundromat, since it generates electricity and utilizes the waste energy produce heat. There is also

a smaller version of CHP systems, called micro CHP that have residential use [7].

Figure 8: The Stirling stove fan by American Stirling Company. [8]

The SAAB company [9], which is a Swedish company specialized in building submarines, uses the Stirling engine in their Gotland and Södermanland submarines classes, essentially because the Stirling engine is silent compared to Diesel engines. SAAB claims that the secret to their world's most silent submarine is Stirling engine based submarines do not need to surface and recharge the batteries, using the air-independent propulsion [9].

4. Enhancement of the Stirling Engine performance

To act on the Stirling engine performance, we are led to optimize the temperature of the cold and hot sources, to obtain an optimal temperature difference. We can also modify the geometry of the engine to keep the losses to an absolute minimum.

The role of the regenerator is to recover the heat from the cooling of the gas to heat it again. It therefore plays a key role in the operation of the engine.

Thus, it seems legitimate to seek to optimize the operation of the regenerator to improve that of the engine.

The MOD II automobile engine [10] that was produced in the 1980's [10] was among the most efficient Stirling engines, it reaches a maximum efficiency of 38.5% [10], compared to a petrol engine which has a yield of (20-25%).

It was abandoned due to high development costs and fears of not being able to compete with internal combustion engines in terms of reactivity.

To reach a high efficiency in a Stirling engine we are led to use a regenerator; imperfect heat transfer that occurs between the engine and the source may lead to external losses of energy as well as internal losses.

The efficiency of an engine varies with the operating speed due to the different losses interactions

5. Modeling of the Stirling Engine

5.1. Efficiency Stirling engine:

r_v : Volume Ratio

λ : Temperature Ratio

S: Entropy

C_v : The molar heat of gas

T_i : Inlet temperature to Urieli's generalized cell

P_i : The pressure at a given time I

T_c : Compression temperature

T_{ck} : mean temperature of working fluid at cooler and compression space

T_e : Temperature at expansion side

T_d : Temperature at dead space

T_{he} : Temperature of working fluid at heater and expansion space.

T_k : Temperature of working gas at cooler.

V_c : Compression cylinder volume variation

V_d : Dead space volume

V_e : Expansion cylinder volume variation

V_r : Regenerator volume

w_c : Compression work

w_d : Work done from engine

w_e : Expansion work

w_s : West number

T_{max} : Maximum cycle temperature

T_{min} : Minimum cycle temperature

X : Distance

Figure 9: Stirling engine cycle. [1]

As the PV diagram for Stirling cycle shows (Figure 9):

4→1: The engine is operating with a minimum value temperature during the isothermal compression. And with a constant energy:

$$P_1 = \frac{P_4 V_4}{V_1} = P_4 r_v \quad (2)$$

$$T_1 = T_4 = T_{min}$$

With the provided heat (Q) = Recovered work (W_c)

$$Q = W_c = P_4 V_4 \ln\left(\frac{1}{r_v}\right) = nRT_4 \ln\left(\frac{1}{r_v}\right) \quad (3)$$

$$\text{Entropy change} = (S_4 - S_1) = R \ln\left(\frac{1}{r_v}\right) \quad (4)$$

1→2 : In the isochoric heating phase, both the compression piston and the expansion piston moving respectively towards the regenerator and away from the regenerator, simultaneously, keeping volume between the two pistons constant. The working fluid is flows from the compression area to the expansion area, making its temperature gradually increasing from T_{min} to T_{max} . This gradual increase of the fluid temperature while it pass through the regenerator creates a gradual increase of pressure. There is no work done and there is an increase in the entropy and the internal energy of the working fluid.

The volume remains constant throughout this process.

$$P_2 = \frac{P_1 T_2}{T_1} = \frac{P_1}{\lambda} ; V_1 = V_2 \quad (5)$$

If:

$$\lambda = \frac{T_1}{T_2} \quad (6)$$

With λ referring to the energy ratio defined by [11].

The provided heat Q will then be equal to:

$$Q = C_v(T_2 - T_1) = 0 \quad (7)$$

Since there is no work done.

$$\text{Change of entropy} = (S_2 - S_1) = R \ln\left(\frac{1}{\lambda}\right) \quad (8)$$

2→3: The temperature is constant during the isothermal relaxation, while the volume increases as well as the entropy. There is no change of energy.

$$P_3 = \frac{P_2 V_2}{V_3} = P_2 \left(\frac{1}{r_v}\right) \quad (9)$$

$$T_2 = T_3 = T_{max} \quad (10)$$

$$Q = W = P_2 V_2 \ln r_v = mRT_2 \ln r_v \quad (11)$$

$$(S_2 - S_3) = R \ln(r_v) \quad (12)$$

3→4: No work is provided during the isochoric cooling, the volume is constant.

$$P_4 = \frac{P_3 T_3}{T_4} = P_3 \lambda \quad (13)$$

$$V_3 = V_4 \quad (14)$$

$$Q = C_v(T_4 - T_3) \quad (15)$$

$$\text{And } (S_4 - S_3) = C_v \ln(\lambda) \quad (16)$$

Si

$$r_v = \frac{V_3}{V_2} = \frac{V_4}{V_1}$$

The provided heat will then be equal to $RT_2 \ln(r_v)$) and the released heat will be equal to $RT_4 \ln(r_v)$.

We can write the output as follows:

$$\eta = \frac{n(RT_2 \ln(r_v) - RT_4 \ln(r_v))}{nRT_2 \ln(r_v)} \quad (17)$$

$$\eta = 1 - \frac{T_{min}}{T_{max}} = 1 - \mathcal{Z} \quad (18)$$

We then find the ideal Carnot efficiency that corresponds to the possible maximum theoretical efficiency in a two heat sources engine.

5.2. Isothermal analysis

According [12], we can obtain an efficient heat transfer by assuming that the total mass of the working gas inside the engine remains constant:

$$M = m_c + m_k + m_r + m_h + m_e \quad (19)$$

And considering that the pressure in all of the engine is constant, and:

$$T_c = T_K \text{ et } T_h = T_e$$

Based on the ideal gas equation, we have:

$$M = \frac{P}{R \left(\frac{V_c}{T_K} + \frac{V_K}{T_K} + \frac{V_r}{T_r} + \frac{V_h}{T_h} + \frac{V_e}{T_e} \right)} \quad (20)$$

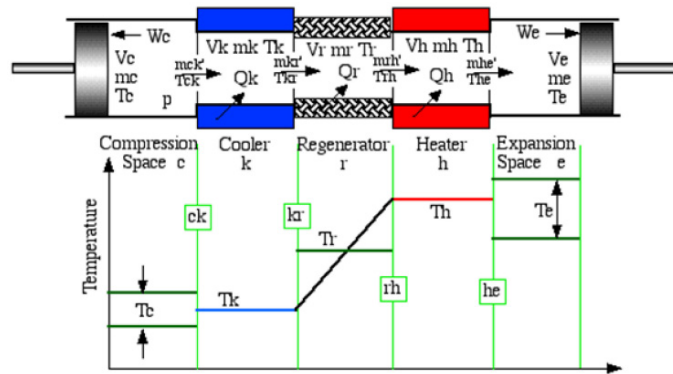

Figure 10: Ideal isothermal model. [13]

Figure 11: Linear profile of regenerator temperature. [13]

Then we can numerically define the assumption that the temperature profile is linear, by the equation of a straight line

$$T(x) = \frac{(T_h - T_k)x}{L_r} + T_K \quad (21)$$

The sum of mass of the gas is:

$$m_r = \int_0^{V_r} \rho dV_r \quad (22)$$

With ρ the density,

$$dV_r = A_r dx \quad (23)$$

Where dx is the derived volume for a constant free flow area, and

$$V_r = A_r L_r$$

And A_r :

$$A_r = \frac{V_r}{L_r} \quad (24)$$

By integrating (25), we obtain:

The definition of the regenerator effective average temperature (T), in terms of ideal gas equation:

$$m_r = \frac{V_r P}{RT_r} \quad (27)$$

Then, by comparing the equations (26) and (27) we obtain:

$$T_r = (T_h - T_k) / \ln\left(\frac{T_h}{T_K}\right) \quad (28)$$

Thus, the pressure of the cycle can be written as:

$$P = MR \left(\frac{V_c}{T_K} + \frac{V_K}{T_K} + \frac{V_r \ln\left(\frac{T_h}{T_K}\right)}{(T_h - T_k)} + \frac{V_h}{T_h} + \frac{V_e}{T_h} \right)^{-1} \quad (29)$$

The total work of the cycle is the sum of the work of compression and expansion.

$$W = W_c + W_e \quad (30)$$

$$W = \int P dV_c + \int P dV_e \quad (31)$$

$$W = \int P \left(\frac{dV_c}{d\phi} + \frac{dV_e}{d\phi} \right) d\phi \quad (32)$$

5.3. Isothermal modeling

To study the heat transfer, it is primordial to consider the energetic equation of ideal gas.

In [14] the author's has modeled a generalized workspace cell, and as shown in Figure 12, it can be reduced to a workspace cell or a heat exchanger cell.

The enthalpy transfer out the cell (resp. into the cell) occurs with a mass flow rate m_0 at temperature T_0 (resp. a mass flow rate m_i at temperature T_i). The derivative operator is noted D and D_m refers to the mass derivative (d_m/d_t).

Figure 12: Generic cell diagram of the engine. [14]

The energy equation of the cell can be written as:

$$\text{Heat transfer rate in the cell} + \text{Net enthalpy converted in the cell} =$$

Rate of work applied on the environment + Rate of increase of internal energy in the cell.

$$DQ + (C_p T_i m_i - C_p T_o m_o) = DW_d + C_v D(mT) \quad (33)$$

where C_p and C_v are respectively the specific heat capacities of gas at constant pressure and constant volume. The equation below is the well-known classical form of the energy equation in which the terms of kinetic energy and potential energy have been neglected.

Then :

$$DQ = C_p T (m_o - m_i) + DW_d + C_v T Dm \quad (34)$$

For reasons of mass conservation, the difference $m_o - m_i$ is simply the rate of mass accumulation inside of the cell

$$R = C_p - C_v$$

Therefore, we can write the equation as:

$$DQ = DW_d + RT Dm \quad (35)$$

$$Q = \int DQ = \int DW_d + RT Dm \quad (36)$$

5.4. Adiabatic modeling

The principle of this method uses a numerical resolution approach, it divides the volume of the engine into a certain number of control volumes, then it applies conversion equations to the momentum of the gas associated with its equation of state. The properties of the gas are considered uniform in each control volume. The interaction between volumes is taken into account when solving differential equations which is done simultaneously.

The complexity of the system to be solved and the calculation time depend on the assumptions used.

- Thermodynamic compression and expansion transformations are adiabatic,

- The gas pressure is uniform throughout the machine,
- The movement of the piston and of the displacer is sinusoidal,
- The working fluid follows the ideal gas law,
- The machine rotation speed is constant

The energy equation is applied to a generalized whole can be written as:

$$DQ + (C_p T_i m_i - C_p T_o m_o) = DW_d + C_v D(mT) \quad (37)$$

The state equation is given by $PV = nRT$

$$\text{And } C_p - C_v = R \quad (38)$$

Therefore:

$$C_p = \frac{R_\gamma}{\gamma - 1}, \quad C_v = \frac{R}{\gamma - 1}$$

With:

$$\gamma = C_p / C_v$$

By taking the logarithm on both sides of the equation and differentiating them, we get a differential form of the equation of state:

$$\frac{Dp}{p} + \frac{DV}{V} = \frac{Dm}{m} + \frac{DV}{V}$$

$$M = m_c + m_k + m_r + m_h + m_e \quad (39)$$

$$Dm_c + Dm_k + Dm_r + Dm_h + Dm_e = 0 \quad (40)$$

Since the volume and the temperature are constant, the differential equation is shortened to:

$$\frac{Dp}{p} = \frac{Dm}{m}$$

$$Dm_c + Dm_e + Dp \left(\frac{m_k}{p} + \frac{m_r}{p} + \frac{m_h}{p} \right) = 0 \quad (41)$$

$$Dm_c + Dm_e + Dp / R \left(\frac{V_k}{T_k} + \frac{V_r}{T_r} + \frac{V_h}{T_h} \right) = 0 \quad (42)$$

We apply the energy equation the equation that we obtain:

$$DQ_c - C_p T_{ck} m_{ck} = DW_c + C_v D(m_c T_c) \quad (43)$$

However, the compression space is adiabatic, $DQ_c = 0$, plus the realised $DW_c = pDV_c$, for continuity reasons, the accumulation rate of gas Dm_c is equal to the mass difference of the gas given by m_{ck} .

$$C_p T_{ck} m_{ck} = pDV_c + C_v D(m_c T_c) \quad (44)$$

$$Dm_c = (pDV_c + \frac{V_c Dp}{\gamma}) / RT_{ck} \quad (45)$$

$$Dm_e = (pDV_e + \frac{V_e Dp}{\gamma}) / RT_{he} \quad (46)$$

Simplifying :

$$Dp = \frac{-\gamma p \left(\left(\frac{DV_c}{T_{ck}} \right) + (DV_e / T_{he}) \right)}{\frac{V_c}{T_{ck}} + \gamma \left(\frac{V_k}{T_k} + \frac{V_r}{T_r} + \frac{V_h}{T_h} \right) + \frac{V_e}{T_{he}}} \quad (47)$$

We consider the continuity equation, given by:

$$Dm = m_i - m_o \quad (48)$$

We apply successively the equation above to each of the cells as shown in the figure:

$$m_{ck} = -Dm_c \quad (49)$$

$$m_{kr} = m_{ck} - Dm_k \quad (50)$$

$$m_{rh} = m_{kr} - Dm_r \quad (51)$$

$$m_{he} = m_{rh} - Dm_h \quad (52)$$

The total work done by the engine is the algebraic sum of the work done by the compression and expansion areas:

$$DW = pDV_c + pDV_e \quad (53)$$

$$DQ + (C_p T_i m_i - C_p T_o m_o) = (C_p pDV + C_v V Dp)/R \quad (54)$$

Dans les espaces d'échangeur de chaleur, aucun travail n'est effectué, car les volumes respectifs sont constants.

$$DQ_k = \frac{V_k Dp C_v}{R} - C_p (T_{ck} m_{ck} - T_{kr} m_{kr}) \quad (55)$$

$$DQ_R = \frac{V_r Dp C_v}{R} - C_p (T_{kr} m_{kr} - T_{rh} m_{rh}) \quad (56)$$

$$DQ_h = \frac{V_h Dp C_v}{R} - C_p (T_{rh} m_{rh} - T_{he} m_{he}) \quad (57)$$

The actual Stirling cycle engine is subject to heat transfer, internal heat losses and mechanical friction losses, to estimate these losses [15] defined certain engine temperature ratios.

The ratio of the lower operating temperature to the upper operating temperature of the engine is defined by: $\xi = \frac{T_k}{T_e}$;

The ratio of the cooler temperature to the heater temperature is defined as: $\epsilon = \frac{T_c}{T_h}$;

The ratio of the expansion area temperature to the heater temperature is noted as: $\mathcal{Z} = \frac{T_e}{T_h}$, with $\alpha = \frac{b}{a}$ and $\beta = \beta = \frac{c}{a}$, heat transfer coefficients.

Therefore, the average energy of the cycle is expressed by:

$$P = Q_s - Q_R \quad (58)$$

$$P = a (T_h - T_e) - b (T_c - T_k) \quad (59)$$

$$P = a T_h (1 + \alpha \epsilon - \mathcal{Z} - \mathcal{Z} \alpha \xi) \quad (60)$$

The thermal efficiency must not exceed the efficiency of the Carnot cycle.

$$\frac{Q_s - Q_R}{Q_s - Q_T} = \frac{P}{Q_s - Q_T} \leq 1 - \frac{T_c}{T_e} = 1 - \mathcal{Z}$$

This condition can be expressed as:

$$\mathcal{Z} ((\alpha+1) \mathcal{Z} - \beta(1 - \mathcal{Z})^2) \geq \alpha \epsilon + \mathcal{Z} \quad (61)$$

To obtain a maximum energy we can write :

$$\mathcal{Z} = \frac{\alpha \epsilon + \mathcal{Z}}{(\alpha+1) \mathcal{Z} - \beta(1 - \mathcal{Z})^2} \quad (62)$$

By replacing (62) in (60)

The maximum power is:

$$P_{Si} = \frac{a T_h [\alpha (\mathcal{Z} - \epsilon)(1 - \mathcal{Z}) - \beta(1 + \alpha \epsilon)(1 - \mathcal{Z})^2]}{(\alpha+1) \mathcal{Z} - \beta(1 - \mathcal{Z})^2} \quad (63)$$

$$\mathcal{Z}_p = \frac{\alpha \epsilon + \beta(\alpha \epsilon + 1)}{\alpha + \beta(\alpha \epsilon + 1)} \quad (64)$$

By differentiating (62) we obtain the point where the power is maximum:

$$\mathcal{Z}_m = \frac{\alpha \beta (1 - \epsilon) + \sqrt{(1 + \alpha)(\alpha + \beta + \alpha \beta)(\beta + \beta \alpha^2 \epsilon^2 + \alpha \epsilon (1 + \alpha + 2\beta))}}{\alpha + \alpha^2 + \beta + 2\beta \alpha + \epsilon \alpha^2 \beta}$$

In [16] the author's has proven that the maximum of the values that we can obtain are independent of the regenerator's conductance value, and thus in the case of a uni-dimensional model of a Stirling engine.

6. Simulation and results

Now once we have characterized the engine geometrically, were all set to implement the isothermal model. The flow diagram in Figure 13 illustrates the steps of the model; we first use as an entry parameter the total mass of the initial engine m and an effective average pressure p.

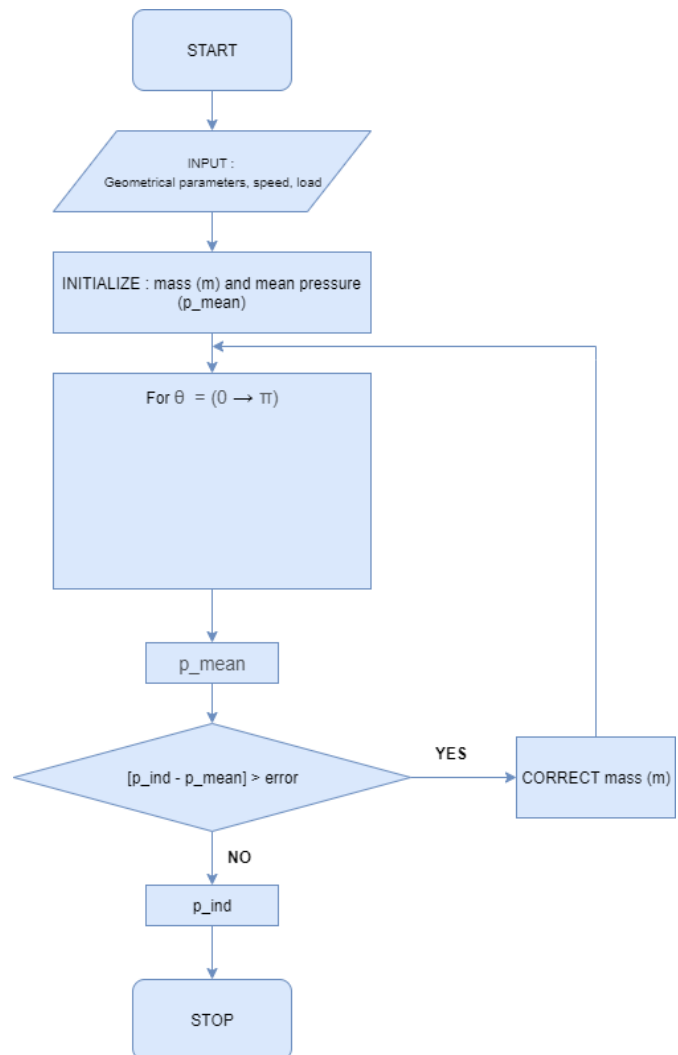

Figure 13: Isothermal model diagram.

Figure 14: Pressure-volume diagram.

The algorithm then, for each value of θ , calculates the total average pressure as a function of the initialized mass m , and compares it with the reference pressure we defined at first. The algorithm iterate this comparison until we have convergence, i.e. the difference between the average pressure and the reference pressure is lower than the error.

The indicated work of the cycle is the obtained.

$$W = 1.9822 \text{ J}$$

In Figure 14 we observe that the curve is closed and cyclical, and in each cycle, the work is obtained by calculating the area inside the curve, while the area below the curve is the heat absorbed during that cycle. The thermodynamic efficiency is the ratio of the work on the amount of heat absorbed

7. Conclusion

The article studies the efficiency and the uses of the Stirling engine, and relies on the process of transforming renewable thermal energy into mechanical work. Renewable thermal energy is available at low cost for the long term and environment friendly. Such engine relying on this process is certainly interesting, even if it has a low thermal efficiency.

We have seen how the Stirling engine's perks can be used in different situations; it can be more advantageous than internal-combustion engine. Especially, at low maximum temperature and low temperature difference, the Stirling engine has virtually no substitute.

We can enhance the thermal efficiency by manipulating the shape of the displacer, the heat exchanger, the crank angle or use If other working fluids. Stirling engine research and enhancements stimulate green education and can help reduce global warming and emissions.

This article is a first part of an modeling and simulation with MATLAB SIMULINK which will have as objective the improvement of the efficiency of the engine based on the difference of temperature, all while working on a concrete model.

ABSTRACT

The main contribution of this paper is the framework of Application Programming Interface (API) to be integrated on a smartphone app. The integration with algorithm that generates fingerprints from the method ST-PSD with several parameter configurations (Windows size, threshold, and sub-score linear combination coefficient). An approach capable of recognizing an audio piece of music with an accuracy equal to 90% was further tested based on this result. In addition the implementation is done by algorithm using Java's programming language, executed through an application developed in the Android operating system. Also, capturing the audio from the smartphone, which is subsequently compared with fingerprints, those present in a database.

1 Introduction

An audio representation includes a recording of a musical piece's output. Digital sound recordings are based on the analog audio signal being sampled. Sampling is achieved by capturing the signal amplitude at a specified sampling rate and storing them in binary format. In terms of recording efficiency, the sampling rate and the bit rate (number of bits used to store each sample) are the two most important variables. Audio CDs use a 44.1 kHz sampling rate or 44,100 samples per second, and each sample uses 16 bits, which mainly an industry standard.

Common audio streaming sites host millions of audio files, and thousands of broadcast stations transmit audio content at any given time. The ever-increasing amount of audio material, whether online or on personal devices, generates tremendous interest in the ability to recognize audio material. It achieves this by using identification technology that seeks to work at the highest degree of accuracy and specificity.

Songs recognition identifies a song segment either from a digital or an analog audio source. Song rankings are based on radio / TV broadcasting or streaming; copyright protection for songs or automatic recognition of songs that a person wishes to identify while listening to them are different applications of such a system. Important information such as song title, artist name, and album title can be provided instantly. To create detailed lists of the particular content played at any given time, the industry uses audio fingerprint-

ing systems to monitor radio and TV broadcast networks. Through automatic fingerprinting devices, royalties' processing relies on the broadcasters who are required to produce accurate lists of content being played.

Given the high demand for an application, several approaches have already been studied based on song fingerprinting recognition, such as [1]–[4] and [5]. Nowadays, the state of the art of recognition techniques are those developed by Shazam [6], [7] and SoundHound [8], and the detection system by [9]. These services are widely known for their mobile device applications.

Audio streams of many broadcast channels or recordings of different events are typically analyzed using fingerprint systems for media monitoring. As these systems work on massive quantities of data, the data models involved should be as small as possible, while the systems need to efficiently run on massive and growing reference databases. Besides, high robustness criteria are determined by the application for media monitoring. Although the sensitivity to noise may not be the primary concern for this use case, the systems need to identify audio content that different effects may have changed.

Android is the most popular mobile operating system globally, despite the presence on the world market of the likes of Apple iOS. It is mainly used for smartphones and tablets, but thanks to its characteristics, it is also extended to other devices, such as laptops, cameras, and IoT devices. Developing applications requires Android Software Development Kit (SDK), which contains all the tools to create and run new software, such as debuggers, libraries,

*Corresponding Author: Murtadha Arif Bin Sahbudin, Department of Engineering, University of Messina, Email: msahbudin@unime.it

and emulators. The integrated development environment (IDE) officially supported for this purpose is Android Studio, released and available for free from the official developer site for Android and the SDK. Applications are Java-based and are distributed through self-installing packages, i.e., Android application package (APK) files (a variant of the format JAR), which contain all the components and resources of the created software, including source code, XML, images, and binary files.

In particular, this research deals with the process and the theoretical notions that lead to the generation of linekeys previously mentioned in [10], and [11]. Music recognition is a method of identifying a segment of an audio signal from a digital or analog source; this process uses the power spectral density (PSD) to process the acquired data to obtain complete information about the audio signal source. The fingerprint generation takes place on the client-side, in this case, the Android mobile application. The communication protocol, shown in Fig. 1, depicts the process of communication and interfacing with the recognition server with database collection.

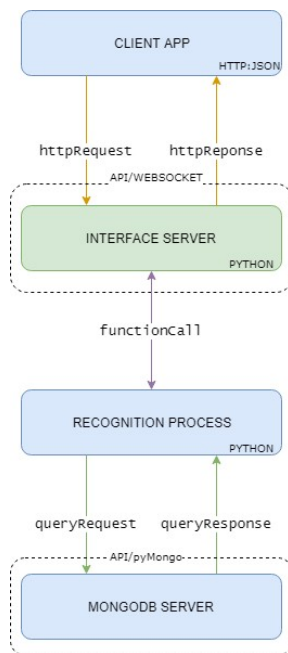

Figure 1: Client and server protocol interface

2 Challenges

The number of songs in the music industry has recently increased significantly, according to a report in [12]. With massive databases, the management and identification of songs using a conventional relational database management system have become more difficult. For large datasets, a common linear search technique that checks the existence of any fingerprint in an array one at a time has a noticeable decrease in efficiency [13]. The stored information, therefore, needs a scalable database system to meet the execution time, memory use, and computing resources for recovery purposes, which is suggested in [14].

Song recognition systems usually operate on vast amounts of data and are expected to meet several robustness requirements de-

pending on the actual use case. Robustness to different kinds of lossy audio compression and a certain degree of noise would seem to be the minimum requirement. Systems designed to detect short audio segments' microphone recordings involve high background noise robustness, such as noise and distortion, or even multiple songs played in the surrounding.

It is crucial to have robust and quick recognition for effective song information retrieval. Major consumers need details about trending tracks, airtime schedules, and song versions, such as music labels, manufacturers, promoters, and radio stations. They, therefore, demand an application that is capable of generating information that is fast and precise.

In the field of real-time song recognition, the entertainment industry, particularly in music, the extensive collection of digital collections, and the commercial interest are opening new doors to research. In 2017, the global digital music industry expanded by 8.1 percent, with total revenues of US\$ 17.3 billion, according to IFPI's Global Music Report 2018 [15]. For the first time in the same survey, 54 percent of the revenue alone comes from digital music revenue.

However, the most challenging application for bringing new songs to listenership is still the FM frequency radio station. The FM frequency channel for music broadcasting in European countries is still actively reliant on radio stations [16]. Radio stations and music companies have been working to advance music industry data analytics by creating ways of analyzing broadcast songs through new services and platforms.

It is an interest to broadcasters and advertisers to measure radio audience size and listening patterns over a broadcast radio station to achieve a source of revenue [17]. However, based on demographics and psychographics (psychological criteria) of the target audience of the station, variations in the region of station promotional material can be predicted [18].

In addition to robustness criteria, the seriousness or effect of incorrect results must be considered, and the necessary performance recognition characteristics of fingerprinting systems must be taken into account. For instance, if a song recognition system is used, an unidentified match is missing, the user can waste storage space. However, on the flip side, a specific song recognized as false match systems that report false positives should be avoided.

Most critically, false positives are expensive for large-scale media monitoring; revenue might be attributed to the wrong artist. False negatives, another form of error, may lead to hours of unidentified material that will have to be checked with manual effort. Any form of error would increase the maintenance cost of a system.

To overcome it, we have proposed a more scalable big data framework using fingerprint clustering. Besides, a new recognition algorithm also was required for the new clustered collection. We also compared the performance from both the legacy system (non-clustered) and the new clustered database.

We define extensions of scale modifications that are likely to be encountered when developing a framework for monitoring FM radio broadcasting stations—investigating our dataset of the reported output of radio segments through the percentage of accuracy. This estimation will serve as the appropriate gold standard throughout this study, i.e., a device should be robust to at least this range of scale noise but may be needed to cope with even more severe distortions.

3 Problem Statement

Fingerprint databases, recognition process instances, and FM transceivers are the legacy system in commercial use. The problems of an audio recognition system in normal use can be described from the following aspects:

a) *Near Similarity*: This occurs when virtually the same audio fingerprints are produced by two or more perceptually different audio recordings, leading to serious problems in the recognition process. Therefore, the key goals when developing an audio fingerprinting algorithm are to keep the probability of collision as minimal as possible.

b) *In-variance to noises and spectral or temporal distortions*: Audio signal is usually degraded to some degree due to some kinds of sounds and vibrations when captured or playing in actual environments. The audio fingerprints of the damaged audio signal can be the same as those of the original signal. Important features are still unchanged. In cases of this fingerprinting technique, high robustness must be obtained.

c) *Minimum length of song track needed for identification*: Due mainly to time and storage limitations, making the entire of an unknown audio track in real-time music recognition is still impractical. Nevertheless, it is ideal that only a few seconds of the track is required to find the unknown audio.

d) *Retrieval speed and computing load*: Recognition results can be provided in a few seconds in most real-time applications. However, with the increase in song recordings in the audio reference database, locating the matching object correctly in real-time becomes very difficult.

A fingerprint is a type of distinct digital representation of the waveform of a song. A fingerprint can be obtained by collecting significant characteristics from the various audio properties. Without sacrificing its signature, the created fingerprint may also be segmented into several parts. Moreover, fingerprints can be processed at a much smaller scale relative to the audio waveform's initial form.

The items below are several criteria that should take into consideration for a robust audio fingerprint:

- **Consistent Feature Extraction**: The key feature of fingerprint generation is that it can replicate an audio fingerprint identical to that of a music section.
- **Fingerprint size**: Fingerprint file size has to be small enough so that more music collections can be stored in the database. In reality, a lightweight fingerprint offers effective memory allocation during processing.
- **Robustness**: Even if external signal noise has affected the source audio, fingerprints may be used for identification.

4 Related Works

We provided our outstanding contributions to the academic literature that satisfy all the success criteria listed above. We show that, despite our large comparison sets, our method is efficient and that there is an extensive search problem caused by the invariances of the hashes and their robustness in signal modifications. Mainly, we

designed the proposed device for low-cost hardware, demonstrated its capabilities, and avoided costly CPU processing.

Despite studies on the identification of songs and fingerprints by other researchers such as Shazam [7] and SoundHound [8]. We understand the clustering design using K-means for an experiment in the real fingerprint database with a set of 2.4 billion fingerprints provided by the company as datasets. We want to emphasize that a database of this scale seldom appears in the research literature, but there is a chance that it exists. The next critical aspect was the audio recognition system. Although initial K-means computing for compilation is resource-intensive, we achieved significant speed efficiency at the end of the day [19]. Also, the proposed architecture and algorithm will lead to a new insight into song recognition.

Moreover, we had introduced an IoT-based solution to song recognition in a cloud environment in this study. We have developed a recognition system to integrate audio streams from remote FM Radio stations [20]. We conducted a song recognition technique based on the K-modes clustered cloud database of MongoDB [11]. We supported various collections of fingerprint length tests to ensure the best accuracy and reliability of the test.

The new fingerprint extraction technique's significant findings focused on Short Time Power Spectral Density (ST-PSD) was also implemented [10]. Later of which binary encoding group's attributes lead to the reliability of K-modes. Besides, this study clarified the identification methodology primarily through hamming distance measure in the predetermined cluster table. The findings were given by sampling 400 random 5-second queries from the initial song set in the experiment. Using this method, the optimal chosen combination of parameters is the identification ratio of 90%.

We have already introduced extracting fingerprints from audio in our previous works based on the ST-PSD calculation. We introduce several significant and remarkable improvements to the previously proposed algorithm to enhance the robustness of the linekeys to temporal shift and the consistency of the fingerprints for perceptually distinct audio signals in this paper. The proposed fingerprints are based on calculating the audio signal's short time spectral power density ST-PSD obtained on the Mel frequency scale.

According to our tests and performance measurements, the framework can be used specifically for different areas of fingerprinting applications. In addition to typical fingerprint applications, these are, for instance, the identification of audio copies and media tracking, copyright identification of songs.

5 K-means Clustering in MongoDB Database Methodology

K-means clustering is used for non-classified results, which performs an unsupervised algorithm for many data. The fingerprints are grouped into subgroups by the K-means classification. As such, objects in the same category (clusters) are more similar to each other. Whereas K-means is often used for high-dimensional data classification, we take advantage of the centroid value as a distance point when executing the nearest computation in this experiment. The basis for using K-means is that we need to create relatively uniform dataset-size clusters.

The K-Means clustering is method of partitioning n data, into k

clusters in which each data is associated with the cluster with the nearest mean (intra-cluster distance). Thus, several different distinct clusters are formed. Therefore, the primary goal of K-means is to minimize intra-cluster distances. This is done by determining the J index as Equation (1) follows:

$$J = \sum_{j=1}^k \sum_{i=1}^{n_j} \|x_i^{(j)} - c_j\|^2, \quad (1)$$

where c_j is the mean value of the j -th cluster with $i \leq j \leq n$, and $x_i^{(j)}$ represents a fingerprint that falls into the j cluster. The c_j is usually called *centroids*. Sets of k clusters, $k+1$ boundaries and k centroids are discovered by the K-means algorithm, reducing the J optimization index. More precisely, a fingerprint partition set of $S = \{S_1, S_2, \dots, S_k\}$ resulting from fingerprint partitions is computed from:

$$\underset{S}{\operatorname{argmin}} J \quad (2)$$

As reference points, the c_j centroids of the clusters are used. Nevertheless, we are expected to specify the number of k clusters subsequently computed. Figure 2 provides an overview of the clustering phase in this implementation, where the original fingerprint collection stored in MongoDB was initiated.

Figure 2: K-means clustering implementation overview

A reduced data sample of $2 \cdot 10^6$ (random segment) was selected from the overall selection based on the fingerprint distribution analysis. There is no particular data restriction that the K-means can carry out. However, this depends on computational power, time constraints, and other hardware specification.

Furthermore, once the calculation is completed, the centroids' values are generated and represent a key value for the MongoDB cluster array. Next, the nearest distance fingerprints were determined to the centroid value and transferred the data to the subgroup collections.

5.1 Stepwise Implementation of K-means

The experimentation aimed to produce several $k = 10,000$ clusters with key centroids values as reference. In the next phase, song fingerprints are distributed into the new clustered collections.

Step 1: Batch Data Processing

The original approach was to separate the first instances into blocks by introducing a segmentation of data while handling many data for K-mean computation. Next, using the *pickle* data structure in

python, the trained model was stored from the computation. Subsequently, once all fingerprint datasets were collected, we used the previous model values and incrementally updated them. Code Listing 1 shows the steps of the python *scikit-learn* library [21] implementation algorithm for K-means. Below describe the steps of the data training sequence:

1. As the first elements of $n_cluster$ centres, the algorithm selects 10,000 points.
2. Then, each 100,000 of linekeys that were loaded into memory and loaded to the K-means calculation using these data. Each cluster center was recomputed as the average of the points in that cluster.
3. Finally, the function at item 2 is repeated until the clusters converge. If there is no further change in the assignment of the fingerprints to clusters, the algorithm converges.

```
def dumpFitKmean(n_clusters, i, chunk, chunksize):
    if i==1:
        X = chunk
        mbk = KMeans(init='K-means++', n_clusters=int(
            n_clusters), n_init=1, random_state=42)
    else:
        X = chunk
        mbk = getFitKmean(i-1)
        mbk.fit(X)
        pickle.dump(mbk, open("pickelDump"+str(i)+".p", "wb"))

def getFitKmean(i):
    dumpFile = "pickelDump"+str(i)+".p"
    mbk = pickle.load(open(dumpFile, "rb"))
    return mbk

if __name__ == "__main__":
    i=1
    chunksize = 100000
    for chunk in pd.read_csv(filename, chunksize=chunksize,
        header=None):
        dumpFitKmean(n_clusters, i, chunk, chunksize)
        i=i+1
```

Listing 1: A Python implementation of K-means computation

Step 2: Building Cluster Segmentation in MongoDB

Once the centroid values were formed, the distance to each centroid was calculated for each fingerprint $f^{(i)}$ in order to find its partition affiliation by Equation (3)

$$p^{(i)} = \underset{j=1}{\operatorname{argmin}}^k \|f^{(i)} - C_j\| \quad (3)$$

In order to obtain the distance for the fingerprint $f^{(i)}$, the Euclidean distance was performed between $f^{(i)}$ and any centroid value C_j . From the distance function list, *argmin* was used to get the minimum distance. As a result, acquired the fingerprint association $p^{(i)}$ with its corresponding cluster $S_{p^{(i)}}$.

The code in Listing 2 demonstrates the steps of the algorithm implemented in python to obtain an aggregation of fingerprint-clusters.

```
def centroid_linekeys_distance(self, linekeys,
    indexCentroids, centroids):
    distance = abs((int(linekeys)-int(centroids)))
```

```

result = distance , centroids , indexCentroids
return result

def get_CentroidsDB(self):
result = self.collection_centroids.find()
result = [[document['_id'],document['centroids']] for
document in result]
result = sorted(result,key=lambda x: x[1])
return result

def update_CentroidsDB(self , sortedDistance , songNo ,
linekeys , linekeysPosition):
self.collection_updateCentroids = self.db['
zentroid2song'+str(centroidIndex)]
self.collection_updateCentroids.insert({'SongNo':
songNo, 'linekeys':linekeys, 'linekeysPos':
linekeysPosition })

```

Listing 2: Python code fingerprint-cluster association

5.2 Song Recognition and Information Retrieval

During the recognition phase, the fingerprint sequence in the clustered fingerprints database must be identified. The algorithm performs a sequential search window in two stages. First, allocate each fingerprint in the query sequence to the nearest centroid value. Then, perform an in-depth search within the corresponding cluster values and obtain a set of candidates. Here, by applying a similar algorithm to the clustering method to ensure the accuracy of the result.

The benefit of the implemented cluster framework is that a binary search technique can be used according to [22]. The first step is to find the position of a specific fingerprint query value within the sorted array. This method examines and searches the nearest key value for the median centroid key value of the selected fingerprint in each step.

5.2.1 Real-Time Slide Window

Figure 3 illustrates the method used to classify a song based on an input fingerprint source. As seen, the fingerprint query stream was chunked into significant portions of the windows. This sliding window approach is a common information retrieval technique used to detect matching sequences. Each window represents a part of the time in the current album. As mentioned above, each fingerprint represents an instant δ of the audio source. Configurable fingerprints window sizes, e.g. 500, 1000, 2000, 3000, 5000 or 6000 which translate into the actual time section, are essential. Here, it is suggested that the window size does not exceed 6000 fingerprints, as this represents around 60 seconds of actual audio.

Figure 3: Fingerprint Windows Slides Recognition

Each fingerprint is not unique, so that it could appear in some songs, and then a set of song candidates will be provided. However,

in the quest for a result, we can exclude those candidates and obtain a winner. It was next, segmenting a sub-window of 3/4 from the fingerprints used in the window. This sub-segment window aims to reduce the time for recognition. Also, the selected fraction size weight is appropriate to reflect the full fingerprint in the window.

5.2.2 Fingerprint Cluster Identification and Recognition

There are two stages of the recognition process for each fingerprint query for the search's effective result. Firstly, to determine the cluster $p^{(i)}$ representing the nearest centroid as in Equation (4). The value of the fingerprints $q^{(i)}$ is compared to the value of each centroid C_j . Therefore, returns the cluster $p^{(i)}$ from the set of partitions to get the nearest reference.

$$p^{(i)} = \underset{j=1}{\operatorname{argmin}}^k \|q^{(i)} - C_j\| \quad (4)$$

Finally, Equation (5) returns the minimum value argmin between the fingerprint query $q^{(i)}$ with the fingerprint set $f_j^{p^{(i)}}$ within the defined cluster $p^{(i)}$. This results in a single result of $wf^{(i)}$ of the song details (title).

$$wf^{(i)} = \underset{j}{\operatorname{argmin}} \|q^{(i)} - f_j^{p^{(i)}}\| \quad (5)$$

Each winner of the fingerprint $wf^{(i)}$ will be associated with a set of songs stored in the collection containing the $wf^{(i)}$ in their sequence. For these songs, the column list entry is set to "1" with an entry for each song to be recorded. For this reason, the following subsection 5.2.3 will be clarified by maintaining a record of N columns forming a matrix called **songs**.

Code Listing 3 shows the steps implemented in python for fingerprint recognition.

```

def centroid_linekeys_distance(linekeys , indexCentroids
, centroids):
distance = abs((linekeys-centroids))

def get_linekeys_match(centroidIndex , linekeys):
collection_centroidsValues = db['zentroid2song'+str(
centroidIndex)]
result = collection_centroidsValues.find({'linekeys':
linekeys})

if __name__ == "__main__":
for lk in inputLinekeys:
sortedDistance = min(distance)

```

Listing 3: Python fingerprint recognition

5.2.3 Candidates Scoring

From the previous step, the information for each song was obtained from a single fingerprint question. However, it is crucial to assess the overall result inside the fingerprint sequence in the defined window. Therefore, using the Equation (6) to determine the frequency of $F_k^{(n)}$ of the song results in a N row fingerprint window. The highest score value of the song would be as winning candidates for the window section.

$$F_k^{(n)} = \sum_{i=1}^N \text{songs}_{k,i} \quad (6)$$

where n is the index of the current window. Thus evaluating the winner song using Equation (7).

$$ws^{(n)} = \underset{k}{\operatorname{argmax}} F_k^{(n)} \quad (7)$$

As an initiation a counter is set to the value 1. Each winning song that is $ws^{(n)} = ws^{(n-1)}$ will increase the counter value. Therefore, as soon as the winning song $ws^{(n)} \neq ws^{(n-1)}$ evaluates the W number of subsequent windows for the same winner it will reset the counter back to 1. Therefore the length of the airtime song is evaluated as $d = N \cdot W \cdot \delta$.

6 IoT Based Song Recognition

As shown in Figure 4, the system framework is planned to access the FM Frequency source at a different location by deploying a low-cost IoT system receiver. This FM receiver streams the audio to a cloud instance that converts it to an audio file that is then processed for recognition. Each module of software and hardware configuration components must be integrated to achieve this implementation. Each of these components is discussed in the next section, which includes the IoT system 6.1, the communication protocol 6.2, the recognition server 6.3, and the clustered database.

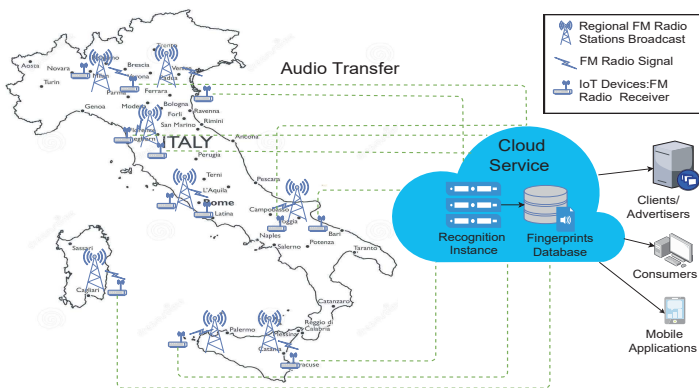

Figure 4: Overview of IoT based Song Recognition Framework

6.1 IoT Device Design

Software-defined radio (SDR) offers a level interface that allows access to filters, mixers, amplifiers, modulators/demodulators on software, meaning on computer embedded systems. This implementation uses RTL-SDR USB dongles based on the RTL2832U chipsets [23] that can read frequencies between 24 and 1,766MHz. The Raspberry Pi is a single-board computer made on a single board and, therefore, small and cheap. It can be used for light programming or, as in this project, to create devices dedicated to the Internet of Things or home automation with various sensors. The operating system used in the project is Raspbian, an official distribution of Raspberry Pi, based on Debian Linux and suitably adapted to the Raspberry Pi. The operating system was downloaded via NOOBS to a 16GB MicroSD.

The FM radio receiver is built using a Raspberry Pi and a dongle, which converts the analog audio signal into a digital audio stream. Python libraries were used for the application, more specifically,

the library to launch RTL-FM. The python syntax with the options required to play an FM radio station is shown in Listing 4.

```
import subprocess, signal, os
def newstation(station):
    global process, stnum

    part1 = "rtl_fm -f "
    part2 = "e6 -M wbfm -s 200000 -r 44100 | aplay -r 44100 -f S16_LE"
    cmd = part1 + station + part2
    print 'Playing station :', station

    # kill the old fm connection
    if process != 0:
        process = int(subprocess.check_output(["pidof", "rtl_fm"]))
    print "Process pid = ", process
    os.kill(process, signal.SIGINT)

    # start the new fm connection
    print cmd
    process = subprocess.Popen(cmd, shell=True)

def setvolume(thevolume):
    os.system('amixer sset "PCM" ' + thevolume)
    print 'volume = ', thevolume

process = 0

while True:
    answer = raw_input("Enter a radio station (i.e. 107.9) or volume (i.e. 50%): ")
    if answer.find('%') > 0:
        setvolume(answer)
    else:
        newstation(answer)
```

Listing 4: Python RTL-FM Frequency Configuration

Figure 5: Raspberry Pi with RTL-SDR module Hardware

Figure 5 shows the actual physical Raspberry Pi device configured with the RTL-SDR hardware module.

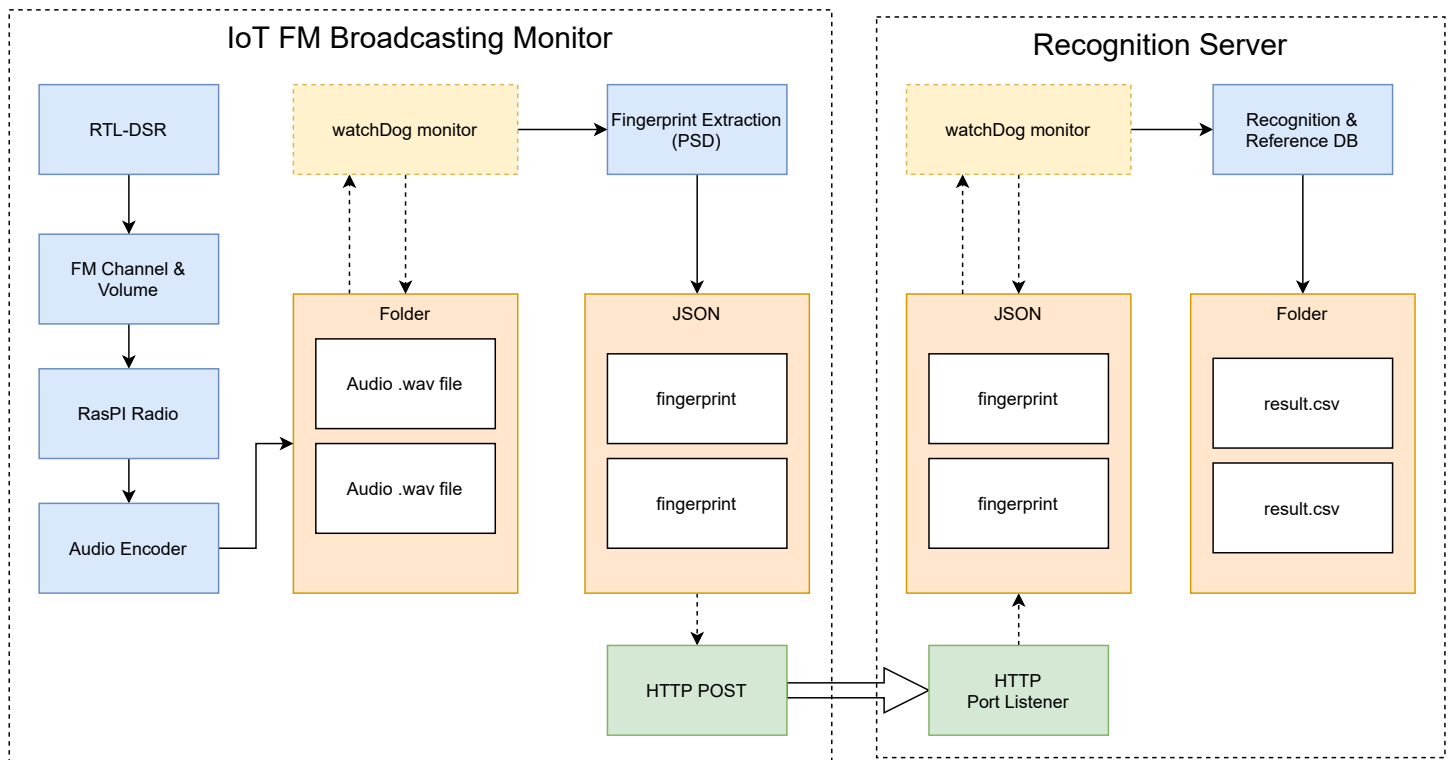

Figure 6: Overview of Framework of IoT device protocol to Recognition Server

6.2 Communication Protocol

Once established the FM frequency channel, we stream the Raspberry Pi output using Real-Time Streaming Protocol (RTSP) with a specific TCP/IP port to maintain end-to-end connection using a python RTSP libraries [24]. The RTSP server will process incoming requests for streams.

Figure 6 shows the component of the Raspberry Pi IoT device and the recognition server communication protocol. The IoT server's final packets consisted of 5 seconds of fingerprint conversion, which is encapsulated as a JSON string as a packet. Additionally, the audio conversion fingerprint algorithm is embedded inside the IoT device; thus, a smaller size packet of string could be transferred much faster. Therefore, the recognition of the fingerprint will be done on the server instance once receiving the packets. The listening port is open as a service for both sides with a directory observer to monitor any incoming packets as demonstrated in code Listing 5.

```
def postJson(linekeys, newFilename):
    print "posting"
    data = {}
    data['fingerprintFile'] = newFilename
    data['linekeys'] = map(str, linekeys.tolist())
    print data

    req = urllib2.Request('http://localhost:8008')
    req.add_header('Content-Type', 'application/json')
    response = urllib2.urlopen(req, json.dumps(data))

    class Watcher:
        DIRECTORY_TO_WATCH = "/home/pi/Desktop/PiRadio/
        inputfile/"
```

```
def __init__(self):
    self.observer = Observer()

def run(self):
    event_handler = Handler()
    self.observer.schedule(event_handler, self.
        DIRECTORY_TO_WATCH, recursive=True)
    self.observer.start()
    try:
        while True:
            time.sleep(5)
    except:
        self.observer.stop()
        print "Error"
    self.observer.join()
```

Listing 5: HTTP Protocol of Fingerprint Exchange

6.3 Recognition Server

A fingerprint is a digital vector that identifies a piece of song signal and can outline the content of that piece of the song. The fingerprint is achieved by removing the main characteristics from audio by choosing distinctive features. Also, fingerprints for storage will minimize the size of the original song with the standard structure.

In this phase, as shown in Listing 6, the streaming audio is converted to .wav file in such a way it could be further converted into a sequence of fingerprints.

```
part1 = "rtl_fm -f "
part2 = "e6 -M wbfm -s 200000 -r 44100 | sox -t raw -e
signed -c 1 -b 16 -r 44100 - inputfile/record"+
str(numberCount)+".wav"
cmd = part1 + station + part2
```

```

def getArrayKey(filename, noOfSplit, windowlength, step):
    fftsize=128
    yFinal=[]
    D, fs = sf.read(filename)
    r = D.size
    c = 0
    if c > 1:
        D = multiToMono(D)
        D = np.array_split(D, noOfSplit)

```

Listing 6: Conversion Recording Stream to Audio .wav

The features below are the qualities of an audio fingerprint that we take into consideration:

- **Consistent Feature Extraction:** The essential part of the fingerprint generation is that it can reproduce a similar audio fingerprint given only a segment of the audio.
- **Fingerprint size:** The fingerprint's size has to be small enough, so a more exhaustive song collection can be archived in the database. Furthermore, a well-compressed fingerprint uses efficient memory allocation during processing.
- **Robustness:** Fingerprint can be used for recognition even if the source audio has been affected by external signal noise.

7 Mobile Music Recognition App

The Android application detects and captures audio through the device's microphone, the audio signals and then converts them into fingerprints. The application was developed and compatible with API version 19 (KitKat) and earlier version. It comprises five object classes that includes *FFT*, *PSD*, *Fingerprint*, *MainActivity*, *RecordAudio*, and *ToolsAudio*. The following will discussed on class *MainActivity* which provides the function *RecordAudio*, as in the UML Figure 7

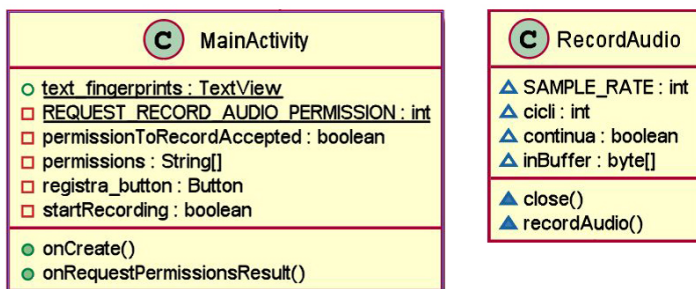

Figure 7: Class MainActivity for RecordAudio

The class *MainActivity* is identified as *Activity*, which is essentially a window containing the application user interface, consisting of a file XML relative to the layout displayed from a class.

Java programming is used to define their behavior; its purpose is to interact with users and goes through various standard functionality cycles, as in Figure 8. When an activity runs, three methods are invoked to interact directly with the user: *onCreate*, *onStart*, *onResume*; when instead Android puts the activity to rest, the methods invoked are *onPause*, *onStop*, *onDestroy*.

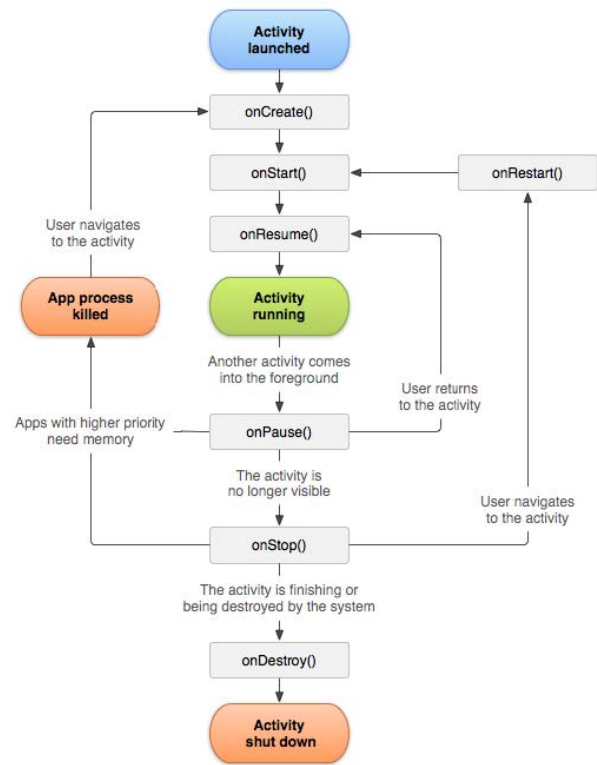

Figure 8: Android Java classes function cycle

Therefore, the graphic interface interacts with the class provided by *MainActivity*; which overrides its default method internally, *onCreate* is invoked when the activity is created.

To manage the user's interaction with the button, it requires to associate a listener method defined as *onClickListener*, through the method *setOnClickListener*. The class *onClickListener* is an abstract however once an instance of it has been created, the method has been redefined through *onClick*.

The *onClick* as in Listing 7, will provide instructions to be executed when the button is clicked. The process flow implemented is as follows: when the "Register" button is press, as shown in Figure 9, the variable is checked *startRecording* to check whether the registration service is started or not. Therefore, the method will be start *recordAudio* of the class *RecordAudio* to record audio signals. Next, the label "Stop" button initiates the stop service. This basic function is almost similar to Shazam's mobile app.

```

register_button.setOnClickListener (new View.
    OnClickListener() {
        public void onClick(View v){
            if (startRecording) {
                au.recordAudio();
                register_button.setText ("Stop");
            }
            else {
                au.close();
                register_button.setText("Register");
            }
            startRecording != startRecording;
        }
    });

```

Listing 7: Java button.setOnClickListener

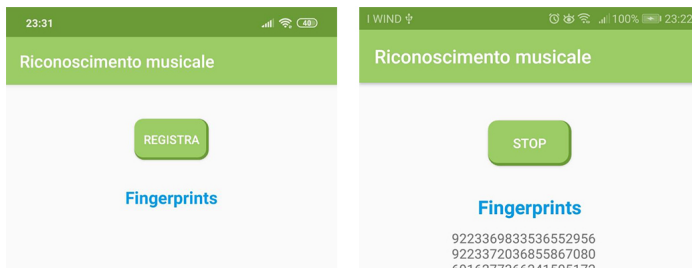

Figure 9: User interface for Start and Stop recoding Audio

The final method implemented was the *requestPermissions*, which allows the application to request user permission for using the internal microphone. This method is related to *onRequestPermissionsResult*, which manages the results granted the use of the physical module from the mobile.

7.1 Audio Recording

The implementation of audio detection is done by the class *RecordAudio*. For this purpose, the use of libraries is particularly important:

- *android.media.MediaRecorder*, for recording an audio stream;
- *android.media.AudioRecord*, to manage audio resources;
- *android.media.AudioFormat*, to access audio formats and channel configurations.

The method *recordAudio* as shown in Listing 8, it is invoked by the *MainActivity* as previously described. The invocation will create a thread that initially does the following:

- the priority of the thread for the acquisition of audio signals is set;
- the *bufferSize*, the maximum size of bytes that the thread can detect at each cycle;
- an object *AudioRecord* is created, which sets different specifications, such as the audio source data (DEFAULT that is the microphone), the sampling frequency (44100), the number of channels (MONO), the coding PCM (16 bit), and the *bufferSize*;
- the method invoked *startRecording* on the newly created object to initialize and start the audio capture session.

```
void recordAudio() {new Thread(new Runnable() {
    @Override
    public void run() {
        android.os.Process.setThreadPriority(
            android.os.Process.THREAD_PRIORITY_AUDIO);
        int bufferSize =
            AudioRecord.getMinBufferSize(SAMPLE_RATE,
            AudioFormat.CHANNEL_IN_MONO,
            AudioFormat.ENCODING_PCM_16BIT);
        byte [] audioBuffer = new byte [bufferSize];
        AudioRecord record = new
            AudioRecord(MediaRecorder.AudioSource.DEFAULT,
            SAMPLE_RATE,
            AudioFormat.CHANNEL_IN_MONO,
```

```
AudioFormat.ENCODING_PCM_16BIT,
bufferSize);
record.startRecording();
```

Listing 8: Mobile Audio Recording

To read input data from smartphone microphone, the class *AudioRecord* is used in a while loop read in which is recorded in a byte array. Therefore, data is not immediately sent to the class *Fingerprint* for their conversion into linekeys, but an adequate number of iterations is expected for a given number of byte to be read. Thus the transformation of a static vector is always performed by creating a thread, as already discussed. The size of the data to be converted has been chosen so that there are no errors in the process they will be requested, especially in the method buffer of the class *Fingerprint*.

7.2 API Design

As part of this project, for communication purposes between client and server, an API has been developed that uses REST's architectural style. The web server was developed in Python. It implements an HTTP server and contains the *pyMongo* API, which is necessary for interfacing with the database. The project foresees the MongoDB non-relational database for the fingerprint storage similarly used in work in [19]. The first step was to install the MongoDB database and all dependencies (Python libraries) required by the source code. MongoDB is a NoSQL type DBMS that stores JSON format. A *cURL* is a command-line tool for transferring data over the network using an HTTP protocol. The advantage lies in its independence from the programming language used. It is proved to be particularly useful for testing the interaction with the server, and therefore the appropriately agreed HTTP request.

7.2.1 Fingerprint Packets Structure

The JSON format for the exchange of data between client and server is constructed. The file is structured in such a way that it has two fields. Firstly, the name-value pair which indicates the *fingerprint-File ID*, therefore of the form "name": "value". The value is a progressive integer that identifies the ID of the JSON request containing the fingerprints. Note that the server requires this to be a string type.

Next, the values contain linekeys, concatenated one after the other. The number of linekeys present in the array is not fixed, but the code must be implemented to parameterize the linekey number, i.e., generalized to number possible values. This is a design parameter, and according to the specifications, it has been set to 50 linekeys.

The following in Listing 9 shows an example of a JSON file, in its complete form, which has 4 set linekeys (fingerprints) and the *fingerprintFile ID* with a value of 2.

```
{
  "linekeys":["13844060856490393600","
8645919525052907526","6054232079929966592","
7274368929366016"],
  "fingerprintFile":"2"
}
```

Listing 9: JSON Fingerprint packets

7.2.2 Web Server and API Protocol

A Python code in the file has been implemented *server.py* API that allows communication with the server. The code is isolated from communication with the MongoDB database for the time being and shows the response of HTTP requests arriving from clients. Some of the classes and their relationships are shown in Figure 10.

The following Listing 10 shows the code fragment related to the HTTP web server's implementation where the parameter server address is defined. By default, the port number set is 8009.

```
def run(server_class=HTTPServer, handler_class=
    Server, port=8009)
    server_address = ('', port)
    httpd = server_class(server_address, handler_class)
    print('Starting httpd on port %d ...' % port)
    httpd.serve_forever()
    print('Started httpd on port %d ...' % port)
```

Listing 10: Python HTTP Class

The code Listing 11 is related to the structure of HTTP header request accepted by the server. The method *headerSet()* handles the parameters of the HTTP request, and the way to response in case errors occur. For example, if the body contained a format other than JSON, a status code would be sent 400.

```
def headerSet(self):
    self.send_response(200, "ok")
    self.send_header('Content-type', 'application/json')
    self.send_header('Accept', 'application/json')
    self.send_header('Access-Control-Allow-Origin', '*')
    self.send_header('Access-Control-Allow-Credentials',
        'true')
    self.send_header('Access-Control-Allow-Methods',
        GET, POST, OPTIONS, HEAD, PUT')
```

Listing 11: Python HTTP Header Request

Next, the deserialization of the JSON file begins: a dictionary data structure is used for data storage. During the test phase, the cURL application was used to initiate the command from client to the server, an example of a request is shown in Listing 12

```
curl--data "{ \"linekey\": \"3441945721\", \"
    requestId\": \"007\" }"
--header "Content -Type: application/json"
http://localhost:8009
```

Listing 12: cURL Application Request

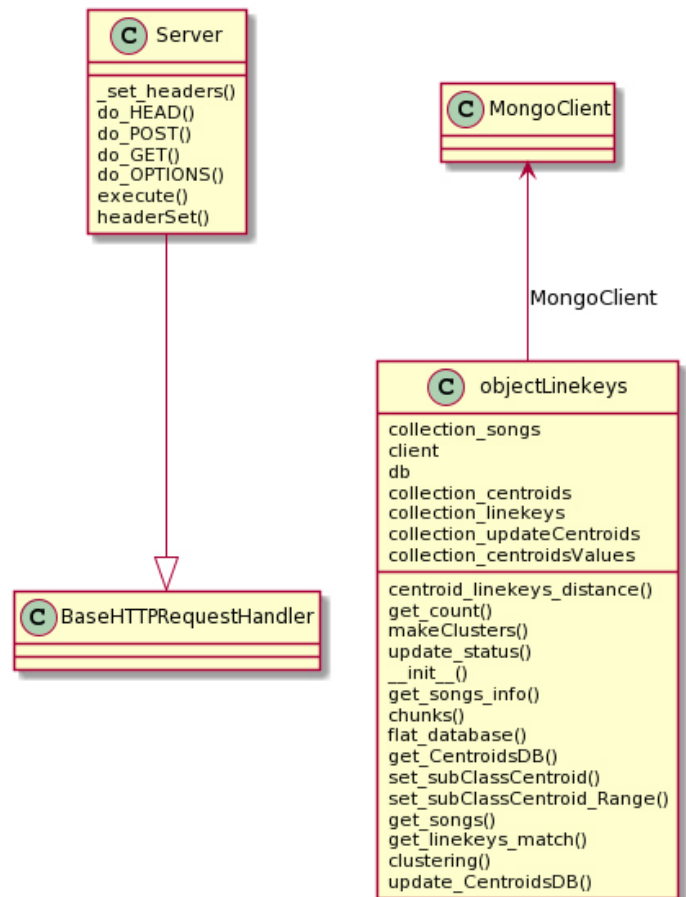

Figure 10: Web server UML classes

8 Evaluation and Performance

The first stages of testing and running the app were carried out using the Android Virtual Device (AVD) Google Pixel 2. Furthermore, the server has been configured to provide the client's data (to verify the correctness). Figure 11 shows the server running while listening on port 8009.

Figure 11: Initiation of server listener

The server open to listening for incoming HTTP requests from android clients. The layout of the android app is shown in Figure 12. As soon as the user taps the button "Register," linekey generation begins. Once the application has reach 50 linekeys, the packets will be sent to the webserver for recognition.

Execution continues and, if the HTTP request was successful and the packet is valid, the server status code is displayed "200 OK". Figure 13 shows that the linekeys have been received while the confirmation is shown on the right.

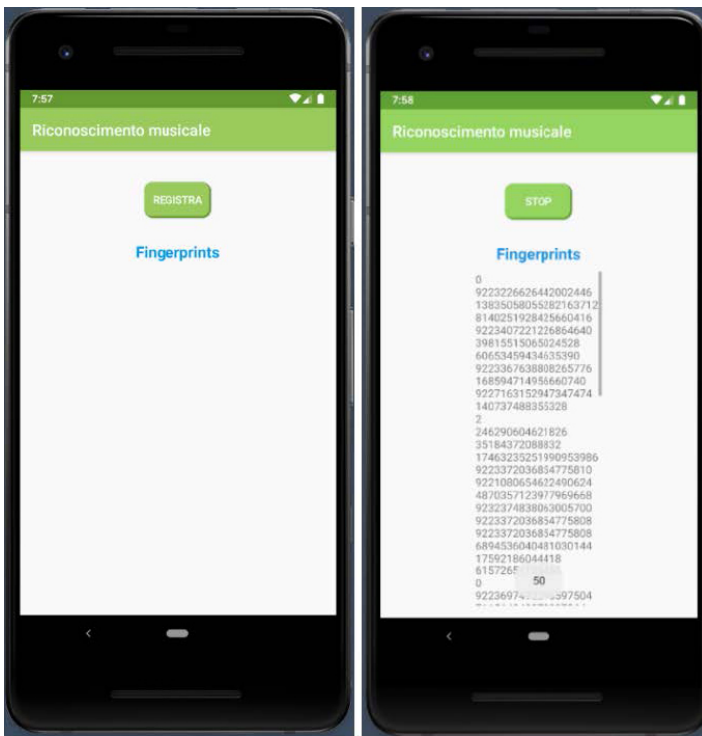

Figure 12: Listening for incoming HTTP requests

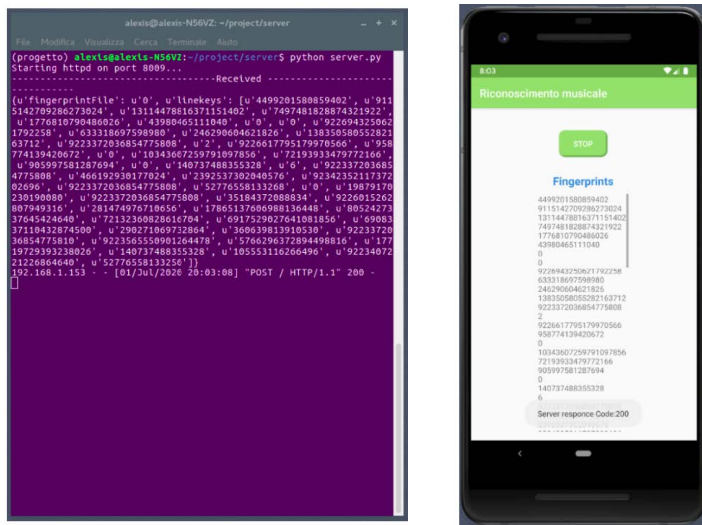

Figure 13: Successful HTTP requests

In any case, the generation of the linekeys proceeds in real-time and received queued HTTP requests follow one after the other until the user immediately ends the generation execution by tapping on the "Stop" button. A web server's public IP address is used in the final phase, which resides in the department lab. The app was installed on a physical Android smartphone using the APK generated by Android Studio for the real purpose.

8.1 Performance Evaluation: ST-PSD Fingerprint

This section provides the evaluation of the proposed method ST-PSD fingerprints. As noted earlier, to verify the proposed hamming

distance computing algorithm for music recognition (a method of exploring the Hamming distance for audio fingerprinting systems), an evaluation was carried out using real music data.

The proposed approach's efficiency was evaluated by experiments using a set of 100 real songs, with 4 real queries for each song, selecting the starting point of the piece of audio to be recognized at random. The random position was selected in the sample domain of the audio so that the extraction of the line keys is not associated with the reference keys found in the collection. Also, each piece of audio corresponds to a length of 5s.

8.1.1 System parameters

Candidates Scoring The linear combination of two sub-score metrics was considered in order to determine a score for each song. The first score is calculated by combining a T_d threshold, i in the fingerprint for each linekey. Provided the matrix \mathbf{H}_d and the matrix T_d , a second matrix of \mathbf{A} has been constructed in Equation (8) where:

$$\mathbf{A}_{i,j} = \begin{cases} 1, & \text{if } H_d(i, j) < T_d. \\ 0, & \text{if } H_d(i, j) \geq T_d. \end{cases} \quad (8)$$

then evaluate the first sub-score in Equation (9) for each song as:

$$B_j = \frac{1}{W} \sum_{k=0}^{W-1} A(i, j) \quad j = 1, \dots, \sigma \quad (9)$$

A third matrix \mathbf{C} as in Equation (10) was considered for the second sub-score where each variable contains a normalized value in the range $[0 - 1]$ approaching 0 when the Hamming distance is large and approaching 1 when the Hamming distance is low:

$$C_{i,j} = \begin{cases} \left(1 - \frac{H_d(i,j)}{T_d}\right), & \text{if } H_d(i, j) < T_d. \\ 0, & \text{if } H_d(i, j) \geq T_d. \end{cases} \quad (10)$$

then evaluate the sub-score for each song as in Equation (11):

$$D_j = \frac{1}{W} \sum_{k=0}^{W-1} C_{i,j} \quad j = 1, \dots, \sigma \quad (11)$$

The final score for each song will be evaluated as Equation (12):

$$FS_j = \alpha B_j + (1 - \alpha) D_j \quad (12)$$

where α is a parameter in the range $[0, 1]$ to be chosen to maximize recognition performance.

The winner song for fingerprint F will be the song with the higher FS_j , by obtaining its index using the relation in Equation (13)

$$WS = \arg \max_{j=0}^{M-1} FS_j \quad (13)$$

The main focus is to use the optimal parameters to perform the proper classification of audio samples. For this reason, a range of potential parameter configurations and corresponding findings have been investigated. Mainly, taking account the size of fingerprint in terms of the number of line keys (W), the size of the threshold used to create the \mathbf{A} and \mathbf{C} matrix (T_d) and the value of the coefficient α used to combine the two sub-scores. The following table 1 indicates all the parameters used to test the performance measure.

Table 1: Parameters used for performance evaluation

α	[0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0]
W	[10, 20, 30, 40, 50]
T_d	[10, 15, 20, 25, 30]

8.1.2 Evaluation steps

Figure 14 indicates a bar graph in which the height of each bar for the various fingerprint sizes used is proportional to the recognition ratio. Mainly, the bar shows the results taking into account the combination of parameters (α and T_d), which allows better results in terms of the recognition ratio. The values of the parameter combination are displayed within each bar.

Figure 14: Recognition rate for different fingerprint size using the better combination of parameters α and T_d

While the identification rate does not seem so high, it must be considered that this rate is compared to a single fingerprint. Using a song piece larger than the fingerprint size for song recognition, the song recognition rate can be improved using fingerprints obtained by a sliding window added to the linekeys sequence. Even so, the fingerprint recognition rate found implies that, on average, 2 would be automatically labeled with the right song, taking a sequence of more than 4 fingerprints. Exploiting this result will dramatically increase the song recognition rate, which will subsequently be clarified.

For that we proposed to extract the fingerprints by applying a sliding window that overlaps the $W - 1$ linekeys with the adjoining linekeys. In this way, the fingerprint produced in each step will be equal to the production step of each linekey (i.e., 100ms per linekeys). Taking into account an audio piece of 5 seconds length which equals to 50 windows (called fingerprint) and denoted as $W = 50$. Thus it's possible to produce a sub-query fingerprint size for evaluation which is equal to $W = 10, W = 20, W = 30, W = 40$ and $W = 50$ respectively.

To improve the proposed recognition system's efficiency, a further discrimination variable was added, based on the distance between the two highest F-Score values obtained for each fingerprint in

the search process. Especially by evaluating the distribution of this distance (called Δ) when the fingerprint was correctly recognized, and the fingerprint was misclassified.

Figure 15 shows the accuracy in terms of

$$\frac{\sum \text{True positive} + \sum \text{True negative}}{\sum \text{Total population}}$$

varying the value of threshold T_Δ in a specific selected 4 windows range with better combination of parameters. Therefore, the best performance using the parameter combination equal to ($W = 10, \alpha = 0.2, T_d = 40$) and a threshold $T_\Delta \approx 0.01$. The accuracy in this case will approach 90%.

Figure 15: Accuracy varying the T_Δ threshold for different better combination of parameters [$W = 10, \alpha = 0.2, T_d = 40$, $W = 20, \alpha = 0, T_d = 20$, $W = 30, \alpha = 0.1, T_d = 40$, $W = 40, \alpha = 0.1, T_d = 20$]

During the recognition step, if the condition $\Delta < T_\Delta$ is true for a given fingerprint, the fingerprint may ignore the relative classification. To recognize a song played in an audio piece, count all the classification for which the condition $\Delta \geq T_\Delta$ is checked. Using this approach for each song in the collection will produce a counting value, called CS_i , $\forall i \in [1, \dots, \sigma]$. Song j is considered recognized for the specified piece of audio if the counter value associated with song j is greater then the counter value associated with all other songs as specified in Equation (14):

$$CS_j > CS_i, \quad \forall i \neq j \quad (14)$$

Using this approach, the selected combination of parameters ($W = 10, \alpha = 0.2, T_d = 40$) and a threshold $T_\Delta = 0.01$ resulting a recognition ratio equal to 100%.

Furthermore, as in Figure 16, this proposed approach was set for comparison with the landmark-based approach by [3]. Using the same data set audio query and creating a landmark song database with 10/sec fingerprint hashes. The landmark-based approach obtains 85.25% which is marginally lower compared to the best output accuracy of 90% with a parameter combination equal to ($W = 10, \alpha = 0.2, T_d = 40$) and a threshold of $T_\Delta \approx 0.01$.

Figure 16: Accuracy comparison between PSD-Hamming and Landmark-Based

9 Conclusions

In conclusion, this research demonstrates the achievement of the project's objectives in the context of musical recognition. Client-server communication has been implemented, managing to work on the server-side with the programming language Python and client-side with language Java on the Android platform.

Also, structuring the information in JSON format is a basic design for this implementation. The client is now able to forward the generated fingerprints to a dedicated server. The graphical interface design for Android enables the audio signal acquisition and displays the screen's generated fingerprints. The implementation has been extended to show the screen feedback on communication with the server by displaying appropriate message notifications. The fingerprints acquired by the server then perform the recognition with that stored database collection.

We believe it would be worthwhile to obtain a more extensive song collection for future analysis and experiments in this direction and be used as a commercial system. This would allow us to gain insight into the types of effects and combinations that prevent an automated recognition system from correctly identifying certain audio query portions. We hope that our contributions can support the active field of audio fingerprinting research. The attention to detail in our evaluation methodology, together with provable reference data collections, will allow our system to serve as a basis for further research in this field.

Acknowledgment We would like to thanks MIUR as the funder of the Industrial PhD program. We are also very grateful for the continuous support from research team members at MDSLabs, University of Messina.

ABSTRACT

It has become difficult to handle traditional networks because of extensive network developments and an increase in the number of network users, and also because of new technologies like cloud computing and big data. Traditional networks are experiencing an increase in VM load and in the time taken for processing tasks. Hence, it has become essential to modify the traditional network architecture. A notion called Load balancing techniques that increases the conformance of network management was presented recently to deal with this problem. The critical need for load balancing emerges due to network resources limitations and requirements fulfillment that facilitates traffic distribution through various resources to enhance the efficiency and reliability of network resources. This task has been carried out by several researchers before, who have presented various algorithms with their benefits and shortcomings. The focus of this research is on the notion of cloud computing load balancing and on the advantages and disadvantages of a chosen load balancing algorithm. Furthermore, it examines the metrics and issues of these algorithms.

1 Introduction

Cloud Computing has universally greater interest in web technologies currently. With the increasing demands of the cloud, popular website's servers are getting overloaded, in order to fulfill users requirement load balancing is one of the promising solutions. Load balancing is the procedure of sharing the load between multiple processors in a distributed environment to minimize the turnaround time taken by the servers to cater service requests and make better utilization of the available resources. cloud computing incorporates and enhances the advantages of a few existing distributed computing technologies. Network computing refers to a "model of distributed computing that employs geographically distant resources and hence, allows users to gain access to computers and data and to handle their accounts from varied locations". Virtualization is another technology that hides the physical properties of computing resources to obscure complexity when dealing with applications, systems or end-users [1]–[3].

Cloud computing initially represented online business applications, referred to as application service provision (ASP). Later on the term was used more extensively following the distribution of services by the company, where the name given to each service provider was based on the service they offered to the customer [4].

Since its introduction in late 2006, several definitions of cloud computing have been formulated. It can essentially be defined as a framework for allowing on-demand network access to a shared set

of online configurable computing resources (like network, storage, server, services and applications) [5],[6].

The definition of cloud computing provided by HP is as follows: "Everything as a Service" [7]. On the other hand, Microsoft considers cloud computing to signify "Cloud and the Client" [8]. According to T-Systems, cloud computing refers to "renting infrastructure, software and bandwidths under specified service conditions. It should be possible to modify these components routinely on the basis of the customer requirements and should be widely available and secure. Furthermore, there are 2-end service level agreements (SLAs) and use-dependent service invoices that are part of cloud computing" [9].

It is possible to distinguish cloud computing into three models, i.e. SaaS (SOFTWARE-AS-A SERVICE), which provides a user interface to the user which they can access through a browser or desktop application; PaaS (PLATFORM-AS-A SERVICE), which offers applications development tools and a programming language execution environment to the user; and finally IaaS (INFRASTRUCTURE- AS-A-SERVICE), which offers virtual computerized resources to the user that they can manage in accordance with their requirements. These models can also be classified in accordance with the services they offer [10], [11].

The Cloud Computing categories are shown in Figure 1.

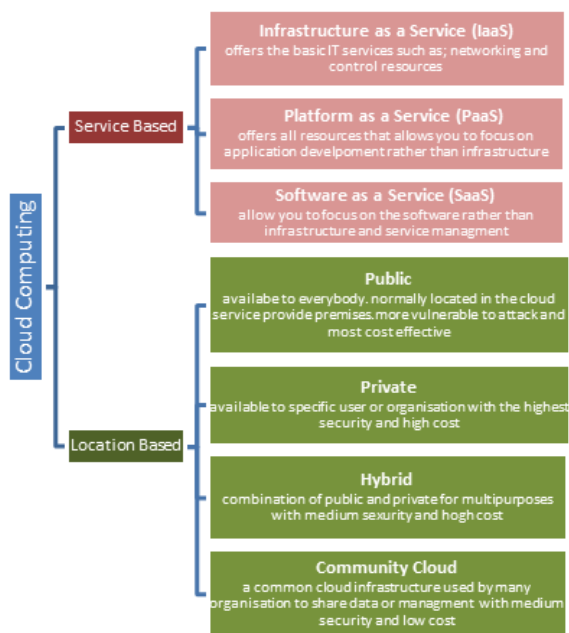

Figure 1: Cloud Computing categories

Cloud computing is becoming quite popular; hence, there has been a significant increase in the amount of processing being carried out in the clouds. However, cloud computing is experiencing several issues in providing the required services [11], including:

- Load Balancing
- Performance analysis and modeling
- Throughput and response time
- Security and privacy
- Resource management
- QoS

The structure of the rest of the paper is as follows: the Load Balancing Concept and Challenges described in Section 2. Section 3 presents the load balancing techniques classification. A few static and dynamic load balancing algorithms are discussed in Section 4. Section 5 Discussion and comparison with the latest studies in this field are compared and Lastly, section 6 gives a conclusion of the study.

2 Load Balancing

There are a series of nodes in the cloud that are connected to one another. Here, one of the nodes is either selected randomly or on the basis of an algorithm to fulfill requests made by users. There may be different data and hence, there is different load on every node, and each node in a cloud can have unequal load of tasks based on the quantity of work requested by clients. Load balancing is a very significant issue that made it imperative for cloud computing to distribute load on the resources available so as to achieve lower response time. This makes sure that no VMs in the system are overloaded at any time [12]. In addition, balance workload continues to be an issue in the cloud as they are unable to determine the quantity of demand that is obtained in the cloud [13].

Load balancing concepts face several challenges because there are various physical and logical issues that may have an impact on the technique being used. A few of these issues are listed in Table I [11]:

Table 1: LOAD BALANCING ISSUES

Graphical Distribution node	There is geographical distribution of data centers in clouds. On the other hand, distributed nodes are considered as a single system without taking into account various factors like communication delay, networking delay and distances between nodes, resources and users.
Virtual Machine Migration	Multiple VM are allowed by the VM concept on the same Physical Machine. Due to the distinct VM structure, the physical machine may become overloaded.
Algorithm Complexity	To ensure that it does not affect the efficiency of the cloud, load balancing algorithm should be simple and concise.
Heterogeneous nodes	In these times, users have different requirements. It is essential to have heterogeneous nodes to fulfill users' need for services. The load balancing decision is influenced by the heterogeneity of the nodes.
Single point of Failure	In general, load balancing algorithm is typically carried out on a central node to assign tasks. The entire computing fails in case the central node fails.
Load Balancer Scalability	Computing power, topology, storage, etc. determine the response time of load balancing

3 Load Balancing Techniques Classification

The classification of the algorithms depends on the existing status of the system and involves two categories [14], [11]: static algorithms that obtain information pertaining to the system and identify the existing resources for using before commencing. The load is distributed on the existing VM till the work concludes, which is preferably used when the VM capabilities are similar to one another. This type of algorithm has various techniques, for example round

robin, Min-Min, weight, Max-Min, honey bee foraging, throttled, etc. The issue faced with static algorithms is that they depend on static information which is unable to effectively demonstrate dynamic load variations taking place within the VMs [15]. Dynamic algorithms are the second kind of algorithms and are different from static algorithms in the sense that they exhibit flexibility. These algorithms work on the basis of rescheduling the tasks allocated to them over the available VM while carrying out the work. Better performance is exhibited by static algorithms in contrast to the dynamic algorithm, whereas with respect to the competitive ratio, dynamic algorithms have a larger ratio compared to the static algorithm [16]. The typical structure of load balancing in cloud environments is demonstrated in Figure 2, whereas Figure 3 shows the classification of the load balancing methods. Several parameters are used to assess load balancing algorithms, which are regulated by various policies. The metrics are presented in Table 3 [15], [17], while an outline of the load balancing policies is given in Table 4.

Table 2: Load Balancing Metrics

Metrics	Description
Performance	It refers to ensuring the consistency and efficiency of the algorithms carried out
Response time	It refers to the time taken by the system to give a reaction to the user request. The more rapid the response time, the higher the satisfaction obtained by the user.
Throughput	The number of tasks carried out for each unit of time.
Scalability	The ability of the algorithm to handle the tasks of the user in an efficient and effective way.
Fault Tolerance	The robustness of the algorithm to solve issues and errors so that its performance can be regained
Migration Time	The time needed to shift the load from a certain VM to another in accordance with the VM loading during situations of overload or under-load.
Resource Usage	Determines the optimum use of computing resources in the data center that should be employed by the algorithm
Makespan	Time needed to carry out and treat a given set of tasks

Figure 2: General Structure of Load balancing in Cloud Environment [18]

Load Balancing Techniques	Static Load Balancing: Fixed Rules without consideration of current status or previous knowledge of resources such as ; storage, processing ..etc	Optimal Load Balancing: Collect information for load balancer to allocate tasks to the resources in optimum time	Examples on Static Techniques : Min-Min, Max-Max, Round Robin, Shortest Job First, <u>opportunistic</u> load balancing, Approximate load balancing, Heuristic load Balancing
	Dynamic Load Balancing : Making decision based on the system current status. In addition to task transfer from overloaded machine to underloaded machine	Sub-optimal Load Balancing : Load Balancer is not able to make optimal decision, so it comes up with suboptimal solution	
		Distributed Load Balancing: All nodes participate in task scheduling, load distribution, resource allocation and distribute and redistribute tasks effectively	Examples on Dynamic Techniques: Cooperative Load Balancing, non-Cooperative Load Balancing, Centralized Load Balancing, Semi-Distributed Load Balancing
		Load Balancing: only Single node responsible for load distributing and decision making.	

Figure 3: Load balancing techniques classification

Table 3: Load Balancing Policies

Selection Policy	The required tasks that need to be transferred from a certain VM to another are specified in this policy. This is done depending on the extent of overhead that is to be transferred
Location policy	In this policy, the tasks are sent to the free, under-loaded and available VMs so that they can be fulfilled. The desired VM is determined in this policy on the basis of the availability of the required services so that the task can be transferred in accordance with the available technique, like Negotiation, Random and Probing.
Transfer policy	In this policy, the conditions for shifting the task from a local VM to another local or remote VM are determined. Two types of tasks are used in this regard: the existing tasks and the last task received.
Information policy	This policy deals with keeping information pertaining to the resources safe in the system to ensure that other policies can benefit from them while making decisions.

4 Load Balancing Common Algorithms

A few static and dynamic load balancing algorithms will be presented in this section, with benefits and drawbacks for each algorithm:

4.1 Round Robin Algorithm

This static algorithm is one of the simplest methods used following the selection of the existing VMs. One of these VMs is randomly chosen by the data center unit to commence its operations. In addition, it is organized in a circular manner. After this, every VM that gets a request is shifted towards the final part of the list [19], [20][21],.

There is, however, no interaction between this algorithm and the distinct abilities of the VMs because the tasks are equally divided on the VMs, even though they have distinct abilities (Figure 4) [15]. Hence, Weight Round Robin algorithm is used to enhance this algorithm, which assigns weight for each VM on the basis of its abilities, and then offers the ability to each node to have a specific number of tasks on the basis of the weights allocated to each VM. This algorithm is considered similar to Round Robin algorithm from the perspective of time division because it distributes the time as a circular. However, the distinction is that the tasks are offered to VM on the basis of particular restrictions, for example checking weights [22], [23].

Figure 4: Round Robin Load Balancer [19]

4.2 Throttled Load Balancer (TLB)

A table is generated in this algorithm that includes the virtual machines as well as the existing state (available/busy). If a specific task is allocated to a virtual machine, a request is made to the control unit within the data center, which will look for the ideal VM suit with respect to their abilities to achieve the required task [24]. The load balancer will send -1 back to the data center if an appropriate VM is not available [15]. Figure 5 presents a demonstration of Throttled Load Balancer.

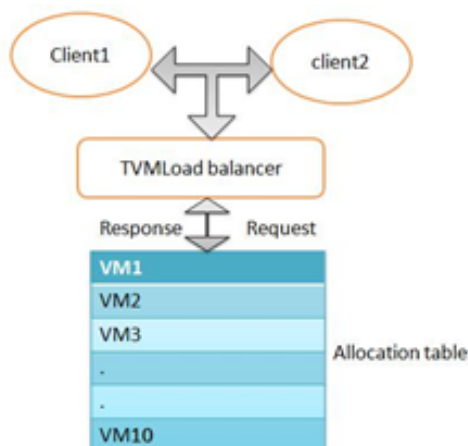

Figure 5: Throttled Load Balancer

In contrast, the process of looking for the ideal virtual machines always takes place from the start of the table each time; therefore, certain VMs are not employed. A modified throttled algorithm was put forward by [25], which works by changing the process of VM

selection. After receiving the subsequent request, the VM at index adjacent to the VM already allocated is selected based on the state of the VM. In addition, [22] presented an efficient throttled algorithm, which consisted of 3 algorithms, i.e. throttled algorithm, ESCE (Equally Spread Current Execution algorithm) and Round Robin. This algorithm is considered as an advancement of the main throttled algorithm, where the enhanced algorithm employed the data structure to maintain information regarding the VMs. In contrast, Hash Map index is used to search for VM and allocated tasks where it works at a faster pace compared to the throttled algorithm.

Furthermore, Divide-and-Conquer and Throttled algorithm (DCBT) approach is taken to be the hybrid approach because it gives preference to the order when allocating the VM. This is done to achieve the highest usage of resources by reducing the overall time taken to execute the task. In addition, this algorithm seeks to update the table by dividing the independent jobs equally among all the VMs. Hence, it works faster than the throttled algorithm [26].

4.3 Min-Min Load Balancing Algorithm

This algorithm is easy to use and works at a faster pace [27]. In addition, it improves performance and consists of a series of tasks. The time taken to execute the task is computed and allocated to VMs on the basis of the smallest completion time for the existing tasks. The process will continue till it is ensured that each task has been allocated to VM [16]. Because of the existence of a greater number of smaller tasks, this algorithm performs better compared to if there were bigger tasks. However, this will lead to starvation because of giving priority to smaller tasks and deferring the bigger tasks [21].

4.4 Max Min Load Balancing Algorithm

As stated by [28], [29], this algorithm is quite similar to the Min-Min Load Balancing, based on the calculation time. In this algorithm, all existing tasks are sent to the system, after which the calculation is carried out for determining the least time to complete each of the given tasks. The selected task then has the maximum time to be completed will be allocated to the relevant machine [11]. A comparison of the performance of this algorithm with the Min-Min algorithm shows that the Max-Min algorithm is better because there is just one large task in the set, which means that the Max-Min algorithm will carry out the shorter tasks alongside the larger task [15].

4.5 Opportunistic Load Balancing Algorithm

This algorithm is a type of static algorithm that is not capable of describing the existing workload of the VM; therefore, it allocates the tasks randomly to all nodes in the system to ensure they are all working [30], [31], and [32]. Tasks are accomplished at a slow pace through this algorithm as it does not compute the existing implementation time [33]. Hence, it provides incorrect outcomes for the load balance [15].

4.6 Ant Colony Optimization

This algorithm that is based on ACO allows for distributing the workload efficiently between the nodes of a cloud. The working of this algorithm is influenced by the Ant concept, where it looks for a new pathway if it comes across an obstacle and allocates a new route between the nodes [34]. The algorithm functions by first initializing the table, carrying out the data flow and achieving the threshold level for the required nodes. When the flow passes through the nodes, the algorithm examines the node; if it is under load, then it uses the highest trailing pheromone (TP) that provides the route for the under-loaded node. The table is then updated till the node achieves the threshold limit. Nonetheless, if the threshold limit is attained, it uses the Foraging Pheromone (FP) to examine new sources of food and update the table till it attains an under-load, after which it reassigns resources. This cycle keeps on occurring till the completion of the process.

4.7 Honey Bee Algorithm

The working of this algorithm is influenced by the way bees behave when looking for honey, because its main objective is to divide the workload on the VM, considering the lack of excessive resource utilization and lack of under-usage of resources. This algorithm works by choosing a VM that fulfills two main requirements. Fewer tasks are allocated to this VM compared to those assigned to other VM machines. The time taken by VM to process falls within the average processing time taken by all other VMs [35], [23].

Figure 6: Active Monitoring Load Balancer

4.8 Active Monitoring Load Balancer (AMLB)

It is a type of dynamic load technology [21]. This technology obtains information relevant to each VM and to the number of requests that are presently allocated to each of them [24]. The Data Center Controller (DCC) scans the VM index table after receiving a new request to determine the VM that is least loaded or idle. First-come-first serve concept is employed by this algorithm to allocate load to the VM that has the smallest index number for more than two servers [21].

The VM ID is sent back by the AMLB algorithm to the DCC which then sends the request to the VM represented by that ID. The AMLB is informed about the new allocation by the DCC and it is sent the cloudlet [24].

Once the task is completed, the information is sent to the DCC and the VM index table is reduced. When a new request is received,

it goes over the table again using load balancer and then the process allocation occurs. Figure 6 presents an illustration of AMLB.

4.9 Genetic Algorithm

In the process of genetic algorithms, scheduling takes place on the basis of the biological notion of population generation. The purpose of using this algorithm was to enhance the distribution of load within the cloud, where the algorithm starts functioning using the preliminary population procedure. The initial population consists of the set of all individuals who are involved in determining the optimal solution. Each solution in the population is referred to as an individual, and each individual is described as a chromosome to make it appropriate for carrying out genetic operations [36]. It was presumed by the authors in [37] that a comparison of the newly developed population will be carried out with the previous one. The solutions are then chosen to obtain solutions (offspring) on the basis of its fitness function [38]. The fitness function is used to determine the quality of individuals in the population with respect to the specified optimization goal [37].

For every chromosome, the fitness function is computed, after which the most appropriate results are chosen to be used as parents. The operation then commences with a crossover process; a part of each parent is used to create a new child; this child is then improved by employing a mutation process. This process keeps on occurring till the best results are obtained [39]. The basis of genetic algorithms is randomness; however, it is not the same as the random search in that it approves the most suitable individuals within a population. The crossover rate and mutation probability values have a significant impact on the performance of the genetic algorithm [38].

The general scheme of the genetic algorithm is shown in Figure 7.

Figure 7: General scheme of genetic algorithm [40]

4.10 First Come First Serve

This algorithm works by distributing new tasks to resources that have the least waiting time (i.e. resources that have the least number of tasks). Here, there is sequential execution of the tasks, with the work commencing from the first task till its completion, after which the subsequent task from the queue is carried out. This algorithm is used as it allocates tasks to the virtual machines without considering the specifications of the virtual machines available and also the time that will be taken by the tasks in queue when allocating new tasks [41].

4.11 Generalized Priority Algorithm

The mechanism of action of this algorithm is to give priority to the tasks according to their size (Higher missions size take higher priority), and the default machines are given priority based on the power of the processor, then the appropriate virtual machine is chosen for the priority of the required task [41]. An example on GPA suppose you have 6 VMs represented by their Id and processor speed VMs = 0, 850, 1, 1000, [5], 3, 150, 4, 250, 5, 750. Here the priority goes to VM 4 will because it has the highest speed, then priority is given to VM 2 and then VM 6 and so on [41]. This algorithm works as in Figure (pseudo):

```
Pseudo code:
For each Datacenter create a VM list
    Find cost processor, processing speed, memory and storage of server (VM)
End loop
For each
    Find length of array
    Sort cloudlet array where computational power is key

For each VM find index in LB table where VM allocation =0
Fill array cloudlet Where array length = MIPS count
Find VM for suitable cloudlet
Find matched VM id
End loop
End loop
Update Datacenter list
Update VM list
```

Figure 8: K. Generalized Priority Algorithm Pseudo code

4.12 NBST Algorithm

Initially, this algorithm assumes that the number of instructions required for the tasks is on the waiting list and their length is known, then it arranges all available virtual devices according to their implementation speed MIPS (Million instructions per second) and arranging the cloudlets according to their length. Where this algorithm depends on dividing the number of VM and cloudlets into two parts after arranging them in descending order until access to the VM or cloudlets one at most, then assigning the VM groups to the cloudlets groups [42].

4.13 Load Balancing Technique based on Cuckoo Search and Firefly

The cuckoo search is based on the brooding behavior of cuckoo bird, where this bird laid their eggs on other bird's nest, the best quality eggs are carried forward to the next generation and the worst nests are abandoned [43]. Cuckoo Search with Firefly is a hybrid algorithm is used for load balancing in a cloud computing environment; this algorithm schedules the tasks and allocates the overloaded VMs tasks to the under-loaded VMs. This algorithm finds the best VM in less time and improves the load balance efficiency and avoids the task imbalanced situations in the entire system [44]. The LB technique starts with scheduling the tasks using Round Robin method, then calculate the capacity and the load of each VM, then it identifies the overloaded and under-loaded tasks using Cuckoo Search with Firefly to start the migration of tasks from overloaded VMs to under-loaded VMs [44]. It avoids the task imbalanced situations in the entire system. Also this method has the advantages of high

interchange rate and less number of tuning parameter. This method has the advantages of high interchange rate and less number of tuning parameter. The proposed method migrates 2 task, while existing method requires 7 task for migration.

4.14 predicted load balancing algorithm based on the dynamic exponential smoothing

This algorithm predicts the load of the VMs by using the dynamic exponential smoothing model. Where the dynamic balancing algorithms focus on the fastest response speed algorithm and the least connection algorithm [45].

Exponential smoothing is one of prediction algorithms based on time series, which takes advantage of all historical data, and differentiates them through the smoothing factor to allow recent data make a greater impact on the analytical value than long-term data, [46].

The allocated node has the shortest corresponding time, when a new request arrives to the server node that has a little connection numbers, the dynamic algorithm takes the load characteristics of the server node as the reference, makes the adjustment with every weighted factor, and reflects the real-time load under the support of weighted value, by that the algorithm helps to find the corresponding smoothing coefficient with the VM load time series of current phrase, and helps to make prediction with the load value at the next moment of this VM[45]. The load predicted balancing algorithm developed by the improvement that permits to construct the dynamic smoothing exponent and to obtain the load prediction with a higher accuracy through the comparison of short load time series. Also it helps to provide more accurate service demand for users and enhance the resource utilization ratio of the server node to a higher level [45]. The accuracy of the model prediction can be affected, because of the selection standard of α exponential smoothing is not very clear [45].

5 Discussion

A comparison of the load balancing algorithms is presented in this section. Each load balancing algorithm is described in specific identifiers with its main properties and limitations.

5.1 Round Robin

- *Algorithm.Name*: [Round Robin].
- *Algorithm.Type*: [Static].
- *Algorithm.Overhead*: [No Overhead].
- *Algorithm.Degree_of_complexity*: [Simple].
- *Algorithm.Strength.points* :
 - Simplicity
 - Easy to install
- *Algorithm.Limitations*:
 - Cannot be improved any more
 - No multi-tasking capabilities

- Could lead to over head
- Does not take capacity importance and task duration into account

- *Algorithm_Performance*: [Low Performance].
- *Algorithm_Throughput*: [Low Throughput].
- *Algorithm_Fault_tolerance*: [No FT].

5.2 Throttled

- *Algorithm_Name*: [Throttled].
- *Algorithm_Type*: [Static].
- *Algorithm_Overhead*: [No Overhead].
- *Algorithm_Degree_of_complexity*: [Medium].
- *Algorithm_Strength_points* :
 - The data center searches for the best VM that fits its capabilities with the task required
 - Maximization of resource usage
 - Increase average of execution time
- *Algorithm_Limitations*:
 - Does not define time limits
 - Could result in idle VMs
- *Algorithm_Performance*: [medium Performance].
- *Algorithm_Throughput*: [high Throughput].
- *Algorithm_Fault_tolerance*: [FT].

5.3 Min-Min

- *Algorithm_Name*: [Min-Min].
- *Algorithm_Type*: [Static].
- *Algorithm_Overhead*: [Medium Overhead].
- *Algorithm_Degree_of_complexity*: [Simple].
- *Algorithm_Strength_points* :
 - Quick
 - Easy to install
- *Algorithm_Limitations*:
 - Leads to starvation
- *Algorithm_Performance*: [Increased performance for smaller tasks].
- *Algorithm_Throughput*: [Improved Throughput].
- *Algorithm_Fault_tolerance*: [No FT].

5.4 Max-Min

- *Algorithm_Name*: [Max-Min].
- *Algorithm_Type*: [Static].
- *Algorithm_Overhead*: [Medium Overhead].
- *Algorithm_Degree_of_complexity*: [Simple].
- *Algorithm_Strength_points* :
 - Execute the large tasks in parallel with short tasks
- *Algorithm_Limitations*:
 - Leads to starvation.
- *Algorithm_Performance*: [Better performance than min-min].
- *Algorithm_Throughput*: [Improved Throughput].
- *Algorithm_Fault_tolerance*: [No FT].

5.5 Opportunistic

- *Algorithm_Name*: [Opportunistic].
- *Algorithm_Type*: [Static].
- *Algorithm_Overhead*: [Low Overhead].
- *Algorithm_Degree_of_complexity*: [Simple].
- *Algorithm_Strength_points* :
 - The advantage is quite simple and reach load balance
- *Algorithm_Limitations*:
 - No fairness in task assignment
 - Tasks are planed slowly because it does not determine the nodes current execution time
 - the whole completion time (Make span) is very poo
- *Algorithm_Performance*: [poor Performance].
- *Algorithm_Throughput*: [Limited Throughput].
- *Algorithm_Fault_tolerance*: [No FT].

5.6 Ant Colony Optimization

- *Algorithm_Name*: [Ant Colony Optimization].
- *Algorithm_Type*: [Dynamic].
- *Algorithm_Overhead*: [High Overhead].
- *Algorithm_Degree_of_complexity*: [High complexity].
- *Algorithm_Strength_points* :
 - The style of living ants depends on the
 - transition from VM to another VM.
 - Better performance
 - Reduce operation time
 - Can be combined with heuristic search algorithm
- *Algorithm_Limitations*:
 - Complex and load on the system unit.
 - Untrusted in reality
- *Algorithm_Performance*: [High Performance].
- *Algorithm_Throughput*: [High Throughput].
- *Algorithm_Fault_tolerance*: [FT].

5.7 Honey Bee

- *Algorithm_Name*: [Honey Bee].
- *Algorithm_Type*: [Dynamic].
- *Algorithm_Overhead*: [High Overhead].
- *Algorithm_Degree_of_complexity*: [High complexity].
- *Algorithm_Strength_points* :
 - it is chosen the best VM by comparing the cost of executing a task on one VM with the other available VMs.
 - Takes into account excessive resources and under used ones
 - Number of assigned tasks less than number of handled by other VMs to reduce execution time
- *Algorithm_Limitations*:
 - Complexity
 - Increase the machine size does not increase throughput
- *Algorithm_Performance*: [High Performance].
- *Algorithm_Throughput*: [Low Throughput].
- *Algorithm_Fault_tolerance*: [FT].

5.8 AMLB

- *Algorithm_Name*: [AMLB].
- *Algorithm_Type*: [Static].
- *Algorithm_Overhead*: [High Overhead].
- *Algorithm_Degree_of_complexity*: [medium complexity].
- *Algorithm_Strength_points* :
 - It identifies the least loaded VM
 - Increase performance
 - Update index table every time task executed
- *Algorithm_Limitations*:
 - Time consuming in index table calculation
 - algorithm gives better results when there is low variation in workload
- *Algorithm_Performance*: [High Performance].
- *Algorithm_Throughput*: [High Throughput].
- *Algorithm_Fault_tolerance*: [FT].

5.9 Genetic Algorithm

- *Algorithm_Name*: [Genetic Algorithm].
- *Algorithm_Type*: [Dynamic].
- *Algorithm_Overhead*: [High Overhead].
- *Algorithm_Degree_of_complexity*: [High complexity].
- *Algorithm_Strength_points* :
 - Executed the cloudlets in less time
 - Improve load distribution in the cloud
 - Better resource usage
 - Better approve the best fitted population indexing in VMs
- *Algorithm_Limitations*:
 - Complexity
 - High resources required for population generation and calculation
 - Crossover mutation is highly effected by probability parameters
- *Algorithm_Performance*: [High Performance].
- *Algorithm_Throughput*: [High Throughput].
- *Algorithm_Fault_tolerance*: [FT].

5.10 First come first serve

- *Algorithm_Name*: [First come first serve].
- *Algorithm_Type*: [Dynamic].
- *Algorithm_Overhead*: [There is Overhead].
- *Algorithm_Degree_of_complexity*: [Simple complexity].
- *Algorithm_Strength_points* :
 - Distribute tasks to all available VMs
- *Algorithm_Limitations*:
 - Not preventive
 - assigning tasks to all virtual machines without paying attention to the specifications of the available virtual machine
 - not paying attention to the time that the tasks in the queue will take when distributing the new tasks
- *Algorithm_Performance*: [Medium Performance].
- *Algorithm_Throughput*: [Medium Throughput].
- *Algorithm_Fault_tolerance*: [No FT].

5.11 Generalized Priority Algorithm

- *Algorithm_Name*: [Generalized Priority Algorithm].
- *Algorithm_Type*: [Dynamic].
- *Algorithm_Overhead*: [No Overhead].
- *Algorithm_Degree_of_complexity*: [medium complexity].
- *Algorithm_Strength_points* :
 - give priority to the tasks according to their size and the machine processor power
- *Algorithm_Limitations*:
 - take more execution time
 - could lead to starvation
- *Algorithm_Performance*: [Increased Performance].
- *Algorithm_Throughput*: [High Throughput].
- *Algorithm_Fault_tolerance*: [FT].

5.12 NBST Algorithm

- *Algorithm_Name*: [NBST Algorithm].
- *Algorithm_Type*: [Dynamic].
- *Algorithm_Overhead*: [Yes the is Overhead].
- *Algorithm_Degree_of_complexity*: [medium complexity].
- *Algorithm_Strength_points* :
 - Distribute all task on all available VM
- *Algorithm_Limitations*:
 - take more time in an assign VMs for cloudlets
- *Algorithm_Performance*: [increased Performance].
- *Algorithm_Throughput*: [High Throughput].
- *Algorithm_Fault_tolerance*: [FT].

5.13 Load Balancing based on CSF

- *Algorithm_Name*: [Load Balancing based on CSF].
- *Algorithm_Type*: [Dynamic].
- *Algorithm_Overhead*: [medium Overhead].
- *Algorithm_Degree_of_complexity*: [medium complexity].
- *Algorithm_Strength_points* :
 - schedules the tasks and allocates the overloaded VMs tasks to the under-loaded VMs
 - avoids the task imbalanced situations in the entire system
 - high interchange rate and less number of tuning parameter
- *Algorithm_Limitations*:
 - multiple algorithms have to be followed
- *Algorithm_Performance*: [Improved Performance].
- *Algorithm_Throughput*: [High Throughput].
- *Algorithm_Fault_tolerance*: [FT].

5.14 predicted load balancing algorithm based on the dynamic exponential smoothing

- *Algorithm_Name*: [predicted load balancing algorithm based on the dynamic exponential smoothing].
- *Algorithm_Type*: [Dynamic].
- *Algorithm_Overhead*: [Yes there is Overhead].
- *Algorithm_Degree_of_complexity*: [High complexity].

- *Algorithm_Strength_points* :
 - *provide more accurate service demand for users and improve the resource utilization of the VMs*
- *Algorithm_Limitations*:
 - *the accuracy of the model prediction can be affected, because of the selection standard of α exponential smoothing is not very clear*
- *Algorithm_Performance*: [Improved Performance].
- *Algorithm_Throughput*: [Medium Throughput].
- *Algorithm_Fault_tolerance*: [No FT].

6 Conclusion and Future Work

This paper presents an extensive Review for load balancing that carry out load distribution among the VM in a different way. considering the lack of excessive resource utilization and not keeping the VMs idle. As a service that is carried out over the network is known as cloud computing, where a lot of significance is given to load balancing issues. The performance will decrease with an overloaded system. Hence, smart load balancing algorithm is needed to maintain the position of QoS. a description for algorithm techniques has been explained and followed by a comparison between them.

Conflict of Interest The authors declare no conflict of interest.

Anonymous data

Random data

ABSTRACT

With a view to detecting whether economic activity deterioration for elderly people at age of sixty-five or over could be observed, anonymous data (AD) were used as analysis data, which were obtained from the National Survey of Family Income and Expenditure (NSFIE) conducted by the Ministry of Internal Affairs and Communications (MIC). We have developed a method to detect dissaving risk among elderly people. In our previous analysis, AD were divided into test data and training data. Three kinds of methods were performed on the basis of income and savings. Then two-step methods were processed to determine dissaving risk. Nevertheless, in utilizing AD as it is, the security of anonymity could be questionable. Therefore, in order to enhance the anonymity of the data, random data (RD) were generated based on AD in this paper. Then RD were compared with the case of analyzing mere AD as it is, for the purpose of performance evaluation. Further analysis results suggest that using both RD and AD would be as effective as using only AD in evaluating the performance of the proposed method.

1. Introduction

This paper is an extension of work originally presented in SNPD2019 [1] by the further detail data analysis and algorithm explanation. It has been widely known that the decrease of nerve cells and the deterioration of cognitive function in accordance with aging can cause the deterioration of memory, thinking, and motivation [2]. As the symptoms of dementia, cerebral disorder is also known, e.g. memory impairment, judgment disorder, execution function disorder, dropping off of cognitive ability, etc. It has also been shown that the older people get, the higher the possibility of the occurrence of disease. In the case of dementia patients, a depressing symptom deprives him/her of vitality and even interest in what he/she used to be interested in before.

Doctors mainly determine whether dementia occurs on the basis of medical diagnostic criterion. Dementia can be classified into several types such as Alzheimer dementia, dementia with Lewy bodies (DLB), etc. Early diagnosis enables the specification of disease and appropriate prognosis treatment. However, there are not a few cases where temporal, economic, and geographical difficulties might obstruct early diagnosis by doctors.

It has been known that the deterioration of brain function can cause the impairment of consumption activity, such as being

unable to withdraw money from banking facilities or to do shopping in spite of ample money. The case of increasing savings without using money because of abnormal adherence to money is also one form of declining consumption activity as well.

The relationships have been revealed between the deterioration of cerebral function and the reduction of consumption activity of elderly people. The malfunction of cerebral function advances if not treated properly or immediately, and can disrupt even daily life owing to dementia, etc.

For the single elderly person, existing techniques enable us to determine dementia by their behaviors in their daily lives. For example, a system has been developed that predicts dementia by using input information in order to inform and input their safety [3]. This system can observe the safety under the protection of the elderly's privacy as well as foresee dementia without regular medical check-ups. Another system is a household electric appliance that determines if the operator is possibly experiencing dementia by obtaining his/her operation history, sleeping hours, commodity purchase history, etc. [4]. If the possibility of dementia is determined, the information is sent to an external device owned by the family of the operator. However, it would be indispensable to monitor the behavior of elderly people to determine if he/she has dementia. Therefore, it would be necessary to purchase the devices and install them to monitor him/her.

The jeopardies of economic activity ability are classified into the following two types: (1) "Dissaving risk," including the possibility of being victimized by fraudulent means, which results from the impairment of judgement, etc., (2) "Under-consumption risk" that is caused by the lowering of motivations. Therefore, the objective of our work is to develop a system that detects those jeopardies early on and issues a warning. In this paper, "dissaving risk" is focused on.

So far we have employed anonymous data (AD) on the basis of the National Survey of Family Income and Expenditure (NSFIE) [5] conducted by Ministry of Internal Affairs and Communications (MIC) in 2004. As a basis of economy activity, for the data of single households at the age of sixty-five or older, clustering was performed with five clusters based on income and saving [6]. As a result of analysis, five clusters were obtained and characteristically classified. Then we developed a method to determine if savings are enough against life expectancy in terms of income and savings [6]. The analysis results revealed that correction detection ratio of the data determined as dissaving risk ranged from 52.6 to 94.1%.

Nevertheless, our first method showed the limitations with the additions of AD years 1994 and 1999. Therefore, our second method has been proposed with a view to determining immediately and easily cerebral function that has started to decline by focusing on economical ability of single-person and two-person households at the age of sixty-five or older [7]. Here, the analysis data were divided into test data and training data [7]. Then two-step methods were then taken to determine dissaving risk [7]. Three kinds of methods were performed in terms of income and savings. However, the security of anonymity for AD could be controversy [1]. In addition, AD can be available and must be returned within the designated durations after application is approved [8]. In order to reinforce the anonymity of AD, random data (RD) is generated along with AD and then compared with the previous analysis [7], for the purpose of performance evaluation. The analysis result conveys the conclusion that using the RD might be as effective as using mere AD [1] in evaluating the performance of the proposed method [7].

In our previous paper [1], the analysis methods and results were superficially and briefly summarized due to space limitations. Therefore, this paper provides more detailed analysis methods and results so that our proposed method [7] would be understood more profoundly.

The remainder of the paper is organized as follows. Related works are referred in Section 2. Preparation of the analysis is summarized in Section 3. The outline of our proposed method [7] using AD is explained in Section 4. Analysis results using RD to evaluate the proposed method [7] is explained in Section 5. Finally, Section 6 concludes the paper.

2. Related Works

In [9], authors pointed out that the shrink of economic activity of rapidly increasing dementia patients along with aging could influence actual economy. For example, when an elderly person develops dementia, he/she might repeat the following experiences; he/she is unable to withdraw money from his/her bank account because of not remembering password, forgets to pay bills,

repeatedly purchases what he/she already had before. These experiences could result in considerable reduction of economic activities. On 2012 fiscal year, among the elderly people at the age of sixty-five or older, the number of dementia patients is approximately 4.62 million, while that of mild cognitive impairment (MCI) attains roughly 4 million [9]. The sum of these patients account for close to 7% of Japanese. Since the elderly people occupy most portions of dementia patients, their figure is expected to go on increasing on a global scale in the upcoming several decades [9]. Thus the shrink of economic activities will extremely impact on economy worldwide. From these viewpoints, our work focuses on the possible decline of economic activities of the elderly people.

In [10], authors conducted an experiment with a view to investigation on annual change of economical ability related to variation from MCI to dementia [10]. They managed the subjects on financial capacity instrument (FCI) under one-year follow-up. The subjects are composed of the following three types: 76 Controls, 25 MCI Converters, and 62 MCI Non-Converters; Control is healthy elderly people, whereas MCI Converter (MCI Non-Converter) is a subject on whom the inflection from MCI to Alzheimer-type dementia was (was not) observed. Using multivariate analysis of variance (MANOVA), the performance of FCI domain and global scores are compared within/among groups. As a result of analysis, MCI Converters fell short of MCI Non-Converters, from the viewpoints of economical concepts, money withdraw management of bank deal specification, payment on invoice, and total FCI scores. Although this research indicates the degradation of economic activities themselves of MCI patients, it is not based on actual consumption behaviors.

In [11], the authors researched on money management issues of the elderly people households along with aging and cognitive ability deterioration. In [12], the authors investigated if the knowledge of basic concepts necessary for effective and economical choice would be degraded after sixty years old, for the purposed of detecting the evidence of intelligence decline in accordance with aging that influences the ability necessary for money management. In [13], the authors analyzed the impact of information against cognitive ability decline of decision maker of finance by using time-series data related to elderly married couples. Authors made an analysis on cognitive ability by employing the actual examples of almost best behaviors and ample economic decisions of consumers. Analysis results conveyed the conclusion that consumers with overall higher scores on analysis items and mathematics are unlikely to end up with economic collapse. These researches [10-13] have been analyzed on the basis of anecdotal reports and multiple manifold methods such as regression analysis. Nevertheless, there have been no researches that focus on the relationships between cognitive ability and purchase motivation.

In [14], the authors evaluated default risks through comparing transition of representative financial ratio considered as the financial safety of companies among bankrupt firms and non-bankrupt firms. For financial ratio, fourteen feature values are extracted; four for profitability and ten for security. These fourteen time-series variation of financial ratio were described to investigate the validity of financial ratio analysis in default risk evaluation. This research analyzes bankrupt risk for enterprises.

However, no indications for individual bankrupt risk were referred.

In [15], the authors used AD to study on relationships between living expenses and fortunes for medical care risks by classifying family budgets, e.g. higher income, lower income, and so on. It has been suggested that appropriate household plans are possible that foresee life cycle of “how much savings will be able to keep covering anticipated household expenditure.”

3. Preparation for Analysis

3.1. Anonymous Data (AD)

The analysis data employed for our previous works [1,6,7] is an AD obtained from National Statistics Center (Japan) [16], based on NSFIE carried out by MIC in 1994, 1999 and 2004. This data contains 1,919 (1,752 and 1,780, respectively) detailed family income and expenditure survey items for 1994 (1999 and 2004), e.g. the amount of income and expenditure, expenditure amount of food such as crop, fish, meat, etc. Among the AD, the present paper uses the data of single elderly people and two-person households (Twos) at the age of sixty-five or over; 717 single males, 3,475 single females, and 11,528 two-person households. There are two types of Twos; head of household is either male or female. However, the Twos whose head is male (1994: 2,607, 1999: 3,840, 2004: 5,081, total: 11,528) considerably outnumbers those whose head is female (1994: 20, 1999: 39, 2004: 44, total: 103). Thus, the Twos whose head is male are used for the analysis data.

3.2. Revised Disbursement

Disbursement consists of the following three components: (1) Expenditure, (2) Disbursements other than expenditure, and (3) Carry-over to next. Among the disbursement, the items that should be exempted from disbursement were considered [6]. As a result, five items were determined to exclude from disbursement [6]; saving, insurance premium payments, security purchase, property purchase and carry-over to next.

In AD, income is provided by ten thousand yen unit per year, whereas each household item related to disbursement is provided by yen per month. Therefore, the value of disbursement exempting the five items above is multiplied by 12 to calculate annual money. This value is defined as “revised disbursement.” The amount of revised disbursement is denoted as D_{rev} . Using Formula (1), D_{rev} is calculated [6].

$$D_{rev} = \frac{12\{D_1 + (D_2 - v_1 - v_2 - v_3 - v_4)\}}{10000} \quad (1)$$

,where D_1 is the amount of expenditure, D_2 is the total amount of disbursements other than expenditure, v_1 is the saving, v_2 is the amount of insurance premium payments, v_3 is the amount of security purchase, and v_4 is the amount of property purchase.

The terms v_1, v_2, v_3, v_4 are the feature values excluded from disbursement. The unit of D_{rev} is ten thousand yen, while those of $D_1, D_2, v_1, v_2, v_3, v_4$ are yen. Therefore, in order to unify the unit yen, the right side of Formula (1) is divided by 10,000.

3.3. Methodology of a Method to Determine Dissaving Risk

(1) Selection of Analysis Data

The analysis data utilized were selected from the following two viewpoints

- The data whose revised disbursement are not more than income were excluded, because their savings are unlikely to be exhausted.
- The data whose savings are 0 yen were also exempted, since their savings are apparently in dissaving risk.

From these two reasons, the data whose revised disbursement are larger than income with savings were extracted; 171 single males, 1,203 single females, and 2,367 two-person households. These data are used as analysis data in our works. These data can be divided in accordance with six groups of attributes made up of house types (“Own” and “Rent”) and year (“1994,” “1999” and “2004”). These amounts are shown in Table 1.

Table 1: Amounts of Analysis Data (Revised Disbursement > Income) [1]

Year	Single						Two-person Household		
	Male			Female					
	Rent	Own	Total	Rent	Own	Total	Rent	Own	Total
1994	11	30	41	104	234	338	78	445	523
1999	24	31	55	105	275	380	96	613	709
2004	26	49	75	122	363	485	132	1003	1135
Total	61	110	171	331	872	1203	306	2061	2367

(2) Condition of Dissaving Risk Determination

In order to determine the condition of dissaving risk, the term in which savings will be exhausted needs to be calculated through dividing savings by the difference between revised disbursement and annual income. The term is named as “saving exhaustion term (SET).” The SET is described as T . T is obtained through Formula (2) [6].

$$T = \frac{S}{D_{rev} - I} \quad (2)$$

, where S is the amount of savings, I is the amount of annual income, and D_{rev} is the revised disbursement.

Provided that P is the ratio of T to L_{exp} corresponding to its age group for each data, P is calculated through Formula (3).

$$P = \frac{T}{L_{exp}} \quad (3)$$

Provided that P_{th} is the threshold to determine dissaving risk, if P is less than P_{th} , the data is determined as having dissaving risk. In our previous analyses, P_{th} was set to 0.1 (0.3, respectively) for single males and females (Twos). In order to avoid confusions, the cases of single males and females ($P_{th} = 0.1$) will be focused on to explain the outlines of analysis method in the subsequent sections.

(3) Classification into Training Data and Test Data

The analysis data selected in Section 3.3-(1) are divided into training data and test data according to the six groups of attributes composed of house types (“Own” and “Rent”) and year (“1994,” “1999” and “2004”). Here, for the respective groups, the analysis data is sequentially classified into training data and test data

according to the ascending order of the amounts of savings. The amounts of training data and those of test data divided through these procedures are shown in Table 2. The columns entitled “R” indicate the training/test data determined as having dissaving risk. How to determine if those data are determined as dissaving risk is explained in Section 3.3-(2). Meanwhile, the columns entitled “N” show those data determined as not having dissaving risk. The columns entitled “T” indicates the sums of the amounts of “R” and those of “N.”

Table 2: Amounts of Training Data and Those of Test Data
(a) Male, Rent

Age Group	Training			Test			Total		
	R	N	T	R	N	T	R	N	T
65 - 69	2	9	11	1	10	11	3	19	22
70 - 74	1	9	10	1	9	10	2	18	20
75 - 79	2	4	6	3	2	5	5	6	11

80 - 84	1	33	34	3	30	33	4	63	67
85 -	1	1	2	1	1	2	2	2	4

(4) Representative Age and Life Expectancy

Dissaving risk is evaluated along with life expectancy (L_{exp}) in 1994, 1999 and 2004 published by Ministry of Health, Labor and Welfare (MHLW) [17]. These values are published for all the ages every year by MHLW. In the AD, age is provided as a form of age groups, e.g. 65 to 69 that ranges from age 65 to 69. Actual age for each data is completely confident. In order to determine L_{exp} , the age of each data is assumed as the youngest of the age group so that dissaving risk must not be underestimated by assuming the unknown age older than actual age. The age determined in this manner is defined as “representative age (A_{rep}).” L_{exp} is used as the form of rounded off to the nearest integer. L_{exp} for each age group is shown in Table 3.

For A_{rep} and L_{exp} of Twos, these values are averaged. Taking an example of a household composed of a male at the age of 70 to 74 whose L_{exp} is 13 years, and a female at the age of 65 to 69 whose L_{exp} is 22 years old, each A_{rep} is 70 and 65, respectively. Their average A_{rep} is 67.5, whose A_{rep} is regarded as 65 since the number is between 65 and 70. Their average L_{exp} is 17.5 years. In this fashion, L_{exp} for Twos are calculated and listed in Table 4.

Table 3: Amounts of Analysis Data (Revised Disbursement > Income) [1]

Age Group	A_{rep}	Male			Female		
		1994	1999	2004	1994	1999	2004
65 - 69	65	17	17	18	21	22	23
70 - 74	70	13	13	15	17	18	19
75 - 79	75	10	10	11	13	14	15
80 - 84	80	7	8	8	9	10	11
85 -	85	5	5	6	7	7	8

Table 4: Life Expectancy for Two-person Households [1]

	Age (A_{rep})	Female				
		65 - 69 (65)	70 - 74 (70)	75 - 79 (75)	80 - 84 (80)	85 - (85)
Male	65 - 69 (65)	65	65	70	70	75
	70 - 74 (70)	65	70	70	75	75
	75 - 79 (75)	70	70	75	75	80

80 - 84 (80)	70	75	75	80	80
85 - (85)	75	75	80	80	85

4. Proposed Method [7] Using Anonymous Data (AD)

4.1. Regression Line to Determine Training Data

Two thresholds of savings (S_{th0} and S_{th}) among the training data are explained by taking an example of single females with own house. The threshold S_{th0} is used to determine if the test data is processed through either primary determination or secondary determination subsequently explained in Section 4.3. On the other hand, threshold S_{th} is utilized to make the training data stated in this section. For each age group, representative age A_{rep} and maximum saving S_{MAX} are shown in Table 5. The column “Rep-Age” indicates the representative age. Here, each value of S_{MAX} is obtained as the maximum savings for each A_{rep} for the data determined as having dissaving risk among the analysis data selected in Section 3.3-(1). In determining each value of S_{MAX} for each A_{rep} , there are several data with greatly high savings despite being determined as dissaving risk. In such cases, their consumption items were investigated to confirm if they were compelled to pay extremely high amounts of money for specific reasons, e.g. renovations, purchasing new furniture, etc. Those data were then discarded for setting S_{MAX} . In Figure 1, S_{MAX} for

Table 5: Representative Age and Savings for Each Age Group (AD: Female, Own) [1]

Age Group	Rep-Age	Savings			
		Max	Predicted Value	Predicted Error	Threshold
	A_{rep}	S_{MAX}	S_{th0}	S_{MAX}	S_{th}
65 - 69	65	506	939.2	-433.2	1403.7
70 - 74	70	1194	729.5	464.5	1194.0
75 - 79	75	800	519.8	280.2	984.3
80 - 84	80	89	310.1	-221.1	774.6
85 -	85	10	100.4	-90.4	564.9

Figure 1: Example of Representative Age and Maximum Savings [1]

each A_{rep} is shown as brown square. The horizontal axis indicates A_{rep} , while the vertical axis indicates S_{MAX} . Regression line R_l is plotted as dashed blue line in Figure 1. R_l is shown as Formula (4).

$$R_l: S_{MAX} = -41.9A_{rep} + 3665.3 \quad (4)$$

The vertical value obtained through R_l at each A_{rep} is defined as predictive value S_{th0} .

Here, the whole set of training data A is defined as “the set whose savings are less than or equal to those of the line R'_l defined as the vertically upward shift of R_l by the maximum of predicted error at the A_{rep} of its range focused on” [7]. Predicted error is calculated through subtracting S_{th0} from S_{MAX} . The line R'_l is plotted as solid red line in Figure 1 and expressed as Formula (5).

$$R'_l: S_{MAX} = -41.9A_{rep} + 4129.8 \quad (5)$$

The maximum of predicted error is 464.5, which is shaded in Table 5. The vertical value obtained through line R'_l at each A_{rep} is defined as threshold S_{th} . On top of the maximum (S_{MAX}), the following three values are also shown in Table 5; predicted value (S_{th0}), predicted error ($S_{MAX} - S_{th0}$), and threshold (S_{th}).

4.2. Training Data and Partial Sets

Provided that D_{rev} is the revised disbursement, I is the amount of annual income, and S is the amount of savings, in order to determine the partial sets of training data, the subsequent two conditions are set [7].

1. Revised disbursement is 1.2 times or more than income. ($D_{rev} \geq 1.2I$)
2. Saving is 0.1 times or less than income. ($S \leq 0.1I$)

These coefficients, 1.2 and 0.1, are determined through trial and error. As defined in Section 4.1, the training data A is the set that satisfies the amounts of savings are not more than S_{th} at A_{rep} . Among the training data A , the set that meets the condition 1 (2, respectively) is denoted as B (C). The partial sets D_1 , D_2 of the training data are then defined as Formulas (6) and (7) [7].

$$D_1 = A \cap (B \cup C) \quad (6)$$

$$D_2 = A \cap (\bar{B} \cap \bar{C}) \quad (7)$$

4.3. Two-Step Methods to Determine Dissaving Risk

The data divided into test data in Section 3.3-(2) is used as test data, while the training data classified in Section 3.3-(2) are used as training data in the following two-step methods. According to the value of S_{th0} set in the fashion explained in Section 4.1, the dissaving risk against each test data is evaluated through either (1) primary determination or (2) secondary determination stated as follows:

(1) Primary Determination

The data whose savings are not less than S_{th0} are determined as “no dissaving risk.” The results of primary determination are shown in Table 6. Each column is explained as follows:

- “P” provides either “ $< P_{th}$ ” or “ $\geq P_{th}$.” As stated in Section 3.3-(2), the threshold P_{th} to determine dissaving risk was set to 0.1 (0.3, respectively) for single males and females (Twos) in the previous analysis [7]. The abbreviation “Act”

listed in the second row stands for “Actual,” indicating that P is an actual value.

- “Det” stands for determination. This column provides the result of determining dissaving risk, either “Dissaving Risk” or “No Dissaving Risk.” For Table 6, mere “No Dissaving Risk” is provided, as explained above.
- “T/F” provides whether determination result is correct or not. If the determination result is correct, this column provides “TRUE,” otherwise “FALSE.”
- “Result” is classified as two results in Table 6. The results are “Leak Detection 1 (LD1)” and “No Risk 1 (NR1).”
- “Abb” indicates the abbreviations of results as stated above.
- “Data” indicates the amounts of the data.

Table 6: Primary Determination Results

No	P	Primary Determination Results				
	Act	Det	T/F	Result	Abb	Data
1	$< P_{th}$	No Dissaving Risk	FALSE	Leak Detection 1	LD1	N_{L1}
2	$\geq P_{th}$		TRUE	No Risk 1	NR1	N_{N1}

(2) Secondary Determination

Secondary determination proceeds through each of three methods, against the test data that have not been determined in primary determination yet.

(i) Method 1

For a test data, estimated saving exhaustion term ($ESET$) is calculated as follows. Provided that D_{rev} is the revised disbursement, I is the amount of annual income, and S is the amount of savings, similar as Formula (2), $ESET$ can be calculated as using Formula (8).

$$ESET = \frac{S}{D_{rev} - I} \quad (8)$$

A further procedure of method 1 will be explained using Figure 2-(a). Here, three training data whose Euclidean distances to the test data are the first to third shortest in terms of savings are extracted from training data belonging to D_1 . The criterion of the training data with first to third shortest determined through trial and error. Among the $ESET$ s of the three training data extracted, the shortest one is set as T_{est} . In Figure 2-(a), the training data with the shortest is described as a red circle, while the other two are shown as orange circles. The red arrow is then derived from the red circle to a blue circle, the test data, to set the shortest $ESET$ as T_{est} .

The T_{est} of the test data will then be divided by the life expectancy L_{exp} corresponding to the age group and the year (1994, 1999 or 2004) of the training data. Provided that P_{est} is the ratio of T_{est} to L_{exp} for each data, similar as Formula (3), P_{est} is calculated through Formula (9).

$$P_{est} = \frac{T_{est}}{L_{exp}} \quad (9)$$

If P_{est} is less than P_{th} , the threshold to determine dissaving risk, the test data is determined as having “Dissaving risk.” Otherwise as “No dissaving risk.” The results of secondary determination are summarized in Table 7. The columns are basically the same as explained in Section 4.3-(1). Minor differences from Table 6 are explained as follows:

- In the column entitled “ P_{est} ”, the abbreviation “Est” is listed, indicating that P_{est} is an estimated value.
- “T/F” provides “TRUE” if the column entitled “Estimated” and “Actual” correspond, otherwise “FALSE.”
- “Result” is classified as four categories in Table 7. The categories are expressed as “Correct Detection (CD),” “Incorrect Detection (ID),” “Leak Detection 2 (LD2)” and “No Risk 2 (NR2).”

(ii) Method 2

For a test data, three training data whose Euclidean distances to the test data are the first to third shortest in terms of savings are extracted from training data belonging to D_1 or D_2 . If training data belonging to D_2 account for at least two out of those three, the test data is determined as having “no dissaving risk.” On the other hand, if training data belonging to D_1 account for at least two out of those three, then similar as method 1, three training data whose Euclidean distances to the test data are the first to third shortest in terms of savings are extracted from the training data belonging to D_1 . The procedure of method 2 is described in Figure 2-(b), with the case when two training data belonging to D_1 . Similar to method 1 and Figure 2-(a), among the training data belonging to D_1 , the smallest is set as T_{est} . Then the test data is determined as having “dissaving risk” if P_{est} is less than P_{th} .

(iii) Method 3

For a test data, three training data whose Euclidean distances to the test data are the first to third shortest in terms of the two-dimensional vector space composed of income and savings are extracted from the training data belonging to D_1 or D_2 . Similar to method 2, if training data belonging to D_2 account for at least two out of those three, the test data is determined as having “no dissaving risk.” Meanwhile, if training data belonging to D_1 account for at least two out of those three, T_{est} is then obtained as explained in methods 1 and 2. The procedure of method 3 is described in Figure 2-(b). Then the test data are determined as having “dissaving risk” if P_{est} is less than P_{th} .

4.4. Measures for Performance Evaluation

The data determined as the total six types of the results are summarized in Tables 6 and 7. For convenience, LD1 and LD2 (NR1 and NR2, respectively) are collectively named as LD (NR). Here, correct detection rate (CDR), leak detection rate (LDR) and correct judgment rate (CJR) are calculated as follows.

- CDR means the ratio of the amount of CD to the sum of the data determined as having dissaving risk in the secondary determination. For the denominator, these data are determined as having “Dissaving Risk” in the column entitled “Det” in Table 7 corresponding to the sum of the amount of CD and that of ID. CDR is calculated with Formula (10):

$$CDR = \frac{100N_C}{N_C + N_I} \quad (10)$$

Table 7: Secondary Determination Results

No.	P_{est}	P	Secondary Determination Results				
	Est	Act	Det	T/F	Result	Abb	Data
1	$< P_{th}$	$< P_{th}$	Dissaving Risk	TRUE	Correct Detection	CD	N_C
2	$< P_{th}$	$\geq P_{th}$		FALSE	Incorrect Detection	ID	N_I
3	$\geq P_{th}$	$< P_{th}$	No Dissaving Risk	FALSE	Leak Detection 2	LD2	N_{L2}
4	$\geq P_{th}$	$\geq P_{th}$		TRUE	No Risk 2	RD2	N_{N2}

(a) Method 1

(b) Method 2 and 3

Figure 2: The Procedures of Three Methods for Secondary Determination

- LDR means the ratio of the amount of LD among the data actually determined as having dissaving risk. For the denominator, these data are expressed as “ $< P_{th}$ ” in the column entitled “ P_{est} ” and “Act” in Tables 6 and 7 corresponding to the sum of the amount of CD and that of LD. LDR is calculated with Formula (11):

$$LDR = \frac{100(N_{L1} + N_{L2})}{N_R + N_{L1} + N_{L2}} \quad (11)$$

- CJR means the ratio of the sum of amount of CD and the amount of NR to the number of all the analysis data. For the numerator, these data are expressed as “TRUE” in the column entitled “T/F” in Tables 6 and 7. CJR is calculated with Formula (12):

$$CJR = \frac{100(N_C + N_{N1} + N_{N2})}{N_C + N_I + N_{L1} + N_{L2} + N_{N1} + N_{N2}} \quad (12)$$

5. Evaluation of Proposed Method through Random Data (RD)

5.1. Division of Anonymous Data (AD)

The use of AD could be controversial in terms of the safety of its anonymity. In order to enforce the anonymity of AD, random data (RD) is generated along with the AD. For the purpose of performance evaluation, RD is then compared with the case of analyzing mere AD as it is.

Determination method is performed by setting each AD as test data and RD as training data. As a preparation of generating RD, AD (single: 171 males, 1,203 females, Twos: 2,367 households) is divided through the following procedures regarding savings and revised disbursements.

(a) The analysis data is just divided into three datasets according to the amount of saving; high-savings (H-s), medium-savings (M-s), and low-savings (L-s). The thresholds between the datasets are determined as follows:

- In AD, the amount of maximum savings is provided with 5.5 million yen. The threshold between M-s and H-s is set as the average of 0 yen and 5.5 million yen: 2.75 million yen.
- Similarly, the threshold between L-s and M-s is set as the average of 0 yen and 2.75 million yen: 1.375 million yen.

(b) Each of the three datasets divided in (a) is respectively divided into two datasets; high-disbursement (H-d), medium-disbursement (M-d), and low-disbursement (L-d) in accordance with the amount of revised disbursement. The threshold D_{rev_th} is set as double of the average of respective datasets. From this viewpoint, for example of single females with own houses, D_{rev_th} for L-s (M-s and H-s, respectively) is set as 483.7 (718.4 and 926.7). These dividing methods are determined thorough trial and error. The amounts of analysis data through the procedure are shown in Table 8. Nevertheless, there could be the case where it would be impossible to divide the test data into any smaller groups. Such cases result from insufficient amount of data after they are divided in accordance with savings and revised disbursements. Taking an example of the single males with rent house, there are only nine data whose savings are over 1.375 million yen (M-s and H-s). In such cases, these groups are not divided into smaller ones.

5.2. Generation of Random Data (RD)

For the analysis data divided into the six attribute datasets as stated in Section 3.3-(3), in accordance with respective savings and revised disbursement, RD are generated along with the following three variables; income, revised disbursement, and savings. Through *mvnrnd* function implemented in MatLAB [18], k sets ($k > 5$) of preliminary RD is generated for each of the respective subdivided datasets in order to avoid failing to extract five sets of RD (amount of data: N) owing to the shortage of preliminary RD.

Table 8: The Amounts of Datasets Divided in Accordance with Saving and Revised Disbursement [1]

(a) Male, Rent				(b) Male, Own			
S\D	L-d	H-d	Total	S\D	L-d	H-d	Total
L-s	52			L-s	58	5	63
M-s	9			M-s	26		
H-s				H-s	18	3	21
Total			61	Total			110

(c) Female, Rent				(d) Female, Own			
S\D	L-d	H-d	Total	S\D	L-d	H-d	Total
L-s	269	10	279	L-s	529	43	572
M-s	37			M-s	171	9	180
H-s	15			H-s	110	10	120
Total			331	Total			872

(e) Twos, Rent				(f) Twos, Own			
S\D	L-d	H-d	Total	S\D	L-d	H-d	Total
L-s	255	10	265	L-s	1388	48	1436
M-s	32			M-s	373	46	419
H-s	5	4	9	H-s	172	34	206
Total			306	Total			2061

Given that income is I , revised disbursement is D_{rev} and amount of savings is S , negative values can be automatically and randomly generated for I , D_{rev} and S . Therefore, the data that absolutely meets $I \geq 0$, $D_{rev} \geq 0$, $S \geq 0$ are sequentially extracted from the preliminary RD generated through *mvnrnd* function [18]. Here, the five sets of RD extracted through these procedures for the respective divided datasets are defined as candidate RD.

Next, one of the five sets of the candidate RD must be chosen to use for the subsequent analysis. In terms of savings exhaustion term (SET), T_{est} for five sets of RD are compared with T for AD by plotting them. Through visual judgment, one set of RD is chosen whose outline is the most similar to AD. How to determine RD out of the five candidate RD are explained by using the actual example of datasets for female with own house divided into L-s and L-D. SET (T for AD and T_{est} for candidate RD) are shown in Figure 3. Here, T and T_{est} shown in Figure 3 range from 0 to 30 years. If these terms are beyond 30 years, T or T_{est} for those data are regarded as just 30 years. Among these values, T for AD is

(a) AD

(b) RD

(c)-1 RD-Cand1

(c)-2 RD-Cand2

(c)-3 RD-Cand3

(c)-4 RD-Cand4

Figure 3: Distribution of Saving Exhaustion Term (Female, Own, L-s and L-d)

Figure 4: The Procedure of Setting Age Group and Life Expectancy on Random Data (RD) obtained from Anonymous Data (AD)

depicted in Figure 3-(a), while (b) T_{est} for the selected RD is shown in Figure 3-(b). On the other hand, T_{est} for the candidate RD that are not selected for the subsequent analysis are shown in Figure 3-(c). These candidate RD are named as RD-Cand1, Rd-Cand2, Rd-Cand3 and Rd-Cand4, respectively. Comparing these values, (b)RD resembles (a)AD more than (c)the rest of candidate RD do. Through these procedures, the selected RD for each of the six attribute datasets is utilized for the following analysis.

5.3. Setting Age Group and Life Expectancy to RD

RD generated and chosen through the procedures described in Section 5.2 already have three attributes; income I , revised disbursement D_{rev} and savings S . Nevertheless, age group A_{rep} and life expectancy L_{exp} of RD have not been assigned yet. Therefore, it would be necessary to determine these attributes. Here, in the three-dimensional space composed of I, D_{rev}, S , for one RD, one among the AD is extracted whose Euclidean distance is shortest. The age group and life expectancy of the AD are then assigned to the RD. The outline of this procedure is shown in Figure 4, similar as that of secondary determination explained in Section 4.3-(2) and shown in Figure 2. One AD with shortest Euclidean distance is denoted as red circle. Then a red arrow starts from the red circle to a blue circle (RD) to set A_{rep} and L_{exp} . The amounts of AD and those of RD determined through this procedure are shown in Table 9. The column entitled “AD (Test)” indicates the amount of AD data used as test data, whereas the column entitled “RD (Train)” means that of RD used as training data.

Table 9: Amounts of AD and RD [1]

(a) Male, Rent			(b) Male, Own		
Age Group	AD (Test)	RD (Train)	Age Group	AD (Test)	RD (Train)
65 - 69	22	24	65 - 69	37	29
70 - 74	20	20	70 - 74	26	38
75 - 79	11	6	75 - 79	32	31

70 - 74	673	645
75 - 79	240	227
80 - 84	67	51
85 -	4	9

5.4. Analysis Results

The validity of AD used along with RD as training data is analyzed in the similar fashion as explained in Section 4.4. Here, RD generated through the method described in Sections 5.1 and 5.2 is utilized as training data, while AD is used as test data. The amounts of partial sets of D_1, D_2 are shown in Table 10.

There are two slight differences from the previous analysis explained in Section 4.4. Firstly, the threshold S_{MAX} is determined in a subtle different fashion. Similar to the AD, there are several RD with substantially high savings in spite of being determined as dissaving risk. Unlike AD, however, RD have no attributions of consumption items. Here, the distributions of savings for each age group are investigated and plotted. Then higher savings that apparently seem isolated from the other lower ones are then discarded for setting S_{MAX} . The thresholds determined are shown in Table 11. Another modification is the threshold P_{th} to determinate dissaving risk for single males and females. In the previous analysis, as stated in Section 3.3-(2), the value of P_{th} was set to 0.1 for single-person households, as explained in Section 3.3-(2). In this analysis, through trial and error, the threshold is set to 0.15 for single households.

In order to compare the analysis results for this section with the previous ones [7], both of the analysis results are summarized in Tables 12 and 13, respectively. See Appendix on the detailed analysis results; the amounts of data determined as LD1, NR1, CD, ID, LD2 and NR2, and the detailed results for each age group.

In order to compare the differences of results between the analysis using RD (Table 12) and that utilizing mere AD (Table 13), their differences are summarized in Table 14. Here, these values are calculated by subtracting those with AD from those with RD. For CDR and CJR, the bigger they are, the better the result is. Therefore, if these values are positive, they are colored blue. Otherwise, if the values are negative, they are colored red.

For LDR, meanwhile, the smaller it is, the better the result is. Thus, on the contrary to CDR and CJR, if these values are negative, they are colored blue. Otherwise, if the values are positive, they are colored red.

	Male			Female					
	CDR	LDR	CJR	CDR	LDR	CJR	CDR	LDR	CJR
Method 1	-5.4	36.8	-8.9	7.8	8.1	-3.0	-4.7	-4.8	-4.3
Method 2	7.1	-3.2	-5.2	6.7	-3.6	-4.8	-3.9	-18.7	-4.4
Method 3	10.0	-3.2	-4.3	3.8	-7.0	-5.8	-1.3	-23.3	-1.5

From the viewpoints of CDR and CJR, for the data with rent house, deterioration is observed in most cases except some for Twos: CDR and CJR for method 1, and CDR for method 3. For the data with own house, CDR is improved for single households except for males for method 1, while it becomes degraded for Twos. CJR becomes deteriorated for both single-person and two-person households. On the other hand, LDR is improved for most of the cases except those with method 1 for Twos with rent and males with own.

5.5. Considerations

Comparing the three methods using RD (Table 12), from the viewpoints of CDR and CJR, as a whole, CDR and CJR become best with method 3. However, for the data with rent house, CDR and CJR equally show similar performance for methods 2 and 3.

For Twos, method 1 outperforms the others. From the viewpoint of LDR, on the other hand, method 1 works best since LDR is the lowest value among the three methods for all the cases. Therefore, method 3 is best in light of CDR and CJR, whereas there is room for improvement for LDR. Meanwhile, method 1 is better than the others considering LDR, while it leaves much to be desired for CDR and CJR.

In the light of the differences of analysis results between RD and AD (Table 14), as a whole, LDR is improved, while CDR and CJR are deteriorated. However, these analysis results are dependent on RD and can be variable. As limitations of analysis, AD are required to be returned within the designated periods [8]. Moreover, there could be insufficient analysis data with certain attributes, especially males. How to cope with the situation where there is not enough data is our requirement for the further analysis.

Nevertheless, these two types of analysis results show the similar results for all the three methods. Therefore, it could be concluded that using RD along with the AD for evaluating the performance of the proposed method [7] could be effective.

6. Conclusion

In the reported study [7], we proposed a method to detect dissaving risk of people at the age of sixty-five or older for AD. In order to strengthen the anonymity of the data, RD used along with the AD is generated and then compared with the previous analysis, with a view to performance evaluation [1]. Here, AD is set as test data, whereas RD is used as training data. As a result of analysis, from the viewpoints of CDR and CJR, for the data with rent house, degradation was observed with most cases. On the other hand, for the data with own house, CDR was improved with most cases for single-person households, while it became deteriorated for Twos. CJR dropped for both single-person and two-person households. Meanwhile, LDR was improved for most of the cases. As a whole, it could be concluded that using RD might be as effective as using AD for evaluating the performance of the proposed method [7].

For future work, while CJR exceeded 80% for single-person households, it attained as high as approximately 70% for two-person households. Therefore, CDR and CJR especially for the data of two-person households must be improved. How to deal with the cases with insufficient analysis data for further analysis is included in our future works.

Fruit tree counting

ABSTRACT

The use of Unmanned Aerial Vehicle (UAV) can contribute to find solutions and add value to several agricultural problems, favoring thus productivity, better quality control processes and flexible farm management. In addition, the strategies that allow the acquisition and analysis of data from agricultural environments can help optimize current practices such as crop counting. The present research proposes a methodology based on the exploitation of deep learning approach, especially Convolutional Neural Networks (CNN) on UAV data for fruit tree detection and counting. We build models for the automatic extraction of fruit trees. This approach is divided into main phases: dataset pre-treatment, implementing a fruit trees detection model by exploiting several CNN architectures, validating and comparing the performances of different models. The exploitation of RGB UAV images as input information will allow the learning models to find a statistical structure, which will result in rules capable of automating the detection task. They can be applied to new images for automatically identify and count fruit trees. The application of the methodology on collected data has made it possible to reach estimates of detection and counting until 96 %.

1. Introduction

Currently, agriculture continues to modernize and follow the evolution of new technologies to improve production practices and crop management. That has become a need in many countries due to the increasing demand for food. The use of new technologies, such as Unmanned Aerial Vehicle (UAV), can help find solutions and add value to several agricultural problems, thus promoting productivity, better quality control processes and flexible tree management [1]. Additionally, strategies that allow data analysis from agricultural environments, including artificial vision systems, can help optimize current practices, such as crop counting, yield estimation, diseases detection and classification of crop maturity [2]. Information on the number of plants in a crop field is essential for farmers as it helps them estimate productivity, assess the density of their plantations and errors occurring during the planting process [3]. From a perspective of detection, delimitation and counting of trees and in particular fruit trees, in [4] the author developed and tested the performance of an approach, based on RGB UAV imagery, to extract information about individual trees

in an orchard with a complicated background which includes apple and pear trees. In [5], the author proposed an efficient method for an individual trees segmentation and the measurement of the width and area of identified trees crowns, based on images acquired by RGB UAV camera. The collected images from a peach orchard in Okayama, Japan, were integrated into Pix4Dmapper software for processing and generation of derived products (Digital Surface Model DSM). Using the intersection of the polygons corresponding to the peach branch line with the summer season DSM as markers indicating the sources of flooding, authors were able to delineate the peach trees crown via watershed segmentation. In [6], the author developed a specialized approach for citrus detection based on the DSM extraction. In [7], the author applied the Canny filter for edge detection applied to the images followed by the "Circular Hough Transform CHM" algorithm thus achieving the extraction and delineation of citrus trees.

The use of UAV in various arboriculture applications has many advantages and benefits. However, this depends on the types of sensors, mission objectives and their platforms [8], [9]. Nevertheless, there are some problems that need to be considered when using UAV such as the reliability of the platform, sensor

capacity and adequate treatment of the images [10]-[12]. To solve the problem of image processing which presents a main source of the success of predictions or good estimation, researchers have in recent years turned to artificial intelligence algorithms, particularly deep learning and especially the convolutional neural network. In [13], the author evaluated the use of convolutional neural network (CNN) -based methods for the detection of legally protected tree species. Three detection methods were evaluated: Faster R-CNN, YOLOv3 and RetinaNet. In [14], the author proposed a deep learning method to accurately detect and count bananas. In [15], the author exploited convolutional neural networks for the detection and enumeration of citrus fruits in an orchard in Brazil characterized by the high density of its trees. In [16], the author developed an automatic strawberry flower detection and yield estimation system.

Following the state of art review, we have selected some of efficient CNN architectures that we have implemented and tested on our context and data. The second phase is the preparation of the data especially the collection, cleaning, analysis, visualization and necessary treatments. The third phase consist to conceive, implement and analysis of the models performance. One of our objectives is to understand the advantage of one architecture over another. We have started by testing different architectures and their hyperparameters. The knowledge acquired as a result of these experiments allowed us to understand the influence of several parameters on the expected performance and to subsequently build a model intended to detect fruit trees.

The rest of this paper is organized as follow. Section 2 gives the material and the used methods. The experimental results and setup are shown in section 3. Section 4 presents the result discussion and section 5 the conclusion followed by the most relevant references.

2. Material and Methods

2.1. Material

2.1.1. Data collection

Among the many challenges of deep learning algorithms is the data collection which is considered to be one of the most critical points in the processes of artificial intelligence in general and deep learning in particular. The required time to run a deep learning algorithm depends on data preparation including collection, cleaning, analysis, and visualization. To answer this problem, we consulted several sources, resulting in a fairly large repertoire of images serving as the basis for feeding our algorithm. In this work, we will not treat the acquisition step and orthophoto establishment. We are limited in their uses and treatment for a successful training operation.

We present in Table 1 the number and size of each of the data acquired as well as the source.

Table 1: The number, size and source of data tested in this study

Data	Image number	Size	Camera resolution MPx	Altitude	Type of flight	Source
D1	103	960 x 540	-	-	-	https://github.com/skygate/skyessays

D5	13	4896 x 3672	16	40	DJI	www.terramodus.ma

2.1.2. Computer tools and deep learning libraries used

Keras

Keras is a high-level neural network Application Programming Interface (API) written in Python and interfaceable with TensorFlow, CNTK and Theano. It was developed with the aim of allowing rapid experiments [17]. Keras can allow rapid and easy prototyping (due to its user-friendliness, modularity and extensibility). It supports both convolutional networks and recurrent networks as well as a combination of the two. Also, it Works seamlessly on CPU and GPU.

Darknet

Darknet is an open source neural network framework written in C and CUDA. It is fast, easy to install, and supports CPU and GPU computing [18]. It was developed by Joseph Redmon. Unlike Keras which is well known as much as a deep learning library, Darknet on the other hand is the library where versions of the YOLO object detector are implemented.

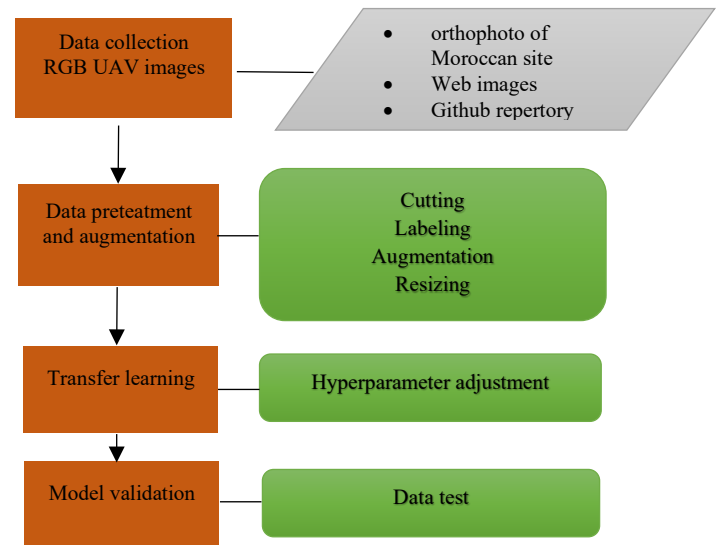

Figure 1. Methodology flowchart.

Google colab

For any neural network, the training phase of the deep learning model is the most resource-intensive task. During training, a neural network receives input data, which is then processed in hidden layers using weights which are adjusted during training and the model then gives a prediction. The weights are adjusted to find patterns to make better predictions. Memory in neural networks is needed to store input data, weight parameters, and activations as an input propagates through the network [19]. Due to the memory and limited power of our computer, we used the Google

colaboratory to perform all of our deep learning operations. Google Colab or Colaboratory is a cloud service, offered by Google (free), based on Jupyter Notebook and intended for training and research in machine learning. This platform allows you to train machine learning models directly in the cloud (Google Colab: The Ultimate Guide). Colab provides a free Tesla K80 type GPU graphics processor and 13 GB of random-access memory (RAM) that work entirely in the cloud.

2.2. Methods

Our methodology is based on a following processes as presented in figure 1.

In the following sections we develop the methodology process.

2.2.1. Cutting operation

In order to increase the images number for the algorithm training, a cropping operation was performed on large images as well as the orthophoto. This operation consisted of splitting the original image to smaller images with a dimension of 816 x 816 pixels, the number of images resulting from the trimming operation depends on the initial dimensions of the image. This was done using the OpenCV image processing graphics library on Python. Figure 2 shows how an image of dimension 4 x 4 is divided into images of dimension 2 x 2.

Figure 2: Cutting the orthophotographie using OpenCV algorithm

2.2.2. Labeling of images

Labeling images is a human task that involves annotating an image with labels. These labels are predetermined by the person and are chosen to give the computer vision model information about what is shown in the image. The tool used for this task is LabelImg. This is a graphical image annotation tool, it is written in Python and uses for its GUI. Annotations are saved as XML files in Pascal VOC format, the format used by ImageNet. Besides, it also supports YOLO format.

2.2.3. Image augmentation

One of the main difficulties in training a CNN model is that of overfitting. That is, the model produced fits too well on the training data. But, therefore the generalization error of the model is much too high, in other words the model modifies its predictions based on the size, angle and position of the image. To deal with the over-adjustment problem, several techniques are used and among them: Dropout, Transfer learning, Batch normalization and data augmentation. Unlike the techniques mentioned above, increasing

the data resolves the problem from its origin, namely the training data set. This is done on the assumption that more information can be extracted from the original dataset through augmentation. Data augmentation is the technique of increasing the size of the data used to train a model. To obtain reliable detection, deep learning models often require a lot of training data, which is not always available. Therefore, the existing data is augmented in order to obtain a better generalized model. Some of the most common data augmentation techniques used and applied to our images are listed below: Scaling, Rotation, Translation, Shear, Brightness, Contrast, Saturation, Hue, Noise, and Blur the image. Figure 3 presents some criteria used in the augmentation phase.

Figure 3: Augmentation algorithm by change of image pixel value : (a) initial image. (b) brightness $\gamma = 1.5$. (c) brightness $\gamma = 2.5$. (d) brightness $\gamma = 5$. (e) brightness $\gamma = 0.3$. (f) brightness $\gamma = 0.4$. (g) brightness $\gamma = 0.7$. (h) Gaussian Blur = 2. (i) Gaussian Blur = 1. (j) Average Blur. (k) Median Blur. (l) rotation $\theta = 90^\circ$. (m) rotation $\theta = 180^\circ$. (n) saturation = 50. (o) saturation = 100. (p) Sharpen. (q) Shear. (r) translation. (s) noise.

2.2.4. Resizing training images

We opted to resize the training images because there is a correlation between the dimensions of the images used for training the model and the RAM size needed for the model training. The dimensions chosen for the images training are 416 x 416 and 608 x 608. By resizing the images, all the annotation files must be adapted to the new dimensions of the images so that each enclosing rectangle drawn during the annotation phase remains placed around the object. For this task, the algorithm used is written in python using the OpenCV library.

2.2.5. CNN models used for fruit trees detection

Considering the huge set of applications for the object detection, a very large number of models suitable has been introduced. In what follows, we present the three models chosen for the realization of our work. To make our choice, we are based on the model's performance as well as on the models used for our similar application. The three models chosen are:

- YOLOv4
- YOLOv3
- RetinaNet-101

YOLO, You Only Look Once, is a real-time object detection system that recognizes various objects in a single enclosure. In addition, it identifies objects faster and more accurately than other recognition systems [20]. A modern detector is generally made up of two parts, a "backbone" part of the detector which is pre-trained on ImageNet and a Head which is used to predict the classes and limit boxes of objects. For detectors running on a GPU platform, their base network can be VGG, ResNet, ResNeXt, or DenseNet. For detectors running on a CPU platform, backbone can be SqueezeNet, MobileNet or ShuffleNet. As for the main part of the detector head, it is generally classified into two categories, namely the single stage object detector and the two-stage object detector. The most representative two-stage object detector is the R-CNN series, which includes Faster R-CNN, R-FCN and R-CNN Libra. For the one-step object detector, the representative models are YOLO, SSD and RetinaNet.

YOLOv4 network implements CSPDarknet53 as the backbone network. YOLOv4 is considering a few options for the neck, including: FPN, PANet, NAS-FPN, BiFPN, ASFF, SFAM. Neck components generally flow from top to bottom between layers and connect only a few layers at the end of the convolutional network. As part of this work, we chose PANet for the aggregation of network characteristics whose efficiency has been approved by the authors [21]. In addition, we have added an SPP block after CSPDarknet53 to increase the receive field and separate the most important features of the backbone.

YOLOv3 addresses object detection as a problem of direct regression from pixels to the coordinates of bounding rectangles and class probabilities. The input image is divided into $S \times S$ tiles. For each bounding rectangle, an objectivity or confidence score is predicted by logistic regression, which indicates the probability that the bounding rectangle in question has an object of interest. In addition, the probabilities of a class C are estimated for each bounding rectangle, which indicates the classes it may contain. In our case, each bounding rectangle can contain a fruit tree or the background (interesting object). Thus, each detection in YOLOv3 is composed of four parameters for the bounding rectangle (coordinates), an objectivity or confidence score and class C probabilities. To improve the precision of detection, YOLOv3 predicts these bounding rectangles at three different scales using the idea of setting up a network of pyramids. As a backbone network YOLOv3 uses Darknet-53.

RetinaNet is a single stage object detector similar to YOLOv4 and EfficientDet. However, unlike these two detectors presented previously and which both recent (2020), RetinaNet on the other hand was introduced in 2018. It is based on the ResNet network which makes it possible to add a connection connecting the input of a layer with its release. In order to reduce the number of

parameters, ResNet does not have fully connected layers. GoogleNet and ResNet are much deeper but contain fewer parameters. This can make them more expensive in memory during training.

2.2.6. Hyperparameters selection

Several hyperparameters have been tested and iterated by empirical tests. We present in what section the hyperparameters whose variation has remarkably influenced the detection results rate.

The epochs number, stages per epoch and the size of the batch

Epoch's number is a hyperparameter that defines the number of times the training algorithm will work through the training data set. The size of the batch is a hyperparameter which defines the number of samples to be processed before updating the internal parameters of the model. The number of samples reviewed in a single epoch is set simultaneously based on the number of steps per epoch and the batch size. For example, taking a batch size of 32 and a number of steps of 1000 per epoch, then the number of the network samples worked on is 32000.

Learning rate

Considered to be the most important of all hyperparameters. If it is too low the convergence is slow, if it is too large the gradient descent algorithm may unintentionally increase the training error rather than decrease it.

Subdivisions Number

This is a specific hyperparameter to YOLO models and which allows the batch to be subdivided into mini batches which will be supplied to the machine during training. For example, a batch size of 64 and a number of subdivisions 16 means that 4 images will be loaded at the same time. It will take 16 of these mini batches to perform a full iteration. For all the hyperparameters, several values were tested for each of the models and on the basis of the performance obtained on the validation data that we validate the best hyperparameters for each of the models. Table 2 presents the hyperparameters values tested during training phase.

Table 2: The hyperparameters values tested during training phase

Hyperparameters	Tested value
Epochs number	Variable according to training time
Learning rate	0.01, 0.001, 0.0001, 0.00001
Subdivisions Number	16, 8

3. Results and experimentation

3.1. Data Preparation Results

The augmentation operation allowed us to have, from a limited number of images, a very large set. We distributed the images obtained respectively into training image, validation image and test image as presented in table 3.

Table 3: Distribution of images on the training, validation and test sets

Set	Training	Validation	Test
Rate	80%	10%	10%

Total number of images	2355	263	266
Tree number	140293	17605	24637

The size of the adopted images depends on the network size and the GPU capacity (graphics card) used for training. You must insert a reasonable size batch into the GPU memory. We did some tests with different images sizes. Then we compared the details obtained for the different sizes and the training time to finally choose the most suitable one. The dimensions of images used for training the models are 416 x 416 and 608 x 608. These dimensions are multiples of 32 since YOLO is designed in such a way that the input images for its training have this characteristic.

3.2. Model training and hyperparameters choice

The goal during the training phase is to minimize the loss function. The optimization algorithm used during this work is that of the gradient descent applied to batches (Mini-batch gradient descent). This method updates the weights for each batch consisting of N training samples. At each iteration, we therefore take a batch. It is said that an epoch has passed after the entire dataset is covered. The number N of samples in a batch represents another hyperparameter to be adjusted. During training, there are several choices available with respect to the sizes of the hyperparameters. These are the parameters whose value are set before the start of the learning process. They cannot be learned directly from data and must be predefined. Unfortunately, there is no generic way to determine the best hyperparameters. The optimization or modification of hyperparameters is the major problem for training our model. The same model with different choices of hyperparameters can generalize different data models. Additionally, the same type of machine learning model may require different constraints, weights, or learning rates to generalize different data models. So we experimented with different values of these parameters including the learning rate, the batch size and the network architecture. We train our model and at the end we choose the parameters that provide the best precision. Table 4 shows the values taken from the hyperparameters to reduce the loss function.

Table 4: the list of the different pre-trained models and their hyperparameters

Model	Basic network	Image size	learning rate
RetinaNet 101	ResNet 101	608	0.00001
YOLOv4	CSPDARKNET53	416	0.001
YOLOv3	DARKNET53	416	0.001

The loss function of training data is plotted over time. We start with the RetinaNet architecture by referring to the hyperparameters presented in Table 4. Figure 4 presents the evolution of loss functions by epoch

Figure 4: The evolution of loss functions by epoch.

We notice a decrease in the loss function. The experienced learning rate is 0.00001. We also observe that the loss function for the classification has a lower value compared to the other two. This is explained by the fact that we only have one class which is fruit trees.

Unlike RetinaNet which is executed using the Keras library and which allows to visualize the progress of the loss function during the training using the tensorboard module, with Darknet (base network of YOLOv3 and YOLOv4) the progress of the training is not recorded. Nevertheless, we were able to visualize his progress during the training.

For the YOLOv3 model, we could not complete training for a frame size of 608 due to the size of the RAM. We were satisfied with images of dimensions 416 x 416 for the training. Furthermore, it was possible to use a larger batch size for YOLOv3 such as 64. This is made possible thanks to a hyperparameter called subdivision. The smaller the number of subdivisions, the faster the training and the more memory it requires. For example, a number of subdivisions of 8 means that 8 images will be loaded at a time, so more memory will be consumed. For us, the number of subdivisions that can support our work environment is 16 that is mean to load 4 images at once for a batch size of 64. Table 5 shows the values of the loss function of the YOLOv3 model.

Table 5: Values of the loss function at the start and the end of learning- YOLOv3.

Model	Batch size	Subdivision Number	Loss at the start of learning	Loss at the end of learning for 5000 iterations
YOLOv3	64	16	2500	3.67

The results of the YOLOv4 model will be presented in a similar way to those of YOLOv3. Unlike YOLOv3, the training for YOLOv4 has been done up to 10000 iterations mainly because the training speed is much faster compared to YOLOv3. Similar to YOLOv3, YOLOv4 is run using DarkNet and not Keras. Thus, we cannot obtain at the end of the training the progress of the latter. However, we can get an idea of the behavior of the loss function. This function has been tested with a learning rate of 0.001 and 0.0001. This decrease is much faster with a learning rate of 0.001. Table 6 presents the values of the loss function of YOLOv4.

Table 6: The values of loss function at the start and the end of learning- YOLOv4

Model	Batch size	Subdivision Number	Loss at the start of learning	Loss at the end of learning for 5000 iterations
YOLOv4	64	16	2800	12.5624

3.3. Detection rate for the 3 architectures

As test data, we will use the 10% of the images reserved for this step. Figure 5 shows the detection results:

From the detection result, we can see that the two models YOLOv3 and YOLOv4 give better predictions. In addition, the RetinaNet model fails to give good detections of trees if the number of trees in the images is very small. Table 7 presents the predictions of tree number detection in UAV images:

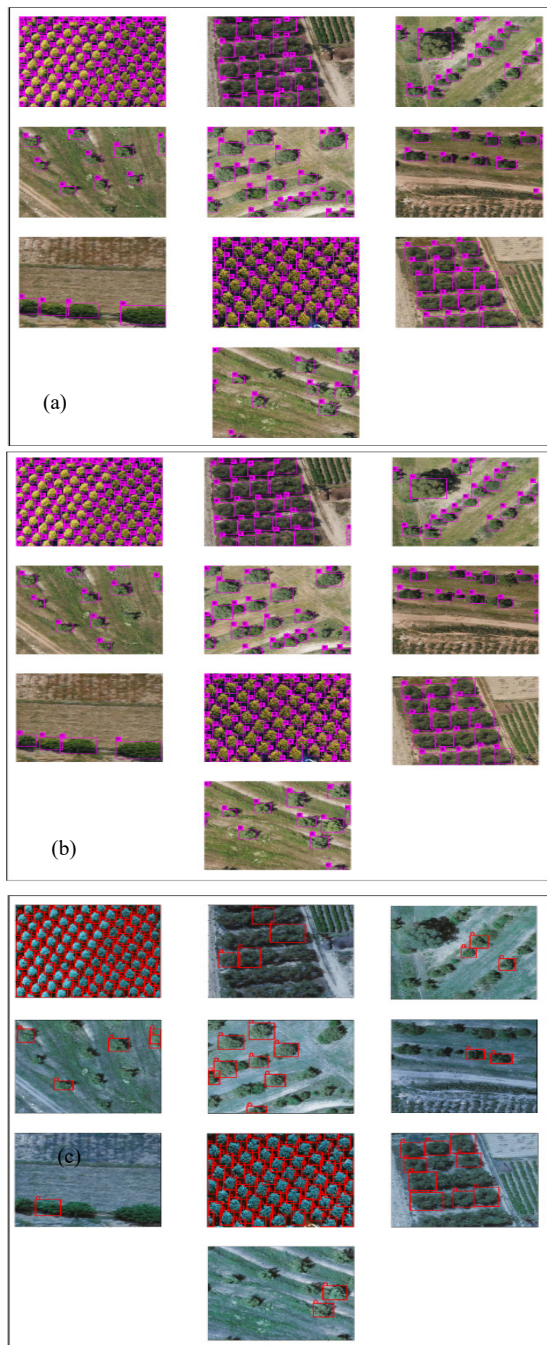

Figure 5: Example of detection results: (a) YOLOv4, (b) YOLOv3, (c) RetinaNet101.

Table 7: The detections obtained for the three tested models

Model	Detection rate %
RetinaNet-101	73%
YOLOv3	80%
YOLOv4	96%

The results obtained demonstrate that the YOLOv4 model is the model which gave the best validation and test results.

The reasons for this choice are as follows:

- ✓ YOLOv4 allowed a faster improvement of the loss function compared to other architectures. For the same number of

epochs, this reaches its lowest value. In addition, it does not require a lot of time for training.

- ✓ YOLOv4 is the model which sacrifices the least precision to improve its Recall.
- ✓ YOLOv4 provides very satisfactory results on the test set where it gives better detections with minimum time and better detection speed.

4. Discussion

Fruit trees have a very complex and heterogeneous form with vegetation classes that appear visually similar in orchards. Their categorizations require the detection model to be able to represent the spatial context of the image appropriately by learning a set of attributes adequate to distinguish between the different categories of the agricultural scene and the efficient extraction of fruit trees. Such an analysis is often carried out on images with very high spatial resolution and which have sufficient detail. Hence the considerable contribution of using RGB UAV images for the detection and enumeration of fruit trees.

The proposed approach based on the YOLOv4 model that we implemented, succeeded in identifying and counting these trees. The results obtained on the validation and test sets are very satisfactory, it gave an accuracy of 96%. In addition, the results on various evaluation metrics undoubtedly confirm the contribution of convolutional neural networks algorithms. Despite their good performance, the use of convolutional neural networks presents challenges, the most important of which is the recurrent risk of overfitting. CNNs are big consumers of data. The general rule of learning algorithms is that a model trained on a large amount of data produces, in the majority of cases, much better results on new data than a model trained on small amounts. The amount of data required is not fixed and depends closely on the complexity and the mission objective.

Finally, despite the relevance of the obtained results, our work nonetheless presents some limitations which are most often due to the available computing resources which have proved insufficient for the conduct of some experiments. In recent years, the graphics processor (GPU) has established itself as an important and even indispensable player in heavy calculations that have long been done only by central processors (CPUs). Fortunately, the Google collaborative cloud space offers excellent technical specifications and allowed us to run several experiments related to this work. Furthermore, we cannot present an experiment that takes place over a succession of stages without addressing the notion of time. Time is one of the deciding factors in choosing the best architecture. Of course, while weighting with the detection rate obtained. Table 5 presents a comparison of the overall training time for the three tested models.

Table 5: The overall training time for the three tested models

Model	Overall training time
RetinaNet-resnet101	11h
Yolov3	5h
Yolov4	8h08min

According to table 5, it can be seen that the Yolov3 and yolov4 model require less time than the Retinanet-101 model. Also the Yolov3 model consumes less time in the training phase. However, as we have mentioned before. Time cannot be the only parameter in the choice of the model. It will be necessary to weight according

to the precision of detection. In this sense, Yolov4 allowed us to obtain the best precision in a fairly satisfactory time.

5. Conclusion

We have tried to simplify the various experiments carried out either on the hyperparameters or on the architectures obtained. Our main goal is to obtain good details on the fruit tree detection and counting. This was accomplished with a detection success to 96%. These results are generally satisfactory given the difficulties encountered either in the availability of data or in the implementation of architectures. During this work, a considerable amount of time is spent for data preparation, collection, cleaning, analysis, visualization and the necessary treatments namely resizing, augmentation and annotation. Our primary concern is to find a sufficient number of images of fruit trees taken by UAV and which can be used subsequently to train, validate and test by the deep learning algorithm. In addition, the field of deep learning is constantly evolving and requires having solid basic knowledge and keeping up with all the news. Something that slowed down our work and took a long time for us to resolve implementation errors. Finally, the complexity of the calculations generated by the different models always makes their training requires more time and powerful machines. In conclusion, despite all these difficulties, it emerges that convolutional neural networks are very promising for the detection and enumeration of fruit trees and open a very interesting field of application for other uses such as yield estimation.

ABSTRACT

Before the COVID-19 crisis, the Southern African Developing Countries (SADC) had a varied energy mix including renewable energy, fossil fuels, and military energy production. The use of fossil fuels in the energy mix is known to be the source of the growing levels of greenhouse gases in the atmosphere. However, there was a reduction in GHG emissions following the pandemic, which reduced travel and trade, and worldwide disruption in economic activities. The priority of priority B in the 2015-2020 Regional Indicative Strategic Development Plan, which is Energy, continues. As a result, the availability of affordable and renewable energy is still a priority for south of the equator countries and their growth agenda. This paper is aimed at exploring the sustainability of SADC countries' electricity sectors by using three sustainability pillars: Social, Environmental and Economic (SEE). SEE offers the main concepts of renewable energy, in a way that is socially, environmentally appropriate and economically viable. Study shows a gap in access rate in SADC countries with only Mauritius and Seychelles reaching 100% access to modern energy services (electricity) for both rural and urban areas. Currently all the member countries have set their RE goals for the year 2030. However, the subsidies by SADC member countries indicate that they are practiced as a way to make electricity affordable, and also to make electricity available to lower income households. In the period 2014-2017, big national budget deficits happened in various Southern African countries because of subsidies. Thus, this paper is of crucial importance to the foundational advancement of sustainable electricity sector growth in the country. The findings of this paper play a crucial role in helping and guiding politicians to better understand the existing and challenges future in the energy market and alternatives to address these problems. Additional research is given on how to arrive at sustainable decisions for the electricity sector in the region.

1. Introduction

This paper is an extension of work originally presented at the IEEE 2nd conference on renewable energy and power engineering [1]. In the past decade, the electricity industry has expanded rapidly with greenhouse gas emissions (see fig.1). As the economy

is rising, carbon dioxide emissions are increasing in proportion to increasing energy demand, industry and access. Electricity is now the number one contributor to greenhouse gases around the globe due to reliance on hydrocarbon (fossil) fuels such as coal, diesel, and gas [2, 3]. There is currently a global concern about environmental impacts due to countless provocations emanating from rapid and extremely precarious demand for energy resulting from population increase, decreased reserves of fossil fuel,

Figure 1: Globe Energy Related CO₂ Emission, 1900-2020 [2, 7]

economic activities and high volatile fossil fuel [4, 5]. Following the COVID-19 pandemic, due to the new trend [6, 7], there will be a decrease in GHG emissions, foreign travel disruptions and economic activities. The electricity sector therefore faces difficulties, both politically and socially, in fostering sustainability.

The most pressing global challenge is the effort to guide the energy industry's future growth in a way that guarantees secure, sustainable, and sufficient access to electricity while being environmentally and socially appropriate as well. But the solutions presented must be commercially viable and must be combined with solutions from the real world. In Sub-Saharan Africa, this is needed in order to resolve numerous pressing energy challenges [8, 9]. Technologies for the generation of low-carbon electricity such as geothermal, solar photovoltaics (PV), wind turbines (WT), concentrated solar power (CSP), biomass energy, and hydroelectric are rapidly recognized as crucial for a renewable electricity industry.

"The ultimate aim of SADC states (2016) is to "ensure that sufficient, effective, low-cost energy supplies are made available to help achieve economic efficiency and eliminate poverty while maintaining the efficient usage of energy resources [10]. The SADC member states have set up several subsidiary bodies to undertake energy related programs and initiatives in order to promote the harmonization of the energy sector. These numerous organizations include the SADC Center for Clean Energy and Energy Conservation, the Southern African Power Pool (SAPP) and the Southern African Regional Electricity Regulators Association (SARERA). These subsidiary organizations manage electricity planning, generation, delivery and marketing, as well as helping to harmonize regulatory policies [11].

The current RISDP 2015-2020 Priority B, provides guidelines on ensuring that regional and national strategies are compatible with the stability, sustainability, and efficiency of the region's

energy market, with Member Countries working together to study and improve low-cost energy technology and energy sources for the region [10, 11]. With regard to the supply of electricity that is secure and affordable, Southern African countries Development Community considers energy access as a very important development priority.

This paper presents a comparative assessment of the SADC countries' electricity industry sustainability using the energy approach of Four (4) Aspects of Electricity (4EA's) which is based on sustainability criteria and indicators. The method was adopted on the basis of claims that it would stick to the four aspects belonging to 4EAs for any energy scheme to be viable. The four aspects of a comprehensive electricity industry assessment in the SADC region are grouped into sixteen (16) indicators. These indicators are linked to the performance of the electricity industry in terms of social and environmental including economical and technical performance. The 4EAs approach includes; Affordability, Accessibility, Availability and Acceptability of electricity sector in the SADC member countries [12]. The methodology of the 4EA discusses the three main sustainability pillars; societal, economic and environmental influences [13]. In particular, these pillars are major principles to achieve electricity sustainability in a way that is technically and economically viable plus a more socially and environmentally acceptable and appropriate for sustainable electricity sectors.

An appropriate quantitative and qualitative indicators and criteria were drawn up for the SADC electricity industry in the evaluation of the SADC Member State electricity sector. The findings of the electricity sector sustainability assessment in the SADC countries will therefore play an essential role to provide a basis to guide and assist policy-makers. The findings will help policy makers have a better understanding of the current and future challenges that arise in the SADC regional electricity industry and by providing alternatives to address them [14]. This will also assist

in the development of an informed investment strategy and decisions to achieve resilience in the region's electricity market.

2. Electricity Industries Sustainability Assessment in the SADC Region

The electricity sector in the SADC region, similarly to other parts of sub-Saharan African, faces numerous energy security related challenges due to rapid energy demand growth, reduced accessibility to energy because of grid lower coverage, high reliance on fossil fuels due to greenhouse gas emissions, leading to environmental and social impacts. Therefore, the SADC region is facing two (2) main energy policy challenges; lower access levels to electricity which are estimated at 48%, with 32% rural and 75% urban (see Table 5), and energy security issues because of dependence on fossil fuels or only single (one) source of energy in the national energy mix [11].

IEA defines energy security as "uninterrupted availability of energy sources at an affordable price" (2019). It can be categorized into two (2) major aspects, short and long-term. The long term aims at making timely investments in the energy system without compromising the environment in meeting economic development. However, the short-term primarily deals with the current energy supply system's ability to meet energy demand sudden changes [15]. Sustainability of energy is one of the key issues in the energy sector because of its strong links to social, economic, and environmental aspects [16]. The effect of access to affordable, reliable, and clean electricity is measured to improve the standard of human well-being. Economic aspects; represents the impact that the energy availability may have on economic growth and development prospects of any society or nation. The research conducted in 2013, highlighted that access to affordable, reliable and clean modern energy services, (e.g. electricity), is essential for the alleviation of poverty and economic development in developing countries [17]. The impact on energy systems that contribute to the environment as a whole is reflected in Environmental Sustainability. Thus, the current main drivers of environmental challenges such as greenhouse gas emission including climate change across the globe are energy systems

based on fossil fuels. Therefore, the use of non-renewable energy sources in the energy mix poses a higher risk to natural environmental sustainability as compared to the use of renewable energy sources.

The 4EA sustainability indicators and criteria adopted for assessing the sustainability of the performance of the electricity industry in SADC member states are illustrated in table 1 below.

2.1. SADC Socio-Economic Development

The SADC consists of sixteen (16) member countries, including, as new Member States, Botswana Angola, Lesotho, the DRC Congo (DRC), Malawi, Madagascar, Eswatini, Mauritius, Namibia, Mozambique, South Africa, Seychelles, Zimbabwe, Zambia and Tanzania. Approximately 33 percent of Sub-Saharan African population belongs to SADC region. The area has a projected 1.9 percent annual population growth. The area has seen an increase in urbanization in recent decades, for example in the period between 2013 and 2017, with the region seeing an increase in urban population share raising to 46% in 2017 from 35% in 2013. However, there exist a differences in the size and complexity of the gross domestic product (GDP) between SADC member states, with the lowest of US\$1.498 billion (Seychelles) and highest of US\$349.3 billion (South Africa) (check Table 2). This is the same with the GDP per capita, with ranges of US\$800 (Malawi) to US\$29300 per capita (Seychelles). However, on the overall, there is decline experienced by the SADC region in GDP per capita annual growth because of a drop in commodity prices on the international market (worldwide) including droughts that caused electricity deficit in industrial and agricultural production [16]. There are also large differences in member countries' economic and social growth profiles in the region. The SADC member countries are classified into three categories, lower, medium and high according to United Nations Human Development Index (HDI). The HDI in the region ranges between 0.418 (Mozambique) and 0.782 (Seychelles), with nine Member States below 0.50, four between 0.50 and 0.70 and only two above 0.70 (see Table 2 [11]).

Table 1: Summary of 4EA's SADC Electricity Industry Sustainability Indicators and Criteria

Aspects of 4A's	Issues	Sustainability Criteria & Indicators
Acceptability	Global Warming	1) Policies on Renewable energy technologies (checklist) 2) Renewable energy share in electricity generation (%) 3) CO ₂ emission per capital (t CO ₂ /capital) 4) CO ₂ emission (ktCO ₂ /year)
Accessibility	Access to Modern Energy Services and Future Targets	5) Electrification rate (%) 6) Electricity consumption per capital(kWh) 7) Electricity Intensity (kWh/GDP) 8) Future Electrification Targets
Availability	Energy security	9) Diversity in Electricity generation mix (% share of each fuel type) 10) Diversity of fuel in Electricity generation (Shannon Wiener Index) 11) Dependence on imported electricity generation ▪ Self-Supply Sufficiency of Electricity (%)
Affordability	Energy Affordability	12) Future Share of Renewable Energy Targets 13) Electricity Prices (\$/kWh) 14) GDP per Capita

Table 2: Socio-Economic Statistics for the SADC Member States [11,18,19]

Member States	Socio-economic indicators for the SADC Countries as of 2017					kWh per Capita	CO2 Emission (kilotons/year)	National Electrification Rates (%)	
	Surface Area (km²)	Population	GDP (US\$ Billion)	GDP per capita (\$)	HDI

Figure 2: Projected Energy Demand in Southern Africa by 2030 [IRENA, 2015b]

2.2. SADC Share of Electricity Industry

As of 2018, the overall installed capacity of the SADC region was estimated at more than 61,859 GW, with 59,539 GW of installed capacity and 54,397 GW of operational capacity for SAPP Member States alone. Regional electricity demand growth is expected at an average rate of between 3 percent and 6 percent annually, in line with economic growth [20]. Complete electricity demand forecasts from the International Renewable Energy Agency (IRENA) (2015) indicate that demand in the SADC region is projected to double from 280 TWh (2010) to 570 TWh (2030) by 2030 (see Fig.2) owing to numerous activities such as strong economic growth, demographic growth, urbanization and industry production in the region [21, 22]. The demand for energy will continue to outpace production, with real costs, unless SADC countries raise cooperation with each other. Electricity will remain high and SADC's aspirations for wide-scale industrialization will continue to be suppressed by an inadequate supply of available electricity at fair prices.

In the region, however, generation capacity and installed power grids are limited; thus, electricity supply has lagged behind demand growth from 2007 until 2018, when the SADC region experienced excess energy supply as the result of the commissioning of the new energy projects [23]. In most SADC member states, this delay in the supply demand balance has

resulted in a complex and persistent electricity shortage. Moreover, even in some highly hydroelectricity dependent SADC Member States due to climate change that has triggered droughts in recent years, the presence of a grid link has not guaranteed access to electricity for the end user, or even would be used by consumers due to prolonged load shedding, brownout and power cuts [24]. The SADC region's level of access to modern energy resources remained lower, with the total level of access to electricity as of 2017 being approximately 48% with 32% for rural and 75% urban areas (checkTable.5). The zone, however, aims to boost levels from the current level to 85.5 percent by 2030 [11].

2.3. SADC CO2 Emission

While Africa contributes little to global CO2 emissions overall, with many countries contributing almost zero, South Africa, by comparison, is the fourteenth largest CO2 emitter in the world. Tackling climate issues and related problems in the SADC region is obviously closely linked to tackling South Africa's and SADC's dependency on coal. At the 2016 Conference of the Parties (COP) to the United Nations Framework on Climate Change in Paris, countries committed to reducing emissions by individual pledges in a collective effort to minimize global emission levels. Such obligations are known as nationally specified contributions (NDCs). Although the SADC does not have a detailed shared strategy on how to achieve NDC targets at regional level,

organized discussions on how to define and formulate national targets were conducted in the lead-up to COP 21. And the SADC Regional Infrastructure Growth Master Plan 2012 sets out the target to increase renewable energy share in the grid to 39% by 2030 from the current 29% and reaching an off-grid share of 7.5% by 2030 [11, 20]. Almost 85.7% of the electricity produced in the SADC region comes from coal-fired thermal power plants, posing a high health risk and rising the region's greenhouse gas emissions. Despite contributing fewer greenhouse gas emissions in the region, which was around 2.2 percent of global emissions in 2011, some SADC Member States, such as South Africa, have remained higher greenhouse gas emitters with 13th place in the world ranking. South Africa alone accounted for 48% of the carbon dioxide released in the SADC region in 2016 (see table 2) [11].

2.4. SADC Electricity Generation and Consumption

The only approach to solving existing electricity problems and promoting natural environmental resilience in the area is the transition to renewable energy in the electricity market of regional. In recent research in the field, the viability of renewable energy projects has been increasingly highlighted as a viable alternative. Renewable energy technologies such as biomass, wind, hydro, geothermal, and solar power is therefore rapidly gaining popularity in the SADC region, with total installed capacity reaching 18,069MW as of 2017 (see Figure 3 and Table 3), and capacity

increased further to 21,760MW as of mid-2018 [11, 25]. The SADC region is projected to have an annual combined wind and solar capacity of 800 TWh, 219.5 TWh (solar PV) and 109.3 TWh (concentrated solar power) [21, 26]. However, the estimated electricity generation capacity from renewable energy sources for the period between 2010 and 2030 [26] in the region for consolidated energy systems is 62,781MW and 24,725MW for decentralized off-grid projects. A recent SACREE report published in 2018 showed that for the SADC area [11], wind and solar power could be an environmentally and economically competitive choice in the near future. Table 4 highlights advances in the generation of renewable energy (RE) for the period 2006-2017 in the SADC Member States.

South Africa	234,5	207,1	16,55	10,56	10	1	4	85	0,39	91,26	95,38
Tanzania	6,699	5,682	0,00	0,102	6	40	0	55	0,79	83,55	98,50
Zambia	11,55	11,04	1,176	2,185	2	93	0	5	0,27	88,94	82,60
Zimbabwe	6,800	7,118	1,239	2,220	5	37	0	58	0,76	92,65	71,47

The primary energy generation combination of imports, exports and consumption as of 2016 by the SADC member states is shown in Table 4. It can be seen that South Africa had the highest generation, consumption, imports and exports in a region followed by Mozambique and, least of all, Seychelles, which has zero imports and exports.

3. Energy Sector Sustainability Evaluation of SADC Countries based on 4EAs

3.1. Electricity Acceptability

In terms of social and environmental acceptability, electricity generation technologies cause various and numerous environmental and social impacts such as visual impacts, land use and degradation, fugitive dust, noise, soil and air pollution including greenhouse gas emission which is the most serious threats to both the environment and society arising from present electricity industry. These impacts pose different policy challenges and there is no one straightforward solution. Hence, this dimension reflects environmental and social acceptability of the electricity sector by society and environmental organizations based on national energy mix. According to WEC(2007), the best alternative to attain environmental sustainability and increase social acceptability is by reducing greenhouse gas emission through adopting of low-carbon renewable energy technologies in the national energy mix [16]. Thus, an electricity generation mix with combination of various sources from low-carbon technologies is expected to increase social and environmental acceptability. Therefore, to assess the acceptability of SADC countries' electricity industry the following criteria have been considered; RE share in electricity production (%), emission of CO₂ per capita (t CO₂/capita), country's CO₂ emission and Policies on Renewable energy technologies.

Figure 4: CO2 Emission per capita in SADC Countries [27]

1) CO2 Emission Per Capita

Figure 4 shows the emissions of CO₂ per capita in the SADC countries as of 2015. The results indicate that, except for South Africa, the region's member countries have lower emissions of CO₂ per capita, mainly because of higher dependence on fossil fuels (coal) in the electricity sector. Therefore, South Africa (SA) has the highest per capita emissions (8,98 tonnes of CO₂) in the country, followed by Seychelles (5,42 tonnes of CO₂) with the lowest value of 0,06 tonnes of CO₂ in DRC [27]. This makes SA, as previously mentioned, the largest contributor and emitter of CO₂ emissions in the SADC region. South Africa draws 85% of its energy from fossil fuels at the same time contributes more than

76% to the final electricity generation in the SADC region, hence contributing to nearly half of the region's CO₂ emissions [27].

2) Policies on Renewable energy technologies

As seen in Table 8, it appears that all SADC member states have progressed towards the establishment of RE technology national and regional policies. These policies, however, differ according to the priorities and objectives of the country set in the national energy master plans.

3) Share of RE in Final Electricity Generation Mix

Figure 5 shows the renewable energy (RE) share in the electricity generation in member states of SADC. It can be seen that due to the high use of hydro for electricity generation, DRC shows a highest share of RE of 92.87 percent in the final national general electricity generation mix, with the lowest share of 1.03 percent shown by Seychelles because of its reliance on fossil fuels. In general, the shares of RE in the final energy generation mix have increased in the region and member countries (see table 4).

Figure 5: RE Share in SADC Countries 'Electricity Generation [11]

4) SADC Countries CO2 Emission Per Year

Most SADC member countries have low CO₂ emissions because the overall generation of electricity is highly dependent on renewable energy. Nonetheless, few Member States such as South Africa, Botswana, Seychelles, Mauritius, and Namibia are heavily dependent on fossil fuels with less than 50% share of RE in the final electricity generation mix. Therefore, in terms of the total contribution of CO₂ emissions to the region, South Africa is at the top of the group, followed by Angola, Zimbabwe, Tanzania and Seychelles at the very least (see table 2 above).

3.2. Electricity Accessibility

This dimension underlines society's accessibility to modern energy facilities, both now and in the future, in a sustainable way for everyone. Access to electricity can have multiple social impacts, including enhancing human well-being by meeting the basic needs of human being, such as entertainment, gender equality, food, education, clean water and health [14]. Moreover, accessibility to energy services will also help to reduce the effects on the environment, such as deforestation. Therefore, the idea of efficiency, quality and easy access to energy services to society poses a policy challenge. Societies must clearly have easy accessibility to critical energy resources, but services must be efficient and of high quality. A comparative study is also

conducted in this dimension to determine the accessibility of electricity in the SADC countries, as well as the possible access goals. In this dimension, three parameters are taken into account: electricity intensity (kWh/GDP) and electricity consumption per capita (kWh/capita), existing levels of electrification and potential access targets for connectivity and electricity Disruption Risk Index [28] to assess the efficiency and quality of services.

1) Consumption of Electricity per Capita

Figure 6 shows the energy consumption per capita in member states as of 2017. In general, electricity consumption per capita in most SADC countries is low below the average value of the region (993.84 kWh/capita), with the exception of Seychelles, Mauritius and South Africa, with more than 2000 kWh per capita. Electricity consumption per capita varies significantly, with the smallest being 66.42kWh per capita for Madagascar and the highest of 4234.36kWh per capita for South Africa.

Figure 6: Consumptions of Electricity per Capita

2) Electricity Intensity

Figure 7 shows the energy intensity (kWh per US\$) in member states. With Mauritius, Botswana, Seychelles and Namibia having the lowest because of higher GDP due to lower population with Zimbabwe, Madagascar and DRC having the highest energy

intensity among the member countries. This means that growth in electricity demand is far below economic growth in most member countries. Hence, this shows that there is less modern energy services accessibility including lower penetration and utilization of electrical appliances and equipment in the region and in the member States.

Figure 7: Energy Intensity in SADC Member States in 2017 [11]

3) Electrification Levels and Future Access Targets

Table 5 shows the electricity accessibility in SADC member states and the potential goals for access to electricity as set in the Member States' national energy master plans to be achieved by 2030. As of now, with the exception of a few countries like: Botswana, South Africa, Eswatini, and Namibia that are above 50%, the country and several Member States have lower access levels to electricity. The only two member countries that are now able to have 100% access to electricity are Mauritius and Seychelles. For most member countries, however, urban electrification levels are above 60 percent, with only Malawi having the lowest 42 percent. Nevertheless, with the exception of Mauritius and Seychelles, which have already crossed 100 percent, rural electrification levels are still lower in most member countries. Rural electrification should therefore be listed as a priority area for the SADC region and its member countries in order to achieve this aim.

Table 5: Electrification Rates in SADC Member, 2016 [11]

Member States	Electrification Rates (%)				Energy Access Targets (%)
	Rural	Urban	National	People without Access to Electricity (million)	
Angola	16	69	41	17	100% by 2030
Botswana	37	78	61	1	100% by 2030
DRC	.	78	17	68	60% by 2025
Eswatini	61	83	66	<1	100% by 2030; 75% by 2018; 85% by 2020
Lesotho	16	66	34	1	40% by 2020
Madagascar	17	67	23	19	-
Malawi	4	42	11	16	30% by 2030
Mauritius	100	100	100	-	-
Mozambique	5	65	24	21	100% by 2030; 30% Modern Cooking Fuel by 2030
Namibia	29	77	56	1	50% by 2020; 100% by 2030
Seychelles	100	100	100	-	-
South Africa	68	93	86	8	100% by 2025
Tanzania	17	65	33	36	75% by 2030
Zambia	4	67	31	11	66% by 2030; 90% by 2030
Zimbabwe	16	86	38	11	urban, 51% by 3030 rural
SADC	32	75	48	49	100% by 2030

3.3. Electricity Availability

Electricity reliability and supply continuity are very vital for the social and economic development of every community, society or country. In order to achieve the social and economic well-being of every community and country, electricity plays an important role. However, there are different issues that can cause short-term and long-term unreliability and electricity discontinuity. These vary from nation to nation, but it's very similar and popular in the SADC member states. The causes maybe due to insufficient electricity generating units, insufficient transmission lines to transport electricity generated to demand centers, inadequate demand-compliant generating units, poor maintenance of transmission networks or generating power station, weak electricity systems to withstand disruptions and contingencies. For example, severe weather conditions such as low precipitation (droughts) and potential availability of primary energy sources such as fossil fuels may be other factors [16]. However, it is argued, according to the [16] literature, that a well-diversified energy generation industry comprising of different types of local primary energy sources, including reliable generation technologies, is capable of helping to improve energy security and to reduce the risks that may arise from high and volatile fluctuations in fuel prices.

Therefore, the use of available local resources in the generation of electricity is important. Furthermore, timely and adequate investment in the electricity sector is essential to ensure the reliability and continuity of the supply of electricity [17]. This dimension examines the energy security of the SADC countries with regard to the short and long-term reliability and continuity of the supply of electricity by meeting four of the following availability indicators and criteria: the reserve margin of the supply of electricity, the efficiency of the supply of electricity, the diversification of the supply of electricity, the sufficiency of the self-supply of electricity (SSR).

1) Efficiency of Electricity Supply (ESE) in SADC Countries

The ESE is described as "the ratio of electricity not lost (ENL) to the total supply of electricity (TES)" [28]. This indicator shows the overall output of the country. The estimate was made using Equation 1 (1a to 1d). As given below, the general equation is expressed as.

$$ESE = \left(\frac{ENL}{TES} \right) \quad (1a)$$

In SADC countries that are involved in exporting electricity to other SADC countries within the region.

$$ESE = \left(\frac{EC + EXE}{EP} \right) \quad (1b)$$

On the other hand, for such SADC member countries that export and imports electricity from other SADC countries, the ESE was calculated using equation 1c given below

$$ESE = \left(\frac{EC}{EP + IE} \right) \quad (1c)$$

However, for those countries in SADC region that are not involved in either exports or import of electricity such as Angola, Madagascar, Malawi, Seychelles and Mauritius. The ESE was calculated using the equation 1d.

$$ESE = \left(\frac{EC}{EP} \right) \quad (1d)$$

where, "EC" denotes consumption of electricity, IE-import of electricity, EP-output of electricity, EXE-export of electricity. Figure 8 below shows the output of SADC countries in terms of electricity supply reliability. The results show that among the member countries, the lowest ESE is shown by Tanzania whereas highest ESE is shown by Eswatini. In other words, with the exception of Eswatini, the majority of SADC countries have an ESE of less than 95%. This shows that the general electricity industry faces problems with electricity losses in most of the member countries. This may be due to theft of electricity or losses in the grid due to long grid distances or inadequate maintenance.

Figure 8: ESE in SADC Countries

2) Electricity Supply Diversification of SADC Countries

Using the Shannon Wiener Index given in equation 2 [5,29], the diversification of electricity supply is calculated.

$$SWI = - \frac{\sum_{i=1}^n s_i * \log(s_i)}{\log(n)} \quad (2)$$

In the equation "si" represents the portion of each energy source in the electricity generation mix, "I and n" is the number of main energy sources in the electricity generation mix. When the equal share (1/n) of all energy sources contributes to the final electricity generation mix, the maximum "Ln(n)" occurs. In terms of electricity supply diversification, the higher the value means higher energy resilience and security. Hence, lower risk for the electricity industry (see Fig.9). The findings show that diversification in the SADC countries' electricity industry varies widely, with highest in Eswatini and lowest in Botswana. However, Table 7 below shows that all SADC member states have put in place plans for the diversification of the local mix of electricity production by 2030. Hence, it is expected that the future of SADC electricity industry of the Member States will be more diversified. However, the energy security and accessibility will be strengthened only if all Member States follow and meet their planned targets. Nonetheless, fossil fuels (natural gas and coal) which are readily available locally are expected to continue playing a major role in the region's energy generation mix.

Figure 9: Energy Diversification in SADC Countries, 2016

3) Self-Supply Sufficiency Rate of SADC Countries

For each member state, the Self-Supply Sufficiency Rate (SSR) in the national electricity sector was assessed using equations 3a-d [28] to determine the energy diversification impact on the SADC member countries' electricity sector. This deminsulation tests the capability of the SADC countries' electricity sector to meet the current demand with local generation. Consequently, greater the value or equal to 100% represents that the nation is self-sufficient, while less than 100% means that the country is dependent on the energy it imports. General equation 3a.

$$SSR = \left(1 - \frac{NIE}{TDES} \right) \quad (3a)$$

For nations importing part of their electricity from other SADC members within the region, SSR was estimated using equation 3b.

$$SSR = \left(1 - \frac{NIE}{EP + IE} \right) \quad (3b)$$

In case of nations that are exporting their electricity surplus to other SADC member states, SSR was estimated using equation 3c.

$$SSR = \left(1 - \frac{NIE}{EP - EXE} \right) \quad (3c)$$

The SSR given in equation 3d represents countries that are not interconnected nor export or imports electricity from other SADC countries (Madagascar, Seychelles, and Mauritius).

$$SSR = \left(1 - \frac{NIE}{EP} \right) \quad (3d)$$

Where "NIE" denotes the net electricity imports whereas "TDES" is the total electricity generation. In terms of sustainability, the country with higher SSR value have higher energy security hence lower the risk due to lower dependency on the imports of electricity (see fig.10). The results shows that the majority of the SADC countries are self-sufficient in the electricity supply with only handful of countries facing challenges.

4) RE Share and Reserve Margin in Electricity Supply in SADC Countries

As of mid-2018, Table 6 highlights the share of RE in SADC member countries. In spite of the number of Member States producing electricity from RESs, the majority of electricity production in the region is highly dependent on fossil fuels. However, the region and Member States have increased their RE

share in the overall mix of final electricity generation as of 2018, with South Africa leading the ladder (see table 4). As regards the reserve margin, it can be seen that, as of 2016, seven of the member countries had an energy deficit. Except for South Africa, which had more than 10.0GW, the other member countries had negligible reserve margins. These negligible reserve margins are mainly due to the region's rapid electricity demand, but also due to underinvestment in the electricity industry in many SADC nations.

Figure 10: SSR for SADC Countries

Table 6: Share of Energy Sources in Total Final Energy Generation (TFEG)in SADC Countries, 2016[18,20]

Member States	Share of Energy Sources in TFEG (%)			
	Other RES	Hydro	Nuclear	Fossil
Angola	2	64	0	34
Botswana	0	0	0	100
DRC	0	98	0	2
Eswatini	41	20	0	39
Lesotho	1	99	0	0
Madagascar	2	24	0	74
Malawi	6	93	0	1
Mauritius	14	7	0	79
Mozambique	1	83	0	16
Namibia	8	64	0	28
Seychelles	9	0	0	91
South Africa	10	1	4	85
Tanzania	6	40	0	55
Zambia	2	93	0	5
Zimbabwe	5	37	0	58
SADC	7,0	48,2	0,3	44,5

5) RE Share Targets and Interconnection in SADC Countries by 2030

In order to promote in the regional and national electricity supply in the sustainable manner and promote the use of and increase access to clean modern energy services for the greater benefit of all people in the region and member states. The region and SADC states have set up targets plans to be achieved by 2030 for the renewable energy share in the electricity generation as illustrated in Table 7. In addition, to increase regional and national energy security and reliability in electricity sector almost all mainland member countries are interconnected and are involved in international electricity trade except for Malawi and Tanzania which are expected to be interconnected with other members by 2030. However, Madagascar, Mauritius and Seychelles due to their geographical location will always remain not connected to the region electricity grid. Furthermore, in terms of grid losses as shown in table 7, it indicates that Lesotho followed by Angola have higher losses in the SADC region with South Africa having the lowest among the member states. Hence, it can be concluded that the South African power grid has higher efficiency in the region.

Table 7: Regional and National Targets in SADC Member States by 2030 [11]

Member States	Renewable Energy Targets	Transmission and Distribution Losses (%)	Interconnections with other countries
Angola	Increase in RE capacity by 2025 as follows: <ul style="list-style-type: none"> Small Hydro:100MW with 60MW for municipalities Solar:100MW with 10MW off-grid Wind:100MW Biomass:500MW 	10	✓
Botswana	100% access to modern energy services by 2030 Capacity increase expected from REFIT programme 15% RE share in final energy consumption by 2025 but may increase to 20%	3,7	✓
DRC	60% overall energy access by 2025	9	✓
Eswatini	50% RE share in Electricity Consumption by 2030 60MW intermittent resource by 2030 e.g solar	6	✓
Lesotho	Targets pnding completion of Sustainable Energy Strategy 2018	11	✓
Madagascar	85% RE Share in final energy by 2030	-	❖
Malawi	By 2025/2030 307% access to electricity 100% use of efficient cook stoves in off grid households 6% RE share in energy mix Biofuels mandate of 20% ethanol and 30% biodiesel	6	▪
Mauritius	35% RE Share in electricity generation by 2025: Bagasse:17%, Wind:8%, Waste to enrgy:4%, Hydro:2%, Solar:2%, Geothermal: 2%	6	❖
Mozambique	400MW increase in installed RE capacity by 2024 Wind:150MW Hydro:100MW large\scale & 100MW small scale	6,4	✓
Namibia	70% RE share in electricity generation by 2030	3,2	
Seychelles	5% RE share in electricity generation by 2020 & 20% by 2030	-	❖
South Africa	21% RE Share in electricity generation by 2030 17.6GW solar capacity by 2050 37.4GW wind capacity by 2050	0,1	✓
Tanzania	5% RE share in electricity generation by 2030	6,0	▪
Zambia	200MW increase in RE capacity by 2020	6,2	✓
Zimbabwe	16-5% RE Share increase in overall 1100MW increase in RE capacity by 2025 2100MW increase by 2030 2400GWh increase in RE generation by 2025 4600GWh increase in RE generation by 2030 (26.5%overall increase)	4	✓
SADC	71% by 2025, 85,5% by 2030 Regional Electricity Access targets 39% Regional Renewable Energy Mix target in the grid 7,5% Off-Grid share of RE as per total grid electricity capacity 15% Energy efficiency % savings achieved from grid consumption	5.97	✓

3.4. Electricity Affordability

According to literature [13], for electricity to be considered as being affordable the following conditions have to be fulfilled:

- The electricity tariffs should be low as compared to household income, that is, the household should be able to afford their electricity bills.
- The electricity tariffs should be low as compared to other alternative prices of competitor, that is, the price of electricity should be lower than other option such as wood fuel, traditional fuels, fossil fuels etc.
- The electricity tariffs should be low enough to ensure the energy import bill is small compared to export earnings [13],
- The electricity tariff should be high enough to ensure sufficient benefit and profitability for independent Power Producers and Utility Companies i.e., the tariff should be able to reflect the real value of the electricity supply. In short, the electricity price should take care of all the value chain cost of electricity

supply (Production, Transmission/Distribution and other cost of the industry) [16].

This dimension investigates the electricity affordability of SADC countries using the following affordability indicators and criteria; Electricity Prices, GDP per Capita and Cost of Electricity Supply (i.e. the amount spent on electricity as compared to national GDP).

1) Electricity Tariffs

Figure 11 highlights the average tariffs for electricity as of 2018 in the SADC countries. The lower the price of electricity in terms of affordability, means the higher the government subsidies practiced, hence, a huge burden on expenditure of government. This suggests that the supply of energy is heavily subsidized and does not reflect the actual electricity cost. The results shows that the majority of SADC member countries have electricity tariff rates of less than US\$c10/kWh. However, Namibia among member states has the highest electricity tariff. These lower tariffs

suggest that majority of SADC countries' energy is heavily government-subsidized, hence does not attract the private investors, which is the biggest obstacles to the sustainable growth of the electricity industry in the region. Nonetheless, with expectation to meet the cost-reflective rates in SADC member countries, it is expected that the sector will draw a lot of private investment by 2030.

Figure 11: Electricity Tariffs in SADC Member, 2018 [24]

2) GDP per Capita

The per capita GDP reflects the citizen's purchasing power, thus nations with higher per capita GDP mean that people have more buying power and vice versa. The scenario represents electricity investment in terms household electricity affordability. Figure 12 shows that most SADC states face problems because the population has less purchasing power, so government subsidies are required to make electricity affordable.

Figure 12: GDP per Capita in SADC Countries, 2016

3) Real Cost of Electricity Supply (RCES)

RCES is defined as “the ratio of the proportion of real GDP not dedicated to cover the net electricity supply expenditures (NESE) to real GDP (RGDP) or it is one minus the share of GDP dedicated to cover the cost of the electricity supply (ES)” [28]. The criteria measures the ability of the SADC countries to reduce the RCES and the vulnerability of member states to high RCES. The higher the RCES shows the country's ability to reduce its RCES whereas low values shows exposure of the country to high RCES. RCES is estimated using equation 4 given below.

$$RCES = \left(1 - \frac{ES}{RGDP}\right) = \left(\frac{NESE}{RGDP}\right) \quad (4)$$

Where ES is estimated by firstly converting the total electricity supply into barrel of oil equivalent (bbl) and multiplying it with the annual real average crude oil price (COP) given in US\$ per bbl. Figure 13 below indicates the RCES for SADC member states as of 2019 at COP of US\$59.06 per barrel (1kWh=0,006Barrels of Oil Equivalent) [30]. Apart from South Africa, it can be seen that the SADC member countries have RCES above 80%. As earlier mentioned this shows that the member countries have the ability to reduce their RCES. In short this indicates that the majority of SADC countries spend less on electricity from their GDP.

Figure 13: Real Cost of Electricity Supply of SADC Countries

4. RE Support Policies for improving the Sustainability of Energy in the SADC Countries

To ensure private sector participation in electricity Ensuring the participation of the private sector in the electricity industry and the successful development and dissemination of programs for renewable energy technologies (RETs) in the SADC region, as well as encouraging investment in RETs. A number of additional incentives and RE support policies have been/have been established by the SADC member countries, including (see table 8)[11,31,32]:

- Renewable Energy Targets
- Renewable Energy in NDC or INDC
- Regulatory Policies
 - Feed-in-Tariff/ Premium Payment
 - Electric Utility Quota Obligation
 - Net Metering
 - Grid Code Revisions
 - Tradable Renewable Energy Credit
 - Renewable Energy Project Tendering
 - Capital Subsidy' Grant or Rebate
- Fiscal Incentives & Public Financing
 - Investment /Production Tax Credits
 - Reductions in Sales, Energy' CO2, VAT or other taxes
 - Energy Production Payment
 - Public Investment Loans or Grants

As illustrated in Table 8, all SADC member countries have progressed to establishing policies on RE technologies. However, these policies vary according to the country targets and goals set in the national master plans.

Table 8: RE Support Policies in SADC Member States as of Mid-2018 [9,31]

Member States	RE Targets	RE in NDC or INDC	Regulatory Policies								Fiscal Incentives & Public Financing			
			FiT/Premium Payment	Electric Utility Quota Obligation	Net Metering	Biofuels Obligation/Mandates	Grid Code Revisions	Tradable RE Credit	Tendering	Capital Subsidy* Grant or Rebate	Investment /Production Tax Credits	Reductions in Sales, Energy* CO2,VAT or other taxes	Energy Production Payment	Public Investment Loans or Grants

5. Key Findings and Conclusion

A total of 15 SADC Member States are analyzed in this paper, with a focus on the ability to provide reliable, effective and environmentally friendly energy systems. The analysis was carried out on the basis of performance measures of the electricity sector and factors such as availability, supply and demand for electricity, access to electricity and the environmental social effects of the use and development of electricity in the Member States. The research outcomes;

The economy of the SADC region is highly dependent on commodities. The world market saw a decline in oil prices over time and this culminated in a dramatic decrease in the SADC countries' economy. SADC Member States are currently facing a challenge with regard to electricity access levels, especially in rural areas, with only Mauritius and Seychelles achieving 100% access to electricity in both rural and urban areas. The region's population is around 341 million people, but just 48 percent of the total households have access to electricity. Studies by SACREE (2018) show that the majority of people live in rural areas and only 32% of the total population in rural areas has access to modern energy facilities, with electricity being available to only 75% of the total urban population.

- Low-carbon renewable energy technologies (RETs) are expected to contribute significantly to future electricity as all SADC member countries set goals are met by 2030, and the SADC region will be greener and cleaner relative to current trends.

SADC member countries have adopted subsidies as a affordability and accelerate access to electricity. Subsidies are proving to burden the national budget. In the case of Zambia, the country experienced enormous costs between the years 2014-2017 due to the electricity deficit resulting from electricity imports priced in neighboring countries at a cost-reflective tariff. This increased expenditure for the utility company (ZESCO) and the government.

- SADC Member States will benefit greatly from the diversification of RET and energy conservation policies as set out in the regional objectives. Adherence to the vast potential of RE sources in the area will negatively increase the degree of access to electricity in the region. In addition, the use of RE in the regional and national mix of electricity generation would lead to better health services and better living conditions for the population in both urban and rural areas, which will be significantly enhanced, resulting in safe and clean cities and communities.

It is therefore argued that policies addressing basic human needs, such as increased access to electricity and improved national or regional energy protection, are required in developing countries, and environmental and social acceptability should be taken into account. The cost of electricity is ideally representative of the cost and also represents the true cost of electricity services.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

In this paper, a novel is proposed for real-time tracking human targets in cases of high influence from complexity environment with a normal camera. Firstly, based on Oriented FAST and Rotated BRIEF features, the Lucas-Kanade Optical Flow algorithm is used to track reliable keypoints. This method represents a valuable performance to decline the effect of the illumination or displacement of human targets. Secondly, the area of the human target in the frame is determined more precise by using the Camshift algorithm. Compared to the existing approaches, the proposed method has some merits to some extents including rapid calculations in implementation, high accuracy in case of similar objects detection, the ability to deploy easily on mobile devices. Finally, the effectiveness of the proposed tracking algorithm is demonstrated via experimental results.

1. Introduction

These days, with the continuous development of high precision, cost-effective computer imaging hardware equipment and corresponding auxiliary detection algorithm, real-time target human tracking technology [1]-[8] has become a research hotspot in various fields such as interactive video games, military, robotic, etc. Human tracking is the process of locating moving targets by performing tracking algorithms and analyzing that trajectory in many applications over sequential video frames [9]-[12]. The models of the target could be a single human or multiple humans based on different applications. However, human tracking is a difficult task with many challenges such as the system needs to be fast enough to carry out real-time applications or operate in different environments with high accuracy. The impact of external factors affects the accuracy of the algorithm such as moving obstacles, illuminations, or similar targets, etc. Hence, researches of higher accuracy and better computer vision detection algorithm are still developed.

With the development of technology, various methodologies have been proposed to solve real-time human tracking. In the literature review, the Kalman Filter algorithm [13] could only be used in a linear system in case of mimic real scenarios. In [14] - [16], Laser Range Finder to track human is proposed to determine the human's leg and analyze the human tracking motion. However, the measurement of this method is limited in case of long distance between human's leg and sensor. The multi-camera systems [17] -

[21] are also designed to track human, but those approaches only process in a small area which installs cameras. The hand-held cameras system is equipped for the sports player in [22] to synthesize a stroboscopic image of a moving target. Nevertheless, its computational speed and accuracy could not be optimal in case of the elaborate environments. In [23]-[25], Particle filter-based vehicle tracking via HOG features is very robust when fast-moving human target but this algorithm is hard to integrate with a mobile system. In [26] and [27], the Camshift algorithm is well-known as popular tracking human method. The advantages of this methodology are low-cost computation, easy to manipulate, etc. The Camshift algorithm follows the track of the targets based on histogram back projection. The stability of this method is impacted by color, illumination, and noise. Hence, this method suffers from series of errors in case of similar color background.

In light of the remarkable importance and advantages previously mentioned, a real-time tracking human system is proposed for normal cameras under the circumstances of high influence from complicated environments. Lucas-Kanade Optical Flow Algorithm is a well-known method for tracking humans for a decade [28]-[30]. The method is designed based on the combination between Camshift algorithm and Lucas-Kanade Optical Flow Algorithm (LK-OFA) [31], [32] with Oriented FAST and Rotated BRIEF features [33]. Compared to the existing works, the proposed approach has several contributions as follows:

(1) The reliable keypoints which are less affected by illumination or displacement of the human targets are tracked based on the LK-OFA features. It is noted that optical flow algorithm is very good at tracking points in the next frame from

www.astesj.com

<https://dx.doi.org/10.25046/aj0602103>

the locations of them in the previous frame. The Camshift algorithm is carried out to determine the area of the human target with similar appearances in the frames more precisely.

(2) Since the proposed method reduces number of loops that need to converge the center of the search window and centroid of human target, it is easy to implement on mobile devices.

(3) The designed system generates a small amount of data to be processed; therefore, this could be simply done in real-time, and a powerful computer is not required.

The rest of the paper is organized as follows. The next section analyses the detailed structure of the proposed approach. Section 3 summarizes the experiment platform and its result, followed by the brief conclusions and the outlook in section 4.

2. Proposed Methodology

In this section, a short overview of the human tracking algorithm is illustrated in the flowchart as Fig.1. To begin with, for

choosing the tracking target person, a region of interest (ROI) is created manually. After that, HSV histogram of ROI is computed to prepare for CAMSHIFT later. At the following stage, the system finds ORB features in both ROI and initial frame. In the subsequent step, 50 best keypoints are chosen from best matched features based on Bruce-Force matcher. Those keypoints are traced by using Optical flow with Lucas-Kanade algorithm. At the next stage, the failed tracked points are totally removed by utilizing sum square of difference (SSD) and Backward tracking method. If the number of the keypoints is smaller than three, the process comes back to the finding ORB features step. In contrast, the process continues with good keypoints left, the center of them is determined using first and zeros moment. This center is used to create the initial search window of Camshift. By applying Camshift algorithm, the area of the human target can be found. Finally, the accuracy of tracking human's center is improved by Kalman filter.

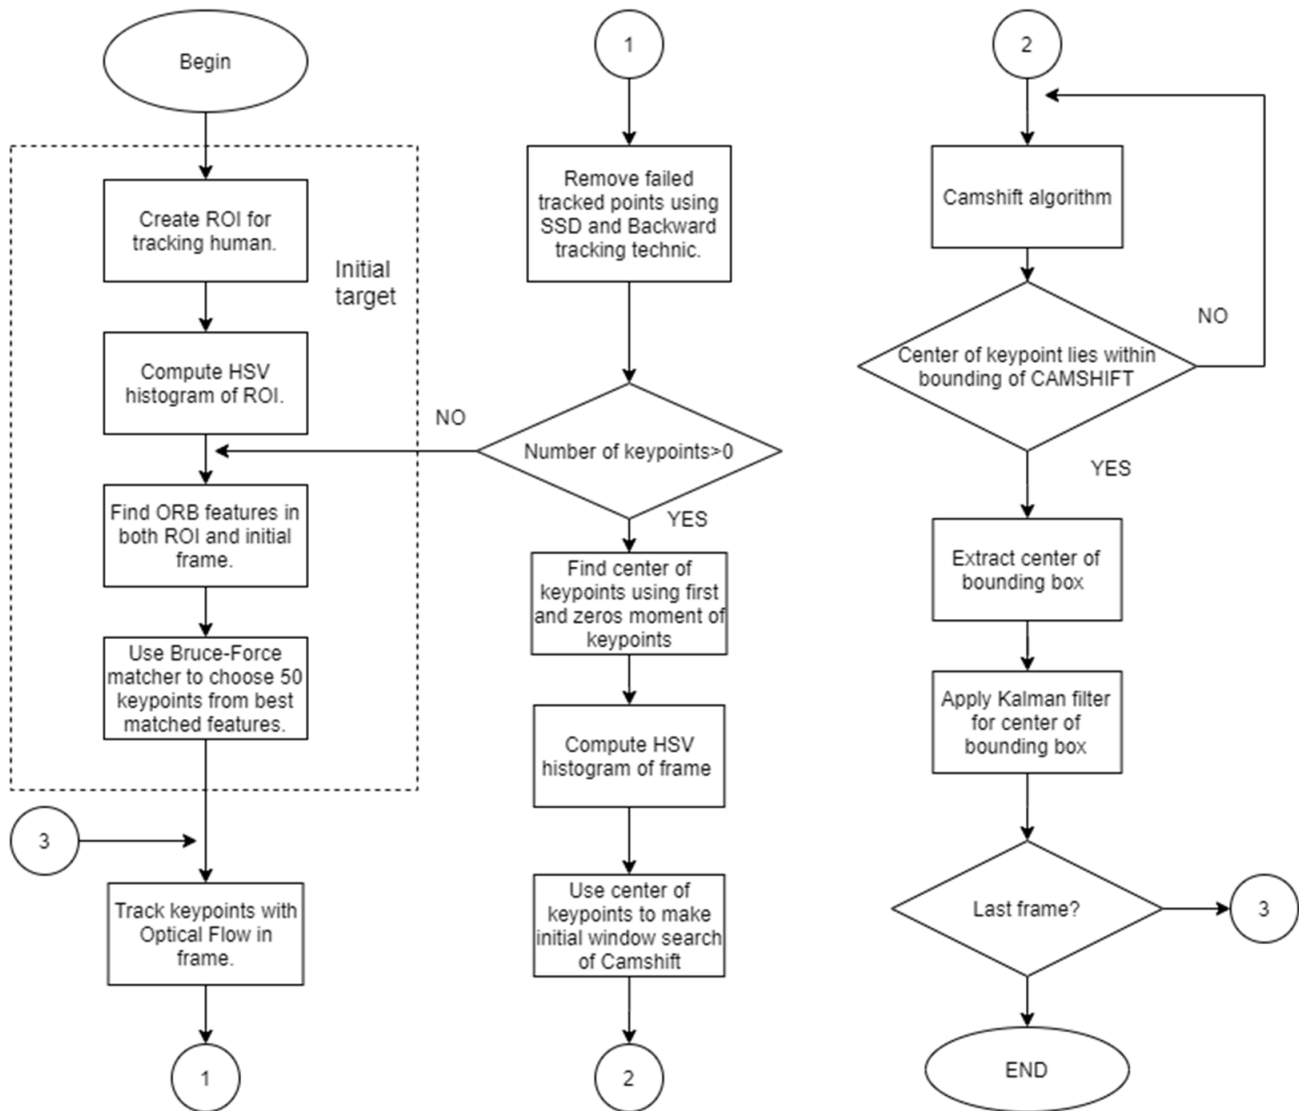

Figure 1: Flow diagram of system

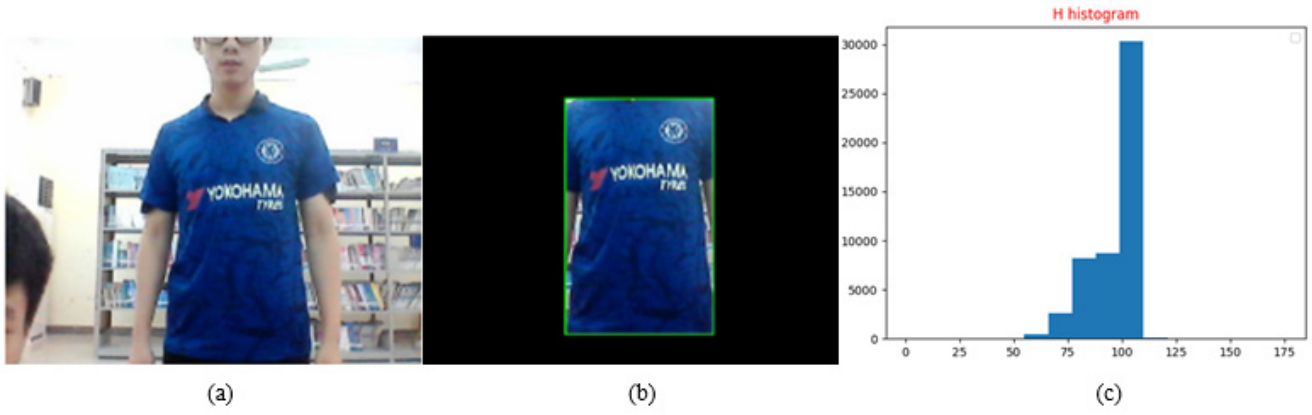

Figure 2: Create ROI and calculate H histogram of ROI

2.1. Create ROI and compute H histogram

Before tracking human, an area (ROI) on the target person is established (Figure 2 (b)). This ROI is used as a template of the target. Then, the HSV histogram of ROI is computed, but only the H channel is used with 16 bins to get the best result (Figure 2 (c)).

2.2. ORB feature and matching

For the purpose of tracking and creating the initial window for Camshift, this paper selected ORB feature detector (Oriented FAST and Rotated BRIEF) to find the best points. ORB algorithm modifies both FAST [34] keypoint detector and BRIEF [35] descriptor to reach the best result. ORB algorithm detects FAST points in the image, then applies Harris corner measure to discover top N points among them. After that, the algorithm searches for the intensity weighted centroid of the patch with the located corner at the center in order to calculate the orientation of points. The orientation value is computed by using direction of the vector from this corner point to centroid. After finishing the implementation of FAST, ORB algorithm modifies BRIEF descriptors or rBRIEF to create a descriptor for each keypoint.

Figure 3: Matching keypoints between ROI and initial Frame

In our system, ORB algorithm is implemented by extracting keypoints from both ROI and frame. The keypoints are searched in Gray image extracting from the original image and the archetype of ROI. Bruce-Force matcher is used to calculate the distance value between each pair of keypoints in both Gray images. By sorted pair of keypoints based on distance value, some keypoints best matched will be kept to use later as shown in Figure 3. To be more specific, the algorithm could operate with higher accuracy in case of more keypoints selection. However, if the number of keypoints incline too big, the calculation process would be taken

long time to finish, especially, in case of mobile robots. In this paper, based on trial and errors method, having 50 keypoints enabled us to ensure the balance between the calculation time and the accuracy of our algorithm effectively.

2.3. Track keypoints and remove failure points

The positions of the previous keypoints are tracked by using Optical Flow with Lucas-Kanade Method. Here, a 3x3 patch around the points with an assumption that all the neighboring pixels have similar motion is applied to estimate the new locations of keypoints in the frame based on their previous positions by using equation (1).

$$\begin{bmatrix} u \\ v \end{bmatrix} = \begin{bmatrix} \sum_i f_{x_i}^2 & \sum_i f_{y_i} \sum_i f_{x_i} \\ \sum_i f_{x_i} \sum_i f_{y_i} & \sum_i f_{y_i}^2 \end{bmatrix}^{-1} \begin{bmatrix} \sum_i f_{x_i} \cdot f_{t_i} \\ \sum_i f_{y_i} \cdot f_{t_i} \end{bmatrix} \quad (1)$$

where $u = \frac{dx}{dt}$, $v = \frac{dy}{dt}$ and f_x, f_y are gradient of keypoints and surrounding points along x, y axis.

After updating, some of those keypoints in the frame might be failed. In order to remove these failure points, this article combines two methods at the same time: SSD and the Backward tracking technic. Firstly, the SSD in RGB color-space for consecutive frames is expressed as:

$$SSD_R = \sum_{m,n} \left(\begin{matrix} R_{t-1}(k_x^{t-1} + m, k_y^{t-1} + n) \\ -R_t(k_x^t + m, k_y^t + n) \end{matrix} \right)^2 \quad (2)$$

$$SSD_G = \sum_{m,n} \left(\begin{matrix} G_{t-1}(k_x^{t-1} + m, k_y^{t-1} + n) \\ -G_t(k_x^t + m, k_y^t + n) \end{matrix} \right)^2 \quad (3)$$

$$SSD_B = \sum_{m,n} \left(\begin{matrix} B_{t-1}(k_x^{t-1} + m, k_y^{t-1} + n) \\ -B_t(k_x^t + m, k_y^t + n) \end{matrix} \right)^2 \quad (4)$$

where k^t is the position of keypoint, m and n are width and height of the compared window. The idea of SSD is to compute the total error between a patch around keypoint in the current frame

with the location of them in the previous frame. Figure 4 and Figure 5 illustrate errors between the location of keypoints in consecutive frames corresponding to two cases: small error and big error. After reckoning the SSD values in three channels, the total error is expressed as follows:

$$Error = \alpha SSD_R + \beta SSD_G + \gamma SSD_B \quad (5)$$

where α , β , γ are three positive coefficients and the sum of α , β , γ is equal to one:

$$\alpha, \beta, \gamma > 0, \alpha + \beta + \gamma = 1 \quad (6)$$

In this paper, the coefficients are chosen as follows: $\alpha = 0.3, \beta = 0.4, \gamma = 0.3$. The error value of all keypoints are illustrated in Figure 6.

Figure 4: Small error between the location of key points in consecutive frames

Figure 5: Big error between the location of key points in consecutive frames

Figure 6: Error value of all key points

After applying SSD for the first filter, the Backward tracking technic examines all keypoints again and removes the failed points. As shown in Figure 7, the keypoints in the current frame are tracked back to the previous frame by applying Optical Flow.

Let denote r^{t-1} is the estimated position of k^t in the previous frame. The distance d between r^{t-1} and k^{t-1} is calculated by using

the Euclid distance method. All keypoints whose distance value is smaller than a threshold hold are kept.

$$d = \sqrt{(k_x^{t-1} - r_x^{t-1})^2 + (k_y^{t-1} - r_y^{t-1})^2} \quad (7)$$

By utilizing two mentioned method above, all failed keypoints are removed. If all keypoints are failed, our method has a viable improvement on current methods. To be more detailed, in this case, a new set of keypoints would be created inside Camshift bounding box of the target.

2.4. Initial search Window for Camshift algorithm

By applying first and zeros moment for all remain keypoints, the mean position of them is indicated as:

$$M_{00} = \sum_x \sum_y I(x, y) \quad (8)$$

$$M_{10} = \sum_x \sum_y xI(x, y) \quad (9)$$

$$M_{01} = \sum_x \sum_y yI(x, y) \quad (10)$$

$$X_c = \frac{M_{10}}{M_{00}}, Y_c = \frac{M_{01}}{M_{00}} \quad (11)$$

with I is the intensity of keypoints. Since we project all keypoints into a bitmask, so $I = 1$. Location of initial search window Camshift is created from the center points.

Figure 7: Backward tracking technic

2.5. Human tracking with Camshift

Camshift algorithm is an effective method to find color feature of target in frame. The principle of Camshift algorithm bases on Meanshift algorithm. However, it was modified to update the size of the tracking window in the next frame and find the orientation of the target. For more specific, Camshift computes H histogram of both ROI and Frame, and then exchanges pixel' value in the frame with the probability value of its color appearance. Then, it creates the color probability distribution image that performs the probability of appearance of each pixel within the range. Camshift algorithm uses a search window and loops it until the center of the search window converges with the centroid of points having high probability. By using an initial search window created with tracking keypoints, it reduces the number of iterations to find the area of the target. The size of tracking window is updated by zeros moment as follows:

$$S = 2 \times \sqrt{\frac{M_{00}}{256}} \quad (12)$$

Then, the orientation of the target is obtained by using the second central moments:

$$\theta = \frac{1}{2} \arctan \left(\frac{2 \left(\frac{M_{11}}{M_{00}} \right) - X_c Y_c}{\left(\frac{M_{20}}{M_{00}} - X_c^2 \right) - \left(\frac{M_{02}}{M_{00}} - Y_c^2 \right)} \right) \quad (13)$$

The aspect ratio is expressed as:

$$Ratio = \frac{M_{20}}{X_c^2} \frac{Y_c^2}{M_{02}} \quad (14)$$

The width and the height of the window in the frame are estimated as follows:

$$w = 2.M_{00}.Ratio \quad (15)$$

$$h = 2.M_{00}.Ratio \quad (16)$$

2.6. Kalman filter for the position of the human target

The center of human target finding by Camshift algorithm has some vibration and needs to be removed to improve the smoothness of the human tracking process. Kalman filter is used in this paper to solve the vibration of center position. Kalman filter method estimates the location of the center based on value prediction and the new location of the center. It contains two main stages: prediction and correction.

Let denote $X_t = [x_t, y_t, v_{xt}, v_{yt}]$ as a state variable and $Z_t = [x, y]^T$ as measurement variable. Here, x_t, y_t are the positions of the center along x -axis and y -axis in the image. v_{xt} and v_{yt} are displaced in the direction of the horizontal position and vertical position. The equations of the motions on the x -axis and y -axis without the acceleration are calculated as follows:

$$\hat{x}_t = x_{t-1} + v_{xt} \cdot \Delta t \quad (17)$$

$$\hat{y}_t = y_{t-1} + v_{yt} \cdot \Delta t \quad (18)$$

The following equation is inferred.

$$\hat{X}_t = F.X_{t-1} \quad (19)$$

With \hat{X}_t is the value prediction of X_t , F is translation matrix.

The predictor covariance equation is expressed as follows:

$$\hat{P}_t = F.P_{t-1}.F^T + Q \quad (20)$$

In the equation, \hat{P}_t is the value prediction of covariance \hat{P}_t , Q is the interference factor.

In correction step, there are three equations named as: the Kalman gain equation, the State update equation, and the Covariance update equation:

$$K_t = \hat{P}_t.H^T.(H.\hat{P}_t.H^T + R)^{-1} \quad (21)$$

$$X_t = \hat{X}_t + K_t.(Z_t - H\hat{X}_t) \quad (22)$$

$$P_t = \hat{P}_t + K_t.H.\hat{P}_t \quad (23)$$

In these above equations, R is measurement noise covariance matrix, H is measurement matrix. The value of R, H, F and Q is implemented as follows:

$$F = \begin{bmatrix} 1 & 0 & \Delta t & 0 \\ 0 & 1 & 0 & \Delta t \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, Q = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix},$$

$$H = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix}, R = \begin{bmatrix} 2 & 0 \\ 0 & 2 \end{bmatrix}.$$

2.7. Summary methodology

Our algorithm is carried out with the following step:

Step 1: Create ROI for human target and analysis the HSV Histogram of ROI.

Step 2: Compute ORB features in ROI.

Step 3: Compute ORB features in the first frame and match them with ORB features in ROI using BruceForce matching. Take 50 best matching points to track later.

Step 4: Tracking those keypoints in the previous step by using the Lucas-Kanade Optical Flow algorithm.

Step 5: Remove failed keypoints by using SSD and Backward tracking technic.

Step 6: Find the center k of remain keypoints in the frame with zeros and the first moment.

Step 7: Use the center k to create the initial window for Camshift algorithm.

Step 8: Find the bounding box and update centroid of the tracking human by applying Camshift algorithm.

Step 9: Use the Kalman filter to improve the smoothness of the human tracking process.

3. Experiment results

During the experimental process, the configuration of the computer is as follows: 4 GB ram, Intel(R) Celeron (R) CPU N3350 @ 1.1 GHz, webcam with 0.3 Mpx (480x640) and 2 Mpx Webcam. The algorithm is carried out in Python with the support of OpenCV library and Numpy Library.

For the purpose of showing the development in performance, this paper offers comparisons between the proposed method and the original Camshift [36]. The comparisons are checked in different scenes as shown in Figure 8 and Figure 9. To be more specific, the blue bounding box is created by using Camshift and the green one is created by using the proposed method.

Table 1: Average Frame per second value

Criteria	Laptop webcam (0.3Mpx)	Webcam (2Mpx)
Set FPS	30	30
Real FPS	20-25	14-17
Processing time (s)	0.04-0.05	0.06-0.07

Table 2: Experiment results

Environmental conditions	Cases	Number of tests frames	Results of Original Camshift		Results of the proposed method	
			Number of false frames	Accuracy (%)	Number of false frames	Accuracy (%)
Good lighting room condition (500 lux)	One person	323	8	97.5	5	98.45
	Group of people wearing the same shirts	412	298	27.66	15	96.35
	Group of people wearing the different shirts	452	15	96.68	12	97.34
Poor lighting room condition (250 lux)	One person	255	24	90.58	22	91.37
	Group of people wearing the same shirts	542	420	22.5	49	90.95
	Group of people wearing the different shirts	526	47	91.06	38	92.77
Outdoor Condition (700 lux)	One person	552	53	90.39	45	91.84
	Group of people wearing the same shirts	587	401	31.68	55	90.06
	Group of people wearing the different shirts	479	48	89.97	44	90.81

Firstly, in the case of different color shirts as shown in Figure 8, it could be seen that there are almost none of the differences between two approaches. In the second case, we evaluate the performance of the proposed algorithm with undesired humans having the same shirt in random backgrounds. From Figure 9, it is noticeable that the original Camshift recognizes and tracks the wrong target. In contrast, the analyzing and human tracking of the proposed method is very clear and precise.

Table 1 provides the data about the Average Frame per second value of the proposed algorithm on both 0.3 Mpx webcam and 2 Mpx Webcam. On average, it could be seen that the system is fast enough to be utilized in real-time with FPS value of up to 25. Meanwhile, the effect of Kalman filter is evaluated over 400 frames and the results are shown in Figure 10. Furthermore, the proposed method indicates a significant decline in the chattering of the bounding box centre especially in x-axis when human target moves.

Figure 8: Tracking human in case of different color shirts

Table 2 compares the experimental results between the Original Camshift and the proposed approach among different

types of the environmental conditions. In each scene, we test 60 times for 3 cases: One person, Group of people wearing the same shirts, Group of people wearing the different shirts. Out of three environmental conditions, it is clear that the false frames in poor lighting room condition of the Original Camshift is the highest, at about 420. By contrast, the figure for the proposed method is only 49. Over different cases, the precision rate of the proposed method is quite higher compared to the Original Camshift. For instance, the accuracy of Original Camshift in good lighting room condition is just over 27.66%, while the proportion of the proposed method is nearly 96.35%. In addition, for tracking human wearing the same shirts, the tracking rates of the Original Camshift are noticeably low, at about 27% in average. On the other hand, the percentages of the developed method always maintain over 90%. Furthermore, the results illustrate that the proposed system could work effectively even in the indoor environments or the outdoor environments with the accuracy up to 98%.

4. Conclusions

In this article, the new method of human tracking is analyzed in depth. The proposed method is developed based on Camshift algorithm and the Lucas-Kanade Optical Flow Algorithm with Oriented FAST and Rotated BRIEF features. The experiment results indicate that the proposed system could be well-adjusted in real-time applications. By comparing with the existing human tracking algorithms, it could be noted that the proposed algorithm reaches to the higher accuracy. Furthermore, its computing time is relatively faster. Hence, the adaptability of the proposed method is better in practical applications. In conclusion, the present results provide practical reference values about human tracking algorithm for the development of equipment with high anti-interference performance, the design of test plans, and the establishment of international standards in the future.

Pick and Place

ABSTRACT

Programming industrial robots in a real-life environment is a significant task necessary to be dealt with in modern facilities. The "pick up and place" task is undeniably one of the regular robot programming problems which needs to be solved. At the beginning of the "pick and place" task, the position determination and exact detection of the objects for picking must be performed. In this paper, an advanced approach to the detection and positioning of various objects is introduced. The approach is based on two consecutive steps. Firstly, the captured scene, containing attentive objects, is transformed using a segmentation neural network. The output of the segmentation process is a schematic image in which the types and positions of objects are represented by gradient circles of various colors. Secondly, these particular circle positions are determined by finding the local maxima in the schematic image. The proposed approach is tested on a complex detection and positioning problem by evaluation of total accuracy.

1. Introduction

Automated systems have been developing rapidly for decades and they have increasingly helped to improve the reliability and productivity in all domains of industry. Machine vision, which is the family of methods used to provide imaging-based and image-processing-based inspections and analyses, is an indispensable element of automation. The implementations of machine vision approaches can be found in process control [1], automatic quality control [2], and especially in industrial robot programming and guidance [3].

Considering robot programming and guidance in an industrial environment, more and more intelligent machines are being utilized to deal with various applications. These days, a static and unchanging production environment is often being replaced by dynamically adapting production plans and conditions. Therefore, the assembly lines are managed on a daily basis and consequently, the automated systems and industrial robots need to be capable of dealing with more generalized tasks (general-purpose robotics). Although most robotic applications are still developed analytically or based on expert knowledge of the application approach [4], some industrial robotics producers have begun to implement deep

learning methods in their applications like Keyence and their IV2 Vision Sensor. It is beginning to be generally recognized, that deep learning methods can play a significant role especially in the mentioned general-purpose robotics [5].

Deep learning consists of a family of modified machine learning methods aiming to solve the tasks that come naturally to human beings. Deep learning methods are performed directly on the available task-specific data in order to get a heuristic relation between the input data and the expected output. Various deep learning approaches have already been applied successfully to deal with various classification and detection tasks [6, 7] and are also utilized in other domains.

In general-purpose robotics, the "pick and place" task is the key problem to deal with. Generally, a "pick and place" task consists of a robotic manipulator (or group of manipulators) able to pick a particular object of attention and place it in a specific location with defined orientation.

In this contribution, the initial part of the "pick and place" issue is examined. To be more specific, the grasp point or grasping pose, which defines how a robotic arm end-effector should be set in order to efficiently pick up the object, is dealt with. Clearly, there is a broad group of grasp point detection techniques which can be listed either according to the type of perception sensor, or by a

* Corresponding Author: Dominik Štursa, nám. Čs. Legií 565, 530 02 Pardubice, Czech Republic, +420466037124, dominik.stursa@upce.cz

procedure used for object and grasp point detection and positioning. The most current methods are clearly described in survey [8]. Deep learning approaches for the detection of robotic grasping poses are summarized in review [4]. In this contribution, we propose a rapid, efficient, and accurate system for finding multiple object centers for flat and moving surfaces.

The key contribution of this article is:

- Proposal of an efficient grasp point detection method for a robotic arm capable of handling more types of objects. This method uses a classical industrial camera as the input data source.
- As an important part of the method, proposal of a deep learning-based approach to transform an RGB image of the scene of interest into a schematic grayscale frame. In this frame, the types of objects and the feasible positions of the grasp points are coded into gradient shapes of various colors. To the authors' knowledge, this is the first application of this approach to the grasp point detection.
- The proposed grasp point detection method is insensitive to changing light conditions and highly variable surroundings. In addition, it is efficient enough to be used in real time with specific edge computing tools, such as NVIDIA Jetson Nano, Google Coral or Intel Movidius.

The structure of the article is as follows. The aim of the work is formulated, and the goals are defined in the next section. Then, the solution based on deep learning approach is proposed. After that, the case study, which should demonstrate the main features of the proposed solution, is presented. Finally, the results are summarized, and the article is finished with some conclusions. This paper is an extension of work originally presented in the 24th International Conference on System Theory, Control and Computing (ICSTCC) [9].

2. Problem Formulation

As stated already in the preceding section, we deal with the essential task of industrial robotics called the “pick and place” problem. To be more specific, we are interested in the first challenge of this problem, i.e. detection and positioning of the objects. As a very necessary and attractive problem, detection and positioning of objects of interest has been examined and researched from many points of view [10, 11]. These days, due to a greater use of laser scanner technology (e.g. Photoneo Phoxi 3D Laser Scanner, Faro Focus 3D Laser Scanner), clouds of points are often used for object detection and positioning [12, 13]. Apparently, laser scanners in combination with robust 3D object registration algorithms, provide a strong tool to be applied in “pick and place” problems. Nevertheless, solutions based on clouds of points are generally costly and for some materials (shiny metal, glass, etc.), their accuracy decreases. In addition, a large number of laser scanners provide framerates too low to be used with moving objects of interest. Therefore, we propose an alternative solution based on a classical monocular RGB industrial camera as an image acquisition sensor. Besides, we suggest a novel approach based on a fully convolutional neural network in combination with a classical image processing routine, in order to analyze the signal from the industrial camera.

The proposed solution is supposed to meet the requirements of the industrial sector, i.e. stable performance, insensitivity to light conditions, quick response and reasonable cost. In order to demonstrate these requirements, we perform a case study, which is summarized at the end of this article. This case study is supposed to fulfill the following conditions:

- Objects – up to four different complex objects should be detected and located.
- Conditions – Detection and positioning accuracy should not be affected by background surface change.
- Framerate – In order to be able to register moving objects, the framerate should exceed 10 frames per second.
- Hardware – The detection and positioning system should be based on hardware suitable for industrial applications. However, the costs should not exceed \$500 to be economically viable.

The graphic plan of our task is depicted in Figure 1.

Figure 1: The arrangement of the task - the conveyor belt (1) brings the objects, the industrial camera (2) takes the image of the area, the detection and positioning system (3) determines the grasp points for manipulation and the robotic arm (4) puts the objects to the desired positions (5)

3. Proposed Approach

We propose that the approach for object detection and positioning is composed of two parts. The first part is designed to perform the scanning of the area and it provides the visual data to be processed by the following part. The second part then processes the data and provides particular detected objects and their positions. Using this information, a parent control system should be able to manipulate the objects in order to achieve the desired positions.

3.1. Camera sensor

In order to achieve a sufficient framerate, we propose to implement an ordinary industrial monocular RGB sensor equipped with a corresponding lens as the source of input image. Ostensibly, the camera and lens should be chosen according to the situation in the specific task (the scanned scene size, light, the distance of the camera from the objects, etc.). The tutorials of a camera sensor and lens combination selection are available at the vision technology producer information sources e.g. the Basler Lens Selector provided by Basler AG.

3.2. Detection and positioning system

Various studies published in recent years prove that the family of convolutional neural network topologies (CNN) outperforms classical image processing methods in tasks of object detection and classification benchmarked on various datasets [14, 15]. Following this fact, we propose a detection and positioning system, that uses CNN to transform the original RGB image of the monitored area into a specific schematic image. The main purpose of this particular operation is to create a graphic representation, where the positions of the detected objects are highlighted as gradient circles in defined colors, while the rest of the image is black. Specifically, each pixel in an RGB image representing the scene is labeled with a float number in the range $<0; 1>$, where 1 means the optimal and 0 means the most unsuited grasp point position. These labels are situated in the R layer, G layer, B layer or all layers of the output of the CNN, according to the type of object. Hence, the positions of the gradient circles represent not only the positions of the detected objects, but the exact points on the object body, which are optimal for manipulation by a robotic arm (grasp points). The proposed approach is described in Figure 2.

Figure 2: The proposed approach - the original RGB image of the scanned area is transformed with a convolutional neural network into the schematic image, where

the optimal grasp point positions for manipulation are highlighted by gradient circles of various colors, each particular color then represents the type of the object

The first step of the proposed procedure, i.e. the transformation of the RGB image into a graphical representation of the object positions, is a key element of our approach. We propose to implement a fully convolutional neural network connected as an encoder-decoder processor. Such a processor provides encoding the original input into a small shape and restoring it using the decoder's capabilities. If the process is successful, the approach provides a correctly transformed image as the output from the decoder. We believe, that the correctly designed fully convolutional neural network is able to code gradient circles of defined colors on the exact positions of grasp points on the object bodies.

Therefore, in the next subsection, we introduce a specific fully convolutional neural network, that transforms an original RGB image into a graphical representation, where object grasp points are represented as radial gradients of defined colors.

3.3. Fully convolutional neural network for image transformation

Apparently, many different fully convolutional neural networks, such as ResNet [16], SegNet [17] or PSPNet [18], have been proposed to deal with various image processing tasks. From a wide family of neural network topologies, we select U-net as an initial point of development.

Figure 3: The development of the proposed topology of a fully convolutional neural network - layers removed from the original U-Net are crossed

U-Net is a fully convolutional neural network proposed initially for image segmentation tasks in biological and medical fields. However, it was then adapted to many other applications across different fields. This topology follows a typical encoder-decoder scheme with a bottleneck. In addition, it also contains a direct link between the parts of the encoder and the decoder, which is allowing the network to propagate contextual information to higher resolution layers. U-net topology is adopted from [19].

We streamline U-Net to fit our task in a more efficient way. To be more specific, U-Net originally provides the output data of the same dimensions as the input data. Such a detailed output is not required for a “pick and place” problem in industrial applications. Hence, we reduce the decoder part of U-Net topology. In our case, the output data is 16 times lower, which still provides an accuracy sufficient enough for object detection and positioning, and the topology itself is less computationally demanding. See Figure 3, where the changes applied to U-Net topology are shown in detail.

3.4. Locator for positioning of grasp points

Positioning of the gradient circles in a schematic image (last step in Figure 2) is a generic process of finding local maxima of each implemented color. These positions of the maxima directly represent the grasp points for manipulation using a robotic arm.

Generally, the process of finding local maxima in an array can be performed in several ways. The most obvious solution is to find the indices of the values, which are greater than all their neighbors. However, this approach is very sensitive to noise or small errors in the input data. Hence, it is more appropriate to implement a maximum filter operation, which dilates the original array and merges neighboring local maxima closer than the size of the dilation. Coordinates, where the original array is equal to the dilated array, are returned as local maxima. Clearly, the size of the dilation must be set. In the proposed locator, it is suitable to set it equal to the radius of the gradient circles.

4. Case Study

The aim of this section is to demonstrate the features of our detection and positioning system through the solution of a particular task. The task is properly defined in the next subsection. Subsequently, we propose a hardware implementation of the system and, as the final step of the procedure, a fully convolutional neural network is trained to be able to transform the original RGB images into a graphical representation of object types and positions.

4.1. Object detection and positioning task

For this case study, we need to develop a system for different object detection and positioning. The four object combinations placed on five different types of surfaces were used. The objects of interest are shown in Figure 4 and the surfaces are shown in Figure 5. The objects are of a similar size. Three of them are metallic and one is of black plastic.

4.2. Hardware implementation

The system is composed from a camera sensor and a processing unit, which should process data acquired by the RGB sensor, in order to determine the types and positions of the objects of interest.

In this case study, we implement a Basler acA2500-14uc industrial RGB camera as a data acquisition tool. This sensor is able to provide up to 14 5-MPx RGB frames per second. The camera is equipped with a Computar M3514-MP lens in order to monitor the 300 x 420 mm scan area from above at a distance of 500 mm.

Figure 4: Objects of interest - objects are labelled as Obj1 to Obj4

Figure 5: Various types of surfaces used in case study

The processing unit is supposed to be capable of processing images in real-time, as mentioned above. For this case study, the single-board NVIDIA Jetson NANO computer is used. It offers the NVIDIA Tegra X2 (2.0 GHz, 6 cores) CPU together with 8 GiB RAM. Furthermore, it provides wide communication possibilities (USB 2.0, 3.0, SATA, WiFi). The total price of components used for hardware implementation costs around \$500.

4.3. Datasets

In this case study, we prepare 1021 original RGB images using various combinations of objects (Figure 4) and surfaces (Figure 5). In order to follow the topology of the CNN (Figure 3), we transform the images to 288×288 px. Then, we randomly divide the images into the training set (815 samples) and the testing set (206 samples).

After that, the trickiest part of the development follows. The target images for the training set (the graphical representations of the object types and positions) should be manually prepared. Hence, for any RGB image, we construct a target artificial image, where the optimal grasp point of each individual object in the original image is highlighted by a colored gradient circle. Four colors (red, green, blue and white) are implemented, since we consider four types of objects in this case study. We prepared a custom labeling application to prepare target images. In this application, each input image is displayed, and a human user labels all feasible grasp points using a computer mouse. The application then generates the target images. Several examples of input-expected output pairs are demonstrated in Figure 6.

Figure 6: Two input-target pairs in training set - input image resolution is 288×288 px, target image resolution is 72×72 px

4.4. Fully convolutional neural network training

As the last step of the development, we train the network topology depicted in Figure 3.

We select the ADAM algorithm for the neural network weights and biases optimization as it is generally considered as an acceptable performing technique in most of the cases [20]. The random initial weights set with gaussian distribution was used. The experiments are run fifty times in order to reduce the stochastic character of training. The best instance is then evaluated. The training process and its parameters are depicted in Figure 7.

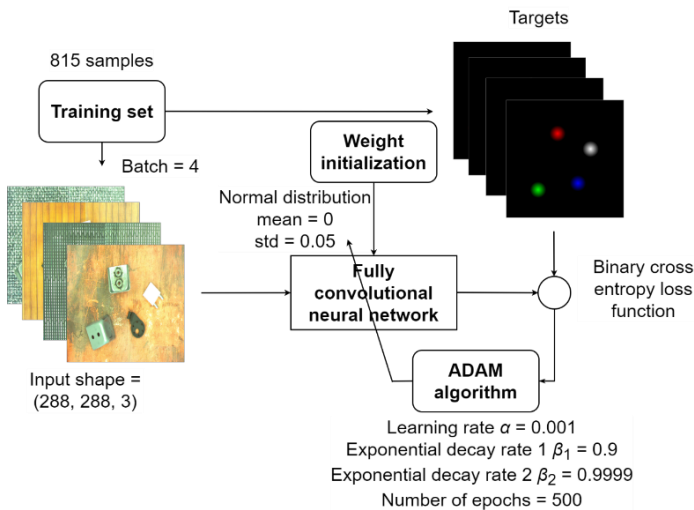

Figure 7: Training process

4.5. Results

We select a confusion matrix as an evaluation metric for detection and positioning system performance. The prediction of the type of the object and position of the grasp point is labeled as correctly predicted, if the local maximum position of the gradient circle of the defined color directly corresponds to the original position of the particular object using the 72 x 72 px map, i.e. the map defined by the target image.

The confusion matrix for the best network trained according to the previous paragraph for the testing set, is summarized in Table 1. Note that the number of correctly predicted free spaces in the image is not present, because it is essentially a black surface that cannot be explicitly evaluated. However, as seen in the table, the detection and positioning system provides 100 % accuracy over the testing set. In addition, implementing Jetson NANO described above, the detection and positioning system is capable of processing 13 frames per second, which is more than required at the beginning of the paper.

Table 1: Confusion matrix (206 images, 611 objects in total)

-	Obj1 pred.	Obj2 pred.	Obj3 pred.	Obj4 pred.	Free space pred.
Obj1 actual	149	0	0	0	0
Obj2 actual	0	153	0	0	0
Obj3 actual	0	0	158	0	0

Obj4 actual	0	0	0	151	0
Free space actual	0	0	0	0	Irrelevant

5. Conclusion

In this contribution, we introduced a novel engineering approach to object grasp point detection and positioning for “pick and place” applications. The approach is based on two consecutive steps. At first, a fully convolutional neural network is implemented in order to transform the original input image of the monitored scene. Output of this process is a graphical representation of the types and positions of the objects present in the monitored scene. Secondly, the locator is used to analyze the graphical representation to get the explicit information of object type and position.

We also performed a case study to demonstrate the proposed approach. In this study, the proposed system provided accurate grasp point positions of four considered objects for manipulation.

In future work, we will try to enhance the system in several ways. Critically, the approach should provide not only the positions of the grasp points, but also the required pose of the robotic arm. This feature will be advantageous especially for clamp grippers. Apart from that, we will try to optimize the processing unit, both from the hardware and software point of view, in order to get the close-to-optimal topology of the fully convolutional neural network and the hardware suitable for it.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Static Application Security Testing (SAST) is a popular quality assurance technique in software engineering. However, integrating SAST tools into industry-level product development and security assessment poses various technical and managerial challenges. In this work, we reported a longitudinal case study of adopting SAST as a part of a human-driven security assessment for an open-source e-government project. We described how SASTs are selected, evaluated, and combined into a novel approach for software security assessment. The approach was preliminarily evaluated using semi-structured interviews. Our result shows that (1) while some SAST tools outperform others, it is possible to achieve better performance by combining more than one SAST tools and (2) SAST tools should be used towards a practical performance and in the combination with triangulated approaches for human-driven vulnerability assessment in real-world projects.

1. Introduction

Digital transformation promises to fundamentally reshape organizations and businesses by adopting cloud computing, big data, e-government [1], artificial intelligence [2], and internet-of-things [3, 4]. Before the potential benefits of adopting technologies are fulfilled, it is essential to ensure the transformation does not lead to additional harm or danger to customers and end-users. Several global, large-scale reports have shown that security and privacy continue to be major concerns to a successful digital transformation. An independent survey in 2016 reveals that almost 60 percent of participated organizations experienced a security attack and in 30 percent of them, it occurs every day [5]. Moreover, 20 percent of them are dealing with internal vulnerabilities at least quarterly. According to another report from the Identify Theft Resource Center (ITRC), data breaches in 2017 increase 45 percent than those in 2016 [6]. In another report, it is estimated that the annual cost from security issues to the global economy is more than 400 billion dollars per year [7].

Software is a common component of any digital system or service. A software vulnerability can be seen as a flaw, weakness, or even an error in the codebase that can be exploited by hackers to violate the security and privacy attributes of end-users and the software [8]. Security engineering research has investigated various approaches to identify, model, and protect software against vulnerability. One of the most common identification techniques is the static analysis of source code, which investigates the written source code to find software flaws or weak points. Static Application Security Testing (SASTs) is accepted and used in many software development companies as a gatekeeper of code quality [9, 10]. There are many different SAST tools available, ranging from commercial tools to open-source projects, from using simple lexical analyses to more comprehensive and complex analysis techniques, from a stand-alone tool to a component in a development pipeline. Some popular SAST tools, such as SonarQube or IntelliJ IDEA are integral parts of continuous software development cycles. Given the wide range of SAST tools, software developers, security professionals, and auditors might face a question: how to choose a suitable SAST for their project?

*Corresponding Author: Anh Nguyen-Duc. anhnd85@gmail.com

One of the known problems of using SASTs is the possibly large number of misleading warnings [11, 12]. SASTs can report many false positives that attract unnecessary debugging efforts. In practice, the usefulness of SASTs depends on the project and organizational context and in general requires empirical investigation before the full adoption. The combination of SAST tools could also be an interesting approach to increase the overall effectiveness of static testing. There exist several empirical studies about the effectiveness of SASTs [9, 11-16]. Most of these studies base on test data or open-source data and do not reflect the adoption of this type of tool in a real-world context.

We conducted a case study in a large-scale government project that aims at developing a secured and open-source software system for e-government. SASTs were integrated into a so-called security gate that analyzes and assesses the vulnerability level of incoming source code. The security gate needs to ensure that all software will go through a security analysis before going further to end-users. In this project, SAST tools are experimented with and adopted to assist vulnerability assessment of open-source software.

This paper reports our experience with adopting SAST tools in the e-government project through a research-driven process. We proposed two Research Questions (RQs) to guide the development of this paper. Firstly, we would like to investigate the state-of-the-art SAST tools and the ability to combine them in detecting software vulnerabilities. Secondly, we explore an industrial experience that adopted a combination of SAST tools in supporting security assessment in an e-government project.

- *RQ1: Is it possible to increase the performance of SAST tools by combining them?*
 - *RQ1a. Which SAST tool has the best performance against the Juliet Test suite?*
 - *RQ1b. Is the performance of SAST increased when combining different tools?*
- *RQ2: How SAST tools can support security assessment activities in an open-source e-government project?*

The contribution of this paper as follows:

- An overview of state-of-the-art SAST tools and their applications
- An experiment that evaluates the performance of these tools
- An in-depth case study about the adoption of SAST tools in e-government projects.
- The paper is organized as follows. Section 2 presents backgrounds about software security, SAST, and security in e-government sectors. Section 3 describes our case study of the Secured Open source-software Repository for E-Government (SOREG). Two main research components of the projects are presented in this paper, an experiment with different SAST tools in Section 4 and a qualitative evaluation of a combined SAST approach for support-ing security assessment in Section 5. After that, Section 6 discusses the experience in this paper, and Section 7 concludes the paper.

2. Background

2.1. Software security and vulnerabilities

Software security is “the idea of engineering software so that it continues to function correctly under malicious attack” [17]. Factors impacting whether code is secured or not include the skills

and competencies of the developers, the complexity level of the software components and its associated data, and the organizational security policies [17, 18]. We need to distinguish relevant or similar terms about software security:

- **Vulnerability:** can be defined as flaws or weaknesses in software design, implementation or operation management and can be exposed to break through security policies [19].
- **Fault:** a condition that causes the software to fail to perform its required function [10].
- **Failure:** is the deviation of actual functioning outputs from its expected outputs, or in another word, is when a fault is exploited leading to a negative consequence to the software [10].
- **Attack:** an unauthorized attempt to steal, damage, or expose systems and data via exploiting vulnerabilities [20].

Table 1: CWE categories and examples [20]

Class Id	Weakness class	Example Weakness (CWE Entry)
W321	Authentication and Access Control	CWE-285: Improper Authorization
W322	Buffer Handling (C/C++ only)	CWE-120: Buffer Copy without Checking Size of Input
W323	Code Quality	CWE-561: Dead Code
W324	Control Flow Management	CWE-705: Incorrect Control Flow Scoping
W325	Encryption and Randomness	CWE-328: Reversible One-Way Hash
W326	Error Handling	CWE-755: Improper Handling of Exceptional Conditions
W327	File Handling	CWE-23: Relative Path Traversal
W328	Information Leaks	CWE-534: Information Exposure Through Debug Log Files
W329	Injection	CWE-564: SQL Injection:
W3210	Malicious Logic	CWE-506: Embedded Malicious Code
W3211	Number Handling	CWE-369: Divide by Zero
W3212	Pointer and Reference Handling	CWE-476: NULL Pointer Dereference

Security experts and communities maintain different databases and taxonomies of vulnerabilities, for instance, CVE, CWE, NPD, MFSA, OWASP, and Bugzilla. The common weaknesses and enumeration (CWE) dictionary by MITRE provides common categories of software vulnerabilities. For instance, cross-site scripting (XSS) describes a type of vulnerability that occurs when form input is taken from a user and not properly validated, hence, allowing for malicious code to be injected into a web browser and subsequently displayed to end-users. SQL-Injection is another common type of vulnerability, where user input is not correctly validated and directly inserted in a database query. A path manipulation type occurs when users can view files or folders outside of those intended by the application. Buffer handling vulnerabilities allow users to exceed the buffer's bounds which can

result in attacks ranging from writing instructions to gaining full system access or control. The overview of different CWE categories is given in Table 1.

2.2. Static Application Security Testing (SAST)

Security testing is an area of testing that verifies the software with the purpose of identifying any fault, attack, or failure that is different from the given security requirements. There are two major types of security testing, i.e. static testing and dynamic testing [17]. Static Application Security Testing (SAST) utilizes a static code analysis tool to analyze source code to identify potential vulnerabilities or software faults. Different from dynamic approaches, SAST examines source code without executing it, and by checking the code structure, the logic flows of statements, the usage of variables, values, functions, and procedures. Common techniques used in SAST tools include (1) syntactic analysis, such as calling insecure API functions or using insecure configuration options, and (2) semantic analysis that requires an understanding of the program semantics, i.e. data flow or control flows. This analysis starts by representing the source code by an abstract model (e.g., call graph, control-flow graph, or UML class/sequence diagram).

As SAST tools work as white box testing and do not actually run the source code, a reported vulnerability from the tool might not necessarily be an actual one. The reason for a wrong warning might be because (1) the source code is secure (true negative) or (2) the source code has a vulnerability but is not reported by the tools (false negative).

Research about SAST tools is not new. The Center for Assured Software (CAS) developed a test suite with “good code” and “faulted code” across different languages to evaluate the performance of static analysis tools [16]. Tracing research work that has used this test suite, we found several existing empirical studies that assessed the effectiveness of SAST tools, in terms of accuracy, precision, and recall. In [16], the authors assessed five commercial SAST tools and reported the highest recall score of 0.67 and the highest precision score of 0.45. In [21], the authors compared the performance of nine SAST tools, including commercial ones, and found an average recall value of 0.527 and an average precision value of 0.7. In [22], the author investigated four different SAST tools in detecting a class of CWE using the Juliet test suite. The best-observed performance in terms of recall was 0.46 for CWE89 with an average precision of 0.21. In [23], the authors evaluated the use of a commercial SAST tool and found it is difficult to apply in an industrial setting. In this case, the process of correcting false-positive findings leads to additional vulnerability in the existing secure source code. In [15], the authors conducted few experiments and found that different SAST tools detected different kinds of weaknesses. In this research, we will analyze the effectiveness of seven different SAST tools. Different from previous research, we also investigate the performance of combining these tools.

2.3. Vulnerability databases

It has been a worldwide effort of capturing and publishing known vulnerabilities in common software via vulnerability databases. The vulnerability databases record structured instances of vulnerabilities with their potential consequences. It helps developers and testers be aware of and keep track of existing vulnerabilities in their developing systems [23]. According to a public report [24], there are more than 20 active vulnerability databases. Many of the databases are the results of a global effort by communities to leverage the existing large number of diverse real-world vulnerabilities. The most popular databases include:

- National Vulnerability Database (NVD)¹ - operated by the US National Institute of Standards and Technology, NVD contains known vulnerable information in the form of security checklists, vulnerability descriptions, misconfigurations, product names, and impact metrics.
- Common Vulnerabilities and Exposures (CVE)² – operated by the MITRE Corporation, CVE contains publicly known information-security vulnerabilities and exposures.
- Common Weakness Enumeration (CWE)³ – sponsored by the MITRE Corporation with support from US-CERT and the National Cyber Security Division of the U.S. Department of Homeland Security, CWE is a community-developed category that provides a common language to describe software security weaknesses and classifies them based on their reported weaknesses.
- MFSA⁴ or Mozilla Foundation Security Advisory, created by Mozilla, contains vulnerabilities detected by the community. Every vulnerability record is associated with a title, impact, announced, reporter, product, and fix. It also provides links to the associated files, codes and patches via the Bugzilla⁵.
- OSVDB⁶ - It is an independent open-source database contributed by various researchers. It currently covers about 69.885 vulnerabilities in 31.109 software.
- OWASP TOP 10⁷, created by OWASP (Open Web Application Security Project) – the non-profit organization on software security, provides the annually updated list of top ten most critical security risks to web applications. The OWASP Top 10 list is based on vulnerabilities gathered from hundreds of organizations and over 10.0000 real-world applications and APIs.

2.4. Security concerns in e-Government

e-Government is defined as the combination of information technologies and organizational transformation in governmental bodies to improve their structures and operations of government [25]. The potential benefits of e-government are (1) internal and central management of governmental information, (2) increased effectiveness of governmental services, (3) better connections between citizens, businesses, and different units in public sectors [26]. Many challenges during the deployment and operation of e-Government, particularly in development countries, are reported. The challenges include inadequate digital infrastructure, a lack of skills and competencies for design, implementation, use, and

⁶ <https://vuln.whitesourcesoftware.com/>

⁷ <https://owasp.org/www-project-top-ten/>

management of e-government systems, and a lack of trust in the security and privacy of the systems, to name a few [27-29].

Security and privacy threats are always major concerns for operations of e-government projects [1]. If an e-government system are not well secured, security attacks may harm the system and its users at any time, leading to different types of financial, psychological and personal damages. In [30], the authors reported common security threats to e-government systems, including Denial of Service (DoS), unauthorized network access, cross-site scripting (XSS), and penetration attacking. In [31], the authors emphasized that privacy and security must be protected to increase the user's trust while using e-government services. Security measures in an e-government system can be implemented at physical, technical, or management levels [30]. From a software engineering perspective, we focused on the technical level, in which SAST plays an important role as both vulnerability detection software and security assessment tools [32].

3. Research Methodology

This section presents our case study and the overview of the research design. The detailed description of the experiments and qualitative validation of the selected SASTs is described in Section 4 and Section 5.

3.1. The longitudinal case study

Vietnam is a developing country with a significant investment on a country-wide digital transformation. During the last decade, several initiatives have been implemented at regional and national levels to increase the digital capacity of the government, provide e-services to some extent, develop IT infrastructure and integrate national information systems and database. Aligned with the national strategy, a government-funded project, entitled "Secured Open source-software Repository for E-Government" (SOREG) has been conducted. It is noted that the project is among several funded R&D projects towards the implementation of the whole e-government systems in a large-scale. The project was led by a domestic software company so-called MQ Solution.

We participated in the project with both passive and participant observation. The first author of the paper participated

in the project as a researcher, and is responsible for the plan and conducting an experiment with SAST tools. The research design was conducted and the experiment was carried on without affecting the original project plan. The second, third, and fourth authors of the paper directly performed the experiment following a predetermined design and also participated in developing different software modules in the projects. The first part of SOREG with literature review and market research has been partly reported in our previous work [33].

3.2. Research design

Since the project involves both research and development activities, we will only focus on the research-relevant parts. Figure 1 describes the research process leading to the selection and evaluation of SAST tools in supporting vulnerability assessment in SOREG. In the scope of this work, we focus on the research activity; hence, the open-source repository development is not mentioned (represented as a grey box). We also exclude the research and development of Dynamic Application Security Testing (DAST) and the integration of DAST and SAST tools in this paper (the other two grey boxes in Figure 1).

This paper reports a part of the case study with two parts, an experiment that investigates SAST tools with a test suite and a qualitative evaluation of the proposed SAST solution. When the project had started, we conducted an ad hoc literature review to understand the research area of software security testing and particularly SAST and DAST tools. After that, as a feasibility analysis, we selected a set of SAST tools and conducted an experiment to evaluate the possibility of combining SAST tools. A development activity follows with the architectural design of the integrated SAST solution and prototype development. After that, we conducted a preliminary evaluation of the prototype with expert interviews.

We described which SAST tools are selected (Section 4.1), the test suite to compare them (Section 4.2), the evaluation metric (Section 4.3), and the experiment result (Section 4.4). We briefly describe the outcome of the integrated SAST solution (Section 4.5) in this paper. The analysis of semi-structured interviews is shown in Section 5.

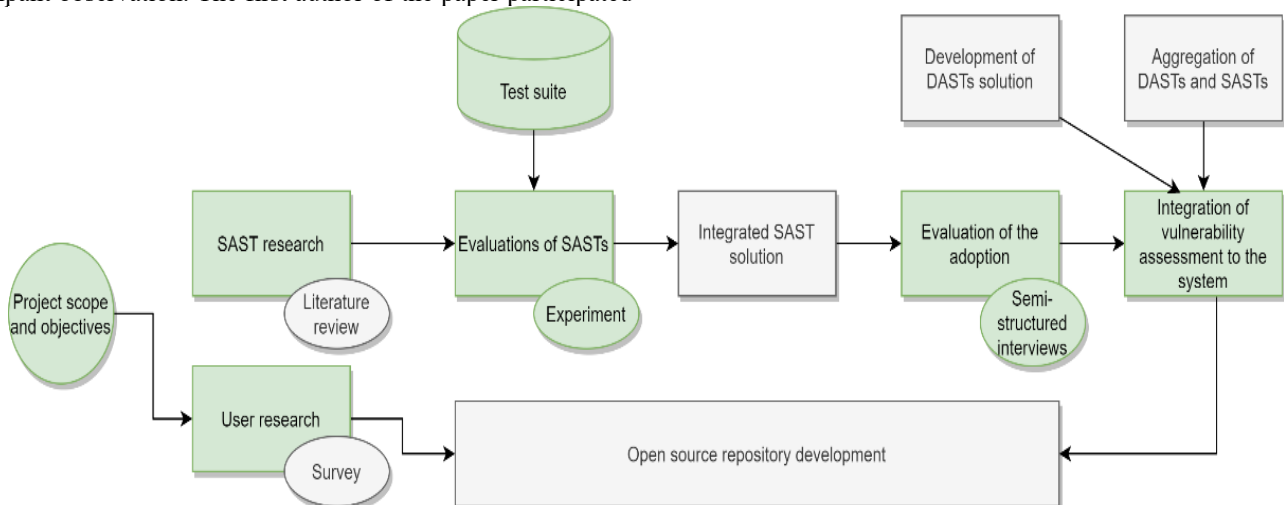

Figure 1: An overview of the research (green boxes) and development (grey boxes) process

3.3. SOREG – Secured Open source-software Repository for E-Government

Aligned with the e-government policy, the development and security assurance of an open-source repository is necessary. The repository will serve for ca. 2.8 million government officers. Therefore, the security aspect is of high priority. The project was funded by the Ministry of Science and Technology of Vietnam from November 2018 to February 2021. The initiated budget is 200.000 Eur. The project team includes 23 key members who participate in project planning, implementation, and closure. The main objectives of SOREG are (1) proposal and development of a prototype of a community-driven open-source software repository, (2) development and validation of a security assessment approach using SAST and DAST tools. The security assessment module focuses on software vulnerability. The expectation is that the module can detect existing vulnerabilities from dependent components, such as libraries, frameworks, plugins, and other software modules. Issues with X-injections, e.g. SQL injection, LDAP injection should be detected at a practical rate. Other types of vulnerabilities as described in CWE should also be covered at an acceptable level.

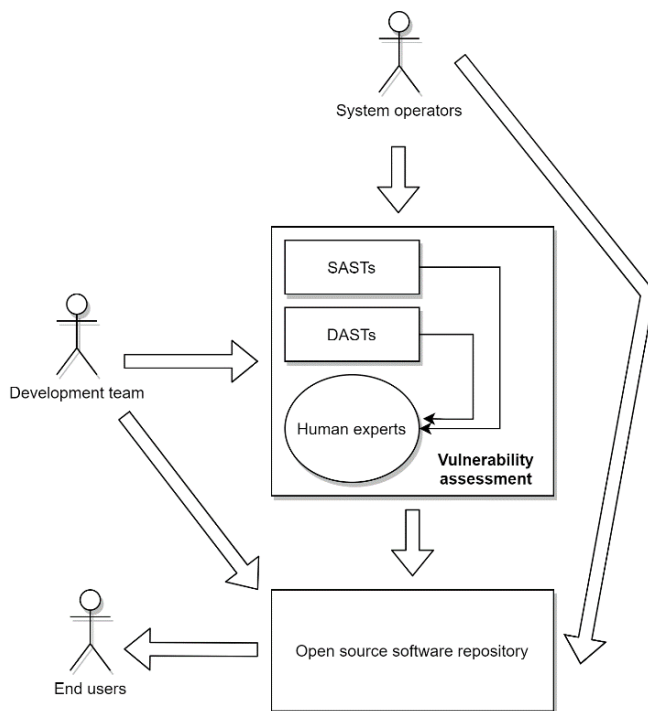

Figure 2: An overview of the open source software repository

All software submitted to the repository must go through a vulnerability assessment, as shown in Figure 2. The assessment module includes two parts (1) tools including both DAST and SAST tools, and (2) experts as moderators. The experts received reported results from tools and decide the vulnerability level of the inputted software. If the software passes the check, it will be published in the repository and available to all users. Otherwise, the software will be sent back to the submitters and not accepted for publishing.

4. RQ1: Is it possible to increase the performance of SAST tools by combining them?

This section presents an experiment that answers the RQ1. We explored two sub research questions:

RQ1a. Which SAST tool has the best performance against the Juliet Test suite?

RQ1b. Is the performance of SAST increased when combining different tools?

We selected seven SAST tools (Section 4.1), prepared the test suite (Section 4.2), performance metrics (Section 4.3) and reported the results for RQ1a (Section 4.4.1) and RQ1b (Section 4.4.2).

4.1. The selected SAST tools

The literature review on SAST and experts' opinions are the two main inputs for selecting SAST tools. We gathered seven tools that attract both research and practitioners by the time the research project was conducted (end of October 2018). The list of the tools is summarized in Table 2.

Table 2: A list of popular SAST tools by the end of 2018

Tool name	Description
SonarQube	Scans source code for more than 20 languages for Bugs, Vulnerabilities, and Code Smells
Infer	Static check for C, C++, Objective-C and Java, work for iOS and Android
IntelliJ IDEA	integrated development environment (IDE) written in Java, support multiple languages
VCG	an automated code security review tool that handles C/C++, Java, C#, VB and PL/SQL
Huntbug	A Java bytecode static analyzer tool based on Procyon Compiler tools aimed to supersede the FindBugs
PMD	A cross-language static code analyzer
Spotbug	A static analysis for Java code, a successor of FindBugs

4.1.1. SonarQube

SonarQube is one of the most common open-source static code analysis tools for measuring quality aspects of source code, including vulnerability. SonarQube implements two fundamental approaches to check for issues in source code:

- **Syntax trees and API basics:** Before running any rules, a code analyzer parses the given source code file and produces the syntax tree. The structure is used to clarify the problem as well as determine the strategy to use when analyzing a file.
- **Semantic API:** In addition to enforcing rules based on data provided by the syntax tree, SonarQube provides more information through a semantic representation of the source code. However, this model currently only works with Java source code. This semantic model provides information regarding each symbol manipulated.

Using the API, Sonar has built-in several popular and proven tools available in the open-source community. These tools, through the implementation of standardized testing source code, consider possible errors and errors, each in their own opinion. The nature of checks ranges from small styles, for example detecting unwanted gaps, to more complex spaces that are more prone to potential errors, such as variables that cannot qualify checks result in null references.

4.1.2. Infer

Infer, also referred to as "Facebook Infer", is a static code analysis tool developed Facebook engineers and an open-source community. Infer is a compositional program analysis, which allows feedback to be given to developers in tune with their flow of incremental development [34, 35]. Common quality checks include null pointer exceptions, resource leaks, annotation reachability, and concurrency race conditions. Infer is reportedly able to support scalable security assurance process, to run quickly and continuously on code-changes while still performing an inter-procedural analysis [36].

4.1.3. IntelliJ's IDEA

IntelliJ IDEA is a static code analysis feature that provides an on-the-fly code check when using IntelliJ development environment. Common vulnerabilities, inconsistencies, probable bugs, and violations can be detected during development time and later stages. The special point with IntelliJ IDEA is its source-code indexing feature that is able to produce smart quick-fixes and on-the-fly code analysis.

4.1.4. Visual Code Grepper (VCG)

VCG is an automated code security review tool that is applicable to many different programming languages. In addition to performing some more complex analysis, it has a portable and expandable configuration that allows users to add any bad functions (or other text). VCG offers a powerful visualization for both individual files and the codebase, showing relative proportions of code, whitespace, comments, styling comments and code smell. It is also able to identify vulnerabilities, such as buffer overflows and signed/unsigned comparisons.

4.1.5. Huntbug

Huntbug is a Java static analyzer tool based on Procyon Compiler tools, which aims at outperforming the famous tool FindBugs.

4.1.6. PMD

PMD is another popular source code analyzer that works with common programming flaws, including unused variables, empty catch blocks, and unnecessary object creation. It supports Java, JavaScript, Salesforce.com Apex and Visualforce, PLSQL,

Apache Velocity, XML, XSL. Similar to SonarQube or Huntbug, PMD adopts rule-based and pattern-comparison mechanisms.

4.1.7. SpotBug

SpotBugs is a program that uses static analysis to look for bugs in Java code. SpotBugs checks for more than 400 bug patterns.

4.2. Test suite

Different open-source test suites exist for the purpose of security testing. Two popular examples are the Juliet test suite and OWASP Benchmark. We decided to use the Juliet test suite because it is not only limited to the top 10 vulnerabilities as of the OWASP benchmark dataset. In addition, the test suite covers a comprehensive list of weaknesses and supports multiple languages. One of the goals for developing the Juliet test suite was to enable open dataset for empirical research. The test suite has been popular among software and security engineering research [7, 12-14]. The latest version (Ver 1.3) comprises 64,099 test cases in C/C++ and 28,881 test cases in Java⁸. In the scope of SOREG project, it is fair to focus on these two programming languages due to the dominance of them in SOREG's source code.

4.3. Evaluation metrics

Evaluation metrics are used extensively in empirical study about data mining, software quality predictions and software metrics. We adopted the set of evaluation metrics in our previous work [37, 38]. These metrics are also successfully adopted in studies about security before [13, 20]:

- True Positive (TP): the reported flaw is an actual flaw (vulnerability) that needs to be fixed
- False Positive (FP): the normal non-flawed code is reported as a flaw. This warning should be ignored.
- True Negative (TN): the reported normal code is actually a non-flawed code. We do not need to do anything in this case.
- False Negative (FN): the actual flaw (embedded in the test suite) is not detected by the tool. This is a serious issue
- Recall = $TP / (TP + FN)$
- Precision = $TP / (TP + FP)$
- F1 Score = $2 (Recall \times Precision) / (Recall + Precision)$

It is possible to have both TP and FP in a test file. In this case, our SAST is not sophisticated enough to discriminate for instance when the data source is hardcoded and therefore does not need to be sanitized. We adopt the "strict" metrics defined in [39], as they truly reflect a real-world situation.

4.4. Experiment Results

4.4.1. RQ1.a. Which SAST tool has the best performance against the Juliet Test suite?

We report the evaluation results of the seven tools on Juliet Test Suite v1.3. as shown in Table 3. Looking at the number of outputs from each tool, IntelliJ is on top of the list with 37,694

⁸ <https://samate.nist.gov/SARD/testsuite.php>
www.astesj.com

reported issues. PMD is in second place with 37.405 reported issues and after that Sonarqube finds 28.875 reported issues. To measure the accuracy of the tools, we calculated the F1 score as shown in Table 3. The top three most accurate tools in our experiment are IntelliJ, PMD, and Sonarqube accordingly. The successors of FindBugs, i.e. Huntbugs and Spotbugs detect a small number of issues, showing their limited capacity in a software security area. Infer, the SAST promoted by Facebook finds only 428 issues from our test suite.

False Positives are also of our concern since this is one of the main barriers to adopt SAST tools in industrial projects [20]. This reflects the value of precisions. The rank of SAST is a bit different here, as Sonarqube has the best precision value (0,6), following by VCG (0,59) and IntelliJ (0,57).

We looked into details how each tool performs regarding CWE categories. Table 4 reports the F1 score of the seven tools across our 12 weakness categories.

Authentication and Authorization include vulnerabilities relating to unauthorized access to a system. IntelliJ IDEA has the best F1 score of 0.53 and followed by Sonar Qube with 0.26. Overall the ability to detect issues with SAST tools in this category is quite limited.

Answer to RQ1a: Sonarqube has the best precision score of 0.6. IntelliJ has the best F1 score of 0.69. For a single CWE class, the best achieved F1 score is from PMD for the error handling class.

Code quality includes Issues not typically security-related but could lead to performance and maintenance issues. IntelliJ IDEA has the best F1 score of 0.83 and followed by PMD with 0.79. Sonar Qube has an F1 score of 0.63, which is in third place. Other tools are not able to detect any issues in this category. This can be explained by the coverage-by-design of the tools. SASTs such as SonarQube and IntelliJ cover not only vulnerabilities but also many other types of concerns, e.g. code smells, bugs, and hot spots.

Control Flow Management explores issues of sufficiently managing source code control flow during execution, creating conditions in which the control flow can be modified in unexpected ways. PMD has the best F1 score of 0.69 and followed by Sonarqube with an F1 score of 0.62.

Encryption and Randomness refer to a weak or improper usage of encryption algorithms. IntelliJ IDEA has the best F1 score of 0.53 and followed by Sonar Qube with an F1 score of 0.26. Overall the ability to detect issues with SAST tools in this category is quite limited.

Table 3: Evaluation results of SAST tools against Juliet 3.1. Testsuite

Tool	No. Detections	TP	FP	FN	Recall	Precision	F1-Score
Sonarqube	28875	9381	6216	17321	0.35	0.6	0.44
Infer	428	1564	1364	45768	0.03	0.53	0.06
IntelliJ	37694	52276	40026	8502	0.86	0.57	0.69
VCG	8143	8900	6164	38053	0.19	0.59	0.29
PMD	37405	12094	10389	8791	0.58	0.54	0.56
Huntbugs	2677	1873	2138	43519	0.04	0.47	0.07
SpotBug	624	347	313	45572	0.01	0.53	0.02

Table 4: Evaluation results of SAST tools across different CWE categories

CWE Class	Sonar Quebe	Infer	IntelliJ IDEA	VCG	PMD	Huntbugs	Spotbugs
Authentication and Access Control	0.26	0.17	0.53	0.19	0.25	0.07	0
Code quality	0.63	0	0.83	0	0.79	0	0
Control Flow Management	0.38	0	0.69	0.28	0.65	0	0
Encryption and Randomness	0.62	0	0.6	0.15	0.68	0	0
Error Handling	0.64	0	0.73	0	0.84	0	0
File Handling	0.35	0	0.7	0.23	0.63	0.07	0
Information Leaks	0.67	0	0.62	0.45	0.63	0	0
Initialization and Shutdown	0.16	0	0.73	0.39	0.72	0	0
X-Injection	0.51	0	0.72	0.36	0.68	0.15	0.04
Malicious Logic	0.79	0.02	0.8	0.08	0.6	0	0
Number Handling	0.29	0.12	0.56	0.17	0.29	0	0
Pointer and Reference Handling	0.23	0	0.71	0.21	0.75	0	0

Table 5: The effectiveness of combining various SAST tools

Tool	TP	FP	FN	Recall	Precision	F-score	No of outputs	Type
Sonarqube + Intellij	65927	49518	2199	0,97	0,57	0,72	43997	Best F-Score
Sonarqube + SpotBug	9722	6544	17296	0,36	0,62	0,45	28900	Best Precision
Sonarqube + Intellij + VCG + Infer	73811	55692	2095	0,97	0,57	0,72	44101	Largest amount of outputs
Intellij IDEA	52276	40026	8502	0,86	0,57	0,69	37694	

Error Handling includes failure to handle errors properly that could lead to unexpected consequences. PMD has the best F1 score of 0.84 and followed by IntelliJ IDEA with an F1 score of 0.73.

File Handling includes checks for proper file handling during reading and writing to stored files. IntelliJ IDEA has the best F1 score of 0.7 and followed by PMD with an F1 score of 0.63. Sonarqube works not so well with this category as its F1 score is only 0.35.

Information Leaks contain vulnerabilities about exposing sensitive information to an actor that is not explicitly authorized to have access to that information. SonarQube has the best F1 score of 0.67 and followed by IntelliJ IDEA and PMD with similar scores.

Initialization and Shutdown concern improper initializing and shutting down of resources. We see that IntelliJ IDEA has the best F1 score of 0.73 and followed by PMD with an F1 score of 0.72.

X-Injection: a malicious code injected in the network which fetched all the information from the database to the attacker. This is probably one of the most important types of vulnerability. In this category, IntelliJ IDEA is the most accurate tool with an F1 score of 0.72 followed by PMD (0.68) and Sonar Qube (0.51)

Malicious Logic concerns the Implementation of a program that performs an unauthorized or harmful action (e.g. worms, backdoors). This is also a very important type of vulnerability and probably among the most common ones. In this category, IntelliJ IDEA is the most accurate tool with an F1 score of 0.8 followed by Sonar Qube (0.79) and PMD (0.6)

Number Handling include issues with incorrect calculations, number storage, and conversion weaknesses. IntelliJ IDEA has the best F1 score of 0.56 and followed by PMD and Sonar Qube with the same F1 score of 0.29.

Pointer and Reference Handling issues, for example, the program obtains a value from an untrusted source, converts this value to a pointer, and dereferences the resulting pointer. PMD has the best F1 score of 0.75 and followed by PMD and IntelliJ IDEA with the same F1 score of 0.71.

4.4.2. RQ1.b. Is the performance of SAST increased when combining different tools?

We also investigated if combining various SAST tools can produce better performance. We run the combination of two, three, and four SAST tools and compare them against our performance metrics.

We wrote a script to try all possible combination and then step-wise reduction of tools. Table 5 presents our results in three categories (1) the combination that gives the best F1 score, (2) the combination that gives the best precision, and (3) the combination

that produces the largest number of outputs. We reported again the result with IntelliJ IDEA as a benchmark for comparison.

The result shows that it is possible to increase some performance metrics by combining different SAST tools. However, there are none of the combinations can produce the best value for all performance metrics. Interestingly, we see that Sonarqube appears in all best combinations, even though the SAST does not perform the best among single SAST tools. From Table 5, we can say that the 5-tools combination including SonarQube, Intellij, VCG, Infer and SpotBug would probably give the best outcome in all of our metrics. However, this is beyond our experiment.

Answer to RQ1b: Combining SAST tools does give a better performance than of a single SAST, and this depends on the performance metrics

4.5. The integrated SAST tools solution

The experiment produces an input for the design and development of the SAST module for the security assessment (as shown in Figure 2). We present only briefly the architectural decisions that are taken and some architectural views of the solution.

From practical aspects, there are several requirements for SAST modules from the repository development and operation team. The team emphasized five criteria while working with SAST tools:

- Result accuracy. SAST modules should produce results within a limited time and produce accurate enough according to the project stakeholders. The development team emphasizes the importance of False Positives (TPs).
- Simplicity. Key features like security check and visualizing the result should be straightforward so that users without security background can operate the tool autonomously. The user interface should be easy-to-understand and configurable to the local language.
- Vulnerability coverage. We focused on the ability to detect different categories in the CWE database. Besides, detection of common vulnerabilities as identified by other industry standards such as OWASP Top 10 and SANS is desirable.
- Supports multiple languages. Ensure that the SAST tool supports popular programming languages such as Java and C++. It should also have a possibility to support both mobile and web development, including Python, PHP, Javascript, Objective C, and Ruby on Rails.
- Customizability. The ability to adapt the scan results to the different output format and integrate to different business

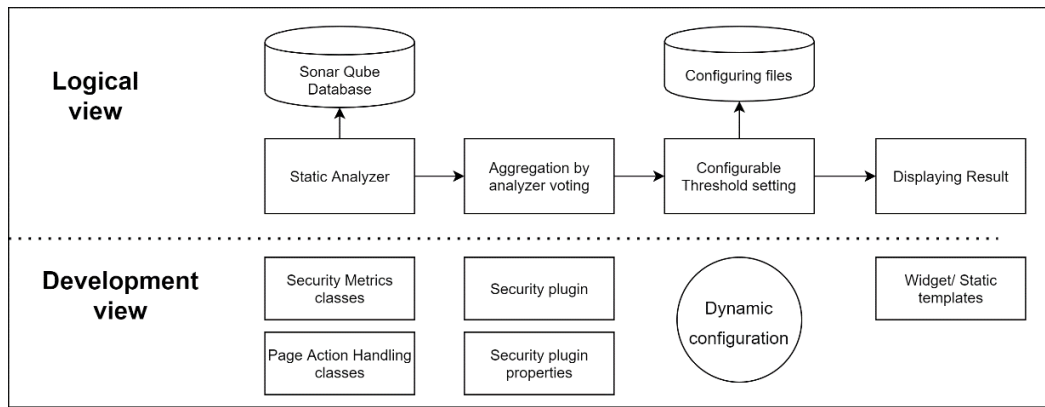

Figure 3: The logical view and development view of an integrated SAST solution

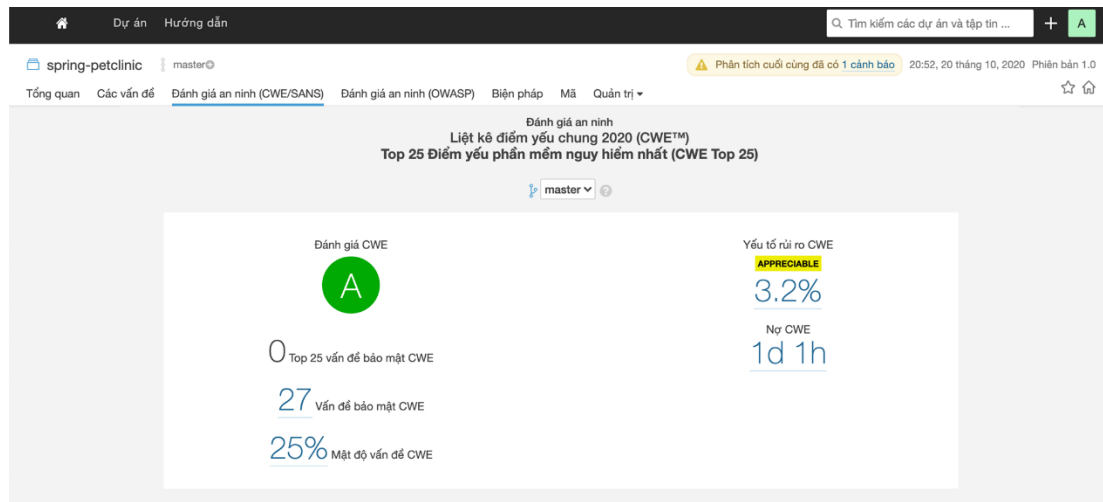

Figure 4: The UX prototype of the solution

logics. The tools should be highly portable and extendable to include new plug-ins or features by request.

Especially, when looking at the focus on FP, simplicity and the ability to customize, the development team had decided to select the combination of SonarQube and SpotBug as the most practical solution with SAST tools. The further development includes SpotBug plugin to a community-version SonarQube and a new SonarQube widget to customize the scanning result. The logical view and development view of the integrated solution is shown in Figure 3. The localized and customized user interface of the tool is illustrated in Figure 4.

5. RQ2: How SAST tools can support security assessment activities in an open-source e-government project?

After conducting the experiment (Section 4) and deciding on SonarQube and Spotbug as the foundation for static testing, the next step is to explore how the tool can be integrated into the e-government system. Semi-structured interviews were conducted with four stakeholders in the project. The profile of the interviewee is given in Table 6. The same interview guideline was used, including three main sections (1) Questions regarding the usability of the tool, (2) Questions regarding the usefulness of the tools for vulnerability assessment, and (3) Questions regarding the

performance of the tools. The interviews ranged from 20 to 30 mins in total. We did note-taking during the interviews and summarized them into three main themes. It is noted that all interviews were done in Vietnamese, so the quotes are translated into English.

Perceptions about the usability of the SAST tools: there has been a consensus among interviewees about the usability of the tool. The user interface has been continuously improved and the final version has been tested with different stakeholders in the project. Before the tool's effectiveness can be evaluated, it is practically important that it can be accessed and operable by targeted users. Some feedback about the interfaces are:

"The user interface is lean and intuitive!" (P04)

"I think the web interface looks good. It is easy to use and for me all the key features are visible. I do not need any manual documents to work with this tool" (P02)

Perceptions about the performance of the SAST tools: the performance of the tools originally refers to the technical capacity of the tools against real-world applications. Our interviewee highlighted the importance of showing the possibility of capture vulnerabilities across different categories of weakness:

“SonarQube has a wide range of test coverage. The adopted version inherited this from the community version and covers different types of vulnerabilities. It is important to be aware of different possible threats to our repository” (P03)

Table 6: Profiles of interviewees

ID	Title	Role in the project	Security expertise (1-lowest 5-highest)
P01	Project manager	Lead the project from planning to completion. Coordinating vulnerability assessment modules with the repository	2
P02	Security expert	Representative of an expert user of a pilot organization	5
P03	System operator	Representative of a system operator in the pilot organization	4
P04	Project developer	A developer of the repository	3

We also see that performance is interpreted as a practical performance, that is the tools should be an indicator of security level and can be integrated into other ways of security assessment:

“The experiments show that the effectiveness of top 3 SAST tools does not differ much from each other. Then we care about how difficult it is and how much time it takes to develop and integrate the selected SAST tools to our repository. The proposed architecture looks great and integral into the overall system.” (P04)

“Testing SAST tools is an important step that giving us confidence in adopting the right tool in the next step. Performance and coverage are important insights for expert teams to decide the security level of software apps” (P01)

Perceptions about the usefulness of the SAST tools: in the nutshell, it seems that the automated tools will not be fully automatically operated in this project. The tools are perceived as useful as a complementary means to assess security. It should be combined with another type of security testing, i.e. DAST and other types of security assessment to give a triangulated result.

“SAST or even the combination of SAST tools and DASTs and other automated tools are not sufficient to ensure a safe software repository. I think the tools play important roles as inputs for expert teams who operate and manage security aspects of the repository.” (P03)

“I think the tool has a good potential! I am looking forward to seeing how DASTs and SAST tools can be combined in this project” (P02)

Answer to RQ2: SAST tools should be used towards a practical performance and in the combination with triangulated approaches for human-driven vulnerability assessment in real-world projects.

6. Discussion

The experiment conducted in this research strengthens the findings from previous empirical studies on SAST tools. We updated the research of SAST tools with the state of the art tool list in 2018. By this time, we still see that using one SAST tool is not enough to cover the whole range of security weaknesses at the implementation phase. This aligns with the observation by [20]. However, the current SAST tools are rich in their features, e.g. ability to support multiple languages, various visualization options, and customizability. Previous studies reported the best precisions values of SAST tools around 0.45 – 0.7 [13, 15, 16]. Our study also reported the precision values of our best tools in this range. We also observed that SAST tools work relatively better in some CWE categories, such as Code quality, Encryption and Randomness, Error Handling, Information Leaks, and Malicious Logic.

In addition to existing studies, we revealed the possibility of combining different SAST tools to achieve better performance. In particular, we have used SonarQube and the base platform and combine the rulesets from other tools. As static analysis uses basically whitebox testing to explore source code, this result shows the potential to improve existing tools, and probably towards a universal security static security ruleset.

Previous studies reported many challenges in adopting SAST tools during different stages of software project life cycles [11-13, 20]. In this study, we focus on the deployment stage where software from other parties is tested before publishing. This quality check gate is common in all software repository models, such as Apple Store or Google Play. The objective of SAST here is different; we aim at supporting security assessment, not guiding software developers to improve their source code. Within the scope of SOREG, we see that the adopted approach is practically useful and contribute to the overall project scope.

Our research also has some limitations. Firstly, we only include open-source SAST tools and only conduct security testing for open-source software. However, as we see from existing research, it might not be too much different in terms of tool performance with commercial SAST tools. Secondly, our research aims at developing a prototype and evaluating the proposed solution, therefore, we did not focus on architectural details and implementation. It could be that the perceived usefulness can be improved when we have a full-scale development of the combined SAST solution. Thirdly, we preliminary tested our SAST tools with a simple software application. The claimed results are mainly based on our experiments with the Juliet test suite. A case study with a large-scale industrial application might provide more insight that is complementary to our findings. Last but not least, the study is conducted in the context of a Vietnamese government project, which would have certain unique characteristics regarding organizational and managerial aspects. However, the research design was conducted separately in Norway and the observation process has been conducted with scientific and professional

attitudes. The experiment data is available published at https://docs.google.com/spreadsheets/d/18FXJKWsO6m9Ac9_-92aGmDqMd6QdFLK_rIZ9P7fF_wQ/edit#gid=2107814246.

We tried to report as detail as possible the experiment process so that one can replicate our work in the same condition.

7. Conclusions

We have conducted a case study on a 2-year project that develop and evaluate a secured open-source software repository for the Vietnamese government. This paper reports a part of the paper about evaluating and combining SAST tools for security assessment. Among evaluated SAST tools, we have found that Sonarqube and IntelliJ have the best performance. The combination does give a better performance than a single SAST, depending on the performance metrics. Practically, these SAST tools should be used towards a practical performance and in the combination with triangulated approaches for human-driven vulnerability assessment in real-world projects. In the future work, we will report the next step of the project, with a similar investigation on DAST and the effectiveness of combining SAST tools and DASTs in supporting software security assessment.

ABSTRACT

Light Emitting Diode (LED) lamps are used as a replacement of “old-fashioned” or incandescent lighting sources, as they reduce the amount of energy consumed. As a side-effect of more efficient energy usage they produce electrical noise. This noise reduces the efficiency of information signal transfer when Power Line Communications (PLC) are used. This study focuses on the noise signatures of LED lamps which have a direct impact on the information transfer of the PLC channel. The contribution of this study is that two categories of noise characterisations are given. First is equations describing the maximum and minimum bounds of the lamp noise current. This is useful in calculating channel throughput where an equation for the noise is required. For example, the Shannon-Hartley theorem. Second is a methodology to determine individual frequencies in the spectrum of harmonics emanating from the lamp. Both these characterisations will aid in designing communication schemes for PLC. An unexpected result of this study was to find LED lamps which had inadequate or no Electromagnetic Interference (EMI) filters. These lamps produce noise in orders of magnitude higher than properly filtered LED lamps.

1. Introduction

Light Emitting Diode (LED) lamps or bulbs are used as a replacement of “old-fashioned” or incandescent lighting sources. They reduce the amount of energy consumed. As lighting is a main category in electricity consumption [1], improving efficiency of light sources are paramount to long term energy savings. Although LED lighting is more energy efficient its operation produces electrical noise [2]. This can have a detrimental effect on Power Line Communications (PLC) [3].

PLC is used in lieu of physical data cable connections or wireless connections such as Wi-Fi. Since power cables already connect different nodes possible to communicate, PLC usage is advantageous where a minimum of added infrastructure is required. An application of importance is for the Smart Grid [4]. It is envisaged that a future Smart Grid will control and schedule loads actively and in real time with PLC. By doing this, energy transfer via the electrical network will be optimised. In the future,

households will communicate via the power lines (i.e. PLC) to not only provide control but also Information and Communications Technology ICT services. Since the electronics for using PLC is cheaper and radio spectrum need not to be used, PLC seems to be the economical option [5].

PLC is used to transmit and receive data across physical power cables. PLC systems are divided into so called Narrow Band (NB) and Broad Band (BB) types.

NB PLC is used for control signals with a low data rate and typically has a carrier frequency of up to 150 kHz [6,7]. BB PLC is used to convey internet on the power line in lieu of Wi-Fi. It has carrier frequencies typically up to 30 MHz [8]. For further investigation, readers are referred to [9-12].

The PLC channel can be viewed as a classical communications channel. In such a channel, the Shannon-Hartley equation [13] for information transfer holds or:

*Corresponding Author: Hendrik Ferreira, Email: telecoms@uj.ac.za

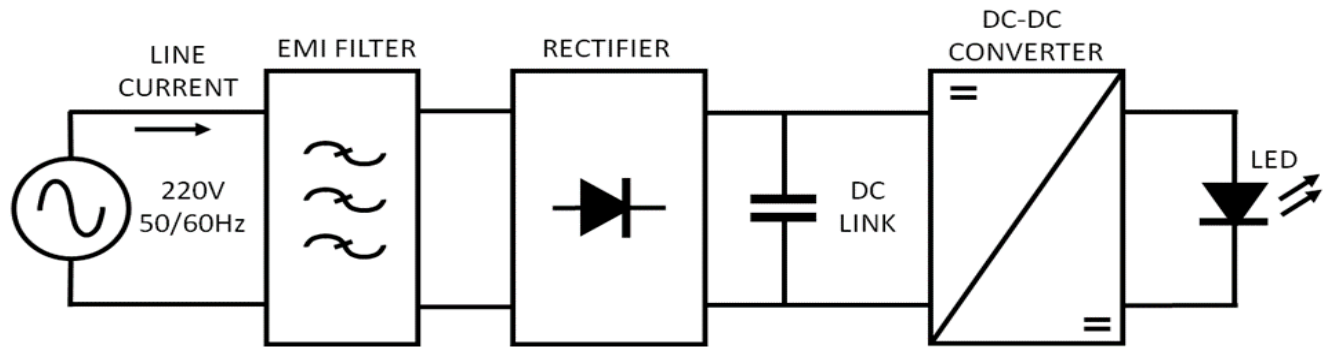

Figure 1: Block diagram of a typical LED lamp of the type used in this study

$$C = B \log_2 \left(1 + \frac{S}{N} \right) \quad (1)$$

where C is the maximum theoretical channel capacity in bits per second, B is the bandwidth of the channel in hertz, S the signal strength or averaged received signal power across the bandwidth in watts and N is the average power of the noise / interference across the bandwidth, also measured in watts. The purpose of this paper is to characterise N , as S and B are usually predetermined as follows:

- The signal strength S is subject to Electromagnetic Compatibility standards [14] where a maximum signal strength is specified.
- The bandwidth B is allocated by spectrum regulations.

It therefore stands to reason that in (1), C is determined by N if B and S are fixed. In this paper the noise characteristics of LED lamps (N in (1)) are investigated and measured. The noise spectra measured from the lamps can therefore be applied as the channel noise for a PLC channel.

This paper characterises the LED lamp noise spectra in two ways:

- First is to describe the noise spectrum across a band. Two bands have been chosen: 150 kHz for representing NB PLC and 30 MHz for representing BB PLC. In both cases the bands are characterized by equations giving an upper limit for maximum noise and lower limit for minimum created noise.
- The second part is to determine unique harmonics in the noise signature. It is shown that when zooming into the created noise spectra, certain harmonics (governed by switching and rectification) stand out and can uniquely be identified.

Results from both of these two vantage points can aid a designer in estimating channel throughput and designing modulation schemes for a channel with LED lamp noise present.

An unexpected result of this study was to find LED lamps which had inadequate or no Electromagnetic Interference (EMI) filters. These lamps produce noise in orders of magnitude higher than properly filtered LED lamps. This can have a large adverse effect on PLC channel throughput.

2. LED Lamp Structure

In this section a generic model of an LED lamp is proposed and used to explain how interference is created on the power line by

the lamp operation. Lamps measured in this study follow this broad topology.

Figure 1 shows a high level block diagram of a typical LED lamp of the type that was measured in this study.

Starting at the left hand side of figure 1, is the source of 220VAC or 110VAC, 50 Hz or 60 Hz. This passes through an EMI filter. The filter reduces the noise being generated by the LED lamp as seen on the supply grid. One must not confuse the direction of main power flow with that of the noise. The main power flow is from left to right, AC supply to LED while noise is generated by the lamp circuitry and permeates through to the supply grid (right to left). A rectifier is used to produce DC from AC. At the rectifier output is a DC-link capacitor reducing the ripple on the DC link. A DC-to-DC converter is used to drive the LED. This converter usually operates with a current output as the brightness of the LED is determined by current through the LED but with a relatively constant voltage.

Figure 2 illustrates noise generation in an LED lamp. High frequency switching noise is produced by the DC-to-DC converter and present itself on the DC-link current. Conventional wisdom will have it that this high frequency noise (in the tens of kHz) will be supplied by the DC-link capacitor and not seen on the line. This is however not the case. The DC-link capacitor is rated for 50Hz/60Hz and have a large Equivalent Series Inductance (ESL). The capacitor ESL keeps it from by-passing the high frequency noise. Subsequently the DC-DC converter noise travels through the rectifier (when a rectifying diode is conducting) and presents itself on the line current – superimposed on the nonlinear rectifier current shape.

EMI Filters are used to mitigate noise to below compliance levels [15]. These filters reduce noise from two noise sources. One is the high frequency noise from the DC-to-DC converter and another is line rectifier harmonics. It is interesting to note that some LED lamps have no EMI filters. This was found when using both local and imported brands. This is apparently done to save costs and where enforcement of EMI standards is not very strict. Typical results of LED lamp noise with sufficient EMI filtering vs those with low or no filter are shown later in this article.

Throughout this article noise from LED lamps is measured as current. Noise currents are converted to voltages after flowing thorough line impedances. These impedances are highly network specific and noise voltages will vary depending on the network

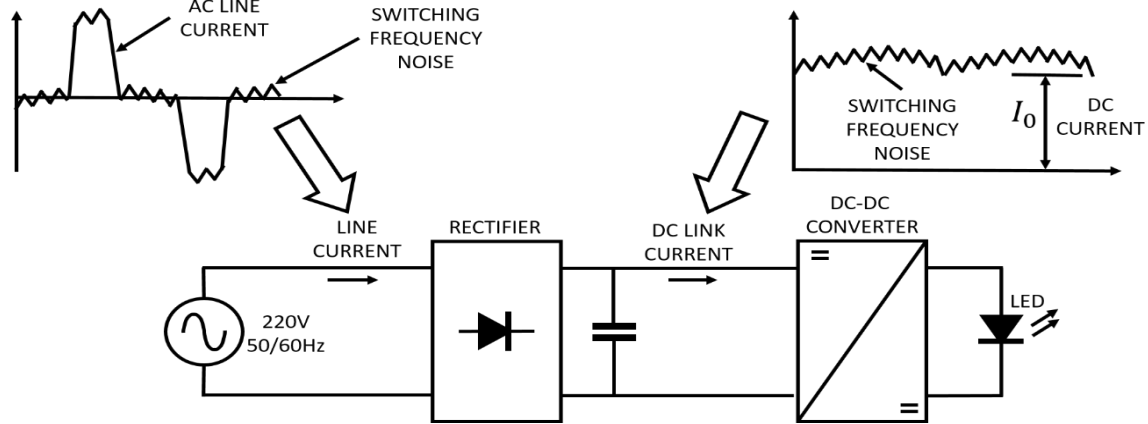

Figure 2: Illustration of LED lamp noise generated by the DC-to-DC converter and processed through the rectifier

Figure 3: Measured input voltage to the LED lamp and current drawn for a 5.5W LED lamp at the AC line side

Figure 4: Measured harmonics for the input current drawn (figure 3) in a 5.5W LED lamp

configuration. The results given in this study is worst case as if the network is short and noise currents are directly converted to voltages.

3. Rectification

As can be seen in figure 2, DC-link current is converted from a predominant DC current at the DC-link capacitor to the typical wave shape of current through a rectifier. For details see [16] and [17]. The difference between a normally rectified current at the input to the rectifier is the presence of high frequency noise in a LED lamp. This is the “switching frequency noise” shown in figure 2. In this study two “types” of noise are investigated; the low frequency rectifier noise (and subsequent harmonics) and the high frequency switching noise. This section deals with the rectifier noise (or creation of rectifier harmonics) while the rest of this paper deals with the added high frequency switching noise.

As an example, measured time domain line voltage and current waveforms for a 5.5W LED lamp are given in figure 3. For this low frequency (50 Hz to 1 kHz) time domain measurement, voltage and current probes (Tektronix TCP0030) were directly attached at the line side of the LED lamp. A Tektronix (DPO7254) oscilloscope was also used in this experimental measurement.

Figure 4 gives the line current harmonics for the current waveform of figure 3 up to 1kHz. It shows current components (harmonics) in 50Hz intervals – as the fundamental is 50Hz. It is important to take note of this spectrum shape as it becomes the modulating function for the DC-to-DC converter switching (carrier) frequencies – as showed later in this paper.

4. High Frequency Measurement Set-Up

Figure 5 shows the current measurement setup for higher frequencies (typically up to tens of MHz). This set-up is different from that of the previous section where the voltage and the current were of relatively low frequency (up to 1kHz) and in Differential Mode (DM) only. In the previous section voltage and current were directly measured on the incoming line. Higher frequency conducted noise usually has components in both differential and Common Mode (CM). Since the PLC channel is differential in nature, measurements were made in DM and CM discarded. The CM contribution of the LED lamp noise source was cancelled as

shown by the routing of the power cables through the high frequency current probe in figure 5.

Also shown in figure 5 is a Line Impedance Stabilisation Network (LISN). This device supplies the lamp with 220V/50Hz for power but blocks higher frequency noise from the supply network from interfering with the measurement side noise that is generated by the LED lamp. Since it has a high leakage current to earth, an isolation transformer is used; keeping the LISN from tripping the protective earth leakage. The LISN also provides a standardised high frequency noise load impedance to the noise generating LED lamp.

The high frequency current harmonics produced by the LED lamp are measured using a Rhode & Schwarz FSH323 Spectrum Analyzer and ETS-Lindgren 94111-1L 1GHz bandwidth current probe and processed by a PC.

5. Measurement Results

Using the measurement set-up of figure 5, the noise current of different LED lamps was measured. Figure 6 shows results for a measurement span of 30MHz. This span is representative of a broad band high frequency PLC operating region. Figure 6 also shows the Electromagnetic Compatibility (EMC) Limits (according to EN55015: 2013 for lighting) – for reference. Background noise levels were conducted with the set-up as shown in figure 5, but with the power switched off.

Some of the LED lamps do not produce noise current significantly above the background noise levels. Two of the measured LED lamps however, produce noise levels comparable and exceeding the EN55015 limit - implying non-compliance. Note that in the original EN55015 specification, the noise limit is indicated in volts generated across the LISN impedance. This was converted to a current limit by using the DM LISN impedance for comparison in figure 6.

The large difference in interference produced by different LED lamps is due to the inclusion (or exclusion) of an EMI filter in the product. Lamps that produce noise current at levels just above the background have EMI filters. The FS200 and 3W LED lamps in figure 6 do not have or have limited EMI filtering and are therefore noisy.

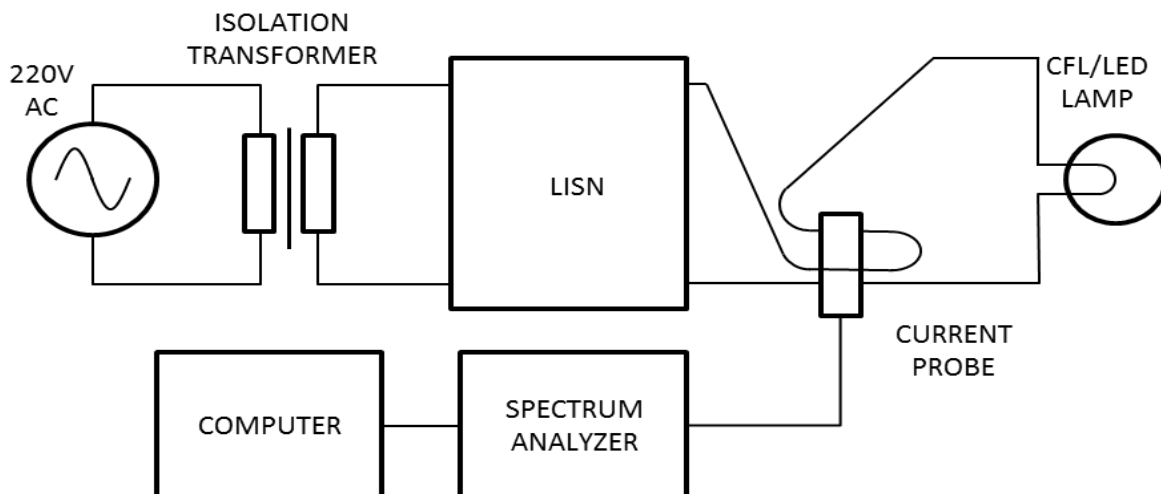

Figure 5: Measurement set-up for higher frequencies

Figure 6: Noise current measurements for different LED lamps across a span of 30MHz

Figure 7: Noise current measurements for different LED lamps across a span of 150kHz

With the same set-up as in figure 5, measurements were taken across a span of 150kHz. This span is equal to the so called 'CENELEC' band (or Narrow Band) [14] for low frequency PLC operation. The results are shown in figure 7. As with the results across 30MHz (figure 6), measurements of the background noise floor were done to compare noise contributions of the different LED lamps.

Figure 7 clearly shows the switching frequency spectrum of the DC-DC converter part (see figure 1) of the different LED lamps. As examples, the FS200 type and a 3W type switch around 40kHz (switching fundamental). Harmonics are present around 80kHz (2nd harmonic) and 120kHz (3rd harmonic). The other LED lamps' noise spectra that is above the noise floor also follow this pattern.

Figure 8: Curve fitting to noise current measurements for different LED lamps across a span of 30MHz

An interesting aspect of the measurements done is that at higher frequencies (kHz and MHz) the power line noise is not influenced primarily by the amount of power consumed. It is rather a function of the quality of the EMI filters and the original amount of noise produced (pre-filtered). For example, in figure 7, the 1.2W type G219RD generates more noise than the 10W, G965 type. It has been found that some LED lamps do not contain EMI filters (or inadequate filtering) - especially produced for the local market where EMI regulations are not strictly enforced.

6. Bounds on Interference Through Curve Fitting

To use the interference measurements in an equation (for example (1)), it is convenient to have an expression for the noise current. To this end, the worst case noise current spectra (upper bounds) in figure 6 and figure 7 were curve fitted. A typical low noise LED lamp from figure 6 and figure 7 were also curve fitted giving to give a maxima and minima (lower bound) for figure 6 as well as for figure 7.

The table below illustrates the peak values obtained from all LED lamps used for experimental measurements in figures 6 and 7.

Table 1: Summary of significant values obtained from figures 6 & 7

LED Size (Watt)	Noise Frequency (kHz)		Noise Value (dBμA)	
	Figure 6	Figure 7	Figure 6	Figure 7
1.5	1900	17	-10	13
3	3200	38	25	46
4	1200	67	0	48
5	3000	12	-4	35

6	1500	52	4	53
10	1600	57	3	40
20	3600	38	47	73

Figure 8 shows the curve fitting results across a 30MHz span with data taken from figure 6. The expression for the upper bound noisiest LED lamp (FS200) is:

$$y = -6.041 \ln(x) + 141.41 \quad (2)$$

The lower bound for a low noise lamp (G219GN) is:

$$y = -10.81 \ln(x) + 155.85 \quad (3)$$

The y-values are the noise current in dBμA and the x-values the frequency in Hz.

Figure 9 shows the curve fitting results across a 150kHz span with data taken from figure 7. The expression for the upper bound of the noisiest LED lamp (FS200) is:

$$y = -6 \cdot 10^{-15}x^3 + 3 \cdot 10^{-9}x^2 + 0.0005x + 88.236 \quad (4)$$

The lower bound for a low noise lamp (G965) is:

$$y = -17.03 \ln(x) + 194.95 \quad (5)$$

The y-values are the noise current in dBμA and the x-values the frequency in Hz.

7. Amplitude Modulation

The bounds expressed in the previous section are useful when uniform noise spectra are used to determine PLC channel interference across a large bandwidth. This section however,

Figure 9: Curve fitting to noise current measurements for different LED lamps across a span of 150kHz

Figure 10: Spectrum of the line current consisting of the combination of the DC-to-DC converter switching harmonics and the line rectifier harmonics (flipped around the converter switching harmonics).

shows how a high frequency carrier signal (for example a single converter switching frequency harmonic) is modulated by a lower frequency signal (the rectifier harmonic spectrum (see figure 4)). This leads to determining specific harmonic content as opposed to the blanket bound description where specific frequencies are not addressed. This is useful to know when particular frequencies interfere with the PLC. If this happens either the NB PLC carrier

must be shifted or the switching frequency of the DC-to-DC converter or both.

Figure 2 shows how high frequency switching noise is permeated by the DC-to-DC converter to appear at the LED lamp input. This converter noise is also seen on the DC link current. The high frequency switching noise is exaggerated in figure 2 for

Figure 11: Measured line current harmonics around a switching frequency of 54.058 kHz for a 5.5W LED lamp from a 50 Hz supply. The harmonics surrounding the switching frequency are similar than the rectifier harmonics and spaced in 50 Hz increments

illustration purposes. The DC link capacitor is usually not sufficient to reduce this noise as the capacitor is large with a significant Equivalent Series Inductance (ESL).

In the rest of this section it is shown how the harmonics surrounding the switching frequency are similar than the rectifier harmonics and spaced in 50 Hz increments. This is graphically illustrated in figure 10. Using the structure of an LED-lamp as shown in figure 1 and the extended version showing noise added from the lamp in figure 2, the harmonics of the line current are graphically illustrated in figure 10. Figure 11 shows a practical measurement that is a part of the spectrum shown at the bottom of figure 10.

The bottom graph of figure 10 is a harmonic interpretation of the line current seen at the input of the LED lamp. This line current spectrum is a convolution of two noise source spectra. The first is the high frequency switching harmonics of the DC-to-DC converter and the second is the low frequency line rectifier harmonics. The line current rectifier spectrum is repeated (in frequency components) by the switching frequency harmonics. Every switching frequency harmonic is flanked with the positive and negative of the rectifier spectrum.

To show this theoretically (and to simplify the mathematics), a single carrier (switching frequency harmonic) is shown to be modulated by a single low frequency harmonic (rectifier frequency).

The rest of this section shows theoretically how the process of figure 10 works. The line current signature frequencies are illustrated by simplifying the mathematics to use a single

frequency amplitude modulating a higher single frequency carrier. Say for example a low frequency $\omega_l f = 2\pi f$ ($f=50\text{Hz}$) is modulating a carrier of higher switching frequency $\omega_h f$ (around 55 kHz). With reference to figure 2, $\omega_h f$ is representing the switching frequency noise on top of the DC link current and $\omega_l f$ the line frequency at the lamp input.

From [18] it can be shown that the first harmonic of an ideal single-phase rectifier line current can be written as:

$$i_{line_harm1}(t) = \frac{4i_{DC-link}}{\pi} \sin(\omega_f t) \quad (6)$$

An idealized constant DC link current of 10 is specified in [18]. A high frequency switching converter will draw a high frequency current from the source through the rectifier. The DC-link current (for the first harmonic of switching converter current) is:

$$i_{DC-link}(t) = I_0 + I_{hf} \sin(\omega_{hf} t) \quad (7)$$

The modulation index is $m = I_0/I_{hf}$ and generally $m \gg 1$, as the switching harmonic current is much smaller than I_0 in practical converters. Combining (6) and (7) and using trigonometrical identities, the idealized single harmonic line current is:

$$i_{line_harm1}(t) = \frac{4I_{hf}}{\pi} \left[m \sin(\omega_f t) + \frac{1}{2} \cos[(\omega_{hf} - \omega_f)t] - \frac{1}{2} \cos[(\omega_{hf} + \omega_f)t] \right] \quad (8)$$

Equation (8) shows an AM signal with fundamental at ωf and sidebands (of distance ωf) around ωf . This pattern, where the rectifier harmonics present around the switching frequency and its harmonics are experimentally shown in figure 11. Note that the carrier (ωf or f_{switch}) is not present (or suppressed) as with a conventional AM signal as $m \gg 1$.

If the spectrum is enlarged around the first switching frequency (54.058 kHz in figure 11) the line current harmonics become clearly visible in 50Hz increments and is indicative of a switching converter / rectifier combination. In this case, the carrier (f_{switch}) is not dominant as with a conventional AM signal.

An EMI signal from a LED lamp can thus be identified by first finding the switching harmonics. Around the switching harmonics will be the rectifier spectrum with main components flipped at $f_{\text{switch}} \pm 50\text{Hz}$, $f_{\text{switch}} \pm 150\text{Hz}$, $f_{\text{switch}} \pm 250\text{Hz}$ and so on (in the case of a 50Hz line frequency).

8. Conclusion

In this paper it is argued that noise from an LED lamp can interfere with PLC. The LED lamp noise will have an impact on the PLC channel throughput. It is argued that high frequency noise permeates from an LED lamp to the input line over which PLC takes place.

In this paper only LED lamps with a rectifier and high frequency DC-to-DC converter combination are dealt with.

A contribution of this study is that result sections for LED-lamp noise are provided. The noise spectra of LED lamps (across a band) are described with expressions for upper and lower bounds giving maximum and minimum interference (NB up to 150 kHz and BB up to 30 MHz). These are useful when expressing the noise in channel throughput calculations (such as (1)). It was shown that some LED lamps radiate above the EMC limit and the interference level can decrease PLC operations, resulting in reduced data throughput.

The second contribution of this paper shows how individual noise harmonics can be identified. The rectifier line spectra modulate (in AM fashion) around switching frequency harmonics and appears as spectra with a switching frequency at its centre. This knowledge is useful for fixed carrier PLC where specific frequencies are of concern; for example, if a noise harmonic blanks a valid PLC carrier frequency.

An interesting conclusion arrived at when testing different LED lamps for noise are that some lamps employ poorly designed or no EMI filtering.

Using the results from this paper, designers should be able to estimate some of the adverse effects of LED lamps on the PLC channel.

Permanent magnet synchronous motors

ABSTRACT

This paper presents a new observer-based method which deals with the extraction of amplitude of characteristic frequencies for the fault diagnosis in permanent magnet synchronous motors (PMSM). First, a pilot survey is made to investigate the typical harmonics in the line currents of PMSM. Second, an appropriate structure of observer is formulated with the input of current signature in the time domain. By transforming into the Laplace domain, the convergence of the observer is proven. Using the proposed observer, a feature extraction method for fault detection can be introduced; in which the Park's vector module (PVM) of the line currents is selected as the signature for the feature extraction of the amplitude at the second order harmonic. Simulation and experiment of the PMSM operating in speed control mode are carried out to provide the line current data for analysis. The results show that the amplitude of second order harmonic can be calculated and on-line monitored that demonstrates the effectiveness of the proposed method.

1. Introduction

The permanent magnet synchronous motors have been widely used in various industrial applications due to several advantages, including small size, light weight, and simple structure. Regarding the operation variables, these motors are known with prominent features of high efficiency, high power and torque density. Therefore, they are usually preferred selection in various home and industrial applications, such as electric vehicles, manufacturing systems, full-rated converter-based wind power systems and so on [1].

During the service, the motor suffers from electrical, mechanical and thermal stresses that several faults, including the electrical, mechanical and magnetic faults, may occur. Stator inter-turn short circuit is considered as the most common fault in permanent magnet synchronous motors (PMSM) with about 31% of all failures [2]. The inherent aggressive growth and self-intensifying feature of the inter-turn fault in the stator lead to more faulty turns, phase-to-phase and phase-to-ground fault or can demagnetize permanent magnets irreversibly [1]. Consequently, the motor performance is seriously affected in the breakdown duration. Hence, it is essential to adopt a timely and precise diagnosis method in order to quickly detect the faults in PMSM system and have the warning signal to operators.

The literature review shows that diagnostic techniques for machines can be divided into three groups: model-based fault diagnosis methods, signal-based fault diagnosis methods and data-driven intelligent diagnosis methods [1], [3]. The fault diagnosis methods of the PMSM have been primarily built on the basis of the knowledge of machine model or signals. The model-based techniques are used to detect the fault by monitoring the difference between the measured output and model output to determine the fault type. Electrical equivalent circuit (EEC) models, magnetic equivalent circuit (MEC) models and finite element model (FEM) are commonly used to identify the inter-turn short circuit, eccentricity and demagnetization faults. However, the effectiveness of this method depends on the accuracy of the machine model. Meanwhile, in the signal-based methods, the measured signals are extracted to obtain the faulty feature in order to issue diagnosis decision. The feature can be extracted in frequency domain, time-frequency domain, wavelet domain or in the form of statistical one [1], [4]. The classical method carried out in frequency domain was fast Fourier transform (FFT) where the characteristic frequency could be clearly shown in the spectrum of the faulty signatures [4]. The FFT was extended to Short-time Fourier transform (STFT), which was implemented with time-frequency analysis in order to keep the time information [5]. The signal was divided into small time windows to provide a high resolution. This method allows dealing with nonlinear complex signal. However, the disadvantage of this STFT is the time and

*Corresponding Author: Hoàng Giang Vu, giangvh@epu.edu.vn

frequency resolution does not accurate at the same time, therefore it requires a high computation cost in order to get great resolution. This drawback is overcome by using Hilbert-Huang transform (HHT) method. Based on Hilbert-Huang transform, a signal processing in time-frequency domain could be achieved and implemented in transient conditions [2], [6]. To deal with the problem of false alarm in transient conditions, the wavelet-based technique was another favorite choice to be applied in the diagnosis systems [7]. In company with the development of artificial intelligence and machine learning, many data-driven intelligent diagnosis algorithms have been suggested recently to identify PMSM faults. Deep learning and support vector machine have been interested by many researchers because of their high intelligence. But the drawback of high requirements for hardware and long processing time limit the application of data-driven intelligent diagnosis method [1].

In the case of stator inter-turn short circuit, several methods that are classified by the applied signals, such as the current, voltage, torque, flux, electric and magnetic parameters, have been introduced [8]. Because the appearance of the inter-turn short circuit modifies the spectra of the current, the fault can be recognized. Once the fault occurs, the magnetic field distribution in the motor will vary. Therefore, there will be an increase in the amplitude of high-order harmonics or the appearance of new inter-harmonics. It is noted that, the harmonics in the line current are not only due to the imperfect sinusoidal flux distribution, the dead time of converter and the offset of sensor [9] but also the occurrence of inter-turn short-circuit faults in the machine [10]. The most common technique in the fault diagnosis, which always comes first in the selection for the fault diagnosis in both steady state and transient conditions, is based on the machine current signature analysis (MCSA).

In what follows, the indexes that are applied in the steady state operation of PMSMs will be synthesized.

Spectral analysis of magnetic field signal in the air gap shows that the inter-turn short-circuit faults cause an increase in the amplitude of sideband components at the different frequencies (f_B) as calculated in (1) [11]:

$$f_B = \left(1 \pm \frac{2k}{P}\right) f_1 \quad (1)$$

where $k = 1, 3, 5, \dots$; P is the number of poles; and f_1 is the fundamental frequency.

Consequently, the spectrum of other motor state variables such as current, torque, and speed will include some interest frequencies. In case the supplied voltage is sinusoidal, the frequency pattern in the current due to inter-turn short circuit (f_i) is presented as [8], [11], [12]:

$$f_i = \left(1 \pm \frac{2k+1}{P}\right) f_1 \quad (2)$$

where $n = 1, 3, 5, \dots$; $k = 1, 2, 3, \dots$

Thus, the amplitude of this harmonic is a good indicator for fault diagnosis. The third-order harmonic of the negative frequency in the line current of permanent magnet brushless DC motor's (BLDC motor) was reported and used as the fault index

since it is independent from the imbalance of supplied source and operating conditions. However, the drawback of this method is inefficient in low speed or light load [13]-[15]. Moreover, the inter-turn fault also causes the third-order harmonic in the line current [2].

Monitoring the amplitude of the second-order harmonics in both current and voltage also allows detecting the inter-turn short-circuit fault. In [8], the Park's vector is transformed from three phase line currents; and its module is extracted to obtain the amplitude at $2f_1$ (two times of the fundamental frequency) as the index for the fault detection. In [16] authors have shown the noticed feature of the inter-turn short-circuit fault is the magnitude of the second harmonic of the control voltages.

In this study, we propose a method to extract the second order harmonic amplitude in the PVM spectrum for detecting the stator inter-turn fault of PMSM at varying load levels by using an observer. The feature extraction can be implemented online that allows establishing a detection method to timely monitor the machine condition. Since only second order harmonic is focused, the method offers a robust signal analysis and a narrow window of frequency to be concerned.

The paper is organized as follows. Section 2 shows the performance of proposed observer. Section 3 introduces the model of PMSM. Afterwards, the extraction method using the proposed observer is presented. Simulation and experimental results are shown in Section 4 to illustrate the effectiveness of the proposed method. Finally, some conclusions are given in Section 5.

2. Observer-based extraction method

This section presents the convergence proof for the observer in the condition that the PVM of line currents includes multiple harmonics. As aforementioned in section 1, in the three-phase system, the currents of PMSM include offset and principal harmonics of 5th, 7th, 11th, 13th order components. Consequently, the PVM is composed of a DC component and other harmonic components in which the second order needs to be extracted for fault detection. Hence, the PVM can be expressed as:

$$i = I_0 + \sum_{k=1}^n I_k \sin(k\theta + \phi_k) \quad (3)$$

where i is the PVM of the line currents, I_0 is the DC component, I_k, ϕ_k represent respectively amplitudes and phase angles of k^{th} harmonics ($k = 1$ for the fundamental), and n is the highest harmonic order that is taken into account. Note that the electrical angle $\theta = \omega t$ where ω denotes the fundamental angular frequency.

It is equivalent to rewrite currents from (1) in the following form:

$$i = I_0 + \sum_{k=1}^n (I_{k1} \sin(k\theta) + I_{k2} \cos(k\theta)) \quad (4)$$

where $I_{k1} = I_k \cos(\phi_{ak})$, $I_{k2} = I_k \sin(\phi_k)$

Thus, the values of I_{k1} and I_{k2} are estimated to determinate k^{th} harmonic in the current i . Following this, the current harmonic observer is described as follows:

$$\hat{I}_0 = \alpha(i - \hat{i}); \hat{I}_{k1} = \alpha \cdot \sin(k\theta)(i - \hat{i}); \hat{I}_{k2} = \alpha \cdot \cos(k\theta)(i - \hat{i}) \quad (5)$$

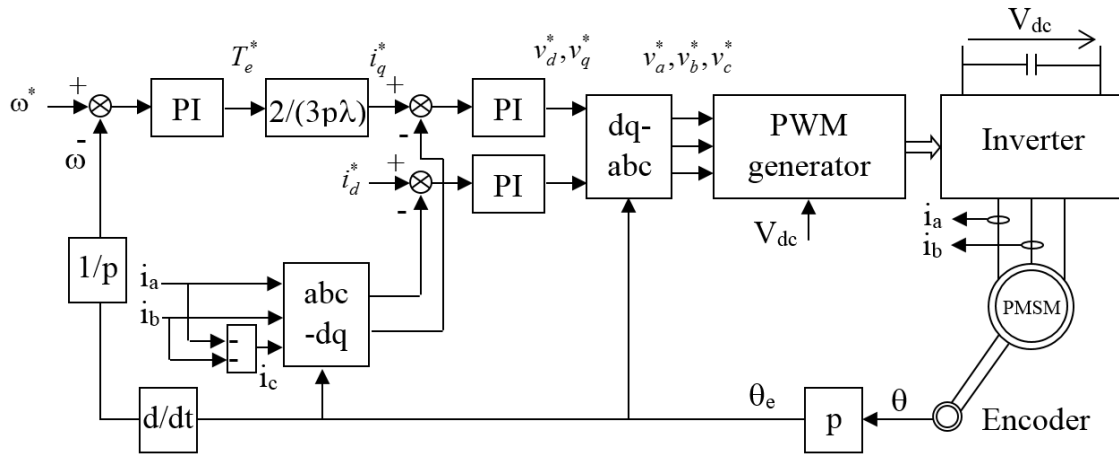

Figure 1: Control diagram of PMSM.

where

$$\hat{i} = \hat{i}_0 + \sum_{k=1}^n \hat{i}_{k1} \sin(\theta) + \hat{i}_{k2} \cos(\theta) \quad (6)$$

Let denote for each estimated components from (4):

$H_k(t) = \hat{i}_{k1}(t) \sin(k\omega t) + \hat{i}_{k2}(t) \cos(k\omega t)$, and for DC part $H_0(t) = \hat{i}_{a0}(t)$. Hence $\hat{i}(s) = H_0 + \sum_{k=1}^n H_k$

Inspired of frequency analysis idea in [17] with Laplace transform, we obtain the following:

$$H_0(s) = (i(s) - \hat{i}(s)) \frac{\alpha}{s}, \quad H(s) = (i(s) - \hat{i}(s)) \frac{\alpha s}{s^2 + (k\omega)^2} \quad (7)$$

Furthermore, it can be deduced that

$$\hat{i}(s) = H_0 + \sum_{k=1}^n H_k = (i(s) - \hat{i}(s)) \left(\frac{\alpha}{s} + \sum_{k=1}^n \frac{\alpha s}{s^2 + (k\omega)^2} \right) \quad (8)$$

Therefore,

$$G(s) = \frac{\hat{i}(s)}{i(s)} = \frac{\frac{\alpha}{s} + \sum_{k=1}^n \frac{\alpha s}{s^2 + (k\omega)^2}}{1 + \frac{\alpha}{s} + \sum_{k=1}^n \frac{\alpha s}{s^2 + (k\omega)^2}} \quad (9)$$

Considering the transfer function $G(s)$: its gain is one at $s = 0$ and $s = jk\omega$, and almost zero if not. It implies the convergence $\hat{i}(t) \rightarrow i(t)$ when $t \rightarrow \infty$, and other convergences of harmonic observer components.

Applying proposed observer, a method of feature extraction can be developed. Specifically, the line current is collected and transformed into the synchronous reference frame to obtain PVM, which is used as the faulty signature for the PMSM diagnosis. The amplitude of second order harmonic is computed and on-line monitored using the observer. Accordingly, whenever there is an increase in the amplitude, the alarm signal can be issued warning the fault.

3. PMSM model

The mathematical model of the PMSM in the synchronous reference frame can be expressed by [18]:

$$\begin{cases} \frac{di_d}{dt} = -\frac{R_s}{L_d} i_d + p\omega \frac{L_q}{L_d} i_q + \frac{v_d}{L_d} \\ \frac{di_q}{dt} = -\frac{R_s}{L_q} i_q - p\omega \frac{L_d}{L_q} i_d - p\omega \frac{\lambda}{L_q} + \frac{v_q}{L_q} \\ \frac{d\omega}{dt} = \frac{1}{J} (T_e - F_v \omega - T_m) \end{cases} \quad (10)$$

where

i_d, i_q : d-axis and q-axis stator currents, respectively;

v_d, v_q : d-axis and q-axis stator voltages, respectively;

ω : Angular velocity of the rotor;

λ : Amplitude of the flux induced by the permanent magnets of the rotor in the stator phases;

R_s : Resistance of stator windings;

L_d, L_q : d-axis and q-axis inductances;

T_e : Electromagnetic torque, $T_e = 1.5p[\lambda i_q + (L_d - L_q)i_d i_q]$;

T_m : load torque; J : Inertia coefficient; and F_v : Friction coefficient.

Figure 1 shows the control diagram of PMSM, which is designed with the speed and stator current controllers. The line currents (i_a and i_b) and the rotor position (θ) are the feedback of the controllers. In the next section, the simulation will be carried out to provide the necessary data for the feature extraction.

4. Estimation results

In order to demonstrate the performance of the observer, simulation of PMSM is developed in the following conditions:

- The motor is simulated using the model given in Eq. (10) of the Section 3; and the motor parameters are given in Table 2;
- The PMSM is inverter-fed and controlled to operate in speed control mode, shown in Figure 1. The reference speed is set equal to 500 rpm;

- In order to simulate the faulty condition, a resistor is added to one phase of the motor creating an unbalance condition in the stator windings, as illustrated in Figure 2, which is similar to inter-turn short circuit condition.

Figure 2: Stator windings with additional resistance [19].

- Three levels of load torque are applied to the PMSM system, i.e $T_m = 0.05$ N.m; $T_m = 0.15$ N.m; and $T_m = 0.075$ N.m, shown in Figure2; They are selected to observe whether the amplitude of the second order harmonic in the PVM signal varies due to load conditions or the appearance of fault.

Figure 3: Torque level applied to the PMSM (upper) and PVM of stator currents (lower).

- The PVM is calculated by Eq. (11) from the two-axis currents (i_d , i_q), which are obtained by the Park transformation of the line currents (i_a , i_b).

$$PVM = \sqrt{i_d^2 + i_q^2} \quad (11)$$

Table 1: Data of the permanent magnet synchronous motor

Motor voltage	V_{nom}	20.12 V
Motor current	I_{nom}	3.42 A
Load torque	T_{max}	0.2259 N.m
Line-line stator resistance	R_s	0.57 Ω
Line-line stator inductance	L_s	0.64 mH
Torque constant	K_t	0.0592 Nm/A
Total inertia coefficient	J	$1.7721 \cdot 10^{-5}$ N.m/rad/s ²
Voltage constant	K_e	6.2 Vpeak L – L/krpm

If the load torque depicted in Figure3 (upper) is applied to the motor, the PVM is correspondingly obtained as in Figure3 (lower).

The PVM is used as the input of the observer which computes the amplitude of second order harmonic by using the algorithm presented in section 2. The implementation of this observer is illustrated in Figure4, in which $K = 10$ that is obtained by tuning.

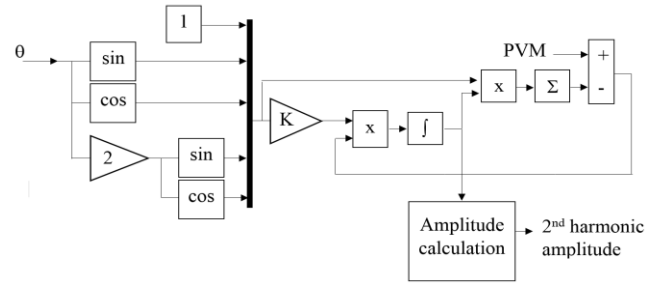

Figure 4: Diagram of observer implementation.

In order to create a reference for validation of the estimated results of the observer, the PVM is analyzed by Fast Fourier Transform algorithm. As a result, the spectral of PVM are obtained and depicted in Figs. 5, 6 and 7 for load torque levels of 0.05 N.m, 0.15 N.m and 0.075 N.m respectively. It can be seen in all figures that the amplitudes of second order harmonics of the PVM in faulty conditions are 0.04 A, 0.013 A and 0.07 A corresponding to the three load torque levels, which are much greater than that of healthy state (nearly equal zero).

Figure 5: Three first harmonics in the FFT spectral of PVM: healthy condition (upper) and faulty condition (lower) ($T_m = 0.005$ N.m)

Figure 6: Three first harmonics in the FFT spectral of PVM: healthy condition (upper) and faulty condition (lower) ($T_m = 0.15$ N.m)

Figure 7: Three first harmonics in the FFT spectral of PVM: healthy condition (upper) and faulty condition (lower) ($T_m = 0.075$ N.m)

Figure 8: Observation results of 2nd harmonic amplitude of PVM $T_m = 0.05$ N.m

Following this, the simulation is implemented with three selected level of load torque. Simultaneously, the observer is utilized to calculate the second order harmonic amplitude. Figs. 8, 9 and 10 present the results of amplitude calculation at three given

load torque levels, which are respectively compared with the FFT analysis results in Figs. 5, 6 and 7.

Figure 9: Observation results of 2nd harmonic amplitude of PVM ($T_m = 0.15$ N.m)

Figure 10: Observation results of 2nd harmonic amplitude of PVM ($T_m = 0.075$ N.m)

It can also be seen in these figures that there is an increase in the amplitude due to the fault, which varies dependent on the level of load torques. As can be seen, the FFT calculation and the observed results are in good agreement that successfully demonstrates the performance of the observer.

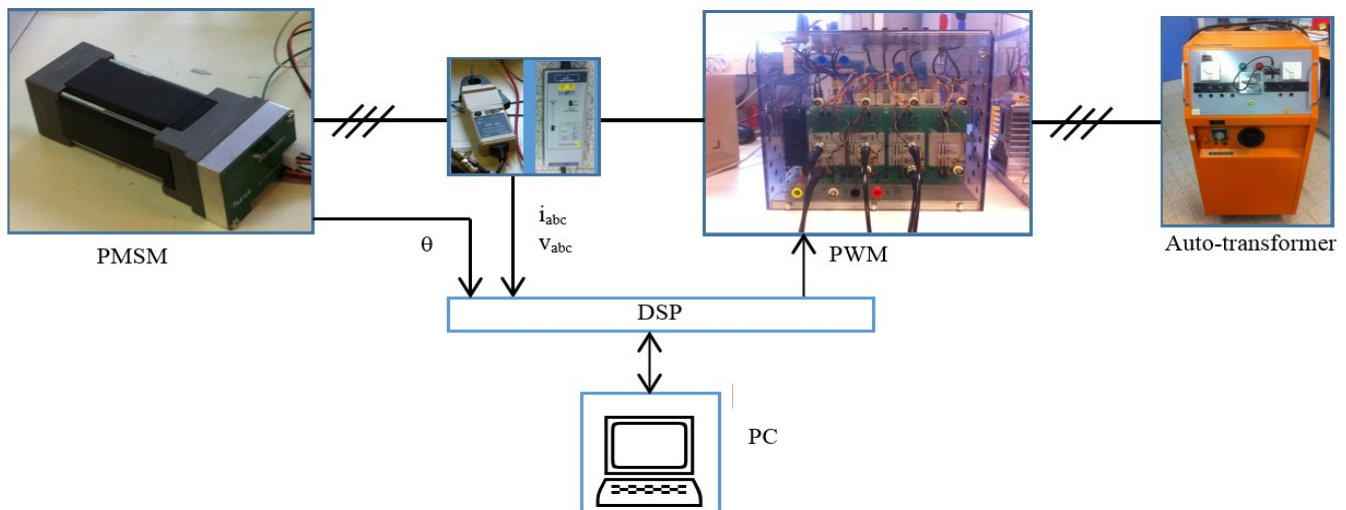

Figure 10: Test-bed of PMSM

The observer is also validated with experiment data to show the possibility of extracting the feature in the real condition which is disturbed by noise and other harmonics originated from the machine construction. The estimation is carried out offline with the data of currents and rotor position at the test-bed, depicted in Figure 10. The test-bed is composed of a Hurst PMSM, an inverter, an auto-transformer, and a real-time controller board (DSP) which allows to send the control signal to the inverter from the personal computer. The data of currents, voltages, and rotor position are acquired by using dedicated sensors. The auto-transformer is used to transform the 400 V AC voltage of the main grid into an appropriated level to supply the inverter.

Figure 11: PVM of stator currents (experiment).

Figure 12: Observation results of 2nd harmonic amplitude of PVM (experiment).

The acquired stator currents are used to calculate the PVM, shown in Figure 11. Figure 12 presents the FFT analysis of the PVM (upper) in which the magnitude of the second order harmonic can be observed. It is then compared to the feature extraction result by the observer. The level of second order harmonic magnitude observed is at the mean value of around 0.013 A, agreed with the value in FFT analysis.

In summary, as an application of the proposed observer, the procedure for detecting inter-turn short circuit fault can be proposed that consists of following main steps:

- Acquire samples of stator currents and rotor position;
- Compute PVM of the stator currents;
- Calculate the amplitude of the second order harmonic by using the proposed observer;
- Evaluate the amplitude levels of second order harmonic in the PVM signal for the fault tripping mechanism to detect inter-turn short circuit.

5. Conclusion

In this paper, a feature extraction based on observer has been presented in which the second order harmonics in the PVM of line

currents can be successfully managed. This harmonics is not observed in the simulation PVM signal. However, it is recorded in the faulty condition at different amplitude levels due to the load variation. The feature has been also extracted from the experimental PVM signal to show the performance of the observer in the noised conditions. The advance of proposed observer-based method to FFT-based method is that it can be applied to the online feature extraction during the operation of the PMSM. Moreover, the only second order of harmonic of the PVM is analyzed that allows to obtain a narrow window of frequency in signal analysis.

As a future work, the faults characterized by different faulty frequencies and other signals in the motor will be investigated for the extraction and fault diagnosis. The works will be focused on the validation of this technique on the evaluation of further harmonic components, which can theoretically arise from different types of faults in the PMSM.

Conflict of Interest

The authors declare that there is no conflict of interests regarding to the publication of this paper.

ABSTRACT

Artificial intelligence (AI) systems have been applied not only to numerical simulations of the economical sequences but also to the bio-signal, for instance, the statokinesigrams (SKGs). According to the nonlinear analysis of the bio-signal, we have considered that the motion process of the body sway is more random than that of the other bio-signal. In this study, we proposed a method for the numerical analysis of biological data using AI. The AI numerical solutions can indicate graphs that are very similar to the SKGs in degree of the determinism. In addition, we succeeded in extracting partial figure patterns that the AI regarded as a feature of 3D sickness. Comparing with the properties resulting from the mathematical analysis, interpretations can be given for the black box processing in the AI.

1. Introduction

In recent years, artificial intelligence (AI) has been incorporated into the automatic algorithms for buying and selling stocks and bonds. NASDAQ-100, actual stock prices, Standard & Poor's 500 Stock Index, and historical exchange rates have been analyzed to develop an automated trading algorithm. However, when using past stock price fluctuations, there is a drawback in that the test pattern is limited. In addition, when the time series generated by the stochastic process is used, there is a drawback wherein the actual fluctuation of the stock price is not reflected. Therefore, neither case is sufficient to trust the test results. In this study, we attempted to create a mathematical model that can generate innumerable fluctuation patterns after reflecting the fluctuation characteristics of the time series. In previous studies, the generative adversarial network (GAN) was applied to the time-series generation of exchange rates. GAN is attracting attention because it has succeeded in generating high-precision images. Stationarity [1], fractalness [2], and determinism [3] were measured to compare the actual exchange rates with the pseudo exchange rates generated by GAN. Using these indices, we also measured the similarity between the actual exchange rates and the time series generated by the Winner process [4]. From the stationary perspective, the pseudo-exchange rates generated by GAN showed higher similarity than those of the Winner process,

and from the deterministic point of view, both showed higher similarity.

On February 2, 2018, the Dow Jones Industrial Average had the largest decline to date [5]. The actual reason for this decline has not been clarified, but one of the possible causes cited by market participants is continuous selling, such as a chain of automatic loss cuts by the AI or automatic trading algorithms [6]. As a similar example, from March 9th to 18th, 2020, the decline in Standard & Poor's 500 Stock Index triggered four circuit breakers, temporarily suspending trading on the NYSE and NASDAQ [7–10]. This may indicate that the introduction of AI or automated trading algorithms is accelerating in financial markets. Some financial institutions, for instance, offer mechanical investment services to consumers. These services have solved the wealth-management problem of the general public.

However, mechanical investment services using AI cannot always protect assets. This is because reliability and robustness of the system is insufficient, owing to the limited number of tests. As mentioned above, the automatic trading algorithm uses past fluctuations in stock prices and exchange rates. In addition, even if the results look good at first glance, they may be overfitting to past fluctuations. To solve this problem, we propose an evaluation using a new simulated time series that does not depend only on historical data of past stock prices and exchange rates. It is conceivable to use the stochastic process as an idea to generate a simulated time series, but so far, many researchers have considered the stock price as the stochastic process [11, 12]. Another approach is the generation of a simulated time series by GAN. In previous

*Corresponding Author: Hiroki Takada, Department of Human & Artificial Intelligence Systems, Graduate School of Engineering, University of Fukui, 910-8507, Japan Email: takada@u-fukui.ac.jp

studies, the pseudo-exchange rate generated by GAN showed higher similarity to the actual exchange rate in terms of stationarity than the time series generated by the Winner process. In terms of determinism, both showed high similarity.

The body sway is of particular interest regarding the assessment of changes in the postural control, as it is highly related to the risk of falling [13]. In the stabilometry, displacement in the center of pressure (CoP) is recorded in the medial-lateral (x) and the antero-posterior (y) directions as a statokinesigram (SKG). In the SKGs, variables x and y are regarded to be independent [14]. The linear stochastic differential equation (Brownian motion process) has been proposed as a mathematical model to describe the body sway [15–17].

Therefore, the purpose of this study was to establish a new numerical simulation method for biological signals using the same method as the numerical simulation in the exchange rate. We examined whether it is possible to generate a highly accurate simulation for the SKGs by applying the GAN to the SKGs with an unknown mechanism by which 3D images affect the CoP. In addition, if we were able to generate SKGs, we would also verify whether the characteristics of SKGs could be visualized.

2. Mathematical Model

Stochastic differential equations (SDEs)

$$\dot{x} = -gradU_x(x) + \mu_x w_x(t), \quad (1)$$

$$\dot{y} = -gradU_y(y) + \mu_y w_y(t), \quad (2)$$

have been proposed as mathematical models describing the body sway [18-20], where μ and ω represent the noise amplitude and the Gaussian white noise, respectively. In Eqs.(1.1)-(1.2), the time-average potential functions in the x- and y-directions are expressed as $U_x(x)$ and $U_y(y)$, respectively. These functions were estimated from

$$U_x(x) = -\frac{\mu_x^2}{2} \ln G_x(x) + const., \quad (3)$$

$$U_y(y) = -\frac{\mu_y^2}{2} \ln G_y(y) + const., \quad (4)$$

where distributions in the x- and y-directions are expressed as $G_x(x)$ and $G_y(y)$, respectively. Each distribution is determined as a histogram for each component in the experiment. In some studies, the SDEs have been applied to conduct the numerical analysis of the body sway, however, there is no research using the AI. Using the AI, we perform a numerical simulation in this research.

3. Model Design

3.1. GAN

In recent years, neural network models, for instance, convolutional neural networks (CNNs) have been used as image-classification models [21].

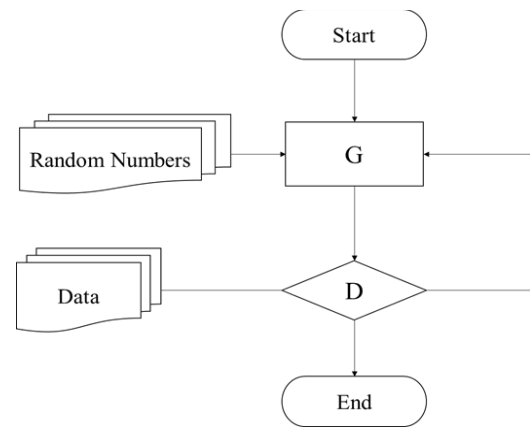

Figure 1: GAN model.

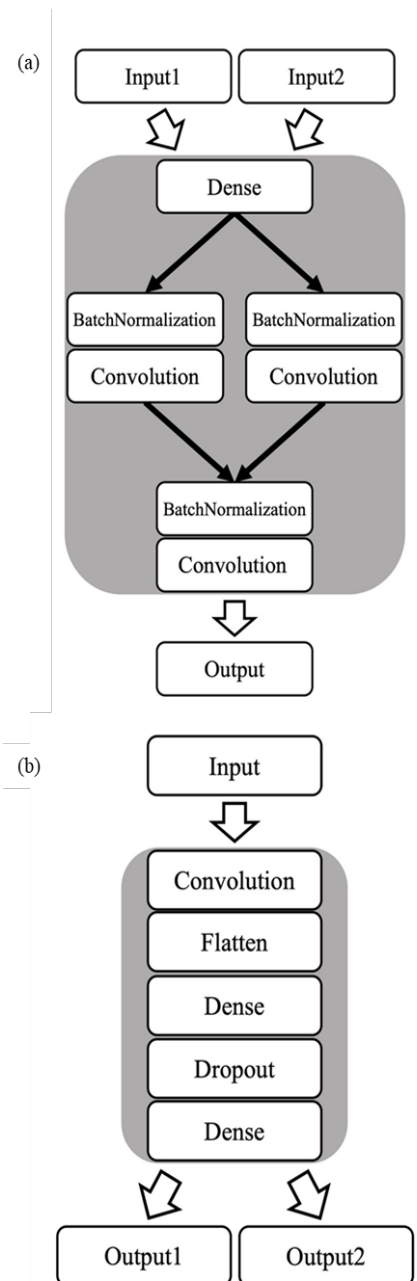

Figure 2: Constructed GAN model: generator (a), discriminator (b).

In addition, deep-neural-network, which are deeply stacked CNNs, has been used not only for image classification but also for a wide range of applications such as object detection [22], semantic segmentation [23], and the image generation [24]. Two advantages of the GANs use are that it is not necessary to define properties in the images to be generated beforehand, and that a number of images can be generated by using noise as the input to the network. In this study, the GAN was applied to the generator of time series. We can generate time series for the numerical simulation.

In this study, simulative time series (i.e., fake data) can be obtained from the generator G, which is defined as a network input noise. As the side note, the discriminator D distinguishes whether generated data are real (i.e., true data). “G” learns so that “D” determines the fake data as genuine. Inversely, “D” learns so that it can correctly determine whether the input data is true data or false data generated by “G”. By repeatedly learning these networks (Figure 1), it can be generated for a large number of simulated time series if the output of “G” can generate data that is very close to true data.

3.1. Learning Statokinesigrams in GAN Model

It has been reported that it is difficult to stabilize in the GAN learning. Several models were, in fact, designed and trained to generate pseudo-exchange rates, however, few models could be found to exhibit stable learning. The way has been already suggested how to stabilize the GAN learning [25]. Based on these proposals, the hyperbolic tangent function (tanh) was herein used as an activation function in the output layer of the generator. LeakyReLU was used as an activation function, except for the output layer/fully connected layer in “D” [26]. The hyperbolic tangent function is defined as

$$\tanh(x) = \frac{e^x - e^{-x}}{e^x + e^{-x}},$$

where the derivative is given as

$$\tanh'(x) = 1 - \tanh(x)^2.$$

The advantage of using Eq. (4) is firstly that it can output any input value within the range of -1 to 1, thus reducing numerical divergence. Secondly, the hyperbolic tangent function does not have a large maximum value of the differential coefficient, which makes it stop vanishing gradients.

3.2. Parameter Optimization

To design a neural network model that achieves the desired performance, it is necessary to adjust the layer configuration to the optimum configuration. In general models for classification and prediction, the accuracy rate is often used as the objective variable [27]. However, because the aim of this study is to simulate the characteristics of SKGs, it cannot be evaluated using the accuracy rate. Therefore, it is necessary to define a new objective variable. In this study, we defined the following optimization function using the learning error for “G” and “D”, which was developed in a previous study [28].

$$\text{Opt.Function}(G_{\text{LOSS}}, D_{\text{LOSS}}) = \ln \frac{G_{\text{LOSS}} + D_{\text{LOSS}}}{D_{\text{LOSS}} / G_{\text{LOSS}}}, \quad (5)$$

where the training error for “G” and the training error for “D” are expressed as G_{LOSS} and D_{LOSS} , respectively.

In this study, parameters in the GAN model (see Appendix) were set to minimize the value of the optimization function [29]. The value was evaluated after the parameters were optimized. It should be noted that the parameters in “D” was fixed because of the high computational expense (Table 1). Figures 2 show the a generator model and a discriminator model developed in this study. The “G” uses the combination input of noise and the label. In the subsequent generation process, a branch structure was added so that the variables x and y could be generated independently. This is based on the idea that the variables x and y are considered to be independent in the body sway. The “D”, in contrast to the “G”, did not have a branched structure. This is because both series are referred to when determining the state of body sway.

Table 1: Network configuration in the discriminator.

Layers	Layer Name	Units	Kernel Size	Filters	Output Shape	Activation
0	Input	-	-	-	-	-
1	Convolution	-	1×3	32	2×600	LeakyReLU
2	Convolution	-	1×3	64	2×300	LeakyReLU

8-2	Dense	32	-	-	32	LeakyReLU
9-2	Dense	32	-	-	32	LeakyReLU
10-2	Dense	1	-	-	1	Sigmoid

4. Experiment

In this study, we measured the sway of the CoP of the elderly for the GAN learning. Next, pseudo SKGs were generated by the numerical simulation. Finally, SKGs was colored using a GAN discriminator to visualize the characteristics of the sickness.

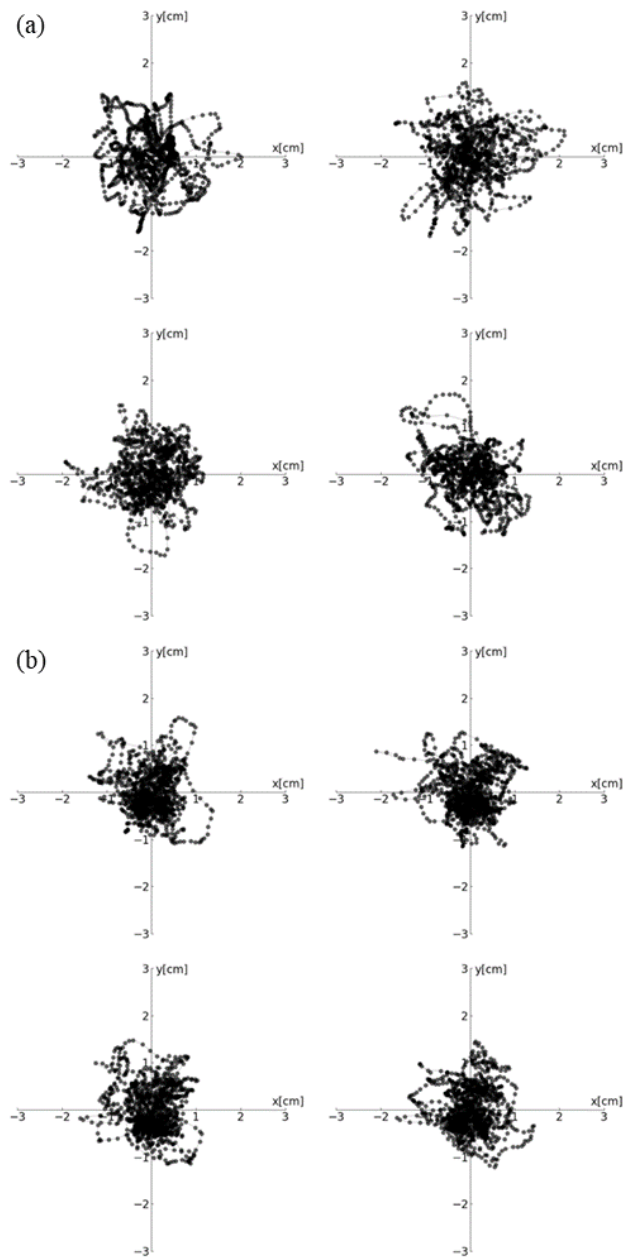

Figure 3: Typical SKGs: (a) measured data, (b) AI simulations

4.1. Measurement

In order to investigate the effects of stereoscopic video clips on the elderly, the body sway was simultaneously measured with the radial motion while/after viewing 2D/3D video clips for 60 s. In this experiment, 204 SKGs were observed from the elderly subjects that stood with Romberg posture on a gravicorder GS3000 (Anima Corp. Ltd., Tokyo) [30]. The SKGs were recorded at 20 Hz sampling in this experiment, which was approved by the Ethics

Committee of the Graduate School of Information Science, Nagoya University.

Figure 4: Translation errors for each learning step in the simulation of SKGs.

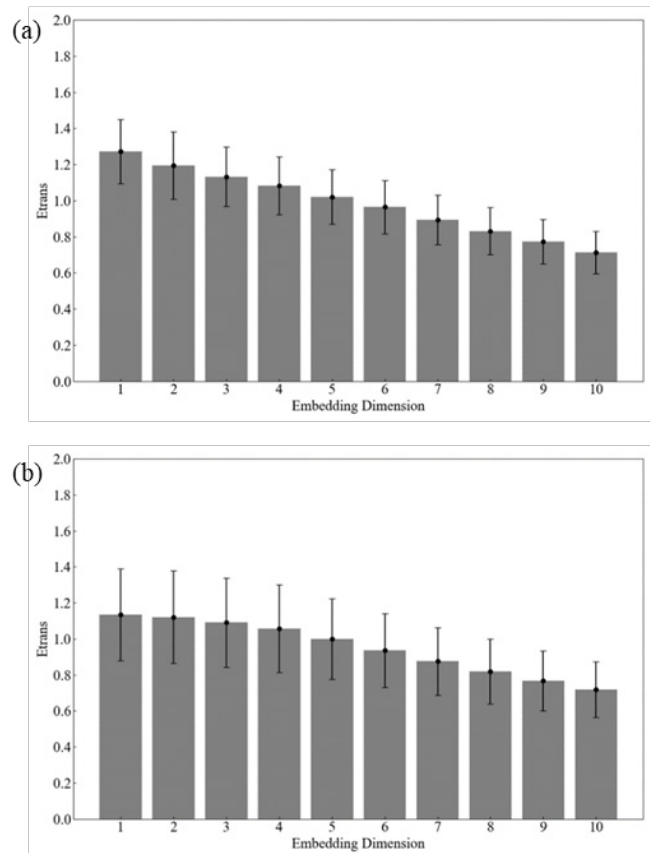

Figure 5: Translation error in SKGs: measured data (a), simulation pattern (b).

The results have shown that, in the elderly, the equilibrium function is affected while/after tracking the visual target in 3D video clips without statistical significance (sickness-induced) [30]. Based on the previous studies on visually induced motion sickness (VIMS) [18-20], [30], the motion sickness is expected to be induced after/while viewing 3D video clips rather than 2D ones.

4.2. Simulation

In the constructed GAN model, it was confirmed that the machine-learning was not stable due to the small amount of raw data. Therefore, independent two-dimensional noise was generated

from the Winner process, and one million time series were obtained for each component. Using the weights of the GAN model obtained from this learning process, the model was reconstructed so that GAN simulation that imitated the SKGs of 204 cases in the measurements could be generated (Tables 1–2). At this time, the information is also input to “D” to determine whether the input data is a sickness-induced SKGs or a sickness-free SKGs in addition to the condition whether the input data is raw data or fake data and determines. A total of 100,000 steps were learned. Thus, 2D/3D video clips are herein regarded as visual stimulus that do not/do induce the VIMS, respectively. SKGs generated from the GAN every 10,000 steps was evaluated by calculating the translation error using the Wayland algorithm [31–32].

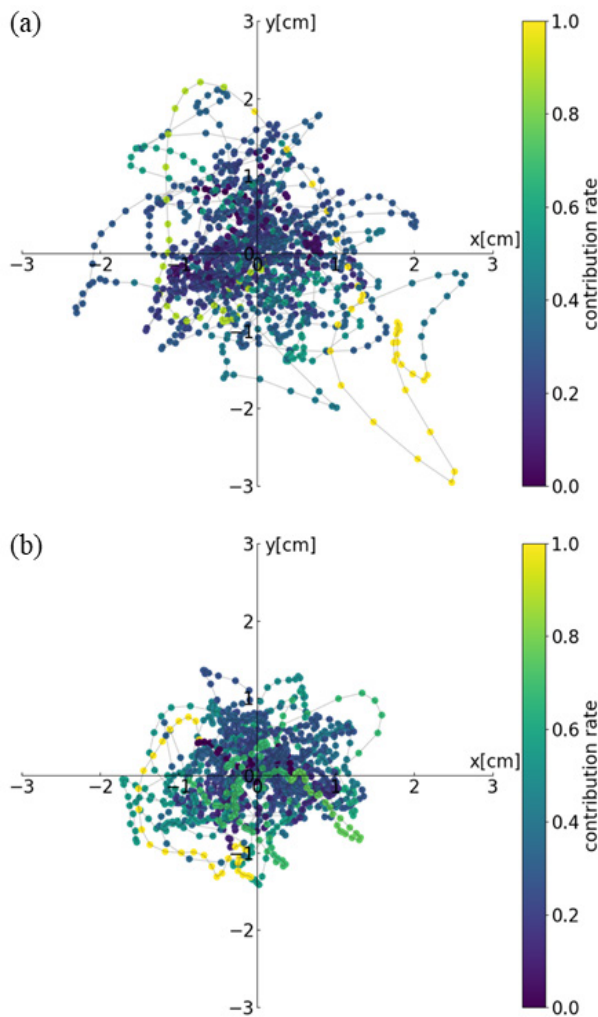

Figure 6: Patterns in SKGs that visualizes the characteristics of the following observation: sickness-induced (a), sickness-free (b)

4.3. Visualization of 3D Sickness Criteria

Using the trained GAN, the data obtained from the subject with the VIMS and the those without sickness were firstly input into the “D”, respectively. Secondly, outputs of the intermediate layer close to the output layer were recorded to calculate the contribution rate for the discrimination of the VIMS. Lastly, the input SKGs were a colored with values of the contribution rate.

5. Results and Discussion

For the simulation SKGs (Figure 3b) generated by the GAN, the translation error was calculated every 10,000 steps using the Wayland algorithm (Figure 4). As a result, the value was approximately 0.7 after the machine learning up to 20,000 steps, and it decreased sharply to approximately 0.3 after 30,000 steps. After that, values of translation error increased to 70,000 steps again, and then decreased in learning after 80,000 steps. The GAN simulation might be influenced by the Winner process used for the pre-learning. That is why values of the translation error was high up to 20,000 steps. After that, the influence of the Winner process would be weakened around 30,000 steps. It was considered that the influence of the SKGs observed up to 70,000 steps gradually increased. After that, mode collapse might occur during the GAN-learning process. That is why values of the translation error decreased again after 80,000 steps. Mode collapse is a problem in which the generated data become similar because the variation of the data generated by “G” becomes smaller. This problem may occur in learning after 80,000 steps.

Next, the translation error of the observed SKGs (Figure 3a) are compared with that of the GAN simulation (Figure 3b) after 70,000 steps in the GAN-learning. Both values were about 0.8 in 10-dimensional embedding space, indicating very similar determinism (Figures 5).

Finally, the SKGs was colored using a GAN discriminator to visualize the characteristics of the sickness (Figures 6). It could be seen that the sickness-induced SKGs were widespread with respect to the sickness-free SKGs. It has been also discovered that GAN captures the shape of the cusp as a factor to determine the sickness. The contribution rate to judge the sickness-induced SKGs has been enhanced by the trajectories of the cusp (Figure 6a). We succeeded in extracting partial figure patterns that the AI regards as a property of 3D sickness. Consistency can be seen in the figure patterns that have been also extracted by our previous mathematical method [33]. Comparing with the properties resulting from the mathematical analysis, interpretations can be given for the black box processing in the AI.

6. Conclusion

In this study, we proposed a method for the numerical analysis of biological data using AI. So far, there have been many studies that have attempted numerical simulations using SDE, but there is no research that performs simulations using GAN and visualizes/extracts the properties of the time series as shapes. As a result, the possibility of SKGs simulation using GAN was suggested. In the next steps, we would like to accumulate fundamental knowledge so that simulations using GAN can be applied in all fields.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Face Recognition (FR) is considered as a heavily studied topic in computer vision field. The capability to automatically identify and authenticate human's faces using real-time images is an important aspect in surveillance, security, and other related domains. There are separate applications that help in identifying individuals at specific locations which help in detecting intruders. The real-time recognition is mandatory for surveillance purposes. A number of machine learning methods along with classifiers are used for the recognition of faces. Existing Machine Learning (ML) methods are failed to achieve optimal performance due to their inability to accurately extract the features from the face image, and enhancing system's recognition accuracy system becomes very difficult task. Majority of designed FR systems has two major steps: extraction of feature and classifier. Accurate FR system is still a challenge, primarily due to the higher computational time and separate feature extraction. In general, for various applications using images, deep learning algorithms are mostly recommended for solving these problems because it performs combined feature extraction and classification task. Deep learning algorithm reduces the computation time and enhances the recognition accuracy because of automatic extraction of feature. The major novelty of the work is to design a new VGG-16 with Transfer Learning algorithm for face recognition by varying active layers with three levels (3, 4, and 7). It also designs the Convolutional Neural Network (CNN) for FR system. The proposed work introduced a new Real Time Face Recognition (RTFR) system. The process is broken into three major steps: (1) database collection, (2) FR to identify particular persons and (3) Performance evaluation. For the first step, the system collects 1056 faces in real time for 24 persons using a camera with resolution of 112*92. Second step, efficient RTFR algorithm is then used to recognize faces with a known database. Here two different deep learning algorithms such as CNN and VGG-16 with Transfer Learning are introduced for RTFR system. This proposed system is implemented using Keras. Thirdly the performance of these two classifiers is measured using of precision, recall, F1-score, accuracy and k-fold cross validation. From results it concludes that proposed algorithm produces higher accuracy results of 99.37%, whereas the other existing classifiers such as VGG3, VGG7, and CNN gives the accuracy results of 75.71%, 96.53%, and 69.09% values respectively.

1. Introduction

In recent years, an active research area is Face Recognition (FR) technology because of technology's potential in commercial use and law enforcement as well as rise in security demands [1]. The issues and developments in face recognition have been alluring a lot of scientists working in computer vision, pattern recognition, and biometrics domain. Various face recognition

algorithms are used in diverse applications like indexing and video compression that comes under the domain of biometrics. Face recognition concepts can be used in classifying multimedia content and to help in the quick searching of materials that interests the end user. A comprehensive face recognition mechanism can be of assistance in domains like surveillance and forensic sciences. It can also be used in the areas of law enforcement and to authenticate security and banking systems. In addition to that, it also gives control and preferential access to

<https://dx.doi.org/10.25046/aj0602109>

secured areas and authorized users. The issues in face recognition have garnered even more significance after the spike in terrorism in the recent years. It largely decreases the need for passwords and can offer enhanced security. For this, FR should be used with additional security mechanisms.

In spite of facial recognition's rapid growth and acclaim as a critical authentication mechanism, the algorithms used for facial recognition have not been developed significantly. It has been close to two decades since facial recognition has come to the fore but a comprehensive system that is capable of producing positive results in real-time conditions has not been developed yet. The Face Recognition Vendor Test (FRVT) test carried out by National Institute of Standards and Technology (NIST) is demonstrated that modern face recognition mechanisms will not be able to perform optimally under certain circumstances.

Modern FR systems intended for complex environments has attracted a huge attention in recent years. FR systems that are automated is a developing technology that has garnered a lot of interest. There are a number of conventional algorithms that are used in developing color images and still-face images. The data complexity is increased in color images as the pixels are mapped to a high-dimensional space. This significantly decreases the accuracy and processing efficiency of FR [2].

There are four stages in FR technology namely, classification, representation (extraction of facial feature), alignment and detection [3]. Feature representation technique used for extracting features is the major challenge of FR system. For a specified biometric trait, representations are done using better techniques. In image classification, highly important step is feature extraction. Highly important information is retained in feature extraction, which is used in classification. Feature extraction methods improved FR accuracy slowly.

FR systems are reported with failures or unstable performance often with different false rates in real-world environment due to technical insufficiency. Making it formal and complete use of its performance is being yet a final solution. In the recent years, it has been inferred that deep learning works a lot better for face recognition [4]. For classification and feature extraction, processing unit's multiple layer cascading is used in deep learning techniques. Facial image's very high recognition rate is achieved by this.

The proposed study processes color images to recognize and detect faces with a good deal of accuracy in a real-time scenario. This work aims to apply pre-trained Convolutional Neural Network (CNN) with VGG-16 algorithm for FR and classification accuracy using analysis. These methods have been used for enhancing recognition accuracy. Most relevant challenge for such a system is recognition and feature extraction. A system has been proposed here that makes use of deep learning techniques to extract features. System uses deep learning to recognize faces in an accurate manner. The proposed system will be capable of recognizing more number of faces which can be used for searching suspects as the errors are reduced significantly.

2. Literature Review

FR has become a popular topic of research recently due to increases in demand for security. Highly attractive biometric

technology is FR and its accuracy is highly enhanced using recent advancements in technology. According to Deep Learning (DL) and Machine Learning (ML) techniques, FR techniques are performed.

In [5] proposed Haar classifier that made use of a surveillance camera for face recognition. The system had four sequential steps that included (1) real-time image training (2) face recognition with the help of Haar-classifier (3) comparing the real-time images having images that were captured from camera (4) generation of the result as per the comparison. Haar is used to detect the faces in a robust manner in real-time scenarios. Face detection uses an algorithm called as Haar cascading. A system called as Aadhar has been adopted by India for recognizing the citizens. If this is used as a database for the citizens, a local citizen and a foreigner can be easily recognized. This information can be eventually used for identifying if the person is a criminal or not. The major advantage of this work is to apply this system to citizenship database. This has less computational cost, better discriminatory power and high recognition precision. Least processing is required by main features in small images for training Haar wavelets. If number of features becomes more it requires increased computation time for FR system. It is left as scope of the work.

In [6] proposed a Local Binary Pattern (LBP) for identifying faces. This was used along with other image processing methods like Histogram Equalization (HE), Bilateral Filter, Contrast Adjustment and Image Blending to improve overall system accuracy. The LBP codes are improved here due to which the performance of the system is enhanced. The major advantage of this work is that it is reliable, robust and accurate. In real-life setting, this may be used as an attendance management system. But this solution limits only the noise. In facial recognition, mask faces and occlusion issues are not addressed by this system. But, in future, this work can be extended for addressing these issues.

For face feature extraction, combination of Local Binary Pattern (LBP) and Histograms of Oriented Gradients (HOG) descriptors [7]. Low computation power is required by these descriptors. For face classification, Random Forest (RF) classifier based accurate and latest methods are applied. Under a controlled environment, from video broadcast, identification and verification of one or more person can be done accurately using this proposed algorithm. For FR system. Still there is a need to have separate feature extraction technique.

For facial expression recognition, a real-time system is presented [8]. Student's 8 basic facial expressions can be recognized using this proposed system and expressions includes natural, surprise, sad, nervous, happy, feat, disgust and anger inside E-learning environment. Proposed system's efficiency is tested by using Support Vector Machine (SVM), k-Nearest Neighbor (k-NN) classifiers and their results are compared. Techniques used in this study for recognizing facial expressions includes SVM and k-NN classifiers for expression recognition, feature selection based on Principal Component Analysis (PCA), feature extraction based on Gabor Feature approach, Viola-Jones technique based face detection. In a real-time system, for facial expression recognition, it can be used. However the k-NN and

SVM classifier needs more time complete the FR process due to feature extraction and feature selection steps.

For addressing partial face images irrespective of its size, Fully Convolutional Network (FCN) with Sparse Representation Classification (SRC) [9] and it is termed as Dynamic Feature Matching (DFM). For optimizing FCN, introduced a sliding loss based on DFM. Between subject's face image and face patch, an intra-variation is reduced for enhancing DFM performance. For other visual recognition tasks like partial person re-identification, this technique can be extended very easily. This solution limits the noise alone and image count is also restricted.

For suppressing unreliable local features from occluded regions, a fuzzy max-pooling scheme [10]. On every subclass, automatic weighting is done for enhancing robustness in final average-pooling. While dealing with data sufficiency and occlusion problem simultaneously, better performance enhancement is shown by this technique, which is a major advantage of this technique. Every subclass is treated as an individual classifier, where ensemble late fusion framework is used for obtaining final decision. Remarkable enhancement in performance can be achieved as shown in results.

Under various conditions, for face recognition, a framework called Optimized Symmetric Partial Face graph (OSPE) [11]. For instance, light variation, facial expression; occluded faces are used in their experimentation. Partial facial data are introduced for enhancing recognition rate as shown in their experimental results. Local spatial information is not explored fully in these techniques, which is a major drawback of it.

For dealing with FR, a Principal Component Analysis (PCA) technique based on patch [12]. Total scatter is computed for computing divided patches correlation directly. For feature extraction, projection matrix is obtained by optimizing projected samples total scatter. Nearest Neighbor (NN) classifier is used at last. For this large sized covariance matrix, eigenvectors evaluation consumes more time.

For real time face recognition, a LBP [13]. The image of the face is represented by using information about the texture and shape. For representing the face comprehensively, the facial area is divided into different sections. LBP histograms are then extorted which are combined to a single histogram. Facial recognition is then using the Nearest Neighbor (NN) classifier. The validation of the algorithm is carried out by devising a prototype model that makes use of the raspberry Pi single-board computer, Matrix Laboratory (MATLAB). The results indicate that LBP algorithm's recognition rate is relatively higher when compared to other approaches.

In [14], four various algorithms are combined with Discrete Wavelet Transform (DWT). Algorithm includes Convolutional Neural Network (CNN), Linear Discriminant Analysis (LDA) Eigen vector, PCA Eigen vector and Principal Component Analysis (PCA) error vector. Then Fuzzy system and detection probability's entropy are used for combining these four results. Database diversity and image defines the recognition accuracy as indicated in results. For best case, 93.34% recognition rate and for worst case, 89.56% recognition rate are provided by this technique. This technique is better than other techniques, where

individual technique is implemented on specific images set. In human face recognition, illumination impact is ignored, which is a only limitation in this work.

All these techniques, reviewed don't completely address issues affecting facial recognition accuracy like feature extraction and noise variation. Unfortunately, the processing time and training period for these algorithms are considerably large. In the recent times, Face Recognition (FR) techniques have been replaced by deep learning. Deep learning has been observed to perform better for large datasets. On the contrary, traditional ML algorithms at an optimum level with comparatively smaller datasets. In conventional ML algorithms, a difficulty needs to be broken down into individual steps. FR based on CNN is trained with large datasets and has attained a high level of accuracy. The increased use of deep learning has accelerated the research involved in FR. Recently, with deep learning emergence, impressive results are achieved in face recognition. In computer vision applications, most popular deep neural network is CNN and it has automatic visual feature extraction which is a major advantage [15].

For recognizing face images, Support Vector Machine (SVM) and Convolutional Neural Network (CNN) [16]. For automatically acquiring remarkable features, CNN is utilized as feature extractor. Using ancillary data, CNN pre-training is proposed at first and updated weights are computed. Target dataset is used for training CNN, which extracts highly hidden facial features. At last, for recognizing all classes, proposed a SVM classifier. With high accuracy, face images are recognized using SVM where facial features extracted from CNN are given as an input. In experimentation, for pre-training, images in Casia-Webfaces database are used and to test and train, used the Facial Recognition Technology (FERET) database. With less training time and high recognition rate, efficiency is demonstrated in experimentation results. Moreover, it is highly difficult to acquire some facial features manually from face images. But, effective facial features are automatically extracted using CNN. With more optimization techniques, deeper CNN based training time and recognition rate's balance point are computed and larger dataset is left as scope of this work.

A modified CNN architecture [17], where two normalization operations are added to two layers. Batch normalization is used as a normalization operation and network is accelerated using this. Distinctive face features are extracted using CNN architecture and in CNN's fully connected layer, faces are classified using Softmax classifier. With better recognition results, face recognition performance is enhanced using this proposed technique as shown in experiment part and it uses Georgia Tech Database.

A novel technique based on CNN [18] which is termed as Deep Coupled ResNet (DCR) model. It consists of two branch networks and trunk network. For face images with various resolutions, discriminative features are extracted using trunk network. High-Resolution (HR) images are transformed using two branch networks and targeted Low Resolution (LR) images are also transformed using this.

Pre-trained CNN's performance [19] with multi-class Support Vector Machine (SVM) classifier and for performing classification, AlexNet model based transfer learning

performance is also proposed. An excellent performance is achieved using hybrid deep learning as shown in results when compared with other techniques of face verification.

For facial recognition, CNN and Multi-Layer Perceptron (MLP) [20]. For performing facial recognition, it is a system based on open code deep-learning. For fiducial point embedding and extraction, deep learning techniques are used. For classification task, SVM is used. In inference and training, it has fast performance. For facial features detection, 0.12103 error rate is achieved using this system, which is pretty close for state of the art algorithms and for face recognition, it has 0.05. In real-time, it can run.

In [21] proposed a CNN for facial recognition that has been implemented on the embedded GPU system. The method uses facial recognition based on CNN along with face tracking and deep CNN facial recognition algorithm. The results have indicated that the system is capable of recognizing different faces. An estimated 8 faces can be recognized simultaneously within a span of 0.23 seconds. The recognition rate has been above 83.67%. As a result, processing time is enhanced and for real-time multiple face recognition, it can be used with acceptable recognition rate.

For face recognition, a Pyramid-Based Scale-Invariant - CNN model (PSI-CNN) [22]. From image, untrained features are extracted using PSI-CNN model and with original feature maps, these features are fused. With respect to matching accuracy, experimentation results are shown and it outperforms model derived from VGG-Face model. Stable performance is maintained using PSI-CNN during the experimentation with low-resolution images which are acquired from CCTV cameras. Robust performance is exhibited with image quality and resolution change.

For regressing facial landmark coordinates, at CNN's intermediate layers [23]. In specific poses and appearances, for regressing facial landmark coordinates, specialized architecture is designed in novel CNN architecture. For every specialized sub-networks, for providing sufficient training examples, designed a data augmentation techniques and it address training data's shortage specifically in extreme profile poses. On true positive detected faces, accuracy is reflected by this. At last, trained and code models are made publicly available using project webpage, for promoting results reproducibility.

Using CNN, real-time face recognition system's evaluation [24]. Standard AT&T datasets is used for performing proposed design's initial evaluation and for designing a real-time system, same can be extended. For enhancing and assessing proposed system's recognition accuracy, CNN parameters tuning are used. For enhancing system performance, systematic technique for tuning parameters is proposed. From the review it concludes that the deep learning algorithms give lesser computation time and more recognition accuracy than the other methods.

The VGG16 based multi-level information fusion model [25]. On fully connected neural network, enhancement is proposed. Computation time is reduced using this technique. In calculation and propagation process, some useful feature information are lost in CNN model. This work enhances model to be a convolution calculation's multi-level information fusion and discarded feature

information are also recovered and it enhances image's recognition rate. Network is divided into five groups using VGG and they are combined as a convolution sequence. The main advantage here is the representational efficiency. Face recognition can be attained using 128 bytes per face.

3. Proposed Methodology

The proposed system is broken into three major steps: (1) database collection, (2) face recognition to identify particular persons, and (3) Performance evaluation. For the first step, the system collects the faces in real time. In the database consists of 24 different persons are in the form of 1056 images having the resolution of 112*92; Olivetti Dataset is also used for implementation. In second step, Convolutional Neural Network (CNN) and VGG-16 Deep Convolutional Neural Network (DCNN) are introduced for improving recognition accuracy. Finally results evaluation of these two classifiers is measured using precision, F1-score, recall and accuracy. These classifiers recognize faces in real-time with high accuracy. The recognition building blocks are shown in the Figure 1.

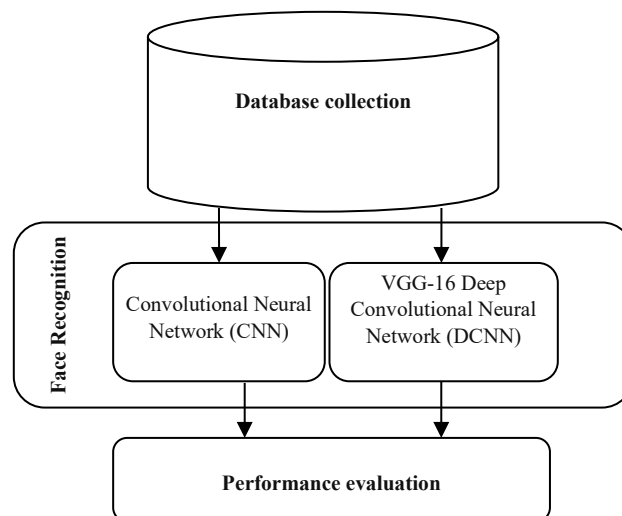

Figure 1: Face Recognition Building Blocks

3.1. Convolutional Neural Network (CNN)

Convolutional Neural Network (CNN) is attracted image processing application's attraction [26, 27, 28] and it is also used for feature extraction capacity from real-time facial images. General CNN model which is used for real time facial recognition has been illustrated in Figure 2. The CNN architecture has three major layers: Convolutional, Fully Connected, and Pooling Layer. The initial layer, facial image samples are given as input. Then in convolution layer, real time face images are converted into facial feature vectors via the kernel with filters=5. It is followed by ReLU activation function for recognition as well as maximum pooling layer. Next in line comes the full connection layer followed by the output layer.

CNN's basic building blocks are explained as follows:

Input layer- This layer has image's raw input having width 112, height 92, depth 3.

Convolution Layer – In CNN, a matrix called as the kernel is passed over the input real time face matrix with size of (112*92)

to devise a feature map for subsequent layer. Mathematical operation termed as the convolution is executed via sliding Kernel size (3*3) over input real time face matrix. On each of the locations, real time face matrix multiplication is carried out and adds result set onto final feature map. For example, let us consider a 2-Dimensional kernel filter (K=5, 3*3), and a 2-Dimensional real time facial input image, I. This layer computes output volume via computing dot product between all filters and facial image. Output volume is computed using this layer via computing dot product between facial image and all filters. In this layer, filters are used to produce output volume with 112x 92 x 5 dimension.

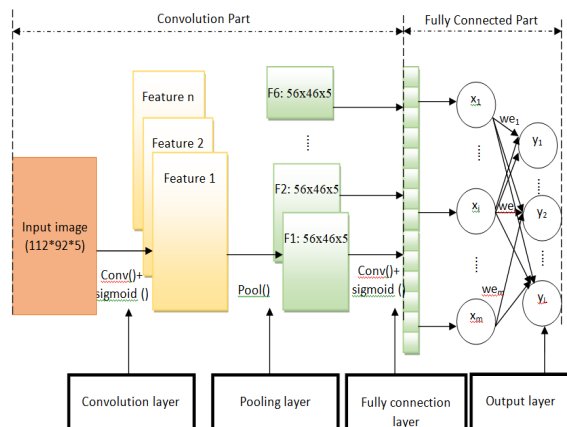

Figure 2: Convolutional Neural Networks Architecture

In layer l , assume In^l as neurons input and as neurons output Op^l . Every neuron's activation function and input are used for computing every neurons output. Layer number is represented as l , for instance, for first layer $l=1$ and for last layer, $l=-1$. Row number is expressed as i and column number is represented as j . Three-dimensional matrix is produced by CNN's every In^l and Op^l layers data structures, while one dimensional vector is produced by every layer In^l and Op^l in FC.

Assume layer l 's weight as we_{ij}^l and bias as ba_j^l . FC last layer's weight is represented as we_{ij}^{l-1} and bias is represented as ba_j^{l-1} . If layer l is pooling or convolutional layer, pooling windows or convolutional kernel's size is represented as $size^l \times size^l$. If layer l is fully-connected layer, neurons count is given by $size^l$. In layer l , neurons every input value is represented as In_{mn}^l . For convolution computation, $convolution(Op^{l-1}, we^l, m, n)$ function is used. Previous layer's output is given by Op^{l-1} . Between layer l (In^l)'s input and previous layer (Op^{l-1})'s output, weights matrix is given by we^l . Layer l 's bias is given by ba^l . The convolutional layer (In^l)'s input is computed as,

$$In_{mn}^l = Convolution(Op^{l-1}, we^l, m, n) + ba^l = \sum_{i=0}^{size^l-1} \sum_{j=0}^{size^l-1} (Op_{m+i, n+j}^{l-1} \cdot we_{ij}^l + ba^l) \quad (1)$$

The convolutional layer l (Op_{mn}^l)'s output is calculated as equation (2), where, $sigmoid()$ is activation function

$$Op_{mn}^l = F(net_{mn}^l) = sigmoid(net_{mn}^l) = \frac{1}{1+e^{-In_{mn}^l}} \quad (2)$$

Non-linear activation functions (ReLU) –Once the kernel filter is formed then the next step is to perform FR system. A node that comes next to the convolutional layer is called as activation function. The Rectified Linear Unit (ReLU) can be considered as piecewise linear function which is given as output, if it is positive, or else the output will be given as zero. Total 5 filters for this layer will get output volume 112x 92 x 5 dimension. The expression of ReLu function is $R(z)=\max(0,z)$ the function and its derivative image are shown in Figure 3.

Figure 3: ReLU Activation Function

Pooling Layer– In convnets, pooling layer is inserted periodically and its major objective are, minimization of volume size, making fast computation, reducing memory and prevention of overfitting. With stride 2 and 2*2 filters, this work uses a max pool. For face images recognition, resultant volume will have 56x46x5 dimension. Face matrix's average pooling is represented as $pool(x)$ function. Expression (3) gives formula used for computing $pool(x)$. Pooling window size is represented as $size^l$.

$$y_{ij} = pool(x, i, j) = \frac{\sum_{m=1}^{size^l} \sum_{n=1}^{size^l} x^{l-1}_{size^l \times (i-1) + m, size^l \times (j-1) + n}}{size^l \times size^l} \quad (3)$$

As indicated in expression (3), previous layer (Op^{l-1})'s output forms base for pooling layer Op^l 's output. In other words, previous layer (Op^{l-1})'s output will be equal to pooling layer l (net^l)'s input. As mentioned in above definition, last FC layer's input is represented as t^{-1} , first FC layer's input is represented as net^{-2} , layer before FC's input (pooling layer's last layer) is represented as net^{-3} .

Fully Connected Layer (FC)- Fully Connected (FC) Layer indicates that every node in initial layer is connected with next layer's every node. It computes class scores of facial images and outputs 1-D array of size equal to classes count via softmax function. The CNN model that was proposed was trained with 5 epochs, batch size=32 and using Adam optimizer (adaptive moment estimation). Specify optimizer's learning rate is set at 0.001. The forward propagation's result is \hat{y}_n , which is formulated in equation (4) to equation (6).

$$In_j^{-1} = \sum_{m=1}^{size^{-2}} (Op_m^{-2} \cdot we_{ij}^{-1} + ba^{-1}), j = 1, \dots, size^{-1} \quad (4)$$

$$Op_j^{-1} = F(In_j^{-1}) = Sigmoid(In_j^{-1}) = \frac{1}{1+e^{-In_j^{-1}}} \quad (5)$$

$$\hat{y}_n = Op^{-1} \quad (6)$$

The CNN's pseudocode is listed in Algorithm 1.

Algorithm 1: Training Algorithm of CNN

Input: tr_x, tr_y is considered as the features and labels of training facial images set

te_x, te_y is considered as the features and labels of testing facial images set.

Output: $we_{i,j}^l, ba_j^l$ weights and bias of convolution and pooling layers respectively

we_{jk}, ba_{jk} weights and bias of Fully Connected (FC) layer respectively

Required parameters: Max_{iter} Maximum number of iterations to complete face recognition task,

Error: when the training error is less than error, the training is finished, η : learning rate of the classifier

Initialization work:

t: t is the current iteration which is initialized as t=1 before training loop, L(t): L(t) is the Mean Square Error (MSE) at iteration t, $L(t)$ is initialized as $L(1) = 1 \geq error$

Begin

Set the required parameters and complete the initialization work

While $t < Max_{iter} \& L(t) > error$

For all tr_x

tr_r (Recognition label of training set tr_x and compute calculation from equation (1-6)

End for

Lt is recalculated as $L(t) = \frac{1}{2} \sum_{n=1}^N (tr_r(n) - tr_y(n))^2$, N is the total images count in dataset

Increment $t=t+1$

End

3.2. VGG-16 Deep Convolutional Neural Network (DCNN) with Transfer Learning

VGG16 is considered to be a CNN model that enhances the AlexNet by making replacements of the large kernel-sized filters [29] having various 3×3 kernel-sized filters sequentially. VGG-16 proposed method has four major building blocks namely Softmax classifier, FC-layer, convolution module and attention module.

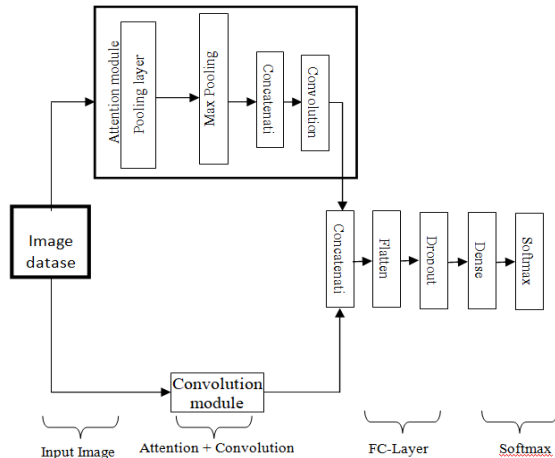

Figure 4: Block Diagram of the Proposed Attention-Based VGG-16 for Face Recognition

3.2.1. Attention Module

In facial image's feature's relationship are captured using this module. On input tensor, average pooling and max pooling are performed and in this technique, VGG-16 technique's 4th pooling layer is formed using this. For performing 7×7 filter size (f)'s convolution, max pooled 2D tensor is concatenated with every other layer via sigmoid function (σ). Figure 4 shows attention module's high level diagram. Expression (7) gives concatenated resultant tensor ($M_s(F)$).

$$M_s(F) = \sigma(f^{7 \times 7}[F^s_{max}]) \quad (7)$$

where $F^s_{avg} \in \mathbb{R}^{1 \times H \times W}$ gives 2D tensors achieved using max pooling operation on input tensor F. Here tensor's height is represented as H and width is represented as W.

3.2.2. Convolutional Module

Convolution module is used which is VGG-16 model's 4th pooling layer. Facial image's features are captured using scale-invariant convolution module. From midlevel layer, extracted the features which are highly needed for real time facial images. For real time facial images, features from other layers like low or high are not appropriate as images are neither more specific nor more general. Thus, attention module is given with 4th pooling layer as first input. Then, that module's result is concatenated using 4th pooling layer.

3.3.3. Fully Connected (FC)-Layers

For representing concatenated features derived from convolution and attention block are converted as one-dimensional (1D) features using fully connected layers. It has three layers namely, dense, dropout and flatten as illustrated in Figure 4. Dropout is fixed as 0.5 and dense layer is limited to 24.

3.3.4. Softmax Classifier

From FC layer, features are extracted for classification and for facial image's final recognition, softmax layer is used. The unit number is defined by categories count in softmax layer, which is a last dense layer. According to classification, probability score's multinomial distribution is produced at softmax layer output. This distribution's output is given by,

$$P(a = c|b) = \frac{e^{b_k}}{\sum_j e^{b_j}} \quad (8)$$

where b probabilities that are retrieved from softmax layer and c represents facial image recognition dataset class used in proposed method. Table 1 gives proposed model's architecture details. Here, units in final dense layer (softmax layer) varies from one dataset to another based on categories count. ReLu activation function is applied in all layers except last one.

Table 1: VGG16 Proposed Model's Architecture

Layer (Type)	Output shape
VGG-16 model	90×110×5
conv2d_6 (Conv2D) layer	90×110×5
max_pooling2d_6(MaxPooling2) layer	45×55×5

conv2d_7 (Conv2D)	layer	43×53×5
max_pooling2d_7 (MaxPooling2D)	(None, 21, 26, 5)	21×26×5
flatten_3 (Flatten)		2730
dense_3 (Dense)		24
Total params: 65,914		
Trainable params: 65,914		
Non-trainable params: 0		

4. Results and Discussion

This section evaluates facial recognitions method's performance. Real time database consists of 1056 images each of size 112×92. Olivetti database [30], dataset has 400 images with grayscale 64×64 pixels. For every person, there are 10 images so there is 40 persons (target) which make it 40×10 equals 400 rows of data. A confusion matrix needs to be computed for each class $g_i \in G = \{1, \dots, K\}$, in such a way that the i^{th} confusion matrix assumes class g_i as the positive class and the remaining classes g_j with $j \neq i$ as negative class. As each confusion matrix pools together the entire observations labelled with a separate class apart from g_i as the negative class, this method increases the number of true negatives. This gives us:

- “**True Positive (TN)**” for event values that are correctly analyzed.
- “**False Positive (FP)**” for event values that are incorrectly analyzed.
- “**True Negative (TN)**” for no-event values that are correctly analyzed.

“**False Negative (FN)**” for no-event values that are incorrectly analyzed

Let us TP_i, TN_i, FP_i and FN_i to indicate the true positives respectively, false negatives, true negatives, false positives, in the confusion matrix associated with the i^{th} class. Let their call here be indicated by R and precision by P.

Micro average pools the performance over the least possible unit (the overall facial images):

$$P_{micro} = \frac{\sum_{i=1}^{|G|} TP_i}{\sum_{i=1}^{|G|} TP_i + FP_i} \quad (9)$$

$$R_{micro} = \frac{\sum_{i=1}^{|G|} TP_i}{\sum_{i=1}^{|G|} TP_i + FN_i} \quad (10)$$

The micro-averaged precision, P_{micro} , and recall, R_{micro} , give rise to the micro F1-score:

$$F1_{micro} = 2 \cdot \frac{P_{micro} \cdot R_{micro}}{P_{micro} + R_{micro}} \quad (11)$$

Given that a classifier gets a large $F1_{micro}$, it denotes that it performs exceedingly well. Here, micro-average may not be sensitive to the overall predictive performance. Due to this, the micro-average can be misleading when there is an imbalance in the class distribution.

Macro average averages over bigger groups and over the performance of individual classes than observations:

$$P_{macro} = \frac{1}{|G|} \sum_{i=1}^{|G|} TP_i / TP_i + FP_i \quad (12)$$

$$R_{macro} = \frac{1}{|G|} \sum_{i=1}^{|G|} TP_i / TP_i + FN_i \quad (13)$$

The recall and macro-averaged precision leads to the macro F1-score:

$$F1_{macro} = 2 \cdot \frac{P_{macro} \cdot R_{macro}}{P_{macro} + R_{macro}} \quad (14)$$

If $F1_{macro}$ has a bigger value, it points out to the fact that a classifier is able to perform well for each of the individual class.

Multi-class accuracy is termed as the average of the correct predictions:

$$accuracy = \frac{1}{N} \sum_{k=1}^{|G|} \sum_{x:g(x)=k} I(g(x) = \hat{g}(x)) \quad (13)$$

where I is defined as the indicator function, which returns 1 when there is a match between the classes and 0 otherwise. For significance testing, cross-validation is a statistical method used for estimating skill of classifiers. k-fold cross validation is a procedure used for estimating skill of model on new data. The value for k is fixed as 10, value that is found using experimentation to generally result in model skill estimate with low bias modest variance.

Table 2: Benchmark Datasets Results Comparison of Metrics Vs. Classifiers

Metrics	Dataset s	kNN	SV M	CNN	VGG 3	VGG 7	VGG1 6
Macro Average-Precision (%)	Real Time face	65.00	70.00	72.00	78.00	97.00	99.00
	Olivetti	72.00	76.00	79.00	83.00	85.00	90.00
Macro Average-Recall (%)	Real Time face	67.00	71.00	74.00	80.00	97.00	99.00
	Olivetti	75.00	78.00	82.00	87.00	88.00	92.00
Macro Average-F1-score (%)	Real Time face	66.00	70.50	73.00	79.00	97.00	99.00
	Olivetti	73.50	77.00	80.50	85.00	86.50	91.00
Accuracy (%)	Real Time face	64.00	67.00	69.00	75.71	96.53	99.37
	Olivetti	75.00	80.00	84.00	88.00	90.00	94.00
K-fold cross validation Accuracy (%)	Real Time face	65.23	67.86	70.48	76.94	97.23	99.52
	Olivetti	76.10	81.24	84.90	88.66	91.81	95.18

Figure 5 shows the macro average-precision results comparison of six different classifiers like kNN, SVM, CNN, VGG3, VGG7, and VGG16 with two datasets. The proposed VGG16 classifier gives higher macro-average precision results of 99%, the other methods such as kNN, SVM, CNN, VGG3, VGG7 gives 65%, 70%, 72%, 78%, and 97% in real time dataset. The proposed VGG16 classifier gives higher macro-average precision results of 34%, 29%, 27%, 21% and 2% for kNN, SVM, CNN,

VGG3, and VGG7 methods respectively in real time dataset (See Table 2). It can be concluded that VGG16 gives higher macro average-precision, since the proposed work 16 sequential layers are used for recognition.

Figure 5: Macro Average-Precision Results Comparison vs. Classifiers

Figure 6: Macro Average-Recall Results Comparison vs. Classifiers

Figure 7 : Macro Average-F1-Score Results Comparison vs. Classifiers

Figure 6 shows macro average-recall results comparison of six different classifiers like kNN, SVM, CNN, VGG3, VGG7, and VGG16 with two datasets. The proposed VGG16 classifier gives higher macro-average recall results of 99%, the other methods such as kNN, SVM, CNN, VGG3, VGG7 gives 67%, 71%, 74%, 80%, and 97% in real time dataset. The proposed VGG16 classifier gives higher macro-average recall results of 32%, 28%,

25%, 19% and 2% for kNN, SVM, CNN, VGG3, and VGG7 methods respectively in real time dataset (See Table 2).

Macro average-F1-score results comparison of four different classifiers such of six different classifiers such as kNN, SVM, CNN, VGG3, VGG7, and VGG16 with two datasets are shown in the figure 7. The proposed VGG16 classifier gives higher macro-average F1-score results of 99%, the other methods such as kNN, SVM, CNN, VGG3, VGG7 gives 66%, 70.5%, 73%, 79%, and 97% in real time dataset. The proposed VGG16 classifier gives higher macro-average F1-score results of 33%, 28.5%, 26%, 20% and 2% for kNN, SVM, CNN, VGG3, and VGG7 methods respectively in real time dataset (See Table 2). On VGG16 based transfer learning, for getting better results, proposed model is applied with both datasets.

Figure 8: Accuracy Results Comparison VS. Classifiers

Figure 8 shows the accuracy results comparison of six different classifiers such as kNN, SVM, CNN, VGG3, VGG7, and VGG16 with two datasets. The proposed VGG16 classifier gives higher accuracy results of 99.37%, the other methods such as kNN, SVM, CNN, VGG3, VGG7 gives 64%, 67%, 69.09%, 75.71%, and 96.53% in real time dataset. The proposed VGG16 classifier gives higher accuracy results of 35.37%, 32.37%, 30.28%, 23.66% and 2.84% for kNN, SVM, CNN, VGG3, and VGG7 methods respectively in real time dataset (See Table 2). On VGG16 based transfer learning, for getting better results, proposed model is applied with both datasets. The proposed classifier achieved a very high facial image's recognition rate which approaches human recognition rate.

5. Conclusion and future work

The term Biometrics defines individual's DNA along with other aspects like their facial features, geometry of the hands etc. In addition to that, the behavioral aspects like hand signatures, tone of voice and keystrokes are also taken into consideration. In many circumstances, the recognition of face is becoming more accepted and acclaimed in bio-metric based technologies. This helps in measuring an individual's natural data. This work puts forth a real time face recognition using classification methods. The proposed system contains three major steps that include (1) collection of facial images (2) comparison of trained real time face images via two classifiers such as CNN and VGG16 with transfer learning (3) Results comparison with respect to the metrics like recall, accuracy, precision, F1-score, and precision. The CNN and

VGG16 classifiers recognize faces in real-time with higher accuracy. Both of the classifiers are performed in sequential manner. For VGG16 model is performed based on the transfer learning. Transfer learning intends to extract information from a number of sources tasks and applies it to target task. So VGG16 gives improved accuracy than the CNN classifier. Classifiers are implemented with 1056 face images of 24 different persons. The proposed system can successfully recognize 24 different person faces which are which could be useful in searching suspects as its accuracy is much higher than other methods. The proposed VGG16 classifier gives higher values of 99% of macro-average precision, 99% of macro-average recall, 99% of macro-average f1-score and 99.37% accuracy results for real time face images. The major limitation of this work is that it ignores illumination impact in human face recognition which is left as scope of the future work. In future, in various human face sections, this concept can be applied for detecting facial expression for more security.

Conflict of Interest

The authors confirm that there is no conflict of interest to declare for this publication.

Markerless

ABSTRACT

Early detection and proper management of adult degenerative scoliosis (ADS) are important for health promotion. This study aims to develop an ADS screening tool from markerless digital photography and verify its reliability. The study included 17 participants. Outer canthus–horizontal angle (OHA) and trapezius–horizontal angle (THA) were calculated from the image of the upper body of the subject in a coronal plane using ImageJ. The Cobb angle was measured to investigate the correlation between OHA and THA. The intraclass correlation coefficient was analyzed to verify the reliability using the values of skilled and unskilled physiotherapists. The study results demonstrated an excellent correlation between THA and Cobb angle. THA also had an almost perfect intra- and interrater reliability. Because scoliosis is characterized by shoulder imbalance and THA is an index that reflects shoulder imbalance, the correlation with Cobb angle was excellent. THA is a scoliosis screening tool that can be used not only in hospitals but also in various places because even unskilled physiotherapists can measure highly reliable values.

1. Introduction

Human posture changes with age, illness, and disability. Postural changes are accompanied by joint deformities. Knee osteoarthritis and lumbar spondylosis rapidly increase after 40 years of age, causing pain and falls, leading to disability and the need for support for activities related to daily living [1, 2]. Abnormal alignment of the spinal column is classified into hyperkyphosis, which is an abnormality of the sagittal plane, and scoliosis, which is an abnormality of the coronal plane. Hyperkyphosis is common in the elderly, with a prevalence of 20%–40% [3-4], and it has a negative effect on gait, activities of daily living, and respiratory function [5-8]. Adult degenerative scoliosis (ADS) is another common posture abnormality of the

coronal plane in the elderly, with a reported prevalence of 20% or more [9]. It has been reported that ADS cause a difference in the cross-sectional area of the left and right erector spinae muscles, leads to fear and anxiety about walking, and has a negative effect on health-related quality of life [10-12].

Because the degree of spinal misalignment increases with age, early detection and preventative approaches are important [13, 14]. We believe that low-cost early detection and preventative approaches are needed to curb the enormous increase in costs required for medical and long-term care, especially in Japan. Measuring postural alignment using a digital photograph is useful for screening purposes because it does not require a visit to a medical institution, has no side effects, and is inexpensive. However, available ADS screening tools are few. Previous studies have used photographs and iPhones to screen for the degree of idiopathic scoliosis (IS), which requires the attachment of markers to bone indicators or undressing [15, 16]. In addition, although

these methods are inexpensive, they require specialists to obtain measurements; thus, performing repeated measurements at a location different from that of medical institutions is difficult. We have previously published a work regarding the development of a measurement method for the resolution of the abovementioned problems. In other words, we are developing a measurement method that does not require markers, participants to undress, and specialists for measurements. This method has the potential to become a tool that allows older people to measure their postural alignment at home in the future. Posture alignment screening tool using markerless digital photography was devised for the measurement of hyperkyphosis and reportedly has excellent reliability [17]. However, it has not yet been applied to the measurement of ADS.

Therefore, we have developed a markerless measurement method that does not require undressing for ADS screening using digital photographs. The purpose of this study is to verify the correlation and reliability of the ADS screening tool that has been developed using X-rays.

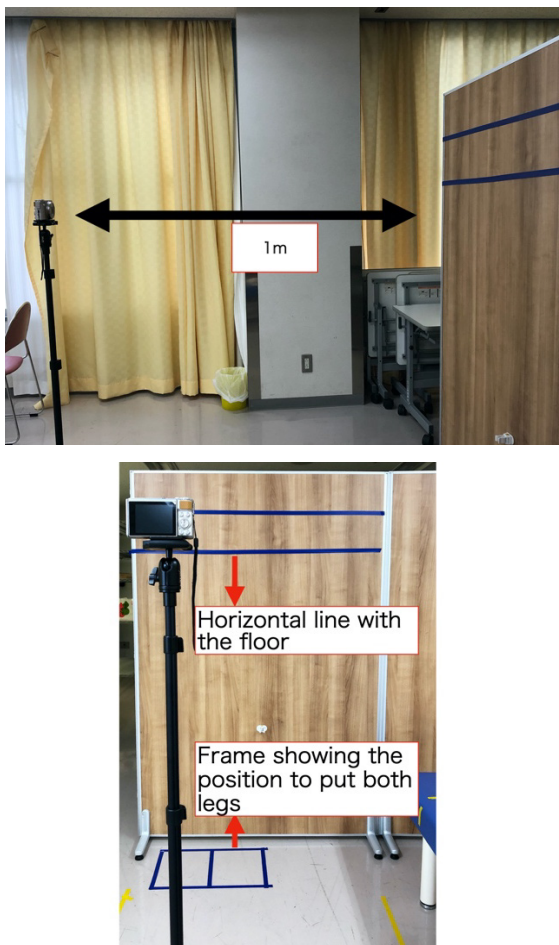

Figure 1: Filming Location

2. Methods

2.1. Subjects

Subjects were 18 elderly people (5 men and 13 women; mean age, 78.1 ± 7.4 years) who visited the outpatient rehabilitation facility. Exclusion criteria included patients with difficulty maintaining a standing position and those with severe dementia.

www.astesj.com

The examiners were two physiotherapists working at the hospital; examiner A had 2 years of experience as a physiotherapist, and examiner B had 18 years of experience. All participants provided informed consent, and the study was approved by our institutional ethics review board (approval number: OKRU19-A012). This study conforms to the principles of the Declaration of Helsinki.

2.2. Measurements

2.2.1 Coronal Spinal Postural Alignment Measurement Using Digital Photography

The subjects were asked to be in a standing position. We instructed the subjects to “do not extend the trunk or raise the shoulders” and “keep an eye on the camera lens.” They were also instructed to wear a shirt without a collar on the day of the measurement. The digital camera (PowerShot SX740 HS, Canon Inc., Tokyo, Japan) was installed at a position 1 m away from the subjects (Figure 1).

The line parallel to the floor was prepared in advance and affixed to the wall behind the subject. The resolution of the camera was 1824×1824 pixels. The focus of the lens was on the subject’s eyebrows (Figure 2).

Figure 2: Standing Image Taken to Screen for ADS. The rear line is the horizontal line with the floor.

The images were captured on a PC, and two angles were calculated for ADS screening using ImageJ (version 1.52, National Institutes of Health, Bethesda, MD, USA). According to previous studies, ImageJ has been used for posture assessment, wheelchair sitting posture, and brow position measurements [18-20]. Landmarks for ADS screening were placed on both the lateral canthus and trapezius muscles using the ImageJ point tool. The “find edges” tool was used to accurately point to the landmark (Figure 3). The outer canthus is a landmark used for postural measurement as an index to reflect head position [21]. Head position is related to scoliosis [22]. Because the left and right outer canthus position can change, we used the outer canthus as a landmark tool for screening ADS. In addition, patients with scoliosis are characterized by shoulder imbalance. Because the trapezius angle is one of the key determinants of shoulder imbalance, we chose the trapezius muscle, which reflects the inclination of the shoulder, as a landmark [23].

The angle formed by the horizontal line and the line connecting the left and right external canthus angles was called the outer canthus–horizontal angle (OHA). The angle between the trapezius muscle and the horizon for measuring shoulder tilt was called the trapezius–horizontal angle (THA). The right THA was subtracted from the left THA, and the absolute value was calculated (Figure 3a,3b). A manual was prepared for OHA and THA measurement, and the measurer confirmed it in advance. This manual included an explanation with illustrations for accurately marking the external canthus and trapezius muscles. In addition, ImageJ's operation manual was also published in the manual (Appendix).

Figure 3: Measurement Using ImageJ's "Find Edges" Tool. A: Outer canthus–horizontal angle. B: Trapezius–horizontal angle (right). C: Trapezius–horizontal angle (left). a: normal subject. b: scoliosis subject

2.2.2 Radiograph

The Cobb angle was measured from a radiograph taken from the subject's posterior. In American Scoliosis Study Group,

The measurement method was carried out according to the method of the American Scoliosis Study Group [24]. Intersecting perpendiculars were drawn from the superior surface of the proximal end vertebra and the inferior surface of the distal end vertebra of the curve. The angle formed by the perpendiculars was then described as the angle of the scoliotic curve.

2.2.3 Statistical Analysis

The relationship between OHA, THA, and Cobb angle was investigated using the Pearson product–moment correlation coefficient. We then calculated the standard error and 95% confidence interval for the significantly correlated indexes of OHA

and THA. The intraclass correlation coefficient (ICC) was used to analyze the interrater reliability (ICC1.1) and intrarater reliability (ICC2.1). The agreement was also tested by plotting the Bland–Altman plot. SPSS (version 26.0, IBM, New York, NY, USA) was used for statistical analyses, and the significance level was set to 5%.

3. Results

In one subject, accurate measurements could not be made because of the standing posture with hyperextension of the trunk and elevation of the scapula; thus, this subject was excluded from the measurements. Therefore, we analyzed the data obtained from 17 subjects. Table 1 shows the results of each measurement. The overall Cobb angle was $17.3^\circ \pm 2.9^\circ$, OHA was $2.5^\circ \pm 1.0^\circ$, and absolute value of THA was 6.9 ± 5.1 .

Table 1: Characteristics of the subjects

Age (y)	78.1 \pm 7.4
Cobb angle ($^\circ$)	17.3 \pm 2.9
OHA ($^\circ$)	2.5 \pm 1.0
THA of absolute value	6.9 \pm 5.1

Mean \pm SD. OHA: outer canthus–horizontal angle, THA: trapezius–horizontal angle

The correlation coefficient between the Cobb angle and OHA was 0.23, the correlation coefficient for THA was 0.74, and THA was significantly correlated with the Cobb angle (Table 2). Therefore, the reliability verification was performed only by THA.

Table 2: The relationship with the Cobb angle

	OHA	THA
Cobb angle	0.23	0.74*

OHA: outer canthus–horizontal angle, THA: trapezius–horizontal angle. *: $p < 0.05$

The interrater reliability (ICC1.1) of THA was 0.98, and the intrarater reliability (ICC2.1) of THA was 0.90 (Table 3). Bland–Altman analyses showed a 100% agreement, suggesting a perfect correlation between the first and second measurements (Figure 4A) and 94.1% agreement, suggesting a good correlation between the two examiners (Figure 4B).

Table 3: Intraclass correlation coefficient of THA

	Interrater Correlation Coefficient (ICC1,1)		Interrater Correlation Coefficient (ICC2,1)	
	First	Second	Examiner A	Examiner B
Mean \pm SD	6.9 \pm 5.1	6.9 \pm 4.8	6.9 \pm 5.1	7.0 \pm 4.4
ICC	0.98*		0.90*	
95% CI	0.96–0.99		0.76–0.96	

*: $p < 0.05$. CI: confidence interval

4. Discussion

The results of this study indicate that the absolute value of the THA for estimating scoliosis with the shoulder line highly

correlated with the Cobb angle. Previous studies have noted that scoliosis and shoulder line are related. IS patients had a large angle of shoulder inclination [25]. One of the goals of the surgical treatment of IS is the generation of horizontal shoulders [26].

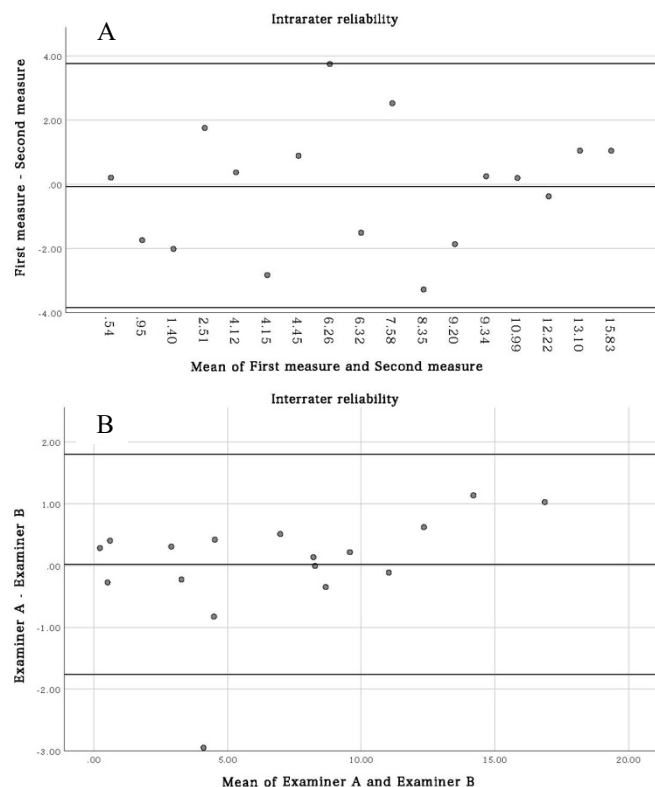

Figure 4: Bland–Altman plot comparing the mean of two measures (X-axis) to the difference between the two measures (Y-axis). The thick center line represents the mean of the difference between the two measures, and the thick top and bottom lines represent the limits of agreement (mean \pm 2SD of difference). There was perfect agreement between the two measures and between the first and second measures.

However, thus far, to the best of our knowledge, there has been no tool developed for screening ADS using the shoulder line. Considering the shoulder alignment mismatch in patients with IS reported in previous studies, we attempted to estimate scoliosis by selecting the shoulder inclination angle as a landmark. Defining the start and end points of the markerless shoulder slope was a challenge, but the manual for improving measurement discrepancies and ImageJ's "find edges" tool contributed to the excellent intra- and interrater reliability, while the Bland–Altman analysis showed perfect agreement. ImageJ's "find edges" tool can utilize the Sobel edge detector to emphasize sudden changes in the brightness of an image [27]. The "find edges" tool is one of the tools used to quantify images in the field of cell biology, but it may also be applied to postural analysis [28-29]. The images taken in this study included the participant and the wall, and it was concluded that the varying brightness between the shoulder line and the wall contributed to the accurate measurement. The intrarater and interrater reliability of THA were almost perfect in the Landis classification [30]. Our proposed ADS screening tool has the advantage of being markerless and not requiring undressing. In addition, the examiners in this study included one experienced physiotherapist and one inexperienced physiotherapist. THA will provide reliable measurements even for examiners with inadequate clinical skills.

On the other hand, we found that the external canthus used to screen for scoliosis from the subject's head position is an inappropriate landmark. We believe that this is because of the righting reflex. The human head tends to maintain a median position in relation to the position of the trunk and neck via the righting reflex. Because the righting reflex involuntarily changes the subject's head position, any facial area is considered unsuitable for screening for scoliosis.

Using digital images for measurement purposes is inexpensive, and when performed according to procedure, measurements can be made by a nonexpert and can be repeatedly made, unlike X-rays, which expose subjects to radiation. In other words, posture alignment measurement using digital images may be possible at various locations outside a medical institution and perhaps even at home. This measurement method may be effectively aligned with the attitudes of many countries that are taking measures against COVID-19 spread. In addition, the repeated measurable advantage is that, by confirming the regular posture alignment, increasing the subject's motivation to improve their posture may become possible. To measure postural alignment in various locations without the need to visit a medical institution, a markerless method to minimize undressing is required. Because the new scoliosis screening tool developed in this study meets these conditions, it has the advantage of reducing medical costs for measuring postural alignment abnormalities. In addition, this method of measurement may aid in early detection and will decrease the number of patients with ADS in the future.

This study is limited by the fact that the physiotherapist was an examiner. Physical therapists employ techniques to analyze the patient posture in detail [31]. To allow generalization of the results of the present study, different individuals need to serve as examiners, and we are currently conducting research for this generalization. We used the measurement manual for generalization but used ImageJ for angle screening. Although ImageJ is freeware, it has barriers to its use by nonexperts. Furthermore, the THA proposed in this study cannot be used for accurate diagnosis because it cannot identify the site of the curved spinal column. However, we are convinced that THA is a simpler method for screening ADS and a more compliant measurement for the subject, making it a suitable technique for early detection and regular postural observation. In the future, we will develop an application that measures hyperkyphosis and ADS using the digital camera of a smartphone.

5. Conclusion

The present study aims to develop an ADS screening tool from markerless digital photography and verify its reliability. Our results indicate an excellent correlation between THA and Cobb angle. THA is a scoliosis screening tool that can be used not only in hospitals but also in various other venues, because even unskilled physiotherapists can obtain highly reliable measurements.

Conflict of Interest

The authors declared no potential conflicts of interest with respect to the research, authorship, and/or publication of this article.

Appendix

Procedure of Scoliosis Measurement

1. Preparation for the measurement of scoliosis

- ① Put a sticker on the wall to show the horizon.
- ② Create an index for standing with both legs shoulder-width apart.
- ③ Place the digital camera 1 m away from the wall.

2. Taking a photograph

(Please be prepared to wear light clothes on the day of shooting [e.g., a T-shirt]).

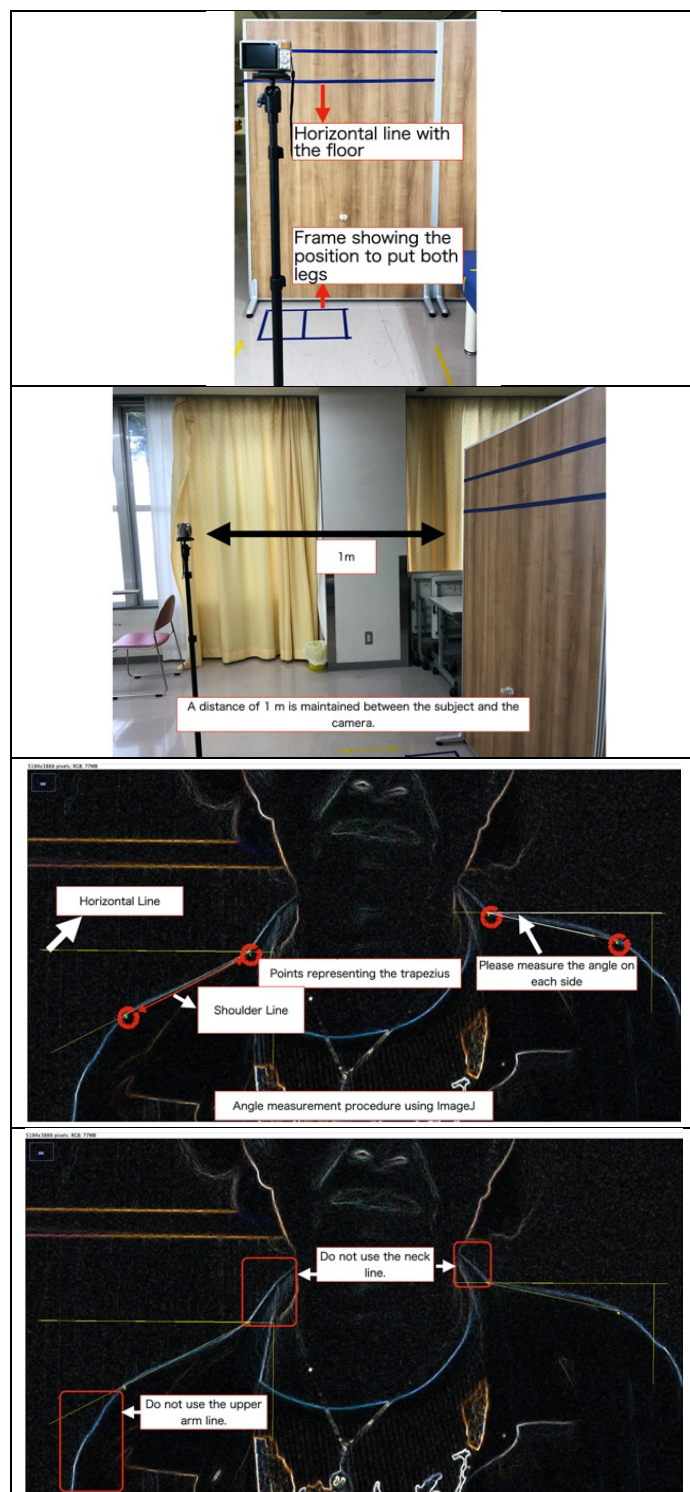

- ① Focus on the subject's eyebrows.
- ② Instruct them to stand in their usual posture.
- ③ Instruct them to keep their eyes open.

3. Trapezius–Horizontal Angle (THA) Measurement tool

(Please install ImageJ on your PC in advance)

- ① Draw a horizontal line.
- ② Make points at both ends of the shoulder line, which represents the trapezius muscle.
- ③ Measure THA.
- ④ Calculate the absolute value of the difference between the left and right THAs.

* Ensure that the shoulder line does not mix with the neck and upper arm lines.

Deep convolutional neural network

ABSTRACT

In recent days, the fast growth of populations leading to an increase in medically complicated cases, especially fast spread viral cases around the world. These phenomena increased demand on auto-diagnose systems to speed up the diagnosis process and reduce human contacts, especially for the COVID-19 pandemic using deep learning (DL). DL methods can successfully carry out these complicated works. A Deep Convolutional Neural Network (Deep CNN) is the most appropriate model for the medical image diagnosis process among DL techniques. This study focuses on follow-up and diagnosis of COVID-19 pneumonia cases. Deep CNN model can learn the chest computed tomography (CT) features properly synchronizing with the training options that involve the optimizer, number of epochs, and learning rate to get optimal accuracy with the lowest error rate. The auto diagnosis process aims to follow-up and diagnosis COVID-19 pneumonia and illuminate it from Streptococcus pneumonia and normal chest. Executed the present study on were 840 CT images of 24 patients from the Radiopedia database. Computed tomography (CT) is the best modality to visualize lung diseases, which own enough positions to interpret everything inside lung anatomy. Deep CNN model owns of enough layers and enable the model to extract and learn pneumonia features from the training set images. This process applied on MATLAB software. The model's result exhibits that the proposed deep CNN approach had an accuracy level of 99.37%.

1. Introduction

In 2019, new type of coronavirus found in china for first time which known as COVID-19 [1]. It is a type of corona virus family, which causes of pneumonia in severe situations [2]. With increasing the COVID-19 cases around the world, demand of advanced computer-aided lung CT diagnosis systems to follow-up and surveillance severe cases increased [1], [3]. Similar pulmonary syndrome shows same features between various Corona virus types, such as COVID-19, Severe Acute Respiratory Syndrome (SARS), and Middle East Respiratory Syndrome (MERS) [2]. The main benefit of DL is speeding up the diagnosis process compare to manually diagnosis. It is dominant field among all machine-learning techniques. It is too beneficial to reduce misdiagnosis and false positives (FP). Deep convolutional

neural network (deep CNN) or ConvNet in DL can learn such complex features to diagnosis process. In addition, it can differentiate in histologically similar tissues more accurate than manually diagnosis [4]. DL involves the processes of feature extraction and classification together for medical image diagnosis process [5]. It can detect ground glass opacity (GGO) and conjunction spot places as significance features [2]. In severe situations, this viral contagious varies to a type of pneumonia. Sometimes causes to multi-organ failure. CT modality is the best technique to follow-up the novel COVID-19 pneumonia (NCP) cases. It can exhibit significant features of COVID-19 pneumonia [6]. CT images of the types of corona virus family have similar features in pneumonia situations [3]. Chest CT features of COVID-19 are different from other types of viral pneumonia, such as; seasonal flu pneumonia or Streptococcus pneumonia [7]. Huge number of COVID-19 cases in everywhere made the medical scientists and researchers think about various ways to

*Corresponding Author: Bakhtyar Ahmed Mohammed, Email: bakhtyar.mohammed@uhd.edu.iq

diagnose suspected cases. Chest CT scan is one way to diagnose COVID-19, which causes medication staffs, use it to follow-up severe cases [2], [8]. Collecting datasets is challenging processes that need a lot of time to solve of this problem is getting AI-driven tool, which invented to work parallel with real-time diagnosis in hospitals to speed up the COVID-19 diagnosis process [9]. Deep CNN compatible with scalability of datasets automatically, such as highly representative, layered hierarchical image features from sufficient training data [10]. In back-propagation process, deep learning enables methods to learn features which relies on the derivative of loss function as gradient descent [11]- [13]. Features of CT images for chest diagnosis, such as ground glass opacity (GGO) to detect COVID-19 pneumonia cases, made it useful in training process in improving computer-aided methods as a fast process. In addition, it aids the clinicians especially in the diagnosis of COVID-19 infection cases [1].

Usually this severe viral contagious confirms by reverse-transcription polymerase chain reaction (RT-PCR). Sensitivity of RT-PCR, which is not properly finding COVID-19 because it cannot activate the virus antigen in early stages of the disease. Because of this reason, CT modality use as an effective way to early screening and follow-up the virus impacts on patients' lungs [3]. Availability of fast and accurate method to diagnose COVID-19 pneumonia is cause to effective treatment properly. This approach implemented appropriate deep CNN method to recognize COVID-19 pneumonia among three classes of viral pneumonia, bacterial pneumonia and normal lung. The training method sat to optimum situation.

2. Background

COVID-19 is the seventh member of corona virus family that infect human and animal. Similarity gene of the COVID-19 with SARS is above 70% and identically of the virus with corona virus of bats is 96% [14]. In 2020, Julian Liu exhibited how symptomatic and asymptomatic COVID-19 diagnosed for first time using chest CT via similar features with old versions of corona virus family types, such as; SARS and MERS. Generally, three clinical manifestations rely on to diagnose COVID-19, such as; symptoms, PCR nuclei test, and CT scan. However, for suspicious cases, at the first stage confirming by CT is effective, reliable, and accessibility aid of diagnosing the suspicious cases. He showed the importance of artificial intelligence (AI) device of Infer vision Inferred CT Pneumonia AI of software support improvements in radiology branch especially COVID-19 pneumonia diagnose process using AI. It is safe contact-free software to recognize COVID-19 pneumonia features using DL in short period of time [15].

Clinicians distributed COVID-19 patients into four groups, such as; mild, moderate, severe, and crucial types according to their lung CTs to follow-up the patients who classified accurately especially in severe conditions using deep learning [16]. In 2020, Dimpy Varshni determined an optimal CNN model for binary classification of pneumonia patients which known as Streptococcus pneumonia and normal cases based on their chest x-rays. This system is too beneficial especially in remote areas [17]. Also, Lin Li developed 3D DL framework to detect COVID-19. He used segmentation and detection for the classes of COVID-19, community acquired pneumonia (CAP), and non-pneumonia.

First process starts by pre-processing to extract lung regions, as regions of interest (ROI) using U-net segmentation method. Second step involve ResNet-50 architecture to extract 2D, and 3D representative features depend on CT slices to detect the classes [3].

In 2020, Song Ying proposed a useful developed computer aided method for clinicians to fast diagnoses of the COVID-19 infectious cases. The method is DRE-net as new DL technique. It can localize main lesion features like GGO in 30 seconds using Tianhe-2 super computer. This device can perform southern tasks simultaneously with the online available server with accuracy 94% [1].

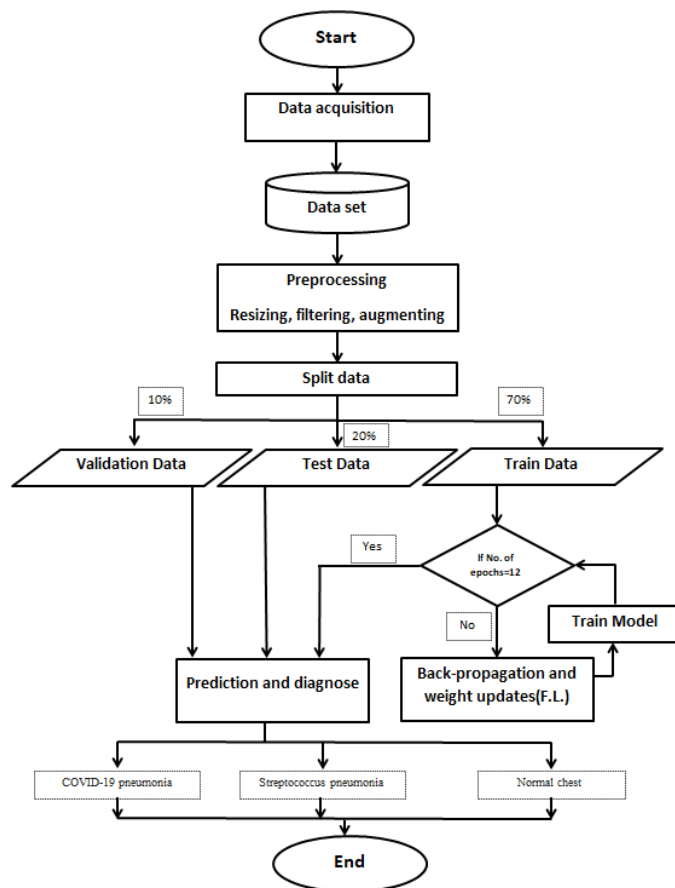

Figure 1: Basic Flow Chart

In addition, Xiaowei Xu proposed a DL system for early screening COVID-19 according to three classes of COVID-19 pneumonia, Influenza-A viral pneumonia, a normal chest via their CT images using DL. However, the problem of real-time RT-PCR to diagnose RNA of the virus in sputum and nasopharyngeal swap is too low rate of positive cases in early stages of COVID-19, but CT scan exhibits the features of COVID-19 pneumonia [7]. In spite of, Chuansheng Zheng proposed a pre-trained UNet for lung region segmentation and weakly supervised deep learning model. It is 3D deep neural network to predict the probability of COVID-19 infections using 499 CT volumes without need for annotating the lesions for training with accuracy 95.9% [18].

In 2020, Ali Narin proposed a quick automatic detection system rely on five pre-trained CNN models of ResNet50 with highest accuracy which is 96.1%, ResNet101, ResNet152,

InceptionV3 and Inception-ResNetV2 according to the classes of COVID-19, normal (healthy), viral pneumonia and bacterial pneumonia [19]. Furthermore, Mohamed Loey proposed a generative adversarial network (GAN) with deep transfer to detect COVID-19 in early stages that increase recovery possibilities. The study relied on 307 chest x-ray images according to four classes of COVID-19, normal chest, bacterial pneumonia, and viral pneumonia depend on the models of AlexNet, GoogleNet and ResNet18 [20].

The COVID-19 auto-diagnose system relies on two important factors which are materials and methodology. Materials compose of the dataset of chest CT raw data and hardware parts. Methodology involves the steps of the proposed system. The current study applied on the CT chest images dataset from Radiopedia in 2020 using deep CNN in order to follow-up and auto-diagnosis COVID-19 pneumonia cases. The proposed approach concentrated on using suitable deep CNN architecture, and the training process options properly with the dataset and necessary tools.

3. Materials and Methodology

It involves every imperative things to implement the system, such as; the labeled dataset to train, test and validate the deep CNN model, suitable platform to run the deep CNN codes on which uses MATLAB and hardware resource like; graphical processing unit (GPU). Preparing the necessary things is the most imperative processes to implement the auto-system via optimum way.

3.1. Methodology

It consists of the practice part of auto-diagnosis processes according to the task priorities. The auto-diagnose system involve some operations, as illustrated in Fig. 1. As indicated in the figure, the system involves the steps of; CT chest data acquisition, pre-processing, distributing the dataset, data augmentation, creating deep CNN, selecting training options, predict and diagnosis.

- **CT chest data acquisition:** It is an essential process to perform the process accurately because supervising learns models learn from the labeled dataset. It is the primary handle to form a good dataset in any case, which is challenging. Medical image modalities are the foremost imperative components to urge the fitting dataset. The examined depended on utilizing computed tomography (CT) picture methodology. It is the foremost prevailing one to display the lungs. The dataset composed of 840 CT images obtained from Radiopedia database of 24 patients for the classes of COVID-19 pneumonia, Streptococcus pneumonia and normal chest. (See Fig. 2).
- **Pre-processing:** It composed of three processes, which are; resizing, de-noising, and CT image data augmenting. CT chest images in situations of pneumonia diagnosis have some problems, which cause of lessening of diagnosis accuracy, such as; noise, missing values, and inhomogeneous region of interest (ROI). In this regard, pre-processing processes solve these processes of the collected dataset. First pre-processing process performs by standardizing the dataset image sizes into an appropriate size, which set to 512*512*1. Second pre-

processing process is filtering. This process performed using median filter for de-noising and preserves edges. It used to solve the problem of missing values. Data augmentation enables the system to interpret images from positions of rotation, scaling, reflection, translation, and cropping. In addition, it used instead of solving the lack of the dataset and increasing capacity to analyze maximum features.

- **Distributing the dataset:** It is partitioning process for each of the classes into 70% for training set, 20% for testing set, and 10% for validation sets. MATLAB tool has ready function to split each of labeled classes according to their rations.
- **Creating Deep CNN:** It is another imperative step in the process because it determines which architecture is suitable to solve the case. Deep CNN enables the auto-diagnosis system to extract GGO features properly with the deep CNN architecture and training process parameters, such as; number of epochs, optimizer, and learning rate. These two parts have the most influences on the process accuracy. Architecture of the deep CNN involves the feature extraction and classification layers. Feature extraction layers composed of image input layer, convolution 2D layer, rectified linear unit (ReLU) layer, batch normalization layer, max pooling 2D Layer. This process repeats until the final pooled feature maps produce. Classification layers composed of fully connected layer (FCN), SoftMax, classification layers. Some parameters have the most influences on accuracy of the proposed approach, such as; organizations of the deep CNN method, datasets, optimizers, learning rate, and the number of epochs.

Figure 2: Used CT image

The proposed deep CNN model utilizes based on the mechanism of the CNN. The components of the deep CNN explained below:

Convolution layer: it is linear process between input images and impulse response. Impulse response knew as mask or filter. The processes performed using a 2-dimensional (2D) convolution, as shown in Equation 1. It performed by convolving both horizontal and vertical directions in 2D spatial domain.

$$Z_{x,y} = \sum_l \sum_k W_{l,k} a_{x-l,y-k} + b = W \otimes a_{x,y} + b \quad (1)$$

where ($a_{x,y}$) is 2d input image values, (w) is kernel or weight, (b) is bias, (x, y) extends the dimensions of the input, and l, k extends the dimensions of the kernel.

ReLU layer: it is a non-linear relationship of convolution result process. Its primary utilization is using for hidden layers of the neural network. This function only lets the maximum values pass during the front propagation. As shown in Equation 2.

$$W_{l,k} = h(Z_{x,y}) \quad (2)$$

Batch normalization layer: This layer is responsible for distributing each class of the CT images dataset into smaller batch sizes in order to run the program properly with the processing unit. It is a procedure for preparing as well profound neural systems and standardizing the inputs to a layer for each mini-batch. The algorithm distributed the classes by mini batch sizes of 32, which cause decline run-time.

Max pooling: It discounts includes sizes indeed, when zero cushioning increments include more extended interior the image. Pooling may be a way to require huge pictures and shrivel them down whereas protecting the foremost critical data in them, which declare to as highlights. After all these forms, the highlights arranged by means of the pooled highlight, maps. This process continues until the final max-pooling layer in the last epochs.

Include extraction in each directed learning strategy depends on datasets. In this respect, DL strategies are cleverly strategies to memorize highlights from the preparing set.

Fully connected (FCN) layer: it is the first layer of classification process. The image values arrange in this layer in the form of a vector. FCN is the advanced level of filtered images. The images values interpret vertically, and it translates to prediction and vote.

SoftMax layer: It is an activation function that typically applied on the output of the final layer.

Classification Layer: It is the last layer inside the deep CNN architecture, which is responsible for selecting the number of the classes.

After any forward propagation, a result produces which called actual result. In addition, every process has target result. These two results determine error total. As shown in Equation 3.

$$E_{\text{total}} = \sum \frac{1}{2} (\text{Output}_{\text{target}} - \text{Output}_{\text{actual}})^2 \quad (3)$$

After each of the forward propagation process, the backward propagation process comes to adjust the weight values to make the system train to learn the features to increase the accuracy, (See Equation 4).

$$\delta_{x,y}(l) = \frac{\partial E}{\partial Z_{x,y}(l)} = \sum_u \sum_v \frac{\partial E}{\partial Z_{u,v}(l+1)} \frac{\partial Z_{u,v}(l+1)}{\partial Z_{x,y}(l)} \quad (4)$$

The processes of forward and backward propagation continue from under-fitting to optimal means the accuracy arrives to the highest plateau, which is lowest error rate. As shown in Figure 3.

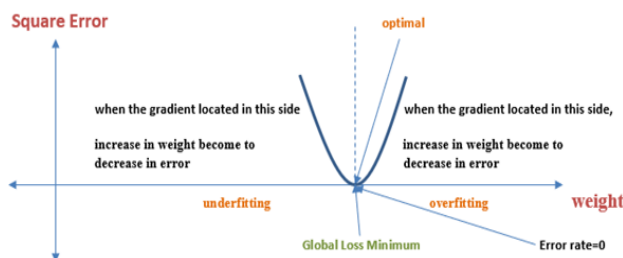

Figure 3: Optimum case in Gradient Descent

This study relied on multi-classification to classify three types of chest situations relate to COVID-19 pneumonia diagnosis. It arranged in three classes, including COVID-19 pneumonia, Streptococcus pneumonia and normal chest with accuracy of 99.37%.

Selecting training options: Training options are the most effective factors to increase the learning capacity. It controls the learning process appropriately. The learning process or training performed through back-propagation process. The training option of auto-diagnose the process involve such effective parameters as; stochastic gradient descent with momentum (SGDM), epoch numbers, and learning rate. Gradient descent method is responsible for adapting the parameters to decrease error rate gradually according to epoch numbers. SGDM optimizer is an important parameter for the training process. It is an adaptive learning rate method, which calculates the derivative of total error with output of each process via back-propagation and updates their weights. The optimizer determines next place where it goes on the curve. It calculates the individual learning rates to various parameters with the initial learn the rate of 0.001. These factors are important and effective to the training process because they enable the method to get maximum accuracy and the lowest error rate. It solves according to the equation 5.

$$M = a - N \Delta f(a) \quad (5)$$

while M; is next value, a; is current value, N; is the learning rate which is a hyper-parameter, $\Delta f(a)$ is the path of the steepest descent. This process determines the path of optimal weights the formula tells the next position where the optimal way goes, which is the direction of the steepest descent.

- **Diagnose and detection:** This process indicates true positive and negative situations of the classes relate to the decision making about the pneumonia cases. The proposed method can recognize the new image features accurately based on the trained features.

In this study, the dataset labeled according to three classes, such as; COVID-19 pneumonia, Streptococcus pneumonia and normal chest. The chest CT image dataset collected from Radiopedia of 840 lung CT images of 24 cases with both axial and coronal states. The dataset included the images, which own of the most significance features. Then the images pass through pre-processing step using image resizing, filtration and augmentation to decrease noise and enhance the images quality and increase readability. The images resized to size of 512*512*1. Median filter used to remove noise problem of missing values and compensating missing values without removing original image pixels and the images augmented to increase feature extraction capacity.

After that, the images feed to the Deep CNN method to recognize and diagnose COVID-19 pneumonia and compared it to; Streptococcus pneumonia and Normal chest according to tested image features. DL is capable to learn complicated features, as; ground glass opacity (GGO) of COVID-19 pneumonia features which reveal them by CT images. Every methods of CNN model pass through the processes inside the deep CNN model for feature extraction and classification purposes.

Figure 4: The process implemented on MATLAB

Organization of the Deep CNN is the most important factor in the diagnosis process. Because it determines which architecture, appropriate to solve the case. The architecture of the proposed model involves multi-hidden layers for feature extraction process. This process relies on multi-layer perceptron (MLP). While the digital image values pass through the deep CNN method. The transmission of image values in neural network depends on two processes according to how the adjacent nodes transmit image values to next layer node. The image values go through the convolution layer by convolving the image values and weights, and pooling and ReLU layers. These layers perform the process of feature learning. Weights represent filters. The input image passes through forward and backward propagation in an epoch, while the connections between adjacent layer nodes are weighted.

The weights essentially are highest similar feature values, which own of the most similarity. According to these similar features, the deep CNN method can select the most significant features. The model extracts the homogeneity of the images based on the training set labeled classes.

Goal of the back-propagation process is to update each of the weights of the nodes or neurons from the output layer to the input layer according to the number of epochs in the network in order to the actual output is closer to the target output. Feature learning or feature extraction learns in the backward process according to the number of epochs and iterations, Batch size, learning rate and optimizer. Number of epochs and iterations are the important factors to enhance the performance of the operation. One epoch means one time the process completes forward and backward propagation according to stochastic gradient descent method. As the number of epochs increases, a greater number of times the weights changed in the neural network and the curve go from under-fitting to optimal then to over-fitting according to the repeating number of epochs. Batch size determines how many iterations need in one epoch.

The role of training dataset in deep CNN is the source of features. It works as image library to track features based on it the model can decide and predict.

An imperative thing in back-propagation process is getting Global Loss Minimum which mean square error is equal to the lowest error rate. After setting the factors, which cause to get the best performance, the model can recognize the images according to the classes. Some factors increase performance of intelligent methods, such as; dataset, optimizer, number of epochs, batch size, learning rate, in addition to some other pre-processes operations as; resizing images dataset to a desired size which cause to accelerate the process, and data augmentation. In the processes of classification and detection, datasets can use as resource to deep learning methods especially for the proposed method. The proposed method capable to expand and manipulate many complex problems relate to computer vision, which can manipulate higher image quality compare with some of other methods. In addition, this method can involve many image types relating to COVID-19 pneumonia to diagnose and follow-up the COVID-19 pneumonia progression situations, also evaluate the stages. It can use as criterion to classify the patients, which aid the medication process. This process implemented on MATLAB with best accuracy, which is 99.37% according to the collected dataset, as shown in Figure 4 and it fixed to set on optimum situation.

4. Conclusions

The study reveals that auto-diagnoses of the COVID-19 are too necessary. CT images of the classes are too different from each other. Some factors have the most impacts to increase accuracy. The factors consist of the dataset, deep CNN method, training options. The dataset represents as the feature bank. Deep CNN method involves feature extraction and classification processes together and necessary layers until the most significant features arrive to the classification layers to vote. Training options,

which include the optimizer and number of epochs and learning rate. The performance of Deep CNN in terms of its feature learning accuracy is highly dependent on the number of utilized epochs, which set to 12 in the present study. The whole auto-diagnoses system runtime did not subtend more than 2 minutes, representing real-time diagnosis. Accurate diagnosis of COVID-19 pneumonia CT images is highly useful in follow-up and diagnosis, in turn rising the patient's lifetime. In this regard, deep CNN is one of the most significant and effective models that in automated COVID-19 pneumonia diagnosis, with the classification capacity of hundreds of images per second.

ABSTRACT

Blockchain (BC) as the widespread innovations in the 21st century has recognized itself to be immutable, tamper-resistant, decentralize and secure. This emerging technology is used as a functional technology for refining present technology and forming new applications for its robustness and disintermediation. Decentralized Digital Self-Sovereign Identity (DDSSI) is an identity mapped with individual identity information along with the user's reputation in the transaction. User's information will be preserved in the decentralized cloud server which will be controlled and maintained by the user. In this research work, we suggest a Blockchain-centered DDSSI wallet to modernizes the existing identity management system that will be used to identify as well as access control to provide validation and endorsement of entities in a digital system. BC technology in this innovation ensures credible and safe information in a transaction besides. Here, we use Bitcoin cryptocurrencies to generate secure and unique DDSSI public key addresses by integrating the private key with the random number for transferring and accepting information and a token-based system to identify customer reputation.

1. Introduction

The Internet of Things (IoT) targets linking the whole thing from human-being, households, organizations, and objects in the real world. About 13.5 billion devices will be connected which are equipped with actuating and sensing abilities [1]. This very fast-growing innovation in the digital ecosystem with the diversity of e-services, a variety of entities, billions of people, trillions of devices need to have their own digital identities to be easily identified and interrelate with each other in this virtual world safely and securely. In the early decades, credentials as username and password were commonly used for every individual to do registration, access and manage in the different online platform. Societal security address, National identification number, passport number, and other authentication numbers were used in the traditional approach. The systems have a centralized databank for storing individual records [2]. The national identity management systems experience security instabilities subject to

system downtime, attacking hackers and software up-gradation as well as network traffic restrictions [3]. Identification, authorization and authentication process of individuals must have mechanisms to manage the information about individual trustworthily. In recent times, the internet security issue is very challenging and crucial. The secure access demand is a very significant assurance for the information technology workforce. As a result, individual information is often tampered with or leaked. Therefore, society demands secure identity management. With the benefits of BC technology, identity management offers a decentralization feature without using any centralized database or dedicated databank where information can be stored and verified your identity on the internet. Our DDSSI ensures secure, safe and authentic identity management with the integration of BC technology. DDSSI is a unique perfect in which somebody, organization, or entities completely preserves as well as panels their data that is not administered by the federal system which can never be unconcerned from the identity owner. The necessities of the SSI are designated below:

*Corresponding Author: Md. Tarequl Islam, Department of Computer Science and Engineering, Mawlana Bhashani Science and Technology University, Tangail, Bangladesh, Email: tareq.cse@gmail.com

The owners of the Identity have full control over the data. Data reliability, safety, and confidentiality are ensured by the system where central authority is not mandatory for reliance.

It arranges for full transportability of the information where owners can procedure their uniqueness documents in where they want for example accessing an online service.

Changes to the data are clear, and clearness is continued by the system [4]. BC proprietors are recognized by public-key cryptography based on unique elucidations to develop the conception of asymmetric cryptography to assign digital identity. Several features of BC mark the technology appropriate for well-organized and secure identity supervision: BC is a digital ledger system that is immutable and transparent (based on permissions or permission-less) where immutability and transparency are important for identity management. Single point of catastrophe and denial of service (DoS) attacks can be unaffected by BC technology. BC offers a proficient application of public-key cryptography and hashing which:

- can be persistent for digital identity control.
- provisions protect the integrity and validity of identity-centered records.
- can be developed for third-party attestation of proceedings.
- supports simplifying agreement-oriented record delivery with smart contracts. technology.

BC eradicates domination in identity management, as it is not controlled by a central power that permits identity and records amalgamation on a worldwide scale. BC chains inducements via crypto-currencies that can be applied for convinced responsibilities such as providing incentives to the participants for data sharing.

2. Background Work

This section represents the advancement of identity management systems: Centralized ID System, Integrated ID system, and Self-sovereign ID system.

Figure 1: Advancement of the Identity Management System

2.1. Centralized Identity System (CIS)

A centralized identity system is the SILOED and the simplest traditional identity system which was used in the early days of the

internet. Organization issues digital credentials that users can use to access the services of the organization [5]. In this system, the organization controls and stores the identity-related credential of the user. Besides, to obtain service, the user needs separate credentials for each system or organization. The trust association between user and organization is built on a mutual secret, in most circumstances, log-in username is typically linked with a password. Recently, with the advancement of the Internet of Things, every organization, and billions of people are now connected over online, problems such as fraud are rising fast.

2.2. Integrated Identity System (IIS)

This integrated identity system incorporates a third-party enterprise or confederation to act as a centrally controlled identity provider between an organization and user [6], [7]. In IIS, the identity provider issues digital credentials to the user to access the services of the organization integrated with the identity provider. IIS resolves two major issues, firstly, IIS provides seamless access to the services of the organization where the liability of handling identity as well as password confidentially by integrating an entity who provides identity, which is a supplementary duty besides the core commercial procedures and secondly, it eliminates the encumbrance from account holders to accomplish numerous identity-associated information for numerous entities by proposing a Single-Sign-On (SSO) benefits. IIS works as a user login to the identity provider portal, which then “federates” login to the facility using numerous protocols such as OAuth, SAML, or OpenID [8] Connect. Trust between the user and the identity provider is preserved similarly to CIS.

2.3. Self-Sovereign Identity System (SIS)

SIS is a two-parties relationship identity system which is the advancement of IIS, where no third entity coming between the user and the organization [7]. SIS directly connects user and organization as a peer. Users have full control over their confidential and personal data by using a digital wallet. SIS wallet stores all the trustworthy and private data on the system that is maintained by the user. SIS introduces three significant entities i.e. owners, issuers, and verifiers. Credentials are created and issued to the owners by an issuer who gets credentials from an issuer, stores it, and submits these credentials to the verifier to verify once required [9]. The verifier accepts and authenticates credentials claimed by owners.

2.4. Blockchain and Bitcoin

To keep pace with the era, there is no alternative way to the development of technology. A trustworthy system is a key objective to deal with profound data such as commercial transactions with digital currencies even when it is very difficult where no authentication nor assessment apparatuses are delivered. This framework presented two essential thoughts[10]. The first one is Bitcoin which is a virtual value of cryptocurrency without depending on any centralized organization. Somewhat, the currency is held collectively and securely by a distributed network of the user that makes up an auditable and confirmable network. The other concept, whose reputation has away even further than the cryptocurrency itself, is BC. BC is the approach that consents communications to be tested by a group of untrustworthy users. It delivers a disseminated, immutable, apparent, confident and

auditable register [11]. The BC can be accessed willingly and entirely, permitting access to all contacts that have arisen since the first transaction of the approach, and can be certified and organized by any individual at any instance. The BC protocol organizes data in a chain of blocks, where a set of Bitcoin transaction details accomplished at certain instances are stored. Every block is associated with the prior block, for developing a chain. To support and operate with the BC, network peers have to provide, the functionalities of storage, transmitting, mining and wallet amenities [5] are delivered by network peers to control and provision with the BC. BC is a digital ledger where a paired node shares their data transacted between them. As it was earlier stated that this approach is deliberated as the key contribution of Bitcoin since it resolved a long-lifelong commercial issue known as the dual-spend problem. The explanation anticipated by Bitcoin comprised in looking for the consensus of the most mining nodes, who affix the effective transactions to the BC. Although the BC concept was initiated as a means for a cryptocurrency, it is not obligatory to improve a cryptocurrency to practice BC and construct the decentralized solicitations [12]. A BC is a chain of time-stamped blocks that are connected by hashing address of cryptocurrency and is the process by which data is distributed among all nodes [13].

Table 1: Comparison of different types of an identity management system

	PKI	Bitcoin Based	Ethereum Based	Reputation	Privacy	Year
Namecoin		●				2014
Certcoin	●	●				2014
Fromknecht	●	●				2014

Axon	●	●			●	2017
Augot	●	●			●	2017
SCPKI	●		●		●	2017
DDSSI	●	●		●	●	2021

The Namecoin [14] used a Bitcoin-based BC system to provide domain naming systems along with the IP address identification. The next that has been modified by Namecoin, Certcoin [15] forms decentralized validation system PKI. A paper of decentralized PKI [16] proposed certcoin factors to certify the preservation of identities where entities could not register multiple times. Privacy-awareness in blockchain-based PKI [17] scrutinizes privacy desires when planning decentralized PKI methods and a blockchain-based PKI with concealment

consciousness has been signified here. According to a user system for verified identities [18] amend the Bitcoin stack to construct an identity management resolution and introduce a zero-knowledge proof. Secure identity registration on distributed ledgers [19] are other decentralized systems along with confidentiality preserving landscapes using blind signatures. Besides, several setups and researchers collaborating with technological experts are concentrating on the improvement of identity methods such as Evernym, Uport [8], [20], Shocard [21], Civic [22], Jolocom [23], Bitnation [24] and Sovrin [8] to solve the digital identity problem. We also propose PKI based DDSSI identity system where we use a Bitcoin system along with the combination of privacy [25] and reputation with the collaboration of BC [26].

3. Proposed Method

In this research, we suggest a DDSSI structure using a Bitcoin cryptocurrency-based BC system. Unlike other identity systems, our proposed method contains three parts: i) identity address ii) user information and iii) reputation task of the user. Here, we use bitcoin cryptocurrency to generate secure addresses by Elliptic curve formula where a random number is integrated with a user private key. In general, a pseudo-random number generator generates a random number that is almost deterministic. Therefore, we have proposed to ingrate private keys with a random number to generate the secure address. The private key (pK) is very important in cryptography. Here, we integrate a user-defined private key and a random number to generate a digital identification address (dSI_{address}) for transferring and accepting data by using SHA-256 hash function. In this system, the number of bits is reduced and the security is enhanced compare to RSA encryption [27]. User information (dSI_{info}) is user-controlled data as biometric data, images and other attribute inherited from national identity (NID). User can set any other attribute belongs to them those are encrypted by pK and are hashed to create dSI_{info} which is controlled and maintained by the user. User can update their information at any time. uRtoken is used to detect user behavior. Therefore, a user is individually recognized by the amalgamation of their record, public key Bitcoin address, and uRtoken.

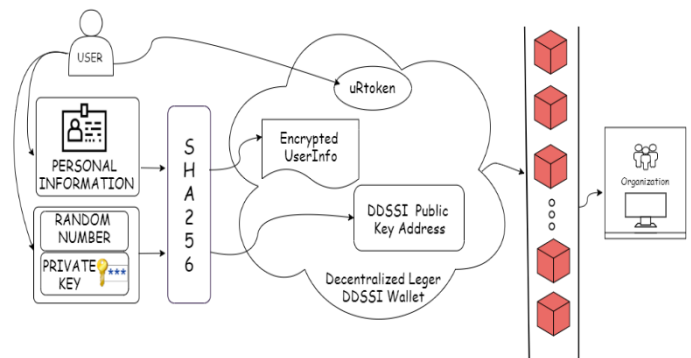

Figure 2: Block diagram of DDSSI Wallet

An entity user may change their information even the address dSI_{address} may be updated which will not impact the user behavior uRtoken. While updating the user information, a new hash value to be generated and uRtoken will not be impacted and migrated to the new one. Users may request to change their address. In this case, the user information and token will be transferred to the new

one. In both cases, the old information is stored in BC. Sidestepping the attackers conceal their credentials by altering their addresses. The amendment of the user's information must require their aforementioned address which was delivered to ensure the acceptability of the information alteration process. Reputation is the behavior in which the aspect of identity in the scheme is noted. uRtoken is one type of reputation system where no one can alter the manipulator's information to confirm the protection of the individuality connected information. As soon as manipulator comportment meets the execution situations, the convention is inevitably completed with the data precisely written or improved, confirming the safety of the associated information.

3.1. Algorithm

Input: a \in Private key, National Identification Number, Random Number, user information

output: a gateway to access enterprise platform, validation and mine transactions

- Generate Bitcoin address $dSI_{address}$ by using a random number of generator and Private key (pK)
 $dSI_{address} = SHA256(RANDOM_NUMBER, pK)$
- Create user digital identity information by hashing and encrypting user information and NID by the private key.
 $dSI_{info} = SHA256(NID_{info}, entity\ information)$
- Organize wallet to authenticate and authorization of access.
 $dSI_{wallet} = (dSI_{info}, dSI_{address}, uRtoken)$ where $uRtoken: \in$ (Reputation of user)

Another way, uRtoken is cast-off to recognize the manipulator's character which is an object of the manipulator in a physical world to distinctively recognize. The feature of uRtoken is that the alteration of distinctiveness information will not distress the manipulator's character by avoiding the formation of various identities, the system accomplishes uRtoken alteration when a manipulator changes his uniqueness info.

Another way, uRtoken is cast-off to recognize the manipulator's character which is an object of the manipulator in a physical world to distinctively recognize. The feature of uRtoken is that the alteration of distinctiveness information will not distress the manipulator's character by avoiding the formation of various identities, the system accomplishes uRtoken alteration when a manipulator changes his uniqueness info.

An alternative form of uniqueness amendment is the modification of manipulators' Bitcoin-based public identity. Once a manipulator desires to alter his Bitcoin-based public identity, the scheme will also create a new address, and the ancient identity will persist warehoused in the BC. Consequently, the individuality information and uRtoken are lifted from the ancient identity to the reorganized one, circumventing the invader's hide their uniqueness by changing their identity. It is well-known that the alteration of a manipulator's address entails the manipulator deliver his ancient address of the ID to confirm the lawfulness of the address amendment procedure. Once a manipulator always behaves honestly and energetically, the manipulator's reputation

should be high, and verse vice. As a result, the uRtoken score of a manipulator replicates the manipulator performance variation with time.

Figure 3: Identification of user behavior by reputation token.

The uRtoken is symbolic related to the reputate parameters and inducement responsibilities. In this paper, we recommend a new perception uRtoken day that gathers the stricture apprehending the entire number of days a manipulator grasps uRtoken. For example, a manipulator has convinced figure of uRtoken at time t , at that time the manipulator's uRtoken day upsurge by uRtoken at time $t+1$. In other words, a manipulator's uRtokenday is a snowballing function of time, and it rises quicker when the manipulator has more uRtoken. When uRtoken of a manipulator is positive, the manipulator's uRtokenday resolve reliably rises gradually.

Figure 4: Changing the behavior of uRtoken concerning time.

Consequently, uRtokenday organizes not only replicate the number of tokens that manipulators holding, but also imitate the days that uRtoken holds the day. When the manipulator holds a static uRtoken, and the manipulator's uRtokenday will increase linearly. On the other hand, when the manipulator holds a smaller amount of uRtoken primarily and gains more and more uRtoken concerning time. As a result, the user's uRtokenday rises convexly. In the same way, if the manipulator holds a greater volume of uRtoken at first and loses it progressively. In this case, the manipulator's uRtokenday will be increased concavely.

- $\Delta uRtoken_i = 0$ which indicates that the amount of $uRtoken$ held by the manipulator i with time T remnants unaffected.
- $\Delta uRtoken_i < 0$ which represents that the quantity of $uRtoken$ held by the manipulator i with time T is diminished.
- $\Delta uRtoken_i > 0$ which represents that the quantity of $uRtoken$ held by the manipulator i with time T is improved.

Let us consider m manipulators in a particular scheme. In the first stage, the manipulators are graded according to the rising sequence, and we signify the manipulator address of the manipulator with the minimum S_i as S_1 , and so on. In the second phase, we bounce 1 to manipulator 1, and 2 to manipulator 2, and so on. Here, when the manipulators with a similar representative deviation, the score will remain similar. In other arguments, if $S_i = S_{i+1}$, then $R_{si} = R_{si+1} = i$, which resultant the extreme value of the status score k is a reduced amount of or equal to m .

Table 2: Ranking Score of $uRtoken$

S_i (ascending)	S_1	S_2	S_{m-1}	S_m
R_{si}	1	2	k-1	k

Figure 5: Bitcoin address generation

3.2. Bitcoin Address Generation

The random numeral is a procedure through which an expedient, produces an order of facts or signs that cannot be sensibly forecast restored than by a haphazard casual. Random number producers which is hardware random-number producers which produce haphazard records as an occupation of present charge of some physical environment quality. Produce haphazard information within a min and max series that describe and category the outcomes as well as to create a usual of one to ten thousand arbitrarily chosen information. By integrating a private key with a random number, we can generate a secure number. A sequestered key, also recognized as an undisclosed key, is adjustable in steganography that is cast-off with an algorithm to encrypt and decrypt code. Clandestine secrets are only communal with the key's producer, creating it extremely protected. Private keys play an important role in symmetric cryptography, asymmetric cryptography, and cryptocurrencies. The SHA is one of a numeral of cryptographic hash functions. A cryptographic botch is like a signature for a piece of information. If you would compare two cliques of raw data, it is always restored to hash it and equivalence of SHA256 principles. It is the fingerprints of the information. Even if only one sign is altered the algorithm will yield diverse hash value. SHA256 algorithm produces an almost-

unique, static size 256-bit hash. Hash is also known as a one-way occupation. This type is appropriate for scrutiny truthfulness of our data, contest hash verification, anti-tamper, digital autographs, BC. If we generate a random number and add it to a user-defined private key, then we pass it SHA256 hash-based algorithm to generate DDSI number.

3.3 Elliptic curve along with bitcoin address

We can generate secure random number by programming coding using java, C++ etc. Generating cryptographic pseudorandom numbers, total number of combinations have been found:

$$2^{(32*8)} = 2^{256} = 115,792,089,237,316,195,423,570,985,008,687,907,853,269,984,665,640,564,039,457,584,007,913,129,639,936 \text{ (78 digits or approximately } 10^{77}\text{)}$$

After generating the pseudorandom numbers, we have added the private key as a password. As a result, we will get.

$$\text{Random number} = \text{SHA256}(\text{SHA256}(\text{password}))$$

Password: selimtareq@csekyau-12. The 32 bytes signature generating by cryptographic secure SHA256 algorithm that is almost impossible to guess and decryption to the original number in impossible. This omnidirectional algorithm generates HashA1 value that is always 256 bits in length.

By using elliptic curve cryptocurrency can be calculated: $y^2 = x^3 + ax + b$. Elliptic curve assets:

- If a line crosses twofold themes P and Q , it crosses the third point $-R$.
- If a line is a digression to the curve, an alternate point will be crossed.
- The curve will be intersected by all vertical lines at an extent.

3.4. Calculation of BITCOIN Public Key

Elliptic curve (ECC) was developed by Neal Koblitz and Victor Miller in 198 and used in Bitcoin or Litecoin Cryptocurrencies. A 256-bits ECC key is more beneficial in terms of security compared to RSA public key encryption of 3072 bits. Therefore, processing power consumption is also very less for using ECC. Ellipses are designed by quadratic curves (x^2) where the elliptic is cubic (x^3).

Public Key Version Hash D = Version "00 " || HashD2: Hash the Public Key Version Hash D value using the cryptographic hash function SHA256. This omnidirectional Secure SHA256 algorithm generates 256 bits signatures. The Public Address Compressed is the Public Key Checksum D value coded into a Base58 value. The Public Key Compressed value can be made public and can be transformed into QR cryptographs and can be written on paper wallets.

Koblitz curve using standard efficient cryptography tools	
Parameter	Value
a, b	The elliptic curve is defined by the constant a and b, $y^2 = x^3 + ax + b$, $a = 0$, $y^2 = x^3 + ax + b$, $b = 7$
p	The finite number of elements is the prime number p. F_p is called the prime field of order p along with class modulo p, where the p elements are denoted 0, ..., p - 1. This means prime number p should be used for all the finite field math operations (better known as modulo operation), for example: $y^2 \bmod p = (x^3 + ax + b) \bmod p$. The output of the math operation should never be bigger than the p value. $p = 2^{256} - 2^{32} - 2^9 - 2^8 - 2^7 - 2^6 - 24 - 1 = 2^{256} - 2^{32} - 977$
G	On the elliptic curve, the predetermined base spot (xG, yG). By the equation, $yG = (xG^3 + 7)^{1/2}$, we can obtain yG coordinate Therefore, xG and yG are the first and last half of the coordinate as followings: xG: 79BE667EF9DCBBAC55A06295CE870B07029BFCDB2DCE28D959F2815B16F81798 yG: 483ADA7726A3C4655DA4FBFC0E1108A8FD17B448A68554199C47D08FFB10D4B8
n	n is the prime number of basepoint. 32 bytes number in the series [1, n - 1] is a endorsed private key. Thus the range of any 32 bytes number from 0x1 to 0xFFFFFFFFFFFFFFFFFFFFFFFFFEBAAEDCE6AF48A03BBFD25E8CD0364140 is a valid private key.
h	The cofactor: 01

Figure 6: Generation of public key using elliptic curve approach.

Figure 7: Fundamental characteristics of DDSSI

4. Major Outcomes of DDSSI

There are lots of benefits to using this proposed identity management system that can make the system is desirable for every nation, organization and person to maintain secure and timely manner transaction.

Existence: Each user must have a unique self-governing digital existence in the DDSSI system.

Control: User acts as decisive experts who must have full control over the data as well as their identities.

Access: Users must be able to access their identities effortlessly without any overseer. They should be cognizant about any alterations at each time that have been amended to all claims correlated to their identities at each time.

Transparency: All the algorithms and systems that are being used in the DDSSI wallet must be transparent. Therefore, each user can monitor how they are controlled, reorganized and worked accurately.

Minimization: Disclosure of information must be minimized and provide data as minimal as necessary.

Persistence: Data must be retained unchanged even the system is being upgraded or any changes made in the algorithm. User identities must be perdurable until the user's desire.

Portability: Each user can disseminate their identities and make them usable once they need it even, they can dispel third-party dependency. Similarly, the user can transmit the identity when they need it.

Interoperability: Identities must be adequate anyplace in the sphere as serviceable as possible, the system would drop flexibility without ensuring interoperability.

Protection: User rights acts as a key purpose and guideline principle of an owner. The boundary of user rights must be stated and protected.

Consent: Individual identity repositories may be stolen by the intruder. Users must have a prior agreement for using their identity.

Apart from those properties we propose one further requirement Non-repudiation to make any transaction trustworthy between DDSSI owners. Therefore, one entity can't throw away the validity of a claim or action taken earlier. Based on the above features we propose a typical architecture of DDSSI to provide a decentralized secure and safe platform to store user's identity information and every smart transaction that happened by itself. Compare to other approaches, it would be more beneficial as this approach used reputation-based transaction management as a digital signature of behavior by that users can define borders within which they make the decision and outside of which they negotiate with others as peers.

5. Conclusion

In every single moment, an enormous digital revolution is experienced in the world. And now, the physical entity along with digital instances is merging to form a single reality. Therefore, we unquestionably need a new approach to manage all the digital entities. Specifically, the approach should have privacy and security in every circumstance. That's why DDSSI shows light in the way for this picture-perfect solution. In practice, the approach offers rights and full control of user identity along with makes the system manage it effortlessly. As we have used the immutable decentralized BC with Bitcoin technology to maintain the system safe, secure and fast. Therefore, in the coming days, we believe that the proposal would be the best approach to make the system decentralized.

AC-DC Conversion

ABSTRACT

A new approach for designing RF energy harvester with a single stage converter circuit is presented in this paper. The proposed converter configuration is integrated with an antenna that is based on the coplanar waveguide (CPW) transmission line with improved gain resonated at 2.45 frequency ISM band. The CPW patch antenna as a harvester antenna is designed in a rectangular shape that uses FR-4 substrate with a loss tangent and relative permittivity of 0.025 and 4.3 respectively. The output from the harvester antenna is connected to the converter circuit using only two Schottky diodes. The rectifier design achieves between 0.1% to 37% of RF-DC power conversion efficiency over the ambient RF input signal range from -20 dBm to 0 dBm and the antenna exhibits a directivity of 3.896 dBi as well as a return loss of -48.85 dB. For an input power of 0 dBm, the proposed circuit can rectify an AC signal up to 6.09 V. Moreover, the proposed CPW antenna that is integrated with a converter circuit agrees for the harvesting of ambient electromagnetic energy to power low power electronic devices.

1. Introduction

Advancements in energy harvesting from the environment or ambient have grown a lot of attention in recent years as ambient energy harvesting delivers a green self-sustainable operation for powering low power electronics devices [1–3]. This technology exploits energy from several sources from the environment, for example solar light, heat, vibration, thermal energy and electromagnetic waves [4, 5]. It has become an alternative for powering low power electronic devices instead of using a conventional method which is battery plug in mainly used in wireless sensor networks of the Internet of Things (IoT), wearable electronic devices and implantable biomedical devices [6–9].

Today, batteries remain the vital source to power up these system devices. Nevertheless, the method has various inherent disadvantages. For instance, the battery size and weight are huge, limitation of battery lifespan and also requires more cost of battery replacement for these devices [8, 10–12]. To overcome these drawbacks, engineers have exploited a new approach called energy harvesting, to extend the battery life and empower an autonomous manoeuvre of the IoT end nodes [13, 14]. The energy harvesting has rendered an attractive approach for energizing low power electronic devices [2, 15]. It empowers wireless charging, battery-less and a reasonable alternative for supplying the wireless nodes

even in cold, dark, and static environments without requiring power cables or battery replacement [14, 16–18].

The past decade has seen an increase in the use of an ambient environment as the source of radio frequency (RF) energy harvesting. This harvesting system is the most prominent of its accessibility and easy scavenging system compared to other sources. Other sources are far from human control as thermal energy requires heat, vibration needs motion while solar requires light present [19, 20]. This alternative approach used the concept of capturing the ambient power, including the wasted power that hovering in the surrounding environment without any distraction to the environment [21–23]. In contrast, the naturally low ambient RF energy can be significantly challenging. Also, it is easily carried or wear, especially when the RF energy harvester is combined with completely autonomous systems due to its low input power and voltage necessities [24, 25]. To overcome this issue, the Schottky diode has been commonly used for RF energy harvesting as it has a minimum threshold voltage and fast switching diode speed [10, 13].

The RF energy harvesting system comprises an antenna that captures an RF incoming signal, a network that represents impedance matching for exploiting power transfer from the antenna and the rectifier or converter circuit. The rectifier circuit is a key component in the system block which determines the system efficiency. It converts the RF signal to DC voltage and stores the energy in holding load storage devices such as capacitor

and battery. Figure 1 illustrates the basic block diagram of energy harvesting structures. The following sections describe four main parts of this system.

Figure 1: Block diagram of RF energy harvesting system [13]

The major challenge in designing an ambient RF energy harvesting system is the requirement to operate with low power RF signals. The works published in [13,26,27] have achieved the maximum power conversion efficiency (PCE) of the rectifier at relatively high input power levels, which is above 5 dBm while the available ambient RF signals are much lower levels in the environment which are lower than -15 dBm. In order to reach high maximum PCE, multistage rectifier is the most commonly used technique among previous researchers [28,29]. Nevertheless, the high power efficiency results from high input RF signals that are applied to the multistage rectifier. The circuit designed in [30] needs four stages in rectifier configuration for their circuit optimization when -15 dBm input power signal is applied. They observed that the number of stages does not help to improve efficiency for low power RF input signal. As the number of stages increases, the peak of the efficiency curve decreases toward higher powers.

This paper is an expansion of work originally reported in Proceedings of the 2019 IEEE Asia-Pacific Conference on Applied Electromagnetics (APACE) [31]. In the previous work, a square patch antenna was designed and analysed with a matching converter circuit. In this proposed work, the antenna and the rectifier of the converter circuit have been enhanced for both parts. This work also highlights a single RF energy harvesting circuit that aims to convert the power within the 2.45 frequency band RF signal into usable DC supply. As compared with previous work [31], the gain of the enhancement antenna has been improved. Meanwhile, the ripple voltage of the output signal that occurred in previous work has been resolved with a new arrangement of components in converter circuit design. In the end, a novel RF energy harvesting system using only one stage converter circuit is presented which is able to harvest low input power signal.

2. Harvesting Antenna Design

An antenna is required in the receiving part for harvesting RF energy as it captures energy from ambient. The RF energy is then rectified and converted into DC voltage. The proposed harvesting antenna design as illustrated in Figure 2 is a rectangular patch antenna with co-planar waveguide feed. This arrangement is preferred due to its simple impedance matching and high circuit density on one layer. Besides, its active and passive elements are easy to integrate and it has low dispersion and low radiation loss. All these make the co-planar waveguide preferable for rectifying circuit design.

The low-cost FR-4 substrate with a dielectric constant $\epsilon_r = 4.3$, $\tan \delta = 0.025$ and thickness of 1.6 mm are used for designing

the proposed CPW antenna. The area of $30 \times 38 \text{ mm}^2$ where the width and length area calculated using equation (1) and (2) respectively. This antenna is excited by a feeding line of 50Ω characteristic impedance with a width of 4.235 mm. Both gaps between the feeding line and the ground plane are $g = 0.5 \text{ mm}$. The detailed geometry structure of the proposed antenna design after optimization is shown in Table 1.

Figure 2: Geometry of the proposed antenna based on co-planar waveguide feed

3. Converter Circuit Design

In the RF energy harvesting system, a rectifier circuit is required for converting RF input energy into functional DC energy. The rectifier that acts as a converter circuit converts the AC input signal from the RF source. AC to DC conversion is required for this system as the RF source is being received in the form of a sine wave signal. Hence, the RF source is represented by a sinusoidal voltage source V_s as depicted in Figure 3. The arrangement of

rectifier circuit contains three parts which are a matching network, a conversion circuit and a load. The converter circuit and the circuit components with parameters after optimization are shown in Figure 3 and Table 2 respectively. Two Schottky diodes of MBR0520L are used for the rectification process. The Schottky diode is preferred due to its attractive feature of low substrate losses and quick switching. Moreover, the Schottky diode has a high sensitivity to the very small ambient signal.

Figure 3: The proposed RF harvesting converter circuit using Schottky connected diodes

For simulation study, V_s is connected to the converter circuit in a sinusoidal source that represents an RF energy harvester from the receiving antenna. The antenna port impedance represented by internal resistance, R_s is set to 50Ω . In this circuit topology, the matching circuit is simply constructed using capacitor C_1 and inductor L_1 . This matching circuit is required to match their impedances between the receiving antenna and converter circuit where a good matching network will allow a maximum power transfer between them. The vital part in this harvesting circuit is the conversion where it rectifies RF input signal to DC signal. Both Schottky diodes and inductor L_2 are needed for this circuit to convert AC to DC signal. In this circuit design, the capacitor C_2 is important in order to eliminate ripple DC voltage that occurs at the output terminal. After the DC signal is passed through the DC bypass filter, then it appears as a useable voltage across the load, R_L .

Table 2: Circuit Components and Parameters

Components	Value	Unit
R_s	50	Ω
L_1	33	nH
L_2	3	nH
C_1	1	pF
C_2	33	μ F
R_L	100	k Ω

The circuit analysis examines the constant input ac voltage with low amplitude sinusoidal voltage and it is separated into four operating modes for each cycle.

Mode 1: During the positive half input cycle, the inductor, L and capacitor, C_1 are charged by the sinusoidal voltage source. Both D_1 and D_2 are in OFF state. The load, R_L is feed by the energy stored in the C_2 that acts as a filter capacitor.

Mode 2: The mode starts when $V_{C1} = V_{IN} - V_L > V_{OUT}$, where Diode D_2 is switched to ON state. The capacitor C_2 is energized. All the energy stored in L_1 and C_1 during *Mode 1* is fed to the load.

The saturated current of inductor, L_1 and capacitor, C_1 drops linearly. The changing state of D_2 influence the loss during this mode.

Mode 3: This mode happens as $V_{IN} = V_{C1} + V_{L2} > V_{OUT}$, D_2 is switched to ON state. As capacitor C_2 is energizing, the energy stored in L_2 and C_1 during *Mode 3* is transferred to the load. The changing state of D_1 influences the loss during this mode.

Mode 4: When V_{C1} and $V_{L1} + V_{C1} > V_{OUT}$, the diodes, D_1 and D_2 are switched to ON state. The load is driven by the energy stored in L_1 and C_1 as they transferred to the load through L_2 and C_2 .

4. Results and Discussion

The simulation results are discussed in two parts; the receiving antenna and the converter circuit design.

4.1. Receiving Antenna

The receiving antenna design has been simulated using CST Microwave Studio Software. Before connecting to the converter circuit, the proposed CPW antenna is analysed separately by evaluating the S-parameters. This is to ensure the performance of the proposed antenna achieve a good return loss with perfect matching impedance ($\approx 50 \Omega$) and better gain compared to previous work. Figure 4 indicates the simulation result for return loss, S_{11} is -48.85 dB at 2.4976 GHz resonating frequency. The operating bandwidth of 309 MHz in the range between 2.3618 to 2.707 GHz, covers the IEEE 802.11 standard in the 2.45 GHz wireless ISM band. Matching impedance is approximate to 50Ω while VSWR is 1.007 as shown in Figure 5 and Figure 6 respectively. Since the value of VSWR is under 2 , the proposed antenna is worth mentioning that it has a good match and is applicable for most antenna applications.

Figure 4: Return loss simulation result of proposed CPW antenna

Figure 5: Line impedance at 2.4976 resonant frequency

Figure 6: Voltage standing wave ratio (VSWR) for the CPW antenna

The good values of S_{11} and VSWR are insufficient to prove an antenna has good radiation. Antenna gain is one of the key elements that needs to be considered in antenna design as it is an essential metric. The gain of an antenna highlights how much transmitted power in the direction of peak directivity to that of radiation energy. The simulated far-field radiation pattern can be observed in Figure 7 where it shows the gain and the 3-D forward directional pattern of the proposed CPW antenna. The gain of this antenna is 3.896 dBi and it is better compared to previous work [31] which is less than 1 dBi.

Figure 7: Simulated 3-D radiation pattern of CPW antenna

Figure 8: Simulated 2-D radiation pattern

Figure 8 indicates the main and side lobes of the proposed antenna. From this simulated 2-D radiation pattern figure, it indicates that the dipole antenna has an elevation plane beamwidth of 88.8 degrees. Since all metal patches of the substrate for this proposed CPW antenna are designed on one side, the antenna radiates in both front and back directions.

4.2. Converter Circuit

To determine the harvested voltage and current, LTSpice software is used to simulate the converter circuit. The output voltage and current for 0 dBm input power are depicted in Figure 9. From this output, it shows that both output current and voltage are simultaneously harvested to 6.09 V and 0.06 mA respectively. In this work, the ripple output voltage is successfully eliminated as compared to previous work that had large ripple voltage [31].

Equation (3) is the RF to DC power conversion efficiency (PCE) which is defined as the ratio of the DC power P_{DC} and the

RF power P_{RF} , where P_{DC} is the dc power produced at the load resistance while P_{RF} is the power received by the antenna.

Figure 9: The output voltage and current obtained from the converter circuit for 0 dBm RF input power

$$\eta \% = \frac{P_{DC}}{P_{RF}} \times 100\% \quad (3)$$

Table 3 shows the output voltage and the PCE for every single input power level. Both the output voltage and efficiency of the circuit are increased as the input power varies from -20 dBm to 0 dBm. As seen in Figure 10, the DC output voltage exceeds 6.09 V with 37.0% efficiency when the input power is 0 dBm. Hence, the energy stored in capacitor C2 is 100.5 μ J.

Table 3: The output voltage and PCE with respect to five different input power levels

Input Power (dBm)	Output Voltage (V)	PCE (%)
-20	0.02	0.1
-15	0.12	0.5
-10	0.52	2.7
-5	1.85	10.9
0	6.09	37.0

Figure 10: The output voltages with respect to different input power level

4.3. S-Parameter Analysis

The antenna and the converter circuit are matched to maximize the stored energy. Results from S-parameter are used to analyze the signal performance of the converter circuit regarding the difference in circuit component value. Figure 11 shows the connection between the CPW antenna and the converter circuit by using CST Microwave Studio integrated with CST Design Studio.

Table 4: Performance summary and distinction with related works

Figure 11: The integrated of the proposed CPW antenna and converter circuit

The result of the S-parameter for the proposed antenna integrated with the converter circuit is simulated by using CST Design Studio as illustrated in Figure 12. The results for both return loss, $|S_{11}| = 0.197$ and transfer coefficient $|S_{21}| = 0.4$ at 2.4659 GHz frequency are good since the magnitude value of $|S_{11}|$ and $|S_{21}|$ are ideal to be close to 0.1 and 1 respectively.

Figure 12: The circuit return loss $|S_{11}|$ and transfer coefficient $|S_{21}|$

4.4. Comparison with Previous Work

Table 4 summarizes a distinction between the proposed study and previous researchers' work based on rectifier used. Since the incident power can never be 0 dBm for 900 MHz and 2.45 GHz ISM band, the comparison is made up of input power between -15 dBm to -20 dBm. As observed at the input power level of -15 dBm, this work provides a low cost antenna substrate with lower PCE compared to [32]. However, the load resistance in [32] is 10 times greater than this work, which contributes large power efficiency. In terms of the PCE, this proposed work indicates the lowest performance as compared to the same type of rectifier used in [7] and [33]. Nevertheless, the output voltage in this work is

not much different compared to both of them. Meanwhile, reference [24] shows the second highest power conversion efficiency among other work, but the load resistance used is also high, which is 5 times greater than this work. Besides, the proposed circuits in [16] and [24] are much more costly since they use 10 cascoded and 10 stages of CMOS respectively. The power efficiency in this proposed work needs to be optimized to give higher efficiency. This can be done by optimizing the impedance matching between the antenna and the rectifier circuit. Moreover, diode characteristics need to be considered since this work uses only non-zero bias diode which degrades the power efficiency. Besides, the influence of saturation current of schottky diode to output voltage needs to be investigated.

5. Conclusion

In this work, a coplanar waveguide antenna with a gain of 3.896 dBi at the resonated frequency of 2.4976 GHz is analyzed for RF energy harvesting applications. A setup has been employed here to study the behaviour of the co-planar waveguide antenna integrated with two Schottky diodes in converter circuit design. Our proposed design has returned very satisfactory results that are applicable for the 2.45 GHz ISM band. The proposed converter circuit specifies the input power can be rectified up to 6.09 V DC signal with power conversion efficiency of 37% and energy of 100.5 μ J for input power of 0 dBm. The findings indicated that a sinusoidal RF incoming signal can be converted to a smooth DC voltage using a proposed RF energy harvesting circuit for powering wireless sensor nodes. For future improvements, matching impedance, diode characteristics and saturation current are essential for improving power efficiency.

ABSTRACT

The Micro-facial expression is the most effective way to display human emotional state. But it needs an expert coder to be decoded. Recently, new computer vision technologies have emerged to automatically extract facial expressions from human faces. In this study, a video-based emotion analysis system is implemented to detect human faces and recognize their emotions from recorded videos. Relevant information is presented on graphs and can be viewed on video to help understanding expressed emotions responses. The system recognizes and analyzes emotions frame by frame. The image-based facial expressions model used deep learning methods. It was tested with two pre-trained models on two different databases. To validate the video-based emotion analysis system, the aim of this study is to challenge it by comparing the performance of the initial implemented model to the iMotions Affectiva AFFDEX emotions analysis software on labeled sequences. These sequences were recorded and performed by a Tunisian actor and validated by an expert psychologist. Emotions to be recognized correspond to the six primary emotions defined by Paul Ekman : anger, disgust, fear, joy, sadness, surprise, and then their possible combinations according to Robert Plutchik's psycho-evolutionary theory of emotions. Results show a progressive increase of the system's performance, achieving a high correlation with Affectiva. Joy, surprise and disgust expressions can reliably be detected with an underprediction of anger from the two systems. The implemented system has shown more efficient results on recognizing sadness, fear and secondary emotions. Contrary to iMotions Affectiva analysis results, VEMOS system has recognized correctly sadness and contempt. It has also successfully recognized surprise and fear and detect the alarm secondary emotion. iMotions Affectiva has confused surprise and fear. Finally, compared to iMotions the system was also able to detect peak of morbidity and remorse secondary emotions.

1. Introduction

Humans communicate through the expression of their emotions, using various channels (physiological reactions, behaviors, voice, etc.). The emotion is the strong link between cognition and behavior, and between attention, representation and human performance [1]. Facial expression is the most direct and effective way to display human emotional states [2]. In addition, humans use involuntary micro-expressions to unveil their feelings [3]. Nevertheless, they are unable to recognize them accurately.

Indeed, only 47% of recognition accuracy is observed at trained adults [4].

Since the 1960's, several facial expressions and emotions classification models have been psychologically studied. Psychologists such as Paul Ekman and Friesen have studied micro-expressions in their research, showing that these micro-expressions are involuntary, uncontrollable, and expressed by humans as a very short reaction to a lived situation. Usually, they last less than 1/25 second which makes it hard to find them in real-time [5, 6].

*Corresponding Author: Nadia Jmour, nadiajmour@gmail.com

The authors showed that micro-expressions can be a lie detection tool. In fact, micro-expressions allow recognizing the real emotions expressed by people being in critical situations as the case of criminal interrogation or job recruitment interview [7].

Thus, psychologists established a method to recognize micro-expressions by defining criteria of the facial muscles' movements related to each specific micro-expression. Facial movements are defined into 46 action units and each unit presents a contraction or relaxation of a facial muscle. Thereafter, each micro-expression corresponds to the presence of several action units. This allows, for example, recognizing a true involuntary smile, characterized by the movement of the zygomaticus major and of the orbicularis of the eye muscles, [8], from a false smile activating with the movement of the zygomaticus muscle. The developed system is known as the Facial Action Coding System (FACS) and it has become the most used in scientific research [9].

However, intelligent automated recognition of emotional micro-expressions is still a quite new topic in computer vision. Recently, based on machine learning algorithms, and with the availability of facial expressions databases, emotion analysis systems have become able to automatically recognize micro-facial expressions and emotional states, and give an added value technological undertaking [10, 11].

As defined in [12], these systems operate in three steps: Face detection, feature extraction, facial expression and emotion classification.

In traditional methods, feature extraction and feature classification steps are independent. Compared to recent research [13], these machine learning techniques for facial expression recognition are considered as classical techniques.

Nowadays, researchers tend to highlight the advantage of applying deep learning techniques for facial expression recognition in different applications [14, 15]. They consider that applying deep learning reduces human intervention in the analysis process by automating the phase of extracting and learning features [16, 17]. Also, illumination, identity bias and head pose problems are avoided. The need of a large amount of data is also resolved, [18–20].

Several researchers as [21–24], have studied and developed emotion analysis systems for applications in different fields such as human resources, medical field, etc. Authors in [11], employed in his research a deep learning system based on face analysis for monitoring customer behavior specifically for detection of interest. Authors in [25], applied deep learning-based face analysis system in radiotherapy that monitors the patient's facial expressions and predicts patient's advanced movement during the treatment. Authors in [26], considered that facial expression analysis system can be applied on the field of marketing.

Systems such as EmotionNet, iMotions platform [27], using Affectiva Affdex algorithm, [28], Noldus [29], EmoVu [30], and Emotient employ facial expression recognition technologies to create commercial products using information related to their customers. These systems are able to recognize different metrics as head orientation, facial landmarks and basic emotions and most of them apply deep learning [31–33].

The first contribution of this study is to develop an emotion analysis system that recognizes human emotions from recorded videos.

The second contribution is to challenge the system's performance by comparing measures with iMotions Affectiva analysis software measures obtained by analyzing labeled recorded videos.

This study aims also to employ the deep learning-based image analysis model presented in our recent research [18, 20].

Since micro-facial expressions occur during a split second, the proposed system extracts images frame by frame, and every frame is analyzed by the implemented deep learning model. Recorded information is viewed either in an analyzed video and/or presented on the business analysis Power BI Desktop from Microsoft [34], by using visualization graphs to help understanding expressed emotional responses.

Emotions to be recognized correspond to the six facial expressions defined by authors: anger, disgust, fear, joy, sadness, surprise, and then their possible combinations according to Robert Plutchik's psycho-evolutionary theory of emotions.

We expected that the six basic facial expressions can be correctly recognized by the implemented system, with a relatively high accuracy, and can give as an output person's true emotions. As a criterion/external validity of the implemented system, we further expected its significant correlations with iMotions Affectiva measures. Also, secondary emotions identified by Plutchik were expected to be correctly recognized by the proposed new system.

The remainder of this paper is organized into four sections. Section 2 presents the implemented video-based emotion analysis system with an example of a tested scenario. Section 3 presents comparison and challenging results of the implemented system with iMotions Affectiva software. Finally, section 4 summarizes the conclusions

2. Video-based Emotion analysis system (VEMOS) implementation

2.1. Process analysis description

Micro-expressions cannot be controlled, difficult to hide and occur within a split of second. The proposed system extracts first frames from recording video every 1/25 second.

Then, it analyzes and recognizes automatically frame by frame the six basic emotions [32]. Extracted frames are affected as input in the image-based facial expression analysis system, which was implemented in our recent research [18].

This system used deep learning techniques to recognize facial expression images more accurately. It performed by training a deep convolutional neural network (CNN) on a set of face images. This network is composed of two parts:

- The convolutional part for feature extraction: it takes the image as input of the model and then convolution maps are flattened and concatenated into a features vector, called CNN code.

- The fully connected layer part: this part combines the characteristics of the CNN code to classify the image.

To explore the power of these CNN with accessible equipment and a reasonable amount of annotated data, it is possible to explore pre-trained neural networks available publicly [35].

This technique is called transfer learning, it uses knowledge and information acquired from a general classification task and applies it again to a particular new one.

In our recent research, we compared the use of the VGG-16 and the InceptionV3 pre-trained models on the ImageNet dataset, [36], by applying transfer learning technique using the Kaggle (Facial Expression Recognition Challenge) and Extended Cohn-Kanade CK+ facial expression datasets [37].

We used for our implementation Python libraries such OpenCV and TensorFlow on GPU NVIDIA version 391.25, processor type 16xi5-7300HQ. We trained the model on 100 epochs, with a learning rate of 0.0001 [20]. We leveraged the Keras implementation of VGG-16 and InceptionV3.

The data is split into 90% for training and 10% for testing. Experiments had accuracies of 45.83% and 43.22% using the two pre-trained models on the FER-2013. Then, an accuracy of 73.98% was observed by transferring information from the VGG-16, and by training the new architecture on the Extended Cohn-Kanade facial expression dataset using the top frame from every sequence.

Thus, our recent research approved the effect of the distribution and the quality of the data for an efficient training and application of the facial expression recognition task. So, every fraction of a second, this model assigns a score corresponding to each emotion. Output Information is recorded from every analyzed frame.

Based on the recorded facial expressions information, we proposed a new approach for the determination of other emotional states from video data. This approach is inspired from the Robert Plutchik's psycho-evolutionary theory of emotions [38–40].

According to Plutchik, basic emotions can be combined with each other to form different emotions. Table 1 presents the possible combinations.

Table 1: Plutchik's emotions possible combinations.

Primary dyads	Results
Joy and Trust	Love
Trust and fear	Submission
Fear and surprise	Alarm
Surprise and sadness	Disappointment
Sadness and disgust	Remorse
Disgust and anger	Contempt
Anger and anticipation	Aggression
Joy and fear	Guilt
Trust and surprise	Curiosity
Fear and sadness	Despair
surprise and disgust	horror
sadness and anger	Envy
Disgust and anticipation	Cynism
Anger and joy	Pride
Anticipation and trust	Fatalism
Joy and surprise	Delight

Trust and sadness	Sentimentality
Fear and disgust	Shame
Surprise and anger	Outrage
Sadness and anticipation	Pessimism
Disgust and Joy	Morbidness
Anger and trust	Dominance
Anticipation and fear	Anxiety

The Plutchik theory defines emotions as confidence and anticipation. In our case, we explore only combinations based on the six emotions below: anger, disgust, fear, joy, sadness and surprise. Emotions which Plutchik presents as conflict combinations are not considered in our approach.

This approach allows having more information about the emotional state of the person from the video data type. For example, according to Plutchik's theory, the emotion of delight would be a mixture of joy and surprise. Delight's score is defined as the mean of the two basic emotions.

At the end of the process, two types of output are provided. First, the following output information is extracted and visualized through graphs on the Power BI Desktop [41] :

- Dominant basic emotion occurrence: It gives dominant and non-dominant emotion occurrence.
- Maximum basic emotion peak: It gives maximum peak and the corresponding time.
- Emotions Variability: Its records frame by frame the six emotions score over the time.
- Dominant secondary emotion occurrence: It gives dominant and non-dominant secondary emotion occurrence.
- Maximum secondary emotion peak: It gives maximum peak and the corresponding time.

Then, an analyzed video is extracted where face tracking and basic and secondary emotions scores over the time are displayed. We leveraged Pandas, and Csv librairies for recording pertinent information from extracted images. Opencv, Matplotlib and Dlib librairies were used for a better visualization of the resulting analyzed video.

2.2. Tested scenario and results visualization

We chose Carlos Ghosn intervention as a tested video. Carlos Ghosn is the head of Nissan and the French automaker Renault. In November, 2018, Nissan announced that an internal investigation into Ghosn and another executive found Ghosn's compensation had been underreported. There was also evidence that Ghosn committed other misconduct, including personal use of company assets. Japanese authorities arrested Ghosn in Tokyo. He has already spent a hundred and eight days before his second arrestation. On April 9th, 2019, Ghosn posted a structured YouTube video, [42], that he recorded four days before, in which he presented three messages and where he publicly proclaimed that he was innocent of all the accusations that came around these charges that are all biased, taken out of context, twisted in a way to paint a personage of greed, and a personage of dictatorship. Carlos Ghosn spoke calmly, neutral and looked fixedly at the camera in the recorded video.

We analyzed the first message in the video with our implemented video-based emotion analysis system.

Output Extracted information is presented using visualization graphs on the Power BI desktop. Primary and secondary emotions occurrences are shown in Figure 1.

Figure 1: Emotions Occurrence.

Neutral and Anger categories dominated on the whole video with 59.9% and 33.56% respectively. Envy and contempt secondary emotions occurred with 72.1% and 27% respectively.

The variability of each basic emotion over the time is presented in Figure 2. Each color describes an emotion as it is presented on the legend.

Figure 2: Basic emotions variability.

The figure shows that the two dominant emotions vary with important values. The maximal recorded peak value of the Anger micro-facial expression is 50%. Disgust and Sadness appear with smaller values and they do not exceed 30%.

Secondary emotions are also detected by the system and analysis results are presented in Figure 3.

We noticed the appearance of contempt and envy during the time. Peaks values are 30% and 39% respectively.

The authors tried to be calm and keep his emotions stables. The switch between Anger, Neutrality, on one hand, and contempt, envy, on the other hand, explains also how he maybe tried to manage his emotions.

Figure 4 presents a screenshot from the analyzed video. It shows Carlos while announcing his innocence and expressing envy combining anger and sadness emotions.

Figure 4: Screenshot of Carlos Ghosn's analyzed video.

Thanks to VEMOS, we unveiled the undetected basic and secondary emotions by a human.

Later, we correlate our results with the 22th April event where the Ex-CEO of Renault-Nissan Carlos Ghosn has been charged again, for breach of trust aggravated by the Tokyo court. This can maybe explain the presence of the detected negative emotions.

3. Comparison with iMotions Affectiva facial expressions analysis software

The performance of the implemented video-based emotions analysis system VEMOS had to be validated. So, we decided to challenge the system by comparing the performance with the iMotions Affectiva AFFDEX emotion analysis software.

3.1. iMotions Biometric Research Platform

iMotions [27, 43], is a software solution helping for data collection, analysis, and quantifying engagement and emotional responses. The iMotions Platform is an emotional recognition software that integrates multiple sensors including facial expression analysis, GSR, eye tracking, EEG, and ECG/EMG along with survey technologies for multimodal human behavior research.

Videos are imported and analyzed in iMotions Platform using the Affectiva Affdex facial expression recognition engine [27, 28].

The Affectiva's Affdex SDK toolkit (in collaboration with iMotions) [28, 44–46], is one of the most known and used emotions analysis tool. It uses the Facial Action Coding system (FACS). The tool detects facial landmark, classify facial action, and recognizes the seven basic emotions.

The system's algorithm uses first a histogram of oriented gradient (HOG) to extract pertinent images regions. Then, an SVM is used for the classification step. The training process is applied on 10000 images and determined a score of 0–100 for each class. The testing process is applied on 10000 images.

3.2. Carlos Ghosn's video correlation results

The video of Carlos Ghosn is analyzed with iMotions Affectiva software. Extracted information are presented in the Table 2.

Table 2: iMotions Affectiva emotions occurrence results.

Emotion	Occurrence
Anger	184
Disgust	22
Fear	0
Joy	0
Sadness	29
Surprise	321
Neutral	1429

Through the iMotions Affectiva system, the occurrence of emotions is detected when its corresponding score exceeds the threshold value of 50%.

Taking into account this characteristic, we noticed that results given by iMotions and VEMOS systems lead to the same psychological interpretation of the emotional state of Carlos that we have concluded from the video. Then, we used the Bravais-Pearson correlation coefficient to compare analysis results obtained by the two systems.

Obtained values range between -1.0 and 1.0. A correlation of -1.0 shows a perfect negative correlation, while a correlation of 1.0 shows a perfect positive correlation. A correlation of 0.0 shows no linear relationship between the movement of the two variables. We considered that values less than 0.5 as low values and values greater than 0.5 as high values. Table 3 shows the correlation results.

Table 3: Correlation coefficient with iMotions software

Emotion	Correlation coefficient Initial model	<i>p</i>
Anger	0.051	$p > .05$
Disgust	0.38	$p < .05$
Fear	-0.19	$p < .05$
Joy	0.11	$p < .05$
Sadness	0.06	$p > .05$
Surprise	0.0015	$p > .05$

We obtained low values of correlation for the six basic emotions. As the video is not labeled and is not analyzed by non-verbal professional decoder, results remain open and they do not validate the performance of the system.

To ensure the reliability of our results we proposed to apply our analysis on labeled videos. So, we suggested to prepare two corpus of labeled sequences that were recorded and performed by a Tunisian actor and validated by a professional psychologist. The first corpus contains basic emotions sequences and the second one contains secondary emotions sequences.

3.3. Labeled recorded Sequences

We first collected labeled sequences from YouTube video. The psychologist confirms that emotions expressed in these sequences present muscles' mouvement that correspond to the needed emotions. Then, a Tunisian Actor was hired to perform videos under the monitoring and guidance of a professional psychological doctor.

Before recording the videos, the psychologist gives more details about the muscles to move specifying the facial action coding units per emotion. Then, video recording starts with the actor looking into the camera and showing successively the six facial expressions anger, disgust, fear, joy, sadness, and surprise, repeating the action several times. Thus, many sequences were recorded and only one per emotion was chosen and validated by the psychologist. Table 4 shows the details about the videos characteristics.

Table 4: Basic emotions Sequences characteristics

Attribute	Description
Length of sequences	5000 to 10000 milliseconds
Number of frames	25 fps
Expressions classes annotation	Angry, disgust, fear, happy, sad, surprise
Video format	mp4
Number of subjects	2

Similarly, the actor looked into the camera and expressed the expected secondary emotions. Sequences were recorded and validated by the psychologist. Table 5 below presents characteristics of the prepared sequences.

Table 5: Prepared secondary emotions Sequences characteristics.

Attribute	Description
Length of sequences	5000 to 10000 milliseconds
Number of frames	25 fps
Expressions classes annotation	alarm, contempt, morbidness, despair, remorse
Video format	mp4
Number of subjects	1

3.4. Basic emotions correlation results

To explore the reliability of the Affectiva algorithm for basic emotions recognition, we proposed to take advantages of the constructed corpus of the labeled sequences. So, recorded primary emotion sequences were analyzed by the VEMOS implemented system. They were also analyzed by the iMotions Affectiva Affdex algorithm and temporal information was imported for the 6 sequences.

The analysis results should first correlate with the expected emotion. Then, for a better visualization, the extracted values are presented on graphs using the Power BI Desktop.

By plotting these graphs, facial expression measures are compared to iMotions stored facial expression measures.

Figure 5 shows emotions variability over the time obtained by the VEMOS system for every sequence. Analysis results show that the initial implemented system has difficulties on classifying some facial expressions. Compared to the expected emotions disgust, fear, joy and sadness categories are misclassified. Emotions as angry and surprise are correctly classified and reached maximum values of 87% and 99% respectively.

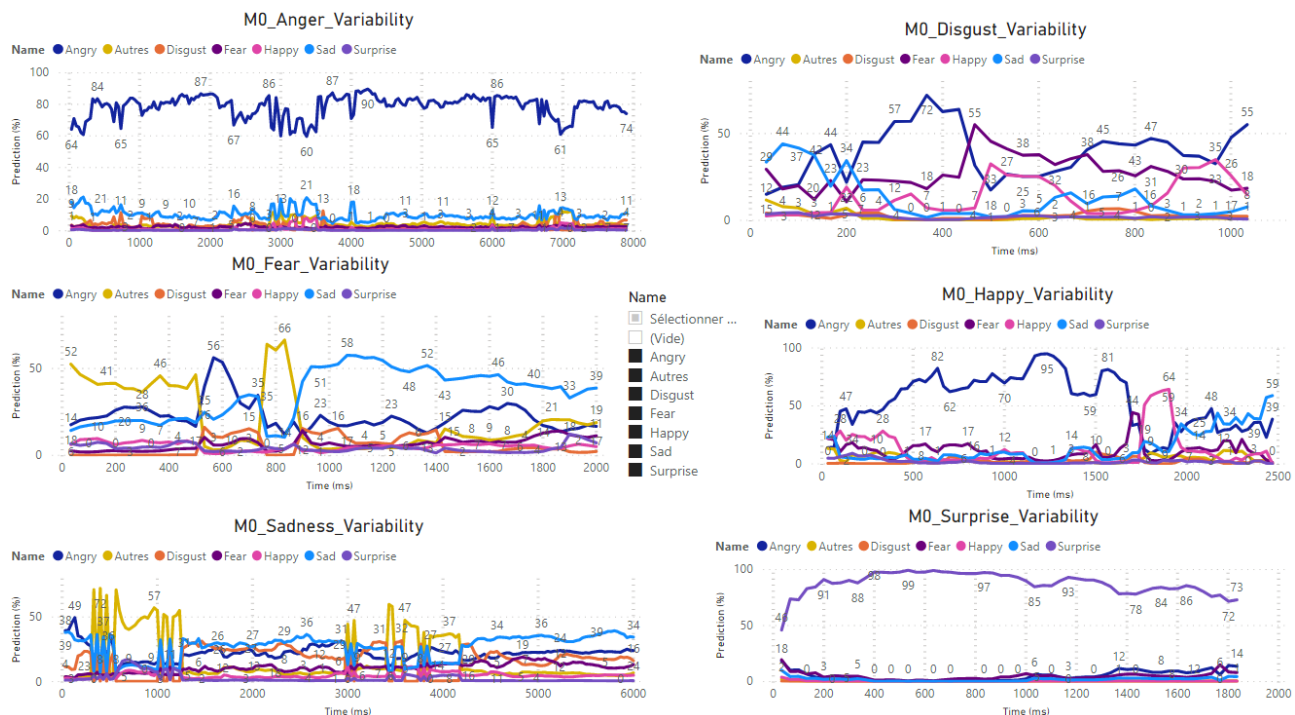

Figure 5: Analysis results with the initial implemented model.

In order to compare results to iMotions platform analysis results, we used the Bravais-Pearson correlation coefficient. Table 6 shows correlation coefficient of each emotion.

Table 6: Correlation coefficient with iMotions software

Emotion	Correlation coefficient Initial model	p
Anger	0.01	$p > .05$
Disgust	0.33	$p < .05$
Fear	-0.41	$p < .05$
Joy	0.19	$p < .05$
Sadness	0.03	$p > .05$
Surprise	0.15	$p < .05$

Obtained results show small values and low correlation between the implemented VEMOS system and iMotions Affectiva results.

Consequently, we proposed to challenge the system and improve its performance. The idea was to challenge the number of data and the distribution of emotions categories used for the training of the image-based facial expression system.

Our recent approach, [18], has shown the importance of the quality of the data in the performance of the implemented model. The Fer-2013 dataset presents images that were collected from google and not properly treated. Sometimes, we found images where there is text on the faces. So, compared to the Fer-2013, our best accuracy was obtained by training and testing the model on the CK+ dataset, which was implemented by exploring the top frame of each sequence from the data.

In this approach, we propose to increase the number of input frames from the CK+ dataset by taking in consideration the data distribution. Then, the model is trained by keeping the same

proposed architecture and its same characteristics. We propose to construct a new corpus based on the CK+ dataset by taking five frames per sequence and to integrate a new category called "others". Neutral faces and all other faces movements that are not recognized by the model as one of the basic emotions are put on the new class "others".

The model reached 93.98% test accuracy. Confusion matrix is shown in Figure 6.

Figure 6: Confusion matrix.

To test the reliability and the performance of the challenging system, we used the same labeled sequences. Sequences are already analyzed by the iMotions Affectiva software. So, they were only imported and analyzed by the VEMOS system. The following output information is used for comparison:

- Basic emotions variability of the VEMOS system over the time.

- Basic emotions variability of the iMotions software over the time.

Bravais-Pearson Correlation coefficient is then applied to these measures. Variability over the time of the class anger is presented on Figure 7.

Figure 7: Anger sequence's analysis.

The two systems confirm the presence of the same emotions over the time and recorded correlation coefficient is 0.22 ($p < .05$). Compared to the initial model, correlation has increased with 0.12 ($p < .05$). But compared to the expected emotion, the two systems show confusion between anger and sadness emotions. It is noteworthy that AFFDEX often confused anger with sadness.

So, we can conclude that VEMOS has this same characteristic. It has an underprediction of anger and overprediction of sadness. Figure 8 presents the analysis results for sadness sequence.

Figure 8: Sadness sequence's analysis.

Sadness is dominating in this sequence and correctly classified by the VEMOS system. Moreover, we recorded satisfying correlation coefficients with values of 0.32 ($p < .05$) with iMotions Affectiva results.

Although the dominance of sadness shown in the analysis results of iMotions Affectiva, we can see again the same confusion of recognizing anger and sadness. VEMOS recognizes sadness emotion with 100% of occurrence.

For disgust sequence, analysis results are presented in Figure 9.

Disgust is correctly recognized by the VEMOS system and reaches a maximum value of 98% over time. Correlation between the two measures is significant 0.21 ($p < .05$).

Happy and surprise sequences analysis are presented on Figures 10 and 11.

The corresponding graphs show that these emotions are correctly classified compared to the expected emotion and reach a maximum peak of 100%. We also recorded high significant correlations with 0.81 ($p < .05$) and 0.54 ($p < .05$).

Figure 12 shows the analysis results for fear sequence. It shows the dominance of the expected category, and measured correlation coefficient is 0.79 ($p < .05$).

Our analysis shows that the implemented VEMOS system recognizes correctly joy, fear, surprise, sadness and disgust. But we can notice a rarely confusion of the anger with sadness.

Figure 9: Disgust sequence's analysis.

Figure 10: Surprise sequence's analysis

Figure 11: Happy sequence's analysis

Figure 12: Fear sequence's analysis

Figure 13: Secondary emotions occurrence

3.5. Secondary Emotions correlation results

The authors defined 13 possible combinations based on the 6 primary emotions: anger, disgust, fear, joy, sadness, surprise. Our system was able to analyze the 13 possible combinations.

Tested emotions are: alarm, contempt, despair, morbidity and remorse. As we have mentioned in section 1, the recorded score for each secondary emotion presents the average of the defined combination. We proposed that at a given moment, if one of the basic emotions is zero, the secondary emotion is assigned to 0. In

this case, the detected emotion at this moment will be the primary detected emotion.

To validate and test the performance of the VEMOS system, secondary emotions sequences of the corpus 2 recorded by the actor, are analyzed.

For each sequence, the analysis results are presented on the Power BI Desktop based on the following information:

- Basic emotions variability from the challenging system (VEMOS).

- Basic emotions variability from the iMotions Affectiva software.
- Dominant Secondary emotions occurrence from the challenging system (VEMOS).

Similarly, these sequences were imported and analyzed by the iMotions Affectiva software. The first analysis and validation considered the comparison with the expected emotion.

The graphs describing the dominant secondary emotions for each sequence are presented in Figure 13.

These graphs allow us to compare the dominant emotion with the expected emotion expressed by the actor. Results show relevant information.

We notice that alarm is correctly recognized by the VEMOS system. 96.9% of the extracted frames expressed the expected emotion and only 3% show despair. Contempt is correctly recognized compared to the sequence's label. It dominates with 19.49%.

Figure 14 presents a screenshot of the analyzed video of the actor while expressing contempt emotion. The display of information to be visualized has also been modified and improved. The complete analyzed video of the actor is also available in, [47]¹.

Figure 14: Screenshot of the Actor while expressing Contempt¹.

Analyses of despair and morbidity sequences show that the two emotions are correctly recognized and occurred with 11.19% and 100% respectively.

Figure 13 shows also that the remorse is not correctly recognized. Thus, compared to the expected emotion, alarm, contempt, despair and morbidity are correctly recognized by our system.

Then, second analysis and validation considers the comparison with iMotions Affectiva software results. Basically, this comparison concerns primary emotion defined in the combination of each secondary emotion. So, the variability of these primary emotions over the time was recorded for each

sequence by the two systems and compared by measuring the correlation coefficient.

Consequently, we can see how close the VEMOS results are to that of iMotions Affectiva Software and we can take advantages to confirm again the performance of our system on recognizing primary emotions.

Alarm emotion is a combination of the fear and surprise. Compared to the meaning of fear emotion, Alarm is unexpected and apprehended. It can concern a doubt or lack of self-confidence. Alarm basic emotions variability over the time is analyzed by the two systems. Graphs are presented in the Figure 15.

Figure 15: Alarm's sequence analysis.

Figure 16: Contempt's correlation analysis.

Analysis present relevant results compared to iMotions Affectiva. The system shows an appearance of fear and surprise over the time. Obtained correlation coefficients of fear and

¹https://youtu.be/W_0-CuAwDFE

surprise are -0.03 and 0.14 respectively. But in this case, iMotions shows only surprise.

Another peculiarity to note is that Affectiva AFFDEX usually confused fear with surprise. This can probably explain the obtained results.

Contempt has the characteristics of anger and disgust. Analyses results are presented in Figure 16.

The two graphs show an appearance of anger and disgust over the time. iMotions analysis also shows the appearance of small variations of sadness. Obtained correlation coefficients of anger and disgust are 0.24 and -0.25 respectively.

Despair emotion combines sadness and fear. This emotion expresses a complete despondency and a loss of hope. We analyzed the sequence with the two systems. Basic emotions variability is recorded and presented on graphs in Figure 17.

Figure 17: Despair's emotion analysis.

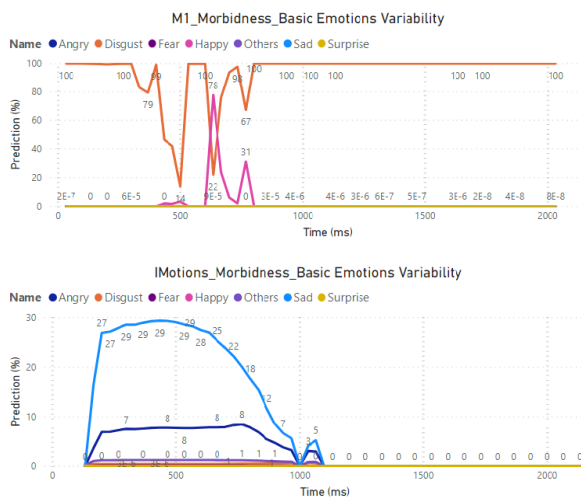

Figure 18: Morbidity's correlation analysis

Our system showed performing results. Sadness and fear appear over the time as it is defined on the Plutchik's emotion

combination. Obtained values of correlation coefficient for fear and sadness with iMotions Affectiva analysis results are 0.65 and 0.11, respectively. The second graph in Figure 17 shows iMotions Affectiva analysis. Results show dominance of sadness and fear. Graph also shows an appearance of the surprise with high values. This appearance can be explained by the fact that iMotions Affectiva confuses surprise and fear. Anger is shown with small variations at the recorded resulting variability of emotions. This can be explained by the fact that iMotions confuses between anger and sadness.

For morbidity, analyzes are presented in Figure 18. According to Plutchik, morbidity combines disgust and joy emotions.

The first graph shows that the two dominant emotions throughout the video are happiness and disgust. It shows that the secondary emotion appears as a peak between 500 and 1000 milliseconds.

iMotions Affectiva analysis shows that the person has expressed sadness and anger. Therefore, the iMotions Affectiva system did not show the expected result. Obtained values of correlation coefficient for disgust and happiness are -0.35 and -0.02 respectively. Figure 19 presents analysis results for remorse emotion.

Figure 19: Remorse's correlation analysis.

In the case of the remorse sequence, only sadness has occurred with high scores. The second emotion is disgust, as it is defined in the remorse combination. But disgust appears with one peak all over the video and with low score of 39.53%. iMotions Affectiva system assigned the sequence to the fear category. The correlation values of the basic emotions for remorse combination are 0.05 for disgust and 0.016 for sadness.

We can conclude that our system has successfully recognized secondary emotions. First, results were validated by comparing them to the expected emotion expressed by the actor and validated by the psychologist. These results were also validated according to Plutchik's definition of the basic emotions combination.

Analysis results were also compared to those of iMotions Affectiva results. Joy, disgust and surprise were correctly recognized by the two systems.

More efficient performance was obtained by our implemented system VEMOS for the other emotions.

We notice that iMotions Affectiva confuses anger and sadness emotions. Analysis results of the primary emotions sequences have shown that the system has an underprediction of sadness and overprediction of anger. Because of this confusion, the system was not able to recognize correctly despair and contempt emotions that combine one on the confused primary emotion.

VEMOS system presents an underprediction of anger. But, the system recognizes correctly the sadness emotion. Then, results have shown that the implemented system recognizes correctly despair and contempt emotions.

In addition, VEMOS recognizes more efficiently fear and surprise emotions. Besides, Alarm was correctly recognized. But, we noticed that iMotions Affectiva system has an overprediction of surprise and underprediction of fear. This was shown in the analysis results of Alarm sequence that combine fear and surprise emotions. Only surprise was detected.

Finally, morbidity and remorse secondary emotions were not recognized by iMotions Affectiva system. But, VEMOS was able to detect a maximum peak of the corresponding combination.

4. Conclusion

In this study, a video-based emotion analysis system, VEMOS, was implemented. It detected frame by frame images from video. Then, it employed deep learning techniques for basic emotions recognition. Information about emotions occurrence, emotions variability during the time and maximum peak of each emotions are detected and presented in Power BI Report. Also, an analyzed video showing the variation of pertinent information during the time is obtained.

Then, the system was validated and challenged by comparing correlation with the iMotions Affectiva software on labeled sequences. These sequences were recorded by an actor and validated by a psychologist.

Our validation studies reveal that the implemented system has the potential to recognize basic emotions expressed by individuals. Then, we obtained significant correlations between the implemented system and Affectiva measures. More efficiently than Affectiva, VEMOS system recognizes successfully 5 secondary emotions defined by Plutchik.

With this efficient performance, VEMOS can be exploited in different application. It can help customs officers, known as detection officer, to unveil travelers with illegal items or goods in the customs airport. It is also able to unveil wanted and terrorist people in airport. So, detection officer can stop them from entering and leaving the country. Furthermore, judge can resort to VEMOS

to reveal criminal people. Thus, it can assist to know the truth and change the verdict, from a criminal to an innocent.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

The suitability of incorporating waste transfer stations (WTS) in likely future Municipal Solid Waste Management (MSWM) systems for Harare city and neighbouring urban centres was assessed under this study. WTS will bring about location of landfills and other MSWM facilities further away from population centres, increasing recycling, reducing waste collection costs and burden on the overall MSWM budget, an increase in waste collection effectiveness and efficiency, reduction in waste collection derived greenhouse gases (GHG) emissions and other associated impacts. Life cycle Assessment (LCA) on contribution of waste collection to human health impact potential of 34 DALYs as well as acidification, global warming and eutrophication impact potentials of 0.012, 0.065 and 0.0002 species.year respectively under all the six MSWM options were observed. Highest impacts in the species extinction impact categories was realised in the global warming impact category resultant of GHG emissions from fuel combustion during waste collection. The unavailability of land and the above factors support the incorporation of WTS in future MSWM options for Harare City and surrounding urban centres under a separation at source waste collection system to derive maximum benefits. Citizens drop off centres (CDOPs) and buy-back centres (BBCs) could also compliment the WTS leading to increased recycling. Though there is a relative sound supportive legislative, regulatory and policy framework that supports the need for waste recycling consequently supporting WTS, CDOPS and BBCs due to their recycling promotion capabilities, there is need for specific legislation, regulation and policies that supports the development and operation of such facilities that will bring interest amongst would be operators, effectiveness and efficiency resultantly reducing associated human health and environmental impacts. Further studies that determine the breakeven distance and LCA studies that specifically assess the associated environmental loads of incorporating WTS within the likely future MSWM systems are recommended.

1. Introduction

This paper is a revised and extended version of a paper entitled, "Suitability of municipal solid waste transfer stations in Harare, Zimbabwe", that was presented at the 7th International Renewable and Sustainable Energy Conference (IRSEC' 19), Sofitel Agadir Royal Bay, Agadir, Morocco, November 27-30, 2019.

*Corresponding Author: Trust Nhubu, Department of Chemical Engineering Technology, University of Johannesburg, P O Box 17011, 2028, South Africa, 2094, +263777342295, nhubutrust@gmail.com

The continued population increases together with the prevailing rapid urbanization has resulted in astronomical increase in MSW generation rendering the management of municipal solid waste (MSW) a challenging and difficult task for urban local authorities (ULAs) especially in low income countries. In [1], the authors projected annual global MSW generation to increase from 1.3 x 10⁹ tons (1.42kg/capita/day) in 2012 to 2.2 x 10⁹ tons in 2025. This results in an evident mismatch between increased population and urbanisation rate with the necessary corresponding municipal solid waste management (MSWM) investment, infrastructure,

equipment and expertise in the face of the MSW generation spike [2]. Significant increase in urbanization from general population increases coupled with rural to urban migration in pursuit of better life and jobs [3] has been a global phenomenon characterizing the recent past decades. In [4], the author reported global urbanization levels of 29.6% and 55.3% in 1950 and 2018 respectively, simultaneously projecting global urbanisation to increase to 68.4% by the middle of the 21st century. Increasing urbanisation rates were reported in the 1982, 1992, 2002 and 2012 Zimbabwe national census reports [5]. The increase in the urbanisation is also confirmed by [4] which reported urbanisation levels of 32.2% in 2018 and 45.9% in 2050 for Zimbabwe as well as 40.4% in 2018 and 58.1% in 2050 for Sub Saharan Africa (SSA) implying that by mid-21st century, urban population in SSA would have outstripped rural population constituting over 58% of the total population. Increased population densities together with the corresponding increases in MSW generation characterise these reported increasing urbanization rates [6, 7]. The increase in MSW generation is significantly not matched with the required corresponding expertise and infrastructural (equipment and technology) development with regards to MSW storage, collection and transportation, management, treatment and disposal.

Increased MSW generation associated challenges are realised or manifest first in the first stages of a MSWM system namely storage, collection and transportation. MSW collection figures of slightly above 40% were reported by [1] for developing nations as shown in Figure 1. MSW collection figures of below half of the MSW generated in the Zimbabwean ULAs have been reported with the collected waste disposed of at official open dumpsites whilst the over 50% non-collected MSW generated is subjected to any of the following illegal methods namely; burning, burying, dumping in undesignated areas like road sides, vacant spaces, alleys, storm water drains. All these MSW disposal methods including the dumping of the officially collected MSW at official dumpsites pose potential and imminent human health and environmental disasters already manifesting or in the making. MSW disposal thus becomes as equally vital stage as the first stages of a MSWM system. Figure 2 provides a comparative overview of the dominant MSW disposal methods in Harare (Zimbabwe) as reported by [8] and those reported by [1] for low income countries.

In Zimbabwe, ULAs including municipalities, city and town councils, rural district councils as well as local boards are authorised entities responsible for MSWM [9] largely under centralised and conventional models inherited from the colonial error which has no clear mechanisms for cooperation between the ULAs and other stakeholders especially residents to be served by such a MSWM system who have developed a *'we dumb they collect attitude'* [10]. ULAs are authorised also to engage other players for the purposes of managing waste on their behalf. MSWM was singled out by [11] amongst the enormous challenges facing ULAs within the vicinity of Harare the Capital City of Zimbabwe including Chitungwiza municipality, Epworth, Ruwa and Norton local boards largely due to the astronomical increase in MSW generation presently estimated at above 400,000 tons [12] which has not been matched with corresponding increases in capacity development with regards to financial, infrastructure (equipment and technology) and technical expertise. The population increases together with the associated increased

population density and the ensuing MSWM challenges from the mismatch between the population dynamics and developments in MSWM with regards to infrastructure (technology and equipment), finance and investment and technical expertise to manage the ever-increasing amount of MSW being generated evidently manifest in the form of water pollution (both surface and groundwater) together with the perennial water borne diseases outbreaks namely Cholera, Typhoid and Dysentery [13-15].

MSW collection and transportation (MSW-CT) from its sources to final disposal dumpsites in Harare city, Chitungwiza, Ruwa, Epworth and Norton consume more than the expected reported proportion on MSWM budget of between 20 to 50% [16] and 50 to 70% [17]. Therefore, there is need to redesign future MSW-CT to possibly allow for significant cost reductions on MSW-CT cost which will result in savings on the MSWM budget with the savings possibly channeled towards other developments in other MSWM downstream processes, infrastructure and technical expertise. The incorporation of appropriately designed, sited and constructed WTS in MSWM systems is such a strategy towards bringing cost effective and savings in MSW-CT [18-21]. WTS apart from their costs abatement capabilities they could possibly bring about reduced environmental impacts of future MSWM systems that could be implemented in Harare city, Chitungwiza, Ruwa, Epworth and Norton. In [22], the authors observed that the recycling of atleast 20% of the recoverable materials contributes to significant reductions of environmental impacts (acidification, eutrophication, human health and global warming) of MSWM options that could be earmarked for future implementation in Harare city, Chitungwiza, Ruwa, Epworth and Norton. WTS have largely been reported that they can act as platforms for recycling and materials recovery hence their incorporation in future MSWM systems as platforms for recycling and materials recovery will result in reduced environmental impacts. This study therefore complements extensive literature review with LCA of the suitability of WTS for Harare city, Chitungwiza, Ruwa, Epworth and Norton considering the need to redesign and implement future sustainable MSWM systems along the integrated waste management model, the likely capacity exhaustion by 2020 of the only dumpsite for Harare (Pomona dumpsite), key national priorities and objectives under the Zimbabwe National Integrated Solid Waste Management Plan (ZNISWMP) that came into effect in July of 2014 and the Zimbabwean Government waste sector Low Emission Development Strategies (LEDS) for the Nationally Determined Contributions (NDCs) to its Paris Agreement differential obligations or responsibilities under the United Nations Framework Convention on Climate Change (UNFCCC).

2. Waste Transfer Stations

WTS provide linkages between MSW generation, storage, collection and transportation and final disposal (landfill or MSW processing facility) for a specific spatial scale (locality or community over a given temporal scale [23]. WTS consolidate MSW from different primary small or low volume MSW collection vehicles from MSW sources into secondary large or high volume collection vehicles to effect low MSW transportation cost by using the secondary large or high volume collection vehicles to haul MSW to distantly located waste treatment (anaerobic digestion and or a composting, incineration, pyrolysis,

gasification, waste to energy facilities etc) and disposal sites mainly landfills. Material Recovery Facilities (MRFs) are specialised WTS where recyclables are segregated and consolidated prior to waste transportation to landfills or other MSW treatment and disposal facilities [19, 21]. Therefore WTS operating as MRFs diverts waste sent to landfills thereby bringing along with significant environmental benefits such as reduced land sizes for landfills and demand for land considering its competing interests amongst its uses.

Figure 1: MSW collection according to country income levels [1]

Figure 2: Dominant disposal methods in Harare (a) [8, 24] and low income countries (b) [1]

2.1. Reasons for Waste Transfer Stations

WTS bring about a number of benefits to a MSWM system including reduced transport costs, reduced pollution, easing of selecting new sites for MSW disposal or processing facilities,

enhanced timeous collection and improved MSW collection efficiency. The construction of MSW-WTS results from the need for remote and regional landfills which are large and require tracks of land and have to be located further away from urban population centres where there is no land for constructing such large landfills coupled with the human health concerns of having landfills near population centres emanating from flies, rodents, mosquitoes as well as stray animals [2, 18]. Low tipping fees can be charged at large regional landfills due to their economies of scale which enable them to handle high MSW volumes from different sources under wider spatial scales thereby attracting more clients. Where MSW disposal and processing plants are over 15km from MSW sources from which MSW is collected, there is a possibility of establishing WTS at strategic sites within an urban area to cut on MSW transportation costs. The general rule with regards to the siting of MSW disposal sites and processing facilities is that they have to be established distant away from the urban population centres due to their associated potential human health and environmental impacts. This makes the primary MSW collection vehicles to travel long distances from MSW sources to the disposal sites and processing facilities leading to increased duration of travelling to and from disposal and processing facilities, increased number of primary MSW collection vehicles and cost in the MSW collection system. The increased number of primary MSW collection vehicles emanates from increased MSW generation coupled with the increased duration the vehicles take to and from MSW disposal sites and processing facilities since primary waste collection vehicles are light weight carrying vehicles capable to navigate the streets collecting waste at sources a difficult undertaking using heavy vehicles. WTS therefore provide the necessary infrastructure or platform for the transfer of MSW from light weight carrying vehicles to heavy weight carrying vehicles commonly referred to as secondary waste carrying vehicles. This combination of low weight and heavy weight carrying vehicles in a MSW collection system brings about costs reduction compared to the use of primary waste collection vehicles alone.

Apart from waste transportation cost reduction, the consolidation of light waste weight or smaller waste volumes from light weight carrying vehicles into heavy weight carrying vehicles increases the effectiveness and efficiency of a waste collection system through the reduction of the time waste collection teams take transporting MSW between MSW sources and disposal and or processing facilities giving more time for waste collection [25]. Ultimately this reduces the number of light weight carrying vehicles subsequently reducing pollution, noise and traffic congestion within an urban centre. Considering the atleast 40% organic waste composition in MSW generated in Harare [12] and high temperatures for Harare which speeds up the decomposition of biodegradable waste, WTS provide mechanisms for frequent and timeous biodegradable MSW collection prior to its decomposition resultantly avoiding potential human health and environmental risks, odours etc as argued by [26]. The timeous or just in time MSW collection thus is enhanced by the increased collection frequency brought about by the WTS emanating from the reduced durations taken and distances travelled by primary waste collection vehicles collecting waste from sources to WTS.

MSW transportation is associated with the consumption of fuel by waste collection vehicles subsequently causing air pollution and other accompanying environmental and human health impacts. The Global Warming Potential (GWP) emanates from the

emission of greenhouse gas (GHG) from waste collection vehicles travelling to and from waste disposal and processing facilities as well as during waste collection at sources. Therefore, the associated reductions in times spent and distances travelled by primary waste collection vehicles or at source collection vehicles brought about by incorporating WTS in MSWM systems reduce the associated potential global warming impacts and other environmental impacts. This is so because WTS reduces the total distance MSW-CT vehicles travel resulting in reduced fuel consumption, GHG emissions and costs of maintaining MSW-CT vehicles.

The United Nations Environmental Program (UNEP) reported over ten thousand climate change induced disasters to have occurred and been witnessed, destroyed and killed property and millions respectively, affecting many more globally. MSW was cited by [27] amongst the primary contributors to the emissions of GHG that cause global warming or climate change that has led to these disasters. MSW derived GHG emissions significantly emanate from MSW-CT. Two hundred and fifty million tons of MSW were reported by [28] to have been processed in the United States of America, producing GHG emissions that accounted for over 8% of non-energy derived GHG emissions and 2% of total net GHG emissions. The projected increase in global MSW generation from 1.3 billion tons to 2.2 billion tons in 2011 and 2025 respectively [1, 28], has brought and anticipated to result in increased MSW-CT derived GHG emissions. Efforts towards reducing MSW derived GHG emissions require the design, development and implementation of technically feasible and sound, economically viable, environmentally sustainable and socially acceptable MSW-CT systems [29] that makes the reduction of carbon dioxide emission feasible [30]. In [31], the authors therefore, noted the appropriateness with regards to financial savings and environmental benefits include land use planning of incorporating WTS in the MSW-CT systems within developing nations.

WTS also ease the selection of new sites for waste disposal and processing by eliminating the overreliance on at source collection vehicles accessibility to the sites giving preferences and considerations to human health and environmental concerns. Therefore, WTS allows for waste disposal and processing facilities location further away from human settlements thereby reducing human health risks from disease causing vectors like mosquitoes, flies, stray animals, rodents and leachates. WTS further provide platforms for waste screening before final disposal, the needed flexibility to choose MSW treatment and disposal options as well as serving as citizen drop off station.

2.2. Siting WTS

The selection or identification of a suitable location of a WTS is a tedious and difficult process. Environmental and human health potential hazards need to be taken into consideration when assessing all potential WTS locations. Such factors include but not limited to potential nuisance, odours, noise from primary and secondary waste collection vehicles as well as WTS equipment, proximity and accessibility to sources with high waste throughput. A number of potential locations are identified first after which a comparative evaluation is undertaken to identify the best site that has minimum impacts with regards to some or all of the factors highlighted above. A number of studies have been conducted

during the past twenty years using different approaches and considering different factors to identify the best WTS locations in different countries. The need for waste management cost minimisation as a factor for best WTS location was observed in most of the studies namely; [32]-[40] etc. In [37], the authors further observed other economic, environmental and social benefits of WTS incorporation and its suitable location in a waste management system that results in the simultaneous reduction of GHG emissions and resultant visual pollution apart from the reduced overall waste management costs in Tehran, Iran. In [34] and [40], the authors also noted revenue generation from waste processing facilities associated with WTS. For Harare therefore, MSWM costs and pollution reduction as well as revenue generation from MSW processing should be considered when deciding for the establishment and location of WTS. Thus, sustainability indicators for WTS in Harare will be based on cost effectiveness, reduction in water, land and water pollution, ability to accommodate the already at source collection vehicles being used by the ULAs, local expertise capable of designing, constructing and operating the WTS and energy efficiency.

2.3. Economic viability of WTS

As previously highlighted that WTS reduces the duration at source waste collection vehicles take collecting MSW and hence the reduction of primary MSW collection costs as well as the number of involved vehicles, economic viability of WTS is based on the breakeven point. This involves the comparison of WTS costs, hauling costs of primary or at source waste collection vehicles and secondary waste collection vehicles. Hauling costs have variable and fixed costs. Variable costs include fuel consumption, tyre, maintenance, depreciation, engine oil, and grease and waste collection crew wages. WTS costs encompass construction, operation and maintenance costs, calculated based on capacity basis with the distances between MSW final disposal and processing facilities and MSW sources being the only key consideration in determining WTS need. The following derivation by [41] identified the dependency and is used for assessing economic viability.

By having the following;

- i. The hauling costs with primary or at source collection vehicles be $a\$/\text{ton/km}$
- ii. The hauling costs with secondary collection vehicles be $c\$/\text{ton/km}$
- iii. The WTS costs be $b\$/\text{ton}$
- iv. The distance between MSW sources and WTS be $x \text{ km}$
- v. The distance between WTS and MSW disposal and or processing facility be $y \text{ km}$
- vi. Total hauling costs with WTS using primary or at source collection vehicles and secondary collection vehicles be TC_1 and without a WTS using only the primary or at source collection vehicles be TC_2 respectively

Therefore;

$$TC_1 = ax + b + cy \quad (1)$$

$$TC_2 = ax + ay \quad (2)$$

For WTS to be economically viable;

$$TC_1 \leq TC_2 \quad (3)$$

Thus,

$$ax + b + cy \leq ax + ay$$

$$y \geq \frac{b}{a-c} \quad (4)$$

Therefore, the breakeven distance between WTS and MSW disposal or processing facilities is site specific and depends on a number of different input parameters.

2.4. LCA in MSWM

Developments in the management of MSW has brought about the advent of the Integrated Municipal Solid Waste Management (IMSWM) model that entails combining socially acceptable, technically sound, economically feasible and environmentally sustainable MSW storage, collection and transportation, treatment and final disposal systems to manage MSW [42]. Such MSWM systems are complex to design and implement due to the difficulties associated with the need to optimize more than one variable hence the need for tradeoffs. LCA has come in handy as a computer based tool that can be applied during the design, development and implementation of such complex MSWM systems within the framework of the IMSWM model. LCA was described by [43] as a computer aided tool or decision support system that holistically quantifies estimates of potential environmental loads and or impacts of the entire life cycles of products and or processes. In [44], the authors described LCA further as a science-based method of assessing the environmental impacts of a system and or product though not being an entire scientific tool.

Three LCA methodologies have been described by [45] namely Social LCA (S-LCA), Environmental LCA (E-LCA) and Life Cycle Costing (LCC) based on the 3Ps - three-pillar approach towards sustainable development namely People, Planet, and Profit respectively. Despite the reported development of more integrated Life Cycle Sustainability Assessment (LCSA) approaches by [46] and [47], in [45] the authors noted the difficulties of combining the three methodologies due to overlapping issues during results interpretation thus it is advisable to undertake E-LCA, LCC and S-LCA separately. In [45], the authors however, reported the possibility of applying S-LCA individually or combined with E-LCA and/or LCC.

LCA application in informing decision making and policy formulation in MSWM systems design, development and implementation has been used since 1995 [48]. Its application in MSWM strategy development including decision making and policy formulation has expanded significantly during the past few years as a sustainability assessment tool that assists in solving the complexities and interdependencies of modern IMSWM systems [49]. In [50], the authors reported its potential in helping the designing of MSWM systems that reduce local pressures and associated MSWM costs, simultaneously considering the wider trade-offs and impacts of a MSWM system felt in other areas across a specific spatial scale. Spatial scale differences together with those differences with regards to MSW generation rates,

composition and characteristics, sources of energy, available MSW treatment and disposal methods with their associated products and services renders LCA appropriate or suitable to aid MSWM strategy development, decision making and policy formulation [51, 52]. It has emerged therefore as an appropriate and suitable holistic method with increasing wider application in MSWM strategy development, decision making and policy formulation [52, 53]. Several MSWM based LCA studies have therefore been carried out in the past with [54] having reviewed one hundred and fifty three studies carried out and published globally from 2013 to 2018, [55] analysed 91 studies carried out from 2006 to 2017 in Asian nations, [56] and [57] reviewed two hundred and twenty two studies they accessed including two hundred and seventeen from peer reviewed journal articles and fifteen public reports.

MSWM based LCA studies assesses different MSW management processes usually referred to as life cycle stages of MSW individually or a combination of processes within a MSWM system with regards to storage, collection, transportation or transfer, treatment and final disposal. These MSW life cycle stages includes the collection and transportation or transfer of MSW including WTS operations. For example, in [52], the authors incorporated WTS in their MSWM based LCA in Greece assuming that all the MSW generated is collected and transported to WTS prior to being sent to the different MSWM, treatment and disposal facilities. Other studies do not incorporate WTS and MSW-CT under the different scenarios arguing that the impacts will be the same under the different scenarios considering same functional unit. However, by considering the reducing effect that WTS have on the impacts from MSW-CT, it is wise to estimate the impacts associated with MSW-CT as it is likely to give an indication of its contribution to the overall MSWM scenario impacts. Higher contributions of MSW-CT will entail the need to redesign the collection and transportation system with the incorporation of WTS being a worthwhile consideration. Likewise MSWM based LCA studies were undertaken to inform possible least impactful MSWM systems that could be considered by decision makers and policy formulators for future implementation in and around Harare City, in Zimbabwe [15, 22, 58]. There is therefore need to assess the contribution of MSW-CT to the impacts of the overall MSWM options that were developed and assessed for their Life Cycle Impacts (LCI) to evaluate any need thereof of WTS considering their reducing effect on MSW-CT derived impacts.

2.5. MSW-CT contribution to LCI of MSWM in Harare

WTS incorporation in a waste management system brings about reductions in environmental or life cycle impacts. In [59], the authors observed a possible 16.8% average reduction in environmental or life cycle impacts when WTS are incorporated in a waste management system. MSWM based LCA studies were carried out to assess impacts of six developed MSWM scenarios that could be put for future implementation considerations in Harare. One of the MSW life cycle stages within the MSWM scenarios that was assessed for its impacts was the MSW-CT considering its contribution to Human Health Potential (HHP), Acidification Potential (AP), GWP or climate change and Eutrophication Potential (EP) of six developed MSWM scenarios for Harare City, Chitungwiza, Ruwa, Epworth and Norton.

The 467,303 tons of MSW generated in Harare City, Chitungwiza, Ruwa, Epworth and Norton [12, 22, 24, 60] are indiscriminately collected and transported for their subsequent landfilling and incineration under MSWM options 1 and 2 respectively with the recovery of energy and landfill leachate, incineration bottom ash and flue gas treatment. Zimbabwe's road infrastructural needs will likely provide a ready market for incineration bottom ash use in road construction. 196,167 tons of source separated biodegradable MSW fraction is subjected to anaerobic digestion (AD) with the recovery of energy from produced biogas whilst the remainder amounting to 271,036 tons mixed bag non-biodegradable MSW fraction undergo incineration under MSWM option 3 with incinerator bottom ash and flue gas treatment. The only distinction under MSWM option 3 and 4 is the landfilling of the remaining 271,036 tons mixed bag non-biodegradable MSW fraction associated with landfill leachate treatment and energy recovery. MSWM option 5 and 6 involve the same processes under MSWM options 3 and 4 respectively serve for the recovery of 20% of the 271,036 tons mixed bag non-biodegradable MSW fraction that are recovered for recycling and reuse purposes being the sole difference.

Several LCA softwares exist in the market. SimaPro software and its embedded Ecoinvent database has been widely used for MSWM based LCA studies having been used by a significant majority of studies reviewed by [53]-[57] and [61]. SimaPro has been and is widely applied because it is generic in nature with universal application capabilities. It also possess a broad database with embedded features from environmental product declarations generation, carbon and water footprints provision as well as sustainability and multi-language interface reporting [55]. SimaPro is standardized which enables it to generate universal and reliable results. It is capable of analysing complex MSWM systems and is based on the Ecoinvent database that has a wide parametric coverage [62]. SimaPro gives MSWM scenarios with description of MSW streams rather than product terms [63] and can be used under spatial scales characterised by general lack of information on MSWM practices [52]. Therefore SimaPro 8.5.2 software and update852 together with the embedded Ecoinvent 3 database (2018) were used [64]. The reference flow of 467,300 tons of MSW generated per annum was used as the functional unit as having been applied in other studies [65-67]. Results are shown in Figure 3 and Tables 1 to 4.

3. MSW Recycling Promotion

The MSW generated in Harare City, Chitungwiza, Ruwa, Epworth and Norton is reportedly suitable for recycling and reuse with [12] and [68] having observed respectively at least 75% and 90% reusability and recyclability potentials. The potential reusability and recyclability of the MSW has remained an untapped low hanging fruit that could address some of the MSWM challenges considering the 10% recycling reported by [8] and [24] shown in Figure 2a. WTS have largely been reported to provide platforms towards materials recovery and recycling promotion hence their design, construction and operation could significantly increase the MSW recycling and reuse figures to levels that could reduce or result in net zero HHP, AP, EP, and GWP observed by [22] for the MSWM options that could be earmarked for future

implementation in Harare City and its surrounding urban population centres of Chitungwiza, Epworth, Ruwa and Norton.

WTS could be operated under a mixed bag MSW collection system or a source separation MSW collection system. Incorporating source separation and WTS operation apart from easing and enhancing MSW recycling, was observed that it brings along with it environmental benefits due to the reduced environmental impacts. In [52], the authors identified that combining WTS with a separation at source MSW collection system and the recycling of plastics, metals, paper and glass MSW fractions as well as biological treatment of biodegradable MSW fraction yielded the overall optimum results with regards to GWP, Human Toxicity, AP, EP, Ozone Layer Depletion, and Photochemical Ozone Creation Potentials under the CML 2001 Method and HHP, Ecosystems and Resources Damage under Eco-indicator 99 method. Interestingly, the Zimbabwe National Integrated Solid Waste Management Plan provides for source separation of MSW thus providing a solid basis and foundation for having WTS under a separation at source MSW-CT systems whose opportunities and challenges are extensively discussed in [14].

Though they are not regarded WTS in the strictest terms, Citizens Drop Off Points (CDOPs) or Centres (CDOCs) sometimes referred to as Citizens Convenient Centres (CCCs) together with Buy Back Centres (BBCs) can also be considered to compliment WTS in aiding recycling and addressing some of the MSWM challenges associated with increased amounts of waste being sent to landfills. CDOPs are facilities where residents dispose of their recyclable MSW materials. CDOPs provides specific recyclable MSW receptacles where citizens or residents come and deposit or dispose of their recyclable MSW. CDOPs demands a great deal of citizens effort, willingness and time to transfer their recyclable MSW hence the need for them to be located within a radius easily accessible to residents. BBCs are facilities where individuals and or businesses sell recyclable MSW materials for BBCs to either process or sell to recycling companies. They provide the much needed linkage between MSW generators and recyclers. Unlike at WTS where those who come to drop waste are supposed to pay tipping fees, at BBCs only appropriate recyclables are to be dropped off with those bringing in the recyclable materials paid. However waste pickers can also get paid for delivering recyclable MSW to the Materials Recovery Facilities based WTS. BBCs and MRFs therefore provide a source of livelihoods for both formal and informal waste pickers. BBCs however, must be appropriately located for ease access to waste pickers after ascertaining the availability of reasonable recyclable MSW quantities. The price of recyclable materials determines the sustainability of BBCs whereas tipping fees largely determines the sustainability of WTS. Therefore WTS, CDOPs and BBCs can be considered for incorporation within future MSWM strategies that seek to reduce the human health and environmental impacts currently being experienced in Harare city and its surrounding urban centres. Their consideration for development and operation will aid the diversion of MSW from landfills through materials recycling.

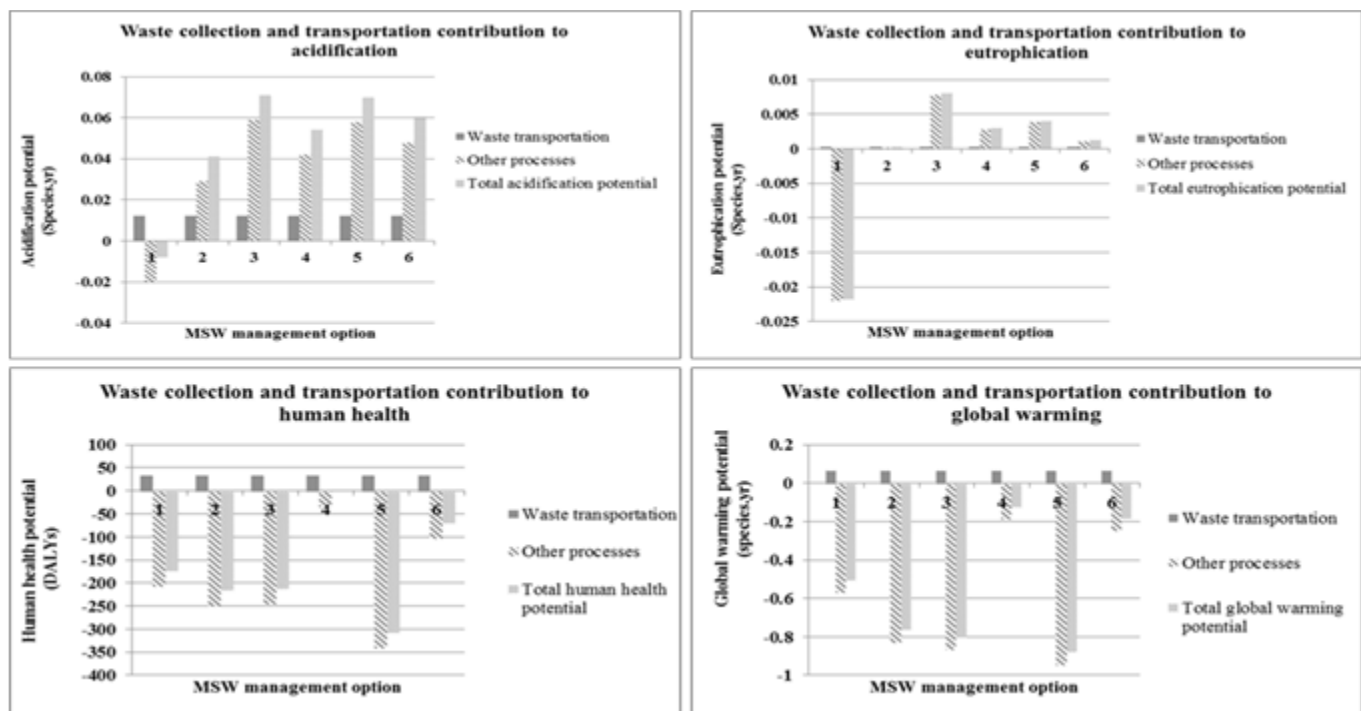

Figure 3: MSW-CT contribution to LCI

4. Supporting Legislation and institutional framework

The Environmental Management Act [Chapter 20:27] Subsection 1b(ii) under Section 10 of the Act mandates or authorizes the Environmental Management Agency in Zimbabwe to regulate and monitor the recycling of waste among other MSWM including MSW-CT and disposal. The Director General, inspectors and other officers of the Agency are authorised to ensure through monitoring that waste is either recycled and or re-used whenever possible and disposed only in a responsible manner under Subsection (d) of Section 36 of the Act. Every waste generator is obliged to take appropriate measures essential for

waste minimisation through recycling amongst other actions under subsection 3 of Section 70 of the Act. Statutory Instrument (SI) 10 of 2007 which authorizes ULAs to manage MSW provides for MSW recycling amongst the MSWM functions and demand every waste generator including ULAS to prepare annual waste management plans that provides for waste recycling wherever practicable in an environmentally safe form and manner amongst the specific goals provided under Subsection 1b(iii) of Section 13. Environmental Impact Assessments (EIAs) are required prior to the establishment of MSW recovery/recycling plants under 11b of the First Schedule of the Act. This could bring challenges in

attracting private players in establishing WTS, CDOPs and BBCs considering the bottlenecks and associated bureaucratic challenges associated with EIA approvals.

The Zimbabwe Waste Sector Low Emission Development Strategy (LEDS) for the Nationally Determined Contributions to its Paris Agreement differential obligations or responsibilities under the UNFCCC does not include MSW recycling despite the need to increase the MSW recycling levels provided for in the ZNISWMP and the Zimbabwe National Climate Change Response Strategy (ZNCCRS). This is a clear policy inconsistency that brings about challenges towards policy implementation. Though the ZNISWMP did not specifically provides for the construction of WTS, CDOPs and BBCs, amongst its strategic objectives is the need to develop infrastructure for waste management including waste recycling centres. Therefore it could be argued that the plan do provides for the development and operation of WTS, CDOPs and BBCs under the recycling centres considering the role they play to promote recycling as facilities for recycling. Goal 4 of the plan seeks to optimize resource recovery through the creation of an enabling environment for recovery; expansion of markets for recyclable MSW and forging partnerships in the recyclable waste value addition chain. It is evidently clear that a relatively fair legislative and institutional framework is available for recycling promotion and the establishment of recycling facilities. However specific provisions with regards to the siting, construction and operation of WTS, CDOPs and BBCs are absent. The other ingredient which is stakeholder involvement is at an undesirably low to support the construction and operation of CDOPs and BBCs based on the prevailing “*We Dumb They Collect*” attitude and general lack of willingness to pay for MSWM services provided by the ULAs amongst the residents.

5. Results and Discussion

The factors that support the need for WTS incorporation in a MSWM system identified from literature justifies the need for WTS to contribute to addressing the significant MSWM challenges currently prevailing in Harare City and the surrounding urban centres of Chitungwiza, Ruwa, Epworth and Norton. The increased population densities and major infrastructural developments coupled with their demand for residential and commercial land bring about increased competition for land leading to the unavailability of land for MSWM facilities especially landfills which require large pieces of land. In [2] and [18], the authors reported that landfill facilities provides favorable environment and conditions for flies, mosquitoes, rodents and mosquitoes together with stray animals to thrive. Therefore, apart from their demand for land which has numerous competing interests, landfill facilities are not desirable in the vicinity of Harare city and the surrounding urban centres which are already experiencing perennial and annual outbreaks of water borne diseases (cholera, dysentery, typhoid etc). This is so because siting landfills near these population centres will further these current human health and environmental impacts, hence landfill facilities to manage MSW generated in Harare City and the surrounding urban centres of Chitungwiza, Ruwa, Epworth and Norton must be sited further away from these population centres due to the already prevailing human health and environmental impacts coupled with the unavailability of affordable land for landfill facilities and other

MSWM operations such as MSW incineration, pyrolysis, gasification and anaerobic digestion.

The location of MSW landfills further from the population centres entails an increased MSW-CT costs and by considering the high MSW-CT costs being reported for Harare and its dormitory urban centres, the incorporation of WTS in future MSWM systems pose to be an ideal strategy with the potential to bring significant MSW-CT costs reduction overallly reducing the burden on the MSWM budget. However, quantitative assessments need to be carried out to determine the possible MSW-CT costs reductions that WTS will bring about. This will also entail the determination of the breakeven distance between MSW sources and the WTS that bring about effectiveness in MSW-CT cost. It has been reported that WTS lead to increased effectiveness and efficiency in MSW-CT through the reduction of time spent by waste collection teams moving to and fro MSW disposal facilities availing more time to be spent on MSW collection [25]. This will likely reduce the likelihood of organic MSW fraction decomposition prior to its collection and associated diseases outbreaks. Reductions in fuel consumptions and accompanying GHG emissions as well as waste collection vehicles maintenance costs are anticipated from incorporating WTS in a MSWM system. The reduction in GHG emissions will contribute to the global and national efforts on GHG emission reduction targets hence these reductions will contribute to the Zimbabwe LEDs towards fulfilling its NDCs within the Paris Agreement on differential responsibilities framework. Certain waste fractions such as stumps, fuel tanks despite being empty or filled, furniture, explosives, hazardous waste, electrical appliances, explosives, dead animals, sludge, oils and liquids are not ideal for deposition or disposal at WTS. Fortunately MSW generated in Harare and its surrounding urban centres does not include such waste as defined in the SI of 2007 under the Environmental Management Act [Chapter 20:27]. This further supports and justifies the need to incorporate WTS in future MSWM systems for Harare City, Chitungwiza, Ruwa, Epworth and Norton.

Results from LCA study on the contribution of MSW-CT to the AP, GWP, HHP and EP of MSWM options for possible future implementation considerations are given in Tables 1 to 4 and Figure 3. Results show that MSW-CT bring significant contributions to the AP, GWP, HHP and EP under all the six MSWM options. MSW-CT contributes to increased AP, EP, GWP and HHP of 0.012 species.year, 0.0002 species.year, 0.065 species.year and 34 DALYs respectively under all the six MSWM options. It is interesting to note that GWP brought the highest impact with regards to species extinction rate (species.year), largely emanating from the GHG emissions that cause climate change derived from fuel combustion in MSW collection vehicles during MSW-CT. The positive contributions of MSW-CT to all the four impacts categories entails the need to redesign future MSW-CT systems that could bring reductions to these impacts with the incorporation of distantly located WTS from population centres in such future systems likely to be an economically viable, environmentally sustainable and socially acceptable option. However, incorporating WTS with the source separation of MSW was found to bring optimal environmental performance of a MSWM system hence the need to design future MSW-CT under a source separation system to ensure the derivation of maximum environmental benefits. Consequently, the ZNISWMP provides for the need for separation at source thus providing an enabling framework or background to operate WTS under a separation at source MSW-CT system.

Table 3: MSW-CT contribution to GWP (species.year)

Processes	MSWM option					
	1	2	3	4	5	6

WTS, CDOPs and BBCs enhance recycling and divert a significant amount of waste from final disposal sites mainly landfills. The recycling of recyclable MSW fraction has been found to bring about significant environmental benefits from a review of LCA studies by [53]-[57] and [61]. In [22], the authors also noted significant environmental benefits that materials recovery and recycling bring about when it was considered under the study to determine least impactful MSWM option for possible future implementation in Harare City and surrounding urban centres. Incorporating WTS, CDOPs and BBCs in future MSWM systems in Harare City will likely to come with significant environmental benefits contributing to the addressing of the prevailing MSWM challenges and the low recycling figures of below 10% reported by [8] and [24]. Several legislations and policy documents provides for the need for MSW recycling namely the Environmental Management Act [Chapter 20:27], SI 10 of 2007, ZNCCRS and the ZNISWMP. Since WTS, CDOPs and BBCs facilitates the promotion and increase of recycling, it is therefore evident that they have a strong footing for their development and operation in Zimbabwean urban centres. However caution need to be noted in that there are no specific provisions for their construction within these pieces of legislative and policy documents serve for the ZNISWMP which generally provides for the need to develop infrastructure for waste management including waste recycling centres amongst its numerous objectives. Such lack of clarity on specific legislative, policy and institutional arrangements with regards to WTS, CDOPs and BBCs does not provide the needed confidence and certainty to would be operators of such facilities. The need for EIAs prior to the construction and operation of such facilities like WTS as provided for under the First Schedule of the Environmental Management Act [Chapter 20:27] will also bring its own challenges. Worryingly despite the reported provisions for the need for MSW recycling in a number of legislative and policy documents as well as WTS recycling promotion and GHG emission reductions, the National LEDs towards NDCs fulfillment

under the Paris Agreement did not incorporate recycling which could justify WTS operationalization. This policy inconsistency brings challenges for institutional prioritisation of key action plans as decision makers and policy formulators at ULA level will justify none recycling to such inconsistencies.

6. Conclusion and Recommendations

Study findings have largely shown the suitability of incorporating WTS in future MSWM systems for Harare City and its surrounding urban centres as they will contribute to reducing the current human health and environmental impacts currently characterizing these urban environments. WTS will bring about location of landfills and other MSWM facilities further away from population centers, increasing recycling, reducing MSW-CT costs and burden on the overall MSWM budget, increase in MSW-CT effectiveness and efficiency, reduction in MSW-CT derived GHG emissions and other environmental and human health impacts etc. Combining WTS with a source separation MSW-CT system brings about maximum environmental benefits of a MSWM system hence future MSWM systems for Harare City and surrounding urban centres must incorporate WTS under a separation at source MSW-CT system. A sound background that could be used to justify WTS as well as CDOPs and BBCs based on their potential to increase recycling is available based on the need to promote recycling as provided in the Environmental Management Act [Chapter 20:27], SI 10 of 2007, NCCRS and the ZNISWMP. However, there is need to strengthen the legislation with regards to the development and operationalization of WTS as well as CDOPs and BBCs because specific legislative, policy and institutional framework are absent. Such specific legislative framework complimented with a corresponding regulatory and institutional framework for the design, proper siting and location as well as operation of WTS together with CDOPs and BBCs is needed. This will increase their effectiveness and efficiency simultaneously reducing their associated negative human health and environmental impacts. Unfortunately, the absence of such an enabling legislative,

regulatory and institutional framework could have contributed to the evident silence on WTS incorporation in the proposed MSWM interventions in the ZNISWMP. Source reduction of MSW, materials recovery and recycling must be encouraged to lower the amount (volume and weight) of MSW that is earmarked for collection and transportation to distantly located facilities which will lead to fewer and smaller WTS and preservation of land. WTS have the potential of acting as CDOPs or CCCs resulting in reduced amount of MSW that is illegally dumped. Despite the observed suitability of incorporating WTS in the MSWM systems for possible future implementation in Harare City and its surrounding urban centres, there is however, need for further studies that determine the breakeven distance and LCA studies that specifically assess the associated environmental loads of incorporating WTS within the likely future MSWM systems.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

Special thanks go to University of Johannesburg Postdoctoral fellowship that supported this study. The authors would like to thank the Life Cycle Initiative for the 2017 Life Cycle award in the form of SimaPro software that was used to carry out the LCIA.

Plastic waste management practices

Separation of waste at source

Waste collection

ABSTRACT

Municipal Solid Waste (MSW) is composed of items that are discarded or disposed of daily including paper, plastics, glass, metals, used gadgets, paint and old furniture. The plastic waste stream has proven to be problematic to manage sustainably on a global scale. Various researchers are trying to come up with innovative ways of alleviating the detrimental effects of plastic on the environment. Examples include the production of liquid fuel and synthetic gas through pyrolysis and gasification of plastic waste, use of microbial strains that can break down polyethylene, manufacture of plastic-infused tar, use of plastic waste in cement and concrete as well as its use in the manufacture of bricks. Conducting public awareness and outreach programmes has also been found to be beneficial in reducing plastic littering. This paper reviews South Africa's strengths, weaknesses, and opportunities in plastic waste management as well as lessons from other jurisdictions that can be adopted in South Africa making it a role model for Africa with regards to plastic waste management. There exists an untapped opportunity for improvement of post-consumer plastic recycling rates to levels comparable to other recyclables in the country through compulsory separation of waste at source. Hence an enabling environment should be created to encourage this practice. Since this will require a fully functional waste management infrastructure, collection services should expand to cover rural areas and informal settlements while industries can assist municipalities to upgrade infrastructure through the extended producer responsibility (EPR) scheme. In addition, there is potential for more jobs to be created in the waste sector through recycling as compared to landfilling, thus urgent attention is needed to divert 100% waste from the landfill. Finally, the integration of informal waste pickers into the waste management chain should be prioritised.

1. Introduction

This paper is an extension of work originally reported in *Proceedings of the 7th International Renewable and Sustainable Energy Conference* and assesses plastic waste management implemented in Belgium, Australia, South Korea and Canada against that implemented in South Africa. Belgium and South Korea could potentially become the gold standards for South Africa to follow while Australia and Canada have a wealth of information and a clearly laid out vision of the direction the countries intend to take in fighting plastic pollution. Mini descriptive reviews of studies highlighting current plastic waste management practices as well as EPR studies from various countries have also been conducted. The aim of the paper is to

determine the lessons that South Africa can learn as we navigate the path to zero waste in line with circular economy principles. MSW, loosely termed garbage is composed of items that are discarded or disposed of daily including paper, plastics, glass, metals, used gadgets, paint and old furniture [1-3]. Waste is defined as any item that has reached the end of its usefulness and needs to be discarded [4]. MSW is generated from households, institutions (e.g. schools), businesses and non-hazardous waste from industries [2, 3] evidencing a "resource-intensive" lifestyle by consumers [5]. The management of MSW is critical because unmanaged waste is an eyesore, can be a breeding ground for disease-causing organisms, can block water drains and sewer networks leading to flooding episodes as well as cause damage to the marine environment and animals [3, 4, 6, 7]. The characteristics or composition and quantity of MSW vary between communities

*Corresponding Author: Zvanaka S. Mazhandu, zvanaka@gmail.com

and countries [3,8]. Consequently, waste management practices employed within the different communities and countries will also differ. Figure 1 shows the various fundamental stages involved in waste management.

Figure 1: Stages in Waste Management [3, 9]

The plastic waste stream has proven to be problematic to manage sustainably on a global scale. In Sub Saharan Africa, plastic waste constitutes 13% of the total MSW [5, 7].

In an earlier study, [7] highlighted leakages of small plastic items unnoticeably into the environment post-consumer use in South Africa. This is rampant in areas where there are no systems in place to collect them [7]. Albeit small, their continuous accumulation in the environment poses danger to animals as well as humans [7] in the short to long term.

To put this into perspective using bread tags as an example, the annual bread consumption in South Africa with a population of 59.7 million [10] is reportedly 25.8 kgs per capita [11] implying that over a billion tags weighing 300 tonnes are used yearly. Dedicated collection points for bread tags will go a long way in preventing such leakages. The Bread Tags for Wheelchairs an initiative started in 2006 by Mary Honeybun in South Africa, collects bread tags and sells to recyclers in order to buy wheelchairs from the proceeds. Approximately 600,000 tags weighing 200 kgs are used to purchase one wheelchair [12]. Therefore, 300 tonnes worth of tags would result in approximately 1 500 wheelchairs annually, Figure 2.

Figure 2: Number of Wheelchairs Expected Annually from Sale of Bread Tags

Various researchers are trying to come up with innovative ways of alleviating the detrimental effects of plastic waste on the environment. Examples include the production of liquid fuel and synthetic gas through pyrolysis and gasification, respectively of plastic waste [13-16], use of microbial strains that can break down polyethylene [17], manufacture of plastic-infused tar [18], use of plastic waste in cement [19] and concrete [20] as well as its use in the manufacture of bricks [21].

Conducting public awareness and outreach programmes has also been found to be beneficial in reducing plastic waste littering [22]. In 2013, the authors in [23] advocated for plastic waste to be considered hazardous unlike the current status quo where plastic waste falls under solid waste. The authors argue that if this is undertaken, countries would be compelled to put more effort in finding ways to mitigate plastic waste leakage as well as finding replacements for single use plastics (SUPs).

2. Data Sources

Data for this study was gathered from peer reviewed journals and grey literature. Authors' observations are also included. Some of the academic databases accessed include Google Scholar, Web of Science, Scopus, Science Direct and Springer Link with studies undertaken between 2010 and 2021 considered. Phrases and key words used to acquire relevant literature include plastic waste management practices, separation at source, waste collection, and extended producer responsibility which were either used singly or in combination. Quotation marks "" were also used to restrict the literature pool.

3. Review of Waste Management Practices

In 2015, the authors in [24] conducted a study to assess innovations in plastic waste management in Kenya. The author found out that; there were no incentives for innovators, recycling guidelines were lacking and working conditions were poor. With regards to plastic waste management practices, landfilling, illegal dumping and littering were prevalent in the country. The authors recommended the drafting of a plastic recycling framework by all stakeholders including those in the informal sector. This framework would include compulsory recycling targets, guidelines on quality of plastic products and training of informal sector workers.

In 2017, the authors in [25] assessed the management of plastic waste in Bangladesh with the aim of recommending the best way forward. The authors noted that hindrances to effective plastic waste management in the country included poor infrastructure, lack of recycling technologies and inadequate funds to advance waste management services. In addition, recycling and reuse were found to be minimal; with only 20% plastic waste collected while landfilling, open and indiscriminate dumping were the predominant disposal methods. They recommended the use of alternative plastic waste management technologies such as pyrolysis, bitumen production and use of plastic waste as solid refuse fuel in cement kilns in addition to recycling.

In the same year of 2017, the authors in [26] assessed current solid waste management practices and policies in Malaysia. Their findings were that there was limited separation of waste at source in the country hence poor recycling. In addition, the authors noted the lack of commitment by the public to participate in the initiative as well as the unavailability of accurate documented data. Open dumping and landfills were observed to be prevalent with 95% of waste being disposed of through these methods and the balance being recycled/treated or illegally dumped. In [26], the authors recommended; regularisation of informal waste pickers, updating of waste management policies and mandatory separation of waste at source to increase recycling rates and reduce illegal dumping incidences.

In 2018, the authors in [27] conducted a sustainability impact assessment of three scenarios for plastic waste management in Sweden. According to the authors, the country's dependence on incineration hampers recycling efforts. Plastic waste is also not prioritised in the different waste management policies of the country. The authors concluded that increasing recycling rates and phasing out incineration will be the most sustainable pathway to manage plastic waste in the country.

A study in Austria on plastic packaging waste management conducted in 2018, found that in the year 2013:

- $300,000 \pm 3\%$ tonnes of packaging waste was produced at 35 kg per capita,
- recycling rate was $26\% \pm 7\%$,
- use of plastic packaging waste in the cement industry was $32\% \pm 6\%$ and,
- waste to energy plants (WtE) used $40\% \pm 3\%$ packaging waste [28].

The authors recommended that recycling rates should be calculated using the output rate and not the recycling input rate to improve accuracy of results.

In 2019, the authors in [29] reviewed plastic waste management strategies in Nigeria and concluded that lack of funds and mismanagement of this limited resource and poor infrastructure hampered waste management in the country. Furthermore, over 50% of generated plastic wastes are either indiscriminately dumped or in drains and waterways. The authors recommended; educating the public on separation of waste at source; institution of fines for unsorted waste, setting up of collection centres, WtE plants, and establishing frameworks that enhance sufficient record keeping.

In the same year of 2019, a study in Singapore was conducted to determine the best environmentally performing plastic waste management scenario [30]. The author highlighted the dominance of WtE plants in the country due to shortage of space for landfilling. WtE plants result in a reduction in volume of waste by 90%. Approximately 634 kWh of energy is released from a tonne of mixed plastic waste. Residues (fly and bottom ash) from WtE plants are landfilled offshore. In addition, recycling is minimal in the country. In [30], the author recommended the use of pyrolysis in addition to WtE plants and mechanical recycling.

In [31], the author assessed plastic waste management practices in the United Kingdom (UK). According to the study's findings, of the 3.3 million tonnes of plastic waste produced in 2013, 2.26 million tonnes was packaging. The author also highlighted the need for attention to be directed to other plastics such as nurdles, synthetic fibres and microbeads and not only on plastic waste packaging. The commonly practiced waste management methods in UK are WtE plants followed by recycling and landfilling while some waste is also exported. Some of the recommendations given based on findings included enforcement of bans on fishing residues, enforcement of Operation Clean Sweep to prevent leakages of nurdles, extending ban of microbeads to all products and installation of sand filters in wastewater treatment facilities for the removal of plastic fibres.

In [32], the authors also conducted a 2020 study to assess plastic waste management practices in the Kingdom of Eswatini rural households. The amount of plastic waste generated per household was found to be 15.9 g/day. Common practices employed to manage waste were open burning, burying, indiscriminate dumping, use of pits at the backyard, reuse, upcycling, and recycling. The authors suggested the roll out of waste collection services in rural areas as well as educating consumers on plastic pollution effects and various ways of managing plastic waste sustainably.

In 2020, the authors in [33] assessed plastic packaging waste management in South Korea. Three million tonnes of plastic packaging waste were generated. The packaging waste was managed as follows; use as solid refuse fuel (39.3%), incineration without energy recovery (33.4%), recycling (13%) and the balance landfilled. The authors noted that only 22.3% of plastic packaging waste was under the EPR scheme and therefore they advocated for the list of plastic items covered by EPR to be expanded to reduce plastic pollution.

In 2021, the authors in [34] investigated SUP waste management in Hanoi, Vietnam and described the secondary use of plastic shopping bags as bin liners after single use. In addition, although plastic bags should be taxed, implementation is lacking. Landfilling was found to be prevalent while recycling is limited. According to the authors, there are gaps in drafted waste management policies which need to be addressed.

Waste management practices from five countries namely, Belgium (Europe), Australia, South Korea (Asia), Canada (North America) and South Africa (Africa) were also studied in this paper and these are highlighted in the ensuing sections.

3.1. Europe

Many countries in the European Union (EU) are trying to avoid landfilling, simultaneously improving their recycling rates of plastic waste. The EU must be admired for its unified approach as a region in trying to address waste challenges although countries like Malta, Greece, Romania and Cyprus still have a long way to go in reducing their rates of landfilled plastic waste from the current 70-80%. In Europe, a recycling fund is included on purchases which is subsequently reimbursed on returning bottles. This compels the public to recycle. Denmark, Germany, Austria, Sweden and Belgium have the lowest disposal rates; with less than 3% of MSW generated heading to landfills, Figure 3 [35-37].

Compared to the 50% target of recycled household waste by 2020, as outlined in the Waste Framework Directive of 2008, these 5 countries have indeed set the bar extremely high for other countries in the region. From the beginning of 2006 to 2016, the amount of plastic waste recycled in the region increased by 79%, an increase of 61% was observed for energy production while plastic waste landfilling decreased by 43%. During the same period, the recycling of plastic packaging increased by nearly 75% [36].

Extended Producer Responsibility, where manufacturers of products are responsible for their products throughout their entire life cycles [7, 38] is another scheme that is being advocated for within the European Union [35].

Figure 3: Recycling, Landfilling and Energy Recovery rates in Europe, 2016 [36, 37]

3.1.1 Belgium's Case

Belgium has a population of 11.6 million [39] and is comprised of three regions; namely Brussels Capital Region, Flanders and Wallonia. The enactment of Article 11(2), of the Waste Directive of 2008 has been instrumental in the way Belgium manages its waste. In the directive the various waste types such as glass, paper, plastic and garden waste are separated at source. The Pay as You Throw (PAYT) schemes have also been fundamental in compelling the public to adhere to the sorting of waste regulations. Residents are given about 4 bags to sort their waste in their homes. The bag of waste meant for disposal, costs more than the bags for recyclable waste. In 2013, Belgium was the leader in waste management across Europe [40] and profound lessons can be learnt by other governments by emulating Belgium. The amount of waste either disposed off or incinerated was a low 197 kgs per capita compared to its other counterparts in Europe as a result of reduced waste generation and increased rates of recycling [40].

According to the authors in [35], in 2015, US\$2.45 was charged per bag of waste to be disposed in Northern Belgium. This was approximately 5 times more than the rest of the bags and discourages waste dumping. In South Africa this would have been equivalent to R35.80 per bag versus R7.16 for recyclables. However, credit should also be given to the Belgians for playing their part in sorting waste and not resisting change in attitudes [35].

The company, Fost Plus, responsible for financing and handling the collection, sorting and recycling of waste has also been impeccable in its operations [41]. This has had an enormous positive impact on Belgium's waste statistics. Residents are also given a waste collection calendar yearly or they can download the Recycle mobile application since collections for different coloured bags may be carried out on different days. Residents are also fined if they do not sort or leave an improperly sorted bag in the street. In a report written in 2013 by authors in [42], the region, Brussels-Capital was apparently penalising residents as much as €625. Training is also offered to the public including children in schools, emphasizing the importance of waste sorting and its benefits [41]. Belgium is also a signatory to the conventions outlined in Figure 4.

Figure 4: Conventions and Bodies Supported by Belgium

3.2. Australia's case

Australia has a population of 25.6 million [43] and is made up of six states namely New South Wales, Queensland, South Australia, Tasmania, Victoria, and Western Australia as well as three internal territories and seven external territories each with its own government except the Jervis Bay Territory [44]. Australia set itself some ambitious targets in its 2018 National Waste Policy, among which was the ban after June 2020 on plastic, tyres, glass and paper exports. The country has realised that these materials often regarded as waste are a resource that can be used to; generate valuable products, create employment, boost the economy, protect the environment and health of its people. Approximately 9.2 jobs are created from 10 000 tonnes of recycled material in comparison to 2.8 jobs from landfilling [45]. The policy also reflects the banning of SUPs and the need for recording (and sharing) of accurate waste data including imports almost on a real time basis to assist with decision making coupled with unsophisticated online systems that are easy for everyone to understand. Other highlighted targets included a recovery rate of 80% for recyclables in MSW, purchasing of recycled materials by government and industries in order to increase the demand for these, and drive innovation by funding upcoming plastic recycling and waste prevention solutions. The underlying principle in Australia's Waste policy is the circular economy approach; a concept discussed in greater detail in an earlier study in [37].

The 2019 National Action Plan was then drafted to aid in the implementation of the National Waste Policy. Some of the documented strategies and targets given are shown in Table 1 [46]:

Table 1: 2019 National Action Plan Strategies

Strategy	Target
Drafting of legislation to avoid landfilling of recyclable material	2022
Sourcing new markets for recycled products	ongoing
Funding industries that make recycled products	2020
Increasing kerbside recycling rates through education and use of the Australasian Recycling Label (ARL)	ongoing
Launching a recycled products online market where buyers and sellers can connect	2021
Development of an application that helps the public to minimise contamination of recyclables in MSW	2020

Determining factors contributing to contamination of recyclables in kerbside collections and implement remedial actions	2020
Instituting an investment fund for Product Stewardship of oil containers made of plastic	(2020)
Development or adoption of standards that extend the life of a product including standards for use of recycled products in roads (Reconophalt) [42] and rail projects	2020
Develop national standards for collections	2022

Figure 5 shows the targets in relation to packaging and plastic as detailed in the 2019 action plan in [46].

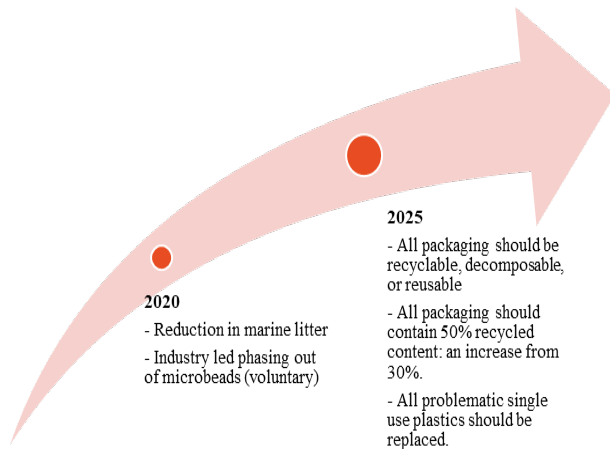

Figure 5: Targets in relation to packaging and plastic

In [47], the authors also mentioned programmes such as Do the Right Thing, Neat Streets, Don't be a Tosser and Bin your Butts which all help to make the public aware of the need to prevent littering. Another programme; Keep Australia Beautiful (KAB) outlined in [48] is also linked to initiatives such as Tidy Towns, Clean Beaches, Sustainable Cities, National Litter Index (NLI), Beverage Container Recycling Grants, Eco-Schools, Adopt a Patch, and KAB Week which occurs annually in August [48]. The NLI measures the degree of littering across the country annually.

Australia also formulated a framework known as the Threat Abatement Plan for the impact of marine debris on the vertebrate wildlife of Australia's coasts and oceans (2018), to protect marine animals from injury or death caused by marine debris. Australia also has two national plans namely, the Marine Turtle Recovery Plan (implemented in 2003 and reviewed in 2013) and the Grey Nurse Recovery Plan (initially adopted in 2002 and a new plan initiated in 2014) which are meant to boost the numbers of these species [49].

Australia is also actively involved in the United Nations General Assembly and the United Nations Environment Programme (UNEP) which seeks to protect the marine environment from land-based pollution. Australia, therefore, is in full support of the UN's Sustainable Development Goal 12 which encourages sustainable consumption and production. The country participates in regional initiatives such as the Coral Triangle Initiative, the Coordinating Body on the Seas of East Asia (COBSEA) and the Marine Resources Conservation Working Group of Asia Pacific Economic Cooperation (APEC) [49] and is launching in 2021, the Australia, New Zealand and Pacific Island nations (ANZPAC) Plastics Pact; a collaboration between Australia, New Zealand and other Pacific island countries which will be part of Ellen MacArthur's Plastics Pact. The pact is led by

APCO and The Waste and Resources Action Programme (WRAP), based in the United Kingdom (UK) is offering support. WRAP also manages the UK Plastics Pact [50].

In addition to this, the country is a member of other various international conventions and agreements on waste control, as shown in Figure 6. This ensures that the country is accountable, a trait that can only be of benefit to the country. Australia has managed to meet its international commitments by instituting regulations.

Figure 6: Conventions and Bodies Supported by Australia

3.3. South Korea's case

South Korea has a population of about 51.3 million [51] and the country is divided into 9 provinces namely North Chungcheong, South Chungcheong, Gangwon, Gyeonggi, North Gyeongsang, South Gyeongsang, North Jeolla, South Jeolla, and Jeju Special Self-Governing Province [52]. The Ministry of Environment in South Korea oversees the waste disposal policy referred to as "jongnyangje". The policy emphasises mandatory separation of waste into various fractions namely, recyclables, organics, large waste and landfill wastes. Fines are instituted for failure to abide by the policy guidelines [53,54]. Rewards are also given as an incentive to people who report non-compliance [54]. This explains why South Korea placed second out of 37 countries in the Organisation for Economic Co-operation and Development (OECD) for achieving a recycling rate of 59% in 2013 [53,55] and placed fifth globally in 2018 with a recycling rate of 53.7% [56]. On produced plastic products, over 60% of these are recycled [57].

The collection of waste is done at municipal level where revenue for this service is generated from the sale of differently coloured garbage bags. The purchase of the bin bags is compulsory and colour codes also differ per district. While organic wastes should be dried before disposal, recyclables should be flattened, and large wastes such as televisions should bear large object disposal stickers that are purchased from district offices [58]. The government of South Korea has been lauded for financially supporting the 48 plastic recycling businesses in the country which were struggling as a result of the ban imposed by China on importation of recyclable wastes which had resulted in piles of plastic waste in the country [58].

Figure 7 shows the progression of waste management acts and schemes implemented in the country and these are described in more detail in Table 2.

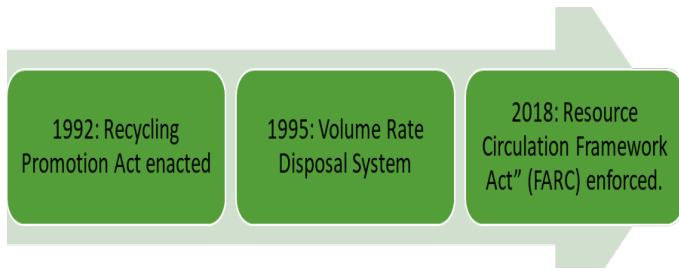

Figure 7: Progression of Waste Management Acts/Schemes [58]

Table 2: Description of Waste Management Acts/Schemes in South Korea [58]

Act/Policy	About the Act/Scheme
Recycling Promotion Act enacted	The aim was to promote recycling through introducing once-off use product laws, waste deposit and fee schemes and establishment of recycling industries.
Volume Rate Disposal System	Established on the premise of the “Pay as you throw scheme” similar to Belgium’s case. The aim was to discourage waste generation and increase recycling. This was a deviation from the fixed charges which were previously imposed regardless of the amount of waste a household would generate.
Resource Circulation Framework Act” (FARC)	The aim of this framework was to shift from the linear “take-make-waste” model to a circular economy approach. Hence the country is now working towards a “Zero Waste” policy. The country expects to yield socio-economic and environmental benefits from the framework as a result of reduced pollution and better managed resources.

Between 1994 and 2013, household waste per capita reduced from 1.3 kg to 0.94 kg (47,940 tonnes per day in total), buried waste decreased from 81.2% to 9.6%, burned waste decreased from 15.3% to 6.4% while recycled waste increased from 15.3% to 83.2%, Figure 8 [59]. These outstanding figures brought rapid economic growth into the country [55,60].

Figure 8: South Korea Waste Management Successes

The government of South Korea aims to reduce plastic waste by 50% as well as increase recycling rate from 34% to 70% by 2030. In 2020, coloured plastic bottles were also banned as they are difficult to recycle and polyvinyl chloride products may also

follow suit. A target has also been set to eliminate disposal cups and straws by 2027 while cafés can be fined as much as US\$1800 for using plastic cups for indoor sitting [60].

South Korea is also a signatory to the international conventions and agreements shown in Figure 9.

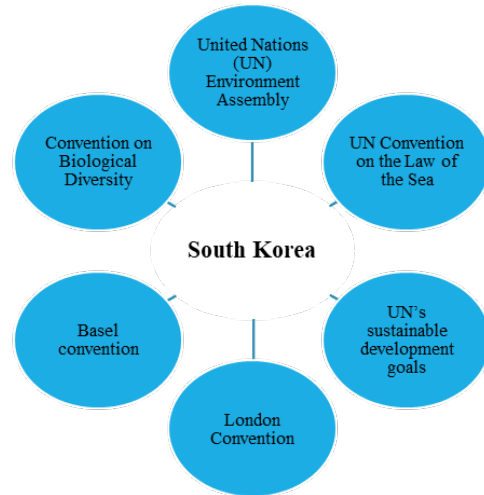

Figure 9: Conventions and Agreements Supported by South Korea

3.4. Canada's case

Canada's population is around 38 million [61] and the country has ten provinces namely Alberta, British Columbia, Manitoba, New Brunswick, Newfoundland and Labrador, Nova Scotia, Ontario, Prince Edward Island, Quebec, and Saskatchewan and three territories namely, Northwest Territories, Nunavut, and Yukon [62]. The Environment and Climate Change Canada (ECCC) is the government entity mandated to coordinate environmental policies to protect the environment and the public [63]. In 2018, the Aspirational Canada-wide Waste Reduction Goal was approved with the aim of promoting waste reduction and assessing progress in the country. The goal is to reduce the annual waste generation rate per person from 706 kg (2014) to 490 kg per person in 9 years (2030) and eventually 350 kg per person in 19 years (2040) [64].

On the international stage, during the tenure of the country's G7 Presidency in 2018, Canada launched the Ocean Plastics Charter aimed at protecting the marine environment and was adopted by over 20 countries and more than 50 organisations around the globe [65-67]. The charter outlines:

- the prevention of plastic waste mismanagement
- redesign of plastic products to ensure ease of recovery and recyclability.
- recycling and recycled content targets
- commitment to reduce plastic usage and waste generation.
- importance of seeing plastic as a valuable and not trash [66].

1	2	3	4
• 100% reusable & recyclable plastics by 2030.	• increase recycled content by 50% in products by 2030.	• recycle at least 55% plastic packaging by 2030 and 100% recovery of all plastics by 2040.	• Reducing use of microbeads in personal care products by 2020 and stamping out other microplastics sources.

Figure 10: Targets set by Canada

Figure 10 shows the targets set which require collaborations between governments and industry [67].

Canada also pledged \$100 million towards the improvement of waste management services in developing countries [65] and is a signatory to the conventions and agreements in Figure 11.

Figure 11: Conventions and Agreements Supported by Canada

Building on the Charter, Canada drafted its zero plastic waste strategy and its success hinges on enforcement of regulations, voluntary industry led initiatives, partnerships with various environment organisations and the community as well as EPR initiatives. In 2019, the Canadian Council of Ministers of the Environment (CCME) drafted an action plan to meet the goals of the zero-waste strategy [67]. The six broad action items outlined in the plan are outlined in Figure 12 below.

Figure 12: Action Areas of the Canada-Wide Action Plan on Zero Plastic Waste Phase 1

Figure 13: Action Areas of the Canada-Wide Action Plan on Zero Plastic Waste Phase 2

In 2020, the CCME launched Phase 2 of the Action Plan whose main focus areas are highlighted in Figure 13 [68].

Figure 14 shows plastic waste management practices in Canada in 2016 which reveal the linearity of the country's waste management techniques. According to the report by authors in [69] Canada lost around US\$6 billion through failure to recycle plastic waste and this will increase to US\$8.7 billion with a "business as usual" approach [69]. However, with the zero-waste strategy that has been commissioned in the country, this will avert the problems associated with a linear waste management model.

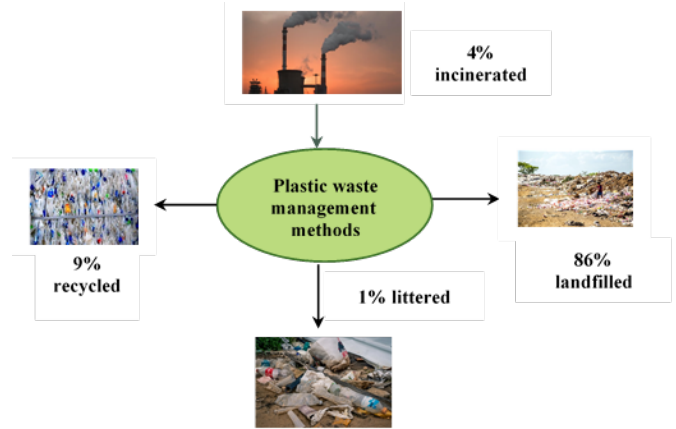

Figure 14: Plastic Waste Management Practices in Canada in 2016 [69]

Although Canada's track record in managing plastic waste still has a long way to go, it has begun to move on a positive trajectory with all the strategies that are being implemented. There are lessons that can be learnt from these and the wealth of research that has been conducted in the country. The success of the zero-waste strategy will result in the following benefits for the country:

- annual cost saving of about US\$400 million
- creation of 42,000 jobs
- Greenhouse gas savings of 1.8Mt of CO₂e [69].

Figure 15: Map of South Africa [70]

3.5. South Africa's case

South Africa has nine provinces, Figure 15 [70] and eight metropolitan municipalities [71], namely; Buffalo City (East London), City of Cape Town (Western Cape), Ekurhuleni Metropolitan Municipality (East Rand, Gauteng), City of

eThekweni (Durban, KwaZulu Natal), City of Johannesburg (Gauteng)), Mangaung Municipality (Free State), Nelson Mandela Metropolitan Municipality (Eastern Cape) and City of Tshwane (Gauteng).

The annual plastic consumption per capita in South Africa is 30-50kg [72] which gives a total consumption of approximately 1.8 to 3 million tonnes. Figure 16 shows a comparison of the daily generation of plastic waste per person for Australia, Belgium, South Korea, Canada and South Africa [73].

Figure 16: Comparison of the daily generation of plastic waste per person for South Africa and previously mentioned countries Data sourced from [73,74].

However, in [75] the authors argue that the data used in [74] was inaccurate and as a result they determined a significantly lower daily plastic waste generation rate of 0.053kgs/per capita. The authors in [75] used data from the Department of Environmental Affairs (DEA) in [76] in their calculations although the authors in [76] highlighted in their report that there was under-reporting for waste streams such as plastic, organic waste, glass and tyres due to lack of weigh bridges for example at landfill sites as well as the classification of these streams under MSW. The inconsistencies in literature on the waste management statistics reported for South Africa are also highlighted by various authors in [77-79]. Inaccurate data results in the understating of the environmental impact of plastic waste [78].

Furthermore, approximately 19.7 million people (34.1%) in South Africa do not have access to waste collection services and consequently resort to either burning or illegally dumping their waste, in which case valuable recyclable materials leak into the environment and are also not accounted for [7,80]. Availability of correct data ensures that costly problems of over-designing and under-designing equipment for example in an incineration plant, are avoided, as well as allow for effective and appropriate mitigation strategies to be employed. Lack of “buy in” from stakeholders on proposed projects citing exorbitant costs can be a negative consequence that arises from over-designing.

Figure 17 shows the disparity in waste collection services in South Africa's provinces [76]. Provinces with a higher urban population have higher collection rates compared to those with a higher rural population. As the population of informal settlements residents who do not pay rates in cities continues to increase due to rural-urban migration, problems associated with waste management in these cities will intensify [79].

In [81], the authors reported that Europe and other developed countries are 20 to 30 years ahead of South Africa when it comes to waste management. Unlike South Africa, these countries have

diverted from the use of landfills and adopted a culture of prevention, reuse, recycling, and recovery [81]. In 2018, Plastics South Africa, classified the country as a “mechanical recycling champion” for having recycled 46.3% of all the plastic waste generated taking into consideration locally manufactured products only [82] against 31.1% for Europe [80]. In the same year, 2018, the highest figure of US\$354.4 million was recorded for imports of Plastic & Rubber Articles in South Africa [83], while in 2019, the country imported plastics and plastic articles worth US\$2.5 billion, representing a proportion of 2.8% of the overall value of products imported [84]. It is very crucial for recycling statistics reported to consider all imported plastic products for a clearer picture on plastic waste management to be ascertained.

Figure 17: Waste Collection Services in South Africa Per Province (data sourced from [76])

In [85], the authors also argue that since countries employ various approaches when determining recycling rates, comparisons per country are difficult to undertake. In addition, it is also worthwhile to note that, in Europe, the balance of plastic waste remaining after recycling, was either used for energy generation in WtE plants (41.6%) or landfilled (27.3%) while in South Africa's case, the balance of 53.7% was landfilled.

In South Africa, plastic is the material which has the lowest recycling rate among other recyclables such as paper, glass, tyres and metals. In a State of Waste Report released in 2018, plastic had a recycling rate of 43.7% in 2017, while glass, metals (ferrous and non-ferrous) and tyres were at 78.4%, 75% and 100%, respectively, Figure 18.

Figure 18: Percentage of Waste Recycled and Landfilled Per Waste Type (data sourced from [76])

The balance of 56.3% plastic was disposed off at landfills [76] an indication of significant plastic leakage.

Further accumulation of plastics in landfills, which are running low on landfill space as well and reaching maximum acceptable height should be prevented [86]. The lack of innovative ideas and research and development inadequacies have been cited as a limitation in South Africa's progression in the Plastics sector [87]. The recycling rate of 100% for tyres is disputable though, since it is common to see tyres indiscriminately dumped.

The World Wide Fund for Nature (WWF), however put the plastics recycling rate for South Africa at 16% with 84% being dumped in waste bins and ending up in landfills while some plastic wastes are transported by wind and end up in the marine environment through storm water drains [72]. It is not clearly defined in [72], whether the mentioned figures are from the input or output recycling rate.

Nonetheless, South Africa still needs to be complimented for the strides that it has made in managing plastic waste. Voluntary producer responsibility organisations (PROs) such as the PET Recycling Company (PETCO) for polyethylene terephthalate (PET) [7], Polystyrene Association of South Africa for all variants of polystyrene, Southern African Vinyls Association (SAVA) for plastics such as polyvinyl chloride and Polyco responsible for polypropylene, high and low density polyethylene and other types [88] have been formed to assist with the recycling of the various plastic waste streams thereby preventing the leakage of plastic into the environment as well as attaining value from post-consumer and landfilled plastics. These companies all fall under the umbrella body Plastics South Africa.

Figure 19a: Shrink wrap before baling

Figure 19b: Baled mixed PET bottles

Figure 19c: Baled plastic bags

Figure 19d: Separately baled coloured PET bottles

Figure 19: The recyclable waste

At the heart of South Africa's recycling industry are about 60 000 waste pickers [89]. However, according to the authors in [81], this figure may be conservative, and they estimated the number to be around 215 000 in 2017 [81]. Waste pickers rummage through bins or are based at landfills where they remove recyclables from MSW destined for the landfill such as plastics which they take to buy-back centres and get paid to earn a living. Approximately 80 to 90% of packaging is recovered by waste pickers [79]. The presence of waste pickers resulted in a landfill cost saving of around \$US21.3-US\$51.5 million (R309.2-R748.8 million) for municipalities in 2014 [89]. Buy back centres such as

Remade Recycling have also been key in South Africa's plastic waste management, receiving all types of plastic waste from waste pickers and collectors, sorting, and baling the recyclable waste before transporting it to converters as feedstock (Figure 19a-d).

3.5.1 The Role of Government

The National Waste Management Strategy (NWMS) is a statutory requirement of the National Environmental Management Act: Waste Act, 2008 (Act No. 59 of 2008) referred to as the "Waste Act". This strategy aims to ensure that the objectives of the Waste Act are fulfilled [90]. The NWMS of 2011 stressed the importance of re-using, recycling, and recovering waste (3Rs), Figure 20. In [91], targets to have waste collection in 95% of households in urban areas and 75% in the rural areas by 2016 are given. To date, in urban areas and rural areas, 64.7% of households and 75.1% households respectively now have access to waste collection services.

Figure 20: The 3 Rs

On separation of waste at source, the 2011 strategy failed to meet its target of ensuring that households in different municipalities would be separating their waste at source by 2016 [91]. Prior to the drafting of the NWMS, the Polokwane Declaration which envisioned zero waste to landfill for South Africa was signed in September 2001. In the declaration, South Africa set ambitious targets which are summarised in Figure 21.

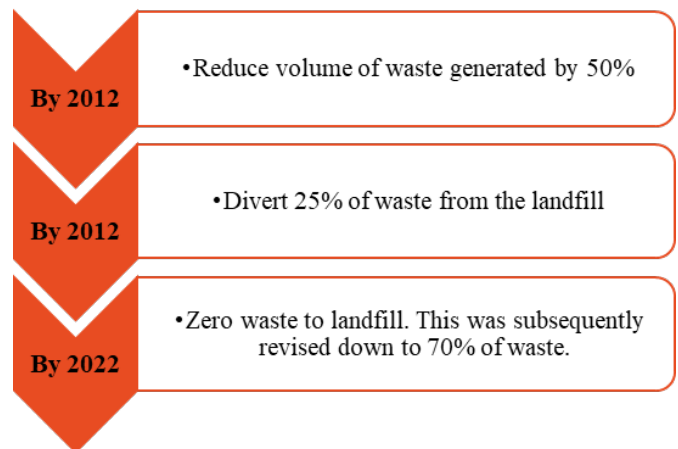

Figure 21: Polokwane Declaration Targets [92,93].

In 2020, the government released a new NWMS which now advocates not only for the 3Rs but also a circular economy approach coupled with EPR, which encourages waste prevention and product regeneration at the end of its lifecycle [37,86] whose waste reduction to landfill pathway is shown in Figure 22. The failure of the Polokwane Declaration to achieve zero waste to landfill has resulted in a new target being set in the 2020 NWMS which goes beyond 2035.

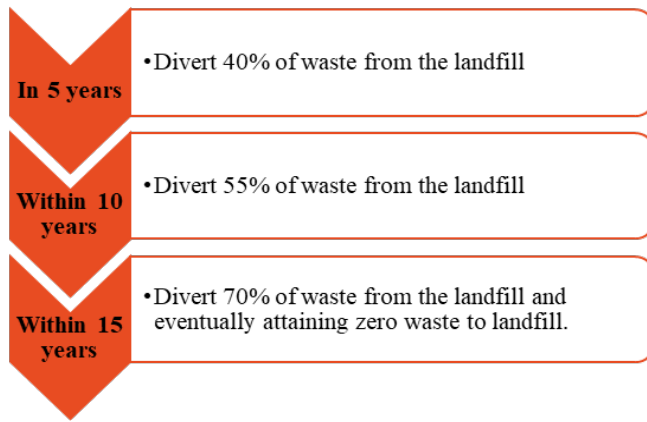

Figure 22: Reduction of waste to landfill pathway

The current NWMS of 2020 also reinforces the need for the continuation of awareness campaigns [86]; which was first outlined in the 2011 NWMS. The objective was to have 80% of municipalities and 80% of schools conducting such campaigns by 2016 [91] and to date 60% of municipalities are conducting these awareness programmes while all schools now teach about waste as part of the curriculum [86].

Minimisation of illegal dumping of waste, littering and the use of single use plastics such as disposable cups and straws is also outlined in the 2020 NWMS. One of the main drivers for this strategy is the need to prevent landfilling, as previously reflected in the 2011 strategy [91]. It remains to be seen whether the latest NWMS strategy will succeed in the areas where the 2011 NWMS strategy has not with the new target year for waste collection in 95% of households set for 2024.

The prevalence landfilling in South Africa has been attributed to the absence of alternatives as well as the belief that this method of waste management, despite being the least recommended in the waste hierarchy, is less costly to implement and yet its environmental impacts are not accounted for [86]. According to the authors in [94], recycling reduces the environmental impact of a product, therefore, increasing recycling rates in South Africa, can only benefit the country.

3.5.1.1. Introduction of other Policy Initiatives

In May 2003, South Africa instituted plastic bag regulations meant to stop the production and importation of sub-standard plastics that could neither be reused nor recycled. This meant that only bags with a minimum thickness of 30 μm were permissible [7,95]. This regulation was accompanied by a plastic levy of 3 cents (R0.03) in 2004, which latter increased to 6 cents (R0.06) and 25 cents (R0.25) in 2017 and 2020, respectively. However, this policy intervention has not yielded the expected results of curtailing plastic bag consumption [96,97].

The Department of Environmental Affairs (DEA) has also begun discussions with businesses to ban microbeads in the cosmetic industry. It is not clear at what stage these consultations are now at [98]. Other initiatives launched by the government to change the public's attitudes and perceptions and lessen the impact of plastic waste while creating employment at the same time include Operation Phakisa (2014) [99], the Recycling Enterprise Support Programme (RESP) (2016) [100], and the Good Green Deeds programme (2019) [101].

On the international stage, South Africa has pledged to support several Conventions on the protection of the environment, Figure 23.

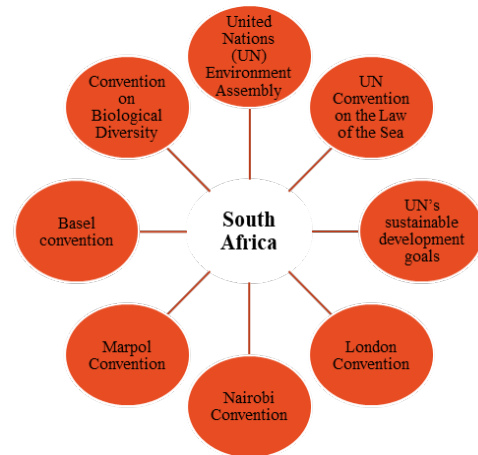

Figure 23: Conventions and Bodies supported by South Africa.

3.5.2 Waste Management Services: A Case Study of Pikitup

Pikitup, which provides waste management services to the City of Johannesburg in the Gauteng Province rolled out a voluntary separation of waste at source programme in some of its suburbs in 2009 [102]. This programme has been moving at a snail's pace because more than a decade later, it has not moved into the rest of Johannesburg. The amount of dry waste collected in the financial year 2016/17 was reportedly 4.5 kgs of dry recyclables per household per month out of an expected 13 kgs per household because not all households separated their waste. On 1 July 2018, Pikitup implemented mandatory waste separation in the communities where the programme had been rolled out, to increase the recycling rates [102]. Therefore, this mandatory call covered approximately 26% of all the households in Johannesburg [102]. Despite the mandatory call, there are no fines instituted for households that do not separate the waste, opting instead to incentivise residents whilst still collecting mixed waste. This creates a point of plastic waste leakage.

The company has mentioned that the roll out to all of Gauteng will happen around 2021 and they expect that this campaign will eventually be implemented not only in Johannesburg but the rest of South Africa. Households where this initiative has not been commenced are encouraged to separate their waste and drop off at nearby drop off centres. Pikitup also mention that dirty clamshell containers, sweet wrappers, detergent bags, potato crisps and sauce packaging are not recyclable [102].

This information and the motivation behind it, needs to be communicated to all households for the programme to be a success. We are now in 2021, so the complete rollout of the separation of waste at source programme appears not achievable. The positive however, is that it shows that the country is aware of what needs to be done but a shift in gears is required so that targets can be met within reasonable and set timeframes. It is undeniable that if this programme is to move like a well-oiled machine, its success hinges on the availability of financial resources as well as willingness by the public to separate their waste. The public also needs to be aware of the various plastic types and the recycling codes associated with them, as shown in Table 3.

Table 3: Plastic Recycling Codes [103]

Recycling Code	Plastic Type	Application
1	Polyethylene terephthalate (PETE)	Soft drink bottles, mineral water, fruit juice container, cooking oil
2	High density polyethylene (HDPE)	Milk jugs, detergents, shampoo bottles
3	Poly vinyl chloride (PVC)	Trays for sweets, fruit, plastic packaging (bubble foil), food wrapping foils
4	Low density polyethylene (LDPE)	Crushed bottles, shopping bags, wrappings
5	Polypropylene (PP)	Furniture, toys, car bumpers
6	Polystyrene	Hard packaging, cosmetic bags, CD cases
7	Other	Acrylic, polycarbonate, fibres, nylon

Figure 24 shows the household separation levels in South Africa's nine provinces, with the Western Cape Province having the highest level of 20% followed by Gauteng Province with 13%.

Figure 24: Household separation level per province in South Africa [104]

3.5.3 Other Waste Campaigns

There are also other campaigns that are happening in South Africa. However, it is not clear to what extent the public is aware about them and a national survey would need to be conducted to assess public awareness and knowledge levels. These include the annual Clean-up and Recycle SA Week, the International Coastal Clean-up Day (ICC) [105] and the weekly #KleenaJoburg campaign launched in December 2019 [106]. The Two Oceans Aquarium in Cape Town also runs a campaign called “Rethink the Bag”, which educates people on the harm that SUP bags can cause in the marine environment. They have also launched a petition to urge the government to ban single use plastic bags [107]. In some municipalities, beach clean-up campaigns are also done.

4. EPR Reviewed Studies

Various studies on EPR have been conducted across the globe; some of which have been reviewed in this study under this section. In [108] (2010), the author compared mandatory and voluntary EPR schemes in South Africa and found that the latter appeared more effective after comparing the Plastic bag regulations instituted by the government against the PETCO initiative for PET recycling. However, the study also highlights that the differences could also be attributed to the fact that unlike PET, plastic bags are not easily recyclable, are of lower value, recycled bags have limited areas of application and their use as plastic bag liners leads to leakages into the environment. The need to avoid government

regulations thought to be harsh may also have possibly fuelled voluntary EPR's success.

In [109], the authors conducted a study in Serbia which revealed several problems. First, the quantity of recyclables recovered from MSW is low due to lack of recycling infrastructure, programmes, and funding. Further to this, landfill taxes are not applied to all municipalities, consequently there is no motivation to remove recyclables from MSW. However, if landfill taxes are exorbitant, this can result in an increase in illegal dumping. In addition, the exclusion of waste pickers from projects involving municipalities and PROs was also observed to be an impediment in the collection of recyclables with waste pickers vandalising infrastructure put in place to take out the recyclables. Lack of expertise during policy formulation was also highlighted. For example, after providing colour coded bins to residents, a single truck would be used to collect the separated waste, which then demotivated the residents. Setting low recycling targets has also affected recovery of materials from MSW. For example, PROs can meet these targets by collecting waste from industrial and commercial wastes such that there is no motivation to collect from residential areas. PROs may also prioritise funding towards one type of recyclable and not others while some may not contribute to infrastructure development. In addition the authors in [109] also mention that there needs to be monitoring of operations of PROs, a minimum target that PROs should contribute towards recovery of recyclables from MSW and these organisations should submit reports to the government annually detailing expenditure for the sake of transparency.

In [110], the authors conducted a study in Colombia (2018), and recommended having multiple PROs for a product as well as delegating enforcement of laws to more than one organisation.

In [111], the authors conducted a study in Europe and found that strict enforcement of EPR related regulations was deficient. Further to this, the lack of incentives for companies that comply resulted in companies not participating in the programme. Despite these limitations, the study concluded that EPR programmes can boost recycling levels and this increase in plastic recycle, will in turn require effective collection, sorting and treatment of the plastic waste. Therefore, regional and local authorities together with PROs should ensure that collection services are efficient as well as educate the public on how to properly sort waste. Revenue from EPR schemes can be used for these initiatives. The study also highlights the importance of EPR in achieving a circular economy and recommended implantation of Deposit Refund Schemes (DPR) across the European Union. In addition, the need for the opinions of manufacturers, packers, fillers and retailers to be considered when implementing DPR as well as the importance of the public advocating for the use of biodegradable plastics were highlighted. Success of EPR will depend on its confluence with other initiatives such as, labelling, procurement policies, pay-as-you-throw schemes, recycling goals, prohibitions, goods and waste taxes, non-mandatory agreements and public consciousness with no seclusion of any type of plastic.

In [112], the authors refer to the EU Waste Framework Directive, which has assisted waste management in Europe to remain financially viable and independent. The study recommend the roll out of a global EPR as well as ensuring that plastic product

designs are standardised at a global level such that products that do not meet the specifications are banned or taxed. However, the authors also highlight the possibility of resistance from industry regarding the Polluter Pays principle. Deposit return schemes as well as consumer pay-as-you-throw programmes which discourage unsustainable consumption patterns are recommended.

In [113], the authors revealed that EPR in China is hindered by low levels of recycling including lack of recycling technology and therefore, producers should be encouraged to develop sorting and recycling technologies. The study mentions the importance of citizenry involvement, in assisting the government to identify industries not complying with the EPR regulations.

In [33], the authors explained that the reliance of the EPR scheme in South Korea on money paid by producers is a drawback. The study found that some recycled products were of poor quality and therefore, investing in modern recycling equipment is crucial. In South Korea, producers are given an annual target of plastic waste to recycle and this can be done directly or through a PRO, which they pay a fee to. The PRO then pays a subsidy to the Korea Resource Circulation Service Agency (KORA) which is responsible for collection and recycling. Recycling subsidies and private investments have sustained the EPR scheme. Producers that fail to meet their recycling targets are fined a fee that is higher than the recycling fee. PRO and KORA submit reports on the performance of the producers under the EPR scheme to the Korea Environment Corporation. The authors recommended the inclusion of more plastic products under the EPR scheme to improve recycling rates. The study also highlights that since recycling plants operate on a small-scale basis, they are affected by domestic and global trends in the recycling market.

In [114], the authors revealed a number of hindrances to the successful implementation of EPR schemes in Brazil (São Paulo). First, lack of enforcement of the law for those not practicing in EPR schemes as well as absence of incentives could demotivate companies that are practicing. Incentives include offering tax rebates to companies in the scheme. In addition, consumers do not always return the waste, for example if drop off centres are far, while some would rather keep the waste, for example in the case of cell phones and resell. Discounts given on raw materials also do not promote the use of recycled products. Collection of waste may also be a problem if the distances to be covered are long and the waste is little. The authors recommended industry led EPR schemes and that retailers should also form part of the schemes as they are involved in waste collection from consumers. Integration of municipalities into the scheme although necessary, could pose a challenge when determining how much compensation they should get if they are part of the scheme. It was noted that many cases have gone to court because of these disputes and as a result binding agreement must be drafted to avoid such disputes. The importance of awareness campaigns which should be funded by retailers and producers was also noted. Other recommendations include;

- banning the sale of goods subject to EPR but without the scheme in place
- the need for collaborations between municipalities and businesses to also build infrastructure and to stamp out non-compliance

- that all new companies should have a proposed EPR scheme before they can be given permits to operate.

5. Discussion and Conclusions

5.1. Setting of Targets

Reviewing findings from the authors in [74]; of the five countries studied in this paper, South Africa has the highest plastic waste generation rates per capita. There are vital lessons to learn from Belgium, Australia, South Korea and Canada. South Africa has many right elements in its policies to become a pace setter in the continent when it comes to plastic waste management. However, implementation seems to be lacking as set target dates continue to be shifted forward without tangible results being realised in some cases; an example being the “zero waste to landfill target” which was reduced from 100% to 70% waste diversion from landfill by 2022 [93]. Further to this, the target year of 2022 has now been moved to 2035 as highlighted in the 2020 NWMS [86]. Continuous resetting of goals will be detrimental to the country’s success in managing its plastic waste as it does not yield benefits except shifting responsibility from one actor to another and this can persist for decades to come. Moreover, if 9.2 jobs are being created for every 10 000 tonnes of waste recycled compared to 2.8 jobs with landfilling [45], then South Africa is losing a significant number of jobs in the waste sector by not stamping out the practice of landfilling which is the main waste management method. Despite these challenges, South Africa has made some headways in trying to manage plastic pollution.

5.2. Waste Collection Services

Ensuring that the entire population of the country has access to waste collection services followed by compulsory separation of waste at source and dedicated collection points for small plastic items are key elements to successful waste management. Currently, with a single bin of mixed waste in most households, 34.1% of the population lacks waste management services [80] and at times refuse collections are not always on schedule as a result of backlogs caused by breakdowns. Therefore, unless there are other role players to assist with the collection of sorted recyclable bins or bags the separation of waste at source programme will be unsuccessful.

5.3. Data Accuracy

This study noted the problem of data inconsistencies in the country making it difficult to ascertain with confidence, the country’s waste management record as has been highlighted by other authors in [76-79]. Perhaps, the accuracy of data can be improved by employing real time data logging at recycling centres that receive post-consumer plastic as highlighted in Australia’s National Action Plan, installing and properly maintaining weigh bridges at landfills as well as stamping out illegal dumping and burning of plastic waste which both contribute to the load of unaccounted waste.

5.4. Public’s Attitudes

As the government and various stakeholders drive the agenda of zero waste to landfill, the consumers should not be left behind because they are also vital in achieving a future where plastic waste is not dumped but repurposed (circular economy). Behaviour

changes go hand in glove with knowledge and if the public is not made aware of the importance or need to separate waste, then the amount of waste sent to the landfills will not decrease to levels observed in Belgium. A change in the public's attitudes has been highlighted as one of the reasons why waste management in Belgium has been a success [35]. Investment in awareness campaigns is necessary and these must reach as far as informal settlements and rural areas. It was noted that rural households are less likely to recycle as compared to urban households [115] and this could be attributed to South Africa's National Domestic Waste Collection Standards which put more emphasis on waste separation in urban areas. Furthermore, young adults and families were also found less likely to recycle [115], and therefore, campaigns like Europe's Generation Awake, which encouraged sustainable living for young adults (25-40 years old) and children, can play a very important role in educating this group. This campaign involved the release of short films such as *The Awakeners* and *Water Maniac Walter* [116], which were comical, but got the message through [117]. The Generation Awake campaign was a success as more than 1 million people reportedly accessed their website, their videos were watched over 10 million times, they reached 140 000 followers on Facebook and over 2000 articles were written regarding the campaign [117]. Incentives such as the PAYT scheme practised in Belgium will also encourage reciprocation [118] as seen in Belgium; while enforcing this, will strengthen the regulation.

Moreover, the public should be educated on the different plastic recycling codes. However, a major challenge that is likely to be encountered is that some plastic products in the country do not have recycling codes. Therefore, regulations should be put in place to ensure that all plastic products including imports have these codes. In addition, some of the printed codes are quite small to detect and therefore, increasing their size on the product will also make it easier for the consumer to separate or recycle. A National Littering Index (NLI) similar to the one employed in Australia can be used as one of the tools to assess change in the attitudes and behaviours of people post anti-littering campaigns.

5.5. Lessons from the Covid-19 Pandemic

The Covid 19 phase exposed a major weakness in our waste management system. When the government declared a Level 5 lockdown of the country from the 27th of March 2020 to 30 April 2020 (35 days), where only people regarded as essential services were allowed to work, waste pickers were not on that list, but the municipalities still carried out their mandate of collecting MSW. With no one to remove recyclables such as plastic, this meant that plastic in the MSW was landfilled. It could be argued by some, that since over 70% of South Africa's plastic waste that is recycled is from landfills; the plastic that leaked into these landfills during the lockdown will eventually be reclaimed. However, plastic from landfills is contaminated and therefore not only does this restrict its uses but it also requires washing and is sometimes rejected by recyclers. South Africa, being a water scarce country, with several municipalities under water restrictions means diverting water towards washing of plastic from landfills will only strain this resource further [119]. Therefore, it is necessary to develop a framework to regularise and integrate informal waste pickers in the waste management value chain of all municipalities across the

country as they have an important role to play in the prevention of leakages of recyclables.

5.6. Alternatives to mechanical recycling

Other innovative projects such as the construction of a section of a road in Jeffreys Bay with plastic infused tar need to be expanded. About 1.8 million plastic bags can be used for a 1 km stretch of road [120]. Similarly, to Australia as highlighted in [46] South Africa should consider also developing its own standards for use of plastic waste and other recyclables in roads and rail projects.

In Ivory Coast, the country in partnership with the United Nations Children's Emergency Fund (UNICEF) has begun building schools using plastic bricks that are also resistant to fire and are waterproof. The bricks also do not require cement and sand and only require a hammer to lay them [121]. UNICEF has projected that a total of 500 schools; enough to accommodate 25 000 students, will be built by 2021. This project has also empowered women in the process as they are the ones collecting the plastic for recycling into bricks. UNICEF also built a plastic brick making factory in the country to enable all the manufacturing to be done in Ivory Coast. The bricks were initially made by Conceptos Plasticos, a Colombian company. Prior to this initiative, only 5% of Ivory Coast's waste was recycled, so this figure is set to rise as more people begin to realise the value of plastic that is in their own "backyard" [121]. There is a significant amount of plastic that can be reclaimed from South Africa's landfills and used in such projects where contamination may not be a problem.

5.7. Lessons for South Africa from the Reviewed EPR Studies

To ensure EPR's success in South Africa, Multi-National Companies should disclose how much plastic they are putting on the market as well as how they are managing it post-consumer use [6]. Furthermore, producers must meet the recycling targets set by the government otherwise they should be fined fees that are higher than the recycling fees [33]. As industries in South Africa work on producing integrated waste management plans as requested by the government, informal waste pickers, retailers, municipalities and consumers should not be left out. As evidenced in the Serbia study, the exclusion of waste pickers led them to damage infrastructure in order to access the collected recyclables [109].

The government should also be wary not to set low recycling targets, as this can result in depressed recoveries of recyclables [109]. Plastic producers must continue to pay their recycling fees to PROs, which is currently being done in SA for voluntary PROs and plastic importers should not be absolved from paying [110]. The government should also periodically review and ascertain if the fees that are being contributed by producers to PROs are enough to sustain the sector.

Where a producer decides to take the responsibility, and bypass the PRO, although the producer may submit performance reports, honesty and auditing are also required in this case. Furthermore, the quality of recyclables should also be of high standard so that the recycling industry remains viable up to a point where it can sustain itself without requiring external investments. A high quality will enable high value products to be made as well as increasing the product range that can be made. In that regard, the public should be aware [111,114] of how to sort waste, avoiding contamination of recyclables and to clean any

contaminated plastic waste preferably with used water (grey water).

On the other hand, retailers also play a crucial role in the collection of post-consumer plastic [111,114], for example through deposit refund schemes (DRS). Further to this, municipalities currently own the existing infrastructure for waste collection and therefore may only need assistance from industry to increase capacity [114]. The inclusion of consumers will also be critical as they need to ensure that waste is sorted correctly as well as be prepared to return the waste to the retailers for the DRS to work. In addition, consumers may also play a role by reporting industries flouting the EPR laws [111,113,114].

Enforcement of the law where compliance is lacking which has also been a concern in South Africa [77,79] should also be prioritised in order to avoid frustrating companies that are observing the law [111,114]. Other aspects to be considered are; whether it will be advantageous to have multiple PROs to make them competitive [110], whether it would be beneficial to ban products whose companies are not implementing their EPR schemes [114], and whether permits to operate should only be given to industries who have a proposed EPR scheme in place on registration [114]. There are many lessons on EPR implementation that South Africa can learn as it prepares its own blueprint on EPR and these should be enumerated and deliberated by the government and all concerned stakeholders.

6. Road Map for Future Actions in Plastic Waste Management in South Africa

Figure 25 shows a proposed road map that South Africa can implement moving forward.

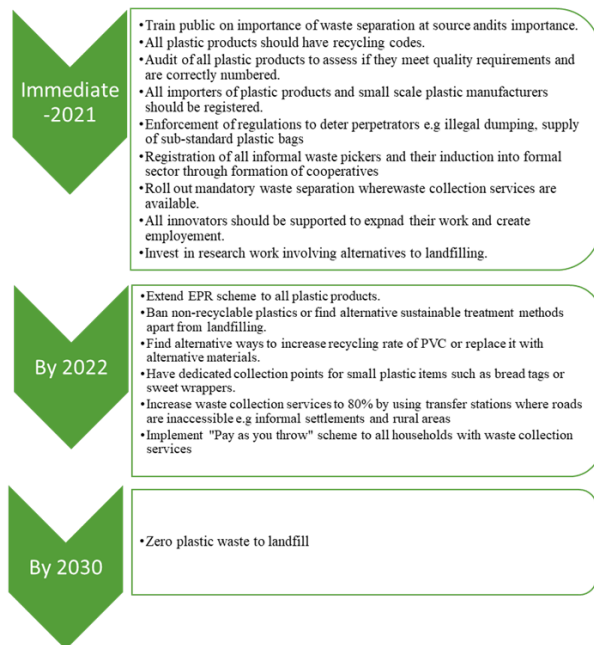

Figure 25: Road Map for South Africa

This paper has highlighted South Africa's strengths, weaknesses, and opportunities in waste management as well as lessons from Belgium, Australia, South Korea and Canada that can be adopted by the country in order to make it a role model for Africa in plastic waste management. There exists an untapped

opportunity for improvement of plastic recycling rates to levels comparable to other recyclables in the country through compulsory separation of waste at source. Hence an enabling environment should be created to encourage this practice. Since this will require a fully functional waste management infrastructure, collection services should expand to cover rural areas and informal settlements while industries can assist municipalities to upgrade infrastructure through the EPR scheme. In addition, there is potential for more jobs to be created in the waste sector through recycling than landfilling, thus urgent attention is needed to divert 100% waste from the landfill. Finally, the integration of informal waste pickers into the waste management should be prioritised. If the above-mentioned action points in the road map are succinctly applied, then zero plastic waste to landfill can be achieved earlier (2030) rather than aiming for a 70% reduction in plastic waste to landfill in the same year.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The authors are grateful to the University of Johannesburg and the Botswana International University of Science and Technology for the financial and technical support.

ABSTRACT

Municipal Solid Waste Management (MSWM) decentralisation brings about reductions in the amount of municipal solid waste (MSW) earmarked for landfilling worse still under situations where MSW is being sent to dumpsites. It also reduces the distances MSW collection vehicles travel during MSW collection, maintenance and transport costs due to the establishment of local level decentralised MSWM and treatment facilities. Subsequently fuel use, greenhouse gas and other emissions together with MSWM associated environmental and human health risks are reduced. The Zimbabwe National Integrated Solid Waste Management Plan (ZNISWMP) provides for the need for decentralisation in MSWM. This study therefore assessed the framework along which MSWM decentralisation can be achieved in Harare. The study noted the presence of various opportunities for MSWM decentralisation in Harare namely household backyard composting, community level and industrial scale anaerobic digestion or composting of organic MSW fraction, anaerobic co-digestion of organic MSW fraction and dewatered sewage sludge, MSW source separation for material recovery, establishment of waste transfer stations, citizens drop off centers, buy back centers and thermal treatment facilities associated with energy recovery. Though the NISWMP plan provides for concrete actions for MSWM decentralisation, the study observed that almost all of the proposed actions have not been implemented hence the need for urgent review and subsequent operationalization and implementation of the review findings. MSWM has also been hindered by the lack of legislative and institutional reforms with ULAs remaining reluctant to devolve and delegate some of the MSWM responsibilities and functions to other players prompting the need for such reforms to be implemented as provided in goal 10 of plan. The Presidential national cleanup day proclamation needs to be complemented with other initiatives that will increase residents' interest in participation, allow for different types of participation such as provision of resources and equipment and above all the development of sustainable MSW disposal facilities unlike dumpsites.

1. Introduction

This paper is a revised and extended version of a paper entitled, "Options for decentralised municipal solid waste management in Harare, Zimbabwe", that was presented at the 7th International Renewable and Sustainable Energy Conference (IRSEC' 19), Sofitel Agadir Royal Bay, Agadir, Morocco, November 27-30, 2019.

*Corresponding Author: Trust Nhubu, Cr Siemert & Beit Streets, Doornfontein, Johannesburg, South Africa, 2094, +263777342295, nhubutrust@gmail.com

In Zimbabwe, municipal solid waste management (MSWM) is a designated authority of urban local authorities (ULAs) including municipalities, town councils, local boards and rural district councils largely implemented under a conventional and centralised system [1-3]. Like most ULAs in Africa, the ULAs within and in the vicinity of the Harare metropolitan province in Zimbabwe are experiencing MSWM failures. These failures are largely due to increased municipal solid waste (MSW) generation emanating from increased urban population and improved lifestyles. The

MSWM failures thus are a manifestation of mismatch between increased MSW generation and investment in MSWM and accompanying necessary infrastructural development. Other factors leading to MSWM failures are poor governance and inadequate capacity to fully adopt technology intensive MSWM and treatment methods being developed in the developed world.

The limited and or no external investment as well as the over reliance on rate payers characterizing the MSWM in the ULAs in and around Harare is largely unsustainable posing MSWM related human health and environmental hazards. Residents have developed general unwillingness to pay attitude and regard MSWM a sole responsibility of ULAs thus they resort to indiscriminate or irresponsible dumping of MSW in undesignated areas when over 50% of the MSW generated remain uncollected as reported by [4]. ULAs regard residents as MSWM rates or service payers who must only participate in MSWM through paying for MSWM services that would have been provided. The prevailing MSWM model thus lacks all the necessary partnership and cooperation ingredients amongst the stakeholders specifically between the residents served by MSWM systems and ULAs [2, 5]. The model does not provide adequate environment for residents as well as other stakeholders involvement in MSWM [6].

ULAs attributes the residents' inability and unwillingness to pay to the unsustainable, ineffective and inefficient MSWM systems currently prevailing within their jurisdictions. The residents on the other hand attribute their unwillingness and failure to pay for MSWM services to the poor MSWM services delivered, abuse of resources by the ULAs' executives and the general economic hardships emanating from the prevailing economic environment. Such contradictions shows the ineffectiveness, inefficiency and unsustainability of the conventional and centralised MSWM model inherited from the colonial era and being implemented in developing countries [7, 8]. Municipalities and or ULAs face financial constraints that hinder MSWM efficiency [9-11] leading to low or no collection of MSW generated [12-14]. The low or no MSW collection fuels illegal as well as indiscriminate open dumping, burying and burning of MSW in undesignated areas [4, 15, 16]. MSWM system failures, therefore, become inevitable and expected to worsen in Harare due to the residents' unwillingness and inability to pay as well as the absence of alternative financing sources. In addition MSWM system failures in developing countries has also been linked to the continued dependence on the linear MSW generation, collection, transportation and final disposal model or approach under the conventional and centralised system because of its rigidity that hinders the local level solutions acceptance and adoption of specific and unique local MSWM requirements [17]. Such MSWM approaches are not designed to bring solutions to MSWM associated complexity since one compartmentalized MSWM solution is likely to generate other MSWM problems [18]. Therefore, the linear (generation, collection, transportation and disposal), conventional and centralised model being implemented in developing countries and specifically in Harare is discredited for being a problem transfer (MSW transfer) from MSW sources to disposal sites especially land intensive dumpsites and landfills [19]. Zimbabwe thus realised and noted its lack of capacity to effectively provide MSWM services in its urban environments under the prevailing MSWM system or model and initiated the

process of developing a national integrated solid waste management plan (NISWMP) in 2010 [20].

The Zimbabwe NISWMP amongst eight of the issues it sought to address noted in another study [21] speak on the limitations of the conventional and centralised MSWM system specifically the continued reliance on MSW generation, storage, collection and transportation and then final disposal by ULAs in Zimbabwe with major challenges being experienced under collection, transportation and disposal resulting from failures to meet the increased waste generation; lack of effort towards avoiding or preventing, reducing and controlling the increasing waste generation; and non-involvement, lack of participation and consultation of stakeholders especially the residents who are served by MSWM systems as well as the private sector since MSWM is largely a preserve of ULAs and their hired agents. In attempting to address the mentioned shortcomings the Zimbabwe NISWMP provides for decentralised MSWM options and the promotion of stakeholders' participation in MSWM within Zimbabwean urban environments. The Zimbabwe NISWMP's goal 10 of strategy C under action 5 (A5) provides for MSWM authority to be decentralised to the lowest appropriate level and enhancing ULAs' capacities to fulfil their obligations. Zimbabwe does not have a national waste management policy and Goal 10 provides for the need to develop one and review and assess the current legislative and institutional arrangements for the purpose of improving implementation [20]. This study, therefore, reviews MSWM models together with the associated available options for MSWM decentralisation in ULAs within and surrounding Harare City considering the MSWM decentralisation proposals in the Zimbabwe NISWMP as well as from other literature sources.

2. Decentralisation in MSWM

MSWM decentralisation encompasses relevant stakeholders' involvement and participation especially the residents and those who use and are served by the MSWM system. Stakeholder participation is integral in both community based municipal solid waste management (CBMSWM) and integrated municipal solid waste management (IMSWM) considering that MSWM sustainability is attained only when local authorities accept its corresponding management system. Such a MSWM system must be realistic and appropriate in providing solutions to the available and specific MSWM circumstances and challenges of an urban area (city, town, local board, growth point etc) and its surroundings. It must also be able to engage and capacitate all its stakeholders and users namely households, private businesses together with their employees, government departments (local, regional and national), non-governmental organisations including donors and international financing simultaneously recognizing and considering their socio-economic, political, cultural and environmental status.

2.1. Community Based Municipal Solid Waste Management (CBMSWM)

Communities are considered active role players under CBMSWM when it comes to the cleaning of their environments which has the potential of providing them with livelihoods in as far as earning an income from MSW [22, 23] and by taking advantage of the belief and understanding that people are likely to change their behaviours and attitudes towards something if they are part

of problem identification and solution design. Strong relationships are therefore built amongst the various MSWM stakeholders namely ULAs, residents and private business. It is under such CBMSWM that communities and residents bear the responsibility of providing clean and sanitary environments in the vicinity of their households and residences by discarding MSW in designated receptacles. Communities and residents are also potential agents for materials recovery (recycling and reuse) from MSW, backyard composting of organic MSW fraction, MSW separation at source including at households and or other MSW generation sources which will be collected by respective MSW fractions collectors. They can as well resultantly deliver their source separated MSW fractions to any of the following: citizens drop of centers (CDOPs) or citizens convenient centers (CCCs), buy back centers (BBCs), waste transfer stations (WTS), materials recovery facilities, specific MSW fraction treatment facilities (anaerobic digestion and or composting for organic MSW fractions, incinerators, pyrolysis and gasification plants and landfills). In addition, they can as well perform other administrative MSWM functions such as recording MSW collection services like the daily number of premises and households served, quantity of MSW collected etc. within their localities [9, 14, 24].

CBMSWM provides communities and residents with the opportunity to be involved and participate in MSWM meetings, elect their local representatives and leaders responsible for the management of MSW collection and providing residents feedback and complaints to the ULAs. In addition to the role played by communities and residents in MSWM, CBMSWM recognizes the vital role of community-based organisations (CBOs) and that of local private businesses. Authors in [25] and [26] reported that CBMSWM has brought some improvements in MSWM in household or residential areas regardless of the other social challenges reported to have been encountered in some developing countries during its implementation [3, 27] as well as the negative perception regarding MSWM being considered a sole responsibility of ULAs [3, 28].

2.2. Integrated Municipal Solid Waste Management (IMSWM)

IMSWM model has received global acceptance as a system that could address the current MSWM challenges with full scale operationalisation and implementation having been achieved in the developed nations whereas developing nations are also making significant strides towards its operationalisation and implementation. IMSWM emerged from the need for MSWM shift from landfilling as the sole disposal method to a wider and holistic perspective that incorporated value extraction through materials and energy recovery from MSW that started in the 1990s. The need to shift from MSW landfilling as envisaged under the IMSWM model however is despite the continued reliance on dumpsites in some or majority of developing countries making the transition from dumpsites to landfilling inevitable, thus a transition that will not include landfilling which is to be avoided under the IMSWM for these developing countries will be too huge and difficult to implement. The IMSWM model is meant to bring about the necessary trade-offs regarding the effectiveness of the environmental sustainability, economic affordability and social acceptability dimensions of a MSWM system [29, 30]. The authors in [29] further pointed out that IMSWM focuses on integrating the numerous MSWM processes namely; MSW generation, storage,

collection and transportation, treatment or processing methods, recovery of materials and energy, final disposal and entities (MSW producers and users, managers and policy formulators, governments, financiers and funders) that form a MSWM system to bring about continuous improvement together with the MSWM associated environmental impacts and costs reduction. The design of IMSWM systems is meant to achieve specific local level MSWM goals taking into consideration the prevailing MSW generation and characteristic together with the available and appropriate MSW prevention, reduction, reuse and recycle and final disposal methods, political, socio-economic, cultural, environmental and institutional systems factoring in stakeholders' perspectives and needs [29, 31, 32] which guarantees the needed MSWM systems decentralisation and sustainability since ignoring these social aspects and other local level priorities have led to systems failures [33, 34].

Effectiveness in a MSWM system is attained when both ULAs and residents fully embrace it thus departing from the traditional system where experts design and outline MSWM solutions prior to the involvement of residents meant to be serviced by the MSWM system. This is largely so since MSWM system acceptance by residents is anchored on their involvement and participation during planning, design, development, implementation and operationalisation with the evolving value systems, consumer attitudes, perceptions and behaviours being equally important as the technical and economic aspects [33, 34].

The traditional meaning of waste which is subjective in that it attaches a negative value on MSW by regarding it an unwanted item or material to the disposer is regarded only true in the IMSWM system only when the MSW waste has been utilised to its full potential leaving no further processing potential to recover materials and energy [18, 32]. IMSWM thus brings together the waste hierarchy elements factoring in the associated MSWM direct impacts from MSW generation, storage, collection and transportation, treatment and processing and final disposal together with indirect impacts from the use of recovered materials and energy [10]. Various players therefore, can take different roles along the different IMSWM system stages instead of having ULAs being the sole players responsible for the entire MSWM system functions. This brings about the much-needed decentralisation as well as specialisation. For instance, collection and transportation, treatment and processing may be delegated to other players whilst the final disposal be the duty of other players.

3. Support Pillars for MSWM Decentralisation in the NISWMP

The NISWMP provides several key strategies and action points under its goals 1 to 10 that support decentralisation of MSWM within ULAs in Zimbabwe. Such key actions include but not limited to the need for reduction in waste, source separation of MSW, reuse of biodegradable MSW for gardening and livestock feed at household level, establishment of viable markets for biodegradable MSW, production of manure from biodegradable MSW composting or vermi-composting, establishment of community and industrial recycling centers, development of recycling projects at institutions such as schools, tertiary education institutions and hotels, construction of AD facilities at established recycling centers and institutions like schools, universities, prisons

as well as markets and hotels, establish combined Heat and Power (CHP) generation facilities from AD derived biogas, putting in place a kerbside collection system with citizens' drop off or citizens' convenient centers where households or institutions bring waste as provided in Table 1.

All these key actions provided in the NISWMP with regards to enhancing decentralisation speaks on the need for stakeholder participation in MSWM which is further affirmed under goal 8 which seeks to promote cleanliness in Zimbabwe by involving the public, industry and government in efforts towards reducing, reusing and recycling all solid waste materials to manage and mitigate the MSW associated public health and environmental impacts. In addition, Goal 7 of the NISWMP supports decentralisation as it seeks to educate and raise awareness amongst Zimbabwean citizens to better understand the importance of participating in source separation; materials and resources recovery and integrated and sustainable solid waste management thus the high literacy level in Zimbabwe is believed will enhance citizens participation easing the introduction and implementation of decentralised waste management systems. Interestingly the tenth goal of the plan seeks to review and assess current legislation and institutional arrangements to improve implementation of ISWM amongst its key actions under its strategy C is the need to decentralize MSWM authority to the lowest appropriate level as well as strengthening the capacities of ULAs to meet their obligations with regards to decentralizing MSWM authorities.

4. Proposals for MSWM Decentralisation in Harare

The ULAs that constitutes Harare metropolitan province include Harare the Capital City of Zimbabwe, Chitungwiza municipality and Epworth Local Board. Other two ULAs that borders Harare city namely Ruwa Local Board to the east and Norton Local Boards to the west are generally considered part of ULAs that constitutes what is loosely termed Harare. The waste generation figures in these ULAs are as given in Table 2. Currently each ULA is responsible for the management of the MSW generated within their jurisdictions. These ULAs are indiscriminately collecting less than 50% of the MSW generated and dump it at open non engineered or sanitary dumpsites serve for Norton which has an engineered sanitary landfill whose environmental soundness is under questioning. Several options for decentralised management and treatment of the MSW fractions generated within a specific jurisdiction as shown in Table 2 can be pursued. The options for treating these MSW fractions generated should be focused on AD of biodegradable MSW fraction, recycling of at least 20% and incineration of at most 80% of the non-biodegradable fractions. The focus on the mentioned MSW treatment is informed by study findings from [35] which identified the option incorporating AD of organic fraction of MSW, at least 20% and at most 80 percent recycling and incineration of the non-organic MSW fraction generated in Harare respectively being the least environmentally impactful option. Composting of the biodegradable MSW fractions could also be considered after AD due to the better environmental performance and overall edge of AD over composting resulting from its renewable energy production capabilities and other associated benefits noted by [36].

4.1. Biological Treatment

The AD of the organic MSW fraction generated in Harare (136,612 tons), Chitungwiza (32, 822tons), Norton (6,21tons), Ruwa (5, 213tons) and Epworth (15,403tons) could be done at household, institutional, community or industrial scale. Households and institutions (schools, universities, hotels etc.) could source separate their biodegradable MSW they generate and feed it into purposely built small biogas digesters from which they can get biogas for their domestic cooking. Community level AD systems could therefore bring medium to large scale operation of up to 100,000 tons per annum where ULAs could partner with private sector, institutions and local residents. Further upgrading of biogas utilisation at institutional or community levels to install combined heat and power (CHP) generation units where the biogas produced from AD is burnt to generate renewable electricity and heat. The biodegradable MSW could also be composted at household and institutional level through backyard composting thereby reducing MSW amount transported for disposal at landfills in the face of heightened global concern against the landfilling of biodegradable MSW fractions. Other medium and large-scale composting facilities could also be established by the private sectors, ULAs and residents. The establishment of household and institutional AD and composting facilities as well as community or industrial scale AD and composting facilities within the neighborhood where the biodegradable MSW is generated brings about a reduction in MSW amount on a weight and volume basis to be transported to landfills. The number of trips and distance travelled by MSW collection vehicles are reduced subsequently reducing fuel consumption, MSW collection and transportation associated greenhouse gases (GHG) emissions, vehicles maintenance and overall costs. However, need for capacity building arises to avoid any unintended health and environmental impacts from the improper operation of household AD and backyard composting. Medium scale to large scale AD and composting facilities under decentralisation can be operated by the private operators with communities, institutions and ULAs facilitating source separation of organics to ensure the necessary AD and composting feedstock quality. ULAs will therefore collect and deposit their sorted organic waste to the composting and AD facilities at nominal agreed gate fees.

Alternatively, private players will be responsible for the collection of the source separated organics. The communities involved in source separation could benefit from the source separation associated incentives likely through MSWM fees reduction. Other benefits are largely the accompanying reduced environmental and human health risks from the AD and composting of biodegradable MSW compared to its open and indiscriminate dumping. Communities will also benefit from biogas which they could purchase and alternatively use for cooking. There is also envisaged increased availability of renewable electricity from the AD biogas associated CHP generation. The biogas potential production is as shown in Table 3.

Table 1: Goals, strategies and key actions in the Zimbabwe NISWMP promoting MSWM decentralisation

Goal	Strategies	Key Actions
Minimize SW generation.	Encourage the public to prevent SW generation.	i. Promote reduction of waste generation at household level.
Ensure source separation of solid waste.	Put in place appropriate source separation of SW systems at sources.	i. Separate waste into biodegradable and non-biodegradable fractions. ii. Introduce incentives for source separation to bring in public and industry buy in.
Promote the reuse of biodegradable SW to reduce its quantities earmarked for disposal sites.	Use biodegradable SW for gardening and livestock feed.	i. Use of biodegradable SW for gardening and livestock feed at household level. ii. Establish viable markets for biodegradable SW. iii. Packaged manure production from biodegradable SW composting or vermi-composting.
Maximize materials and resource recovery.	Support the development of a recycling economy.	i. Allocate land to enable informal waste traders/community groups to separate and sort recyclable SW. ii. Establish industrial sites or recycling centers where a multitude of recycling firms can rent space. iii. Establish waste recycling projects at institutions such as schools, tertiary education institutions and hotels. iv. Encourage the private sector, small and medium enterprises to develop and upgrade SW management facilities. v. Establish a supportive institutional framework for private recycling enterprises. vi. Establish research informed markets for recycled materials and resources.
	Promote SW value addition and innovation on recycled materials and resources.	i. Invest in the development of technologies for SW value addition and innovation on recycled materials and resources. ii. Use of indigenous knowledge systems on SW value addition like basket weaving, local crafts etc.
	Establish an enabling policy and legal framework for multi stakeholder participation in SW recycling.	i. Institute legislative, regulatory and institutional review to support recycling markets and promote SW recycling. ii. Introduce licensing system for SW recycling, incentives and subsidies for investment in SW recycling promotion. iii. Establish a Green Fund where individuals, banks and private sector contribute to support SW recycling.
	Explore and promote energy recovery from SW.	i. Construction of AD facilities at established recycling centers and institutions like schools, universities, prisons as well as markets and hotels. ii. Establish combined Heat and Power generation facilities from AD derived biogas.
Restructure and introduce an efficient source separated waste collection system.	Establish strong diversified and appropriate SW collection systems for source separated biodegradable (wet waste) and non-biodegradable waste (dry waste) fractions.	i. Introduce a collection system for recyclables where collection points include schools, office blocks and apartments. ii. Establish a kerbside collection system with citizens' drop off or citizens' convenient centers where households or institutions bring the recyclables. iii. Establish partnerships amongst stakeholders namely residents, ULAs, CBOs, individual waste collectors and private sector to optimize collection of sorted SW. iv. Integrate the residents, ULAs, private sector, informal collectors and CBOs into the IMSWM system within their local authorities.
	Pilot various SW management and collection systems in different residential areas.	i. Pilot ISWM systems in high density areas where individuals and CBOs collect, sort and recover, value add, compost and sell the products. ii. Pilot ISWM systems in high density areas characterised by a kerbside collection system with citizens' drop off or citizens' convenient centers where citizens bring in their source separated waste and subjected to a subsidy to reduce their individual household SW collection fee.
	Enhance ULAs capacity to provide efficient SW management services.	i. Review ULAs by laws to equip residents to provide appropriate SW receptacles at their households and have SW collection fees reduction incentive.

Invest in and build environmentally sustainable SW management infrastructure and systems.	Construct, upgrade and or rehabilitate SW collection, management, treatment and disposal infrastructure.	i. Construct, upgrade and or rehabilitate SW incineration, composting, treatment/neutralization and energy recovery facilities.

4.2. Recycling

There is great emphasis on the need to increase the recycling levels in Zimbabwe. For example, in Harare only 9.6% of the MSW generated in Harare is recycled translating to only 23,000 tons of the over 467,000 tons generated. At least 20% of the non-biodegradable MSW equivalent to at least 56,000 tons has to be recycled [35] thus double the current recycling level. To meet this target therefore, recycling could be done at household, institutional and community level. It will have to be enhanced by the source separation of MSW generated. Source separation of MSW promotes stakeholder and citizens participation in any waste management system thus enhancing decentralisation. Citizens drop off or convenient centers could also be established under a kerbside waste collection system where those in the recycling business will come and separate the materials, they want for their recycling business. Recycling provides economic and employment opportunities to communities who would be involved either in source separation through incentives or those collecting recyclable materials to recycling facilities. The model for operation under a decentralised model will be to have recycling companies either collecting the source separated recyclables or having ULAs depositing the recyclables at a mutually agreed gate fee with waste pickers depositing their recyclable materials at an agreed cost. Those involved in source separation will benefit from reduced waste management fees they pay to ULAs through incentives for their participation in source separation.

4.3. Thermal Treatment

The incineration of MSW generated in Harare is likely to be done at institutional, community or industrial scale. In addition to

the better environmental performance of incinerating MSW generated in Harare compared to its landfilling observed by [35], authors in [37] reported the suitability of MSW generated in Harare to be treated via incineration with a lower heating value of between 10100 kJ/kg and 9320 kJ/kg giving an estimated 3.8×10^6 GJ per annum. The lower heating value and incineration efficiency thus could be enhanced by the source separation of biodegradable MSW. The incineration of at most 80% of the non-biodegradable MSW generated translates to the incineration of at most 217,000 tons of non-biodegradable MSW estimated to give at most 1.96×10^6 GJ per annum. Like under AD and composting, ULAs could collect the source separated non-biodegradable MSW meant for incineration and deposit at incineration facilities at an agreed gate fee whereas incinerator operators can as well do the collection with residents benefiting in various forms from their participation in the decentralised MSWM system. Table 4 thus gives the estimates of potential energy generation from the incineration of the non-biodegradable MSW under each jurisdiction within and surrounding Harare.

5. Discussion

MSWM decentralisation promotes the backyard composting of organic MSW fraction at households and or the industrial scale AD and composting of source separated or mechanically separated organic MSW fraction. The industrial scale AD and composting of source separated organic MSW fraction leads to the production of a biofertilizer from the AD digestate and compost from composting thereby providing the safe utilisation or disposal of the digestate and compost as a nutrient rich biofertilizer devoid of biological, chemical and physical pollutants. Source separated

organic MSW fraction provides the AD and composting feedstock quality necessary for the production of biofertilizer from high quality AD digestate and compost that will be used for agricultural application [38]. The AD and composting associated nuisance in the form of noise from heavy MSW collection vehicles and facility operations, odours, bio-aerosols, environmental and human health impacts has however raised concerns from residents despite the undisputed associated benefits [39-42]. Solutions to these concerns could incorporate the installation of smaller decentralised AD and composting facilities of low operational capacities distributed within the ULAs as proposed by [43] unlike the large centralised facilities. These distributed and decentralised smaller AD and composting facilities of low capacities results in the reduction of distances travelled by MSW collection vehicles subsequently yielding corresponding reductions in fuel consumed, transport costs, GHG and other emissions namely traffic and noise. The renewable electricity generated from the CHP generation through the combustion of AD derived biogas will serve the local communities to bring about increased residents' acceptance of the AD and composting facilities in their neighbourhoods.

Opportunities for the anaerobic co-digestion of source separated organic MSW fraction and dewatered sewage sludge in the smaller decentralised facilities of low capacities distributed across the ULAs in and around Harare also exist. This will entail composting of the co-digestion digestate regarded ideal for localized and small communities' setups. The co-digestion of organic MSW fraction and sewage sludge increases the AD biogas yield and improves AD process stability [45, 46]. Decentralisation potentially facilitates for the participation of residents in material recovery or recycling activities which is anticipated to increase materials recycling levels beyond the current 9.6% of MSW generated reported by [4]. Decentralisation promotes the development and construction of decentralised community level WTS, CDOPs or CCCs as well as BBCs. All the proposed decentralised MSWM systems can reduce the amount of MSW on a volumetric and weight basis to be sent to landfills subsequently reduce land demand for MSW landfilling purposes. Thermal waste treatment methods to recover energy through incineration, pyrolysis and gasification facilities can potentially be integrated into the proposed MSWM decentralisation models.

A life cycle assessment (LCA) study by [47] on future likely least impactful MSWM systems for ULAs in and around Harare showed that incorporating the AD of organic MSW fraction generated in ULAs in and around Harare for CHP generation with 20% recovery of materials from the inorganic MSW fraction and incineration of 80% of the remaining inorganic MSW fraction for CHP generation with flue gas treatment and incinerator bottom ash use as road construction material yields the least environmental impacts (acidification, eutrophication, global warming and human health) potentials. Authors in [37] observed that 75% on a weight basis of MSW generated in ULAs in and around Harare is suitable for treatment via incineration without the need for supplementary fuel due to its lower heating value of 10.1MJ per kg with a potential annual energy yield of 3.8×10^6 GJ (112 GWh per annum) which will increase the national annual electricity share from MSW and bio-fuels by over 0.9% to 2.2% from the prevailing minimum of 1.3%. The incineration of the MSW generated in ULAs in and around Harare will potentially reduce the amount of MSW earmarked for landfilling by 40% [37]. Therefore, source

separation of organic MSW fraction and subjecting it to either composting or AD is likely to increase the efficiency during the inorganic MSW incineration since organic biodegradable MSW fractions have been widely reported to compromise the incineration performance. Just like small scale distributed AD and composting facilities for managing and treating the organic MSW fraction generated in ULAs in and around Harare, small scale distributed incineration facilities can be deployed to manage and treat the inorganic and combustible MSW fractions.

MSWM decentralisation has largely failed to take off in Zimbabwe due to residents' attitudes and behaviors towards MSWM and MSW disposal. Authors in [3] noted that initiatives towards CBMSWM implementations in Bulawayo, Zimbabwe's second biggest City, failed since it failed to change the attitudes and behaviors of Bulawayo residents on MWSM and MSW disposal. The authors [3] further noted absence of different MSWM initiatives undertaken by CBOs that embraced and incorporated materials recycling. This is however different with Harare where the Zimbabwe Sunshine group has a MSWM system developed based on CBMSWM and IMSWM model in selected suburbs and at the Zimbabwe Exhibition Park. Interestingly the Zimbabwe Sunshine Group has already constructed CDOPs or CCCs where recyclable MSW fractions are brought and sorted having also started the collection of MSW fractions for their reuse and recycling from households and institutions. The success story of the Zimbabwe Sunshine Group should be used to scale up such initiatives across all the ULAs in and around Harare and possibly nationally.

The coming into effect of the NISWMP in July 2014 was viewed as a welcome development as it provided for decentralisation hence MSWM decentralisation initiatives were envisaged to emerge from its provisions. The plan provides several key strategies and action points that support the decentralisation of MSWM within ULAs in Zimbabwe. Key actions include education in waste reduction, source separation of MSW, reuse of biodegradable MSW for gardening and livestock feed at household level, establishment of viable markets for biodegradable SW, production of manure from biodegradable SW composting or vermi-composting, establishment of community and industrial recycling centers, development of recycling projects at institutions, construction of AD facilities at established recycling centers and institutions, establish combined Heat and Power (CHP) generation facilities for AD derived biogas, putting in place a MSW collection system with CDOPS or CCCS and BBCs where households or institutions bring in MSW etc. as provided in Table 1. Worryingly all of these key actions as provided in the plan have not taken off over six years since the plan came into effect hence the need for urgent review and subsequent operationalization and implementation of the review findings.

The need for stakeholder inclusion and participation in all these key actions provided in the NISWMP is evidently clear. This is affirmed under goal 8 which seeks to promote cleanliness in Zimbabwe by involving the public, industry and government in efforts towards reducing, reusing and recycling all solid waste materials to manage and mitigate the SW associated public health and environmental impacts. Goal 7 further supports decentralisation as it provides for the need to educate and raise awareness amongst Zimbabwean citizens to better understand the

Table 4: Estimated Energy potential from the incineration of the non-biodegradable MSW Harare City and its surrounding ULAs

ULA	Harare	Chitungwiza	Norton	Ruwa	Epworth	Total
Non-biodegradable MSW generated (tons)	188,654.28	45,325.84	8,585.16	7,198.96	21,270.92	271,035.16
Estimated annual biogas potential (GJ per annum)	1.36E+06	3.28E+05	6.21E+04	5.21E+04	1.54E+05	1.96E+06

importance of participating in source separation, materials and resources recovery and integrated and sustainable solid waste management. There is need for the reform of the available national legislation and ULAs' bylaws to ease the flexibility for entry and inclusion of other players in MSWM as ULAs are somehow reluctant to devolve and delegate some of the MSWM functions and roles despite their glaring failures to manage the MSW. Interestingly the tenth goal of the plan seeks to review and assess current legislation and institutional arrangements to improve implementation of ISWM amongst its key actions. Under strategy C of the plan is the need to decentralize MSWM authority to the lowest appropriate level as well as strengthening the capacities of ULAs to meet their obligations with regards to decentralizing MSWM authorities.

The Presidency, the highest office in Zimbabwe, made a proclamation that declared the first Friday of each calendar month being a national cleanup day for communities and citizens to take part in cleaning their surroundings. This is a significant milestone towards changing the citizens mindsets, attitudes and behaviors on MSWM, MSW disposal and general environmental stewardship. The Presidential proclamation is a significant and welcome development; however, it has to be complimented with the construction of safe MSW disposal facilities for the MSW that would have been collected during the national clean up since it is currently being dumped at dumpsites which are already classified as human health and environmental hazards thus the national clean up become another unsustainable problem transfer from communities to dumpsites. There is need for urgent development and construction of recycling, AD and composting, incineration and landfill facilities with only the inert materials and those from which materials and energy could not be further derived from sent to landfills. Zimbabwean citizens have not yet fully embraced the national cleanup day hence the need for extensive awareness raising together with other initiatives that will attract citizens to participate with the participation not only limited to sweeping and cleaning but allowing those who could provide the needed resources and equipment given the opportunity to do so. Above all the high literacy level in Zimbabwe is believed will enhance citizens participation easing the introduction and implementation of decentralised waste management systems.

6. Conclusion and Recommendations

The study has attempted to show that numerous MSWM decentralisation opportunities in ULAs in and around Harare exist anchored on the quantities of MSW generated and its characteristics, suitability for biological and thermal treatment methods as well as the available recycling potential. This is despite the prevailing MSWM challenges which have become potential human health and environmental hazards. The NISWMP thus has

noted MSWM decentralisation potential and provides for the decentralisation of MSWM systems and functions. Another high-level commitment for decentralisation is noted from the Presidential proclamation that declared the first Friday of every calendar month a national cleanup day which provide for every stakeholder's participation in MSWM in their local communities. However, reluctance to devolve MSWM functions by ULAs has been noted hence the need for legislative and institutional reforms as provided for under goal 10 of the plan. All the key actions regarding MSWM decentralisation in the plan have not been implemented with no waste management policy in sight as provided six years after the plan came into effect thus the need for urgent review and subsequent operationalization and implementation of the review findings. The lack of review on the available legislations and institutions has hindered MSWM decentralisation. Despite the available opportunities for MSWM decentralisation in Harare, there is need for environmental sustainability, economic feasibility, social acceptability and material and energy recovery potential assessment studies of the likely decentralised IMSWM and CBMSWM models. Further studies that quantify the associated environmental impacts, materials and energy recovery potentials as well as the economic feasibility of local level decentralised MSWM need to be undertaken.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

Special thanks go to University of Johannesburg postdoctoral fellowship that supported this study. The authors would like to thank the Life Cycle Initiative for the 2017 Life Cycle award with SimaPro software used for LCIA.

ABSTRACT

This article extends novelty of modeling capacitive accelerometer with PID controller to provide PI controller for better tuning and statistical test to determine the linear validation characteristics of closed capacitive accelerometer. Capacitive accelerometer is a sensor which uses the dynamic law of physics model Position-Velocity-Accelerator (PVA) by the movement of an electrode coupled to mass proof sandwich between parallel plates to detect vehicle/object displacement. The modelling of closed loop system helps to mitigate steady state error accumulation of measurements in open loop model. The accelerometer gives linear time dependence on output displacement after an input step-like function of acceleration. The closed model can predict the desired output signal. The linearity of the model is tested statistically using simple regression of 120 dataset. This shows a p-value of $2e-16$ indicating that at any time, the acceleration predicts the displacement/position of vehicle/object.

1. Introduction

Accelerometer is a microelectromechanical sensor (MEMS) which is generally used in the measurement of moving body's acceleration [1]. MEMS is widely used across the current settings of interconnected world in our daily lives [2]. The obtained acceleration is measured in gravity (g) [3]. The measurements of g can be transformed into velocity and position/displacement.

In the application of accelerometer, it provides a wide range of services in a lot of technologies aiding the prediction of most human and no-human activities. In [4], accelerometer is used on a bridge in Nottingham Wilford in the UK with the main purpose of determining the dynamic characteristics. This provided real-time information on suspended deck movement. It is applied using triaxial accelerometer and Real-time Kinematic Global position system (RTK-GPS). The inclusion of the RTK-GPS is applied to measure the low-frequency vibrations of medium span suspension bridge. The reason for this inclusion is to aid the accelerometer which measures based on high-frequency rate. Similar bridge technique is used but in this domain it is applied in bridge management system and land safety [5]. The only component which changed is the replacement of RTK-GPS with three Leica-GPS.

In the determination of human kinematics, accelerometer places an exceptional role as well. According to [6], the authors presented triaxial accelerometer with a specific value of CDXL04M3 is applied in the recognition of classification of problem during people activities. Also in [7], the article provides a description in the development real-time classification persons activities such as: walking, standing and running using wearable device. The only differentiation this application is the system composition where a two-accelerometer (ADXL202JE) layer model that integrates multiple component Gaussian mixture model with Markov models is applied. This is to accurately classify the zone of user state.

Accelerometer application in human context [8, 9] applied triaxial accelerometer (ActiGraph GT3X+) to validate the process of determining everyday human physical activities. The device is placed at the thigh and hip to identify: cycling, walking, climbing of stairs, running, sitting, and no movements. In [10], authors worked on the determination and understanding of physical activities and key behavioral changes among children. This led to the implemented four different accelerometers namely: ActiGraph, Actical, Actiwatch, and RT3 Triaxial devices. This produces a regression model. According to [11] and [12], triaxial accelerometer and Wireless Wearable Multisensory Integrated Measurement System (WIMS) were implemented together to measure activities such as human heartbeats, hip motion, and other sensors. Additionally, in [13], the author developed a wearable

*Corresponding Author: Mamudu Hamidu, Email: drsennet@gmail.com

wireless base displacement system which utilizes inertial measurement unit (IMU) having triaxial accelerometer onboard. This system monitors the daily indoor activities of humans in buildings such as health statuses and locations.

In other applications such as vehicular domain, the triaxial has received enormous integrated application. Especially, the use of tracking of vehicle velocity and position coupled with other MEMS sensors [14].

There is another form of accelerometer called uniaxial or single axial which used in predicting the behavior of person in motion [15]-[20]. In [19], the authors presented ideas of applying 2 to 3 uniaxial sensors mounted on human body for behavioral investigations. All uniaxial accelerometers were in 2-dimensions. According to [20], the author comparison between uniaxial and triaxial accelerometer application in human activities, showed no difference in the results obtained.

However, in this paper the research design looks at the implementation of the triaxial accelerometer since it is in a 3D form associated in measuring X, Y and Z of the acceleration of vehicle dynamics.

Velocity and position are computed mathematically from acceleration. The position represents the displacement from the mechanical model. This displacement measurement very small. To achieve a better measurement, and electronic readout unit is attached. There are various types of mechanical models. These include: capacitive [21]-[31], piezo-resistive [32], and thermal [33], [34].

The choice of capacitive accelerometer in vehicle tracking is mainly based on its advantages such as:

- Zero static biasing with high sensitivity ability, and better thermal stability. According to [35], these characteristics make capacitive accelerometer model preferred to others.
- It has the edge over other due to size, less expensive, and more flexible in interfacing with other circuitry [36].
- Low temperature and better linearity [37]

However, the capacitive accelerometer has the challenge of high capacitance variation sometimes due the type of mass proof, low damping factor, high sensitivity providing higher resolution that give higher frequencies [38].

A triaxial capacitive accelerometer IC module is integrated with GPS module used in determining vehicle position. The integrations provides a uniform sensitivity which is distributed in the 3D of the vehicle position in the x-y-z domain. [39], [40]. The accelerometer used is made up of glass-silicon which serves as a mass proof. This glass is suspended to the chassis of the vehicle with four locks [41]. This detects parallel motion in z-acceleration and measurements are made in X or Y axis acceleration during tilting of the proof mass. Displacement is detected when electrodes connected to the mass proof which is then sandwich between parallel plates. By this mechanism, the acceleration is measured in the X, Y, and Z axis (a_x, a_y, a_z) [9], [3].

It is based on this that the velocity and position can be obtained using Position-Velocity-Acceleration (PVA) model which obeys Newton's law of physical object in motion and that of Hooke's law [31]. the principle underlining PVA is the first and second integral of acceleration model to produce velocity and position respectively [42]. Therefore, for any measurements of acceleration should provide a proportional outputs of velocity and position of a body in motion with an accelerometer [40], [43], [44].

This article looks at modelling the linear characteristics of capacitive accelerometer using PI-controller to determine the linear dependence relationship between acceleration and position. It also verifies the model for statistical significance using simple regression model. The model is based on mathematical modelling simulations using MATLAB/Simulink.

2. Method of analysis

The method of design is by mathematical modelling of system dynamics of a moving mass proof using law of physics. Figure 1 shows an eight stage methodological view of analyzing and simulating of the capacitive accelerometer.

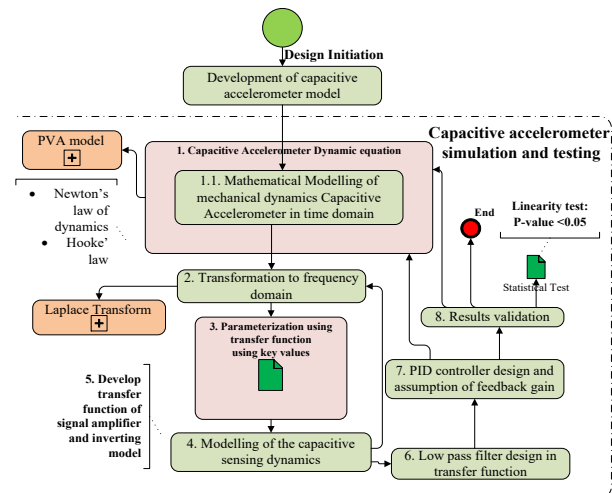

Figure 1: Methodological view of modelling a capacitive accelerometer

- Sensing dynamics: is the model for the change in capacitance during the movement of object (vehicle) [30].
- Model for capacitive sensing dynamics: is the model for the change in capacitance during the movement of object (vehicle) [30].
- Develop transfer function of signal amplifier-inverting model: the output from 4 is amplified using OpAmp and inverted to obtain the original signal. These are all handled in frequency domain for easy computation.
- Low pass filter transfer function: this filters high frequency measurements associated with acceleration measurements. LPF will allow only the low frequency for better measurements of position variables.
- PI controller design and assumption of feedback gain: this stage is done by developing a controller gain matrix and a feedback gain.

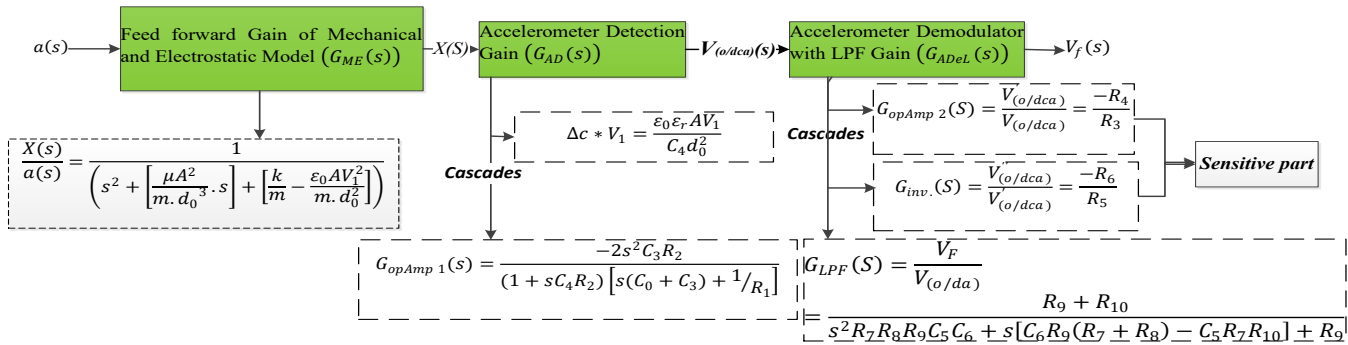

Figure 2: open loop accelerometer system with readout components[50].

- Results validation: to validate the results from the model, data collected is tested using simple regression model for input to output linear dependency using the P-value as a criteria of validity.

3. Open loop accelerometer system

The linear time variant (LTV) model of the mechanical model consisting of mass, damper and spring is represented in (1) [45]-[48]:

$$\left. \begin{aligned} m \frac{d^2 x}{dt^2} &= kx + b \frac{dx}{dt} + m \frac{dx^2}{dt^2} \\ b &= \frac{1}{2} \mu A^2 \left[\frac{1}{(d_0 - d_x)^3} + \frac{1}{(d_0 + d_x)^3} \right] \\ \frac{d^2 y}{dt^2} &= \frac{d^2 x}{dt^2} - \left[\frac{k}{m} x + \frac{1}{2} \mu A^2 \left[\frac{1}{(d_0 - x)^3} + \frac{1}{(d_0 + x)^3} \right] \cdot \frac{dx}{dt} \right] + \frac{\epsilon_0 A V_1^2}{4m} \cdot x \\ a &= \frac{d^2 y}{dt^2} \\ a &= \frac{d^2 x}{dt^2} + \left[\frac{\mu A^2}{d_0^3} \cdot \frac{dx}{dt} \right] + x \cdot \left[\frac{k}{m} - \frac{\epsilon_0 A V_1^2}{4m} \right] \end{aligned} \right\} (1)$$

where:

b : damping coefficient.

μ : Air gap displacement

A : Mobile plaque area

(d_0 , d_x): Distance of electrode displacement between parallel plates.

The Laplace transfer of (1) is provided in (2):

$$\left. \begin{aligned} s^2 \cdot X(s) + \left[\frac{\mu A^2}{d_0^3} \cdot s \right] \cdot X(s) + X(s) \cdot \left[k - \frac{\epsilon_0 A V_1^2}{d_0^2} \right] &= a(s) \cdot m \\ G_{ME}(s) = \frac{X(s)}{a(s)} &= \frac{1}{\left(s^2 + \left[\frac{\mu A^2}{m \cdot d_0^3} \right] s + \left[\frac{k}{m} - \frac{\epsilon_0 A V_1^2}{m \cdot d_0^2} \right] \right)} \end{aligned} \right\} (2)$$

$G_{ME}(s)$: Gain of Mechanical module

In figure 2, block diagrams of various units of the accelerometer and their models for open loop system is represented. the diagram has the mechanical unit, electronic readout circuit which consist of gain detection the demodulation unit with low pass filter (LPF) [19], [45]-[47], [49].

The following represent key nomenclature in Figure 2:

(G_{AD}) : Gain Detection

$G_{opAmp1}(s)$: signal Detection unit

$G_{ADeL}(s)$: Demodulation and LPF Gain

$G_{opAmp2}(s)$: Electronic Read-out Operational Amplifier Gain

$G_{inv.}(s)$: Electronic Read-out inverter Gain

$G_{LPF}(s)$: Electronic Read-out Low Pass Filter Gain

$V_F(s)$: output displacement of x

Accelerometer detection block is the block which electronically detects the displacement of the mass proof with a rod to dangle between the parallel plate. This unit produces a gain, $G_{AD}(s)$. This gain consists of the electrostatic force of parallel plate and the operational amplifier. The operational amplifier helps boost the electrical signal detected from the mechanical displacement for processing [34].

$V_{(o/dca)}$ in Figure 2 is passed through a Accelerometer Demodulation unit to produce $V_f(s)$.

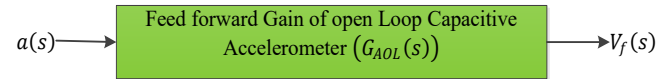

Figure 3: The open loop gain ($G_{AOL}(s)$) block diagram

Figure 3 represents overall open loo transfer function, ($G_{AOL}(s)$) which consists of the cascade of ($G_{ME}(s)$), ($G_{AD}(s)$) and ($G_{ADeL}(s)$).

$$G_{AOL}(s) = (G_{ME}(s)) * (G_{AD}(s)) * (G_{ADeL}(s)) \quad (3)$$

The open loop function is represented in (4) using the models from Figure 2:

$$\Rightarrow G_{AOL}(s) = (V_f(s)) / a(s); V_f(s) = G_{AOL}(s) a(s) \quad (4)$$

By inputting all functions into (4), (5) is obtained:

$$\left. \begin{aligned} V_F(s) &\equiv V_{(o/dca)}(s) G_{ADeL}(s) = (V_{(o/dca)}(s)) * \\ &\quad (G_{inv.}(s) G_{opAmp2}(s)) (R_9 + R_{10}) \\ V_{(o/dca)} &= \frac{1}{T} \left[\int_0^T (V_1(t)) dt - \int_{\frac{T}{2}}^T (V_1(t)) dt \right] [\Delta C x] \\ V_1(t) &= V_1 \sin(\omega t) \\ &= \frac{1}{T} \left[\int_0^T (V_1 \sin(\omega t)) dt - \int_{\frac{T}{2}}^T (V_1 \sin(\omega t)) dt \right] \left[\frac{\epsilon_0 \epsilon_r A}{C_4 d_0^2} x \right] \\ &\quad \text{solving, } V_{(o/dca)} \gg \frac{4V_1}{T\omega} \left[\frac{\epsilon_0 \epsilon_r A}{C_4 d_0^2} x \right] \\ \therefore V_f(s) &= \frac{4V_1}{T\omega} \left[\frac{\epsilon_0 \epsilon_r A}{C_4 d_0^2} x \right] \left[(G_{inv.}(s) G_{opAmp2}(s)) * (R_9 + R_{10}) \right] \\ &\quad \text{Finally; } V_f(s) = \\ &\quad \frac{4V_1}{\pi} \left[\frac{\epsilon_0 \epsilon_r A}{C_4 d_0^2} x \right] \left[(G_{inv.}(s) G_{opAmp2}(s)) (R_9 + R_{10}) \right] \end{aligned} \right\} (5)$$

The open loop of the capacitive accelerometer in (5) is now simplified into two main function blocks, thus the mechanical unit and the electronic readout unit in Figure 4.

Figure 4: Mechanical and electronic readout of accelerometer

The modeling of the two blocks is represented in (6):

$$\left. \begin{aligned} G_{AOL}(s) &= \frac{G_{ocf}^1}{\left(s^2 + \left[\frac{\mu A^2}{m \cdot d_0^3} \cdot s \right] + \left[\frac{k}{m} - \frac{\epsilon_0 A V_1^2}{m \cdot d_0^2} \right] \right)} \\ G_{AOL}(s) &= \frac{7.436e10}{s^2 + 316.1 s + 1.016e04} \end{aligned} \right\} \quad (6)$$

The modeling of (6) into a closed loop form is discussed in the next section using Proportional-Integral (PI) controller.

4. Closed loop accelerometer modeling

The design of a closed loop accelerometer is considered in this section by designing the feedback and control gain matrices of PI controller models.

4.1. Designing of feedback model

Feedback model is designed to help compare the acceleration (reference signal) to the position (output signal). Base on the feedback a suitable controller can be tuned to achieve a desirable output.

4.2. Choosing Feedback signal

According to [51], feedback model is based the type of sensor which provides a proportional signal to the dynamic model (mechanical unit). Therefore, in choosing the feedback signal, a balancing force is needed to check the inertial forces mechanical unit of the accelerometer. This balancing force is called the electrostatic force. It is chosen because it establishes the reading of small displacement from the proof mass between the two fixed electrodes in parallel plates[23]. The electrostatic force is used to provide restoration of sensing force to balance acceleration force. Figure 5 shows the representation of the accelerometer closed loop structure.

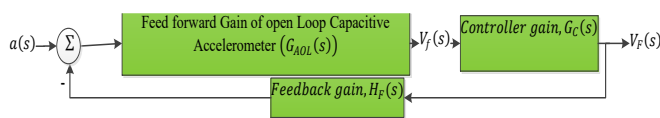

Figure 5: closed loop structure of accelerometer

A bias signal V_b is introduced with excitation signal v_1 to obtain a feedback signal V_F to the two electrodes. This generates

the V_{ne} and V_{pe} as negative electrode and positive electrode supplies respectively. This is represented in (7) as:

$$\left. \begin{aligned} V_{ne} &= v_1 - V_b + V_F \\ V_{pe} &= v_2 + V_b + V_F \end{aligned} \right\} \& \left. \begin{aligned} v_1 &= V_1 \sin \omega t \\ v_2 &= -V_1 \sin \omega t \end{aligned} \right\} \quad (7)$$

The resultant signal gives (8):

$$V_{npe} = V_{ne} - V_{pe} \quad (8)$$

The application of the electrostatic force feedback gives (9):

$$\left. \begin{aligned} F_{elF} &= F_{elne} + F_{elpe} \\ &= \frac{\epsilon_0 \epsilon_r A}{4} \cdot \left[\frac{V_{ne}^2}{(d_0 - d_x)^2} - \frac{V_{pe}^2}{(d_0 + d_x)^2} \right] \\ F_{elF} &= \frac{\epsilon_0 \epsilon_r A}{4} \cdot \left[\frac{(V_1 \sin \omega t - V_b + V_F)^2}{(d_0 - d_x)^2} - \frac{(-V_1 \sin \omega t + V_b + V_F)^2}{(d_0 + d_x)^2} \right] \end{aligned} \right\} \quad (9)$$

The accelerometer having high system frequency and considering the initial position of the proof mass, the electrostatic force feedback mean signal is represented mathematically in (10):

$$F_{elF} = \frac{1}{T} \int F_{elF} dt = \frac{2\epsilon_0 \epsilon_r A}{d_0^3} \cdot \int [x(V_1 \sin \omega t - V_b + V_F)^2 - (-V_1 \sin \omega t + V_b + V_F)^2] dt \quad (10)$$

Expanding and integrating all terms with respect to t gives (11):

$$\left. \begin{aligned} F_{elF} &= \frac{2\epsilon_0 \epsilon_r A}{d_0^3} \left[x \left(\frac{V_1^2}{2} + V_b^2 + V_F^2 \right) - V_b V_F d_0 \right]; \\ &\text{with inertial displacement of } x = 0 \\ &\therefore \text{the feedback electrostatic force,} \\ F_{elF} &= -\frac{2\epsilon_0 \epsilon_r A V_b V_F}{d_0^2} \end{aligned} \right\} \quad (11)$$

Rewriting the equations again for all the acting forces on the proof mass the feedback sensor gives (12):

$$\left. \begin{aligned} \vec{F}_i &= \vec{F}_e + \vec{F}_a + \vec{a}_x - F_{elF} \\ ma &= kx + \frac{1}{2} \mu A^2 \left[\frac{1}{d_0^3} + \frac{1}{d_0^3} \right] \frac{dx}{dt} + m \frac{d^2 x}{dt^2} + \frac{2\epsilon_0 \epsilon_r A V_b V_F}{d_0^2} \\ ma &= kx + \left[\frac{\mu A^2}{d_0^3} \right] \frac{dx}{dt} + m \frac{d^2 x}{dt^2} + \frac{2\epsilon_0 \epsilon_r A V_b V_F}{d_0^2} \\ a &= \frac{k}{m} x + \frac{1}{m} \left[\frac{\mu A^2}{d_0^3} \right] \frac{dx}{dt} + \frac{d^2 x}{dt^2} + \frac{1}{m} \cdot \frac{2\epsilon_0 \epsilon_r A V_b V_F}{d_0^2} \end{aligned} \right\} \quad (12)$$

The model for feedforward including the controller in figure 5 represented in (13):

$$V_F(s) = V_f(s) * G_C(s)$$

¹ G_{ocf} : open loop cascade factor = $\left[\frac{4V_1}{\pi} \left(\frac{\epsilon_0 \epsilon_r A}{C_A d_0^2} \right) \right] * \left[(G_{inv}(s) * G_{opAmp2}(s)) * (R_9 + R_{10}) \right]$

$$\Rightarrow V_F(s) = (G_{AOL}(s)) * (G_C(s)) \quad (13)$$

\therefore the close Accelerometer Loop Transfer function ($G_{ACL}(s)$) is in (14):

$$G_{ACL}(s) = \frac{V_F(s)}{a(s)} = \frac{(G_{AOL}(s)) * (G_C(s))}{1 + (G_{AOL}(s)) * (G_C(s)) * (H_F(s))} = \frac{\left[\frac{7.436e10}{s^2 + 316.1s + 1.016e04} \right]^2 * (G_C(s))}{1 + \left[\frac{7.436e10}{s^2 + 316.1s + 1.016e04} \right] * (H_F(s))} \quad (14)$$

$$G_{ACL}(s) = \frac{(7.436e10) * (G_C(s))}{denum^3}$$

5. Closed loop accelerometer simulation and results

5.1. Open loop accelerometer model and characteristics

The open loop model of accelerometer is represented by the mechanical-charge detection model and the electronic demodulator model in Figure 6 and 7, respectively.

Figure 6: Acceleration Charge Detection unit

Figure 7: Demodulator Electronic processor

The mechanical, charge detection, and electronic demodulator transfer function is given in (15):

$$G_{opl}(s) = \frac{7.436e10}{7.29e8 s^4 + 5.13 s^3 + 11620s^2 + 3.213e6 s + 1.16e8} \quad (15)$$

The open loop characteristics are shown in Figure 8 is based on Figure 6 and 7. For an input acceleration of 1g the model

provides Mechanical displacement response of 1.969×10^{-4} and the respective charge detection unit and low pass filter output is displayed as well.

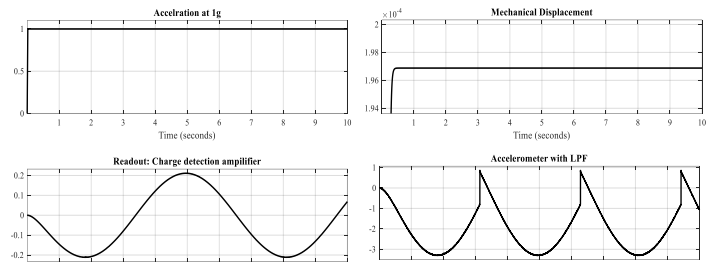

Figure 8: open loop characteristics of accelerometer model.

The overall transfer function of the open loop model in (15) produces an overshoot of about 641 with an input-output response rise time of 0.0528s as shown in Figure 9.

Figure 9: overall open loop transfer function characteristics of accelerometer model.

In Figure 10, the open loop bode plot shows system gain of 56.1 dB which was constant until it reached a frequency response is 791 rad/s ($\omega = 791$).

Figure 10: the magnitude and phase of the open loop accelerometer transfer function $G_{opl}(s)$ against angular frequency.

The open loop gain gives the open loop minimum stability margins at $Gain = -20.3 \text{ dB}$ and frequency= 791rad/s.

² Feed forward Gain of open Loop Capacitive Accelerometer ($G_{AOL}(s)$) with electronic readout circuit.

$$^3 denum = [s^2 + 316.1s + 1.016e04] + (7.436e10) * (G_C(s)) * (H_F(s))$$

For the phase, at low frequency, the phase is 0° and at high frequency is -268° . The minimum stability margins are -40.4° against frequency of 2.21krad/s .

5.2. Accelerometer closed loop model and characteristics

This section looks at the modelling of the close system of the accelerometer. The system uses proportional integral (PI) controller to establish the stability of the open loop gain. The gain of the controller is represented in (16):

$$G_c(s) = \frac{K_p s + K_i}{s} \quad (16)$$

The control gain matrices are represented by:

$$\begin{bmatrix} K_p \\ K_i \end{bmatrix} = \begin{bmatrix} 0.002369 \\ 0.1613 \end{bmatrix} \quad (17)$$

Considering (15) and (116) with a feedback of 1 gives the closed loop gain in (18):

$$G_{CLP}(s) = \frac{K_1 s + K_{CLP}}{K_2 s^5 + K_3 s^4 + K_4 s^3 + K_5 s^2 + K_6 s + K_{CLP}} \quad (18)$$

where:

$$K_1 = 1.027 \times 10^8, K_{CLP} = 2.87 \times 10^9, K_2 = 7.29e \times 10^8, K_3 = 5.13, K_4 = 1.162 \times 10^4, K_5 = 3.213 \times 10^6, \text{ and } K_6 = 2.043 \times 10^8$$

The overall closed loop transfer function gain in (18) is represented in Figure 11.

Figure 11: closed loop accelerometer model in MATLAB/SIMULINK.

In Figure 12, the response time is 0.0132s at amplitude of 0.9 with an overshoot of 10.4% at 0.04s and an amplitude of 1.1 the model shows a settling in at 0.0696s .

Figure 12: Closed loop accelerometer characteristics with PI controller.

Figure 13 represents the Bode plot for closed loop gain which gives a minimum stability margin at $\text{Gain} = -29.5\text{dB}$ and $\text{frequency} = 689\text{rad/s}$.

Figure 13: Bode plot for closed loop accelerometer.

The minimum stability margins are -120° against frequency of 73.5rad/s having a delay margin of 0.0285s .

6. Statistical Test on Accelerometer Linearity

In this section, a linearity test is applied on the acceleration model. The test uses simple regression and p-value to establish linearity of the model.

A simple regression model is developed for the accelerometer model using the algorithm in (19):

$$x = b + w * a \quad (19)$$

where:

Dependent variable: Displacement (x)

Independent variable: Accelerometer (a)

b : Bias term

w : Weight

By building a simple regression model using sample test run of 120 datasets, the model for the accelerometer is obtained statistically, (20) and the figure 14 shows the linear relationship.

$$x = 9.224e - 08 + 1.00 * a \quad (20)$$

where: $b = 9.224e - 08$, and $w = 1.00$

Figure 14: Linearity test of closed loop accelerometer.

In Figure 14, it is shown that the acceleration and the displacement are linearly dependent. The statistical test of p-value is below 0.05. The model's p-value is 641, which means the acceleration can predict the displacement.

7. Conclusion

This paper looks at the modelling and simulation of closed loop capacitive accelerometer. The model applied is the Position-Velocity-Acceleration (PVA) which consist of mechanical unit, charge detection unit, and signal demodulator with filter unit.

The results from the open loop after applying acceleration of 1g shows an overshoot to an amplitude of 641. However, the by controlling the accelerometer in in a closed loop form with a Proportional-Integral (PI) control gain, the desirable output is obtained.

The linearity of the model is with simple regression which shows it is predictable with a statistical significance of $2e - 16$ as its p-value. However, for better optimization, the accelerometer model must be modelled in a state space domain using Gaussian stochastic model where noise is factored as independent of system memory. This would also provide a better technique for better prediction of position. In another vein, future model can consider temperature as a component of damping coefficient (b).

Conflict of Interest

The authors of this manuscript have seen and agree with the contents. We declare that this work is the original work submitted for publication and has undergone peer review process in no other journal other than this.

South Africa

Waste tyre management

ABSTRACT

Municipal general waste accumulation, including the general waste category of end-of-life tyres (EOLT), has become a universal predicament especially in the majority of first world as well as in the third world countries. South Africa is recognized for its economic growth and improved living standards of people which has led to the increased accumulation rates of waste tyres. Consequently, the South African government declared its intentions to divert all categories of end-of-life tyres away from municipal dumping grounds as they present acute health and ecological threats. The government gazetted the Recycling and Economic Development Initiative of South Africa (REDISA) Integrated Industry Waste Tyre Management Plan (IIWTMP) in 2015. The Plan seeks to manage and reprocess waste tyres, bringing about environmental sustainability and economic prosperity through the simultaneous creation of jobs. This work is a theoretical literature review study that highlights the achievements and failures of the Plan. Despite it being a comprehensively drafted and well-rationalized Plan, REDISA drew negative public scrutiny from various stakeholders and institutions such as the Organization Undoing Tax Abuse (OUTA), Retail Motor Industry Organization (RMI), and television programs like Carte Blanche. The findings show that REDISA did manage to make significant contributions to the different sectors governing the Plan such as the creation of jobs and small, medium, and micro-sized enterprises (SMMEs), the establishment of depots and waste tyre processing facilities, and the investment into several institutions of higher learning to further research and development in the waste tyre sector. The plan ultimately ceased operation citing several unsound practices such as corporate administrative issues, deviating from the National Environmental Management (NEM) Amendment Law Bill, failing to carry out the duties outlined in the original Plan, and REDISA did not comply with operational and performance goals.

1. Introduction

This article comes as a result of work previously presented on the REDISA Plan by [1, 2] and an extension of a paper originally presented in the Proceedings of the 7th International Renewable and Sustainable Energy Conference, IRSEC 2019 [3]. In this study, the capabilities of the REDISA Plan to deal with waste tyre

management in South Africa are critically discussed. Consequently, this present paper serves to provide a follow-up and also reports on the successes and failures of the Plan.

The South African economy has in the past two decades experienced rapid growth, resulting in significant mass production of goods and services to realize the socio-economic demands of its rapidly increasing society [4]. This phenomenon has resulted in the increasing growth of municipal general waste earmarked for

*Corresponding Author: Nhlanhla Nkosi, Email: nkosinhlanhla1@gmail.com

landfilling despite the unavailability of land. In 2011, an approximated quantity of 60 million scrap tyres was estimated to have been illegally dumped in open fields across the country, moreover, roughly 11 million waste tyres are supplemented annually into the accumulation figures [5]. In response to the waste tyre predicament, the South African Government endorsed the IIWTMP for REDISA in accordance with the NEM: Waste Act, 2008 as specified in the Government Gazette 35147 of 17 April 2012. The REDISA Plan showed promising prospects as it satisfied and acted in response to the fundamental requirements of the IIWTMP, for instance; the incorporation of the waste hierarchy; the inclusion of previously underprivileged societies; employment creation prospects particularly the previously economically excluded and the poor and its impartiality from national and local government structures. The Plan came into existence in 2013 for the sole purposes of reprocessing waste tyres in order to grow the waste tyre industry and create marketplaces for re-purposed tyre end-products; the establishment of viable green jobs as well as advancing SMMEs. Affirmatively, in 2017 approximately 221,751 tonnes of waste were generated with 64,061 tonnes (29%) being recycled/recovered and the remaining 157,690 were disposed of at landfill sites [6]. In 2019, the Waste Management Bureau (WMB) reported the generation of 170,266 tonnes of waste tyres of which approximately 77% was collected while 24% of the collected tyres were processed [7]. Also, promising waste plastic recycling rates were reported by Plastics SA in June 2018, 46.3% [8] of plastic products were recycled which is significantly above the recorded European recycling rate of 41.9 % for 2017 [9].

The South African Government is known for drafting excellent policies and regulations with little movement with regards to execution and implementation. It is our view and suggestion that the South African government should start focusing on putting mechanisms that progress the execution and implementation of policies and regulations.

Numerous programmes that seek to address the management challenges associated with municipal general waste accumulation have been proposed and adopted by different countries, One such program is the “Extended Producer Responsibility” (EPR) policy which South Africa has also adopted [10]. Other waste management programs include the: Tax Program, Free Market Program, Product Stewardship Program and Hellenic Program which were adopted by other countries. They are comprehensively discussed in section 2. The adoption of the EPR in South Africa has led to the development of the IIWTMP, which is intended at satisfying the tyre producer’s responsibilities for EOLT, through an obligatory EPR scheme [11].

2. Alternative Waste Tyre Management Programs

In July 2003, The European Union (EU) member states banned the landfill disposal of solid tyres [12] and subsequently; the landfilling of crushed tyres in July 2006 [12, 13]. This gave rise to the statutory framework to remedy the predicaments presented by waste tyres across EU member states. As a result , the EU developed several forms of waste tyre management models, namely the Tax Program; Free Market Program and the EPR Program that can be implemented to oversee the

management, directing, and reclaiming of waste tyres in a systematic and ecologically friendly manner. Two additional programs, namely, the Product Stewardship Program and the Hellenic Program have been employed by other developed and developing countries. The most common models are reviewed in this section.

2.1. Tax Model

In this model, the state is responsible for the reclamation and reprocessing of waste tyres. This program is funded by a tariff imposed on the retail purchasing of new tyres by consumers. Denmark and the Slovak Republic are examples of states that have adopted this scheme [13, 14].

2.2. Liberal Market Model

The policymakers put in place the aims and objectives that this scheme will operate under; conversely, they do not delegate any duties to any individual body. All stakeholders within the production chain function under free-market specifications, however, must conform to policy regulations. States operating in this program are Austria, Bulgaria, Croatia, Germany, Ireland, Switzerland, and the United Kingdom [13, 14].

2.3. Extended Producer Responsibility Model

This program requires tyre manufacturers and distributors to take accountability for handling waste tyres as they have initially positioned them in the market. These parties are responsible for the establishment and management of initiatives that will ensure the recycling/recovery of waste tyres. The program is funded through a fare levied against the acquisition of new tyres. Similarly, with South Africa, 75% of EU States have employed the EPR Program [15]. This model has yielded positive outcomes and is realized to be financially and ecologically sustainable. In 2010, EU countries operating under this scheme reprocessed 44% of EU waste tyres generated and in 2011, the figure rose to 57% [13]. Likewise, with the REDISA Plan, records from EU member states show that substantial funds have been provisioned for research and development where capacity development and technological improvements on waste tyre reprocessing are being advanced. Over the years, the scheme in numerous EU states has recorded decreases in the collection of revenues and increases in the various ELT recovery schemes [13]. Reprocessed waste tyres were employed in various sectors, for instance; government-funded construction projects and civil works or as fuel replacement in cement production and power plants [13]. EU states such as Belgium, Czech Republic, Finland, France, Greece, Hungary, Norway, Netherlands, Poland, Portugal, Romania, Spain, and Sweden operate under the EPR Programme and some have managed to obtain 100% waste tyre recovery rates [14].

2.4. Product Stewardship Model

In Canada, the Product Stewardship Program is used in conjunction with the EPR Program to manage end-of-life tyres. Conversely, this Program appoints the recovery duties of waste tyres to provincial or local governments utilizing the levy imposed on tyre producers. The Canadian Council of Ministers of the Environment (CCME), in 2017, pronounced its intentions to entirely adopt the EPR scheme [16]. The funds collected from

Canada's EPR Program aids in the gathering, shipping, and reprocessing of waste tyres [17]. Similarly, with EPR models of other states, a certain percentage of the finances is designated to research, the expansion of new products and to invest in further technological advancements [16]. Brazil and Korea have adopted the Product Stewardship Programme to oversee the management of their waste tyres. In Brazil, tyre distributors are obligated to manage 20% extra scrap tyres in addition to the quantities they import yearly, while in Korea manufacturers and distributors are reimbursed their funds subsequent to the collection of waste [15].

2.5. Hellenic Model

In July 2004, this Program was introduced by Greece to manage their waste tyres. In a nutshell, the Hellenic system incorporates all the other conventional systems in a single scheme [18]. It is evident in literature that in 2018, under the Hellenic model, Greece successfully collected a total of 49,783 tonnes of waste tyres of which 75.6 % was recovered and 15.8% was applied in energy recovery initiatives [19].

In the United States (US), the following bodies: customers, producers, recyclers, traders, states, and end-users shoulder the obligation to contribute towards the subsidy required to manage waste tyres [20]. The funds are utilized in the reclaiming, recycling or the material and energy recovery from waste tyres. Furthermore, a portion of the resources may be utilized to offer financial support to local communities for the establishment of waste tyre market initiatives, create licensing/enforcement systems, and to organize tyre educational programmes. National or local governments may also use the funds to provide grants or advances to waste tyre reclaimers and end-users of tyre-derived products [21]. The U.S. Tire Manufacturers Association in 2017 reported that 4.20 million tonnes of waste tyres were generated of which 3.40 million (81%) tons were designated for the market [22]. Conversely, 96.9% of scrap tyres were handled in an ecologically sound approach, 43% was designated for tyre-derived fuel in cement production and the paper industry; 25% was used as ground rubber; 8% was utilized for civil engineering purposes, and 3% was exported [22].

3. The Synopsis of The REDISA Plan

The minister of the Department of Environmental Affairs (DEA), in 2012 affirmed the South African Government's objectives to ban the land disposal of all waste tyres varieties [23]. REDISA proposed an all-encompassing plan whereby an array of waste tyres would be redirected away from landfills for recycling and reprocessing. Previously excluded communities such as waste pickers were incorporated into the Plan to provide sustainable jobs and to prevent EOLT from being burnt in open fields or repurposed to be utilized in motor vehicles presenting possible threats. The various types of tyres that were incorporated in the REDISA Plan are shown in Table 1. The waste pickers took responsibility for the collection of waste tyres where they would at a later stage deliver them at designated collections depots across the country. The tyres are subsequently trucked and transported to processing facilities. A greater share of the tyres is grounded for use in the formation of road works and playing fields [6]. Several South African based companies, namely; Portland Pozzolana Cement (PPC), Lafarge, Afrisam, and Natal Portland Cement have realized the benefit of

supplementing their cement kilns with waste tyres for their cement manufacturing processes, such as a 15% save in coal usage and fewer emissions of noxious gases [24]. Furthermore, Langkloof Brickworks, a brick manufacturing company based in Eastern Cape, is co-combusting coal and waste tyres, resulting in reduced CO₂ emissions and energy consumption [25].

Table 1: REDISA tyre classifications [26].

Tyre classifications	Type
1	Passenger
2	Light- duty industrial tyres
3	Heavy-duty industrial tyres
4	Earthmoving
5	Agricultural
6	Motorcycle
7	Industrial
8	Aircraft
9	Any other pneumatic

The imposed levy of (South African Rand) R2.30 per kilogram (1United States Dollar = 14.97 South African Rand) of each tyre sold was perceived to be the revenue utilized to fund the REDISA Plan, this was founded on the notion of "the polluter pays" [26]. To recuperate the expenditure of the waste tyre management process, REDISA imposed a levy on contributors considering the initial costs apportionments, shown in Figure 1. REDISA had previously proclaimed there will be minimal manipulation of the Plan by influential individuals [26]. However, the approval and implementation thereafter of a single waste tyre management Plan might be recognised as the weakness of the REDISA Plan. The monopoly created by the REDISA Plan resulted in challenges in the systemic implementation of the approved Plan and failures in reaching pre-planned targets. This eventually led to its collapse and insolvency.

In 2015, when the REDISA Plan was legislated, the organization was granted the freedom to treasure the waste tyre fee, where preferably it could have been channelled to the general fiscus [27]. This flaw in the Plan received criticism from many organisations such as the South Africa Tyre Manufacturing Conference, the Retail Motor Industry Organisation, and the Tyre Dealers Association. Consequently, these organisations instigated court applications arguing against REDISA's dominance in the IIWTMP and the gathering of levies instead of assigning the responsibility to the South African Revenue Services (SARS) [27]. Despite the controversy associated with the acceptance of the REDISA Plan, the Plan was effected in 2015 using the half a billion Rands accumulated during its first year of inception. Presently, it is evident that the criticism argued by these organisations were justifiable and held merit. This led to REDISA experiencing lots of implementation challenges and ultimately its failure. In contrast to the REDISA Plan, the plastic bag waste management levy was launched in May 2003, where revenues of approximately R200 million were accumulated annually [28]. However, only 15%, equating to R30 million, of the collected funds were reserved for the DEA to directly contribute to the development of the plastics sector [28]. Likewise, the goals of the REDISA Plan and the plastic bag project were comparable in nature. The core objectives of the two initiatives were to further

develop the waste collection value chain, create viable jobs, establish SMMEs, capacity development and skills advancement. However, the set targets did not materialize in both instances. The successes and failures of the plastic bag levy initiative are comprehensively reviewed by [28].

Figure 1: REDISA initial costs allocations [26].

4. REDISA Accomplishments

Statistics show that the South African recycling industry currently provides jobs for 100,000 individuals [29] and the waste recycling industry is recognized for its significant contribution to the country's wealth, public health, welfare, and in environmental conservation [30]. Moreover, the waste recycling sector has the potency of making advancements in the waste to energy and material recovery fields. This denotes the capacity that the collection and utilization of waste may have in the creation of sustainable employment for the non-formal sector. This can be achieved through the collection of waste, the establishment of waste processing enterprises, the transportation of waste, the expansion of capacity within the waste sector, as well as research and development to advance the sector and its end products.

4.1. Micro collectors

Micro collectors play a pivotal role in the waste tyre management chain, as they are directly involved in the sourcing and collecting of waste tyres. The collection of waste tyres is perceived as a practice that has the potential to alleviate unemployment and poverty in disadvantaged communities. Micro collectors from, Soweto, Johannesburg have found a profitable opening from discarded tyres through the founding of a collaborative business enterprise [31]. Nevertheless, micro collectors still experience challenges like demeaned social value, substandard living, poor occupational conditions, and the scarcity of state funding.

4.2. Transporters

REDISA further saw an opportunity to create more sustainable jobs by contracting self-sufficient transporters for the shipping of waste tyres to storage depots and processing plants [31]. Waste collection and transportation, in this instance, provide livelihoods to many underprivileged communities and contributes to the establishment of micro-businesses.

4.3. SMMEs

The establishment of SMMEs was one of the key objectives of the REDISA Plan, this was realized with the founding of Dinotshi Waste Into Worth Project (Pty) Ltd., a waste tyre pre-processing depot in Midrand, Gauteng [32]. This was perceived as a noble initiative for the empowerment of underprivileged societies and the youth.

4.4. Research and Development

The authors in [27] and [28], reported that REDISA during their tenure sponsored 19 student bursary beneficiaries. Considering the large sums of funds that REDISA collected, the company could have done better by providing financial aid to students from various institutions in multiple disciplines and educational echelons. Sponsoring students at advanced graduate level could have aided in the research informed development of the waste tyre sector, creation of local expertise and ultimately contribute towards the benefit of REDISA and the South African economy.

5. REDISA Failures

In November 2012, the REDISA IIWTMP was accepted and contracted to oversee the collection, management, and processing of waste tyres for a term of 5 years, till 30 November 2017. In 2013, the DEA and numerous interested parties began questioning the execution of the REDISA Plan [33]. Consequently, in 2015, the DEA commenced examining the plan and subsequently an intermediary assessment was conducted during 2016.

5.1. Operational non-conformities

In reaction to proposals presented by various participants, the DEA initiated countrywide compliance and administration campaign at all the depots registered under REDISA in the country from the 25th to the 27th of November 2015.

One of the depots that were investigated was the Midrand Depot. The review team, appointed by the DEA, was privy to the Environmental Management Inspector (EMI)'s Report which cited several areas of concerns at the depot, such as; non-compliances with the Waste Tyre Regulations (WTR) of 2009; daily running of business activities while lacking the necessary Fire Registration Certificates and Occupational Health and Safety Certification; the non-existence of site-detailed waste tyre stockpile area plans (drawings and site-specific plans pertaining the management of the stockpiles at the numerous sites), and the authorisations thereof. Moreover, the depot neglected to deliver documentation/ records to the EMI to demonstrate conformity due to REDISA limiting the depot access to critical data, lastly, the depot manager lacked understanding of the REDISA IIWTMP

and the necessities of the WTR,2009 [6]. Furthermore, the investigative journalism television program, Carte Blanche, compiled an exposé which aired in late 2015, where numerous disparagements were made against REDISA and the inadequate execution of its Plan. Consequently, the DEA instigated criminal indictments against the Midrand Depot founded upon the EMI's findings on the substandard status of the depot [34]. Owing to the acute effect of fires posed by tyres, collectively with the effect they have on the environment, human health, and general safety concerns; the DEA has an obligation to act on non-conformities. Subsequently, the DEA released pre-compliance notices to the management of all depots operating under REDISA [34]. Table 2 shows the status of the reviewed depots as of 23 February 2017 and the improvements conducted by the WMB by May 2018.

In February 2016, a private consulting firm, iSolveit, was assigned by the DEA to carry out a performance review on REDISA. The findings of the review were later substantiated by Ernst and Young after REDISA refuted the outcomes of the report. The results and conclusions of the review report indicated the failure by REDISA to meet its implementation objectives, lack of proper management, nonconformities to the approved Plan, misuse of finances and non-compliance to the latest governing framework [34].

5.2. Organizational non-conformities

The major administrative issue presented was that three REDISA directors were found to also hold indirect shareholding in other businesses that are associates of REDISA, namely, Kusaga Taka Consulting (KTC) Proprietary Limited and the Product Testing Institute (PTI) [34-36]. This constituted opposing interests for all parties concerned, thus, presenting a digression from the initial Plan. This is an oversight in the part of REDISA; however, the overseeing government ministry should also shoulder the responsibility for its lack of monitoring and assessment. The DEA conceded in court documents that it became aware of this relationship in May 2016 and failed to act promptly [35]. After endorsing a single waste tyre management plan, constant monitoring, and administration of REDISA were required from the part of the DEA.

Furthermore, allegations of excessive remuneration packages were levelled against non-managing directors of REDISA that were discovered to earn over R1.92 million annually, apart from extra company benefits. The collective earnings of managing directors and staff of REDISA (roughly 7 individuals) were reported to be R20.40 million per annum in totality [34]. A parallel evaluation on non-profit organisations shows that a Chief Executive Officer (CEO) of a non-commercial entity earns typically a salary of R469,587.00 yearly [34], however, the REDISA CEO was found to earn an exorbitant remuneration of R4,164, 840.00 per annum [35]. This scenario at REDISA only perpetuated the inequalities that already exist in South Africa by increasing the income disproportion between the impoverished and the wealthy.

The Plan instructs for the employment of an external administrative company that will manage and implement the mandates of the REDISA Plan and the management body is to report annually to the DEA on all matters pertaining to the Plan

as stated in section 28 of the REDISA IIWTMP [26]. REDISA's memorandum of incorporation (MOI) also makes provision for this clause [35]. However, since the commencement of the Plan, all reports were presented by REDISA to the DEA [34]. This is a divergence from the governing framework detailed in the Plan. There seem to be evident associations between REDISA NPC and KTC (the administrative firm employed by REDISA). Consequently, this would directly influence on monitoring and assessment as well as performance management of the different organizations, in this lies the administrative error [34], [37]. REDISA was also found not to have a suitable record-documentation system [34]. There were also concerns regarding meeting resolutions and their legitimacy or lawfulness [37]. Additionally, REDISA's monetary books of the year ended 29 February 2016 indicate substantial capital financing into the PTI of R61,852,000.00 [34], [37]. Yet, the department could not categorically determine how the investment advances the benefits of REDISA and its mandate. Lastly, it was reported that some of the family members of REDISA directors were also the directors in a privately-owned company, namely Nine Years Investment (Pty) Ltd (NYI), that leased office space to REDISA, moreover, NYI possesses 75% shareholding in KTC [35], [37].

On the 24th of January 2019, the Supreme Court of Appeal acquitted REDISA of all liquidation charges brought against the company in 2017 at the request of the then environmental affairs minister. However, one of the proceeding judges strongly criticized her colleagues for completely discounting the proven exorbitant salaries of REDISA executives.

5.3. Performance nonconformities

Employment creation: One of the key objectives of REDISA was the creation of employment particularly for the destitute, previously disadvantaged, and small enterprises through the collection and distribution of tyres to the 150 REDISA depots situated countrywide [26]. As mandated in the REDISA Plan, the organization was liable for the identification of micro-collectors, providing the necessary training and development, the creation of business opportunities and the awarding of specific collection points. Ultimately, this will ensure that the operator will have the needed skills to own and successfully operate and manage the depots. Table 3 shows REDISA's records of achieved job targets; the organization only created 1435 jobs instead of the projected 2860 jobs at the close of year 4. As a result, REDISA accomplished 50 % of its job creation objective for the year ending 2016.

Skills training and development: Section 25 of the Plan, states that free training of individuals for basic skills and specialized proficiencies in the waste tyre industry value chain should be provided. This is inclusive of drivers, their crews as well as accounting and management staff [26] utilizing 1% of the received earnings earmarked for training and development. Thereafter, the attendance reports were to be documented in the National Centralised Computer Systems (NCCS) [26]. However, REDISA failed to provide records for this. For the financial year ending 29 February 2016, the organization collected R432,372,000.00 from the waste tyre levy and 1 % of this amount, equating to R4,323,720.00 was supposed to be spent on training and development [34]. However, their financial records show that

Table 2: REDISA tyre classifications [26].

No	REDISA depot	Non-compliance notices	Non-Compliance noted	Improvements conducted by WMB as of May 2018
1	Polokwane Depot, Plot 10, Geluk, Dalmada, Limpopo	09/12/2016	Outstanding registration with the Limpopo Provincial Department, Fire and safety compliance certificate outstanding, Storage layout plan not approved.	Registration forms submitted. Storage layout plan submitted to the Municipality.
2	Waltloo Depot, Pretoria East, Gauteng	07/11/2016	Fire and safety clearance certificates renewal, Records of compliance checklist outstanding, Storage layout plan not approved.	Fire certificate renewed, Inspections conducted by safety, health and environmental (SHE) representative, Storage layout plan endorsed by Fire Chief.
3	Silverton Depot, 309 Derdepoort Road, Silverton, Gauteng	18/12/2015	Site closed on 15/08/2016.	Site closed on 15/08/2016.
4	Midrand Depot, Boxer Road, Midrand, Gauteng	28/10/2016	No registration with Gauteng Department of Agriculture and Rural Development (GDARD) as a storage facility, Waste not removed from 2016.	Registration form submitted. Waste not yet removed.
5	Thembisa Depot, Midrand, Gauteng	28/10/2016	No stormwater management onsite, No registration with GDARD as a storage facility.	Registration form submitted
6	Springs Bailing, Depot, Springs, Gauteng	24/10/2016	Site closed.	Site closed.
8	Westonaria Depot, Gauteng		Poor stormwater management.	Stormwater issue not addressed. WMB in the process of closing site
9	Witbank Depot, Emalahleni, Mpumalanga (MP)	02/12/2016	None	None
10	Nelspruit Depot, Industrial Park, MP	04/11/2016	Waste tyre storage not approved, Signage for operating hours and contact details not displayed at the main entrance, Site regulations not displayed at the entrance of the operational facility, Proof of fire prevention training outstanding for the security attendant, Waste tyre storage area haphazardly used with no demarcation lines, Storage area congested, No records available to confirm stormwater management provision, Waste tyre storage not cleared of vegetation.	Approval of storage layout plan is in progress, Fire Chief scheduled to visit site on 11 May 2018, Signage has been installed, Training for security not undertaken yet, Tyres stored in compliance with WTR, 2009 with visible demarcation lines, Stormwater management not fixed yet, The vegetation is cleared regularly.
11	Tlabane Depot, Moraka, Rustenburg, North West	02/12/2016	No fire breaks maintained from the perimeter fence, Entrance signage does not display operating hours.	Site still congested and the fire breaks along the perimeter fence, Signage not updated
12	Bloemfontein Depot, Bloemfontein, Free State (FS)	28/10/2016	Poor stormwater management	Stormwater issue not addressed, WMB closed site in May 2018
13	Bloemfontein Depot, FS		Tyres not stored according to the WTR	Depot no longer operational
14	Ladysmith Depot, Ladysmith	04/11/2016	No stormwater management on site	Stormwater management issue not addressed
15	Pietermaritzburg Depot, KwaZulu Natal (KZN)	28/10/2016	Site closed	Site closed
16	Cato Ridge Depot, Durban, KZN		No stormwater management on site	Stormwater management issue not addressed
17	Clairwaste, Durban, KZN	24/10/2016	No stormwater management on-site, Site not registered with the KZN Department of Agriculture and Environmental Affairs (DAEA).	Stormwater management issue not addressed, Registration form submitted.
18	East London Depot, East London, Eastern Cape (EC)	04/11/2016	None noted – New site	None noted – New site
19	Arlington (Port Elizabeth) Depot, EC	24/10/2016	No stormwater management on-site, No Waste Tyre Storage Plan, No fire breaks in storage area.	Stormwater channels developed and maintained, Storage layout plan in place, Fire breaks established.
20	Atlantis Depot, Western Cape (WC)		No Fire and Safety certificate, REDISA approved storage plan does not correspond to the current storage plan, 14 tyre piles exceeded the height of 3m, and 3 piles exceeded the prescribed length, 4 firebreaks were less than the prescribed 5m in the WTRs, No stormwater management on-site, Edges of the piles were outside the prescribed 8 meters fence perimeter, Site not cleared of vegetation.	The plan has been submitted to the local authorities and the Fire Chief has responded with recommendations to be implemented, Depot capacity is continually monitored, and tyres being placed in designated area.
21	Mossel Bay Depot, Mossel Bay, WC	07/11/2016	Piles more than 3 meters in height, Piles also stacked outside the perimeter of the site.	Site is compliant with its storage plan.

Table 3: Projected rates of employment creation [26].

Department	Commencement	First-year projection		Second-year projections		Third-year projections		Fourth-year projections		Fifth-year projections		Final projections	
		Magnification	Sum	Magnification	Sum	Magnification	Sum	Magnification	Sum	Magnification	Sum	Magnification	Sum
Head office	200	1	200									1	200
Depots	12	3	36	27	324	40	480	40	480	40	480	150	1800
Recycling	20	2	40	8	160	12	240	14	280	14	280	50	1000
Transportation	1.75	300	525	600	1050	800	1400	1200	2100	1100	1925	4000	7000
Total jobs			801				2120		2860		2685		10 000

only R779,000.00, 18% of the target, was utilized on training [34].

The advancement of SMMEs: REDISA outlined that managers of depots can in the long run after acquiring the necessary skills and competencies to become fully independent and occupy ownership of the depots, as stated in section 2.1 in the Plan [26]. REDISA failed to report on the statuses, and growth magnitude of all SMMEs contracted under REDISA. Furthermore, with the recent Covid-19 pandemic affecting global markets, including the South African economy, the SMME sector has also been severely affected. This is phenomenon is expected to further reduce the already diminished number of successful small businesses in South Africa.

Table 4: REDISA targets and actual performance figures [38].

Target	Estimated 5 Year Target	Actual performance figures as of year 4
Jobs	10 000	1435 employment opportunities created by REDISA – 50% of the projected target.
Depots	150	25 depots of the projected 110 – 23% of the target
Processors	50	21 processors of the estimated 36 – 58% of the target
Transporters	4000	121 transporters of the estimated 2900 – 4 % of the target
Training	1% of revenue	18% of the training budget was utilized.
Research and Development	2,5 of revenue	0,26% of the research budget was utilized.

Research and development: Section 25 of the Plan makes provision for research and development and this was included in the organization's deliverables. The cost allocation for research and development was 2.5% of the earnings received. Also, this revenue stream was to be inclusive of funding research and development at institutions of higher learning. It is well documented that REDISA partnered with Stellenbosch University and gave attention to the advancement of technologies for the valorisation of scrap tyres, with the core focus of establishing novel commercial opportunities and ventures. On record, REDISA subsidized a mere 2 out of 26 tertiary institutions in the country [34], the organization could have supported more tertiary institutions and thus expanding on their waste tyre technology research. The monies spent on research and development as recorded in December 2015 in the company accounts was R1.14 million, suggesting that only 0.26% of the research funds we utilized which is far less than the 2.5% allocation as part of the Plan [34].

Table 4 assesses the goals set by REDISA ahead of the approval and execution of the Plan with the actual attained performance figures. It is evident from Table 4 that REDISA managed to make significant contributions to the different sectors under their Plan, but it did not attempt to meet any of its set objectives.

5.4. Deviances from the REDISA Plan

The exportation of tyres: In section 12 of the Plan, a provision for the exporting of tyre derived goods is made, however, the export of waste tyres is not catered for. Moreover, the Plan pronounces that modifications to the Plan can only be accepted by the DEA minister [26], [34], [36]. The report submitted by REDISA on 31 October 2016 details the percentage quantity of waste tyres that were exported. Roughly 30% of the monthly received tonnages were exported whilst the remaining tonnages featured minimally in the tyre recycling processes and rarely recorded in the monthly processing statistics [34].

Compensation of collectors: The findings from iSolveit Consulting in 2017 show that waste collectors were compensated a standard rate of R2.00 per tyre [34], [38], conflicting with the rand per kilogram rate stipulated in the Plan. The Plan suggests that the informalized economy (waste pickers) handles the greatest share of waste tyre projected to be roughly 75% [34]. In July 2016, REDISA provided a list of all the waste collectors captured in their database. A total of 965 pickers were enlisted, of which only 8.7% of the total were gathering tyres. Of the remaining 881 pickers, 53.1% were registered in the database but failed to gain position of their identification cards, whereas 39.2% had received their cards but did not manage to supply tyres [34]. On average, the yearly earnings of the 512 waste pickers varies between R463.14 to R14,935.55 during the 2016/2017 financial year. An additional 370 waste collectors had R1,681.55 distributed to them [34]. Consequently, REDISA retained monies for 881 waste pickers which were designated for salaries, registration, and training. A comparison study was conducted to assess the earnings of approximately 7 REDISA executive management against those of waste collector (965 individuals), generally, R20,40 million and R280,036.00 respectively were the averages remunerated to the different groups in the 2016/17 fiscal year. The earnings paid to the informal waste collectors only equates to 1.37% when compared to the remuneration of REDISA executives. This indicates that REDISA was unsuccessful in the creation of sustainable employment, consequently, did not meet the performance targets as stated in the Plan, and failed in lessening the income inequity between management and labourers.

Compensation of transporters: Section 25 of the Plan specifies that primary and secondary tyre transporters should be remunerated per kilometre travelled [26]. However, contracted transporters were reimbursed a standard rate per route not as initially stipulated in the Plan [34], [38].

Additional waste stream: In December 2015, the REDISA management accounts reflected an R11 million investment in the investigation of a new waste stream, however, this is not within the prescript of the Plan [34], [38]. This decision is perceived to be financially unsound as this venture does not institute additional revenues.

Table 5 summarizes all the non-conformity concerns established during the implementation of the REDISA IIWTMP.

Regardless of the criticism and shortcomings of the implementation of the REDISA Plan, in principle, the plan was sound and showed great potential if implemented in the approved manner. At current, the WMB has been assigned the responsibility to oversee the collection, storage, transportation, and processing of waste tyres in South Africa. Table 6 shows the statistics of active participants of the WMB as of June 2018. In May 2018, the then minister of the DEA gazetted the receipt of four new proposals for the Industry Waste Tyre Management Plans in South Africa, namely, Tyre Waste Abatement & Minimisation Initiative of South Africa, Evergreen Energy, JPC Energy Systems and South African Tyre Reuse Company [39]. However, the current Minister of Environment, Forestry and Fisheries, on 19 September 2019, issued a notice of rejection for all the previously submitted IIWMPs and found them unsuitable to address the waste tyre challenges in South Africa [40]. The Minister later issued a directive for the Council of Scientific and Industrial Research (CSIR) to draft an industry waste management plan for waste tyres [9].

Table 5: The abstract of REDISA's performance assessment [38].

Administrative errors	Performance	Deviations	Alignment
Contradictory interests (executives at KTC, NYI and linked companies associated with REDISA).	Job performance figures below estimated targets. Only 50% achieved by Year 4.	56% of waste tyres were exported, this was done against the approved Plan	REDISA was not affiliated with the new governing framework.
Board of Directors structure did not conform to the requirements in Plan.	NCCS was bought using REDISA funds, but KTC owned and managed the system and was also outdated.	Employment targets were revised.	
Functions and duties between REDISA and KTC not distinctively outlined.	Training targets not achieved – only 18% of training budget used.	R 150 million investment was provided to the Product Testing Institute	
Insufficient archiving of records (Board minutes, resolutions).	Employment targets for depots, processors and transporters not accomplished	Investments and investigations into an additional waste stream were embarked upon.	

Business did not conform to MOI-suitability of directors.	Excessively spent on marketing by 0,96%.	Waste collectors were remunerated a standard rate of R2,00 per tyre.	
	Only 0,26% of research and development revenue was spent.	Transporters were remunerated a standard rate per route in a place of a per kilogram charge.	
		Yearly performance audits were never presented to the DEA	

Table 6: Waste Bureau Management performance figures as of June 2018 [41].

Target	Active participants	
Micro collectors	213	
Transporters	77	Primary = 67
		Secondary = 10
Micro depots	23	
Processors	21	Registered = 12
		Active = 9

6. Conclusion

The approval of the IIWTMP REDISA Plan was recognized as a progressive scheme from the South African Government that envisaged the integration of previously underprivileged societies, the establishment of tenable green jobs, a capacity-development project, and the commitment to deal with social and economic issues. The findings show that REDISA did manage to make significant contributions to the different sectors governing the Plan such as the creation of jobs and small, medium, and micro-sized enterprises (SMMEs), the establishment of depots and waste tyre processing facilities, and the investment into several institutions of higher learning to further research and development in the waste tyre sector. However, with REDISA not meeting its planned targets, non-conformities to functional and administrative commitments; monetary challenges as well the non-compliances of the initial Plan, REDISA saw its demise. The experiences realized with the REDISA Plan should give guidance to present and future policy and decision-making on waste tyre management and processing in South Africa.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

More than one year after the outbreak of the COVID-19 pandemic the behavior of figures published by official sources of the countries are skeptical for the public. Many probability tests are used to detect the reliability of information among which Benford's Law. This study focused on the Western Balkan countries, as one of the foremost regions of South East Europe, where the appearance of COVID-19 was delayed by almost two months compared to the rest of Europe. In our work, we have analyzed the reliability of new cases and deaths figures published daily by official sources. Two study periods are considered separating the two waves of infections in the region. We have used Benford Law as one of the probability laws which has shown effectiveness in detecting possible data incorrectness or lack of information. Statistical tests such as Chi-Square have been used to check the probability adequacy of real data with Benford distribution. The results show a significant fluctuation of the figures from the Benford Law, especially during the first observed period. The study may be used by the policy makers to detect incorrectness or delays in reported number of new cases and/or deaths that have occurred during the COVID-19 pandemic.

1. Introduction

1.1. Evolution of COVID-19 in Western Balkan Countries

It all started in December 2019 in Wuhan, Hubei Province of China and in January this outbreak was attributed to SARS-CoV-2. On 30 January WHO declares a global public-health emergency and on 11 March declares the outbreak a pandemic. Globally based on the reports of WHO, up to 5 December 2020, there have been 65,007,974 confirmed cases of COVID-19, including 1,507,018 death [1].

In Western Balkan countries the first state which confirmed to be affected by the virus was North Macedonia. Its first case was reported on 26 February 2020, latter on 10 March, the Ministry of Health of North Macedonia implemented more reliable measures to prevent further spreading of the virus, including temporary two-week closure of all education institutes, the prohibition of travelling to the most infected countries and the ban of all public events. In North Macedonia up to 5 December, have been 65,231 confirmed cases of COVID-19 with 1,847 deaths [1]. Current population is 2,083,337 people.

*Corresponding Author: Eralda Gjika, Email: eralda.dhamo@fshn.edu.al

Latter on the last week of November, North Macedonia has experienced a sharp increase of new cases arriving at a confirmed number of 2,768 active cases per 100,000 inhabitants and 57,451 cases in total, almost the double from October reported figures. It reported 1,600 deaths [2].

The second country which reported the first case of COVID-19 was Bosnia and Herzegovina on 5 March 2020. On 17 March, a state of emergency in the entire country was declared and from 30 March 2020 all borders were closed for passengers. In Bosnia and Herzegovina, from January 3 to 5 December 2020, have been 91,539 confirmed cases of COVID-19 with 2,812 deaths [1]. Current population is 3,272,109 people. By this date, 432,980 people were tested [3]. In mid-October the situation in Bosnia and Herzegovina significantly worsened displaying an exponential increase in the number of new cases. In mid-November, the number of new cases slowly started being rewarded by recoveries, showing a noticeable stabilization in the growth of active cases. At the end of November the number of confirmed cases was 2,402 cases per 100,000 inhabitants [2].

Serbia was the third country which reported the first case of COVID-19 on 6 March 2020. Latter on 15 March, closed its borders to all foreigners not living in Serbia and schools, faculties

and kindergartens were also closed. On 17 March, the country introduced night curfew as a protection measure. As of 5 December 2020 there have been 199,158 confirmed cases of COVID-19 with 1,765 deaths [1]. By that time, 1,844,731 individuals had been tested [3]. Current population is 8,722,302 people which makes Serbia the largest country in Western Balkan. In early September the government declared the epidemiological situation stable and under control with a decreasing trend observed in new cases. This was a short period because at the end of September and start of October the situation began to worsen with reported number of a total 155,994 registered cases with 1,423 fatalities, and a rate of 123 active cases per 100,000 inhabitants at the end of November [2].

The fourth country, Albania has confirmed the first case of the virus on 8 March 2020. Immediately on 8 March, the country stopped all flights and ferries with quarantined areas of northern Italy until 3 April, halted all schools for two weeks, ordered cancellation of all large public gatherings, and asked sports federations to cancel scheduled matches. On 15 March, Albania closed all of its land borders until further notice, making all travel from Montenegro, Kosovo, North Macedonia, and Greece prohibited. In Albania, up to 5 December have been 41,302 confirmed cases of COVID-19 with 870 deaths. Total number of tests is 194,927 [4]. Current population in Albania is 2,876,446 people. After the summer touristic season the number of new cases in Albania has been steadily growing which forced the government to a re-introduction of restrictive measures. During the first part of November the daily rate of new cases surprisingly almost tripled from a minimum of 321 to 836 new cases per day [2].

Only one week later on 13 March, the first two cases were confirmed in Kosovo and on 15 March, the Ministry of Health requested that the Government of Kosovo declare a state of public health emergency. In Kosovo, up to 5 December, have been 41,256 confirmed cases of COVID-19 with 1,052 deaths [1]. Current population in Kosovo is 1,811,377 people. During November the COVID-19 situation significantly aggravated showing a rapidly increase of the new cases reported per day. The same situation as in Albania, was observed also in Kosovo. After a decline through August and September, a rise from 300 up to 715 new cases per day was recorded in the country [2].

Table 1: Population, cases, deaths and tests by country

Country	Population	Total cases	Total deaths	Tests
Albania	2,876,446	41,302	870	194,927
Kosovo	1,811,377	41,256	1,052	Missing
Montenegro	628,100	37,015	516	Missing
North Macedonia	2,083,337	65,231	1,847	Missing
Serbia	8,722,302	199,158	1,765	1,844,731
Bosnia and Herzegovina	3,272,109	91,539	2,812	432,980

(Period: up to 5 December 2020)

The last country in Western Balkan and also the last European country to register the first case of COVID-19 was Montenegro on 17 March 2020. From 24 May until 14 June when the first imported case was reported, Montenegro had no active cases. However, by 14th June, Montenegro undergo to a second wave of infections

which this time was significantly observed in the evolution of the cases and deaths figures reported. In Montenegro, up to 5 December, have been 37,015 confirmed cases of COVID-19 with 516 deaths. Current population is 628,100 people. During September and October the situation aggravated in the country and on 23 November, the total number of cases reached 31,618 and 11,143 active cases. This figures make Montenegro the second state in Europe with the highest rate of cases about 5,034 total cases per 100 000 people [2].

1.2. Review of literature on COVID-19

Observing the development situation of COVID-19 in the Western Balkan countries with a very close resemblance to developments in economy, social life and demography, we consider that their response to this pandemic will be similar. Therefore, one of the purposes of this paper is to test whether this data reported by these countries leaves room for uncertainty in the rapid and accurate response to daily reporting.

One of the indicators of reliability we have studied is Benford Law (BL) applied in daily reported numbers of new cases and deaths.

It has been shown in the study of [5, 6], that if random numbers are simulated from an exponential distribution with a parameter λ then they will follow Benford Law. As a result, if we start observing that the curve of epidemic growth in these countries does not seem to follow an exponential distribution than we can start suspect that they do not obey the Benford's Law.

Starting from March 2020, when the epidemic was confirmed as a pandemic a huge work has been done by many researchers in different countries to study the behavior of this virus through mathematical methods and up to the construction of models to predict the future. In their work [7], discuss on country-based mitigation measures that will influence the course of the COVID-19 epidemic. The reporting process was studied by [8], who observed the number of infections in China, USA and Italy and confirmed that the reported numbers match the distribution expected in Benford's Law. An epidemic growth model that could capture the intrusion efforts in different countries in order to obtain a better understanding of the growth rate for COVID-19 infections was proposed by [9]. In their work they showed that epidemic growths without intervention are likely to satisfy Benford Law. They reported that all countries they took into consideration, except Japan, satisfied this law and indicating the growth rates of COVID-19 were close to an exponential trend. This exponential trend was also observed by [10], in the number of infected patients in Italy. In another study by [11], a digital forensic analysis technique based on Benford's Law was used to analyze the COVID-19 data for 23 countries and conclude that results from some countries were suspicious of manipulated arranged data.

The reliability of COVID-19 was studied by [12], which also used Benford Law to the total number, new cases and deaths in Russia and found a high possibility of incorrectness manipulation on reported numbers. In their report [13] found for European countries such as: France, Germany, Spain, UK, Switzerland and Italy that records of cumulative infections and deaths fitted well to the BL and show consistent reporting. Other work on modelling and analysis of COVID-19 has been done also by [14], who

provide a toolkit of statistical and mathematical models for analysing the early stages of an outbreak and assessing interventions. A further study [15], looked at an SEIR (susceptible, exposed, infected, and recovered) type of a mathematical model to describe the COVID-19 dynamic in Sri Lanka. A comparison of the COVID-19 events in the Asian countries and studied a new flexible extended Weibull distribution to describe the total death data in the Asian countries was presented by [16].

Another side of analysing COVID-19 was trying to make predictions about the impact of this virus. In their paper [17], lists some main reasons underlying forecasting failure in COVID-19 data. A pandemic time series is a sequence of regular observations observed over time (each day) and it is also an univariate time series, which is considered also as the simplest form of temporal data [18, 19].

Can we have reliable predictions if the data are not reported correctly? If so, what forecasting methodology can be justified for the given numbers? During this period there are enough scientific research articles which have used many forecasting models to predict the evolution of COVID-19 time series. The accuracy of classical, smoothing, advance, machine learning, hybrid and ensemble time series models by analyzing the accuracy of the forecasting models in: USA, Russia, Brazil, India and Peru was presented by [20]. They show that the predicted numbers for Russia are not quite good. Russia is one of the countries where other research authors also have found data incorrectness. The interest for the study of COVID-19 has expanded towards finding the key parameters responsible for outbreak [21, 22].

We are aware that, for many reasons, such as the lack of information on the signs of the virus, the logistics, the ability to provide medical care in the Western Balkans, the figures reported at the early phase of the pandemic may raise obvious doubts.

2. Benford Law

This is an added value of COVID-19 study in many countries around the world. In this study we focused our interest on using Benford Law to investigate whether the epidemic growth model can be affected by errors in reported number of new cases and deaths in Western Balkan countries.

Table 2: Benford's law distribution of first and second digit.

Benford distribution	0	1	2	3	4
1 st digit		0.301	0.176	0.125	0.097
2 nd digit	0.1018	0.1139	0.1088	0.1043	0.1003
Benford distribution	5	6	7	8	9
1 st digit	0.079	0.067	0.058	0.051	0.046
2 nd digit	0.0967	0.0934	0.0904	0.0876	0.085

Benford Law (also known as Law of anomalous numbers) was presented in [23]. This law is the observation that in many collections of numbers from real-life data or mathematical tables, the significant digits are not uniformly distributed; they are heavily skewed toward the smaller digits. Specifically, the significant digits in many real data sets obey a very particular logarithmic distribution where the law for the first significant digit is:

$$P(D = d) = \log_{10}\left(1 + \frac{1}{d}\right) \quad (1)$$

$d=1,2,\dots,9$, where D denotes the first significant digit.

The probability that d ($d = 0, 1, \dots, 9$) is encountered as the p -th ($p > 1$) digit is:

$$\sum_{j=10^{p-2}}^{10^p-1} \log\left(1 + \frac{1}{10j+d}\right) \quad (2)$$

Figure 1: Benford's expected frequencies for the first and second digits. The values on the vertical axis are the distribution probabilities of digit d as shown on the horizontal axis, where $d=1,2,\dots,9$ in first digit graph (left) and $d=0,1,2,\dots,9$ in the second digit graph (right)

Among many statistical tests for comparing a random sample with a theoretical probability distribution to analyze the goodness of fit of the reported data we have used the **Chi-Square Goodness-of-Fit Test** [24]. The objective of the test is to conduct a hypothesis test of matching a theoretical distribution using histogram representation of the data. The null hypothesis is that the random variable corresponding to the sample variable follows the theoretical distribution (using the parameter estimates). The null hypothesis is rejected if the test statistic: $\chi_0^2 > \chi_{\alpha,k-s-1}^2$.

In our situation the null hypothesis and the alternative hypothesis are as below:

H_0 : Data follow Benford distribution

H_1 : Data do NOT follow Benford distribution

Chi-Square statistics is used as a measure of the divergence between the observed data and theoretical Benford distribution. A value of the Chi-Square statistic greater than the critical value yields to hypothesis H_1 . A value of the Chi-Square statistics less than the critical value, yields to the null hypothesis and conclude that the data follow the Benford distribution. *Anderson-Darling* and *Kolmogorov-Smirnov* goodness-of-fit tests are an alternate of the chi-square test, but are restricted to continuous distributions. We choose to use *chi-square goodness-of-fit test* in our data because it can be applied to multinomial distributions. The conditions of expected frequency to be at least 5 for approximation by the chi-square test are valid.

In his paper [25], suggest that the probability distributions of the data fluctuate around Benford distributions but in the view of Blondeau there is an upper bound which enables to find a better adjusted law compared with Benford's one. We have used the *BeyondBenford* package in the R statistical environment which enables to compare the goodness of fit of Benford's and Blondeau

Da Silva's [24] digit distributions in a given dataset using as a measure of accuracy the Pearson Chi-Squared test. Through this package we first draw the histograms of digit frequencies and the prediction confidence intervals.

3. Empirical analysis

3.1. Data

The confirmed COVID-19 data of new cases and deaths used in this analysis are publicly available from the European Center for Disease Prevention and Control [26]. The database contains information about the daily number of confirmed COVID-19 daily new cases and confirmed daily deaths in various countries worldwide. The reported data have different durations in time as different countries were affected by the pandemic in different periods. We must emphasize that the data after 14 December are made public only on weekly basis from this source.

Figure 2: Cumulative new cases and deaths reported in Western Balkan countries (from start up to 14 December 2020)

As observed from Figure 2 above the epidemic growths in some of the countries naturally follow an exponential family distribution which may be a suspicious that the data may follow Benford Law [9]. The new cases time series for Serbia show a rapid increase in the figures especially after September 2020. The same is also observed for the deaths in Serbia and Bosnia and Herzegovina.

Below is the evolution of the new cases for each country from the first reported case (which differs from one country to another) up to 14 December 2020.

www.astesj.com

Epidemic outbreaks of COVID-19 in many countries of the world show a rapid increase and a more smooth decrease in the daily number of new cases. A reason for this behavior may be the fact that most lockdowns are enforced promptly, whereas lockdown measures instructed by governments have been absorbed gradually by individuals.

Figure 3: New cases reported in Western Balkan (start-14 December 2020)

In Albania the situation of COVID-19 was felt from the end of February, but the alarm was given in 9 March 2020 and was followed by a long quarantine till the beginning of June. The situation advanced until the middle of October where the situation moves up to 289 new reporter cases. The numbers are evolving rapidly for the country.

For Kosovo the beginning of the COVID-19 pandemic was similar to Albania. The situation changed for Kosovo in the start of the touristic season which enables a large number of Kosovo residents to visit Albania for their summer vacations. This period was a fluctuating period for the country and then it start to fall down until the middle of October.

In Bosnia and Herzegovina the number of new cases started to be public in the first part of March and the situation was under control for the government till the beginning of July when the authorities opened the border for the touristic season. The new cases reported by the authorities in Montenegro seem to have been “frozen” for some months giving reasons to doubt for withholding information on new cases.

North Macedonia was another Western Balkan country which has a delay in the first cases reported with COVID-19. The situation in the country was under control with a low declared number until the start of the touristic season. The tourists from North Macedonia focus their attention on Albania and Greece, increasing in this way the risk of spreading the virus. Greece was the country which closed the borders with the neighbor countries for the summer period trying to slow down the spread. The situation in Serbia was different than in other Western Balkan countries. It seems to have a 3 month seasonal pattern with peak in April and July.

The evolution of number of deaths per day reported by the authorities in the Western Balkan countries are shown in figure 4.

What is clearly observed is the fact that for Albania the figures are not changing, they are in the interval of 0 to 6 deaths per day.

Kosovo has a peak of number of deaths from COVID-19 in August and a drop in figures to October. Bosnia and Herzegovina have had the maximum number of deaths in August (23 deaths) and have shown a weekly seasonality from then. Montenegro number of deaths range in the interval 0 to 13 and are showing stability. The number of deaths in North Macedonia has a seasonal pattern which is also observed in Serbia. Even that the figures are low we may see a presence of an increased trend during the winter.

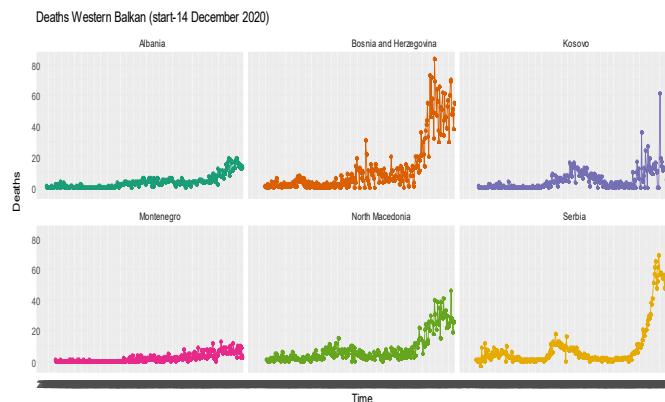

Figure 4: Deaths reported in Western Balkan (start-14 December 2020)

3.2. Time periods of study

Some studies on COVID-19 spread have tried to achieve at conclusions and presented attempts to model the reported numbers but most of these studies concentrate their attention on the initial phase of the COVID-19 which by the way do not offer enough data. In our analysis we choose to end the first period in 13 October where the new wave was still not clearly observed in Western Balkan countries. And then we enlarged the data up to 14 December which was almost 2 months after the second wave has begun to show in the region.

Figure 5: Boxplot of new cases for the two periods in Western Balkan countries

Period 1: 26 February up to 13 October 2020. The first wave of COVID-19 infections and the start (not included) of the second wave in Western Balkan countries.

Period 2: 26 February up to 14 December 2020. It includes the two waves of COVID-19 infections in Western Balkan countries.

To achieve a better view of the situation and start analyzing the reported data we analyze first the box plot of every country on each period for new cases and deaths.

Observing carefully the two periods we notice that in the first period the distribution situation was mostly stable in all countries except Bosnia and Herzegovina, Montenegro and Serbia which have presence of some significant outliers. The situation in the second period seems to change significantly, now the extreme values presence situation is clearer in countries such as Serbia (the country with the highest population in Western Balkan countries). Presence of extreme values is also observed in Bosnia and Herzegovina, and Kosovo. (Figure 5 and Figure 6)

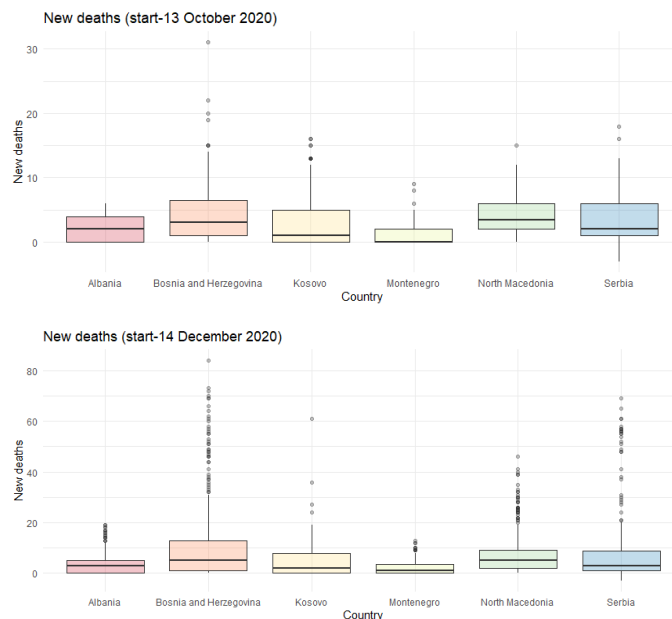

Figure 6: Boxplot of deaths for the two periods in Western Balkan countries

In the first period most of the countries experienced low numbers of deaths per day. Some days with high reported values are observed for Bosnia and Herzegovina Kosovo, Serbia, Montenegro. Albania seems to have a stable reported number of daily deaths which in this period was not higher than 7 deaths a day. When the second wave of the pandemic swept through the Western Balkans, there was an immediate increase in the number of reported daily deaths. Here, as in the reported cases, there was observed an increase in the number of reported deaths but also the presence of the extreme values displayed clearly as outliers. Among those states which show a considerable number of the outliers are Bosnia and Herzegovina, North Macedonia and Serbia.

4. Results

For the data analysis procedure we have used the *BeyondBenford* package in R statistical environment. This enables to compare the goodness of fit of Benford's and Blomdeau Da Silva's digit distributions in a given dataset using as a measure of accuracy the Pearson Chi-Squared test. Through this package we first draw the histograms of digit frequencies and the prediction confidence intervals for every country and variables taken into consideration: new cases and deaths per day.

In their work with the data (up to June 2020), [9] found that in countries where the precautions and interventions were made to

control the expansion of the COVID-19 pandemic the reported data satisfied Benford Law. Based on this result and considering the fact that all the Western Balkan countries took measures until quarantine (period that ended in early June) we studied the reported data if they should satisfied Benford Law.

Figure 7 (a) show the histograms of new cases for the two periods. Benford and Blondeau theoretical distribution histograms are plotted together with the empirical distribution of the variable new cases in each country.

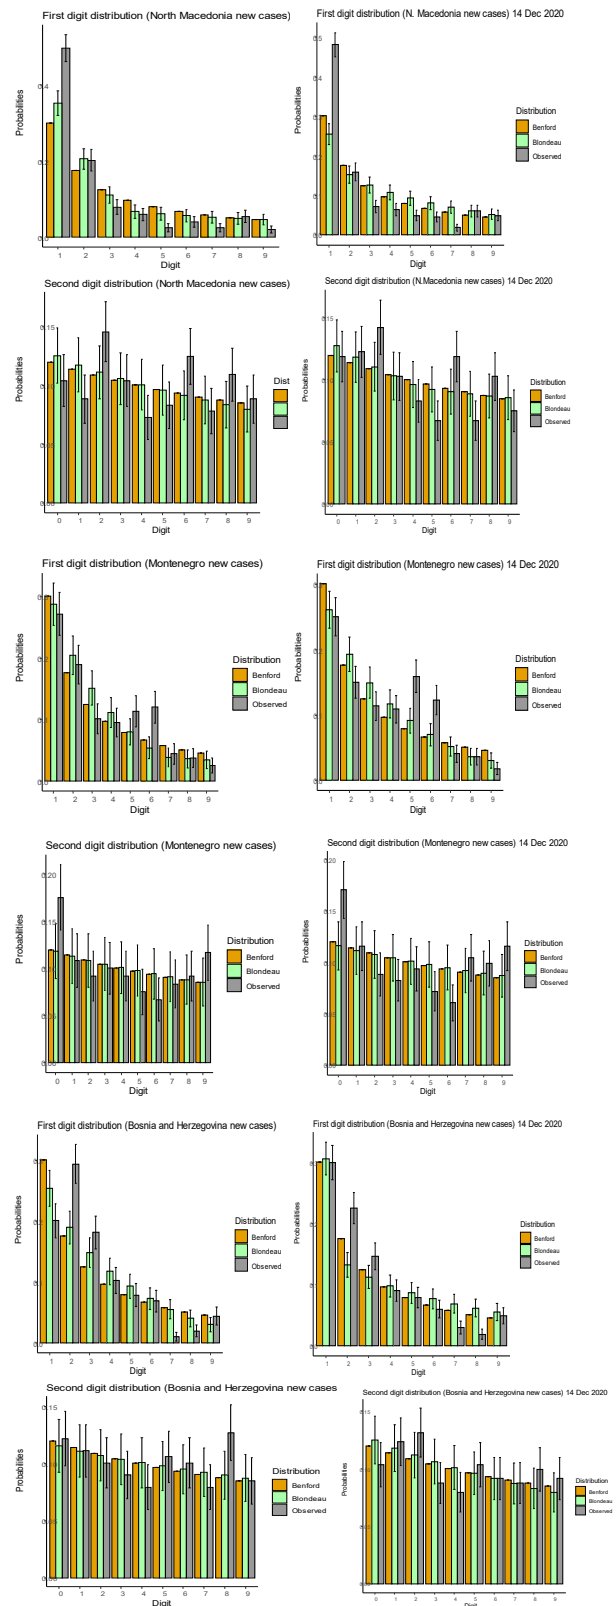

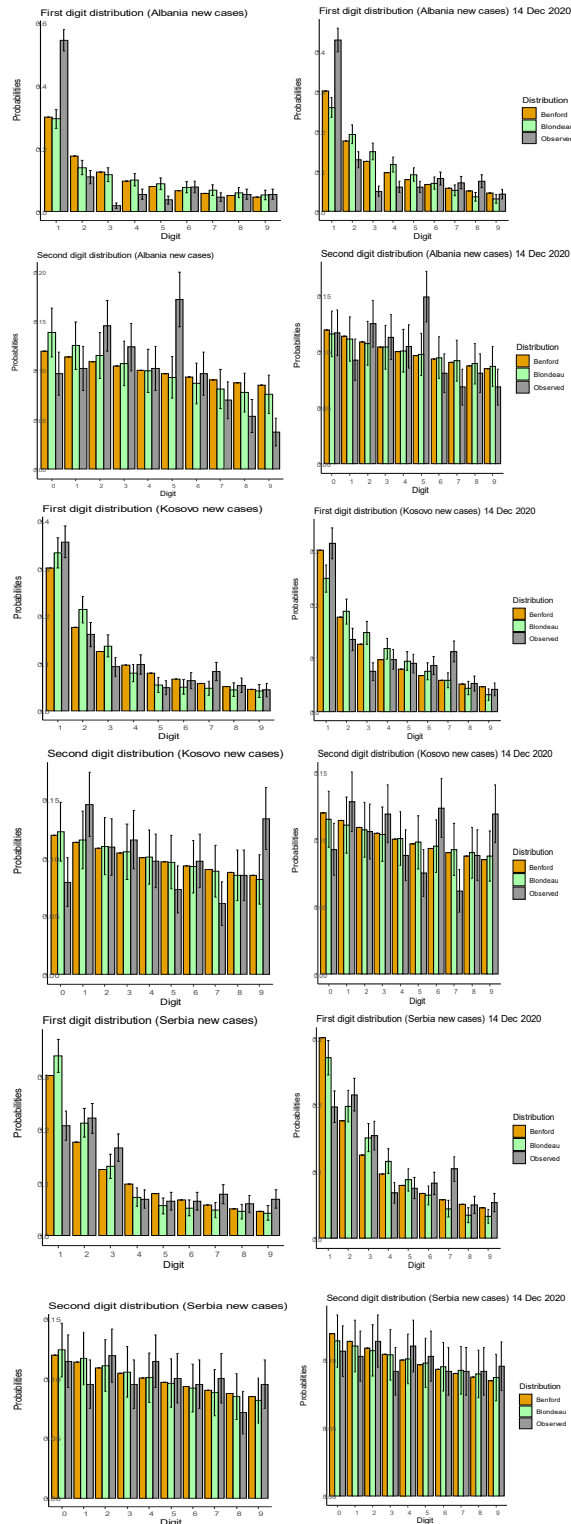

Figure 7: (a) Number of new COVID-19 cases (Histogram of the observed new cases; first digit and second digit of Benford and Blondeau law)

From Figure 7(a) we observe that Albanian and North Macedonia new cases numbers seems to not display an exponential family distribution and the situation of first digit distribution also does not display a Benford distribution, which is confirmed again for the second digit in the two periods. We may attribute this to the

delay on the publications of new cases for Albania. But it has also some numbers at the level of 140-160 new cases per day which seem to not obey the Benford distribution.

Kosovo and Serbia are the two countries which seem to naturally follow the Benford Law for the first digit in the two periods. Kosovo faced the situation of COVID-19 at the beginning of March. Forced measures and further quarantine delayed the spread of the pandemic in the country. It is observed that in the two periods of investigation the distribution for the first digit is not showing a good fitting with the theoretical distribution of Benford and Blondeau. For the second digit in both periods as well we observe some deviations from BL for Albania, Kosovo, North Macedonia and Montenegro. Serbia and Bosnia and Herzegovina seems to overcome with the additional information from the second period.

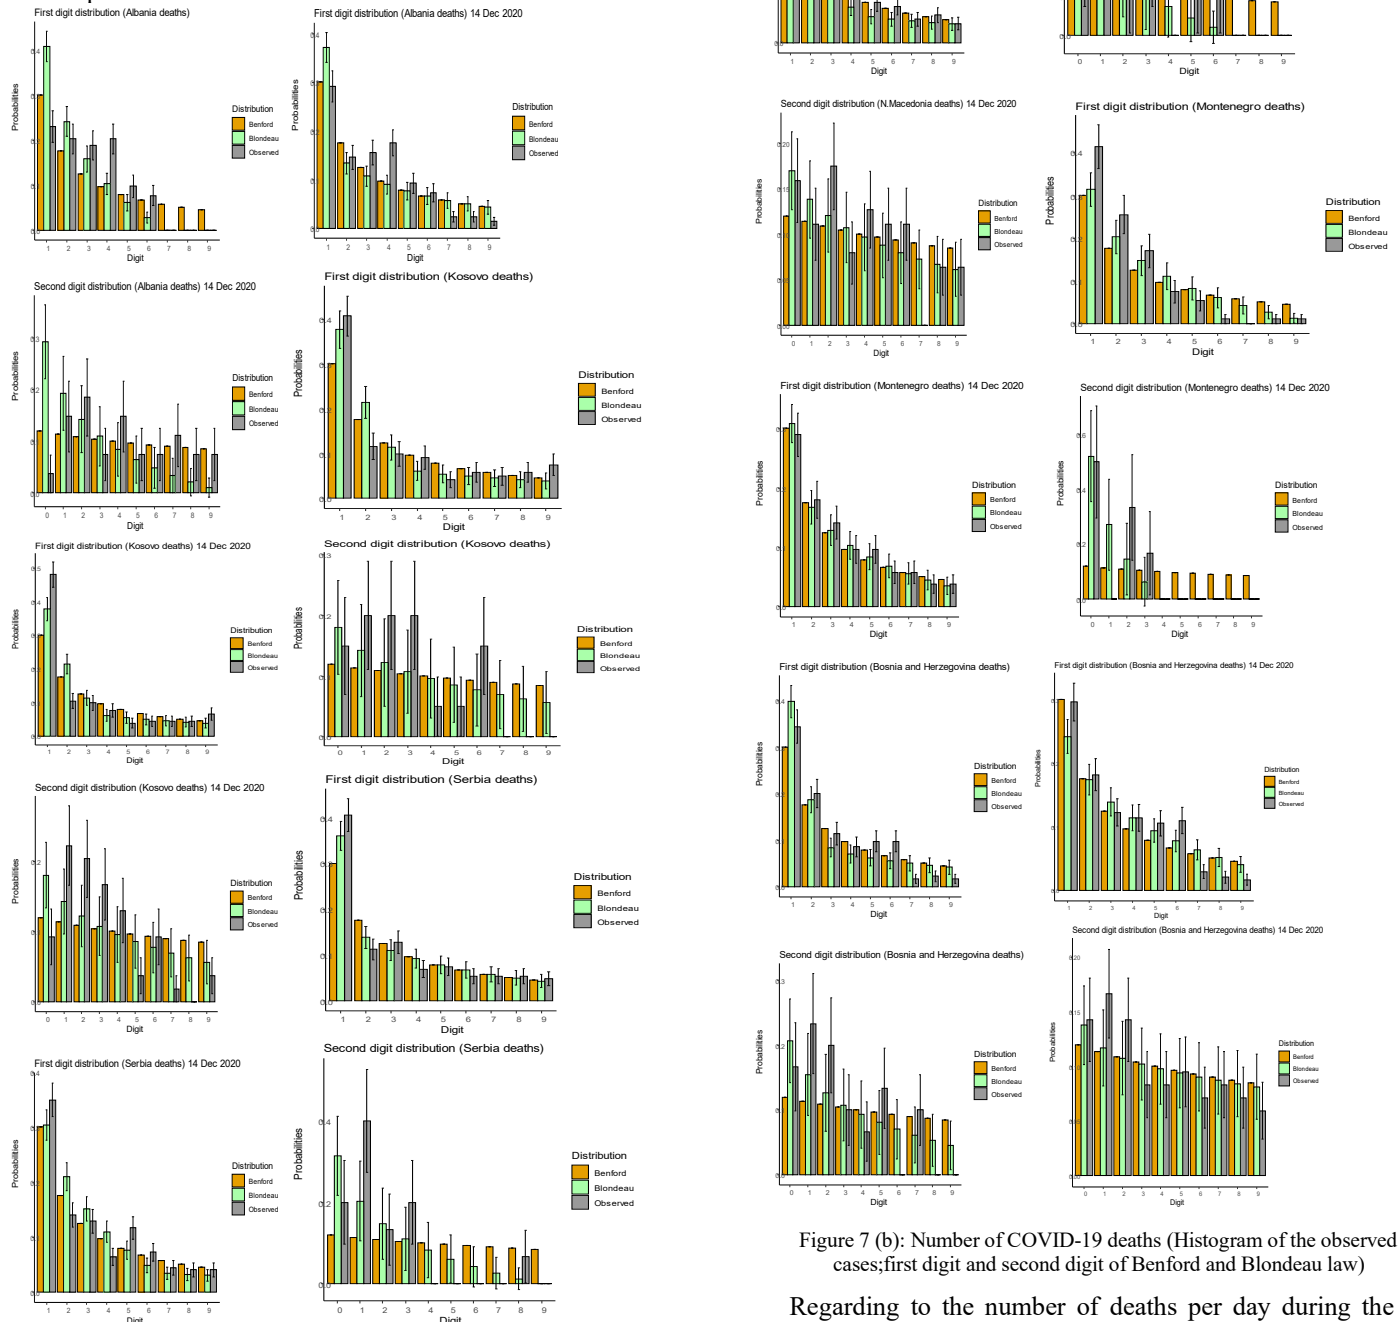

Figure 7 (b): Number of COVID-19 deaths (Histogram of the observed new cases; first digit and second digit of Benford and Blondeau law)

Regarding to the number of deaths per day during the first period, this number was not higher than 10 for all the countries, so

for those countries the second digit histogram and also Chi-Square test are not obtained. (Figure 7.b)

Kosovo and Serbia are the countries which seem to naturally follow the Benford Law for first digit of daily deaths for both periods but they don't show a significant fitting for the second digit in either the two periods. Albania seems to deviate significantly from BL especially with the addition of the information during the second period. Montenegro first digits of daily deaths obey to the Benford Law especially for the second period and display a clear deviation for the second digit in the second period.

For Bosnia and Herzegovina the second period seems to have gained an adjustment for the first and second digit of daily deaths. North Macedonia histograms for the first digit in both periods seem to obey to BL but this is not observed in the second period. Special case was observed for the number of deaths in Montenegro for the second period where the number of deaths seem to be lower than 15 a day.

Table 3 shows the results obtained from the Chi-Square test for every country and separately for new cases and deaths reported daily. The output also shows the Chi-Square statistics and the p-value of the test. With a p-value < 0.05 we can reject the null hypothesis (H_0 : the data obey to Benford Law). The results are summarized in Table 3, 4, 5 and 6 for new cases and deaths for the two periods.

	P-value	0.995	0.00011	0.0156

Table 3 up to 6 shows the value of the Chi-Squared test and *p-value* for the countries. A *p-value* < 0.05 indicate the observed values do not confirm the theoretical values of Benford Law. The *p-values* for new cases reported are lower than 0.05 which is an argument for rejecting the null hypothesis; the reported data do not follow the Benford Law probability distribution for the first and second digit.

The same situation is observed from the histogram of the first and second digit and the results of the Chi-squared test for the reported number of deaths. The chi-squared test gives a Chi-square value of approximately 47 and a *p-value* lower than 0.05 regarding the Benford Law but it does not give a result of the confidence interval proposed by Blondeau.

5. Conclusions

The study presents an overview of the Benford probability distributions in the COVID-19 reported figures for Western Balkan countries (which are not part of the European Union). During the situation of quarantine (which for many countries of WB was the beginning of March to the end of May) and post quarantine, the authorities of each country were not able to do many tests per day. This and also the rules imposed by governments and the closure of a considerable part of public activities may have lead to low reported numbers during this period. Perhaps the onset of the pandemic frightened the Western Balkan, and they hid the timely reporting of new cases and deaths. They were faced with a lack of experience dealing with pandemic situations and unprepared for recording and reporting real-time figures.

Other factors that may have affected the reporting process during the first wave may also be the lack of a culture of the population to report cases and conduct tests. The middle-low economic level in these countries is another factor that affects the number of tests which directly affects the detection of the number of people diagnosed with COVID-19. Also, lack of the condition in hospitalization made that many COVID-19 patients were going to get medication at home. Advices of government representative to stay home and take precautions from their GP (family doctor) because even that hospital staff are doing their best, but hospitals will likely be overwhelmed by COVID-19 aggravated patients which need more professional services and medical equipment's. Events reported by COVID-19 hospitals of persons who have attempted suicide, may be another cause of persons who neglect to be diagnosed, by this way many of them have preferred to be cured at home and are not reported.

Summer touristic season was another factor that has affected the reported number of new cases and deaths in the first period. Especially for the coastal countries, the reported number may have been intervened to help the touristic season especially those businesses in the country which have been highly affected after quarantine.

For some of the states it is noticed that Benford Law is not applied. Here another reason may be the small number of daily reports in both periods under consideration (during the first period the number of deaths ranged from 0-6 and during the second period from 0 to 13).

Almost all Western Balkan countries have reported a high number of COVID-19 cases during November 2020, but they alter the speed of reported numbers.

The study may be used by the policy makers to detect incorrectness or delays in reported number of new cases and/or deaths that have occurred during the COVID-19 pandemic. Hence, in most cases the results of divergence with Benford's Law should not be interpreted as a reliable indicator of incorrectness in the pandemic declared figures. The histogram diagnosis and the statistical test results, show that the expansion of the study period in most cases did not affect the quality of the compliance with Benford Law. On the contrary, the increase of information in the second period has increased the level of unreliability to these data.

Parallel Gripper Finger

Robotic Dual-Arm

Automatic Bottle Opener

ABSTRACT

This paper presents a design of parallel gripper finger for robotic dual-arm working with an automatic push-down bottle crown cork cap opener on ABB's Yumi collaborative bartender robot. A safe gripper finger is made from ABS plastic by 3D printing for human-based interaction design for grasping and holding a glass bottle. Rack design and proposed automatic push-down bottle cap opener using pneumatics are presented to support a gripper finger. Experimental tests as bartender environment with 4-different types of carbonated soft drink with crown cork cap show that can be achieved effectively with average of 91.5% percentage of successful cap opener.

1 Introduction

In recent years, many types of safe collaborative robot with single arm and dual-arm intended for direct collaboration with human-based workers in the industrial automation with incrementally superior capacities have been invented to handle bimanual tasks in the product assembly [1]- [4]. Robot can assist humans in many tasks [5], [6]. Performance of picking and placing objects using robotics technology is an important objective of industrial automation for picking and packing boxes [3], [4] with computer-based vision [7]. Robot Arm is being used the manipulation of static objects that are fast and proven to be reliable. There are many types of robotic arm used. A picking robot arm is scheduled to pick a task in the specific working space to enhance the stability and movement with a specific trajectory points [8]. In [9], the authors have presented a cable-driven underactuated robotic gripper, which is designed for adaptable picking objects in different shapes, weights, sizes, and textures. ABB's Yumi robot has been reported many successful efforts to improve dual-arm operations for synchronized programming in industrial tasks detailed in [3]. Kinematic plan for conventional industrial robotic arms are capable of moving the static object manipulation. However, there is a trouble when moving object manipulation such as a smooth picking up a bottle

and a grasping motion [10]. Our inspiration of this research came from the Japanese news that the Japanese owner of restaurants and shops are struggling to hire staff in an aging society. Then in 2020, the Japan's first robot bartender [11] has begun serving up drinks in a Tokyo pub with the industrial robot. In order to avoid jerking the object and figuring out the reasonable time in safety, we present a design of gripper for industrial ABB's Yumi robotic dual-arm.

To enhance the gripping performance, the grippers perform a pick-place process by using the force to compensate the gravitational force of objects in motion [12].

Moreover, the grippers have to be mated with objects to ensure that the objects do not either fall off or get damage from the grippers. The 2-finger parallel gripper was chose because it is the most flexible design and is able to carry out most percentage of applications. The ABB's YuMi is offered gripper options. The basic function of the option is to grasp parts using a parallel grip [13]. There are some inventions related to a crown cap bottle opener [14],[15]. A conventional bottle opener is a specialised lever inserted beneath the pleated metalwork pulling it off when upward force is applied to the handle end of the opener. Autonomous bottle opener robot [14] has presented with a simple bottle opener to assist the bartender. Without suffering from wrist motion disorder while opening, a push bottle opener [15] includes a mechanism configured to remove a

^{*}Corresponding Author: Suchada Sitjongsataporn, Mahanakorn University of Technology, ssuchada@mut.ac.th

bottle cap when the opener is introduced over a bottle and pushed downwardly.

To our best knowledge, a design of gripper finger on ABB's Yumi collaborative robot is presented for human-based tasks performing automatic manipulation collaboration with an automatic push-down glass bottle opener using pneumatics in order to operate on grasped objects.

Figure 1: Gripper finger design for grasping a bottle.

Figure 2: Prototype of gripper on ABB's Yumi robot.

In this paper, a design of parallel gripper finger of dual arm robot working by holding safely a glass bottle is proposed for carbonated beverage and opening the crown cork cap opener with the automatic push-down bottle opener using the pneumatics.

The contribution of this research are listed as follows.

- The learning human motion pattern on the left-hand and right-hand side gestures of ABB's Yumi collaborative bartender robot working with the automatic push-down bottle opener

will be proposed for gasping a glass, preparing a glass and pouring a beverage, which will be able to replace humans in the future.

- To design a safe gripper finger for holding a glass while movement based on the dual-arm industrial robot.
- To propose an automatic push-down crown cap bottle opener based on the dual-arm industrial robot.

2 Proposed Gripper Finger of Robotic Dual-Arm

In this section, the gripper finger of robotic dual-arm is proposed to apply with an automatic bottle opener. The design of automatic bottle opener controlled by the solenoid circuit are presented as follows.

2.1 Proposed Gripper Finger

In this paper, gripper finger design is to optimise the collaborative robot for picking and placing a bottle with a specific process. The robotic parts handler that physically interacts with the working environment. This leads to increase throughput, improve system reliability and compensate for robot inaccuracy.

The objective is to gasp and hold safely a glass bottle with a parallel gripper while using pneumatic for opening a bottle crown cork cap with an automatic push-down bottle opener. The dimension of carbonated soft drink in 250 ml glass bottle is of $11 \times 20 \times 13$ cm with the 25mm crown cork bottle cap. The design of safe gripper finger is made by 3D-printing ABS (Acrylonitrile Butadiene Styrene) plastic for grasping and holding a glass bottle and human-friendly interaction is shown in Figure 1.

Depending on the material used, a stress limit of designed gripper finger is tested on the stress analysis by the Autodesk Inventor. Prototype of gripper on ABB's Yumi robot is shown in Figure 2.

2.2 Proposed Automatic Bottle opener

The concept of an automatic bottle cap opener mechanism is to effortlessly open and remove the bottle cap in one push-down by single handed robot. Rack design for proposed automatic bottle opener implementation using pneumatics is being worked reliably with the collaborative robot.

Mechanism of proposed automatic bottle opener consists of aluminium profile, bracket, a bottle stand, an automatic push-down bottle cap opener at the top of rack, a bottle opener stand, a pneumatic air cylinder, and a stroke adjustment sensor. Installation of an automatic bottle crown cap opener is shown in Figure 3. The dimension of rack design is $15.1 \times 17.4 \times 42$ cm connected with the pneumatic systems.

Figure 3: Mechanism of proposed automatic push-down bottle opener: 1) Aluminium profile; 2) Bracket; 3) Bottle stand; 4) Automatic push-down bottle cap opener; 5) Bottle opener stand; 6) Pneumatic cylinder; 7) Stroke adjustment sensor.

Figure 4: Diagram of solenoid circuit and I/O robot interface: 1) Solenoid circuit for automatic bottle opener; 2) Stroke adjustment sensor circuit at the upper of bottle opener; 3) Stroke adjustment sensor circuit at the lower of bottle opener.

The process of an automatic bottle cap opener starts with the right-hand side of robot arm released a bottle into a bottle stand after selecting and picking a beverage. Then an automatic bottle opener moves vertically by the pneumatic air cylinder in order to remove a crown cap by an automatic push-down bottle cap opener installed at the top of rack in one push down motion. A stroke adjust sensor is referred as a switch for controlling the outstroke of air cylinder while operation.

The relationship on outstroke between force, radius and pressure that can given from

$$F_r = A_e \cdot P, \quad (1)$$

where F_r is the resultant force, P is the pressure on the surface and A_e is the effective cross-sectional area of the piston surface.

Solenoid circuit is connected with I/O robot interface as shown in Figure 4. The output signal voltage of robot is used at 24 Vdc while operating. Prototype of automatic push-down bottle opener using pneumatics including with the rack for safety is shown in Figure 5.

3 Coordinate systems of collaborative robot

The mechanical arm of ABB's Yumi robot is divided into an arm, a wrist and an end-manipulator. All the manipulators have marked for four reference points used during process to posture the tool in the workspace with a given orientation. The robot orientation is described with three-dimensional rotation using an order set of four numbers named *quaternions*. The ABB collaborative robots are able to control manually by using the flex pendant [16], which is a hand held controller connected to the robot.

Figure 5: Prototype of automatic push-down bottle opener using pneumatics.

The robot movement is programmed by teach pedant, which are relative to the Tool Center Point (TCP). Normally, TCP is defined as the active point of the tool as one point for each tool at a given time. When the robot is programmed to move along a given path following by TCP expressed in relation to the coordinate system.

Let t_{co} be the translation vector from the original coordinate system of tool flange to TCP as [17]

$$t_{co} = [t_x \ t_y \ t_z]^T. \quad (2)$$

Consider M be the translation matrix from the tool flange to

TCP as

$$\mathbf{M} = \begin{bmatrix} \mathbf{I} & \mathbf{t}_{co} \\ \mathbf{0} & 1 \end{bmatrix}, \quad (3)$$

where \mathbf{I} is the identity matrix and $\mathbf{0}$ is a zero vector.

TCP is assumed at the same coordinate independent of N robot positions that is determined by

$$\mathbb{P}_{1,i} \mathbf{M} = \mathbb{P}_{1,j} \mathbf{M}, \quad (4)$$

where $i, j \in [1 \dots N]$ and $i \neq j$.

Consider that

$$\begin{aligned} \mathbb{P}_{1,i} \mathbf{M} &= \begin{bmatrix} a_{11} & a_{12} & a_{13} & a_{14} \\ a_{21} & a_{22} & a_{23} & a_{24} \\ a_{31} & a_{32} & a_{33} & a_{34} \\ a_{41} & a_{42} & a_{43} & a_{44} \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & t_x \\ 0 & 1 & 0 & t_y \\ 0 & 0 & 1 & t_z \\ 0 & 0 & 0 & 1 \end{bmatrix} \\ &= \begin{bmatrix} \mathbb{B}_a & \tilde{\mathbf{t}}_a \\ \mathbf{0} & 1 \end{bmatrix}, \end{aligned}$$

and

$$\begin{aligned} \mathbb{P}_{1,j} \mathbf{M} &= \begin{bmatrix} b_{11} & b_{12} & b_{13} & b_{14} \\ b_{21} & b_{22} & b_{23} & b_{24} \\ b_{31} & b_{32} & b_{33} & b_{34} \\ b_{41} & b_{42} & b_{43} & b_{44} \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & t_x \\ 0 & 1 & 0 & t_y \\ 0 & 0 & 1 & t_z \\ 0 & 0 & 0 & 1 \end{bmatrix} \\ &= \begin{bmatrix} \mathbb{B}_b & \tilde{\mathbf{t}}_b \\ \mathbf{0} & 1 \end{bmatrix}. \end{aligned} \quad (6)$$

Therefore, the linear equation of system can be expressed as

$$[\mathbb{B}_a - \mathbb{B}_b] \begin{bmatrix} t_x \\ t_y \\ t_z \end{bmatrix} + [\tilde{\mathbf{t}}_b - \tilde{\mathbf{t}}_a] = \mathbf{0}. \quad (7)$$

It is seen that all information determining the coordinate of TCP is achieved following (7).

4 Experimental Setup

Simulation setup for ABB's Yumi bartender on specific environment is illustrated with the four different type of beverages. Experimental setup of ABB's Yumi collaborative robot bartender consists of TCP calibration and workobject using the ABB Teach Pedant controller on chessboard pattern [18] at the base frame, including with the proposed bartender algorithm.

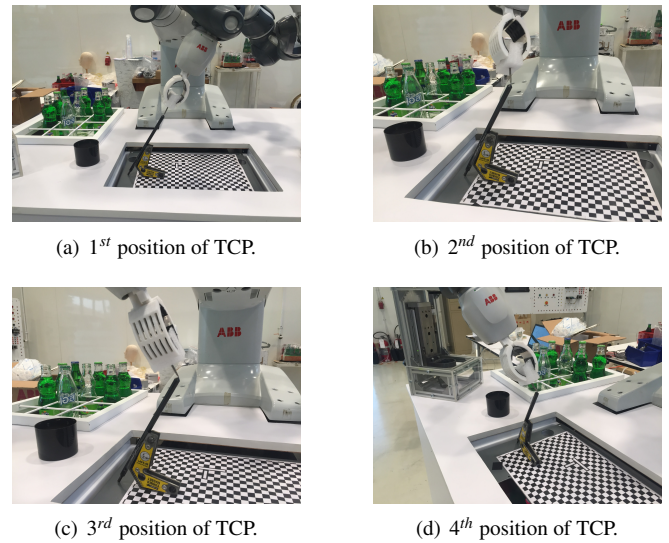

Figure 6: TCP calibration on chessboard pattern.

Figure 7: Demonstration of ABB's Yumi bartender robot with gripper finger dual-arm.

4.1 TCP calibration

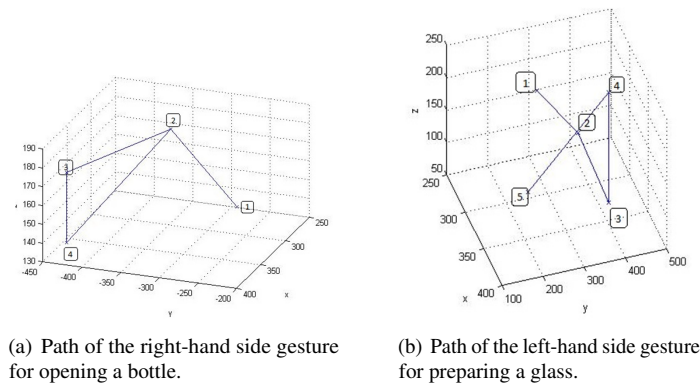

TCP calibration is modified on the chessboard pattern by determining the TCP 4-reference position with different type of grasping gesture object using ABB Teach Pendant as shown in Figure 6.

4.2 Workobject

A workobject [19] is a coordinate system used to describe the position of a work piece. The workobject consists of two frames as a user frame and an object frame. All positions will be related to the object frame, which is related to the user frame and world coordinate system. Working movement is modified on the chessboard pattern by marking the 3-reference point on x-axis and y-axis using ABB Teach Pedant.

4.3 Bartender algorithm

The proposed ABB's Yumi bartender algorithm is as shown in Algorithm 1. The process is starting from taking order from user via GUI interface on web application, then select one beverage and open the cap with an automatic push-down cap opener using the right-hand side of robot. Finally, to pick a glass and then pour the selected beverage into a glass by the left-hand side of robot. Demonstration of ABB's Yumi bartender robot with gripper finger dual-arm working with the automatic push-down bottle opener is depicted in Figure 7.

(a) Path of the right-hand side gesture for opening a bottle.

(b) Path of the left-hand side gesture for preparing a glass.

Figure 8: Path of ABB robot gripper gesture for opening a bottle on the right-hand side and preparing a glass on the left-hand side of robot.

5 Experimental Results

Experimental results show that ABB dual-arm robot performing gesture-based robotic gripper capable of being human-based recognised consist of four paths as two paths for opening a bottle cap using an automatic push-down bottle cap opener by pneumatics and preparing a glass. Next two paths for pouring a selected drink by the right-hand side into a glass holding by the left-hand side of robot gripper as follows.

(a) Right gripper involved taking up a bottle.

(b) Right gripper involved moving a bottle to bottle opener stand.

(c) Left gripper involved rotating a glass right-side up, while cap was being opened.

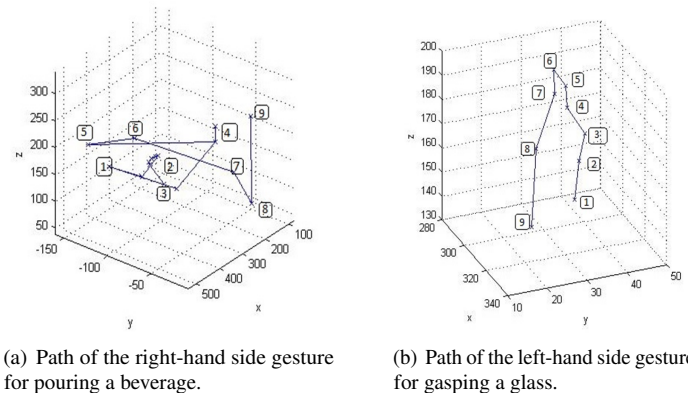

(d) Right gripper involved taking an uncapped bottle, while glass was prepared.

Figure 9: Grasping and movement of opening a bottle cap along Route 1 and Route 2.

5.1 Path for opening a bottle and preparing a glass

Figure 8 shows the paths of gripper gesture controlled the right-hand side robot for opening a bottle and for preparing a glass on the left-hand side of robot. Experimental route for opening a bottle cap by a right-hand side gripper were the No. 1-4 shown in Figure 8(a). Route 1 started at location No. 1, involved taking up a bottle from location No. 2 and moving it to replace on the bottle opener stand at location No. 3 and waiting for opening a bottle cap at location No. 4, then taking up a bottle to location No. 2 again waiting for pouring in the next route. Route for preparing a glass by a left-hand side gripper were the No. 1-5 shown in Figure 8(b). Route 2 started at location No. 1, involved picking up a glass from location No. 2 and moving it to location No. 3 and then rotating a glass right-side up to location No. 4, then standby for the next route at the location No. 5.

Figure 9 demonstrates the step-by-step of gesture movement of ABB's Yumi bartender collaborative robot while using an automatic push-down bottle cap opener by pneumatics at the right-hand and holding a glass prepared by a left-hand side of robot gripper followed Route 1 and Route 2. Figure 9(a) shows the right gripper was taking a bottle to the rack of automatic push-down bottle opener, while the left gripper prepared to

(a) Path of the right-hand side gesture for pouring a beverage.

(b) Path of the left-hand side gesture for grasping a glass.

Figure 10: Path of ABB robot gesture movement for pouring an uncapped beverage.

pick up a glass depicted in Figure 9(b). Meanwhile the bottle was being uncapped by automatic push-down opener using pneumatic, the right gripper was prepared into standby mode and left gripper was rotating a glass right-side up as shown in Figure 9(c). After that, the right gripper was taking out an uncapped bottle presented in Fig 9(d) and left gripper was waiting for pouring in the next route.

(a) Right gripper involved holding an uncapped bottle and left gripper prepared holding a glass.

(b) Right gripper involved pouring a beverage slowly into a glass, while left gripper tilted a glass at a 45 degree angle.

(c) Right gripper involved shaking a bottle softly, while left gripper straightened holding a glass.

(d) Right gripper involved taking an empty bottle into a bottle stand, while left gripper involved moving a full glass ready to serve.

Figure 11: Grasping and movement of pouring an uncapped beverage into a glass along Route 3 and Route 4.

5.2 Path for pouring a beverage into a glass

Figure 10 shows the paths of gripper gesture controlled the right-hand side robot for pouring a selected beverage without cap into a glass held by the left-hand side of robot. Experimental route for pouring a uncapped bottle by a right-hand side gripper were the No. 1-9 shown in Figure 10(a). Route 3 started at location No. 1, involved holding an uncapped bottle to location No. 2 and moving it at the front of a glass holding by a left-hand side gripper to location No. 3, pouring slowly from location No. 5 to No. 6 and shaking softly from location No. 7 to No. 8, and then taking up an empty bottle to location No. 9 at the end route.

Now that a glass has been prepared by a left-hand side gripper and ready to pour. Route for pouring a beverage were the No. 1-9 shown in Figure 10(b). Route 4 started at location No. 1, moving a glass prepared from location No. 2 to No. 3, tilted a glass at a 45 degree angle from the location No. 4 to No. 5 and then poured a beverage slowly by a right-hand side gripper so that the liquid landed directly in the middle side of a glass holding by a left-hand side gripper of robot. Once a robot poured about half of beverage into a glass at the location No. 6, then straightened a glass and poured a rest of beverage directly into the center of glass from the location No. 7 to No. 8, and then moving a full glass with beverage to location No. 9 at the end route.

Figure 12: Percentage of opening the bottle cap by automatic push-down bottle opener using pneumatics.

Figure 11 demonstrates the step-by-step of gesture movement of ABB's Yumi bartender collaborative robot while pouring a beverage using a right-hand side gripper into a glass holding by a left-hand side of robot gripper followed Route 3 and Route 4. Figure 11(a) shows that the right gripper was holding an uncapped bottle and then pouring a beverage slowly into the middle side of glass, while the left gripper tilted a glass at a 45 degree angle depicted in Figure 11(b). Until the bottle was empty, the right gripper was shaking a bottle softly, while the left gripper was holding straighten a glass in Figure 11(c). After that, the right gripper was taking an empty bottle into a bottle stand and left gripper was ready to serve as shown in Figure 11(d).

The average percentage of the results from opening a bottle cap is as the success of opening bottle cap is given for 91.5 %, the bottle cap doesn't pop up the opener for 6.75 % and the failure for 1.75 % presented in Figure 12, which are achieved effectively.

6 Conclusion

In this paper, a design of gripper finger working with an automatic push-down bottle crown cork cap opener has been presented using pneumatics on ABB's Yumi collaborative robot for the bartender environments with the 4-different types of carbonated soft drink. The proposed semi-circular shaped gripper is appropriately designed for grasping and holding a bottle safely and working with the automatic bottle opener. The design of safe parallel gripper finger made by ABS plastic for grasping and holding a glass bottle and human-based interaction has been introduced. A gripper finger design with the industrial specification is tested on the stress analysis depending on the material used by the Autodesk Inventor. Rack design for an automatic push-down bottle cap opener using pneumatics supported a proposed gripper finger has been proposed.

All proposed paths are introduced for safely working on bartender responsibilities including with opening a bottle, pouring a beverage and serving a beverage. The paths of successful gesture for grasping a bottle and hold a glass by proposed gripper finger have been presented that they can apply effectively and safely to work as a bartender controlled through a web application. Experimental results shown that the average percentage of 91.5% of successful cap opener can be achieved effectively.

Conflict of Interest The authors declare no conflict of interest.

Acknowledgment ABB Robotics provided a YuMi robot for the co-operative education and valuable support regarding YuMi programming. The authors would like to thank Pongthanakorn Yaibutong, Department of Mechatronic Engineering and Automation, Faculty of Engineering, Mahanakorn University of Technology, Bangkok, Thailand for his support.

Synthesis of things

CV presentation

ABSTRACT

To get hired, an aspiring candidate needs a good CV/résumé. This is not an easy task as it must be readable, well structured, concise with no grammatical errors, and containing all relevant information needed by employers. In this paper, we present a newly designed context-free grammar for the dynamic synthesis of a CV. The grammar rules were implemented in a software tool called Flex-CV. Flex-CV makes use of user input and selected CV templates to produce many CV instances in LaTeX. Examples of CVs generated with Flex-CV can be found at <https://tinyurl.com/cv-instances>. We then evaluated this tool based on its perceived usefulness among job seekers. Evaluation results indicated that this tool will be useful to those aiming to improve their employment prospects through better CV presentation.

1 Introduction

Curriculum Vitaé, often abbreviated as “CV”, roughly translates in Latin as “life’s course” [1]. It is important to note that in some countries CV and résumé are not synonymous. In commonwealth countries, a CV is merely a short document — detailing professional and academic careers — serving as a summary of the job seekers personal information, employment, education, qualification, and other information relating to a job applicant [2]. While in other countries such as USA, Canada, Australia, India, etc; a CV is a comprehensive document mainly used in academic [3]–[5] and medical fields [6, 7]; such that, a résumé — meaning short summary — is used for industry, non-profit, and public sector job applications [8]. This paper refers to CV and résumé synonymously as a means towards job application.

A CV is usually provided to a potential employer when seeking employment; this serves as a means to screen applicants before the interview process is conducted [9]. In search for employment, CV presentation may greatly influence the likelihood of a job seeker being a potential job candidate [10]. Previous studies give an insight into how relevant information and personal characteristics from a CV are often omitted or incorrectly stated in such a way employers are not able to extract positive attributes [11].

With successful job search comes employment such that we can easily account for our most needed basic needs — including living expenses such basic housing, food, and water among other needs.

Apart from also providing much needed economic growth [12]. Employment also contributes to our mental health and physical health [13]–[15] — affecting confidence and self-efficacy [16]. As a result, endeavours undertaken to improve CV writing significantly increase the chances of obtaining employment [9].

In computing, string generation and manipulation has become important in many different fields [17]–[19]. In this paper, we focus on providing a theoretical and practical solution to the problem of CV presentation. This is achieved by designing a new context-free grammar (CFG) for the synthesis of a user’s CV, which we implemented in a tool that aids with the job search process. The use of grammars is critical as we can specify input by the user, and get a pseudorandomly generated number of CVs, each having shuffled sections and subsections, with minor errors pre-checked. A CFG consists of several rules which are simply a model of a language. One rule which does not depend on context can be applied in order to generate a sentence [20].

Many tools exist as solutions to CV problems but many are lacking in features and fail to deliver on what makes a good CV, i.e. readable, well structured, concise with no grammatical errors, and containing all relevant information. However, there exist many job search intervention programs and they seek to further develop skills such as communication. It is known that a tool that helps with CV presentation can improve an applicant’s CV for a better job search process. In order to address issues related to CVs a means

^{*}Corresponding Author: Darren Tafadzwa Semusemu, darrensemusemu@gmail.com

for job applications, Figure 1 illustrates the process this research undertakes for the synthesis of a CV. This process requires that a user completes a form with the details that should go into their CV, then the CV synthesiser normalises, standardises and synthesises a CV based on existing templates underlined by CFG rules. The result is an instance of a CV (and in some cases, many instances of a CV for the candidate to choose from).

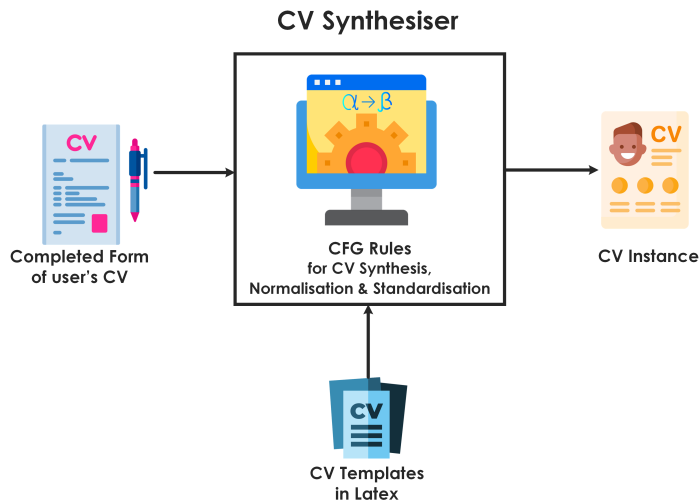

Figure 1: The Process of CV Synthesis

Recently there has been many works on the synthesis of things using CFGs [21]–[24]. This paper makes the following contributions to these trend of works:

1. designed a new CFG for the dynamic synthesis of a CV, and
2. presented an online tool that implements the newly designed CFG rules.

This paper is structured as follows. Section 2 present a background to this paper, Section 3 discussed related works. In Section 4, we presented the design of a new CFG for the synthesis of a CV. Section 5 showcases the implementation of a tool (named Flex-CV) that implements the CFG rules and sample results of synthesised CVs. In Section 7 the conclusion and future work is presented.

2 Background

In this section, we first give an in-depth analysis on the use of a CV as a means towards employment and as a self presentation tool. We consider factors during initial job fit valuations and common sections found in CVs.

2.1 A Means to Employment: Major Theories

In a study aimed at understanding how CVs are handled by recruiters, in [2], the author noted there exist defining factors influencing hiring managers decisions during the hiring process; such that, these factors need to be well understood. Although dependent on the communication channel, these factors help filter out candidates

in the recruitment process. Some of these factors include and are not limited to: conducted interviews [25], CV presentation [26], related work experience and skills [27], personal or behavioural traits [28], any form of formal assessments [29], gender [12], social economic status [30], and the recruitment channel used [31]. For an individual, employment and its perceived benefits are important.

In [32], the author stated that employment offers benefits associated with our psychological well-being (latent benefits) and benefits associated with remuneration (manifest benefits). Individuals only realise manifest benefits when engaged in paid work, while employment then provides latent benefits such as time structure, social interaction, shared goals, status, and activity [33, 34]. However, unemployed individuals lack these benefits. When compared to their employed counterparts, they then experience lower psychological health [34]. In [35], the author note that psychological health — our emotional and mental well-being — was significantly lower in studies with unemployed long-term workers. Further supported in [15] and [13], the study notes that for unemployed individuals, physical health greatly suffers as the transition to unemployment starts; as for mental health, the decline starts even before the result of unemployment. However, job search interventions can be set as a means to help with employment.

In an aim to better understand the effectiveness of job search interventions, in [9], the author identified four theoretical mechanisms which may be used as a guide for planning job search interventions. These four mechanisms are as follows [9]:

Behavioural learning theory: result of behaviour modification [36]. As opposed to learning from direct instruction, this learning theory suggests it may be more effective to change behaviours when the desired behaviour is constantly reinforced. As such, job searching consists of many sets of behaviours, some of which include networking and CV writing.

Theory of planned behaviour: result of predicting one's behaviours [37]. In job search, this theory aims to predict behavioural performance, as such, predicting the effort put in by the job seekers and the likelihood of success.

Social cognitive theory: result from the analysis of social behaviours associated with physical functioning [16]. This theory notes the importance of goal setting, specifically, the relationship that exists between a job seeker's present reality and their expected outcome.

Coping theory: results from managing stress over time [38]. In the context of job search, unemployment harms the psychological and physical well-being. This has serious outcomes when reconsidering employment.

Encompassing some of the major theories discussed, in [9], the author identified a self-regulated framework of critical components most seen in job search programs. The focus being on skills development and motivation enhancement. Skills development was identified as being made up of: (1) a self-presentation component, where training and helping an individual's skills (e.g. CV/resume writing, interview preparations, application forms) is important; and (2) a teaching job skills component; whereby job seekers are taught to find relevant jobs based on skills such as how to network in order

to obtain possible job leads over others. In the next subsection we discuss the use of a CV as a self-presentation component.

2.2 Curriculum Vitae: A Self Presentation Component

Self-presentation makes use of the following major theories: Behavioural learning and Social cognitive theory [9]. As previously stated, improving self-presentation provides assistance related to CV writing. In line with interview question conducted by recruiters, CV presentation is one of the main factors affecting the application success even before the screening process is conducted by recruiters [12]. In order to screen applicants, [2] acknowledge how recruiters use different tools, including CVs, as one of the more formal recruitment techniques towards employment. In [10], the author argue that the way job seekers present themselves on CVs, as well as during interviews, greatly influences their chance of employment. However, most job seekers are not aware of what makes an overall good CV.

Initial valuations of job fit are made by examining an applicant's CV, thereafter, comparing knowledge, skills, and abilities of the individuals with stated job requirements [10]. In [11], the author indicated how during the job search process, individuals ignore and dismiss information that enables an employer to discern important attributes and traits. As with job search interventions perceived success [9, 39], aiding job seekers by highlighting their skills through self-presentation strategies, such as CVs, greatly increases the chances of employment.

In [2], the author note of various changes in the Human Resources domain, one being of how there is a shift towards more autonomy resulting in less human oversight during the recruitment process. As it is common with the use of CV screening applications, missing key information (e.g. a key word) results in several applicants being left out. It is up to these applicants to have to be willing to adjust to these screening processes in hopes of employment. In an attempt to increase the likelihood of employment, [12] indicate that correctly highlighting knowledge, skills, and attributes in CVs is a step towards closer step to obtaining employment.

There are key problems in current literature. In [40], the author note of how in literature, more endeavours are undertaken to understand and further describe the realities of unemployment; as a result, work aimed at assisting individuals has attracted less interest. In an effort to better understand the success associated with job search interventions, the likelihood of obtaining employment is three times higher when job seekers are participants in job search intervention programs [40]. Contrary, there are many other claims of that show no inherent benefits associated with job search programs [9].

In [41], the author argue on the convergence of artificial intelligence (AI) and its perceived economic reasoning. One of the primary goals of AI is on the development of computational methods for natural language understanding [42]. Recently there has been rise on works in natural language processing (NLP). In NLP, it is important to look at a target's language grammatical structure; thereafter, through syntax we are then able to apply the rules of a certain language's grammar [43]. In [17], the author notes of how artefact generation has advanced in many notable different fields of work, some of which include the synthesis of things and procedural content generation.

3 Related Work and Gap

In this section, we discuss related works with regards to synthesis of things, procedural generation and similar tools which exists for CV synthesis. We compare these tool by discussing what they offer and what they lack. We also note the gap and motivation of this study.

3.1 Synthesis of Things

Several papers have been published on the synthesis of things in different environments. Some related work in this domain are as follows:

Program Synthesis using Natural Language In [44], the author presented a framework for taking natural language inputs and producing a domain specific language as a result.

Synthesis of Integration Problems and Solutions: In [17], the author presented grammar rules, along with a tool, for the synthesis of integration problems along with the solutions.

Generation of Practice Programs in Python Using CFGs, in [22] the author presented automatic generation of procedural python programs.

SQLizer: Query Synthesis from Natural Language In [23], the author presented an end-to-end system whereby from natural language, SQL queries can be synthesised.

Interactive Synthesis using Free-Form Queries In [24], the author present a tool for code assistance where the system uses free from queries as input and outputs Java code adhering to the syntactic rules of the language.

Synthesis of Social Media Profiles In [45], the author presented a Probabilistic CFG which was then implemented in a synthesiser tool for social media profiles.

3.2 Procedural Content Generation (PCG)

Widely used in game development, procedural generation makes use of human generated assets which are used to algorithmically produce computer content. In [46], the author noted that PCG is not random but based on a systematic approach to content generation, and that simple PCG may not be adaptive unless an adaptive approach is taken. Game content usually generated includes game structures, maps, levels, characters designs, and rules [47]. Some of the work related to PCG includes the following:

The Level Generation Competitions: competitors submit level generators based on the Mario Bros game series [46, 48].

No Man's Sky: a game where players are able to explore 18 quintillion unique planets and moons [49].

SpeedTree: a middleware used for vegetation generation in game development [50].

Borderlands: a game where the weapon system generation was done algorithmically [51].

Based on the input obtained through web forms, we can then use PCG, with CV templates as assets, to layout and present in L^AT_EX the results of a synthesised CV.

3.3 Existing Tools for CV Synthesis

There exist many tools for the synthesis of a CV. However, these tools are limited in use leaving much to be desired for a better CV. Table 1 lists some examples of these tools, gives a description on the uses these tools, and compares with the tool (Flex-CV) we have developed.

3.4 Gap and Motivation

3.4.1 Gap

Prior to this work, there has not previously been a CFG for the synthesis of a CV. This work, in doing so, is a first to help with CV presentation problems with the use of CFGs. Current tools which exist make use of template based CV generation, whereas Flex-CV is dynamic in design, based on its use of grammar rules. As a result, Flex-CV can dynamically generate many CV instances compared to the static templates used by existing tools.

3.4.2 Motivation

Many tools exist which can help with constructing a CV, however, there are limitations which affect the rules of what makes a good CV. Given our aim is to produce a tool that will help with the job search process. We consider CV normalisation and standardisation towards a comprehensive tool for CV generation. This allows us to address common errors, focusing on capitalisation mistakes. We can then address one of the main factors affecting job application success.

3.5 Why Use Context-free Grammars?

CFGs are used to specify context-free languages. We have used CFGs for the synthesis of a CV based on the following reasons:

Production of Pseudorandom CV Sections One reason why we have chosen to use a CFG for the synthesis of CVs is the ability to write rules that can be compiled into modules that generate pseudorandom (or shuffled) permutations of CV sections. This is shown in Section 4, where rules allow the generation of CV sections that have different orderings, i.e. Education may come before Work Experience in one derivation, or it may be ordered differently in another derivation sequence.

Not a “Machine Learning” Task Another reason why CFG is appropriate for this task is that statistical approaches have not performed “spectacularly enough” to fool humans, in the synthesis of natural language texts [59, 60]. This is because Machine Learning models perform well with estimated guesses and not exactness — whereas, in the composition of a text like CV, results have to be 100% exact. Hence, CFG becomes appropriate for this task, as it can be proven that correct rules, will always generate correct strings (or texts).

Sharing Grammar Rules Using CFGs allows others to easily expand on the grammar rules and to synthesis other patterns of CVs (or other forms of text) based on the re-use of sub-structures within the CFG rules. This lays a scientific foundation to assist those who undertake such research in the future.

Applications of FLAT Formal Languages and Automata Theory (FLAT) is a theoretical aspect of Computer Science; mostly not attributed to many real-life applications (few exceptions are in the design of compilers, and language recognisers). Using a CFG, an aspect of FLAT, demonstrates that FLAT can find applications in topics such as PCG and social sciences application.

4 Design: CFG For CV Synthesis

In this section, we present a newly designed CFG for the synthesis of a CV. A CFG consists of grammar rules, whereby, the rules are a finite set. We define a four tuple CFG, $G = (N, \Sigma, P, S_{\text{start}})$ where N consists of non-terminal symbols as a placeholders, set Σ of terminal symbols, set P of production rules, and S_{start} as our start symbol. In this section, we describe a CFG for the synthesis of a CVs.

4.1 Grammar Rules

Here we define a rule for the start symbol of this grammar, denoted as S_{start} . In Rule 1, we define S_{start} as consisting of compulsory and optional sections that appear in a CV.

$$S_{\text{start}} \rightarrow \langle \text{Comp_Sec} \rangle^+ \langle \text{Opt_Sec} \rangle^* \quad (1)$$

In Rule 2, we proceed to define the compulsory sections as consisting of biographical information, work experience, and education/qualifications obtained. We ensure that the compulsory part of the synthesised CV always starts with the biographical information and contains either an educational section, experience section, or both sections ordered differently.

$$\begin{aligned} \langle \text{Comp_Sec} \rangle &\rightarrow \langle \text{Bio_Sec} \rangle (\langle \text{Edu_Sec} \rangle \mid \langle \text{Exp_Sec} \rangle \mid \\ &\quad \langle \text{Edu_Sec} \rangle \langle \text{Exp_Sec} \rangle \mid \langle \text{Exp_Sec} \rangle \langle \text{Edu_Sec} \rangle \mid \\ &\quad \lambda) \end{aligned} \quad (2)$$

In Rule 3, we proceed to define the optional sections as consisting of either relevant skills, activities, awards, publications, or projects. We ensure that any optional section in the CV appears only once and any in order possible.

$$\begin{aligned} \langle \text{Opt_Sec} \rangle &\rightarrow x \subseteq \{ \langle \text{Skills_Sec} \rangle, \langle \text{Projs_Sec} \rangle, \\ &\quad \langle \text{Publ_Sec} \rangle, \langle \text{Awrds_Sec} \rangle, \langle \text{Acts_Sec} \rangle \} \\ &\quad \exists: |x| \neq 0 \end{aligned} \quad (3)$$

Table 1: Existing Tools for CV Synthesis

Tool	Description	Limitations	Comparison with Flex-CV
Microsoft Word's CV Assistant.	Powered by LinkedIn, this tool assists individuals to create a CV. The main use of this tool is showing professional CVs of notable individuals in specific industries or according to job specifications as examples [52].	Microsoft Word's CV Assistant helps by showing attributes based on related roles, and/or industry. However, no emphasis is put on an individual's own content.	Emphasises on an individual's content, giving a more comprehensive CV as a result.
LinkedIn Resume Builder	Leverages the details (experience, education, skills, etc.) a user has on the LinkedIn social platform and builds a CV based on that available information [53].	The rules of a good CV and a good LinkedIn profile are distinct and there exist a problem if a profile is incorrectly setup up as a CV based on a user profile.	Focuses on the rules of what makes a good CV rather than what makes a good LinkedIn profile.
Vmock	A resume reviewing platform that allows students to upload resume and then receive feed. This platform works by bench-marking and scoring the uploaded towards a specific targeted audience [54].	This tool is great at formatting content, however, limited at analysing content.	Focuses not only on analysing content through data normalisation and standardisation.
Ceev	A google chrome extension that transforms a LinkedIn profile page into a CV ready for print. In addition, this tool allows for the customisation of a template [55].	This tool relies on the use of LinkedIn and the same problems with LinkedIn résumé builder apply to this tool. A good LinkedIn profile does not necessary result in a good CV.	Focuses on the rules of what makes a good CV rather than what makes a good LinkedIn profile.
Resume.io	An online résumé builder that enable users to easily create a résumé. This online tool includes automatic spell-checker, summary generator, and a cover letter builder [56].	This tool is not freely available as pricing options are in place. This is not ideal for individuals looking for employment with no financial means to support themselves.	Does not limit usability in hopes for monetary gain but seeks to help individuals better their livelihoods.
Resumonk	An online tool that by default, you can add contact information, summary, experience, education and skills. This tool also allows for the importing of a LinkedIn generated CV [57].	This tool is not freely available as pricing options are in place. This is not ideal for individuals looking for employment with no financial means to support themselves.	Does not limit usability in hopes for monetary gain but seeks to help individuals better their livelihood.
Zety CV Builder	Allows individuals to re-create their CV in a better looking way. It allows a user to pick a template, fill in relevant details and customise the document for a unique look [58].	This tool is not freely available as pricing options are in place. This is not ideal for individuals looking for employment with no financial means to support themselves.	Does not limit usability in hopes for monetary gain but seeks to help individuals better their livelihood.

In Rule 4, we define personal information as having an a name, and the other details (i.e. arrangements of id, email, contact number, and gender) related to the individual. In Rule 5, 4P_4 is a k-permutation of x without repetitions. We ensure those arrangements are dynamic as the order may differ based on a chosen template or formatting.

$$\langle \text{Bio_Sec} \rangle \longrightarrow (\langle \text{Title} \rangle \mid \lambda) \langle \text{Fst_Nm} \rangle (\langle \text{Mid_Nm} \rangle \mid \lambda) \langle \text{Lst_Nm} \rangle (\langle \text{Other_Dtls} \rangle \mid \lambda) \quad (4)$$

$$\langle \text{Other_Dtls} \rangle \longrightarrow x \in \{ \langle \text{Id} \rangle, \langle \text{Email} \rangle, \langle \text{Phone} \rangle, \langle \text{Gender} \rangle \}^4 \ni x \in {}^4P_4 \quad (5)$$

In Rule 6, we define the education section as having one or more instances of qualifications obtained. Each entry consisting of the following: qualification, date obtained, institution, location, and the description. Here 4P_4 is a k-permutation of x (i.e. arrangements of qual, date, inst, and place without repetitions). We ensure those arrangements, with the excepting of the description, are dynamic as

the order may differ based on a chosen template or formatting.

$$\begin{aligned}
 \langle \text{Edu_Sec} \rangle &\rightarrow \langle \text{Edu_Ent} \rangle^+ \\
 \langle \text{Edu_Ent} \rangle &\rightarrow \langle \text{Edu_Field} \rangle \langle \text{Desc} \rangle \\
 \langle \text{Edu_Field} \rangle &\rightarrow x \in \{ \langle \text{Date} \rangle, \langle \text{Inst} \rangle, \langle \text{Place} \rangle, \langle \text{Qual} \rangle \}^4 \\
 &\quad \exists: x \in {}^4P_4
 \end{aligned} \tag{6}$$

In Rule 7, we define the experience section as having one or more instances of relevant experience. Each entry consisting of the following: the date, organisation, location, position, and description. Here 4P_4 is a k -permutation of x (i.e. arrangements of date, org, place, and pos without repetitions). We ensure those arrangements, with the excepting of the description, are dynamic as the order may differ based on a chosen template or formatting.

$$\begin{aligned}
 \langle \text{Exp_Sec} \rangle &\rightarrow \langle \text{Exp_Ent} \rangle^+ \\
 \langle \text{Exp_Ent} \rangle &\rightarrow \langle \text{Exp_Field} \rangle \langle \text{Desc} \rangle \\
 \langle \text{Exp_Field} \rangle &\rightarrow x \in \{ \langle \text{Date} \rangle, \langle \text{Org} \rangle, \langle \text{Place} \rangle, \langle \text{Pos} \rangle \}^4 \\
 &\quad \exists: x \in {}^4P_4
 \end{aligned} \tag{7}$$

In Rule 8, we define the skills sections as having transferable skills (i.e. soft skills) and technical skills (i.e. hard skills). We ensure that either hard skills, soft skills, or both or none can appear in this section.

$$\begin{aligned}
 \langle \text{Skills_Sec} \rangle &\rightarrow \langle \text{Hard_Skills} \rangle | \langle \text{Soft_Skills} \rangle | \\
 &\rightarrow \langle \text{Hard_Skills} \rangle \langle \text{Soft_Skills} \rangle | \\
 &\rightarrow \langle \text{Soft_Skills} \rangle \langle \text{Hard_Skills} \rangle
 \end{aligned} \tag{8}$$

In Rule 9, we define the projects section as having one or more instances of relevant projects. Each entry consisting of the following: the date, title, organisation, and description of the project. Here 3P_3 is a k -permutation of x (i.e. arrangements of date, title, and org without repetitions). We ensure those arrangements, with the excepting of the description, are dynamic as the order may differ based on a chosen template or formatting.

$$\begin{aligned}
 \langle \text{Projs_Sec} \rangle &\rightarrow \langle \text{Projs_Ent} \rangle^+ \\
 \langle \text{Projs_Ent} \rangle &\rightarrow \langle \text{Projs_Field} \rangle \langle \text{Desc} \rangle \\
 \langle \text{Projs_Field} \rangle &\rightarrow x \in \{ \langle \text{Title} \rangle, \langle \text{Date} \rangle, \langle \text{Org} \rangle \}^3 \\
 &\quad \exists: x \in {}^3P_3
 \end{aligned} \tag{9}$$

In Rule 10, we define the publications section as having one or more instances of published works. Each entry consisting of the following: the year, title, publisher, and journal or conference name. Here 3P_3 is a k -permutation of x (i.e. arrangements of year, title, publisher, and journal/conference without repetitions). We ensure those arrangements are dynamic as the order may differ based on a chosen template or formatting.

$$\begin{aligned}
 \langle \text{Publ_Sec} \rangle &\rightarrow \langle \text{Publ_Ent} \rangle^+ \\
 \langle \text{Publ_Ent} \rangle &\rightarrow x \in \{ \langle \text{Title} \rangle, \langle \text{Year} \rangle, \langle \text{Publisher} \rangle, \\
 &\quad \langle \text{Journ_Conf} \rangle \}^4 \exists: x \in {}^4P_4
 \end{aligned} \tag{10}$$

In Rule 11, we define the awards section as one or more instances of awards received. Each entry consisting of the following: the year, and a description of the award.

$$\langle \text{Awrds_Sec} \rangle \rightarrow (\langle \text{Year} \rangle \langle \text{Desc} \rangle)^+ \tag{11}$$

In Rule 12, we define the activities section as one or more instances of involved activities. Each entry consisting of the following: the year, and a description of the activity.

$$\langle \text{Acts_Sec} \rangle \rightarrow (\langle \text{Year} \rangle \langle \text{Desc} \rangle)^+ \tag{12}$$

4.2 CV Normalisation and Standardisation

In this section we present algorithms for CV normalisation and standardisation. Firstly, we present new definitions of standardisation and normalisation of CVs in our context. This is given in Definitions 1 and 2.

Definition 1 (CV Normalisation) We define the normalisation of a CV as a way to ensure no capitalisation errors and mistakes are present within the CV.

Definition 2 (CV Standardisation) We define the standardisation of a CV as the use of CFG rules to enforce the automatic organisation of CV sections and flow of CV contents.

Algorithm 1: Normalisation

```

1 Function NormaliseText(text):
2   isNewSentence ← true;
3   new_text ← null;
4   foreach chr ∈ text do
5     new_char ← null;
6     if isNewSentence = true then
7       new_char ← CapitaliseChar(char);
8       isNewSentence ← false;
9     else if isEndingPunctuation(chr) then
10      new_char ← char;
11      isNewSentence ← true;
12      new_text ← new_text + new_char;
13   end
14   return new_text;
15 End Function

```

Algorithm 1 shows that once submitted, a CV synthesiser then receives the data which is then normalised to ensure no capitalisation mistakes are found.

Algorithm 2: Standardisation

```

1 Function Standardisation(cv_data, section_order):
2   template ← null;
3   foreach section ∈ section_order do
4     section_data ← CFGRules(cv_data, section);
5     template ←
6       template + TemplateCode(section_data);
7   end
8   return template;
9 End Function

```

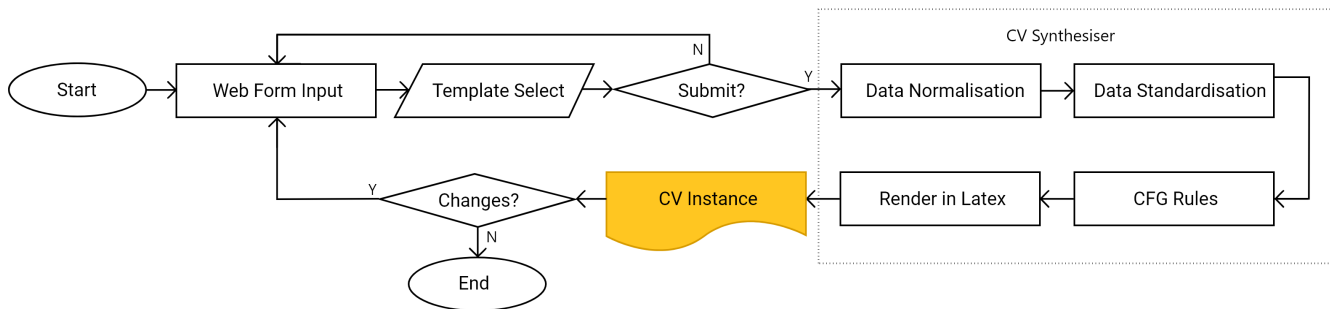

Figure 2: Flow diagram of Flex-CV Web Implementation

The synthesiser proceeds to standardise the data to a common format. Indicated in Algorithm 2, the synthesiser applies CFG rules on a section by section basis and prepares it be rendered as a PDF in \LaTeX based on the selected template.

5 Implementation and Results

The rules defined in Section 4.1 can be used to dynamically synthesis an instance of a CV, whereby an individual's information is provided. In this section, we present implementation details of the designed grammar rules and the results obtained.

5.1 Implementation Details

The CFG presented in Section 4.1 was implemented in a web application (Flex-CV) using the ASP.NET Framework. Web forms were used to collect user data regarding content of the CV. In order to carry out this study, the CV sections used were those outlined in our grammar rules. Figure 2 illustrates the implementation of Flex-CV as a flow diagram.

As opposed to mobile applications, web applications provide certain benefits to our research. Essentially, mobile applications live and run on a device itself while web applications can seamlessly be assessed through any web browser. Web applications need not be downloaded and can be used on any modern smart phone. Hence, web forms were used to collect user data regarding content of the CV, i.e. biographical information, education, experience, skills, projects, publications, activities, and awards. The front-end (user interaction side) of the application can be viewed at: <https://cv-synthesis.web.app>. This then communicates with a back-end (server side) which is responsible for receiving data, implementation of our algorithms on the data, and sending results back to the front-end.

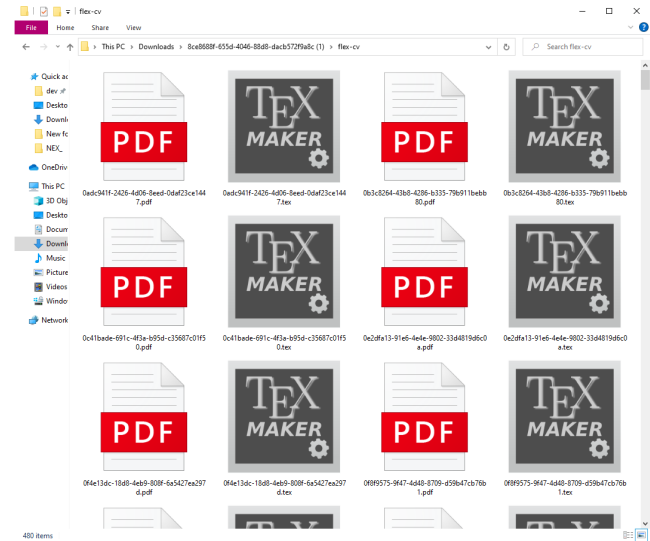

Figure 3: Output CVs from Flex-CV

5.2 Results

Upon submission, the user may generate a single CV or permutation of possible instances (see Figure 3). As for the option to generate a single CV instance, a PDF is rendered in \LaTeX and returned along with an editable TEX file for future reference. As for the option to generate multiple instances, all possible instances with regards to the section ordering are returned to the user. Rendering these CV documents in \LaTeX then provides high quality and consistent output using the TEX typesetting. As for using and providing an editable TEX file a user can then seamlessly use that to make changes, or use Flex-CV again for the benefits it offers.

5.3 More Results

Using the designed grammar rules, more results of synthesised CVs and the TEX files can be found at: tinyurl.com/cv-instances.

6 Evaluation of Flex-CV

In this section, we present the results of the survey that evaluates the impact of Flex-CV. This survey was conducted with the aim of understanding Flex-CV and its usefulness. This survey was conducted

online and respondents were individuals looking to improve their CVs. The survey was distributed online in a manner that allowed random respondents to complete the survey.

Results in Figure 4 indicate that 55.6% of respondents often struggle with writing a good CV, while none indicated as having not struggled. As seen in Figure 5, only 5.6% indicated as never having discovered grammatical errors in their CV. These results are quite problematic, however with Flex-CV we are able to help with CV presentation as means towards potential employment for individual. With 83.3% having tried Flex-CV, majority agree (Figure 6) with Flex-CV potentially providing candidates with lesser or no errors. Job search intervention can be setup to assist in job search programs, this can be seen in Figure 7 as 61.1% had never used a CV/résumé assistant tool before, however as indicated in Figure 8, an overwhelming majority later then stated as likely to use a tool such a tool in the future.

Correctly highlighting knowledge, skills, and attributes is a step closer to obtaining employment. Considering whether individuals struggle with writing a rather good CV, we indicate this as a problematic issue given how a good CV/resume is a gateway to employment and benefits that come with it [33]. Considering whether respondents had ever discovered grammatical errors in their CVs, we note that a way to lessen error occurrences is needed as they are found. Considering all the results, we therefore state that job search intervention can assist in the job search process. As such, Rayman and Atanasoff [40] note that the likelihood of obtaining employment is three times higher when job seekers are participants in job search intervention programs. This further indicates how tools, such as Flex-CV, are essential as job search intervention assistants.

Figure 4: Struggle With Writing A Good CV

Figure 6: Flex-CV Can Give Candidates Good CVs With Lesser Or No Errors

Figure 7: Used A CV Assistant Tool

7 Conclusion and Future Work

7.1 Conclusion

In this paper, we presented a CFG for the dynamic synthesis of a CV. The use of formal grammars in synthesising things has recently had many works done and in this paper, grammar rules were implemented in a software tool that produces CV instances to help with CV presentation problems. We presented a survey to many individuals who found the tool to be useful as a means towards better employment prospects through better CV presentation. The impact of job search interventions, Flex-CV included, are beneficial as a way to help with employment in many communities.

7.2 Future Work

From here, we will expand the grammar rules to be more complex and include the following: more sections, usually those not common in many CVs; and more templates.

Figure 8: Likely To Use Such A Tool In The Future

ABSTRACT

A Decision-Making Centers (DMCs) Environment facilitates stakeholders' decision-making processes using predictive models and diverse what-if scenarios. An essential element of this environment is the management of Decision Support Components (e.g., models or systems) that need to be created with mature methodologies and good delivery time. However, there has been a gap in the understanding of project management best practices in DMC environments and in the application of methodologies to ease project execution. In the following paper, we address that gap by analyzing six predictive analytics projects executed in a Mexican DMC using Process Mining techniques. We perform process discovery using a detailed activity event log, which has not been possible in previous studies. Additionally, we perform a compliance evaluation versus the de facto methodology to identify the current process alignment gaps, and finally, we analyze the social networks present in the process execution. The research reveals that (1) process mining models are helpful to address management issues of PA/DM projects (2) PA/DM projects require alignment to mature methodologies to improve process performance and avoid execution problems (3) PA/DM project execution should be revised at the activity level to identify issues and to propose specific strategies. This study's findings can help project managers to perform process analyses and to make informed decisions in PA/DM projects. The following paper is an extension of the article "Applying Process Mining to Support Management of Predictive Analytics/Data Mining Projects in a Decision-Making Center" presented in the 2019 International Conference on Systems and Informatics (ICSAI 2019).

1. Introduction

Decision-Making Centers (DMCs) are immersive virtual environments used to understand complex problems, simplify decision-making, and visualize the results of predictive and scenario-based models [1]. These environments depend on the creation process of tools like: Predictive Analytics/Data Mining (PA/DM) models to operate [2]. Nevertheless, the authors have demonstrated in previous studies that DMC processes focus on high-level tasks and exclude detailed and standard PA/DM activities [2]. The absence of commonality in PA/DM project execution, generates issues, since (1) models are built using empiric methodologies and (2) managers cannot follow up specific technical activities since they are different in every project.

In this research, we propose three approaches to overcome the mentioned issues and help managers and modelers make informed decisions about PA/DM projects. In the first, we apply process mining techniques to a set of PA/DM processes to discover the timing, flow, frequency, and performance of activities from diverse perspectives (e.g., process, organizational, and case). Second, we compare a real PA/DM project execution with an accepted PA/DM methodology, to identify how aligned are the real processes to the formal methodology (i.e., CRISP-DM) and what gaps need to be closed to achieve compliance. Third, we perform complementary human resources analyses to visualize the relationship between resources and communication channels during process execution.

We expect that managers in DMCs use the models presented in this study to evaluate their processes and to consider the implementation of specific management strategies.

Finally, the organization of the paper is as follows: Section 2 and 3 presents the background and the literature review respectively. Section 4 describes the experimental design. Section 5 provides final results and discussion, and section 6 describes conclusions and future work.

2. Background

2.1. Process Mining Techniques and Project Management applications

The Process Mining (PM) technique is a reverse engineering approach where process models are generated using event logs [2]. In [3], the author classifies the following PM techniques that we use for our analysis: discover, conformance, and enhancement.

The process discovery technique aims to mine process models using discovery algorithms, so the process helps managers answer specific questions [4]. Examples of discovery algorithms include alpha algorithm, heuristic miner, fuzzy miner, genetic miner, region miner, and integer linear programming (ILP). Differently, the process conformance technique aims to measure the process quality through metrics like: fitness, precision, generalization, and simplicity [4]. In this category, conformance checking is used to compare the expected model and the reality obtained from event logs. Likewise, it is possible to identify processes, commonalities, similarities, and deviations [3]. Finally, the process enhancement technique aims to extend the model with relevant information [4]. For instance, statistical metrics based on timestamps (e.g., throughput time, working time, and waiting time) or the use of replay analysis to visualize process execution. In this research, we use Disco and ProM 6 tools to implement the process mining techniques previously explained.

Finally, in [5], the authors explain that the project management field requires the process mining discipline to identify optimal workflows within project life cycles. In this regard, we consider that the following managerial issues identified in PA/DM projects can be analyzed using process mining techniques: establishing realistic goals, the creation of good teams, gaining knowledge of data, lack of infrastructure, poor project communication methodology, lack of risks management and change management [6], [7].

2.2. CRISP-DM Framework

The Cross-Industry Standard Process for Data Mining (i.e., CRISP-DM) is the most accepted methodology in the field for executing data mining projects [8]-[10]. In the framework, the project life cycle includes the following key phases [11]: Business Understanding, Data Understanding, Data Preparation, Modelling, Evaluation, and Deployment. The methodology provides a universal process with generic tasks that can be executed for all data mining projects. The CRISP-DM reference model can be regarded in Figure 1, and the generic tasks to be performed in each phase are listed in Table 1. As can be noticed, the generic tasks are defined at the activity level, which facilitates its integration to high-level DMC process. In this study, we examine the data understanding, data preparation, modeling, and evaluation phases of CRISP-DM methodology, given information constraints.

2.3. PA/DM processes with CRISP-DM

We discussed in [2] the importance of integrating PA/DM processes with DMC processes, and we make an integration effort. However, PA/DM processes at the level of activity have not been studied separately. In this study, we focus just on PA/DM processes, as a part of DMC processes, since there is no work in the literature that performs such analysis using process mining techniques. Finally, we assume that the CRISP-DM methodology matches DMC's PA/DM processes.

Figure 1: CRISP-DM phases and activity flow. Adapted from (Chapman, 2000)

Table 1: CRISP-DM phases and generic tasks

Phase	Generic Task
Business understanding	Determine business objectives Assess situation Determine Data Mining goals Produce Project Plan
Data Understanding	Collect Initial Data Describe Data Explore Data Verify Data Quality
Data Preparation	Select Data Clean Data Construct Data Integrate Data Format Data
Modeling	Select Modeling Technique Generate Test Design Build Model Assess Model
Evaluation	Evaluate Results Review Process Determine Next Steps
Deployment	Plan Deployment Plan Monitoring and Maintenance Produce Final Report Review Project

3. Literature review

Limited research has focused on Project Management using Process Mining techniques. In the literature, studies concentrate on the analysis of project management processes using data mining [12]-[14] and predictive analytics [15]-[17] techniques, but not process mining techniques. Likewise, we identify that most analyses are focused on software life cycles [12]-[18], but not on DA/PM processes. For instance, in [18], the authors use conformance checking techniques to reveal aspects of processes and identify deviations in software project execution. Additionally, the author presented an application to optimize the software development life cycle of projects using process mining [5]. However, in both cases, research is not focused on PA/DM projects or DMC environments.

Finally, the authors developed a previous study to analyze PA/DM processes in a DMC [2]. Nevertheless, the paper is oriented to analyze project phases and not project activities. Thus, that limits the possibility to discover low-level issues and applying target strategies. Besides, the study uses only in its majority enhancement techniques and a limited number of discovery algorithms. In the present study, we address those limitations.

4. Experimental Design

The DMC located at Tecnológico de Monterrey, Mexico City campus also referred as “Decision Laboratory”, is a room with seven big format and high-definition screens that offers a space to make consensual decisions and to present solution proposals to a group of decision-makers [19]. This last with the goal of selecting the best possible solution. A picture of Tecnológico de Monterrey’s DMC can be regarded in Figure 2.

Figure 2: Tecnológico de Monterrey’s DMC

In the Mexican DMC, managers execute PA/DM projects to create models that support decision-making. The team organization is defined according to the knowledge of resources and their affinity to develop specific models. The project manager role is performed by one resource, and one or more product owners define the business requirements. After project execution, the modelers report that no formal methodology is applied to create the models.

Even though project managers try to deliver models with quality and on time, modelers and the supervisor report the following issues during project execution: (1) Wrong selection of modeling technique and (2) lack of standardization of data glossary among models.

With this in mind, we examine the possible causes behind the reported issues and perform a complete analysis of the PA/DM process execution in the Mexican center.

4.1. Question to be answered

For this experiment, we aim to answer the following questions about the execution of PA/DM projects in a DMC.

1) RQ1: What do the dependency, frequency, and performance statistics of the process model reveal?

2) RQ2: How compliant is the discovered model vs. the CRISP-DM reference model?

3) RQ3: How is the interaction among resources during process execution?

4) RQ4: What are the possible causes for the reported issues?

4.2. Information Gathering

We obtained qualitative and quantitative information from six real PA projects executed at Tecnológico de Monterrey DMC by interviewing modelers and managers. The format utilized for quantitative data gathering is available in Appendix A.

During this phase, five modelers and one manager were interviewed. The requested data include information from four CRISP-DM process stages (i.e., data understanding, data preparation, modeling, and evaluation), since we do not have access to data from the business understanding and deployment phases.

Finally, the following data was obtained from stakeholders: start and finish dates of activities, the average number of hours per activity per day, and the number of resources involved in each activity. At the end of the interview, we request impressions about execution processes to identify specific issues.

4.3. Event Log Generation

We create 4945 records with timestamps based on the provided information. The corresponding records per project can be regarded in Table 2. In this phase, no assumptions were considered since the modelers provide specific times and dates for each activity.

Table 2: Event Log record generation by the project.

Project	Records generated
P1	504
P2	1262
P3	1496
P4	463
P5	599
P6	621

4.4. Event Log Analysis

We use Disco and ProM 6 applications to perform process mining. The first is a commercial tool that provides accurate process models [20]. While the second supports other types of functionalities like Petri nets and Social Networks [21]. Table 3 shows the modules used in each application.

Table 3: Models used in PM applications

Application	Models used
Disco	(1) Map (2) Statistic (3) Filter by case
ProM	(1) Social Network Miner

We use the Map view from the disco application to visualize the flow of activities, dependencies, frequencies, and performance. Likewise, the statistics view is used to identify the process event distribution, the activities, and the frequency of resources. Finally, we use the Filtering functionality to analyze the process model by specific cases. From ProM application, we use Social Network Miner to identify relationships among resources.

5. Results and Discussion

During process analysis, we document the global statistics shown in Table 4. As can be noted, the number of events represents the total records in the event log, and the cases correspond to the number of processes. The activities represent 16 generic tasks of the following phases of the CRISP-DM methodology: data understanding, data preparation, modeling, and evaluation. Finally, we examine projects that were executed in the next time range (April 25th, 2016 to June 30th, 2019). The statistics reveal that, on average, the project duration is 30 weeks.

Table 4: Process global statistics

Metric	Value
Events	4945
Cases	6
Activities	16
Median Case Duration	27 weeks
Mean Case Duration	30 weeks
Start	4/25/2016 9:00:00
End	06/30/2019 18:00:00

On the other hand, the statistics per activity showed in Table 5 reveal the most, the average, and the least executed activities in the project.

Table 5: Statistics per activity

Activity	Relative Frequency
Build model	19.38%
Evaluate results	10.11%
Select modeling technique	8.15%
Verify data quality	7.28%
Construct data	6.23%
Assess model	6.15%
Explore data	6.09%
Integrate data	5.46%
Collect initial data	5.42%
Review process	5.04%
Determine next steps	4.99%
Generate test design	4.77%
Select data	3.94%
Describe data	3.28%
Clean data	2.93%
Format data	.79%

In the following subsections, we respond to the defined research questions.

RQ1: What do dependency, frequency, and performance statistics of the process model reveal?

Figure 3 shows the process map of the event log. As can be noticed, there are four thick arrows in the diagram that represents significant dependence among activities. For instance, the most substantial and unique bidirectional dependency is present between the review process and the determination of Next steps activities. Likewise, a significant reliance is visible between the process review and next steps activities, which means that those tasks execution order is the same in cases majority. Besides, managers should pay attention to the iteration that involves all data manipulation activities (i.e., collect, explore, verify, select, clean, construct, and integrate data) with the modeling selection technique. The evidence support that the team is having trouble with gaining knowledge of the data, which is a common problem in these kinds of models. We can assume that the lack of consistent execution of the description and selection of data could be the cause of the described problem.

Lastly, the diagram shows a dependency between the modeling technique selection and the initial data collection, which should be revised. Strangely, a change in data impacts the modeling technique and also the model construction. We recommend the inclusion of roles with expertise in modeling techniques to break that dependency.

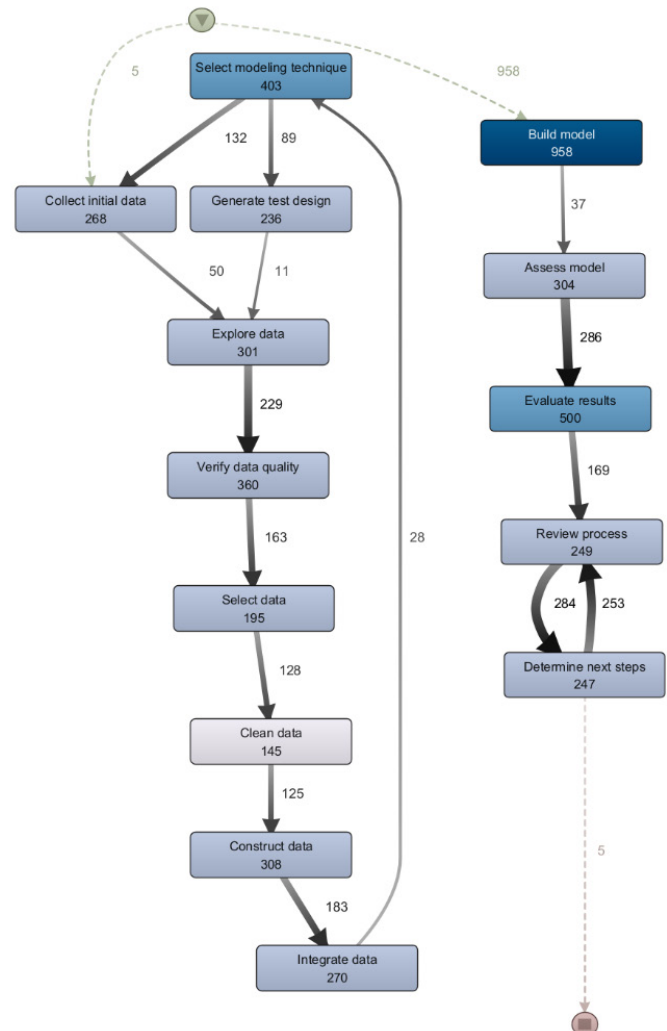

Figure 3: Process map by absolute frequency

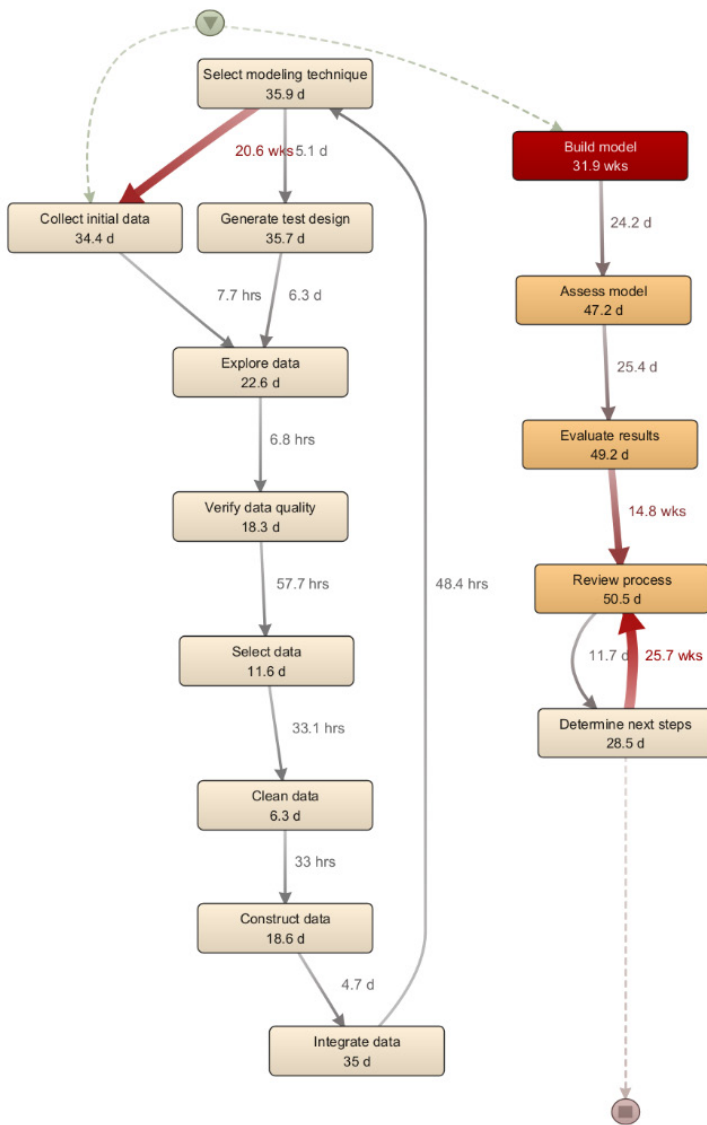

Figure 4: Process map by total duration

On the other hand, the absolute frequency of activities is represented with color. A high-frequency task is painted with intense blue, while one with low frequency is depicted with light blue. For this process model, the activity with the most significant frequency is the model's construction, followed by evaluating results and selecting the modeling technique. As we have mentioned, the model construction is affected by previous executed or non-executed activities. We can assume that previous activities improvement has a positive impact on the construction activity. In this case, we recommend using lean prototypes to facilitate the technique selection and diminish the time devoted to the model construction.

Finally, the performance of the model can be regarded in Figure 4. The model shows the total task duration and delays between activities. The model's construction is the most significant task with 31.9 wks. Likewise, a delay of 20.6 weeks is present between the select modeling technique and collect initial data activities. In this case, managers should focus on diminishing the time between those two activities, by involving more resources or/and experts to the project.

A second delay is exposed between the process review and the definition of the next steps; however, this case should be analyzed separately since all resources execute these activities simultaneously, and that variable could affect the metric and not represent the real delay.

RQ2: How compliant is the discovered model vs the CRISP-DM reference model?

Figure 5 shows the process map by case frequency that is useful to analyze compliance. For instance, we are examining six cases, and theoretically, all activities should be present in all cases; however, in reality, this is not the case. Specifically, for this DMC, we discovered that the activities with a lower presence in the execution are the data formatting and data description. This last represents an issue in subsequent tasks since modelers report that the lack of data description has delayed the model's development and integration processes. Likewise, data cleaning and construction activities have problems with compliance in one of the cases, so DMC managers need to review these deviations.

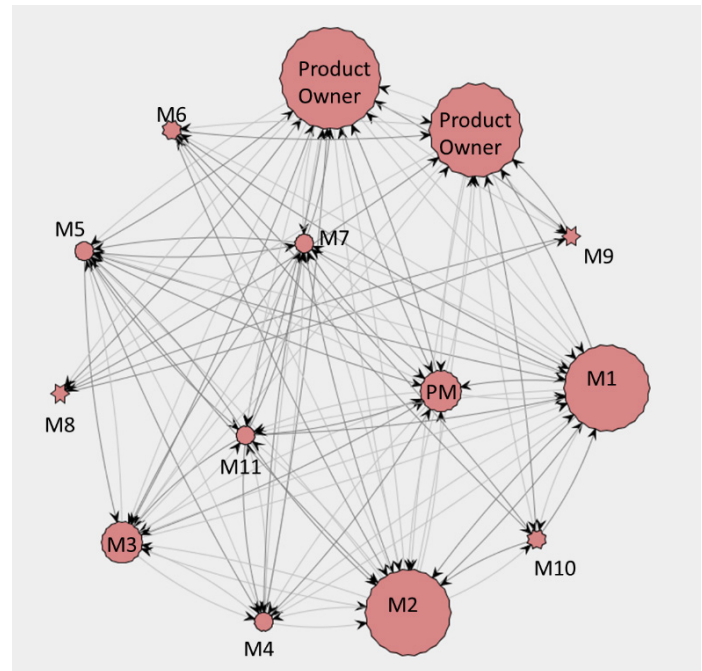

Figure 6: Social Networks of the process execution

Finally, the flow of activities has some compliance issues. In contrast to CRISP-DM, the actual execution is iterative in the data understanding and preparation phases. With this information, managers can create initiatives to align the model to CRISP-DM by stages and increase its performance.

RQ3: How is the interaction among resources during process execution?

To answer this question, we use the Social Network mining capability of ProM. As can be regarded in Figure 6, the two product owners are critical intermediaries in the project execution. In this case, the PM role is key in the process; however, the manager seems distant from individual modelers. On the other hand, M1 and M2 modelers seem to be more connected to the group. This last can have two explanations: (1) The existence of a functional dependency among parties (e.g., infrastructure,

software, etc.) or (2) the modeler has participated in several projects which allow him to collaborate with more people. Finally, managers must pay attention to isolated modelers M8 and M9 and understand why they are separated from the group.

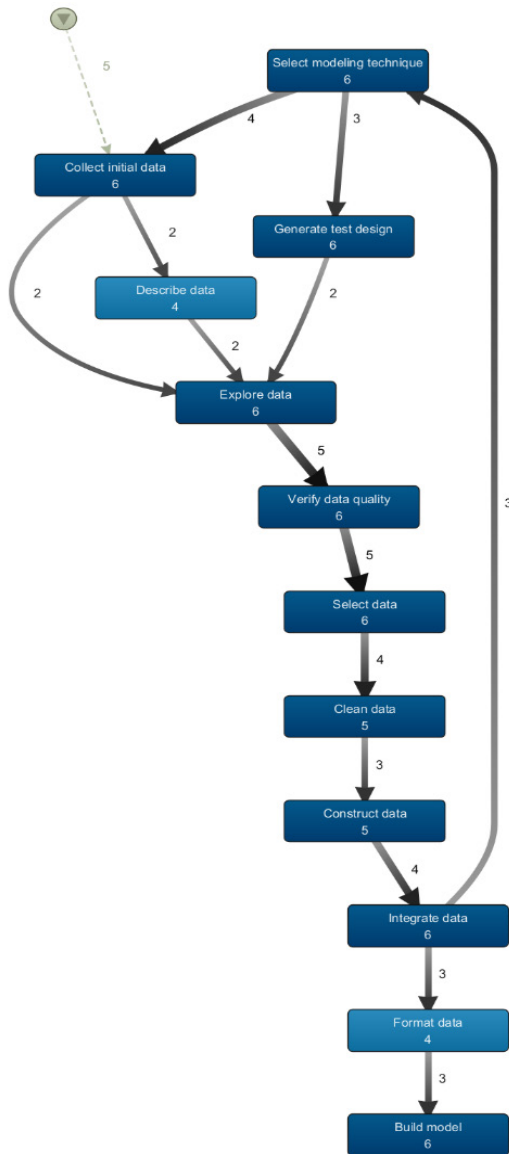

Figure 5: Process map by case frequency

RQ4: What are the possible causes for the reported issues?

We analyze the possible causes of the reported issues using previous process maps.

Wrong selection of modeling technique. It seems that the modeling technique selection is an exploratory process that takes too much time to define. As we have recommended before, inclusion of an expert and the implementation of prototypes can address this problem. Since the modeling technique can be evaluated with a prototype and with the expert support.

Lack of standardization of data glossary among models: This problem is caused by the lack of execution of the data documentation activity. We believe that an alignment to CRISP-DM methodology can solve this problem.

Finally, it is relevant to mention the limitations of the present study, which can be addressed in future research.

First, the presented model represents PA/DM execution processes of DMCs exclusively, so other PA/DM processes outside this environment are not represented in the research. Second, we don't include the business understanding and deployment phases in the modeling given data restrictions. So we represent part of the PA/DM process in this study. Lastly, the absence of previous research limits the possibility to compare and contrast our model with others and evaluate its completeness.

6. Conclusions and Future Work

In this research, we reveal the value of process mining as a tool to support project management of PA/DM projects in DMCs. Likewise, we expose the need to implement mature PA/DM processes in DMCs that facilitate (1) project management and (2) process improvement.

In this study, we create a process model to identify project execution issues, gaps in compliance, and the interaction of resources. We perform interviews to obtain detailed data from the PA process execution from modelers and managers. An event log at the level of activities was created considering CRISP-DM generic tasks, timestamps, and resources. Disco application was used to apply process discovery and process enhancement techniques. ProM application was used to perform Social Network mining. The results of the study reveal that: (1) Process mining models are helpful to analyze and address common management issues of PA/DM projects (2) PA/DM projects require alignment to mature methodologies to improve process performance and avoid execution problems (3) PA/DM project execution should be revised at the activity level to identify issues and to propose specific strategies (4) PA/DM projects should be analyzed from different perspectives to obtain valuable information for the management team.

Although it has been proved that Process Mining techniques are useful tools to support the management of PA/DM projects, there is work that needs to be addressed in the future. For instance, we need to use ProM tool to obtain compliance metrics of process models. Likewise, we need to use additional social network algorithms to analyze other organizational relationships.

Conflict of Interest

The authors of this paper certify that they have NO affiliations with or involvement in any organization or entity with any financial interest (such as honoraria; educational grants; participation in speakers' bureaus; membership, employment, consultancies, stock ownership, or other equity interest; and expert testimony or patent-licensing arrangements), or non-financial interest (such as personal or professional relationships, affiliations, knowledge or beliefs) in the subject matter or materials discussed in this manuscript.

Acknowledgment

This work was supported by CONACYT Project 266632, identified as "Binational Laboratory on Smart Sustainable Energy Management and Technology Training." Additionally, the

authors would like to thank the following experts for the provided information about PA project execution: Jose Hugo Carmona, Luis Alberto Lira, Ricardo Granados, Aban Moreno, Eduardo Meza, and Paolo Paez.

ABSTRACT

In recent years, the applications in the field of Unmanned Aerial Vehicle (UAV) systems has procured research interests among various communities. One of the primary factors being, thinking beyond the box of what could UAV system bring to the table other than military applications? Evidence to any answer for this question is the current day scenarios. We could see numerous applications of UAV starting from commercial applications of delivering consumer goods to life saving medical applications such as delivery of medical products. Using UAVs in for data transportation in remote locations or locations with no internet is a trivial challenge. In-order to perform the tasks and satisfy the requirement, the UAVs should be equipped with sensors and transmitters. Addition of hardware devices increases the number of connections in hardware design, leading to exposure during flight operation. This research proposes an advanced UAV system enabling wireless data transfer ability and secure data transmission with reduced wiring in comparison to a traditional design of UAV. The applications of this research idea targets using edge computing devices to acquire data in areas where internet connectivity is poor and regions where secured data transmission can be used along with UAV system for secure data transport.

1 Introduction

In current day scenarios, internet is playing a significant role in everyone's daily life. There has been a expeditious technological developments in various fields for betterment of human life. One of such developments is discovering various new modes of data exchange like heterogeneous communication between humans and things compared to a long standing traditional homogeneous communication. Wireless Sensor Networks (WSN) has amplified the applications of embedded systems and Internet of Things (IoT). WSN, a network of randomly dispersed nodes which can have communication with every other node in the network with help of radio signals.

WSN is made up of independent micro-sensor nodes which can sense and communicate the information further to other nodes. A single micro-sensor node can be embedded with a sensor, a micro-controller or a microprocessor, depending upon the target applications [1], [2]. The micro-sensor nodes comes with an advantage of inbuilt power source and a wireless transmitter to enable wireless data transfer facility both online and offline environments. A classic example of WSN is using them to sense atmospheric conditions like

temperature and humidity. The usefulness of WSN is tremendous in industrial sectors with hazardous nature where it is difficult to deploy humans for data acquirement.

If the WSN are enhanced with wireless technologies such as ble, thread and zigbee it would enable them to send the data without the need for internet or physical wired connections. These technologies can operate on coin cell battery for years which makes this WSN a low-power architecture. By deploying of edge devices, wireless mesh networks such as ble mesh, thread mesh network would enable a single node to transfer data for longer distance to avoid any failures and ensure no data is lost during transmission [3]. Owing to above factors, the WSN is used in industrial and non industrial applications. At the same time, there has been an increasing demand to use WSN at remote locations to acquire sensitive data but the problem arises how can the data be transmitted for longer distance when it exceeds the limitations of mesh technologies? On the other had, how can we secure the data when it is being transmitted and make it readily available around the globe at the same time? Is it possible to carry out the operation using IoT edge devices?

Edge computing devices helped us to understand and answer

^{*}Corresponding Author: Niranjan Ravi, ECE Department, IUPUI, IN, USA & ravin@iu.edu

the questions. These unanswered questions triggered the motivation to use UAV to transport the acquired data from remote WSN when it is difficult for any human to enter the region. UAVs also has a significant quality of quicker transportation owing to less air traffic.

To ensure a secure data transmission, a ready to use solution, NXP's A71ch, a secure element which can store provision credentials and aid in connecting to private/public clouds [4] was utilized. This process would require new hardware installation in UAV design. The increment of hardware comes with a cost of increased wiring which is addressed by using light-weight protocol called Unmanned Aerial Vehicle Controller Area Network (UAVCAN).

2 Literature Review

In 1999, when term IoT was first coined, it was believed that in future every object would have a globally unique Radio Frequency Identification tag (RFID). IoT provides a new path to explore the data which has been gathered by the embedded systems using its sensors. IoT provides a guiding hand to devices which are resource constrained and would require additional computational and communication capabilities. They help in monitoring the devices at remote locations through the internet in event of any failures. Embedded system devices used in IoT applications are referred as smart objects because they act according to environment changes. But the question of storage arises. How much data can these devices store? Would it be efficient to store the data in the stand-alone device? Is there any alternative?

Cloud platform answers these questions. Cloud computing plays a vital role in enhancing IoT sector. The smart objects are resource-constrained and performing advanced computational would require re-designing the hardware which would result in increased production and operating costs. Also, it would increase the size of the component. Cloud provides alternate approach like data storage, handling and unlimited distributions. This brings up new features like scalability and flexibility for the researchers to deploy the products in various new applications. By uploading the data to cloud complex machine learning algorithms can be deployed to observe patterns in the data on real-time. This cloud infrastructure solves the problem of storage and real-time data visualization. But how secure is the data transmission to the cloud?

Cryptographic solutions answers the above questions by offering end-to-end security to minimize data breach. The idea of choosing a right encryption technique in IoT field is widely debated. Because, the data generated by IoT devices are of vast magnitude ranging from a temperature sensor value to medical records which are exchanged with cloud platforms. A pressing need for security measures that should be compatible enough to be deployed in IoT devices is required.

Elliptic Curve Cryptography (ECC), a type of asymmetric cryptography is focused in this research. Asymmetric cryptography knows as public key cryptography algorithm involves a pair of keys: a public key which can be shared/exchanged and a private key, kept as a secret. This provides higher security level at Transport Layer Security (TLS) for devices which are resource constrained, as shown in this research. TLS handshake is for authentication and key exchange in order to establish a secured connection. TLS protocol

version and usage of asymmetric encryption algorithm is managed by TLS handshake protocol.

On the other hand, taking advantage of some of the above developments in the field of sensors and electronics, UAV system has evolved its reach into civilian and military applications [5]. They are currently used in surveillance of a location and even launch drone strike on enemy targets. One of the primary reasons for advancement in the field of UAV systems are

1. Environmental safety and protection.
2. Military drone strikes.
3. Drone surveillance during natural disasters.
4. Geological study.

A flight controller module, GPS for navigation purpose, a telemetry device to transmit and receive data from ground control station are used in design and construction of a traditional UAV. It is also equipped with 9 axis sensors to get real time flight dimensions in motion [6]. A lot of new physical interfaces have been introduced in the flight controller design. One such development is introduction of CAN port to reduce the wiring and reduce the noise. A thorough background study on UAVCAN principles was carried out with help of this research [7] where the author has experimented a proof of concept of establishing a one way CAN bus communication between flight controller with an arduino module.

The basic understanding of arduino was helpful but further questions arose like how would this interface work when flight controller is paired with a resource constrained microcontroller? What are the parameters needed to be considered when integrating various operating systems with different clock frequencies and operating speed? How much of the payload(data) can be transmitted for the usage? How many devices can be connected in a single UAVCAN bus? What are the applications it would bring on this successful completion? How to transmit data from a drone system securely to a data centre/cloud networks ? The results of the question are discussed on this research.

3 Background Study

3.1 802.15.4 Standard

This standard defines an effective Medium Access Control (MAC) layer with numerous physical layers (PHY) which can be optional. IEEE 802.15.4 outlines Information elements (IEs) to help in better utilization of the standard. The header IE and payload IE. The header can be useful in authentication and payload can be encrypted. IE is advantageous such as providing backwards-compatibility for future versions of the standard.

3.2 6LowPAN

6LowPAN is abbreviated as IPv6 over Low Power Wireless Personal Networks. As a successor of IPv4, IPv6 has increased the address size of 128 bits as compared to 32 bits. 6LowPAN transmits and receives IPv6 packets over IEEE 802.15.4 link. Enabling the

maximum frame size to be sent transmitted. It is aimed at low power and low cost applications. In places of Ethernet, a packet of Maximum Transmission Unit (MTU) size can be transmitted in a single frame. Between 802.15.4 link layer and IPv6 networking layer, 6LoWPAN exists as an intermediate layer. This aids in the process of fragmentation of sender's packet and re-fragmenting it on the receiver node. The transmission load is reduced when fewer bits of data is transmitted. Thread network inherits this feature to transmit data packets. Mesh header supports more efficient methods of compression of messages inside a thread network .

3.3 Constrained Application Protocol

Most of the resources deployed in the field of IoT are resource-constrained in nature. In order to support the data transmission, a specialized web transfer method/protocol called constrained application protocol (CoAP) is deployed. CoAP contains RESTful features to run on any resource constrained embedded devices. CoAP works on User Datagram Protocol (UDP) protocol than Transfer Control Protocol (TCP). A feature of getting response from destination nodes to parent node called Confirmable requests (CON) is also present.

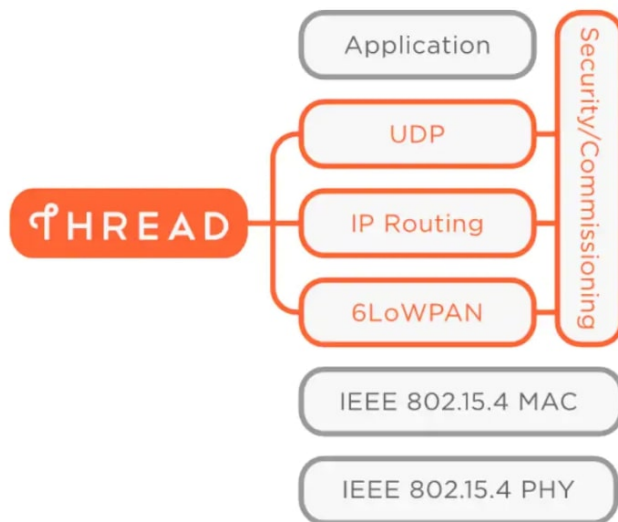

Figure 1: Thread network stack [8]

3.4 Thread Protocol

Thread is an Internet Protocol (IP) based on wireless networking protocol aimed at low powered applications in the field of embedded systems and IoT. Thread is developed based on many standards resulting in providing many advantages like reliability, cost-effective and low power consumption. Thread used UDP on Network layer and uses IEEE 802.15.4 PHY and MAC layers wireless specifications supporting up to 250 devices in a mesh network by operating at 2.4 GHz band as shown in Figure 1. With help of Wi-Fi on their Home Area Network (HAN), users can exchange and communicate with other thread devices within the thread network by using smartphones.

3.4.1 Thread and Border Router

Thread router offer connectivity for the devices inside the network and offers security services to new devices trying to join the network. Border router carries out connectivity between one network and its adjacent. A thread network would consists of at least one border router and it can have many as well depending upon the application. A leader in the thread network would receive requests from end devices to become router. The leader also contains the registry of router IDs in the network. In any instance of the application, if the leader fails, another router is elected to be the leader immediately without any user intervention .

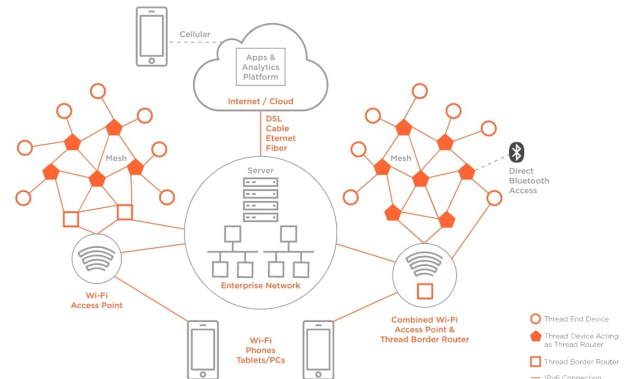

Figure 2: Commercial thread network topology

3.4.2 Router Eligible End Devices (REEDS)

As the name suggest REEDs are devices which primarily acts as end devices. The REEDs are eligible to become active routers. This action is carried out by the network topology without any user intervention. The REEDs can also act as sleepy end devices which has the function to gather data and transmit the information further to the parent node. Sleepy end devices are highly efficient since they are helpful in extending the battery life .

3.4.3 Ensuring No Failure

The thread system has the advantage of working to full efficiency despite network failure or nodes losing connectivity by autonomously re configuring itself in-case of any faults. For instance if a end devices requires a parent node to transmit and the parent node fails due to connectivity problems, then the end device would choose another parent to transmit the data. Thread network topology is shown in Figure 2. A similar procedure is applied in case of failure of border router as well without any user intervention .

3.5 Real-Time Operating Systems (RTOS)

RTOS can be visualized as a software component that allows the system to rapidly switch between various tasks simultaneously on a single processing core and it gives an impression to the user that the system is working on various operations at a same time. Because in reality, the system can run only a single thread and RTOS decides the priority of the task to be handled to execute an efficient operation [9].

3.5.1 FreeRTOS

FreeRTOS is designed to run even on a small microcontroller applications. Microcontroller is an important component of a deeply embedded system and it would require a freeRTOS system to maximize the efficiency during critical applications. The critical features of RTOS are

1. Interrupt latency.
2. Resource-constrained processors.
3. Priority scheduling.
4. Improved efficiency.

3.6 Fight Controller and QGround Control

The flight controller acts like a heart to the drone system. The usage of fibre optics provide considerable advantages to the design. The flight movements are converted into electric signals and are transmitted to ground control station to monitor the flight activity. Pixhawk and Ardupilot are predominantly used flight controllers [10]. QGround control provides complete UI setup and configuration for PX4 software. Real-time screenshot of QGround system is shown Figure 3. Currently, PX4 is predominantly used in developing UAV applications. QGC provides flight map, way points and flight track which are essential to plan a flight mission.

Figure 3: QGroundControl - Ground control station

3.7 Controller Area Network

CAN standard was introduced to harness complex wiring with two wires. It has more immunity to electrical noises and became a popular standard in automobile industries and other sectors. CAN bus works on the principle of multi-master and multi-slave system with message broadcast and maximum signalling rate of about 1 Mbps. The message/payload is Figure 4. ISO specification For CAN Bus broadcasted to all other nodes in the system. Types of CAN,

1. Standard CAN.
2. Extended CAN.

Figure 4: ISO specification for CAN Bus

3.8 UAVCAN

Unmanned Aerial Vehicle Controller Area Network (UAVCAN) protocol was initially designed for robotic and aerospace communications over the robust networks such as CAN bus. The design goals of UAVCAN are

1. Democratic network.
2. Nodes can exchange payloads.
3. Support for redundant interfaces and redundant nodes.
4. High throughput, low latency communication.
5. Simple logic, low computational requirements.
6. Common high-level functions to be defined.

In UAVCAN, each node is equipped with unique numeric identifier known as node ID as shown in Figure 5. 8 bytes of data can be sent in a single frame. In the event of huge payload, payload is divided and transmitted in multi CAN frames. CAN payload structure is displayed in Figure 6.

Message frame																			
Field name	Priority			Message type ID													Service not message		
CAN ID bits	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10
Allowed values																	6	5	4
CAN ID bytes	3			2													1		
																	0		

Figure 5: CAN frame format

Each published message would consists of an unique data type ID and each node in the network would consists of a node ID. This helps in preventing the redundancy in the network. Data Structure Description Language (DSDL) defines data structures format of data which has to be transmitted. Each DSDL file would consists of an unique identifier and a data type name. Few data types in the system are reserved for Vendor specific data types. DSDL helps in optimization which is predominant in deeply embedded systems where dynamic memory allocations may not be permitted. Two methods of data exchange are observed in UAVCAN. They are

- Message broadcasting.
- Service invocation.

4. Software enablement including RTOS drivers, middleware and cloud platforms.
5. System enablement with advanced sensors like temperature, humidity, light sensors and digital air quality. Temperature sensor was utilized to get real time temperature values to cloud.

Temperature sensors values generated from rapid IoT at predefined intervals are utilized in this research testing.

4.2 Pixhawk/PX4

Pixhawk works on light-weight and energy efficient real-time operating system called NuttX. In order to access Ground Control Station, a command line interface called NuttShell (nsh) is utilized. It also provides micro Object Request Broker (uORB). uORB is used for asynchronous mode of communication to switch between tasks. Data transfer is done by using a simple publish-subscribe pattern. The transmitted and received data is visualized using ground control station. There are multiple feature advancement in recent years and key features utilized in this research are

1. 32bit STM32F427 Cortex M7.
2. 2 MB of memory.
3. 512 KB RAM.
4. ST Micro L3GD20H - 16 bit gyroscope, ST Micro LSM303D - 14 bit accelerometer / magnetometer.
5. Interfaces such as CAN, SPI, UART, I2C, ADC, PWM.

4.3 A71CH - Plug and Trust for secure IoT applications

The data generated by IoT devices is increasing everyday and ways to secure the data is a popular question among research communities nowadays.

Figure 9: A71ch - Root Of trust

A71ch is a ready-to use solution since it contains necessary private and public keys for the device which enables the device to securely connect to private/public clouds. Figure 9 shows A71ch product features. This security IC can be easily interfaced with various hardware and operating systems. This security IC comes in two product variants:

1. Customer programmable Type.

2. Provisioned and programmable type.

The first type is delivered without any credentials and used in designing new products, to test and evaluate the designs. The second type is ready-to-use IC which is already provisioned by NXP trust provisioning support to ensure a secured TLS connection with IBM Bluemix. A71ch is interfaced to Micro-controller Unit (MCU) using Inter-Integrated Circuit (I2C) protocol. A71ch provides root of trust at the IC level. It delivers proven, chip to the cloud security so connection can be established with cloud platforms such as IBM, AWS and google cloud without the need to write security keys or exposing certificates/credentials. But when the data transmission occurs for the first time, proof of origin of the device and anti-counterfeit protection are required to protect server and device authenticity and avoiding un-trusted servers attacking the system. The complete authentication procedure is composed of below steps:

1. Server certificate verification.
2. Server authenticity verification.
1. IoT device certificate verification.
2. IoT device authenticity verification.

A71ch is used for anti-counterfeit protection of the device against many physical and logical attacks by operating autonomously based on integration of Javacard operating systems and applet firmware. Physical attacks on the system is narrowed down by allowing direct memory access only by fixed functionalities of applet. This isolates the content of memory from host system. The server stores a unique key pair and a digital certificate signed by trusted CA. On the other hand, the IoT device would also have a key pair and a signed digital certificate. The digital certificate's are issued by same trusted CA. These credentials are stored inside the A71ch chip. Server's certificate and authenticity is verified by IoT device using the CA certificate and a random challenge as a sequential process. The challenge involving generating and sending random message to validate the server. The same steps are followed to verify the IoT device's certificate and authenticity. It can be deployed across a broad range of systems to establish a secure connection. Since the communication between A71ch and the Host is based on I2C protocol, it can be carried out through a Secure Channel Protocol (SCP03). This would protect the channel against external attacks such as replay attacks. Also ensuring only the authenticated MCU can exchange information with our security IC by use of session keys. The features of A71ch include

1. Systematic enforced authentication.
2. ECDSA.
3. An unique chip ID.
4. Freezing of credentials.
5. Possibility to lock A71ch as transport lock mechanism.
6. HMAC SHA256 calculation in one shot.

The applications of A71ch include home gateways, home appliances, sensor networks gathering confidential data, connected industrial devices, Figure 10.

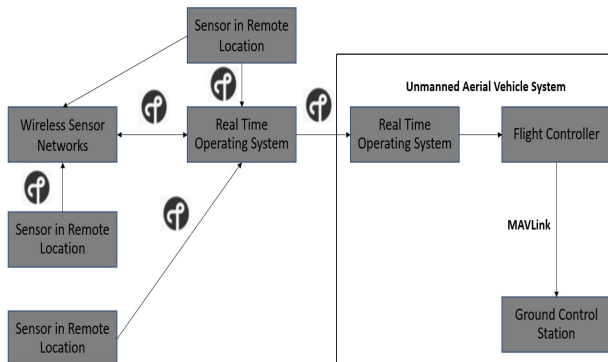

Figure 11: Data transfer using thread protocol from WSN to UAV system

5 Proposed Model and Implementation

This sections explains the initial design phase construction and the modifications in hardware platforms applied for this research work.

5.1 Design Phase

With the help of hardware and software information detailed in section 4, the design phase includes construction of an UAV system using Pixhawk board as flight controller. The interfaces in Pixhawk are helpful in connecting external peripherals like motor, telemetry and GPS module to the UAV system. In order to make the UAV system to adapt for this research, the system was modified by utilizing the CAN bus interface present in flight controller. Two new systems

such as Rapid IoT and A71ch are connected to flight controller module.

In order to facilitate the data exchange and visualization aspect, inside the PX4 firmware, two new UAVCAN messages were created each having unique .c and .h files structures. One message to receive data from external input sources and other message to send the information to external devices using a simple uORB pub-sub methodology. In order to encrypt and decode the CAN frame, UAVCAN GUI tool was adopted in testing and result phases.

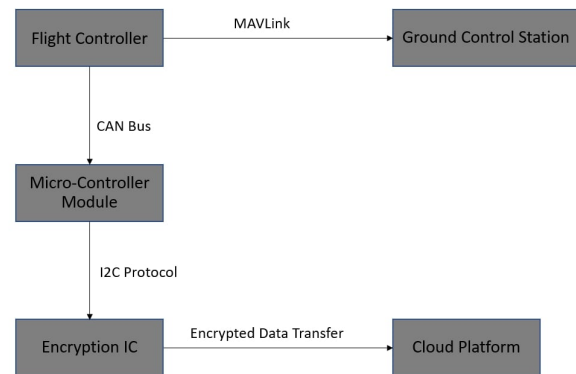

Figure 12: Data transfer to cloud platforms from UAV system

5.2 Integration of Rapid IoT with Pixhawk

Owing to advantages of rapid IoT system, documented in section 4.1, it is embedded with the UAV design using UAVCAN (CAN bus interface) and with help of a docking station. External CAN transreceivers are attached to the docking station. They convert CAN TX and RX signals into CAN High and Low signals which in-turn will be used for transmission. NXP's FRDM KW41Z is assigned to be remote wireless sensor node and it is placed at a distance of 70 - 100 metre. Both the Rapid IoT and remote node are pre-programmed with thread for this research. The remote node would gather atmospheric temperature value for every second. Any sensor data/ raw data can be used here. Once the UAV system is armed, the data from remote node is transmitted wirelessly using thread to rapid IoT in the UAV system, Figure 11.

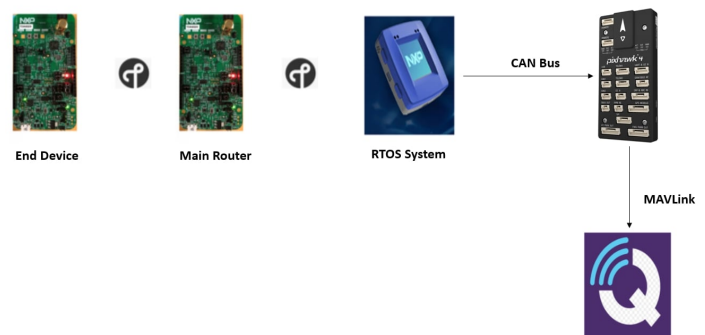

Figure 13: Integration of rapid IoT with pixhawk

The rapid IoT would in-turn send the data as CAN signals to the flight module/controller. The flight controller would re-transmit the data to ground Control station using telemetry and readings are visualized in QGroundControl. This testing phase was carried out at initial step. The design setup was increased by increasing the number of wireless sensor nodes and establishing a mesh network connectivity among them. This enabled UAV system to gather data from the nodes which are about 350 metres. Figure 13 shows the hardware design of UAV system with rapid IoT.

5.3 Establishing a secure data transmission

Using telemetry, the data from flight controller is sent to ground station as radio signals. In order to secure the data, A71ch is connected to Pixhawk using CAN bus protocol. Provisioned and programmable type of A71ch was used in this research. But A71ch is a security IC and it has to be used along with a base board like NXP's LPC54018 which has an inbuilt WiFi module. Establishing a secure connection between A71ch and IBM cloud require three steps. In the first step, A71ch is interfaced with host MCU using I2C protocol. Using the host MCU's debugger port, keys and certificates are inserted into A71ch. Device ID (Identification number - unique number) and generated CA certificate from the device will be utilized in next step. Later, a new user account was created in IBM Bluemix with an organization ID (name of your organization) and registration is completed by entering the device ID and uploading CA certificate from previous step. This portion of initial setup is important to establish a secured connection between cloud and security IC. The final step would be to acquire API key, authentication token from cloud and use it in our code base to initiate the connection from our IC. If the API key is lost or keys are refreshed, the connection setup will not succeed. The above process has to be repeated again in this case. Every provisioned A71ch has to carry-out this one step procedure to function without any failures. The generated data from flight controller is transmitted as CAN frames to LPC module, where security IC receives the data through I2C communication. It would encrypt the data and upload it to cloud as shown in Figure 12. This process would secure the data to prevent data leakage and restrict unwanted access to the data. Hardware design is shown in Figure 14.

Figure 14: Integration of security IC with pixhawk

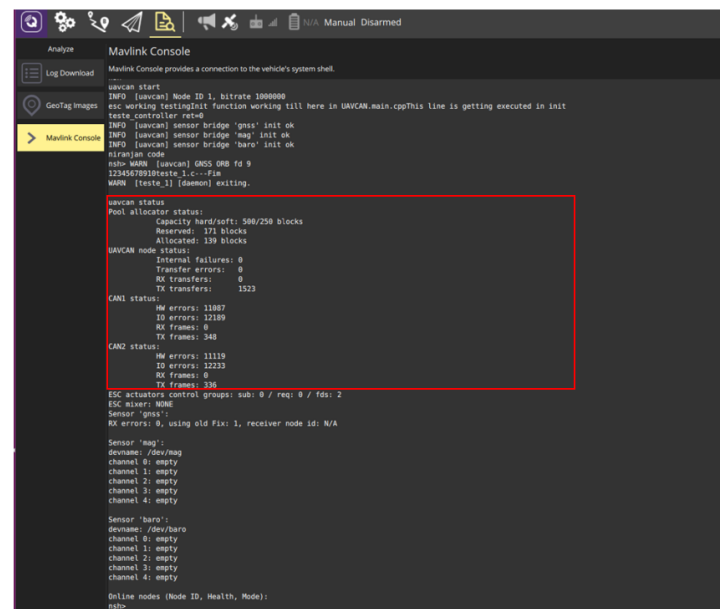

6 Testing Phase And Deployment Design

At first, the hardware connections were tested and telemetry was checked if a proper communication channel has been established with the UAV system from the ground control station. The CAN communication was tested between NXP's Kinetis boards using Tera term.

Figure 15: Deployment system of UAV to acquire data from WSN

Later, the interfaced connections were also tested. In various phases of testing, an oscilloscope was used to check for CAN frames. As a next step, UAVCAN functionality in Pixhawk was tested in the lab environment. To ensure whether the CAN frames are being transmitted from the hardware. A publish-subscribe pattern is tested initially to understand the uORB functionality. The status of UAVCAN frames transmitted is witnessed with the help of UAVCAN frame status command in nsh shell.

After the testing, two advanced design were implemented using above specified hardware designs.

Figure 17: Deployment design of UAV to transmit data to IBM Bluemix

The designs are shown separate for a better understanding, Figure 15, 17. They can be integrated together and deployed as a single design as well. It had also been tested in this research.

7 Results And Demonstration

Extending the range of data transmission using wireless technologies like thread and incorporating security IC to secure the data transport is tested with the help of NXPhlite, Pixhawk, NXP's rapid IoT and NXP's security IC in real-time environment is tested. Before performing an actual field testing, an initial testing was carried out in two steps. The first step is to ensure the connectivity of hardware to check if there are any wiring issues and second step ensuring all the network devices were working perfectly.

As a first step, Pixhawk module was interfaced with four devices using a CAN network. 8 bytes of data for each CAN frame was transmitted and it was received successfully by other devices as well. This data transmission rate of 8 bytes/second is significantly higher compared to traditional UART (Universal Asynchronous Receiver/Transmitter). The successful completion of this step ensured a fully functional CAN network was established between all the hardware with varied CAN protocols.

In the second step, thread network connectivity was tested between the network devices and connection establishment to IBM cloud was also verified. As mentioned in section 5.3, the unique device ID of A71ch IC is cross-checked with ID displayed in IBM cloud, Figure 19. After successful completion, field testing was carried out.

Figure 18: CAN frames - UAVCAN GUI tool

As proposed in section 5.2, with the help of QGround control, Figure 16 shows status of CAN frames both received/transmitted. Standard CAN of payload 8 bytes is tested in this practice. UAVCAN GUI tool displays the values displaying the CAN frames, 8 individual bytes which are being sent from rapid IoT system and which are received by the flight controller, Figure 18.

Property	Value	Type	Event	Last Received
status	52:73	String	status	a few seconds ago

Figure 19: IBM Bluemix - Output data visualization

To establish a secure data transmission, as proposed in section 5.3, the generated values from the flight controller is transmitted to security module which then encrypts and shows the value in IBM Bluemix for each second/whenever the data is published. Figure 19, shows the device ID of the security IC and value column displays the actual value in a string datatype. This is give access across the globe to see the results instantly regarding the flight data. Figure 19 displays instant data transfer into the IBM cloud.

8 Design Challenges

Various design challenges were faced during the research. NuttX operating system had very little documentation with regards to UAVCAN. GitHub repository of PX4 is also being upgraded from time to time but the documentation did not reflect all the changes and new features. UAVCAN is a developing research area and it is difficult for developers to re-design/upgrade the existing design. Only few articles/documentations were available on how to interface flight controller with external hardware devices with UAVCAN [12]. Next challenge was, NXP's rapid IoT used FlexCAN and Pixhawk had UAVCAN. The CAN frame structures were different and without suitable debugging tool, it was difficult to proceed further. To facilitate communication in CAN network, external CAN transmitters were used.

Another challenge was to place the new hardware in UAV system. 3D printed models were very helpful in overcoming above issue. With regards to security IC, understanding the background of security concepts was mandatory. Initial setup and key exchange between IBM cloud and security IC had to be carried out in sequential steps. Any error in the steps will lead to failure and start the process all over again.

9 Conclusion

Technological development and growth in various sectors of life plays a crucial role in making human lives better each day. Internet, a recent trend acts as a stimuli to the process. But there are places in globe, where technological advancements are not fully available and such places remains isolated from the rest of the world. The ideal aim of the research is to provide connectivity/access to areas where

internet connectivity is not good and the places where it is difficult to reach because of terrain. Also, ensuring secure data transport in regions where limited internet connectivity is available.

To achieve that, the design system of an UAV system was proposed. The background knowledge of software technologies and hardware components were detailed in sections 3 and 4. The system was equipped with remote wireless devices which are connected with thread network, the interfacing of flight controller module with other MCUs were carried out using UAVCAN, security of data transmission during over the air transfer (OTA) was addressed with the help of security IC, A71ch. Using the proposed UAV system with wireless data transfer facility, would foster growth quick data gathering and transmission compared to traditional methods. By combining these two ideas, it would result in building an Eco-friendly and a safe environment all over the globe.

Conflict of Interest The authors declare no conflict of interest.

Acknowledgments We would like to thank NXP, UAVCAN forums for guidance and supporting in completion of this research.
